>>> s.str.replace("_", "")
0    AStrSeries
dtype: object
```

pandas.Series.sub

Series.**sub**(*other*, *level=None*, *fill_value=None*, *axis=0*)

Return Subtraction of series and other, element-wise (binary operator *sub*).

Equivalent to `series - other`, but with support to substitute a fill_value for missing data in either one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

Series The result of the operation.

See also:

Series.rsub Reverse of the Subtraction operator, see Python documentation for more details.

Examples

```
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
```

(continues on next page)

(continued from previous page)

```
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.subtract(b, fill_value=0)
a    0.0
b    1.0
c    1.0
d   -1.0
e    NaN
dtype: float64
```

pandas.Series.subtract

Series.**subtract**(*other*, *level=None*, *fill_value=None*, *axis=0*)

Return Subtraction of series and other, element-wise (binary operator *sub*).

Equivalent to `series - other`, but with support to substitute a fill_value for missing data in either one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

Series The result of the operation.

See also:

Series.rsub Reverse of the Subtraction operator, see Python documentation for more details.

Examples

```
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
```

(continues on next page)

(continued from previous page)

```
dtype: float64
>>> a.subtract(b, fill_value=0)
a    0.0
b    1.0
c    1.0
d   -1.0
e    NaN
dtype: float64
```

pandas.Series.sum

Series.**sum**(*axis=None*, *skipna=None*, *level=None*, *numeric_only=None*, *min_count=0*, ***kwargs*)

Return the sum of the values for the requested axis.

This is equivalent to the method `numpy.sum`.

Parameters

axis [{index (0)}] Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

min_count [int, default 0] The required number of valid values to perform the operation. If fewer than `min_count` non-NA values are present the result will be NA.

New in version 0.22.0: Added with the default being 0. This means the sum of an all-NA or empty Series is 0, and the product of an all-NA or empty Series is 1.

****kwargs** Additional keyword arguments to be passed to the function.

Returns

scalar or Series (if level specified)

See also:

Series.sum Return the sum.

Series.min Return the minimum.

Series.max Return the maximum.

Series.idxmin Return the index of the minimum.

Series.idxmax Return the index of the maximum.

DataFrame.sum Return the sum over the requested axis.

DataFrame.min Return the minimum over the requested axis.

DataFrame.max Return the maximum over the requested axis.

DataFrame.idxmin Return the index of the minimum over the requested axis.

DataFrame.idxmax Return the index of the maximum over the requested axis.

Examples

```
>>> idx = pd.MultiIndex.from_arrays([
...     ['warm', 'warm', 'cold', 'cold'],
...     ['dog', 'falcon', 'fish', 'spider']],
...     names=['blooded', 'animal'])
>>> s = pd.Series([4, 2, 0, 8], name='legs', index=idx)
>>> s
blooded  animal
warm     dog       4
         falcon    2
cold     fish      0
         spider    8
Name: legs, dtype: int64
```

```
>>> s.sum()
14
```

Sum using level names, as well as indices.

```
>>> s.sum(level='blooded')
blooded
warm    6
cold    8
Name: legs, dtype: int64
```

```
>>> s.sum(level=0)
blooded
warm    6
cold    8
Name: legs, dtype: int64
```

By default, the sum of an empty or all-NA Series is `0`.

```
>>> pd.Series([]).sum()  # min_count=0 is the default
0.0
```

This can be controlled with the `min_count` parameter. For example, if you'd like the sum of an empty series to be NaN, pass `min_count=1`.

```
>>> pd.Series([]).sum(min_count=1)
nan
```

Thanks to the `skipna` parameter, `min_count` handles all-NA and empty series identically.

```
>>> pd.Series([np.nan]).sum()
0.0
```

```
>>> pd.Series([np.nan]).sum(min_count=1)
nan
```

pandas.Series.swapaxes

Series.**swapaxes**(*axis1*, *axis2*, *copy=True*)

Interchange axes and swap values axes appropriately.

Returns

y [same as input]

pandas.Series.swaplevel

Series.**swaplevel**(*i=-2*, *j=-1*, *copy=True*)

Swap levels i and j in a *MultiIndex*.

Default is to swap the two innermost levels of the index.

Parameters

i, j [int, str] Level of the indices to be swapped. Can pass level name as string.

copy [bool, default True] Whether to copy underlying data.

Returns

Series Series with levels swapped in MultiIndex.

pandas.Series.tail

Series.**tail**(*n=5*)

Return the last *n* rows.

This function returns last *n* rows from the object based on position. It is useful for quickly verifying data, for example, after sorting or appending rows.

For negative values of *n*, this function returns all rows except the first *n* rows, equivalent to `df[n:]`.

Parameters

n [int, default 5] Number of rows to select.

Returns

type of caller The last *n* rows of the caller object.

See also:

DataFrame.head The first *n* rows of the caller object.

Examples

```
>>> df = pd.DataFrame({'animal': ['alligator', 'bee', 'falcon', 'lion',
...                    'monkey', 'parrot', 'shark', 'whale', 'zebra']})
>>> df
      animal
0  alligator
1        bee
2     falcon
3       lion
```

(continues on next page)

(continued from previous page)

```
4     monkey
5     parrot
6      shark
7      whale
8      zebra
```

Viewing the last 5 lines

```
>>> df.tail()
   animal
4  monkey
5  parrot
6   shark
7   whale
8   zebra
```

Viewing the last *n* lines (three in this case)

```
>>> df.tail(3)
  animal
6  shark
7  whale
8  zebra
```

For negative values of *n*

```
>>> df.tail(-3)
   animal
3    lion
4  monkey
5  parrot
6   shark
7   whale
8   zebra
```

pandas.Series.take

`Series.`**`take`**(*indices*, *axis=0*, *is_copy=None*, ***kwargs*)

Return the elements in the given *positional* indices along an axis.

This means that we are not indexing according to actual values in the index attribute of the object. We are indexing according to the actual position of the element in the object.

Parameters

indices [array-like] An array of ints indicating which positions to take.

axis [{0 or 'index', 1 or 'columns', None}, default 0] The axis on which to select elements. `0` means that we are selecting rows, `1` means that we are selecting columns.

is_copy [bool] Before pandas 1.0, `is_copy=False` can be specified to ensure that the return value is an actual copy. Starting with pandas 1.0, `take` always returns a copy, and the keyword is therefore deprecated.

Deprecated since version 1.0.0.

****kwargs** For compatibility with `numpy.take()`. Has no effect on the output.

Returns

taken [same type as caller] An array-like containing the elements taken from the object.

See also:

DataFrame.loc Select a subset of a DataFrame by labels.

DataFrame.iloc Select a subset of a DataFrame by positions.

numpy.take Take elements from an array along an axis.

Examples

```
>>> df = pd.DataFrame([('falcon', 'bird', 389.0),
...                    ('parrot', 'bird', 24.0),
...                    ('lion', 'mammal', 80.5),
...                    ('monkey', 'mammal', np.nan)],
...                   columns=['name', 'class', 'max_speed'],
...                   index=[0, 2, 3, 1])
>>> df
     name   class  max_speed
0  falcon    bird      389.0
2  parrot    bird       24.0
3    lion  mammal       80.5
1  monkey  mammal        NaN
```

Take elements at positions 0 and 3 along the axis 0 (default).

Note how the actual indices selected (0 and 1) do not correspond to our selected indices 0 and 3. That's because we are selecting the 0th and 3rd rows, not rows whose indices equal 0 and 3.

```
>>> df.take([0, 3])
     name   class  max_speed
0  falcon    bird      389.0
1  monkey  mammal        NaN
```

Take elements at indices 1 and 2 along the axis 1 (column selection).

```
>>> df.take([1, 2], axis=1)
    class  max_speed
0    bird      389.0
2    bird       24.0
3  mammal       80.5
1  mammal        NaN
```

We may take elements using negative integers for positive indices, starting from the end of the object, just like with Python lists.

```
>>> df.take([-1, -2])
     name   class  max_speed
1  monkey  mammal        NaN
3    lion  mammal       80.5
```

pandas.Series.to_clipboard

`Series.to_clipboard(excel=True, sep=None, **kwargs)`

Copy object to the system clipboard.

Write a text representation of object to the system clipboard. This can be pasted into Excel, for example.

Parameters

excel [bool, default True] Produce output in a csv format for easy pasting into excel.

- True, use the provided separator for csv pasting.
- False, write a string representation of the object to the clipboard.

sep [str, default `'\t'`] Field delimiter.

****kwargs** These parameters will be passed to DataFrame.to_csv.

See also:

DataFrame.to_csv Write a DataFrame to a comma-separated values (csv) file.

read_clipboard Read text from clipboard and pass to read_table.

Notes

Requirements for your platform.

- Linux : *xclip*, or *xsel* (with *PyQt4* modules)
- Windows : none
- OS X : none

Examples

Copy the contents of a DataFrame to the clipboard.

```
>>> df = pd.DataFrame([[1, 2, 3], [4, 5, 6]], columns=['A', 'B', 'C'])
```

```
>>> df.to_clipboard(sep=',')
... # Wrote the following to the system clipboard:
... # ,A,B,C
... # 0,1,2,3
... # 1,4,5,6
```

We can omit the index by passing the keyword *index* and setting it to false.

```
>>> df.to_clipboard(sep=',', index=False)
... # Wrote the following to the system clipboard:
... # A,B,C
... # 1,2,3
... # 4,5,6
```

pandas.Series.to_csv

Series.**to_csv**(*path_or_buf=None*, *sep=','*, *na_rep=''*, *float_format=None*, *columns=None*, *header=True*, *index=True*, *index_label=None*, *mode='w'*, *encoding=None*, *compression='infer'*, *quoting=None*, *quotechar='"'*, *line_terminator=None*, *chunksize=None*, *date_format=None*, *doublequote=True*, *escapechar=None*, *decimal='.'*, *errors='strict'*)

Write object to a comma-separated values (csv) file.

Changed in version 0.24.0: The order of arguments for Series was changed.

Parameters

path_or_buf [str or file handle, default None] File path or object, if None is provided the result is returned as a string. If a file object is passed it should be opened with *newline=''*, disabling universal newlines.

Changed in version 0.24.0: Was previously named "path" for Series.

sep [str, default ','] String of length 1. Field delimiter for the output file.

na_rep [str, default ''] Missing data representation.

float_format [str, default None] Format string for floating point numbers.

columns [sequence, optional] Columns to write.

header [bool or list of str, default True] Write out the column names. If a list of strings is given it is assumed to be aliases for the column names.

Changed in version 0.24.0: Previously defaulted to False for Series.

index [bool, default True] Write row names (index).

index_label [str or sequence, or False, default None] Column label for index column(s) if desired. If None is given, and *header* and *index* are True, then the index names are used. A sequence should be given if the object uses MultiIndex. If False do not print fields for index names. Use index_label=False for easier importing in R.

mode [str] Python write mode, default 'w'.

encoding [str, optional] A string representing the encoding to use in the output file, defaults to 'utf-8'.

compression [str or dict, default 'infer'] If str, represents compression mode. If dict, value at 'method' is the compression mode. Compression mode may be any of the following possible values: {'infer', 'gzip', 'bz2', 'zip', 'xz', None}. If compression mode is 'infer' and *path_or_buf* is path-like, then detect compression mode from the following extensions: '.gz', '.bz2', '.zip' or '.xz'. (otherwise no compression). If dict given and mode is one of {'zip', 'gzip', 'bz2'}, or inferred as one of the above, other entries passed as additional compression options.

Changed in version 1.0.0: May now be a dict with key 'method' as compression mode and other entries as additional compression options if compression mode is 'zip'.

Changed in version 1.1.0: Passing compression options as keys in dict is supported for compression modes 'gzip' and 'bz2' as well as 'zip'.

quoting [optional constant from csv module] Defaults to csv.QUOTE_MINIMAL. If you have set a *float_format* then floats are converted to strings and thus csv.QUOTE_NONNUMERIC will treat them as non-numeric.

quotechar [str, default '"'] String of length 1. Character used to quote fields.

line_terminator [str, optional] The newline character or character sequence to use in the output file. Defaults to *os.linesep*, which depends on the OS in which this method is called ('n' for linux, 'rn' for Windows, i.e.).

Changed in version 0.24.0.

chunksize [int or None] Rows to write at a time.

date_format [str, default None] Format string for datetime objects.

doublequote [bool, default True] Control quoting of *quotechar* inside a field.

escapechar [str, default None] String of length 1. Character used to escape *sep* and *quotechar* when appropriate.

decimal [str, default '.'] Character recognized as decimal separator. E.g. use ',' for European data.

errors [str, default 'strict'] Specifies how encoding and decoding errors are to be handled. See the errors argument for `open()` for a full list of options.

New in version 1.1.0.

Returns

None or str If path_or_buf is None, returns the resulting csv format as a string. Otherwise returns None.

See also:

read_csv Load a CSV file into a DataFrame.

to_excel Write DataFrame to an Excel file.

Examples

```
>>> df = pd.DataFrame({'name': ['Raphael', 'Donatello'],
...                    'mask': ['red', 'purple'],
...                    'weapon': ['sai', 'bo staff']})
>>> df.to_csv(index=False)
'name,mask,weapon\nRaphael,red,sai\nDonatello,purple,bo staff\n'
```

Create 'out.zip' containing 'out.csv'

```
>>> compression_opts = dict(method='zip',
...                         archive_name='out.csv')
>>> df.to_csv('out.zip', index=False,
...           compression=compression_opts)
```

pandas.Series.to_dict

Series.**to_dict**(*into=<class 'dict'>*)

Convert Series to {label -> value} dict or dict-like object.

Parameters

into [class, default dict] The collections.abc.Mapping subclass to use as the return object. Can be the actual class or an empty instance of the mapping type you want. If you want a collections.defaultdict, you must pass it initialized.

Returns

collections.abc.Mapping Key-value representation of Series.

Examples

```
>>> s = pd.Series([1, 2, 3, 4])
>>> s.to_dict()
{0: 1, 1: 2, 2: 3, 3: 4}
>>> from collections import OrderedDict, defaultdict
>>> s.to_dict(OrderedDict)
OrderedDict([(0, 1), (1, 2), (2, 3), (3, 4)])
>>> dd = defaultdict(list)
>>> s.to_dict(dd)
defaultdict(<class 'list'>, {0: 1, 1: 2, 2: 3, 3: 4})
```

pandas.Series.to_excel

Series.**to_excel**(*excel_writer*, *sheet_name='Sheet1'*, *na_rep=''*, *float_format=None*, *columns=None*, *header=True*, *index=True*, *index_label=None*, *startrow=0*, *startcol=0*, *engine=None*, *merge_cells=True*, *encoding=None*, *inf_rep='inf'*, *verbose=True*, *freeze_panes=None*)

Write object to an Excel sheet.

To write a single object to an Excel .xlsx file it is only necessary to specify a target file name. To write to multiple sheets it is necessary to create an *ExcelWriter* object with a target file name, and specify a sheet in the file to write to.

Multiple sheets may be written to by specifying unique *sheet_name*. With all data written to the file it is necessary to save the changes. Note that creating an *ExcelWriter* object with a file name that already exists will result in the contents of the existing file being erased.

Parameters

excel_writer [str or ExcelWriter object] File path or existing ExcelWriter.

sheet_name [str, default 'Sheet1'] Name of sheet which will contain DataFrame.

na_rep [str, default ''] Missing data representation.

float_format [str, optional] Format string for floating point numbers. For example `float_format="%.2f"` will format 0.1234 to 0.12.

columns [sequence or list of str, optional] Columns to write.

header [bool or list of str, default True] Write out the column names. If a list of string is given it is assumed to be aliases for the column names.

index [bool, default True] Write row names (index).

index_label [str or sequence, optional] Column label for index column(s) if desired. If not specified, and *header* and *index* are True, then the index names are used. A sequence should be given if the DataFrame uses MultiIndex.

startrow [int, default 0] Upper left cell row to dump data frame.

startcol [int, default 0] Upper left cell column to dump data frame.

engine [str, optional] Write engine to use, 'openpyxl' or 'xlsxwriter'. You can also set this via the options `io.excel.xlsx.writer`, `io.excel.xls.writer`, and `io.excel.xlsm.writer`.

merge_cells [bool, default True] Write MultiIndex and Hierarchical Rows as merged cells.

encoding [str, optional] Encoding of the resulting excel file. Only necessary for xlwt, other writers support unicode natively.

inf_rep [str, default 'inf'] Representation for infinity (there is no native representation for infinity in Excel).

verbose [bool, default True] Display more information in the error logs.

freeze_panes [tuple of int (length 2), optional] Specifies the one-based bottommost row and rightmost column that is to be frozen.

See also:

to_csv Write DataFrame to a comma-separated values (csv) file.

ExcelWriter Class for writing DataFrame objects into excel sheets.

read_excel Read an Excel file into a pandas DataFrame.

read_csv Read a comma-separated values (csv) file into DataFrame.

Notes

For compatibility with *to_csv()*, to_excel serializes lists and dicts to strings before writing.

Once a workbook has been saved it is not possible write further data without rewriting the whole workbook.

Examples

Create, write to and save a workbook:

```
>>> df1 = pd.DataFrame([['a', 'b'], ['c', 'd']],
...                    index=['row 1', 'row 2'],
...                    columns=['col 1', 'col 2'])
>>> df1.to_excel("output.xlsx")
```

To specify the sheet name:

```
>>> df1.to_excel("output.xlsx",
...              sheet_name='Sheet_name_1')
```

If you wish to write to more than one sheet in the workbook, it is necessary to specify an ExcelWriter object:

```
>>> df2 = df1.copy()
>>> with pd.ExcelWriter('output.xlsx') as writer:
...     df1.to_excel(writer, sheet_name='Sheet_name_1')
...     df2.to_excel(writer, sheet_name='Sheet_name_2')
```

ExcelWriter can also be used to append to an existing Excel file:

```
>>> with pd.ExcelWriter('output.xlsx',
...                     mode='a') as writer:
...     df.to_excel(writer, sheet_name='Sheet_name_3')
```

To set the library that is used to write the Excel file, you can pass the *engine* keyword (the default engine is automatically chosen depending on the file extension):

```
>>> df1.to_excel('output1.xlsx', engine='xlsxwriter')
```

pandas.Series.to_frame

Series.**to_frame**(*name=None*)

Convert Series to DataFrame.

Parameters

name [object, default None] The passed name should substitute for the series name (if it has one).

Returns

DataFrame DataFrame representation of Series.

Examples

```
>>> s = pd.Series(["a", "b", "c"],
...               name="vals")
>>> s.to_frame()
  vals
0    a
1    b
2    c
```

pandas.Series.to_hdf

Series.**to_hdf**(*path_or_buf*, *key*, *mode='a'*, *complevel=None*, *complib=None*, *append=False*, *format=None*, *index=True*, *min_itemsize=None*, *nan_rep=None*, *dropna=None*, *data_columns=None*, *errors='strict'*, *encoding='UTF-8'*)

Write the contained data to an HDF5 file using HDFStore.

Hierarchical Data Format (HDF) is self-describing, allowing an application to interpret the structure and contents of a file with no outside information. One HDF file can hold a mix of related objects which can be accessed as a group or as individual objects.

In order to add another DataFrame or Series to an existing HDF file please use append mode and a different a key.

For more information see the *user guide*.

Parameters

path_or_buf [str or pandas.HDFStore] File path or HDFStore object.

key [str] Identifier for the group in the store.

mode [{'a', 'w', 'r+'}, default 'a'] Mode to open file:

- 'w': write, a new file is created (an existing file with the same name would be deleted).
- 'a': append, an existing file is opened for reading and writing, and if the file does not exist it is created.
- 'r+': similar to 'a', but the file must already exist.

complevel [{0-9}, optional] Specifies a compression level for data. A value of 0 disables compression.

complib [{'zlib', 'lzo', 'bzip2', 'blosc'}, default 'zlib'] Specifies the compression library to be used. As of v0.20.2 these additional compressors for Blosc are supported (default if no compressor specified: 'blosc:blosclz'): {'blosc:blosclz', 'blosc:lz4', 'blosc:lz4hc', 'blosc:snappy', 'blosc:zlib', 'blosc:zstd'}. Specifying a compression library which is not available issues a ValueError.

append [bool, default False] For Table formats, append the input data to the existing.

format [{'fixed', 'table', None}, default 'fixed'] Possible values:

- 'fixed': Fixed format. Fast writing/reading. Not-appendable, nor searchable.
- 'table': Table format. Write as a PyTables Table structure which may perform worse but allow more flexible operations like searching / selecting subsets of the data.
- If None, pd.get_option('io.hdf.default_format') is checked, followed by fallback to "fixed"

errors [str, default 'strict'] Specifies how encoding and decoding errors are to be handled. See the errors argument for `open()` for a full list of options.

encoding [str, default "UTF-8"]

min_itemsize [dict or int, optional] Map column names to minimum string sizes for columns.

nan_rep [Any, optional] How to represent null values as str. Not allowed with append=True.

data_columns [list of columns or True, optional] List of columns to create as indexed data columns for on-disk queries, or True to use all columns. By default only the axes of the object are indexed. See *Query via data columns*. Applicable only to format='table'.

See also:

`DataFrame.read_hdf` Read from HDF file.

`DataFrame.to_parquet` Write a DataFrame to the binary parquet format.

`DataFrame.to_sql` Write to a sql table.

`DataFrame.to_feather` Write out feather-format for DataFrames.

`DataFrame.to_csv` Write out to a csv file.

Examples

```
>>> df = pd.DataFrame({'A': [1, 2, 3], 'B': [4, 5, 6]},
...                   index=['a', 'b', 'c'])
>>> df.to_hdf('data.h5', key='df', mode='w')
```

We can add another object to the same file:

```
>>> s = pd.Series([1, 2, 3, 4])
>>> s.to_hdf('data.h5', key='s')
```

Reading from HDF file:

```
>>> pd.read_hdf('data.h5', 'df')
A  B
a  1  4
b  2  5
c  3  6
>>> pd.read_hdf('data.h5', 's')
0    1
1    2
2    3
3    4
dtype: int64
```

Deleting file with data:

```
>>> import os
>>> os.remove('data.h5')
```

pandas.Series.to_json

Series.**to_json**(*path_or_buf=None*, *orient=None*, *date_format=None*, *double_precision=10*, *force_ascii=True*, *date_unit='ms'*, *default_handler=None*, *lines=False*, *compression='infer'*, *index=True*, *indent=None*)

Convert the object to a JSON string.

Note NaN's and None will be converted to null and datetime objects will be converted to UNIX timestamps.

Parameters

path_or_buf [str or file handle, optional] File path or object. If not specified, the result is returned as a string.

orient [str] Indication of expected JSON string format.

- Series:
  - default is 'index'
  - allowed values are: {'split','records','index','table'}.
- DataFrame:
  - default is 'columns'
  - allowed values are: {'split', 'records', 'index', 'columns', 'values', 'table'}.
- The format of the JSON string:

- 'split' : dict like {'index' -> [index], 'columns' -> [columns], 'data' -> [values]}
- 'records' : list like [{column -> value}, ... , {column -> value}]
- 'index' : dict like {index -> {column -> value}}
- 'columns' : dict like {column -> {index -> value}}
- 'values' : just the values array
- 'table' : dict like {'schema': {schema}, 'data': {data}}

Describing the data, where data component is like `orient='records'`.

Changed in version 0.20.0.

date_format [{None, 'epoch', 'iso'}] Type of date conversion. 'epoch' = epoch milliseconds, 'iso' = ISO8601. The default depends on the *orient*. For `orient='table'`, the default is 'iso'. For all other orients, the default is 'epoch'.

double_precision [int, default 10] The number of decimal places to use when encoding floating point values.

force_ascii [bool, default True] Force encoded string to be ASCII.

date_unit [str, default 'ms' (milliseconds)] The time unit to encode to, governs timestamp and ISO8601 precision. One of 's', 'ms', 'us', 'ns' for second, millisecond, microsecond, and nanosecond respectively.

default_handler [callable, default None] Handler to call if object cannot otherwise be converted to a suitable format for JSON. Should receive a single argument which is the object to convert and return a serialisable object.

lines [bool, default False] If 'orient' is 'records' write out line delimited json format. Will throw ValueError if incorrect 'orient' since others are not list like.

compression [{'infer', 'gzip', 'bz2', 'zip', 'xz', None}] A string representing the compression to use in the output file, only used when the first argument is a filename. By default, the compression is inferred from the filename.

Changed in version 0.24.0: 'infer' option added and set to default

index [bool, default True] Whether to include the index values in the JSON string. Not including the index (`index=False`) is only supported when orient is 'split' or 'table'.

New in version 0.23.0.

indent [int, optional] Length of whitespace used to indent each record.

New in version 1.0.0.

Returns

None or str If path_or_buf is None, returns the resulting json format as a string. Otherwise returns None.

See also:

read_json Convert a JSON string to pandas object.

Notes

The behavior of `indent=0` varies from the stdlib, which does not indent the output but does insert newlines. Currently, `indent=0` and the default `indent=None` are equivalent in pandas, though this may change in a future release.

Examples

```
>>> import json
>>> df = pd.DataFrame(
...     [["a", "b"], ["c", "d"]],
...     index=["row 1", "row 2"],
...     columns=["col 1", "col 2"],
... )
```

```
>>> result = df.to_json(orient="split")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
{
    "columns": [
        "col 1",
        "col 2"
    ],
    "index": [
        "row 1",
        "row 2"
    ],
    "data": [
        [
            "a",
            "b"
        ],
        [
            "c",
            "d"
        ]
    ]
}
```

Encoding/decoding a Dataframe using `'records'` formatted JSON. Note that index labels are not preserved with this encoding.

```
>>> result = df.to_json(orient="records")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
[
    {
        "col 1": "a",
        "col 2": "b"
    },
    {
        "col 1": "c",
        "col 2": "d"
    }
]
```

Encoding/decoding a Dataframe using `'index'` formatted JSON:

```
>>> result = df.to_json(orient="index")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
{
    "row 1": {
        "col 1": "a",
        "col 2": "b"
    },
    "row 2": {
        "col 1": "c",
        "col 2": "d"
    }
}
```

Encoding/decoding a Dataframe using `'columns'` formatted JSON:

```
>>> result = df.to_json(orient="columns")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
{
    "col 1": {
        "row 1": "a",
        "row 2": "c"
    },
    "col 2": {
        "row 1": "b",
        "row 2": "d"
    }
}
```

Encoding/decoding a Dataframe using `'values'` formatted JSON:

```
>>> result = df.to_json(orient="values")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
[
    [
        "a",
        "b"
    ],
    [
        "c",
        "d"
    ]
]
```

Encoding with Table Schema:

```
>>> result = df.to_json(orient="table")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
{
    "schema": {
        "fields": [
            {
                "name": "index",
```

(continues on next page)

(continued from previous page)

```
                "type": "string"
            },
            {
                "name": "col 1",
                "type": "string"
            },
            {
                "name": "col 2",
                "type": "string"
            }
        ],
        "primaryKey": [
            "index"
        ],
        "pandas_version": "0.20.0"
    },
    "data": [
        {
            "index": "row 1",
            "col 1": "a",
            "col 2": "b"
        },
        {
            "index": "row 2",
            "col 1": "c",
            "col 2": "d"
        }
    ]
}
```

pandas.Series.to_latex

Series.**to_latex**(*buf=None*, *columns=None*, *col_space=None*, *header=True*, *index=True*, *na_rep='NaN'*, *formatters=None*, *float_format=None*, *sparsify=None*, *index_names=True*, *bold_rows=False*, *column_format=None*, *longtable=None*, *escape=None*, *encoding=None*, *decimal='.'*, *multicolumn=None*, *multicolumn_format=None*, *multirow=None*, *caption=None*, *label=None*)

Render object to a LaTeX tabular, longtable, or nested table/tabular.

Requires `\usepackage{booktabs}`. The output can be copy/pasted into a main LaTeX document or read from an external file with `\input{table.tex}`.

Changed in version 0.20.2: Added to Series.

Changed in version 1.0.0: Added caption and label arguments.

Parameters

buf [str, Path or StringIO-like, optional, default None] Buffer to write to. If None, the output is returned as a string.

columns [list of label, optional] The subset of columns to write. Writes all columns by default.

col_space [int, optional] The minimum width of each column.

header [bool or list of str, default True] Write out the column names. If a list of strings is given, it is assumed to be aliases for the column names.

index [bool, default True] Write row names (index).

na_rep [str, default 'NaN'] Missing data representation.

formatters [list of functions or dict of {str: function}, optional] Formatter functions to apply to columns' elements by position or name. The result of each function must be a unicode string. List must be of length equal to the number of columns.

float_format [one-parameter function or str, optional, default None] Formatter for floating point numbers. For example `float_format="%.2f"` and `float_format="{:0.2f}".format` will both result in 0.1234 being formatted as 0.12.

sparsify [bool, optional] Set to False for a DataFrame with a hierarchical index to print every multiindex key at each row. By default, the value will be read from the config module.

index_names [bool, default True] Prints the names of the indexes.

bold_rows [bool, default False] Make the row labels bold in the output.

column_format [str, optional] The columns format as specified in LaTeX table format e.g. 'rcl' for 3 columns. By default, 'l' will be used for all columns except columns of numbers, which default to 'r'.

longtable [bool, optional] By default, the value will be read from the pandas config module. Use a longtable environment instead of tabular. Requires adding a usepackage{longtable} to your LaTeX preamble.

escape [bool, optional] By default, the value will be read from the pandas config module. When set to False prevents from escaping latex special characters in column names.

encoding [str, optional] A string representing the encoding to use in the output file, defaults to 'utf-8'.

decimal [str, default '.'] Character recognized as decimal separator, e.g. ',' in Europe.

multicolumn [bool, default True] Use multicolumn to enhance MultiIndex columns. The default will be read from the config module.

multicolumn_format [str, default 'l'] The alignment for multicolumns, similar to *column_format* The default will be read from the config module.

multirow [bool, default False] Use multirow to enhance MultiIndex rows. Requires adding a usepackage{multirow} to your LaTeX preamble. Will print centered labels (instead of top-aligned) across the contained rows, separating groups via clines. The default will be read from the pandas config module.

caption [str, optional] The LaTeX caption to be placed inside `\caption{}` in the output.

New in version 1.0.0.

label [str, optional] The LaTeX label to be placed inside `\label{}` in the output. This is used with `\ref{}` in the main `.tex` file.

New in version 1.0.0.

Returns

str or None If buf is None, returns the result as a string. Otherwise returns None.

See also:

DataFrame.to_string Render a DataFrame to a console-friendly tabular output.

DataFrame.to_html Render a DataFrame as an HTML table.

Examples

```
>>> df = pd.DataFrame({'name': ['Raphael', 'Donatello'],
...                    'mask': ['red', 'purple'],
...                    'weapon': ['sai', 'bo staff']})
>>> print(df.to_latex(index=False))
\begin{tabular}{lll}
 \toprule
       name &    mask &    weapon \\
 \midrule
    Raphael &     red &       sai \\
  Donatello &  purple &  bo staff \\
\bottomrule
\end{tabular}
```

pandas.Series.to_list

Series.**to_list**()
Return a list of the values.

These are each a scalar type, which is a Python scalar (for str, int, float) or a pandas scalar (for Timestamp/Timedelta/Interval/Period)

Returns

list

See also:

numpy.ndarray.tolist Return the array as an a.ndim-levels deep nested list of Python scalars.

pandas.Series.to_markdown

Series.**to_markdown**(*buf=None*, *mode=None*, *index=True*, ***kwargs*)
Print Series in Markdown-friendly format.

New in version 1.0.0.

Parameters

buf [str, Path or StringIO-like, optional, default None] Buffer to write to. If None, the output is returned as a string.

mode [str, optional] Mode in which file is opened.

index [bool, optional, default True] Add index (row) labels.

New in version 1.1.0.

****kwargs** These parameters will be passed to tabulate.

Returns

str Series in Markdown-friendly format.

Examples

```
>>> s = pd.Series(["elk", "pig", "dog", "quetzal"], name="animal")
>>> print(s.to_markdown())
|    | animal   |
|---:|:---------|
|  0 | elk      |
|  1 | pig      |
|  2 | dog      |
|  3 | quetzal  |
```

Output markdown with a tabulate option.

```
>>> print(s.to_markdown(tablefmt="grid"))
+----+----------+
|    | animal   |
+====+==========+
|  0 | elk      |
+----+----------+
|  1 | pig      |
+----+----------+
|  2 | dog      |
+----+----------+
|  3 | quetzal  |
+----+----------+
```

pandas.Series.to_numpy

Series.**to_numpy**(*dtype=None*, *copy=False*, *na_value=<object object>*, ***kwargs*)

A NumPy ndarray representing the values in this Series or Index.

New in version 0.24.0.

Parameters

dtype [str or numpy.dtype, optional] The dtype to pass to `numpy.asarray()`.

copy [bool, default False] Whether to ensure that the returned value is not a view on another array. Note that `copy=False` does not *ensure* that `to_numpy()` is no-copy. Rather, `copy=True` ensure that a copy is made, even if not strictly necessary.

na_value [Any, optional] The value to use for missing values. The default value depends on *dtype* and the type of the array.

New in version 1.0.0.

****kwargs** Additional keywords passed through to the `to_numpy` method of the underlying array (for extension arrays).

New in version 1.0.0.

Returns

numpy.ndarray

See also:

Series.array Get the actual data stored within.

Index.array Get the actual data stored within.

DataFrame.to_numpy Similar method for DataFrame.

Notes

The returned array will be the same up to equality (values equal in *self* will be equal in the returned array; likewise for values that are not equal). When *self* contains an ExtensionArray, the dtype may be different. For example, for a category-dtype Series, `to_numpy()` will return a NumPy array and the categorical dtype will be lost.

For NumPy dtypes, this will be a reference to the actual data stored in this Series or Index (assuming `copy=False`). Modifying the result in place will modify the data stored in the Series or Index (not that we recommend doing that).

For extension types, `to_numpy()` *may* require copying data and coercing the result to a NumPy type (possibly object), which may be expensive. When you need a no-copy reference to the underlying data, *Series.array* should be used instead.

This table lays out the different dtypes and default return types of `to_numpy()` for various dtypes within pandas.

dtype	array type
category[T]	ndarray[T] (same dtype as input)
period	ndarray[object] (Periods)
interval	ndarray[object] (Intervals)
IntegerNA	ndarray[object]
datetime64[ns]	datetime64[ns]
datetime64[ns, tz]	ndarray[object] (Timestamps)

Examples

```
>>> ser = pd.Series(pd.Categorical(['a', 'b', 'a']))
>>> ser.to_numpy()
array(['a', 'b', 'a'], dtype=object)
```

Specify the *dtype* to control how datetime-aware data is represented. Use `dtype=object` to return an ndarray of pandas *Timestamp* objects, each with the correct `tz`.

```
>>> ser = pd.Series(pd.date_range('2000', periods=2, tz="CET"))
>>> ser.to_numpy(dtype=object)
array([Timestamp('2000-01-01 00:00:00+0100', tz='CET', freq='D'),
       Timestamp('2000-01-02 00:00:00+0100', tz='CET', freq='D')],
      dtype=object)
```

Or `dtype='datetime64[ns]'` to return an ndarray of native datetime64 values. The values are converted to UTC and the timezone info is dropped.

```
>>> ser.to_numpy(dtype="datetime64[ns]")
...
array(['1999-12-31T23:00:00.000000000', '2000-01-01T23:00:00...'],
      dtype='datetime64[ns]')
```

pandas.Series.to_period

Series.**to_period**(*freq=None*, *copy=True*)

Convert Series from DatetimeIndex to PeriodIndex.

Parameters

freq [str, default None] Frequency associated with the PeriodIndex.

copy [bool, default True] Whether or not to return a copy.

Returns

Series Series with index converted to PeriodIndex.

pandas.Series.to_pickle

Series.**to_pickle**(*path*, *compression='infer'*, *protocol=5*)

Pickle (serialize) object to file.

Parameters

path [str] File path where the pickled object will be stored.

compression [{'infer', 'gzip', 'bz2', 'zip', 'xz', None}, default 'infer'] A string representing the compression to use in the output file. By default, infers from the file extension in specified path.

protocol [int] Int which indicates which protocol should be used by the pickler, default HIGHEST_PROTOCOL (see [1] paragraph 12.1.2). The possible values are 0, 1, 2, 3, 4. A negative value for the protocol parameter is equivalent to setting its value to HIGHEST_PROTOCOL.

See also:

read_pickle Load pickled pandas object (or any object) from file.

DataFrame.to_hdf Write DataFrame to an HDF5 file.

DataFrame.to_sql Write DataFrame to a SQL database.

DataFrame.to_parquet Write a DataFrame to the binary parquet format.

Examples

```
>>> original_df = pd.DataFrame({"foo": range(5), "bar": range(5, 10)})
>>> original_df
   foo  bar
0    0    5
1    1    6
2    2    7
3    3    8
4    4    9
>>> original_df.to_pickle("./dummy.pkl")
```

```
>>> unpickled_df = pd.read_pickle("./dummy.pkl")
>>> unpickled_df
   foo  bar
```

(continues on next page)

(continued from previous page)

```
0    0    5
1    1    6
2    2    7
3    3    8
4    4    9
```

```
>>> import os
>>> os.remove("./dummy.pkl")
```

pandas.Series.to_sql

Series.**to_sql**(*name*, *con*, *schema=None*, *if_exists='fail'*, *index=True*, *index_label=None*, *chunksize=None*, *dtype=None*, *method=None*)

Write records stored in a DataFrame to a SQL database.

Databases supported by SQLAlchemy [1] are supported. Tables can be newly created, appended to, or overwritten.

Parameters

name [str] Name of SQL table.

con [sqlalchemy.engine.(Engine or Connection) or sqlite3.Connection] Using SQLAlchemy makes it possible to use any DB supported by that library. Legacy support is provided for sqlite3.Connection objects. The user is responsible for engine disposal and connection closure for the SQLAlchemy connectable See here.

schema [str, optional] Specify the schema (if database flavor supports this). If None, use default schema.

if_exists [{'fail', 'replace', 'append'}, default 'fail'] How to behave if the table already exists.

- fail: Raise a ValueError.
- replace: Drop the table before inserting new values.
- append: Insert new values to the existing table.

index [bool, default True] Write DataFrame index as a column. Uses *index_label* as the column name in the table.

index_label [str or sequence, default None] Column label for index column(s). If None is given (default) and *index* is True, then the index names are used. A sequence should be given if the DataFrame uses MultiIndex.

chunksize [int, optional] Specify the number of rows in each batch to be written at a time. By default, all rows will be written at once.

dtype [dict or scalar, optional] Specifying the datatype for columns. If a dictionary is used, the keys should be the column names and the values should be the SQLAlchemy types or strings for the sqlite3 legacy mode. If a scalar is provided, it will be applied to all columns.

method [{None, 'multi', callable}, optional] Controls the SQL insertion clause used:

- None : Uses standard SQL `INSERT` clause (one per row).
- 'multi': Pass multiple values in a single `INSERT` clause.

- callable with signature `(pd_table, conn, keys, data_iter)`.

Details and a sample callable implementation can be found in the section *insert method*.

New in version 0.24.0.

Raises

ValueError When the table already exists and *if_exists* is 'fail' (the default).

See also:

read_sql Read a DataFrame from a table.

Notes

Timezone aware datetime columns will be written as `Timestamp with timezone` type with SQLAlchemy if supported by the database. Otherwise, the datetimes will be stored as timezone unaware timestamps local to the original timezone.

New in version 0.24.0.

References

[1], [2]

Examples

Create an in-memory SQLite database.

```
>>> from sqlalchemy import create_engine
>>> engine = create_engine('sqlite://', echo=False)
```

Create a table from scratch with 3 rows.

```
>>> df = pd.DataFrame({'name' : ['User 1', 'User 2', 'User 3']})
>>> df
     name
0  User 1
1  User 2
2  User 3
```

```
>>> df.to_sql('users', con=engine)
>>> engine.execute("SELECT * FROM users").fetchall()
[(0, 'User 1'), (1, 'User 2'), (2, 'User 3')]
```

An *sqlalchemy.engine.Connection* can also be passed to to *con*: >>> with engine.begin() as connection: ... df1 = pd.DataFrame({'name' : ['User 4', 'User 5']}) ... df1.to_sql('users', con=connection, if_exists='append')

This is allowed to support operations that require that the same DBAPI connection is used for the entire operation.

```
>>> df2 = pd.DataFrame({'name' : ['User 6', 'User 7']})
>>> df2.to_sql('users', con=engine, if_exists='append')
>>> engine.execute("SELECT * FROM users").fetchall()
[(0, 'User 1'), (1, 'User 2'), (2, 'User 3'),
 (0, 'User 4'), (1, 'User 5'), (0, 'User 6'),
 (1, 'User 7')]
```

Overwrite the table with just `df2`.

```
>>> df2.to_sql('users', con=engine, if_exists='replace',
...            index_label='id')
>>> engine.execute("SELECT * FROM users").fetchall()
[(0, 'User 6'), (1, 'User 7')]
```

Specify the dtype (especially useful for integers with missing values). Notice that while pandas is forced to store the data as floating point, the database supports nullable integers. When fetching the data with Python, we get back integer scalars.

```
>>> df = pd.DataFrame({"A": [1, None, 2]})
>>> df
     A
0  1.0
1  NaN
2  2.0
```

```
>>> from sqlalchemy.types import Integer
>>> df.to_sql('integers', con=engine, index=False,
...           dtype={"A": Integer()})
```

```
>>> engine.execute("SELECT * FROM integers").fetchall()
[(1,), (None,), (2,)]
```

pandas.Series.to_string

Series.**to_string**(*buf=None*, *na_rep='NaN'*, *float_format=None*, *header=True*, *index=True*, *length=False*, *dtype=False*, *name=False*, *max_rows=None*, *min_rows=None*)

Render a string representation of the Series.

Parameters

buf [StringIO-like, optional] Buffer to write to.

na_rep [str, optional] String representation of NaN to use, default 'NaN'.

float_format [one-parameter function, optional] Formatter function to apply to columns' elements if they are floats, default None.

header [bool, default True] Add the Series header (index name).

index [bool, optional] Add index (row) labels, default True.

length [bool, default False] Add the Series length.

dtype [bool, default False] Add the Series dtype.

name [bool, default False] Add the Series name if not None.

max_rows [int, optional] Maximum number of rows to show before truncating. If None, show all.

min_rows [int, optional] The number of rows to display in a truncated repr (when number of rows is above *max_rows*).

Returns

str or None String representation of Series if `buf=None`, otherwise None.

pandas.Series.to_timestamp

`Series.to_timestamp`(*freq=None*, *how='start'*, *copy=True*)

Cast to DatetimeIndex of Timestamps, at *beginning* of period.

Parameters

freq [str, default frequency of PeriodIndex] Desired frequency.

how [{'s', 'e', 'start', 'end'}] Convention for converting period to timestamp; start of period vs. end.

copy [bool, default True] Whether or not to return a copy.

Returns

Series with DatetimeIndex

pandas.Series.to_xarray

`Series.to_xarray`()

Return an xarray object from the pandas object.

Returns

xarray.DataArray or xarray.Dataset Data in the pandas structure converted to Dataset if the object is a DataFrame, or a DataArray if the object is a Series.

See also:

DataFrame.to_hdf Write DataFrame to an HDF5 file.

DataFrame.to_parquet Write a DataFrame to the binary parquet format.

Notes

See the xarray docs

Examples

```
>>> df = pd.DataFrame([('falcon', 'bird', 389.0, 2),
...                    ('parrot', 'bird', 24.0, 2),
...                    ('lion', 'mammal', 80.5, 4),
...                    ('monkey', 'mammal', np.nan, 4)],
...                   columns=['name', 'class', 'max_speed',
...                            'num_legs'])
>>> df
     name   class  max_speed  num_legs
0  falcon    bird      389.0         2
```

(continues on next page)

(continued from previous page)

```
1  parrot    bird       24.0         2
2    lion  mammal       80.5         4
3  monkey  mammal        NaN         4
```

```
>>> df.to_xarray()
<xarray.Dataset>
Dimensions:    (index: 4)
Coordinates:
  * index      (index) int64 0 1 2 3
Data variables:
    name       (index) object 'falcon' 'parrot' 'lion' 'monkey'
    class      (index) object 'bird' 'bird' 'mammal' 'mammal'
    max_speed  (index) float64 389.0 24.0 80.5 nan
    num_legs   (index) int64 2 2 4 4
```

```

```

```
>>> dates = pd.to_datetime(['2018-01-01', '2018-01-01',
...                         '2018-01-02', '2018-01-02'])
>>> df_multiindex = pd.DataFrame({'date': dates,
...                               'animal': ['falcon', 'parrot',
...                                          'falcon', 'parrot'],
...                               'speed': [350, 18, 361, 15]})
>>> df_multiindex = df_multiindex.set_index(['date', 'animal'])
```

```
>>> df_multiindex
                   speed
date       animal
2018-01-01 falcon    350
           parrot     18
2018-01-02 falcon    361
           parrot     15
```

```
>>> df_multiindex.to_xarray()
<xarray.Dataset>
Dimensions:  (animal: 2, date: 2)
Coordinates:
  * date     (date) datetime64[ns] 2018-01-01 2018-01-02
  * animal   (animal) object 'falcon' 'parrot'
Data variables:
    speed    (date, animal) int64 350 18 361 15
```

pandas.Series.tolist

Series.**tolist**()

Return a list of the values.

These are each a scalar type, which is a Python scalar (for str, int, float) or a pandas scalar (for Timestamp/Timedelta/Interval/Period)

Returns

list

See also:

numpy.ndarray.tolist Return the array as an a.ndim-levels deep nested list of Python scalars.

pandas.Series.transform

Series.**transform**(*func*, *axis=0*, **args*, ***kwargs*)

Call `func` on self producing a Series with transformed values.

Produced Series will have same axis length as self.

Parameters

func [function, str, list or dict] Function to use for transforming the data. If a function, must either work when passed a Series or when passed to Series.apply.

Accepted combinations are:

- function
- string function name
- list of functions and/or function names, e.g. `[np.exp. 'sqrt']`
- dict of axis labels -> functions, function names or list of such.

axis [{0 or 'index'}] Parameter needed for compatibility with DataFrame.

***args** Positional arguments to pass to *func*.

****kwargs** Keyword arguments to pass to *func*.

Returns

Series A Series that must have the same length as self.

Raises

ValueError [If the returned Series has a different length than self.]

See also:

Series.agg Only perform aggregating type operations.

Series.apply Invoke function on a Series.

Examples

```
>>> df = pd.DataFrame({'A': range(3), 'B': range(1, 4)})
>>> df
   A  B
0  0  1
1  1  2
2  2  3
>>> df.transform(lambda x: x + 1)
   A  B
0  1  2
1  2  3
2  3  4
```

Even though the resulting Series must have the same length as the input Series, it is possible to provide several input functions:

```
>>> s = pd.Series(range(3))
>>> s
0    0
1    1
2    2
dtype: int64
>>> s.transform([np.sqrt, np.exp])
       sqrt        exp
0  0.000000   1.000000
1  1.000000   2.718282
2  1.414214   7.389056
```

pandas.Series.transpose

Series.**transpose**(**args*, ***kwargs*)

Return the transpose, which is by definition self.

Returns

%(klass)s

pandas.Series.truediv

Series.**truediv**(*other*, *level=None*, *fill_value=None*, *axis=0*)

Return Floating division of series and other, element-wise (binary operator *truediv*).

Equivalent to `series / other`, but with support to substitute a fill_value for missing data in either one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

Series The result of the operation.

See also:

Series.rtruediv Reverse of the Floating division operator, see Python documentation for more details.

Examples

```
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.divide(b, fill_value=0)
a    1.0
b    inf
c    inf
d    0.0
e    NaN
dtype: float64
```

pandas.Series.truncate

Series.**truncate**(*before=None*, *after=None*, *axis=None*, *copy=True*)

Truncate a Series or DataFrame before and after some index value.

This is a useful shorthand for boolean indexing based on index values above or below certain thresholds.

Parameters

before [date, str, int] Truncate all rows before this index value.

after [date, str, int] Truncate all rows after this index value.

axis [{0 or 'index', 1 or 'columns'}, optional] Axis to truncate. Truncates the index (rows) by default.

copy [bool, default is True,] Return a copy of the truncated section.

Returns

type of caller The truncated Series or DataFrame.

See also:

DataFrame.loc Select a subset of a DataFrame by label.

DataFrame.iloc Select a subset of a DataFrame by position.

Notes

If the index being truncated contains only datetime values, *before* and *after* may be specified as strings instead of Timestamps.

Examples

```
>>> df = pd.DataFrame({'A': ['a', 'b', 'c', 'd', 'e'],
...                    'B': ['f', 'g', 'h', 'i', 'j'],
...                    'C': ['k', 'l', 'm', 'n', 'o']},
...                   index=[1, 2, 3, 4, 5])
>>> df
   A  B  C
1  a  f  k
2  b  g  l
3  c  h  m
4  d  i  n
5  e  j  o
```

```
>>> df.truncate(before=2, after=4)
   A  B  C
2  b  g  l
3  c  h  m
4  d  i  n
```

The columns of a DataFrame can be truncated.

```
>>> df.truncate(before="A", after="B", axis="columns")
   A  B
1  a  f
2  b  g
3  c  h
4  d  i
5  e  j
```

For Series, only rows can be truncated.

```
>>> df['A'].truncate(before=2, after=4)
2    b
3    c
4    d
Name: A, dtype: object
```

The index values in `truncate` can be datetimes or string dates.

```
>>> dates = pd.date_range('2016-01-01', '2016-02-01', freq='s')
>>> df = pd.DataFrame(index=dates, data={'A': 1})
>>> df.tail()
                     A
2016-01-31 23:59:56  1
2016-01-31 23:59:57  1
2016-01-31 23:59:58  1
```

(continues on next page)

(continued from previous page)

```
2016-01-31 23:59:59  1
2016-02-01 00:00:00  1
```

```
>>> df.truncate(before=pd.Timestamp('2016-01-05'),
...              after=pd.Timestamp('2016-01-10')).tail()
                     A
2016-01-09 23:59:56  1
2016-01-09 23:59:57  1
2016-01-09 23:59:58  1
2016-01-09 23:59:59  1
2016-01-10 00:00:00  1
```

Because the index is a DatetimeIndex containing only dates, we can specify *before* and *after* as strings. They will be coerced to Timestamps before truncation.

```
>>> df.truncate('2016-01-05', '2016-01-10').tail()
                     A
2016-01-09 23:59:56  1
2016-01-09 23:59:57  1
2016-01-09 23:59:58  1
2016-01-09 23:59:59  1
2016-01-10 00:00:00  1
```

Note that `truncate` assumes a 0 value for any unspecified time component (midnight). This differs from partial string slicing, which returns any partially matching dates.

```
>>> df.loc['2016-01-05':'2016-01-10', :].tail()
                     A
2016-01-10 23:59:55  1
2016-01-10 23:59:56  1
2016-01-10 23:59:57  1
2016-01-10 23:59:58  1
2016-01-10 23:59:59  1
```

pandas.Series.tshift

`Series.`**`tshift`**(*periods=1*, *freq=None*, *axis=0*)

Shift the time index, using the index's frequency if available.

Deprecated since version 1.1.0: Use *shift* instead.

Parameters

periods [int] Number of periods to move, can be positive or negative.

freq [DateOffset, timedelta, or str, default None] Increment to use from the tseries module or time rule expressed as a string (e.g. 'EOM').

axis [{0 or 'index', 1 or 'columns', None}, default 0] Corresponds to the axis that contains the Index.

Returns

shifted [Series/DataFrame]

Notes

If freq is not specified then tries to use the freq or inferred_freq attributes of the index. If neither of those attributes exist, a ValueError is thrown

pandas.Series.tz_convert

Series.**tz_convert**(*tz*, *axis=0*, *level=None*, *copy=True*)

Convert tz-aware axis to target time zone.

Parameters

tz [str or tzinfo object]

axis [the axis to convert]

level [int, str, default None] If axis is a MultiIndex, convert a specific level. Otherwise must be None.

copy [bool, default True] Also make a copy of the underlying data.

Returns

{klass} Object with time zone converted axis.

Raises

TypeError If the axis is tz-naive.

pandas.Series.tz_localize

Series.**tz_localize**(*tz*, *axis=0*, *level=None*, *copy=True*, *ambiguous='raise'*, *nonexistent='raise'*)

Localize tz-naive index of a Series or DataFrame to target time zone.

This operation localizes the Index. To localize the values in a timezone-naive Series, use *Series.dt.tz_localize()*.

Parameters

tz [str or tzinfo]

axis [the axis to localize]

level [int, str, default None] If axis ia a MultiIndex, localize a specific level. Otherwise must be None.

copy [bool, default True] Also make a copy of the underlying data.

ambiguous ['infer', bool-ndarray, 'NaT', default 'raise'] When clocks moved backward due to DST, ambiguous times may arise. For example in Central European Time (UTC+01), when going from 03:00 DST to 02:00 non-DST, 02:30:00 local time occurs both at 00:30:00 UTC and at 01:30:00 UTC. In such a situation, the *ambiguous* parameter dictates how ambiguous times should be handled.

- 'infer' will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- 'NaT' will return NaT where there are ambiguous times
- 'raise' will raise an AmbiguousTimeError if there are ambiguous times.

nonexistent [str, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST. Valid values are:

- 'shift_forward' will shift the nonexistent time forward to the closest existing time
- 'shift_backward' will shift the nonexistent time backward to the closest existing time
- 'NaT' will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- 'raise' will raise an NonExistentTimeError if there are nonexistent times.

New in version 0.24.0.

Returns

Series or DataFrame Same type as the input.

Raises

TypeError If the TimeSeries is tz-aware and tz is not None.

Examples

Localize local times:

```
>>> s = pd.Series([1],
...               index=pd.DatetimeIndex(['2018-09-15 01:30:00']))
>>> s.tz_localize('CET')
2018-09-15 01:30:00+02:00    1
dtype: int64
```

Be careful with DST changes. When there is sequential data, pandas can infer the DST time:

```
>>> s = pd.Series(range(7),
...               index=pd.DatetimeIndex(['2018-10-28 01:30:00',
...                                       '2018-10-28 02:00:00',
...                                       '2018-10-28 02:30:00',
...                                       '2018-10-28 02:00:00',
...                                       '2018-10-28 02:30:00',
...                                       '2018-10-28 03:00:00',
...                                       '2018-10-28 03:30:00']))
>>> s.tz_localize('CET', ambiguous='infer')
2018-10-28 01:30:00+02:00    0
2018-10-28 02:00:00+02:00    1
2018-10-28 02:30:00+02:00    2
2018-10-28 02:00:00+01:00    3
2018-10-28 02:30:00+01:00    4
2018-10-28 03:00:00+01:00    5
2018-10-28 03:30:00+01:00    6
dtype: int64
```

In some cases, inferring the DST is impossible. In such cases, you can pass an ndarray to the ambiguous parameter to set the DST explicitly

```
>>> s = pd.Series(range(3),
...               index=pd.DatetimeIndex(['2018-10-28 01:20:00',
...                                       '2018-10-28 02:36:00',
...                                       '2018-10-28 03:46:00']))
>>> s.tz_localize('CET', ambiguous=np.array([True, True, False]))
2018-10-28 01:20:00+02:00    0
2018-10-28 02:36:00+02:00    1
2018-10-28 03:46:00+01:00    2
dtype: int64
```

If the DST transition causes nonexistent times, you can shift these dates forward or backward with a timedelta object or *'shift_forward'* or *'shift_backward'*.

```
>>> s = pd.Series(range(2),
...               index=pd.DatetimeIndex(['2015-03-29 02:30:00',
...                                       '2015-03-29 03:30:00']))
>>> s.tz_localize('Europe/Warsaw', nonexistent='shift_forward')
2015-03-29 03:00:00+02:00    0
2015-03-29 03:30:00+02:00    1
dtype: int64
>>> s.tz_localize('Europe/Warsaw', nonexistent='shift_backward')
2015-03-29 01:59:59.999999999+01:00    0
2015-03-29 03:30:00+02:00              1
dtype: int64
>>> s.tz_localize('Europe/Warsaw', nonexistent=pd.Timedelta('1H'))
2015-03-29 03:30:00+02:00    0
2015-03-29 03:30:00+02:00    1
dtype: int64
```

pandas.Series.unique

Series.**unique**()

Return unique values of Series object.

Uniques are returned in order of appearance. Hash table-based unique, therefore does NOT sort.

Returns

ndarray or ExtensionArray The unique values returned as a NumPy array. See Notes.

See also:

unique Top-level unique method for any 1-d array-like object.

Index.unique Return Index with unique values from an Index object.

Notes

Returns the unique values as a NumPy array. In case of an extension-array backed Series, a new *ExtensionArray* of that type with just the unique values is returned. This includes

- Categorical
- Period
- Datetime with Timezone
- Interval
- Sparse
- IntegerNA

See Examples section.

Examples

```
>>> pd.Series([2, 1, 3, 3], name='A').unique()
array([2, 1, 3])
```

```
>>> pd.Series([pd.Timestamp('2016-01-01') for _ in range(3)]).unique()
array(['2016-01-01T00:00:00.000000000'], dtype='datetime64[ns]')
```

```
>>> pd.Series([pd.Timestamp('2016-01-01', tz='US/Eastern')
...             for _ in range(3)]).unique()
<DatetimeArray>
['2016-01-01 00:00:00-05:00']
Length: 1, dtype: datetime64[ns, US/Eastern]
```

An unordered Categorical will return categories in the order of appearance.

```
>>> pd.Series(pd.Categorical(list('baabc'))).unique()
['b', 'a', 'c']
Categories (3, object): ['b', 'a', 'c']
```

An ordered Categorical preserves the category ordering.

```
>>> pd.Series(pd.Categorical(list('baabc'), categories=list('abc'),
...                          ordered=True)).unique()
['b', 'a', 'c']
Categories (3, object): ['a' < 'b' < 'c']
```

pandas.Series.unstack

`Series.`**`unstack`**(*level=-1*, *fill_value=None*)

Unstack, also known as pivot, Series with MultiIndex to produce DataFrame.

Parameters

level [int, str, or list of these, default last level] Level(s) to unstack, can pass level name.

fill_value [scalar value, default None] Value to use when replacing NaN values.

Returns

DataFrame Unstacked Series.

Examples

```
>>> s = pd.Series([1, 2, 3, 4],
...               index=pd.MultiIndex.from_product([['one', 'two'],
...                                                 ['a', 'b']]))
>>> s
one  a    1
     b    2
two  a    3
     b    4
dtype: int64
```

```
>>> s.unstack(level=-1)
     a  b
one  1  2
two  3  4
```

```
>>> s.unstack(level=0)
   one  two
a    1    3
b    2    4
```

pandas.Series.update

`Series.`**`update`**(*other*)

Modify Series in place using values from passed Series.

Uses non-NA values from passed Series to make updates. Aligns on index.

Parameters

other [Series, or object coercible into Series]

Examples

```
>>> s = pd.Series([1, 2, 3])
>>> s.update(pd.Series([4, 5, 6]))
>>> s
0    4
1    5
2    6
dtype: int64
```

```
>>> s = pd.Series(['a', 'b', 'c'])
>>> s.update(pd.Series(['d', 'e'], index=[0, 2]))
>>> s
0    d
1    b
2    e
dtype: object
```

```
>>> s = pd.Series([1, 2, 3])
>>> s.update(pd.Series([4, 5, 6, 7, 8]))
>>> s
0    4
1    5
2    6
dtype: int64
```

If `other` contains NaNs the corresponding values are not updated in the original Series.

```
>>> s = pd.Series([1, 2, 3])
>>> s.update(pd.Series([4, np.nan, 6]))
>>> s
0    4
1    2
2    6
dtype: int64
```

`other` can also be a non-Series object type that is coercible into a Series

```
>>> s = pd.Series([1, 2, 3])
>>> s.update([4, np.nan, 6])
>>> s
0    4
1    2
2    6
dtype: int64
```

```
>>> s = pd.Series([1, 2, 3])
>>> s.update({1: 9})
>>> s
0    1
1    9
2    3
dtype: int64
```

pandas.Series.value_counts

Series.**value_counts**(*normalize=False*, *sort=True*, *ascending=False*, *bins=None*, *dropna=True*)

Return a Series containing counts of unique values.

The resulting object will be in descending order so that the first element is the most frequently-occurring element. Excludes NA values by default.

Parameters

normalize [bool, default False] If True then the object returned will contain the relative frequencies of the unique values.

sort [bool, default True] Sort by frequencies.

ascending [bool, default False] Sort in ascending order.

bins [int, optional] Rather than count values, group them into half-open bins, a convenience for `pd.cut`, only works with numeric data.

dropna [bool, default True] Don't include counts of NaN.

Returns

Series

See also:

Series.count Number of non-NA elements in a Series.

DataFrame.count Number of non-NA elements in a DataFrame.

DataFrame.value_counts Equivalent method on DataFrames.

Examples

```
>>> index = pd.Index([3, 1, 2, 3, 4, np.nan])
>>> index.value_counts()
3.0    2
4.0    1
2.0    1
1.0    1
dtype: int64
```

With *normalize* set to *True*, returns the relative frequency by dividing all values by the sum of values.

```
>>> s = pd.Series([3, 1, 2, 3, 4, np.nan])
>>> s.value_counts(normalize=True)
3.0    0.4
4.0    0.2
2.0    0.2
1.0    0.2
dtype: float64
```

bins

Bins can be useful for going from a continuous variable to a categorical variable; instead of counting unique apparitions of values, divide the index in the specified number of half-open bins.

```
>>> s.value_counts(bins=3)
(2.0, 3.0]      2
(0.996, 2.0]    2
(3.0, 4.0]      1
dtype: int64
```

dropna

With *dropna* set to *False* we can also see NaN index values.

```
>>> s.value_counts(dropna=False)
3.0    2
NaN    1
4.0    1
2.0    1
1.0    1
dtype: int64
```

pandas.Series.var

Series.**var**(*axis=None*, *skipna=None*, *level=None*, *ddof=1*, *numeric_only=None*, ***kwargs*)

Return unbiased variance over requested axis.

Normalized by N-1 by default. This can be changed using the ddof argument

Parameters

axis [{index (0)}]

skipna [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

ddof [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is N - ddof, where N represents the number of elements.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

Returns

scalar or Series (if level specified)

pandas.Series.view

Series.**view**(*dtype=None*)

Create a new view of the Series.

This function will return a new Series with a view of the same underlying values in memory, optionally reinterpreted with a new data type. The new data type must preserve the same size in bytes as to not cause index misalignment.

Parameters

dtype [data type] Data type object or one of their string representations.

Returns

Series A new Series object as a view of the same data in memory.

See also:

numpy.ndarray.view Equivalent numpy function to create a new view of the same data in memory.

Notes

Series are instantiated with `dtype=float64` by default. While `numpy.ndarray.view()` will return a view with the same data type as the original array, `Series.view()` (without specified dtype) will try using `float64` and may fail if the original data type size in bytes is not the same.

Examples

```
>>> s = pd.Series([-2, -1, 0, 1, 2], dtype='int8')
>>> s
0   -2
1   -1
2    0
3    1
4    2
dtype: int8
```

The 8 bit signed integer representation of *-1* is *0b11111111*, but the same bytes represent 255 if read as an 8 bit unsigned integer:

```
>>> us = s.view('uint8')
>>> us
0    254
1    255
2      0
3      1
4      2
dtype: uint8
```

The views share the same underlying values:

```
>>> us[0] = 128
>>> s
0   -128
1     -1
2      0
3      1
4      2
dtype: int8
```

pandas.Series.where

Series.**where**(*cond*, *other=nan*, *inplace=False*, *axis=None*, *level=None*, *errors='raise'*, *try_cast=False*)

Replace values where the condition is False.

Parameters

cond [bool Series/DataFrame, array-like, or callable] Where *cond* is True, keep the original value. Where False, replace with corresponding value from *other*. If *cond* is callable, it is computed on the Series/DataFrame and should return boolean Series/DataFrame or array. The callable must not change input Series/DataFrame (though pandas doesn't check it).

other [scalar, Series/DataFrame, or callable] Entries where *cond* is False are replaced with corresponding value from *other*. If other is callable, it is computed on the Series/DataFrame and should return scalar or Series/DataFrame. The callable must not change input Series/DataFrame (though pandas doesn't check it).

inplace [bool, default False] Whether to perform the operation in place on the data.

axis [int, default None] Alignment axis if needed.

level [int, default None] Alignment level if needed.

errors [str, {'raise', 'ignore'}, default 'raise'] Note that currently this parameter won't affect the results and will always coerce to a suitable dtype.

- 'raise' : allow exceptions to be raised.
- 'ignore' : suppress exceptions. On error return original object.

try_cast [bool, default False] Try to cast the result back to the input type (if possible).

Returns

Same type as caller

See also:

DataFrame.mask() Return an object of same shape as self.

Notes

The where method is an application of the if-then idiom. For each element in the calling DataFrame, if `cond` is `True` the element is used; otherwise the corresponding element from the DataFrame `other` is used.

The signature for *DataFrame.where()* differs from `numpy.where()`. Roughly `df1.where(m, df2)` is equivalent to `np.where(m, df1, df2)`.

For further details and examples see the `where` documentation in *indexing*.

Examples

```
>>> s = pd.Series(range(5))
>>> s.where(s > 0)
0    NaN
1    1.0
2    2.0
3    3.0
4    4.0
dtype: float64
```

```
>>> s.mask(s > 0)
0    0.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

```
>>> s.where(s > 1, 10)
0    10
1    10
2    2
3    3
4    4
dtype: int64
```

```
>>> df = pd.DataFrame(np.arange(10).reshape(-1, 2), columns=['A', 'B'])
>>> df
   A  B
0  0  1
1  2  3
2  4  5
3  6  7
4  8  9
>>> m = df % 3 == 0
>>> df.where(m, -df)
   A  B
0  0 -1
1 -2  3
2 -4 -5
3  6 -7
4 -8  9
>>> df.where(m, -df) == np.where(m, df, -df)
      A     B
0  True  True
1  True  True
2  True  True
3  True  True
4  True  True
>>> df.where(m, -df) == df.mask(~m, -df)
      A     B
0  True  True
1  True  True
2  True  True
3  True  True
4  True  True
```

pandas.Series.xs

Series.**xs**(*key*, *axis=0*, *level=None*, *drop_level=True*)

Return cross-section from the Series/DataFrame.

This method takes a *key* argument to select data at a particular level of a MultiIndex.

Parameters

key [label or tuple of label] Label contained in the index, or partially in a MultiIndex.

axis [{0 or 'index', 1 or 'columns'}, default 0] Axis to retrieve cross-section on.

level [object, defaults to first n levels (n=1 or len(key))] In case of a key partially contained in a MultiIndex, indicate which levels are used. Levels can be referred by label or position.

drop_level [bool, default True] If False, returns object with same levels as self.

Returns

Series or DataFrame Cross-section from the original Series or DataFrame corresponding to the selected index levels.

See also:

DataFrame.loc Access a group of rows and columns by label(s) or a boolean array.

DataFrame.iloc Purely integer-location based indexing for selection by position.

Notes

xs can not be used to set values.

MultiIndex Slicers is a generic way to get/set values on any level or levels. It is a superset of *xs* functionality, see *MultiIndex Slicers*.

Examples

```
>>> d = {'num_legs': [4, 4, 2, 2],
...      'num_wings': [0, 0, 2, 2],
...      'class': ['mammal', 'mammal', 'mammal', 'bird'],
...      'animal': ['cat', 'dog', 'bat', 'penguin'],
...      'locomotion': ['walks', 'walks', 'flies', 'walks']}
>>> df = pd.DataFrame(data=d)
>>> df = df.set_index(['class', 'animal', 'locomotion'])
>>> df
                           num_legs  num_wings
class  animal  locomotion
mammal cat     walks              4          0
       dog     walks              4          0
       bat     flies              2          2
bird   penguin walks              2          2
```

Get values at specified index

```
>>> df.xs('mammal')
                    num_legs  num_wings
animal locomotion
cat    walks              4          0
dog    walks              4          0
bat    flies              2          2
```

Get values at several indexes

```
>>> df.xs(('mammal', 'dog'))
            num_legs  num_wings
locomotion
walks              4          0
```

Get values at specified index and level

```
>>> df.xs('cat', level=1)
                    num_legs  num_wings
class  locomotion
mammal walks              4          0
```

Get values at several indexes and levels

```
>>> df.xs(('bird', 'walks'),
...       level=[0, 'locomotion'])
         num_legs  num_wings
animal
penguin         2          2
```

Get values at specified column and axis

```
>>> df.xs('num_wings', axis=1)
class   animal   locomotion
mammal  cat      walks         0
        dog      walks         0
        bat      flies         2
bird    penguin  walks         2
Name: num_wings, dtype: int64
```

3.3.2 Attributes

Axes

Series.index	The index (axis labels) of the Series.

Series.array	The ExtensionArray of the data backing this Series or Index.
Series.values	Return Series as ndarray or ndarray-like depending on the dtype.
Series.dtype	Return the dtype object of the underlying data.
Series.shape	Return a tuple of the shape of the underlying data.
Series.nbytes	Return the number of bytes in the underlying data.
Series.ndim	Number of dimensions of the underlying data, by definition 1.
Series.size	Return the number of elements in the underlying data.
Series.T	Return the transpose, which is by definition self.
Series.memory_usage([index, deep])	Return the memory usage of the Series.
Series.hasnans	Return if I have any nans; enables various perf speedups.
Series.empty	Indicator whether DataFrame is empty.
Series.dtypes	Return the dtype object of the underlying data.
Series.name	Return the name of the Series.

pandas.Series.empty

property Series.**empty**

Indicator whether DataFrame is empty.

True if DataFrame is entirely empty (no items), meaning any of the axes are of length 0.

Returns

bool If DataFrame is empty, return True, if not return False.

See also:

Series.dropna Return series without null values.

DataFrame.dropna Return DataFrame with labels on given axis omitted where (all or any) data are missing.

Notes

If DataFrame contains only NaNs, it is still not considered empty. See the example below.

Examples

An example of an actual empty DataFrame. Notice the index is empty:

```
>>> df_empty = pd.DataFrame({'A' : []})
>>> df_empty
Empty DataFrame
Columns: [A]
Index: []
>>> df_empty.empty
True
```

If we only have NaNs in our DataFrame, it is not considered empty! We will need to drop the NaNs to make the DataFrame empty:

```
>>> df = pd.DataFrame({'A' : [np.nan]})
>>> df
    A
0 NaN
>>> df.empty
False
>>> df.dropna().empty
True
```

3.3.3 Conversion

Series.astype(dtype[, copy, errors])	Cast a pandas object to a specified dtype `dtype`.
Series.convert_dtypes([infer_objects, ...])	Convert columns to best possible dtypes using dtypes supporting `pd.NA`.
Series.infer_objects()	Attempt to infer better dtypes for object columns.
Series.copy([deep])	Make a copy of this object's indices and data.
Series.bool()	Return the bool of a single element Series or DataFrame.
Series.to_numpy([dtype, copy, na_value])	A NumPy ndarray representing the values in this Series or Index.
Series.to_period([freq, copy])	Convert Series from DatetimeIndex to PeriodIndex.
Series.to_timestamp([freq, how, copy])	Cast to DatetimeIndex of Timestamps, at *beginning* of period.
Series.to_list()	Return a list of the values.
Series.__array__([dtype])	Return the values as a NumPy array.

pandas.Series.__array__

Series.**__array__**(*dtype=None*)

Return the values as a NumPy array.

Users should not call this directly. Rather, it is invoked by `numpy.array()` and `numpy.asarray()`.

Parameters

dtype [str or numpy.dtype, optional] The dtype to use for the resulting NumPy array. By default, the dtype is inferred from the data.

Returns

numpy.ndarray The values in the series converted to a `numpy.ndarray` with the specified *dtype*.

See also:

array Create a new array from data.
Series.array Zero-copy view to the array backing the Series.
Series.to_numpy Series method for similar behavior.

Examples

```
>>> ser = pd.Series([1, 2, 3])
>>> np.asarray(ser)
array([1, 2, 3])
```

For timezone-aware data, the timezones may be retained with `dtype='object'`

```
>>> tzser = pd.Series(pd.date_range('2000', periods=2, tz="CET"))
>>> np.asarray(tzser, dtype="object")
array([Timestamp('2000-01-01 00:00:00+0100', tz='CET', freq='D'),
       Timestamp('2000-01-02 00:00:00+0100', tz='CET', freq='D')],
      dtype=object)
```

Or the values may be localized to UTC and the tzinfo discarded with `dtype='datetime64[ns]'`

```
>>> np.asarray(tzser, dtype="datetime64[ns]")
array(['1999-12-31T23:00:00.000000000', ...],
      dtype='datetime64[ns]')
```

3.3.4 Indexing, iteration

Series.get(key[, default])	Get item from object for given key (ex: DataFrame column).
Series.at	Access a single value for a row/column label pair.
Series.iat	Access a single value for a row/column pair by integer position.
Series.loc	Access a group of rows and columns by label(s) or a boolean array.
Series.iloc	Purely integer-location based indexing for selection by position.
Series.__iter__()	Return an iterator of the values.

continues on next page

Table 33 – continued from previous page

Series.items()	Lazily iterate over (index, value) tuples.
Series.iteritems()	Lazily iterate over (index, value) tuples.
Series.keys()	Return alias for index.
Series.pop(item)	Return item and drops from series.
Series.item()	Return the first element of the underlying data as a python scalar.
Series.xs(key[, axis, level, drop_level])	Return cross-section from the Series/DataFrame.

pandas.Series.__iter__

Series.__iter__()

Return an iterator of the values.

These are each a scalar type, which is a Python scalar (for str, int, float) or a pandas scalar (for Timestamp/Timedelta/Interval/Period)

Returns

iterator

For more information on `.at`, `.iat`, `.loc`, and `.iloc`, see the *indexing documentation*.

3.3.5 Binary operator functions

Series.add(other[, level, fill_value, axis])	Return Addition of series and other, element-wise (binary operator *add*).
Series.sub(other[, level, fill_value, axis])	Return Subtraction of series and other, element-wise (binary operator *sub*).
Series.mul(other[, level, fill_value, axis])	Return Multiplication of series and other, element-wise (binary operator *mul*).
Series.div(other[, level, fill_value, axis])	Return Floating division of series and other, element-wise (binary operator *truediv*).
Series.truediv(other[, level, fill_value, axis])	Return Floating division of series and other, element-wise (binary operator *truediv*).
Series.floordiv(other[, level, fill_value, axis])	Return Integer division of series and other, element-wise (binary operator *floordiv*).
Series.mod(other[, level, fill_value, axis])	Return Modulo of series and other, element-wise (binary operator *mod*).
Series.pow(other[, level, fill_value, axis])	Return Exponential power of series and other, element-wise (binary operator *pow*).
Series.radd(other[, level, fill_value, axis])	Return Addition of series and other, element-wise (binary operator *radd*).
Series.rsub(other[, level, fill_value, axis])	Return Subtraction of series and other, element-wise (binary operator *rsub*).
Series.rmul(other[, level, fill_value, axis])	Return Multiplication of series and other, element-wise (binary operator *rmul*).
Series.rdiv(other[, level, fill_value, axis])	Return Floating division of series and other, element-wise (binary operator *rtruediv*).
Series.rtruediv(other[, level, fill_value, axis])	Return Floating division of series and other, element-wise (binary operator *rtruediv*).

continues on next page

Table 34 – continued from previous page

Series.rfloordiv(other[, level, fill_value, ...])	Return Integer division of series and other, element-wise (binary operator *rfloordiv*).
Series.rmod(other[, level, fill_value, axis])	Return Modulo of series and other, element-wise (binary operator *rmod*).
Series.rpow(other[, level, fill_value, axis])	Return Exponential power of series and other, element-wise (binary operator *rpow*).
Series.combine(other, func[, fill_value])	Combine the Series with a Series or scalar according to *func*.
Series.combine_first(other)	Combine Series values, choosing the calling Series's values first.
Series.round([decimals])	Round each value in a Series to the given number of decimals.
Series.lt(other[, level, fill_value, axis])	Return Less than of series and other, element-wise (binary operator *lt*).
Series.gt(other[, level, fill_value, axis])	Return Greater than of series and other, element-wise (binary operator *gt*).
Series.le(other[, level, fill_value, axis])	Return Less than or equal to of series and other, element-wise (binary operator *le*).
Series.ge(other[, level, fill_value, axis])	Return Greater than or equal to of series and other, element-wise (binary operator *ge*).
Series.ne(other[, level, fill_value, axis])	Return Not equal to of series and other, element-wise (binary operator *ne*).
Series.eq(other[, level, fill_value, axis])	Return Equal to of series and other, element-wise (binary operator *eq*).
Series.product([axis, skipna, level, ...])	Return the product of the values for the requested axis.
Series.dot(other)	Compute the dot product between the Series and the columns of other.

3.3.6 Function application, GroupBy & window

Series.apply(func[, convert_dtype, args])	Invoke function on values of Series.
Series.agg([func, axis])	Aggregate using one or more operations over the specified axis.
Series.aggregate([func, axis])	Aggregate using one or more operations over the specified axis.
Series.transform(func[, axis])	Call `func` on self producing a Series with transformed values.
Series.map(arg[, na_action])	Map values of Series according to input correspondence.
Series.groupby([by, axis, level, as_index, ...])	Group Series using a mapper or by a Series of columns.
Series.rolling(window[, min_periods, ...])	Provide rolling window calculations.
Series.expanding([min_periods, center, axis])	Provide expanding transformations.
Series.ewm([com, span, halflife, alpha, ...])	Provide exponential weighted (EW) functions.
Series.pipe(func, *args, **kwargs)	Apply func(self, *args, **kwargs).

3.3.7 Computations / descriptive stats

Series.abs()	Return a Series/DataFrame with absolute numeric value of each element.
Series.all([axis, bool_only, skipna, level])	Return whether all elements are True, potentially over an axis.
Series.any([axis, bool_only, skipna, level])	Return whether any element is True, potentially over an axis.
Series.autocorr([lag])	Compute the lag-N autocorrelation.
Series.between(left, right[, inclusive])	Return boolean Series equivalent to left <= series <= right.
Series.clip([lower, upper, axis, inplace])	Trim values at input threshold(s).
Series.corr(other[, method, min_periods])	Compute correlation with *other* Series, excluding missing values.
Series.count([level])	Return number of non-NA/null observations in the Series.
Series.cov(other[, min_periods, ddof])	Compute covariance with Series, excluding missing values.
Series.cummax([axis, skipna])	Return cumulative maximum over a DataFrame or Series axis.
Series.cummin([axis, skipna])	Return cumulative minimum over a DataFrame or Series axis.
Series.cumprod([axis, skipna])	Return cumulative product over a DataFrame or Series axis.
Series.cumsum([axis, skipna])	Return cumulative sum over a DataFrame or Series axis.
Series.describe([percentiles, include, ...])	Generate descriptive statistics.
Series.diff([periods])	First discrete difference of element.
Series.factorize([sort, na_sentinel])	Encode the object as an enumerated type or categorical variable.
Series.kurt([axis, skipna, level, numeric_only])	Return unbiased kurtosis over requested axis.
Series.mad([axis, skipna, level])	Return the mean absolute deviation of the values for the requested axis.
Series.max([axis, skipna, level, numeric_only])	Return the maximum of the values for the requested axis.
Series.mean([axis, skipna, level, numeric_only])	Return the mean of the values for the requested axis.
Series.median([axis, skipna, level, ...])	Return the median of the values for the requested axis.
Series.min([axis, skipna, level, numeric_only])	Return the minimum of the values for the requested axis.
Series.mode([dropna])	Return the mode(s) of the dataset.
Series.nlargest([n, keep])	Return the largest *n* elements.
Series.nsmallest([n, keep])	Return the smallest *n* elements.
Series.pct_change([periods, fill_method, ...])	Percentage change between the current and a prior element.
Series.prod([axis, skipna, level, ...])	Return the product of the values for the requested axis.
Series.quantile([q, interpolation])	Return value at the given quantile.
Series.rank([axis, method, numeric_only, ...])	Compute numerical data ranks (1 through n) along axis.
Series.sem([axis, skipna, level, ddof, ...])	Return unbiased standard error of the mean over requested axis.
Series.skew([axis, skipna, level, numeric_only])	Return unbiased skew over requested axis.
Series.std([axis, skipna, level, ddof, ...])	Return sample standard deviation over requested axis.
Series.sum([axis, skipna, level, ...])	Return the sum of the values for the requested axis.
Series.var([axis, skipna, level, ddof, ...])	Return unbiased variance over requested axis.

continues on next page

Table 36 – continued from previous page

Series.kurtosis([axis, skipna, level, ...])	Return unbiased kurtosis over requested axis.
Series.unique()	Return unique values of Series object.
Series.nunique([dropna])	Return number of unique elements in the object.
Series.is_unique	Return boolean if values in the object are unique.
Series.is_monotonic	Return boolean if values in the object are monotonic_increasing.
Series.is_monotonic_increasing	Alias for is_monotonic.
Series.is_monotonic_decreasing	Return boolean if values in the object are monotonic_decreasing.
Series.value_counts([normalize, sort, ...])	Return a Series containing counts of unique values.

3.3.8 Reindexing / selection / label manipulation

Series.align(other[, join, axis, level, ...])	Align two objects on their axes with the specified join method.
Series.drop([labels, axis, index, columns, ...])	Return Series with specified index labels removed.
Series.droplevel(level[, axis])	Return DataFrame with requested index / column level(s) removed.
Series.drop_duplicates([keep, inplace])	Return Series with duplicate values removed.
Series.duplicated([keep])	Indicate duplicate Series values.
Series.equals(other)	Test whether two objects contain the same elements.
Series.first(offset)	Select initial periods of time series data based on a date offset.
Series.head([n])	Return the first *n* rows.
Series.idxmax([axis, skipna])	Return the row label of the maximum value.
Series.idxmin([axis, skipna])	Return the row label of the minimum value.
Series.isin(values)	Whether elements in Series are contained in *values*.
Series.last(offset)	Select final periods of time series data based on a date offset.
Series.reindex([index])	Conform Series to new index with optional filling logic.
Series.reindex_like(other[, method, copy, ...])	Return an object with matching indices as other object.
Series.rename([index, axis, copy, inplace, ...])	Alter Series index labels or name.
Series.rename_axis(**kwargs)	Set the name of the axis for the index or columns.
Series.reset_index([level, drop, name, inplace])	Generate a new DataFrame or Series with the index reset.
Series.sample([n, frac, replace, weights, ...])	Return a random sample of items from an axis of object.
Series.set_axis(labels[, axis, inplace])	Assign desired index to given axis.
Series.take(indices[, axis, is_copy])	Return the elements in the given *positional* indices along an axis.
Series.tail([n])	Return the last *n* rows.
Series.truncate([before, after, axis, copy])	Truncate a Series or DataFrame before and after some index value.
Series.where(cond[, other, inplace, axis, ...])	Replace values where the condition is False.
Series.mask(cond[, other, inplace, axis, ...])	Replace values where the condition is True.
Series.add_prefix(prefix)	Prefix labels with string *prefix*.
Series.add_suffix(suffix)	Suffix labels with string *suffix*.
Series.filter([items, like, regex, axis])	Subset the dataframe rows or columns according to the specified index labels.

3.3.9 Missing data handling

Series.backfill([axis, inplace, limit, downcast])	Synonym for DataFrame.fillna() with method='bfill'.
Series.bfill([axis, inplace, limit, downcast])	Synonym for DataFrame.fillna() with method='bfill'.
Series.dropna([axis, inplace, how])	Return a new Series with missing values removed.
Series.ffill([axis, inplace, limit, downcast])	Synonym for DataFrame.fillna() with method='ffill'.
Series.fillna([value, method, axis, ...])	Fill NA/NaN values using the specified method.
Series.interpolate([method, axis, limit, ...])	Please note that only method='linear' is supported for DataFrame/Series with a MultiIndex.
Series.isna()	Detect missing values.
Series.isnull()	Detect missing values.
Series.notna()	Detect existing (non-missing) values.
Series.notnull()	Detect existing (non-missing) values.
Series.pad([axis, inplace, limit, downcast])	Synonym for DataFrame.fillna() with method='ffill'.
Series.replace([to_replace, value, inplace, ...])	Replace values given in *to_replace* with *value*.

3.3.10 Reshaping, sorting

Series.argsort([axis, kind, order])	Return the integer indices that would sort the Series values.
Series.argmin([axis, skipna])	Return int position of the smallest value in the Series.
Series.argmax([axis, skipna])	Return int position of the largest value in the Series.
Series.reorder_levels(order)	Rearrange index levels using input order.
Series.sort_values([axis, ascending, ...])	Sort by the values.
Series.sort_index([axis, level, ascending, ...])	Sort Series by index labels.
Series.swaplevel([i, j, copy])	Swap levels i and j in a MultiIndex.
Series.unstack([level, fill_value])	Unstack, also known as pivot, Series with MultiIndex to produce DataFrame.
Series.explode([ignore_index])	Transform each element of a list-like to a row.
Series.searchsorted(value[, side, sorter])	Find indices where elements should be inserted to maintain order.
Series.ravel([order])	Return the flattened underlying data as an ndarray.
Series.repeat(repeats[, axis])	Repeat elements of a Series.
Series.squeeze([axis])	Squeeze 1 dimensional axis objects into scalars.
Series.view([dtype])	Create a new view of the Series.

3.3.11 Combining / comparing / joining / merging

`Series.append`(to_append[, ignore_index, ...])	Concatenate two or more Series.
`Series.compare`(other[, align_axis, ...])	Compare to another Series and show the differences.
`Series.replace`([to_replace, value, inplace, ...])	Replace values given in *to_replace* with *value*.
`Series.update`(other)	Modify Series in place using values from passed Series.

3.3.12 Time Series-related

`Series.asfreq`(freq[, method, how, ...])	Convert TimeSeries to specified frequency.
`Series.asof`(where[, subset])	Return the last row(s) without any NaNs before *where*.
`Series.shift`([periods, freq, axis, fill_value])	Shift index by desired number of periods with an optional time *freq*.
`Series.first_valid_index`()	Return index for first non-NA/null value.
`Series.last_valid_index`()	Return index for last non-NA/null value.
`Series.resample`(rule[, axis, closed, label, ...])	Resample time-series data.
`Series.tz_convert`(tz[, axis, level, copy])	Convert tz-aware axis to target time zone.
`Series.tz_localize`(tz[, axis, level, copy, ...])	Localize tz-naive index of a Series or DataFrame to target time zone.
`Series.at_time`(time[, asof, axis])	Select values at particular time of day (e.g., 9:30AM).
`Series.between_time`(start_time, end_time[, ...])	Select values between particular times of the day (e.g., 9:00-9:30 AM).
`Series.tshift`([periods, freq, axis])	(DEPRECATED) Shift the time index, using the index's frequency if available.
`Series.slice_shift`([periods, axis])	Equivalent to *shift* without copying data.

3.3.13 Accessors

Pandas provides dtype-specific methods under various accessors. These are separate namespaces within `Series` that only apply to specific data types.

Data Type	Accessor
Datetime, Timedelta, Period	*dt*
String	*str*
Categorical	*cat*
Sparse	*sparse*

Datetimelike properties

`Series.dt` can be used to access the values of the series as datetimelike and return several properties. These can be accessed like `Series.dt.<property>`.

Datetime properties

Series.dt.date	Returns numpy array of python datetime.date objects (namely, the date part of Timestamps without timezone information).
Series.dt.time	Returns numpy array of datetime.time.
Series.dt.timetz	Returns numpy array of datetime.time also containing timezone information.
Series.dt.year	The year of the datetime.
Series.dt.month	The month as January=1, December=12.
Series.dt.day	The day of the datetime.
Series.dt.hour	The hours of the datetime.
Series.dt.minute	The minutes of the datetime.
Series.dt.second	The seconds of the datetime.
Series.dt.microsecond	The microseconds of the datetime.
Series.dt.nanosecond	The nanoseconds of the datetime.
Series.dt.week	(DEPRECATED) The week ordinal of the year.
Series.dt.weekofyear	(DEPRECATED) The week ordinal of the year.
Series.dt.dayofweek	The day of the week with Monday=0, Sunday=6.
Series.dt.weekday	The day of the week with Monday=0, Sunday=6.
Series.dt.dayofyear	The ordinal day of the year.
Series.dt.quarter	The quarter of the date.
Series.dt.is_month_start	Indicates whether the date is the first day of the month.
Series.dt.is_month_end	Indicates whether the date is the last day of the month.
Series.dt.is_quarter_start	Indicator for whether the date is the first day of a quarter.
Series.dt.is_quarter_end	Indicator for whether the date is the last day of a quarter.
Series.dt.is_year_start	Indicate whether the date is the first day of a year.
Series.dt.is_year_end	Indicate whether the date is the last day of the year.
Series.dt.is_leap_year	Boolean indicator if the date belongs to a leap year.
Series.dt.daysinmonth	The number of days in the month.
Series.dt.days_in_month	The number of days in the month.
Series.dt.tz	Return timezone, if any.
Series.dt.freq	Return the frequency object for this PeriodArray.

pandas.Series.dt.date

Series.dt.**date**
Returns numpy array of python datetime.date objects (namely, the date part of Timestamps without timezone information).

pandas.Series.dt.time

Series.dt.**time**
Returns numpy array of datetime.time. The time part of the Timestamps.

pandas.Series.dt.timetz

Series.dt.**timetz**
Returns numpy array of datetime.time also containing timezone information. The time part of the Timestamps.

pandas.Series.dt.year

Series.dt.**year**
The year of the datetime.

Examples

```
>>> datetime_series = pd.Series(
...     pd.date_range("2000-01-01", periods=3, freq="Y")
... )
>>> datetime_series
0   2000-12-31
1   2001-12-31
2   2002-12-31
dtype: datetime64[ns]
>>> datetime_series.dt.year
0    2000
1    2001
2    2002
dtype: int64
```

pandas.Series.dt.month

Series.dt.**month**
The month as January=1, December=12.

Examples

```
>>> datetime_series = pd.Series(
...     pd.date_range("2000-01-01", periods=3, freq="M")
... )
>>> datetime_series
0   2000-01-31
1   2000-02-29
2   2000-03-31
dtype: datetime64[ns]
>>> datetime_series.dt.month
0    1
1    2
2    3
dtype: int64
```

pandas.Series.dt.day

Series.dt.**day**
The day of the datetime.

Examples

```
>>> datetime_series = pd.Series(
...     pd.date_range("2000-01-01", periods=3, freq="D")
... )
>>> datetime_series
0   2000-01-01
1   2000-01-02
2   2000-01-03
dtype: datetime64[ns]
>>> datetime_series.dt.day
0    1
1    2
2    3
dtype: int64
```

pandas.Series.dt.hour

Series.dt.**hour**
The hours of the datetime.

Examples

```
>>> datetime_series = pd.Series(
...     pd.date_range("2000-01-01", periods=3, freq="h")
... )
>>> datetime_series
0   2000-01-01 00:00:00
1   2000-01-01 01:00:00
2   2000-01-01 02:00:00
dtype: datetime64[ns]
>>> datetime_series.dt.hour
0    0
1    1
2    2
dtype: int64
```

pandas.Series.dt.minute

Series.dt.**minute**
The minutes of the datetime.

Examples

```
>>> datetime_series = pd.Series(
...     pd.date_range("2000-01-01", periods=3, freq="T")
... )
>>> datetime_series
0   2000-01-01 00:00:00
1   2000-01-01 00:01:00
2   2000-01-01 00:02:00
dtype: datetime64[ns]
>>> datetime_series.dt.minute
0    0
1    1
2    2
dtype: int64
```

pandas.Series.dt.second

Series.dt.**second**

The seconds of the datetime.

Examples

```
>>> datetime_series = pd.Series(
...     pd.date_range("2000-01-01", periods=3, freq="s")
... )
>>> datetime_series
0   2000-01-01 00:00:00
1   2000-01-01 00:00:01
2   2000-01-01 00:00:02
dtype: datetime64[ns]
>>> datetime_series.dt.second
0    0
1    1
2    2
dtype: int64
```

pandas.Series.dt.microsecond

Series.dt.**microsecond**

The microseconds of the datetime.

Examples

```
>>> datetime_series = pd.Series(
...     pd.date_range("2000-01-01", periods=3, freq="us")
... )
>>> datetime_series
0   2000-01-01 00:00:00.000000
1   2000-01-01 00:00:00.000001
2   2000-01-01 00:00:00.000002
dtype: datetime64[ns]
>>> datetime_series.dt.microsecond
0       0
1       1
2       2
dtype: int64
```

pandas.Series.dt.nanosecond

Series.dt.**nanosecond**
The nanoseconds of the datetime.

Examples

```
>>> datetime_series = pd.Series(
...     pd.date_range("2000-01-01", periods=3, freq="ns")
... )
>>> datetime_series
0   2000-01-01 00:00:00.000000000
1   2000-01-01 00:00:00.000000001
2   2000-01-01 00:00:00.000000002
dtype: datetime64[ns]
>>> datetime_series.dt.nanosecond
0       0
1       1
2       2
dtype: int64
```

pandas.Series.dt.week

Series.dt.**week**
The week ordinal of the year.

Deprecated since version 1.1.0.

Series.dt.weekofyear and Series.dt.week have been deprecated. Please use Series.dt.isocalendar().week instead.

pandas.Series.dt.weekofyear

Series.dt.**weekofyear**
The week ordinal of the year.

Deprecated since version 1.1.0.

Series.dt.weekofyear and Series.dt.week have been deprecated. Please use Series.dt.isocalendar().week instead.

pandas.Series.dt.dayofweek

Series.dt.**dayofweek**
The day of the week with Monday=0, Sunday=6.

Return the day of the week. It is assumed the week starts on Monday, which is denoted by 0 and ends on Sunday which is denoted by 6. This method is available on both Series with datetime values (using the *dt* accessor) or DatetimeIndex.

Returns

Series or Index Containing integers indicating the day number.

See also:

Series.dt.dayofweek Alias.
Series.dt.weekday Alias.

Series.dt.day_name Returns the name of the day of the week.

Examples

```
>>> s = pd.date_range('2016-12-31', '2017-01-08', freq='D').to_series()
>>> s.dt.dayofweek
2016-12-31    5
2017-01-01    6
2017-01-02    0
2017-01-03    1
2017-01-04    2
2017-01-05    3
2017-01-06    4
2017-01-07    5
2017-01-08    6
Freq: D, dtype: int64
```

pandas.Series.dt.weekday

Series.dt.**weekday**

The day of the week with Monday=0, Sunday=6.

Return the day of the week. It is assumed the week starts on Monday, which is denoted by 0 and ends on Sunday which is denoted by 6. This method is available on both Series with datetime values (using the *dt* accessor) or DatetimeIndex.

Returns

Series or Index Containing integers indicating the day number.

See also:

Series.dt.dayofweek Alias.
Series.dt.weekday Alias.
Series.dt.day_name Returns the name of the day of the week.

Examples

```
>>> s = pd.date_range('2016-12-31', '2017-01-08', freq='D').to_series()
>>> s.dt.dayofweek
2016-12-31    5
2017-01-01    6
2017-01-02    0
2017-01-03    1
2017-01-04    2
2017-01-05    3
2017-01-06    4
2017-01-07    5
2017-01-08    6
Freq: D, dtype: int64
```

pandas.Series.dt.dayofyear

Series.dt.**dayofyear**
The ordinal day of the year.

pandas.Series.dt.quarter

Series.dt.**quarter**
The quarter of the date.

pandas.Series.dt.is_month_start

Series.dt.**is_month_start**
Indicates whether the date is the first day of the month.

Returns

Series or array For Series, returns a Series with boolean values. For DatetimeIndex, returns a boolean array.

See also:

is_month_start Return a boolean indicating whether the date is the first day of the month.
is_month_end Return a boolean indicating whether the date is the last day of the month.

Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on DatetimeIndex.

```
>>> s = pd.Series(pd.date_range("2018-02-27", periods=3))
>>> s
0   2018-02-27
1   2018-02-28
2   2018-03-01
dtype: datetime64[ns]
>>> s.dt.is_month_start
0    False
1    False
2    True
dtype: bool
>>> s.dt.is_month_end
0    False
1    True
2    False
dtype: bool
```

```
>>> idx = pd.date_range("2018-02-27", periods=3)
>>> idx.is_month_start
array([False, False, True])
>>> idx.is_month_end
array([False, True, False])
```

pandas.Series.dt.is_month_end

Series.dt.**is_month_end**

Indicates whether the date is the last day of the month.

Returns

Series or array For Series, returns a Series with boolean values. For DatetimeIndex, returns a boolean array.

See also:

is_month_start Return a boolean indicating whether the date is the first day of the month.
is_month_end Return a boolean indicating whether the date is the last day of the month.

Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on DatetimeIndex.

```
>>> s = pd.Series(pd.date_range("2018-02-27", periods=3))
>>> s
0   2018-02-27
1   2018-02-28
2   2018-03-01
dtype: datetime64[ns]
>>> s.dt.is_month_start
0    False
1    False
2    True
dtype: bool
>>> s.dt.is_month_end
0    False
1    True
2    False
dtype: bool
```

```
>>> idx = pd.date_range("2018-02-27", periods=3)
>>> idx.is_month_start
array([False, False, True])
>>> idx.is_month_end
array([False, True, False])
```

pandas.Series.dt.is_quarter_start

Series.dt.**is_quarter_start**

Indicator for whether the date is the first day of a quarter.

Returns

is_quarter_start [Series or DatetimeIndex] The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

See also:

quarter Return the quarter of the date.
is_quarter_end Similar property for indicating the quarter start.

Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on DatetimeIndex.

```
>>> df = pd.DataFrame({'dates': pd.date_range("2017-03-30",
...                   periods=4)})
>>> df.assign(quarter=df.dates.dt.quarter,
...           is_quarter_start=df.dates.dt.is_quarter_start)
       dates  quarter  is_quarter_start
0 2017-03-30        1             False
1 2017-03-31        1             False
2 2017-04-01        2              True
3 2017-04-02        2             False
```

```
>>> idx = pd.date_range('2017-03-30', periods=4)
>>> idx
DatetimeIndex(['2017-03-30', '2017-03-31', '2017-04-01', '2017-04-02'],
              dtype='datetime64[ns]', freq='D')
```

```
>>> idx.is_quarter_start
array([False, False,  True, False])
```

pandas.Series.dt.is_quarter_end

Series.dt.**is_quarter_end**

Indicator for whether the date is the last day of a quarter.

Returns

is_quarter_end [Series or DatetimeIndex] The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

See also:

quarter Return the quarter of the date.
is_quarter_start Similar property indicating the quarter start.

Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on DatetimeIndex.

```
>>> df = pd.DataFrame({'dates': pd.date_range("2017-03-30",
...                    periods=4)})
>>> df.assign(quarter=df.dates.dt.quarter,
...           is_quarter_end=df.dates.dt.is_quarter_end)
       dates  quarter    is_quarter_end
0 2017-03-30        1             False
1 2017-03-31        1              True
2 2017-04-01        2             False
3 2017-04-02        2             False
```

```
>>> idx = pd.date_range('2017-03-30', periods=4)
>>> idx
DatetimeIndex(['2017-03-30', '2017-03-31', '2017-04-01', '2017-04-02'],
              dtype='datetime64[ns]', freq='D')
```

```
>>> idx.is_quarter_end
array([False,  True, False, False])
```

pandas.Series.dt.is_year_start

Series.dt.**is_year_start**

Indicate whether the date is the first day of a year.

Returns

Series or DatetimeIndex The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

See also:

is_year_end Similar property indicating the last day of the year.

Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on DatetimeIndex.

```
>>> dates = pd.Series(pd.date_range("2017-12-30", periods=3))
>>> dates
0   2017-12-30
1   2017-12-31
2   2018-01-01
dtype: datetime64[ns]
```

```
>>> dates.dt.is_year_start
0    False
1    False
2    True
dtype: bool
```

```
>>> idx = pd.date_range("2017-12-30", periods=3)
>>> idx
DatetimeIndex(['2017-12-30', '2017-12-31', '2018-01-01'],
              dtype='datetime64[ns]', freq='D')
```

```
>>> idx.is_year_start
array([False, False,  True])
```

pandas.Series.dt.is_year_end

Series.dt.**is_year_end**

Indicate whether the date is the last day of the year.

Returns

Series or DatetimeIndex The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

See also:

is_year_start Similar property indicating the start of the year.

Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on DatetimeIndex.

```
>>> dates = pd.Series(pd.date_range("2017-12-30", periods=3))
>>> dates
0   2017-12-30
1   2017-12-31
2   2018-01-01
dtype: datetime64[ns]
```

```
>>> dates.dt.is_year_end
0    False
1     True
2    False
dtype: bool
```

```
>>> idx = pd.date_range("2017-12-30", periods=3)
>>> idx
DatetimeIndex(['2017-12-30', '2017-12-31', '2018-01-01'],
              dtype='datetime64[ns]', freq='D')
```

```
>>> idx.is_year_end
array([False,  True, False])
```

pandas.Series.dt.is_leap_year

Series.dt.**is_leap_year**

Boolean indicator if the date belongs to a leap year.

A leap year is a year, which has 366 days (instead of 365) including 29th of February as an intercalary day. Leap years are years which are multiples of four with the exception of years divisible by 100 but not by 400.

Returns

Series or ndarray Booleans indicating if dates belong to a leap year.

Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on DatetimeIndex.

```
>>> idx = pd.date_range("2012-01-01", "2015-01-01", freq="Y")
>>> idx
DatetimeIndex(['2012-12-31', '2013-12-31', '2014-12-31'],
              dtype='datetime64[ns]', freq='A-DEC')
>>> idx.is_leap_year
array([ True, False, False])
```

```
>>> dates_series = pd.Series(idx)
>>> dates_series
0   2012-12-31
1   2013-12-31
2   2014-12-31
dtype: datetime64[ns]
>>> dates_series.dt.is_leap_year
```

(continues on next page)

(continued from previous page)

```
0     True
1    False
2    False
dtype: bool
```

pandas.Series.dt.daysinmonth

Series.dt.**daysinmonth**
The number of days in the month.

pandas.Series.dt.days_in_month

Series.dt.**days_in_month**
The number of days in the month.

pandas.Series.dt.tz

Series.dt.**tz**
Return timezone, if any.

Returns

datetime.tzinfo, pytz.tzinfo.BaseTZInfo, dateutil.tz.tz.tzfile, or None Returns None when the array is tz-naive.

pandas.Series.dt.freq

Series.dt.**freq**

Datetime methods

Series.dt.to_period(*args, **kwargs)	Cast to PeriodArray/Index at a particular frequency.
Series.dt.to_pydatetime()	Return the data as an array of native Python datetime objects.
Series.dt.tz_localize(*args, **kwargs)	Localize tz-naive Datetime Array/Index to tz-aware Datetime Array/Index.
Series.dt.tz_convert(*args, **kwargs)	Convert tz-aware Datetime Array/Index from one time zone to another.
Series.dt.normalize(*args, **kwargs)	Convert times to midnight.
Series.dt.strftime(*args, **kwargs)	Convert to Index using specified date_format.
Series.dt.round(*args, **kwargs)	Perform round operation on the data to the specified *freq*.
Series.dt.floor(*args, **kwargs)	Perform floor operation on the data to the specified *freq*.
Series.dt.ceil(*args, **kwargs)	Perform ceil operation on the data to the specified *freq*.
Series.dt.month_name(*args, **kwargs)	Return the month names of the DateTimeIndex with specified locale.

continues on next page

Table 43 – continued from previous page

Series.dt.day_name(*args, **kwargs)	Return the day names of the DateTimeIndex with specified locale.

pandas.Series.dt.to_period

Series.dt.**to_period**(**args*, ***kwargs*)

Cast to PeriodArray/Index at a particular frequency.

Converts DatetimeArray/Index to PeriodArray/Index.

Parameters

freq [str or Offset, optional] One of pandas' *offset strings* or an Offset object. Will be inferred by default.

Returns

PeriodArray/Index

Raises

ValueError When converting a DatetimeArray/Index with non-regular values, so that a frequency cannot be inferred.

See also:

PeriodIndex Immutable ndarray holding ordinal values.
DatetimeIndex.to_pydatetime Return DatetimeIndex as object.

Examples

```
>>> df = pd.DataFrame({"y": [1, 2, 3]},
...                   index=pd.to_datetime(["2000-03-31 00:00:00",
...                                         "2000-05-31 00:00:00",
...                                         "2000-08-31 00:00:00"]))
>>> df.index.to_period("M")
PeriodIndex(['2000-03', '2000-05', '2000-08'],
            dtype='period[M]', freq='M')
```

Infer the daily frequency

```
>>> idx = pd.date_range("2017-01-01", periods=2)
>>> idx.to_period()
PeriodIndex(['2017-01-01', '2017-01-02'],
            dtype='period[D]', freq='D')
```

pandas.Series.dt.to_pydatetime

Series.dt.**to_pydatetime**()

Return the data as an array of native Python datetime objects.

Timezone information is retained if present.

Warning: Python's datetime uses microsecond resolution, which is lower than pandas (nanosecond). The values are truncated.

Returns

numpy.ndarray Object dtype array containing native Python datetime objects.

See also:

`datetime.datetime` Standard library value for a datetime.

Examples

```
>>> s = pd.Series(pd.date_range('20180310', periods=2))
>>> s
0   2018-03-10
1   2018-03-11
dtype: datetime64[ns]
```

```
>>> s.dt.to_pydatetime()
array([datetime.datetime(2018, 3, 10, 0, 0),
       datetime.datetime(2018, 3, 11, 0, 0)], dtype=object)
```

pandas' nanosecond precision is truncated to microseconds.

```
>>> s = pd.Series(pd.date_range('20180310', periods=2, freq='ns'))
>>> s
0   2018-03-10 00:00:00.000000000
1   2018-03-10 00:00:00.000000001
dtype: datetime64[ns]
```

```
>>> s.dt.to_pydatetime()
array([datetime.datetime(2018, 3, 10, 0, 0),
       datetime.datetime(2018, 3, 10, 0, 0)], dtype=object)
```

pandas.Series.dt.tz_localize

`Series.dt.tz_localize(*args, **kwargs)`

Localize tz-naive Datetime Array/Index to tz-aware Datetime Array/Index.

This method takes a time zone (tz) naive Datetime Array/Index object and makes this time zone aware. It does not move the time to another time zone. Time zone localization helps to switch from time zone aware to time zone unaware objects.

Parameters

tz [str, pytz.timezone, dateutil.tz.tzfile or None] Time zone to convert timestamps to. Passing `None` will remove the time zone information preserving local time.

ambiguous ['infer', 'NaT', bool array, default 'raise'] When clocks moved backward due to DST, ambiguous times may arise. For example in Central European Time (UTC+01), when going from 03:00 DST to 02:00 non-DST, 02:30:00 local time occurs both at 00:30:00 UTC and at 01:30:00 UTC. In such a situation, the *ambiguous* parameter dictates how ambiguous times should be handled.

- 'infer' will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False signifies a non-DST time (note that this flag is only applicable for ambiguous times)
- 'NaT' will return NaT where there are ambiguous times

- 'raise' will raise an AmbiguousTimeError if there are ambiguous times.

nonexistent ['shift_forward', 'shift_backward, 'NaT', timedelta, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- 'shift_forward' will shift the nonexistent time forward to the closest existing time
- 'shift_backward' will shift the nonexistent time backward to the closest existing time
- 'NaT' will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- 'raise' will raise an NonExistentTimeError if there are nonexistent times.

New in version 0.24.0.

Returns

Same type as self Array/Index converted to the specified time zone.

Raises

TypeError If the Datetime Array/Index is tz-aware and tz is not None.

See also:

DatetimeIndex.tz_convert Convert tz-aware DatetimeIndex from one time zone to another.

Examples

```
>>> tz_naive = pd.date_range('2018-03-01 09:00', periods=3)
>>> tz_naive
DatetimeIndex(['2018-03-01 09:00:00', '2018-03-02 09:00:00',
               '2018-03-03 09:00:00'],
              dtype='datetime64[ns]', freq='D')
```

Localize DatetimeIndex in US/Eastern time zone:

```
>>> tz_aware = tz_naive.tz_localize(tz='US/Eastern')
>>> tz_aware
DatetimeIndex(['2018-03-01 09:00:00-05:00',
               '2018-03-02 09:00:00-05:00',
               '2018-03-03 09:00:00-05:00'],
              dtype='datetime64[ns, US/Eastern]', freq=None)
```

With the `tz=None`, we can remove the time zone information while keeping the local time (not converted to UTC):

```
>>> tz_aware.tz_localize(None)
DatetimeIndex(['2018-03-01 09:00:00', '2018-03-02 09:00:00',
               '2018-03-03 09:00:00'],
              dtype='datetime64[ns]', freq=None)
```

Be careful with DST changes. When there is sequential data, pandas can infer the DST time:

```
>>> s = pd.to_datetime(pd.Series(['2018-10-28 01:30:00',
...                               '2018-10-28 02:00:00',
...                               '2018-10-28 02:30:00',
```

(continues on next page)

(continued from previous page)

```
...                                 '2018-10-28 02:00:00',
...                                 '2018-10-28 02:30:00',
...                                 '2018-10-28 03:00:00',
...                                 '2018-10-28 03:30:00']))
>>> s.dt.tz_localize('CET', ambiguous='infer')
0   2018-10-28 01:30:00+02:00
1   2018-10-28 02:00:00+02:00
2   2018-10-28 02:30:00+02:00
3   2018-10-28 02:00:00+01:00
4   2018-10-28 02:30:00+01:00
5   2018-10-28 03:00:00+01:00
6   2018-10-28 03:30:00+01:00
dtype: datetime64[ns, CET]
```

In some cases, inferring the DST is impossible. In such cases, you can pass an ndarray to the ambiguous parameter to set the DST explicitly

```
>>> s = pd.to_datetime(pd.Series(['2018-10-28 01:20:00',
...                                 '2018-10-28 02:36:00',
...                                 '2018-10-28 03:46:00']))
>>> s.dt.tz_localize('CET', ambiguous=np.array([True, True, False]))
0   2018-10-28 01:20:00+02:00
1   2018-10-28 02:36:00+02:00
2   2018-10-28 03:46:00+01:00
dtype: datetime64[ns, CET]
```

If the DST transition causes nonexistent times, you can shift these dates forward or backwards with a timedelta object or *'shift_forward'* or *'shift_backwards'*.

```
>>> s = pd.to_datetime(pd.Series(['2015-03-29 02:30:00',
...                                 '2015-03-29 03:30:00']))
>>> s.dt.tz_localize('Europe/Warsaw', nonexistent='shift_forward')
0   2015-03-29 03:00:00+02:00
1   2015-03-29 03:30:00+02:00
dtype: datetime64[ns, Europe/Warsaw]
```

```
>>> s.dt.tz_localize('Europe/Warsaw', nonexistent='shift_backward')
0   2015-03-29 01:59:59.999999999+01:00
1   2015-03-29 03:30:00+02:00
dtype: datetime64[ns, Europe/Warsaw]
```

```
>>> s.dt.tz_localize('Europe/Warsaw', nonexistent=pd.Timedelta('1H'))
0   2015-03-29 03:30:00+02:00
1   2015-03-29 03:30:00+02:00
dtype: datetime64[ns, Europe/Warsaw]
```

pandas.Series.dt.tz_convert

Series.dt.**tz_convert**(**args*, ***kwargs*)

Convert tz-aware Datetime Array/Index from one time zone to another.

Parameters

tz [str, pytz.timezone, dateutil.tz.tzfile or None] Time zone for time. Corresponding timestamps would be converted to this time zone of the Datetime Array/Index. A *tz* of None will convert to UTC and remove the timezone information.

Returns

Array or Index

Raises

TypeError If Datetime Array/Index is tz-naive.

See also:

DatetimeIndex.tz A timezone that has a variable offset from UTC.

DatetimeIndex.tz_localize Localize tz-naive DatetimeIndex to a given time zone, or remove timezone from a tz-aware DatetimeIndex.

Examples

With the *tz* parameter, we can change the DatetimeIndex to other time zones:

```
>>> dti = pd.date_range(start='2014-08-01 09:00',
...                     freq='H', periods=3, tz='Europe/Berlin')
```

```
>>> dti
DatetimeIndex(['2014-08-01 09:00:00+02:00',
               '2014-08-01 10:00:00+02:00',
               '2014-08-01 11:00:00+02:00'],
              dtype='datetime64[ns, Europe/Berlin]', freq='H')
```

```
>>> dti.tz_convert('US/Central')
DatetimeIndex(['2014-08-01 02:00:00-05:00',
               '2014-08-01 03:00:00-05:00',
               '2014-08-01 04:00:00-05:00'],
              dtype='datetime64[ns, US/Central]', freq='H')
```

With the `tz=None`, we can remove the timezone (after converting to UTC if necessary):

```
>>> dti = pd.date_range(start='2014-08-01 09:00', freq='H',
...                     periods=3, tz='Europe/Berlin')
```

```
>>> dti
DatetimeIndex(['2014-08-01 09:00:00+02:00',
               '2014-08-01 10:00:00+02:00',
               '2014-08-01 11:00:00+02:00'],
                dtype='datetime64[ns, Europe/Berlin]', freq='H')
```

```
>>> dti.tz_convert(None)
DatetimeIndex(['2014-08-01 07:00:00',
               '2014-08-01 08:00:00',
```

(continues on next page)

(continued from previous page)

```
               '2014-08-01 09:00:00'],
                dtype='datetime64[ns]', freq='H')
```

pandas.Series.dt.normalize

Series.dt.**normalize**(**args*, ***kwargs*)

Convert times to midnight.

The time component of the date-time is converted to midnight i.e. 00:00:00. This is useful in cases, when the time does not matter. Length is unaltered. The timezones are unaffected.

This method is available on Series with datetime values under the `.dt` accessor, and directly on Datetime Array/Index.

Returns

DatetimeArray, DatetimeIndex or Series The same type as the original data. Series will have the same name and index. DatetimeIndex will have the same name.

See also:

floor Floor the datetimes to the specified freq.
ceil Ceil the datetimes to the specified freq.
round Round the datetimes to the specified freq.

Examples

```
>>> idx = pd.date_range(start='2014-08-01 10:00', freq='H',
...                     periods=3, tz='Asia/Calcutta')
>>> idx
DatetimeIndex(['2014-08-01 10:00:00+05:30',
               '2014-08-01 11:00:00+05:30',
               '2014-08-01 12:00:00+05:30'],
                dtype='datetime64[ns, Asia/Calcutta]', freq='H')
>>> idx.normalize()
DatetimeIndex(['2014-08-01 00:00:00+05:30',
               '2014-08-01 00:00:00+05:30',
               '2014-08-01 00:00:00+05:30'],
              dtype='datetime64[ns, Asia/Calcutta]', freq=None)
```

pandas.Series.dt.strftime

Series.dt.**strftime**(**args*, ***kwargs*)

Convert to Index using specified date_format.

Return an Index of formatted strings specified by date_format, which supports the same string format as the python standard library. Details of the string format can be found in python string format doc.

Parameters

date_format [str] Date format string (e.g. "%Y-%m-%d").

Returns

ndarray NumPy ndarray of formatted strings.

See also:

to_datetime Convert the given argument to datetime.
DatetimeIndex.normalize Return DatetimeIndex with times to midnight.
DatetimeIndex.round Round the DatetimeIndex to the specified freq.
DatetimeIndex.floor Floor the DatetimeIndex to the specified freq.

Examples

```
>>> rng = pd.date_range(pd.Timestamp("2018-03-10 09:00"),
...                     periods=3, freq='s')
>>> rng.strftime('%B %d, %Y, %r')
Index(['March 10, 2018, 09:00:00 AM', 'March 10, 2018, 09:00:01 AM',
       'March 10, 2018, 09:00:02 AM'],
      dtype='object')
```

pandas.Series.dt.round

Series.dt.**round**(**args*, ***kwargs*)

Perform round operation on the data to the specified *freq*.

Parameters

freq [str or Offset] The frequency level to round the index to. Must be a fixed frequency like 'S' (second) not 'ME' (month end). See *frequency aliases* for a list of possible *freq* values.

ambiguous ['infer', bool-ndarray, 'NaT', default 'raise'] Only relevant for DatetimeIndex:

- 'infer' will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- 'NaT' will return NaT where there are ambiguous times
- 'raise' will raise an AmbiguousTimeError if there are ambiguous times.

New in version 0.24.0.

nonexistent ['shift_forward', 'shift_backward', 'NaT', timedelta, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- 'shift_forward' will shift the nonexistent time forward to the closest existing time
- 'shift_backward' will shift the nonexistent time backward to the closest existing time
- 'NaT' will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- 'raise' will raise an NonExistentTimeError if there are nonexistent times.

New in version 0.24.0.

Returns

DatetimeIndex, TimedeltaIndex, or Series Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

Raises

ValueError if the *freq* cannot be converted.

Examples

DatetimeIndex

```
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
               '2018-01-01 12:01:00'],
              dtype='datetime64[ns]', freq='T')
>>> rng.round('H')
DatetimeIndex(['2018-01-01 12:00:00', '2018-01-01 12:00:00',
               '2018-01-01 12:00:00'],
              dtype='datetime64[ns]', freq=None)
```

Series

```
>>> pd.Series(rng).dt.round("H")
0   2018-01-01 12:00:00
1   2018-01-01 12:00:00
2   2018-01-01 12:00:00
dtype: datetime64[ns]
```

pandas.Series.dt.floor

Series.dt.**floor**(**args*, ***kwargs*)

Perform floor operation on the data to the specified *freq*.

Parameters

freq [str or Offset] The frequency level to floor the index to. Must be a fixed frequency like 'S' (second) not 'ME' (month end). See *frequency aliases* for a list of possible *freq* values.

ambiguous ['infer', bool-ndarray, 'NaT', default 'raise'] Only relevant for DatetimeIndex:

- 'infer' will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- 'NaT' will return NaT where there are ambiguous times
- 'raise' will raise an AmbiguousTimeError if there are ambiguous times.

New in version 0.24.0.

nonexistent ['shift_forward', 'shift_backward', 'NaT', timedelta, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- 'shift_forward' will shift the nonexistent time forward to the closest existing time
- 'shift_backward' will shift the nonexistent time backward to the closest existing time
- 'NaT' will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta

- 'raise' will raise an NonExistentTimeError if there are nonexistent times.

New in version 0.24.0.

Returns

DatetimeIndex, TimedeltaIndex, or Series Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

Raises

ValueError if the *freq* cannot be converted.

Examples

DatetimeIndex

```
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
               '2018-01-01 12:01:00'],
              dtype='datetime64[ns]', freq='T')
>>> rng.floor('H')
DatetimeIndex(['2018-01-01 11:00:00', '2018-01-01 12:00:00',
               '2018-01-01 12:00:00'],
              dtype='datetime64[ns]', freq=None)
```

Series

```
>>> pd.Series(rng).dt.floor("H")
0   2018-01-01 11:00:00
1   2018-01-01 12:00:00
2   2018-01-01 12:00:00
dtype: datetime64[ns]
```

pandas.Series.dt.ceil

Series.dt.**ceil**(**args*, ***kwargs*)

Perform ceil operation on the data to the specified *freq*.

Parameters

freq [str or Offset] The frequency level to ceil the index to. Must be a fixed frequency like 'S' (second) not 'ME' (month end). See *frequency aliases* for a list of possible *freq* values.

ambiguous ['infer', bool-ndarray, 'NaT', default 'raise'] Only relevant for DatetimeIndex:

- 'infer' will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- 'NaT' will return NaT where there are ambiguous times
- 'raise' will raise an AmbiguousTimeError if there are ambiguous times.

New in version 0.24.0.

nonexistent ['shift_forward', 'shift_backward', 'NaT', timedelta, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- 'shift_forward' will shift the nonexistent time forward to the closest existing time
- 'shift_backward' will shift the nonexistent time backward to the closest existing time
- 'NaT' will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- 'raise' will raise an NonExistentTimeError if there are nonexistent times.

New in version 0.24.0.

Returns

DatetimeIndex, TimedeltaIndex, or Series Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

Raises

ValueError if the *freq* cannot be converted.

Examples

DatetimeIndex

```
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
               '2018-01-01 12:01:00'],
              dtype='datetime64[ns]', freq='T')
>>> rng.ceil('H')
DatetimeIndex(['2018-01-01 12:00:00', '2018-01-01 12:00:00',
               '2018-01-01 13:00:00'],
              dtype='datetime64[ns]', freq=None)
```

Series

```
>>> pd.Series(rng).dt.ceil("H")
0   2018-01-01 12:00:00
1   2018-01-01 12:00:00
2   2018-01-01 13:00:00
dtype: datetime64[ns]
```

pandas.Series.dt.month_name

`Series.dt.`**`month_name`**`(*args, **kwargs)`

Return the month names of the DateTimeIndex with specified locale.

New in version 0.23.0.

Parameters

locale [str, optional] Locale determining the language in which to return the month name. Default is English locale.

Returns

Index Index of month names.

Examples

```
>>> idx = pd.date_range(start='2018-01', freq='M', periods=3)
>>> idx
DatetimeIndex(['2018-01-31', '2018-02-28', '2018-03-31'],
              dtype='datetime64[ns]', freq='M')
>>> idx.month_name()
Index(['January', 'February', 'March'], dtype='object')
```

pandas.Series.dt.day_name

Series.dt.**day_name**(**args*, ***kwargs*)

Return the day names of the DateTimeIndex with specified locale.

New in version 0.23.0.

Parameters

locale [str, optional] Locale determining the language in which to return the day name. Default is English locale.

Returns

Index Index of day names.

Examples

```
>>> idx = pd.date_range(start='2018-01-01', freq='D', periods=3)
>>> idx
DatetimeIndex(['2018-01-01', '2018-01-02', '2018-01-03'],
              dtype='datetime64[ns]', freq='D')
>>> idx.day_name()
Index(['Monday', 'Tuesday', 'Wednesday'], dtype='object')
```

Period properties

Series.dt.qyear
Series.dt.start_time
Series.dt.end_time

pandas.Series.dt.qyear

Series.dt.**qyear**

pandas.Series.dt.start_time

Series.dt.**start_time**

pandas.Series.dt.end_time

Series.dt.**end_time**

Timedelta properties

Series.dt.days	Number of days for each element.
Series.dt.seconds	Number of seconds (>= 0 and less than 1 day) for each element.
Series.dt.microseconds	Number of microseconds (>= 0 and less than 1 second) for each element.
Series.dt.nanoseconds	Number of nanoseconds (>= 0 and less than 1 microsecond) for each element.
Series.dt.components	Return a Dataframe of the components of the Timedeltas.

pandas.Series.dt.days

Series.dt.**days**
Number of days for each element.

pandas.Series.dt.seconds

Series.dt.**seconds**
Number of seconds (>= 0 and less than 1 day) for each element.

pandas.Series.dt.microseconds

Series.dt.**microseconds**
Number of microseconds (>= 0 and less than 1 second) for each element.

pandas.Series.dt.nanoseconds

Series.dt.**nanoseconds**
Number of nanoseconds (>= 0 and less than 1 microsecond) for each element.

pandas.Series.dt.components

Series.dt.**components**
Return a Dataframe of the components of the Timedeltas.

Returns

DataFrame

Examples

```
>>> s = pd.Series(pd.to_timedelta(np.arange(5), unit='s'))
>>> s
0   0 days 00:00:00
1   0 days 00:00:01
2   0 days 00:00:02
3   0 days 00:00:03
4   0 days 00:00:04
dtype: timedelta64[ns]
>>> s.dt.components
   days  hours  minutes  seconds  milliseconds  microseconds  nanoseconds
0     0      0        0        0             0             0            0
1     0      0        0        1             0             0            0
2     0      0        0        2             0             0            0
3     0      0        0        3             0             0            0
4     0      0        0        4             0             0            0
```

Timedelta methods

Series.dt.to_pytimedelta()	Return an array of native *datetime.timedelta* objects.
Series.dt.total_seconds(*args, **kwargs)	Return total duration of each element expressed in seconds.

pandas.Series.dt.to_pytimedelta

Series.dt.**to_pytimedelta**()
Return an array of native *datetime.timedelta* objects.

Python's standard *datetime* library uses a different representation timedelta's. This method converts a Series of pandas Timedeltas to *datetime.timedelta* format with the same length as the original Series.

Returns

numpy.ndarray Array of 1D containing data with *datetime.timedelta* type.

See also:

datetime.timedelta

Examples

```
>>> s = pd.Series(pd.to_timedelta(np.arange(5), unit="d"))
>>> s
0   0 days
1   1 days
2   2 days
3   3 days
4   4 days
dtype: timedelta64[ns]
```

```
>>> s.dt.to_pytimedelta()
array([datetime.timedelta(0), datetime.timedelta(days=1),
datetime.timedelta(days=2), datetime.timedelta(days=3),
datetime.timedelta(days=4)], dtype=object)
```

pandas.Series.dt.total_seconds

Series.dt.**total_seconds**(**args*, ***kwargs*)

Return total duration of each element expressed in seconds.

This method is available directly on TimedeltaArray, TimedeltaIndex and on Series containing timedelta values under the `.dt` namespace.

Returns

seconds [[ndarray, Float64Index, Series]] When the calling object is a TimedeltaArray, the return type is ndarray. When the calling object is a TimedeltaIndex, the return type is a Float64Index. When the calling object is a Series, the return type is Series of type *float64* whose index is the same as the original.

See also:

datetime.timedelta.total_seconds Standard library version of this method.
TimedeltaIndex.components Return a DataFrame with components of each Timedelta.

Examples

Series

```
>>> s = pd.Series(pd.to_timedelta(np.arange(5), unit='d'))
>>> s
0   0 days
1   1 days
2   2 days
3   3 days
4   4 days
dtype: timedelta64[ns]
```

```
>>> s.dt.total_seconds()
0         0.0
1     86400.0
2    172800.0
3    259200.0
4    345600.0
dtype: float64
```

TimedeltaIndex

```
>>> idx = pd.to_timedelta(np.arange(5), unit='d')
>>> idx
TimedeltaIndex(['0 days', '1 days', '2 days', '3 days', '4 days'],
               dtype='timedelta64[ns]', freq=None)
```

```
>>> idx.total_seconds()
Float64Index([0.0, 86400.0, 172800.0, 259200.00000000003, 345600.0],
             dtype='float64')
```

String handling

`Series.str` can be used to access the values of the series as strings and apply several methods to it. These can be accessed like `Series.str.<function/property>`.

Series.str.capitalize(*args, **kwargs)	Convert strings in the Series/Index to be capitalized.
Series.str.casefold(*args, **kwargs)	Convert strings in the Series/Index to be casefolded.
Series.str.cat(*args, **kwargs)	Concatenate strings in the Series/Index with given separator.
Series.str.center(*args, **kwargs)	Pad left and right side of strings in the Series/Index.
Series.str.contains(*args, **kwargs)	Test if pattern or regex is contained within a string of a Series or Index.
Series.str.count(*args, **kwargs)	Count occurrences of pattern in each string of the Series/Index.
Series.str.decode(encoding[, errors])	Decode character string in the Series/Index using indicated encoding.
Series.str.encode(*args, **kwargs)	Encode character string in the Series/Index using indicated encoding.
Series.str.endswith(*args, **kwargs)	Test if the end of each string element matches a pattern.
Series.str.extract(*args, **kwargs)	Extract capture groups in the regex *pat* as columns in a DataFrame.
Series.str.extractall(*args, **kwargs)	Extract capture groups in the regex *pat* as columns in DataFrame.
Series.str.find(*args, **kwargs)	Return lowest indexes in each strings in the Series/Index.
Series.str.findall(*args, **kwargs)	Find all occurrences of pattern or regular expression in the Series/Index.
Series.str.get(i)	Extract element from each component at specified position.
Series.str.index(*args, **kwargs)	Return lowest indexes in each string in Series/Index.
Series.str.join(*args, **kwargs)	Join lists contained as elements in the Series/Index with passed delimiter.
Series.str.len(*args, **kwargs)	Compute the length of each element in the Series/Index.
Series.str.ljust(*args, **kwargs)	Pad right side of strings in the Series/Index.
Series.str.lower(*args, **kwargs)	Convert strings in the Series/Index to lowercase.
Series.str.lstrip(*args, **kwargs)	Remove leading characters.
Series.str.match(*args, **kwargs)	Determine if each string starts with a match of a regular expression.
Series.str.normalize(*args, **kwargs)	Return the Unicode normal form for the strings in the Series/Index.

continues on next page

Table 47 – continued from previous page

Series.str.pad(*args, **kwargs)	Pad strings in the Series/Index up to width.
Series.str.partition(*args, **kwargs)	Split the string at the first occurrence of *sep*.
Series.str.repeat(*args, **kwargs)	Duplicate each string in the Series or Index.
Series.str.replace(*args, **kwargs)	Replace each occurrence of pattern/regex in the Series/Index.
Series.str.rfind(*args, **kwargs)	Return highest indexes in each strings in the Series/Index.
Series.str.rindex(*args, **kwargs)	Return highest indexes in each string in Series/Index.
Series.str.rjust(*args, **kwargs)	Pad left side of strings in the Series/Index.
Series.str.rpartition(*args, **kwargs)	Split the string at the last occurrence of *sep*.
Series.str.rstrip(*args, **kwargs)	Remove trailing characters.
Series.str.slice([start, stop, step])	Slice substrings from each element in the Series or Index.
Series.str.slice_replace(*args, **kwargs)	Replace a positional slice of a string with another value.
Series.str.split(*args, **kwargs)	Split strings around given separator/delimiter.
Series.str.rsplit(*args, **kwargs)	Split strings around given separator/delimiter.
Series.str.startswith(*args, **kwargs)	Test if the start of each string element matches a pattern.
Series.str.strip(*args, **kwargs)	Remove leading and trailing characters.
Series.str.swapcase(*args, **kwargs)	Convert strings in the Series/Index to be swapcased.
Series.str.title(*args, **kwargs)	Convert strings in the Series/Index to titlecase.
Series.str.translate(*args, **kwargs)	Map all characters in the string through the given mapping table.
Series.str.upper(*args, **kwargs)	Convert strings in the Series/Index to uppercase.
Series.str.wrap(*args, **kwargs)	Wrap strings in Series/Index at specified line width.
Series.str.zfill(*args, **kwargs)	Pad strings in the Series/Index by prepending '0' characters.
Series.str.isalnum(*args, **kwargs)	Check whether all characters in each string are alphanumeric.
Series.str.isalpha(*args, **kwargs)	Check whether all characters in each string are alphabetic.
Series.str.isdigit(*args, **kwargs)	Check whether all characters in each string are digits.
Series.str.isspace(*args, **kwargs)	Check whether all characters in each string are whitespace.
Series.str.islower(*args, **kwargs)	Check whether all characters in each string are lowercase.
Series.str.isupper(*args, **kwargs)	Check whether all characters in each string are uppercase.
Series.str.istitle(*args, **kwargs)	Check whether all characters in each string are titlecase.
Series.str.isnumeric(*args, **kwargs)	Check whether all characters in each string are numeric.
Series.str.isdecimal(*args, **kwargs)	Check whether all characters in each string are decimal.
Series.str.get_dummies(*args, **kwargs)	Return DataFrame of dummy/indicator variables for Series.

pandas.Series.str.capitalize

Series.str.**capitalize**(**args*, ***kwargs*)

Convert strings in the Series/Index to be capitalized.

Equivalent to `str.capitalize()`.

Returns

Series or Index of object

See also:

Series.str.lower	Converts all characters to lowercase.
Series.str.upper	Converts all characters to uppercase.
Series.str.title	Converts first character of each word to uppercase and remaining to lowercase.
Series.str.capitalize	Converts first character to uppercase and remaining to lowercase.
Series.str.swapcase	Converts uppercase to lowercase and lowercase to uppercase.
Series.str.casefold	Removes all case distinctions in the string.

Examples

```
>>> s = pd.Series(['lower', 'CAPITALS', 'this is a sentence', 'SwApCaSe'])
>>> s
0                 lower
1              CAPITALS
2    this is a sentence
3              SwApCaSe
dtype: object
```

```
>>> s.str.lower()
0                 lower
1              capitals
2    this is a sentence
3              swapcase
dtype: object
```

```
>>> s.str.upper()
0                 LOWER
1              CAPITALS
2    THIS IS A SENTENCE
3              SWAPCASE
dtype: object
```

```
>>> s.str.title()
0                 Lower
1              Capitals
2    This Is A Sentence
3              Swapcase
dtype: object
```

```
>>> s.str.capitalize()
0                 Lower
1              Capitals
2    This is a sentence
3              Swapcase
dtype: object
```

```
>>> s.str.swapcase()
0                 LOWER
1              capitals
2    THIS IS A SENTENCE
3              sWaPcAsE
dtype: object
```

pandas.Series.str.casefold

Series.str.**casefold**(**args*, ***kwargs*)

Convert strings in the Series/Index to be casefolded.

New in version 0.25.0.

Equivalent to `str.casefold()`.

Returns

Series or Index of object

See also:

Series.str.lower	Converts all characters to lowercase.
Series.str.upper	Converts all characters to uppercase.
Series.str.title	Converts first character of each word to uppercase and remaining to lowercase.
Series.str.capitalize	Converts first character to uppercase and remaining to lowercase.
Series.str.swapcase	Converts uppercase to lowercase and lowercase to uppercase.
Series.str.casefold	Removes all case distinctions in the string.

Examples

```
>>> s = pd.Series(['lower', 'CAPITALS', 'this is a sentence', 'SwApCaSe'])
>>> s
0                 lower
1              CAPITALS
2    this is a sentence
3              SwApCaSe
dtype: object
```

```
>>> s.str.lower()
0                 lower
1              capitals
2    this is a sentence
3              swapcase
dtype: object
```

```
>>> s.str.upper()
0                 LOWER
1              CAPITALS
2    THIS IS A SENTENCE
3              SWAPCASE
dtype: object
```

```
>>> s.str.title()
0                 Lower
```

(continues on next page)

(continued from previous page)

```
1              Capitals
2    This Is A Sentence
3              Swapcase
dtype: object
```

```
>>> s.str.capitalize()
0                 Lower
1              Capitals
2    This is a sentence
3              Swapcase
dtype: object
```

```
>>> s.str.swapcase()
0                 LOWER
1              capitals
2    THIS IS A SENTENCE
3              sWaPcAsE
dtype: object
```

pandas.Series.str.cat

Series.str.**cat**(**args*, ***kwargs*)

Concatenate strings in the Series/Index with given separator.

If *others* is specified, this function concatenates the Series/Index and elements of *others* element-wise. If *others* is not passed, then all values in the Series/Index are concatenated into a single string with a given *sep*.

Parameters

others [Series, Index, DataFrame, np.ndarray or list-like] Series, Index, DataFrame, np.ndarray (one- or two-dimensional) and other list-likes of strings must have the same length as the calling Series/Index, with the exception of indexed objects (i.e. Series/Index/DataFrame) if *join* is not None.

If others is a list-like that contains a combination of Series, Index or np.ndarray (1-dim), then all elements will be unpacked and must satisfy the above criteria individually.

If others is None, the method returns the concatenation of all strings in the calling Series/Index.

sep [str, default ‘’] The separator between the different elements/columns. By default the empty string *‘’* is used.

na_rep [str or None, default None] Representation that is inserted for all missing values:

- If *na_rep* is None, and *others* is None, missing values in the Series/Index are omitted from the result.
- If *na_rep* is None, and *others* is not None, a row containing a missing value in any of the columns (before concatenation) will have a missing value in the result.

join [{‘left’, ‘right’, ‘outer’, ‘inner’}, default ‘left’] Determines the join-style between the calling Series/Index and any Series/Index/DataFrame in *others* (objects without an index need to match the length of the calling Series/Index). To disable alignment, use *.values* on any Series/Index/DataFrame in *others*.

New in version 0.23.0.

Changed in version 1.0.0: Changed default of *join* from None to *‘left’*.

Returns

str, Series or Index If *others* is None, *str* is returned, otherwise a *Series/Index* (same type as caller) of objects is returned.

See also:

split Split each string in the Series/Index.
join Join lists contained as elements in the Series/Index.

Examples

When not passing *others*, all values are concatenated into a single string:

```
>>> s = pd.Series(['a', 'b', np.nan, 'd'])
>>> s.str.cat(sep=' ')
'a b d'
```

By default, NA values in the Series are ignored. Using *na_rep*, they can be given a representation:

```
>>> s.str.cat(sep=' ', na_rep='?')
'a b ? d'
```

If *others* is specified, corresponding values are concatenated with the separator. Result will be a Series of strings.

```
>>> s.str.cat(['A', 'B', 'C', 'D'], sep=',')
0    a,A
1    b,B
2    NaN
3    d,D
dtype: object
```

Missing values will remain missing in the result, but can again be represented using *na_rep*

```
>>> s.str.cat(['A', 'B', 'C', 'D'], sep=',', na_rep='-')
0    a,A
1    b,B
2    -,C
3    d,D
dtype: object
```

If *sep* is not specified, the values are concatenated without separation.

```
>>> s.str.cat(['A', 'B', 'C', 'D'], na_rep='-')
0    aA
1    bB
2    -C
3    dD
dtype: object
```

Series with different indexes can be aligned before concatenation. The *join*-keyword works as in other methods.

```
>>> t = pd.Series(['d', 'a', 'e', 'c'], index=[3, 0, 4, 2])
>>> s.str.cat(t, join='left', na_rep='-')
0    aa
1    b-
2    -c
3    dd
```

(continues on next page)

(continued from previous page)

```
dtype: object
>>>
>>> s.str.cat(t, join='outer', na_rep='-')
0    aa
1    b-
2    -c
3    dd
4    -e
dtype: object
>>>
>>> s.str.cat(t, join='inner', na_rep='-')
0    aa
2    -c
3    dd
dtype: object
>>>
>>> s.str.cat(t, join='right', na_rep='-')
3    dd
0    aa
4    -e
2    -c
dtype: object
```

For more examples, see *here*.

pandas.Series.str.center

`Series.str.`**`center`**`(*args, **kwargs)`

Pad left and right side of strings in the Series/Index.

Equivalent to `str.center()`.

Parameters

width [int] Minimum width of resulting string; additional characters will be filled with `fillchar`.

fillchar [str] Additional character for filling, default is whitespace.

Returns

filled [Series/Index of objects.]

pandas.Series.str.contains

`Series.str.`**`contains`**`(*args, **kwargs)`

Test if pattern or regex is contained within a string of a Series or Index.

Return boolean Series or Index based on whether a given pattern or regex is contained within a string of a Series or Index.

Parameters

pat [str] Character sequence or regular expression.

case [bool, default True] If True, case sensitive.

flags [int, default 0 (no flags)] Flags to pass through to the re module, e.g. re.IGNORECASE.

na [default NaN] Fill value for missing values.

regex [bool, default True] If True, assumes the pat is a regular expression.

If False, treats the pat as a literal string.

Returns

Series or Index of boolean values A Series or Index of boolean values indicating whether the given pattern is contained within the string of each element of the Series or Index.

See also:

match Analogous, but stricter, relying on re.match instead of re.search.
Series.str.startswith Test if the start of each string element matches a pattern.
Series.str.endswith Same as startswith, but tests the end of string.

Examples

Returning a Series of booleans using only a literal pattern.

```
>>> s1 = pd.Series(['Mouse', 'dog', 'house and parrot', '23', np.NaN])
>>> s1.str.contains('og', regex=False)
0    False
1     True
2    False
3    False
4      NaN
dtype: object
```

Returning an Index of booleans using only a literal pattern.

```
>>> ind = pd.Index(['Mouse', 'dog', 'house and parrot', '23.0', np.NaN])
>>> ind.str.contains('23', regex=False)
Index([False, False, False, True, nan], dtype='object')
```

Specifying case sensitivity using *case*.

```
>>> s1.str.contains('oG', case=True, regex=True)
0    False
1    False
2    False
3    False
4      NaN
dtype: object
```

Specifying *na* to be *False* instead of *NaN* replaces NaN values with *False*. If Series or Index does not contain NaN values the resultant dtype will be *bool*, otherwise, an *object* dtype.

```
>>> s1.str.contains('og', na=False, regex=True)
0    False
1     True
2    False
3    False
4    False
dtype: bool
```

Returning ‘house’ or ‘dog’ when either expression occurs in a string.

```
>>> s1.str.contains('house|dog', regex=True)
0    False
1     True
2     True
3    False
4      NaN
dtype: object
```

Ignoring case sensitivity using *flags* with regex.

```
>>> import re
>>> s1.str.contains('PARROT', flags=re.IGNORECASE, regex=True)
0    False
1    False
2     True
3    False
4      NaN
dtype: object
```

Returning any digit using regular expression.

```
>>> s1.str.contains('\d', regex=True)
0    False
1    False
2    False
3     True
4      NaN
dtype: object
```

Ensure *pat* is a not a literal pattern when *regex* is set to True. Note in the following example one might expect only *s2[1]* and *s2[3]* to return *True*. However, '.0' as a regex matches any character followed by a 0.

```
>>> s2 = pd.Series(['40', '40.0', '41', '41.0', '35'])
>>> s2.str.contains('.0', regex=True)
0     True
1     True
2    False
3     True
4    False
dtype: bool
```

pandas.Series.str.count

`Series.str.count(*args, **kwargs)`

Count occurrences of pattern in each string of the Series/Index.

This function is used to count the number of times a particular regex pattern is repeated in each of the string elements of the *Series*.

Parameters

pat [str] Valid regular expression.

flags [int, default 0, meaning no flags] Flags for the *re* module. For a complete list, see here.

****kwargs** For compatibility with other string methods. Not used.

Returns

Series or Index Same type as the calling object containing the integer counts.

See also:

`re` Standard library module for regular expressions.
`str.count` Standard library version, without regular expression support.

Notes

Some characters need to be escaped when passing in *pat*. eg. `'$'` has a special meaning in regex and must be escaped when finding this literal character.

Examples

```
>>> s = pd.Series(['A', 'B', 'Aaba', 'Baca', np.nan, 'CABA', 'cat'])
>>> s.str.count('a')
0    0.0
1    0.0
2    2.0
3    2.0
4    NaN
5    0.0
6    1.0
dtype: float64
```

Escape `'$'` to find the literal dollar sign.

```
>>> s = pd.Series(['$', 'B', 'Aab$', '$$ca', 'C$B$', 'cat'])
>>> s.str.count('\$')
0    1
1    0
2    1
3    2
4    2
5    0
dtype: int64
```

This is also available on Index

```
>>> pd.Index(['A', 'A', 'Aaba', 'cat']).str.count('a')
Int64Index([0, 0, 2, 1], dtype='int64')
```

pandas.Series.str.decode

`Series.str.`**`decode`**(*encoding*, *errors='strict'*)

Decode character string in the Series/Index using indicated encoding.

Equivalent to `str.decode()` in python2 and `bytes.decode()` in python3.

Parameters

encoding [str]

errors [str, optional]

Returns

Series or Index

pandas.Series.str.encode

Series.str.**encode**(**args*, ***kwargs*)

Encode character string in the Series/Index using indicated encoding.

Equivalent to `str.encode()`.

Parameters

encoding [str]

errors [str, optional]

Returns

encoded [Series/Index of objects]

pandas.Series.str.endswith

Series.str.**endswith**(**args*, ***kwargs*)

Test if the end of each string element matches a pattern.

Equivalent to `str.endswith()`.

Parameters

pat [str] Character sequence. Regular expressions are not accepted.

na [object, default NaN] Object shown if element tested is not a string.

Returns

Series or Index of bool A Series of booleans indicating whether the given pattern matches the end of each string element.

See also:

str.endswith Python standard library string method.
Series.str.startswith Same as endswith, but tests the start of string.
Series.str.contains Tests if string element contains a pattern.

Examples

```
>>> s = pd.Series(['bat', 'bear', 'caT', np.nan])
>>> s
0     bat
1    bear
2     caT
3     NaN
dtype: object
```

```
>>> s.str.endswith('t')
0     True
1    False
2    False
3      NaN
dtype: object
```

Specifying *na* to be *False* instead of *NaN*.

```
>>> s.str.endswith('t', na=False)
0     True
1    False
2    False
3    False
dtype: bool
```

pandas.Series.str.extract

Series.str.**extract**(**args*, ***kwargs*)

Extract capture groups in the regex *pat* as columns in a DataFrame.

For each subject string in the Series, extract groups from the first match of regular expression *pat*.

Parameters

pat [str] Regular expression pattern with capturing groups.

flags [int, default 0 (no flags)] Flags from the `re` module, e.g. `re.IGNORECASE`, that modify regular expression matching for things like case, spaces, etc. For more details, see `re`.

expand [bool, default True] If True, return DataFrame with one column per capture group. If False, return a Series/Index if there is one capture group or DataFrame if there are multiple capture groups.

Returns

DataFrame or Series or Index A DataFrame with one row for each subject string, and one column for each group. Any capture group names in regular expression pat will be used for column names; otherwise capture group numbers will be used. The dtype of each result column is always object, even when no match is found. If `expand=False` and pat has only one capture group, then return a Series (if subject is a Series) or Index (if subject is an Index).

See also:

extractall Returns all matches (not just the first match).

Examples

A pattern with two groups will return a DataFrame with two columns. Non-matches will be NaN.

```
>>> s = pd.Series(['a1', 'b2', 'c3'])
>>> s.str.extract(r'([ab])(\d)')
     0    1
0    a    1
1    b    2
2  NaN  NaN
```

A pattern may contain optional groups.

```
>>> s.str.extract(r'([ab])?(\d)')
     0  1
0    a  1
1    b  2
2  NaN  3
```

Named groups will become column names in the result.

```
>>> s.str.extract(r'(?P<letter>[ab])(?P<digit>\d)')
  letter digit
0      a     1
1      b     2
2    NaN   NaN
```

A pattern with one group will return a DataFrame with one column if expand=True.

```
>>> s.str.extract(r'[ab](\d)', expand=True)
     0
0    1
1    2
2  NaN
```

A pattern with one group will return a Series if expand=False.

```
>>> s.str.extract(r'[ab](\d)', expand=False)
0      1
1      2
2    NaN
dtype: object
```

pandas.Series.str.extractall

`Series.str.`**`extractall`**`(*args, **kwargs)`

Extract capture groups in the regex *pat* as columns in DataFrame.

For each subject string in the Series, extract groups from all matches of regular expression pat. When each subject string in the Series has exactly one match, extractall(pat).xs(0, level='match') is the same as extract(pat).

Parameters

pat [str] Regular expression pattern with capturing groups.

flags [int, default 0 (no flags)] A `re` module flag, for example `re.IGNORECASE`. These allow to modify regular expression matching for things like case, spaces, etc. Multiple flags can be combined with the bitwise OR operator, for example `re.IGNORECASE | re.MULTILINE`.

Returns

DataFrame A `DataFrame` with one row for each match, and one column for each group. Its rows have a `MultiIndex` with first levels that come from the subject `Series`. The last level is named 'match' and indexes the matches in each item of the `Series`. Any capture group names in regular expression pat will be used for column names; otherwise capture group numbers will be used.

See also:

`extract` Returns first match only (not all matches).

Examples

A pattern with one group will return a DataFrame with one column. Indices with no matches will not appear in the result.

```
>>> s = pd.Series(["a1a2", "b1", "c1"], index=["A", "B", "C"])
>>> s.str.extractall(r"[ab](\d)")
        0
  match
A 0     1
  1     2
B 0     1
```

Capture group names are used for column names of the result.

```
>>> s.str.extractall(r"[ab](?P<digit>\d)")
        digit
  match
A 0         1
  1         2
B 0         1
```

A pattern with two groups will return a DataFrame with two columns.

```
>>> s.str.extractall(r"(?P<letter>[ab])(?P<digit>\d)")
        letter digit
  match
A 0          a     1
  1          a     2
B 0          b     1
```

Optional groups that do not match are NaN in the result.

```
>>> s.str.extractall(r"(?P<letter>[ab])?(?P<digit>\d)")
        letter digit
  match
A 0          a     1
  1          a     2
B 0          b     1
C 0        NaN     1
```

pandas.Series.str.find

Series.str.**find**(**args*, ***kwargs*)

Return lowest indexes in each strings in the Series/Index.

Each of returned indexes corresponds to the position where the substring is fully contained between [start:end]. Return -1 on failure. Equivalent to standard `str.find()`.

Parameters

sub [str] Substring being searched.

start [int] Left edge index.

end [int] Right edge index.

Returns

Series or Index of int.

See also:

rfind Return highest indexes in each strings.

pandas.Series.str.findall

Series.str.**findall**(**args*, ***kwargs*)

Find all occurrences of pattern or regular expression in the Series/Index.

Equivalent to applying `re.findall()` to all the elements in the Series/Index.

Parameters

pat [str] Pattern or regular expression.

flags [int, default 0] Flags from `re` module, e.g. *re.IGNORECASE* (default is 0, which means no flags).

Returns

Series/Index of lists of strings All non-overlapping matches of pattern or regular expression in each string of this Series/Index.

See also:

count Count occurrences of pattern or regular expression in each string of the Series/Index.

extractall For each string in the Series, extract groups from all matches of regular expression and return a DataFrame with one row for each match and one column for each group.

re.findall The equivalent `re` function to all non-overlapping matches of pattern or regular expression in string, as a list of strings.

Examples

```
>>> s = pd.Series(['Lion', 'Monkey', 'Rabbit'])
```

The search for the pattern 'Monkey' returns one match:

```
>>> s.str.findall('Monkey')
0          []
1    [Monkey]
2          []
dtype: object
```

On the other hand, the search for the pattern 'MONKEY' doesn't return any match:

```
>>> s.str.findall('MONKEY')
0    []
1    []
2    []
dtype: object
```

Flags can be added to the pattern or regular expression. For instance, to find the pattern 'MONKEY' ignoring the case:

```
>>> import re
>>> s.str.findall('MONKEY', flags=re.IGNORECASE)
0          []
```

(continues on next page)

(continued from previous page)

```
1    [Monkey]
2          []
dtype: object
```

When the pattern matches more than one string in the Series, all matches are returned:

```
>>> s.str.findall('on')
0    [on]
1    [on]
2      []
dtype: object
```

Regular expressions are supported too. For instance, the search for all the strings ending with the word 'on' is shown next:

```
>>> s.str.findall('on$')
0    [on]
1      []
2      []
dtype: object
```

If the pattern is found more than once in the same string, then a list of multiple strings is returned:

```
>>> s.str.findall('b')
0        []
1        []
2    [b, b]
dtype: object
```

pandas.Series.str.get

Series.str.**get**(*i*)

Extract element from each component at specified position.

Extract element from lists, tuples, or strings in each element in the Series/Index.

Parameters

i [int] Position of element to extract.

Returns

Series or Index

Examples

```
>>> s = pd.Series(["String",
...                (1, 2, 3),
...                ["a", "b", "c"],
...                123,
...                -456,
...                {1: "Hello", "2": "World"}])
>>> s
0                       String
1                    (1, 2, 3)
```

(continues on next page)

(continued from previous page)

```
2                      [a, b, c]
3                            123
4                           -456
5    {1: 'Hello', '2': 'World'}
dtype: object
```

```
>>> s.str.get(1)
0        t
1        2
2        b
3      NaN
4      NaN
5    Hello
dtype: object
```

```
>>> s.str.get(-1)
0      g
1      3
2      c
3    NaN
4    NaN
5    None
dtype: object
```

pandas.Series.str.index

`Series.str.`**`index`**(**args*, ***kwargs*)

Return lowest indexes in each string in Series/Index.

Each of the returned indexes corresponds to the position where the substring is fully contained between [start:end]. This is the same as `str.find` except instead of returning -1, it raises a ValueError when the substring is not found. Equivalent to standard `str.index`.

Parameters

sub [str] Substring being searched.

start [int] Left edge index.

end [int] Right edge index.

Returns

Series or Index of object

See also:

rindex Return highest indexes in each strings.

pandas.Series.str.join

Series.str.**join**(**args*, ***kwargs*)

Join lists contained as elements in the Series/Index with passed delimiter.

If the elements of a Series are lists themselves, join the content of these lists using the delimiter passed to the function. This function is an equivalent to `str.join()`.

Parameters

sep [str] Delimiter to use between list entries.

Returns

Series/Index: object The list entries concatenated by intervening occurrences of the delimiter.

Raises

AttributeError If the supplied Series contains neither strings nor lists.

See also:

`str.join` Standard library version of this method.
`Series.str.split` Split strings around given separator/delimiter.

Notes

If any of the list items is not a string object, the result of the join will be *NaN*.

Examples

Example with a list that contains non-string elements.

```
>>> s = pd.Series([['lion', 'elephant', 'zebra'],
...                [1.1, 2.2, 3.3],
...                ['cat', np.nan, 'dog'],
...                ['cow', 4.5, 'goat'],
...                ['duck', ['swan', 'fish'], 'guppy']])
>>> s
0        [lion, elephant, zebra]
1                [1.1, 2.2, 3.3]
2                [cat, nan, dog]
3               [cow, 4.5, goat]
4    [duck, [swan, fish], guppy]
dtype: object
```

Join all lists using a '-'. The lists containing object(s) of types other than str will produce a NaN.

```
>>> s.str.join('-')
0    lion-elephant-zebra
1                    NaN
2                    NaN
3                    NaN
4                    NaN
dtype: object
```

pandas.Series.str.len

Series.str.**len**(**args*, ***kwargs*)

Compute the length of each element in the Series/Index.

The element may be a sequence (such as a string, tuple or list) or a collection (such as a dictionary).

Returns

Series or Index of int A Series or Index of integer values indicating the length of each element in the Series or Index.

See also:

str.len Python built-in function returning the length of an object.
Series.size Returns the length of the Series.

Examples

Returns the length (number of characters) in a string. Returns the number of entries for dictionaries, lists or tuples.

```
>>> s = pd.Series(['dog',
...                '',
...                5,
...                {'foo' : 'bar'},
...                [2, 3, 5, 7],
...                ('one', 'two', 'three')])
>>> s
0                  dog
1
2                    5
3       {'foo': 'bar'}
4         [2, 3, 5, 7]
5    (one, two, three)
dtype: object
>>> s.str.len()
0    3.0
1    0.0
2    NaN
3    1.0
4    4.0
5    3.0
dtype: float64
```

pandas.Series.str.ljust

Series.str.**ljust**(**args*, ***kwargs*)

Pad right side of strings in the Series/Index.

Equivalent to `str.ljust()`.

Parameters

width [int] Minimum width of resulting string; additional characters will be filled with `fillchar`.

fillchar [str] Additional character for filling, default is whitespace.

Returns

filled [Series/Index of objects.]

pandas.Series.str.lower

Series.str.**lower**(**args*, ***kwargs*)

Convert strings in the Series/Index to lowercase.

Equivalent to `str.lower()`.

Returns

Series or Index of object

See also:

Series.str.lower Converts all characters to lowercase.
Series.str.upper Converts all characters to uppercase.
Series.str.title Converts first character of each word to uppercase and remaining to lowercase.
Series.str.capitalize Converts first character to uppercase and remaining to lowercase.
Series.str.swapcase Converts uppercase to lowercase and lowercase to uppercase.
Series.str.casefold Removes all case distinctions in the string.

Examples

```
>>> s = pd.Series(['lower', 'CAPITALS', 'this is a sentence', 'SwApCaSe'])
>>> s
0                 lower
1              CAPITALS
2    this is a sentence
3              SwApCaSe
dtype: object
```

```
>>> s.str.lower()
0                 lower
1              capitals
2    this is a sentence
3              swapcase
dtype: object
```

```
>>> s.str.upper()
0                 LOWER
1              CAPITALS
2    THIS IS A SENTENCE
3              SWAPCASE
dtype: object
```

```
>>> s.str.title()
0                 Lower
1              Capitals
2    This Is A Sentence
3              Swapcase
dtype: object
```

```
>>> s.str.capitalize()
0                 Lower
1              Capitals
```

(continues on next page)

(continued from previous page)

```
2    This is a sentence
3              Swapcase
dtype: object
```

```
>>> s.str.swapcase()
0                 LOWER
1              capitals
2    THIS IS A SENTENCE
3              sWaPcAsE
dtype: object
```

pandas.Series.str.lstrip

Series.str.**lstrip**(**args*, ***kwargs*)

Remove leading characters.

Strip whitespaces (including newlines) or a set of specified characters from each string in the Series/Index from left side. Equivalent to `str.lstrip()`.

Parameters

to_strip [str or None, default None] Specifying the set of characters to be removed. All combinations of this set of characters will be stripped. If None then whitespaces are removed.

Returns

Series or Index of object

See also:

Series.str.strip Remove leading and trailing characters in Series/Index.
Series.str.lstrip Remove leading characters in Series/Index.
Series.str.rstrip Remove trailing characters in Series/Index.

Examples

```
>>> s = pd.Series(['1. Ant.  ', '2. Bee!\n', '3. Cat?\t', np.nan])
>>> s
0    1. Ant.
1    2. Bee!\n
2    3. Cat?\t
3          NaN
dtype: object
```

```
>>> s.str.strip()
0    1. Ant.
1    2. Bee!
2    3. Cat?
3        NaN
dtype: object
```

```
>>> s.str.lstrip('123.')
0    Ant.
1    Bee!\n
```

(continues on next page)

(continued from previous page)

```
2    Cat?\t
3       NaN
dtype: object
```

```
>>> s.str.rstrip('.!? \n\t')
0    1. Ant
1    2. Bee
2    3. Cat
3       NaN
dtype: object
```

```
>>> s.str.strip('123.!? \n\t')
0    Ant
1    Bee
2    Cat
3    NaN
dtype: object
```

pandas.Series.str.match

Series.str.**match**(**args*, ***kwargs*)

Determine if each string starts with a match of a regular expression.

Parameters

pat [str] Character sequence or regular expression.

case [bool, default True] If True, case sensitive.

flags [int, default 0 (no flags)] Regex module flags, e.g. re.IGNORECASE.

na [default NaN] Fill value for missing values.

Returns

Series/array of boolean values

See also:

fullmatch Stricter matching that requires the entire string to match.
contains Analogous, but less strict, relying on re.search instead of re.match.
extract Extract matched groups.

pandas.Series.str.normalize

Series.str.**normalize**(**args*, ***kwargs*)

Return the Unicode normal form for the strings in the Series/Index.

For more information on the forms, see the unicodedata.normalize().

Parameters

form [{'NFC', 'NFKC', 'NFD', 'NFKD'}] Unicode form.

Returns

normalized [Series/Index of objects]

pandas.Series.str.pad

Series.str.**pad**(**args*, ***kwargs*)

Pad strings in the Series/Index up to width.

Parameters

width [int] Minimum width of resulting string; additional characters will be filled with character defined in *fillchar*.

side [{'left', 'right', 'both'}, default 'left'] Side from which to fill resulting string.

fillchar [str, default ' '] Additional character for filling, default is whitespace.

Returns

Series or Index of object Returns Series or Index with minimum number of char in object.

See also:

Series.str.rjust Fills the left side of strings with an arbitrary character. Equivalent to `Series.str.pad(side='left')`.

Series.str.ljust Fills the right side of strings with an arbitrary character. Equivalent to `Series.str.pad(side='right')`.

Series.str.center Fills boths sides of strings with an arbitrary character. Equivalent to `Series.str.pad(side='both')`.

Series.str.zfill Pad strings in the Series/Index by prepending '0' character. Equivalent to `Series.str.pad(side='left', fillchar='0')`.

Examples

```
>>> s = pd.Series(["caribou", "tiger"])
>>> s
0    caribou
1      tiger
dtype: object
```

```
>>> s.str.pad(width=10)
0       caribou
1         tiger
dtype: object
```

```
>>> s.str.pad(width=10, side='right', fillchar='-')
0    caribou---
1    tiger-----
dtype: object
```

```
>>> s.str.pad(width=10, side='both', fillchar='-')
0    -caribou--
1    --tiger---
dtype: object
```

pandas.Series.str.partition

Series.str.**partition**(**args*, ***kwargs*)

Split the string at the first occurrence of *sep*.

This method splits the string at the first occurrence of *sep*, and returns 3 elements containing the part before the separator, the separator itself, and the part after the separator. If the separator is not found, return 3 elements containing the string itself, followed by two empty strings.

Parameters

sep [str, default whitespace] String to split on.

expand [bool, default True] If True, return DataFrame/MultiIndex expanding dimensionality. If False, return Series/Index.

Returns

DataFrame/MultiIndex or Series/Index of objects

See also:

rpartition Split the string at the last occurrence of *sep*.
Series.str.split Split strings around given separators.
str.partition Standard library version.

Examples

```
>>> s = pd.Series(['Linda van der Berg', 'George Pitt-Rivers'])
>>> s
0    Linda van der Berg
1    George Pitt-Rivers
dtype: object
```

```
>>> s.str.partition()
        0  1             2
0   Linda     van der Berg
1  George      Pitt-Rivers
```

To partition by the last space instead of the first one:

```
>>> s.str.rpartition()
               0  1            2
0  Linda van der            Berg
1         George     Pitt-Rivers
```

To partition by something different than a space:

```
>>> s.str.partition('-')
                    0  1       2
0  Linda van der Berg
1         George Pitt  -  Rivers
```

To return a Series containing tuples instead of a DataFrame:

```
>>> s.str.partition('-', expand=False)
0    (Linda van der Berg, , )
1    (George Pitt, -, Rivers)
dtype: object
```

Also available on indices:

```
>>> idx = pd.Index(['X 123', 'Y 999'])
>>> idx
Index(['X 123', 'Y 999'], dtype='object')
```

Which will create a MultiIndex:

```
>>> idx.str.partition()
MultiIndex([('X', ' ', '123'),
            ('Y', ' ', '999')],
           )
```

Or an index with tuples with `expand=False`:

```
>>> idx.str.partition(expand=False)
Index([('X', ' ', '123'), ('Y', ' ', '999')], dtype='object')
```

pandas.Series.str.repeat

`Series.str.repeat(*args, **kwargs)`

Duplicate each string in the Series or Index.

Parameters

repeats [int or sequence of int] Same value for all (int) or different value per (sequence).

Returns

Series or Index of object Series or Index of repeated string objects specified by input parameter repeats.

Examples

```
>>> s = pd.Series(['a', 'b', 'c'])
>>> s
0    a
1    b
2    c
dtype: object
```

Single int repeats string in Series

```
>>> s.str.repeat(repeats=2)
0    aa
1    bb
2    cc
dtype: object
```

Sequence of int repeats corresponding string in Series

```
>>> s.str.repeat(repeats=[1, 2, 3])
0      a
1     bb
2    ccc
dtype: object
```

pandas.Series.str.replace

Series.str.**replace**(**args*, ***kwargs*)

Replace each occurrence of pattern/regex in the Series/Index.

Equivalent to `str.replace()` or `re.sub()`, depending on the regex value.

Parameters

pat [str or compiled regex] String can be a character sequence or regular expression.

repl [str or callable] Replacement string or a callable. The callable is passed the regex match object and must return a replacement string to be used. See `re.sub()`.

n [int, default -1 (all)] Number of replacements to make from start.

case [bool, default None] Determines if replace is case sensitive:

- If True, case sensitive (the default if *pat* is a string)
- Set to False for case insensitive
- Cannot be set if *pat* is a compiled regex.

flags [int, default 0 (no flags)] Regex module flags, e.g. re.IGNORECASE. Cannot be set if *pat* is a compiled regex.

regex [bool, default True] Determines if assumes the passed-in pattern is a regular expression:

- If True, assumes the passed-in pattern is a regular expression.
- If False, treats the pattern as a literal string
- Cannot be set to False if *pat* is a compiled regex or *repl* is a callable.

New in version 0.23.0.

Returns

Series or Index of object A copy of the object with all matching occurrences of *pat* replaced by *repl*.

Raises

ValueError

- if *regex* is False and *repl* is a callable or *pat* is a compiled regex
- if *pat* is a compiled regex and *case* or *flags* is set

Notes

When *pat* is a compiled regex, all flags should be included in the compiled regex. Use of *case*, *flags*, or *regex=False* with a compiled regex will raise an error.

Examples

When *pat* is a string and *regex* is True (the default), the given *pat* is compiled as a regex. When *repl* is a string, it replaces matching regex patterns as with `re.sub()`. NaN value(s) in the Series are left as is:

```
>>> pd.Series(['foo', 'fuz', np.nan]).str.replace('f.', 'ba', regex=True)
0    bao
1    baz
2    NaN
dtype: object
```

When *pat* is a string and *regex* is False, every *pat* is replaced with *repl* as with `str.replace()`:

```
>>> pd.Series(['f.o', 'fuz', np.nan]).str.replace('f.', 'ba', regex=False)
0    bao
1    fuz
2    NaN
dtype: object
```

When *repl* is a callable, it is called on every *pat* using `re.sub()`. The callable should expect one positional argument (a regex object) and return a string.

To get the idea:

```
>>> pd.Series(['foo', 'fuz', np.nan]).str.replace('f', repr)
0    <re.Match object; span=(0, 1), match='f'>oo
1    <re.Match object; span=(0, 1), match='f'>uz
2                                            NaN
dtype: object
```

Reverse every lowercase alphabetic word:

```
>>> repl = lambda m: m.group(0)[::-1]
>>> pd.Series(['foo 123', 'bar baz', np.nan]).str.replace(r'[a-z]+', repl)
0    oof 123
1    rab zab
2        NaN
dtype: object
```

Using regex groups (extract second group and swap case):

```
>>> pat = r"(?P<one>\w+) (?P<two>\w+) (?P<three>\w+)"
>>> repl = lambda m: m.group('two').swapcase()
>>> pd.Series(['One Two Three', 'Foo Bar Baz']).str.replace(pat, repl)
0    tWO
1    bAR
dtype: object
```

Using a compiled regex with flags

```
>>> import re
>>> regex_pat = re.compile(r'FUZ', flags=re.IGNORECASE)
>>> pd.Series(['foo', 'fuz', np.nan]).str.replace(regex_pat, 'bar')
0    foo
1    bar
2    NaN
dtype: object
```

pandas.Series.str.rfind

Series.str.**rfind**(**args*, ***kwargs*)

Return highest indexes in each strings in the Series/Index.

Each of returned indexes corresponds to the position where the substring is fully contained between [start:end]. Return -1 on failure. Equivalent to standard `str.rfind()`.

Parameters

sub [str] Substring being searched.

start [int] Left edge index.

end [int] Right edge index.

Returns

Series or Index of int.

See also:

find Return lowest indexes in each strings.

pandas.Series.str.rindex

Series.str.**rindex**(**args*, ***kwargs*)

Return highest indexes in each string in Series/Index.

Each of the returned indexes corresponds to the position where the substring is fully contained between [start:end]. This is the same as `str.rfind` except instead of returning -1, it raises a ValueError when the substring is not found. Equivalent to standard `str.rindex`.

Parameters

sub [str] Substring being searched.

start [int] Left edge index.

end [int] Right edge index.

Returns

Series or Index of object

See also:

index Return lowest indexes in each strings.

pandas.Series.str.rjust

Series.str.**rjust**(**args*, ***kwargs*)

Pad left side of strings in the Series/Index.

Equivalent to `str.rjust()`.

Parameters

width [int] Minimum width of resulting string; additional characters will be filled with `fillchar`.

fillchar [str] Additional character for filling, default is whitespace.

Returns

filled [Series/Index of objects.]

pandas.Series.str.rpartition

Series.str.**rpartition**(**args*, ***kwargs*)

Split the string at the last occurrence of *sep*.

This method splits the string at the last occurrence of *sep*, and returns 3 elements containing the part before the separator, the separator itself, and the part after the separator. If the separator is not found, return 3 elements containing two empty strings, followed by the string itself.

Parameters

sep [str, default whitespace] String to split on.

expand [bool, default True] If True, return DataFrame/MultiIndex expanding dimensionality. If False, return Series/Index.

Returns

DataFrame/MultiIndex or Series/Index of objects

See also:

partition Split the string at the first occurrence of *sep*.
Series.str.split Split strings around given separators.
str.partition Standard library version.

Examples

```
>>> s = pd.Series(['Linda van der Berg', 'George Pitt-Rivers'])
>>> s
0    Linda van der Berg
1    George Pitt-Rivers
dtype: object
```

```
>>> s.str.partition()
        0  1             2
0   Linda     van der Berg
1  George      Pitt-Rivers
```

To partition by the last space instead of the first one:

```
>>> s.str.rpartition()
               0  1            2
0  Linda van der            Berg
1         George     Pitt-Rivers
```

To partition by something different than a space:

```
>>> s.str.partition('-')
                    0  1       2
0  Linda van der Berg
1         George Pitt  -  Rivers
```

To return a Series containing tuples instead of a DataFrame:

```
>>> s.str.partition('-', expand=False)
0    (Linda van der Berg, , )
1    (George Pitt, -, Rivers)
dtype: object
```

Also available on indices:

```
>>> idx = pd.Index(['X 123', 'Y 999'])
>>> idx
Index(['X 123', 'Y 999'], dtype='object')
```

Which will create a MultiIndex:

```
>>> idx.str.partition()
MultiIndex([('X', ' ', '123'),
            ('Y', ' ', '999')],
           )
```

Or an index with tuples with `expand=False`:

```
>>> idx.str.partition(expand=False)
Index([('X', ' ', '123'), ('Y', ' ', '999')], dtype='object')
```

pandas.Series.str.rstrip

`Series.str.`**`rstrip`**(**args*, ***kwargs*)

Remove trailing characters.

Strip whitespaces (including newlines) or a set of specified characters from each string in the Series/Index from right side. Equivalent to `str.rstrip()`.

Parameters

to_strip [str or None, default None] Specifying the set of characters to be removed. All combinations of this set of characters will be stripped. If None then whitespaces are removed.

Returns

Series or Index of object

See also:

Series.str.strip Remove leading and trailing characters in Series/Index.
Series.str.lstrip Remove leading characters in Series/Index.
Series.str.rstrip Remove trailing characters in Series/Index.

Examples

```
>>> s = pd.Series(['1. Ant.  ', '2. Bee!\n', '3. Cat?\t', np.nan])
>>> s
0    1. Ant.
1    2. Bee!\n
2    3. Cat?\t
3          NaN
dtype: object
```

```
>>> s.str.strip()
0    1. Ant.
1    2. Bee!
2    3. Cat?
3        NaN
dtype: object
```

```
>>> s.str.lstrip('123.')
0    Ant.
1    Bee!\n
2    Cat?\t
3       NaN
dtype: object
```

```
>>> s.str.rstrip('.!? \n\t')
0    1. Ant
1    2. Bee
2    3. Cat
3       NaN
dtype: object
```

```
>>> s.str.strip('123.!? \n\t')
0    Ant
1    Bee
2    Cat
3    NaN
dtype: object
```

pandas.Series.str.slice

Series.str.**slice**(*start=None*, *stop=None*, *step=None*)

Slice substrings from each element in the Series or Index.

Parameters

start [int, optional] Start position for slice operation.

stop [int, optional] Stop position for slice operation.

step [int, optional] Step size for slice operation.

Returns

Series or Index of object Series or Index from sliced substring from original string object.

See also:

Series.str.slice_replace Replace a slice with a string.

Series.str.get Return element at position. Equivalent to *Series.str.slice(start=i, stop=i+1)* with *i* being the position.

Examples

```
>>> s = pd.Series(["koala", "fox", "chameleon"])
>>> s
0        koala
1          fox
2    chameleon
dtype: object
```

```
>>> s.str.slice(start=1)
0        oala
1          ox
```

(continues on next page)

(continued from previous page)

```
2    hameleon
dtype: object
```

```
>>> s.str.slice(start=-1)
0           a
1           x
2           n
dtype: object
```

```
>>> s.str.slice(stop=2)
0    ko
1    fo
2    ch
dtype: object
```

```
>>> s.str.slice(step=2)
0      kaa
1       fx
2    caeen
dtype: object
```

```
>>> s.str.slice(start=0, stop=5, step=3)
0    kl
1     f
2    cm
dtype: object
```

Equivalent behaviour to:

```
>>> s.str[0:5:3]
0    kl
1     f
2    cm
dtype: object
```

pandas.Series.str.slice_replace

Series.str.**slice_replace**(**args*, ***kwargs*)

Replace a positional slice of a string with another value.

Parameters

start [int, optional] Left index position to use for the slice. If not specified (None), the slice is unbounded on the left, i.e. slice from the start of the string.

stop [int, optional] Right index position to use for the slice. If not specified (None), the slice is unbounded on the right, i.e. slice until the end of the string.

repl [str, optional] String for replacement. If not specified (None), the sliced region is replaced with an empty string.

Returns

Series or Index Same type as the original object.

See also:

Series.str.slice Just slicing without replacement.

Examples

```
>>> s = pd.Series(['a', 'ab', 'abc', 'abdc', 'abcde'])
>>> s
0        a
1       ab
2      abc
3     abdc
4    abcde
dtype: object
```

Specify just *start*, meaning replace *start* until the end of the string with *repl*.

```
>>> s.str.slice_replace(1, repl='X')
0    aX
1    aX
2    aX
3    aX
4    aX
dtype: object
```

Specify just *stop*, meaning the start of the string to *stop* is replaced with *repl*, and the rest of the string is included.

```
>>> s.str.slice_replace(stop=2, repl='X')
0       X
1       X
2      Xc
3     Xdc
4    Xcde
dtype: object
```

Specify *start* and *stop*, meaning the slice from *start* to *stop* is replaced with *repl*. Everything before or after *start* and *stop* is included as is.

```
>>> s.str.slice_replace(start=1, stop=3, repl='X')
0      aX
1      aX
2      aX
3     aXc
4    aXde
dtype: object
```

pandas.Series.str.split

`Series.str.`**`split`**`(*args, **kwargs)`

Split strings around given separator/delimiter.

Splits the string in the Series/Index from the beginning, at the specified delimiter string. Equivalent to `str.split()`.

Parameters

pat [str, optional] String or regular expression to split on. If not specified, split on whitespace.

n [int, default -1 (all)] Limit number of splits in output. `None`, 0 and -1 will be interpreted as return all splits.

expand [bool, default False] Expand the split strings into separate columns.

- If `True`, return DataFrame/MultiIndex expanding dimensionality.
- If `False`, return Series/Index, containing lists of strings.

Returns

Series, Index, DataFrame or MultiIndex Type matches caller unless `expand=True` (see Notes).

See also:

Series.str.split Split strings around given separator/delimiter.
Series.str.rsplit Splits string around given separator/delimiter, starting from the right.
Series.str.join Join lists contained as elements in the Series/Index with passed delimiter.
str.split Standard library version for split.
str.rsplit Standard library version for rsplit.

Notes

The handling of the *n* keyword depends on the number of found splits:

- If found splits > *n*, make first *n* splits only
- If found splits <= *n*, make all splits
- If for a certain row the number of found splits < *n*, append *None* for padding up to *n* if `expand=True`

If using `expand=True`, Series and Index callers return DataFrame and MultiIndex objects, respectively.

Examples

```
>>> s = pd.Series(
...     [
...         "this is a regular sentence",
...         "https://docs.python.org/3/tutorial/index.html",
...         np.nan
...     ]
... )
>>> s
0                       this is a regular sentence
1    https://docs.python.org/3/tutorial/index.html
2                                              NaN
dtype: object
```

In the default setting, the string is split by whitespace.

```
>>> s.str.split()
0                   [this, is, a, regular, sentence]
1    [https://docs.python.org/3/tutorial/index.html]
2                                                NaN
dtype: object
```

Without the *n* parameter, the outputs of *rsplit* and *split* are identical.

```
>>> s.str.rsplit()
0                   [this, is, a, regular, sentence]
1    [https://docs.python.org/3/tutorial/index.html]
2                                                NaN
dtype: object
```

The *n* parameter can be used to limit the number of splits on the delimiter. The outputs of *split* and *rsplit* are different.

```
>>> s.str.split(n=2)
0                     [this, is, a regular sentence]
1    [https://docs.python.org/3/tutorial/index.html]
2                                                NaN
dtype: object
```

```
>>> s.str.rsplit(n=2)
0                     [this is a, regular, sentence]
1    [https://docs.python.org/3/tutorial/index.html]
2                                                NaN
dtype: object
```

The *pat* parameter can be used to split by other characters.

```
>>> s.str.split(pat="/")
0                         [this is a regular sentence]
1    [https:, , docs.python.org, 3, tutorial, index...
2                                                  NaN
dtype: object
```

When using `expand=True`, the split elements will expand out into separate columns. If NaN is present, it is propagated throughout the columns during the split.

```
>>> s.str.split(expand=True)
                                           0     1     2        3         4
0                                       this    is     a  regular  sentence
1  https://docs.python.org/3/tutorial/index.html  None  None     None      None
2                                         NaN   NaN   NaN      NaN       NaN
```

For slightly more complex use cases like splitting the html document name from a url, a combination of parameter settings can be used.

```
>>> s.str.rsplit("/", n=1, expand=True)
                                    0           1
0          this is a regular sentence        None
1  https://docs.python.org/3/tutorial  index.html
2                                 NaN         NaN
```

Remember to escape special characters when explicitly using regular expressions.

```
>>> s = pd.Series(["1+1=2"])
>>> s
0    1+1=2
dtype: object
>>> s.str.split(r"\+|=", expand=True)
     0    1    2
0    1    1    2
```

pandas.Series.str.rsplit

Series.str.**rsplit**(**args*, ***kwargs*)

Split strings around given separator/delimiter.

Splits the string in the Series/Index from the end, at the specified delimiter string. Equivalent to `str.rsplit()`.

Parameters

pat [str, optional] String or regular expression to split on. If not specified, split on whitespace.

n [int, default -1 (all)] Limit number of splits in output. `None`, 0 and -1 will be interpreted as return all splits.

expand [bool, default False] Expand the split strings into separate columns.

- If `True`, return DataFrame/MultiIndex expanding dimensionality.
- If `False`, return Series/Index, containing lists of strings.

Returns

Series, Index, DataFrame or MultiIndex Type matches caller unless `expand=True` (see Notes).

See also:

Series.str.split Split strings around given separator/delimiter.
Series.str.rsplit Splits string around given separator/delimiter, starting from the right.
Series.str.join Join lists contained as elements in the Series/Index with passed delimiter.
str.split Standard library version for split.
str.rsplit Standard library version for rsplit.

Notes

The handling of the *n* keyword depends on the number of found splits:

- If found splits > *n*, make first *n* splits only
- If found splits <= *n*, make all splits
- If for a certain row the number of found splits < *n*, append *None* for padding up to *n* if `expand=True`

If using `expand=True`, Series and Index callers return DataFrame and MultiIndex objects, respectively.

Examples

```
>>> s = pd.Series(
...     [
...         "this is a regular sentence",
...         "https://docs.python.org/3/tutorial/index.html",
...         np.nan
...     ]
... )
>>> s
0                    this is a regular sentence
1    https://docs.python.org/3/tutorial/index.html
2                                              NaN
dtype: object
```

In the default setting, the string is split by whitespace.

```
>>> s.str.split()
0                   [this, is, a, regular, sentence]
1    [https://docs.python.org/3/tutorial/index.html]
2                                                NaN
dtype: object
```

Without the *n* parameter, the outputs of *rsplit* and *split* are identical.

```
>>> s.str.rsplit()
0                   [this, is, a, regular, sentence]
1    [https://docs.python.org/3/tutorial/index.html]
2                                                NaN
dtype: object
```

The *n* parameter can be used to limit the number of splits on the delimiter. The outputs of *split* and *rsplit* are different.

```
>>> s.str.split(n=2)
0                     [this, is, a regular sentence]
1    [https://docs.python.org/3/tutorial/index.html]
2                                                NaN
dtype: object
```

```
>>> s.str.rsplit(n=2)
0                     [this is a, regular, sentence]
1    [https://docs.python.org/3/tutorial/index.html]
2                                                NaN
dtype: object
```

The *pat* parameter can be used to split by other characters.

```
>>> s.str.split(pat="/")
0                         [this is a regular sentence]
1    [https:, , docs.python.org, 3, tutorial, index...
2                                                  NaN
dtype: object
```

When using `expand=True`, the split elements will expand out into separate columns. If NaN is present, it is propagated throughout the columns during the split.

```
>>> s.str.split(expand=True)
                                               0     1     2        3         4
0                                           this    is     a  regular  sentence
1  https://docs.python.org/3/tutorial/index.html  None  None     None      None
2                                            NaN   NaN   NaN      NaN       NaN
```

For slightly more complex use cases like splitting the html document name from a url, a combination of parameter settings can be used.

```
>>> s.str.rsplit("/", n=1, expand=True)
                                    0           1
0          this is a regular sentence        None
1  https://docs.python.org/3/tutorial  index.html
2                                 NaN         NaN
```

Remember to escape special characters when explicitly using regular expressions.

```
>>> s = pd.Series(["1+1=2"])
>>> s
0    1+1=2
dtype: object
>>> s.str.split(r"\+|=", expand=True)
     0    1    2
0    1    1    2
```

pandas.Series.str.startswith

Series.str.**startswith**(**args*, ***kwargs*)

Test if the start of each string element matches a pattern.

Equivalent to `str.startswith()`.

Parameters

pat [str] Character sequence. Regular expressions are not accepted.

na [object, default NaN] Object shown if element tested is not a string.

Returns

Series or Index of bool A Series of booleans indicating whether the given pattern matches the start of each string element.

See also:

str.startswith Python standard library string method.
Series.str.endswith Same as startswith, but tests the end of string.
Series.str.contains Tests if string element contains a pattern.

Examples

```
>>> s = pd.Series(['bat', 'Bear', 'cat', np.nan])
>>> s
0     bat
1    Bear
2     cat
3     NaN
dtype: object
```

```
>>> s.str.startswith('b')
0     True
1    False
2    False
3      NaN
dtype: object
```

Specifying *na* to be *False* instead of *NaN*.

```
>>> s.str.startswith('b', na=False)
0     True
1    False
2    False
3    False
dtype: bool
```

pandas.Series.str.strip

Series.str.**strip**(**args*, ***kwargs*)

Remove leading and trailing characters.

Strip whitespaces (including newlines) or a set of specified characters from each string in the Series/Index from left and right sides. Equivalent to `str.strip()`.

Parameters

to_strip [str or None, default None] Specifying the set of characters to be removed. All combinations of this set of characters will be stripped. If None then whitespaces are removed.

Returns

Series or Index of object

See also:

Series.str.strip Remove leading and trailing characters in Series/Index.
Series.str.lstrip Remove leading characters in Series/Index.
Series.str.rstrip Remove trailing characters in Series/Index.

Examples

```
>>> s = pd.Series(['1. Ant.  ', '2. Bee!\n', '3. Cat?\t', np.nan])
>>> s
0    1. Ant.
1    2. Bee!\n
2    3. Cat?\t
3          NaN
dtype: object
```

```
>>> s.str.strip()
0    1. Ant.
1    2. Bee!
2    3. Cat?
3        NaN
dtype: object
```

```
>>> s.str.lstrip('123.')
0    Ant.
1    Bee!\n
2    Cat?\t
3       NaN
dtype: object
```

```
>>> s.str.rstrip('.!? \n\t')
0    1. Ant
1    2. Bee
2    3. Cat
3       NaN
dtype: object
```

```
>>> s.str.strip('123.!? \n\t')
0    Ant
```

(continues on next page)

(continued from previous page)

```
1    Bee
2    Cat
3    NaN
dtype: object
```

pandas.Series.str.swapcase

Series.str.**swapcase**(**args*, ***kwargs*)

Convert strings in the Series/Index to be swapcased.

Equivalent to `str.swapcase()`.

Returns

Series or Index of object

See also:

Series.str.lower	Converts all characters to lowercase.
Series.str.upper	Converts all characters to uppercase.
Series.str.title	Converts first character of each word to uppercase and remaining to lowercase.
Series.str.capitalize	Converts first character to uppercase and remaining to lowercase.
Series.str.swapcase	Converts uppercase to lowercase and lowercase to uppercase.
Series.str.casefold	Removes all case distinctions in the string.

Examples

```
>>> s = pd.Series(['lower', 'CAPITALS', 'this is a sentence', 'SwApCaSe'])
>>> s
0                 lower
1              CAPITALS
2    this is a sentence
3              SwApCaSe
dtype: object
```

```
>>> s.str.lower()
0                 lower
1              capitals
2    this is a sentence
3              swapcase
dtype: object
```

```
>>> s.str.upper()
0                 LOWER
1              CAPITALS
2    THIS IS A SENTENCE
3              SWAPCASE
dtype: object
```

```
>>> s.str.title()
0                 Lower
1              Capitals
2    This Is A Sentence
3              Swapcase
dtype: object
```

```
>>> s.str.capitalize()
0                 Lower
1              Capitals
2    This is a sentence
3              Swapcase
dtype: object
```

```
>>> s.str.swapcase()
0                 LOWER
1              capitals
2    THIS IS A SENTENCE
3              sWaPcAsE
dtype: object
```

pandas.Series.str.title

Series.str.**title**(**args*, ***kwargs*)

Convert strings in the Series/Index to titlecase.

Equivalent to `str.title()`.

Returns

Series or Index of object

See also:

Series.str.lower Converts all characters to lowercase.
Series.str.upper Converts all characters to uppercase.
Series.str.title Converts first character of each word to uppercase and remaining to lowercase.
Series.str.capitalize Converts first character to uppercase and remaining to lowercase.
Series.str.swapcase Converts uppercase to lowercase and lowercase to uppercase.
Series.str.casefold Removes all case distinctions in the string.

Examples

```
>>> s = pd.Series(['lower', 'CAPITALS', 'this is a sentence', 'SwApCaSe'])
>>> s
0                 lower
1              CAPITALS
2    this is a sentence
3              SwApCaSe
dtype: object
```

```
>>> s.str.lower()
0                 lower
1              capitals
2    this is a sentence
3              swapcase
dtype: object
```

```
>>> s.str.upper()
0                 LOWER
1              CAPITALS
2    THIS IS A SENTENCE
```

(continues on next page)

(continued from previous page)

```
3              SWAPCASE
dtype: object
```

```
>>> s.str.title()
0                 Lower
1              Capitals
2    This Is A Sentence
3              Swapcase
dtype: object
```

```
>>> s.str.capitalize()
0                 Lower
1              Capitals
2    This is a sentence
3              Swapcase
dtype: object
```

```
>>> s.str.swapcase()
0                 LOWER
1              capitals
2    THIS IS A SENTENCE
3              sWaPcAsE
dtype: object
```

pandas.Series.str.translate

Series.str.**translate**(**args*, ***kwargs*)

Map all characters in the string through the given mapping table.

Equivalent to standard `str.translate()`.

Parameters

table [dict] Table is a mapping of Unicode ordinals to Unicode ordinals, strings, or None. Unmapped characters are left untouched. Characters mapped to None are deleted. `str.maketrans()` is a helper function for making translation tables.

Returns

Series or Index

pandas.Series.str.upper

Series.str.**upper**(**args*, ***kwargs*)

Convert strings in the Series/Index to uppercase.

Equivalent to `str.upper()`.

Returns

Series or Index of object

See also:

Series.str.lower	Converts all characters to lowercase.
Series.str.upper	Converts all characters to uppercase.
Series.str.title	Converts first character of each word to uppercase and remaining to lowercase.

Series.str.capitalize Converts first character to uppercase and remaining to lowercase.
Series.str.swapcase Converts uppercase to lowercase and lowercase to uppercase.
Series.str.casefold Removes all case distinctions in the string.

Examples

```
>>> s = pd.Series(['lower', 'CAPITALS', 'this is a sentence', 'SwApCaSe'])
>>> s
0                 lower
1              CAPITALS
2    this is a sentence
3              SwApCaSe
dtype: object
```

```
>>> s.str.lower()
0                 lower
1              capitals
2    this is a sentence
3              swapcase
dtype: object
```

```
>>> s.str.upper()
0                 LOWER
1              CAPITALS
2    THIS IS A SENTENCE
3              SWAPCASE
dtype: object
```

```
>>> s.str.title()
0                 Lower
1              Capitals
2    This Is A Sentence
3              Swapcase
dtype: object
```

```
>>> s.str.capitalize()
0                 Lower
1              Capitals
2    This is a sentence
3              Swapcase
dtype: object
```

```
>>> s.str.swapcase()
0                 LOWER
1              capitals
2    THIS IS A SENTENCE
3              sWaPcAsE
dtype: object
```

pandas.Series.str.wrap

Series.str.**wrap**(**args*, ***kwargs*)

Wrap strings in Series/Index at specified line width.

This method has the same keyword parameters and defaults as `textwrap.TextWrapper`.

Parameters

width [int] Maximum line width.

expand_tabs [bool, optional] If True, tab characters will be expanded to spaces (default: True).

replace_whitespace [bool, optional] If True, each whitespace character (as defined by string.whitespace) remaining after tab expansion will be replaced by a single space (default: True).

drop_whitespace [bool, optional] If True, whitespace that, after wrapping, happens to end up at the beginning or end of a line is dropped (default: True).

break_long_words [bool, optional] If True, then words longer than width will be broken in order to ensure that no lines are longer than width. If it is false, long words will not be broken, and some lines may be longer than width (default: True).

break_on_hyphens [bool, optional] If True, wrapping will occur preferably on whitespace and right after hyphens in compound words, as it is customary in English. If false, only whitespaces will be considered as potentially good places for line breaks, but you need to set break_long_words to false if you want truly insecable words (default: True).

Returns

Series or Index

Notes

Internally, this method uses a `textwrap.TextWrapper` instance with default settings. To achieve behavior matching R's stringr library str_wrap function, use the arguments:

- expand_tabs = False
- replace_whitespace = True
- drop_whitespace = True
- break_long_words = False
- break_on_hyphens = False

Examples

```
>>> s = pd.Series(['line to be wrapped', 'another line to be wrapped'])
>>> s.str.wrap(12)
0             line to be\nwrapped
1    another line\nto be\nwrapped
dtype: object
```

pandas.Series.str.zfill

Series.str.**zfill**(**args*, ***kwargs*)

Pad strings in the Series/Index by prepending '0' characters.

Strings in the Series/Index are padded with '0' characters on the left of the string to reach a total string length *width*. Strings in the Series/Index with length greater or equal to *width* are unchanged.

Parameters

width [int] Minimum length of resulting string; strings with length less than *width* be prepended with '0' characters.

Returns

Series/Index of objects.

See also:

Series.str.rjust Fills the left side of strings with an arbitrary character.
Series.str.ljust Fills the right side of strings with an arbitrary character.
Series.str.pad Fills the specified sides of strings with an arbitrary character.
Series.str.center Fills boths sides of strings with an arbitrary character.

Notes

Differs from `str.zfill()` which has special handling for '+'/'-' in the string.

Examples

```
>>> s = pd.Series(['-1', '1', '1000', 10, np.nan])
>>> s
0      -1
1       1
2    1000
3      10
4     NaN
dtype: object
```

Note that `10` and `NaN` are not strings, therefore they are converted to `NaN`. The minus sign in `'-1'` is treated as a regular character and the zero is added to the left of it (`str.zfill()` would have moved it to the left). `1000` remains unchanged as it is longer than *width*.

```
>>> s.str.zfill(3)
0     0-1
1     001
2    1000
3     NaN
4     NaN
dtype: object
```

pandas.Series.str.isalnum

Series.str.**isalnum**(**args*, ***kwargs*)

Check whether all characters in each string are alphanumeric.

This is equivalent to running the Python string method `str.isalnum()` for each element of the Series/Index. If a string has zero characters, `False` is returned for that check.

Returns

Series or Index of bool Series or Index of boolean values with the same length as the original Series/Index.

See also:

Series.str.isalpha Check whether all characters are alphabetic.
Series.str.isnumeric Check whether all characters are numeric.
Series.str.isalnum Check whether all characters are alphanumeric.
Series.str.isdigit Check whether all characters are digits.
Series.str.isdecimal Check whether all characters are decimal.
Series.str.isspace Check whether all characters are whitespace.
Series.str.islower Check whether all characters are lowercase.
Series.str.isupper Check whether all characters are uppercase.
Series.str.istitle Check whether all characters are titlecase.

Examples

Checks for Alphabetic and Numeric Characters

```
>>> s1 = pd.Series(['one', 'one1', '1', ''])
```

```
>>> s1.str.isalpha()
0     True
1    False
2    False
3    False
dtype: bool
```

```
>>> s1.str.isnumeric()
0    False
1    False
2     True
3    False
dtype: bool
```

```
>>> s1.str.isalnum()
0     True
1     True
2     True
3    False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```
>>> s2 = pd.Series(['A B', '1.5', '3,000'])
>>> s2.str.isalnum()
```

(continues on next page)

(continued from previous page)

```
0    False
1    False
2    False
dtype: bool
```

More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```
>>> s3 = pd.Series(['23', '³', '', ''])
```

The `s3.str.isdecimal` method checks for characters used to form numbers in base 10.

```
>>> s3.str.isdecimal()
0     True
1    False
2    False
3    False
dtype: bool
```

The `s.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```
>>> s3.str.isdigit()
0     True
1     True
2    False
3    False
dtype: bool
```

The `s.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```
>>> s3.str.isnumeric()
0     True
1     True
2     True
3    False
dtype: bool
```

Checks for Whitespace

```
>>> s4 = pd.Series([' ', '\t\r\n ', ''])
>>> s4.str.isspace()
0     True
1     True
2    False
dtype: bool
```

Checks for Character Case

```
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])
```

```
>>> s5.str.islower()
0     True
1    False
```

(continues on next page)

(continued from previous page)

```
2    False
3    False
dtype: bool
```

```
>>> s5.str.isupper()
0    False
1    False
2     True
3    False
dtype: bool
```

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```
>>> s5.str.istitle()
0    False
1     True
2    False
3    False
dtype: bool
```

pandas.Series.str.isalpha

`Series.str.`**`isalpha`**(**args*, ***kwargs*)

Check whether all characters in each string are alphabetic.

This is equivalent to running the Python string method `str.isalpha()` for each element of the Series/Index. If a string has zero characters, `False` is returned for that check.

Returns

Series or Index of bool Series or Index of boolean values with the same length as the original Series/Index.

See also:

Series.str.isalpha Check whether all characters are alphabetic.
Series.str.isnumeric Check whether all characters are numeric.
Series.str.isalnum Check whether all characters are alphanumeric.
Series.str.isdigit Check whether all characters are digits.
Series.str.isdecimal Check whether all characters are decimal.
Series.str.isspace Check whether all characters are whitespace.
Series.str.islower Check whether all characters are lowercase.
Series.str.isupper Check whether all characters are uppercase.
Series.str.istitle Check whether all characters are titlecase.

Examples

Checks for Alphabetic and Numeric Characters

```
>>> s1 = pd.Series(['one', 'one1', '1', ''])
```

```
>>> s1.str.isalpha()
0     True
1    False
2    False
3    False
dtype: bool
```

```
>>> s1.str.isnumeric()
0    False
1    False
2     True
3    False
dtype: bool
```

```
>>> s1.str.isalnum()
0     True
1     True
2     True
3    False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```
>>> s2 = pd.Series(['A B', '1.5', '3,000'])
>>> s2.str.isalnum()
0    False
1    False
2    False
dtype: bool
```

More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```
>>> s3 = pd.Series(['23', '³', '', ''])
```

The `s3.str.isdecimal` method checks for characters used to form numbers in base 10.

```
>>> s3.str.isdecimal()
0     True
1    False
2    False
3    False
dtype: bool
```

The `s.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```
>>> s3.str.isdigit()
0     True
```

(continues on next page)

(continued from previous page)

```
1     True
2    False
3    False
dtype: bool
```

The `s.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```
>>> s3.str.isnumeric()
0     True
1     True
2     True
3    False
dtype: bool
```

Checks for Whitespace

```
>>> s4 = pd.Series([' ', '\t\r\n ', ''])
>>> s4.str.isspace()
0     True
1     True
2    False
dtype: bool
```

Checks for Character Case

```
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])
```

```
>>> s5.str.islower()
0     True
1    False
2    False
3    False
dtype: bool
```

```
>>> s5.str.isupper()
0    False
1    False
2     True
3    False
dtype: bool
```

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```
>>> s5.str.istitle()
0    False
1     True
2    False
3    False
dtype: bool
```

pandas.Series.str.isdigit

Series.str.**isdigit**(**args*, ***kwargs*)

Check whether all characters in each string are digits.

This is equivalent to running the Python string method `str.isdigit()` for each element of the Series/Index. If a string has zero characters, `False` is returned for that check.

Returns

Series or Index of bool Series or Index of boolean values with the same length as the original Series/Index.

See also:

Series.str.isalpha Check whether all characters are alphabetic.
Series.str.isnumeric Check whether all characters are numeric.
Series.str.isalnum Check whether all characters are alphanumeric.
Series.str.isdigit Check whether all characters are digits.
Series.str.isdecimal Check whether all characters are decimal.
Series.str.isspace Check whether all characters are whitespace.
Series.str.islower Check whether all characters are lowercase.
Series.str.isupper Check whether all characters are uppercase.
Series.str.istitle Check whether all characters are titlecase.

Examples

Checks for Alphabetic and Numeric Characters

```
>>> s1 = pd.Series(['one', 'one1', '1', ''])
```

```
>>> s1.str.isalpha()
0     True
1    False
2    False
3    False
dtype: bool
```

```
>>> s1.str.isnumeric()
0    False
1    False
2     True
3    False
dtype: bool
```

```
>>> s1.str.isalnum()
0     True
1     True
2     True
3    False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```
>>> s2 = pd.Series(['A B', '1.5', '3,000'])
>>> s2.str.isalnum()
```

(continues on next page)

(continued from previous page)

```
0    False
1    False
2    False
dtype: bool
```

More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```
>>> s3 = pd.Series(['23', '³', '', ''])
```

The `s3.str.isdecimal` method checks for characters used to form numbers in base 10.

```
>>> s3.str.isdecimal()
0     True
1    False
2    False
3    False
dtype: bool
```

The `s.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```
>>> s3.str.isdigit()
0     True
1     True
2    False
3    False
dtype: bool
```

The `s.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```
>>> s3.str.isnumeric()
0     True
1     True
2     True
3    False
dtype: bool
```

Checks for Whitespace

```
>>> s4 = pd.Series([' ', '\t\r\n ', ''])
>>> s4.str.isspace()
0     True
1     True
2    False
dtype: bool
```

Checks for Character Case

```
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])
```

```
>>> s5.str.islower()
0     True
1    False
```

(continues on next page)

(continued from previous page)

```
2    False
3    False
dtype: bool
```

```
>>> s5.str.isupper()
0    False
1    False
2     True
3    False
dtype: bool
```

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```
>>> s5.str.istitle()
0    False
1     True
2    False
3    False
dtype: bool
```

pandas.Series.str.isspace

`Series.str.`**`isspace`**(**args*, ***kwargs*)

Check whether all characters in each string are whitespace.

This is equivalent to running the Python string method `str.isspace()` for each element of the Series/Index. If a string has zero characters, `False` is returned for that check.

Returns

Series or Index of bool Series or Index of boolean values with the same length as the original Series/Index.

See also:

Series.str.isalpha Check whether all characters are alphabetic.
Series.str.isnumeric Check whether all characters are numeric.
Series.str.isalnum Check whether all characters are alphanumeric.
Series.str.isdigit Check whether all characters are digits.
Series.str.isdecimal Check whether all characters are decimal.
Series.str.isspace Check whether all characters are whitespace.
Series.str.islower Check whether all characters are lowercase.
Series.str.isupper Check whether all characters are uppercase.
Series.str.istitle Check whether all characters are titlecase.

Examples

Checks for Alphabetic and Numeric Characters

```
>>> s1 = pd.Series(['one', 'one1', '1', ''])
```

```
>>> s1.str.isalpha()
0     True
1    False
2    False
3    False
dtype: bool
```

```
>>> s1.str.isnumeric()
0    False
1    False
2     True
3    False
dtype: bool
```

```
>>> s1.str.isalnum()
0     True
1     True
2     True
3    False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```
>>> s2 = pd.Series(['A B', '1.5', '3,000'])
>>> s2.str.isalnum()
0    False
1    False
2    False
dtype: bool
```

More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```
>>> s3 = pd.Series(['23', '³', '', ''])
```

The `s3.str.isdecimal` method checks for characters used to form numbers in base 10.

```
>>> s3.str.isdecimal()
0     True
1    False
2    False
3    False
dtype: bool
```

The `s.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```
>>> s3.str.isdigit()
0     True
```

(continues on next page)

(continued from previous page)

```
1     True
2    False
3    False
dtype: bool
```

The `s.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```
>>> s3.str.isnumeric()
0     True
1     True
2     True
3    False
dtype: bool
```

Checks for Whitespace

```
>>> s4 = pd.Series([' ', '\t\r\n ', ''])
>>> s4.str.isspace()
0     True
1     True
2    False
dtype: bool
```

Checks for Character Case

```
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])
```

```
>>> s5.str.islower()
0     True
1    False
2    False
3    False
dtype: bool
```

```
>>> s5.str.isupper()
0    False
1    False
2     True
3    False
dtype: bool
```

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```
>>> s5.str.istitle()
0    False
1     True
2    False
3    False
dtype: bool
```

pandas.Series.str.islower

Series.str.**islower**(**args*, ***kwargs*)

Check whether all characters in each string are lowercase.

This is equivalent to running the Python string method `str.islower()` for each element of the Series/Index. If a string has zero characters, `False` is returned for that check.

Returns

Series or Index of bool Series or Index of boolean values with the same length as the original Series/Index.

See also:

Series.str.isalpha Check whether all characters are alphabetic.
Series.str.isnumeric Check whether all characters are numeric.
Series.str.isalnum Check whether all characters are alphanumeric.
Series.str.isdigit Check whether all characters are digits.
Series.str.isdecimal Check whether all characters are decimal.
Series.str.isspace Check whether all characters are whitespace.
Series.str.islower Check whether all characters are lowercase.
Series.str.isupper Check whether all characters are uppercase.
Series.str.istitle Check whether all characters are titlecase.

Examples

Checks for Alphabetic and Numeric Characters

```
>>> s1 = pd.Series(['one', 'one1', '1', ''])
```

```
>>> s1.str.isalpha()
0     True
1    False
2    False
3    False
dtype: bool
```

```
>>> s1.str.isnumeric()
0    False
1    False
2     True
3    False
dtype: bool
```

```
>>> s1.str.isalnum()
0     True
1     True
2     True
3    False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```
>>> s2 = pd.Series(['A B', '1.5', '3,000'])
>>> s2.str.isalnum()
```

(continues on next page)

(continued from previous page)

```
0    False
1    False
2    False
dtype: bool
```

More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```
>>> s3 = pd.Series(['23', '³', '', ''])
```

The `s3.str.isdecimal` method checks for characters used to form numbers in base 10.

```
>>> s3.str.isdecimal()
0     True
1    False
2    False
3    False
dtype: bool
```

The `s.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```
>>> s3.str.isdigit()
0     True
1     True
2    False
3    False
dtype: bool
```

The `s.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```
>>> s3.str.isnumeric()
0     True
1     True
2     True
3    False
dtype: bool
```

Checks for Whitespace

```
>>> s4 = pd.Series([' ', '\t\r\n ', ''])
>>> s4.str.isspace()
0     True
1     True
2    False
dtype: bool
```

Checks for Character Case

```
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])
```

```
>>> s5.str.islower()
0     True
1    False
```

(continues on next page)

(continued from previous page)

```
2    False
3    False
dtype: bool
```

```
>>> s5.str.isupper()
0    False
1    False
2     True
3    False
dtype: bool
```

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```
>>> s5.str.istitle()
0    False
1     True
2    False
3    False
dtype: bool
```

pandas.Series.str.isupper

Series.str.**isupper**(**args*, ***kwargs*)

Check whether all characters in each string are uppercase.

This is equivalent to running the Python string method `str.isupper()` for each element of the Series/Index. If a string has zero characters, `False` is returned for that check.

Returns

Series or Index of bool Series or Index of boolean values with the same length as the original Series/Index.

See also:

Series.str.isalpha Check whether all characters are alphabetic.
Series.str.isnumeric Check whether all characters are numeric.
Series.str.isalnum Check whether all characters are alphanumeric.
Series.str.isdigit Check whether all characters are digits.

Series.str.isspace Check whether all characters are whitespace.
Series.str.islower Check whether all characters are lowercase.
Series.str.isupper Check whether all characters are uppercase.
Series.str.istitle Check whether all characters are titlecase.

Examples

Checks for Alphabetic and Numeric Characters

```
>>> s1 = pd.Series(['one', 'one1', '1', ''])
```

```
>>> s1.str.isalpha()
0     True
1    False
2    False
3    False
dtype: bool
```

```
>>> s1.str.isnumeric()
0    False
1    False
2     True
3    False
dtype: bool
```

```
>>> s1.str.isalnum()
0     True
1     True
2     True
3    False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```
>>> s2 = pd.Series(['A B', '1.5', '3,000'])
>>> s2.str.isalnum()
0    False
1    False
2    False
dtype: bool
```

More Detailed Checks for Numeric Characters

Series.str.isspace Check whether all characters are whitespace.
Series.str.islower Check whether all characters are lowercase.
Series.str.isupper Check whether all characters are uppercase.
Series.str.istitle Check whether all characters are titlecase.

Examples

Checks for Alphabetic and Numeric Characters

```
>>> s1 = pd.Series(['one', 'one1', '1', ''])
```

```
>>> s1.str.isalpha()
0     True
1    False
2    False
3    False
dtype: bool
```

```
>>> s1.str.isnumeric()
0    False
1    False
2     True
3    False
dtype: bool
```

```
>>> s1.str.isalnum()
0     True
1     True
2     True
3    False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```
>>> s2 = pd.Series(['A B', '1.5', '3,000'])
>>> s2.str.isalnum()
0    False
1    False
2    False
dtype: bool
```

More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```
>>> s3 = pd.Series(['23', '³', '', ''])
```

The `s3.str.isdecimal` method checks for characters used to form numbers in base 10.

```
>>> s3.str.isdecimal()
0     True
1    False
2    False
3    False
dtype: bool
```

The `s.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```
>>> s3.str.isdigit()
0     True
```

(continues on next page)

```

```
>>> s5.str.islower()
0     True
1    False
2    False
3    False
dtype: bool
```

```
>>> s5.str.isupper()
0    False
1    False
2     True
3    False
dtype: bool
```

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```
>>> s5.str.istitle()
0    False
1     True
2    False
3    False
dtype: bool
```

pandas.Series.str.isdecimal

Series.str.**isdecimal**(**args*, ***kwargs*)

Check whether all characters in each string are decimal.

This is equivalent to running the Python string method `str.isdecimal()` for each element of the Series/Index. If a string has zero characters, `False` is returned for that check.

Returns

Series or Index of bool Series or Index of boolean values with the same length as the original Series/Index.

See also:

Series.str.isalpha Check whether all characters are alphabetic.
Series.str.isnumeric Check whether all characters are numeric.
Series.str.isalnum Check whether all characters are alphanumeric.

Series.str.isspace Check whether all characters are whitespace.
Series.str.islower Check whether all characters are lowercase.
Series.str.isupper Check whether all characters are uppercase.
Series.str.istitle Check whether all characters are titlecase.

Examples

Checks for Alphabetic and Numeric Characters

```
>>> s1 = pd.Series(['one', 'one1', '1', ''])
```

```
>>> s1.str.isalpha()
0     True
1    False
2    False
3    False
dtype: bool
```

```
>>> s1.str.isnumeric()
0    False
1    False
2     True
3    False
dtype: bool
```

```
>>> s1.str.isalnum()
0     True
1     True
2     True
3    False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```
>>> s2 = pd.Series(['A B', '1.5', '3,000'])
>>> s2.str.isalnum()
```

(continues on next page)

(continued from previous page)

```
0    False
1    False
2    False
dtype: bool
```

More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```
>>> s3 = pd.Series(['23', '³', '', ''])
```

The `s3.str.isdecimal` method checks for characters used to form numbers in base 10.

```
>>> s3.str.isdecimal()
0     True
1    False
2    False
3    False
dtype: bool
```

The `s.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```
>>> s3.str.isdigit()
0     True
1     True
2    False
3    False
dtype: bool
```

The `s.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```
>>> s3.str.isnumeric()
0     True
1     True
2     True
3    False
dtype: bool
```

Checks for Whitespace

```
>>> s4 = pd.Series([' ', '\t\r\n ', ''])
>>> s4.str.isspace()
0     True
1     True
2    False
dtype: bool
```

Checks for Character Case

```
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])
```

```
>>> s5.str.islower()
0     True
1    False
```

(continues on next page)

(continued from previous page)

```
2    False
3    False
dtype: bool
```

```
>>> s5.str.isupper()
0    False
1    False
2     True
3    False
dtype: bool
```

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```
>>> s5.str.istitle()
0    False
1     True
2    False
3    False
dtype: bool
```

pandas.Series.str.get_dummies

Series.str.**get_dummies**(**args*, ***kwargs*)

Return DataFrame of dummy/indicator variables for Series.

Each string in Series is split by sep and returned as a DataFrame of dummy/indicator variables.

Parameters

sep [str, default "|"] String to split on.

Returns

DataFrame Dummy variables corresponding to values of the Series.

See also:

get_dummies Convert categorical variable into dummy/indicator variables.

Examples

```
>>> pd.Series(['a|b', 'a', 'a|c']).str.get_dummies()
   a  b  c
0  1  1  0
1  1  0  0
2  1  0  1
```

```
>>> pd.Series(['a|b', np.nan, 'a|c']).str.get_dummies()
   a  b  c
0  1  1  0
1  0  0  0
2  1  0  1
```

Categorical accessor

Categorical-dtype specific methods and attributes are available under the `Series.cat` accessor.

Series.cat.categories	The categories of this categorical.
Series.cat.ordered	Whether the categories have an ordered relationship.
Series.cat.codes	Return Series of codes as well as the index.

pandas.Series.cat.categories

`Series.cat.`**`categories`**

The categories of this categorical.

Setting assigns new values to each category (effectively a rename of each individual category).

The assigned value has to be a list-like object. All items must be unique and the number of items in the new categories must be the same as the number of items in the old categories.

Assigning to *categories* is a inplace operation!

Raises

ValueError If the new categories do not validate as categories or if the number of new categories is unequal the number of old categories

See also:

rename_categories Rename categories.
reorder_categories Reorder categories.
add_categories Add new categories.
remove_categories Remove the specified categories.
remove_unused_categories Remove categories which are not used.
set_categories Set the categories to the specified ones.

pandas.Series.cat.ordered

`Series.cat.`**`ordered`**

Whether the categories have an ordered relationship.

pandas.Series.cat.codes

`Series.cat.`**`codes`**

Return Series of codes as well as the index.

Series.cat.rename_categories(*args, **kwargs)	Rename categories.
Series.cat.reorder_categories(*args, **kwargs)	Reorder categories as specified in new_categories.
Series.cat.add_categories(*args, **kwargs)	Add new categories.
Series.cat.remove_categories(*args, **kwargs)	Remove the specified categories.
Series.cat.remove_unused_categories(*args, ...)	Remove categories which are not used.

continues on next page

Table 49 – continued from previous page

Series.cat.set_categories(*args, **kwargs)	Set the categories to the specified new_categories.
Series.cat.as_ordered(*args, **kwargs)	Set the Categorical to be ordered.
Series.cat.as_unordered(*args, **kwargs)	Set the Categorical to be unordered.

pandas.Series.cat.rename_categories

Series.cat.**rename_categories**(**args*, ***kwargs*)

Rename categories.

Parameters

new_categories [list-like, dict-like or callable] New categories which will replace old categories.

- list-like: all items must be unique and the number of items in the new categories must match the existing number of categories.
- dict-like: specifies a mapping from old categories to new. Categories not contained in the mapping are passed through and extra categories in the mapping are ignored.
- callable : a callable that is called on all items in the old categories and whose return values comprise the new categories.

New in version 0.23.0..

inplace [bool, default False] Whether or not to rename the categories inplace or return a copy of this categorical with renamed categories.

Returns

cat [Categorical or None] With `inplace=False`, the new categorical is returned. With `inplace=True`, there is no return value.

Raises

ValueError If new categories are list-like and do not have the same number of items than the current categories or do not validate as categories

See also:

reorder_categories Reorder categories.
add_categories Add new categories.
remove_categories Remove the specified categories.
remove_unused_categories Remove categories which are not used.
set_categories Set the categories to the specified ones.

Examples

```
>>> c = pd.Categorical(['a', 'a', 'b'])
>>> c.rename_categories([0, 1])
[0, 0, 1]
Categories (2, int64): [0, 1]
```

For dict-like `new_categories`, extra keys are ignored and categories not in the dictionary are passed through

```
>>> c.rename_categories({'a': 'A', 'c': 'C'})
['A', 'A', 'b']
Categories (2, object): ['A', 'b']
```

You may also provide a callable to create the new categories

```
>>> c.rename_categories(lambda x: x.upper())
['A', 'A', 'B']
Categories (2, object): ['A', 'B']
```

pandas.Series.cat.reorder_categories

Series.cat.**reorder_categories**(**args*, ***kwargs*)

Reorder categories as specified in new_categories.

new_categories need to include all old categories and no new category items.

Parameters

new_categories [Index-like] The categories in new order.

ordered [bool, optional] Whether or not the categorical is treated as a ordered categorical. If not given, do not change the ordered information.

inplace [bool, default False] Whether or not to reorder the categories inplace or return a copy of this categorical with reordered categories.

Returns

cat [Categorical with reordered categories or None if inplace.]

Raises

ValueError If the new categories do not contain all old category items or any new ones

See also:

rename_categories Rename categories.
add_categories Add new categories.
remove_categories Remove the specified categories.
remove_unused_categories Remove categories which are not used.
set_categories Set the categories to the specified ones.

pandas.Series.cat.add_categories

Series.cat.**add_categories**(**args*, ***kwargs*)

Add new categories.

new_categories will be included at the last/highest place in the categories and will be unused directly after this call.

Parameters

new_categories [category or list-like of category] The new categories to be included.

inplace [bool, default False] Whether or not to add the categories inplace or return a copy of this categorical with added categories.

Returns

cat [Categorical with new categories added or None if inplace.]

Raises

ValueError If the new categories include old categories or do not validate as categories

See also:

rename_categories Rename categories.
reorder_categories Reorder categories.
remove_categories Remove the specified categories.
remove_unused_categories Remove categories which are not used.
set_categories Set the categories to the specified ones.

pandas.Series.cat.remove_categories

Series.cat.**remove_categories**(**args*, ***kwargs*)

Remove the specified categories.

removals must be included in the old categories. Values which were in the removed categories will be set to NaN

Parameters

removals [category or list of categories] The categories which should be removed.

inplace [bool, default False] Whether or not to remove the categories inplace or return a copy of this categorical with removed categories.

Returns

cat [Categorical with removed categories or None if inplace.]

Raises

ValueError If the removals are not contained in the categories

See also:

rename_categories Rename categories.
reorder_categories Reorder categories.
add_categories Add new categories.
remove_unused_categories Remove categories which are not used.
set_categories Set the categories to the specified ones.

pandas.Series.cat.remove_unused_categories

Series.cat.**remove_unused_categories**(**args*, ***kwargs*)

Remove categories which are not used.

Parameters

inplace [bool, default False] Whether or not to drop unused categories inplace or return a copy of this categorical with unused categories dropped.

Returns

cat [Categorical with unused categories dropped or None if inplace.]

See also:

rename_categories Rename categories.
reorder_categories Reorder categories.
add_categories Add new categories.
remove_categories Remove the specified categories.
set_categories Set the categories to the specified ones.

pandas.Series.cat.set_categories

Series.cat.**set_categories**(**args*, ***kwargs*)

Set the categories to the specified new_categories.

new_categories can include new categories (which will result in unused categories) or remove old categories (which results in values set to NaN). If *rename==True*, the categories will simple be renamed (less or more items than in old categories will result in values set to NaN or in unused categories respectively).

This method can be used to perform more than one action of adding, removing, and reordering simultaneously and is therefore faster than performing the individual steps via the more specialised methods.

On the other hand this methods does not do checks (e.g., whether the old categories are included in the new categories on a reorder), which can result in surprising changes, for example when using special string dtypes, which does not considers a S1 string equal to a single char python string.

Parameters

new_categories [Index-like] The categories in new order.

ordered [bool, default False] Whether or not the categorical is treated as a ordered categorical. If not given, do not change the ordered information.

rename [bool, default False] Whether or not the new_categories should be considered as a rename of the old categories or as reordered categories.

inplace [bool, default False] Whether or not to reorder the categories in-place or return a copy of this categorical with reordered categories.

Returns

Categorical with reordered categories or None if inplace.

Raises

ValueError If new_categories does not validate as categories

See also:

rename_categories Rename categories.
reorder_categories Reorder categories.
add_categories Add new categories.
remove_categories Remove the specified categories.
remove_unused_categories Remove categories which are not used.

pandas.Series.cat.as_ordered

Series.cat.**as_ordered**(**args*, ***kwargs*)

Set the Categorical to be ordered.

Parameters

inplace [bool, default False] Whether or not to set the ordered attribute in-place or return a copy of this categorical with ordered set to True.

Returns

Categorical Ordered Categorical.

pandas.Series.cat.as_unordered

Series.cat.**as_unordered**(**args*, ***kwargs*)

Set the Categorical to be unordered.

Parameters

inplace [bool, default False] Whether or not to set the ordered attribute in-place or return a copy of this categorical with ordered set to False.

Returns

Categorical Unordered Categorical.

Sparse accessor

Sparse-dtype specific methods and attributes are provided under the `Series.sparse` accessor.

Series.sparse.npoints	The number of non- `fill_value` points.
Series.sparse.density	The percent of non- `fill_value` points, as decimal.
Series.sparse.fill_value	Elements in *data* that are *fill_value* are not stored.
Series.sparse.sp_values	An ndarray containing the non- `fill_value` values.

pandas.Series.sparse.npoints

Series.sparse.**npoints**

The number of non- `fill_value` points.

Examples

```
>>> s = SparseArray([0, 0, 1, 1, 1], fill_value=0)
>>> s.npoints
3
```

pandas.Series.sparse.density

Series.sparse.**density**

The percent of non- `fill_value` points, as decimal.

Examples

```
>>> s = SparseArray([0, 0, 1, 1, 1], fill_value=0)
>>> s.density
0.6
```

pandas.Series.sparse.fill_value

`Series.sparse.`**`fill_value`**
Elements in *data* that are *fill_value* are not stored.

For memory savings, this should be the most common value in the array.

pandas.Series.sparse.sp_values

`Series.sparse.`**`sp_values`**
An ndarray containing the non- `fill_value` values.

Examples

```
>>> s = SparseArray([0, 0, 1, 0, 2], fill_value=0)
>>> s.sp_values
array([1, 2])
```

Series.sparse.from_coo(A[, dense_index])	Create a Series with sparse values from a scipy.sparse.coo_matrix.
Series.sparse.to_coo([row_levels, ...])	Create a scipy.sparse.coo_matrix from a Series with MultiIndex.

pandas.Series.sparse.from_coo

classmethod `Series.sparse.`**`from_coo`**(*A*, *dense_index=False*)
Create a Series with sparse values from a scipy.sparse.coo_matrix.

Parameters

A [scipy.sparse.coo_matrix]

dense_index [bool, default False] If False (default), the SparseSeries index consists of only the coords of the non-null entries of the original coo_matrix. If True, the SparseSeries index consists of the full sorted (row, col) coordinates of the coo_matrix.

Returns

s [Series] A Series with sparse values.

Examples

```
>>> from scipy import sparse
```

```
>>> A = sparse.coo_matrix(
...      ([3.0, 1.0, 2.0], ([1, 0, 0], [0, 2, 3])), shape=(3, 4)
... )
>>> A
<3x4 sparse matrix of type '<class 'numpy.float64'>'
with 3 stored elements in COOrdinate format>
```

```
>>> A.todense()
matrix([[0., 0., 1., 2.],
[3., 0., 0., 0.],
[0., 0., 0., 0.]])
```

```
>>> ss = pd.Series.sparse.from_coo(A)
>>> ss
0  2    1.0
   3    2.0
1  0    3.0
dtype: Sparse[float64, nan]
```

pandas.Series.sparse.to_coo

`Series.sparse.to_coo`(*row_levels=0*, *column_levels=1*, *sort_labels=False*)

Create a scipy.sparse.coo_matrix from a Series with MultiIndex.

Use row_levels and column_levels to determine the row and column coordinates respectively. row_levels and column_levels are the names (labels) or numbers of the levels. {row_levels, column_levels} must be a partition of the MultiIndex level names (or numbers).

Parameters

row_levels [tuple/list]

column_levels [tuple/list]

sort_labels [bool, default False] Sort the row and column labels before forming the sparse matrix.

Returns

y [scipy.sparse.coo_matrix]

rows [list (row labels)]

columns [list (column labels)]

Examples

```
>>> s = pd.Series([3.0, np.nan, 1.0, 3.0, np.nan, np.nan])
>>> s.index = pd.MultiIndex.from_tuples(
...     [
...         (1, 2, "a", 0),
...         (1, 2, "a", 1),
...         (1, 1, "b", 0),
...         (1, 1, "b", 1),
...         (2, 1, "b", 0),
...         (2, 1, "b", 1)
...     ],
...     names=["A", "B", "C", "D"],
... )
>>> s
A  B  C  D
1  2  a  0    3.0
          1    NaN
   1  b  0    1.0
```

(continues on next page)

(continued from previous page)

```
          1    3.0
2  1  b  0    NaN
          1    NaN
dtype: float64
```

```
>>> ss = s.astype("Sparse")
>>> ss
A  B  C  D
1  2  a  0    3.0
          1    NaN
   1  b  0    1.0
          1    3.0
2  1  b  0    NaN
          1    NaN
dtype: Sparse[float64, nan]
```

```
>>> A, rows, columns = ss.sparse.to_coo(
...     row_levels=["A", "B"], column_levels=["C", "D"], sort_labels=True
... )
>>> A
<3x4 sparse matrix of type '<class 'numpy.float64'>'
with 3 stored elements in COOrdinate format>
>>> A.todense()
matrix([[0., 0., 1., 3.],
[3., 0., 0., 0.],
[0., 0., 0., 0.]])
```

```
>>> rows
[(1, 1), (1, 2), (2, 1)]
>>> columns
[('a', 0), ('a', 1), ('b', 0), ('b', 1)]
```

Metadata

Series.attrs is a dictionary for storing global metadata for this Series.

Warning: `Series.attrs` is considered experimental and may change without warning.

Series.attrs	Dictionary of global attributes on this object.

3.3.14 Plotting

`Series.plot` is both a callable method and a namespace attribute for specific plotting methods of the form `Series.plot.<kind>`.

Series.plot([kind, ax, figsize, ...])	Series plotting accessor and method

Series.plot.area([x, y])	Draw a stacked area plot.
Series.plot.bar([x, y])	Vertical bar plot.
Series.plot.barh([x, y])	Make a horizontal bar plot.
Series.plot.box([by])	Make a box plot of the DataFrame columns.
Series.plot.density([bw_method, ind])	Generate Kernel Density Estimate plot using Gaussian kernels.
Series.plot.hist([by, bins])	Draw one histogram of the DataFrame's columns.
Series.plot.kde([bw_method, ind])	Generate Kernel Density Estimate plot using Gaussian kernels.
Series.plot.line([x, y])	Plot Series or DataFrame as lines.
Series.plot.pie(**kwargs)	Generate a pie plot.

pandas.Series.plot.area

`Series.plot.`**`area`**(*x=None*, *y=None*, ***kwargs*)

Draw a stacked area plot.

An area plot displays quantitative data visually. This function wraps the matplotlib area function.

Parameters

x [label or position, optional] Coordinates for the X axis. By default uses the index.

y [label or position, optional] Column to plot. By default uses all columns.

stacked [bool, default True] Area plots are stacked by default. Set to False to create a unstacked plot.

****kwargs** Additional keyword arguments are documented in *DataFrame.plot()*.

Returns

matplotlib.axes.Axes or numpy.ndarray Area plot, or array of area plots if subplots is True.

See also:

DataFrame.plot Make plots of DataFrame using matplotlib / pylab.

Examples

Draw an area plot based on basic business metrics:

```
>>> df = pd.DataFrame({
...     'sales': [3, 2, 3, 9, 10, 6],
...     'signups': [5, 5, 6, 12, 14, 13],
...     'visits': [20, 42, 28, 62, 81, 50],
... }, index=pd.date_range(start='2018/01/01', end='2018/07/01',
...                        freq='M'))
>>> ax = df.plot.area()
```

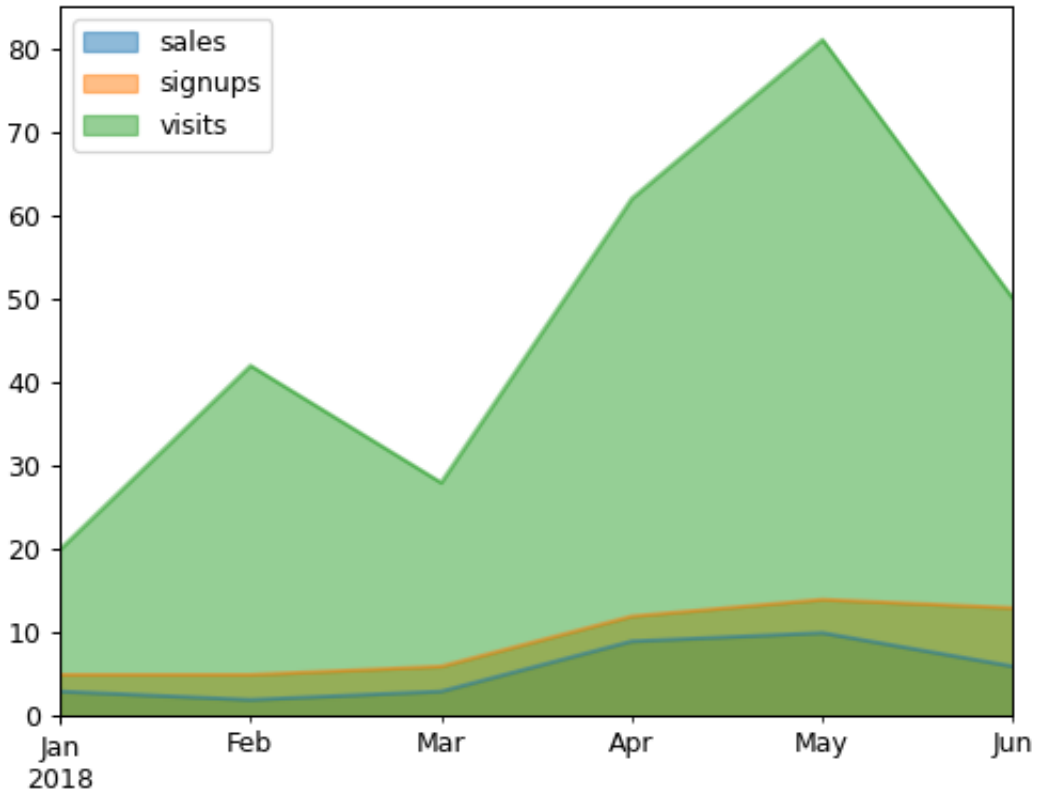
Area plots are stacked by default. To produce an unstacked plot, pass `stacked=False`:

```
>>> ax = df.plot.area(stacked=False)
```



Draw an area plot for a single column:

```
>>> ax = df.plot.area(y='sales')
```

Draw with a different *x*:

```
>>> df = pd.DataFrame({
...     'sales': [3, 2, 3],
...     'visits': [20, 42, 28],
...     'day': [1, 2, 3],
... })
>>> ax = df.plot.area(x='day')
```

pandas.Series.plot.bar

`Series.plot.bar(x=None, y=None, **kwargs)`

Vertical bar plot.

A bar plot is a plot that presents categorical data with rectangular bars with lengths proportional to the values that they represent. A bar plot shows comparisons among discrete categories. One axis of the plot shows the specific categories being compared, and the other axis represents a measured value.

Parameters

x [label or position, optional] Allows plotting of one column versus another. If not specified, the index of the DataFrame is used.

y [label or position, optional] Allows plotting of one column versus another. If not specified, all numerical columns are used.

color [str, array_like, or dict, optional] The color for each of the DataFrame's columns. Possible values are:

- **A single color string referred to by name, RGB or RGBA code,** for instance 'red' or '#a98d19'.
- **A sequence of color strings referred to by name, RGB or RGBA** code, which will be used for each column recursively. For instance ['green','yellow'] each column's bar will be filled in green or yellow, alternatively.
- **A dict of the form {column name** [color}, so that each column will be] colored accordingly. For example, if your columns are called *a* and *b*, then passing {'a': 'green', 'b': 'red'} will color bars for column *a* in green and bars for column *b* in red.

New in version 1.1.0.

****kwargs** Additional keyword arguments are documented in *DataFrame.plot()*.

Returns

matplotlib.axes.Axes or np.ndarray of them An ndarray is returned with one `matplotlib.axes.Axes` per column when `subplots=True`.

See also:

DataFrame.plot.barh Horizontal bar plot.
DataFrame.plot Make plots of a DataFrame.
matplotlib.pyplot.bar Make a bar plot with matplotlib.

Examples

Basic plot.

```
>>> df = pd.DataFrame({'lab':['A', 'B', 'C'], 'val':[10, 30, 20]})
>>> ax = df.plot.bar(x='lab', y='val', rot=0)
```

Plot a whole dataframe to a bar plot. Each column is assigned a distinct color, and each row is nested in a group along the horizontal axis.

```
>>> speed = [0.1, 17.5, 40, 48, 52, 69, 88]
>>> lifespan = [2, 8, 70, 1.5, 25, 12, 28]
>>> index = ['snail', 'pig', 'elephant',
...          'rabbit', 'giraffe', 'coyote', 'horse']
```

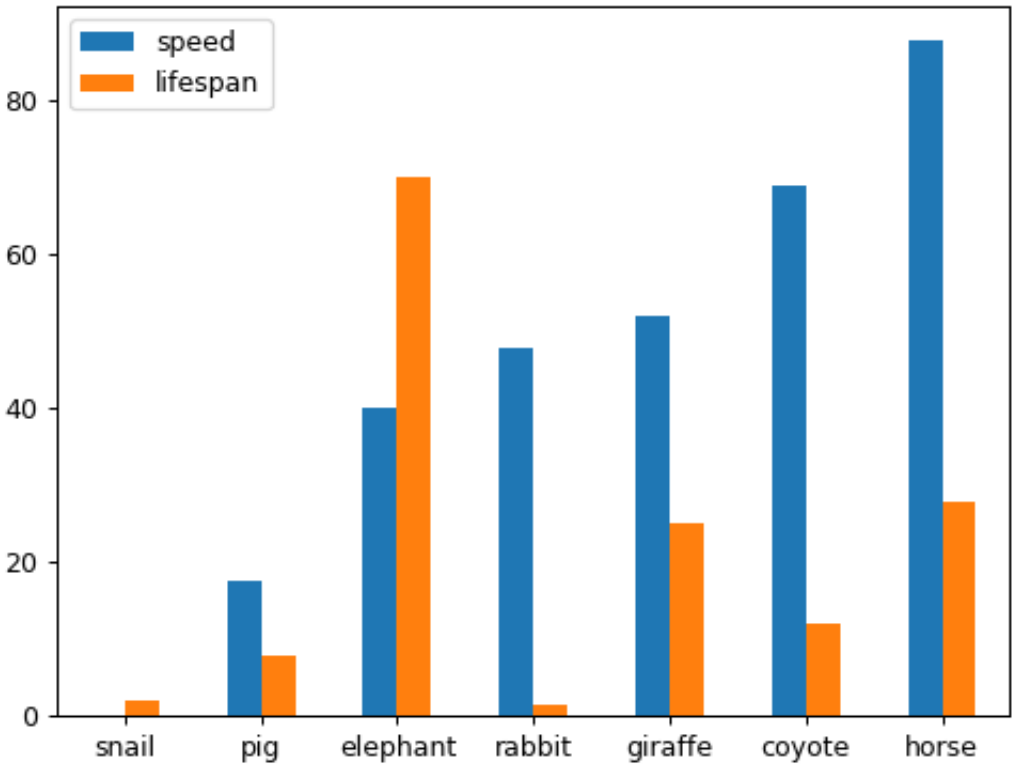
```
>>> df = pd.DataFrame({'speed': speed,
...                    'lifespan': lifespan}, index=index)
>>> ax = df.plot.bar(rot=0)
```



Plot stacked bar charts for the DataFrame

```
>>> ax = df.plot.bar(stacked=True)
```

Instead of nesting, the figure can be split by column with `subplots=True`. In this case, a `numpy.ndarray` of `matplotlib.axes.Axes` are returned.

```
>>> axes = df.plot.bar(rot=0, subplots=True)
>>> axes[1].legend(loc=2)
```

If you don't like the default colours, you can specify how you'd like each column to be colored.

```
>>> axes = df.plot.bar(
...     rot=0, subplots=True, color={"speed": "red", "lifespan": "green"}
... )
>>> axes[1].legend(loc=2)
```

Plot a single column.

```

pandas.Series.plot.barh

`Series.plot.`**`barh`**(*x=None*, *y=None*, ***kwargs*)

Make a horizontal bar plot.

A horizontal bar plot is a plot that presents quantitative data with rectangular bars with lengths proportional to the values that they represent. A bar plot shows comparisons among discrete categories. One axis of the plot shows the specific categories being compared, and the other axis represents a measured value.

Parameters

x [label or position, optional] Allows plotting of one column versus another. If not specified, the index of the DataFrame is used.

y [label or position, optional] Allows plotting of one column versus another. If not specified, all numerical columns are used.

color [str, array_like, or dict, optional] The color for each of the DataFrame's columns. Possible values are:

- **A sequence of color strings referred to by name, RGB or RGBA** code, which will be used for each column recursively. For instance ['green','yellow'] each column's bar will be filled in green or yellow, alternatively.
- **A dict of the form {column name** [color}, so that each column will be] colored accordingly. For example, if your columns are called *a* and *b*, then passing {'a': 'green', 'b': 'red'} will color bars for column *a* in green and bars for column *b* in red.

New in version 1.1.0.

****kwargs** Additional keyword arguments are documented in *DataFrame.plot()*.

Returns

matplotlib.axes.Axes or np.ndarray of them An ndarray is returned with one `matplotlib.axes.Axes` per column when `subplots=True`.

See also:

DataFrame.plot.bar Vertical bar plot.
DataFrame.plot Make plots of DataFrame using matplotlib.
matplotlib.axes.Axes.bar Plot a vertical bar plot using matplotlib.

Examples

Basic example

```
>>> df = pd.DataFrame({'lab': ['A', 'B', 'C'], 'val': [10, 30, 20]})
>>> ax = df.plot.barh(x='lab', y='val')
```

Plot a whole DataFrame to a horizontal bar plot

```
>>> speed = [0.1, 17.5, 40, 48, 52, 69, 88]
>>> lifespan = [2, 8, 70, 1.5, 25, 12, 28]
>>> index = ['snail', 'pig', 'elephant',
...          'rabbit', 'giraffe', 'coyote', 'horse']
>>> df = pd.DataFrame({'speed': speed,
...                    'lifespan': lifespan}, index=index)
>>> ax = df.plot.barh()
```

Plot stacked barh charts for the DataFrame

```
>>> ax = df.plot.barh(stacked=True)
```

We can specify colors for each column

```
>>> ax = df.plot.barh(color={"speed": "red", "lifespan": "green"})
```

Plot a column of the DataFrame to a horizontal bar plot

```
>>> speed = [0.1, 17.5, 40, 48, 52, 69, 88]
>>> lifespan = [2, 8, 70, 1.5, 25, 12, 28]
>>> index = ['snail', 'pig', 'elephant',
...          'rabbit', 'giraffe', 'coyote', 'horse']
>>> df = pd.DataFrame({'speed': speed,

pandas.Series.plot.box

Series.plot.**box**(*by=None*, ***kwargs*)

Make a box plot of the DataFrame columns.

A box plot is a method for graphically depicting groups of numerical data through their quartiles. The box extends from the Q1 to Q3 quartile values of the data, with a line at the median (Q2). The whiskers extend from the edges of box to show the range of the data. The position of the whiskers is set by default to 1.5*IQR (IQR = Q3 - Q1) from the edges of the box. Outlier points are those past the end of the whiskers.

For further details see Wikipedia's entry for boxplot.

A consideration when using this chart is that the box and the whiskers can overlap, which is very common when plotting small sets of data.

Parameters

by [str or sequence] Column in the DataFrame to group by.

****kwargs** Additional keywords are documented in *DataFrame.plot()*.

Returns

matplotlib.axes.Axes or numpy.ndarray of them

See also:

DataFrame.boxplot Another method to draw a box plot.
Series.plot.box Draw a box plot from a Series object.
matplotlib.pyplot.boxplot Draw a box plot in matplotlib.

Examples

Draw a box plot from a DataFrame with four columns of randomly generated data.

```
>>> data = np.random.randn(25, 4)
>>> df = pd.DataFrame(data, columns=list('ABCD'))
>>> ax = df.plot.box()
```

pandas.Series.plot.density

Series.plot.**density**(*bw_method=None*, *ind=None*, ***kwargs*)

Generate Kernel Density Estimate plot using Gaussian kernels.

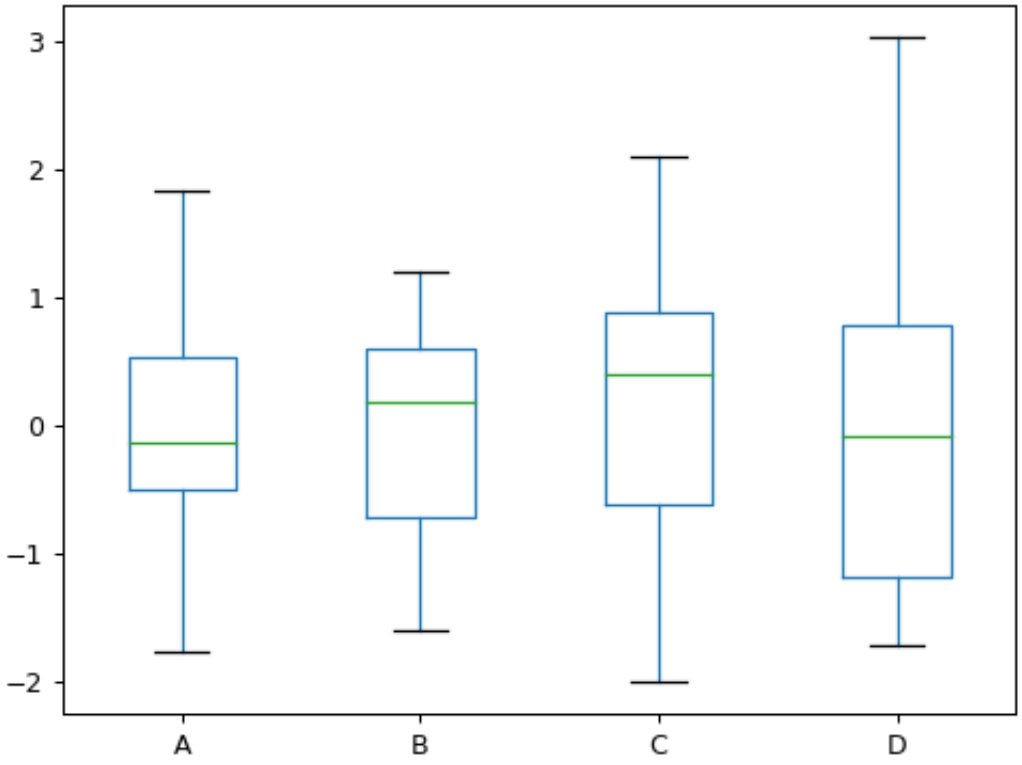
In statistics, kernel density estimation (KDE) is a non-parametric way to estimate the probability density function (PDF) of a random variable. This function uses Gaussian kernels and includes automatic bandwidth determination.

Parameters

bw_method [str, scalar or callable, optional] The method used to calculate the estimator bandwidth. This can be 'scott', 'silverman', a scalar constant or a callable. If None (default), 'scott' is used. See `scipy.stats.gaussian_kde` for more information.

ind [NumPy array or int, optional] Evaluation points for the estimated PDF. If None (default), 1000 equally spaced points are used. If *ind* is a NumPy array, the KDE is evaluated at the points passed. If *ind* is an integer, *ind* number of equally spaced points are used.

****kwargs** Additional keyword arguments are documented in `pandas.%(this-datatype)s.plot()`.



3
2
1
0
−1
−2
A
B
C
D

Returns

matplotlib.axes.Axes or numpy.ndarray of them

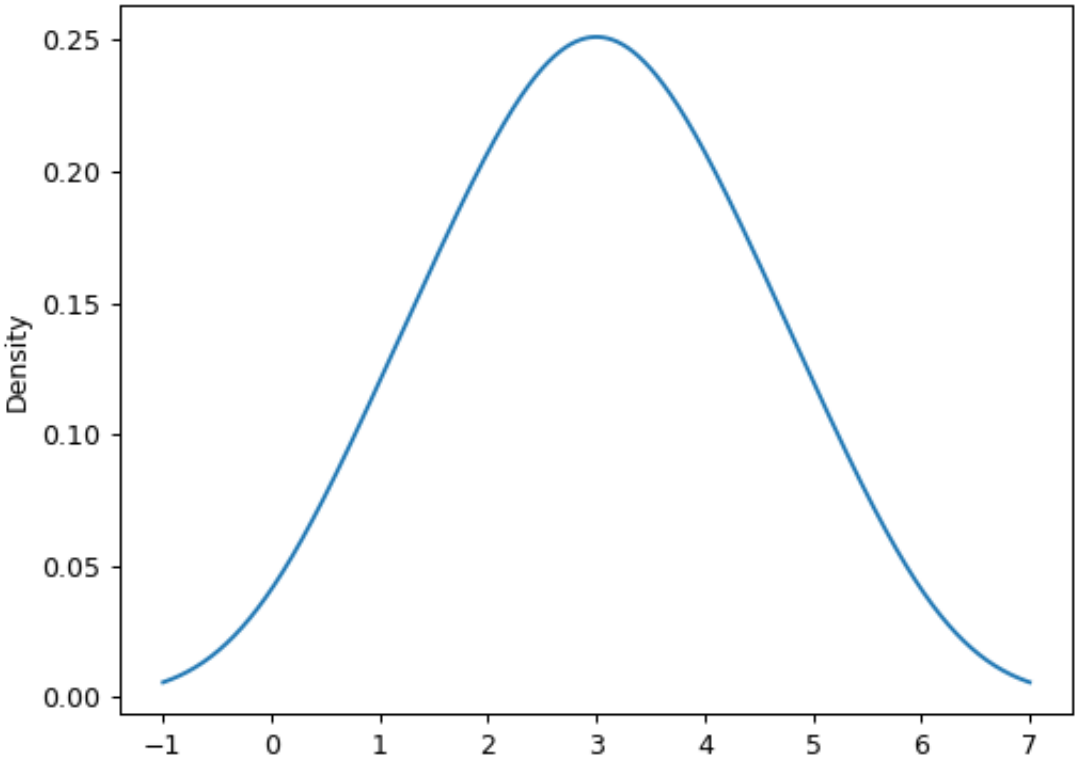
See also:

`scipy.stats.gaussian_kde` Representation of a kernel-density estimate using Gaussian kernels. This is the function used internally to estimate the PDF.

Examples

Given a Series of points randomly sampled from an unknown distribution, estimate its PDF using KDE with automatic bandwidth determination and plot the results, evaluating them at 1000 equally spaced points (default):

```
>>> s = pd.Series([1, 2, 2.5, 3, 3.5, 4, 5])
>>> ax = s.plot.kde()
```



A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:

```
>>> ax = s.plot.kde(bw_method=0.3)
```

```
>>> ax = s.plot.kde(bw_method=3)
```

Finally, the *ind* parameter determines the evaluation points for the plot of the estimated PDF:

7

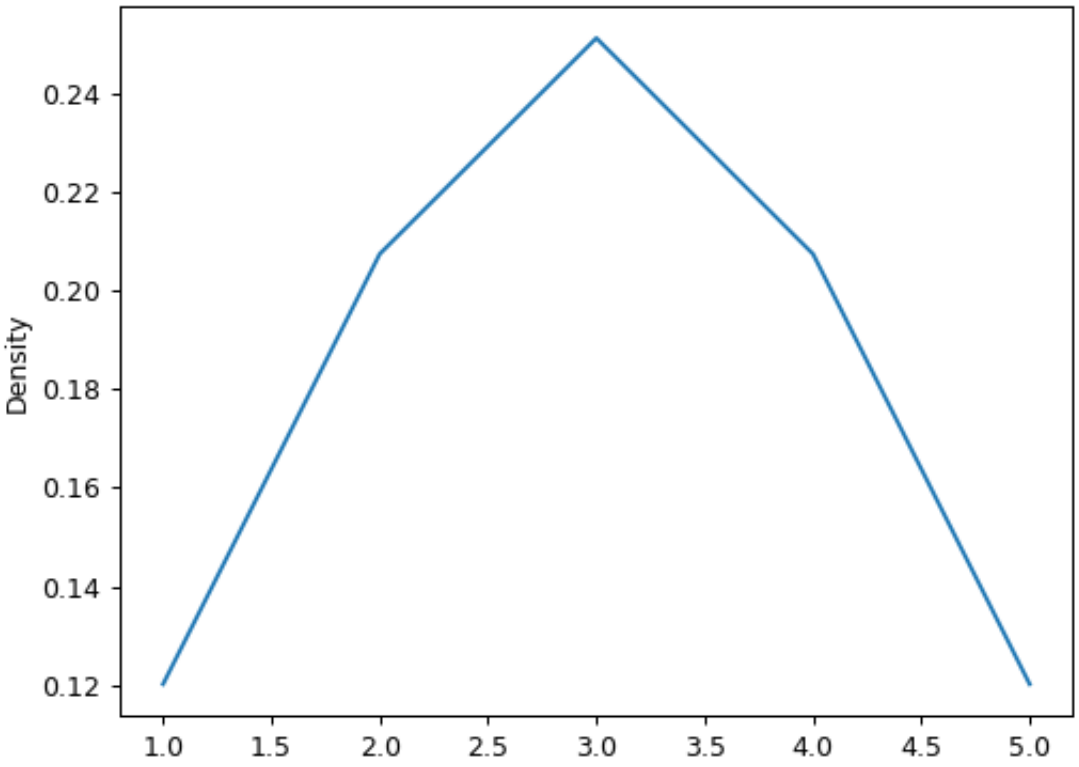
```
>>> ax = s.plot.kde(ind=[1, 2, 3, 4, 5])
```



For DataFrame, it works in the same way:

```
>>> df = pd.DataFrame({
...     'x': [1, 2, 2.5, 3, 3.5, 4, 5],
...     'y': [4, 4, 4.5, 5, 5.5, 6, 6],
... })
>>> ax = df.plot.kde()
```

A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:

```
>>> ax = df.plot.kde(bw_method=0.3)
```

```
>>> ax = df.plot.kde(bw_method=3)
```

Finally, the *ind* parameter determines the evaluation points for the plot of the estimated PDF:

```
>>> ax = df.plot.kde(ind=[1, 2, 3, 4, 5, 6])
```

pandas.Series.plot.hist

Series.plot.**hist**(*by=None*, *bins=10*, ***kwargs*)

Draw one histogram of the DataFrame's columns.

A histogram is a representation of the distribution of data. This function groups the values of all given Series in the DataFrame into bins and draws all bins in one matplotlib.axes.Axes. This is useful when the DataFrame's Series are in a similar scale.

Parameters

by [str or sequence, optional] Column in the DataFrame to group by.

bins [int, default 10] Number of histogram bins to be used.

****kwargs** Additional keyword arguments are documented in *DataFrame.plot()*.

Returns

class:*matplotlib.AxesSubplot* Return a histogram plot.

See also:

DataFrame.hist Draw histograms per DataFrame's Series.
Series.hist Draw a histogram with Series' data.

Examples

When we draw a dice 6000 times, we expect to get each value around 1000 times. But when we draw two dices and sum the result, the distribution is going to be quite different. A histogram illustrates those distributions.

```
>>> df = pd.DataFrame(
...     np.random.randint(1, 7, 6000),
...     columns = ['one'])
>>> df['two'] = df['one'] + np.random.randint(1, 7, 6000)
>>> ax = df.plot.hist(bins=12, alpha=0.5)
```

pandas.Series.plot.kde

Series.plot.**kde**(*bw_method=None*, *ind=None*, ***kwargs*)

Generate Kernel Density Estimate plot using Gaussian kernels.

In statistics, kernel density estimation (KDE) is a non-parametric way to estimate the probability density function (PDF) of a random variable. This function uses Gaussian kernels and includes automatic bandwidth determination.

Parameters

bw_method [str, scalar or callable, optional] The method used to calculate the estimator bandwidth. This can be 'scott', 'silverman', a scalar constant or a callable. If None (default), 'scott' is used. See scipy.stats.gaussian_kde for more information.

ind [NumPy array or int, optional] Evaluation points for the estimated PDF. If None (default), 1000 equally spaced points are used. If *ind* is a NumPy array, the KDE is evaluated at the points passed. If *ind* is an integer, *ind* number of equally spaced points are used.

****kwargs** Additional keyword arguments are documented in pandas.%(this-datatype)s.plot().

matplotlib.axes.Axes or numpy.ndarray of them

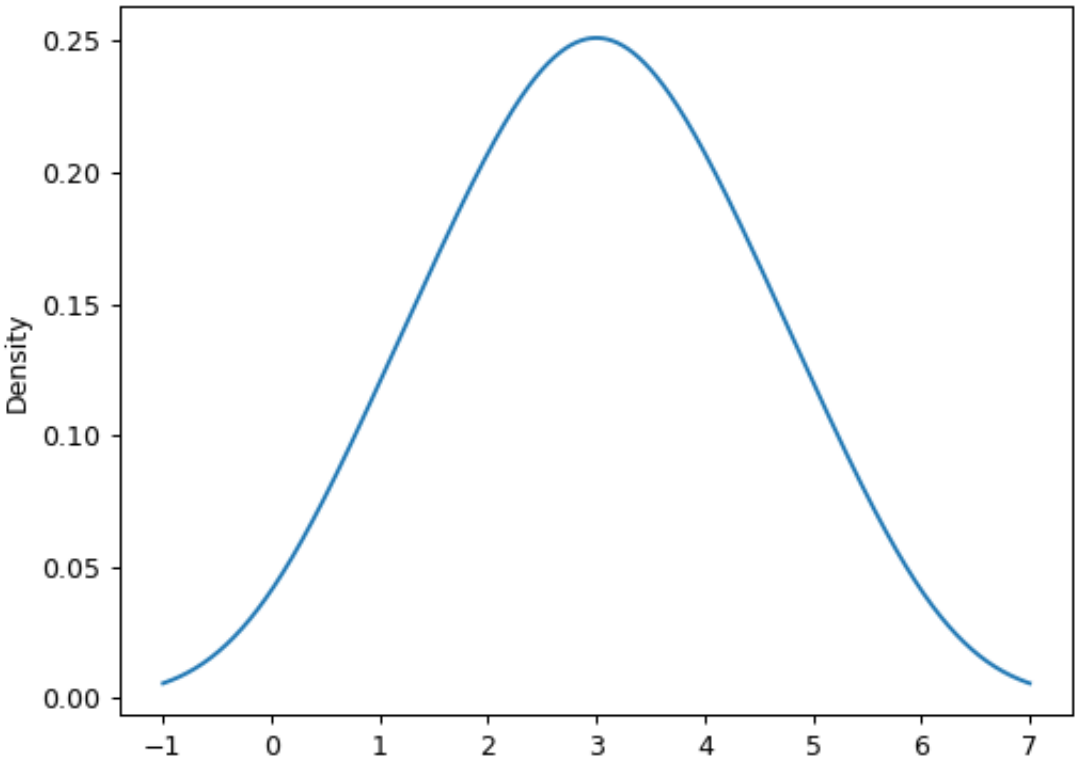
See also:

`scipy.stats.gaussian_kde` Representation of a kernel-density estimate using Gaussian kernels. This is the function used internally to estimate the PDF.

Examples

Given a Series of points randomly sampled from an unknown distribution, estimate its PDF using KDE with automatic bandwidth determination and plot the results, evaluating them at 1000 equally spaced points (default):

```
>>> s = pd.Series([1, 2, 2.5, 3, 3.5, 4, 5])
>>> ax = s.plot.kde()
```



A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:

```
>>> ax = s.plot.kde(bw_method=0.3)
```

```
>>> ax = s.plot.kde(bw_method=3)
```

Finally, the *ind* parameter determines the evaluation points for the plot of the estimated PDF:

pandas.Series.plot.line

Series.plot.**line**(*x=None*, *y=None*, ***kwargs*)

Plot Series or DataFrame as lines.

This function is useful to plot lines using DataFrame's values as coordinates.

Parameters

x [label or position, optional] Allows plotting of one column versus another. If not specified, the index of the DataFrame is used.

y [label or position, optional] Allows plotting of one column versus another. If not specified, all numerical columns are used.

color [str, array_like, or dict, optional] The color for each of the DataFrame's columns. Possible values are:

- **A single color string referred to by name, RGB or RGBA code,** for instance 'red' or '#a98d19'.
- **A sequence of color strings referred to by name, RGB or RGBA** code, which will be used for each column recursively. For instance ['green','yellow'] each column's line will be filled in green or yellow, alternatively.
- **A dict of the form {column name** [color}, so that each column will be] colored accordingly. For example, if your columns are called *a* and *b*, then passing {'a': 'green', 'b': 'red'} will color lines for column *a* in green and lines for column *b* in red.

New in version 1.1.0.

****kwargs** Additional keyword arguments are documented in *DataFrame.plot()*.

Returns

matplotlib.axes.Axes or np.ndarray of them An ndarray is returned with one matplotlib.axes.Axes per column when subplots=True.

See also:

matplotlib.pyplot.plot Plot y versus x as lines and/or markers.

Examples

```
>>> s = pd.Series([1, 3, 2])
>>> s.plot.line()
```

The following example shows the populations for some animals over the years.

```
>>> df = pd.DataFrame({
...     'pig': [20, 18, 489, 675, 1776],
...     'horse': [4, 25, 281, 600, 1900]
...     }, index=[1990, 1997, 2003, 2009, 2014])
>>> lines = df.plot.line()
```

An example with subplots, so an array of axes is returned.

```
>>> axes = df.plot.line(subplots=True)
>>> type(axes)
<class 'numpy.ndarray'>
```

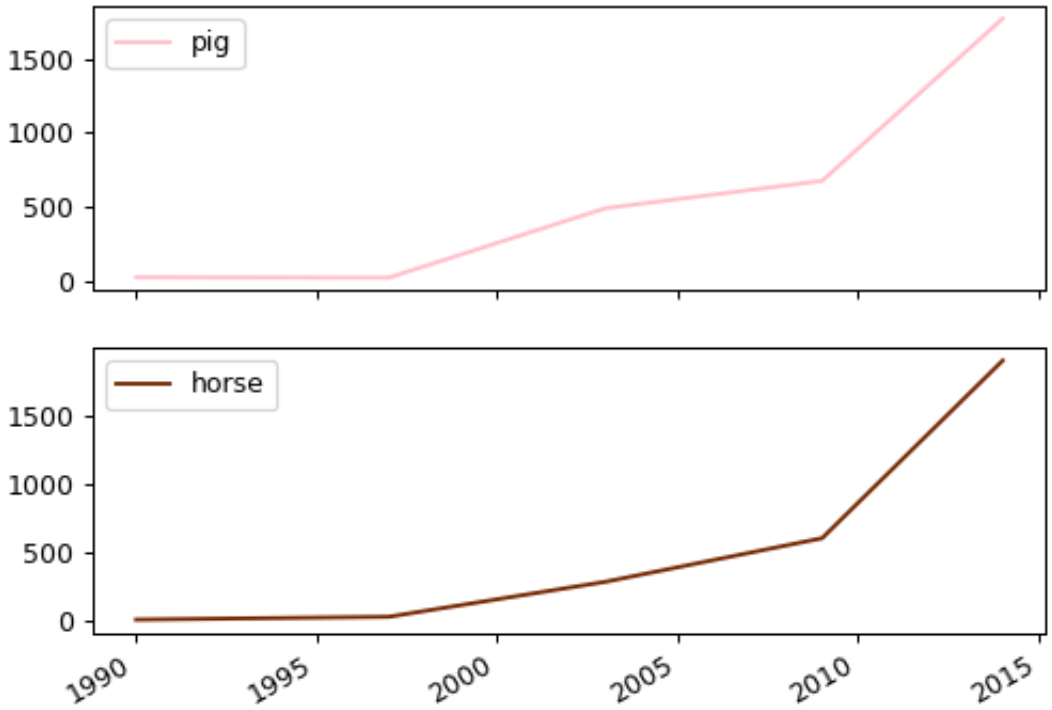
Let's repeat the same example, but specifying colors for each column (in this case, for each animal).

```
>>> axes = df.plot.line(
...     subplots=True, color={"pig": "pink", "horse": "#742802"}
... )
```



The following example shows the relationship between both populations.

```
>>> lines = df.plot.line(x='pig', y='horse')
```

pandas.Series.plot.pie

`Series.plot.`**`pie`**`(**kwargs)`

Generate a pie plot.

A pie plot is a proportional representation of the numerical data in a column. This function wraps `matplotlib.pyplot.pie()` for the specified column. If no column reference is passed and `subplots=True` a pie plot is drawn for each numerical column independently.

Parameters

y [int or label, optional] Label or position of the column to plot. If not provided, `subplots=True` argument must be passed.

****kwargs** Keyword arguments to pass on to *`DataFrame.plot()`*.

Returns

matplotlib.axes.Axes or np.ndarray of them A NumPy array is returned when *subplots* is True.

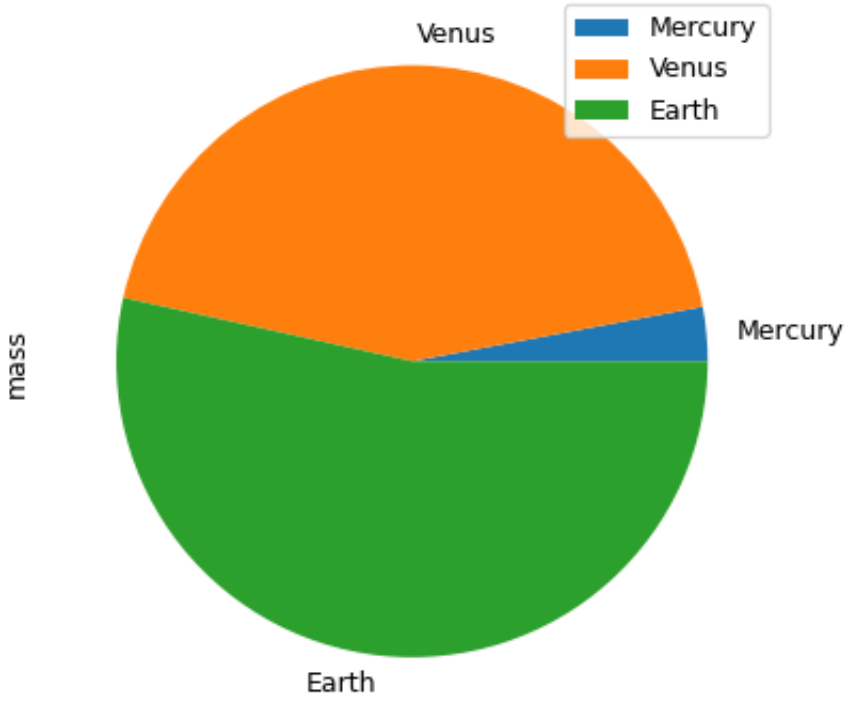
See also:

Series.plot.pie Generate a pie plot for a Series.
DataFrame.plot Make plots of a DataFrame.

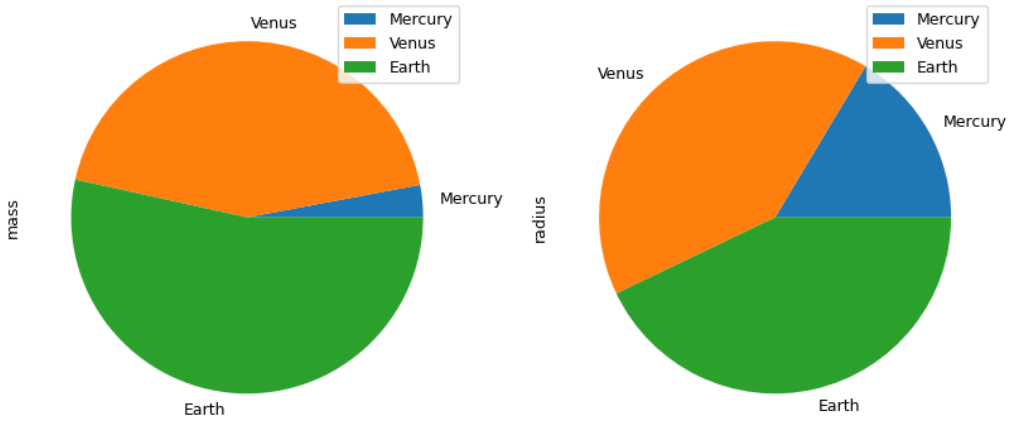
Examples

In the example below we have a DataFrame with the information about planet's mass and radius. We pass the 'mass' column to the pie function to get a pie plot.

```
>>> df = pd.DataFrame({'mass': [0.330, 4.87 , 5.97],
...                    'radius': [2439.7, 6051.8, 6378.1]},
...                   index=['Mercury', 'Venus', 'Earth'])
>>> plot = df.plot.pie(y='mass', figsize=(5, 5))
```



```
>>> plot = df.plot.pie(subplots=True, figsize=(11, 6))
```



`Series.hist`([by, ax, grid, xlabelsize, ...])	Draw histogram of the input series using matplotlib.

3.3.15 Serialization / IO / conversion

`Series.to_pickle`(path[, compression, protocol])	Pickle (serialize) object to file.
`Series.to_csv`([path_or_buf, sep, na_rep, ...])	Write object to a comma-separated values (csv) file.
`Series.to_dict`([into])	Convert Series to {label -> value} dict or dict-like object.
`Series.to_excel`(excel_writer[, sheet_name, ...])	Write object to an Excel sheet.
`Series.to_frame`([name])	Convert Series to DataFrame.
`Series.to_xarray`()	Return an xarray object from the pandas object.
`Series.to_hdf`(path_or_buf, key[, mode, ...])	Write the contained data to an HDF5 file using HDFStore.
`Series.to_sql`(name, con[, schema, ...])	Write records stored in a DataFrame to a SQL database.
`Series.to_json`([path_or_buf, orient, ...])	Convert the object to a JSON string.
`Series.to_string`([buf, na_rep, ...])	Render a string representation of the Series.
`Series.to_clipboard`([excel, sep])	Copy object to the system clipboard.
`Series.to_latex`([buf, columns, col_space, ...])	Render object to a LaTeX tabular, longtable, or nested table/tabular.
`Series.to_markdown`([buf, mode, index])	Print Series in Markdown-friendly format.

3.4 DataFrame

3.4.1 Constructor

`DataFrame`([data, index, columns, dtype, copy])	Two-dimensional, size-mutable, potentially heterogeneous tabular data.

pandas.DataFrame

columns [Index or array-like] Column labels to use for resulting frame. Will default to RangeIndex (0, 1, 2, …, n) if no column labels are provided.

dtype [dtype, default None] Data type to force. Only a single dtype is allowed. If None, infer.

copy [bool, default False] Copy data from inputs. Only affects DataFrame / 2d ndarray input.

See also:

DataFrame.from_records Constructor from tuples, also record arrays.
DataFrame.from_dict From dicts of Series, arrays, or dicts.
read_csv Read a comma-separated values (csv) file into DataFrame.
read_table Read general delimited file into DataFrame.
read_clipboard Read text from clipboard into DataFrame.

Examples

Constructing DataFrame from a dictionary.

```
>>> d = {'col1': [1, 2], 'col2': [3, 4]}
>>> df = pd.DataFrame(data=d)
>>> df
   col1  col2
0     1     3
1     2     4
```

Notice that the inferred dtype is int64.

```
>>> df.dtypes
col1    int64
col2    int64
dtype: object
```

To enforce a single dtype:

```
>>> df = pd.DataFrame(data=d, dtype=np.int8)
>>> df.dtypes
col1    int8
col2    int8
dtype: object
```

Constructing DataFrame from numpy ndarray:

```
>>> df2 = pd.DataFrame(np.array([[1, 2, 3], [4, 5, 6], [7, 8, 9]]),
...                    columns=['a', 'b', 'c'])
>>> df2
   a  b  c
0  1  2  3
1  4  5  6
2  7  8  9
```

Attributes

at	Access a single value for a row/column label pair.
attrs	Dictionary of global attributes on this object.
axes	Return a list representing the axes of the DataFrame.
columns	The column labels of the DataFrame.
dtypes	Return the dtypes in the DataFrame.
empty	Indicator whether DataFrame is empty.
iat	Access a single value for a row/column pair by integer position.
iloc	Purely integer-location based indexing for selection by position.
index	The index (row labels) of the DataFrame.
loc	Access a group of rows and columns by label(s) or a boolean array.
ndim	Return an int representing the number of axes / array dimensions.
shape	Return a tuple representing the dimensionality of the DataFrame.
size	Return an int representing the number of elements in this object.
style	Returns a Styler object.
values	Return a Numpy representation of the DataFrame.

pandas.DataFrame.at

property DataFrame.**at**

Access a single value for a row/column label pair.

Similar to `loc`, in that both provide label-based lookups. Use `at` if you only need to get or set a single value in a DataFrame or Series.

Raises

KeyError If 'label' does not exist in DataFrame.

See also:

DataFrame.iat Access a single value for a row/column pair by integer position.

DataFrame.loc Access a group of rows and columns by label(s).

Series.at Access a single value using a label.

Examples

```
>>> df = pd.DataFrame([[0, 2, 3], [0, 4, 1], [10, 20, 30]],
...                   index=[4, 5, 6], columns=['A', 'B', 'C'])
>>> df
    A   B   C
4   0   2   3
5   0   4   1
6  10  20  30
```

Get value at specified row/column pair

```
>>> df.at[4, 'B']
2
```

Set value at specified row/column pair

```
>>> df.at[4, 'B'] = 10
>>> df.at[4, 'B']
10
```

Get value within a Series

```
>>> df.loc[5].at['B']
4
```

pandas.DataFrame.attrs

property DataFrame.**attrs**

Dictionary of global attributes on this object.

> **Warning:** attrs is experimental and may change without warning.

pandas.DataFrame.axes

property DataFrame.**axes**

Return a list representing the axes of the DataFrame.

It has the row axis labels and column axis labels as the only members. They are returned in that order.

Examples

```
>>> df = pd.DataFrame({'col1': [1, 2], 'col2': [3, 4]})
>>> df.axes
[RangeIndex(start=0, stop=2, step=1), Index(['col1', 'col2'],
dtype='object')]
```

pandas.DataFrame.columns

DataFrame.**columns: Index**
The column labels of the DataFrame.

pandas.DataFrame.dtypes

property DataFrame.**dtypes**
Return the dtypes in the DataFrame.

This returns a Series with the data type of each column. The result's index is the original DataFrame's columns. Columns with mixed types are stored with the `object` dtype. See *the User Guide* for more.

Returns

pandas.Series The data type of each column.

Examples

```
>>> df = pd.DataFrame({'float': [1.0],
...                    'int': [1],
...                    'datetime': [pd.Timestamp('20180310')],
...                    'string': ['foo']})
>>> df.dtypes
float              float64
int                  int64
datetime    datetime64[ns]
string              object
dtype: object
```

pandas.DataFrame.empty

property DataFrame.**empty**
Indicator whether DataFrame is empty.

True if DataFrame is entirely empty (no items), meaning any of the axes are of length 0.

Returns

bool If DataFrame is empty, return True, if not return False.

See also:

Series.dropna Return series without null values.

DataFrame.dropna Return DataFrame with labels on given axis omitted where (all or any) data are missing.

Notes

If DataFrame contains only NaNs, it is still not considered empty. See the example below.

Examples

An example of an actual empty DataFrame. Notice the index is empty:

```
>>> df_empty = pd.DataFrame({'A' : []})
>>> df_empty
Empty DataFrame
Columns: [A]
Index: []
>>> df_empty.empty
True
```

If we only have NaNs in our DataFrame, it is not considered empty! We will need to drop the NaNs to make the DataFrame empty:

```
>>> df = pd.DataFrame({'A' : [np.nan]})
>>> df
    A
0 NaN
>>> df.empty
False
>>> df.dropna().empty
True
```

pandas.DataFrame.iat

property DataFrame.**iat**

Access a single value for a row/column pair by integer position.

Similar to `iloc`, in that both provide integer-based lookups. Use `iat` if you only need to get or set a single value in a DataFrame or Series.

Raises

IndexError When integer position is out of bounds.

See also:

DataFrame.at Access a single value for a row/column label pair.

DataFrame.loc Access a group of rows and columns by label(s).

DataFrame.iloc Access a group of rows and columns by integer position(s).

Examples

```
>>> df = pd.DataFrame([[0, 2, 3], [0, 4, 1], [10, 20, 30]],
...                   columns=['A', 'B', 'C'])
>>> df
    A   B   C
0   0   2   3
1   0   4   1
2  10  20  30
```

Get value at specified row/column pair

```
>>> df.iat[1, 2]
1
```

Set value at specified row/column pair

```
>>> df.iat[1, 2] = 10
>>> df.iat[1, 2]
10
```

Get value within a series

```
>>> df.loc[0].iat[1]
2
```

pandas.DataFrame.iloc

property DataFrame.**iloc**

Purely integer-location based indexing for selection by position.

`.iloc[]` is primarily integer position based (from `0` to `length-1` of the axis), but may also be used with a boolean array.

Allowed inputs are:

- An integer, e.g. `5`.
- A list or array of integers, e.g. `[4, 3, 0]`.
- A slice object with ints, e.g. `1:7`.
- A boolean array.
- A `callable` function with one argument (the calling Series or DataFrame) and that returns valid output for indexing (one of the above). This is useful in method chains, when you don't have a reference to the calling object, but would like to base your selection on some value.

`.iloc` will raise `IndexError` if a requested indexer is out-of-bounds, except *slice* indexers which allow out-of-bounds indexing (this conforms with python/numpy *slice* semantics).

See more at *Selection by Position*.

See also:

DataFrame.iat Fast integer location scalar accessor.

DataFrame.loc Purely label-location based indexer for selection by label.

Series.iloc Purely integer-location based indexing for selection by position.

Examples

```
>>> mydict = [{'a': 1, 'b': 2, 'c': 3, 'd': 4},
...           {'a': 100, 'b': 200, 'c': 300, 'd': 400},
...           {'a': 1000, 'b': 2000, 'c': 3000, 'd': 4000 }]
>>> df = pd.DataFrame(mydict)
>>> df
      a     b     c     d
0     1     2     3     4
1   100   200   300   400
2  1000  2000  3000  4000
```

Indexing just the rows

With a scalar integer.

```
>>> type(df.iloc[0])
<class 'pandas.core.series.Series'>
>>> df.iloc[0]
a    1
b    2
c    3
d    4
Name: 0, dtype: int64
```

With a list of integers.

```
>>> df.iloc[[0]]
   a  b  c  d
0  1  2  3  4
>>> type(df.iloc[[0]])
<class 'pandas.core.frame.DataFrame'>
```

```
>>> df.iloc[[0, 1]]
     a    b    c    d
0    1    2    3    4
1  100  200  300  400
```

With a *slice* object.

```
>>> df.iloc[:3]
      a     b     c     d
0     1     2     3     4
1   100   200   300   400
2  1000  2000  3000  4000
```

With a boolean mask the same length as the index.

```
>>> df.iloc[[True, False, True]]
      a     b     c     d
0     1     2     3     4
2  1000  2000  3000  4000
```

With a callable, useful in method chains. The *x* passed to the `lambda` is the DataFrame being sliced. This selects the rows whose index label even.

```
>>> df.iloc[lambda x: x.index % 2 == 0]
      a     b     c     d
0     1     2     3     4
2  1000  2000  3000  4000
```

Indexing both axes

You can mix the indexer types for the index and columns. Use `:` to select the entire axis.

With scalar integers.

```
>>> df.iloc[0, 1]
2
```

With lists of integers.

```
>>> df.iloc[[0, 2], [1, 3]]
      b     d
0     2     4
2  2000  4000
```

With *slice* objects.

```
>>> df.iloc[1:3, 0:3]
      a     b     c
1   100   200   300
2  1000  2000  3000
```

With a boolean array whose length matches the columns.

```
>>> df.iloc[:, [True, False, True, False]]
      a     c
0     1     3
1   100   300
2  1000  3000
```

With a callable function that expects the Series or DataFrame.

```
>>> df.iloc[:, lambda df: [0, 2]]
      a     c
0     1     3
1   100   300
2  1000  3000
```

pandas.DataFrame.index

DataFrame.**index: Index**
The index (row labels) of the DataFrame.

pandas.DataFrame.loc

property DataFrame.**loc**

Access a group of rows and columns by label(s) or a boolean array.

`.loc[]` is primarily label based, but may also be used with a boolean array.

Allowed inputs are:

- A single label, e.g. `5` or `'a'`, (note that `5` is interpreted as a *label* of the index, and **never** as an integer position along the index).
- A list or array of labels, e.g. `['a', 'b', 'c']`.
- A slice object with labels, e.g. `'a':'f'`.

  Warning: Note that contrary to usual python slices, **both** the start and the stop are included

- A boolean array of the same length as the axis being sliced, e.g. `[True, False, True]`.
- A `callable` function with one argument (the calling Series or DataFrame) and that returns valid output for indexing (one of the above)

See more at *Selection by Label*

Raises

KeyError If any items are not found.

See also:

DataFrame.at Access a single value for a row/column label pair.

DataFrame.iloc Access group of rows and columns by integer position(s).

DataFrame.xs Returns a cross-section (row(s) or column(s)) from the Series/DataFrame.

Series.loc Access group of values using labels.

Examples

Getting values

```
>>> df = pd.DataFrame([[1, 2], [4, 5], [7, 8]],
...       index=['cobra', 'viper', 'sidewinder'],
...       columns=['max_speed', 'shield'])
>>> df
            max_speed  shield
cobra               1       2
viper               4       5
sidewinder          7       8
```

Single label. Note this returns the row as a Series.

```
>>> df.loc['viper']
max_speed    4
shield       5
Name: viper, dtype: int64
```

List of labels. Note using `[[]]` returns a DataFrame.

```
>>> df.loc[['viper', 'sidewinder']]
            max_speed  shield
viper               4       5
sidewinder          7       8
```

Single label for row and column

```
>>> df.loc['cobra', 'shield']
2
```

Slice with labels for row and single label for column. As mentioned above, note that both the start and stop of the slice are included.

```
>>> df.loc['cobra':'viper', 'max_speed']
cobra    1
viper    4
Name: max_speed, dtype: int64
```

Boolean list with the same length as the row axis

```
>>> df.loc[[False, False, True]]
            max_speed  shield
sidewinder          7       8
```

Conditional that returns a boolean Series

```
>>> df.loc[df['shield'] > 6]
            max_speed  shield
sidewinder          7       8
```

Conditional that returns a boolean Series with column labels specified

```
>>> df.loc[df['shield'] > 6, ['max_speed']]
            max_speed
sidewinder          7
```

Callable that returns a boolean Series

```
>>> df.loc[lambda df: df['shield'] == 8]
            max_speed  shield
sidewinder          7       8
```

Setting values

Set value for all items matching the list of labels

```
>>> df.loc[['viper', 'sidewinder'], ['shield']] = 50
>>> df
            max_speed  shield
cobra               1       2
viper               4      50
sidewinder          7      50
```

Set value for an entire row

```
>>> df.loc['cobra'] = 10
>>> df
            max_speed  shield
cobra              10      10
viper               4      50
sidewinder          7      50
```

Set value for an entire column

```
>>> df.loc[:, 'max_speed'] = 30
>>> df
            max_speed  shield
cobra              30      10
viper              30      50
sidewinder         30      50
```

Set value for rows matching callable condition

```
>>> df.loc[df['shield'] > 35] = 0
>>> df
            max_speed  shield
cobra              30      10
viper               0       0
sidewinder          0       0
```

Getting values on a DataFrame with an index that has integer labels

Another example using integers for the index

```
>>> df = pd.DataFrame([[1, 2], [4, 5], [7, 8]],
...      index=[7, 8, 9], columns=['max_speed', 'shield'])
>>> df
   max_speed  shield
7          1       2
8          4       5
9          7       8
```

Slice with integer labels for rows. As mentioned above, note that both the start and stop of the slice are included.

```
>>> df.loc[7:9]
   max_speed  shield
7          1       2
8          4       5
9          7       8
```

Getting values with a MultiIndex

A number of examples using a DataFrame with a MultiIndex

```
>>> tuples = [
...     ('cobra', 'mark i'), ('cobra', 'mark ii'),
...     ('sidewinder', 'mark i'), ('sidewinder', 'mark ii'),
...     ('viper', 'mark ii'), ('viper', 'mark iii')
... ]
>>> index = pd.MultiIndex.from_tuples(tuples)
>>> values = [[12, 2], [0, 4], [10, 20],
...           [1, 4], [7, 1], [16, 36]]
```

(continues on next page)

(continued from previous page)

```
>>> df = pd.DataFrame(values, columns=['max_speed', 'shield'], index=index)
>>> df
                     max_speed  shield
cobra      mark i            12       2
           mark ii            0       4
sidewinder mark i            10      20
           mark ii            1       4
viper      mark ii            7       1
           mark iii          16      36
```

Single label. Note this returns a DataFrame with a single index.

```
>>> df.loc['cobra']
         max_speed  shield
mark i          12       2
mark ii          0       4
```

Single index tuple. Note this returns a Series.

```
>>> df.loc[('cobra', 'mark ii')]
max_speed    0
shield       4
Name: (cobra, mark ii), dtype: int64
```

Single label for row and column. Similar to passing in a tuple, this returns a Series.

```
>>> df.loc['cobra', 'mark i']
max_speed    12
shield        2
Name: (cobra, mark i), dtype: int64
```

Single tuple. Note using `[[]]` returns a DataFrame.

```
>>> df.loc[[('cobra', 'mark ii')]]
               max_speed  shield
cobra mark ii          0       4
```

Single tuple for the index with a single label for the column

```
>>> df.loc[('cobra', 'mark i'), 'shield']
2
```

Slice from index tuple to single label

```
>>> df.loc[('cobra', 'mark i'):'viper']
                     max_speed  shield
cobra      mark i            12       2
           mark ii            0       4
sidewinder mark i            10      20
           mark ii            1       4
viper      mark ii            7       1
           mark iii          16      36
```

Slice from index tuple to index tuple

```
>>> df.loc[('cobra', 'mark i'):('viper', 'mark ii')]
                     max_speed  shield
cobra      mark i           12       2
           mark ii           0       4
sidewinder mark i           10      20
           mark ii           1       4
viper      mark ii           7       1
```

pandas.DataFrame.ndim

property DataFrame.**ndim**

Return an int representing the number of axes / array dimensions.

Return 1 if Series. Otherwise return 2 if DataFrame.

See also:

ndarray.ndim Number of array dimensions.

Examples

```
>>> s = pd.Series({'a': 1, 'b': 2, 'c': 3})
>>> s.ndim
1
```

```
>>> df = pd.DataFrame({'col1': [1, 2], 'col2': [3, 4]})
>>> df.ndim
2
```

pandas.DataFrame.shape

property DataFrame.**shape**

Return a tuple representing the dimensionality of the DataFrame.

See also:

ndarray.shape

Examples

```
>>> df = pd.DataFrame({'col1': [1, 2], 'col2': [3, 4]})
>>> df.shape
(2, 2)
```

```
>>> df = pd.DataFrame({'col1': [1, 2], 'col2': [3, 4],
...                    'col3': [5, 6]})
>>> df.shape
(2, 3)
```

pandas.DataFrame.size

property DataFrame.**size**
Return an int representing the number of elements in this object.

Return the number of rows if Series. Otherwise return the number of rows times number of columns if DataFrame.

See also:

ndarray.size Number of elements in the array.

Examples

```
>>> s = pd.Series({'a': 1, 'b': 2, 'c': 3})
>>> s.size
3
```

```
>>> df = pd.DataFrame({'col1': [1, 2], 'col2': [3, 4]})
>>> df.size
4
```

pandas.DataFrame.style

property DataFrame.**style**
Returns a Styler object.

Contains methods for building a styled HTML representation of the DataFrame.

See also:

io.formats.style.Styler Helps style a DataFrame or Series according to the data with HTML and CSS.

pandas.DataFrame.values

property DataFrame.**values**
Return a Numpy representation of the DataFrame.

Warning: We recommend using *DataFrame.to_numpy()* instead.

Only the values in the DataFrame will be returned, the axes labels will be removed.

Returns

numpy.ndarray The values of the DataFrame.

See also:

DataFrame.to_numpy Recommended alternative to this method.

DataFrame.index Retrieve the index labels.

DataFrame.columns Retrieving the column names.

Notes

The dtype will be a lower-common-denominator dtype (implicit upcasting); that is to say if the dtypes (even of numeric types) are mixed, the one that accommodates all will be chosen. Use this with care if you are not dealing with the blocks.

e.g. If the dtypes are float16 and float32, dtype will be upcast to float32. If dtypes are int32 and uint8, dtype will be upcast to int32. By `numpy.find_common_type()` convention, mixing int64 and uint64 will result in a float64 dtype.

Examples

A DataFrame where all columns are the same type (e.g., int64) results in an array of the same type.

```
>>> df = pd.DataFrame({'age':    [ 3,  29],
...                    'height': [94, 170],
...                    'weight': [31, 115]})
>>> df
   age  height  weight
0    3      94      31
1   29     170     115
>>> df.dtypes
age       int64
height    int64
weight    int64
dtype: object
>>> df.values
array([[  3,  94,  31],
       [ 29, 170, 115]])
```

A DataFrame with mixed type columns(e.g., str/object, int64, float32) results in an ndarray of the broadest type that accommodates these mixed types (e.g., object).

```
>>> df2 = pd.DataFrame([('parrot',   24.0, 'second'),
...                     ('lion',     80.5, 1),
...                     ('monkey', np.nan, None)],
...                    columns=('name', 'max_speed', 'rank'))
>>> df2.dtypes
name          object
max_speed    float64
rank          object
dtype: object
>>> df2.values
array([['parrot', 24.0, 'second'],
       ['lion', 80.5, 1],
       ['monkey', nan, None]], dtype=object)
```

Methods

abs()	Return a Series/DataFrame with absolute numeric value of each element.
add(other[, axis, level, fill_value])	Get Addition of dataframe and other, element-wise (binary operator *add*).
add_prefix(prefix)	Prefix labels with string *prefix*.
add_suffix(suffix)	Suffix labels with string *suffix*.
agg([func, axis])	Aggregate using one or more operations over the specified axis.
aggregate([func, axis])	Aggregate using one or more operations over the specified axis.
align(other[, join, axis, level, copy, ...])	Align two objects on their axes with the specified join method.
all([axis, bool_only, skipna, level])	Return whether all elements are True, potentially over an axis.
any([axis, bool_only, skipna, level])	Return whether any element is True, potentially over an axis.
append(other[, ignore_index, ...])	Append rows of *other* to the end of caller, returning a new object.
apply(func[, axis, raw, result_type, args])	Apply a function along an axis of the DataFrame.
applymap(func)	Apply a function to a Dataframe elementwise.
asfreq(freq[, method, how, normalize, ...])	Convert TimeSeries to specified frequency.
asof(where[, subset])	Return the last row(s) without any NaNs before *where*.
assign(**kwargs)	Assign new columns to a DataFrame.
astype(dtype[, copy, errors])	Cast a pandas object to a specified dtype `dtype`.
at_time(time[, asof, axis])	Select values at particular time of day (e.g., 9:30AM).
backfill([axis, inplace, limit, downcast])	Synonym for *DataFrame.fillna()* with `method='bfill'`.
between_time(start_time, end_time[, ...])	Select values between particular times of the day (e.g., 9:00-9:30 AM).
bfill([axis, inplace, limit, downcast])	Synonym for *DataFrame.fillna()* with `method='bfill'`.
bool()	Return the bool of a single element Series or DataFrame.
boxplot([column, by, ax, fontsize, rot, ...])	Make a box plot from DataFrame columns.
clip([lower, upper, axis, inplace])	Trim values at input threshold(s).
combine(other, func[, fill_value, overwrite])	Perform column-wise combine with another DataFrame.
combine_first(other)	Update null elements with value in the same location in *other*.
compare(other[, align_axis, keep_shape, ...])	Compare to another DataFrame and show the differences.
convert_dtypes([infer_objects, ...])	Convert columns to best possible dtypes using dtypes supporting `pd.NA`.
copy([deep])	Make a copy of this object's indices and data.
corr([method, min_periods])	Compute pairwise correlation of columns, excluding NA/null values.
corrwith(other[, axis, drop, method])	Compute pairwise correlation.

continues on next page

Table 59 – continued from previous page

count([axis, level, numeric_only])	Count non-NA cells for each column or row.
cov([min_periods, ddof])	Compute pairwise covariance of columns, excluding NA/null values.
cummax([axis, skipna])	Return cumulative maximum over a DataFrame or Series axis.
cummin([axis, skipna])	Return cumulative minimum over a DataFrame or Series axis.
cumprod([axis, skipna])	Return cumulative product over a DataFrame or Series axis.
cumsum([axis, skipna])	Return cumulative sum over a DataFrame or Series axis.
describe([percentiles, include, exclude, ...])	Generate descriptive statistics.
diff([periods, axis])	First discrete difference of element.
div(other[, axis, level, fill_value])	Get Floating division of dataframe and other, element-wise (binary operator *truediv*).
divide(other[, axis, level, fill_value])	Get Floating division of dataframe and other, element-wise (binary operator *truediv*).
dot(other)	Compute the matrix multiplication between the DataFrame and other.
drop([labels, axis, index, columns, level, ...])	Drop specified labels from rows or columns.
drop_duplicates([subset, keep, inplace, ...])	Return DataFrame with duplicate rows removed.
droplevel(level[, axis])	Return DataFrame with requested index / column level(s) removed.
dropna([axis, how, thresh, subset, inplace])	Remove missing values.
duplicated([subset, keep])	Return boolean Series denoting duplicate rows.
eq(other[, axis, level])	Get Equal to of dataframe and other, element-wise (binary operator *eq*).
equals(other)	Test whether two objects contain the same elements.
eval(expr[, inplace])	Evaluate a string describing operations on DataFrame columns.
ewm([com, span, halflife, alpha, ...])	Provide exponential weighted (EW) functions.
expanding([min_periods, center, axis])	Provide expanding transformations.
explode(column[, ignore_index])	Transform each element of a list-like to a row, replicating index values.
ffill([axis, inplace, limit, downcast])	Synonym for DataFrame.fillna() with `method='ffill'`.
fillna([value, method, axis, inplace, ...])	Fill NA/NaN values using the specified method.
filter([items, like, regex, axis])	Subset the dataframe rows or columns according to the specified index labels.
first(offset)	Select initial periods of time series data based on a date offset.
first_valid_index()	Return index for first non-NA/null value.
floordiv(other[, axis, level, fill_value])	Get Integer division of dataframe and other, element-wise (binary operator *floordiv*).
from_dict(data[, orient, dtype, columns])	Construct DataFrame from dict of array-like or dicts.
from_records(data[, index, exclude, ...])	Convert structured or record ndarray to DataFrame.
ge(other[, axis, level])	Get Greater than or equal to of dataframe and other, element-wise (binary operator *ge*).
get(key[, default])	Get item from object for given key (ex: DataFrame column).

continues on next page

Table 59 – continued from previous page

groupby([by, axis, level, as_index, sort, ...])	Group DataFrame using a mapper or by a Series of columns.
gt(other[, axis, level])	Get Greater than of dataframe and other, element-wise (binary operator *gt*).
head([n])	Return the first *n* rows.
hist([column, by, grid, xlabelsize, xrot, ...])	Make a histogram of the DataFrame's.
idxmax([axis, skipna])	Return index of first occurrence of maximum over requested axis.
idxmin([axis, skipna])	Return index of first occurrence of minimum over requested axis.
infer_objects()	Attempt to infer better dtypes for object columns.
info([verbose, buf, max_cols, memory_usage, ...])	Print a concise summary of a DataFrame.
insert(loc, column, value[, allow_duplicates])	Insert column into DataFrame at specified location.
interpolate([method, axis, limit, inplace, ...])	Please note that only `method='linear'` is supported for DataFrame/Series with a MultiIndex.
isin(values)	Whether each element in the DataFrame is contained in values.
isna()	Detect missing values.
isnull()	Detect missing values.
items()	Iterate over (column name, Series) pairs.
iteritems()	Iterate over (column name, Series) pairs.
iterrows()	Iterate over DataFrame rows as (index, Series) pairs.
itertuples([index, name])	Iterate over DataFrame rows as namedtuples.
join(other[, on, how, lsuffix, rsuffix, sort])	Join columns of another DataFrame.
keys()	Get the 'info axis' (see Indexing for more).
kurt([axis, skipna, level, numeric_only])	Return unbiased kurtosis over requested axis.
kurtosis([axis, skipna, level, numeric_only])	Return unbiased kurtosis over requested axis.
last(offset)	Select final periods of time series data based on a date offset.
last_valid_index()	Return index for last non-NA/null value.
le(other[, axis, level])	Get Less than or equal to of dataframe and other, element-wise (binary operator *le*).
lookup(row_labels, col_labels)	Label-based "fancy indexing" function for DataFrame.
lt(other[, axis, level])	Get Less than of dataframe and other, element-wise (binary operator *lt*).
mad([axis, skipna, level])	Return the mean absolute deviation of the values for the requested axis.
mask(cond[, other, inplace, axis, level, ...])	Replace values where the condition is True.
max([axis, skipna, level, numeric_only])	Return the maximum of the values for the requested axis.
mean([axis, skipna, level, numeric_only])	Return the mean of the values for the requested axis.
median([axis, skipna, level, numeric_only])	Return the median of the values for the requested axis.
melt([id_vars, value_vars, var_name, ...])	Unpivot a DataFrame from wide to long format, optionally leaving identifiers set.
memory_usage([index, deep])	Return the memory usage of each column in bytes.
merge(right[, how, on, left_on, right_on, ...])	Merge DataFrame or named Series objects with a database-style join.

continues on next page

Table 59 – continued from previous page

min([axis, skipna, level, numeric_only])	Return the minimum of the values for the requested axis.
mod(other[, axis, level, fill_value])	Get Modulo of dataframe and other, element-wise (binary operator *mod*).
mode([axis, numeric_only, dropna])	Get the mode(s) of each element along the selected axis.
mul(other[, axis, level, fill_value])	Get Multiplication of dataframe and other, element-wise (binary operator *mul*).
multiply(other[, axis, level, fill_value])	Get Multiplication of dataframe and other, element-wise (binary operator *mul*).
ne(other[, axis, level])	Get Not equal to of dataframe and other, element-wise (binary operator *ne*).
nlargest(n, columns[, keep])	Return the first *n* rows ordered by *columns* in descending order.
notna()	Detect existing (non-missing) values.
notnull()	Detect existing (non-missing) values.
nsmallest(n, columns[, keep])	Return the first *n* rows ordered by *columns* in ascending order.
nunique([axis, dropna])	Count distinct observations over requested axis.
pad([axis, inplace, limit, downcast])	Synonym for DataFrame.fillna() with method='ffill'.
pct_change([periods, fill_method, limit, freq])	Percentage change between the current and a prior element.
pipe(func, *args, **kwargs)	Apply func(self, *args, **kwargs).
pivot([index, columns, values])	Return reshaped DataFrame organized by given index / column values.
pivot_table([values, index, columns, ...])	Create a spreadsheet-style pivot table as a DataFrame.
plot	alias of pandas.plotting._core.PlotAccessor
pop(item)	Return item and drop from frame.
pow(other[, axis, level, fill_value])	Get Exponential power of dataframe and other, element-wise (binary operator *pow*).
prod([axis, skipna, level, numeric_only, ...])	Return the product of the values for the requested axis.
product([axis, skipna, level, numeric_only, ...])	Return the product of the values for the requested axis.
quantile([q, axis, numeric_only, interpolation])	Return values at the given quantile over requested axis.
query(expr[, inplace])	Query the columns of a DataFrame with a boolean expression.
radd(other[, axis, level, fill_value])	Get Addition of dataframe and other, element-wise (binary operator *radd*).
rank([axis, method, numeric_only, ...])	Compute numerical data ranks (1 through n) along axis.
rdiv(other[, axis, level, fill_value])	Get Floating division of dataframe and other, element-wise (binary operator *rtruediv*).
reindex(**kwargs)	Conform Series/DataFrame to new index with optional filling logic.
reindex_like(other[, method, copy, limit, ...])	Return an object with matching indices as other object.

continues on next page

Table 59 – continued from previous page

rename(**kwargs)	Alter axes labels.
rename_axis(**kwargs)	Set the name of the axis for the index or columns.
reorder_levels(order[, axis])	Rearrange index levels using input order.
replace([to_replace, value, inplace, limit, ...])	Replace values given in *to_replace* with *value*.
resample(rule[, axis, closed, label, ...])	Resample time-series data.
reset_index([level, drop, inplace, ...])	Reset the index, or a level of it.
rfloordiv(other[, axis, level, fill_value])	Get Integer division of dataframe and other, element-wise (binary operator *rfloordiv*).
rmod(other[, axis, level, fill_value])	Get Modulo of dataframe and other, element-wise (binary operator *rmod*).
rmul(other[, axis, level, fill_value])	Get Multiplication of dataframe and other, element-wise (binary operator *rmul*).
rolling(window[, min_periods, center, ...])	Provide rolling window calculations.
round([decimals])	Round a DataFrame to a variable number of decimal places.
rpow(other[, axis, level, fill_value])	Get Exponential power of dataframe and other, element-wise (binary operator *rpow*).
rsub(other[, axis, level, fill_value])	Get Subtraction of dataframe and other, element-wise (binary operator *rsub*).
rtruediv(other[, axis, level, fill_value])	Get Floating division of dataframe and other, element-wise (binary operator *rtruediv*).
sample([n, frac, replace, weights, ...])	Return a random sample of items from an axis of object.
select_dtypes([include, exclude])	Return a subset of the DataFrame's columns based on the column dtypes.
sem([axis, skipna, level, ddof, numeric_only])	Return unbiased standard error of the mean over requested axis.
set_axis(labels[, axis, inplace])	Assign desired index to given axis.
set_index(keys[, drop, append, inplace, ...])	Set the DataFrame index using existing columns.
shift([periods, freq, axis, fill_value])	Shift index by desired number of periods with an optional time *freq*.
skew([axis, skipna, level, numeric_only])	Return unbiased skew over requested axis.
slice_shift([periods, axis])	Equivalent to *shift* without copying data.
sort_index([axis, level, ascending, ...])	Sort object by labels (along an axis).
sort_values(by[, axis, ascending, inplace, ...])	Sort by the values along either axis.
sparse	alias of pandas.core.arrays.sparse.accessor.SparseFrameAccessor
squeeze([axis])	Squeeze 1 dimensional axis objects into scalars.
stack([level, dropna])	Stack the prescribed level(s) from columns to index.
std([axis, skipna, level, ddof, numeric_only])	Return sample standard deviation over requested axis.
sub(other[, axis, level, fill_value])	Get Subtraction of dataframe and other, element-wise (binary operator *sub*).
subtract(other[, axis, level, fill_value])	Get Subtraction of dataframe and other, element-wise (binary operator *sub*).
sum([axis, skipna, level, numeric_only, ...])	Return the sum of the values for the requested axis.
swapaxes(axis1, axis2[, copy])	Interchange axes and swap values axes appropriately.
swaplevel([i, j, axis])	Swap levels i and j in a MultiIndex on a particular axis.
tail([n])	Return the last *n* rows.

continues on next page

Table 59 – continued from previous page

take(indices[, axis, is_copy])	Return the elements in the given *positional* indices along an axis.
to_clipboard([excel, sep])	Copy object to the system clipboard.
to_csv([path_or_buf, sep, na_rep, ...])	Write object to a comma-separated values (csv) file.
to_dict([orient, into])	Convert the DataFrame to a dictionary.
to_excel(excel_writer[, sheet_name, na_rep, ...])	Write object to an Excel sheet.
to_feather(**kwargs)	Write a DataFrame to the binary Feather format.
to_gbq(destination_table[, project_id, ...])	Write a DataFrame to a Google BigQuery table.
to_hdf(path_or_buf, key[, mode, complevel, ...])	Write the contained data to an HDF5 file using HDFStore.
to_html([buf, columns, col_space, header, ...])	Render a DataFrame as an HTML table.
to_json([path_or_buf, orient, date_format, ...])	Convert the object to a JSON string.
to_latex([buf, columns, col_space, header, ...])	Render object to a LaTeX tabular, longtable, or nested table/tabular.
to_markdown([buf, mode, index])	Print DataFrame in Markdown-friendly format.
to_numpy([dtype, copy, na_value])	Convert the DataFrame to a NumPy array.
to_parquet(**kwargs)	Write a DataFrame to the binary parquet format.
to_period([freq, axis, copy])	Convert DataFrame from DatetimeIndex to PeriodIndex.
to_pickle(path[, compression, protocol])	Pickle (serialize) object to file.
to_records([index, column_dtypes, index_dtypes])	Convert DataFrame to a NumPy record array.
to_sql(name, con[, schema, if_exists, ...])	Write records stored in a DataFrame to a SQL database.
to_stata(**kwargs)	Export DataFrame object to Stata dta format.
to_string([buf, columns, col_space, header, ...])	Render a DataFrame to a console-friendly tabular output.
to_timestamp([freq, how, axis, copy])	Cast to DatetimeIndex of timestamps, at *beginning* of period.
to_xarray()	Return an xarray object from the pandas object.
transform(func[, axis])	Call `func` on self producing a DataFrame with transformed values.
transpose(*args[, copy])	Transpose index and columns.
truediv(other[, axis, level, fill_value])	Get Floating division of dataframe and other, element-wise (binary operator *truediv*).
truncate([before, after, axis, copy])	Truncate a Series or DataFrame before and after some index value.
tshift([periods, freq, axis])	(DEPRECATED) Shift the time index, using the index's frequency if available.
tz_convert(tz[, axis, level, copy])	Convert tz-aware axis to target time zone.
tz_localize(tz[, axis, level, copy, ...])	Localize tz-naive index of a Series or DataFrame to target time zone.
unstack([level, fill_value])	Pivot a level of the (necessarily hierarchical) index labels.
update(other[, join, overwrite, ...])	Modify in place using non-NA values from another DataFrame.
value_counts([subset, normalize, sort, ...])	Return a Series containing counts of unique rows in the DataFrame.
var([axis, skipna, level, ddof, numeric_only])	Return unbiased variance over requested axis.
where(cond[, other, inplace, axis, level, ...])	Replace values where the condition is False.

continues on next page

Table 59 – continued from previous page

xs(key[, axis, level, drop_level])	Return cross-section from the Series/DataFrame.

pandas.DataFrame.abs

DataFrame.**abs**()

Return a Series/DataFrame with absolute numeric value of each element.

This function only applies to elements that are all numeric.

Returns

abs Series/DataFrame containing the absolute value of each element.

See also:

numpy.absolute Calculate the absolute value element-wise.

Notes

For `complex` inputs, `1.2 + 1j`, the absolute value is $\sqrt{a^2 + b^2}$.

Examples

Absolute numeric values in a Series.

```
>>> s = pd.Series([-1.10, 2, -3.33, 4])
>>> s.abs()
0    1.10
1    2.00
2    3.33
3    4.00
dtype: float64
```

Absolute numeric values in a Series with complex numbers.

```
>>> s = pd.Series([1.2 + 1j])
>>> s.abs()
0    1.56205
dtype: float64
```

Absolute numeric values in a Series with a Timedelta element.

```
>>> s = pd.Series([pd.Timedelta('1 days')])
>>> s.abs()
0   1 days
dtype: timedelta64[ns]
```

Select rows with data closest to certain value using argsort (from StackOverflow).

```
>>> df = pd.DataFrame({
...     'a': [4, 5, 6, 7],
...     'b': [10, 20, 30, 40],
...     'c': [100, 50, -30, -50]
... })
```

(continues on next page)

(continued from previous page)

```
>>> df
     a    b    c
0    4   10  100
1    5   20   50
2    6   30  -30
3    7   40  -50
>>> df.loc[(df.c - 43).abs().argsort()]
     a    b    c
1    5   20   50
0    4   10  100
2    6   30  -30
3    7   40  -50
```

pandas.DataFrame.add

DataFrame.**add**(*other*, *axis='columns'*, *level=None*, *fill_value=None*)

Get Addition of dataframe and other, element-wise (binary operator *add*).

Equivalent to `dataframe + other`, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, *radd*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: +, -, *, /, //, %, **.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

See also:

DataFrame.add Add DataFrames.

DataFrame.sub Subtract DataFrames.

DataFrame.mul Multiply DataFrames.

DataFrame.div Divide DataFrames (float division).

DataFrame.truediv Divide DataFrames (float division).

DataFrame.floordiv Divide DataFrames (integer division).

DataFrame.mod Calculate modulo (remainder after division).

DataFrame.pow Calculate exponential power.

Notes

Mismatched indices will be unioned together.

Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                   index=['circle', 'triangle', 'rectangle'])
>>> df
           angles  degrees
circle          0      360
triangle        3      180
rectangle       4      360
```

Add a scalar with operator version which return the same results.

```
>>> df + 1
           angles  degrees
circle          1      361
triangle        4      181
rectangle       5      361
```

```
>>> df.add(1)
           angles  degrees
circle          1      361
triangle        4      181
rectangle       5      361
```

Divide by constant with reverse version.

```
>>> df.div(10)
           angles  degrees
circle        0.0     36.0
triangle      0.3     18.0
rectangle     0.4     36.0
```

```
>>> df.rdiv(10)
             angles   degrees
circle          inf  0.027778
triangle   3.333333  0.055556
rectangle  2.500000  0.027778
```

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
           angles  degrees
circle         -1      358
triangle        2      178
rectangle       3      358
```

```
>>> df.sub([1, 2], axis='columns')
           angles  degrees
circle         -1      358
triangle        2      178
rectangle       3      358
```

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...         axis='index')
           angles  degrees
circle         -1      359
triangle        2      179
rectangle       3      359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                      index=['circle', 'triangle', 'rectangle'])
>>> other
           angles
circle          0
triangle        3
rectangle       4
```

```
>>> df * other
           angles  degrees
circle          0      NaN
triangle        9      NaN
rectangle      16      NaN
```

```
>>> df.mul(other, fill_value=0)
           angles  degrees
circle          0      0.0
triangle        9      0.0
rectangle      16      0.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                              'degrees': [360, 180, 360, 360, 540, 720]},
...                             index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                    ['circle', 'triangle', 'rectangle',
...                                     'square', 'pentagon', 'hexagon']])
>>> df_multindex
             angles  degrees
A circle          0      360
  triangle        3      180
  rectangle       4      360
B square          4      360
  pentagon        5      540
  hexagon         6      720
```

```
>>> df.div(df_multindex, level=1, fill_value=0)
             angles  degrees
A circle        NaN      1.0
  triangle      1.0      1.0
  rectangle     1.0      1.0
B square        0.0      0.0
  pentagon      0.0      0.0
  hexagon       0.0      0.0
```

pandas.DataFrame.add_prefix

DataFrame.**add_prefix**(*prefix*)

Prefix labels with string *prefix*.

For Series, the row labels are prefixed. For DataFrame, the column labels are prefixed.

Parameters

prefix [str] The string to add before each label.

Returns

Series or DataFrame New Series or DataFrame with updated labels.

See also:

Series.add_suffix Suffix row labels with string *suffix*.

DataFrame.add_suffix Suffix column labels with string *suffix*.

Examples

```
>>> s = pd.Series([1, 2, 3, 4])
>>> s
0    1
1    2
2    3
3    4
dtype: int64
```

```
>>> s.add_prefix('item_')
item_0    1
item_1    2
item_2    3
item_3    4
dtype: int64
```

```
>>> df = pd.DataFrame({'A': [1, 2, 3, 4], 'B': [3, 4, 5, 6]})
>>> df
   A  B
0  1  3
1  2  4
2  3  5
3  4  6
```

```
>>> df.add_prefix('col_')
     col_A  col_B
0       1       3
1       2       4
2       3       5
3       4       6
```

pandas.DataFrame.add_suffix

DataFrame.**add_suffix**(*suffix*)

Suffix labels with string *suffix*.

For Series, the row labels are suffixed. For DataFrame, the column labels are suffixed.

Parameters

suffix [str] The string to add after each label.

Returns

Series or DataFrame New Series or DataFrame with updated labels.

See also:

Series.add_prefix Prefix row labels with string *prefix*.

DataFrame.add_prefix Prefix column labels with string *prefix*.

Examples

```
>>> s = pd.Series([1, 2, 3, 4])
>>> s
0    1
1    2
2    3
3    4
dtype: int64
```

```
>>> s.add_suffix('_item')
0_item    1
1_item    2
2_item    3
3_item    4
dtype: int64
```

```
>>> df = pd.DataFrame({'A': [1, 2, 3, 4], 'B': [3, 4, 5, 6]})
>>> df
   A  B
0  1  3
1  2  4
2  3  5
3  4  6
```

```
>>> df.add_suffix('_col')
     A_col  B_col
0       1       3
1       2       4
2       3       5
3       4       6
```

pandas.DataFrame.agg

DataFrame.**agg**(*func=None*, *axis=0*, **args*, ***kwargs*)

Aggregate using one or more operations over the specified axis.

New in version 0.20.0.

Parameters

func [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a DataFrame or when passed to DataFrame.apply.

Accepted combinations are:

- function
- string function name
- list of functions and/or function names, e.g. `[np.sum, 'mean']`
- dict of axis labels -> functions, function names or list of such.

axis [{0 or 'index', 1 or 'columns'}, default 0] If 0 or 'index': apply function to each column. If 1 or 'columns': apply function to each row.

***args** Positional arguments to pass to *func*.

****kwargs** Keyword arguments to pass to *func*.

Returns

scalar, Series or DataFrame The return can be:

- scalar : when Series.agg is called with single function
- Series : when DataFrame.agg is called with a single function
- DataFrame : when DataFrame.agg is called with several functions

Return scalar, Series or DataFrame.

The aggregation operations are always performed over an axis, either the index (default) or the column axis. This behavior is different from *numpy* aggregation functions (*mean*, *median*, *prod*, *sum*, *std*, *var*), where the default is to compute the aggregation of the flattened array, e.g., `numpy.mean(arr_2d)` as opposed to `numpy.mean(arr_2d, axis=0)`.

***agg* is an alias for *aggregate*. Use the alias.**

See also:

DataFrame.apply Perform any type of operations.

DataFrame.transform Perform transformation type operations.

core.groupby.GroupBy Perform operations over groups.

core.resample.Resampler Perform operations over resampled bins.

core.window.Rolling Perform operations over rolling window.

core.window.Expanding Perform operations over expanding window.

core.window.ExponentialMovingWindow Perform operation over exponential weighted window.

Notes

agg is an alias for *aggregate*. Use the alias.

A passed user-defined-function will be passed a Series for evaluation.

Examples

```
>>> df = pd.DataFrame([[1, 2, 3],
...                    [4, 5, 6],
...                    [7, 8, 9],
...                    [np.nan, np.nan, np.nan]],
...                   columns=['A', 'B', 'C'])
```

Aggregate these functions over the rows.

```
>>> df.agg(['sum', 'min'])
        A     B     C
sum  12.0  15.0  18.0
min   1.0   2.0   3.0
```

Different aggregations per column.

```
>>> df.agg({'A' : ['sum', 'min'], 'B' : ['min', 'max']})
        A    B
max   NaN  8.0
min   1.0  2.0
sum  12.0  NaN
```

Aggregate over the columns.

```
>>> df.agg("mean", axis="columns")
0    2.0
1    5.0
2    8.0
3    NaN
dtype: float64
```

pandas.DataFrame.aggregate

DataFrame.**aggregate**(*func=None*, *axis=0*, **args*, ***kwargs*)

Aggregate using one or more operations over the specified axis.

New in version 0.20.0.

Parameters

func [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a DataFrame or when passed to DataFrame.apply.

Accepted combinations are:

- function

- string function name
- list of functions and/or function names, e.g. `[np.sum, 'mean']`
- dict of axis labels -> functions, function names or list of such.

axis [{0 or 'index', 1 or 'columns'}, default 0] If 0 or 'index': apply function to each column. If 1 or 'columns': apply function to each row.

***args** Positional arguments to pass to *func*.

****kwargs** Keyword arguments to pass to *func*.

Returns

scalar, Series or DataFrame The return can be:

- scalar : when Series.agg is called with single function
- Series : when DataFrame.agg is called with a single function
- DataFrame : when DataFrame.agg is called with several functions

Return scalar, Series or DataFrame.

The aggregation operations are always performed over an axis, either the index (default) or the column axis. This behavior is different from *numpy* aggregation functions (*mean*, *median*, *prod*, *sum*, *std*, *var*), where the default is to compute the aggregation of the flattened array, e.g., `numpy.mean(arr_2d)` as opposed to `numpy.mean(arr_2d, axis=0)`.

***agg* is an alias for *aggregate*. Use the alias.**

See also:

DataFrame.apply Perform any type of operations.

DataFrame.transform Perform transformation type operations.

`core.groupby.GroupBy` Perform operations over groups.

`core.resample.Resampler` Perform operations over resampled bins.

`core.window.Rolling` Perform operations over rolling window.

`core.window.Expanding` Perform operations over expanding window.

`core.window.ExponentialMovingWindow` Perform operation over exponential weighted window.

Notes

agg is an alias for *aggregate*. Use the alias.

A passed user-defined-function will be passed a Series for evaluation.

Examples

```
>>> df = pd.DataFrame([[1, 2, 3],
...                    [4, 5, 6],
...                    [7, 8, 9],
...                    [np.nan, np.nan, np.nan]],
...                   columns=['A', 'B', 'C'])
```

Aggregate these functions over the rows.

```
>>> df.agg(['sum', 'min'])
        A     B     C
sum  12.0  15.0  18.0
min   1.0   2.0   3.0
```

Different aggregations per column.

```
>>> df.agg({'A' : ['sum', 'min'], 'B' : ['min', 'max']})
        A    B
max   NaN  8.0
min   1.0  2.0
sum  12.0  NaN
```

Aggregate over the columns.

```
>>> df.agg("mean", axis="columns")
0    2.0
1    5.0
2    8.0
3    NaN
dtype: float64
```

pandas.DataFrame.align

DataFrame.**align**(*other*, *join='outer'*, *axis=None*, *level=None*, *copy=True*, *fill_value=None*, *method=None*, *limit=None*, *fill_axis=0*, *broadcast_axis=None*)

Align two objects on their axes with the specified join method.

Join method is specified for each axis Index.

Parameters

other [DataFrame or Series]

join [{'outer', 'inner', 'left', 'right'}, default 'outer']

axis [allowed axis of the other object, default None] Align on index (0), columns (1), or both (None).

level [int or level name, default None] Broadcast across a level, matching Index values on the passed MultiIndex level.

copy [bool, default True] Always returns new objects. If copy=False and no reindexing is required then original objects are returned.

fill_value [scalar, default np.NaN] Value to use for missing values. Defaults to NaN, but can be any "compatible" value.

method [{'backfill', 'bfill', 'pad', 'ffill', None}, default None] Method to use for filling holes in reindexed Series:

- pad / ffill: propagate last valid observation forward to next valid.
- backfill / bfill: use NEXT valid observation to fill gap.

limit [int, default None] If method is specified, this is the maximum number of consecutive NaN values to forward/backward fill. In other words, if there is a gap with more than this number of consecutive NaNs, it will only be partially filled. If method is not specified, this is the maximum number of entries along the entire axis where NaNs will be filled. Must be greater than 0 if not None.

fill_axis [{0 or 'index', 1 or 'columns'}, default 0] Filling axis, method and limit.

broadcast_axis [{0 or 'index', 1 or 'columns'}, default None] Broadcast values along this axis, if aligning two objects of different dimensions.

Returns

(left, right) [(DataFrame, type of other)] Aligned objects.

pandas.DataFrame.all

DataFrame.**all**(*axis=0*, *bool_only=None*, *skipna=True*, *level=None*, ***kwargs*)

Return whether all elements are True, potentially over an axis.

Returns True unless there at least one element within a series or along a Dataframe axis that is False or equivalent (e.g. zero or empty).

Parameters

axis [{0 or 'index', 1 or 'columns', None}, default 0] Indicate which axis or axes should be reduced.

- 0 / 'index' : reduce the index, return a Series whose index is the original column labels.
- 1 / 'columns' : reduce the columns, return a Series whose index is the original index.
- None : reduce all axes, return a scalar.

bool_only [bool, default None] Include only boolean columns. If None, will attempt to use everything, then use only boolean data. Not implemented for Series.

skipna [bool, default True] Exclude NA/null values. If the entire row/column is NA and skipna is True, then the result will be True, as for an empty row/column. If skipna is False, then NA are treated as True, because these are not equal to zero.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

****kwargs** [any, default None] Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

Series or DataFrame If level is specified, then, DataFrame is returned; otherwise, Series is returned.

See also:

Series.all Return True if all elements are True.

DataFrame.any Return True if one (or more) elements are True.

Examples

Series

```
>>> pd.Series([True, True]).all()
True
>>> pd.Series([True, False]).all()
False
>>> pd.Series([]).all()
True
>>> pd.Series([np.nan]).all()
True
>>> pd.Series([np.nan]).all(skipna=False)
True
```

DataFrames

Create a dataframe from a dictionary.

```
>>> df = pd.DataFrame({'col1': [True, True], 'col2': [True, False]})
>>> df
   col1   col2
0  True   True
1  True  False
```

Default behaviour checks if column-wise values all return True.

```
>>> df.all()
col1     True
col2    False
dtype: bool
```

Specify `axis='columns'` to check if row-wise values all return True.

```
>>> df.all(axis='columns')
0     True
1    False
dtype: bool
```

Or `axis=None` for whether every value is True.

```
>>> df.all(axis=None)
False
```

pandas.DataFrame.any

DataFrame.**any**(*axis=0*, *bool_only=None*, *skipna=True*, *level=None*, ***kwargs*)

Return whether any element is True, potentially over an axis.

Returns False unless there at least one element within a series or along a Dataframe axis that is True or equivalent (e.g. non-zero or non-empty).

Parameters

axis [{0 or 'index', 1 or 'columns', None}, default 0] Indicate which axis or axes should be reduced.

- 0 / 'index' : reduce the index, return a Series whose index is the original column labels.
- 1 / 'columns' : reduce the columns, return a Series whose index is the original index.
- None : reduce all axes, return a scalar.

bool_only [bool, default None] Include only boolean columns. If None, will attempt to use everything, then use only boolean data. Not implemented for Series.

skipna [bool, default True] Exclude NA/null values. If the entire row/column is NA and skipna is True, then the result will be False, as for an empty row/column. If skipna is False, then NA are treated as True, because these are not equal to zero.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

****kwargs** [any, default None] Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

Series or DataFrame If level is specified, then, DataFrame is returned; otherwise, Series is returned.

See also:

numpy.any Numpy version of this method.

Series.any Return whether any element is True.

Series.all Return whether all elements are True.

DataFrame.any Return whether any element is True over requested axis.

DataFrame.all Return whether all elements are True over requested axis.

Examples

Series

For Series input, the output is a scalar indicating whether any element is True.

```
>>> pd.Series([False, False]).any()
False
>>> pd.Series([True, False]).any()
True
>>> pd.Series([]).any()
```

(continues on next page)

(continued from previous page)

```
False
>>> pd.Series([np.nan]).any()
False
>>> pd.Series([np.nan]).any(skipna=False)
True
```

DataFrame

Whether each column contains at least one True element (the default).

```
>>> df = pd.DataFrame({"A": [1, 2], "B": [0, 2], "C": [0, 0]})
>>> df
   A  B  C
0  1  0  0
1  2  2  0
```

```
>>> df.any()
A     True
B     True
C    False
dtype: bool
```

Aggregating over the columns.

```
>>> df = pd.DataFrame({"A": [True, False], "B": [1, 2]})
>>> df
       A  B
0   True  1
1  False  2
```

```
>>> df.any(axis='columns')
0    True
1    True
dtype: bool
```

```
>>> df = pd.DataFrame({"A": [True, False], "B": [1, 0]})
>>> df
       A  B
0   True  1
1  False  0
```

```
>>> df.any(axis='columns')
0    True
1    False
dtype: bool
```

Aggregating over the entire DataFrame with `axis=None`.

```
>>> df.any(axis=None)
True
```

any for an empty DataFrame is an empty Series.

```
>>> pd.DataFrame([]).any()
Series([], dtype: bool)
```

pandas.DataFrame.append

DataFrame.**append**(*other*, *ignore_index=False*, *verify_integrity=False*, *sort=False*)

Append rows of *other* to the end of caller, returning a new object.

Columns in *other* that are not in the caller are added as new columns.

Parameters

other [DataFrame or Series/dict-like object, or list of these] The data to append.

ignore_index [bool, default False] If True, the resulting axis will be labeled 0, 1, . . . , n - 1.

verify_integrity [bool, default False] If True, raise ValueError on creating index with duplicates.

sort [bool, default False] Sort columns if the columns of *self* and *other* are not aligned.

New in version 0.23.0.

Changed in version 1.0.0: Changed to not sort by default.

Returns

DataFrame

See also:

concat General function to concatenate DataFrame or Series objects.

Notes

If a list of dict/series is passed and the keys are all contained in the DataFrame's index, the order of the columns in the resulting DataFrame will be unchanged.

Iteratively appending rows to a DataFrame can be more computationally intensive than a single concatenate. A better solution is to append those rows to a list and then concatenate the list with the original DataFrame all at once.

Examples

```
>>> df = pd.DataFrame([[1, 2], [3, 4]], columns=list('AB'))
>>> df
   A  B
0  1  2
1  3  4
>>> df2 = pd.DataFrame([[5, 6], [7, 8]], columns=list('AB'))
>>> df.append(df2)
   A  B
0  1  2
1  3  4
0  5  6
1  7  8
```

With *ignore_index* set to True:

```
>>> df.append(df2, ignore_index=True)
   A  B
0  1  2
1  3  4
2  5  6
3  7  8
```

The following, while not recommended methods for generating DataFrames, show two ways to generate a DataFrame from multiple data sources.

Less efficient:

```
>>> df = pd.DataFrame(columns=['A'])
>>> for i in range(5):
...     df = df.append({'A': i}, ignore_index=True)
>>> df
   A
0  0
1  1
2  2
3  3
4  4
```

More efficient:

```
>>> pd.concat([pd.DataFrame([i], columns=['A']) for i in range(5)],
...           ignore_index=True)
   A
0  0
1  1
2  2
3  3
4  4
```

pandas.DataFrame.apply

`DataFrame.`**`apply`**(*func*, *axis=0*, *raw=False*, *result_type=None*, *args=()*, ***kwds*)

Apply a function along an axis of the DataFrame.

Objects passed to the function are Series objects whose index is either the DataFrame's index (`axis=0`) or the DataFrame's columns (`axis=1`). By default (`result_type=None`), the final return type is inferred from the return type of the applied function. Otherwise, it depends on the *result_type* argument.

Parameters

func [function] Function to apply to each column or row.

axis [{0 or 'index', 1 or 'columns'}, default 0] Axis along which the function is applied:

- 0 or 'index': apply function to each column.
- 1 or 'columns': apply function to each row.

raw [bool, default False] Determines if row or column is passed as a Series or ndarray object:

- `False` : passes each row or column as a Series to the function.

- `True` : the passed function will receive ndarray objects instead. If you are just applying a NumPy reduction function this will achieve much better performance.

result_type [{'expand', 'reduce', 'broadcast', None}, default None] These only act when `axis=1` (columns):

- 'expand' : list-like results will be turned into columns.
- 'reduce' : returns a Series if possible rather than expanding list-like results. This is the opposite of 'expand'.
- 'broadcast' : results will be broadcast to the original shape of the DataFrame, the original index and columns will be retained.

The default behaviour (None) depends on the return value of the applied function: list-like results will be returned as a Series of those. However if the apply function returns a Series these are expanded to columns.

New in version 0.23.0.

args [tuple] Positional arguments to pass to *func* in addition to the array/series.

****kwds** Additional keyword arguments to pass as keywords arguments to *func*.

Returns

Series or DataFrame Result of applying `func` along the given axis of the DataFrame.

See also:

DataFrame.applymap For elementwise operations.

DataFrame.aggregate Only perform aggregating type operations.

DataFrame.transform Only perform transforming type operations.

Examples

```
>>> df = pd.DataFrame([[4, 9]] * 3, columns=['A', 'B'])
>>> df
   A  B
0  4  9
1  4  9
2  4  9
```

Using a numpy universal function (in this case the same as `np.sqrt(df)`):

```
>>> df.apply(np.sqrt)
     A    B
0  2.0  3.0
1  2.0  3.0
2  2.0  3.0
```

Using a reducing function on either axis

```
>>> df.apply(np.sum, axis=0)
A    12
B    27
dtype: int64
```

```
>>> df.apply(np.sum, axis=1)
0    13
1    13
2    13
dtype: int64
```

Returning a list-like will result in a Series

```
>>> df.apply(lambda x: [1, 2], axis=1)
0    [1, 2]
1    [1, 2]
2    [1, 2]
dtype: object
```

Passing `result_type='expand'` will expand list-like results to columns of a Dataframe

```
>>> df.apply(lambda x: [1, 2], axis=1, result_type='expand')
   0  1
0  1  2
1  1  2
2  1  2
```

Returning a Series inside the function is similar to passing `result_type='expand'`. The resulting column names will be the Series index.

```
>>> df.apply(lambda x: pd.Series([1, 2], index=['foo', 'bar']), axis=1)
   foo  bar
0    1    2
1    1    2
2    1    2
```

Passing `result_type='broadcast'` will ensure the same shape result, whether list-like or scalar is returned by the function, and broadcast it along the axis. The resulting column names will be the originals.

```
>>> df.apply(lambda x: [1, 2], axis=1, result_type='broadcast')
   A  B
0  1  2
1  1  2
2  1  2
```

pandas.DataFrame.applymap

DataFrame.**applymap**(*func*)

Apply a function to a Dataframe elementwise.

This method applies a function that accepts and returns a scalar to every element of a DataFrame.

Parameters

func [callable] Python function, returns a single value from a single value.

Returns

DataFrame Transformed DataFrame.

See also:

DataFrame.apply Apply a function along input axis of DataFrame.

Examples

```
>>> df = pd.DataFrame([[1, 2.12], [3.356, 4.567]])
>>> df
       0      1
0  1.000  2.120
1  3.356  4.567
```

```
>>> df.applymap(lambda x: len(str(x)))
   0  1
0  3  4
1  5  5
```

Note that a vectorized version of *func* often exists, which will be much faster. You could square each number elementwise.

```
>>> df.applymap(lambda x: x**2)
           0          1
0   1.000000   4.494400
1  11.262736  20.857489
```

But it's better to avoid applymap in that case.

```
>>> df ** 2
           0          1
0   1.000000   4.494400
1  11.262736  20.857489
```

pandas.DataFrame.asfreq

DataFrame.**asfreq**(*freq*, *method=None*, *how=None*, *normalize=False*, *fill_value=None*)

Convert TimeSeries to specified frequency.

Optionally provide filling method to pad/backfill missing values.

Returns the original data conformed to a new index with the specified frequency. `resample` is more appropriate if an operation, such as summarization, is necessary to represent the data at the new frequency.

Parameters

freq [DateOffset or str] Frequency DateOffset or string.

method [{'backfill'/'bfill', 'pad'/'ffill'}, default None] Method to use for filling holes in reindexed Series (note this does not fill NaNs that already were present):

- 'pad' / 'ffill': propagate last valid observation forward to next valid
- 'backfill' / 'bfill': use NEXT valid observation to fill.

how [{'start', 'end'}, default end] For PeriodIndex only (see PeriodIndex.asfreq).

normalize [bool, default False] Whether to reset output index to midnight.

fill_value [scalar, optional] Value to use for missing values, applied during upsampling (note this does not fill NaNs that already were present).

Returns

Same type as caller Object converted to the specified frequency.

See also:

reindex Conform DataFrame to new index with optional filling logic.

Notes

To learn more about the frequency strings, please see this link.

Examples

Start by creating a series with 4 one minute timestamps.

```
>>> index = pd.date_range('1/1/2000', periods=4, freq='T')
>>> series = pd.Series([0.0, None, 2.0, 3.0], index=index)
>>> df = pd.DataFrame({'s':series})
>>> df
                     s
2000-01-01 00:00:00    0.0
2000-01-01 00:01:00    NaN
2000-01-01 00:02:00    2.0
2000-01-01 00:03:00    3.0
```

Upsample the series into 30 second bins.

```
>>> df.asfreq(freq='30S')
                     s
2000-01-01 00:00:00    0.0
2000-01-01 00:00:30    NaN
2000-01-01 00:01:00    NaN
2000-01-01 00:01:30    NaN
2000-01-01 00:02:00    2.0
2000-01-01 00:02:30    NaN
2000-01-01 00:03:00    3.0
```

Upsample again, providing a `fill value`.

```
>>> df.asfreq(freq='30S', fill_value=9.0)
                     s
2000-01-01 00:00:00    0.0
2000-01-01 00:00:30    9.0
2000-01-01 00:01:00    NaN
2000-01-01 00:01:30    9.0
2000-01-01 00:02:00    2.0
2000-01-01 00:02:30    9.0
2000-01-01 00:03:00    3.0
```

Upsample again, providing a `method`.

```
>>> df.asfreq(freq='30S', method='bfill')
                     s
2000-01-01 00:00:00    0.0
2000-01-01 00:00:30    NaN
2000-01-01 00:01:00    NaN
2000-01-01 00:01:30    2.0
2000-01-01 00:02:00    2.0
```

(continues on next page)

(continued from previous page)

```
2000-01-01 00:02:30    3.0
2000-01-01 00:03:00    3.0
```

pandas.DataFrame.asof

DataFrame.**asof**(*where*, *subset=None*)

Return the last row(s) without any NaNs before *where*.

The last row (for each element in *where*, if list) without any NaN is taken. In case of a *DataFrame*, the last row without NaN considering only the subset of columns (if not *None*)

If there is no good value, NaN is returned for a Series or a Series of NaN values for a DataFrame

Parameters

where [date or array-like of dates] Date(s) before which the last row(s) are returned.

subset [str or array-like of str, default *None*] For DataFrame, if not *None*, only use these columns to check for NaNs.

Returns

scalar, Series, or DataFrame The return can be:

- scalar : when *self* is a Series and *where* is a scalar
- Series: when *self* is a Series and *where* is an array-like, or when *self* is a DataFrame and *where* is a scalar
- DataFrame : when *self* is a DataFrame and *where* is an array-like

Return scalar, Series, or DataFrame.

See also:

merge_asof Perform an asof merge. Similar to left join.

Notes

Dates are assumed to be sorted. Raises if this is not the case.

Examples

A Series and a scalar *where*.

```
>>> s = pd.Series([1, 2, np.nan, 4], index=[10, 20, 30, 40])
>>> s
10    1.0
20    2.0
30    NaN
40    4.0
dtype: float64
```

```
>>> s.asof(20)
2.0
```

For a sequence *where*, a Series is returned. The first value is NaN, because the first element of *where* is before the first index value.

```
>>> s.asof([5, 20])
5     NaN
20    2.0
dtype: float64
```

Missing values are not considered. The following is `2.0`, not NaN, even though NaN is at the index location for `30`.

```
>>> s.asof(30)
2.0
```

Take all columns into consideration

```
>>> df = pd.DataFrame({'a': [10, 20, 30, 40, 50],
...                    'b': [None, None, None, None, 500]},
...                   index=pd.DatetimeIndex(['2018-02-27 09:01:00',
...                                           '2018-02-27 09:02:00',
...                                           '2018-02-27 09:03:00',
...                                           '2018-02-27 09:04:00',
...                                           '2018-02-27 09:05:00']))
>>> df.asof(pd.DatetimeIndex(['2018-02-27 09:03:30',
...                           '2018-02-27 09:04:30']))
                     a   b
2018-02-27 09:03:30 NaN NaN
2018-02-27 09:04:30 NaN NaN
```

Take a single column into consideration

```
>>> df.asof(pd.DatetimeIndex(['2018-02-27 09:03:30',
...                           '2018-02-27 09:04:30']),
...          subset=['a'])
                       a   b
2018-02-27 09:03:30   30.0 NaN
2018-02-27 09:04:30   40.0 NaN
```

pandas.DataFrame.assign

`DataFrame.`**`assign`**`(**kwargs)`

Assign new columns to a DataFrame.

Returns a new object with all original columns in addition to new ones. Existing columns that are re-assigned will be overwritten.

Parameters

****kwargs** [dict of {str: callable or Series}] The column names are keywords. If the values are callable, they are computed on the DataFrame and assigned to the new columns. The callable must not change input DataFrame (though pandas doesn't check it). If the values are not callable, (e.g. a Series, scalar, or array), they are simply assigned.

Returns

DataFrame A new DataFrame with the new columns in addition to all the existing columns.

Notes

Assigning multiple columns within the same `assign` is possible. Later items in '**kwargs' may refer to newly created or modified columns in 'df'; items are computed and assigned into 'df' in order.

Changed in version 0.23.0: Keyword argument order is maintained.

Examples

```
>>> df = pd.DataFrame({'temp_c': [17.0, 25.0]},
...                   index=['Portland', 'Berkeley'])
>>> df
          temp_c
Portland    17.0
Berkeley    25.0
```

Where the value is a callable, evaluated on *df*:

```
>>> df.assign(temp_f=lambda x: x.temp_c * 9 / 5 + 32)
          temp_c  temp_f
Portland    17.0    62.6
Berkeley    25.0    77.0
```

Alternatively, the same behavior can be achieved by directly referencing an existing Series or sequence:

```
>>> df.assign(temp_f=df['temp_c'] * 9 / 5 + 32)
          temp_c  temp_f
Portland    17.0    62.6
Berkeley    25.0    77.0
```

You can create multiple columns within the same assign where one of the columns depends on another one defined within the same assign:

```
>>> df.assign(temp_f=lambda x: x['temp_c'] * 9 / 5 + 32,
...           temp_k=lambda x: (x['temp_f'] +  459.67) * 5 / 9)
          temp_c  temp_f  temp_k
Portland    17.0    62.6  290.15
Berkeley    25.0    77.0  298.15
```

pandas.DataFrame.astype

DataFrame.**astype**(*dtype*, *copy=True*, *errors='raise'*)

Cast a pandas object to a specified dtype `dtype`.

Parameters

dtype [data type, or dict of column name -> data type] Use a numpy.dtype or Python type to cast entire pandas object to the same type. Alternatively, use {col: dtype, ...}, where col is a column label and dtype is a numpy.dtype or Python type to cast one or more of the DataFrame's columns to column-specific types.

copy [bool, default True] Return a copy when `copy=True` (be very careful setting `copy=False` as changes to values then may propagate to other pandas objects).

errors [{'raise', 'ignore'}, default 'raise'] Control raising of exceptions on invalid data for provided dtype.

- `raise` : allow exceptions to be raised
- `ignore` : suppress exceptions. On error return original object.

Returns

casted [same type as caller]

See also:

to_datetime Convert argument to datetime.

to_timedelta Convert argument to timedelta.

to_numeric Convert argument to a numeric type.

numpy.ndarray.astype Cast a numpy array to a specified type.

Examples

Create a DataFrame:

```
>>> d = {'col1': [1, 2], 'col2': [3, 4]}
>>> df = pd.DataFrame(data=d)
>>> df.dtypes
col1    int64
col2    int64
dtype: object
```

Cast all columns to int32:

```
>>> df.astype('int32').dtypes
col1    int32
col2    int32
dtype: object
```

Cast col1 to int32 using a dictionary:

```
>>> df.astype({'col1': 'int32'}).dtypes
col1    int32
col2    int64
dtype: object
```

Create a series:

```
>>> ser = pd.Series([1, 2], dtype='int32')
>>> ser
0    1
1    2
dtype: int32
>>> ser.astype('int64')
0    1
1    2
dtype: int64
```

Convert to categorical type:

```
>>> ser.astype('category')
0    1
1    2
dtype: category
Categories (2, int64): [1, 2]
```

Convert to ordered categorical type with custom ordering:

```
>>> cat_dtype = pd.api.types.CategoricalDtype(
...     categories=[2, 1], ordered=True)
>>> ser.astype(cat_dtype)
0    1
1    2
dtype: category
Categories (2, int64): [2 < 1]
```

Note that using `copy=False` and changing data on a new pandas object may propagate changes:

```
>>> s1 = pd.Series([1, 2])
>>> s2 = s1.astype('int64', copy=False)
>>> s2[0] = 10
>>> s1  # note that s1[0] has changed too
0    10
1     2
dtype: int64
```

Create a series of dates:

```
>>> ser_date = pd.Series(pd.date_range('20200101', periods=3))
>>> ser_date
0   2020-01-01
1   2020-01-02
2   2020-01-03
dtype: datetime64[ns]
```

Datetimes are localized to UTC first before converting to the specified timezone:

```
>>> ser_date.astype('datetime64[ns, US/Eastern]')
0   2019-12-31 19:00:00-05:00
1   2020-01-01 19:00:00-05:00
2   2020-01-02 19:00:00-05:00
dtype: datetime64[ns, US/Eastern]
```

pandas.DataFrame.at_time

`DataFrame.`**`at_time`**(*time*, *asof=False*, *axis=None*)

Select values at particular time of day (e.g., 9:30AM).

Parameters

time [datetime.time or str]

axis [{0 or 'index', 1 or 'columns'}, default 0] New in version 0.24.0.

Returns

Series or DataFrame

Raises

TypeError If the index is not a *DatetimeIndex*

See also:

between_time Select values between particular times of the day.

first Select initial periods of time series based on a date offset.

last Select final periods of time series based on a date offset.

DatetimeIndex.indexer_at_time Get just the index locations for values at particular time of the day.

Examples

```
>>> i = pd.date_range('2018-04-09', periods=4, freq='12H')
>>> ts = pd.DataFrame({'A': [1, 2, 3, 4]}, index=i)
>>> ts
                     A
2018-04-09 00:00:00  1
2018-04-09 12:00:00  2
2018-04-10 00:00:00  3
2018-04-10 12:00:00  4
```

```
>>> ts.at_time('12:00')
                     A
2018-04-09 12:00:00  2
2018-04-10 12:00:00  4
```

pandas.DataFrame.backfill

DataFrame.**backfill**(*axis=None*, *inplace=False*, *limit=None*, *downcast=None*)

Synonym for *DataFrame.fillna()* with `method='bfill'`.

Returns

{klass} or None Object with missing values filled or None if `inplace=True`.

pandas.DataFrame.between_time

DataFrame.**between_time**(*start_time*, *end_time*, *include_start=True*, *include_end=True*, *axis=None*)

Select values between particular times of the day (e.g., 9:00-9:30 AM).

By setting `start_time` to be later than `end_time`, you can get the times that are *not* between the two times.

Parameters

start_time [datetime.time or str] Initial time as a time filter limit.

end_time [datetime.time or str] End time as a time filter limit.

include_start [bool, default True] Whether the start time needs to be included in the result.

include_end [bool, default True] Whether the end time needs to be included in the result.

axis [{0 or 'index', 1 or 'columns'}, default 0] Determine range time on index or columns value.

New in version 0.24.0.

Returns

Series or DataFrame Data from the original object filtered to the specified dates range.

Raises

TypeError If the index is not a *DatetimeIndex*

See also:

at_time Select values at a particular time of the day.

first Select initial periods of time series based on a date offset.

last Select final periods of time series based on a date offset.

DatetimeIndex.indexer_between_time Get just the index locations for values between particular times of the day.

Examples

```
>>> i = pd.date_range('2018-04-09', periods=4, freq='1D20min')
>>> ts = pd.DataFrame({'A': [1, 2, 3, 4]}, index=i)
>>> ts
                     A
2018-04-09 00:00:00  1
2018-04-10 00:20:00  2
2018-04-11 00:40:00  3
2018-04-12 01:00:00  4
```

```
>>> ts.between_time('0:15', '0:45')
                     A
2018-04-10 00:20:00  2
2018-04-11 00:40:00  3
```

You get the times that are *not* between two times by setting `start_time` later than `end_time`:

```
>>> ts.between_time('0:45', '0:15')
                     A
2018-04-09 00:00:00  1
2018-04-12 01:00:00  4
```

pandas.DataFrame.bfill

DataFrame.**bfill**(*axis=None*, *inplace=False*, *limit=None*, *downcast=None*)

Synonym for *DataFrame.fillna()* with `method='bfill'`.

Returns

{klass} or None Object with missing values filled or None if `inplace=True`.

pandas.DataFrame.bool

DataFrame.**bool**()

Return the bool of a single element Series or DataFrame.

This must be a boolean scalar value, either True or False. It will raise a ValueError if the Series or DataFrame does not have exactly 1 element, or that element is not boolean (integer values 0 and 1 will also raise an exception).

Returns

bool The value in the Series or DataFrame.

See also:

Series.astype Change the data type of a Series, including to boolean.

DataFrame.astype Change the data type of a DataFrame, including to boolean.

numpy.bool_ NumPy boolean data type, used by pandas for boolean values.

Examples

The method will only work for single element objects with a boolean value:

```
>>> pd.Series([True]).bool()
True
>>> pd.Series([False]).bool()
False
```

```
>>> pd.DataFrame({'col': [True]}).bool()
True
>>> pd.DataFrame({'col': [False]}).bool()
False
```

pandas.DataFrame.boxplot

DataFrame.**boxplot**(*column=None*, *by=None*, *ax=None*, *fontsize=None*, *rot=0*, *grid=True*, *figsize=None*, *layout=None*, *return_type=None*, *backend=None*, ***kwargs*)

Make a box plot from DataFrame columns.

Make a box-and-whisker plot from DataFrame columns, optionally grouped by some other columns. A box plot is a method for graphically depicting groups of numerical data through their quartiles. The box extends from the Q1 to Q3 quartile values of the data, with a line at the median (Q2). The whiskers extend from the edges of box to show the range of the data. By default, they extend no more than *1.5 * IQR (IQR = Q3 - Q1)* from the edges of the box, ending at the farthest data point within that interval. Outliers are plotted as separate dots.

For further details see Wikipedia's entry for boxplot.

Parameters

column [str or list of str, optional] Column name or list of names, or vector. Can be any valid input to *pandas.DataFrame.groupby()*.

by [str or array-like, optional] Column in the DataFrame to *pandas.DataFrame.groupby()*. One box-plot will be done per value of columns in *by*.

ax [object of class matplotlib.axes.Axes, optional] The matplotlib axes to be used by boxplot.

fontsize [float or str] Tick label font size in points or as a string (e.g., *large*).

rot [int or float, default 0] The rotation angle of labels (in degrees) with respect to the screen coordinate system.

grid [bool, default True] Setting this to True will show the grid.

figsize [A tuple (width, height) in inches] The size of the figure to create in matplotlib.

layout [tuple (rows, columns), optional] For example, (3, 5) will display the subplots using 3 columns and 5 rows, starting from the top-left.

return_type [{'axes', 'dict', 'both'} or None, default 'axes'] The kind of object to return. The default is `axes`.

- 'axes' returns the matplotlib axes the boxplot is drawn on.
- 'dict' returns a dictionary whose values are the matplotlib Lines of the boxplot.
- 'both' returns a namedtuple with the axes and dict.
- when grouping with `by`, a Series mapping columns to `return_type` is returned.

  If `return_type` is *None*, a NumPy array of axes with the same shape as `layout` is returned.

backend [str, default None] Backend to use instead of the backend specified in the option `plotting.backend`. For instance, 'matplotlib'. Alternatively, to specify the `plotting.backend` for the whole session, set `pd.options.plotting.backend`.

New in version 1.0.0.

****kwargs** All other plotting keyword arguments to be passed to `matplotlib.pyplot.boxplot()`.

Returns

result See Notes.

See also:

Series.plot.hist Make a histogram.

matplotlib.pyplot.boxplot Matplotlib equivalent plot.

Notes

The return type depends on the *return_type* parameter:

- 'axes' : object of class matplotlib.axes.Axes
- 'dict' : dict of matplotlib.lines.Line2D objects
- 'both' : a namedtuple with structure (ax, lines)

For data grouped with `by`, return a Series of the above or a numpy array:

- *Series*
- `array` (for `return_type = None`)

Use `return_type='dict'` when you want to tweak the appearance of the lines after plotting. In this case a dict containing the Lines making up the boxes, caps, fliers, medians, and whiskers is returned.

Examples

Boxplots can be created for every column in the dataframe by `df.boxplot()` or indicating the columns to be used:

```
>>> np.random.seed(1234)
>>> df = pd.DataFrame(np.random.randn(10, 4),
...                   columns=['Col1', 'Col2', 'Col3', 'Col4'])
>>> boxplot = df.boxplot(column=['Col1', 'Col2', 'Col3'])
```

Boxplots of variables distributions grouped by the values of a third variable can be created using the option `by`. For instance:

```
>>> df = pd.DataFrame(np.random.randn(10, 2),
...                   columns=['Col1', 'Col2'])
>>> df['X'] = pd.Series(['A', 'A', 'A', 'A', 'A',
...                      'B', 'B', 'B', 'B', 'B'])
>>> boxplot = df.boxplot(by='X')
```

A list of strings (i.e. `['X', 'Y']`) can be passed to boxplot in order to group the data by combination of the variables in the x-axis:

```
>>> df = pd.DataFrame(np.random.randn(10, 3),
...                   columns=['Col1', 'Col2', 'Col3'])
>>> df['X'] = pd.Series(['A', 'A', 'A', 'A', 'A',
...                      'B', 'B', 'B', 'B', 'B'])
>>> df['Y'] = pd.Series(['A', 'B', 'A', 'B', 'A',
...                      'B', 'A', 'B', 'A', 'B'])
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], by=['X', 'Y'])
```

The layout of boxplot can be adjusted giving a tuple to `layout`:

```
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], by='X',
...                      layout=(2, 1))
```

Additional formatting can be done to the boxplot, like suppressing the grid (`grid=False`), rotating the labels in the x-axis (i.e. `rot=45`) or changing the fontsize (i.e. `fontsize=15`):

```
>>> boxplot = df.boxplot(grid=False, rot=45, fontsize=15)
```

The parameter `return_type` can be used to select the type of element returned by *boxplot*. When `return_type='axes'` is selected, the matplotlib axes on which the boxplot is drawn are returned:

```
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], return_type='axes')
>>> type(boxplot)
<class 'matplotlib.axes._subplots.AxesSubplot'>
```

When grouping with `by`, a Series mapping columns to `return_type` is returned:

```
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], by='X',
...                      return_type='axes')
>>> type(boxplot)
<class 'pandas.core.series.Series'>
```

If `return_type` is *None*, a NumPy array of axes with the same shape as `layout` is returned:

```
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], by='X',
...                      return_type=None)
>>> type(boxplot)
<class 'numpy.ndarray'>
```

pandas.DataFrame.clip

DataFrame.**clip**(*lower=None*, *upper=None*, *axis=None*, *inplace=False*, **args*, ***kwargs*)

Trim values at input threshold(s).

Assigns values outside boundary to boundary values. Thresholds can be singular values or array like, and in the latter case the clipping is performed element-wise in the specified axis.

Parameters

lower [float or array_like, default None] Minimum threshold value. All values below this threshold will be set to it.

upper [float or array_like, default None] Maximum threshold value. All values above this threshold will be set to it.

axis [int or str axis name, optional] Align object with lower and upper along the given axis.

inplace [bool, default False] Whether to perform the operation in place on the data.

***args, **kwargs** Additional keywords have no effect but might be accepted for compatibility with numpy.

Returns

Series or DataFrame Same type as calling object with the values outside the clip boundaries replaced.

See also:

Series.clip Trim values at input threshold in series.

DataFrame.clip Trim values at input threshold in dataframe.

numpy.clip Clip (limit) the values in an array.

Examples

```
>>> data = {'col_0': [9, -3, 0, -1, 5], 'col_1': [-2, -7, 6, 8, -5]}
>>> df = pd.DataFrame(data)
>>> df
   col_0  col_1
0      9     -2
1     -3     -7
2      0      6
3     -1      8
4      5     -5
```

Clips per column using lower and upper thresholds:

```
>>> df.clip(-4, 6)
   col_0  col_1
0      6     -2
1     -3     -4
2      0      6
3     -1      6
4      5     -4
```

Clips using specific lower and upper thresholds per column element:

```
>>> t = pd.Series([2, -4, -1, 6, 3])
>>> t
0    2
1   -4
2   -1
3    6
4    3
dtype: int64
```

```
>>> df.clip(t, t + 4, axis=0)
   col_0  col_1
0      6      2
1     -3     -4
2      0      3
3      6      8
4      5      3
```

pandas.DataFrame.combine

DataFrame.**combine**(*other*, *func*, *fill_value=None*, *overwrite=True*)

Perform column-wise combine with another DataFrame.

Combines a DataFrame with *other* DataFrame using *func* to element-wise combine columns. The row and column indexes of the resulting DataFrame will be the union of the two.

Parameters

other [DataFrame] The DataFrame to merge column-wise.

func [function] Function that takes two series as inputs and return a Series or a scalar. Used to merge the two dataframes column by columns.

fill_value [scalar value, default None] The value to fill NaNs with prior to passing any column to the merge func.

overwrite [bool, default True] If True, columns in *self* that do not exist in *other* will be overwritten with NaNs.

Returns

DataFrame Combination of the provided DataFrames.

See also:

DataFrame.combine_first Combine two DataFrame objects and default to non-null values in frame calling the method.

Examples

Combine using a simple function that chooses the smaller column.

```
>>> df1 = pd.DataFrame({'A': [0, 0], 'B': [4, 4]})
>>> df2 = pd.DataFrame({'A': [1, 1], 'B': [3, 3]})
>>> take_smaller = lambda s1, s2: s1 if s1.sum() < s2.sum() else s2
>>> df1.combine(df2, take_smaller)
   A  B
0  0  3
1  0  3
```

Example using a true element-wise combine function.

```
>>> df1 = pd.DataFrame({'A': [5, 0], 'B': [2, 4]})
>>> df2 = pd.DataFrame({'A': [1, 1], 'B': [3, 3]})
>>> df1.combine(df2, np.minimum)
   A  B
0  1  2
1  0  3
```

Using *fill_value* fills Nones prior to passing the column to the merge function.

```
>>> df1 = pd.DataFrame({'A': [0, 0], 'B': [None, 4]})
>>> df2 = pd.DataFrame({'A': [1, 1], 'B': [3, 3]})
>>> df1.combine(df2, take_smaller, fill_value=-5)
   A    B
0  0 -5.0
1  0  4.0
```

However, if the same element in both dataframes is None, that None is preserved

```
>>> df1 = pd.DataFrame({'A': [0, 0], 'B': [None, 4]})
>>> df2 = pd.DataFrame({'A': [1, 1], 'B': [None, 3]})
>>> df1.combine(df2, take_smaller, fill_value=-5)
    A    B
0  0 -5.0
1  0  3.0
```

Example that demonstrates the use of *overwrite* and behavior when the axis differ between the dataframes.

```
>>> df1 = pd.DataFrame({'A': [0, 0], 'B': [4, 4]})
>>> df2 = pd.DataFrame({'B': [3, 3], 'C': [-10, 1], }, index=[1, 2])
>>> df1.combine(df2, take_smaller)
     A    B     C
```

(continues on next page)

(continued from previous page)

```
0  NaN  NaN   NaN
1  NaN  3.0 -10.0
2  NaN  3.0   1.0
```

```
>>> df1.combine(df2, take_smaller, overwrite=False)
     A    B     C
0  0.0  NaN   NaN
1  0.0  3.0 -10.0
2  NaN  3.0   1.0
```

Demonstrating the preference of the passed in dataframe.

```
>>> df2 = pd.DataFrame({'B': [3, 3], 'C': [1, 1], }, index=[1, 2])
>>> df2.combine(df1, take_smaller)
   A    B   C
0  0.0  NaN NaN
1  0.0  3.0 NaN
2  NaN  3.0 NaN
```

```
>>> df2.combine(df1, take_smaller, overwrite=False)
     A    B   C
0  0.0  NaN NaN
1  0.0  3.0 1.0
2  NaN  3.0 1.0
```

pandas.DataFrame.combine_first

DataFrame.**combine_first**(*other*)

Update null elements with value in the same location in *other*.

Combine two DataFrame objects by filling null values in one DataFrame with non-null values from other DataFrame. The row and column indexes of the resulting DataFrame will be the union of the two.

Parameters

other [DataFrame] Provided DataFrame to use to fill null values.

Returns

DataFrame

See also:

DataFrame.combine Perform series-wise operation on two DataFrames using a given function.

Examples

```
>>> df1 = pd.DataFrame({'A': [None, 0], 'B': [None, 4]})
>>> df2 = pd.DataFrame({'A': [1, 1], 'B': [3, 3]})
>>> df1.combine_first(df2)
     A    B
0  1.0  3.0
1  0.0  4.0
```

Null values still persist if the location of that null value does not exist in *other*

```
>>> df1 = pd.DataFrame({'A': [None, 0], 'B': [4, None]})
>>> df2 = pd.DataFrame({'B': [3, 3], 'C': [1, 1]}, index=[1, 2])
>>> df1.combine_first(df2)
     A    B    C
0  NaN  4.0  NaN
1  0.0  3.0  1.0
2  NaN  3.0  1.0
```

pandas.DataFrame.compare

DataFrame.**compare**(*other*, *align_axis=1*, *keep_shape=False*, *keep_equal=False*)

Compare to another DataFrame and show the differences.

New in version 1.1.0.

Parameters

other [DataFrame] Object to compare with.

align_axis [{0 or 'index', 1 or 'columns'}, default 1] Determine which axis to align the comparison on.

- **0, or 'index'** [Resulting differences are stacked vertically] with rows drawn alternately from self and other.
- **1, or 'columns'** [Resulting differences are aligned horizontally] with columns drawn alternately from self and other.

keep_shape [bool, default False] If true, all rows and columns are kept. Otherwise, only the ones with different values are kept.

keep_equal [bool, default False] If true, the result keeps values that are equal. Otherwise, equal values are shown as NaNs.

Returns

DataFrame DataFrame that shows the differences stacked side by side.

The resulting index will be a MultiIndex with 'self' and 'other' stacked alternately at the inner level.

See also:

Series.compare Compare with another Series and show differences.

Notes

Matching NaNs will not appear as a difference.

Examples

```
>>> df = pd.DataFrame(
...     {
...         "col1": ["a", "a", "b", "b", "a"],
...         "col2": [1.0, 2.0, 3.0, np.nan, 5.0],
...         "col3": [1.0, 2.0, 3.0, 4.0, 5.0]
...     },
...     columns=["col1", "col2", "col3"],
... )
>>> df
  col1  col2  col3
0    a   1.0   1.0
1    a   2.0   2.0
2    b   3.0   3.0
3    b   NaN   4.0
4    a   5.0   5.0
```

```
>>> df2 = df.copy()
>>> df2.loc[0, 'col1'] = 'c'
>>> df2.loc[2, 'col3'] = 4.0
>>> df2
  col1  col2  col3
0    c   1.0   1.0
1    a   2.0   2.0
2    b   3.0   4.0
3    b   NaN   4.0
4    a   5.0   5.0
```

Align the differences on columns

```
>>> df.compare(df2)
  col1       col3
  self other self other
0    a     c  NaN   NaN
2  NaN   NaN  3.0   4.0
```

Stack the differences on rows

```
>>> df.compare(df2, align_axis=0)
        col1  col3
0 self     a   NaN
  other    c   NaN
2 self   NaN   3.0
  other  NaN   4.0
```

Keep the equal values

```
>>> df.compare(df2, keep_equal=True)
  col1       col3
  self other self other
```

(continues on next page)

(continued from previous page)

```
0    a     c  1.0   1.0
2    b     b  3.0   4.0
```

Keep all original rows and columns

```
>>> df.compare(df2, keep_shape=True)
  col1       col2       col3
  self other self other self other
0    a     c  NaN   NaN  NaN   NaN
1  NaN   NaN  NaN   NaN  NaN   NaN
2  NaN   NaN  NaN   NaN  3.0   4.0
3  NaN   NaN  NaN   NaN  NaN   NaN
4  NaN   NaN  NaN   NaN  NaN   NaN
```

Keep all original rows and columns and also all original values

```
>>> df.compare(df2, keep_shape=True, keep_equal=True)
  col1       col2       col3
  self other self other self other
0    a     c  1.0   1.0  1.0   1.0
1    a     a  2.0   2.0  2.0   2.0
2    b     b  3.0   3.0  3.0   4.0
3    b     b  NaN   NaN  4.0   4.0
4    a     a  5.0   5.0  5.0   5.0
```

pandas.DataFrame.convert_dtypes

DataFrame.**convert_dtypes**(*infer_objects=True*, *convert_string=True*, *convert_integer=True*, *convert_boolean=True*)

Convert columns to best possible dtypes using dtypes supporting `pd.NA`.

New in version 1.0.0.

Parameters

infer_objects [bool, default True] Whether object dtypes should be converted to the best possible types.

convert_string [bool, default True] Whether object dtypes should be converted to `StringDtype()`.

convert_integer [bool, default True] Whether, if possible, conversion can be done to integer extension types.

convert_boolean [bool, defaults True] Whether object dtypes should be converted to `BooleanDtypes()`.

Returns

Series or DataFrame Copy of input object with new dtype.

See also:

infer_objects Infer dtypes of objects.

to_datetime Convert argument to datetime.

to_timedelta Convert argument to timedelta.

to_numeric Convert argument to a numeric type.

Notes

By default, `convert_dtypes` will attempt to convert a Series (or each Series in a DataFrame) to dtypes that support `pd.NA`. By using the options `convert_string`, `convert_integer`, and `convert_boolean`, it is possible to turn off individual conversions to `StringDtype`, the integer extension types or `BooleanDtype`, respectively.

For object-dtyped columns, if `infer_objects` is `True`, use the inference rules as during normal Series/DataFrame construction. Then, if possible, convert to `StringDtype`, `BooleanDtype` or an appropriate integer extension type, otherwise leave as `object`.

If the dtype is integer, convert to an appropriate integer extension type.

If the dtype is numeric, and consists of all integers, convert to an appropriate integer extension type.

In the future, as new dtypes are added that support `pd.NA`, the results of this method will change to support those new dtypes.

Examples

```
>>> df = pd.DataFrame(
...     {
...         "a": pd.Series([1, 2, 3], dtype=np.dtype("int32")),
...         "b": pd.Series(["x", "y", "z"], dtype=np.dtype("O")),
...         "c": pd.Series([True, False, np.nan], dtype=np.dtype("O")),
...         "d": pd.Series(["h", "i", np.nan], dtype=np.dtype("O")),
...         "e": pd.Series([10, np.nan, 20], dtype=np.dtype("float")),
...         "f": pd.Series([np.nan, 100.5, 200], dtype=np.dtype("float")),
...     }
... )
```

Start with a DataFrame with default dtypes.

```
>>> df
   a  b      c    d     e      f
0  1  x   True    h  10.0    NaN
1  2  y  False    i   NaN  100.5
2  3  z    NaN  NaN  20.0  200.0
```

```
>>> df.dtypes
a      int32
b     object
c     object
d     object
e    float64
f    float64
dtype: object
```

Convert the DataFrame to use best possible dtypes.

```
>>> dfn = df.convert_dtypes()
>>> dfn
   a  b      c     d     e      f
0  1  x   True     h    10    NaN
```

(continues on next page)

(continued from previous page)

```
1  2  y  False     i  <NA>  100.5
2  3  z   <NA>  <NA>    20  200.0
```

```
>>> dfn.dtypes
a      Int32
b     string
c    boolean
d     string
e      Int64
f    float64
dtype: object
```

Start with a Series of strings and missing data represented by `np.nan`.

```
>>> s = pd.Series(["a", "b", np.nan])
>>> s
0      a
1      b
2    NaN
dtype: object
```

Obtain a Series with dtype `StringDtype`.

```
>>> s.convert_dtypes()
0       a
1       b
2    <NA>
dtype: string
```

pandas.DataFrame.copy

`DataFrame.`**`copy`**(*deep=True*)

Make a copy of this object's indices and data.

When `deep=True` (default), a new object will be created with a copy of the calling object's data and indices. Modifications to the data or indices of the copy will not be reflected in the original object (see notes below).

When `deep=False`, a new object will be created without copying the calling object's data or index (only references to the data and index are copied). Any changes to the data of the original will be reflected in the shallow copy (and vice versa).

Parameters

deep [bool, default True] Make a deep copy, including a copy of the data and the indices. With `deep=False` neither the indices nor the data are copied.

Returns

copy [Series or DataFrame] Object type matches caller.

Notes

When `deep=True`, data is copied but actual Python objects will not be copied recursively, only the reference to the object. This is in contrast to *copy.deepcopy* in the Standard Library, which recursively copies object data (see examples below).

While `Index` objects are copied when `deep=True`, the underlying numpy array is not copied for performance reasons. Since `Index` is immutable, the underlying data can be safely shared and a copy is not needed.

Examples

```
>>> s = pd.Series([1, 2], index=["a", "b"])
>>> s
a    1
b    2
dtype: int64
```

```
>>> s_copy = s.copy()
>>> s_copy
a    1
b    2
dtype: int64
```

Shallow copy versus default (deep) copy:

```
>>> s = pd.Series([1, 2], index=["a", "b"])
>>> deep = s.copy()
>>> shallow = s.copy(deep=False)
```

Shallow copy shares data and index with original.

```
>>> s is shallow
False
>>> s.values is shallow.values and s.index is shallow.index
True
```

Deep copy has own copy of data and index.

```
>>> s is deep
False
>>> s.values is deep.values or s.index is deep.index
False
```

Updates to the data shared by shallow copy and original is reflected in both; deep copy remains unchanged.

```
>>> s[0] = 3
>>> shallow[1] = 4
>>> s
a    3
b    4
dtype: int64
>>> shallow
a    3
b    4
dtype: int64
```

(continues on next page)

(continued from previous page)

```
>>> deep
a    1
b    2
dtype: int64
```

Note that when copying an object containing Python objects, a deep copy will copy the data, but will not do so recursively. Updating a nested data object will be reflected in the deep copy.

```
>>> s = pd.Series([[1, 2], [3, 4]])
>>> deep = s.copy()
>>> s[0][0] = 10
>>> s
0    [10, 2]
1     [3, 4]
dtype: object
>>> deep
0    [10, 2]
1     [3, 4]
dtype: object
```

pandas.DataFrame.corr

DataFrame.**corr**(*method='pearson'*, *min_periods=1*)

Compute pairwise correlation of columns, excluding NA/null values.

Parameters

method [{'pearson', 'kendall', 'spearman'} or callable] Method of correlation:

- pearson : standard correlation coefficient
- kendall : Kendall Tau correlation coefficient
- spearman : Spearman rank correlation
- **callable: callable with input two 1d ndarrays** and returning a float. Note that the returned matrix from corr will have 1 along the diagonals and will be symmetric regardless of the callable's behavior.

  New in version 0.24.0.

min_periods [int, optional] Minimum number of observations required per pair of columns to have a valid result. Currently only available for Pearson and Spearman correlation.

Returns

DataFrame Correlation matrix.

See also:

DataFrame.corrwith Compute pairwise correlation with another DataFrame or Series.

Series.corr Compute the correlation between two Series.

Examples

```
>>> def histogram_intersection(a, b):
...     v = np.minimum(a, b).sum().round(decimals=1)
...     return v
>>> df = pd.DataFrame([(.2, .3), (.0, .6), (.6, .0), (.2, .1)],
...                   columns=['dogs', 'cats'])
>>> df.corr(method=histogram_intersection)
      dogs  cats
dogs   1.0   0.3
cats   0.3   1.0
```

pandas.DataFrame.corrwith

DataFrame.**corrwith**(*other*, *axis=0*, *drop=False*, *method='pearson'*)

Compute pairwise correlation.

Pairwise correlation is computed between rows or columns of DataFrame with rows or columns of Series or DataFrame. DataFrames are first aligned along both axes before computing the correlations.

Parameters

other [DataFrame, Series] Object with which to compute correlations.

axis [{0 or 'index', 1 or 'columns'}, default 0] The axis to use. 0 or 'index' to compute column-wise, 1 or 'columns' for row-wise.

drop [bool, default False] Drop missing indices from result.

method [{'pearson', 'kendall', 'spearman'} or callable] Method of correlation:

- pearson : standard correlation coefficient
- kendall : Kendall Tau correlation coefficient
- spearman : Spearman rank correlation
- **callable: callable with input two 1d ndarrays** and returning a float.

New in version 0.24.0.

Returns

Series Pairwise correlations.

See also:

DataFrame.corr Compute pairwise correlation of columns.

pandas.DataFrame.count

DataFrame.**count**(*axis=0*, *level=None*, *numeric_only=False*)

Count non-NA cells for each column or row.

The values *None*, *NaN*, *NaT*, and optionally *numpy.inf* (depending on *pandas.options.mode.use_inf_as_na*) are considered NA.

Parameters

axis [{0 or 'index', 1 or 'columns'}, default 0] If 0 or 'index' counts are generated for each column. If 1 or 'columns' counts are generated for each row.

level [int or str, optional] If the axis is a *MultiIndex* (hierarchical), count along a particular *level*, collapsing into a *DataFrame*. A *str* specifies the level name.

numeric_only [bool, default False] Include only *float*, *int* or *boolean* data.

Returns

Series or DataFrame For each column/row the number of non-NA/null entries. If *level* is specified returns a *DataFrame*.

See also:

Series.count Number of non-NA elements in a Series.

DataFrame.shape Number of DataFrame rows and columns (including NA elements).

DataFrame.isna Boolean same-sized DataFrame showing places of NA elements.

Examples

Constructing DataFrame from a dictionary:

```
>>> df = pd.DataFrame({"Person":
...                    ["John", "Myla", "Lewis", "John", "Myla"],
...                    "Age": [24., np.nan, 21., 33, 26],
...                    "Single": [False, True, True, True, False]})
>>> df
   Person   Age  Single
0    John  24.0   False
1    Myla   NaN    True
2   Lewis  21.0    True
3    John  33.0    True
4    Myla  26.0   False
```

Notice the uncounted NA values:

```
>>> df.count()
Person    5
Age       4
Single    5
dtype: int64
```

Counts for each **row**:

```
>>> df.count(axis='columns')
0    3
1    2
2    3
3    3
4    3
dtype: int64
```

Counts for one level of a *MultiIndex*:

```
>>> df.set_index(["Person", "Single"]).count(level="Person")
        Age
Person
John      2
Lewis     1
Myla      1
```

pandas.DataFrame.cov

DataFrame.**cov**(*min_periods=None*, *ddof=1*)

Compute pairwise covariance of columns, excluding NA/null values.

Compute the pairwise covariance among the series of a DataFrame. The returned data frame is the covariance matrix of the columns of the DataFrame.

Both NA and null values are automatically excluded from the calculation. (See the note below about bias from missing values.) A threshold can be set for the minimum number of observations for each value created. Comparisons with observations below this threshold will be returned as `NaN`.

This method is generally used for the analysis of time series data to understand the relationship between different measures across time.

Parameters

min_periods [int, optional] Minimum number of observations required per pair of columns to have a valid result.

ddof [int, default 1] Delta degrees of freedom. The divisor used in calculations is `N - ddof`, where `N` represents the number of elements.

New in version 1.1.0.

Returns

DataFrame The covariance matrix of the series of the DataFrame.

See also:

Series.cov Compute covariance with another Series.

core.window.ExponentialMovingWindow.cov Exponential weighted sample covariance.

core.window.Expanding.cov Expanding sample covariance.

core.window.Rolling.cov Rolling sample covariance.

Notes

Returns the covariance matrix of the DataFrame's time series. The covariance is normalized by N-ddof.

For DataFrames that have Series that are missing data (assuming that data is missing at random) the returned covariance matrix will be an unbiased estimate of the variance and covariance between the member Series.

However, for many applications this estimate may not be acceptable because the estimate covariance matrix is not guaranteed to be positive semi-definite. This could lead to estimate correlations having absolute values which are greater than one, and/or a non-invertible covariance matrix. See Estimation of covariance matrices for more details.

Examples

```
>>> df = pd.DataFrame([(1, 2), (0, 3), (2, 0), (1, 1)],
...                   columns=['dogs', 'cats'])
>>> df.cov()
          dogs      cats
dogs  0.666667 -1.000000
cats -1.000000  1.666667
```

```
>>> np.random.seed(42)
>>> df = pd.DataFrame(np.random.randn(1000, 5),
...                   columns=['a', 'b', 'c', 'd', 'e'])
>>> df.cov()
          a         b         c         d         e
a  0.998438 -0.020161  0.059277 -0.008943  0.014144
b -0.020161  1.059352 -0.008543 -0.024738  0.009826
c  0.059277 -0.008543  1.010670 -0.001486 -0.000271
d -0.008943 -0.024738 -0.001486  0.921297 -0.013692
e  0.014144  0.009826 -0.000271 -0.013692  0.977795
```

Minimum number of periods

This method also supports an optional `min_periods` keyword that specifies the required minimum number of non-NA observations for each column pair in order to have a valid result:

```
>>> np.random.seed(42)
>>> df = pd.DataFrame(np.random.randn(20, 3),
...                   columns=['a', 'b', 'c'])
>>> df.loc[df.index[:5], 'a'] = np.nan
>>> df.loc[df.index[5:10], 'b'] = np.nan
>>> df.cov(min_periods=12)
          a         b         c
a  0.316741       NaN -0.150812
b       NaN  1.248003  0.191417
c -0.150812  0.191417  0.895202
```

pandas.DataFrame.cummax

DataFrame.**cummax**(*axis=None*, *skipna=True*, **args*, ***kwargs*)

Return cumulative maximum over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative maximum.

Parameters

axis [{0 or 'index', 1 or 'columns'}, default 0] The index or the name of the axis. 0 is equivalent to None or 'index'.

skipna [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

***args, **kwargs** Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

Series or DataFrame Return cumulative maximum of Series or DataFrame.

See also:

core.window.Expanding.max Similar functionality but ignores NaN values.

DataFrame.max Return the maximum over DataFrame axis.

DataFrame.cummax Return cumulative maximum over DataFrame axis.

DataFrame.cummin Return cumulative minimum over DataFrame axis.

DataFrame.cumsum Return cumulative sum over DataFrame axis.

DataFrame.cumprod Return cumulative product over DataFrame axis.

Examples

Series

```
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0    2.0
1    NaN
2    5.0
3   -1.0
4    0.0
dtype: float64
```

By default, NA values are ignored.

```
>>> s.cummax()
0    2.0
1    NaN
2    5.0
3    5.0
4    5.0
dtype: float64
```

To include NA values in the operation, use `skipna=False`

```
>>> s.cummax(skipna=False)
0    2.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

DataFrame

```
>>> df = pd.DataFrame([[2.0, 1.0],
...                    [3.0, np.nan],
...                    [1.0, 0.0]],
...                    columns=list('AB'))
>>> df
     A    B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```

By default, iterates over rows and finds the maximum in each column. This is equivalent to `axis=None` or `axis='index'`.

```
>>> df.cummax()
     A    B
0  2.0  1.0
1  3.0  NaN
2  3.0  1.0
```

To iterate over columns and find the maximum in each row, use `axis=1`

```
>>> df.cummax(axis=1)
     A    B
0  2.0  2.0
1  3.0  NaN
2  1.0  1.0
```

pandas.DataFrame.cummin

DataFrame.**cummin**(*axis=None*, *skipna=True*, **args*, ***kwargs*)

Return cumulative minimum over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative minimum.

Parameters

axis [{0 or 'index', 1 or 'columns'}, default 0] The index or the name of the axis. 0 is equivalent to None or 'index'.

skipna [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

***args, **kwargs** Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

Series or DataFrame Return cumulative minimum of Series or DataFrame.

See also:

core.window.Expanding.min Similar functionality but ignores `NaN` values.

DataFrame.min Return the minimum over DataFrame axis.

DataFrame.cummax Return cumulative maximum over DataFrame axis.

DataFrame.cummin Return cumulative minimum over DataFrame axis.

DataFrame.cumsum Return cumulative sum over DataFrame axis.

DataFrame.cumprod Return cumulative product over DataFrame axis.

Examples

Series

```
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0    2.0
1    NaN
2    5.0
3   -1.0
4    0.0
dtype: float64
```

By default, NA values are ignored.

```
>>> s.cummin()
0    2.0
1    NaN
2    2.0
3   -1.0
4   -1.0
dtype: float64
```

To include NA values in the operation, use `skipna=False`

```
>>> s.cummin(skipna=False)
0    2.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

DataFrame

```
>>> df = pd.DataFrame([[2.0, 1.0],
...                    [3.0, np.nan],
...                    [1.0, 0.0]],
...                    columns=list('AB'))
>>> df
     A    B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```

By default, iterates over rows and finds the minimum in each column. This is equivalent to `axis=None` or `axis='index'`.

```
>>> df.cummin()
     A    B
0  2.0  1.0
1  2.0  NaN
2  1.0  0.0
```

To iterate over columns and find the minimum in each row, use `axis=1`

```
>>> df.cummin(axis=1)
     A    B
```

(continues on next page)

(continued from previous page)

```
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```

pandas.DataFrame.cumprod

DataFrame.**cumprod**(*axis=None*, *skipna=True*, **args*, ***kwargs*)

Return cumulative product over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative product.

Parameters

axis [{0 or 'index', 1 or 'columns'}, default 0] The index or the name of the axis. 0 is equivalent to None or 'index'.

skipna [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

***args, **kwargs** Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

Series or DataFrame Return cumulative product of Series or DataFrame.

See also:

core.window.Expanding.prod Similar functionality but ignores NaN values.

DataFrame.prod Return the product over DataFrame axis.

DataFrame.cummax Return cumulative maximum over DataFrame axis.

DataFrame.cummin Return cumulative minimum over DataFrame axis.

DataFrame.cumsum Return cumulative sum over DataFrame axis.

DataFrame.cumprod Return cumulative product over DataFrame axis.

Examples

Series

```
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0    2.0
1    NaN
2    5.0
3   -1.0
4    0.0
dtype: float64
```

By default, NA values are ignored.

```
>>> s.cumprod()
0     2.0
1     NaN
2    10.0
3   -10.0
4    -0.0
dtype: float64
```

To include NA values in the operation, use `skipna=False`

```
>>> s.cumprod(skipna=False)
0    2.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

DataFrame

```
>>> df = pd.DataFrame([[2.0, 1.0],
...                    [3.0, np.nan],
...                    [1.0, 0.0]],
...                   columns=list('AB'))
>>> df
     A    B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```

By default, iterates over rows and finds the product in each column. This is equivalent to `axis=None` or `axis='index'`.

```
>>> df.cumprod()
     A    B
0  2.0  1.0
1  6.0  NaN
2  6.0  0.0
```

To iterate over columns and find the product in each row, use `axis=1`

```
>>> df.cumprod(axis=1)
     A    B
0  2.0  2.0
1  3.0  NaN
2  1.0  0.0
```

pandas.DataFrame.cumsum

DataFrame.**cumsum**(*axis=None*, *skipna=True*, **args*, ***kwargs*)

Return cumulative sum over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative sum.

Parameters

axis [{0 or 'index', 1 or 'columns'}, default 0] The index or the name of the axis. 0 is equivalent to None or 'index'.

skipna [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

***args, **kwargs** Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

Series or DataFrame Return cumulative sum of Series or DataFrame.

See also:

core.window.Expanding.sum Similar functionality but ignores NaN values.

DataFrame.sum Return the sum over DataFrame axis.

DataFrame.cummax Return cumulative maximum over DataFrame axis.

DataFrame.cummin Return cumulative minimum over DataFrame axis.

DataFrame.cumsum Return cumulative sum over DataFrame axis.

DataFrame.cumprod Return cumulative product over DataFrame axis.

Examples

Series

```
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0    2.0
1    NaN
2    5.0
3   -1.0
4    0.0
dtype: float64
```

By default, NA values are ignored.

```
>>> s.cumsum()
0    2.0
1    NaN
2    7.0
3    6.0
4    6.0
dtype: float64
```

To include NA values in the operation, use `skipna=False`

```
>>> s.cumsum(skipna=False)
0    2.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

DataFrame

```
>>> df = pd.DataFrame([[2.0, 1.0],
...                    [3.0, np.nan],
...                    [1.0, 0.0]],
...                    columns=list('AB'))
>>> df
     A    B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```

By default, iterates over rows and finds the sum in each column. This is equivalent to `axis=None` or `axis='index'`.

```
>>> df.cumsum()
     A    B
0  2.0  1.0
1  5.0  NaN
2  6.0  1.0
```

To iterate over columns and find the sum in each row, use `axis=1`

```
>>> df.cumsum(axis=1)
     A    B
0  2.0  3.0
1  3.0  NaN
2  1.0  1.0
```

pandas.DataFrame.describe

`DataFrame.`**`describe`**(*percentiles=None*, *include=None*, *exclude=None*, *datetime_is_numeric=False*)

Generate descriptive statistics.

Descriptive statistics include those that summarize the central tendency, dispersion and shape of a dataset's distribution, excluding `NaN` values.

Analyzes both numeric and object series, as well as `DataFrame` column sets of mixed data types. The output will vary depending on what is provided. Refer to the notes below for more detail.

Parameters

percentiles [list-like of numbers, optional] The percentiles to include in the output. All should fall between 0 and 1. The default is `[.25, .5, .75]`, which returns the 25th, 50th, and 75th percentiles.

include ['all', list-like of dtypes or None (default), optional] A white list of data types to include in the result. Ignored for `Series`. Here are the options:

- 'all' : All columns of the input will be included in the output.
- A list-like of dtypes : Limits the results to the provided data types. To limit the result to numeric types submit `numpy.number`. To limit it instead to object columns submit the `numpy.object` data type. Strings can also be used in the style of `select_dtypes` (e.g. `df.describe(include=['O'])`). To select pandas categorical columns, use `'category'`
- None (default) : The result will include all numeric columns.

exclude [list-like of dtypes or None (default), optional,] A black list of data types to omit from the result. Ignored for `Series`. Here are the options:

- A list-like of dtypes : Excludes the provided data types from the result. To exclude numeric types submit `numpy.number`. To exclude object columns submit the data type `numpy.object`. Strings can also be used in the style of `select_dtypes` (e.g. `df.describe(include=['O'])`). To exclude pandas categorical columns, use `'category'`
- None (default) : The result will exclude nothing.

datetime_is_numeric [bool, default False] Whether to treat datetime dtypes as numeric. This affects statistics calculated for the column. For DataFrame input, this also controls whether datetime columns are included by default.

New in version 1.1.0.

Returns

Series or DataFrame Summary statistics of the Series or Dataframe provided.

See also:

DataFrame.count Count number of non-NA/null observations.

DataFrame.max Maximum of the values in the object.

DataFrame.min Minimum of the values in the object.

DataFrame.mean Mean of the values.

DataFrame.std Standard deviation of the observations.

DataFrame.select_dtypes Subset of a DataFrame including/excluding columns based on their dtype.

Notes

For numeric data, the result's index will include `count`, `mean`, `std`, `min`, `max` as well as lower, `50` and upper percentiles. By default the lower percentile is `25` and the upper percentile is `75`. The `50` percentile is the same as the median.

For object data (e.g. strings or timestamps), the result's index will include `count`, `unique`, `top`, and `freq`. The `top` is the most common value. The `freq` is the most common value's frequency. Timestamps also include the `first` and `last` items.

If multiple object values have the highest count, then the `count` and `top` results will be arbitrarily chosen from among those with the highest count.

For mixed data types provided via a `DataFrame`, the default is to return only an analysis of numeric columns. If the dataframe consists only of object and categorical data without any numeric columns,

the default is to return an analysis of both the object and categorical columns. If `include='all'` is provided as an option, the result will include a union of attributes of each type.

The *include* and *exclude* parameters can be used to limit which columns in a `DataFrame` are analyzed for the output. The parameters are ignored when analyzing a `Series`.

Examples

Describing a numeric `Series`.

```
>>> s = pd.Series([1, 2, 3])
>>> s.describe()
count    3.0
mean     2.0
std      1.0
min      1.0
25%      1.5
50%      2.0
75%      2.5
max      3.0
dtype: float64
```

Describing a categorical `Series`.

```
>>> s = pd.Series(['a', 'a', 'b', 'c'])
>>> s.describe()
count     4
unique    3
top       a
freq      2
dtype: object
```

Describing a timestamp `Series`.

```
>>> s = pd.Series([
...   np.datetime64("2000-01-01"),
...   np.datetime64("2010-01-01"),
...   np.datetime64("2010-01-01")
... ])
>>> s.describe(datetime_is_numeric=True)
count                      3
mean     2006-09-01 08:00:00
min      2000-01-01 00:00:00
25%      2004-12-31 12:00:00
50%      2010-01-01 00:00:00
75%      2010-01-01 00:00:00
max      2010-01-01 00:00:00
dtype: object
```

Describing a `DataFrame`. By default only numeric fields are returned.

```
>>> df = pd.DataFrame({'categorical': pd.Categorical(['d','e','f']),
...                    'numeric': [1, 2, 3],
...                    'object': ['a', 'b', 'c']
...                   })
>>> df.describe()
       numeric
```

(continues on next page)

(continued from previous page)

```
count      3.0
mean       2.0
std        1.0
min        1.0
25%        1.5
50%        2.0
75%        2.5
max        3.0
```

Describing all columns of a `DataFrame` regardless of data type.

```
>>> df.describe(include='all')
       categorical  numeric object
count            3      3.0      3
unique           3      NaN      3
top              f      NaN      a
freq             1      NaN      1
mean           NaN      2.0    NaN
std            NaN      1.0    NaN
min            NaN      1.0    NaN
25%            NaN      1.5    NaN
50%            NaN      2.0    NaN
75%            NaN      2.5    NaN
max            NaN      3.0    NaN
```

Describing a column from a `DataFrame` by accessing it as an attribute.

```
>>> df.numeric.describe()
count    3.0
mean     2.0
std      1.0
min      1.0
25%      1.5
50%      2.0
75%      2.5
max      3.0
Name: numeric, dtype: float64
```

Including only numeric columns in a `DataFrame` description.

```
>>> df.describe(include=[np.number])
       numeric
count      3.0
mean       2.0
std        1.0
min        1.0
25%        1.5
50%        2.0
75%        2.5
max        3.0
```

Including only string columns in a `DataFrame` description.

```
>>> df.describe(include=[object])
       object
count       3
```

(continues on next page)

(continued from previous page)

```
unique      3
top         a
freq        1
```

Including only categorical columns from a `DataFrame` description.

```
>>> df.describe(include=['category'])
       categorical
count            3
unique           3
top              f
freq             1
```

Excluding numeric columns from a `DataFrame` description.

```
>>> df.describe(exclude=[np.number])
       categorical object
count            3      3
unique           3      3
top              f      a
freq             1      1
```

Excluding object columns from a `DataFrame` description.

```
>>> df.describe(exclude=[object])
       categorical  numeric
count            3      3.0
unique           3      NaN
top              f      NaN
freq             1      NaN
mean           NaN      2.0
std            NaN      1.0
min            NaN      1.0
25%            NaN      1.5
50%            NaN      2.0
75%            NaN      2.5
max            NaN      3.0
```

pandas.DataFrame.diff

`DataFrame.`**`diff`**(*periods=1*, *axis=0*)

First discrete difference of element.

Calculates the difference of a Dataframe element compared with another element in the Dataframe (default is element in previous row).

Parameters

periods [int, default 1] Periods to shift for calculating difference, accepts negative values.

axis [{0 or 'index', 1 or 'columns'}, default 0] Take difference over rows (0) or columns (1).

Returns

Dataframe First differences of the Series.

See also:

`Dataframe.pct_change` Percent change over given number of periods.

`Dataframe.shift` Shift index by desired number of periods with an optional time freq.

`Series.diff` First discrete difference of object.

Notes

For boolean dtypes, this uses `operator.xor()` rather than `operator.sub()`. The result is calculated according to current dtype in Dataframe, however dtype of the result is always float64.

Examples

Difference with previous row

```
>>> df = pd.DataFrame({'a': [1, 2, 3, 4, 5, 6],
...                    'b': [1, 1, 2, 3, 5, 8],
...                    'c': [1, 4, 9, 16, 25, 36]})
>>> df
   a  b   c
0  1  1   1
1  2  1   4
2  3  2   9
3  4  3  16
4  5  5  25
5  6  8  36
```

```
>>> df.diff()
     a    b     c
0  NaN  NaN   NaN
1  1.0  0.0   3.0
2  1.0  1.0   5.0
3  1.0  1.0   7.0
4  1.0  2.0   9.0
5  1.0  3.0  11.0
```

Difference with previous column

```
>>> df.diff(axis=1)
    a    b     c
0 NaN  0.0   0.0
1 NaN -1.0   3.0
2 NaN -1.0   7.0
3 NaN -1.0  13.0
4 NaN  0.0  20.0
5 NaN  2.0  28.0
```

Difference with 3rd previous row

```
>>> df.diff(periods=3)
     a    b     c
0  NaN  NaN   NaN
1  NaN  NaN   NaN
2  NaN  NaN   NaN
```

(continues on next page)

(continued from previous page)

```
3  3.0  2.0  15.0
4  3.0  4.0  21.0
5  3.0  6.0  27.0
```

Difference with following row

```
>>> df.diff(periods=-1)
     a    b     c
0 -1.0  0.0  -3.0
1 -1.0 -1.0  -5.0
2 -1.0 -1.0  -7.0
3 -1.0 -2.0  -9.0
4 -1.0 -3.0 -11.0
5  NaN  NaN   NaN
```

Overflow in input dtype

```
>>> df = pd.DataFrame({'a': [1, 0]}, dtype=np.uint8)
>>> df.diff()
       a
0    NaN
1  255.0
```

pandas.DataFrame.div

DataFrame.**div**(*other*, *axis='columns'*, *level=None*, *fill_value=None*)

Get Floating division of dataframe and other, element-wise (binary operator *truediv*).

Equivalent to `dataframe / other`, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, *rtruediv*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: +, -, *, /, //, %, **.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

See also:

DataFrame.add Add DataFrames.

DataFrame.sub Subtract DataFrames.

DataFrame.mul Multiply DataFrames.

DataFrame.div Divide DataFrames (float division).

DataFrame.truediv Divide DataFrames (float division).

DataFrame.floordiv Divide DataFrames (integer division).

DataFrame.mod Calculate modulo (remainder after division).

DataFrame.pow Calculate exponential power.

Notes

Mismatched indices will be unioned together.

Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                   index=['circle', 'triangle', 'rectangle'])
>>> df
           angles  degrees
circle          0      360
triangle        3      180
rectangle       4      360
```

Add a scalar with operator version which return the same results.

```
>>> df + 1
           angles  degrees
circle          1      361
triangle        4      181
rectangle       5      361
```

```
>>> df.add(1)
           angles  degrees
circle          1      361
triangle        4      181
rectangle       5      361
```

Divide by constant with reverse version.

```
>>> df.div(10)
           angles  degrees
circle        0.0     36.0
triangle      0.3     18.0
rectangle     0.4     36.0
```

```
>>> df.rdiv(10)
             angles   degrees
circle          inf  0.027778
triangle   3.333333  0.055556
rectangle  2.500000  0.027778
```

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
           angles  degrees
circle         -1      358
triangle        2      178
rectangle       3      358
```

```
>>> df.sub([1, 2], axis='columns')
           angles  degrees
circle         -1      358
triangle        2      178
rectangle       3      358
```

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...         axis='index')
           angles  degrees
circle         -1      359
triangle        2      179
rectangle       3      359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                      index=['circle', 'triangle', 'rectangle'])
>>> other
           angles
circle          0
triangle        3
rectangle       4
```

```
>>> df * other
           angles  degrees
circle          0      NaN
triangle        9      NaN
rectangle      16      NaN
```

```
>>> df.mul(other, fill_value=0)
           angles  degrees
circle          0      0.0
triangle        9      0.0
rectangle      16      0.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                              'degrees': [360, 180, 360, 360, 540, 720]},
...                             index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                    ['circle', 'triangle', 'rectangle',
...                                     'square', 'pentagon', 'hexagon']])
>>> df_multindex
             angles  degrees
A circle          0      360
  triangle        3      180
  rectangle       4      360
B square          4      360
  pentagon        5      540
  hexagon         6      720
```

```
>>> df.div(df_multindex, level=1, fill_value=0)
             angles  degrees
A circle        NaN      1.0
  triangle      1.0      1.0
  rectangle     1.0      1.0
B square        0.0      0.0
  pentagon      0.0      0.0
  hexagon       0.0      0.0
```

pandas.DataFrame.divide

DataFrame.**divide**(*other*, *axis='columns'*, *level=None*, *fill_value=None*)

Get Floating division of dataframe and other, element-wise (binary operator *truediv*).

Equivalent to `dataframe / other`, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, *rtruediv*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: +, -, *, /, //, %, **.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

See also:

DataFrame.add Add DataFrames.

DataFrame.sub Subtract DataFrames.

DataFrame.mul Multiply DataFrames.

DataFrame.div Divide DataFrames (float division).

DataFrame.truediv Divide DataFrames (float division).

DataFrame.floordiv Divide DataFrames (integer division).

DataFrame.mod Calculate modulo (remainder after division).

DataFrame.pow Calculate exponential power.

Notes

Mismatched indices will be unioned together.

Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                   index=['circle', 'triangle', 'rectangle'])
>>> df
           angles  degrees
circle          0      360
triangle        3      180
rectangle       4      360
```

Add a scalar with operator version which return the same results.

```
>>> df + 1
           angles  degrees
circle          1      361
triangle        4      181
rectangle       5      361
```

```
>>> df.add(1)
           angles  degrees
circle          1      361
triangle        4      181
rectangle       5      361
```

Divide by constant with reverse version.

```
>>> df.div(10)
           angles  degrees
circle        0.0     36.0
triangle      0.3     18.0
rectangle     0.4     36.0
```

```
>>> df.rdiv(10)
             angles   degrees
circle          inf  0.027778
triangle   3.333333  0.055556
rectangle  2.500000  0.027778
```

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
           angles  degrees
circle         -1      358
triangle        2      178
rectangle       3      358
```

```
>>> df.sub([1, 2], axis='columns')
           angles  degrees
circle         -1      358
triangle        2      178
rectangle       3      358
```

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...         axis='index')
           angles  degrees
circle         -1      359
triangle        2      179
rectangle       3      359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                      index=['circle', 'triangle', 'rectangle'])
>>> other
           angles
circle          0
triangle        3
rectangle       4
```

```
>>> df * other
           angles  degrees
circle          0      NaN
triangle        9      NaN
rectangle      16      NaN
```

```
>>> df.mul(other, fill_value=0)
           angles  degrees
circle          0      0.0
triangle        9      0.0
rectangle      16      0.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                              'degrees': [360, 180, 360, 360, 540, 720]},
...                             index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                    ['circle', 'triangle', 'rectangle',
...                                     'square', 'pentagon', 'hexagon']])
>>> df_multindex
             angles  degrees
A circle          0      360
  triangle        3      180
  rectangle       4      360
B square          4      360
  pentagon        5      540
  hexagon         6      720
```

```
>>> df.div(df_multindex, level=1, fill_value=0)
             angles  degrees
A circle        NaN      1.0
  triangle      1.0      1.0
  rectangle     1.0      1.0
B square        0.0      0.0
  pentagon      0.0      0.0
  hexagon       0.0      0.0
```

pandas.DataFrame.dot

DataFrame.**dot**(*other*)

Compute the matrix multiplication between the DataFrame and other.

This method computes the matrix product between the DataFrame and the values of an other Series, DataFrame or a numpy array.

It can also be called using `self @ other` in Python >= 3.5.

Parameters

other [Series, DataFrame or array-like] The other object to compute the matrix product with.

Returns

Series or DataFrame If other is a Series, return the matrix product between self and other as a Series. If other is a DataFrame or a numpy.array, return the matrix product of self and other in a DataFrame of a np.array.

See also:

Series.dot Similar method for Series.

Notes

The dimensions of DataFrame and other must be compatible in order to compute the matrix multiplication. In addition, the column names of DataFrame and the index of other must contain the same values, as they will be aligned prior to the multiplication.

The dot method for Series computes the inner product, instead of the matrix product here.

Examples

Here we multiply a DataFrame with a Series.

```
>>> df = pd.DataFrame([[0, 1, -2, -1], [1, 1, 1, 1]])
>>> s = pd.Series([1, 1, 2, 1])
>>> df.dot(s)
0    -4
1     5
dtype: int64
```

Here we multiply a DataFrame with another DataFrame.

```
>>> other = pd.DataFrame([[0, 1], [1, 2], [-1, -1], [2, 0]])
>>> df.dot(other)
    0   1
0   1   4
1   2   2
```

Note that the dot method give the same result as @

```
>>> df @ other
    0   1
0   1   4
1   2   2
```

The dot method works also if other is an np.array.

```
>>> arr = np.array([[0, 1], [1, 2], [-1, -1], [2, 0]])
>>> df.dot(arr)
    0   1
0   1   4
1   2   2
```

Note how shuffling of the objects does not change the result.

```
>>> s2 = s.reindex([1, 0, 2, 3])
>>> df.dot(s2)
0    -4
1     5
dtype: int64
```

pandas.DataFrame.drop

DataFrame.**drop**(*labels=None*, *axis=0*, *index=None*, *columns=None*, *level=None*, *inplace=False*, *errors='raise'*)

Drop specified labels from rows or columns.

Remove rows or columns by specifying label names and corresponding axis, or by specifying directly index or column names. When using a multi-index, labels on different levels can be removed by specifying the level.

Parameters

labels [single label or list-like] Index or column labels to drop.

axis [{0 or 'index', 1 or 'columns'}, default 0] Whether to drop labels from the index (0 or 'index') or columns (1 or 'columns').

index [single label or list-like] Alternative to specifying axis (`labels, axis=0` is equivalent to `index=labels`).

columns [single label or list-like] Alternative to specifying axis (`labels, axis=1` is equivalent to `columns=labels`).

level [int or level name, optional] For MultiIndex, level from which the labels will be removed.

inplace [bool, default False] If False, return a copy. Otherwise, do operation inplace and return None.

errors [{'ignore', 'raise'}, default 'raise'] If 'ignore', suppress error and only existing labels are dropped.

Returns

DataFrame DataFrame without the removed index or column labels.

Raises

KeyError If any of the labels is not found in the selected axis.

See also:

`DataFrame.loc` Label-location based indexer for selection by label.

DataFrame.dropna Return DataFrame with labels on given axis omitted where (all or any) data are missing.

DataFrame.drop_duplicates Return DataFrame with duplicate rows removed, optionally only considering certain columns.

Series.drop Return Series with specified index labels removed.

Examples

```
>>> df = pd.DataFrame(np.arange(12).reshape(3, 4),
...                   columns=['A', 'B', 'C', 'D'])
>>> df
   A  B   C   D
0  0  1   2   3
1  4  5   6   7
2  8  9  10  11
```

Drop columns

```
>>> df.drop(['B', 'C'], axis=1)
   A   D
0  0   3
1  4   7
2  8  11
```

```
>>> df.drop(columns=['B', 'C'])
   A   D
0  0   3
1  4   7
2  8  11
```

Drop a row by index

```
>>> df.drop([0, 1])
   A  B   C   D
2  8  9  10  11
```

Drop columns and/or rows of MultiIndex DataFrame

```
>>> midx = pd.MultiIndex(levels=[['lama', 'cow', 'falcon'],
...                              ['speed', 'weight', 'length']],
...                      codes=[[0, 0, 0, 1, 1, 1, 2, 2, 2],
...                             [0, 1, 2, 0, 1, 2, 0, 1, 2]])
>>> df = pd.DataFrame(index=midx, columns=['big', 'small'],
...                   data=[[45, 30], [200, 100], [1.5, 1], [30, 20],
...                         [250, 150], [1.5, 0.8], [320, 250],
...                         [1, 0.8], [0.3, 0.2]])
>>> df
                big     small
lama    speed   45.0    30.0
        weight  200.0   100.0
        length  1.5     1.0
cow     speed   30.0    20.0
        weight  250.0   150.0
        length  1.5     0.8
falcon  speed   320.0   250.0
```

(continues on next page)

(continued from previous page)

```
        weight  1.0     0.8
        length  0.3     0.2
```

```
>>> df.drop(index='cow', columns='small')
                big
lama    speed   45.0
        weight  200.0
        length  1.5
falcon  speed   320.0
        weight  1.0
        length  0.3
```

```
>>> df.drop(index='length', level=1)
                big     small
lama    speed   45.0    30.0
        weight  200.0   100.0
cow     speed   30.0    20.0
        weight  250.0   150.0
falcon  speed   320.0   250.0
        weight  1.0     0.8
```

pandas.DataFrame.drop_duplicates

DataFrame.**drop_duplicates**(*subset=None*, *keep='first'*, *inplace=False*, *ignore_index=False*)

Return DataFrame with duplicate rows removed.

Considering certain columns is optional. Indexes, including time indexes are ignored.

Parameters

subset [column label or sequence of labels, optional] Only consider certain columns for identifying duplicates, by default use all of the columns.

keep [{'first', 'last', False}, default 'first'] Determines which duplicates (if any) to keep. - `first` : Drop duplicates except for the first occurrence. - `last` : Drop duplicates except for the last occurrence. - False : Drop all duplicates.

inplace [bool, default False] Whether to drop duplicates in place or to return a copy.

ignore_index [bool, default False] If True, the resulting axis will be labeled 0, 1, . . . , n - 1.

New in version 1.0.0.

Returns

DataFrame DataFrame with duplicates removed or None if `inplace=True`.

See also:

DataFrame.value_counts Count unique combinations of columns.

Examples

Consider dataset containing ramen rating.

```
>>> df = pd.DataFrame({
...     'brand': ['Yum Yum', 'Yum Yum', 'Indomie', 'Indomie', 'Indomie'],
...     'style': ['cup', 'cup', 'cup', 'pack', 'pack'],
...     'rating': [4, 4, 3.5, 15, 5]
... })
>>> df
    brand style  rating
0  Yum Yum   cup     4.0
1  Yum Yum   cup     4.0
2  Indomie   cup     3.5
3  Indomie  pack    15.0
4  Indomie  pack     5.0
```

By default, it removes duplicate rows based on all columns.

```
>>> df.drop_duplicates()
    brand style  rating
0  Yum Yum   cup     4.0
2  Indomie   cup     3.5
3  Indomie  pack    15.0
4  Indomie  pack     5.0
```

To remove duplicates on specific column(s), use `subset`.

```
>>> df.drop_duplicates(subset=['brand'])
    brand style  rating
0  Yum Yum   cup     4.0
2  Indomie   cup     3.5
```

To remove duplicates and keep last occurences, use `keep`.

```
>>> df.drop_duplicates(subset=['brand', 'style'], keep='last')
    brand style  rating
1  Yum Yum   cup     4.0
2  Indomie   cup     3.5
4  Indomie  pack     5.0
```

pandas.DataFrame.droplevel

`DataFrame.`**`droplevel`**(*level*, *axis=0*)

Return DataFrame with requested index / column level(s) removed.

New in version 0.24.0.

Parameters

level [int, str, or list-like] If a string is given, must be the name of a level If list-like, elements must be names or positional indexes of levels.

axis [{0 or 'index', 1 or 'columns'}, default 0] Axis along which the level(s) is removed:

- 0 or 'index': remove level(s) in column.
- 1 or 'columns': remove level(s) in row.

Returns

DataFrame DataFrame with requested index / column level(s) removed.

Examples

```
>>> df = pd.DataFrame([
...     [1, 2, 3, 4],
...     [5, 6, 7, 8],
...     [9, 10, 11, 12]
... ]).set_index([0, 1]).rename_axis(['a', 'b'])
```

```
>>> df.columns = pd.MultiIndex.from_tuples([
...     ('c', 'e'), ('d', 'f')
... ], names=['level_1', 'level_2'])
```

```
>>> df
level_1   c   d
level_2   e   f
a b
1 2       3   4
5 6       7   8
9 10     11  12
```

```
>>> df.droplevel('a')
level_1   c   d
level_2   e   f
b
2         3   4
6         7   8
10       11  12
```

```
>>> df.droplevel('level_2', axis=1)
level_1   c   d
a b
1 2       3   4
5 6       7   8
9 10     11  12
```

pandas.DataFrame.dropna

DataFrame.**dropna**(*axis=0*, *how='any'*, *thresh=None*, *subset=None*, *inplace=False*)

Remove missing values.

See the *User Guide* for more on which values are considered missing, and how to work with missing data.

Parameters

axis [{0 or 'index', 1 or 'columns'}, default 0] Determine if rows or columns which contain missing values are removed.

- 0, or 'index' : Drop rows which contain missing values.
- 1, or 'columns' : Drop columns which contain missing value.

Changed in version 1.0.0: Pass tuple or list to drop on multiple axes. Only a single axis is allowed.

how [{'any', 'all'}, default 'any'] Determine if row or column is removed from DataFrame, when we have at least one NA or all NA.

- 'any' : If any NA values are present, drop that row or column.
- 'all' : If all values are NA, drop that row or column.

thresh [int, optional] Require that many non-NA values.

subset [array-like, optional] Labels along other axis to consider, e.g. if you are dropping rows these would be a list of columns to include.

inplace [bool, default False] If True, do operation inplace and return None.

Returns

DataFrame DataFrame with NA entries dropped from it.

See also:

DataFrame.isna Indicate missing values.

DataFrame.notna Indicate existing (non-missing) values.

DataFrame.fillna Replace missing values.

Series.dropna Drop missing values.

Index.dropna Drop missing indices.

Examples

```
>>> df = pd.DataFrame({"name": ['Alfred', 'Batman', 'Catwoman'],
...                    "toy": [np.nan, 'Batmobile', 'Bullwhip'],
...                    "born": [pd.NaT, pd.Timestamp("1940-04-25"),
...                             pd.NaT]})
>>> df
       name        toy       born
0    Alfred        NaN        NaT
1    Batman  Batmobile 1940-04-25
2  Catwoman   Bullwhip        NaT
```

Drop the rows where at least one element is missing.

```
>>> df.dropna()
     name        toy       born
1  Batman  Batmobile 1940-04-25
```

Drop the columns where at least one element is missing.

```
>>> df.dropna(axis='columns')
       name
0    Alfred
1    Batman
2  Catwoman
```

Drop the rows where all elements are missing.

```
>>> df.dropna(how='all')
       name        toy       born
0    Alfred        NaN        NaT
1    Batman  Batmobile 1940-04-25
2  Catwoman   Bullwhip        NaT
```

Keep only the rows with at least 2 non-NA values.

```
>>> df.dropna(thresh=2)
       name        toy       born
1    Batman  Batmobile 1940-04-25
2  Catwoman   Bullwhip        NaT
```

Define in which columns to look for missing values.

```
>>> df.dropna(subset=['name', 'born'])
       name        toy       born
1    Batman  Batmobile 1940-04-25
```

Keep the DataFrame with valid entries in the same variable.

```
>>> df.dropna(inplace=True)
>>> df
     name        toy       born
1  Batman  Batmobile 1940-04-25
```

pandas.DataFrame.duplicated

`DataFrame.`**`duplicated`**(*subset=None*, *keep='first'*)

Return boolean Series denoting duplicate rows.

Considering certain columns is optional.

Parameters

subset [column label or sequence of labels, optional] Only consider certain columns for identifying duplicates, by default use all of the columns.

keep [{'first', 'last', False}, default 'first'] Determines which duplicates (if any) to mark.

- `first` : Mark duplicates as `True` except for the first occurrence.
- `last` : Mark duplicates as `True` except for the last occurrence.
- False : Mark all duplicates as `True`.

Returns

Series Boolean series for each duplicated rows.

See also:

Index.duplicated Equivalent method on index.

Series.duplicated Equivalent method on Series.

Series.drop_duplicates Remove duplicate values from Series.

DataFrame.drop_duplicates Remove duplicate values from DataFrame.

Examples

Consider dataset containing ramen rating.

```
>>> df = pd.DataFrame({
...     'brand': ['Yum Yum', 'Yum Yum', 'Indomie', 'Indomie', 'Indomie'],
...     'style': ['cup', 'cup', 'cup', 'pack', 'pack'],
...     'rating': [4, 4, 3.5, 15, 5]
... })
>>> df
    brand style  rating
0  Yum Yum   cup     4.0
1  Yum Yum   cup     4.0
2  Indomie   cup     3.5
3  Indomie  pack    15.0
4  Indomie  pack     5.0
```

By default, for each set of duplicated values, the first occurrence is set on False and all others on True.

```
>>> df.duplicated()
0    False
1     True
2    False
3    False
4    False
dtype: bool
```

By using 'last', the last occurrence of each set of duplicated values is set on False and all others on True.

```
>>> df.duplicated(keep='last')
0     True
1    False
2    False
3    False
4    False
dtype: bool
```

By setting `keep` on False, all duplicates are True.

```
>>> df.duplicated(keep=False)
0     True
1     True
2    False
3    False
4    False
dtype: bool
```

To find duplicates on specific column(s), use `subset`.

```
>>> df.duplicated(subset=['brand'])
0    False
1     True
2    False
3     True
4     True
dtype: bool
```

pandas.DataFrame.eq

DataFrame.**eq**(*other*, *axis='columns'*, *level=None*)

Get Equal to of dataframe and other, element-wise (binary operator *eq*).

Among flexible wrappers (*eq*, *ne*, *le*, *lt*, *ge*, *gt*) to comparison operators.

Equivalent to ==, =!, <=, <, >=, > with support to choose axis (rows or columns) and level for comparison.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}, default 'columns'] Whether to compare by the index (0 or 'index') or columns (1 or 'columns').

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

DataFrame of bool Result of the comparison.

See also:

DataFrame.eq Compare DataFrames for equality elementwise.

DataFrame.ne Compare DataFrames for inequality elementwise.

DataFrame.le Compare DataFrames for less than inequality or equality elementwise.

DataFrame.lt Compare DataFrames for strictly less than inequality elementwise.

DataFrame.ge Compare DataFrames for greater than inequality or equality elementwise.

DataFrame.gt Compare DataFrames for strictly greater than inequality elementwise.

Notes

Mismatched indices will be unioned together. *NaN* values are considered different (i.e. *NaN* != *NaN*).

Examples

```
>>> df = pd.DataFrame({'cost': [250, 150, 100],
...                    'revenue': [100, 250, 300]},
...                   index=['A', 'B', 'C'])
>>> df
   cost  revenue
A   250      100
B   150      250
C   100      300
```

Comparison with a scalar, using either the operator or method:

```
>>> df == 100
    cost  revenue
A  False     True
```

(continues on next page)

(continued from previous page)

```
B  False    False
C   True    False
```

```
>>> df.eq(100)
    cost  revenue
A  False     True
B  False    False
C   True    False
```

When *other* is a *Series*, the columns of a DataFrame are aligned with the index of *other* and broadcast:

```
>>> df != pd.Series([100, 250], index=["cost", "revenue"])
    cost  revenue
A   True     True
B   True    False
C  False     True
```

Use the method to control the broadcast axis:

```
>>> df.ne(pd.Series([100, 300], index=["A", "D"]), axis='index')
   cost  revenue
A  True    False
B  True     True
C  True     True
D  True     True
```

When comparing to an arbitrary sequence, the number of columns must match the number elements in *other*:

```
>>> df == [250, 100]
    cost  revenue
A   True     True
B  False    False
C  False    False
```

Use the method to control the axis:

```
>>> df.eq([250, 250, 100], axis='index')
    cost  revenue
A   True    False
B  False     True
C   True    False
```

Compare to a DataFrame of different shape.

```
>>> other = pd.DataFrame({'revenue': [300, 250, 100, 150]},
...                      index=['A', 'B', 'C', 'D'])
>>> other
   revenue
A      300
B      250
C      100
D      150
```

```
>>> df.gt(other)
    cost  revenue
```

(continues on next page)

(continued from previous page)

```
A  False    False
B  False    False
C  False     True
D  False    False
```

Compare to a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'cost': [250, 150, 100, 150, 300, 220],
...                              'revenue': [100, 250, 300, 200, 175, 225]},
...                             index=[['Q1', 'Q1', 'Q1', 'Q2', 'Q2', 'Q2'],
...                                    ['A', 'B', 'C', 'A', 'B', 'C']])
>>> df_multindex
      cost  revenue
Q1 A   250      100
   B   150      250
   C   100      300
Q2 A   150      200
   B   300      175
   C   220      225
```

```
>>> df.le(df_multindex, level=1)
       cost  revenue
Q1 A   True     True
   B   True     True
   C   True     True
Q2 A  False     True
   B   True    False
   C   True    False
```

pandas.DataFrame.equals

DataFrame.**equals**(*other*)

Test whether two objects contain the same elements.

This function allows two Series or DataFrames to be compared against each other to see if they have the same shape and elements. NaNs in the same location are considered equal. The column headers do not need to have the same type, but the elements within the columns must be the same dtype.

Parameters

other [Series or DataFrame] The other Series or DataFrame to be compared with the first.

Returns

bool True if all elements are the same in both objects, False otherwise.

See also:

Series.eq Compare two Series objects of the same length and return a Series where each element is True if the element in each Series is equal, False otherwise.

DataFrame.eq Compare two DataFrame objects of the same shape and return a DataFrame where each element is True if the respective element in each DataFrame is equal, False otherwise.

testing.assert_series_equal Raises an AssertionError if left and right are not equal. Provides an easy interface to ignore inequality in dtypes, indexes and precision among others.

testing.assert_frame_equal Like assert_series_equal, but targets DataFrames.

numpy.array_equal Return True if two arrays have the same shape and elements, False otherwise.

Notes

This function requires that the elements have the same dtype as their respective elements in the other Series or DataFrame. However, the column labels do not need to have the same type, as long as they are still considered equal.

Examples

```
>>> df = pd.DataFrame({1: [10], 2: [20]})
>>> df
    1   2
0  10  20
```

DataFrames df and exactly_equal have the same types and values for their elements and column labels, which will return True.

```
>>> exactly_equal = pd.DataFrame({1: [10], 2: [20]})
>>> exactly_equal
    1   2
0  10  20
>>> df.equals(exactly_equal)
True
```

DataFrames df and different_column_type have the same element types and values, but have different types for the column labels, which will still return True.

```
>>> different_column_type = pd.DataFrame({1.0: [10], 2.0: [20]})
>>> different_column_type
   1.0  2.0
0   10   20
>>> df.equals(different_column_type)
True
```

DataFrames df and different_data_type have different types for the same values for their elements, and will return False even though their column labels are the same values and types.

```
>>> different_data_type = pd.DataFrame({1: [10.0], 2: [20.0]})
>>> different_data_type
      1     2
0  10.0  20.0
>>> df.equals(different_data_type)
False
```

pandas.DataFrame.eval

DataFrame.**eval**(*expr*, *inplace=False*, ***kwargs*)

Evaluate a string describing operations on DataFrame columns.

Operates on columns only, not specific rows or elements. This allows *eval* to run arbitrary code, which can make you vulnerable to code injection if you pass user input to this function.

Parameters

expr [str] The expression string to evaluate.

inplace [bool, default False] If the expression contains an assignment, whether to perform the operation inplace and mutate the existing DataFrame. Otherwise, a new DataFrame is returned.

****kwargs** See the documentation for *eval()* for complete details on the keyword arguments accepted by *query()*.

Returns

ndarray, scalar, or pandas object The result of the evaluation.

See also:

DataFrame.query Evaluates a boolean expression to query the columns of a frame.

DataFrame.assign Can evaluate an expression or function to create new values for a column.

eval Evaluate a Python expression as a string using various backends.

Notes

For more details see the API documentation for *eval()*. For detailed examples see *enhancing performance with eval*.

Examples

```
>>> df = pd.DataFrame({'A': range(1, 6), 'B': range(10, 0, -2)})
>>> df
   A   B
0  1  10
1  2   8
2  3   6
3  4   4
4  5   2
>>> df.eval('A + B')
0    11
1    10
2     9
3     8
4     7
dtype: int64
```

Assignment is allowed though by default the original DataFrame is not modified.

```
>>> df.eval('C = A + B')
   A   B   C
0  1  10  11
1  2   8  10
2  3   6   9
3  4   4   8
4  5   2   7
>>> df
   A   B
0  1  10
1  2   8
2  3   6
3  4   4
4  5   2
```

Use `inplace=True` to modify the original DataFrame.

```
>>> df.eval('C = A + B', inplace=True)
>>> df
   A   B   C
0  1  10  11
1  2   8  10
2  3   6   9
3  4   4   8
4  5   2   7
```

Multiple columns can be assigned to using multi-line expressions:

```
>>> df.eval(
...       '''
... C = A + B
... D = A - B
... '''
... )
   A   B   C  D
0  1  10  11 -9
1  2   8  10 -6
2  3   6   9 -3
3  4   4   8  0
4  5   2   7  3
```

pandas.DataFrame.ewm

DataFrame.**ewm**(*com=None*, *span=None*, *halflife=None*, *alpha=None*, *min_periods=0*, *adjust=True*, *ignore_na=False*, *axis=0*, *times=None*)

Provide exponential weighted (EW) functions.

Available EW functions: `mean()`, `var()`, `std()`, `corr()`, `cov()`.

Exactly one parameter: `com`, `span`, `halflife`, or `alpha` must be provided.

Parameters

com [float, optional] Specify decay in terms of center of mass, $\alpha = 1/(1 + com)$, for $com \geq 0$.

span [float, optional] Specify decay in terms of span, $\alpha = 2/(span+1)$, for $span \geq 1$.

halflife [float, str, timedelta, optional] Specify decay in terms of half-life, $\alpha = 1 - \exp(-\ln(2)/halflife)$, for $halflife > 0$.

If `times` is specified, the time unit (str or timedelta) over which an observation decays to half its value. Only applicable to `mean()` and halflife value will not apply to the other functions.

New in version 1.1.0.

alpha [float, optional] Specify smoothing factor α directly, $0 < \alpha \leq 1$.

min_periods [int, default 0] Minimum number of observations in window required to have a value (otherwise result is NA).

adjust [bool, default True] Divide by decaying adjustment factor in beginning periods to account for imbalance in relative weightings (viewing EWMA as a moving average).

- When `adjust=True` (default), the EW function is calculated using weights $w_i = (1 - \alpha)^i$. For example, the EW moving average of the series $[x_0, x_1, ..., x_t]$ would be:

$$y_t = \frac{x_t + (1 - \alpha)x_{t-1} + (1 - \alpha)^2 x_{t-2} + ... + (1 - \alpha)^t x_0}{1 + (1 - \alpha) + (1 - \alpha)^2 + ... + (1 - \alpha)^t}$$

- When `adjust=False`, the exponentially weighted function is calculated recursively:

$$y_0 = x_0$$
$$y_t = (1 - \alpha)y_{t-1} + \alpha x_t,$$

ignore_na [bool, default False] Ignore missing values when calculating weights; specify `True` to reproduce pre-0.15.0 behavior.

- When `ignore_na=False` (default), weights are based on absolute positions. For example, the weights of x_0 and x_2 used in calculating the final weighted average of [x_0, None, x_2] are $(1 - \alpha)^2$ and 1 if `adjust=True`, and $(1 - \alpha)^2$ and α if `adjust=False`.
- When `ignore_na=True` (reproducing pre-0.15.0 behavior), weights are based on relative positions. For example, the weights of x_0 and x_2 used in calculating the final weighted average of [x_0, None, x_2] are $1 - \alpha$ and 1 if `adjust=True`, and $1 - \alpha$ and α if `adjust=False`.

axis [{0, 1}, default 0] The axis to use. The value 0 identifies the rows, and 1 identifies the columns.

times [str, np.ndarray, Series, default None] New in version 1.1.0.

Times corresponding to the observations. Must be monotonically increasing and `datetime64[ns]` dtype.

If str, the name of the column in the DataFrame representing the times.

If 1-D array like, a sequence with the same shape as the observations.

Only applicable to `mean()`.

Returns

DataFrame A Window sub-classed for the particular operation.

See also:

rolling Provides rolling window calculations.

expanding Provides expanding transformations.

Notes

More details can be found at: *Exponentially weighted windows*.

Examples

```
>>> df = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]})
>>> df
     B
0  0.0
1  1.0
2  2.0
3  NaN
4  4.0
```

```
>>> df.ewm(com=0.5).mean()
          B
0  0.000000
1  0.750000
2  1.615385
3  1.615385
4  3.670213
```

Specifying `times` with a timedelta `halflife` when computing mean.

```
>>> times = ['2020-01-01', '2020-01-03', '2020-01-10', '2020-01-15', '2020-
↪01-17']
>>> df.ewm(halflife='4 days', times=pd.DatetimeIndex(times)).mean()
          B
0  0.000000
1  0.585786
2  1.523889
3  1.523889
4  3.233686
```

pandas.DataFrame.expanding

DataFrame.**expanding**(*min_periods=1*, *center=None*, *axis=0*)

Provide expanding transformations.

Parameters

min_periods [int, default 1] Minimum number of observations in window required to have a value (otherwise result is NA).

center [bool, default False] Set the labels at the center of the window.

axis [int or str, default 0]

Returns

a Window sub-classed for the particular operation

See also:

rolling Provides rolling window calculations.

ewm Provides exponential weighted functions.

Notes

By default, the result is set to the right edge of the window. This can be changed to the center of the window by setting `center=True`.

Examples

```
>>> df = pd.DataFrame({"B": [0, 1, 2, np.nan, 4]})
>>> df
     B
0  0.0
1  1.0
2  2.0
3  NaN
4  4.0
```

```
>>> df.expanding(2).sum()
     B
0  NaN
1  1.0
2  3.0
3  3.0
4  7.0
```

pandas.DataFrame.explode

DataFrame.**explode**(*column*, *ignore_index=False*)

Transform each element of a list-like to a row, replicating index values.

New in version 0.25.0.

Parameters

column [str or tuple] Column to explode.

ignore_index [bool, default False] If True, the resulting index will be labeled 0, 1, . . . , n - 1.

New in version 1.1.0.

Returns

DataFrame Exploded lists to rows of the subset columns; index will be duplicated for these rows.

Raises

ValueError [] if columns of the frame are not unique.

See also:

DataFrame.unstack Pivot a level of the (necessarily hierarchical) index labels.

DataFrame.melt Unpivot a DataFrame from wide format to long format.

Series.explode Explode a DataFrame from list-like columns to long format.

Notes

This routine will explode list-likes including lists, tuples, Series, and np.ndarray. The result dtype of the subset rows will be object. Scalars will be returned unchanged. Empty list-likes will result in a np.nan for that row.

Examples

```
>>> df = pd.DataFrame({'A': [[1, 2, 3], 'foo', [], [3, 4]], 'B': 1})
>>> df
           A  B
0  [1, 2, 3]  1
1        foo  1
2         []  1
3     [3, 4]  1
```

```
>>> df.explode('A')
     A  B
0    1  1
0    2  1
0    3  1
1  foo  1
2  NaN  1
3    3  1
3    4  1
```

pandas.DataFrame.ffill

DataFrame.**ffill**(*axis=None*, *inplace=False*, *limit=None*, *downcast=None*)

Synonym for *DataFrame.fillna()* with `method='ffill'`.

Returns

{klass} or None Object with missing values filled or None if `inplace=True`.

pandas.DataFrame.fillna

DataFrame.**fillna**(*value=None*, *method=None*, *axis=None*, *inplace=False*, *limit=None*, *downcast=None*)

Fill NA/NaN values using the specified method.

Parameters

value [scalar, dict, Series, or DataFrame] Value to use to fill holes (e.g. 0), alternately a dict/Series/DataFrame of values specifying which value to use for each index (for a Series) or column (for a DataFrame). Values not in the dict/Series/DataFrame will not be filled. This value cannot be a list.

method [{'backfill', 'bfill', 'pad', 'ffill', None}, default None] Method to use for filling holes in reindexed Series pad / ffill: propagate last valid observation forward to next valid backfill / bfill: use next valid observation to fill gap.

axis [{0 or 'index', 1 or 'columns'}] Axis along which to fill missing values.

inplace [bool, default False] If True, fill in-place. Note: this will modify any other views on this object (e.g., a no-copy slice for a column in a DataFrame).

limit [int, default None] If method is specified, this is the maximum number of consecutive NaN values to forward/backward fill. In other words, if there is a gap with more than this number of consecutive NaNs, it will only be partially filled. If method is not specified, this is the maximum number of entries along the entire axis where NaNs will be filled. Must be greater than 0 if not None.

downcast [dict, default is None] A dict of item->dtype of what to downcast if possible, or the string 'infer' which will try to downcast to an appropriate equal type (e.g. float64 to int64 if possible).

Returns

DataFrame or None Object with missing values filled or None if `inplace=True`.

See also:

interpolate Fill NaN values using interpolation.

reindex Conform object to new index.

asfreq Convert TimeSeries to specified frequency.

Examples

```
>>> df = pd.DataFrame([[np.nan, 2, np.nan, 0],
...                    [3, 4, np.nan, 1],
...                    [np.nan, np.nan, np.nan, 5],
...                    [np.nan, 3, np.nan, 4]],
...                   columns=list('ABCD'))
>>> df
     A    B   C  D
0  NaN  2.0 NaN  0
1  3.0  4.0 NaN  1
2  NaN  NaN NaN  5
3  NaN  3.0 NaN  4
```

Replace all NaN elements with 0s.

```
>>> df.fillna(0)
    A   B   C   D
0   0.0 2.0 0.0 0
1   3.0 4.0 0.0 1
2   0.0 0.0 0.0 5
3   0.0 3.0 0.0 4
```

We can also propagate non-null values forward or backward.

```
>>> df.fillna(method='ffill')
    A   B   C   D
0   NaN 2.0 NaN 0
```

(continues on next page)

(continued from previous page)

```
1   3.0 4.0 NaN 1
2   3.0 4.0 NaN 5
3   3.0 3.0 NaN 4
```

Replace all NaN elements in column 'A', 'B', 'C', and 'D', with 0, 1, 2, and 3 respectively.

```
>>> values = {'A': 0, 'B': 1, 'C': 2, 'D': 3}
>>> df.fillna(value=values)
    A   B   C   D
0   0.0 2.0 2.0 0
1   3.0 4.0 2.0 1
2   0.0 1.0 2.0 5
3   0.0 3.0 2.0 4
```

Only replace the first NaN element.

```
>>> df.fillna(value=values, limit=1)
    A   B   C   D
0   0.0 2.0 2.0 0
1   3.0 4.0 NaN 1
2   NaN 1.0 NaN 5
3   NaN 3.0 NaN 4
```

pandas.DataFrame.filter

DataFrame.**filter**(*items=None*, *like=None*, *regex=None*, *axis=None*)

Subset the dataframe rows or columns according to the specified index labels.

Note that this routine does not filter a dataframe on its contents. The filter is applied to the labels of the index.

Parameters

items [list-like] Keep labels from axis which are in items.

like [str] Keep labels from axis for which "like in label == True".

regex [str (regular expression)] Keep labels from axis for which re.search(regex, label) == True.

axis [{0 or 'index', 1 or 'columns', None}, default None] The axis to filter on, expressed either as an index (int) or axis name (str). By default this is the info axis, 'index' for Series, 'columns' for DataFrame.

Returns

same type as input object

See also:

DataFrame.loc Access a group of rows and columns by label(s) or a boolean array.

Notes

The `items`, `like`, and `regex` parameters are enforced to be mutually exclusive.

`axis` defaults to the info axis that is used when indexing with `[]`.

Examples

```
>>> df = pd.DataFrame(np.array(([1, 2, 3], [4, 5, 6])),
...                   index=['mouse', 'rabbit'],
...                   columns=['one', 'two', 'three'])
>>> df
        one  two  three
mouse     1    2      3
rabbit    4    5      6
```

```
>>> # select columns by name
>>> df.filter(items=['one', 'three'])
         one  three
mouse     1      3
rabbit    4      6
```

```
>>> # select columns by regular expression
>>> df.filter(regex='e$', axis=1)
         one  three
mouse     1      3
rabbit    4      6
```

```
>>> # select rows containing 'bbi'
>>> df.filter(like='bbi', axis=0)
         one  two  three
rabbit    4    5      6
```

pandas.DataFrame.first

DataFrame.**first**(*offset*)

Select initial periods of time series data based on a date offset.

When having a DataFrame with dates as index, this function can select the first few rows based on a date offset.

Parameters

offset [str, DateOffset or dateutil.relativedelta] The offset length of the data that will be selected. For instance, '1M' will display all the rows having their index within the first month.

Returns

Series or DataFrame A subset of the caller.

Raises

TypeError If the index is not a *DatetimeIndex*

See also:

last Select final periods of time series based on a date offset.

at_time Select values at a particular time of the day.

between_time Select values between particular times of the day.

Examples

```
>>> i = pd.date_range('2018-04-09', periods=4, freq='2D')
>>> ts = pd.DataFrame({'A': [1, 2, 3, 4]}, index=i)
>>> ts
            A
2018-04-09  1
2018-04-11  2
2018-04-13  3
2018-04-15  4
```

Get the rows for the first 3 days:

```
>>> ts.first('3D')
            A
2018-04-09  1
2018-04-11  2
```

Notice the data for 3 first calendar days were returned, not the first 3 days observed in the dataset, and therefore data for 2018-04-13 was not returned.

pandas.DataFrame.first_valid_index

DataFrame.**first_valid_index**()
Return index for first non-NA/null value.

Returns

scalar [type of index]

Notes

If all elements are non-NA/null, returns None. Also returns None for empty Series/DataFrame.

pandas.DataFrame.floordiv

DataFrame.**floordiv**(*other*, *axis='columns'*, *level=None*, *fill_value=None*)
Get Integer division of dataframe and other, element-wise (binary operator *floordiv*).

Equivalent to `dataframe // other`, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, *rfloordiv*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: +, -, *, /, //, %, **.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

See also:

DataFrame.add Add DataFrames.

DataFrame.sub Subtract DataFrames.

DataFrame.mul Multiply DataFrames.

DataFrame.div Divide DataFrames (float division).

DataFrame.truediv Divide DataFrames (float division).

DataFrame.floordiv Divide DataFrames (integer division).

DataFrame.mod Calculate modulo (remainder after division).

DataFrame.pow Calculate exponential power.

Notes

Mismatched indices will be unioned together.

Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                   index=['circle', 'triangle', 'rectangle'])
>>> df
           angles  degrees
circle          0      360
triangle        3      180
rectangle       4      360
```

Add a scalar with operator version which return the same results.

```
>>> df + 1
           angles  degrees
circle          1      361
triangle        4      181
rectangle       5      361
```

```
>>> df.add(1)
           angles  degrees
circle          1      361
triangle        4      181
rectangle       5      361
```

Divide by constant with reverse version.

```
>>> df.div(10)
           angles  degrees
circle        0.0     36.0
triangle      0.3     18.0
rectangle     0.4     36.0
```

```
>>> df.rdiv(10)
             angles   degrees
circle          inf  0.027778
triangle   3.333333  0.055556
rectangle  2.500000  0.027778
```

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
           angles  degrees
circle         -1      358
triangle        2      178
rectangle       3      358
```

```
>>> df.sub([1, 2], axis='columns')
           angles  degrees
circle         -1      358
triangle        2      178
rectangle       3      358
```

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...        axis='index')
           angles  degrees
circle         -1      359
triangle        2      179
rectangle       3      359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                      index=['circle', 'triangle', 'rectangle'])
>>> other
           angles
circle          0
triangle        3
rectangle       4
```

```
>>> df * other
           angles  degrees
circle          0      NaN
triangle        9      NaN
rectangle      16      NaN
```

```
>>> df.mul(other, fill_value=0)
           angles  degrees
circle          0      0.0
triangle        9      0.0
rectangle      16      0.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                              'degrees': [360, 180, 360, 360, 540, 720]},
...                             index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                    ['circle', 'triangle', 'rectangle',
...                                     'square', 'pentagon', 'hexagon']])
>>> df_multindex
             angles  degrees
A circle          0      360
  triangle        3      180
  rectangle       4      360
B square          4      360
  pentagon        5      540
  hexagon         6      720
```

```
>>> df.div(df_multindex, level=1, fill_value=0)
             angles  degrees
A circle        NaN      1.0
  triangle      1.0      1.0
  rectangle     1.0      1.0
B square        0.0      0.0
  pentagon      0.0      0.0
  hexagon       0.0      0.0
```

pandas.DataFrame.from_dict

classmethod DataFrame.**from_dict**(*data*, *orient='columns'*, *dtype=None*, *columns=None*)

Construct DataFrame from dict of array-like or dicts.

Creates DataFrame object from dictionary by columns or by index allowing dtype specification.

Parameters

data [dict] Of the form {field : array-like} or {field : dict}.

orient [{'columns', 'index'}, default 'columns'] The "orientation" of the data. If the keys of the passed dict should be the columns of the resulting DataFrame, pass 'columns' (default). Otherwise if the keys should be rows, pass 'index'.

dtype [dtype, default None] Data type to force, otherwise infer.

columns [list, default None] Column labels to use when `orient='index'`. Raises a ValueError if used with `orient='columns'`.

New in version 0.23.0.

Returns

DataFrame

See also:

DataFrame.from_records DataFrame from structured ndarray, sequence of tuples or dicts, or DataFrame.

DataFrame DataFrame object creation using constructor.

Examples

By default the keys of the dict become the DataFrame columns:

```
>>> data = {'col_1': [3, 2, 1, 0], 'col_2': ['a', 'b', 'c', 'd']}
>>> pd.DataFrame.from_dict(data)
   col_1 col_2
0      3     a
1      2     b
2      1     c
3      0     d
```

Specify `orient='index'` to create the DataFrame using dictionary keys as rows:

```
>>> data = {'row_1': [3, 2, 1, 0], 'row_2': ['a', 'b', 'c', 'd']}
>>> pd.DataFrame.from_dict(data, orient='index')
       0  1  2  3
row_1  3  2  1  0
row_2  a  b  c  d
```

When using the 'index' orientation, the column names can be specified manually:

```
>>> pd.DataFrame.from_dict(data, orient='index',
...                        columns=['A', 'B', 'C', 'D'])
       A  B  C  D
row_1  3  2  1  0
row_2  a  b  c  d
```

pandas.DataFrame.from_records

classmethod DataFrame.**from_records**(*data*, *index=None*, *exclude=None*, *columns=None*, *coerce_float=False*, *nrows=None*)

Convert structured or record ndarray to DataFrame.

Creates a DataFrame object from a structured ndarray, sequence of tuples or dicts, or DataFrame.

Parameters

data [structured ndarray, sequence of tuples or dicts, or DataFrame] Structured input data.

index [str, list of fields, array-like] Field of array to use as the index, alternately a specific set of input labels to use.

exclude [sequence, default None] Columns or fields to exclude.

columns [sequence, default None] Column names to use. If the passed data do not have names associated with them, this argument provides names for the columns. Otherwise this argument indicates the order of the columns in the result (any names not found in the data will become all-NA columns).

coerce_float [bool, default False] Attempt to convert values of non-string, non-numeric objects (like decimal.Decimal) to floating point, useful for SQL result sets.

nrows [int, default None] Number of rows to read if data is an iterator.

Returns

DataFrame

See also:

DataFrame.from_dict DataFrame from dict of array-like or dicts.

DataFrame DataFrame object creation using constructor.

Examples

Data can be provided as a structured ndarray:

```
>>> data = np.array([(3, 'a'), (2, 'b'), (1, 'c'), (0, 'd')],
...                 dtype=[('col_1', 'i4'), ('col_2', 'U1')])
>>> pd.DataFrame.from_records(data)
   col_1 col_2
0      3     a
1      2     b
2      1     c
3      0     d
```

Data can be provided as a list of dicts:

```
>>> data = [{'col_1': 3, 'col_2': 'a'},
...         {'col_1': 2, 'col_2': 'b'},
...         {'col_1': 1, 'col_2': 'c'},
...         {'col_1': 0, 'col_2': 'd'}]
>>> pd.DataFrame.from_records(data)
   col_1 col_2
0      3     a
1      2     b
2      1     c
3      0     d
```

Data can be provided as a list of tuples with corresponding columns:

```
>>> data = [(3, 'a'), (2, 'b'), (1, 'c'), (0, 'd')]
>>> pd.DataFrame.from_records(data, columns=['col_1', 'col_2'])
   col_1 col_2
0      3     a
1      2     b
2      1     c
3      0     d
```

pandas.DataFrame.ge

DataFrame.**ge**(*other*, *axis='columns'*, *level=None*)

Get Greater than or equal to of dataframe and other, element-wise (binary operator *ge*).

Among flexible wrappers (*eq*, *ne*, *le*, *lt*, *ge*, *gt*) to comparison operators.

Equivalent to ==, =!, <=, <, >=, > with support to choose axis (rows or columns) and level for comparison.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}, default 'columns'] Whether to compare by the index (0 or 'index') or columns (1 or 'columns').

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

DataFrame of bool Result of the comparison.

See also:

DataFrame.eq Compare DataFrames for equality elementwise.

DataFrame.ne Compare DataFrames for inequality elementwise.

DataFrame.le Compare DataFrames for less than inequality or equality elementwise.

DataFrame.lt Compare DataFrames for strictly less than inequality elementwise.

DataFrame.ge Compare DataFrames for greater than inequality or equality elementwise.

DataFrame.gt Compare DataFrames for strictly greater than inequality elementwise.

Notes

Mismatched indices will be unioned together. *NaN* values are considered different (i.e. *NaN* != *NaN*).

Examples

```
>>> df = pd.DataFrame({'cost': [250, 150, 100],
...                    'revenue': [100, 250, 300]},
...                   index=['A', 'B', 'C'])
>>> df
   cost  revenue
A   250      100
B   150      250
C   100      300
```

Comparison with a scalar, using either the operator or method:

```
>>> df == 100
    cost  revenue
A  False     True
```

(continues on next page)

(continued from previous page)

```
B  False    False
C   True    False
```

```
>>> df.eq(100)
    cost  revenue
A  False     True
B  False    False
C   True    False
```

When *other* is a *Series*, the columns of a DataFrame are aligned with the index of *other* and broadcast:

```
>>> df != pd.Series([100, 250], index=["cost", "revenue"])
    cost  revenue
A   True     True
B   True    False
C  False     True
```

Use the method to control the broadcast axis:

```
>>> df.ne(pd.Series([100, 300], index=["A", "D"]), axis='index')
   cost  revenue
A  True    False
B  True     True
C  True     True
D  True     True
```

When comparing to an arbitrary sequence, the number of columns must match the number elements in *other*:

```
>>> df == [250, 100]
    cost  revenue
A   True     True
B  False    False
C  False    False
```

Use the method to control the axis:

```
>>> df.eq([250, 250, 100], axis='index')
    cost  revenue
A   True    False
B  False     True
C   True    False
```

Compare to a DataFrame of different shape.

```
>>> other = pd.DataFrame({'revenue': [300, 250, 100, 150]},
...                      index=['A', 'B', 'C', 'D'])
>>> other
   revenue
A      300
B      250
C      100
D      150
```

```
>>> df.gt(other)
    cost  revenue
```

(continues on next page)

(continued from previous page)

```
A  False    False
B  False    False
C  False     True
D  False    False
```

Compare to a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'cost': [250, 150, 100, 150, 300, 220],
...                              'revenue': [100, 250, 300, 200, 175, 225]},
...                             index=[['Q1', 'Q1', 'Q1', 'Q2', 'Q2', 'Q2'],
...                                    ['A', 'B', 'C', 'A', 'B', 'C']])
>>> df_multindex
      cost  revenue
Q1 A   250      100
   B   150      250
   C   100      300
Q2 A   150      200
   B   300      175
   C   220      225
```

```
>>> df.le(df_multindex, level=1)
       cost  revenue
Q1 A   True     True
   B   True     True
   C   True     True
Q2 A  False     True
   B   True    False
   C   True    False
```

pandas.DataFrame.get

DataFrame.**get**(*key*, *default=None*)

Get item from object for given key (ex: DataFrame column).

Returns default value if not found.

Parameters

key [object]

Returns

value [same type as items contained in object]

pandas.DataFrame.groupby

DataFrame.**groupby**(*by=None*, *axis=0*, *level=None*, *as_index=True*, *sort=True*, *group_keys=True*, *squeeze=<object object>*, *observed=False*, *dropna=True*)

Group DataFrame using a mapper or by a Series of columns.

A groupby operation involves some combination of splitting the object, applying a function, and combining the results. This can be used to group large amounts of data and compute operations on these groups.

Parameters

by [mapping, function, label, or list of labels] Used to determine the groups for the groupby. If `by` is a function, it's called on each value of the object's index. If a dict or Series is passed, the Series or dict VALUES will be used to determine the groups (the Series' values are first aligned; see `.align()` method). If an ndarray is passed, the values are used as-is determine the groups. A label or list of labels may be passed to group by the columns in `self`. Notice that a tuple is interpreted as a (single) key.

axis [{0 or 'index', 1 or 'columns'}, default 0] Split along rows (0) or columns (1).

level [int, level name, or sequence of such, default None] If the axis is a MultiIndex (hierarchical), group by a particular level or levels.

as_index [bool, default True] For aggregated output, return object with group labels as the index. Only relevant for DataFrame input. as_index=False is effectively "SQL-style" grouped output.

sort [bool, default True] Sort group keys. Get better performance by turning this off. Note this does not influence the order of observations within each group. Groupby preserves the order of rows within each group.

group_keys [bool, default True] When calling apply, add group keys to index to identify pieces.

squeeze [bool, default False] Reduce the dimensionality of the return type if possible, otherwise return a consistent type.

Deprecated since version 1.1.0.

observed [bool, default False] This only applies if any of the groupers are Categoricals. If True: only show observed values for categorical groupers. If False: show all values for categorical groupers.

New in version 0.23.0.

dropna [bool, default True] If True, and if group keys contain NA values, NA values together with row/column will be dropped. If False, NA values will also be treated as the key in groups

New in version 1.1.0.

Returns

DataFrameGroupBy Returns a groupby object that contains information about the groups.

See also:

resample Convenience method for frequency conversion and resampling of time series.

Notes

See the user guide for more.

Examples

```
>>> df = pd.DataFrame({'Animal': ['Falcon', 'Falcon',
...                               'Parrot', 'Parrot'],
...                    'Max Speed': [380., 370., 24., 26.]})
>>> df
   Animal  Max Speed
0  Falcon      380.0
1  Falcon      370.0
2  Parrot       24.0
3  Parrot       26.0
>>> df.groupby(['Animal']).mean()
        Max Speed
Animal
Falcon      375.0
Parrot       25.0
```

Hierarchical Indexes

We can groupby different levels of a hierarchical index using the *level* parameter:

```
>>> arrays = [['Falcon', 'Falcon', 'Parrot', 'Parrot'],
...           ['Captive', 'Wild', 'Captive', 'Wild']]
>>> index = pd.MultiIndex.from_arrays(arrays, names=('Animal', 'Type'))
>>> df = pd.DataFrame({'Max Speed': [390., 350., 30., 20.]},
...                   index=index)
>>> df
                Max Speed
Animal Type
Falcon Captive      390.0
       Wild         350.0
Parrot Captive       30.0
       Wild          20.0
>>> df.groupby(level=0).mean()
        Max Speed
Animal
Falcon      370.0
Parrot       25.0
>>> df.groupby(level="Type").mean()
         Max Speed
Type
Captive      210.0
Wild         185.0
```

We can also choose to include NA in group keys or not by setting *dropna* parameter, the default setting is *True*:

```
>>> l = [[1, 2, 3], [1, None, 4], [2, 1, 3], [1, 2, 2]]
>>> df = pd.DataFrame(l, columns=["a", "b", "c"])
```

```
>>> df.groupby(by=["b"]).sum()
    a   c
b
1.0 2   3
2.0 2   5
```

```
>>> df.groupby(by=["b"], dropna=False).sum()
    a   c
b
1.0 2   3
2.0 2   5
NaN 1   4
```

```
>>> l = [["a", 12, 12], [None, 12.3, 33.], ["b", 12.3, 123], ["a", 1, 1]]
>>> df = pd.DataFrame(l, columns=["a", "b", "c"])
```

```
>>> df.groupby(by="a").sum()
    b     c
a
a   13.0   13.0
b   12.3  123.0
```

```
>>> df.groupby(by="a", dropna=False).sum()
    b     c
a
a   13.0   13.0
b   12.3  123.0
NaN 12.3   33.0
```

pandas.DataFrame.gt

DataFrame.**gt**(*other*, *axis='columns'*, *level=None*)

Get Greater than of dataframe and other, element-wise (binary operator *gt*).

Among flexible wrappers (*eq*, *ne*, *le*, *lt*, *ge*, *gt*) to comparison operators.

Equivalent to ==, =!, <=, <, >=, > with support to choose axis (rows or columns) and level for comparison.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}, default 'columns'] Whether to compare by the index (0 or 'index') or columns (1 or 'columns').

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

DataFrame of bool Result of the comparison.

See also:

DataFrame.eq Compare DataFrames for equality elementwise.

DataFrame.ne Compare DataFrames for inequality elementwise.

DataFrame.le Compare DataFrames for less than inequality or equality elementwise.

DataFrame.lt Compare DataFrames for strictly less than inequality elementwise.

DataFrame.ge Compare DataFrames for greater than inequality or equality elementwise.

DataFrame.gt Compare DataFrames for strictly greater than inequality elementwise.

Notes

Mismatched indices will be unioned together. *NaN* values are considered different (i.e. *NaN* != *NaN*).

Examples

```
>>> df = pd.DataFrame({'cost': [250, 150, 100],
...                    'revenue': [100, 250, 300]},
...                   index=['A', 'B', 'C'])
>>> df
   cost  revenue
A   250      100
B   150      250
C   100      300
```

Comparison with a scalar, using either the operator or method:

```
>>> df == 100
    cost  revenue
A  False     True
B  False    False
C   True    False
```

```
>>> df.eq(100)
    cost  revenue
A  False     True
B  False    False
C   True    False
```

When *other* is a *Series*, the columns of a DataFrame are aligned with the index of *other* and broadcast:

```
>>> df != pd.Series([100, 250], index=["cost", "revenue"])
    cost  revenue
A   True     True
B   True    False
C  False     True
```

Use the method to control the broadcast axis:

```
>>> df.ne(pd.Series([100, 300], index=["A", "D"]), axis='index')
   cost  revenue
A  True    False
B  True     True
C  True     True
D  True     True
```

When comparing to an arbitrary sequence, the number of columns must match the number elements in *other*:

```
>>> df == [250, 100]
    cost  revenue
A   True     True
```

(continues on next page)

(continued from previous page)

```
B  False    False
C  False    False
```

Use the method to control the axis:

```
>>> df.eq([250, 250, 100], axis='index')
    cost  revenue
A   True    False
B  False     True
C   True    False
```

Compare to a DataFrame of different shape.

```
>>> other = pd.DataFrame({'revenue': [300, 250, 100, 150]},
...                      index=['A', 'B', 'C', 'D'])
>>> other
   revenue
A      300
B      250
C      100
D      150
```

```
>>> df.gt(other)
    cost  revenue
A  False    False
B  False    False
C  False     True
D  False    False
```

Compare to a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'cost': [250, 150, 100, 150, 300, 220],
...                              'revenue': [100, 250, 300, 200, 175, 225]},
...                             index=[['Q1', 'Q1', 'Q1', 'Q2', 'Q2', 'Q2'],
...                                    ['A', 'B', 'C', 'A', 'B', 'C']])
>>> df_multindex
      cost  revenue
Q1 A   250      100
   B   150      250
   C   100      300
Q2 A   150      200
   B   300      175
   C   220      225
```

```
>>> df.le(df_multindex, level=1)
       cost  revenue
Q1 A   True     True
   B   True     True
   C   True     True
Q2 A  False     True
   B   True    False
   C   True    False
```

pandas.DataFrame.head

DataFrame.**head**(*n=5*)

Return the first *n* rows.

This function returns the first *n* rows for the object based on position. It is useful for quickly testing if your object has the right type of data in it.

For negative values of *n*, this function returns all rows except the last *n* rows, equivalent to `df[:-n]`.

Parameters

n [int, default 5] Number of rows to select.

Returns

same type as caller The first *n* rows of the caller object.

See also:

DataFrame.tail Returns the last *n* rows.

Examples

```
>>> df = pd.DataFrame({'animal': ['alligator', 'bee', 'falcon', 'lion',
...                    'monkey', 'parrot', 'shark', 'whale', 'zebra']})
>>> df
      animal
0  alligator
1        bee
2     falcon
3       lion
4     monkey
5     parrot
6      shark
7      whale
8      zebra
```

Viewing the first 5 lines

```
>>> df.head()
      animal
0  alligator
1        bee
2     falcon
3       lion
4     monkey
```

Viewing the first *n* lines (three in this case)

```
>>> df.head(3)
      animal
0  alligator
1        bee
2     falcon
```

For negative values of *n*

```
>>> df.head(-3)
      animal
0  alligator
1        bee
2     falcon
3       lion
4     monkey
5     parrot
```

pandas.DataFrame.hist

DataFrame.**hist**(*column=None*, *by=None*, *grid=True*, *xlabelsize=None*, *xrot=None*, *ylabelsize=None*, *yrot=None*, *ax=None*, *sharex=False*, *sharey=False*, *figsize=None*, *layout=None*, *bins=10*, *backend=None*, *legend=False*, ***kwargs*)

Make a histogram of the DataFrame's.

A histogram is a representation of the distribution of data. This function calls `matplotlib.pyplot.hist()`, on each series in the DataFrame, resulting in one histogram per column.

Parameters

data [DataFrame] The pandas object holding the data.

column [str or sequence] If passed, will be used to limit data to a subset of columns.

by [object, optional] If passed, then used to form histograms for separate groups.

grid [bool, default True] Whether to show axis grid lines.

xlabelsize [int, default None] If specified changes the x-axis label size.

xrot [float, default None] Rotation of x axis labels. For example, a value of 90 displays the x labels rotated 90 degrees clockwise.

ylabelsize [int, default None] If specified changes the y-axis label size.

yrot [float, default None] Rotation of y axis labels. For example, a value of 90 displays the y labels rotated 90 degrees clockwise.

ax [Matplotlib axes object, default None] The axes to plot the histogram on.

sharex [bool, default True if ax is None else False] In case subplots=True, share x axis and set some x axis labels to invisible; defaults to True if ax is None otherwise False if an ax is passed in. Note that passing in both an ax and sharex=True will alter all x axis labels for all subplots in a figure.

sharey [bool, default False] In case subplots=True, share y axis and set some y axis labels to invisible.

figsize [tuple] The size in inches of the figure to create. Uses the value in *matplotlib.rcParams* by default.

layout [tuple, optional] Tuple of (rows, columns) for the layout of the histograms.

bins [int or sequence, default 10] Number of histogram bins to be used. If an integer is given, bins + 1 bin edges are calculated and returned. If bins is a sequence, gives bin edges, including left edge of first bin and right edge of last bin. In this case, bins is returned unmodified.

backend [str, default None] Backend to use instead of the backend specified in the option `plotting.backend`. For instance, 'matplotlib'. Alternatively, to

specify the `plotting.backend` for the whole session, set `pd.options.plotting.backend`.

New in version 1.0.0.

legend [bool, default False] Whether to show the legend.

New in version 1.1.0.

****kwargs** All other plotting keyword arguments to be passed to `matplotlib.pyplot.hist()`.

Returns

matplotlib.AxesSubplot or numpy.ndarray of them

See also:

`matplotlib.pyplot.hist` Plot a histogram using matplotlib.

Examples

This example draws a histogram based on the length and width of some animals, displayed in three bins

```
>>> df = pd.DataFrame({
...     'length': [1.5, 0.5, 1.2, 0.9, 3],
...     'width': [0.7, 0.2, 0.15, 0.2, 1.1]
...     }, index=['pig', 'rabbit', 'duck', 'chicken', 'horse'])
>>> hist = df.hist(bins=3)
```

pandas.DataFrame.idxmax

DataFrame.**idxmax**(*axis=0*, *skipna=True*)

Return index of first occurrence of maximum over requested axis.

NA/null values are excluded.

Parameters

axis [{0 or 'index', 1 or 'columns'}, default 0] The axis to use. 0 or 'index' for row-wise, 1 or 'columns' for column-wise.

skipna [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

Returns

Series Indexes of maxima along the specified axis.

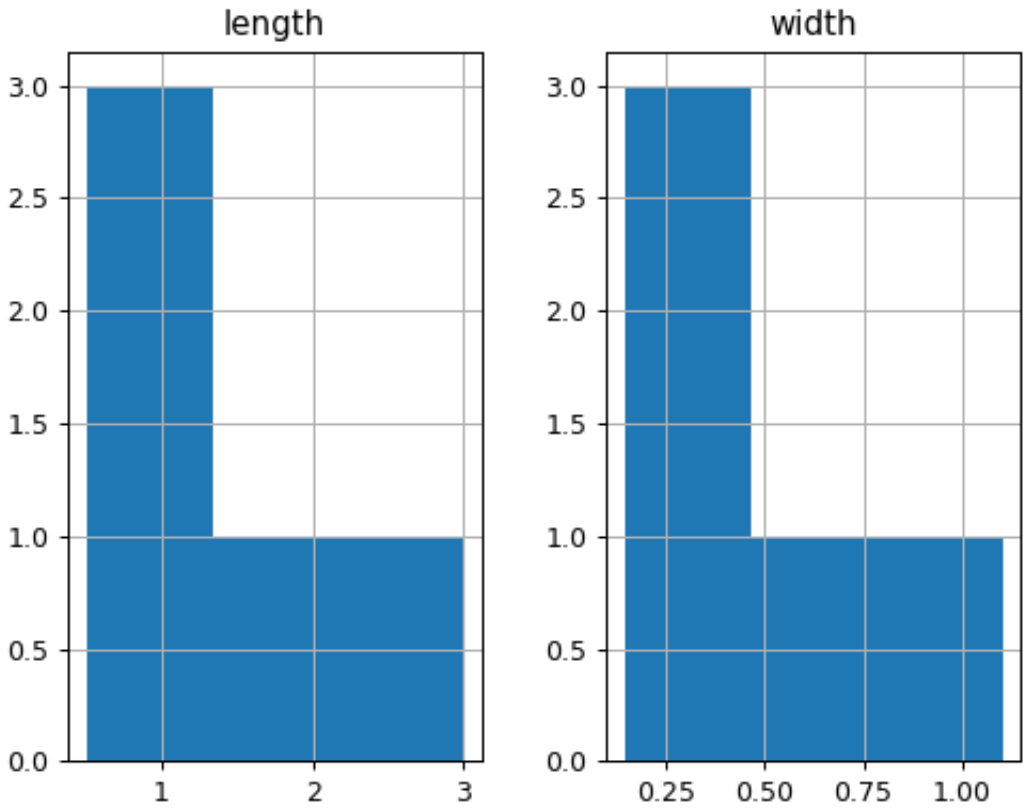
Raises

ValueError

- If the row/column is empty

See also:

`Series.idxmax` Return index of the maximum element.



length
width
3.0
2.5
2.0
1.5
1.0
0.5
0.0
1
2
3
0.25
0.50
0.75
1.00

Notes

This method is the DataFrame version of `ndarray.argmax`.

Examples

Consider a dataset containing food consumption in Argentina.

```
>>> df = pd.DataFrame({'consumption': [10.51, 103.11, 55.48],
...                    'co2_emissions': [37.2, 19.66, 1712]},
...                    index=['Pork', 'Wheat Products', 'Beef'])
```

```
>>> df
                consumption  co2_emissions
Pork                  10.51          37.20
Wheat Products       103.11          19.66
Beef                  55.48        1712.00
```

By default, it returns the index for the maximum value in each column.

```
>>> df.idxmax()
consumption     Wheat Products
co2_emissions             Beef
dtype: object
```

To return the index for the maximum value in each row, use `axis="columns"`.

```
>>> df.idxmax(axis="columns")
Pork              co2_emissions
Wheat Products     consumption
Beef              co2_emissions
dtype: object
```

pandas.DataFrame.idxmin

DataFrame.**idxmin**(*axis=0*, *skipna=True*)

Return index of first occurrence of minimum over requested axis.

NA/null values are excluded.

Parameters

axis [{0 or 'index', 1 or 'columns'}, default 0] The axis to use. 0 or 'index' for row-wise, 1 or 'columns' for column-wise.

skipna [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

Returns

Series Indexes of minima along the specified axis.

Raises

ValueError

- If the row/column is empty

See also:

Series.idxmin Return index of the minimum element.

Notes

This method is the DataFrame version of `ndarray.argmin`.

Examples

Consider a dataset containing food consumption in Argentina.

```
>>> df = pd.DataFrame({'consumption': [10.51, 103.11, 55.48],
...                    'co2_emissions': [37.2, 19.66, 1712]},
...                    index=['Pork', 'Wheat Products', 'Beef'])
```

```
>>> df
                consumption  co2_emissions
Pork                  10.51         37.20
Wheat Products       103.11         19.66
Beef                  55.48       1712.00
```

By default, it returns the index for the minimum value in each column.

```
>>> df.idxmin()
consumption                Pork
co2_emissions    Wheat Products
dtype: object
```

To return the index for the minimum value in each row, use `axis="columns"`.

```
>>> df.idxmin(axis="columns")
Pork                consumption
Wheat Products    co2_emissions
Beef                consumption
dtype: object
```

pandas.DataFrame.infer_objects

DataFrame.**infer_objects**()

Attempt to infer better dtypes for object columns.

Attempts soft conversion of object-dtyped columns, leaving non-object and unconvertible columns unchanged. The inference rules are the same as during normal Series/DataFrame construction.

Returns

converted [same type as input object]

See also:

to_datetime Convert argument to datetime.

to_timedelta Convert argument to timedelta.

to_numeric Convert argument to numeric type.

convert_dtypes Convert argument to best possible dtype.

Examples

```
>>> df = pd.DataFrame({"A": ["a", 1, 2, 3]})
>>> df = df.iloc[1:]
>>> df
   A
1  1
2  2
3  3
```

```
>>> df.dtypes
A    object
dtype: object
```

```
>>> df.infer_objects().dtypes
A    int64
dtype: object
```

pandas.DataFrame.info

DataFrame.**info**(*verbose=None*, *buf=None*, *max_cols=None*, *memory_usage=None*, *null_counts=None*)

Print a concise summary of a DataFrame.

This method prints information about a DataFrame including the index dtype and columns, non-null values and memory usage.

Parameters

data [DataFrame] DataFrame to print information about.

verbose [bool, optional] Whether to print the full summary. By default, the setting in `pandas.options.display.max_info_columns` is followed.

buf [writable buffer, defaults to sys.stdout] Where to send the output. By default, the output is printed to sys.stdout. Pass a writable buffer if you need to further process the output.

max_cols [int, optional] When to switch from the verbose to the truncated output. If the DataFrame has more than *max_cols* columns, the truncated output is used. By default, the setting in `pandas.options.display.max_info_columns` is used.

memory_usage [bool, str, optional] Specifies whether total memory usage of the DataFrame elements (including the index) should be displayed. By default, this follows the `pandas.options.display.memory_usage` setting.

True always show memory usage. False never shows memory usage. A value of 'deep' is equivalent to "True with deep introspection". Memory usage is shown in human-readable units (base-2 representation). Without deep introspection a memory estimation is made based in column dtype and number of rows assuming values consume the same memory amount for corresponding dtypes. With deep memory introspection, a real memory usage calculation is performed at the cost of computational resources.

null_counts [bool, optional] Whether to show the non-null counts. By default, this is shown only if the DataFrame is smaller than `pandas.options.display.max_info_rows` and `pandas.options.display.max_info_columns`. A value of True always shows the counts, and False never shows the counts.

Returns

None This method prints a summary of a DataFrame and returns None.

See also:

DataFrame.describe Generate descriptive statistics of DataFrame columns.

DataFrame.memory_usage Memory usage of DataFrame columns.

Examples

```
>>> int_values = [1, 2, 3, 4, 5]
>>> text_values = ['alpha', 'beta', 'gamma', 'delta', 'epsilon']
>>> float_values = [0.0, 0.25, 0.5, 0.75, 1.0]
>>> df = pd.DataFrame({"int_col": int_values, "text_col": text_values,
...                    "float_col": float_values})
>>> df
    int_col text_col  float_col
0         1    alpha       0.00
1         2     beta       0.25
2         3    gamma       0.50
3         4    delta       0.75
4         5  epsilon       1.00
```

Prints information of all columns:

```
>>> df.info(verbose=True)
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 5 entries, 0 to 4
Data columns (total 3 columns):
 #   Column     Non-Null Count  Dtype
---  ------     --------------  -----
 0   int_col    5 non-null      int64
 1   text_col   5 non-null      object
 2   float_col  5 non-null      float64
dtypes: float64(1), int64(1), object(1)
memory usage: 248.0+ bytes
```

Prints a summary of columns count and its dtypes but not per column information:

```
>>> df.info(verbose=False)
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 5 entries, 0 to 4
Columns: 3 entries, int_col to float_col
dtypes: float64(1), int64(1), object(1)
memory usage: 248.0+ bytes
```

Pipe output of DataFrame.info to buffer instead of sys.stdout, get buffer content and writes to a text file:

```
>>> import io
>>> buffer = io.StringIO()
>>> df.info(buf=buffer)
>>> s = buffer.getvalue()
>>> with open("df_info.txt", "w",
...           encoding="utf-8") as f:
...     f.write(s)
260
```

The *memory_usage* parameter allows deep introspection mode, specially useful for big DataFrames and fine-tune memory optimization:

```
>>> random_strings_array = np.random.choice(['a', 'b', 'c'], 10 ** 6)
>>> df = pd.DataFrame({
...     'column_1': np.random.choice(['a', 'b', 'c'], 10 ** 6),
...     'column_2': np.random.choice(['a', 'b', 'c'], 10 ** 6),
...     'column_3': np.random.choice(['a', 'b', 'c'], 10 ** 6)
... })
>>> df.info()
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 1000000 entries, 0 to 999999
Data columns (total 3 columns):
 #   Column    Non-Null Count    Dtype
---  ------    --------------    -----
 0   column_1  1000000 non-null  object
 1   column_2  1000000 non-null  object
 2   column_3  1000000 non-null  object
dtypes: object(3)
memory usage: 22.9+ MB
```

```
>>> df.info(memory_usage='deep')
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 1000000 entries, 0 to 999999
Data columns (total 3 columns):
 #   Column    Non-Null Count    Dtype
---  ------    --------------    -----
 0   column_1  1000000 non-null  object
 1   column_2  1000000 non-null  object
 2   column_3  1000000 non-null  object
dtypes: object(3)
memory usage: 188.8 MB
```

pandas.DataFrame.insert

DataFrame.**insert**(*loc*, *column*, *value*, *allow_duplicates=False*)

Insert column into DataFrame at specified location.

Raises a ValueError if *column* is already contained in the DataFrame, unless *allow_duplicates* is set to True.

Parameters

loc [int] Insertion index. Must verify 0 <= loc <= len(columns).

column [str, number, or hashable object] Label of the inserted column.

value [int, Series, or array-like]

allow_duplicates [bool, optional]

pandas.DataFrame.interpolate

DataFrame.**interpolate**(*method='linear'*, *axis=0*, *limit=None*, *inplace=False*, *limit_direction=None*, *limit_area=None*, *downcast=None*, ***kwargs*)

Please note that only `method='linear'` is supported for DataFrame/Series with a MultiIndex.

Parameters

method [str, default 'linear'] Interpolation technique to use. One of:

- 'linear': Ignore the index and treat the values as equally spaced. This is the only method supported on MultiIndexes.
- 'time': Works on daily and higher resolution data to interpolate given length of interval.
- 'index', 'values': use the actual numerical values of the index.
- 'pad': Fill in NaNs using existing values.
- 'nearest', 'zero', 'slinear', 'quadratic', 'cubic', 'spline', 'barycentric', 'polynomial': Passed to *scipy.interpolate.interp1d*. These methods use the numerical values of the index. Both 'polynomial' and 'spline' require that you also specify an *order* (int), e.g. `df.interpolate(method='polynomial', order=5)`.
- 'krogh', 'piecewise_polynomial', 'spline', 'pchip', 'akima', 'cubicspline': Wrappers around the SciPy interpolation methods of similar names. See *Notes*.
- 'from_derivatives': Refers to *scipy.interpolate.BPoly.from_derivatives* which replaces 'piecewise_polynomial' interpolation method in scipy 0.18.

axis [{{0 or 'index', 1 or 'columns', None}}, default None] Axis to interpolate along.

limit [int, optional] Maximum number of consecutive NaNs to fill. Must be greater than 0.

inplace [bool, default False] Update the data in place if possible.

limit_direction [{{'forward', 'backward', 'both'}}, Optional] Consecutive NaNs will be filled in this direction.

If limit is specified:

- If 'method' is 'pad' or 'ffill', 'limit_direction' must be 'forward'.
- If 'method' is 'backfill' or 'bfill', 'limit_direction' must be 'backwards'.

If 'limit' is not specified:

- If 'method' is 'backfill' or 'bfill', the default is 'backward'
- else the default is 'forward'

Changed in version 1.1.0: raises ValueError if *limit_direction* is 'forward' or 'both' and method is 'backfill' or 'bfill'. raises ValueError if *limit_direction* is 'backward' or 'both' and method is 'pad' or 'ffill'.

limit_area [{{*None*, 'inside', 'outside'}}, default None] If limit is specified, consecutive NaNs will be filled with this restriction.

- `None`: No fill restriction.

- 'inside': Only fill NaNs surrounded by valid values (interpolate).
- 'outside': Only fill NaNs outside valid values (extrapolate).

New in version 0.23.0.

downcast [optional, 'infer' or None, defaults to None] Downcast dtypes if possible.

****kwargs** Keyword arguments to pass on to the interpolating function.

Returns

Series or DataFrame Returns the same object type as the caller, interpolated at some or all `NaN` values.

See also:

fillna Fill missing values using different methods.

scipy.interpolate.Akima1DInterpolator Piecewise cubic polynomials (Akima interpolator).

scipy.interpolate.BPoly.from_derivatives Piecewise polynomial in the Bernstein basis.

scipy.interpolate.interp1d Interpolate a 1-D function.

scipy.interpolate.KroghInterpolator Interpolate polynomial (Krogh interpolator).

scipy.interpolate.PchipInterpolator PCHIP 1-d monotonic cubic interpolation.

scipy.interpolate.CubicSpline Cubic spline data interpolator.

Notes

The 'krogh', 'piecewise_polynomial', 'spline', 'pchip' and 'akima' methods are wrappers around the respective SciPy implementations of similar names. These use the actual numerical values of the index. For more information on their behavior, see the SciPy documentation and SciPy tutorial.

Examples

Filling in `NaN` in a *Series* via linear interpolation.

```
>>> s = pd.Series([0, 1, np.nan, 3])
>>> s
0    0.0
1    1.0
2    NaN
3    3.0
dtype: float64
>>> s.interpolate()
0    0.0
1    1.0
2    2.0
3    3.0
dtype: float64
```

Filling in `NaN` in a Series by padding, but filling at most two consecutive `NaN` at a time.

```
>>> s = pd.Series([np.nan, "single_one", np.nan,
...                "fill_two_more", np.nan, np.nan, np.nan,
...                4.71, np.nan])
>>> s
0              NaN
1       single_one
2              NaN
3    fill_two_more
4              NaN
5              NaN
6              NaN
7             4.71
8              NaN
dtype: object
>>> s.interpolate(method='pad', limit=2)
0              NaN
1       single_one
2       single_one
3    fill_two_more
4    fill_two_more
5    fill_two_more
6              NaN
7             4.71
8             4.71
dtype: object
```

Filling in `NaN` in a Series via polynomial interpolation or splines: Both 'polynomial' and 'spline' methods require that you also specify an `order` (int).

```
>>> s = pd.Series([0, 2, np.nan, 8])
>>> s.interpolate(method='polynomial', order=2)
0    0.000000
1    2.000000
2    4.666667
3    8.000000
dtype: float64
```

Fill the DataFrame forward (that is, going down) along each column using linear interpolation.

Note how the last entry in column 'a' is interpolated differently, because there is no entry after it to use for interpolation. Note how the first entry in column 'b' remains `NaN`, because there is no entry before it to use for interpolation.

```
>>> df = pd.DataFrame([(0.0, np.nan, -1.0, 1.0),
...                    (np.nan, 2.0, np.nan, np.nan),
...                    (2.0, 3.0, np.nan, 9.0),
...                    (np.nan, 4.0, -4.0, 16.0)],
...                   columns=list('abcd'))
>>> df
     a    b    c     d
0  0.0  NaN -1.0   1.0
1  NaN  2.0  NaN   NaN
2  2.0  3.0  NaN   9.0
3  NaN  4.0 -4.0  16.0
>>> df.interpolate(method='linear', limit_direction='forward', axis=0)
     a    b    c     d
0  0.0  NaN -1.0   1.0
```

(continues on next page)

(continued from previous page)

```
1  1.0  2.0 -2.0   5.0
2  2.0  3.0 -3.0   9.0
3  2.0  4.0 -4.0  16.0
```

Using polynomial interpolation.

```
>>> df['d'].interpolate(method='polynomial', order=2)
0     1.0
1     4.0
2     9.0
3    16.0
Name: d, dtype: float64
```

pandas.DataFrame.isin

DataFrame.**isin**(*values*)

Whether each element in the DataFrame is contained in values.

Parameters

values [iterable, Series, DataFrame or dict] The result will only be true at a location if all the labels match. If *values* is a Series, that's the index. If *values* is a dict, the keys must be the column names, which must match. If *values* is a DataFrame, then both the index and column labels must match.

Returns

DataFrame DataFrame of booleans showing whether each element in the DataFrame is contained in values.

See also:

DataFrame.eq Equality test for DataFrame.

Series.isin Equivalent method on Series.

Series.str.contains Test if pattern or regex is contained within a string of a Series or Index.

Examples

```
>>> df = pd.DataFrame({'num_legs': [2, 4], 'num_wings': [2, 0]},
...                   index=['falcon', 'dog'])
>>> df
        num_legs  num_wings
falcon         2          2
dog            4          0
```

When `values` is a list check whether every value in the DataFrame is present in the list (which animals have 0 or 2 legs or wings)

```
>>> df.isin([0, 2])
        num_legs  num_wings
falcon      True       True
dog        False       True
```

When `values` is a dict, we can pass values to check for each column separately:

```
>>> df.isin({'num_wings': [0, 3]})
        num_legs  num_wings
falcon     False      False
dog        False       True
```

When `values` is a Series or DataFrame the index and column must match. Note that 'falcon' does not match based on the number of legs in df2.

```
>>> other = pd.DataFrame({'num_legs': [8, 2], 'num_wings': [0, 2]},
...                      index=['spider', 'falcon'])
>>> df.isin(other)
        num_legs  num_wings
falcon      True       True
dog        False      False
```

pandas.DataFrame.isna

DataFrame.**isna**()

Detect missing values.

Return a boolean same-sized object indicating if the values are NA. NA values, such as None or `numpy.NaN`, gets mapped to True values. Everything else gets mapped to False values. Characters such as empty strings `''` or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`).

Returns

DataFrame Mask of bool values for each element in DataFrame that indicates whether an element is not an NA value.

See also:

DataFrame.isnull Alias of isna.

DataFrame.notna Boolean inverse of isna.

DataFrame.dropna Omit axes labels with missing values.

isna Top-level isna.

Examples

Show which entries in a DataFrame are NA.

```
>>> df = pd.DataFrame({'age': [5, 6, np.NaN],
...                    'born': [pd.NaT, pd.Timestamp('1939-05-27'),
...                             pd.Timestamp('1940-04-25')],
...                    'name': ['Alfred', 'Batman', ''],
...                    'toy': [None, 'Batmobile', 'Joker']})
>>> df
   age       born    name        toy
0  5.0        NaT  Alfred       None
1  6.0 1939-05-27  Batman  Batmobile
2  NaN 1940-04-25              Joker
```

```
>>> df.isna()
     age   born   name    toy
0  False   True  False   True
1  False  False  False  False
2   True  False  False  False
```

Show which entries in a Series are NA.

```
>>> ser = pd.Series([5, 6, np.NaN])
>>> ser
0    5.0
1    6.0
2    NaN
dtype: float64
```

```
>>> ser.isna()
0    False
1    False
2     True
dtype: bool
```

pandas.DataFrame.isnull

DataFrame.**isnull**()

Detect missing values.

Return a boolean same-sized object indicating if the values are NA. NA values, such as None or `numpy.NaN`, gets mapped to True values. Everything else gets mapped to False values. Characters such as empty strings `''` or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`).

Returns

DataFrame Mask of bool values for each element in DataFrame that indicates whether an element is not an NA value.

See also:

DataFrame.isnull Alias of isna.

DataFrame.notna Boolean inverse of isna.

DataFrame.dropna Omit axes labels with missing values.

isna Top-level isna.

Examples

Show which entries in a DataFrame are NA.

```
>>> df = pd.DataFrame({'age': [5, 6, np.NaN],
...                    'born': [pd.NaT, pd.Timestamp('1939-05-27'),
...                             pd.Timestamp('1940-04-25')],
...                    'name': ['Alfred', 'Batman', ''],
...                    'toy': [None, 'Batmobile', 'Joker']})
>>> df
```

(continues on next page)

(continued from previous page)

```
   age       born    name        toy
0  5.0        NaT  Alfred       None
1  6.0 1939-05-27  Batman  Batmobile
2  NaN 1940-04-25              Joker
```

```
>>> df.isna()
     age   born   name    toy
0  False   True  False   True
1  False  False  False  False
2   True  False  False  False
```

Show which entries in a Series are NA.

```
>>> ser = pd.Series([5, 6, np.NaN])
>>> ser
0    5.0
1    6.0
2    NaN
dtype: float64
```

```
>>> ser.isna()
0    False
1    False
2     True
dtype: bool
```

pandas.DataFrame.items

DataFrame.**items**()

Iterate over (column name, Series) pairs.

Iterates over the DataFrame columns, returning a tuple with the column name and the content as a Series.

Yields

label [object] The column names for the DataFrame being iterated over.

content [Series] The column entries belonging to each label, as a Series.

See also:

DataFrame.iterrows Iterate over DataFrame rows as (index, Series) pairs.

DataFrame.itertuples Iterate over DataFrame rows as namedtuples of the values.

Examples

```
>>> df = pd.DataFrame({'species': ['bear', 'bear', 'marsupial'],
...                    'population': [1864, 22000, 80000]},
...                    index=['panda', 'polar', 'koala'])
>>> df
        species   population
panda   bear      1864
polar   bear      22000
```

(continues on next page)

(continued from previous page)

```
koala   marsupial 80000
>>> for label, content in df.items():
...     print(f'label: {label}')
...     print(f'content: {content}', sep='\n')
...
label: species
content:
panda         bear
polar         bear
koala    marsupial
Name: species, dtype: object
label: population
content:
panda     1864
polar    22000
koala    80000
Name: population, dtype: int64
```

pandas.DataFrame.iteritems

DataFrame.**iteritems**()

Iterate over (column name, Series) pairs.

Iterates over the DataFrame columns, returning a tuple with the column name and the content as a Series.

Yields

label [object] The column names for the DataFrame being iterated over.

content [Series] The column entries belonging to each label, as a Series.

See also:

DataFrame.iterrows Iterate over DataFrame rows as (index, Series) pairs.

DataFrame.itertuples Iterate over DataFrame rows as namedtuples of the values.

Examples

```
>>> df = pd.DataFrame({'species': ['bear', 'bear', 'marsupial'],
...                    'population': [1864, 22000, 80000]},
...                    index=['panda', 'polar', 'koala'])
>>> df
        species   population
panda   bear      1864
polar   bear      22000
koala   marsupial 80000
>>> for label, content in df.items():
...     print(f'label: {label}')
...     print(f'content: {content}', sep='\n')
...
label: species
content:
panda         bear
polar         bear
```

(continues on next page)

(continued from previous page)

```
koala    marsupial
Name: species, dtype: object
label: population
content:
panda     1864
polar    22000
koala    80000
Name: population, dtype: int64
```

pandas.DataFrame.iterrows

DataFrame.**iterrows**()

Iterate over DataFrame rows as (index, Series) pairs.

Yields

index [label or tuple of label] The index of the row. A tuple for a *MultiIndex*.

data [Series] The data of the row as a Series.

it [generator] A generator that iterates over the rows of the frame.

See also:

DataFrame.itertuples Iterate over DataFrame rows as namedtuples of the values.

DataFrame.items Iterate over (column name, Series) pairs.

Notes

1. Because `iterrows` returns a Series for each row, it does **not** preserve dtypes across the rows (dtypes are preserved across columns for DataFrames). For example,

```
>>> df = pd.DataFrame([[1, 1.5]], columns=['int', 'float'])
>>> row = next(df.iterrows())[1]
>>> row
int      1.0
float    1.5
Name: 0, dtype: float64
>>> print(row['int'].dtype)
float64
>>> print(df['int'].dtype)
int64
```

   To preserve dtypes while iterating over the rows, it is better to use *itertuples()* which returns namedtuples of the values and which is generally faster than `iterrows`.

2. You should **never modify** something you are iterating over. This is not guaranteed to work in all cases. Depending on the data types, the iterator returns a copy and not a view, and writing to it will have no effect.

pandas.DataFrame.itertuples

DataFrame.**itertuples**(*index=True*, *name='Pandas'*)

Iterate over DataFrame rows as namedtuples.

Parameters

index [bool, default True] If True, return the index as the first element of the tuple.

name [str or None, default "Pandas"] The name of the returned namedtuples or None to return regular tuples.

Returns

iterator An object to iterate over namedtuples for each row in the DataFrame with the first field possibly being the index and following fields being the column values.

See also:

DataFrame.iterrows Iterate over DataFrame rows as (index, Series) pairs.

DataFrame.items Iterate over (column name, Series) pairs.

Notes

The column names will be renamed to positional names if they are invalid Python identifiers, repeated, or start with an underscore. On python versions < 3.7 regular tuples are returned for DataFrames with a large number of columns (>254).

Examples

```
>>> df = pd.DataFrame({'num_legs': [4, 2], 'num_wings': [0, 2]},
...                   index=['dog', 'hawk'])
>>> df
      num_legs  num_wings
dog          4          0
hawk         2          2
>>> for row in df.itertuples():
...     print(row)
...
Pandas(Index='dog', num_legs=4, num_wings=0)
Pandas(Index='hawk', num_legs=2, num_wings=2)
```

By setting the *index* parameter to False we can remove the index as the first element of the tuple:

```
>>> for row in df.itertuples(index=False):
...     print(row)
...
Pandas(num_legs=4, num_wings=0)
Pandas(num_legs=2, num_wings=2)
```

With the *name* parameter set we set a custom name for the yielded namedtuples:

```
>>> for row in df.itertuples(name='Animal'):
...     print(row)
...
```

(continues on next page)

(continued from previous page)

```
Animal(Index='dog', num_legs=4, num_wings=0)
Animal(Index='hawk', num_legs=2, num_wings=2)
```

pandas.DataFrame.join

DataFrame.**join**(*other*, *on=None*, *how='left'*, *lsuffix=''*, *rsuffix=''*, *sort=False*)

Join columns of another DataFrame.

Join columns with *other* DataFrame either on index or on a key column. Efficiently join multiple DataFrame objects by index at once by passing a list.

Parameters

other [DataFrame, Series, or list of DataFrame] Index should be similar to one of the columns in this one. If a Series is passed, its name attribute must be set, and that will be used as the column name in the resulting joined DataFrame.

on [str, list of str, or array-like, optional] Column or index level name(s) in the caller to join on the index in *other*, otherwise joins index-on-index. If multiple values given, the *other* DataFrame must have a MultiIndex. Can pass an array as the join key if it is not already contained in the calling DataFrame. Like an Excel VLOOKUP operation.

how [{'left', 'right', 'outer', 'inner'}, default 'left'] How to handle the operation of the two objects.

- left: use calling frame's index (or column if on is specified)
- right: use *other*'s index.
- outer: form union of calling frame's index (or column if on is specified) with *other*'s index, and sort it. lexicographically.
- inner: form intersection of calling frame's index (or column if on is specified) with *other*'s index, preserving the order of the calling's one.

lsuffix [str, default ''] Suffix to use from left frame's overlapping columns.

rsuffix [str, default ''] Suffix to use from right frame's overlapping columns.

sort [bool, default False] Order result DataFrame lexicographically by the join key. If False, the order of the join key depends on the join type (how keyword).

Returns

DataFrame A dataframe containing columns from both the caller and *other*.

See also:

DataFrame.merge For column(s)-on-columns(s) operations.

Notes

Parameters *on*, *lsuffix*, and *rsuffix* are not supported when passing a list of *DataFrame* objects.

Support for specifying index levels as the *on* parameter was added in version 0.23.0.

Examples

```
>>> df = pd.DataFrame({'key': ['K0', 'K1', 'K2', 'K3', 'K4', 'K5'],
...                    'A': ['A0', 'A1', 'A2', 'A3', 'A4', 'A5']})
```

```
>>> df
  key   A
0  K0  A0
1  K1  A1
2  K2  A2
3  K3  A3
4  K4  A4
5  K5  A5
```

```
>>> other = pd.DataFrame({'key': ['K0', 'K1', 'K2'],
...                       'B': ['B0', 'B1', 'B2']})
```

```
>>> other
  key   B
0  K0  B0
1  K1  B1
2  K2  B2
```

Join DataFrames using their indexes.

```
>>> df.join(other, lsuffix='_caller', rsuffix='_other')
  key_caller   A key_other    B
0         K0  A0         K0   B0
1         K1  A1         K1   B1
2         K2  A2         K2   B2
3         K3  A3        NaN  NaN
4         K4  A4        NaN  NaN
5         K5  A5        NaN  NaN
```

If we want to join using the key columns, we need to set key to be the index in both *df* and *other*. The joined DataFrame will have key as its index.

```
>>> df.set_index('key').join(other.set_index('key'))
      A    B
key
K0   A0   B0
K1   A1   B1
K2   A2   B2
K3   A3  NaN
K4   A4  NaN
K5   A5  NaN
```

Another option to join using the key columns is to use the *on* parameter. DataFrame.join always uses *other*'s index but we can use any column in *df*. This method preserves the original DataFrame's index in the result.

```
>>> df.join(other.set_index('key'), on='key')
  key   A    B
0  K0  A0   B0
1  K1  A1   B1
2  K2  A2   B2
3  K3  A3  NaN
4  K4  A4  NaN
5  K5  A5  NaN
```

pandas.DataFrame.keys

DataFrame.**keys**()

Get the 'info axis' (see Indexing for more).

This is index for Series, columns for DataFrame.

Returns

Index Info axis.

pandas.DataFrame.kurt

DataFrame.**kurt**(*axis=None*, *skipna=None*, *level=None*, *numeric_only=None*, ***kwargs*)

Return unbiased kurtosis over requested axis.

Kurtosis obtained using Fisher's definition of kurtosis (kurtosis of normal == 0.0). Normalized by N-1.

Parameters

axis [{index (0), columns (1)}] Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

****kwargs** Additional keyword arguments to be passed to the function.

Returns

Series or DataFrame (if level specified)

pandas.DataFrame.kurtosis

DataFrame.**kurtosis**(*axis=None*, *skipna=None*, *level=None*, *numeric_only=None*, ***kwargs*)

Return unbiased kurtosis over requested axis.

Kurtosis obtained using Fisher's definition of kurtosis (kurtosis of normal == 0.0). Normalized by N-1.

Parameters

axis [{index (0), columns (1)}] Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

****kwargs** Additional keyword arguments to be passed to the function.

Returns

Series or DataFrame (if level specified)

pandas.DataFrame.last

DataFrame.**last**(*offset*)

Select final periods of time series data based on a date offset.

When having a DataFrame with dates as index, this function can select the last few rows based on a date offset.

Parameters

offset [str, DateOffset, dateutil.relativedelta] The offset length of the data that will be selected. For instance, '3D' will display all the rows having their index within the last 3 days.

Returns

Series or DataFrame A subset of the caller.

Raises

TypeError If the index is not a *DatetimeIndex*

See also:

first Select initial periods of time series based on a date offset.

at_time Select values at a particular time of the day.

between_time Select values between particular times of the day.

Examples

```
>>> i = pd.date_range('2018-04-09', periods=4, freq='2D')
>>> ts = pd.DataFrame({'A': [1, 2, 3, 4]}, index=i)
>>> ts
            A
2018-04-09  1
2018-04-11  2
2018-04-13  3
2018-04-15  4
```

Get the rows for the last 3 days:

```
>>> ts.last('3D')
            A
2018-04-13  3
2018-04-15  4
```

Notice the data for 3 last calendar days were returned, not the last 3 observed days in the dataset, and therefore data for 2018-04-11 was not returned.

pandas.DataFrame.last_valid_index

DataFrame.**last_valid_index**()

Return index for last non-NA/null value.

Returns

scalar [type of index]

Notes

If all elements are non-NA/null, returns None. Also returns None for empty Series/DataFrame.

pandas.DataFrame.le

DataFrame.**le**(*other*, *axis='columns'*, *level=None*)

Get Less than or equal to of dataframe and other, element-wise (binary operator *le*).

Among flexible wrappers (*eq*, *ne*, *le*, *lt*, *ge*, *gt*) to comparison operators.

Equivalent to ==, =!, <=, <, >=, > with support to choose axis (rows or columns) and level for comparison.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}, default 'columns'] Whether to compare by the index (0 or 'index') or columns (1 or 'columns').

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

DataFrame of bool Result of the comparison.

See also:

DataFrame.eq Compare DataFrames for equality elementwise.

DataFrame.ne Compare DataFrames for inequality elementwise.

DataFrame.le Compare DataFrames for less than inequality or equality elementwise.

DataFrame.lt Compare DataFrames for strictly less than inequality elementwise.

DataFrame.ge Compare DataFrames for greater than inequality or equality elementwise.

DataFrame.gt Compare DataFrames for strictly greater than inequality elementwise.

Notes

Mismatched indices will be unioned together. *NaN* values are considered different (i.e. *NaN* != *NaN*).

Examples

```
>>> df = pd.DataFrame({'cost': [250, 150, 100],
...                    'revenue': [100, 250, 300]},
...                   index=['A', 'B', 'C'])
>>> df
   cost  revenue
A   250      100
B   150      250
C   100      300
```

Comparison with a scalar, using either the operator or method:

```
>>> df == 100
    cost  revenue
A  False     True
B  False    False
C   True    False
```

```
>>> df.eq(100)
    cost  revenue
A  False     True
B  False    False
C   True    False
```

When *other* is a *Series*, the columns of a DataFrame are aligned with the index of *other* and broadcast:

```
>>> df != pd.Series([100, 250], index=["cost", "revenue"])
    cost  revenue
A   True     True
B   True    False
C  False     True
```

Use the method to control the broadcast axis:

```
>>> df.ne(pd.Series([100, 300], index=["A", "D"]), axis='index')
   cost  revenue
A  True    False
B  True     True
C  True     True
D  True     True
```

When comparing to an arbitrary sequence, the number of columns must match the number elements in *other*:

```
>>> df == [250, 100]
    cost  revenue
A   True     True
B  False    False
C  False    False
```

Use the method to control the axis:

```
>>> df.eq([250, 250, 100], axis='index')
    cost  revenue
A   True    False
B  False     True
C   True    False
```

Compare to a DataFrame of different shape.

```
>>> other = pd.DataFrame({'revenue': [300, 250, 100, 150]},
...                      index=['A', 'B', 'C', 'D'])
>>> other
   revenue
A      300
B      250
C      100
D      150
```

```
>>> df.gt(other)
    cost  revenue
A  False    False
B  False    False
C  False     True
D  False    False
```

Compare to a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'cost': [250, 150, 100, 150, 300, 220],
...                              'revenue': [100, 250, 300, 200, 175, 225]},
...                             index=[['Q1', 'Q1', 'Q1', 'Q2', 'Q2', 'Q2'],
...                                    ['A', 'B', 'C', 'A', 'B', 'C']])
>>> df_multindex
      cost  revenue
Q1 A   250      100
   B   150      250
   C   100      300
Q2 A   150      200
   B   300      175
   C   220      225
```

```
>>> df.le(df_multindex, level=1)
       cost  revenue
Q1 A   True     True
   B   True     True
   C   True     True
Q2 A  False     True
   B   True    False
   C   True    False
```

pandas.DataFrame.lookup

DataFrame.**lookup**(*row_labels*, *col_labels*)

Label-based "fancy indexing" function for DataFrame.

Given equal-length arrays of row and column labels, return an array of the values corresponding to each (row, col) pair.

Parameters

row_labels [sequence] The row labels to use for lookup.

col_labels [sequence] The column labels to use for lookup.

Returns

numpy.ndarray The found values.

pandas.DataFrame.lt

DataFrame.**lt**(*other*, *axis='columns'*, *level=None*)

Get Less than of dataframe and other, element-wise (binary operator *lt*).

Among flexible wrappers (*eq*, *ne*, *le*, *lt*, *ge*, *gt*) to comparison operators.

Equivalent to ==, =*!*, <=, <, >=, > with support to choose axis (rows or columns) and level for comparison.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}, default 'columns'] Whether to compare by the index (0 or 'index') or columns (1 or 'columns').

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

DataFrame of bool Result of the comparison.

See also:

DataFrame.eq Compare DataFrames for equality elementwise.

DataFrame.ne Compare DataFrames for inequality elementwise.

DataFrame.le Compare DataFrames for less than inequality or equality elementwise.

DataFrame.lt Compare DataFrames for strictly less than inequality elementwise.

DataFrame.ge Compare DataFrames for greater than inequality or equality elementwise.

DataFrame.gt Compare DataFrames for strictly greater than inequality elementwise.

Notes

Mismatched indices will be unioned together. *NaN* values are considered different (i.e. *NaN* != *NaN*).

Examples

```
>>> df = pd.DataFrame({'cost': [250, 150, 100],
...                    'revenue': [100, 250, 300]},
...                   index=['A', 'B', 'C'])
>>> df
   cost  revenue
A   250      100
B   150      250
C   100      300
```

Comparison with a scalar, using either the operator or method:

```
>>> df == 100
    cost  revenue
A  False     True
B  False    False
C   True    False
```

```
>>> df.eq(100)
    cost  revenue
A  False     True
B  False    False
C   True    False
```

When *other* is a *Series*, the columns of a DataFrame are aligned with the index of *other* and broadcast:

```
>>> df != pd.Series([100, 250], index=["cost", "revenue"])
    cost  revenue
A   True     True
B   True    False
C  False     True
```

Use the method to control the broadcast axis:

```
>>> df.ne(pd.Series([100, 300], index=["A", "D"]), axis='index')
   cost  revenue
A  True    False
B  True     True
C  True     True
D  True     True
```

When comparing to an arbitrary sequence, the number of columns must match the number elements in *other*:

```
>>> df == [250, 100]
    cost  revenue
A   True     True
B  False    False
C  False    False
```

Use the method to control the axis:

```
>>> df.eq([250, 250, 100], axis='index')
    cost  revenue
A   True    False
B  False     True
C   True    False
```

Compare to a DataFrame of different shape.

```
>>> other = pd.DataFrame({'revenue': [300, 250, 100, 150]},
...                      index=['A', 'B', 'C', 'D'])
>>> other
   revenue
A      300
B      250
C      100
D      150
```

```
>>> df.gt(other)
    cost  revenue
A  False    False
B  False    False
C  False     True
D  False    False
```

Compare to a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'cost': [250, 150, 100, 150, 300, 220],
...                              'revenue': [100, 250, 300, 200, 175, 225]},
...                             index=[['Q1', 'Q1', 'Q1', 'Q2', 'Q2', 'Q2'],
...                                    ['A', 'B', 'C', 'A', 'B', 'C']])
>>> df_multindex
      cost  revenue
Q1 A   250      100
   B   150      250
   C   100      300
Q2 A   150      200
   B   300      175
   C   220      225
```

```
>>> df.le(df_multindex, level=1)
       cost  revenue
Q1 A   True     True
   B   True     True
   C   True     True
Q2 A  False     True
   B   True    False
   C   True    False
```

pandas.DataFrame.mad

DataFrame.**mad**(*axis=None*, *skipna=None*, *level=None*)

Return the mean absolute deviation of the values for the requested axis.

Parameters

axis [{index (0), columns (1)}] Axis for the function to be applied on.

skipna [bool, default None] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

Returns

Series or DataFrame (if level specified)

pandas.DataFrame.mask

DataFrame.**mask**(*cond*, *other=nan*, *inplace=False*, *axis=None*, *level=None*, *errors='raise'*, *try_cast=False*)

Replace values where the condition is True.

Parameters

cond [bool Series/DataFrame, array-like, or callable] Where *cond* is False, keep the original value. Where True, replace with corresponding value from *other*. If *cond* is callable, it is computed on the Series/DataFrame and should return boolean Series/DataFrame or array. The callable must not change input Series/DataFrame (though pandas doesn't check it).

other [scalar, Series/DataFrame, or callable] Entries where *cond* is True are replaced with corresponding value from *other*. If other is callable, it is computed on the Series/DataFrame and should return scalar or Series/DataFrame. The callable must not change input Series/DataFrame (though pandas doesn't check it).

inplace [bool, default False] Whether to perform the operation in place on the data.

axis [int, default None] Alignment axis if needed.

level [int, default None] Alignment level if needed.

errors [str, {'raise', 'ignore'}, default 'raise'] Note that currently this parameter won't affect the results and will always coerce to a suitable dtype.

- 'raise' : allow exceptions to be raised.
- 'ignore' : suppress exceptions. On error return original object.

try_cast [bool, default False] Try to cast the result back to the input type (if possible).

Returns

Same type as caller

See also:

DataFrame.where() Return an object of same shape as self.

Notes

The mask method is an application of the if-then idiom. For each element in the calling DataFrame, if `cond` is `False` the element is used; otherwise the corresponding element from the DataFrame `other` is used.

The signature for *`DataFrame.where()`* differs from `numpy.where()`. Roughly `df1.where(m, df2)` is equivalent to `np.where(m, df1, df2)`.

For further details and examples see the `mask` documentation in *indexing*.

Examples

```
>>> s = pd.Series(range(5))
>>> s.where(s > 0)
0    NaN
1    1.0
2    2.0
3    3.0
4    4.0
dtype: float64
```

```
>>> s.mask(s > 0)
0    0.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

```
>>> s.where(s > 1, 10)
0    10
1    10
2    2
3    3
4    4
dtype: int64
```

```
>>> df = pd.DataFrame(np.arange(10).reshape(-1, 2), columns=['A', 'B'])
>>> df
   A  B
0  0  1
1  2  3
2  4  5
3  6  7
4  8  9
>>> m = df % 3 == 0
>>> df.where(m, -df)
   A  B
0  0 -1
1 -2  3
2 -4 -5
3  6 -7
4 -8  9
>>> df.where(m, -df) == np.where(m, df, -df)
      A     B
```

(continues on next page)

(continued from previous page)

```
0  True  True
1  True  True
2  True  True
3  True  True
4  True  True
>>> df.where(m, -df) == df.mask(~m, -df)
      A     B
0  True  True
1  True  True
2  True  True
3  True  True
4  True  True
```

pandas.DataFrame.max

DataFrame.**max**(*axis=None*, *skipna=None*, *level=None*, *numeric_only=None*, ***kwargs*)

Return the maximum of the values for the requested axis.

If you want the *index* of the maximum, use `idxmax`. This isthe equivalent of the `numpy.ndarray` method `argmax`.

Parameters

axis [{index (0), columns (1)}] Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

****kwargs** Additional keyword arguments to be passed to the function.

Returns

Series or DataFrame (if level specified)

See also:

Series.sum Return the sum.

Series.min Return the minimum.

Series.max Return the maximum.

Series.idxmin Return the index of the minimum.

Series.idxmax Return the index of the maximum.

DataFrame.sum Return the sum over the requested axis.

DataFrame.min Return the minimum over the requested axis.

DataFrame.max Return the maximum over the requested axis.

DataFrame.idxmin Return the index of the minimum over the requested axis.

DataFrame.idxmax Return the index of the maximum over the requested axis.

Examples

```
>>> idx = pd.MultiIndex.from_arrays([
...     ['warm', 'warm', 'cold', 'cold'],
...     ['dog', 'falcon', 'fish', 'spider']],
...     names=['blooded', 'animal'])
>>> s = pd.Series([4, 2, 0, 8], name='legs', index=idx)
>>> s
blooded  animal
warm     dog       4
         falcon    2
cold     fish      0
         spider    8
Name: legs, dtype: int64
```

```
>>> s.max()
8
```

Max using level names, as well as indices.

```
>>> s.max(level='blooded')
blooded
warm    4
cold    8
Name: legs, dtype: int64
```

```
>>> s.max(level=0)
blooded
warm    4
cold    8
Name: legs, dtype: int64
```

pandas.DataFrame.mean

DataFrame.**mean**(*axis=None*, *skipna=None*, *level=None*, *numeric_only=None*, ***kwargs*)

Return the mean of the values for the requested axis.

Parameters

axis [{index (0), columns (1)}] Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

****kwargs** Additional keyword arguments to be passed to the function.

Returns

Series or DataFrame (if level specified)

pandas.DataFrame.median

DataFrame.**median**(*axis=None*, *skipna=None*, *level=None*, *numeric_only=None*, ***kwargs*)

Return the median of the values for the requested axis.

Parameters

axis [{index (0), columns (1)}] Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

****kwargs** Additional keyword arguments to be passed to the function.

Returns

Series or DataFrame (if level specified)

pandas.DataFrame.melt

DataFrame.**melt**(*id_vars=None*, *value_vars=None*, *var_name=None*, *value_name='value'*, *col_level=None*, *ignore_index=True*)

Unpivot a DataFrame from wide to long format, optionally leaving identifiers set.

This function is useful to massage a DataFrame into a format where one or more columns are identifier variables (*id_vars*), while all other columns, considered measured variables (*value_vars*), are "unpivoted" to the row axis, leaving just two non-identifier columns, 'variable' and 'value'.

New in version 0.20.0.

Parameters

id_vars [tuple, list, or ndarray, optional] Column(s) to use as identifier variables.

value_vars [tuple, list, or ndarray, optional] Column(s) to unpivot. If not specified, uses all columns that are not set as *id_vars*.

var_name [scalar] Name to use for the 'variable' column. If None it uses `frame.columns.name` or 'variable'.

value_name [scalar, default 'value'] Name to use for the 'value' column.

col_level [int or str, optional] If columns are a MultiIndex then use this level to melt.

ignore_index [bool, default True] If True, original index is ignored. If False, the original index is retained. Index labels will be repeated as necessary.

New in version 1.1.0.

Returns

DataFrame Unpivoted DataFrame.

See also:

melt Identical method.

pivot_table Create a spreadsheet-style pivot table as a DataFrame.

DataFrame.pivot Return reshaped DataFrame organized by given index / column values.

DataFrame.explode Explode a DataFrame from list-like columns to long format.

Examples

```
>>> df = pd.DataFrame({'A': {0: 'a', 1: 'b', 2: 'c'},
...                    'B': {0: 1, 1: 3, 2: 5},
...                    'C': {0: 2, 1: 4, 2: 6}})
>>> df
   A  B  C
0  a  1  2
1  b  3  4
2  c  5  6
```

```
>>> df.melt(id_vars=['A'], value_vars=['B'])
   A variable  value
0  a        B      1
1  b        B      3
2  c        B      5
```

```
>>> df.melt(id_vars=['A'], value_vars=['B', 'C'])
   A variable  value
0  a        B      1
1  b        B      3
2  c        B      5
3  a        C      2
4  b        C      4
5  c        C      6
```

The names of 'variable' and 'value' columns can be customized:

```
>>> df.melt(id_vars=['A'], value_vars=['B'],
...         var_name='myVarname', value_name='myValname')
   A myVarname  myValname
0  a         B          1
1  b         B          3
2  c         B          5
```

Original index values can be kept around:

```
>>> df.melt(id_vars=['A'], value_vars=['B', 'C'], ignore_index=False)
   A variable  value
0  a        B      1
1  b        B      3
2  c        B      5
0  a        C      2
1  b        C      4
2  c        C      6
```

If you have multi-index columns:

```
>>> df.columns = [list('ABC'), list('DEF')]
>>> df
   A  B  C
   D  E  F
```

(continues on next page)

(continued from previous page)

```
0  a  1  2
1  b  3  4
2  c  5  6
```

```
>>> df.melt(col_level=0, id_vars=['A'], value_vars=['B'])
   A variable  value
0  a        B      1
1  b        B      3
2  c        B      5
```

```
>>> df.melt(id_vars=[('A', 'D')], value_vars=[('B', 'E')])
  (A, D) variable_0 variable_1  value
0      a          B          E      1
1      b          B          E      3
2      c          B          E      5
```

pandas.DataFrame.memory_usage

DataFrame.**memory_usage**(*index=True*, *deep=False*)

Return the memory usage of each column in bytes.

The memory usage can optionally include the contribution of the index and elements of *object* dtype.

This value is displayed in *DataFrame.info* by default. This can be suppressed by setting `pandas.options.display.memory_usage` to False.

Parameters

index [bool, default True] Specifies whether to include the memory usage of the DataFrame's index in returned Series. If `index=True`, the memory usage of the index is the first item in the output.

deep [bool, default False] If True, introspect the data deeply by interrogating *object* dtypes for system-level memory consumption, and include it in the returned values.

Returns

Series A Series whose index is the original column names and whose values is the memory usage of each column in bytes.

See also:

numpy.ndarray.nbytes Total bytes consumed by the elements of an ndarray.

Series.memory_usage Bytes consumed by a Series.

Categorical Memory-efficient array for string values with many repeated values.

DataFrame.info Concise summary of a DataFrame.

Examples

```
>>> dtypes = ['int64', 'float64', 'complex128', 'object', 'bool']
>>> data = dict([(t, np.ones(shape=5000).astype(t))
...              for t in dtypes])
>>> df = pd.DataFrame(data)
>>> df.head()
   int64  float64            complex128  object  bool
0      1      1.0    1.000000+0.000000j       1  True
1      1      1.0    1.000000+0.000000j       1  True
2      1      1.0    1.000000+0.000000j       1  True
3      1      1.0    1.000000+0.000000j       1  True
4      1      1.0    1.000000+0.000000j       1  True
```

```
>>> df.memory_usage()
Index           128
int64         40000
float64       40000
complex128    80000
object        40000
bool           5000
dtype: int64
```

```
>>> df.memory_usage(index=False)
int64         40000
float64       40000
complex128    80000
object        40000
bool           5000
dtype: int64
```

The memory footprint of *object* dtype columns is ignored by default:

```
>>> df.memory_usage(deep=True)
Index           128
int64         40000
float64       40000
complex128    80000
object       160000
bool           5000
dtype: int64
```

Use a Categorical for efficient storage of an object-dtype column with many repeated values.

```
>>> df['object'].astype('category').memory_usage(deep=True)
5216
```

pandas.DataFrame.merge

DataFrame.**merge**(*right*, *how='inner'*, *on=None*, *left_on=None*, *right_on=None*, *left_index=False*, *right_index=False*, *sort=False*, *suffixes='_x', '_y'*, *copy=True*, *indicator=False*, *validate=None*)

Merge DataFrame or named Series objects with a database-style join.

The join is done on columns or indexes. If joining columns on columns, the DataFrame indexes *will be ignored*. Otherwise if joining indexes on indexes or indexes on a column or columns, the index will be passed on.

Parameters

right [DataFrame or named Series] Object to merge with.

how [{'left', 'right', 'outer', 'inner'}, default 'inner'] Type of merge to be performed.

- left: use only keys from left frame, similar to a SQL left outer join; preserve key order.
- right: use only keys from right frame, similar to a SQL right outer join; preserve key order.
- outer: use union of keys from both frames, similar to a SQL full outer join; sort keys lexicographically.
- inner: use intersection of keys from both frames, similar to a SQL inner join; preserve the order of the left keys.

on [label or list] Column or index level names to join on. These must be found in both DataFrames. If *on* is None and not merging on indexes then this defaults to the intersection of the columns in both DataFrames.

left_on [label or list, or array-like] Column or index level names to join on in the left DataFrame. Can also be an array or list of arrays of the length of the left DataFrame. These arrays are treated as if they are columns.

right_on [label or list, or array-like] Column or index level names to join on in the right DataFrame. Can also be an array or list of arrays of the length of the right DataFrame. These arrays are treated as if they are columns.

left_index [bool, default False] Use the index from the left DataFrame as the join key(s). If it is a MultiIndex, the number of keys in the other DataFrame (either the index or a number of columns) must match the number of levels.

right_index [bool, default False] Use the index from the right DataFrame as the join key. Same caveats as left_index.

sort [bool, default False] Sort the join keys lexicographically in the result DataFrame. If False, the order of the join keys depends on the join type (how keyword).

suffixes [list-like, default is ("_x", "_y")] A length-2 sequence where each element is optionally a string indicating the suffix to add to overlapping column names in *left* and *right* respectively. Pass a value of *None* instead of a string to indicate that the column name from *left* or *right* should be left as-is, with no suffix. At least one of the values must not be None.

copy [bool, default True] If False, avoid copy if possible.

indicator [bool or str, default False] If True, adds a column to the output DataFrame called "_merge" with information on the source of each row. The column can be given a different name by providing a string argument. The column will have a

Categorical type with the value of "left_only" for observations whose merge key only appears in the left DataFrame, "right_only" for observations whose merge key only appears in the right DataFrame, and "both" if the observation's merge key is found in both DataFrames.

validate [str, optional] If specified, checks if merge is of specified type.

- "one_to_one" or "1:1": check if merge keys are unique in both left and right datasets.
- "one_to_many" or "1:m": check if merge keys are unique in left dataset.
- "many_to_one" or "m:1": check if merge keys are unique in right dataset.
- "many_to_many" or "m:m": allowed, but does not result in checks.

Returns

DataFrame A DataFrame of the two merged objects.

See also:

merge_ordered Merge with optional filling/interpolation.

merge_asof Merge on nearest keys.

DataFrame.join Similar method using indices.

Notes

Support for specifying index levels as the *on*, *left_on*, and *right_on* parameters was added in version 0.23.0
Support for merging named Series objects was added in version 0.24.0

Examples

```
>>> df1 = pd.DataFrame({'lkey': ['foo', 'bar', 'baz', 'foo'],
...                     'value': [1, 2, 3, 5]})
>>> df2 = pd.DataFrame({'rkey': ['foo', 'bar', 'baz', 'foo'],
...                     'value': [5, 6, 7, 8]})
>>> df1
    lkey value
0   foo      1
1   bar      2
2   baz      3
3   foo      5
>>> df2
    rkey value
0   foo      5
1   bar      6
2   baz      7
3   foo      8
```

Merge df1 and df2 on the lkey and rkey columns. The value columns have the default suffixes, _x and _y, appended.

```
>>> df1.merge(df2, left_on='lkey', right_on='rkey')
  lkey  value_x rkey  value_y
0  foo        1  foo        5
```

(continues on next page)

(continued from previous page)

```
1  foo        1  foo        8
2  foo        5  foo        5
3  foo        5  foo        8
4  bar        2  bar        6
5  baz        3  baz        7
```

Merge DataFrames df1 and df2 with specified left and right suffixes appended to any overlapping columns.

```
>>> df1.merge(df2, left_on='lkey', right_on='rkey',
...           suffixes=('_left', '_right'))
  lkey  value_left rkey  value_right
0  foo           1  foo            5
1  foo           1  foo            8
2  foo           5  foo            5
3  foo           5  foo            8
4  bar           2  bar            6
5  baz           3  baz            7
```

Merge DataFrames df1 and df2, but raise an exception if the DataFrames have any overlapping columns.

```
>>> df1.merge(df2, left_on='lkey', right_on='rkey', suffixes=(False, False))
Traceback (most recent call last):
...
ValueError: columns overlap but no suffix specified:
    Index(['value'], dtype='object')
```

pandas.DataFrame.min

DataFrame.**min**(*axis=None*, *skipna=None*, *level=None*, *numeric_only=None*, ***kwargs*)

Return the minimum of the values for the requested axis.

If you want the *index* of the minimum, use `idxmin`. This isthe equivalent of the `numpy.ndarray` method `argmin`.

Parameters

axis [{index (0), columns (1)}] Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

****kwargs** Additional keyword arguments to be passed to the function.

Returns

Series or DataFrame (if level specified)

See also:

Series.sum Return the sum.

Series.min Return the minimum.

Series.max Return the maximum.

Series.idxmin Return the index of the minimum.

Series.idxmax Return the index of the maximum.

DataFrame.sum Return the sum over the requested axis.

DataFrame.min Return the minimum over the requested axis.

DataFrame.max Return the maximum over the requested axis.

DataFrame.idxmin Return the index of the minimum over the requested axis.

DataFrame.idxmax Return the index of the maximum over the requested axis.

Examples

```
>>> idx = pd.MultiIndex.from_arrays([
...     ['warm', 'warm', 'cold', 'cold'],
...     ['dog', 'falcon', 'fish', 'spider']],
...     names=['blooded', 'animal'])
>>> s = pd.Series([4, 2, 0, 8], name='legs', index=idx)
>>> s
blooded  animal
warm     dog       4
         falcon    2
cold     fish      0
         spider    8
Name: legs, dtype: int64
```

```
>>> s.min()
0
```

Min using level names, as well as indices.

```
>>> s.min(level='blooded')
blooded
warm    2
cold    0
Name: legs, dtype: int64
```

```
>>> s.min(level=0)
blooded
warm    2
cold    0
Name: legs, dtype: int64
```

pandas.DataFrame.mod

DataFrame.**mod**(*other*, *axis='columns'*, *level=None*, *fill_value=None*)

Get Modulo of dataframe and other, element-wise (binary operator *mod*).

Equivalent to `dataframe % other`, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, *rmod*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: +, -, *, /, //, %, **.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

See also:

DataFrame.add Add DataFrames.

DataFrame.sub Subtract DataFrames.

DataFrame.mul Multiply DataFrames.

DataFrame.div Divide DataFrames (float division).

DataFrame.truediv Divide DataFrames (float division).

DataFrame.floordiv Divide DataFrames (integer division).

DataFrame.mod Calculate modulo (remainder after division).

DataFrame.pow Calculate exponential power.

Notes

Mismatched indices will be unioned together.

Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                   index=['circle', 'triangle', 'rectangle'])
>>> df
           angles  degrees
circle          0      360
triangle        3      180
rectangle       4      360
```

Add a scalar with operator version which return the same results.

```
>>> df + 1
           angles  degrees
circle          1      361
triangle        4      181
rectangle       5      361
```

```
>>> df.add(1)
           angles  degrees
circle          1      361
triangle        4      181
rectangle       5      361
```

Divide by constant with reverse version.

```
>>> df.div(10)
           angles  degrees
circle        0.0     36.0
triangle      0.3     18.0
rectangle     0.4     36.0
```

```
>>> df.rdiv(10)
             angles   degrees
circle          inf  0.027778
triangle   3.333333  0.055556
rectangle  2.500000  0.027778
```

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
           angles  degrees
circle         -1      358
triangle        2      178
rectangle       3      358
```

```
>>> df.sub([1, 2], axis='columns')
           angles  degrees
circle         -1      358
triangle        2      178
rectangle       3      358
```

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...        axis='index')
           angles  degrees
```

(continues on next page)

(continued from previous page)

```
circle         -1      359
triangle        2      179
rectangle       3      359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                      index=['circle', 'triangle', 'rectangle'])
>>> other
           angles
circle          0
triangle        3
rectangle       4
```

```
>>> df * other
           angles  degrees
circle          0      NaN
triangle        9      NaN
rectangle      16      NaN
```

```
>>> df.mul(other, fill_value=0)
           angles  degrees
circle          0      0.0
triangle        9      0.0
rectangle      16      0.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                              'degrees': [360, 180, 360, 360, 540, 720]},
...                             index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                    ['circle', 'triangle', 'rectangle',
...                                     'square', 'pentagon', 'hexagon']])
>>> df_multindex
             angles  degrees
A circle          0      360
  triangle        3      180
  rectangle       4      360
B square          4      360
  pentagon        5      540
  hexagon         6      720
```

```
>>> df.div(df_multindex, level=1, fill_value=0)
             angles  degrees
A circle        NaN      1.0
  triangle      1.0      1.0
  rectangle     1.0      1.0
B square        0.0      0.0
  pentagon      0.0      0.0
  hexagon       0.0      0.0
```

pandas.DataFrame.mode

DataFrame.**mode**(*axis=0*, *numeric_only=False*, *dropna=True*)

Get the mode(s) of each element along the selected axis.

The mode of a set of values is the value that appears most often. It can be multiple values.

Parameters

axis [{0 or 'index', 1 or 'columns'}, default 0] The axis to iterate over while searching for the mode:

- 0 or 'index' : get mode of each column
- 1 or 'columns' : get mode of each row.

numeric_only [bool, default False] If True, only apply to numeric columns.

dropna [bool, default True] Don't consider counts of NaN/NaT.

New in version 0.24.0.

Returns

DataFrame The modes of each column or row.

See also:

Series.mode Return the highest frequency value in a Series.

Series.value_counts Return the counts of values in a Series.

Examples

```
>>> df = pd.DataFrame([('bird', 2, 2),
...                    ('mammal', 4, np.nan),
...                    ('arthropod', 8, 0),
...                    ('bird', 2, np.nan)],
...                   index=('falcon', 'horse', 'spider', 'ostrich'),
...                   columns=('species', 'legs', 'wings'))
>>> df
           species  legs  wings
falcon        bird     2    2.0
horse       mammal     4    NaN
spider   arthropod     8    0.0
ostrich       bird     2    NaN
```

By default, missing values are not considered, and the mode of wings are both 0 and 2. The second row of species and legs contains `NaN`, because they have only one mode, but the DataFrame has two rows.

```
>>> df.mode()
  species  legs  wings
0    bird   2.0    0.0
1     NaN   NaN    2.0
```

Setting `dropna=False` `NaN` values are considered and they can be the mode (like for wings).

```
>>> df.mode(dropna=False)
  species  legs  wings
0    bird     2    NaN
```

Setting `numeric_only=True`, only the mode of numeric columns is computed, and columns of other types are ignored.

```
>>> df.mode(numeric_only=True)
   legs  wings
0   2.0    0.0
1   NaN    2.0
```

To compute the mode over columns and not rows, use the axis parameter:

```
>>> df.mode(axis='columns', numeric_only=True)
           0    1
falcon   2.0  NaN
horse    4.0  NaN
spider   0.0  8.0
ostrich  2.0  NaN
```

pandas.DataFrame.mul

DataFrame.**mul**(*other*, *axis='columns'*, *level=None*, *fill_value=None*)

Get Multiplication of dataframe and other, element-wise (binary operator *mul*).

Equivalent to `dataframe * other`, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, *rmul*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: +, -, *, /, //, %, **.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

See also:

DataFrame.add Add DataFrames.

DataFrame.sub Subtract DataFrames.

DataFrame.mul Multiply DataFrames.

DataFrame.div Divide DataFrames (float division).

DataFrame.truediv Divide DataFrames (float division).

DataFrame.floordiv Divide DataFrames (integer division).

DataFrame.mod Calculate modulo (remainder after division).

DataFrame.pow Calculate exponential power.

Notes

Mismatched indices will be unioned together.

Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                   index=['circle', 'triangle', 'rectangle'])
>>> df
           angles  degrees
circle          0      360
triangle        3      180
rectangle       4      360
```

Add a scalar with operator version which return the same results.

```
>>> df + 1
           angles  degrees
circle          1      361
triangle        4      181
rectangle       5      361
```

```
>>> df.add(1)
           angles  degrees
circle          1      361
triangle        4      181
rectangle       5      361
```

Divide by constant with reverse version.

```
>>> df.div(10)
           angles  degrees
circle        0.0     36.0
triangle      0.3     18.0
rectangle     0.4     36.0
```

```
>>> df.rdiv(10)
             angles   degrees
circle          inf  0.027778
triangle   3.333333  0.055556
rectangle  2.500000  0.027778
```

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
           angles  degrees
circle         -1      358
triangle        2      178
rectangle       3      358
```

```
>>> df.sub([1, 2], axis='columns')
           angles  degrees
circle         -1      358
triangle        2      178
rectangle       3      358
```

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...         axis='index')
           angles  degrees
circle         -1      359
triangle        2      179
rectangle       3      359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                      index=['circle', 'triangle', 'rectangle'])
>>> other
           angles
circle          0
triangle        3
rectangle       4
```

```
>>> df * other
           angles  degrees
circle          0      NaN
triangle        9      NaN
rectangle      16      NaN
```

```
>>> df.mul(other, fill_value=0)
           angles  degrees
circle          0      0.0
triangle        9      0.0
rectangle      16      0.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                              'degrees': [360, 180, 360, 360, 540, 720]},
...                             index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                    ['circle', 'triangle', 'rectangle',
...                                     'square', 'pentagon', 'hexagon']])
>>> df_multindex
             angles  degrees
A circle          0      360
  triangle        3      180
  rectangle       4      360
B square          4      360
  pentagon        5      540
  hexagon         6      720
```

```
>>> df.div(df_multindex, level=1, fill_value=0)
             angles  degrees
A circle        NaN      1.0
  triangle      1.0      1.0
  rectangle     1.0      1.0
```

(continues on next page)

(continued from previous page)

```
B square        0.0      0.0
  pentagon      0.0      0.0
  hexagon       0.0      0.0
```

pandas.DataFrame.multiply

DataFrame.**multiply**(*other*, *axis='columns'*, *level=None*, *fill_value=None*)

Get Multiplication of dataframe and other, element-wise (binary operator *mul*).

Equivalent to `dataframe * other`, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, *rmul*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: +, -, *, /, //, %, **.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

See also:

DataFrame.add Add DataFrames.

DataFrame.sub Subtract DataFrames.

DataFrame.mul Multiply DataFrames.

DataFrame.div Divide DataFrames (float division).

DataFrame.truediv Divide DataFrames (float division).

DataFrame.floordiv Divide DataFrames (integer division).

DataFrame.mod Calculate modulo (remainder after division).

DataFrame.pow Calculate exponential power.

Notes

Mismatched indices will be unioned together.

Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                   index=['circle', 'triangle', 'rectangle'])
>>> df
           angles  degrees
circle          0      360
triangle        3      180
rectangle       4      360
```

Add a scalar with operator version which return the same results.

```
>>> df + 1
           angles  degrees
circle          1      361
triangle        4      181
rectangle       5      361
```

```
>>> df.add(1)
           angles  degrees
circle          1      361
triangle        4      181
rectangle       5      361
```

Divide by constant with reverse version.

```
>>> df.div(10)
           angles  degrees
circle        0.0     36.0
triangle      0.3     18.0
rectangle     0.4     36.0
```

```
>>> df.rdiv(10)
             angles   degrees
circle          inf  0.027778
triangle   3.333333  0.055556
rectangle  2.500000  0.027778
```

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
           angles  degrees
circle         -1      358
triangle        2      178
rectangle       3      358
```

```
>>> df.sub([1, 2], axis='columns')
           angles  degrees
circle         -1      358
triangle        2      178
rectangle       3      358
```

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...         axis='index')
           angles  degrees
circle         -1      359
triangle        2      179
rectangle       3      359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                      index=['circle', 'triangle', 'rectangle'])
>>> other
           angles
circle          0
triangle        3
rectangle       4
```

```
>>> df * other
           angles  degrees
circle          0      NaN
triangle        9      NaN
rectangle      16      NaN
```

```
>>> df.mul(other, fill_value=0)
           angles  degrees
circle          0      0.0
triangle        9      0.0
rectangle      16      0.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                              'degrees': [360, 180, 360, 360, 540, 720]},
...                             index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                    ['circle', 'triangle', 'rectangle',
...                                     'square', 'pentagon', 'hexagon']])
>>> df_multindex
             angles  degrees
A circle          0      360
  triangle        3      180
  rectangle       4      360
B square          4      360
  pentagon        5      540
  hexagon         6      720
```

```
>>> df.div(df_multindex, level=1, fill_value=0)
             angles  degrees
A circle        NaN      1.0
  triangle      1.0      1.0
  rectangle     1.0      1.0
B square        0.0      0.0
  pentagon      0.0      0.0
  hexagon       0.0      0.0
```

pandas.DataFrame.ne

DataFrame.**ne**(*other*, *axis='columns'*, *level=None*)

Get Not equal to of dataframe and other, element-wise (binary operator *ne*).

Among flexible wrappers (*eq*, *ne*, *le*, *lt*, *ge*, *gt*) to comparison operators.

Equivalent to ==, =!, <=, <, >=, > with support to choose axis (rows or columns) and level for comparison.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}, default 'columns'] Whether to compare by the index (0 or 'index') or columns (1 or 'columns').

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

DataFrame of bool Result of the comparison.

See also:

DataFrame.eq Compare DataFrames for equality elementwise.

DataFrame.ne Compare DataFrames for inequality elementwise.

DataFrame.le Compare DataFrames for less than inequality or equality elementwise.

DataFrame.lt Compare DataFrames for strictly less than inequality elementwise.

DataFrame.ge Compare DataFrames for greater than inequality or equality elementwise.

DataFrame.gt Compare DataFrames for strictly greater than inequality elementwise.

Notes

Mismatched indices will be unioned together. *NaN* values are considered different (i.e. *NaN* != *NaN*).

Examples

```
>>> df = pd.DataFrame({'cost': [250, 150, 100],
...                    'revenue': [100, 250, 300]},
...                   index=['A', 'B', 'C'])
>>> df
   cost  revenue
A   250      100
B   150      250
C   100      300
```

Comparison with a scalar, using either the operator or method:

```
>>> df == 100
    cost  revenue
A  False     True
```

(continues on next page)

(continued from previous page)

```
B  False    False
C   True    False
```

```
>>> df.eq(100)
    cost  revenue
A  False     True
B  False    False
C   True    False
```

When *other* is a *Series*, the columns of a DataFrame are aligned with the index of *other* and broadcast:

```
>>> df != pd.Series([100, 250], index=["cost", "revenue"])
    cost  revenue
A   True     True
B   True    False
C  False     True
```

Use the method to control the broadcast axis:

```
>>> df.ne(pd.Series([100, 300], index=["A", "D"]), axis='index')
   cost  revenue
A  True    False
B  True     True
C  True     True
D  True     True
```

When comparing to an arbitrary sequence, the number of columns must match the number elements in *other*:

```
>>> df == [250, 100]
    cost  revenue
A   True     True
B  False    False
C  False    False
```

Use the method to control the axis:

```
>>> df.eq([250, 250, 100], axis='index')
    cost  revenue
A   True    False
B  False     True
C   True    False
```

Compare to a DataFrame of different shape.

```
>>> other = pd.DataFrame({'revenue': [300, 250, 100, 150]},
...                      index=['A', 'B', 'C', 'D'])
>>> other
   revenue
A      300
B      250
C      100
D      150
```

```
>>> df.gt(other)
    cost  revenue
```

(continues on next page)

(continued from previous page)

```
A  False    False
B  False    False
C  False     True
D  False    False
```

Compare to a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'cost': [250, 150, 100, 150, 300, 220],
...                              'revenue': [100, 250, 300, 200, 175, 225]},
...                             index=[['Q1', 'Q1', 'Q1', 'Q2', 'Q2', 'Q2'],
...                                    ['A', 'B', 'C', 'A', 'B', 'C']])
>>> df_multindex
      cost  revenue
Q1 A   250      100
   B   150      250
   C   100      300
Q2 A   150      200
   B   300      175
   C   220      225
```

```
>>> df.le(df_multindex, level=1)
       cost  revenue
Q1 A   True     True
   B   True     True
   C   True     True
Q2 A  False     True
   B   True    False
   C   True    False
```

pandas.DataFrame.nlargest

`DataFrame.`**`nlargest`**(*n*, *columns*, *keep='first'*)

Return the first *n* rows ordered by *columns* in descending order.

Return the first *n* rows with the largest values in *columns*, in descending order. The columns that are not specified are returned as well, but not used for ordering.

This method is equivalent to `df.sort_values(columns, ascending=False).head(n)`, but more performant.

Parameters

n [int] Number of rows to return.

columns [label or list of labels] Column label(s) to order by.

keep [{'first', 'last', 'all'}, default 'first'] Where there are duplicate values:

- *first* : prioritize the first occurrence(s)
- *last* : prioritize the last occurrence(s)
- **`all`** [do not drop any duplicates, even it means] selecting more than *n* items.

New in version 0.24.0.

Returns

DataFrame The first *n* rows ordered by the given columns in descending order.

See also:

DataFrame.nsmallest Return the first *n* rows ordered by *columns* in ascending order.

DataFrame.sort_values Sort DataFrame by the values.

DataFrame.head Return the first *n* rows without re-ordering.

Notes

This function cannot be used with all column types. For example, when specifying columns with *object* or *category* dtypes, `TypeError` is raised.

Examples

```
>>> df = pd.DataFrame({'population': [59000000, 65000000, 434000,
...                                   434000, 434000, 337000, 11300,
...                                   11300, 11300],
...                    'GDP': [1937894, 2583560 , 12011, 4520, 12128,
...                            17036, 182, 38, 311],
...                    'alpha-2': ["IT", "FR", "MT", "MV", "BN",
...                                "IS", "NR", "TV", "AI"]},
...                   index=["Italy", "France", "Malta",
...                          "Maldives", "Brunei", "Iceland",
...                          "Nauru", "Tuvalu", "Anguilla"])
>>> df
          population      GDP alpha-2
Italy       59000000  1937894      IT
France      65000000  2583560      FR
Malta         434000    12011      MT
Maldives      434000     4520      MV
Brunei        434000    12128      BN
Iceland       337000    17036      IS
Nauru          11300      182      NR
Tuvalu         11300       38      TV
Anguilla       11300      311      AI
```

In the following example, we will use `nlargest` to select the three rows having the largest values in column "population".

```
>>> df.nlargest(3, 'population')
        population      GDP alpha-2
France    65000000  2583560      FR
Italy     59000000  1937894      IT
Malta       434000    12011      MT
```

When using `keep='last'`, ties are resolved in reverse order:

```
>>> df.nlargest(3, 'population', keep='last')
        population      GDP alpha-2
France    65000000  2583560      FR
Italy     59000000  1937894      IT
Brunei      434000    12128      BN
```

When using `keep='all'`, all duplicate items are maintained:

```
>>> df.nlargest(3, 'population', keep='all')
          population      GDP alpha-2
France      65000000  2583560      FR
Italy       59000000  1937894      IT
Malta         434000    12011      MT
Maldives      434000     4520      MV
Brunei        434000    12128      BN
```

To order by the largest values in column "population" and then "GDP", we can specify multiple columns like in the next example.

```
>>> df.nlargest(3, ['population', 'GDP'])
        population      GDP alpha-2
France    65000000  2583560      FR
Italy     59000000  1937894      IT
Brunei      434000    12128      BN
```

pandas.DataFrame.notna

DataFrame.**notna**()

Detect existing (non-missing) values.

Return a boolean same-sized object indicating if the values are not NA. Non-missing values get mapped to True. Characters such as empty strings `''` or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`). NA values, such as None or `numpy.NaN`, get mapped to False values.

Returns

DataFrame Mask of bool values for each element in DataFrame that indicates whether an element is not an NA value.

See also:

DataFrame.notnull Alias of notna.

DataFrame.isna Boolean inverse of notna.

DataFrame.dropna Omit axes labels with missing values.

notna Top-level notna.

Examples

Show which entries in a DataFrame are not NA.

```
>>> df = pd.DataFrame({'age': [5, 6, np.NaN],
...                    'born': [pd.NaT, pd.Timestamp('1939-05-27'),
...                             pd.Timestamp('1940-04-25')],
...                    'name': ['Alfred', 'Batman', ''],
...                    'toy': [None, 'Batmobile', 'Joker']})
>>> df
   age       born    name        toy
0  5.0        NaT  Alfred       None
1  6.0 1939-05-27  Batman  Batmobile
2  NaN 1940-04-25              Joker
```

```
>>> df.notna()
     age   born  name    toy
0   True  False  True  False
1   True   True  True   True
2  False   True  True   True
```

Show which entries in a Series are not NA.

```
>>> ser = pd.Series([5, 6, np.NaN])
>>> ser
0    5.0
1    6.0
2    NaN
dtype: float64
```

```
>>> ser.notna()
0     True
1     True
2    False
dtype: bool
```

pandas.DataFrame.notnull

DataFrame.**notnull**()

Detect existing (non-missing) values.

Return a boolean same-sized object indicating if the values are not NA. Non-missing values get mapped to True. Characters such as empty strings `''` or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`). NA values, such as None or `numpy.NaN`, get mapped to False values.

Returns

DataFrame Mask of bool values for each element in DataFrame that indicates whether an element is not an NA value.

See also:

DataFrame.notnull Alias of notna.

DataFrame.isna Boolean inverse of notna.

DataFrame.dropna Omit axes labels with missing values.

notna Top-level notna.

Examples

Show which entries in a DataFrame are not NA.

```
>>> df = pd.DataFrame({'age': [5, 6, np.NaN],
...                    'born': [pd.NaT, pd.Timestamp('1939-05-27'),
...                             pd.Timestamp('1940-04-25')],
...                    'name': ['Alfred', 'Batman', ''],
...                    'toy': [None, 'Batmobile', 'Joker']})
>>> df
```

(continues on next page)

(continued from previous page)

```
   age       born    name        toy
0  5.0        NaT  Alfred       None
1  6.0 1939-05-27  Batman  Batmobile
2  NaN 1940-04-25              Joker
```

```
>>> df.notna()
     age   born  name    toy
0   True  False  True  False
1   True   True  True   True
2  False   True  True   True
```

Show which entries in a Series are not NA.

```
>>> ser = pd.Series([5, 6, np.NaN])
>>> ser
0    5.0
1    6.0
2    NaN
dtype: float64
```

```
>>> ser.notna()
0     True
1     True
2    False
dtype: bool
```

pandas.DataFrame.nsmallest

DataFrame.**nsmallest**(*n*, *columns*, *keep='first'*)

Return the first *n* rows ordered by *columns* in ascending order.

Return the first *n* rows with the smallest values in *columns*, in ascending order. The columns that are not specified are returned as well, but not used for ordering.

This method is equivalent to `df.sort_values(columns, ascending=True).head(n)`, but more performant.

Parameters

n [int] Number of items to retrieve.

columns [list or str] Column name or names to order by.

keep [{'first', 'last', 'all'}, default 'first'] Where there are duplicate values:

- `first` : take the first occurrence.
- `last` : take the last occurrence.
- `all` : do not drop any duplicates, even it means selecting more than *n* items.

New in version 0.24.0.

Returns

DataFrame

See also:

DataFrame.nlargest Return the first *n* rows ordered by *columns* in descending order.

DataFrame.sort_values Sort DataFrame by the values.

DataFrame.head Return the first *n* rows without re-ordering.

Examples

```
>>> df = pd.DataFrame({'population': [59000000, 65000000, 434000,
...                                   434000, 434000, 337000, 337000,
...                                   11300, 11300],
...                    'GDP': [1937894, 2583560 , 12011, 4520, 12128,
...                            17036, 182, 38, 311],
...                    'alpha-2': ["IT", "FR", "MT", "MV", "BN",
...                                "IS", "NR", "TV", "AI"]},
...                   index=["Italy", "France", "Malta",
...                          "Maldives", "Brunei", "Iceland",
...                          "Nauru", "Tuvalu", "Anguilla"])
>>> df
          population      GDP alpha-2
Italy       59000000  1937894      IT
France      65000000  2583560      FR
Malta         434000    12011      MT
Maldives      434000     4520      MV
Brunei        434000    12128      BN
Iceland       337000    17036      IS
Nauru         337000      182      NR
Tuvalu         11300       38      TV
Anguilla       11300      311      AI
```

In the following example, we will use `nsmallest` to select the three rows having the smallest values in column "population".

```
>>> df.nsmallest(3, 'population')
          population    GDP alpha-2
Tuvalu         11300     38      TV
Anguilla       11300    311      AI
Iceland       337000  17036          IS
```

When using `keep='last'`, ties are resolved in reverse order:

```
>>> df.nsmallest(3, 'population', keep='last')
          population  GDP alpha-2
Anguilla       11300  311      AI
Tuvalu         11300   38      TV
Nauru         337000  182      NR
```

When using `keep='all'`, all duplicate items are maintained:

```
>>> df.nsmallest(3, 'population', keep='all')
          population    GDP alpha-2
Tuvalu         11300     38      TV
Anguilla       11300    311      AI
Iceland       337000  17036      IS
Nauru         337000    182      NR
```

To order by the smallest values in column "population" and then "GDP", we can specify multiple columns like in the next example.

```
>>> df.nsmallest(3, ['population', 'GDP'])
          population  GDP alpha-2
Tuvalu         11300   38      TV
Anguilla       11300  311      AI
Nauru         337000  182      NR
```

pandas.DataFrame.nunique

DataFrame.**nunique**(*axis=0*, *dropna=True*)

Count distinct observations over requested axis.

Return Series with number of distinct observations. Can ignore NaN values.

Parameters

axis [{0 or 'index', 1 or 'columns'}, default 0] The axis to use. 0 or 'index' for row-wise, 1 or 'columns' for column-wise.

dropna [bool, default True] Don't include NaN in the counts.

Returns

Series

See also:

Series.nunique Method nunique for Series.

DataFrame.count Count non-NA cells for each column or row.

Examples

```
>>> df = pd.DataFrame({'A': [1, 2, 3], 'B': [1, 1, 1]})
>>> df.nunique()
A    3
B    1
dtype: int64
```

```
>>> df.nunique(axis=1)
0    1
1    2
2    2
dtype: int64
```

pandas.DataFrame.pad

DataFrame.**pad**(*axis=None*, *inplace=False*, *limit=None*, *downcast=None*)

Synonym for *DataFrame.fillna()* with `method='ffill'`.

Returns

{klass} or None Object with missing values filled or None if `inplace=True`.

pandas.DataFrame.pct_change

DataFrame.**pct_change**(*periods=1*, *fill_method='pad'*, *limit=None*, *freq=None*, ***kwargs*)

Percentage change between the current and a prior element.

Computes the percentage change from the immediately previous row by default. This is useful in comparing the percentage of change in a time series of elements.

Parameters

periods [int, default 1] Periods to shift for forming percent change.

fill_method [str, default 'pad'] How to handle NAs before computing percent changes.

limit [int, default None] The number of consecutive NAs to fill before stopping.

freq [DateOffset, timedelta, or str, optional] Increment to use from time series API (e.g. 'M' or BDay()).

****kwargs** Additional keyword arguments are passed into *DataFrame.shift* or *Series.shift*.

Returns

chg [Series or DataFrame] The same type as the calling object.

See also:

Series.diff Compute the difference of two elements in a Series.

DataFrame.diff Compute the difference of two elements in a DataFrame.

Series.shift Shift the index by some number of periods.

DataFrame.shift Shift the index by some number of periods.

Examples

Series

```
>>> s = pd.Series([90, 91, 85])
>>> s
0    90
1    91
2    85
dtype: int64
```

```
>>> s.pct_change()
0         NaN
1    0.011111
2   -0.065934
dtype: float64
```

```
>>> s.pct_change(periods=2)
0         NaN
1         NaN
2   -0.055556
dtype: float64
```

See the percentage change in a Series where filling NAs with last valid observation forward to next valid.

```
>>> s = pd.Series([90, 91, None, 85])
>>> s
0    90.0
1    91.0
2     NaN
3    85.0
dtype: float64
```

```
>>> s.pct_change(fill_method='ffill')
0         NaN
1    0.011111
2    0.000000
3   -0.065934
dtype: float64
```

DataFrame

Percentage change in French franc, Deutsche Mark, and Italian lira from 1980-01-01 to 1980-03-01.

```
>>> df = pd.DataFrame({
...     'FR': [4.0405, 4.0963, 4.3149],
...     'GR': [1.7246, 1.7482, 1.8519],
...     'IT': [804.74, 810.01, 860.13]},
...     index=['1980-01-01', '1980-02-01', '1980-03-01'])
>>> df
                FR      GR      IT
1980-01-01  4.0405  1.7246  804.74
1980-02-01  4.0963  1.7482  810.01
1980-03-01  4.3149  1.8519  860.13
```

```
>>> df.pct_change()
                  FR        GR        IT
1980-01-01       NaN       NaN       NaN
1980-02-01  0.013810  0.013684  0.006549
1980-03-01  0.053365  0.059318  0.061876
```

Percentage of change in GOOG and APPL stock volume. Shows computing the percentage change between columns.

```
>>> df = pd.DataFrame({
...     '2016': [1769950, 30586265],
...     '2015': [1500923, 40912316],
...     '2014': [1371819, 41403351]},
...     index=['GOOG', 'APPL'])
>>> df
          2016      2015      2014
GOOG   1769950   1500923   1371819
APPL  30586265  40912316  41403351
```

```
>>> df.pct_change(axis='columns')
      2016      2015      2014
GOOG   NaN -0.151997 -0.086016
APPL   NaN  0.337604  0.012002
```

pandas.DataFrame.pipe

DataFrame.**pipe**(*func*, **args*, ***kwargs*)

Apply func(self, *args, **kwargs).

Parameters

func [function] Function to apply to the Series/DataFrame. `args`, and `kwargs` are passed into `func`. Alternatively a `(callable, data_keyword)` tuple where `data_keyword` is a string indicating the keyword of `callable` that expects the Series/DataFrame.

args [iterable, optional] Positional arguments passed into `func`.

kwargs [mapping, optional] A dictionary of keyword arguments passed into `func`.

Returns

object [the return type of `func`.]

See also:

DataFrame.apply Apply a function along input axis of DataFrame.

DataFrame.applymap Apply a function elementwise on a whole DataFrame.

Series.map Apply a mapping correspondence on a *Series*.

Notes

Use `.pipe` when chaining together functions that expect Series, DataFrames or GroupBy objects. Instead of writing

```
>>> func(g(h(df), arg1=a), arg2=b, arg3=c)
```

You can write

```
>>> (df.pipe(h)
...     .pipe(g, arg1=a)
...     .pipe(func, arg2=b, arg3=c)
... )
```

If you have a function that takes the data as (say) the second argument, pass a tuple indicating which keyword expects the data. For example, suppose `f` takes its data as `arg2`:

```
>>> (df.pipe(h)
...     .pipe(g, arg1=a)
...     .pipe((func, 'arg2'), arg1=a, arg3=c)
...  )
```

pandas.DataFrame.pivot

DataFrame.**pivot**(*index=None*, *columns=None*, *values=None*)

Return reshaped DataFrame organized by given index / column values.

Reshape data (produce a "pivot" table) based on column values. Uses unique values from specified *index* / *columns* to form axes of the resulting DataFrame. This function does not support data aggregation, multiple values will result in a MultiIndex in the columns. See the *User Guide* for more on reshaping.

Parameters

index [str or object or a list of str, optional] Column to use to make new frame's index. If None, uses existing index.

Changed in version 1.1.0: Also accept list of index names.

columns [str or object or a list of str] Column to use to make new frame's columns.

Changed in version 1.1.0: Also accept list of columns names.

values [str, object or a list of the previous, optional] Column(s) to use for populating new frame's values. If not specified, all remaining columns will be used and the result will have hierarchically indexed columns.

Changed in version 0.23.0: Also accept list of column names.

Returns

DataFrame Returns reshaped DataFrame.

Raises

ValueError: When there are any *index*, *columns* combinations with multiple values. *DataFrame.pivot_table* when you need to aggregate.

See also:

DataFrame.pivot_table Generalization of pivot that can handle duplicate values for one index/column pair.

DataFrame.unstack Pivot based on the index values instead of a column.

Notes

For finer-tuned control, see hierarchical indexing documentation along with the related stack/unstack methods.

Examples

```
>>> df = pd.DataFrame({'foo': ['one', 'one', 'one', 'two', 'two',
...                            'two'],
...                    'bar': ['A', 'B', 'C', 'A', 'B', 'C'],
...                    'baz': [1, 2, 3, 4, 5, 6],
...                    'zoo': ['x', 'y', 'z', 'q', 'w', 't']})
>>> df
    foo   bar  baz  zoo
0   one   A    1    x
1   one   B    2    y
2   one   C    3    z
```

(continues on next page)

(continued from previous page)

```
3   two   A    4    q
4   two   B    5    w
5   two   C    6    t
```

```
>>> df.pivot(index='foo', columns='bar', values='baz')
bar  A   B   C
foo
one  1   2   3
two  4   5   6
```

```
>>> df.pivot(index='foo', columns='bar')['baz']
bar  A   B   C
foo
one  1   2   3
two  4   5   6
```

```
>>> df.pivot(index='foo', columns='bar', values=['baz', 'zoo'])
      baz         zoo
bar   A  B  C    A  B  C
foo
one   1  2  3    x  y  z
two   4  5  6    q  w  t
```

You could also assign a list of column names or a list of index names.

```
>>> df = pd.DataFrame({
...         "lev1": [1, 1, 1, 2, 2, 2],
...         "lev2": [1, 1, 2, 1, 1, 2],
...         "lev3": [1, 2, 1, 2, 1, 2],
...         "lev4": [1, 2, 3, 4, 5, 6],
...         "values": [0, 1, 2, 3, 4, 5]})
>>> df
    lev1 lev2 lev3 lev4 values
0   1    1    1    1    0
1   1    1    2    2    1
2   1    2    1    3    2
3   2    1    2    4    3
4   2    1    1    5    4
5   2    2    2    6    5
```

```
>>> df.pivot(index="lev1", columns=["lev2", "lev3"],values="values")
lev2    1         2
lev3    1    2    1    2
lev1
1     0.0  1.0  2.0  NaN
2     4.0  3.0  NaN  5.0
```

```
>>> df.pivot(index=["lev1", "lev2"], columns=["lev3"],values="values")
      lev3    1    2
lev1  lev2
   1     1  0.0  1.0
         2  2.0  NaN
   2     1  4.0  3.0
         2  NaN  5.0
```

A ValueError is raised if there are any duplicates.

```
>>> df = pd.DataFrame({"foo": ['one', 'one', 'two', 'two'],
...                    "bar": ['A', 'A', 'B', 'C'],
...                    "baz": [1, 2, 3, 4]})
>>> df
   foo bar  baz
0  one   A    1
1  one   A    2
2  two   B    3
3  two   C    4
```

Notice that the first two rows are the same for our *index* and *columns* arguments.

```
>>> df.pivot(index='foo', columns='bar', values='baz')
Traceback (most recent call last):
   ...
ValueError: Index contains duplicate entries, cannot reshape
```

pandas.DataFrame.pivot_table

DataFrame.**pivot_table**(*values=None*, *index=None*, *columns=None*, *aggfunc='mean'*, *fill_value=None*, *margins=False*, *dropna=True*, *margins_name='All'*, *observed=False*)

Create a spreadsheet-style pivot table as a DataFrame.

The levels in the pivot table will be stored in MultiIndex objects (hierarchical indexes) on the index and columns of the result DataFrame.

Parameters

values [column to aggregate, optional]

index [column, Grouper, array, or list of the previous] If an array is passed, it must be the same length as the data. The list can contain any of the other types (except list). Keys to group by on the pivot table index. If an array is passed, it is being used as the same manner as column values.

columns [column, Grouper, array, or list of the previous] If an array is passed, it must be the same length as the data. The list can contain any of the other types (except list). Keys to group by on the pivot table column. If an array is passed, it is being used as the same manner as column values.

aggfunc [function, list of functions, dict, default numpy.mean] If list of functions passed, the resulting pivot table will have hierarchical columns whose top level are the function names (inferred from the function objects themselves) If dict is passed, the key is column to aggregate and value is function or list of functions.

fill_value [scalar, default None] Value to replace missing values with (in the resulting pivot table, after aggregation).

margins [bool, default False] Add all row / columns (e.g. for subtotal / grand totals).

dropna [bool, default True] Do not include columns whose entries are all NaN.

margins_name [str, default 'All'] Name of the row / column that will contain the totals when margins is True.

observed [bool, default False] This only applies if any of the groupers are Categoricals. If True: only show observed values for categorical groupers. If False: show all values for categorical groupers.

Changed in version 0.25.0.

Returns

DataFrame An Excel style pivot table.

See also:

DataFrame.pivot Pivot without aggregation that can handle non-numeric data.

Examples

```
>>> df = pd.DataFrame({"A": ["foo", "foo", "foo", "foo", "foo",
...                          "bar", "bar", "bar", "bar"],
...                    "B": ["one", "one", "one", "two", "two",
...                          "one", "one", "two", "two"],
...                    "C": ["small", "large", "large", "small",
...                          "small", "large", "small", "small",
...                          "large"],
...                    "D": [1, 2, 2, 3, 3, 4, 5, 6, 7],
...                    "E": [2, 4, 5, 5, 6, 6, 8, 9, 9]})
>>> df
     A    B      C  D  E
0  foo  one  small  1  2
1  foo  one  large  2  4
2  foo  one  large  2  5
3  foo  two  small  3  5
4  foo  two  small  3  6
5  bar  one  large  4  6
6  bar  one  small  5  8
7  bar  two  small  6  9
8  bar  two  large  7  9
```

This first example aggregates values by taking the sum.

```
>>> table = pd.pivot_table(df, values='D', index=['A', 'B'],
...                        columns=['C'], aggfunc=np.sum)
>>> table
C        large  small
A   B
bar one    4.0    5.0
    two    7.0    6.0
foo one    4.0    1.0
    two    NaN    6.0
```

We can also fill missing values using the *fill_value* parameter.

```
>>> table = pd.pivot_table(df, values='D', index=['A', 'B'],
...                        columns=['C'], aggfunc=np.sum, fill_value=0)
>>> table
C        large  small
A   B
bar one      4      5
    two      7      6
foo one      4      1
    two      0      6
```

The next example aggregates by taking the mean across multiple columns.

```
>>> table = pd.pivot_table(df, values=['D', 'E'], index=['A', 'C'],
...                        aggfunc={'D': np.mean,
...                                 'E': np.mean})
>>> table
                D         E
A   C
bar large  5.500000  7.500000
    small  5.500000  8.500000
foo large  2.000000  4.500000
    small  2.333333  4.333333
```

We can also calculate multiple types of aggregations for any given value column.

```
>>> table = pd.pivot_table(df, values=['D', 'E'], index=['A', 'C'],
...                        aggfunc={'D': np.mean,
...                                 'E': [min, max, np.mean]})
>>> table
                D    E
             mean  max      mean  min
A   C
bar large  5.500000  9.0  7.500000  6.0
    small  5.500000  9.0  8.500000  8.0
foo large  2.000000  5.0  4.500000  4.0
    small  2.333333  6.0  4.333333  2.0
```

pandas.DataFrame.plot

DataFrame.**plot**(**args*, ***kwargs*)

Make plots of Series or DataFrame.

Uses the backend specified by the option `plotting.backend`. By default, matplotlib is used.

Parameters

data [Series or DataFrame] The object for which the method is called.

x [label or position, default None] Only used if data is a DataFrame.

y [label, position or list of label, positions, default None] Allows plotting of one column versus another. Only used if data is a DataFrame.

kind [str] The kind of plot to produce:

- 'line' : line plot (default)
- 'bar' : vertical bar plot
- 'barh' : horizontal bar plot
- 'hist' : histogram
- 'box' : boxplot
- 'kde' : Kernel Density Estimation plot
- 'density' : same as 'kde'
- 'area' : area plot
- 'pie' : pie plot
- 'scatter' : scatter plot

- 'hexbin' : hexbin plot.

ax [matplotlib axes object, default None] An axes of the current figure.

subplots [bool, default False] Make separate subplots for each column.

sharex [bool, default True if ax is None else False] In case `subplots=True`, share x axis and set some x axis labels to invisible; defaults to True if ax is None otherwise False if an ax is passed in; Be aware, that passing in both an ax and `sharex=True` will alter all x axis labels for all axis in a figure.

sharey [bool, default False] In case `subplots=True`, share y axis and set some y axis labels to invisible.

layout [tuple, optional] (rows, columns) for the layout of subplots.

figsize [a tuple (width, height) in inches] Size of a figure object.

use_index [bool, default True] Use index as ticks for x axis.

title [str or list] Title to use for the plot. If a string is passed, print the string at the top of the figure. If a list is passed and *subplots* is True, print each item in the list above the corresponding subplot.

grid [bool, default None (matlab style default)] Axis grid lines.

legend [bool or {'reverse'}] Place legend on axis subplots.

style [list or dict] The matplotlib line style per column.

logx [bool or 'sym', default False] Use log scaling or symlog scaling on x axis. .. versionchanged:: 0.25.0

logy [bool or 'sym' default False] Use log scaling or symlog scaling on y axis. .. versionchanged:: 0.25.0

loglog [bool or 'sym', default False] Use log scaling or symlog scaling on both x and y axes. .. versionchanged:: 0.25.0

xticks [sequence] Values to use for the xticks.

yticks [sequence] Values to use for the yticks.

xlim [2-tuple/list] Set the x limits of the current axes.

ylim [2-tuple/list] Set the y limits of the current axes.

xlabel [label, optional] Name to use for the xlabel on x-axis. Default uses index name as xlabel.

New in version 1.1.0.

ylabel [label, optional] Name to use for the ylabel on y-axis. Default will show no ylabel.

New in version 1.1.0.

rot [int, default None] Rotation for ticks (xticks for vertical, yticks for horizontal plots).

fontsize [int, default None] Font size for xticks and yticks.

colormap [str or matplotlib colormap object, default None] Colormap to select colors from. If string, load colormap with that name from matplotlib.

colorbar [bool, optional] If True, plot colorbar (only relevant for 'scatter' and 'hexbin' plots).

position [float] Specify relative alignments for bar plot layout. From 0 (left/bottom-end) to 1 (right/top-end). Default is 0.5 (center).

table [bool, Series or DataFrame, default False] If True, draw a table using the data in the DataFrame and the data will be transposed to meet matplotlib's default layout. If a Series or DataFrame is passed, use passed data to draw a table.

yerr [DataFrame, Series, array-like, dict and str] See *Plotting with Error Bars* for detail.

xerr [DataFrame, Series, array-like, dict and str] Equivalent to yerr.

stacked [bool, default False in line and bar plots, and True in area plot] If True, create stacked plot.

sort_columns [bool, default False] Sort column names to determine plot ordering.

secondary_y [bool or sequence, default False] Whether to plot on the secondary y-axis if a list/tuple, which columns to plot on secondary y-axis.

mark_right [bool, default True] When using a secondary_y axis, automatically mark the column labels with "(right)" in the legend.

include_bool [bool, default is False] If True, boolean values can be plotted.

backend [str, default None] Backend to use instead of the backend specified in the option `plotting.backend`. For instance, 'matplotlib'. Alternatively, to specify the `plotting.backend` for the whole session, set `pd.options.plotting.backend`.

New in version 1.0.0.

****kwargs** Options to pass to matplotlib plotting method.

Returns

`matplotlib.axes.Axes` or numpy.ndarray of them If the backend is not the default matplotlib one, the return value will be the object returned by the backend.

Notes

- See matplotlib documentation online for more on this subject
- If *kind* = 'bar' or 'barh', you can specify relative alignments for bar plot layout by *position* keyword. From 0 (left/bottom-end) to 1 (right/top-end). Default is 0.5 (center)

pandas.DataFrame.pop

`DataFrame.`**`pop`**`(`*`item`*`)`

Return item and drop from frame. Raise KeyError if not found.

Parameters

item [label] Label of column to be popped.

Returns

Series

Examples

```
>>> df = pd.DataFrame([('falcon', 'bird', 389.0),
...                    ('parrot', 'bird', 24.0),
...                    ('lion', 'mammal', 80.5),
...                    ('monkey', 'mammal', np.nan)],
...                   columns=('name', 'class', 'max_speed'))
>>> df
     name   class  max_speed
0  falcon    bird      389.0
1  parrot    bird       24.0
2    lion  mammal       80.5
3  monkey  mammal        NaN
```

```
>>> df.pop('class')
0      bird
1      bird
2    mammal
3    mammal
Name: class, dtype: object
```

```
>>> df
     name  max_speed
0  falcon      389.0
1  parrot       24.0
2    lion       80.5
3  monkey        NaN
```

pandas.DataFrame.pow

DataFrame.**pow**(*other*, *axis='columns'*, *level=None*, *fill_value=None*)

Get Exponential power of dataframe and other, element-wise (binary operator *pow*).

Equivalent to `dataframe ** other`, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, *rpow*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: +, -, *, /, //, %, **.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

See also:

DataFrame.add Add DataFrames.

DataFrame.sub Subtract DataFrames.

DataFrame.mul Multiply DataFrames.

DataFrame.div Divide DataFrames (float division).

DataFrame.truediv Divide DataFrames (float division).

DataFrame.floordiv Divide DataFrames (integer division).

DataFrame.mod Calculate modulo (remainder after division).

DataFrame.pow Calculate exponential power.

Notes

Mismatched indices will be unioned together.

Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                   index=['circle', 'triangle', 'rectangle'])
>>> df
           angles  degrees
circle          0      360
triangle        3      180
rectangle       4      360
```

Add a scalar with operator version which return the same results.

```
>>> df + 1
           angles  degrees
circle          1      361
triangle        4      181
rectangle       5      361
```

```
>>> df.add(1)
           angles  degrees
circle          1      361
triangle        4      181
rectangle       5      361
```

Divide by constant with reverse version.

```
>>> df.div(10)
           angles  degrees
circle        0.0     36.0
triangle      0.3     18.0
rectangle     0.4     36.0
```

```
>>> df.rdiv(10)
             angles   degrees
circle          inf  0.027778
triangle   3.333333  0.055556
rectangle  2.500000  0.027778
```

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
           angles  degrees
circle         -1      358
triangle        2      178
rectangle       3      358
```

```
>>> df.sub([1, 2], axis='columns')
           angles  degrees
circle         -1      358
triangle        2      178
rectangle       3      358
```

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...        axis='index')
           angles  degrees
circle         -1      359
triangle        2      179
rectangle       3      359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                      index=['circle', 'triangle', 'rectangle'])
>>> other
           angles
circle          0
triangle        3
rectangle       4
```

```
>>> df * other
           angles  degrees
circle          0      NaN
triangle        9      NaN
rectangle      16      NaN
```

```
>>> df.mul(other, fill_value=0)
           angles  degrees
circle          0      0.0
triangle        9      0.0
rectangle      16      0.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                              'degrees': [360, 180, 360, 360, 540, 720]},
...                             index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                    ['circle', 'triangle', 'rectangle',
...                                     'square', 'pentagon', 'hexagon']])
```

(continues on next page)

(continued from previous page)

```
>>> df_multindex
              angles  degrees
A circle           0      360
  triangle         3      180
  rectangle        4      360
B square           4      360
  pentagon         5      540
  hexagon          6      720
```

```
>>> df.div(df_multindex, level=1, fill_value=0)
              angles  degrees
A circle         NaN      1.0
  triangle       1.0      1.0
  rectangle      1.0      1.0
B square         0.0      0.0
  pentagon       0.0      0.0
  hexagon        0.0      0.0
```

pandas.DataFrame.prod

DataFrame.**prod**(*axis=None*, *skipna=None*, *level=None*, *numeric_only=None*, *min_count=0*, ***kwargs*)

Return the product of the values for the requested axis.

Parameters

axis [{index (0), columns (1)}] Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

min_count [int, default 0] The required number of valid values to perform the operation. If fewer than `min_count` non-NA values are present the result will be NA.

New in version 0.22.0: Added with the default being 0. This means the sum of an all-NA or empty Series is 0, and the product of an all-NA or empty Series is 1.

****kwargs** Additional keyword arguments to be passed to the function.

Returns

Series or DataFrame (if level specified)

Examples

By default, the product of an empty or all-NA Series is `1`

```
>>> pd.Series([]).prod()
1.0
```

This can be controlled with the `min_count` parameter

```
>>> pd.Series([]).prod(min_count=1)
nan
```

Thanks to the `skipna` parameter, `min_count` handles all-NA and empty series identically.

```
>>> pd.Series([np.nan]).prod()
1.0
```

```
>>> pd.Series([np.nan]).prod(min_count=1)
nan
```

pandas.DataFrame.product

DataFrame.**product**(*axis=None*, *skipna=None*, *level=None*, *numeric_only=None*, *min_count=0*, ***kwargs*)

Return the product of the values for the requested axis.

Parameters

axis [{index (0), columns (1)}] Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

min_count [int, default 0] The required number of valid values to perform the operation. If fewer than `min_count` non-NA values are present the result will be NA.

New in version 0.22.0: Added with the default being 0. This means the sum of an all-NA or empty Series is 0, and the product of an all-NA or empty Series is 1.

****kwargs** Additional keyword arguments to be passed to the function.

Returns

Series or DataFrame (if level specified)

Examples

By default, the product of an empty or all-NA Series is `1`

```
>>> pd.Series([]).prod()
1.0
```

This can be controlled with the `min_count` parameter

```
>>> pd.Series([]).prod(min_count=1)
nan
```

Thanks to the `skipna` parameter, `min_count` handles all-NA and empty series identically.

```
>>> pd.Series([np.nan]).prod()
1.0
```

```
>>> pd.Series([np.nan]).prod(min_count=1)
nan
```

pandas.DataFrame.quantile

`DataFrame.`**`quantile`**(*q=0.5*, *axis=0*, *numeric_only=True*, *interpolation='linear'*)

Return values at the given quantile over requested axis.

Parameters

q [float or array-like, default 0.5 (50% quantile)] Value between 0 <= q <= 1, the quantile(s) to compute.

axis [{0, 1, 'index', 'columns'}, default 0] Equals 0 or 'index' for row-wise, 1 or 'columns' for column-wise.

numeric_only [bool, default True] If False, the quantile of datetime and timedelta data will be computed as well.

interpolation [{'linear', 'lower', 'higher', 'midpoint', 'nearest'}] This optional parameter specifies the interpolation method to use, when the desired quantile lies between two data points *i* and *j*:

- linear: *i* + *(j - i) * fraction*, where *fraction* is the fractional part of the index surrounded by *i* and *j*.
- lower: *i*.
- higher: *j*.
- nearest: *i* or *j* whichever is nearest.
- midpoint: (*i* + *j*) / 2.

Returns

Series or DataFrame

If `q` is an array, a DataFrame will be returned where the index is `q`, the columns are the columns of self, and the values are the quantiles.

If `q` is a float, a Series will be returned where the index is the columns of self and the values are the quantiles.

See also:

core.window.Rolling.quantile Rolling quantile.

numpy.percentile Numpy function to compute the percentile.

Examples

```
>>> df = pd.DataFrame(np.array([[1, 1], [2, 10], [3, 100], [4, 100]]),
...                   columns=['a', 'b'])
>>> df.quantile(.1)
a    1.3
b    3.7
Name: 0.1, dtype: float64
>>> df.quantile([.1, .5])
       a     b
0.1  1.3   3.7
0.5  2.5  55.0
```

Specifying *numeric_only=False* will also compute the quantile of datetime and timedelta data.

```
>>> df = pd.DataFrame({'A': [1, 2],
...                    'B': [pd.Timestamp('2010'),
...                          pd.Timestamp('2011')],
...                    'C': [pd.Timedelta('1 days'),
...                          pd.Timedelta('2 days')]})
>>> df.quantile(0.5, numeric_only=False)
A                    1.5
B    2010-07-02 12:00:00
C        1 days 12:00:00
Name: 0.5, dtype: object
```

pandas.DataFrame.query

DataFrame.**query**(*expr*, *inplace=False*, ***kwargs*)

Query the columns of a DataFrame with a boolean expression.

Parameters

expr [str] The query string to evaluate.

You can refer to variables in the environment by prefixing them with an '@' character like `@a + b`.

You can refer to column names that contain spaces or operators by surrounding them in backticks. This way you can also escape names that start with a digit, or those that are a Python keyword. Basically when it is not valid Python identifier. See notes down for more details.

For example, if one of your columns is called `a a` and you want to sum it with `b`, your query should be `` `a a` + b ``.

New in version 0.25.0: Backtick quoting introduced.

New in version 1.0.0: Expanding functionality of backtick quoting for more than only spaces.

inplace [bool] Whether the query should modify the data in place or return a modified copy.

****kwargs** See the documentation for *eval()* for complete details on the keyword arguments accepted by *DataFrame.query()*.

Returns

DataFrame DataFrame resulting from the provided query expression.

See also:

eval Evaluate a string describing operations on DataFrame columns.

DataFrame.eval Evaluate a string describing operations on DataFrame columns.

Notes

The result of the evaluation of this expression is first passed to *DataFrame.loc* and if that fails because of a multidimensional key (e.g., a DataFrame) then the result will be passed to `DataFrame.__getitem__()`.

This method uses the top-level *eval()* function to evaluate the passed query.

The *query()* method uses a slightly modified Python syntax by default. For example, the `&` and `|` (bitwise) operators have the precedence of their boolean cousins, `and` and `or`. This *is* syntactically valid Python, however the semantics are different.

You can change the semantics of the expression by passing the keyword argument `parser='python'`. This enforces the same semantics as evaluation in Python space. Likewise, you can pass `engine='python'` to evaluate an expression using Python itself as a backend. This is not recommended as it is inefficient compared to using `numexpr` as the engine.

The *DataFrame.index* and *DataFrame.columns* attributes of the *DataFrame* instance are placed in the query namespace by default, which allows you to treat both the index and columns of the frame as a column in the frame. The identifier `index` is used for the frame index; you can also use the name of the index to identify it in a query. Please note that Python keywords may not be used as identifiers.

For further details and examples see the `query` documentation in *indexing*.

Backtick quoted variables

Backtick quoted variables are parsed as literal Python code and are converted internally to a Python valid identifier. This can lead to the following problems.

During parsing a number of disallowed characters inside the backtick quoted string are replaced by strings that are allowed as a Python identifier. These characters include all operators in Python, the space character, the question mark, the exclamation mark, the dollar sign, and the euro sign. For other characters that fall outside the ASCII range (U+0001..U+007F) and those that are not further specified in PEP 3131, the query parser will raise an error. This excludes whitespace different than the space character, but also the hashtag (as it is used for comments) and the backtick itself (backtick can also not be escaped).

In a special case, quotes that make a pair around a backtick can confuse the parser. For example, `` `it's` > `that's` `` will raise an error, as it forms a quoted string (`'s > `that'`) with a backtick inside.

See also the Python documentation about lexical analysis (https://docs.python.org/3/reference/lexical_analysis.html) in combination with the source code in `pandas.core.computation.parsing`.

Examples

```
>>> df = pd.DataFrame({'A': range(1, 6),
...                    'B': range(10, 0, -2),
...                    'C C': range(10, 5, -1)})
>>> df
   A   B  C C
0  1  10   10
1  2   8    9
2  3   6    8
3  4   4    7
4  5   2    6
>>> df.query('A > B')
   A  B  C C
4  5  2    6
```

The previous expression is equivalent to

```
>>> df[df.A > df.B]
   A  B  C C
4  5  2    6
```

For columns with spaces in their name, you can use backtick quoting.

```
>>> df.query('B == `C C`')
   A   B  C C
0  1  10   10
```

The previous expression is equivalent to

```
>>> df[df.B == df['C C']]
   A   B  C C
0  1  10   10
```

pandas.DataFrame.radd

DataFrame.**radd**(*other*, *axis='columns'*, *level=None*, *fill_value=None*)

Get Addition of dataframe and other, element-wise (binary operator *radd*).

Equivalent to `other + dataframe`, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, *add*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: +, -, *, /, //, %, **.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before

computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

See also:

DataFrame.add Add DataFrames.

DataFrame.sub Subtract DataFrames.

DataFrame.mul Multiply DataFrames.

DataFrame.div Divide DataFrames (float division).

DataFrame.truediv Divide DataFrames (float division).

DataFrame.floordiv Divide DataFrames (integer division).

DataFrame.mod Calculate modulo (remainder after division).

DataFrame.pow Calculate exponential power.

Notes

Mismatched indices will be unioned together.

Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                   index=['circle', 'triangle', 'rectangle'])
>>> df
           angles  degrees
circle          0      360
triangle        3      180
rectangle       4      360
```

Add a scalar with operator version which return the same results.

```
>>> df + 1
           angles  degrees
circle          1      361
triangle        4      181
rectangle       5      361
```

```
>>> df.add(1)
           angles  degrees
circle          1      361
triangle        4      181
rectangle       5      361
```

Divide by constant with reverse version.

```
>>> df.div(10)
           angles  degrees
circle        0.0     36.0
triangle      0.3     18.0
rectangle     0.4     36.0
```

```
>>> df.rdiv(10)
             angles   degrees
circle          inf  0.027778
triangle   3.333333  0.055556
rectangle  2.500000  0.027778
```

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
           angles  degrees
circle         -1      358
triangle        2      178
rectangle       3      358
```

```
>>> df.sub([1, 2], axis='columns')
           angles  degrees
circle         -1      358
triangle        2      178
rectangle       3      358
```

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...        axis='index')
           angles  degrees
circle         -1      359
triangle        2      179
rectangle       3      359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                      index=['circle', 'triangle', 'rectangle'])
>>> other
           angles
circle          0
triangle        3
rectangle       4
```

```
>>> df * other
           angles  degrees
circle          0      NaN
triangle        9      NaN
rectangle      16      NaN
```

```
>>> df.mul(other, fill_value=0)
           angles  degrees
circle          0      0.0
triangle        9      0.0
rectangle      16      0.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                              'degrees': [360, 180, 360, 360, 540, 720]},
...                             index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                    ['circle', 'triangle', 'rectangle',
...                                     'square', 'pentagon', 'hexagon']])
>>> df_multindex
             angles  degrees
A circle          0      360
  triangle        3      180
  rectangle       4      360
B square          4      360
  pentagon        5      540
  hexagon         6      720
```

```
>>> df.div(df_multindex, level=1, fill_value=0)
             angles  degrees
A circle        NaN      1.0
  triangle      1.0      1.0
  rectangle     1.0      1.0
B square        0.0      0.0
  pentagon      0.0      0.0
  hexagon       0.0      0.0
```

pandas.DataFrame.rank

DataFrame.**rank**(*axis=0*, *method='average'*, *numeric_only=None*, *na_option='keep'*, *ascending=True*, *pct=False*)

Compute numerical data ranks (1 through n) along axis.

By default, equal values are assigned a rank that is the average of the ranks of those values.

Parameters

axis [{0 or 'index', 1 or 'columns'}, default 0] Index to direct ranking.

method [{'average', 'min', 'max', 'first', 'dense'}, default 'average'] How to rank the group of records that have the same value (i.e. ties):

- average: average rank of the group
- min: lowest rank in the group
- max: highest rank in the group
- first: ranks assigned in order they appear in the array
- dense: like 'min', but rank always increases by 1 between groups.

numeric_only [bool, optional] For DataFrame objects, rank only numeric columns if set to True.

na_option [{'keep', 'top', 'bottom'}, default 'keep'] How to rank NaN values:

- keep: assign NaN rank to NaN values
- top: assign smallest rank to NaN values if ascending
- bottom: assign highest rank to NaN values if ascending.

ascending [bool, default True] Whether or not the elements should be ranked in ascending order.

pct [bool, default False] Whether or not to display the returned rankings in percentile form.

Returns

same type as caller Return a Series or DataFrame with data ranks as values.

See also:

core.groupby.GroupBy.rank Rank of values within each group.

Examples

```
>>> df = pd.DataFrame(data={'Animal': ['cat', 'penguin', 'dog',
...                                    'spider', 'snake'],
...                         'Number_legs': [4, 2, 4, 8, np.nan]})
>>> df
    Animal  Number_legs
0      cat          4.0
1  penguin          2.0
2      dog          4.0
3   spider          8.0
4    snake          NaN
```

The following example shows how the method behaves with the above parameters:

- default_rank: this is the default behaviour obtained without using any parameter.
- max_rank: setting `method = 'max'` the records that have the same values are ranked using the highest rank (e.g.: since 'cat' and 'dog' are both in the 2nd and 3rd position, rank 3 is assigned.)
- NA_bottom: choosing `na_option = 'bottom'`, if there are records with NaN values they are placed at the bottom of the ranking.
- pct_rank: when setting `pct = True`, the ranking is expressed as percentile rank.

```
>>> df['default_rank'] = df['Number_legs'].rank()
>>> df['max_rank'] = df['Number_legs'].rank(method='max')
>>> df['NA_bottom'] = df['Number_legs'].rank(na_option='bottom')
>>> df['pct_rank'] = df['Number_legs'].rank(pct=True)
>>> df
    Animal  Number_legs  default_rank  max_rank  NA_bottom  pct_rank
0      cat          4.0           2.5       3.0        2.5     0.625
1  penguin          2.0           1.0       1.0        1.0     0.250
2      dog          4.0           2.5       3.0        2.5     0.625
3   spider          8.0           4.0       4.0        4.0     1.000
4    snake          NaN           NaN       NaN        5.0       NaN
```

pandas.DataFrame.rdiv

DataFrame.**rdiv**(*other*, *axis='columns'*, *level=None*, *fill_value=None*)

Get Floating division of dataframe and other, element-wise (binary operator *rtruediv*).

Equivalent to `other / dataframe`, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, *truediv*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: +, -, *, /, //, %, **.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

See also:

DataFrame.add Add DataFrames.

DataFrame.sub Subtract DataFrames.

DataFrame.mul Multiply DataFrames.

DataFrame.div Divide DataFrames (float division).

DataFrame.truediv Divide DataFrames (float division).

DataFrame.floordiv Divide DataFrames (integer division).

DataFrame.mod Calculate modulo (remainder after division).

DataFrame.pow Calculate exponential power.

Notes

Mismatched indices will be unioned together.

Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                   index=['circle', 'triangle', 'rectangle'])
>>> df
           angles  degrees
circle          0      360
triangle        3      180
rectangle       4      360
```

Add a scalar with operator version which return the same results.

```
>>> df + 1
           angles  degrees
circle          1      361
triangle        4      181
rectangle       5      361
```

```
>>> df.add(1)
           angles  degrees
circle          1      361
triangle        4      181
rectangle       5      361
```

Divide by constant with reverse version.

```
>>> df.div(10)
           angles  degrees
circle        0.0     36.0
triangle      0.3     18.0
rectangle     0.4     36.0
```

```
>>> df.rdiv(10)
             angles   degrees
circle          inf  0.027778
triangle   3.333333  0.055556
rectangle  2.500000  0.027778
```

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
           angles  degrees
circle         -1      358
triangle        2      178
rectangle       3      358
```

```
>>> df.sub([1, 2], axis='columns')
           angles  degrees
circle         -1      358
triangle        2      178
rectangle       3      358
```

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...        axis='index')
           angles  degrees
```

(continues on next page)

(continued from previous page)

```
circle         -1      359
triangle        2      179
rectangle       3      359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                      index=['circle', 'triangle', 'rectangle'])
>>> other
           angles
circle          0
triangle        3
rectangle       4
```

```
>>> df * other
           angles  degrees
circle          0      NaN
triangle        9      NaN
rectangle      16      NaN
```

```
>>> df.mul(other, fill_value=0)
           angles  degrees
circle          0      0.0
triangle        9      0.0
rectangle      16      0.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                              'degrees': [360, 180, 360, 360, 540, 720]},
...                             index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                    ['circle', 'triangle', 'rectangle',
...                                     'square', 'pentagon', 'hexagon']])
>>> df_multindex
             angles  degrees
A circle          0      360
  triangle        3      180
  rectangle       4      360
B square          4      360
  pentagon        5      540
  hexagon         6      720
```

```
>>> df.div(df_multindex, level=1, fill_value=0)
             angles  degrees
A circle        NaN      1.0
  triangle      1.0      1.0
  rectangle     1.0      1.0
B square        0.0      0.0
  pentagon      0.0      0.0
  hexagon       0.0      0.0
```

pandas.DataFrame.reindex

DataFrame.**reindex**(***kwargs*)

Conform Series/DataFrame to new index with optional filling logic.

Places NA/NaN in locations having no value in the previous index. A new object is produced unless the new index is equivalent to the current one and `copy=False`.

Parameters

keywords for axes [array-like, optional] New labels / index to conform to, should be specified using keywords. Preferably an Index object to avoid duplicating data.

method [{None, 'backfill'/'bfill', 'pad'/'ffill', 'nearest'}] Method to use for filling holes in reindexed DataFrame. Please note: this is only applicable to DataFrames/Series with a monotonically increasing/decreasing index.

- None (default): don't fill gaps
- pad / ffill: Propagate last valid observation forward to next valid.
- backfill / bfill: Use next valid observation to fill gap.
- nearest: Use nearest valid observations to fill gap.

copy [bool, default True] Return a new object, even if the passed indexes are the same.

level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [scalar, default np.NaN] Value to use for missing values. Defaults to NaN, but can be any "compatible" value.

limit [int, default None] Maximum number of consecutive elements to forward or backward fill.

tolerance [optional] Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations most satisfy the equation `abs(index[indexer] - target) <= tolerance`.

Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple, array, Series, and must be the same size as the index and its dtype must exactly match the index's type.

Returns

Series/DataFrame with changed index.

See also:

DataFrame.set_index Set row labels.

DataFrame.reset_index Remove row labels or move them to new columns.

DataFrame.reindex_like Change to same indices as other DataFrame.

Examples

`DataFrame.reindex` supports two calling conventions

- `(index=index_labels, columns=column_labels, ...)`
- `(labels, axis={'index', 'columns'}, ...)`

We *highly* recommend using keyword arguments to clarify your intent.

Create a dataframe with some fictional data.

```
>>> index = ['Firefox', 'Chrome', 'Safari', 'IE10', 'Konqueror']
>>> df = pd.DataFrame({'http_status': [200, 200, 404, 404, 301],
...                    'response_time': [0.04, 0.02, 0.07, 0.08, 1.0]},
...                    index=index)
>>> df
           http_status  response_time
Firefox            200           0.04
Chrome             200           0.02
Safari             404           0.07
IE10               404           0.08
Konqueror          301           1.00
```

Create a new index and reindex the dataframe. By default values in the new index that do not have corresponding records in the dataframe are assigned `NaN`.

```
>>> new_index = ['Safari', 'Iceweasel', 'Comodo Dragon', 'IE10',
...              'Chrome']
>>> df.reindex(new_index)
               http_status  response_time
Safari               404.0           0.07
Iceweasel              NaN            NaN
Comodo Dragon          NaN            NaN
IE10                 404.0           0.08
Chrome               200.0           0.02
```

We can fill in the missing values by passing a value to the keyword `fill_value`. Because the index is not monotonically increasing or decreasing, we cannot use arguments to the keyword `method` to fill the `NaN` values.

```
>>> df.reindex(new_index, fill_value=0)
               http_status  response_time
Safari                 404           0.07
Iceweasel                0           0.00
Comodo Dragon            0           0.00
IE10                   404           0.08
Chrome                 200           0.02
```

```
>>> df.reindex(new_index, fill_value='missing')
              http_status response_time
Safari                404          0.07
Iceweasel         missing       missing
Comodo Dragon     missing       missing
IE10                  404          0.08
Chrome                200          0.02
```

We can also reindex the columns.

```
>>> df.reindex(columns=['http_status', 'user_agent'])
           http_status  user_agent
Firefox            200         NaN
Chrome             200         NaN
Safari             404         NaN
IE10               404         NaN
Konqueror          301         NaN
```

Or we can use "axis-style" keyword arguments

```
>>> df.reindex(['http_status', 'user_agent'], axis="columns")
           http_status  user_agent
Firefox            200         NaN
Chrome             200         NaN
Safari             404         NaN
IE10               404         NaN
Konqueror          301         NaN
```

To further illustrate the filling functionality in `reindex`, we will create a dataframe with a monotonically increasing index (for example, a sequence of dates).

```
>>> date_index = pd.date_range('1/1/2010', periods=6, freq='D')
>>> df2 = pd.DataFrame({"prices": [100, 101, np.nan, 100, 89, 88]},
...                    index=date_index)
>>> df2
            prices
2010-01-01   100.0
2010-01-02   101.0
2010-01-03     NaN
2010-01-04   100.0
2010-01-05    89.0
2010-01-06    88.0
```

Suppose we decide to expand the dataframe to cover a wider date range.

```
>>> date_index2 = pd.date_range('12/29/2009', periods=10, freq='D')
>>> df2.reindex(date_index2)
            prices
2009-12-29     NaN
2009-12-30     NaN
2009-12-31     NaN
2010-01-01   100.0
2010-01-02   101.0
2010-01-03     NaN
2010-01-04   100.0
2010-01-05    89.0
2010-01-06    88.0
2010-01-07     NaN
```

The index entries that did not have a value in the original data frame (for example, '2009-12-29') are by default filled with `NaN`. If desired, we can fill in the missing values using one of several options.

For example, to back-propagate the last valid value to fill the `NaN` values, pass `bfill` as an argument to the `method` keyword.

```
>>> df2.reindex(date_index2, method='bfill')
            prices
```

(continues on next page)

(continued from previous page)

```
2009-12-29   100.0
2009-12-30   100.0
2009-12-31   100.0
2010-01-01   100.0
2010-01-02   101.0
2010-01-03     NaN
2010-01-04   100.0
2010-01-05    89.0
2010-01-06    88.0
2010-01-07     NaN
```

Please note that the `NaN` value present in the original dataframe (at index value 2010-01-03) will not be filled by any of the value propagation schemes. This is because filling while reindexing does not look at dataframe values, but only compares the original and desired indexes. If you do want to fill in the `NaN` values present in the original dataframe, use the `fillna()` method.

See the *user guide* for more.

pandas.DataFrame.reindex_like

`DataFrame.`**`reindex_like`**(*other*, *method=None*, *copy=True*, *limit=None*, *tolerance=None*)

Return an object with matching indices as other object.

Conform the object to the same index on all axes. Optional filling logic, placing NaN in locations having no value in the previous index. A new object is produced unless the new index is equivalent to the current one and copy=False.

Parameters

other [Object of the same data type] Its row and column indices are used to define the new indices of this object.

method [{None, 'backfill'/'bfill', 'pad'/'ffill', 'nearest'}] Method to use for filling holes in reindexed DataFrame. Please note: this is only applicable to DataFrames/Series with a monotonically increasing/decreasing index.

- None (default): don't fill gaps
- pad / ffill: propagate last valid observation forward to next valid
- backfill / bfill: use next valid observation to fill gap
- nearest: use nearest valid observations to fill gap.

copy [bool, default True] Return a new object, even if the passed indexes are the same.

limit [int, default None] Maximum number of consecutive labels to fill for inexact matches.

tolerance [optional] Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations most satisfy the equation `abs(index[indexer] - target) <= tolerance`.

Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple, array, Series, and must be the same size as the index and its dtype must exactly match the index's type.

Returns

Series or DataFrame Same type as caller, but with changed indices on each axis.

See also:

DataFrame.set_index Set row labels.

DataFrame.reset_index Remove row labels or move them to new columns.

DataFrame.reindex Change to new indices or expand indices.

Notes

Same as calling `.reindex(index=other.index, columns=other.columns,...)`.

Examples

```
>>> df1 = pd.DataFrame([[24.3, 75.7, 'high'],
...                     [31, 87.8, 'high'],
...                     [22, 71.6, 'medium'],
...                     [35, 95, 'medium']],
...                    columns=['temp_celsius', 'temp_fahrenheit',
...                             'windspeed'],
...                    index=pd.date_range(start='2014-02-12',
...                                        end='2014-02-15', freq='D'))
```

```
>>> df1
            temp_celsius  temp_fahrenheit windspeed
2014-02-12          24.3             75.7      high
2014-02-13          31.0             87.8      high
2014-02-14          22.0             71.6    medium
2014-02-15          35.0             95.0    medium
```

```
>>> df2 = pd.DataFrame([[28, 'low'],
...                     [30, 'low'],
...                     [35.1, 'medium']],
...                    columns=['temp_celsius', 'windspeed'],
...                    index=pd.DatetimeIndex(['2014-02-12', '2014-02-13',
...                                            '2014-02-15']))
```

```
>>> df2
            temp_celsius windspeed
2014-02-12          28.0       low
2014-02-13          30.0       low
2014-02-15          35.1    medium
```

```
>>> df2.reindex_like(df1)
            temp_celsius  temp_fahrenheit windspeed
2014-02-12          28.0              NaN       low
2014-02-13          30.0              NaN       low
2014-02-14           NaN              NaN       NaN
2014-02-15          35.1              NaN    medium
```

pandas.DataFrame.rename

DataFrame.**rename**(***kwargs*)

Alter axes labels.

Function / dict values must be unique (1-to-1). Labels not contained in a dict / Series will be left as-is. Extra labels listed don't throw an error.

See the *user guide* for more.

Parameters

mapper [dict-like or function] Dict-like or functions transformations to apply to that axis' values. Use either `mapper` and `axis` to specify the axis to target with `mapper`, or `index` and `columns`.

index [dict-like or function] Alternative to specifying axis (`mapper, axis=0` is equivalent to `index=mapper`).

columns [dict-like or function] Alternative to specifying axis (`mapper, axis=1` is equivalent to `columns=mapper`).

axis [{0 or 'index', 1 or 'columns'}, default 0] Axis to target with `mapper`. Can be either the axis name ('index', 'columns') or number (0, 1). The default is 'index'.

copy [bool, default True] Also copy underlying data.

inplace [bool, default False] Whether to return a new DataFrame. If True then value of copy is ignored.

level [int or level name, default None] In case of a MultiIndex, only rename labels in the specified level.

errors [{'ignore', 'raise'}, default 'ignore'] If 'raise', raise a *KeyError* when a dict-like *mapper*, *index*, or *columns* contains labels that are not present in the Index being transformed. If 'ignore', existing keys will be renamed and extra keys will be ignored.

Returns

DataFrame DataFrame with the renamed axis labels.

Raises

KeyError If any of the labels is not found in the selected axis and "errors='raise'".

See also:

DataFrame.rename_axis Set the name of the axis.

Examples

`DataFrame.rename` supports two calling conventions

- `(index=index_mapper, columns=columns_mapper, ...)`
- `(mapper, axis={'index', 'columns'}, ...)`

We *highly* recommend using keyword arguments to clarify your intent.

Rename columns using a mapping:

```
>>> df = pd.DataFrame({"A": [1, 2, 3], "B": [4, 5, 6]})
>>> df.rename(columns={"A": "a", "B": "c"})
   a  c
0  1  4
1  2  5
2  3  6
```

Rename index using a mapping:

```
>>> df.rename(index={0: "x", 1: "y", 2: "z"})
   A  B
x  1  4
y  2  5
z  3  6
```

Cast index labels to a different type:

```
>>> df.index
RangeIndex(start=0, stop=3, step=1)
>>> df.rename(index=str).index
Index(['0', '1', '2'], dtype='object')
```

```
>>> df.rename(columns={"A": "a", "B": "b", "C": "c"}, errors="raise")
Traceback (most recent call last):
KeyError: ['C'] not found in axis
```

Using axis-style parameters

```
>>> df.rename(str.lower, axis='columns')
   a  b
0  1  4
1  2  5
2  3  6
```

```
>>> df.rename({1: 2, 2: 4}, axis='index')
   A  B
0  1  4
2  2  5
4  3  6
```

pandas.DataFrame.rename_axis

DataFrame.**rename_axis**(***kwargs*)

Set the name of the axis for the index or columns.

Parameters

mapper [scalar, list-like, optional] Value to set the axis name attribute.

index, columns [scalar, list-like, dict-like or function, optional] A scalar, list-like, dict-like or functions transformations to apply to that axis' values. Note that the `columns` parameter is not allowed if the object is a Series. This parameter only apply for DataFrame type objects.

Use either `mapper` and `axis` to specify the axis to target with `mapper`, or `index` and/or `columns`.

Changed in version 0.24.0.

axis [{0 or 'index', 1 or 'columns'}, default 0] The axis to rename.

copy [bool, default True] Also copy underlying data.

inplace [bool, default False] Modifies the object directly, instead of creating a new Series or DataFrame.

Returns

Series, DataFrame, or None The same type as the caller or None if *inplace* is True.

See also:

Series.rename Alter Series index labels or name.

DataFrame.rename Alter DataFrame index labels or name.

Index.rename Set new names on index.

Notes

`DataFrame.rename_axis` supports two calling conventions

- `(index=index_mapper, columns=columns_mapper, ...)`
- `(mapper, axis={'index', 'columns'}, ...)`

The first calling convention will only modify the names of the index and/or the names of the Index object that is the columns. In this case, the parameter `copy` is ignored.

The second calling convention will modify the names of the the corresponding index if mapper is a list or a scalar. However, if mapper is dict-like or a function, it will use the deprecated behavior of modifying the axis *labels*.

We *highly* recommend using keyword arguments to clarify your intent.

Examples

Series

```
>>> s = pd.Series(["dog", "cat", "monkey"])
>>> s
0       dog
1       cat
2    monkey
dtype: object
>>> s.rename_axis("animal")
animal
0    dog
1    cat
2    monkey
dtype: object
```

DataFrame

```
>>> df = pd.DataFrame({"num_legs": [4, 4, 2],
...                    "num_arms": [0, 0, 2]},
...                   ["dog", "cat", "monkey"])
>>> df
        num_legs  num_arms
dog             4         0
cat             4         0
monkey          2         2
>>> df = df.rename_axis("animal")
>>> df
        num_legs  num_arms
animal
dog             4         0
cat             4         0
monkey          2         2
>>> df = df.rename_axis("limbs", axis="columns")
>>> df
limbs   num_legs  num_arms
animal
dog             4         0
cat             4         0
monkey          2         2
```

MultiIndex

```
>>> df.index = pd.MultiIndex.from_product([['mammal'],
...                                        ['dog', 'cat', 'monkey']],
...                                       names=['type', 'name'])
>>> df
limbs          num_legs  num_arms
type   name
mammal dog             4         0
       cat             4         0
       monkey          2         2
```

```
>>> df.rename_axis(index={'type': 'class'})
limbs          num_legs  num_arms
class  name
mammal dog             4         0
       cat             4         0
       monkey          2         2
```

```
>>> df.rename_axis(columns=str.upper)
LIMBS          num_legs  num_arms
type   name
mammal dog             4         0
       cat             4         0
       monkey          2         2
```

pandas.DataFrame.reorder_levels

DataFrame.**reorder_levels**(*order*, *axis=0*)

Rearrange index levels using input order. May not drop or duplicate levels.

Parameters

order [list of int or list of str] List representing new level order. Reference level by number (position) or by key (label).

axis [{0 or 'index', 1 or 'columns'}, default 0] Where to reorder levels.

Returns

DataFrame

pandas.DataFrame.replace

DataFrame.**replace**(*to_replace=None*, *value=None*, *inplace=False*, *limit=None*, *regex=False*, *method='pad'*)

Replace values given in *to_replace* with *value*.

Values of the DataFrame are replaced with other values dynamically. This differs from updating with `.loc` or `.iloc`, which require you to specify a location to update with some value.

Parameters

to_replace [str, regex, list, dict, Series, int, float, or None] How to find the values that will be replaced.

- numeric, str or regex:
  - numeric: numeric values equal to *to_replace* will be replaced with *value*
  - str: string exactly matching *to_replace* will be replaced with *value*
  - regex: regexs matching *to_replace* will be replaced with *value*
- list of str, regex, or numeric:
  - First, if *to_replace* and *value* are both lists, they **must** be the same length.
  - Second, if `regex=True` then all of the strings in **both** lists will be interpreted as regexs otherwise they will match directly. This doesn't matter much for *value* since there are only a few possible substitution regexes you can use.
  - str, regex and numeric rules apply as above.
- dict:
  - Dicts can be used to specify different replacement values for different existing values. For example, `{'a': 'b', 'y': 'z'}` replaces the value 'a' with 'b' and 'y' with 'z'. To use a dict in this way the *value* parameter should be *None*.
  - For a DataFrame a dict can specify that different values should be replaced in different columns. For example, `{'a': 1, 'b': 'z'}` looks for the value 1 in column 'a' and the value 'z' in column 'b' and replaces these values with whatever is specified in *value*. The *value* parameter should not be `None` in this case. You can treat this as a special case of passing two lists except that you are specifying the column to search in.

- For a DataFrame nested dictionaries, e.g., `{'a': {'b': np.nan}}`, are read as follows: look in column 'a' for the value 'b' and replace it with NaN. The *value* parameter should be `None` to use a nested dict in this way. You can nest regular expressions as well. Note that column names (the top-level dictionary keys in a nested dictionary) **cannot** be regular expressions.

- None:

  - This means that the *regex* argument must be a string, compiled regular expression, or list, dict, ndarray or Series of such elements. If *value* is also `None` then this **must** be a nested dictionary or Series.

See the examples section for examples of each of these.

value [scalar, dict, list, str, regex, default None] Value to replace any values matching *to_replace* with. For a DataFrame a dict of values can be used to specify which value to use for each column (columns not in the dict will not be filled). Regular expressions, strings and lists or dicts of such objects are also allowed.

inplace [bool, default False] If True, in place. Note: this will modify any other views on this object (e.g. a column from a DataFrame). Returns the caller if this is True.

limit [int, default None] Maximum size gap to forward or backward fill.

regex [bool or same types as *to_replace*, default False] Whether to interpret *to_replace* and/or *value* as regular expressions. If this is `True` then *to_replace must* be a string. Alternatively, this could be a regular expression or a list, dict, or array of regular expressions in which case *to_replace* must be `None`.

method [{'pad', 'ffill', 'bfill', *None*}] The method to use when for replacement, when *to_replace* is a scalar, list or tuple and *value* is `None`.

Changed in version 0.23.0: Added to DataFrame.

Returns

DataFrame Object after replacement.

Raises

AssertionError

- If *regex* is not a `bool` and *to_replace* is not `None`.

TypeError

- If *to_replace* is not a scalar, array-like, `dict`, or `None`
- If *to_replace* is a `dict` and *value* is not a `list`, `dict`, `ndarray`, or `Series`
- If *to_replace* is `None` and *regex* is not compilable into a regular expression or is a list, dict, ndarray, or Series.
- When replacing multiple `bool` or `datetime64` objects and the arguments to *to_replace* does not match the type of the value being replaced

ValueError

- If a `list` or an `ndarray` is passed to *to_replace* and *value* but they are not the same length.

See also:

DataFrame.fillna Fill NA values.

DataFrame.where Replace values based on boolean condition.

Series.str.replace Simple string replacement.

Notes

- Regex substitution is performed under the hood with `re.sub`. The rules for substitution for `re.sub` are the same.
- Regular expressions will only substitute on strings, meaning you cannot provide, for example, a regular expression matching floating point numbers and expect the columns in your frame that have a numeric dtype to be matched. However, if those floating point numbers *are* strings, then you can do this.
- This method has *a lot* of options. You are encouraged to experiment and play with this method to gain intuition about how it works.
- When dict is used as the *to_replace* value, it is like key(s) in the dict are the to_replace part and value(s) in the dict are the value parameter.

Examples

Scalar `to_replace` and `value`

```
>>> s = pd.Series([0, 1, 2, 3, 4])
>>> s.replace(0, 5)
0    5
1    1
2    2
3    3
4    4
dtype: int64
```

```
>>> df = pd.DataFrame({'A': [0, 1, 2, 3, 4],
...                    'B': [5, 6, 7, 8, 9],
...                    'C': ['a', 'b', 'c', 'd', 'e']})
>>> df.replace(0, 5)
   A  B  C
0  5  5  a
1  1  6  b
2  2  7  c
3  3  8  d
4  4  9  e
```

List-like `to_replace`

```
>>> df.replace([0, 1, 2, 3], 4)
   A  B  C
0  4  5  a
1  4  6  b
2  4  7  c
3  4  8  d
4  4  9  e
```

```
>>> df.replace([0, 1, 2, 3], [4, 3, 2, 1])
   A  B  C
0  4  5  a
1  3  6  b
2  2  7  c
3  1  8  d
4  4  9  e
```

```
>>> s.replace([1, 2], method='bfill')
0    0
1    3
2    3
3    3
4    4
dtype: int64
```

dict-like `to_replace`

```
>>> df.replace({0: 10, 1: 100})
     A  B  C
0   10  5  a
1  100  6  b
2    2  7  c
3    3  8  d
4    4  9  e
```

```
>>> df.replace({'A': 0, 'B': 5}, 100)
     A    B  C
0  100  100  a
1    1    6  b
2    2    7  c
3    3    8  d
4    4    9  e
```

```
>>> df.replace({'A': {0: 100, 4: 400}})
     A  B  C
0  100  5  a
1    1  6  b
2    2  7  c
3    3  8  d
4  400  9  e
```

Regular expression `to_replace`

```
>>> df = pd.DataFrame({'A': ['bat', 'foo', 'bait'],
...                    'B': ['abc', 'bar', 'xyz']})
>>> df.replace(to_replace=r'^ba.$', value='new', regex=True)
      A    B
0   new  abc
1   foo  new
2  bait  xyz
```

```
>>> df.replace({'A': r'^ba.$'}, {'A': 'new'}, regex=True)
      A    B
0   new  abc
```

(continues on next page)

(continued from previous page)

```
1   foo  bar
2  bait  xyz
```

```
>>> df.replace(regex=r'^ba.$', value='new')
      A    B
0   new  abc
1   foo  new
2  bait  xyz
```

```
>>> df.replace(regex={r'^ba.$': 'new', 'foo': 'xyz'})
      A    B
0   new  abc
1   xyz  new
2  bait  xyz
```

```
>>> df.replace(regex=[r'^ba.$', 'foo'], value='new')
      A    B
0   new  abc
1   new  new
2  bait  xyz
```

Note that when replacing multiple `bool` or `datetime64` objects, the data types in the *to_replace* parameter must match the data type of the value being replaced:

```
>>> df = pd.DataFrame({'A': [True, False, True],
...                    'B': [False, True, False]})
>>> df.replace({'a string': 'new value', True: False})  # raises
Traceback (most recent call last):
    ...
TypeError: Cannot compare types 'ndarray(dtype=bool)' and 'str'
```

This raises a `TypeError` because one of the `dict` keys is not of the correct type for replacement.

Compare the behavior of `s.replace({'a': None})` and `s.replace('a', None)` to understand the peculiarities of the *to_replace* parameter:

```
>>> s = pd.Series([10, 'a', 'a', 'b', 'a'])
```

When one uses a dict as the *to_replace* value, it is like the value(s) in the dict are equal to the *value* parameter. `s.replace({'a': None})` is equivalent to `s.replace(to_replace={'a': None}, value=None, method=None)`:

```
>>> s.replace({'a': None})
0      10
1    None
2    None
3       b
4    None
dtype: object
```

When `value=None` and *to_replace* is a scalar, list or tuple, *replace* uses the method parameter (default 'pad') to do the replacement. So this is why the 'a' values are being replaced by 10 in rows 1 and 2 and 'b' in row 4 in this case. The command `s.replace('a', None)` is actually equivalent to `s.replace(to_replace='a', value=None, method='pad')`:

```
>>> s.replace('a', None)
0    10
1    10
2    10
3     b
4     b
dtype: object
```

pandas.DataFrame.resample

DataFrame.**resample**(*rule*, *axis=0*, *closed=None*, *label=None*, *convention='start'*, *kind=None*, *loffset=None*, *base=None*, *on=None*, *level=None*, *origin='start_day'*, *offset=None*)

Resample time-series data.

Convenience method for frequency conversion and resampling of time series. Object must have a datetime-like index (*DatetimeIndex*, *PeriodIndex*, or *TimedeltaIndex*), or pass datetime-like values to the *on* or *level* keyword.

Parameters

rule [DateOffset, Timedelta or str] The offset string or object representing target conversion.

axis [{0 or 'index', 1 or 'columns'}, default 0] Which axis to use for up- or down-sampling. For *Series* this will default to 0, i.e. along the rows. Must be *DatetimeIndex*, *TimedeltaIndex* or *PeriodIndex*.

closed [{'right', 'left'}, default None] Which side of bin interval is closed. The default is 'left' for all frequency offsets except for 'M', 'A', 'Q', 'BM', 'BA', 'BQ', and 'W' which all have a default of 'right'.

label [{'right', 'left'}, default None] Which bin edge label to label bucket with. The default is 'left' for all frequency offsets except for 'M', 'A', 'Q', 'BM', 'BA', 'BQ', and 'W' which all have a default of 'right'.

convention [{'start', 'end', 's', 'e'}, default 'start'] For *PeriodIndex* only, controls whether to use the start or end of *rule*.

kind [{'timestamp', 'period'}, optional, default None] Pass 'timestamp' to convert the resulting index to a *DateTimeIndex* or 'period' to convert it to a *PeriodIndex*. By default the input representation is retained.

loffset [timedelta, default None] Adjust the resampled time labels.

Deprecated since version 1.1.0: You should add the loffset to the *df.index* after the resample. See below.

base [int, default 0] For frequencies that evenly subdivide 1 day, the "origin" of the aggregated intervals. For example, for '5min' frequency, base could range from 0 through 4. Defaults to 0.

Deprecated since version 1.1.0: The new arguments that you should use are 'offset' or 'origin'.

on [str, optional] For a DataFrame, column to use instead of index for resampling. Column must be datetime-like.

level [str or int, optional] For a MultiIndex, level (name or number) to use for resampling. *level* must be datetime-like.

origin [{'epoch', 'start', 'start_day'}, Timestamp or str, default 'start_day'] The timestamp on which to adjust the grouping. The timezone of origin must match the timezone of the index. If a timestamp is not used, these values are also supported:

- 'epoch': *origin* is 1970-01-01
- 'start': *origin* is the first value of the timeseries
- 'start_day': *origin* is the first day at midnight of the timeseries

New in version 1.1.0.

offset [Timedelta or str, default is None] An offset timedelta added to the origin.

New in version 1.1.0.

Returns

Resampler object

See also:

groupby Group by mapping, function, label, or list of labels.

Series.resample Resample a Series.

DataFrame.resample Resample a DataFrame.

Notes

See the user guide for more.

To learn more about the offset strings, please see this link.

Examples

Start by creating a series with 9 one minute timestamps.

```
>>> index = pd.date_range('1/1/2000', periods=9, freq='T')
>>> series = pd.Series(range(9), index=index)
>>> series
2000-01-01 00:00:00    0
2000-01-01 00:01:00    1
2000-01-01 00:02:00    2
2000-01-01 00:03:00    3
2000-01-01 00:04:00    4
2000-01-01 00:05:00    5
2000-01-01 00:06:00    6
2000-01-01 00:07:00    7
2000-01-01 00:08:00    8
Freq: T, dtype: int64
```

Downsample the series into 3 minute bins and sum the values of the timestamps falling into a bin.

```
>>> series.resample('3T').sum()
2000-01-01 00:00:00     3
2000-01-01 00:03:00    12
2000-01-01 00:06:00    21
Freq: 3T, dtype: int64
```

Downsample the series into 3 minute bins as above, but label each bin using the right edge instead of the left. Please note that the value in the bucket used as the label is not included in the bucket, which it labels. For example, in the original series the bucket `2000-01-01 00:03:00` contains the value 3, but the summed value in the resampled bucket with the label `2000-01-01 00:03:00` does not include 3 (if it did, the summed value would be 6, not 3). To include this value close the right side of the bin interval as illustrated in the example below this one.

```
>>> series.resample('3T', label='right').sum()
2000-01-01 00:03:00     3
2000-01-01 00:06:00    12
2000-01-01 00:09:00    21
Freq: 3T, dtype: int64
```

Downsample the series into 3 minute bins as above, but close the right side of the bin interval.

```
>>> series.resample('3T', label='right', closed='right').sum()
2000-01-01 00:00:00     0
2000-01-01 00:03:00     6
2000-01-01 00:06:00    15
2000-01-01 00:09:00    15
Freq: 3T, dtype: int64
```

Upsample the series into 30 second bins.

```
>>> series.resample('30S').asfreq()[0:5]   # Select first 5 rows
2000-01-01 00:00:00   0.0
2000-01-01 00:00:30   NaN
2000-01-01 00:01:00   1.0
2000-01-01 00:01:30   NaN
2000-01-01 00:02:00   2.0
Freq: 30S, dtype: float64
```

Upsample the series into 30 second bins and fill the `NaN` values using the `pad` method.

```
>>> series.resample('30S').pad()[0:5]
2000-01-01 00:00:00    0
2000-01-01 00:00:30    0
2000-01-01 00:01:00    1
2000-01-01 00:01:30    1
2000-01-01 00:02:00    2
Freq: 30S, dtype: int64
```

Upsample the series into 30 second bins and fill the `NaN` values using the `bfill` method.

```
>>> series.resample('30S').bfill()[0:5]
2000-01-01 00:00:00    0
2000-01-01 00:00:30    1
2000-01-01 00:01:00    1
2000-01-01 00:01:30    2
2000-01-01 00:02:00    2
Freq: 30S, dtype: int64
```

Pass a custom function via `apply`

```
>>> def custom_resampler(array_like):
...     return np.sum(array_like) + 5
...
```

(continues on next page)

(continued from previous page)

```
>>> series.resample('3T').apply(custom_resampler)
2000-01-01 00:00:00     8
2000-01-01 00:03:00    17
2000-01-01 00:06:00    26
Freq: 3T, dtype: int64
```

For a Series with a PeriodIndex, the keyword *convention* can be used to control whether to use the start or end of *rule*.

Resample a year by quarter using 'start' *convention*. Values are assigned to the first quarter of the period.

```
>>> s = pd.Series([1, 2], index=pd.period_range('2012-01-01',
...                                             freq='A',
...                                             periods=2))
>>> s
2012    1
2013    2
Freq: A-DEC, dtype: int64
>>> s.resample('Q', convention='start').asfreq()
2012Q1    1.0
2012Q2    NaN
2012Q3    NaN
2012Q4    NaN
2013Q1    2.0
2013Q2    NaN
2013Q3    NaN
2013Q4    NaN
Freq: Q-DEC, dtype: float64
```

Resample quarters by month using 'end' *convention*. Values are assigned to the last month of the period.

```
>>> q = pd.Series([1, 2, 3, 4], index=pd.period_range('2018-01-01',
...                                                   freq='Q',
...                                                   periods=4))
>>> q
2018Q1    1
2018Q2    2
2018Q3    3
2018Q4    4
Freq: Q-DEC, dtype: int64
>>> q.resample('M', convention='end').asfreq()
2018-03    1.0
2018-04    NaN
2018-05    NaN
2018-06    2.0
2018-07    NaN
2018-08    NaN
2018-09    3.0
2018-10    NaN
2018-11    NaN
2018-12    4.0
Freq: M, dtype: float64
```

For DataFrame objects, the keyword *on* can be used to specify the column instead of the index for resampling.

```
>>> d = dict({'price': [10, 11, 9, 13, 14, 18, 17, 19],
...           'volume': [50, 60, 40, 100, 50, 100, 40, 50]})
>>> df = pd.DataFrame(d)
>>> df['week_starting'] = pd.date_range('01/01/2018',
...                                     periods=8,
...                                     freq='W')
>>> df
   price  volume week_starting
0     10      50    2018-01-07
1     11      60    2018-01-14
2      9      40    2018-01-21
3     13     100    2018-01-28
4     14      50    2018-02-04
5     18     100    2018-02-11
6     17      40    2018-02-18
7     19      50    2018-02-25
>>> df.resample('M', on='week_starting').mean()
               price  volume
week_starting
2018-01-31     10.75    62.5
2018-02-28     17.00    60.0
```

For a DataFrame with MultiIndex, the keyword *level* can be used to specify on which level the resampling needs to take place.

```
>>> days = pd.date_range('1/1/2000', periods=4, freq='D')
>>> d2 = dict({'price': [10, 11, 9, 13, 14, 18, 17, 19],
...            'volume': [50, 60, 40, 100, 50, 100, 40, 50]})
>>> df2 = pd.DataFrame(d2,
...                    index=pd.MultiIndex.from_product([days,
...                                                      ['morning',
...                                                       'afternoon']]
...                                                     ))
>>> df2
                     price  volume
2000-01-01 morning       10      50
           afternoon     11      60
2000-01-02 morning        9      40
           afternoon     13     100
2000-01-03 morning       14      50
           afternoon     18     100
2000-01-04 morning       17      40
           afternoon     19      50
>>> df2.resample('D', level=0).sum()
            price  volume
2000-01-01     21     110
2000-01-02     22     140
2000-01-03     32     150
2000-01-04     36      90
```

If you want to adjust the start of the bins based on a fixed timestamp:

```
>>> start, end = '2000-10-01 23:30:00', '2000-10-02 00:30:00'
>>> rng = pd.date_range(start, end, freq='7min')
>>> ts = pd.Series(np.arange(len(rng)) * 3, index=rng)
>>> ts
2000-10-01 23:30:00     0
```

(continues on next page)

(continued from previous page)

```
2000-10-01 23:37:00     3
2000-10-01 23:44:00     6

>>> ts.resample('17min', origin='epoch').sum()
2000-10-01 23:18:00     0
2000-10-01 23:35:00    18
2000-10-01 23:52:00    27
2000-10-02 00:09:00    39
2000-10-02 00:26:00    24
Freq: 17T, dtype: int64
```

```
>>> ts.resample('17min', origin='2000-01-01').sum()
2000-10-01 23:24:00     3
2000-10-01 23:41:00    15
2000-10-01 23:58:00    45
2000-10-02 00:15:00    45
Freq: 17T, dtype: int64
```

If you want to adjust the start of the bins with an *offset* Timedelta, the two following lines are equivalent:

```
>>> ts.resample('17min', origin='start').sum()
2000-10-01 23:30:00     9
2000-10-01 23:47:00    21
2000-10-02 00:04:00    54
2000-10-02 00:21:00    24
Freq: 17T, dtype: int64
```

```
>>> ts.resample('17min', offset='23h30min').sum()
2000-10-01 23:30:00     9
2000-10-01 23:47:00    21
2000-10-02 00:04:00    54
2000-10-02 00:21:00    24
Freq: 17T, dtype: int64
```

To replace the use of the deprecated *base* argument, you can now use *offset*, in this example it is equivalent to have *base=2*:

```
>>> ts.resample('17min', offset='2min').sum()
2000-10-01 23:16:00     0
2000-10-01 23:33:00     9
```

(continues on next page)

(continued from previous page)

```
2000-10-01 23:50:00    36
2000-10-02 00:07:00    39
2000-10-02 00:24:00    24
Freq: 17T, dtype: int64
```

To replace the use of the deprecated *loffset* argument:

```
>>> from pandas.tseries.frequencies import to_offset
>>> loffset = '19min'
>>> ts_out = ts.resample('17min').sum()
>>> ts_out.index = ts_out.index + to_offset(loffset)
>>> ts_out
2000-10-01 23:33:00     0
2000-10-01 23:50:00     9
2000-10-02 00:07:00    21
2000-10-02 00:24:00    54
2000-10-02 00:41:00    24
Freq: 17T, dtype: int64
```

pandas.DataFrame.reset_index

DataFrame.**reset_index**(*level=None*, *drop=False*, *inplace=False*, *col_level=0*, *col_fill=''*)

Reset the index, or a level of it.

Reset the index of the DataFrame, and use the default one instead. If the DataFrame has a MultiIndex, this method can remove one or more levels.

Parameters

level [int, str, tuple, or list, default None] Only remove the given levels from the index. Removes all levels by default.

drop [bool, default False] Do not try to insert index into dataframe columns. This resets the index to the default integer index.

inplace [bool, default False] Modify the DataFrame in place (do not create a new object).

col_level [int or str, default 0] If the columns have multiple levels, determines which level the labels are inserted into. By default it is inserted into the first level.

col_fill [object, default ''] If the columns have multiple levels, determines how the other levels are named. If None then the index name is repeated.

Returns

DataFrame or None DataFrame with the new index or None if `inplace=True`.

See also:

DataFrame.set_index Opposite of reset_index.

DataFrame.reindex Change to new indices or expand indices.

DataFrame.reindex_like Change to same indices as other DataFrame.

Examples

```
>>> df = pd.DataFrame([('bird', 389.0),
...                    ('bird', 24.0),
...                    ('mammal', 80.5),
...                    ('mammal', np.nan)],
...                   index=['falcon', 'parrot', 'lion', 'monkey'],
...                   columns=('class', 'max_speed'))
>>> df
         class  max_speed
falcon    bird      389.0
parrot    bird       24.0
lion    mammal       80.5
monkey  mammal        NaN
```

When we reset the index, the old index is added as a column, and a new sequential index is used:

```
>>> df.reset_index()
    index   class  max_speed
0  falcon    bird      389.0
1  parrot    bird       24.0
2    lion  mammal       80.5
3  monkey  mammal        NaN
```

We can use the *drop* parameter to avoid the old index being added as a column:

```
>>> df.reset_index(drop=True)
    class  max_speed
0    bird      389.0
1    bird       24.0
2  mammal       80.5
3  mammal        NaN
```

You can also use *reset_index* with *MultiIndex*.

```
>>> index = pd.MultiIndex.from_tuples([('bird', 'falcon'),
...                                    ('bird', 'parrot'),
...                                    ('mammal', 'lion'),
...                                    ('mammal', 'monkey')],
...                                   names=['class', 'name'])
>>> columns = pd.MultiIndex.from_tuples([('speed', 'max'),
...                                      ('species', 'type')])
>>> df = pd.DataFrame([(389.0, 'fly'),
...                    ( 24.0, 'fly'),
...                    ( 80.5, 'run'),
...                    (np.nan, 'jump')],
...                   index=index,
...                   columns=columns)
>>> df
               speed species
                 max    type
class  name
bird   falcon  389.0     fly
       parrot   24.0     fly
mammal lion     80.5     run
       monkey    NaN    jump
```

If the index has multiple levels, we can reset a subset of them:

```
>>> df.reset_index(level='class')
         class  speed species
                  max    type
name
falcon    bird  389.0     fly
parrot    bird   24.0     fly
lion    mammal   80.5     run
monkey  mammal    NaN    jump
```

If we are not dropping the index, by default, it is placed in the top level. We can place it in another level:

```
>>> df.reset_index(level='class', col_level=1)
                speed species
         class    max    type
name
falcon    bird  389.0     fly
parrot    bird   24.0     fly
lion    mammal   80.5     run
monkey  mammal    NaN    jump
```

When the index is inserted under another level, we can specify under which one with the parameter *col_fill*:

```
>>> df.reset_index(level='class', col_level=1, col_fill='species')
              species  speed species
                class    max    type
name
falcon           bird  389.0     fly
parrot           bird   24.0     fly
lion           mammal   80.5     run
monkey         mammal    NaN    jump
```

If we specify a nonexistent level for *col_fill*, it is created:

```
>>> df.reset_index(level='class', col_level=1, col_fill='genus')
                genus  speed species
                class    max    type
name
falcon           bird  389.0     fly
parrot           bird   24.0     fly
lion           mammal   80.5     run
monkey         mammal    NaN    jump
```

pandas.DataFrame.rfloordiv

`DataFrame.`**`rfloordiv`**(*other*, *axis='columns'*, *level=None*, *fill_value=None*)

Get Integer division of dataframe and other, element-wise (binary operator *rfloordiv*).

Equivalent to `other // dataframe`, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, *floordiv*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: +, -, *, /, //, %, **.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

See also:

DataFrame.add Add DataFrames.

DataFrame.sub Subtract DataFrames.

DataFrame.mul Multiply DataFrames.

DataFrame.div Divide DataFrames (float division).

DataFrame.truediv Divide DataFrames (float division).

DataFrame.floordiv Divide DataFrames (integer division).

DataFrame.mod Calculate modulo (remainder after division).

DataFrame.pow Calculate exponential power.

Notes

Mismatched indices will be unioned together.

Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                   index=['circle', 'triangle', 'rectangle'])
>>> df
           angles  degrees
circle          0      360
triangle        3      180
rectangle       4      360
```

Add a scalar with operator version which return the same results.

```
>>> df + 1
           angles  degrees
circle          1      361
triangle        4      181
rectangle       5      361
```

```
>>> df.add(1)
           angles  degrees
circle          1      361
triangle        4      181
rectangle       5      361
```

Divide by constant with reverse version.

```
>>> df.div(10)
           angles  degrees
circle        0.0     36.0
triangle      0.3     18.0
rectangle     0.4     36.0
```

```
>>> df.rdiv(10)
             angles   degrees
circle          inf  0.027778
triangle   3.333333  0.055556
rectangle  2.500000  0.027778
```

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
           angles  degrees
circle         -1      358
triangle        2      178
rectangle       3      358
```

```
>>> df.sub([1, 2], axis='columns')
           angles  degrees
circle         -1      358
triangle        2      178
rectangle       3      358
```

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...        axis='index')
           angles  degrees
circle         -1      359
triangle        2      179
rectangle       3      359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                      index=['circle', 'triangle', 'rectangle'])
>>> other
           angles
circle          0
triangle        3
rectangle       4
```

```
>>> df * other
           angles  degrees
circle          0      NaN
triangle        9      NaN
rectangle      16      NaN
```

```
>>> df.mul(other, fill_value=0)
           angles  degrees
circle          0      0.0
triangle        9      0.0
rectangle      16      0.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                              'degrees': [360, 180, 360, 360, 540, 720]},
...                             index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                    ['circle', 'triangle', 'rectangle',
...                                     'square', 'pentagon', 'hexagon']])
>>> df_multindex
             angles  degrees
A circle          0      360
  triangle        3      180
  rectangle       4      360
B square          4      360
  pentagon        5      540
  hexagon         6      720
```

```
>>> df.div(df_multindex, level=1, fill_value=0)
             angles  degrees
A circle        NaN      1.0
  triangle      1.0      1.0
  rectangle     1.0      1.0
B square        0.0      0.0
  pentagon      0.0      0.0
  hexagon       0.0      0.0
```

pandas.DataFrame.rmod

DataFrame.**rmod**(*other*, *axis='columns'*, *level=None*, *fill_value=None*)

Get Modulo of dataframe and other, element-wise (binary operator *rmod*).

Equivalent to `other % dataframe`, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, *mod*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: +, -, *, /, //, %, **.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

DataFrame.mod Calculate modulo (remainder after division).

DataFrame.pow Calculate exponential power.

Notes

Mismatched indices will be unioned together.

Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                   index=['circle', 'triangle', 'rectangle'])
>>> df
           angles  degrees
circle          0      360
triangle        3      180
rectangle       4      360
```

Add a scalar with operator version which return the same results.

```
>>> df + 1
           angles  degrees
circle          1      361
triangle        4      181
rectangle       5      361
```

```
>>> df.add(1)
           angles  degrees
circle          1      361
triangle        4      181
rectangle       5      361
```

Divide by constant with reverse version.

```
>>> df.div(10)
           angles  degrees
circle        0.0     36.0
triangle      0.3     18.0
rectangle     0.4     36.0
```

```
>>> df.rdiv(10)
             angles   degrees
circle          inf  0.027778
triangle   3.333333  0.055556
rectangle  2.500000  0.027778
```

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
           angles  degrees
circle         -1      358
triangle        2      178
rectangle       3      358
```

```
>>> df.sub([1, 2], axis='columns')
           angles  degrees
circle         -1      358
triangle        2      178
rectangle       3      358
```

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...         axis='index')
           angles  degrees
circle         -1      359
triangle        2      179
rectangle       3      359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                      index=['circle', 'triangle', 'rectangle'])
>>> other
           angles
circle          0
triangle        3
rectangle       4
```

```
>>> df * other
           angles  degrees
circle          0      NaN
triangle        9      NaN
rectangle      16      NaN
```

```
>>> df.mul(other, fill_value=0)
           angles  degrees
circle          0      0.0
triangle        9      0.0
rectangle      16      0.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                              'degrees': [360, 180, 360, 360, 540, 720]},
...                             index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                    ['circle', 'triangle', 'rectangle',
...                                     'square', 'pentagon', 'hexagon']])
```

(continues on next page)

(continued from previous page)

```
>>> df_multindex
                angles  degrees
A circle             0      360
  triangle           3      180
  rectangle          4      360
B square             4      360
  pentagon           5      540
  hexagon            6      720
```

```
>>> df.div(df_multindex, level=1, fill_value=0)
                angles  degrees
A circle           NaN      1.0
  triangle         1.0      1.0
  rectangle        1.0      1.0
B square           0.0      0.0
  pentagon         0.0      0.0
  hexagon          0.0      0.0
```

pandas.DataFrame.rmul

DataFrame.**rmul**(*other*, *axis='columns'*, *level=None*, *fill_value=None*)

Get Multiplication of dataframe and other, element-wise (binary operator *rmul*).

Equivalent to `other * dataframe`, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, *mul*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: +, -, *, /, //, %, **.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

DataFrame.floordiv Divide DataFrames (integer division).

DataFrame.mod Calculate modulo (remainder after division).

DataFrame.pow Calculate exponential power.

Notes

Mismatched indices will be unioned together.

Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                   index=['circle', 'triangle', 'rectangle'])
>>> df
           angles  degrees
circle          0      360
triangle        3      180
rectangle       4      360
```

Add a scalar with operator version which return the same results.

```
>>> df + 1
           angles  degrees
circle          1      361
triangle        4      181
rectangle       5      361
```

```
>>> df.add(1)
           angles  degrees
circle          1      361
triangle        4      181
rectangle       5      361
```

Divide by constant with reverse version.

```
>>> df.div(10)
           angles  degrees
circle        0.0     36.0
triangle      0.3     18.0
rectangle     0.4     36.0
```

```
>>> df.rdiv(10)
             angles   degrees
circle          inf  0.027778
triangle   3.333333  0.055556
rectangle  2.500000  0.027778
```

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
           angles  degrees
circle         -1      358
triangle        2      178
rectangle       3      358
```

```
>>> df.sub([1, 2], axis='columns')
           angles  degrees
circle         -1      358
triangle        2      178
rectangle       3      358
```

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...         axis='index')
           angles  degrees
circle         -1      359
triangle        2      179
rectangle       3      359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                      index=['circle', 'triangle', 'rectangle'])
>>> other
           angles
circle          0
triangle        3
rectangle       4
```

```
>>> df * other
           angles  degrees
circle          0      NaN
triangle        9      NaN
rectangle      16      NaN
```

```
>>> df.mul(other, fill_value=0)
           angles  degrees
circle          0      0.0
triangle        9      0.0
rectangle      16      0.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                              'degrees': [360, 180, 360, 360, 540, 720]},
...                             index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                    ['circle', 'triangle', 'rectangle',
...                                     'square', 'pentagon', 'hexagon']])
>>> df_multindex
             angles  degrees
A circle          0      360
  triangle        3      180
  rectangle       4      360
B square          4      360
  pentagon        5      540
  hexagon         6      720
```

```
>>> df.div(df_multindex, level=1, fill_value=0)
             angles  degrees
A circle        NaN      1.0
  triangle      1.0      1.0
  rectangle     1.0      1.0
```

(continues on next page)

(continued from previous page)

```
B square        0.0      0.0
  pentagon      0.0      0.0
  hexagon       0.0      0.0
```

pandas.DataFrame.rolling

DataFrame.**rolling**(*window*, *min_periods=None*, *center=False*, *win_type=None*, *on=None*, *axis=0*, *closed=None*)

Provide rolling window calculations.

Parameters

window [int, offset, or BaseIndexer subclass] Size of the moving window. This is the number of observations used for calculating the statistic. Each window will be a fixed size.

If its an offset then this will be the time period of each window. Each window will be a variable sized based on the observations included in the time-period. This is only valid for datetimelike indexes.

If a BaseIndexer subclass is passed, calculates the window boundaries based on the defined `get_window_bounds` method. Additional rolling keyword arguments, namely *min_periods*, *center*, and *closed* will be passed to *get_window_bounds*.

min_periods [int, default None] Minimum number of observations in window required to have a value (otherwise result is NA). For a window that is specified by an offset, *min_periods* will default to 1. Otherwise, *min_periods* will default to the size of the window.

center [bool, default False] Set the labels at the center of the window.

win_type [str, default None] Provide a window type. If `None`, all points are evenly weighted. See the notes below for further information.

on [str, optional] For a DataFrame, a datetime-like column or MultiIndex level on which to calculate the rolling window, rather than the DataFrame's index. Provided integer column is ignored and excluded from result since an integer index is not used to calculate the rolling window.

axis [int or str, default 0]

closed [str, default None] Make the interval closed on the 'right', 'left', 'both' or 'neither' endpoints. For offset-based windows, it defaults to 'right'. For fixed windows, defaults to 'both'. Remaining cases not implemented for fixed windows.

Returns

a Window or Rolling sub-classed for the particular operation

See also:

expanding Provides expanding transformations.

ewm Provides exponential weighted functions.

Notes

By default, the result is set to the right edge of the window. This can be changed to the center of the window by setting `center=True`.

To learn more about the offsets & frequency strings, please see this link.

The recognized win_types are:

- `boxcar`
- `triang`
- `blackman`
- `hamming`
- `bartlett`
- `parzen`
- `bohman`
- `blackmanharris`
- `nuttall`
- `barthann`
- `kaiser` (needs parameter: beta)
- `gaussian` (needs parameter: std)
- `general_gaussian` (needs parameters: power, width)
- `slepian` (needs parameter: width)
- `exponential` (needs parameter: tau), center is set to None.

If `win_type=None` all points are evenly weighted. To learn more about different window types see scipy.signal window functions.

Certain window types require additional parameters to be passed. Please see the third example below on how to add the additional parameters.

Examples

```
>>> df = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]})
>>> df
     B
0  0.0
1  1.0
2  2.0
3  NaN
4  4.0
```

Rolling sum with a window length of 2, using the 'triang' window type.

```
>>> df.rolling(2, win_type='triang').sum()
     B
0  NaN
1  0.5
2  1.5
```

(continues on next page)

(continued from previous page)

```
3  NaN
4  NaN
```

Rolling sum with a window length of 2, using the 'gaussian' window type (note how we need to specify std).

```
>>> df.rolling(2, win_type='gaussian').sum(std=3)
          B
0       NaN
1  0.986207
2  2.958621
3       NaN
4       NaN
```

Rolling sum with a window length of 2, min_periods defaults to the window length.

```
>>> df.rolling(2).sum()
     B
0  NaN
1  1.0
2  3.0
3  NaN
4  NaN
```

Same as above, but explicitly set the min_periods

```
>>> df.rolling(2, min_periods=1).sum()
     B
0  0.0
1  1.0
2  3.0
3  2.0
4  4.0
```

Same as above, but with forward-looking windows

```
>>> indexer = pd.api.indexers.FixedForwardWindowIndexer(window_size=2)
>>> df.rolling(window=indexer, min_periods=1).sum()
     B
0  1.0
1  3.0
2  2.0
3  4.0
4  4.0
```

A ragged (meaning not-a-regular frequency), time-indexed DataFrame

```
>>> df = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]},
...                   index = [pd.Timestamp('20130101 09:00:00'),
...                            pd.Timestamp('20130101 09:00:02'),
...                            pd.Timestamp('20130101 09:00:03'),
...                            pd.Timestamp('20130101 09:00:05'),
...                            pd.Timestamp('20130101 09:00:06')])
```

```
>>> df
                       B
```

(continues on next page)

(continued from previous page)

```
2013-01-01 09:00:00  0.0
2013-01-01 09:00:02  1.0
2013-01-01 09:00:03  2.0
2013-01-01 09:00:05  NaN
2013-01-01 09:00:06  4.0
```

Contrasting to an integer rolling window, this will roll a variable length window corresponding to the time period. The default for min_periods is 1.

```
>>> df.rolling('2s').sum()
                       B
2013-01-01 09:00:00  0.0
2013-01-01 09:00:02  1.0
2013-01-01 09:00:03  3.0
2013-01-01 09:00:05  NaN
2013-01-01 09:00:06  4.0
```

pandas.DataFrame.round

DataFrame.**round**(*decimals=0*, **args*, ***kwargs*)

Round a DataFrame to a variable number of decimal places.

Parameters

decimals [int, dict, Series] Number of decimal places to round each column to. If an int is given, round each column to the same number of places. Otherwise dict and Series round to variable numbers of places. Column names should be in the keys if *decimals* is a dict-like, or in the index if *decimals* is a Series. Any columns not included in *decimals* will be left as is. Elements of *decimals* which are not columns of the input will be ignored.

***args** Additional keywords have no effect but might be accepted for compatibility with numpy.

****kwargs** Additional keywords have no effect but might be accepted for compatibility with numpy.

Returns

DataFrame A DataFrame with the affected columns rounded to the specified number of decimal places.

See also:

numpy.around Round a numpy array to the given number of decimals.

Series.round Round a Series to the given number of decimals.

Examples

```
>>> df = pd.DataFrame([(.21, .32), (.01, .67), (.66, .03), (.21, .18)],
...                   columns=['dogs', 'cats'])
>>> df
    dogs  cats
0  0.21  0.32
1  0.01  0.67
2  0.66  0.03
3  0.21  0.18
```

By providing an integer each column is rounded to the same number of decimal places

```
>>> df.round(1)
    dogs  cats
0   0.2   0.3
1   0.0   0.7
2   0.7   0.0
3   0.2   0.2
```

With a dict, the number of places for specific columns can be specified with the column names as key and the number of decimal places as value

```
>>> df.round({'dogs': 1, 'cats': 0})
    dogs  cats
0   0.2   0.0
1   0.0   1.0
2   0.7   0.0
3   0.2   0.0
```

Using a Series, the number of places for specific columns can be specified with the column names as index and the number of decimal places as value

```
>>> decimals = pd.Series([0, 1], index=['cats', 'dogs'])
>>> df.round(decimals)
    dogs  cats
0   0.2   0.0
1   0.0   1.0
2   0.7   0.0
3   0.2   0.0
```

pandas.DataFrame.rpow

DataFrame.**rpow**(*other*, *axis='columns'*, *level=None*, *fill_value=None*)

Get Exponential power of dataframe and other, element-wise (binary operator *rpow*).

Equivalent to `other ** dataframe`, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, *pow*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: +, -, *, /, //, %, **.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

See also:

DataFrame.add Add DataFrames.

DataFrame.sub Subtract DataFrames.

DataFrame.mul Multiply DataFrames.

DataFrame.div Divide DataFrames (float division).

DataFrame.truediv Divide DataFrames (float division).

DataFrame.floordiv Divide DataFrames (integer division).

DataFrame.mod Calculate modulo (remainder after division).

DataFrame.pow Calculate exponential power.

Notes

Mismatched indices will be unioned together.

Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                   index=['circle', 'triangle', 'rectangle'])
>>> df
           angles  degrees
circle          0      360
triangle        3      180
rectangle       4      360
```

Add a scalar with operator version which return the same results.

```
>>> df + 1
           angles  degrees
circle          1      361
triangle        4      181
rectangle       5      361
```

```
>>> df.add(1)
           angles  degrees
circle          1      361
triangle        4      181
rectangle       5      361
```

Divide by constant with reverse version.

```
>>> df.div(10)
           angles  degrees
circle        0.0     36.0
triangle      0.3     18.0
rectangle     0.4     36.0
```

```
>>> df.rdiv(10)
             angles   degrees
circle          inf  0.027778
triangle   3.333333  0.055556
rectangle  2.500000  0.027778
```

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
           angles  degrees
circle         -1      358
triangle        2      178
rectangle       3      358
```

```
>>> df.sub([1, 2], axis='columns')
           angles  degrees
circle         -1      358
triangle        2      178
rectangle       3      358
```

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...         axis='index')
           angles  degrees
circle         -1      359
triangle        2      179
rectangle       3      359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                      index=['circle', 'triangle', 'rectangle'])
>>> other
           angles
circle          0
triangle        3
rectangle       4
```

```
>>> df * other
           angles  degrees
circle          0      NaN
triangle        9      NaN
rectangle      16      NaN
```

```
>>> df.mul(other, fill_value=0)
           angles  degrees
circle          0      0.0
triangle        9      0.0
rectangle      16      0.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                              'degrees': [360, 180, 360, 360, 540, 720]},
...                             index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                    ['circle', 'triangle', 'rectangle',
...                                     'square', 'pentagon', 'hexagon']])
>>> df_multindex
             angles  degrees
A circle          0      360
  triangle        3      180
  rectangle       4      360
B square          4      360
  pentagon        5      540
  hexagon         6      720
```

```
>>> df.div(df_multindex, level=1, fill_value=0)
             angles  degrees
A circle        NaN      1.0
  triangle      1.0      1.0
  rectangle     1.0      1.0
B square        0.0      0.0
  pentagon      0.0      0.0
  hexagon       0.0      0.0
```

pandas.DataFrame.rsub

DataFrame.**rsub**(*other*, *axis='columns'*, *level=None*, *fill_value=None*)

Get Subtraction of dataframe and other, element-wise (binary operator *rsub*).

Equivalent to `other - dataframe`, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, *sub*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: +, -, *, /, //, %, **.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

DataFrame.add Add DataFrames.

DataFrame.sub Subtract DataFrames.

DataFrame.mul Multiply DataFrames.

DataFrame.div Divide DataFrames (float division).

DataFrame.truediv Divide DataFrames (float division).

DataFrame.floordiv Divide DataFrames (integer division).

DataFrame.mod Calculate modulo (remainder after division).

DataFrame.pow Calculate exponential power.

Notes

Mismatched indices will be unioned together.

Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                   index=['circle', 'triangle', 'rectangle'])
>>> df
           angles  degrees
circle          0      360
triangle        3      180
rectangle       4      360
```

Add a scalar with operator version which return the same results.

```
>>> df + 1
           angles  degrees
circle          1      361
triangle        4      181
rectangle       5      361
```

```
>>> df.add(1)
           angles  degrees
circle          1      361
triangle        4      181
rectangle       5      361
```

Divide by constant with reverse version.

```
>>> df.div(10)
           angles  degrees
circle        0.0     36.0
triangle      0.3     18.0
rectangle     0.4     36.0
```

```
>>> df.rdiv(10)
             angles   degrees
circle          inf  0.027778
triangle   3.333333  0.055556
rectangle  2.500000  0.027778
```

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
           angles  degrees
circle         -1      358
triangle        2      178
rectangle       3      358
```

```
>>> df.sub([1, 2], axis='columns')
           angles  degrees
circle         -1      358
triangle        2      178
rectangle       3      358
```

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...         axis='index')
           angles  degrees
circle         -1      359
triangle        2      179
rectangle       3      359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                      index=['circle', 'triangle', 'rectangle'])
>>> other
           angles
circle          0
triangle        3
rectangle       4
```

```
>>> df * other
           angles  degrees
circle          0      NaN
triangle        9      NaN
rectangle      16      NaN
```

```
>>> df.mul(other, fill_value=0)
           angles  degrees
circle          0      0.0
triangle        9      0.0
rectangle      16      0.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                              'degrees': [360, 180, 360, 360, 540, 720]},
...                             index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                    ['circle', 'triangle', 'rectangle',
...                                     'square', 'pentagon', 'hexagon']])
>>> df_multindex
             angles  degrees
A circle          0      360
  triangle        3      180
  rectangle       4      360
B square          4      360
  pentagon        5      540
  hexagon         6      720
```

```
>>> df.div(df_multindex, level=1, fill_value=0)
             angles  degrees
A circle        NaN      1.0
  triangle      1.0      1.0
  rectangle     1.0      1.0
B square        0.0      0.0
  pentagon      0.0      0.0
  hexagon       0.0      0.0
```

pandas.DataFrame.rtruediv

DataFrame.**rtruediv**(*other*, *axis='columns'*, *level=None*, *fill_value=None*)

Get Floating division of dataframe and other, element-wise (binary operator *rtruediv*).

Equivalent to `other / dataframe`, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, *truediv*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: +, -, *, /, //, %, **.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

See also:

DataFrame.add Add DataFrames.

DataFrame.sub Subtract DataFrames.

DataFrame.mul Multiply DataFrames.

DataFrame.div Divide DataFrames (float division).

DataFrame.truediv Divide DataFrames (float division).

DataFrame.floordiv Divide DataFrames (integer division).

DataFrame.mod Calculate modulo (remainder after division).

DataFrame.pow Calculate exponential power.

Notes

Mismatched indices will be unioned together.

Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                   index=['circle', 'triangle', 'rectangle'])
>>> df
           angles  degrees
circle          0      360
triangle        3      180
rectangle       4      360
```

Add a scalar with operator version which return the same results.

```
>>> df + 1
           angles  degrees
circle          1      361
triangle        4      181
rectangle       5      361
```

```
>>> df.add(1)
           angles  degrees
circle          1      361
triangle        4      181
rectangle       5      361
```

Divide by constant with reverse version.

```
>>> df.div(10)
           angles  degrees
circle        0.0     36.0
triangle      0.3     18.0
rectangle     0.4     36.0
```

```
>>> df.rdiv(10)
             angles   degrees
circle          inf  0.027778
triangle   3.333333  0.055556
rectangle  2.500000  0.027778
```

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
           angles  degrees
circle         -1      358
triangle        2      178
rectangle       3      358
```

```
>>> df.sub([1, 2], axis='columns')
           angles  degrees
circle         -1      358
triangle        2      178
rectangle       3      358
```

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...         axis='index')
           angles  degrees
circle         -1      359
triangle        2      179
rectangle       3      359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                      index=['circle', 'triangle', 'rectangle'])
>>> other
           angles
circle          0
triangle        3
rectangle       4
```

```
>>> df * other
           angles  degrees
circle          0      NaN
triangle        9      NaN
rectangle      16      NaN
```

```
>>> df.mul(other, fill_value=0)
           angles  degrees
circle          0      0.0
triangle        9      0.0
rectangle      16      0.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                              'degrees': [360, 180, 360, 360, 540, 720]},
...                             index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                    ['circle', 'triangle', 'rectangle',
...                                     'square', 'pentagon', 'hexagon']])
>>> df_multindex
             angles  degrees
A circle          0      360
  triangle        3      180
  rectangle       4      360
B square          4      360
  pentagon        5      540
  hexagon         6      720
```

```
>>> df.div(df_multindex, level=1, fill_value=0)
             angles  degrees
A circle        NaN      1.0
  triangle      1.0      1.0
  rectangle     1.0      1.0
B square        0.0      0.0
  pentagon      0.0      0.0
  hexagon       0.0      0.0
```

pandas.DataFrame.sample

DataFrame.**sample**(*n=None*, *frac=None*, *replace=False*, *weights=None*, *random_state=None*, *axis=None*)

Return a random sample of items from an axis of object.

You can use *random_state* for reproducibility.

Parameters

n [int, optional] Number of items from axis to return. Cannot be used with *frac*. Default = 1 if *frac* = None.

frac [float, optional] Fraction of axis items to return. Cannot be used with *n*.

replace [bool, default False] Allow or disallow sampling of the same row more than once.

weights [str or ndarray-like, optional] Default 'None' results in equal probability weighting. If passed a Series, will align with target object on index. Index values in weights not found in sampled object will be ignored and index values in sampled object not in weights will be assigned weights of zero. If called on a DataFrame, will accept the name of a column when axis = 0. Unless weights are a Series, weights must be same length as axis being sampled. If weights do not sum to 1, they will be normalized to sum to 1. Missing values in the weights column will be treated as zero. Infinite values not allowed.

random_state [int, array-like, BitGenerator, np.random.RandomState, optional] If int, array-like, or BitGenerator (NumPy>=1.17), seed for random number generator If np.random.RandomState, use as numpy RandomState object.

Changed in version 1.1.0: array-like and BitGenerator (for NumPy>=1.17) object now passed to np.random.RandomState() as seed

axis [{0 or 'index', 1 or 'columns', None}, default None] Axis to sample. Accepts axis number or name. Default is stat axis for given data type (0 for Series and DataFrames).

Returns

Series or DataFrame A new object of same type as caller containing *n* items randomly sampled from the caller object.

See also:

DataFrameGroupBy.sample Generates random samples from each group of a DataFrame object.

SeriesGroupBy.sample Generates random samples from each group of a Series object.

numpy.random.choice Generates a random sample from a given 1-D numpy array.

Notes

If *frac* > 1, *replacement* should be set to *True*.

Examples

```
>>> df = pd.DataFrame({'num_legs': [2, 4, 8, 0],
...                    'num_wings': [2, 0, 0, 0],
...                    'num_specimen_seen': [10, 2, 1, 8]},
...                   index=['falcon', 'dog', 'spider', 'fish'])
>>> df
        num_legs  num_wings  num_specimen_seen
falcon         2          2                 10
dog            4          0                  2
spider         8          0                  1
fish           0          0                  8
```

Extract 3 random elements from the `Series` `df['num_legs']`: Note that we use *random_state* to ensure the reproducibility of the examples.

```
>>> df['num_legs'].sample(n=3, random_state=1)
fish      0
spider    8
falcon    2
Name: num_legs, dtype: int64
```

A random 50% sample of the `DataFrame` with replacement:

```
>>> df.sample(frac=0.5, replace=True, random_state=1)
      num_legs  num_wings  num_specimen_seen
dog          4          0                  2
fish         0          0                  8
```

An upsample sample of the `DataFrame` with replacement: Note that *replace* parameter has to be *True* for *frac* parameter > 1.

```
>>> df.sample(frac=2, replace=True, random_state=1)
        num_legs  num_wings  num_specimen_seen
dog            4          0                  2
fish           0          0                  8
falcon         2          2                 10
falcon         2          2                 10
fish           0          0                  8
dog            4          0                  2
fish           0          0                  8
dog            4          0                  2
```

Using a DataFrame column as weights. Rows with larger value in the *num_specimen_seen* column are more likely to be sampled.

```
>>> df.sample(n=2, weights='num_specimen_seen', random_state=1)
        num_legs  num_wings  num_specimen_seen
falcon         2          2                 10
fish           0          0                  8
```

pandas.DataFrame.select_dtypes

DataFrame.**select_dtypes**(*include=None*, *exclude=None*)

Return a subset of the DataFrame's columns based on the column dtypes.

Parameters

include, exclude [scalar or list-like] A selection of dtypes or strings to be included/excluded. At least one of these parameters must be supplied.

Returns

DataFrame The subset of the frame including the dtypes in `include` and excluding the dtypes in `exclude`.

Raises

ValueError

- If both of `include` and `exclude` are empty
- If `include` and `exclude` have overlapping elements
- If any kind of string dtype is passed in.

See also:

DataFrame.dtypes Return Series with the data type of each column.

Notes

- To select all *numeric* types, use `np.number` or `'number'`
- To select strings you must use the `object` dtype, but note that this will return *all* object dtype columns
- See the numpy dtype hierarchy
- To select datetimes, use `np.datetime64`, `'datetime'` or `'datetime64'`
- To select timedeltas, use `np.timedelta64`, `'timedelta'` or `'timedelta64'`
- To select Pandas categorical dtypes, use `'category'`
- To select Pandas datetimetz dtypes, use `'datetimetz'` (new in 0.20.0) or `'datetime64[ns, tz]'`

Examples

```
>>> df = pd.DataFrame({'a': [1, 2] * 3,
...                    'b': [True, False] * 3,
...                    'c': [1.0, 2.0] * 3})
>>> df
        a      b  c
0       1   True  1.0
1       2  False  2.0
2       1   True  1.0
3       2  False  2.0
4       1   True  1.0
5       2  False  2.0
```

```
>>> df.select_dtypes(include='bool')
   b
0  True
1  False
2  True
3  False
4  True
5  False
```

```
>>> df.select_dtypes(include=['float64'])
   c
0  1.0
1  2.0
2  1.0
3  2.0
4  1.0
5  2.0
```

```
>>> df.select_dtypes(exclude=['int64'])
       b    c
0   True  1.0
1  False  2.0
2   True  1.0
3  False  2.0
4   True  1.0
5  False  2.0
```

pandas.DataFrame.sem

DataFrame.**sem**(*axis=None*, *skipna=None*, *level=None*, *ddof=1*, *numeric_only=None*, ***kwargs*)

Return unbiased standard error of the mean over requested axis.

Normalized by N-1 by default. This can be changed using the ddof argument

Parameters

axis [{index (0), columns (1)}]

skipna [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

ddof [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is N - ddof, where N represents the number of elements.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

Returns

Series or DataFrame (if level specified)

pandas.DataFrame.set_axis

DataFrame.**set_axis**(*labels*, *axis=0*, *inplace=False*)

Assign desired index to given axis.

Indexes for column or row labels can be changed by assigning a list-like or Index.

Parameters

labels [list-like, Index] The values for the new index.

axis [{0 or 'index', 1 or 'columns'}, default 0] The axis to update. The value 0 identifies the rows, and 1 identifies the columns.

inplace [bool, default False] Whether to return a new DataFrame instance.

Returns

renamed [DataFrame or None] An object of type DataFrame if inplace=False, None otherwise.

See also:

DataFrame.rename_axis Alter the name of the index or columns.

Examples

```
>>> df = pd.DataFrame({"A": [1, 2, 3], "B": [4, 5, 6]})
```

Change the row labels.

```
>>> df.set_axis(['a', 'b', 'c'], axis='index')
   A  B
a  1  4
b  2  5
c  3  6
```

Change the column labels.

```
>>> df.set_axis(['I', 'II'], axis='columns')
   I  II
0  1   4
1  2   5
2  3   6
```

Now, update the labels inplace.

```
>>> df.set_axis(['i', 'ii'], axis='columns', inplace=True)
>>> df
   i  ii
0  1   4
1  2   5
2  3   6
```

pandas.DataFrame.set_index

DataFrame.**set_index**(*keys*, *drop=True*, *append=False*, *inplace=False*, *verify_integrity=False*)

Set the DataFrame index using existing columns.

Set the DataFrame index (row labels) using one or more existing columns or arrays (of the correct length). The index can replace the existing index or expand on it.

Parameters

keys [label or array-like or list of labels/arrays] This parameter can be either a single column key, a single array of the same length as the calling DataFrame, or a list containing an arbitrary combination of column keys and arrays. Here, "array" encompasses *Series*, *Index*, np.ndarray, and instances of Iterator.

drop [bool, default True] Delete columns to be used as the new index.

append [bool, default False] Whether to append columns to existing index.

inplace [bool, default False] Modify the DataFrame in place (do not create a new object).

verify_integrity [bool, default False] Check the new index for duplicates. Otherwise defer the check until necessary. Setting to False will improve the performance of this method.

Returns

DataFrame Changed row labels.

See also:

DataFrame.reset_index Opposite of set_index.

DataFrame.reindex Change to new indices or expand indices.

DataFrame.reindex_like Change to same indices as other DataFrame.

Examples

```
>>> df = pd.DataFrame({'month': [1, 4, 7, 10],
...                    'year': [2012, 2014, 2013, 2014],
...                    'sale': [55, 40, 84, 31]})
>>> df
   month  year  sale
0      1  2012    55
1      4  2014    40
2      7  2013    84
3     10  2014    31
```

Set the index to become the 'month' column:

```
>>> df.set_index('month')
       year  sale
month
1      2012    55
4      2014    40
7      2013    84
10     2014    31
```

Create a MultiIndex using columns 'year' and 'month':

```
>>> df.set_index(['year', 'month'])
            sale
year  month
2012  1     55
2014  4     40
2013  7     84
2014  10    31
```

Create a MultiIndex using an Index and a column:

```
>>> df.set_index([pd.Index([1, 2, 3, 4]), 'year'])
         month  sale
   year
1  2012  1      55
2  2014  4      40
3  2013  7      84
4  2014  10     31
```

Create a MultiIndex using two Series:

```
>>> s = pd.Series([1, 2, 3, 4])
>>> df.set_index([s, s**2])
      month  year  sale
1 1       1  2012    55
2 4       4  2014    40
3 9       7  2013    84
4 16     10  2014    31
```

pandas.DataFrame.shift

DataFrame.**shift**(*periods=1*, *freq=None*, *axis=0*, *fill_value=None*)

Shift index by desired number of periods with an optional time *freq*.

When *freq* is not passed, shift the index without realigning the data. If *freq* is passed (in this case, the index must be date or datetime, or it will raise a *NotImplementedError*), the index will be increased using the periods and the *freq*. *freq* can be inferred when specified as "infer" as long as either freq or inferred_freq attribute is set in the index.

Parameters

periods [int] Number of periods to shift. Can be positive or negative.

freq [DateOffset, tseries.offsets, timedelta, or str, optional] Offset to use from the tseries module or time rule (e.g. 'EOM'). If *freq* is specified then the index values are shifted but the data is not realigned. That is, use *freq* if you would like to extend the index when shifting and preserve the original data. If *freq* is specified as "infer" then it will be inferred from the freq or inferred_freq attributes of the index. If neither of those attributes exist, a ValueError is thrown

axis [{0 or 'index', 1 or 'columns', None}, default None] Shift direction.

fill_value [object, optional] The scalar value to use for newly introduced missing values. the default depends on the dtype of *self*. For numeric data, `np.nan` is used. For datetime, timedelta, or period data, etc. `NaT` is used. For extension dtypes, `self.dtype.na_value` is used.

Changed in version 1.1.0.

Returns

DataFrame Copy of input object, shifted.

See also:

Index.shift Shift values of Index.

DatetimeIndex.shift Shift values of DatetimeIndex.

PeriodIndex.shift Shift values of PeriodIndex.

tshift Shift the time index, using the index's frequency if available.

Examples

```
>>> df = pd.DataFrame({"Col1": [10, 20, 15, 30, 45],
...                    "Col2": [13, 23, 18, 33, 48],
...                    "Col3": [17, 27, 22, 37, 52]},
...                   index=pd.date_range("2020-01-01", "2020-01-05"))
>>> df
            Col1  Col2  Col3
2020-01-01    10    13    17
2020-01-02    20    23    27
2020-01-03    15    18    22
2020-01-04    30    33    37
2020-01-05    45    48    52
```

```
>>> df.shift(periods=3)
            Col1  Col2  Col3
2020-01-01   NaN   NaN   NaN
2020-01-02   NaN   NaN   NaN
2020-01-03   NaN   NaN   NaN
2020-01-04  10.0  13.0  17.0
2020-01-05  20.0  23.0  27.0
```

```
>>> df.shift(periods=1, axis="columns")
            Col1  Col2  Col3
2020-01-01   NaN  10.0  13.0
2020-01-02   NaN  20.0  23.0
2020-01-03   NaN  15.0  18.0
2020-01-04   NaN  30.0  33.0
2020-01-05   NaN  45.0  48.0
```

```
>>> df.shift(periods=3, fill_value=0)
            Col1  Col2  Col3
2020-01-01     0     0     0
2020-01-02     0     0     0
2020-01-03     0     0     0
2020-01-04    10    13    17
2020-01-05    20    23    27
```

```
>>> df.shift(periods=3, freq="D")
            Col1  Col2  Col3
2020-01-04    10    13    17
```

2020-01-08    45    48    52
```

pandas.DataFrame.skew

DataFrame.**skew**(*axis=None*, *skipna=None*, *level=None*, *numeric_only=None*, ***kwargs*)

Return unbiased skew over requested axis.

Normalized by N-1.

Parameters

axis [{index (0), columns (1)}] Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

****kwargs** Additional keyword arguments to be passed to the function.

Returns

Series or DataFrame (if level specified)

pandas.DataFrame.slice_shift

DataFrame.**slice_shift**(*periods=1*, *axis=0*)

Equivalent to *shift* without copying data.

The shifted data will not include the dropped periods and the shifted axis will be smaller than the original.

Parameters

periods [int] Number of periods to move, can be positive or negative.

Returns

shifted [same type as caller]

Notes

While the *slice_shift* is faster than *shift*, you may pay for it later during alignment.

pandas.DataFrame.sort_index

DataFrame.**sort_index**(*axis=0*, *level=None*, *ascending=True*, *inplace=False*, *kind='quicksort'*, *na_position='last'*, *sort_remaining=True*, *ignore_index=False*, *key=None*)

Sort object by labels (along an axis).

Returns a new DataFrame sorted by label if *inplace* argument is `False`, otherwise updates the original DataFrame and returns None.

Parameters

axis [{0 or 'index', 1 or 'columns'}, default 0] The axis along which to sort. The value 0 identifies the rows, and 1 identifies the columns.

level [int or level name or list of ints or list of level names] If not None, sort on values in specified index level(s).

ascending [bool or list of bools, default True] Sort ascending vs. descending. When the index is a MultiIndex the sort direction can be controlled for each level individually.

inplace [bool, default False] If True, perform operation in-place.

kind [{'quicksort', 'mergesort', 'heapsort'}, default 'quicksort'] Choice of sorting algorithm. See also ndarray.np.sort for more information. *mergesort* is the only stable algorithm. For DataFrames, this option is only applied when sorting on a single column or label.

na_position [{'first', 'last'}, default 'last'] Puts NaNs at the beginning if *first*; *last* puts NaNs at the end. Not implemented for MultiIndex.

sort_remaining [bool, default True] If True and sorting by level and index is multilevel, sort by other levels too (in order) after sorting by specified level.

ignore_index [bool, default False] If True, the resulting axis will be labeled 0, 1, . . . , n - 1.

New in version 1.0.0.

key [callable, optional] If not None, apply the key function to the index values before sorting. This is similar to the *key* argument in the builtin `sorted()` function, with the notable difference that this *key* function should be *vectorized*. It should expect an `Index` and return an `Index` of the same shape. For MultiIndex inputs, the key is applied *per level*.

New in version 1.1.0.

Returns

DataFrame The original DataFrame sorted by the labels.

See also:

Series.sort_index Sort Series by the index.

DataFrame.sort_values Sort DataFrame by the value.

Series.sort_values Sort Series by the value.

Examples

```
>>> df = pd.DataFrame([1, 2, 3, 4, 5], index=[100, 29, 234, 1, 150],
...                   columns=['A'])
>>> df.sort_index()
     A
1    4
29   2
100  1
150  5
234  3
```

By default, it sorts in ascending order, to sort in descending order, use `ascending=False`

```
>>> df.sort_index(ascending=False)
     A
234  3
150  5
100  1
29   2
1    4
```

A key function can be specified which is applied to the index before sorting. For a `MultiIndex` this is applied to each level separately.

```
>>> df = pd.DataFrame({"a": [1, 2, 3, 4]}, index=['A', 'b', 'C', 'd'])
>>> df.sort_index(key=lambda x: x.str.lower())
   a
A  1
b  2
C  3
d  4
```

pandas.DataFrame.sort_values

DataFrame.**sort_values**(*by*, *axis=0*, *ascending=True*, *inplace=False*, *kind='quicksort'*, *na_position='last'*, *ignore_index=False*, *key=None*)

Sort by the values along either axis.

Parameters

by [str or list of str] Name or list of names to sort by.

- if *axis* is 0 or *'index'* then *by* may contain index levels and/or column labels.
- if *axis* is 1 or *'columns'* then *by* may contain column levels and/or index labels.

Changed in version 0.23.0: Allow specifying index or column level names.

axis [{0 or 'index', 1 or 'columns'}, default 0] Axis to be sorted.

ascending [bool or list of bool, default True] Sort ascending vs. descending. Specify list for multiple sort orders. If this is a list of bools, must match the length of the by.

inplace [bool, default False] If True, perform operation in-place.

kind [{'quicksort', 'mergesort', 'heapsort'}, default 'quicksort'] Choice of sorting algorithm. See also ndarray.np.sort for more information. *mergesort* is the only

stable algorithm. For DataFrames, this option is only applied when sorting on a single column or label.

na_position [{'first', 'last'}, default 'last'] Puts NaNs at the beginning if *first*; *last* puts NaNs at the end.

ignore_index [bool, default False] If True, the resulting axis will be labeled 0, 1, . . . , n - 1.

New in version 1.0.0.

key [callable, optional] Apply the key function to the values before sorting. This is similar to the *key* argument in the builtin `sorted()` function, with the notable difference that this *key* function should be *vectorized*. It should expect a `Series` and return a Series with the same shape as the input. It will be applied to each column in *by* independently.

New in version 1.1.0.

Returns

DataFrame or None DataFrame with sorted values if inplace=False, None otherwise.

See also:

DataFrame.sort_index Sort a DataFrame by the index.

Series.sort_values Similar method for a Series.

Examples

```
>>> df = pd.DataFrame({
...     'col1': ['A', 'A', 'B', np.nan, 'D', 'C'],
...     'col2': [2, 1, 9, 8, 7, 4],
...     'col3': [0, 1, 9, 4, 2, 3],
...     'col4': ['a', 'B', 'c', 'D', 'e', 'F']
... })
>>> df
  col1  col2  col3 col4
0    A     2     0    a
1    A     1     1    B
2    B     9     9    c
3  NaN     8     4    D
4    D     7     2    e
5    C     4     3    F
```

Sort by col1

```
>>> df.sort_values(by=['col1'])
  col1  col2  col3 col4
0    A     2     0    a
1    A     1     1    B
2    B     9     9    c
5    C     4     3    F
4    D     7     2    e
3  NaN     8     4    D
```

Sort by multiple columns

```
>>> df.sort_values(by=['col1', 'col2'])
  col1  col2  col3 col4
1    A     1     1    B
0    A     2     0    a
2    B     9     9    c
5    C     4     3    F
4    D     7     2    e
3  NaN     8     4    D
```

Sort Descending

```
>>> df.sort_values(by='col1', ascending=False)
  col1  col2  col3 col4
4    D     7     2    e
5    C     4     3    F
2    B     9     9    c
0    A     2     0    a
1    A     1     1    B
3  NaN     8     4    D
```

Putting NAs first

```
>>> df.sort_values(by='col1', ascending=False, na_position='first')
  col1  col2  col3 col4
3  NaN     8     4    D
4    D     7     2    e
5    C     4     3    F
2    B     9     9    c
0    A     2     0    a
1    A     1     1    B
```

Sorting with a key function

```
>>> df.sort_values(by='col4', key=lambda col: col.str.lower())
   col1  col2  col3 col4
0    A     2     0    a
1    A     1     1    B
2    B     9     9    c
3  NaN     8     4    D
4    D     7     2    e
5    C     4     3    F
```

pandas.DataFrame.sparse

DataFrame.**sparse**()

DataFrame accessor for sparse data.

New in version 0.25.0.

pandas.DataFrame.squeeze

DataFrame.**squeeze**(*axis=None*)

Squeeze 1 dimensional axis objects into scalars.

Series or DataFrames with a single element are squeezed to a scalar. DataFrames with a single column or a single row are squeezed to a Series. Otherwise the object is unchanged.

This method is most useful when you don't know if your object is a Series or DataFrame, but you do know it has just a single column. In that case you can safely call *squeeze* to ensure you have a Series.

Parameters

axis [{0 or 'index', 1 or 'columns', None}, default None] A specific axis to squeeze. By default, all length-1 axes are squeezed.

Returns

DataFrame, Series, or scalar The projection after squeezing *axis* or all the axes.

See also:

Series.iloc Integer-location based indexing for selecting scalars.

DataFrame.iloc Integer-location based indexing for selecting Series.

Series.to_frame Inverse of DataFrame.squeeze for a single-column DataFrame.

Examples

```
>>> primes = pd.Series([2, 3, 5, 7])
```

Slicing might produce a Series with a single value:

```
>>> even_primes = primes[primes % 2 == 0]
>>> even_primes
0    2
dtype: int64
```

```
>>> even_primes.squeeze()
2
```

Squeezing objects with more than one value in every axis does nothing:

```
>>> odd_primes = primes[primes % 2 == 1]
>>> odd_primes
1    3
2    5
3    7
dtype: int64
```

```
>>> odd_primes.squeeze()
1    3
2    5
3    7
dtype: int64
```

Squeezing is even more effective when used with DataFrames.

```
>>> df = pd.DataFrame([[1, 2], [3, 4]], columns=['a', 'b'])
>>> df
   a  b
0  1  2
1  3  4
```

Slicing a single column will produce a DataFrame with the columns having only one value:

```
>>> df_a = df[['a']]
>>> df_a
   a
0  1
1  3
```

So the columns can be squeezed down, resulting in a Series:

```
>>> df_a.squeeze('columns')
0    1
1    3
Name: a, dtype: int64
```

Slicing a single row from a single column will produce a single scalar DataFrame:

```
>>> df_0a = df.loc[df.index < 1, ['a']]
>>> df_0a
   a
0  1
```

Squeezing the rows produces a single scalar Series:

```
>>> df_0a.squeeze('rows')
a    1
Name: 0, dtype: int64
```

Squeezing all axes will project directly into a scalar:

```
>>> df_0a.squeeze()
1
```

pandas.DataFrame.stack

DataFrame.**stack**(*level=-1*, *dropna=True*)

Stack the prescribed level(s) from columns to index.

Return a reshaped DataFrame or Series having a multi-level index with one or more new inner-most levels compared to the current DataFrame. The new inner-most levels are created by pivoting the columns of the current dataframe:

- if the columns have a single level, the output is a Series;
- if the columns have multiple levels, the new index level(s) is (are) taken from the prescribed level(s) and the output is a DataFrame.

Parameters

level [int, str, list, default -1] Level(s) to stack from the column axis onto the index axis, defined as one index or label, or a list of indices or labels.

dropna [bool, default True] Whether to drop rows in the resulting Frame/Series with missing values. Stacking a column level onto the index axis can create combinations of index and column values that are missing from the original dataframe. See Examples section.

Returns

DataFrame or Series Stacked dataframe or series.

See also:

DataFrame.unstack Unstack prescribed level(s) from index axis onto column axis.

DataFrame.pivot Reshape dataframe from long format to wide format.

DataFrame.pivot_table Create a spreadsheet-style pivot table as a DataFrame.

Notes

The function is named by analogy with a collection of books being reorganized from being side by side on a horizontal position (the columns of the dataframe) to being stacked vertically on top of each other (in the index of the dataframe).

Examples

Single level columns

```
>>> df_single_level_cols = pd.DataFrame([[0, 1], [2, 3]],
...                                     index=['cat', 'dog'],
...                                     columns=['weight', 'height'])
```

Stacking a dataframe with a single level column axis returns a Series:

```
>>> df_single_level_cols
     weight height
cat       0      1
dog       2      3
>>> df_single_level_cols.stack()
```

(continues on next page)

(continued from previous page)

```
cat  weight    0
     height    1
dog  weight    2
     height    3
dtype: int64
```

Multi level columns: simple case

```
>>> multicol1 = pd.MultiIndex.from_tuples([('weight', 'kg'),
...                                        ('weight', 'pounds')])
>>> df_multi_level_cols1 = pd.DataFrame([[1, 2], [2, 4]],
...                                     index=['cat', 'dog'],
...                                     columns=multicol1)
```

Stacking a dataframe with a multi-level column axis:

```
>>> df_multi_level_cols1
     weight
         kg    pounds
cat       1         2
dog       2         4
>>> df_multi_level_cols1.stack()
            weight
cat kg           1
    pounds       2
dog kg           2
    pounds       4
```

Missing values

```
>>> multicol2 = pd.MultiIndex.from_tuples([('weight', 'kg'),
...                                        ('height', 'm')])
>>> df_multi_level_cols2 = pd.DataFrame([[1.0, 2.0], [3.0, 4.0]],
...                                     index=['cat', 'dog'],
...                                     columns=multicol2)
```

It is common to have missing values when stacking a dataframe with multi-level columns, as the stacked dataframe typically has more values than the original dataframe. Missing values are filled with NaNs:

```
>>> df_multi_level_cols2
    weight height
        kg      m
cat    1.0    2.0
dog    3.0    4.0
>>> df_multi_level_cols2.stack()
        height  weight
cat kg     NaN     1.0
    m      2.0     NaN
dog kg     NaN     3.0
    m      4.0     NaN
```

Prescribing the level(s) to be stacked

The first parameter controls which level or levels are stacked:

```
>>> df_multi_level_cols2.stack(0)
             kg    m
```

(continues on next page)

(continued from previous page)

```
cat height  NaN  2.0
    weight  1.0  NaN
dog height  NaN  4.0
    weight  3.0  NaN
>>> df_multi_level_cols2.stack([0, 1])
cat  height  m     2.0
     weight  kg    1.0
dog  height  m     4.0
     weight  kg    3.0
dtype: float64
```

Dropping missing values

```
>>> df_multi_level_cols3 = pd.DataFrame([[None, 1.0], [2.0, 3.0]],
...                                     index=['cat', 'dog'],
...                                     columns=multicol2)
```

Note that rows where all values are missing are dropped by default but this behaviour can be controlled via the dropna keyword parameter:

```
>>> df_multi_level_cols3
    weight height
        kg      m
cat    NaN    1.0
dog    2.0    3.0
>>> df_multi_level_cols3.stack(dropna=False)
        height  weight
cat kg     NaN     NaN
    m      1.0     NaN
dog kg     NaN     2.0
    m      3.0     NaN
>>> df_multi_level_cols3.stack(dropna=True)
        height  weight
cat m      1.0     NaN
dog kg     NaN     2.0
    m      3.0     NaN
```

pandas.DataFrame.std

DataFrame.**std**(*axis=None*, *skipna=None*, *level=None*, *ddof=1*, *numeric_only=None*, ***kwargs*)

Return sample standard deviation over requested axis.

Normalized by N-1 by default. This can be changed using the ddof argument

Parameters

axis [{index (0), columns (1)}]

skipna [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

ddof [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is N - ddof, where N represents the number of elements.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

Returns

Series or DataFrame (if level specified)

pandas.DataFrame.sub

DataFrame.**sub**(*other*, *axis='columns'*, *level=None*, *fill_value=None*)

Get Subtraction of dataframe and other, element-wise (binary operator *sub*).

Equivalent to `dataframe - other`, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, *rsub*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: +, -, *, /, //, %, **.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

See also:

DataFrame.add Add DataFrames.

DataFrame.sub Subtract DataFrames.

DataFrame.mul Multiply DataFrames.

DataFrame.div Divide DataFrames (float division).

DataFrame.truediv Divide DataFrames (float division).

DataFrame.floordiv Divide DataFrames (integer division).

DataFrame.mod Calculate modulo (remainder after division).

DataFrame.pow Calculate exponential power.

Notes

Mismatched indices will be unioned together.

Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                   index=['circle', 'triangle', 'rectangle'])
>>> df
           angles  degrees
circle          0      360
triangle        3      180
rectangle       4      360
```

Add a scalar with operator version which return the same results.

```
>>> df + 1
           angles  degrees
circle          1      361
triangle        4      181
rectangle       5      361
```

```
>>> df.add(1)
           angles  degrees
circle          1      361
triangle        4      181
rectangle       5      361
```

Divide by constant with reverse version.

```
>>> df.div(10)
           angles  degrees
circle        0.0     36.0
triangle      0.3     18.0
rectangle     0.4     36.0
```

```
>>> df.rdiv(10)
             angles   degrees
circle          inf  0.027778
triangle   3.333333  0.055556
rectangle  2.500000  0.027778
```

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
           angles  degrees
circle         -1      358
triangle        2      178
rectangle       3      358
```

```
>>> df.sub([1, 2], axis='columns')
           angles  degrees
circle         -1      358
triangle        2      178
rectangle       3      358
```

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...         axis='index')
           angles  degrees
circle         -1      359
triangle        2      179
rectangle       3      359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                      index=['circle', 'triangle', 'rectangle'])
>>> other
           angles
circle          0
triangle        3
rectangle       4
```

```
>>> df * other
           angles  degrees
circle          0      NaN
triangle        9      NaN
rectangle      16      NaN
```

```
>>> df.mul(other, fill_value=0)
           angles  degrees
circle          0      0.0
triangle        9      0.0
rectangle      16      0.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                              'degrees': [360, 180, 360, 360, 540, 720]},
...                             index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                    ['circle', 'triangle', 'rectangle',
...                                     'square', 'pentagon', 'hexagon']])
>>> df_multindex
             angles  degrees
A circle          0      360
  triangle        3      180
  rectangle       4      360
B square          4      360
  pentagon        5      540
  hexagon         6      720
```

```
>>> df.div(df_multindex, level=1, fill_value=0)
             angles  degrees
A circle        NaN      1.0
  triangle      1.0      1.0
  rectangle     1.0      1.0
B square        0.0      0.0
  pentagon      0.0      0.0
  hexagon       0.0      0.0
```

pandas.DataFrame.subtract

DataFrame.**subtract**(*other*, *axis='columns'*, *level=None*, *fill_value=None*)

Get Subtraction of dataframe and other, element-wise (binary operator *sub*).

Equivalent to `dataframe - other`, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, *rsub*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: +, -, *, /, //, %, **.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

See also:

DataFrame.add Add DataFrames.

DataFrame.sub Subtract DataFrames.

DataFrame.mul Multiply DataFrames.

DataFrame.div Divide DataFrames (float division).

DataFrame.truediv Divide DataFrames (float division).

DataFrame.floordiv Divide DataFrames (integer division).

DataFrame.mod Calculate modulo (remainder after division).

DataFrame.pow Calculate exponential power.

Notes

Mismatched indices will be unioned together.

Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                   index=['circle', 'triangle', 'rectangle'])
>>> df
           angles  degrees
circle          0      360
triangle        3      180
rectangle       4      360
```

Add a scalar with operator version which return the same results.

```
>>> df + 1
           angles  degrees
circle          1      361
triangle        4      181
rectangle       5      361
```

```
>>> df.add(1)
           angles  degrees
circle          1      361
triangle        4      181
rectangle       5      361
```

Divide by constant with reverse version.

```
>>> df.div(10)
           angles  degrees
circle        0.0     36.0
triangle      0.3     18.0
rectangle     0.4     36.0
```

```
>>> df.rdiv(10)
             angles   degrees
circle          inf  0.027778
triangle   3.333333  0.055556
rectangle  2.500000  0.027778
```

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
           angles  degrees
circle         -1      358
triangle        2      178
rectangle       3      358
```

```
>>> df.sub([1, 2], axis='columns')
           angles  degrees
circle         -1      358
triangle        2      178
rectangle       3      358
```

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...        axis='index')
           angles  degrees
```

(continues on next page)

(continued from previous page)

```
circle         -1      359
triangle        2      179
rectangle       3      359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                      index=['circle', 'triangle', 'rectangle'])
>>> other
           angles
circle          0
triangle        3
rectangle       4
```

```
>>> df * other
           angles  degrees
circle          0      NaN
triangle        9      NaN
rectangle      16      NaN
```

```
>>> df.mul(other, fill_value=0)
           angles  degrees
circle          0      0.0
triangle        9      0.0
rectangle      16      0.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                              'degrees': [360, 180, 360, 360, 540, 720]},
...                             index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                    ['circle', 'triangle', 'rectangle',
...                                     'square', 'pentagon', 'hexagon']])
>>> df_multindex
             angles  degrees
A circle          0      360
  triangle        3      180
  rectangle       4      360
B square          4      360
  pentagon        5      540
  hexagon         6      720
```

```
>>> df.div(df_multindex, level=1, fill_value=0)
             angles  degrees
A circle        NaN      1.0
  triangle      1.0      1.0
  rectangle     1.0      1.0
B square        0.0      0.0
  pentagon      0.0      0.0
  hexagon       0.0      0.0
```

pandas.DataFrame.sum

DataFrame.**sum**(*axis=None*, *skipna=None*, *level=None*, *numeric_only=None*, *min_count=0*, ***kwargs*)

Return the sum of the values for the requested axis.

This is equivalent to the method `numpy.sum`.

Parameters

axis [{index (0), columns (1)}] Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

min_count [int, default 0] The required number of valid values to perform the operation. If fewer than `min_count` non-NA values are present the result will be NA.

New in version 0.22.0: Added with the default being 0. This means the sum of an all-NA or empty Series is 0, and the product of an all-NA or empty Series is 1.

****kwargs** Additional keyword arguments to be passed to the function.

Returns

Series or DataFrame (if level specified)

See also:

Series.sum Return the sum.

Series.min Return the minimum.

Series.max Return the maximum.

Series.idxmin Return the index of the minimum.

Series.idxmax Return the index of the maximum.

DataFrame.sum Return the sum over the requested axis.

DataFrame.min Return the minimum over the requested axis.

DataFrame.max Return the maximum over the requested axis.

DataFrame.idxmin Return the index of the minimum over the requested axis.

DataFrame.idxmax Return the index of the maximum over the requested axis.

Examples

```
>>> idx = pd.MultiIndex.from_arrays([
...     ['warm', 'warm', 'cold', 'cold'],
...     ['dog', 'falcon', 'fish', 'spider']],
...     names=['blooded', 'animal'])
>>> s = pd.Series([4, 2, 0, 8], name='legs', index=idx)
>>> s
blooded  animal
warm     dog       4
         falcon    2
cold     fish      0
         spider    8
Name: legs, dtype: int64
```

```
>>> s.sum()
14
```

Sum using level names, as well as indices.

```
>>> s.sum(level='blooded')
blooded
warm    6
cold    8
Name: legs, dtype: int64
```

```
>>> s.sum(level=0)
blooded
warm    6
cold    8
Name: legs, dtype: int64
```

By default, the sum of an empty or all-NA Series is `0`.

```
>>> pd.Series([]).sum()  # min_count=0 is the default
0.0
```

This can be controlled with the `min_count` parameter. For example, if you'd like the sum of an empty series to be NaN, pass `min_count=1`.

```
>>> pd.Series([]).sum(min_count=1)
nan
```

Thanks to the `skipna` parameter, `min_count` handles all-NA and empty series identically.

```
>>> pd.Series([np.nan]).sum()
0.0
```

```
>>> pd.Series([np.nan]).sum(min_count=1)
nan
```

pandas.DataFrame.swapaxes

DataFrame.**swapaxes**(*axis1*, *axis2*, *copy=True*)

Interchange axes and swap values axes appropriately.

Returns

y [same as input]

pandas.DataFrame.swaplevel

DataFrame.**swaplevel**(*i=-2*, *j=-1*, *axis=0*)

Swap levels i and j in a MultiIndex on a particular axis.

Parameters

i, j [int or str] Levels of the indices to be swapped. Can pass level name as string.

axis [{0 or 'index', 1 or 'columns'}, default 0] The axis to swap levels on. 0 or 'index' for row-wise, 1 or 'columns' for column-wise.

Returns

DataFrame

pandas.DataFrame.tail

DataFrame.**tail**(*n=5*)

Return the last *n* rows.

This function returns last *n* rows from the object based on position. It is useful for quickly verifying data, for example, after sorting or appending rows.

For negative values of *n*, this function returns all rows except the first *n* rows, equivalent to `df[n:]`.

Parameters

n [int, default 5] Number of rows to select.

Returns

type of caller The last *n* rows of the caller object.

See also:

DataFrame.head The first *n* rows of the caller object.

Examples

```
>>> df = pd.DataFrame({'animal': ['alligator', 'bee', 'falcon', 'lion',
...                    'monkey', 'parrot', 'shark', 'whale', 'zebra']})
>>> df
      animal
0  alligator
1        bee
2     falcon
3       lion
4     monkey
```

(continues on next page)

(continued from previous page)

```
5     parrot
6      shark
7      whale
8      zebra
```

Viewing the last 5 lines

```
>>> df.tail()
   animal
4  monkey
5  parrot
6   shark
7   whale
8   zebra
```

Viewing the last *n* lines (three in this case)

```
>>> df.tail(3)
  animal
6  shark
7  whale
8  zebra
```

For negative values of *n*

```
>>> df.tail(-3)
   animal
3    lion
4  monkey
5  parrot
6   shark
7   whale
8   zebra
```

pandas.DataFrame.take

DataFrame.**take**(*indices*, *axis=0*, *is_copy=None*, ***kwargs*)

Return the elements in the given *positional* indices along an axis.

This means that we are not indexing according to actual values in the index attribute of the object. We are indexing according to the actual position of the element in the object.

Parameters

indices [array-like] An array of ints indicating which positions to take.

axis [{0 or 'index', 1 or 'columns', None}, default 0] The axis on which to select elements. `0` means that we are selecting rows, `1` means that we are selecting columns.

is_copy [bool] Before pandas 1.0, `is_copy=False` can be specified to ensure that the return value is an actual copy. Starting with pandas 1.0, `take` always returns a copy, and the keyword is therefore deprecated.

Deprecated since version 1.0.0.

****kwargs** For compatibility with `numpy.take()`. Has no effect on the output.

Returns

taken [same type as caller] An array-like containing the elements taken from the object.

See also:

DataFrame.loc Select a subset of a DataFrame by labels.

DataFrame.iloc Select a subset of a DataFrame by positions.

numpy.take Take elements from an array along an axis.

Examples

```
>>> df = pd.DataFrame([('falcon', 'bird', 389.0),
...                    ('parrot', 'bird', 24.0),
...                    ('lion', 'mammal', 80.5),
...                    ('monkey', 'mammal', np.nan)],
...                   columns=['name', 'class', 'max_speed'],
...                   index=[0, 2, 3, 1])
>>> df
     name   class  max_speed
0  falcon    bird      389.0
2  parrot    bird       24.0
3    lion  mammal       80.5
1  monkey  mammal        NaN
```

Take elements at positions 0 and 3 along the axis 0 (default).

Note how the actual indices selected (0 and 1) do not correspond to our selected indices 0 and 3. That's because we are selecting the 0th and 3rd rows, not rows whose indices equal 0 and 3.

```
>>> df.take([0, 3])
     name   class  max_speed
0  falcon    bird      389.0
1  monkey  mammal        NaN
```

Take elements at indices 1 and 2 along the axis 1 (column selection).

```
>>> df.take([1, 2], axis=1)
    class  max_speed
0    bird      389.0
2    bird       24.0
3  mammal       80.5
1  mammal        NaN
```

We may take elements using negative integers for positive indices, starting from the end of the object, just like with Python lists.

```
>>> df.take([-1, -2])
     name   class  max_speed
1  monkey  mammal        NaN
3    lion  mammal       80.5
```

pandas.DataFrame.to_clipboard

DataFrame.**to_clipboard**(*excel=True*, *sep=None*, ***kwargs*)

Copy object to the system clipboard.

Write a text representation of object to the system clipboard. This can be pasted into Excel, for example.

Parameters

excel [bool, default True] Produce output in a csv format for easy pasting into excel.

- True, use the provided separator for csv pasting.
- False, write a string representation of the object to the clipboard.

sep [str, default `'\t'`] Field delimiter.

****kwargs** These parameters will be passed to DataFrame.to_csv.

See also:

DataFrame.to_csv Write a DataFrame to a comma-separated values (csv) file.

read_clipboard Read text from clipboard and pass to read_table.

Notes

Requirements for your platform.

- Linux : *xclip*, or *xsel* (with *PyQt4* modules)
- Windows : none
- OS X : none

Examples

Copy the contents of a DataFrame to the clipboard.

```
>>> df = pd.DataFrame([[1, 2, 3], [4, 5, 6]], columns=['A', 'B', 'C'])
```

```
>>> df.to_clipboard(sep=',')
... # Wrote the following to the system clipboard:
... # ,A,B,C
... # 0,1,2,3
... # 1,4,5,6
```

We can omit the index by passing the keyword *index* and setting it to false.

```
>>> df.to_clipboard(sep=',', index=False)
... # Wrote the following to the system clipboard:
... # A,B,C
... # 1,2,3
... # 4,5,6
```

pandas.DataFrame.to_csv

DataFrame.**to_csv**(*path_or_buf=None*, *sep=','*, *na_rep=''*, *float_format=None*, *columns=None*, *header=True*, *index=True*, *index_label=None*, *mode='w'*, *encoding=None*, *compression='infer'*, *quoting=None*, *quotechar='"'*, *line_terminator=None*, *chunksize=None*, *date_format=None*, *doublequote=True*, *escapechar=None*, *decimal='.'*, *errors='strict'*)

Write object to a comma-separated values (csv) file.

Changed in version 0.24.0: The order of arguments for Series was changed.

Parameters

path_or_buf [str or file handle, default None] File path or object, if None is provided the result is returned as a string. If a file object is passed it should be opened with *newline=''*, disabling universal newlines.

Changed in version 0.24.0: Was previously named "path" for Series.

sep [str, default ','] String of length 1. Field delimiter for the output file.

na_rep [str, default ''] Missing data representation.

float_format [str, default None] Format string for floating point numbers.

columns [sequence, optional] Columns to write.

header [bool or list of str, default True] Write out the column names. If a list of strings is given it is assumed to be aliases for the column names.

Changed in version 0.24.0: Previously defaulted to False for Series.

index [bool, default True] Write row names (index).

index_label [str or sequence, or False, default None] Column label for index column(s) if desired. If None is given, and *header* and *index* are True, then the index names are used. A sequence should be given if the object uses MultiIndex. If False do not print fields for index names. Use index_label=False for easier importing in R.

mode [str] Python write mode, default 'w'.

encoding [str, optional] A string representing the encoding to use in the output file, defaults to 'utf-8'.

compression [str or dict, default 'infer'] If str, represents compression mode. If dict, value at 'method' is the compression mode. Compression mode may be any of the following possible values: {'infer', 'gzip', 'bz2', 'zip', 'xz', None}. If compression mode is 'infer' and *path_or_buf* is path-like, then detect compression mode from the following extensions: '.gz', '.bz2', '.zip' or '.xz'. (otherwise no compression). If dict given and mode is one of {'zip', 'gzip', 'bz2'}, or inferred as one of the above, other entries passed as additional compression options.

Changed in version 1.0.0: May now be a dict with key 'method' as compression mode and other entries as additional compression options if compression mode is 'zip'.

Changed in version 1.1.0: Passing compression options as keys in dict is supported for compression modes 'gzip' and 'bz2' as well as 'zip'.

quoting [optional constant from csv module] Defaults to csv.QUOTE_MINIMAL. If you have set a *float_format* then floats are converted to strings and thus csv.QUOTE_NONNUMERIC will treat them as non-numeric.

quotechar [str, default ‘”’] String of length 1. Character used to quote fields.

line_terminator [str, optional] The newline character or character sequence to use in the output file. Defaults to *os.linesep*, which depends on the OS in which this method is called (‘n’ for linux, ‘rn’ for Windows, i.e.).

Changed in version 0.24.0.

chunksize [int or None] Rows to write at a time.

date_format [str, default None] Format string for datetime objects.

doublequote [bool, default True] Control quoting of *quotechar* inside a field.

escapechar [str, default None] String of length 1. Character used to escape *sep* and *quotechar* when appropriate.

decimal [str, default ‘.’] Character recognized as decimal separator. E.g. use ‘,’ for European data.

errors [str, default ‘strict’] Specifies how encoding and decoding errors are to be handled. See the errors argument for `open()` for a full list of options.

New in version 1.1.0.

Returns

None or str If path_or_buf is None, returns the resulting csv format as a string. Otherwise returns None.

See also:

read_csv Load a CSV file into a DataFrame.

to_excel Write DataFrame to an Excel file.

Examples

```
>>> df = pd.DataFrame({'name': ['Raphael', 'Donatello'],
...                    'mask': ['red', 'purple'],
...                    'weapon': ['sai', 'bo staff']})
>>> df.to_csv(index=False)
'name,mask,weapon\nRaphael,red,sai\nDonatello,purple,bo staff\n'
```

Create ‘out.zip’ containing ‘out.csv’

```
>>> compression_opts = dict(method='zip',
...                         archive_name='out.csv')
>>> df.to_csv('out.zip', index=False,
...           compression=compression_opts)
```

pandas.DataFrame.to_dict

DataFrame.**to_dict**(*orient='dict'*, *into=<class 'dict'>*)

Convert the DataFrame to a dictionary.

The type of the key-value pairs can be customized with the parameters (see below).

Parameters

orient [str {'dict', 'list', 'series', 'split', 'records', 'index'}] Determines the type of the values of the dictionary.

- 'dict' (default) : dict like {column -> {index -> value}}
- 'list' : dict like {column -> [values]}
- 'series' : dict like {column -> Series(values)}
- 'split' : dict like {'index' -> [index], 'columns' -> [columns], 'data' -> [values]}
- 'records' : list like [{column -> value}, ... , {column -> value}]
- 'index' : dict like {index -> {column -> value}}

Abbreviations are allowed. *s* indicates *series* and *sp* indicates *split*.

into [class, default dict] The collections.abc.Mapping subclass used for all Mappings in the return value. Can be the actual class or an empty instance of the mapping type you want. If you want a collections.defaultdict, you must pass it initialized.

Returns

dict, list or collections.abc.Mapping Return a collections.abc.Mapping object representing the DataFrame. The resulting transformation depends on the *orient* parameter.

See also:

DataFrame.from_dict Create a DataFrame from a dictionary.

DataFrame.to_json Convert a DataFrame to JSON format.

Examples

```
>>> df = pd.DataFrame({'col1': [1, 2],
...                    'col2': [0.5, 0.75]},
...                   index=['row1', 'row2'])
>>> df
      col1  col2
row1     1  0.50
row2     2  0.75
>>> df.to_dict()
{'col1': {'row1': 1, 'row2': 2}, 'col2': {'row1': 0.5, 'row2': 0.75}}
```

You can specify the return orientation.

```
>>> df.to_dict('series')
{'col1': row1    1
         row2    2
Name: col1, dtype: int64,
```

(continues on next page)

(continued from previous page)

```
'col2': row1    0.50
        row2    0.75
Name: col2, dtype: float64}
```

```
>>> df.to_dict('split')
{'index': ['row1', 'row2'], 'columns': ['col1', 'col2'],
 'data': [[1, 0.5], [2, 0.75]]}
```

```
>>> df.to_dict('records')
[{'col1': 1, 'col2': 0.5}, {'col1': 2, 'col2': 0.75}]
```

```
>>> df.to_dict('index')
{'row1': {'col1': 1, 'col2': 0.5}, 'row2': {'col1': 2, 'col2': 0.75}}
```

You can also specify the mapping type.

```
>>> from collections import OrderedDict, defaultdict
>>> df.to_dict(into=OrderedDict)
OrderedDict([('col1', OrderedDict([('row1', 1), ('row2', 2)])),
             ('col2', OrderedDict([('row1', 0.5), ('row2', 0.75)]))])
```

If you want a *defaultdict*, you need to initialize it:

```
>>> dd = defaultdict(list)
>>> df.to_dict('records', into=dd)
[defaultdict(<class 'list'>, {'col1': 1, 'col2': 0.5}),
 defaultdict(<class 'list'>, {'col1': 2, 'col2': 0.75})]
```

pandas.DataFrame.to_excel

DataFrame.**to_excel**(*excel_writer*, *sheet_name='Sheet1'*, *na_rep=''*, *float_format=None*, *columns=None*, *header=True*, *index=True*, *index_label=None*, *startrow=0*, *startcol=0*, *engine=None*, *merge_cells=True*, *encoding=None*, *inf_rep='inf'*, *verbose=True*, *freeze_panes=None*)

Write object to an Excel sheet.

To write a single object to an Excel .xlsx file it is only necessary to specify a target file name. To write to multiple sheets it is necessary to create an *ExcelWriter* object with a target file name, and specify a sheet in the file to write to.

Multiple sheets may be written to by specifying unique *sheet_name*. With all data written to the file it is necessary to save the changes. Note that creating an *ExcelWriter* object with a file name that already exists will result in the contents of the existing file being erased.

Parameters

excel_writer [str or ExcelWriter object] File path or existing ExcelWriter.

sheet_name [str, default 'Sheet1'] Name of sheet which will contain DataFrame.

na_rep [str, default ''] Missing data representation.

float_format [str, optional] Format string for floating point numbers. For example `float_format="%.2f"` will format 0.1234 to 0.12.

columns [sequence or list of str, optional] Columns to write.

header [bool or list of str, default True] Write out the column names. If a list of string is given it is assumed to be aliases for the column names.

index [bool, default True] Write row names (index).

index_label [str or sequence, optional] Column label for index column(s) if desired. If not specified, and *header* and *index* are True, then the index names are used. A sequence should be given if the DataFrame uses MultiIndex.

startrow [int, default 0] Upper left cell row to dump data frame.

startcol [int, default 0] Upper left cell column to dump data frame.

engine [str, optional] Write engine to use, 'openpyxl' or 'xlsxwriter'. You can also set this via the options `io.excel.xlsx.writer`, `io.excel.xls.writer`, and `io.excel.xlsm.writer`.

merge_cells [bool, default True] Write MultiIndex and Hierarchical Rows as merged cells.

encoding [str, optional] Encoding of the resulting excel file. Only necessary for xlwt, other writers support unicode natively.

inf_rep [str, default 'inf'] Representation for infinity (there is no native representation for infinity in Excel).

verbose [bool, default True] Display more information in the error logs.

freeze_panes [tuple of int (length 2), optional] Specifies the one-based bottommost row and rightmost column that is to be frozen.

See also:

to_csv Write DataFrame to a comma-separated values (csv) file.

ExcelWriter Class for writing DataFrame objects into excel sheets.

read_excel Read an Excel file into a pandas DataFrame.

read_csv Read a comma-separated values (csv) file into DataFrame.

Notes

For compatibility with *to_csv()*, to_excel serializes lists and dicts to strings before writing.

Once a workbook has been saved it is not possible write further data without rewriting the whole workbook.

Examples

Create, write to and save a workbook:

```
>>> df1 = pd.DataFrame([['a', 'b'], ['c', 'd']],
...                    index=['row 1', 'row 2'],
...                    columns=['col 1', 'col 2'])
>>> df1.to_excel("output.xlsx")
```

To specify the sheet name:

```
>>> df1.to_excel("output.xlsx",
...              sheet_name='Sheet_name_1')
```

If you wish to write to more than one sheet in the workbook, it is necessary to specify an ExcelWriter object:

```
>>> df2 = df1.copy()
>>> with pd.ExcelWriter('output.xlsx') as writer:
...     df1.to_excel(writer, sheet_name='Sheet_name_1')
...     df2.to_excel(writer, sheet_name='Sheet_name_2')
```

ExcelWriter can also be used to append to an existing Excel file:

```
>>> with pd.ExcelWriter('output.xlsx',
...                     mode='a') as writer:
...     df.to_excel(writer, sheet_name='Sheet_name_3')
```

To set the library that is used to write the Excel file, you can pass the *engine* keyword (the default engine is automatically chosen depending on the file extension):

```
>>> df1.to_excel('output1.xlsx', engine='xlsxwriter')
```

pandas.DataFrame.to_feather

`DataFrame.to_feather(**kwargs)`

Write a DataFrame to the binary Feather format.

Parameters

path [str] String file path.

****kwargs** Additional keywords passed to `pyarrow.feather.write_feather()`. Starting with pyarrow 0.17, this includes the *compression*, *compression_level*, *chunksize* and *version* keywords.

New in version 1.1.0.

pandas.DataFrame.to_gbq

`DataFrame.to_gbq(destination_table, project_id=None, chunksize=None, reauth=False, if_exists='fail', auth_local_webserver=False, table_schema=None, location=None, progress_bar=True, credentials=None)`

Write a DataFrame to a Google BigQuery table.

This function requires the pandas-gbq package.

See the How to authenticate with Google BigQuery guide for authentication instructions.

Parameters

destination_table [str] Name of table to be written, in the form `dataset.tablename`.

project_id [str, optional] Google BigQuery Account project ID. Optional when available from the environment.

chunksize [int, optional] Number of rows to be inserted in each chunk from the dataframe. Set to `None` to load the whole dataframe at once.

reauth [bool, default False] Force Google BigQuery to re-authenticate the user. This is useful if multiple accounts are used.

if_exists [str, default 'fail'] Behavior when the destination table exists. Value can be one of:

'fail' If table exists raise pandas_gbq.gbq.TableCreationError.

'replace' If table exists, drop it, recreate it, and insert data.

'append' If table exists, insert data. Create if does not exist.

auth_local_webserver [bool, default False] Use the local webserver flow instead of the console flow when getting user credentials.

New in version 0.2.0 of pandas-gbq.

table_schema [list of dicts, optional] List of BigQuery table fields to which according DataFrame columns conform to, e.g. `[{'name': 'col1', 'type': 'STRING'},...]`. If schema is not provided, it will be generated according to dtypes of DataFrame columns. See BigQuery API documentation on available names of a field.

New in version 0.3.1 of pandas-gbq.

location [str, optional] Location where the load job should run. See the BigQuery locations documentation for a list of available locations. The location must match that of the target dataset.

New in version 0.5.0 of pandas-gbq.

progress_bar [bool, default True] Use the library *tqdm* to show the progress bar for the upload, chunk by chunk.

New in version 0.5.0 of pandas-gbq.

credentials [google.auth.credentials.Credentials, optional] Credentials for accessing Google APIs. Use this parameter to override default credentials, such as to use Compute Engine `google.auth.compute_engine.Credentials` or Service Account `google.oauth2.service_account.Credentials` directly.

New in version 0.8.0 of pandas-gbq.

New in version 0.24.0.

See also:

pandas_gbq.to_gbq This function in the pandas-gbq library.

read_gbq Read a DataFrame from Google BigQuery.

pandas.DataFrame.to_hdf

DataFrame.**to_hdf**(*path_or_buf*, *key*, *mode='a'*, *complevel=None*, *complib=None*, *append=False*, *format=None*, *index=True*, *min_itemsize=None*, *nan_rep=None*, *dropna=None*, *data_columns=None*, *errors='strict'*, *encoding='UTF-8'*)

Write the contained data to an HDF5 file using HDFStore.

Hierarchical Data Format (HDF) is self-describing, allowing an application to interpret the structure and contents of a file with no outside information. One HDF file can hold a mix of related objects which can be accessed as a group or as individual objects.

In order to add another DataFrame or Series to an existing HDF file please use append mode and a different a key.

For more information see the *user guide*.

Parameters

path_or_buf [str or pandas.HDFStore] File path or HDFStore object.

key [str] Identifier for the group in the store.

mode [{'a', 'w', 'r+'}, default 'a'] Mode to open file:

- 'w': write, a new file is created (an existing file with the same name would be deleted).
- 'a': append, an existing file is opened for reading and writing, and if the file does not exist it is created.
- 'r+': similar to 'a', but the file must already exist.

complevel [{0-9}, optional] Specifies a compression level for data. A value of 0 disables compression.

complib [{'zlib', 'lzo', 'bzip2', 'blosc'}, default 'zlib'] Specifies the compression library to be used. As of v0.20.2 these additional compressors for Blosc are supported (default if no compressor specified: 'blosc:blosclz'): {'blosc:blosclz', 'blosc:lz4', 'blosc:lz4hc', 'blosc:snappy', 'blosc:zlib', 'blosc:zstd'}. Specifying a compression library which is not available issues a ValueError.

append [bool, default False] For Table formats, append the input data to the existing.

format [{'fixed', 'table', None}, default 'fixed'] Possible values:

- 'fixed': Fixed format. Fast writing/reading. Not-appendable, nor searchable.
- 'table': Table format. Write as a PyTables Table structure which may perform worse but allow more flexible operations like searching / selecting subsets of the data.
- If None, pd.get_option('io.hdf.default_format') is checked, followed by fallback to "fixed"

errors [str, default 'strict'] Specifies how encoding and decoding errors are to be handled. See the errors argument for `open()` for a full list of options.

encoding [str, default "UTF-8"]

min_itemsize [dict or int, optional] Map column names to minimum string sizes for columns.

nan_rep [Any, optional] How to represent null values as str. Not allowed with append=True.

data_columns [list of columns or True, optional] List of columns to create as indexed data columns for on-disk queries, or True to use all columns. By default only the axes of the object are indexed. See *Query via data columns*. Applicable only to format='table'.

See also:

`DataFrame.read_hdf` Read from HDF file.

`DataFrame.to_parquet` Write a DataFrame to the binary parquet format.

`DataFrame.to_sql` Write to a sql table.

`DataFrame.to_feather` Write out feather-format for DataFrames.

DataFrame.to_csv Write out to a csv file.

Examples

```
>>> df = pd.DataFrame({'A': [1, 2, 3], 'B': [4, 5, 6]},
...                   index=['a', 'b', 'c'])
>>> df.to_hdf('data.h5', key='df', mode='w')
```

We can add another object to the same file:

```
>>> s = pd.Series([1, 2, 3, 4])
>>> s.to_hdf('data.h5', key='s')
```

Reading from HDF file:

```
>>> pd.read_hdf('data.h5', 'df')
A  B
a  1  4
b  2  5
c  3  6
>>> pd.read_hdf('data.h5', 's')
0    1
1    2
2    3
3    4
dtype: int64
```

Deleting file with data:

```
>>> import os
>>> os.remove('data.h5')
```

pandas.DataFrame.to_html

DataFrame.**to_html**(*buf=None*, *columns=None*, *col_space=None*, *header=True*, *index=True*, *na_rep='NaN'*, *formatters=None*, *float_format=None*, *sparsify=None*, *index_names=True*, *justify=None*, *max_rows=None*, *max_cols=None*, *show_dimensions=False*, *decimal='.'*, *bold_rows=True*, *classes=None*, *escape=True*, *notebook=False*, *border=None*, *table_id=None*, *render_links=False*, *encoding=None*)

Render a DataFrame as an HTML table.

Parameters

buf [str, Path or StringIO-like, optional, default None] Buffer to write to. If None, the output is returned as a string.

columns [sequence, optional, default None] The subset of columns to write. Writes all columns by default.

col_space [str or int, list or dict of int or str, optional] The minimum width of each column in CSS length units. An int is assumed to be px units.

New in version 0.25.0: Ability to use str.

header [bool, optional] Whether to print column labels, default True.

index [bool, optional, default True] Whether to print index (row) labels.

na_rep [str, optional, default 'NaN'] String representation of NAN to use.

formatters [list, tuple or dict of one-param. functions, optional] Formatter functions to apply to columns' elements by position or name. The result of each function must be a unicode string. List/tuple must be of length equal to the number of columns.

float_format [one-parameter function, optional, default None] Formatter function to apply to columns' elements if they are floats. The result of this function must be a unicode string.

sparsify [bool, optional, default True] Set to False for a DataFrame with a hierarchical index to print every multiindex key at each row.

index_names [bool, optional, default True] Prints the names of the indexes.

justify [str, default None] How to justify the column labels. If None uses the option from the print configuration (controlled by set_option), 'right' out of the box. Valid values are

- left
- right
- center
- justify
- justify-all
- start
- end
- inherit
- match-parent
- initial
- unset.

max_rows [int, optional] Maximum number of rows to display in the console.

min_rows [int, optional] The number of rows to display in the console in a truncated repr (when number of rows is above *max_rows*).

max_cols [int, optional] Maximum number of columns to display in the console.

show_dimensions [bool, default False] Display DataFrame dimensions (number of rows by number of columns).

decimal [str, default '.'] Character recognized as decimal separator, e.g. ',' in Europe.

bold_rows [bool, default True] Make the row labels bold in the output.

classes [str or list or tuple, default None] CSS class(es) to apply to the resulting html table.

escape [bool, default True] Convert the characters <, >, and & to HTML-safe sequences.

notebook [{True, False}, default False] Whether the generated HTML is for IPython Notebook.

border [int] A `border=border` attribute is included in the opening <*table*> tag. Default `pd.options.display.html.border`.

encoding [str, default "utf-8"] Set character encoding.

New in version 1.0.

table_id [str, optional] A css id is included in the opening <*table*> tag if specified.

New in version 0.23.0.

render_links [bool, default False] Convert URLs to HTML links.

New in version 0.24.0.

Returns

str or None If buf is None, returns the result as a string. Otherwise returns None.

See also:

to_string Convert DataFrame to a string.

pandas.DataFrame.to_json

`DataFrame.`**`to_json`**(*path_or_buf=None*, *orient=None*, *date_format=None*, *double_precision=10*, *force_ascii=True*, *date_unit='ms'*, *default_handler=None*, *lines=False*, *compression='infer'*, *index=True*, *indent=None*)

Convert the object to a JSON string.

Note NaN's and None will be converted to null and datetime objects will be converted to UNIX timestamps.

Parameters

path_or_buf [str or file handle, optional] File path or object. If not specified, the result is returned as a string.

orient [str] Indication of expected JSON string format.

- Series:
  - default is 'index'
  - allowed values are: {'split','records','index','table'}.
- DataFrame:
  - default is 'columns'
  - allowed values are: {'split', 'records', 'index', 'columns', 'values', 'table'}.
- The format of the JSON string:
  - 'split' : dict like {'index' -> [index], 'columns' -> [columns], 'data' -> [values]}
  - 'records' : list like [{column -> value}, ... , {column -> value}]
  - 'index' : dict like {index -> {column -> value}}
  - 'columns' : dict like {column -> {index -> value}}
  - 'values' : just the values array

– ‘table’ : dict like {‘schema’: {schema}, ‘data’: {data}}

Describing the data, where data component is like `orient='records'`.

Changed in version 0.20.0.

date_format [{None, ‘epoch’, ‘iso’}] Type of date conversion. ‘epoch’ = epoch milliseconds, ‘iso’ = ISO8601. The default depends on the *orient*. For `orient='table'`, the default is ‘iso’. For all other orients, the default is ‘epoch’.

double_precision [int, default 10] The number of decimal places to use when encoding floating point values.

force_ascii [bool, default True] Force encoded string to be ASCII.

date_unit [str, default ‘ms’ (milliseconds)] The time unit to encode to, governs timestamp and ISO8601 precision. One of ‘s’, ‘ms’, ‘us’, ‘ns’ for second, millisecond, microsecond, and nanosecond respectively.

default_handler [callable, default None] Handler to call if object cannot otherwise be converted to a suitable format for JSON. Should receive a single argument which is the object to convert and return a serialisable object.

lines [bool, default False] If ‘orient’ is ‘records’ write out line delimited json format. Will throw ValueError if incorrect ‘orient’ since others are not list like.

compression [{‘infer’, ‘gzip’, ‘bz2’, ‘zip’, ‘xz’, None}] A string representing the compression to use in the output file, only used when the first argument is a filename. By default, the compression is inferred from the filename.

Changed in version 0.24.0: ‘infer’ option added and set to default

index [bool, default True] Whether to include the index values in the JSON string. Not including the index (`index=False`) is only supported when orient is ‘split’ or ‘table’.

New in version 0.23.0.

indent [int, optional] Length of whitespace used to indent each record.

New in version 1.0.0.

Returns

None or str If path_or_buf is None, returns the resulting json format as a string. Otherwise returns None.

See also:

read_json Convert a JSON string to pandas object.

Notes

The behavior of `indent=0` varies from the stdlib, which does not indent the output but does insert newlines. Currently, `indent=0` and the default `indent=None` are equivalent in pandas, though this may change in a future release.

Examples

```
>>> import json
>>> df = pd.DataFrame(
...     [["a", "b"], ["c", "d"]],
...     index=["row 1", "row 2"],
...     columns=["col 1", "col 2"],
... )
```

```
>>> result = df.to_json(orient="split")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
{
    "columns": [
        "col 1",
        "col 2"
    ],
    "index": [
        "row 1",
        "row 2"
    ],
    "data": [
        [
            "a",
            "b"
        ],
        [
            "c",
            "d"
        ]
    ]
}
```

Encoding/decoding a Dataframe using `'records'` formatted JSON. Note that index labels are not preserved with this encoding.

```
>>> result = df.to_json(orient="records")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
[
    {
        "col 1": "a",
        "col 2": "b"
    },
    {
        "col 1": "c",
        "col 2": "d"
    }
]
```

Encoding/decoding a Dataframe using `'index'` formatted JSON:

```
>>> result = df.to_json(orient="index")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
{
    "row 1": {
        "col 1": "a",
        "col 2": "b"
    },
    "row 2": {
        "col 1": "c",
        "col 2": "d"
    }
}
```

Encoding/decoding a Dataframe using `'columns'` formatted JSON:

```
>>> result = df.to_json(orient="columns")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
{
    "col 1": {
        "row 1": "a",
        "row 2": "c"
    },
    "col 2": {
        "row 1": "b",
        "row 2": "d"
    }
}
```

Encoding/decoding a Dataframe using `'values'` formatted JSON:

```
>>> result = df.to_json(orient="values")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
[
    [
        "a",
        "b"
    ],
    [
        "c",
        "d"
    ]
]
```

Encoding with Table Schema:

```
>>> result = df.to_json(orient="table")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
{
    "schema": {
        "fields": [
            {
                "name": "index",
```

(continues on next page)

(continued from previous page)

```
                "type": "string"
            },
            {
                "name": "col 1",
                "type": "string"
            },
            {
                "name": "col 2",
                "type": "string"
            }
        ],
        "primaryKey": [
            "index"
        ],
        "pandas_version": "0.20.0"
    },
    "data": [
        {
            "index": "row 1",
            "col 1": "a",
            "col 2": "b"
        },
        {
            "index": "row 2",
            "col 1": "c",
            "col 2": "d"
        }
    ]
}
```

pandas.DataFrame.to_latex

DataFrame.**to_latex**(*buf=None*, *columns=None*, *col_space=None*, *header=True*, *index=True*, *na_rep='NaN'*, *formatters=None*, *float_format=None*, *sparsify=None*, *index_names=True*, *bold_rows=False*, *column_format=None*, *longtable=None*, *escape=None*, *encoding=None*, *decimal='.'*, *multicolumn=None*, *multicolumn_format=None*, *multirow=None*, *caption=None*, *label=None*)

Render object to a LaTeX tabular, longtable, or nested table/tabular.

Requires `\usepackage{booktabs}`. The output can be copy/pasted into a main LaTeX document or read from an external file with `\input{table.tex}`.

Changed in version 0.20.2: Added to Series.

Changed in version 1.0.0: Added caption and label arguments.

Parameters

buf [str, Path or StringIO-like, optional, default None] Buffer to write to. If None, the output is returned as a string.

columns [list of label, optional] The subset of columns to write. Writes all columns by default.

col_space [int, optional] The minimum width of each column.

header [bool or list of str, default True] Write out the column names. If a list of strings is given, it is assumed to be aliases for the column names.

index [bool, default True] Write row names (index).

na_rep [str, default 'NaN'] Missing data representation.

formatters [list of functions or dict of {str: function}, optional] Formatter functions to apply to columns' elements by position or name. The result of each function must be a unicode string. List must be of length equal to the number of columns.

float_format [one-parameter function or str, optional, default None] Formatter for floating point numbers. For example `float_format="%.2f"` and `float_format="{:0.2f}".format` will both result in 0.1234 being formatted as 0.12.

sparsify [bool, optional] Set to False for a DataFrame with a hierarchical index to print every multiindex key at each row. By default, the value will be read from the config module.

index_names [bool, default True] Prints the names of the indexes.

bold_rows [bool, default False] Make the row labels bold in the output.

column_format [str, optional] The columns format as specified in LaTeX table format e.g. 'rcl' for 3 columns. By default, 'l' will be used for all columns except columns of numbers, which default to 'r'.

longtable [bool, optional] By default, the value will be read from the pandas config module. Use a longtable environment instead of tabular. Requires adding a usepackage{longtable} to your LaTeX preamble.

escape [bool, optional] By default, the value will be read from the pandas config module. When set to False prevents from escaping latex special characters in column names.

encoding [str, optional] A string representing the encoding to use in the output file, defaults to 'utf-8'.

decimal [str, default '.'] Character recognized as decimal separator, e.g. ',' in Europe.

multicolumn [bool, default True] Use multicolumn to enhance MultiIndex columns. The default will be read from the config module.

multicolumn_format [str, default 'l'] The alignment for multicolumns, similar to *column_format* The default will be read from the config module.

multirow [bool, default False] Use multirow to enhance MultiIndex rows. Requires adding a usepackage{multirow} to your LaTeX preamble. Will print centered labels (instead of top-aligned) across the contained rows, separating groups via clines. The default will be read from the pandas config module.

caption [str, optional] The LaTeX caption to be placed inside `\caption{}` in the output.

New in version 1.0.0.

label [str, optional] The LaTeX label to be placed inside `\label{}` in the output. This is used with `\ref{}` in the main `.tex` file.

New in version 1.0.0.

Returns

str or None If buf is None, returns the result as a string. Otherwise returns None.

See also:

DataFrame.to_string Render a DataFrame to a console-friendly tabular output.

DataFrame.to_html Render a DataFrame as an HTML table.

Examples

```
>>> df = pd.DataFrame({'name': ['Raphael', 'Donatello'],
...                    'mask': ['red', 'purple'],
...                    'weapon': ['sai', 'bo staff']})
>>> print(df.to_latex(index=False))
\begin{tabular}{lll}
 \toprule
       name &    mask &    weapon \\
 \midrule
    Raphael &     red &       sai \\
  Donatello &  purple &  bo staff \\
\bottomrule
\end{tabular}
```

pandas.DataFrame.to_markdown

DataFrame.**to_markdown**(*buf=None*, *mode=None*, *index=True*, ***kwargs*)

Print DataFrame in Markdown-friendly format.

New in version 1.0.0.

Parameters

buf [str, Path or StringIO-like, optional, default None] Buffer to write to. If None, the output is returned as a string.

mode [str, optional] Mode in which file is opened.

index [bool, optional, default True] Add index (row) labels.

New in version 1.1.0.

****kwargs** These parameters will be passed to tabulate.

Returns

str DataFrame in Markdown-friendly format.

Examples

```
>>> s = pd.Series(["elk", "pig", "dog", "quetzal"], name="animal")
>>> print(s.to_markdown())
|    | animal   |
|---:|:---------|
|  0 | elk      |
|  1 | pig      |
|  2 | dog      |
|  3 | quetzal  |
```

Output markdown with a tabulate option.

```
>>> print(s.to_markdown(tablefmt="grid"))
+----+----------+
|    | animal   |
+====+==========+
|  0 | elk      |
+----+----------+
|  1 | pig      |
+----+----------+
|  2 | dog      |
+----+----------+
|  3 | quetzal  |
+----+----------+
```

pandas.DataFrame.to_numpy

DataFrame.**to_numpy**(*dtype=None*, *copy=False*, *na_value=<object object>*)

Convert the DataFrame to a NumPy array.

New in version 0.24.0.

By default, the dtype of the returned array will be the common NumPy dtype of all types in the DataFrame. For example, if the dtypes are `float16` and `float32`, the results dtype will be `float32`. This may require copying data and coercing values, which may be expensive.

Parameters

dtype [str or numpy.dtype, optional] The dtype to pass to `numpy.asarray()`.

copy [bool, default False] Whether to ensure that the returned value is not a view on another array. Note that `copy=False` does not *ensure* that `to_numpy()` is no-copy. Rather, `copy=True` ensure that a copy is made, even if not strictly necessary.

na_value [Any, optional] The value to use for missing values. The default value depends on *dtype* and the dtypes of the DataFrame columns.

New in version 1.1.0.

Returns

numpy.ndarray

See also:

Series.to_numpy Similar method for Series.

Examples

```
>>> pd.DataFrame({"A": [1, 2], "B": [3, 4]}).to_numpy()
array([[1, 3],
       [2, 4]])
```

With heterogeneous data, the lowest common type will have to be used.

```
>>> df = pd.DataFrame({"A": [1, 2], "B": [3.0, 4.5]})
>>> df.to_numpy()
array([[1. , 3. ],
       [2. , 4.5]])
```

For a mix of numeric and non-numeric types, the output array will have object dtype.

```
>>> df['C'] = pd.date_range('2000', periods=2)
>>> df.to_numpy()
array([[1, 3.0, Timestamp('2000-01-01 00:00:00')],
       [2, 4.5, Timestamp('2000-01-02 00:00:00')]], dtype=object)
```

pandas.DataFrame.to_parquet

DataFrame.**to_parquet**(***kwargs*)

Write a DataFrame to the binary parquet format.

This function writes the dataframe as a parquet file. You can choose different parquet backends, and have the option of compression. See *the user guide* for more details.

Parameters

path [str or file-like object] If a string, it will be used as Root Directory path when writing a partitioned dataset. By file-like object, we refer to objects with a write() method, such as a file handler (e.g. via builtin open function) or io.BytesIO. The engine fastparquet does not accept file-like objects.

Changed in version 1.0.0.

Previously this was "fname"

engine [{'auto', 'pyarrow', 'fastparquet'}, default 'auto'] Parquet library to use. If 'auto', then the option `io.parquet.engine` is used. The default `io.parquet.engine` behavior is to try 'pyarrow', falling back to 'fastparquet' if 'pyarrow' is unavailable.

compression [{'snappy', 'gzip', 'brotli', None}, default 'snappy'] Name of the compression to use. Use `None` for no compression.

index [bool, default None] If `True`, include the dataframe's index(es) in the file output. If `False`, they will not be written to the file. If `None`, similar to `True` the dataframe's index(es) will be saved. However, instead of being saved as values, the RangeIndex will be stored as a range in the metadata so it doesn't require much space and is faster. Other indexes will be included as columns in the file output.

New in version 0.24.0.

partition_cols [list, optional, default None] Column names by which to partition the dataset. Columns are partitioned in the order they are given. Must be None if path is not a string.

New in version 0.24.0.

****kwargs** Additional arguments passed to the parquet library. See *pandas io* for more details.

See also:

read_parquet Read a parquet file.

DataFrame.to_csv Write a csv file.

DataFrame.to_sql Write to a sql table.

DataFrame.to_hdf Write to hdf.

Notes

This function requires either the fastparquet or pyarrow library.

Examples

```
>>> df = pd.DataFrame(data={'col1': [1, 2], 'col2': [3, 4]})
>>> df.to_parquet('df.parquet.gzip',
...               compression='gzip')
>>> pd.read_parquet('df.parquet.gzip')
   col1  col2
0     1     3
1     2     4
```

If you want to get a buffer to the parquet content you can use a io.BytesIO object, as long as you don't use partition_cols, which creates multiple files.

```
>>> import io
>>> f = io.BytesIO()
>>> df.to_parquet(f)
>>> f.seek(0)
0
>>> content = f.read()
```

pandas.DataFrame.to_period

DataFrame.**to_period**(*freq=None*, *axis=0*, *copy=True*)

Convert DataFrame from DatetimeIndex to PeriodIndex.

Convert DataFrame from DatetimeIndex to PeriodIndex with desired frequency (inferred from index if not passed).

Parameters

freq [str, default] Frequency of the PeriodIndex.

axis [{0 or 'index', 1 or 'columns'}, default 0] The axis to convert (the index by default).

copy [bool, default True] If False then underlying input data is not copied.

Returns

DataFrame with PeriodIndex

pandas.DataFrame.to_pickle

DataFrame.**to_pickle**(*path*, *compression='infer'*, *protocol=5*)

Pickle (serialize) object to file.

Parameters

path [str] File path where the pickled object will be stored.

compression [{'infer', 'gzip', 'bz2', 'zip', 'xz', None}, default 'infer'] A string representing the compression to use in the output file. By default, infers from the file extension in specified path.

protocol [int] Int which indicates which protocol should be used by the pickler, default HIGHEST_PROTOCOL (see [1] paragraph 12.1.2). The possible values are 0, 1, 2, 3, 4. A negative value for the protocol parameter is equivalent to setting its value to HIGHEST_PROTOCOL.

See also:

read_pickle Load pickled pandas object (or any object) from file.

DataFrame.to_hdf Write DataFrame to an HDF5 file.

DataFrame.to_sql Write DataFrame to a SQL database.

DataFrame.to_parquet Write a DataFrame to the binary parquet format.

Examples

```
>>> original_df = pd.DataFrame({"foo": range(5), "bar": range(5, 10)})
>>> original_df
   foo  bar
0    0    5
1    1    6
2    2    7
3    3    8
4    4    9
>>> original_df.to_pickle("./dummy.pkl")
```

```
>>> unpickled_df = pd.read_pickle("./dummy.pkl")
>>> unpickled_df
   foo  bar
0    0    5
1    1    6
2    2    7
3    3    8
4    4    9
```

```
>>> import os
>>> os.remove("./dummy.pkl")
```

pandas.DataFrame.to_records

DataFrame.**to_records**(*index=True*, *column_dtypes=None*, *index_dtypes=None*)

Convert DataFrame to a NumPy record array.

Index will be included as the first field of the record array if requested.

Parameters

index [bool, default True] Include index in resulting record array, stored in 'index' field or using the index label, if set.

column_dtypes [str, type, dict, default None] New in version 0.24.0.

If a string or type, the data type to store all columns. If a dictionary, a mapping of column names and indices (zero-indexed) to specific data types.

index_dtypes [str, type, dict, default None] New in version 0.24.0.

If a string or type, the data type to store all index levels. If a dictionary, a mapping of index level names and indices (zero-indexed) to specific data types.

This mapping is applied only if *index=True*.

Returns

numpy.recarray NumPy ndarray with the DataFrame labels as fields and each row of the DataFrame as entries.

See also:

DataFrame.from_records Convert structured or record ndarray to DataFrame.

numpy.recarray An ndarray that allows field access using attributes, analogous to typed columns in a spreadsheet.

Examples

```
>>> df = pd.DataFrame({'A': [1, 2], 'B': [0.5, 0.75]},
...                   index=['a', 'b'])
>>> df
   A     B
a  1  0.50
b  2  0.75
>>> df.to_records()
rec.array([('a', 1, 0.5 ), ('b', 2, 0.75)],
          dtype=[('index', 'O'), ('A', '<i8'), ('B', '<f8')])
```

If the DataFrame index has no label then the recarray field name is set to 'index'. If the index has a label then this is used as the field name:

```
>>> df.index = df.index.rename("I")
>>> df.to_records()
rec.array([('a', 1, 0.5 ), ('b', 2, 0.75)],
          dtype=[('I', 'O'), ('A', '<i8'), ('B', '<f8')])
```

The index can be excluded from the record array:

```
>>> df.to_records(index=False)
rec.array([(1, 0.5 ), (2, 0.75)],
          dtype=[('A', '<i8'), ('B', '<f8')])
```

Data types can be specified for the columns:

```
>>> df.to_records(column_dtypes={"A": "int32"})
rec.array([('a', 1, 0.5 ), ('b', 2, 0.75)],
          dtype=[('I', 'O'), ('A', '<i4'), ('B', '<f8')])
```

As well as for the index:

```
>>> df.to_records(index_dtypes="<S2")
rec.array([(b'a', 1, 0.5 ), (b'b', 2, 0.75)],
          dtype=[('I', 'S2'), ('A', '<i8'), ('B', '<f8')])
```

```
>>> index_dtypes = f"<S{df.index.str.len().max()}"
>>> df.to_records(index_dtypes=index_dtypes)
rec.array([(b'a', 1, 0.5 ), (b'b', 2, 0.75)],
          dtype=[('I', 'S1'), ('A', '<i8'), ('B', '<f8')])
```

pandas.DataFrame.to_sql

DataFrame.**to_sql**(*name*, *con*, *schema=None*, *if_exists='fail'*, *index=True*, *index_label=None*, *chunksize=None*, *dtype=None*, *method=None*)

Write records stored in a DataFrame to a SQL database.

Databases supported by SQLAlchemy [1] are supported. Tables can be newly created, appended to, or overwritten.

Parameters

name [str] Name of SQL table.

con [sqlalchemy.engine.(Engine or Connection) or sqlite3.Connection] Using SQLAlchemy makes it possible to use any DB supported by that library. Legacy support is provided for sqlite3.Connection objects. The user is responsible for engine disposal and connection closure for the SQLAlchemy connectable See here.

schema [str, optional] Specify the schema (if database flavor supports this). If None, use default schema.

if_exists [{'fail', 'replace', 'append'}, default 'fail'] How to behave if the table already exists.

- fail: Raise a ValueError.
- replace: Drop the table before inserting new values.
- append: Insert new values to the existing table.

index [bool, default True] Write DataFrame index as a column. Uses *index_label* as the column name in the table.

index_label [str or sequence, default None] Column label for index column(s). If None is given (default) and *index* is True, then the index names are used. A sequence should be given if the DataFrame uses MultiIndex.

chunksize [int, optional] Specify the number of rows in each batch to be written at a time. By default, all rows will be written at once.

dtype [dict or scalar, optional] Specifying the datatype for columns. If a dictionary is used, the keys should be the column names and the values should be the SQLAlchemy types or strings for the sqlite3 legacy mode. If a scalar is provided, it will be applied to all columns.

method [{None, 'multi', callable}, optional] Controls the SQL insertion clause used:

- None : Uses standard SQL `INSERT` clause (one per row).
- 'multi': Pass multiple values in a single `INSERT` clause.
- callable with signature `(pd_table, conn, keys, data_iter)`.

Details and a sample callable implementation can be found in the section *insert method*.

New in version 0.24.0.

Raises

ValueError When the table already exists and *if_exists* is 'fail' (the default).

See also:

read_sql Read a DataFrame from a table.

Notes

Timezone aware datetime columns will be written as `Timestamp with timezone` type with SQLAlchemy if supported by the database. Otherwise, the datetimes will be stored as timezone unaware timestamps local to the original timezone.

New in version 0.24.0.

References

[1], [2]

Examples

Create an in-memory SQLite database.

```
>>> from sqlalchemy import create_engine
>>> engine = create_engine('sqlite://', echo=False)
```

Create a table from scratch with 3 rows.

```
>>> df = pd.DataFrame({'name' : ['User 1', 'User 2', 'User 3']})
>>> df
     name
0  User 1
1  User 2
2  User 3
```

```
>>> df.to_sql('users', con=engine)
>>> engine.execute("SELECT * FROM users").fetchall()
[(0, 'User 1'), (1, 'User 2'), (2, 'User 3')]
```

An *sqlalchemy.engine.Connection* can also be passed to to *con*: >>> with engine.begin() as connection: ... df1 = pd.DataFrame({'name' : ['User 4', 'User 5']}) ... df1.to_sql('users', con=connection, if_exists='append')

This is allowed to support operations that require that the same DBAPI connection is used for the entire operation.

```
>>> df2 = pd.DataFrame({'name' : ['User 6', 'User 7']})
>>> df2.to_sql('users', con=engine, if_exists='append')
>>> engine.execute("SELECT * FROM users").fetchall()
[(0, 'User 1'), (1, 'User 2'), (2, 'User 3'),
 (0, 'User 4'), (1, 'User 5'), (0, 'User 6'),
 (1, 'User 7')]
```

Overwrite the table with just `df2`.

```
>>> df2.to_sql('users', con=engine, if_exists='replace',
...            index_label='id')
>>> engine.execute("SELECT * FROM users").fetchall()
[(0, 'User 6'), (1, 'User 7')]
```

Specify the dtype (especially useful for integers with missing values). Notice that while pandas is forced to store the data as floating point, the database supports nullable integers. When fetching the data with Python, we get back integer scalars.

```
>>> df = pd.DataFrame({"A": [1, None, 2]})
>>> df
     A
0  1.0
1  NaN
2  2.0
```

```
>>> from sqlalchemy.types import Integer
>>> df.to_sql('integers', con=engine, index=False,
...           dtype={"A": Integer()})
```

```
>>> engine.execute("SELECT * FROM integers").fetchall()
[(1,), (None,), (2,)]
```

pandas.DataFrame.to_stata

`DataFrame.`**`to_stata`**`(`*`**kwargs`*`)`

Export DataFrame object to Stata dta format.

Writes the DataFrame to a Stata dataset file. "dta" files contain a Stata dataset.

Parameters

path [str, buffer or path object] String, path object (pathlib.Path or py._path.local.LocalPath) or object implementing a binary write() function. If using a buffer then the buffer will not be automatically closed after the file data has been written.

Changed in version 1.0.0.

Previously this was "fname"

convert_dates [dict] Dictionary mapping columns containing datetime types to stata internal format to use when writing the dates. Options are 'tc', 'td', 'tm', 'tw', 'th', 'tq', 'ty'. Column can be either an integer or a name. Datetime columns that do not have a conversion type specified will be converted to 'tc'. Raises NotImplementedError if a datetime column has timezone information.

write_index [bool] Write the index to Stata dataset.

byteorder [str] Can be ">", "<", "little", or "big". default is *sys.byteorder*.

time_stamp [datetime] A datetime to use as file creation date. Default is the current time.

data_label [str, optional] A label for the data set. Must be 80 characters or smaller.

variable_labels [dict] Dictionary containing columns as keys and variable labels as values. Each label must be 80 characters or smaller.

version [{114, 117, 118, 119, None}, default 114] Version to use in the output dta file. Set to None to let pandas decide between 118 or 119 formats depending on the number of columns in the frame. Version 114 can be read by Stata 10 and later. Version 117 can be read by Stata 13 or later. Version 118 is supported in Stata 14 and later. Version 119 is supported in Stata 15 and later. Version 114 limits string variables to 244 characters or fewer while versions 117 and later allow strings with lengths up to 2,000,000 characters. Versions 118 and 119 support Unicode characters, and version 119 supports more than 32,767 variables.

New in version 0.23.0.

Changed in version 1.0.0: Added support for formats 118 and 119.

convert_strl [list, optional] List of column names to convert to string columns to Stata StrL format. Only available if version is 117. Storing strings in the StrL format can produce smaller dta files if strings have more than 8 characters and values are repeated.

New in version 0.23.0.

compression [str or dict, default 'infer'] For on-the-fly compression of the output dta. If string, specifies compression mode. If dict, value at key 'method' specifies compression mode. Compression mode must be one of {'infer', 'gzip', 'bz2', 'zip', 'xz', None}. If compression mode is 'infer' and *fname* is path-like, then detect compression from the following extensions: '.gz', '.bz2', '.zip', or '.xz' (otherwise no compression). If dict and compression mode is one of {'zip', 'gzip', 'bz2'}, or inferred as one of the above, other entries passed as additional compression options.

New in version 1.1.0.

Raises

NotImplementedError

- If datetimes contain timezone information
- Column dtype is not representable in Stata

ValueError

- Columns listed in convert_dates are neither datetime64[ns] or datetime.datetime
- Column listed in convert_dates is not in DataFrame
- Categorical label contains more than 32,000 characters

See also:

read_stata Import Stata data files.

io.stata.StataWriter Low-level writer for Stata data files.

io.stata.StataWriter117 Low-level writer for version 117 files.

Examples

```
>>> df = pd.DataFrame({'animal': ['falcon', 'parrot', 'falcon',
...                               'parrot'],
...                    'speed': [350, 18, 361, 15]})
>>> df.to_stata('animals.dta')
```

pandas.DataFrame.to_string

DataFrame.**to_string**(*buf=None*, *columns=None*, *col_space=None*, *header=True*, *index=True*, *na_rep='NaN'*, *formatters=None*, *float_format=None*, *sparsify=None*, *index_names=True*, *justify=None*, *max_rows=None*, *min_rows=None*, *max_cols=None*, *show_dimensions=False*, *decimal='.'*, *line_width=None*, *max_colwidth=None*, *encoding=None*)

Render a DataFrame to a console-friendly tabular output.

Parameters

buf [str, Path or StringIO-like, optional, default None] Buffer to write to. If None, the output is returned as a string.

columns [sequence, optional, default None] The subset of columns to write. Writes all columns by default.

col_space [int, list or dict of int, optional] The minimum width of each column.

header [bool or sequence, optional] Write out the column names. If a list of strings is given, it is assumed to be aliases for the column names.

index [bool, optional, default True] Whether to print index (row) labels.

na_rep [str, optional, default 'NaN'] String representation of NAN to use.

formatters [list, tuple or dict of one-param. functions, optional] Formatter functions to apply to columns' elements by position or name. The result of each function must be a unicode string. List/tuple must be of length equal to the number of columns.

float_format [one-parameter function, optional, default None] Formatter function to apply to columns' elements if they are floats. The result of this function must be a unicode string.

sparsify [bool, optional, default True] Set to False for a DataFrame with a hierarchical index to print every multiindex key at each row.

index_names [bool, optional, default True] Prints the names of the indexes.

justify [str, default None] How to justify the column labels. If None uses the option from the print configuration (controlled by set_option), 'right' out of the box. Valid values are

- left
- right
- center
- justify
- justify-all
- start
- end
- inherit
- match-parent
- initial
- unset.

max_rows [int, optional] Maximum number of rows to display in the console.

min_rows [int, optional] The number of rows to display in the console in a truncated repr (when number of rows is above *max_rows*).

max_cols [int, optional] Maximum number of columns to display in the console.

show_dimensions [bool, default False] Display DataFrame dimensions (number of rows by number of columns).

decimal [str, default '.'] Character recognized as decimal separator, e.g. ',' in Europe.

line_width [int, optional] Width to wrap a line in characters.

max_colwidth [int, optional] Max width to truncate each column in characters. By default, no limit.

New in version 1.0.0.

encoding [str, default "utf-8"] Set character encoding.

New in version 1.0.

Returns

str or None If buf is None, returns the result as a string. Otherwise returns None.

See also:

`to_html` Convert DataFrame to HTML.

Examples

```
>>> d = {'col1': [1, 2, 3], 'col2': [4, 5, 6]}
>>> df = pd.DataFrame(d)
>>> print(df.to_string())
   col1  col2
0     1     4
1     2     5
2     3     6
```

pandas.DataFrame.to_timestamp

DataFrame.**to_timestamp**(*freq=None*, *how='start'*, *axis=0*, *copy=True*)

Cast to DatetimeIndex of timestamps, at *beginning* of period.

Parameters

freq [str, default frequency of PeriodIndex] Desired frequency.

how [{'s', 'e', 'start', 'end'}] Convention for converting period to timestamp; start of period vs. end.

axis [{0 or 'index', 1 or 'columns'}, default 0] The axis to convert (the index by default).

copy [bool, default True] If False then underlying input data is not copied.

Returns

DataFrame with DatetimeIndex

pandas.DataFrame.to_xarray

DataFrame.**to_xarray**()

Return an xarray object from the pandas object.

Returns

xarray.DataArray or xarray.Dataset Data in the pandas structure converted to Dataset if the object is a DataFrame, or a DataArray if the object is a Series.

See also:

DataFrame.to_hdf Write DataFrame to an HDF5 file.

DataFrame.to_parquet Write a DataFrame to the binary parquet format.

Notes

See the xarray docs

Examples

```
>>> df = pd.DataFrame([('falcon', 'bird', 389.0, 2),
...                    ('parrot', 'bird', 24.0, 2),
...                    ('lion', 'mammal', 80.5, 4),
...                    ('monkey', 'mammal', np.nan, 4)],
...                   columns=['name', 'class', 'max_speed',
...                            'num_legs'])
>>> df
     name   class  max_speed  num_legs
0  falcon    bird      389.0         2
1  parrot    bird       24.0         2
2    lion  mammal       80.5         4
3  monkey  mammal        NaN         4
```

```
>>> df.to_xarray()
<xarray.Dataset>
Dimensions:    (index: 4)
Coordinates:
  * index      (index) int64 0 1 2 3
Data variables:
    name       (index) object 'falcon' 'parrot' 'lion' 'monkey'
    class      (index) object 'bird' 'bird' 'mammal' 'mammal'
    max_speed  (index) float64 389.0 24.0 80.5 nan
    num_legs   (index) int64 2 2 4 4
```

```
>>> df['max_speed'].to_xarray()
<xarray.DataArray 'max_speed' (index: 4)>
array([389. ,  24. ,  80.5,   nan])
Coordinates:
  * index    (index) int64 0 1 2 3
```

```
>>> dates = pd.to_datetime(['2018-01-01', '2018-01-01',
...                         '2018-01-02', '2018-01-02'])
>>> df_multiindex = pd.DataFrame({'date': dates,
...                               'animal': ['falcon', 'parrot',
...                                          'falcon', 'parrot'],
...                               'speed': [350, 18, 361, 15]})
>>> df_multiindex = df_multiindex.set_index(['date', 'animal'])
```

```
>>> df_multiindex
                   speed
date       animal
2018-01-01 falcon    350
           parrot     18
2018-01-02 falcon    361
           parrot     15
```

```
>>> df_multiindex.to_xarray()
<xarray.Dataset>
```

(continues on next page)

(continued from previous page)

```

Coordinates:
  * date     (date) datetime64[ns] 2018-01-01 2018-01-02
  * animal   (animal) object 'falcon' 'parrot'
Data variables:
    speed    (date, animal) int64 350 18 361 15
```

pandas.DataFrame.transform

DataFrame.**transform**(*func*, *axis=0*, **args*, ***kwargs*)

Call `func` on self producing a DataFrame with transformed values.

Produced DataFrame will have same axis length as self.

Parameters

func [function, str, list or dict] Function to use for transforming the data. If a function, must either work when passed a DataFrame or when passed to DataFrame.apply.

Accepted combinations are:

- function
- string function name
- list of functions and/or function names, e.g. `[np.exp. 'sqrt']`
- dict of axis labels -> functions, function names or list of such.

axis [{0 or 'index', 1 or 'columns'}, default 0] If 0 or 'index': apply function to each column. If 1 or 'columns': apply function to each row.

***args** Positional arguments to pass to *func*.

****kwargs** Keyword arguments to pass to *func*.

Returns

DataFrame A DataFrame that must have the same length as self.

Raises

ValueError [If the returned DataFrame has a different length than self.]

See also:

DataFrame.agg Only perform aggregating type operations.

DataFrame.apply Invoke function on a DataFrame.

Examples

```
>>> df = pd.DataFrame({'A': range(3), 'B': range(1, 4)})
>>> df
   A  B
0  0  1
1  1  2
2  2  3
>>> df.transform(lambda x: x + 1)
   A  B
0  1  2
1  2  3
2  3  4
```

Even though the resulting DataFrame must have the same length as the input DataFrame, it is possible to provide several input functions:

```
>>> s = pd.Series(range(3))
>>> s
0    0
1    1
2    2
dtype: int64
>>> s.transform([np.sqrt, np.exp])
       sqrt        exp
0  0.000000   1.000000
1  1.000000   2.718282
2  1.414214   7.389056
```

pandas.DataFrame.transpose

DataFrame.**transpose**(**args*, *copy=False*)

Transpose index and columns.

Reflect the DataFrame over its main diagonal by writing rows as columns and vice-versa. The property *T* is an accessor to the method *transpose()*.

Parameters

***args** [tuple, optional] Accepted for compatibility with NumPy.

copy [bool, default False] Whether to copy the data after transposing, even for DataFrames with a single dtype.

Note that a copy is always required for mixed dtype DataFrames, or for DataFrames with any extension types.

Returns

DataFrame The transposed DataFrame.

See also:

numpy.transpose Permute the dimensions of a given array.

Notes

Transposing a DataFrame with mixed dtypes will result in a homogeneous DataFrame with the *object* dtype. In such a case, a copy of the data is always made.

Examples

Square DataFrame with homogeneous dtype

```
>>> d1 = {'col1': [1, 2], 'col2': [3, 4]}
>>> df1 = pd.DataFrame(data=d1)
>>> df1
   col1  col2
0     1     3
1     2     4
```

```
>>> df1_transposed = df1.T # or df1.transpose()
>>> df1_transposed
      0  1
col1  1  2
col2  3  4
```

When the dtype is homogeneous in the original DataFrame, we get a transposed DataFrame with the same dtype:

```
>>> df1.dtypes
col1    int64
col2    int64
dtype: object
>>> df1_transposed.dtypes
0    int64
1    int64
dtype: object
```

Non-square DataFrame with mixed dtypes

```
>>> d2 = {'name': ['Alice', 'Bob'],
...       'score': [9.5, 8],
...       'employed': [False, True],
...       'kids': [0, 0]}
>>> df2 = pd.DataFrame(data=d2)
>>> df2
    name  score  employed  kids
0  Alice    9.5     False     0
1    Bob    8.0      True     0
```

```
>>> df2_transposed = df2.T # or df2.transpose()
>>> df2_transposed
              0     1
name      Alice   Bob
score       9.5     8
employed  False  True
kids          0     0
```

When the DataFrame has mixed dtypes, we get a transposed DataFrame with the *object* dtype:

```
>>> df2.dtypes
name         object
score       float64
employed       bool
kids          int64
dtype: object
>>> df2_transposed.dtypes
0    object
1    object
dtype: object
```

pandas.DataFrame.truediv

DataFrame.**truediv**(*other*, *axis='columns'*, *level=None*, *fill_value=None*)

Get Floating division of dataframe and other, element-wise (binary operator *truediv*).

Equivalent to `dataframe / other`, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, *rtruediv*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: +, -, *, /, //, %, **.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

See also:

DataFrame.add Add DataFrames.

DataFrame.sub Subtract DataFrames.

DataFrame.mul Multiply DataFrames.

DataFrame.div Divide DataFrames (float division).

DataFrame.truediv Divide DataFrames (float division).

DataFrame.floordiv Divide DataFrames (integer division).

DataFrame.mod Calculate modulo (remainder after division).

DataFrame.pow Calculate exponential power.

Notes

Mismatched indices will be unioned together.

Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                   index=['circle', 'triangle', 'rectangle'])
>>> df
           angles  degrees
circle          0      360
triangle        3      180
rectangle       4      360
```

Add a scalar with operator version which return the same results.

```
>>> df + 1
           angles  degrees
circle          1      361
triangle        4      181
rectangle       5      361
```

```
>>> df.add(1)
           angles  degrees
circle          1      361
triangle        4      181
rectangle       5      361
```

Divide by constant with reverse version.

```
>>> df.div(10)
           angles  degrees
circle        0.0     36.0
triangle      0.3     18.0
rectangle     0.4     36.0
```

```
>>> df.rdiv(10)
             angles   degrees
circle          inf  0.027778
triangle   3.333333  0.055556
rectangle  2.500000  0.027778
```

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
           angles  degrees
circle         -1      358
triangle        2      178
rectangle       3      358
```

```
>>> df.sub([1, 2], axis='columns')
           angles  degrees
circle         -1      358
triangle        2      178
rectangle       3      358
```

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...         axis='index')
           angles  degrees
circle         -1      359
triangle        2      179
rectangle       3      359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                      index=['circle', 'triangle', 'rectangle'])
>>> other
           angles
circle          0
triangle        3
rectangle       4
```

```
>>> df * other
           angles  degrees
circle          0      NaN
triangle        9      NaN
rectangle      16      NaN
```

```
>>> df.mul(other, fill_value=0)
           angles  degrees
circle          0      0.0
triangle        9      0.0
rectangle      16      0.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                              'degrees': [360, 180, 360, 360, 540, 720]},
...                             index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                    ['circle', 'triangle', 'rectangle',
...                                     'square', 'pentagon', 'hexagon']])
>>> df_multindex
             angles  degrees
A circle          0      360
  triangle        3      180
  rectangle       4      360
B square          4      360
  pentagon        5      540
  hexagon         6      720
```

```
>>> df.div(df_multindex, level=1, fill_value=0)
             angles  degrees
A circle        NaN      1.0
  triangle      1.0      1.0
  rectangle     1.0      1.0
B square        0.0      0.0
  pentagon      0.0      0.0
  hexagon       0.0      0.0
```

pandas.DataFrame.truncate

DataFrame.**truncate**(*before=None*, *after=None*, *axis=None*, *copy=True*)

Truncate a Series or DataFrame before and after some index value.

This is a useful shorthand for boolean indexing based on index values above or below certain thresholds.

Parameters

before [date, str, int] Truncate all rows before this index value.

after [date, str, int] Truncate all rows after this index value.

axis [{0 or 'index', 1 or 'columns'}, optional] Axis to truncate. Truncates the index (rows) by default.

copy [bool, default is True,] Return a copy of the truncated section.

Returns

type of caller The truncated Series or DataFrame.

See also:

DataFrame.loc Select a subset of a DataFrame by label.

DataFrame.iloc Select a subset of a DataFrame by position.

Notes

If the index being truncated contains only datetime values, *before* and *after* may be specified as strings instead of Timestamps.

Examples

```
>>> df = pd.DataFrame({'A': ['a', 'b', 'c', 'd', 'e'],
...                    'B': ['f', 'g', 'h', 'i', 'j'],
...                    'C': ['k', 'l', 'm', 'n', 'o']},
...                   index=[1, 2, 3, 4, 5])
>>> df
   A  B  C
1  a  f  k
2  b  g  l
3  c  h  m
4  d  i  n
5  e  j  o
```

```
>>> df.truncate(before=2, after=4)
   A  B  C
2  b  g  l
3  c  h  m
4  d  i  n
```

The columns of a DataFrame can be truncated.

```
>>> df.truncate(before="A", after="B", axis="columns")
   A  B
1  a  f
2  b  g
3  c  h
4  d  i
5  e  j
```

For Series, only rows can be truncated.

```
>>> df['A'].truncate(before=2, after=4)
2    b
3    c
4    d
Name: A, dtype: object
```

The index values in `truncate` can be datetimes or string dates.

```
>>> dates = pd.date_range('2016-01-01', '2016-02-01', freq='s')
>>> df = pd.DataFrame(index=dates, data={'A': 1})
>>> df.tail()
                     A
2016-01-31 23:59:56  1
2016-01-31 23:59:57  1
2016-01-31 23:59:58  1
2016-01-31 23:59:59  1
2016-02-01 00:00:00  1
```

```
>>> df.truncate(before=pd.Timestamp('2016-01-05'),
...             after=pd.Timestamp('2016-01-10')).tail()
                     A
2016-01-09 23:59:56  1
2016-01-09 23:59:57  1
2016-01-09 23:59:58  1
2016-01-09 23:59:59  1
2016-01-10 00:00:00  1
```

Because the index is a DatetimeIndex containing only dates, we can specify *before* and *after* as strings. They will be coerced to Timestamps before truncation.

```
>>> df.truncate('2016-01-05', '2016-01-10').tail()
                     A
2016-01-09 23:59:56  1
2016-01-09 23:59:57  1
2016-01-09 23:59:58  1
2016-01-09 23:59:59  1
2016-01-10 00:00:00  1
```

Note that `truncate` assumes a 0 value for any unspecified time component (midnight). This differs from partial string slicing, which returns any partially matching dates.

```
>>> df.loc['2016-01-05':'2016-01-10', :].tail()
                     A
2016-01-10 23:59:55  1
2016-01-10 23:59:56  1
2016-01-10 23:59:57  1
```

(continues on next page)

(continued from previous page)

```
2016-01-10 23:59:58  1
2016-01-10 23:59:59  1
```

pandas.DataFrame.tshift

DataFrame.**tshift**(*periods=1*, *freq=None*, *axis=0*)

Shift the time index, using the index's frequency if available.

Deprecated since version 1.1.0: Use *shift* instead.

Parameters

periods [int] Number of periods to move, can be positive or negative.

freq [DateOffset, timedelta, or str, default None] Increment to use from the tseries module or time rule expressed as a string (e.g. 'EOM').

axis [{0 or 'index', 1 or 'columns', None}, default 0] Corresponds to the axis that contains the Index.

Returns

shifted [Series/DataFrame]

Notes

If freq is not specified then tries to use the freq or inferred_freq attributes of the index. If neither of those attributes exist, a ValueError is thrown

pandas.DataFrame.tz_convert

DataFrame.**tz_convert**(*tz*, *axis=0*, *level=None*, *copy=True*)

Convert tz-aware axis to target time zone.

Parameters

tz [str or tzinfo object]

axis [the axis to convert]

level [int, str, default None] If axis is a MultiIndex, convert a specific level. Otherwise must be None.

copy [bool, default True] Also make a copy of the underlying data.

Returns

{klass} Object with time zone converted axis.

Raises

TypeError If the axis is tz-naive.

pandas.DataFrame.tz_localize

DataFrame.**tz_localize**(*tz*, *axis=0*, *level=None*, *copy=True*, *ambiguous='raise'*, *nonexistent='raise'*)

Localize tz-naive index of a Series or DataFrame to target time zone.

This operation localizes the Index. To localize the values in a timezone-naive Series, use *Series.dt.tz_localize()*.

Parameters

tz [str or tzinfo]

axis [the axis to localize]

level [int, str, default None] If axis ia a MultiIndex, localize a specific level. Otherwise must be None.

copy [bool, default True] Also make a copy of the underlying data.

ambiguous ['infer', bool-ndarray, 'NaT', default 'raise'] When clocks moved backward due to DST, ambiguous times may arise. For example in Central European Time (UTC+01), when going from 03:00 DST to 02:00 non-DST, 02:30:00 local time occurs both at 00:30:00 UTC and at 01:30:00 UTC. In such a situation, the *ambiguous* parameter dictates how ambiguous times should be handled.

- 'infer' will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- 'NaT' will return NaT where there are ambiguous times
- 'raise' will raise an AmbiguousTimeError if there are ambiguous times.

nonexistent [str, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST. Valid values are:

- 'shift_forward' will shift the nonexistent time forward to the closest existing time
- 'shift_backward' will shift the nonexistent time backward to the closest existing time
- 'NaT' will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- 'raise' will raise an NonExistentTimeError if there are nonexistent times.

New in version 0.24.0.

Returns

Series or DataFrame Same type as the input.

Raises

TypeError If the TimeSeries is tz-aware and tz is not None.

Examples

Localize local times:

```
>>> s = pd.Series([1],
...               index=pd.DatetimeIndex(['2018-09-15 01:30:00']))
>>> s.tz_localize('CET')
2018-09-15 01:30:00+02:00    1
dtype: int64
```

Be careful with DST changes. When there is sequential data, pandas can infer the DST time:

```
>>> s = pd.Series(range(7),
...               index=pd.DatetimeIndex(['2018-10-28 01:30:00',
...                                       '2018-10-28 02:00:00',
...                                       '2018-10-28 02:30:00',
...                                       '2018-10-28 02:00:00',
...                                       '2018-10-28 02:30:00',
...                                       '2018-10-28 03:00:00',
...                                       '2018-10-28 03:30:00']))
>>> s.tz_localize('CET', ambiguous='infer')

pandas.DataFrame.unstack

DataFrame.**unstack**(*level=-1*, *fill_value=None*)

Pivot a level of the (necessarily hierarchical) index labels.

Returns a DataFrame having a new level of column labels whose inner-most level consists of the pivoted index labels.

If the index is not a MultiIndex, the output will be a Series (the analogue of stack when the columns are not a MultiIndex).

Parameters

level [int, str, or list of these, default -1 (last level)] Level(s) of index to unstack, can pass level name.

fill_value [int, str or dict] Replace NaN with this value if the unstack produces missing values.

Returns

Series or DataFrame

See also:

DataFrame.pivot Pivot a table based on column values.

DataFrame.stack Pivot a level of the column labels (inverse operation from *unstack*).

Examples

```
>>> index = pd.MultiIndex.from_tuples([('one', 'a'), ('one', 'b'),
...                                    ('two', 'a'), ('two', 'b')])
>>> s = pd.Series(np.arange(1.0, 5.0), index=index)
>>> s
one  a   1.0
     b   2.0
two  a   3.0
     b   4.0
dtype: float64
```

```
>>> s.unstack(level=-1)
     a   b
one  1.0  2.0
two  3.0  4.0
```

```
>>> s.unstack(level=0)
   one  two
a  1.0   3.0
b  2.0   4.0
```

```
>>> df = s.unstack(level=0)
>>> df.unstack()
one  a  1.0
     b  2.0
two  a  3.0
     b  4.0
dtype: float64
```

pandas.DataFrame.update

DataFrame.**update**(*other*, *join='left'*, *overwrite=True*, *filter_func=None*, *errors='ignore'*)

Modify in place using non-NA values from another DataFrame.

Aligns on indices. There is no return value.

Parameters

other [DataFrame, or object coercible into a DataFrame] Should have at least one matching index/column label with the original DataFrame. If a Series is passed, its name attribute must be set, and that will be used as the column name to align with the original DataFrame.

join [{'left'}, default 'left'] Only left join is implemented, keeping the index and columns of the original object.

overwrite [bool, default True] How to handle non-NA values for overlapping keys:

- True: overwrite original DataFrame's values with values from *other*.
- False: only update values that are NA in the original DataFrame.

filter_func [callable(1d-array) -> bool 1d-array, optional] Can choose to replace values other than NA. Return True for values that should be updated.

errors [{'raise', 'ignore'}, default 'ignore'] If 'raise', will raise a ValueError if the DataFrame and *other* both contain non-NA data in the same place.

Changed in version 0.24.0: Changed from *raise_conflict=False|True* to *errors='ignore'|'raise'*.

Returns

None [method directly changes calling object]

Raises

ValueError

- When *errors='raise'* and there's overlapping non-NA data.
- When *errors* is not either *'ignore'* or *'raise'*

NotImplementedError

- If *join != 'left'*

See also:

dict.update Similar method for dictionaries.

DataFrame.merge For column(s)-on-columns(s) operations.

Examples

```
>>> df = pd.DataFrame({'A': [1, 2, 3],
...                    'B': [400, 500, 600]})
>>> new_df = pd.DataFrame({'B': [4, 5, 6],
...                        'C': [7, 8, 9]})
>>> df.update(new_df)
>>> df
   A  B
0  1  4
1  2  5
2  3  6
```

The DataFrame's length does not increase as a result of the update, only values at matching index/column labels are updated.

```
>>> df = pd.DataFrame({'A': ['a', 'b', 'c'],
...                    'B': ['x', 'y', 'z']})
>>> new_df = pd.DataFrame({'B': ['d', 'e', 'f', 'g', 'h', 'i']})
>>> df.update(new_df)
>>> df
   A  B
0  a  d
1  b  e
2  c  f
```

For Series, it's name attribute must be set.

```
>>> df = pd.DataFrame({'A': ['a', 'b', 'c'],
...                    'B': ['x', 'y', 'z']})
>>> new_column = pd.Series(['d', 'e'], name='B', index=[0, 2])
>>> df.update(new_column)
>>> df
   A  B
0  a  d
1  b  y
2  c  e
>>> df = pd.DataFrame({'A': ['a', 'b', 'c'],
...                    'B': ['x', 'y', 'z']})
>>> new_df = pd.DataFrame({'B': ['d', 'e']}, index=[1, 2])
>>> df.update(new_df)
>>> df
   A  B
0  a  x
1  b  d
2  c  e
```

If *other* contains NaNs the corresponding values are not updated in the original dataframe.

```
>>> df = pd.DataFrame({'A': [1, 2, 3],
...                    'B': [400, 500, 600]})
>>> new_df = pd.DataFrame({'B': [4, np.nan, 6]})
>>> df.update(new_df)
>>> df
   A      B
0  1    4.0
1  2  500.0
2  3    6.0
```

pandas.DataFrame.value_counts

DataFrame.**value_counts**(*subset=None*, *normalize=False*, *sort=True*, *ascending=False*)

Return a Series containing counts of unique rows in the DataFrame.

New in version 1.1.0.

Parameters

subset [list-like, optional] Columns to use when counting unique combinations.

normalize [bool, default False] Return proportions rather than frequencies.

sort [bool, default True] Sort by frequencies.

ascending [bool, default False] Sort in ascending order.

Returns

Series

See also:

Series.value_counts Equivalent method on Series.

Notes

The returned Series will have a MultiIndex with one level per input column. By default, rows that contain any NA values are omitted from the result. By default, the resulting Series will be in descending order so that the first element is the most frequently-occurring row.

Examples

```
>>> df = pd.DataFrame({'num_legs': [2, 4, 4, 6],
...                    'num_wings': [2, 0, 0, 0]},
...                   index=['falcon', 'dog', 'cat', 'ant'])
>>> df
        num_legs  num_wings
falcon         2          2
dog            4          0
cat            4          0
ant            6          0
```

```
>>> df.value_counts()
num_legs  num_wings
4         0            2
6         0            1
2         2            1
dtype: int64
```

```
>>> df.value_counts(sort=False)
num_legs  num_wings
2         2            1
4         0            2
6         0            1
dtype: int64
```

```
>>> df.value_counts(ascending=True)
num_legs  num_wings
2         2            1
6         0            1
4         0            2
dtype: int64
```

```
>>> df.value_counts(normalize=True)
num_legs  num_wings
4         0            0.50
6         0            0.25
2         2            0.25
dtype: float64
```

pandas.DataFrame.var

DataFrame.**var**(*axis=None*, *skipna=None*, *level=None*, *ddof=1*, *numeric_only=None*, ***kwargs*)

Return unbiased variance over requested axis.

Normalized by N-1 by default. This can be changed using the ddof argument

Parameters

axis [{index (0), columns (1)}]

skipna [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

ddof [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is N - ddof, where N represents the number of elements.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

Returns

Series or DataFrame (if level specified)

pandas.DataFrame.where

DataFrame.**where**(*cond*, *other=nan*, *inplace=False*, *axis=None*, *level=None*, *errors='raise'*, *try_cast=False*)

Replace values where the condition is False.

Parameters

cond [bool Series/DataFrame, array-like, or callable] Where *cond* is True, keep the original value. Where False, replace with corresponding value from *other*. If *cond* is callable, it is computed on the Series/DataFrame and should return boolean Series/DataFrame or array. The callable must not change input Series/DataFrame (though pandas doesn't check it).

other [scalar, Series/DataFrame, or callable] Entries where *cond* is False are replaced with corresponding value from *other*. If other is callable, it is computed on the

Series/DataFrame and should return scalar or Series/DataFrame. The callable must not change input Series/DataFrame (though pandas doesn't check it).

inplace [bool, default False] Whether to perform the operation in place on the data.

axis [int, default None] Alignment axis if needed.

level [int, default None] Alignment level if needed.

errors [str, {'raise', 'ignore'}, default 'raise'] Note that currently this parameter won't affect the results and will always coerce to a suitable dtype.

- 'raise' : allow exceptions to be raised.
- 'ignore' : suppress exceptions. On error return original object.

try_cast [bool, default False] Try to cast the result back to the input type (if possible).

Returns

Same type as caller

See also:

DataFrame.mask() Return an object of same shape as self.

Notes

The where method is an application of the if-then idiom. For each element in the calling DataFrame, if `cond` is `True` the element is used; otherwise the corresponding element from the DataFrame `other` is used.

The signature for *DataFrame.where()* differs from `numpy.where()`. Roughly `df1.where(m, df2)` is equivalent to `np.where(m, df1, df2)`.

For further details and examples see the `where` documentation in *indexing*.

Examples

```
>>> s = pd.Series(range(5))
>>> s.where(s > 0)
0    NaN
1    1.0
2    2.0
3    3.0
4    4.0
dtype: float64
```

```
>>> s.mask(s > 0)
0    0.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

```
>>> s.where(s > 1, 10)
0    10
1    10
2    2
3    3
4    4
dtype: int64
```

```
>>> df = pd.DataFrame(np.arange(10).reshape(-1, 2), columns=['A', 'B'])
>>> df
   A  B
0  0  1
1  2  3
2  4  5
3  6  7
4  8  9
>>> m = df % 3 == 0
>>> df.where(m, -df)
   A  B
0  0 -1
1 -2  3
2 -4 -5
3  6 -7
4 -8  9
>>> df.where(m, -df) == np.where(m, df, -df)
      A     B
0  True  True
1  True  True
2  True  True
3  True  True
4  True  True
>>> df.where(m, -df) == df.mask(~m, -df)
      A     B
0  True  True
1  True  True
2  True  True
3  True  True
4  True  True
```

pandas.DataFrame.xs

DataFrame.**xs**(*key*, *axis=0*, *level=None*, *drop_level=True*)

Return cross-section from the Series/DataFrame.

This method takes a *key* argument to select data at a particular level of a MultiIndex.

Parameters

key [label or tuple of label] Label contained in the index, or partially in a MultiIndex.

axis [{0 or 'index', 1 or 'columns'}, default 0] Axis to retrieve cross-section on.

level [object, defaults to first n levels (n=1 or len(key))] In case of a key partially contained in a MultiIndex, indicate which levels are used. Levels can be referred by label or position.

drop_level [bool, default True] If False, returns object with same levels as self.

Returns

Series or DataFrame Cross-section from the original Series or DataFrame corresponding to the selected index levels.

See also:

DataFrame.loc Access a group of rows and columns by label(s) or a boolean array.

DataFrame.iloc Purely integer-location based indexing for selection by position.

Notes

xs can not be used to set values.

MultiIndex Slicers is a generic way to get/set values on any level or levels. It is a superset of *xs* functionality, see *MultiIndex Slicers*.

Examples

```
>>> d = {'num_legs': [4, 4, 2, 2],
...      'num_wings': [0, 0, 2, 2],
...      'class': ['mammal', 'mammal', 'mammal', 'bird'],
...      'animal': ['cat', 'dog', 'bat', 'penguin'],
...      'locomotion': ['walks', 'walks', 'flies', 'walks']}
>>> df = pd.DataFrame(data=d)
>>> df = df.set_index(['class', 'animal', 'locomotion'])
>>> df
                           num_legs  num_wings
class  animal  locomotion
mammal cat     walks              4          0
       dog     walks              4          0
       bat     flies              2          2
bird   penguin walks              2          2
```

Get values at specified index

```
>>> df.xs('mammal')
                    num_legs  num_wings
animal locomotion
cat    walks              4          0
dog    walks              4          0
bat    flies              2          2
```

Get values at several indexes

```
>>> df.xs(('mammal', 'dog'))
            num_legs  num_wings
locomotion
walks              4          0
```

Get values at specified index and level

```
>>> df.xs('cat', level=1)
                    num_legs  num_wings
class  locomotion
mammal walks              4          0
```

Get values at several indexes and levels

```
>>> df.xs(('bird', 'walks'),
...       level=[0, 'locomotion'])
         num_legs  num_wings
animal
penguin         2          2
```

Get values at specified column and axis

```
>>> df.xs('num_wings', axis=1)
class   animal   locomotion
mammal  cat      walks         0
        dog      walks         0
        bat      flies         2
bird    penguin  walks         2
Name: num_wings, dtype: int64
```

3.4.2 Attributes and underlying data

Axes

DataFrame.index	The index (row labels) of the DataFrame.
DataFrame.columns	The column labels of the DataFrame.

DataFrame.dtypes	Return the dtypes in the DataFrame.
DataFrame.info([verbose, buf, max_cols, ...])	Print a concise summary of a DataFrame.
DataFrame.select_dtypes([include, exclude])	Return a subset of the DataFrame's columns based on the column dtypes.
DataFrame.values	Return a Numpy representation of the DataFrame.
DataFrame.axes	Return a list representing the axes of the DataFrame.
DataFrame.ndim	Return an int representing the number of axes / array dimensions.
DataFrame.size	Return an int representing the number of elements in this object.
DataFrame.shape	Return a tuple representing the dimensionality of the DataFrame.
DataFrame.memory_usage([index, deep])	Return the memory usage of each column in bytes.
DataFrame.empty	Indicator whether DataFrame is empty.

3.4.3 Conversion

DataFrame.astype(dtype[, copy, errors])	Cast a pandas object to a specified dtype `dtype`.
DataFrame.convert_dtypes([infer_objects, ...])	Convert columns to best possible dtypes using dtypes supporting `pd.NA`.
DataFrame.infer_objects()	Attempt to infer better dtypes for object columns.
DataFrame.copy([deep])	Make a copy of this object's indices and data.
DataFrame.bool()	Return the bool of a single element Series or DataFrame.

3.4.4 Indexing, iteration

DataFrame.head([n])	Return the first *n* rows.
DataFrame.at	Access a single value for a row/column label pair.
DataFrame.iat	Access a single value for a row/column pair by integer position.
DataFrame.loc	Access a group of rows and columns by label(s) or a boolean array.
DataFrame.iloc	Purely integer-location based indexing for selection by position.
DataFrame.insert(loc, column, value[, ...])	Insert column into DataFrame at specified location.
DataFrame.__iter__()	Iterate over info axis.
DataFrame.items()	Iterate over (column name, Series) pairs.
DataFrame.iteritems()	Iterate over (column name, Series) pairs.
DataFrame.keys()	Get the 'info axis' (see Indexing for more).
DataFrame.iterrows()	Iterate over DataFrame rows as (index, Series) pairs.
DataFrame.itertuples([index, name])	Iterate over DataFrame rows as namedtuples.
DataFrame.lookup(row_labels, col_labels)	Label-based "fancy indexing" function for DataFrame.
DataFrame.pop(item)	Return item and drop from frame.
DataFrame.tail([n])	Return the last *n* rows.
DataFrame.xs(key[, axis, level, drop_level])	Return cross-section from the Series/DataFrame.
DataFrame.get(key[, default])	Get item from object for given key (ex: DataFrame column).
DataFrame.isin(values)	Whether each element in the DataFrame is contained in values.
DataFrame.where(cond[, other, inplace, ...])	Replace values where the condition is False.
DataFrame.mask(cond[, other, inplace, axis, ...])	Replace values where the condition is True.
DataFrame.query(expr[, inplace])	Query the columns of a DataFrame with a boolean expression.

pandas.DataFrame.__iter__

DataFrame.**__iter__**()

Iterate over info axis.

Returns

iterator Info axis as iterator.

For more information on `.at`, `.iat`, `.loc`, and `.iloc`, see the *indexing documentation*.

3.4.5 Binary operator functions

DataFrame.add(other[, axis, level, fill_value])	Get Addition of dataframe and other, element-wise (binary operator *add*).
DataFrame.sub(other[, axis, level, fill_value])	Get Subtraction of dataframe and other, element-wise (binary operator *sub*).
DataFrame.mul(other[, axis, level, fill_value])	Get Multiplication of dataframe and other, element-wise (binary operator *mul*).
DataFrame.div(other[, axis, level, fill_value])	Get Floating division of dataframe and other, element-wise (binary operator *truediv*).

continues on next page

Table 64 – continued from previous page

DataFrame.truediv(other[, axis, level, ...])	Get Floating division of dataframe and other, element-wise (binary operator *truediv*).
DataFrame.floordiv(other[, axis, level, ...])	Get Integer division of dataframe and other, element-wise (binary operator *floordiv*).
DataFrame.mod(other[, axis, level, fill_value])	Get Modulo of dataframe and other, element-wise (binary operator *mod*).
DataFrame.pow(other[, axis, level, fill_value])	Get Exponential power of dataframe and other, element-wise (binary operator *pow*).
DataFrame.dot(other)	Compute the matrix multiplication between the DataFrame and other.
DataFrame.radd(other[, axis, level, fill_value])	Get Addition of dataframe and other, element-wise (binary operator *radd*).
DataFrame.rsub(other[, axis, level, fill_value])	Get Subtraction of dataframe and other, element-wise (binary operator *rsub*).
DataFrame.rmul(other[, axis, level, fill_value])	Get Multiplication of dataframe and other, element-wise (binary operator *rmul*).
DataFrame.rdiv(other[, axis, level, fill_value])	Get Floating division of dataframe and other, element-wise (binary operator *rtruediv*).
DataFrame.rtruediv(other[, axis, level, ...])	Get Floating division of dataframe and other, element-wise (binary operator *rtruediv*).
DataFrame.rfloordiv(other[, axis, level, ...])	Get Integer division of dataframe and other, element-wise (binary operator *rfloordiv*).
DataFrame.rmod(other[, axis, level, fill_value])	Get Modulo of dataframe and other, element-wise (binary operator *rmod*).
DataFrame.rpow(other[, axis, level, fill_value])	Get Exponential power of dataframe and other, element-wise (binary operator *rpow*).
DataFrame.lt(other[, axis, level])	Get Less than of dataframe and other, element-wise (binary operator *lt*).
DataFrame.gt(other[, axis, level])	Get Greater than of dataframe and other, element-wise (binary operator *gt*).
DataFrame.le(other[, axis, level])	Get Less than or equal to of dataframe and other, element-wise (binary operator *le*).
DataFrame.ge(other[, axis, level])	Get Greater than or equal to of dataframe and other, element-wise (binary operator *ge*).
DataFrame.ne(other[, axis, level])	Get Not equal to of dataframe and other, element-wise (binary operator *ne*).
DataFrame.eq(other[, axis, level])	Get Equal to of dataframe and other, element-wise (binary operator *eq*).
DataFrame.combine(other, func[, fill_value, ...])	Perform column-wise combine with another DataFrame.
DataFrame.combine_first(other)	Update null elements with value in the same location in *other*.

3.4.6 Function application, GroupBy & window

DataFrame.apply(func[, axis, raw, ...])	Apply a function along an axis of the DataFrame.
DataFrame.applymap(func)	Apply a function to a Dataframe elementwise.
DataFrame.pipe(func, *args, **kwargs)	Apply func(self, *args, **kwargs).
DataFrame.agg([func, axis])	Aggregate using one or more operations over the specified axis.
DataFrame.aggregate([func, axis])	Aggregate using one or more operations over the specified axis.
DataFrame.transform(func[, axis])	Call `func` on self producing a DataFrame with transformed values.
DataFrame.groupby([by, axis, level, ...])	Group DataFrame using a mapper or by a Series of columns.
DataFrame.rolling(window[, min_periods, ...])	Provide rolling window calculations.
DataFrame.expanding([min_periods, center, axis])	Provide expanding transformations.
DataFrame.ewm([com, span, halflife, alpha, ...])	Provide exponential weighted (EW) functions.

3.4.7 Computations / descriptive stats

DataFrame.abs()	Return a Series/DataFrame with absolute numeric value of each element.
DataFrame.all([axis, bool_only, skipna, level])	Return whether all elements are True, potentially over an axis.
DataFrame.any([axis, bool_only, skipna, level])	Return whether any element is True, potentially over an axis.
DataFrame.clip([lower, upper, axis, inplace])	Trim values at input threshold(s).
DataFrame.corr([method, min_periods])	Compute pairwise correlation of columns, excluding NA/null values.
DataFrame.corrwith(other[, axis, drop, method])	Compute pairwise correlation.
DataFrame.count([axis, level, numeric_only])	Count non-NA cells for each column or row.
DataFrame.cov([min_periods, ddof])	Compute pairwise covariance of columns, excluding NA/null values.
DataFrame.cummax([axis, skipna])	Return cumulative maximum over a DataFrame or Series axis.
DataFrame.cummin([axis, skipna])	Return cumulative minimum over a DataFrame or Series axis.
DataFrame.cumprod([axis, skipna])	Return cumulative product over a DataFrame or Series axis.
DataFrame.cumsum([axis, skipna])	Return cumulative sum over a DataFrame or Series axis.
DataFrame.describe([percentiles, include, ...])	Generate descriptive statistics.
DataFrame.diff([periods, axis])	First discrete difference of element.
DataFrame.eval(expr[, inplace])	Evaluate a string describing operations on DataFrame columns.
DataFrame.kurt([axis, skipna, level, ...])	Return unbiased kurtosis over requested axis.
DataFrame.kurtosis([axis, skipna, level, ...])	Return unbiased kurtosis over requested axis.
DataFrame.mad([axis, skipna, level])	Return the mean absolute deviation of the values for the requested axis.

continues on next page

Table 66 – continued from previous page

DataFrame.max([axis, skipna, level, ...])	Return the maximum of the values for the requested axis.
DataFrame.mean([axis, skipna, level, ...])	Return the mean of the values for the requested axis.
DataFrame.median([axis, skipna, level, ...])	Return the median of the values for the requested axis.
DataFrame.min([axis, skipna, level, ...])	Return the minimum of the values for the requested axis.
DataFrame.mode([axis, numeric_only, dropna])	Get the mode(s) of each element along the selected axis.
DataFrame.pct_change([periods, fill_method, ...])	Percentage change between the current and a prior element.
DataFrame.prod([axis, skipna, level, ...])	Return the product of the values for the requested axis.
DataFrame.product([axis, skipna, level, ...])	Return the product of the values for the requested axis.
DataFrame.quantile([q, axis, numeric_only, ...])	Return values at the given quantile over requested axis.
DataFrame.rank([axis, method, numeric_only, ...])	Compute numerical data ranks (1 through n) along axis.
DataFrame.round([decimals])	Round a DataFrame to a variable number of decimal places.
DataFrame.sem([axis, skipna, level, ddof, ...])	Return unbiased standard error of the mean over requested axis.
DataFrame.skew([axis, skipna, level, ...])	Return unbiased skew over requested axis.
DataFrame.sum([axis, skipna, level, ...])	Return the sum of the values for the requested axis.
DataFrame.std([axis, skipna, level, ddof, ...])	Return sample standard deviation over requested axis.
DataFrame.var([axis, skipna, level, ddof, ...])	Return unbiased variance over requested axis.
DataFrame.nunique([axis, dropna])	Count distinct observations over requested axis.
DataFrame.value_counts([subset, normalize, ...])	Return a Series containing counts of unique rows in the DataFrame.

3.4.8 Reindexing / selection / label manipulation

DataFrame.add_prefix(prefix)	Prefix labels with string *prefix*.
DataFrame.add_suffix(suffix)	Suffix labels with string *suffix*.
DataFrame.align(other[, join, axis, level, ...])	Align two objects on their axes with the specified join method.
DataFrame.at_time(time[, asof, axis])	Select values at particular time of day (e.g., 9:30AM).
DataFrame.between_time(start_time, end_time)	Select values between particular times of the day (e.g., 9:00-9:30 AM).
DataFrame.drop([labels, axis, index, ...])	Drop specified labels from rows or columns.
DataFrame.drop_duplicates([subset, keep, ...])	Return DataFrame with duplicate rows removed.
DataFrame.duplicated([subset, keep])	Return boolean Series denoting duplicate rows.
DataFrame.equals(other)	Test whether two objects contain the same elements.
DataFrame.filter([items, like, regex, axis])	Subset the dataframe rows or columns according to the specified index labels.
DataFrame.first(offset)	Select initial periods of time series data based on a date offset.
DataFrame.head([n])	Return the first *n* rows.
DataFrame.idxmax([axis, skipna])	Return index of first occurrence of maximum over requested axis.
DataFrame.idxmin([axis, skipna])	Return index of first occurrence of minimum over requested axis.

continues on next page

Table 67 – continued from previous page

DataFrame.last(offset)	Select final periods of time series data based on a date offset.
DataFrame.reindex(**kwargs)	Conform Series/DataFrame to new index with optional filling logic.
DataFrame.reindex_like(other[, method, ...])	Return an object with matching indices as other object.
DataFrame.rename(**kwargs)	Alter axes labels.
DataFrame.rename_axis(**kwargs)	Set the name of the axis for the index or columns.
DataFrame.reset_index([level, drop, ...])	Reset the index, or a level of it.
DataFrame.sample([n, frac, replace, ...])	Return a random sample of items from an axis of object.
DataFrame.set_axis(labels[, axis, inplace])	Assign desired index to given axis.
DataFrame.set_index(keys[, drop, append, ...])	Set the DataFrame index using existing columns.
DataFrame.tail([n])	Return the last *n* rows.
DataFrame.take(indices[, axis, is_copy])	Return the elements in the given *positional* indices along an axis.
DataFrame.truncate([before, after, axis, copy])	Truncate a Series or DataFrame before and after some index value.

3.4.9 Missing data handling

DataFrame.backfill([axis, inplace, limit, ...])	Synonym for DataFrame.fillna() with `method='bfill'`.
DataFrame.bfill([axis, inplace, limit, downcast])	Synonym for DataFrame.fillna() with `method='bfill'`.
DataFrame.dropna([axis, how, thresh, ...])	Remove missing values.
DataFrame.ffill([axis, inplace, limit, downcast])	Synonym for DataFrame.fillna() with `method='ffill'`.
DataFrame.fillna([value, method, axis, ...])	Fill NA/NaN values using the specified method.
DataFrame.interpolate([method, axis, limit, ...])	Please note that only `method='linear'` is supported for DataFrame/Series with a MultiIndex.
DataFrame.isna()	Detect missing values.
DataFrame.isnull()	Detect missing values.
DataFrame.notna()	Detect existing (non-missing) values.
DataFrame.notnull()	Detect existing (non-missing) values.
DataFrame.pad([axis, inplace, limit, downcast])	Synonym for DataFrame.fillna() with `method='ffill'`.
DataFrame.replace([to_replace, value, ...])	Replace values given in *to_replace* with *value*.

3.4.10 Reshaping, sorting, transposing

DataFrame.droplevel(level[, axis])	Return DataFrame with requested index / column level(s) removed.
DataFrame.pivot([index, columns, values])	Return reshaped DataFrame organized by given index / column values.
DataFrame.pivot_table([values, index, ...])	Create a spreadsheet-style pivot table as a DataFrame.
DataFrame.reorder_levels(order[, axis])	Rearrange index levels using input order.
DataFrame.sort_values(by[, axis, ascending, ...])	Sort by the values along either axis.

continues on next page

Table 69 – continued from previous page

DataFrame.sort_index([axis, level, ...])	Sort object by labels (along an axis).
DataFrame.nlargest(n, columns[, keep])	Return the first *n* rows ordered by *columns* in descending order.
DataFrame.nsmallest(n, columns[, keep])	Return the first *n* rows ordered by *columns* in ascending order.
DataFrame.swaplevel([i, j, axis])	Swap levels i and j in a MultiIndex on a particular axis.
DataFrame.stack([level, dropna])	Stack the prescribed level(s) from columns to index.
DataFrame.unstack([level, fill_value])	Pivot a level of the (necessarily hierarchical) index labels.
DataFrame.swapaxes(axis1, axis2[, copy])	Interchange axes and swap values axes appropriately.
DataFrame.melt([id_vars, value_vars, ...])	Unpivot a DataFrame from wide to long format, optionally leaving identifiers set.
DataFrame.explode(column[, ignore_index])	Transform each element of a list-like to a row, replicating index values.
DataFrame.squeeze([axis])	Squeeze 1 dimensional axis objects into scalars.
DataFrame.to_xarray()	Return an xarray object from the pandas object.
DataFrame.T	
DataFrame.transpose(*args[, copy])	Transpose index and columns.

pandas.DataFrame.T

property DataFrame.**T**

3.4.11 Combining / comparing / joining / merging

DataFrame.append(other[, ignore_index, ...])	Append rows of *other* to the end of caller, returning a new object.
DataFrame.assign(**kwargs)	Assign new columns to a DataFrame.
DataFrame.compare(other[, align_axis, ...])	Compare to another DataFrame and show the differences.
DataFrame.join(other[, on, how, lsuffix, ...])	Join columns of another DataFrame.
DataFrame.merge(right[, how, on, left_on, ...])	Merge DataFrame or named Series objects with a database-style join.
DataFrame.update(other[, join, overwrite, ...])	Modify in place using non-NA values from another DataFrame.

3.4.12 Time Series-related

DataFrame.asfreq(freq[, method, how, ...])	Convert TimeSeries to specified frequency.
DataFrame.asof(where[, subset])	Return the last row(s) without any NaNs before *where*.
DataFrame.shift([periods, freq, axis, ...])	Shift index by desired number of periods with an optional time *freq*.
DataFrame.slice_shift([periods, axis])	Equivalent to *shift* without copying data.
DataFrame.tshift([periods, freq, axis])	(DEPRECATED) Shift the time index, using the index's frequency if available.
DataFrame.first_valid_index()	Return index for first non-NA/null value.
DataFrame.last_valid_index()	Return index for last non-NA/null value.

continues on next page

Table 71 – continued from previous page

DataFrame.resample(rule[, axis, closed, ...])	Resample time-series data.
DataFrame.to_period([freq, axis, copy])	Convert DataFrame from DatetimeIndex to PeriodIndex.
DataFrame.to_timestamp([freq, how, axis, copy])	Cast to DatetimeIndex of timestamps, at *beginning* of period.
DataFrame.tz_convert(tz[, axis, level, copy])	Convert tz-aware axis to target time zone.
DataFrame.tz_localize(tz[, axis, level, ...])	Localize tz-naive index of a Series or DataFrame to target time zone.

3.4.13 Metadata

DataFrame.attrs is a dictionary for storing global metadata for this DataFrame.

Warning: DataFrame.attrs is considered experimental and may change without warning.

DataFrame.attrs	Dictionary of global attributes on this object.

3.4.14 Plotting

DataFrame.plot is both a callable method and a namespace attribute for specific plotting methods of the form DataFrame.plot.<kind>.

DataFrame.plot([x, y, kind, ax, ...])	DataFrame plotting accessor and method

DataFrame.plot.area([x, y])	Draw a stacked area plot.
DataFrame.plot.bar([x, y])	Vertical bar plot.
DataFrame.plot.barh([x, y])	Make a horizontal bar plot.
DataFrame.plot.box([by])	Make a box plot of the DataFrame columns.
DataFrame.plot.density([bw_method, ind])	Generate Kernel Density Estimate plot using Gaussian kernels.
DataFrame.plot.hexbin(x, y[, C, ...])	Generate a hexagonal binning plot.
DataFrame.plot.hist([by, bins])	Draw one histogram of the DataFrame's columns.
DataFrame.plot.kde([bw_method, ind])	Generate Kernel Density Estimate plot using Gaussian kernels.
DataFrame.plot.line([x, y])	Plot Series or DataFrame as lines.
DataFrame.plot.pie(**kwargs)	Generate a pie plot.
DataFrame.plot.scatter(x, y[, s, c])	Create a scatter plot with varying marker point size and color.

pandas.DataFrame.plot.area

DataFrame.plot.**area**(*x=None*, *y=None*, ***kwargs*)

Draw a stacked area plot.

An area plot displays quantitative data visually. This function wraps the matplotlib area function.

Parameters

x [label or position, optional] Coordinates for the X axis. By default uses the index.

y [label or position, optional] Column to plot. By default uses all columns.

stacked [bool, default True] Area plots are stacked by default. Set to False to create a unstacked plot.

****kwargs** Additional keyword arguments are documented in *DataFrame.plot()*.

Returns

matplotlib.axes.Axes or numpy.ndarray Area plot, or array of area plots if subplots is True.

See also:

DataFrame.plot Make plots of DataFrame using matplotlib / pylab.

Examples

Draw an area plot based on basic business metrics:

```
>>> df = pd.DataFrame({
...     'sales': [3, 2, 3, 9, 10, 6],
...     'signups': [5, 5, 6, 12, 14, 13],
...     'visits': [20, 42, 28, 62, 81, 50],
... }, index=pd.date_range(start='2018/01/01', end='2018/07/01',
...                        freq='M'))
>>> ax = df.plot.area()
```

Area plots are stacked by default. To produce an unstacked plot, pass `stacked=False`:

```
>>> ax = df.plot.area(stacked=False)
```

Draw an area plot for a single column:

```
>>> ax = df.plot.area(y='sales')
```

Draw with a different *x*:

```
>>> df = pd.DataFrame({
...     'sales': [3, 2, 3],
...     'visits': [20, 42, 28],
...     'day': [1, 2, 3],
... })
>>> ax = df.plot.area(x='day')
```

pandas.DataFrame.plot.bar

DataFrame.plot.**bar**(*x=None*, *y=None*, ***kwargs*)

Vertical bar plot.

A bar plot is a plot that presents categorical data with rectangular bars with lengths proportional to the values that they represent. A bar plot shows comparisons among discrete categories. One axis of the plot shows the specific categories being compared, and the other axis represents a measured value.

Parameters

x [label or position, optional] Allows plotting of one column versus another. If not specified, the index of the DataFrame is used.

y [label or position, optional] Allows plotting of one column versus another. If not specified, all numerical columns are used.

color [str, array_like, or dict, optional] The color for each of the DataFrame's columns. Possible values are:

- **A single color string referred to by name, RGB or RGBA code,** for instance 'red' or '#a98d19'.
- **A sequence of color strings referred to by name, RGB or RGBA** code, which will be used for each column recursively. For instance ['green','yellow'] each column's bar will be filled in green or yellow, alternatively.
- **A dict of the form {column name** [color}, so that each column will be] colored accordingly. For example, if your columns are called *a* and *b*, then passing {'a': 'green', 'b': 'red'} will color bars for column *a* in green and bars for column *b* in red.

New in version 1.1.0.

****kwargs** Additional keyword arguments are documented in *DataFrame.plot()*.

Returns

matplotlib.axes.Axes or np.ndarray of them An ndarray is returned with one matplotlib.axes.Axes per column when subplots=True.

See also:

DataFrame.plot.barh Horizontal bar plot.
DataFrame.plot Make plots of a DataFrame.
matplotlib.pyplot.bar Make a bar plot with matplotlib.

Examples

Basic plot.

```
>>> df = pd.DataFrame({'lab':['A', 'B', 'C'], 'val':[10, 30, 20]})
>>> ax = df.plot.bar(x='lab', y='val', rot=0)
```

Plot a whole dataframe to a bar plot. Each column is assigned a distinct color, and each row is nested in a group along the horizontal axis.

```
>>> speed = [0.1, 17.5, 40, 48, 52, 69, 88]
>>> lifespan = [2, 8, 70, 1.5, 25, 12, 28]
>>> index = ['snail', 'pig', 'elephant',
...          'rabbit', 'giraffe', 'coyote', 'horse']
```

(continues on next page)

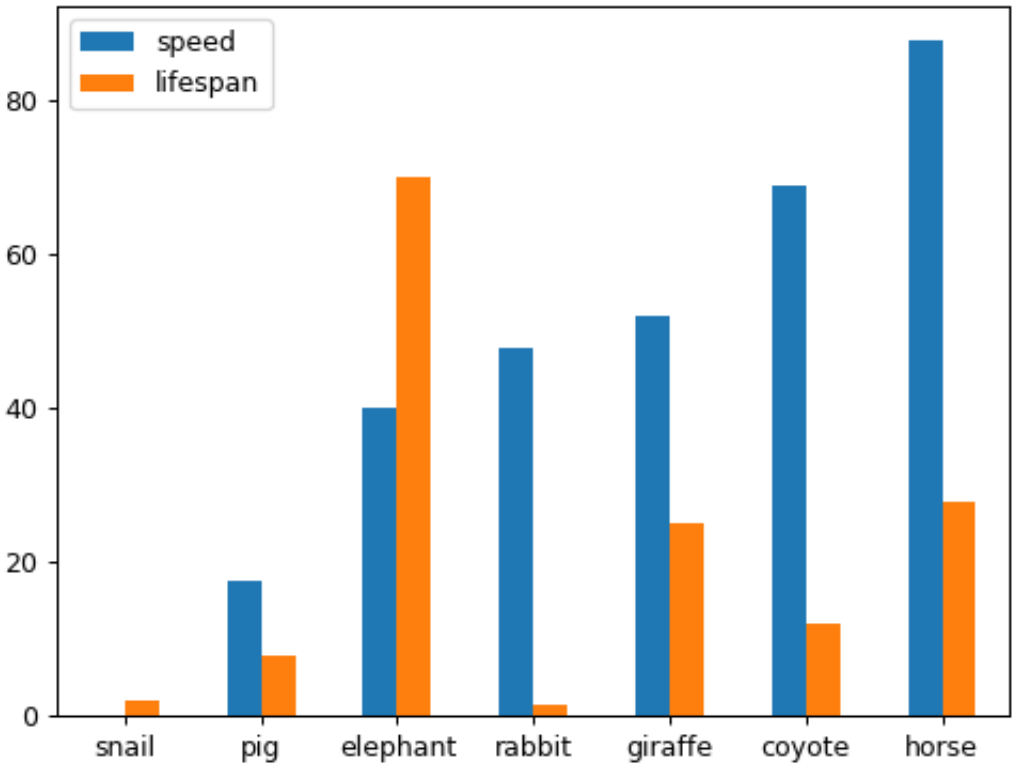
```
>>> df = pd.DataFrame({'speed': speed,
...                    'lifespan': lifespan}, index=index)
>>> ax = df.plot.bar(rot=0)
```



Plot stacked bar charts for the DataFrame

```
>>> ax = df.plot.bar(stacked=True)
```

Instead of nesting, the figure can be split by column with `subplots=True`. In this case, a `numpy.ndarray` of `matplotlib.axes.Axes` are returned.

```
>>> axes = df.plot.bar(rot=0, subplots=True)
>>> axes[1].legend(loc=2)
```

If you don't like the default colours, you can specify how you'd like each column to be colored.

```
>>> axes = df.plot.bar(
...     rot=0, subplots=True, color={"speed": "red", "lifespan": "green"}
... )
>>> axes[1].legend(loc=2)
```

Plot a single column.

```

pandas.DataFrame.plot.barh

`DataFrame.plot.`**`barh`**(*x=None*, *y=None*, ***kwargs*)

Make a horizontal bar plot.

A horizontal bar plot is a plot that presents quantitative data with rectangular bars with lengths proportional to the values that they represent. A bar plot shows comparisons among discrete categories. One axis of the plot shows the specific categories being compared, and the other axis represents a measured value.

Parameters

x [label or position, optional] Allows plotting of one column versus another. If not specified, the index of the DataFrame is used.

y [label or position, optional] Allows plotting of one column versus another. If not specified, all numerical columns are used.

color [str, array_like, or dict, optional] The color for each of the DataFrame's columns. Possible values are:

- **A sequence of color strings referred to by name, RGB or RGBA** code, which will be used for each column recursively. For instance ['green','yellow'] each column's bar will be filled in green or yellow, alternatively.
- **A dict of the form {column name** [color}, so that each column will be] colored accordingly. For example, if your columns are called *a* and *b*, then passing {'a': 'green', 'b': 'red'} will color bars for column *a* in green and bars for column *b* in red.

New in version 1.1.0.

****kwargs** Additional keyword arguments are documented in *DataFrame.plot()*.

Returns

matplotlib.axes.Axes or np.ndarray of them An ndarray is returned with one `matplotlib.axes.Axes` per column when `subplots=True`.

See also:

DataFrame.plot.bar Vertical bar plot.
DataFrame.plot Make plots of DataFrame using matplotlib.
matplotlib.axes.Axes.bar Plot a vertical bar plot using matplotlib.

Examples

Basic example

```
>>> df = pd.DataFrame({'lab': ['A', 'B', 'C'], 'val': [10, 30, 20]})
>>> ax = df.plot.barh(x='lab', y='val')
```

Plot a whole DataFrame to a horizontal bar plot

```
>>> speed = [0.1, 17.5, 40, 48, 52, 69, 88]
>>> lifespan = [2, 8, 70, 1.5, 25, 12, 28]
>>> index = ['snail', 'pig', 'elephant',
...          'rabbit', 'giraffe', 'coyote', 'horse']
>>> df = pd.DataFrame({'speed': speed,
...                    'lifespan': lifespan}, index=index)
>>> ax = df.plot.barh()
```

Plot stacked barh charts for the DataFrame

```
>>> ax = df.plot.barh(stacked=True)
```

We can specify colors for each column

```
>>> ax = df.plot.barh(color={"speed": "red", "lifespan": "green"})
```

Plot a column of the DataFrame to a horizontal bar plot

```
>>> speed = [0.1, 17.5, 40, 48, 52, 69, 88]
>>> lifespan = [2, 8, 70, 1.5, 25, 12, 28]
>>> index = ['snail', 'pig', 'elephant',
...          'rabbit', 'giraffe', 'coyote', 'horse']

pandas.DataFrame.plot.box

DataFrame.plot.**box**(*by=None*, ***kwargs*)

Make a box plot of the DataFrame columns.

A box plot is a method for graphically depicting groups of numerical data through their quartiles. The box extends from the Q1 to Q3 quartile values of the data, with a line at the median (Q2). The whiskers extend from the edges of box to show the range of the data. The position of the whiskers is set by default to 1.5*IQR (IQR = Q3 - Q1) from the edges of the box. Outlier points are those past the end of the whiskers.

For further details see Wikipedia's entry for boxplot.

A consideration when using this chart is that the box and the whiskers can overlap, which is very common when plotting small sets of data.

Parameters

by [str or sequence] Column in the DataFrame to group by.

****kwargs** Additional keywords are documented in *DataFrame.plot()*.

Returns

matplotlib.axes.Axes or numpy.ndarray of them

See also:

DataFrame.boxplot Another method to draw a box plot.
Series.plot.box Draw a box plot from a Series object.
matplotlib.pyplot.boxplot Draw a box plot in matplotlib.

Examples

Draw a box plot from a DataFrame with four columns of randomly generated data.

```
>>> data = np.random.randn(25, 4)
>>> df = pd.DataFrame(data, columns=list('ABCD'))
>>> ax = df.plot.box()
```

pandas.DataFrame.plot.density

DataFrame.plot.**density**(*bw_method=None*, *ind=None*, ***kwargs*)

Generate Kernel Density Estimate plot using Gaussian kernels.

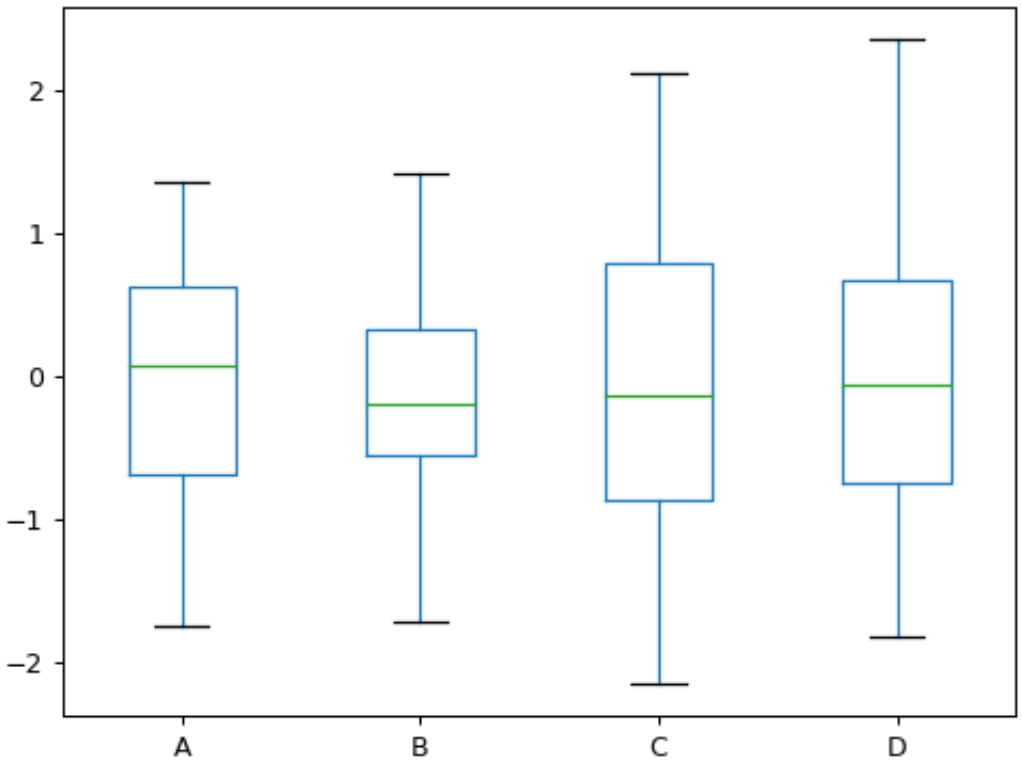
In statistics, kernel density estimation (KDE) is a non-parametric way to estimate the probability density function (PDF) of a random variable. This function uses Gaussian kernels and includes automatic bandwidth determination.

Parameters

bw_method [str, scalar or callable, optional] The method used to calculate the estimator bandwidth. This can be 'scott', 'silverman', a scalar constant or a callable. If None (default), 'scott' is used. See scipy.stats.gaussian_kde for more information.

ind [NumPy array or int, optional] Evaluation points for the estimated PDF. If None (default), 1000 equally spaced points are used. If *ind* is a NumPy array, the KDE is evaluated at the points passed. If *ind* is an integer, *ind* number of equally spaced points are used.

****kwargs** Additional keyword arguments are documented in pandas.%(this-datatype)s.plot().



2
1
0
−1
−2
A
B
C
D

Returns

matplotlib.axes.Axes or numpy.ndarray of them

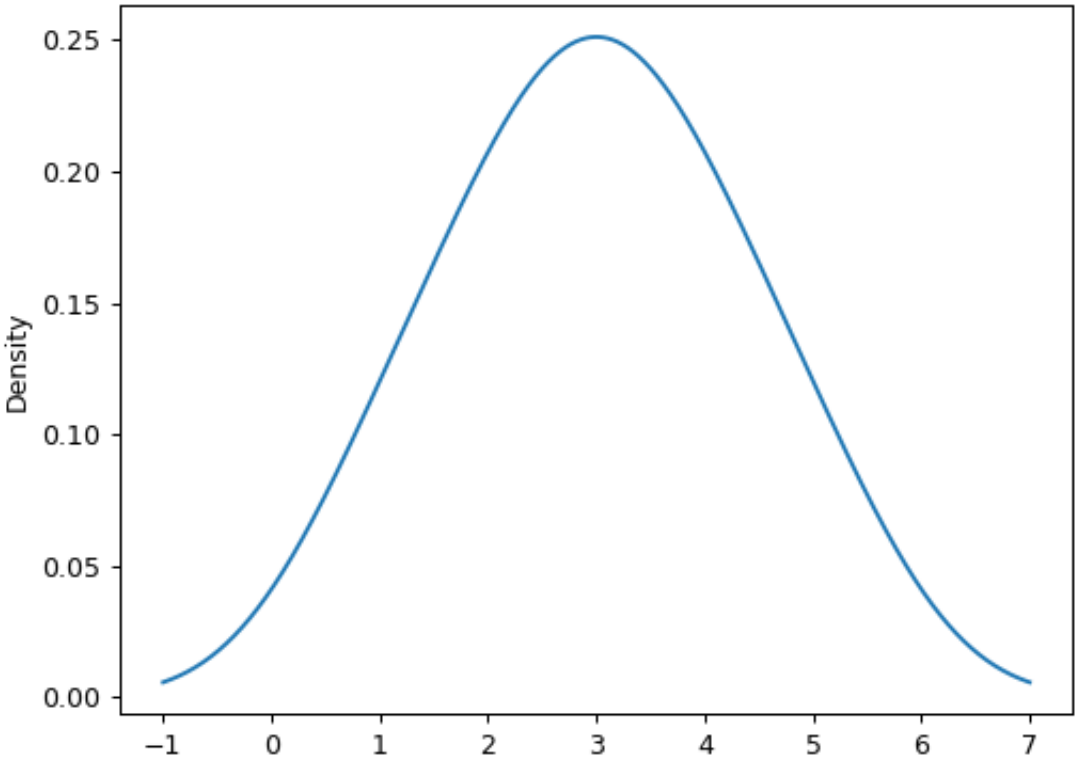
See also:

`scipy.stats.gaussian_kde` Representation of a kernel-density estimate using Gaussian kernels. This is the function used internally to estimate the PDF.

Examples

Given a Series of points randomly sampled from an unknown distribution, estimate its PDF using KDE with automatic bandwidth determination and plot the results, evaluating them at 1000 equally spaced points (default):

```
>>> s = pd.Series([1, 2, 2.5, 3, 3.5, 4, 5])
>>> ax = s.plot.kde()
```



A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:

```
>>> ax = s.plot.kde(bw_method=0.3)
```

```
>>> ax = s.plot.kde(bw_method=3)
```

Finally, the *ind* parameter determines the evaluation points for the plot of the estimated PDF:

4
5
6
7

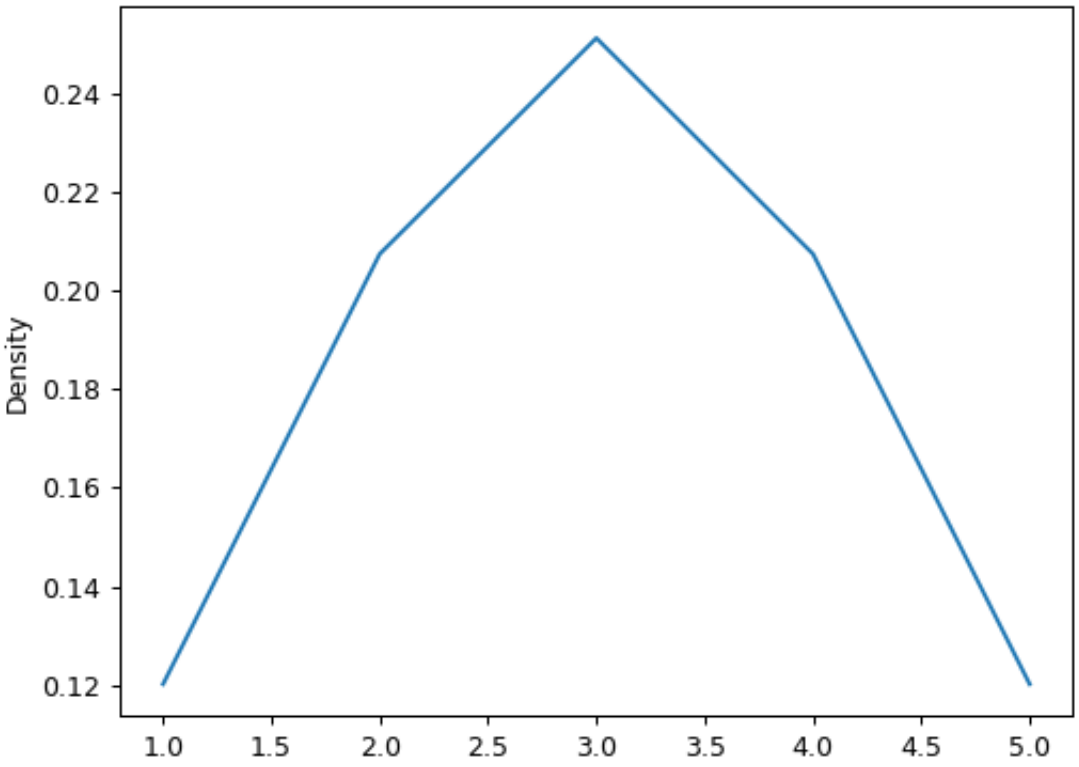
```
>>> ax = s.plot.kde(ind=[1, 2, 3, 4, 5])
```



For DataFrame, it works in the same way:

```
>>> df = pd.DataFrame({
...     'x': [1, 2, 2.5, 3, 3.5, 4, 5],
...     'y': [4, 4, 4.5, 5, 5.5, 6, 6],
... })
>>> ax = df.plot.kde()
```

A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:

```
>>> ax = df.plot.kde(bw_method=0.3)
```

```
>>> ax = df.plot.kde(bw_method=3)
```

Finally, the *ind* parameter determines the evaluation points for the plot of the estimated PDF:

```
>>> ax = df.plot.kde(ind=[1, 2, 3, 4, 5, 6])
```

pandas.DataFrame.plot.hexbin

DataFrame.plot.**hexbin**(*x*, *y*, *C=None*, *reduce_C_function=None*, *gridsize=None*, ***kwargs*)

Generate a hexagonal binning plot.

Generate a hexagonal binning plot of *x* versus *y*. If *C* is *None* (the default), this is a histogram of the number of occurrences of the observations at `(x[i], y[i])`.

If *C* is specified, specifies values at given coordinates `(x[i], y[i])`. These values are accumulated for each hexagonal bin and then reduced according to *reduce_C_function*, having as default the NumPy's mean function (`numpy.mean()`). (If *C* is specified, it must also be a 1-D sequence of the same length as *x* and *y*, or a column label.)

Parameters

x [int or str] The column label or position for x points.

y [int or str] The column label or position for y points.

C [int or str, optional] The column label or position for the value of *(x, y)* point.

reduce_C_function [callable, default *np.mean*] Function of one argument that reduces all the values in a bin to a single number (e.g. *np.mean*, *np.max*, *np.sum*, *np.std*).

gridsize [int or tuple of (int, int), default 100] The number of hexagons in the x-direction. The corresponding number of hexagons in the y-direction is chosen in a way that the hexagons are approximately regular. Alternatively, gridsize can be a tuple with two elements specifying the number of hexagons in the x-direction and the y-direction.

****kwargs** Additional keyword arguments are documented in *DataFrame.plot()*.

Returns

matplotlib.AxesSubplot The matplotlib `Axes` on which the hexbin is plotted.

See also:

DataFrame.plot Make plots of a DataFrame.

matplotlib.pyplot.hexbin Hexagonal binning plot using matplotlib, the matplotlib function that is used under the hood.

Examples

The following examples are generated with random data from a normal distribution.

```
>>> n = 10000
>>> df = pd.DataFrame({'x': np.random.randn(n),
...                    'y': np.random.randn(n)})
>>> ax = df.plot.hexbin(x='x', y='y', gridsize=20)
```

The next example uses *C* and *np.sum* as *reduce_C_function*. Note that *'observations'* values ranges from 1 to 5 but the result plot shows values up to more than 25. This is because of the *reduce_C_function*.

```
>>> n = 500
>>> df = pd.DataFrame({
...     'coord_x': np.random.uniform(-3, 3, size=n),
...     'coord_y': np.random.uniform(30, 50, size=n),
...     'observations': np.random.randint(1,5, size=n)
...     })
>>> ax = df.plot.hexbin(x='coord_x',
...                     y='coord_y',
```

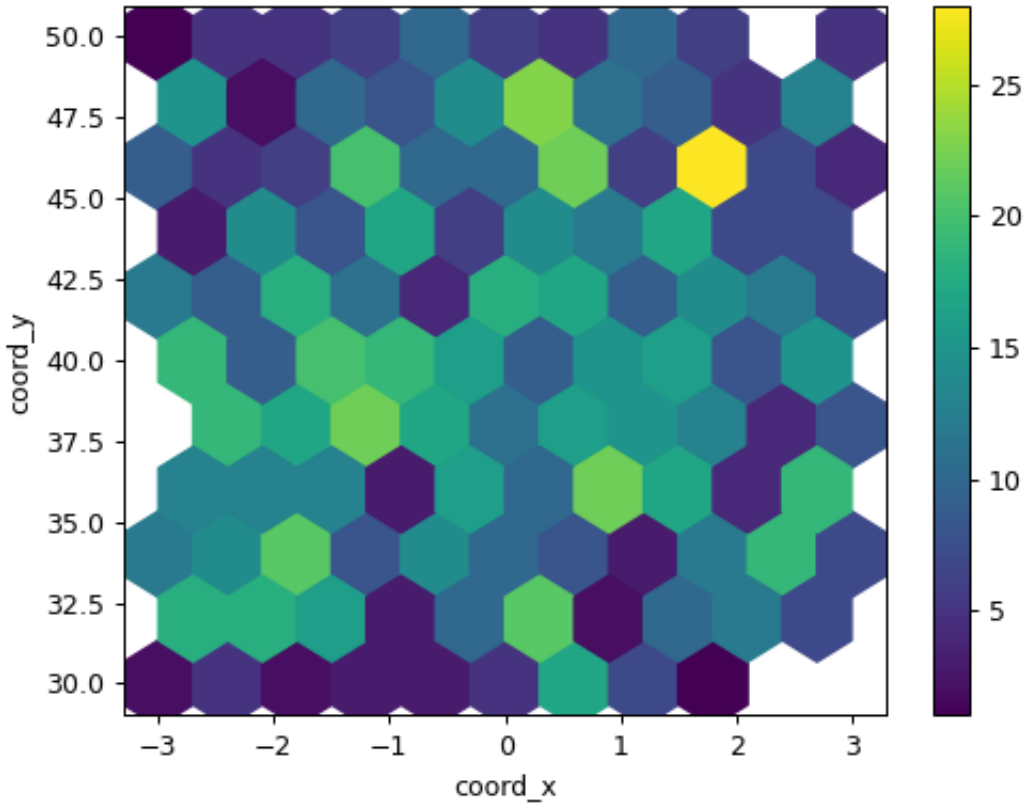
...                       gridsize=10,
...                       cmap="viridis")
```



pandas.DataFrame.plot.hist

`DataFrame.plot.`**`hist`**(*by=None*, *bins=10*, ***kwargs*)

Draw one histogram of the DataFrame's columns.

A histogram is a representation of the distribution of data. This function groups the values of all given Series in the DataFrame into bins and draws all bins in one `matplotlib.axes.Axes`. This is useful when the DataFrame's Series are in a similar scale.

Parameters

by [str or sequence, optional] Column in the DataFrame to group by.

bins [int, default 10] Number of histogram bins to be used.

****kwargs** Additional keyword arguments are documented in *`DataFrame.plot()`*.

Returns

class:*matplotlib.AxesSubplot* Return a histogram plot.

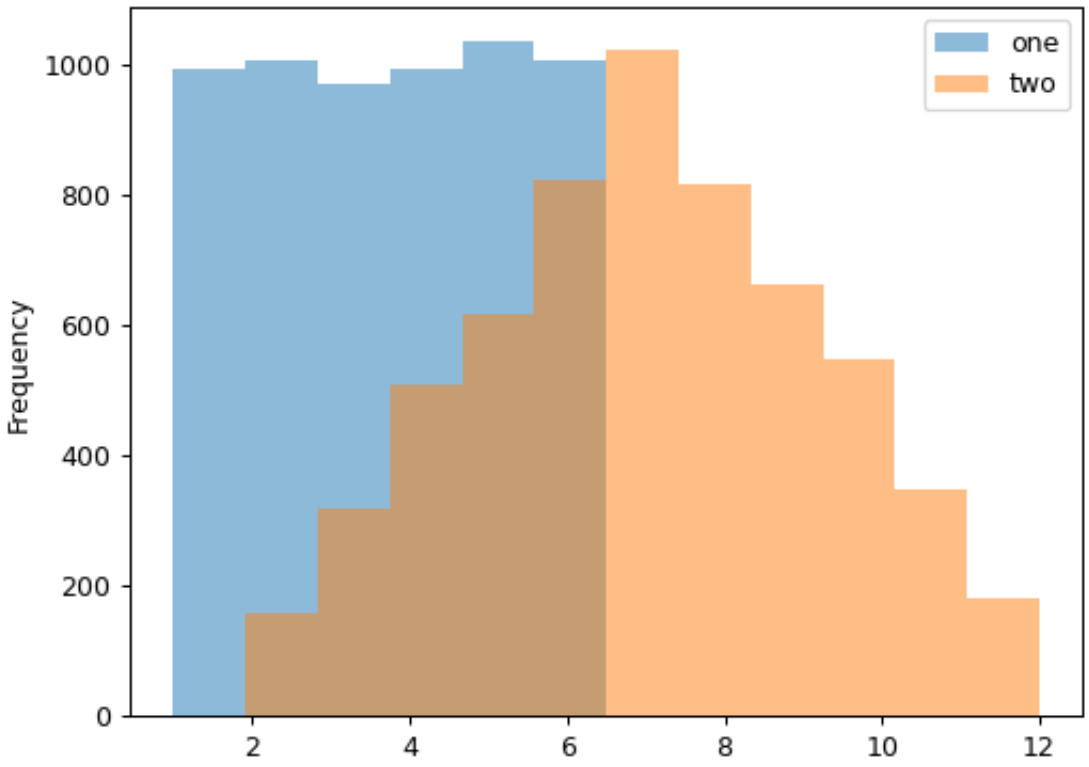
See also:

DataFrame.hist Draw histograms per DataFrame's Series.
Series.hist Draw a histogram with Series' data.

Examples

When we draw a dice 6000 times, we expect to get each value around 1000 times. But when we draw two dices and sum the result, the distribution is going to be quite different. A histogram illustrates those distributions.

```
>>> df = pd.DataFrame(
...     np.random.randint(1, 7, 6000),
...     columns = ['one'])
>>> df['two'] = df['one'] + np.random.randint(1, 7, 6000)
>>> ax = df.plot.hist(bins=12, alpha=0.5)
```



pandas.DataFrame.plot.kde

DataFrame.plot.**kde**(*bw_method=None*, *ind=None*, ***kwargs*)

Generate Kernel Density Estimate plot using Gaussian kernels.

In statistics, kernel density estimation (KDE) is a non-parametric way to estimate the probability density function (PDF) of a random variable. This function uses Gaussian kernels and includes automatic bandwidth determination.

Parameters

bw_method [str, scalar or callable, optional] The method used to calculate the estimator bandwidth. This can be 'scott', 'silverman', a scalar constant or a callable. If None (default), 'scott' is used. See `scipy.stats.gaussian_kde` for more information.

ind [NumPy array or int, optional] Evaluation points for the estimated PDF. If None (default), 1000 equally spaced points are used. If *ind* is a NumPy array, the KDE is evaluated at the points passed. If *ind* is an integer, *ind* number of equally spaced points are used.

****kwargs** Additional keyword arguments are documented in `pandas.%(this-datatype)s.plot()`.

Returns

matplotlib.axes.Axes or numpy.ndarray of them

See also:

scipy.stats.gaussian_kde Representation of a kernel-density estimate using Gaussian kernels. This is the function used internally to estimate the PDF.

Examples

Given a Series of points randomly sampled from an unknown distribution, estimate its PDF using KDE with automatic bandwidth determination and plot the results, evaluating them at 1000 equally spaced points (default):

```
>>> s = pd.Series([1, 2, 2.5, 3, 3.5, 4, 5])
>>> ax = s.plot.kde()
```

A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:

```
>>> ax = s.plot.kde(bw_method=0.3)
```

```
>>> ax = s.plot.kde(bw_method=3)
```

Finally, the *ind* parameter determines the evaluation points for the plot of the estimated PDF:

```
>>> ax = s.plot.kde(ind=[1, 2, 3, 4, 5])
```

For DataFrame, it works in the same way:

```
>>> df = pd.DataFrame({
...     'x': [1, 2, 2.5, 3, 3.5, 4, 5],
...     'y': [4, 4, 4.5, 5, 5.5, 6, 6],
... })
>>> ax = df.plot.kde()
```

```

pandas.DataFrame.plot.line

`DataFrame.plot.`**`line`**(*x=None*, *y=None*, ***kwargs*)

Plot Series or DataFrame as lines.

This function is useful to plot lines using DataFrame's values as coordinates.

Parameters

x [label or position, optional] Allows plotting of one column versus another. If not specified, the index of the DataFrame is used.

y [label or position, optional] Allows plotting of one column versus another. If not specified, all numerical columns are used.

color [str, array_like, or dict, optional] The color for each of the DataFrame's columns. Possible values are:

- **A single color string referred to by name, RGB or RGBA code,** for instance 'red' or '#a98d19'.
- **A sequence of color strings referred to by name, RGB or RGBA** code, which will be used for each column recursively. For instance ['green','yellow'] each column's line will be filled in green or yellow, alternatively.
- **A dict of the form {column name** [color}, so that each column will be] colored accordingly. For example, if your columns are called *a* and *b*, then passing {'a': 'green', 'b': 'red'} will color lines for column *a* in green and lines for column *b* in red.

New in version 1.1.0.

****kwargs** Additional keyword arguments are documented in *DataFrame.plot()*.

Returns

matplotlib.axes.Axes or np.ndarray of them An ndarray is returned with one `matplotlib.axes.Axes` per column when `subplots=True`.

See also:

`matplotlib.pyplot.plot` Plot y versus x as lines and/or markers.

Examples

```
>>> s = pd.Series([1, 3, 2])
>>> s.plot.line()
```

The following example shows the populations for some animals over the years.

```
>>> df = pd.DataFrame({
...    'pig': [20, 18, 489, 675, 1776],
...    'horse': [4, 25, 281, 600, 1900]
...    }, index=[1990, 1997, 2003, 2009, 2014])
>>> lines = df.plot.line()
```

An example with subplots, so an array of axes is returned.

```
>>> axes = df.plot.line(subplots=True)
>>> type(axes)
<class 'numpy.ndarray'>
```

Let's repeat the same example, but specifying colors for each column (in this case, for each animal).

```
>>> axes = df.plot.line(
...     subplots=True, color={"pig": "pink", "horse": "#742802"}
... )
```

The following example shows the relationship between both populations.

```
>>> lines = df.plot.line(x='pig', y='horse')
```

pandas.DataFrame.plot.pie

DataFrame.plot.**pie**(***kwargs*)

Generate a pie plot.

A pie plot is a proportional representation of the numerical data in a column. This function wraps `matplotlib.pyplot.pie()` for the specified column. If no column reference is passed and `subplots=True` a pie plot is drawn for each numerical column independently.

Parameters

y [int or label, optional] Label or position of the column to plot. If not provided, `subplots=True` argument must be passed.

****kwargs** Keyword arguments to pass on to *DataFrame.plot()*.

Returns

matplotlib.axes.Axes or np.ndarray of them A NumPy array is returned when *subplots* is True.

See also:

Series.plot.pie Generate a pie plot for a Series.
DataFrame.plot Make plots of a DataFrame.

Examples

In the example below we have a DataFrame with the information about planet's mass and radius. We pass the 'mass' column to the pie function to get a pie plot.

```
>>> df = pd.DataFrame({'mass': [0.330, 4.87 , 5.97],
...                    'radius': [2439.7, 6051.8, 6378.1]},
...                   index=['Mercury', 'Venus', 'Earth'])
>>> plot = df.plot.pie(y='mass', figsize=(5, 5))
```

```
>>> plot = df.plot.pie(subplots=True, figsize=(11, 6))
```

pandas.DataFrame.plot.scatter

DataFrame.plot.**scatter**(*x*, *y*, *s=None*, *c=None*, ***kwargs*)

Create a scatter plot with varying marker point size and color.

The coordinates of each point are defined by two dataframe columns and filled circles are used to represent each point. This kind of plot is useful to see complex correlations between two variables. Points could be for instance natural 2D coordinates like longitude and latitude in a map or, in general, any pair of metrics that can be plotted against each other.

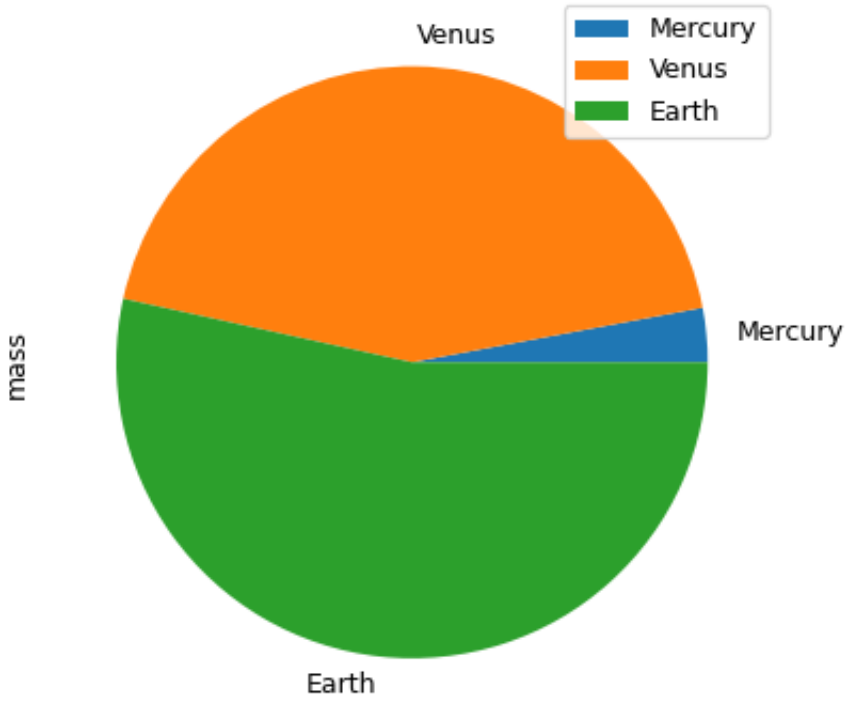
Parameters

x [int or str] The column name or column position to be used as horizontal coordinates for each point.

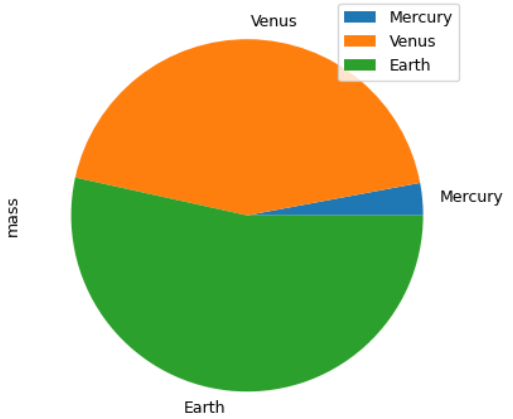
y [int or str] The column name or column position to be used as vertical coordinates for each point.

s [str, scalar or array_like, optional] The size of each point. Possible values are:

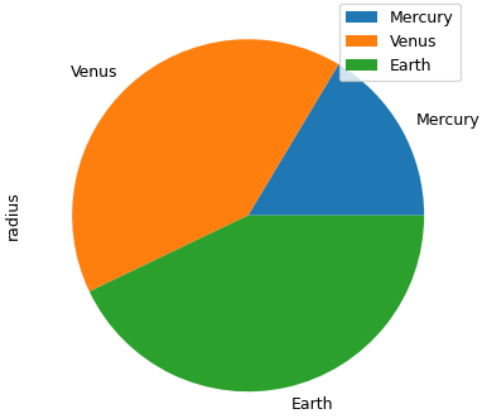
- A string with the name of the column to be used for marker's size.
- A single scalar so all points have the same size.



Venus
Mercury
Venus
Earth
mass
Mercury
Earth



Venus
Mercury
Venus
Earth
mass
Mercury
Earth



Mercury
Venus
Earth
Venus
Mercury
radius
Earth

- A sequence of scalars, which will be used for each point's size recursively. For instance, when passing [2,14] all points size will be either 2 or 14, alternatively.

  Changed in version 1.1.0.

c [str, int or array_like, optional] The color of each point. Possible values are:

- A single color string referred to by name, RGB or RGBA code, for instance 'red' or '#a98d19'.
- A sequence of color strings referred to by name, RGB or RGBA code, which will be used for each point's color recursively. For instance ['green','yellow'] all points will be filled in green or yellow, alternatively.
- A column name or position whose values will be used to color the marker points according to a colormap.

****kwargs** Keyword arguments to pass on to *DataFrame.plot()*.

Returns

matplotlib.axes.Axes or numpy.ndarray of them

See also:

matplotlib.pyplot.scatter Scatter plot using multiple input data formats.

Examples

Let's see how to draw a scatter plot using coordinates from the values in a DataFrame's columns.

```
>>> df = pd.DataFrame([[5.1, 3.5, 0], [4.9, 3.0, 0], [7.0, 3.2, 1],
...                    [6.4, 3.2, 1], [5.9, 3.0, 2]],
...                   columns=['length', 'width', 'species'])
>>> ax1 = df.plot.scatter(x='length',
...                       y='width',
...                       c='DarkBlue')
```

And now with the color determined by a column as well.

```
>>> ax2 = df.plot.scatter(x='length',
...                       y='width',
...                       c='species',
...                       colormap='viridis')
```

DataFrame.boxplot([column, by, ax, ...])	Make a box plot from DataFrame columns.
DataFrame.hist([column, by, grid, ...])	Make a histogram of the DataFrame's.

3.4.15 Sparse accessor

Sparse-dtype specific methods and attributes are provided under the `DataFrame.sparse` accessor.

pandas.DataFrame.sparse.density

DataFrame.sparse.**density**
Ratio of non-sparse points to total (dense) data points.

DataFrame.sparse.from_spmatrix(data[, ...])	Create a new DataFrame from a scipy sparse matrix.
DataFrame.sparse.to_coo()	Return the contents of the frame as a sparse SciPy COO matrix.
DataFrame.sparse.to_dense()	Convert a DataFrame with sparse values to dense.

pandas.DataFrame.sparse.from_spmatrix

classmethod DataFrame.sparse.**from_spmatrix**(*data*, *index=None*, *columns=None*)
Create a new DataFrame from a scipy sparse matrix.

New in version 0.25.0.

Parameters

data [scipy.sparse.spmatrix] Must be convertible to csc format.

index, columns [Index, optional] Row and column labels to use for the resulting DataFrame. Defaults to a RangeIndex.

Returns

DataFrame Each column of the DataFrame is stored as a *arrays.SparseArray*.

Examples

```
>>> import scipy.sparse
>>> mat = scipy.sparse.eye(3)
>>> pd.DataFrame.sparse.from_spmatrix(mat)
     0    1    2
0  1.0  0.0  0.0
1  0.0  1.0  0.0
2  0.0  0.0  1.0
```

pandas.DataFrame.sparse.to_coo

DataFrame.sparse.**to_coo**()
Return the contents of the frame as a sparse SciPy COO matrix.

New in version 0.25.0.

Returns

coo_matrix [scipy.sparse.spmatrix] If the caller is heterogeneous and contains booleans or objects, the result will be of dtype=object. See Notes.

Notes

The dtype will be the lowest-common-denominator type (implicit upcasting); that is to say if the dtypes (even of numeric types) are mixed, the one that accommodates all will be chosen.

e.g. If the dtypes are float16 and float32, dtype will be upcast to float32. By numpy.find_common_type convention, mixing int64 and and uint64 will result in a float64 dtype.

pandas.DataFrame.sparse.to_dense

`DataFrame.sparse.to_dense()`

Convert a DataFrame with sparse values to dense.

New in version 0.25.0.

Returns

DataFrame A DataFrame with the same values stored as dense arrays.

Examples

```
>>> df = pd.DataFrame({"A": pd.arrays.SparseArray([0, 1, 0])})
>>> df.sparse.to_dense()
   A
0  0
1  1
2  0
```

3.4.16 Serialization / IO / conversion

DataFrame.from_dict(data[, orient, dtype, ...])	Construct DataFrame from dict of array-like or dicts.
DataFrame.from_records(data[, index, ...])	Convert structured or record ndarray to DataFrame.
DataFrame.to_parquet(**kwargs)	Write a DataFrame to the binary parquet format.
DataFrame.to_pickle(path[, compression, ...])	Pickle (serialize) object to file.
DataFrame.to_csv([path_or_buf, sep, na_rep, ...])	Write object to a comma-separated values (csv) file.
DataFrame.to_hdf(path_or_buf, key[, mode, ...])	Write the contained data to an HDF5 file using HDFStore.
DataFrame.to_sql(name, con[, schema, ...])	Write records stored in a DataFrame to a SQL database.
DataFrame.to_dict([orient, into])	Convert the DataFrame to a dictionary.
DataFrame.to_excel(excel_writer[, ...])	Write object to an Excel sheet.
DataFrame.to_json([path_or_buf, orient, ...])	Convert the object to a JSON string.
DataFrame.to_html([buf, columns, col_space, ...])	Render a DataFrame as an HTML table.
DataFrame.to_feather(**kwargs)	Write a DataFrame to the binary Feather format.
DataFrame.to_latex([buf, columns, ...])	Render object to a LaTeX tabular, longtable, or nested table/tabular.
DataFrame.to_stata(**kwargs)	Export DataFrame object to Stata dta format.
DataFrame.to_gbq(destination_table[, ...])	Write a DataFrame to a Google BigQuery table.
DataFrame.to_records([index, column_dtypes, ...])	Convert DataFrame to a NumPy record array.

continues on next page

Table 78 – continued from previous page

DataFrame.to_string([buf, columns, ...])	Render a DataFrame to a console-friendly tabular output.
DataFrame.to_clipboard([excel, sep])	Copy object to the system clipboard.
DataFrame.to_markdown([buf, mode, index])	Print DataFrame in Markdown-friendly format.
DataFrame.style	Returns a Styler object.

3.5 pandas arrays

For most data types, pandas uses NumPy arrays as the concrete objects contained with a Index, Series, or DataFrame.

For some data types, pandas extends NumPy's type system. String aliases for these types can be found at *dtypes*.

Kind of Data	Pandas Data Type	Scalar	Array
TZ-aware datetime	DatetimeTZDtype	Timestamp	*Datetime data*
Timedeltas	(none)	Timedelta	*Timedelta data*
Period (time spans)	PeriodDtype	Period	*Timespan data*
Intervals	IntervalDtype	Interval	*Interval data*
Nullable Integer	Int64Dtype, ...	(none)	*Nullable integer*
Categorical	CategoricalDtype	(none)	*Categorical data*
Sparse	SparseDtype	(none)	*Sparse data*
Strings	StringDtype	str	*Text data*
Boolean (with NA)	BooleanDtype	bool	*Boolean data with missing values*

Pandas and third-party libraries can extend NumPy's type system (see *Extension types*). The top-level array() method can be used to create a new array, which may be stored in a Series, Index, or as a column in a DataFrame.

array(data[, dtype, copy])	Create an array.

3.5.1 pandas.array

pandas.**array**(*data*, *dtype=None*, *copy=True*)

Create an array.

New in version 0.24.0.

Parameters

data [Sequence of objects] The scalars inside *data* should be instances of the scalar type for *dtype*. It's expected that *data* represents a 1-dimensional array of data.

When *data* is an Index or Series, the underlying array will be extracted from *data*.

dtype [str, np.dtype, or ExtensionDtype, optional] The dtype to use for the array. This may be a NumPy dtype or an extension type registered with pandas using pandas.api.extensions.register_extension_dtype().

If not specified, there are two possibilities:

1. When *data* is a Series, Index, or ExtensionArray, the *dtype* will be taken from the data.
2. Otherwise, pandas will attempt to infer the *dtype* from the data.

Note that when *data* is a NumPy array, `data.dtype` is *not* used for inferring the array type. This is because NumPy cannot represent all the types of data that can be held in extension arrays.

Currently, pandas will infer an extension dtype for sequences of

Scalar Type	Array Type
pandas.Interval	*pandas.arrays.IntervalArray*
pandas.Period	*pandas.arrays.PeriodArray*
datetime.datetime	*pandas.arrays.DatetimeArray*
datetime.timedelta	*pandas.arrays.TimedeltaArray*
int	*pandas.arrays.IntegerArray*
str	*pandas.arrays.StringArray*
bool	*pandas.arrays.BooleanArray*

For all other cases, NumPy's usual inference rules will be used.

Changed in version 1.0.0: Pandas infers nullable-integer dtype for integer data, string dtype for string data, and nullable-boolean dtype for boolean data.

copy [bool, default True] Whether to copy the data, even if not necessary. Depending on the type of *data*, creating the new array may require copying data, even if `copy=False`.

Returns

ExtensionArray The newly created array.

Raises

ValueError When *data* is not 1-dimensional.

See also:

numpy.array Construct a NumPy array.
Series Construct a pandas Series.
Index Construct a pandas Index.
arrays.PandasArray ExtensionArray wrapping a NumPy array.
Series.array Extract the array stored within a Series.

Notes

Omitting the *dtype* argument means pandas will attempt to infer the best array type from the values in the data. As new array types are added by pandas and 3rd party libraries, the "best" array type may change. We recommend specifying *dtype* to ensure that

1. the correct array type for the data is returned
2. the returned array type doesn't change as new extension types are added by pandas and third-party libraries

Additionally, if the underlying memory representation of the returned array matters, we recommend specifying the *dtype* as a concrete object rather than a string alias or allowing it to be inferred. For example, a future version of pandas or a 3rd-party library may include a dedicated ExtensionArray for string data. In this event, the following would no longer return a *arrays.PandasArray* backed by a NumPy array.

```
>>> pd.array(['a', 'b'], dtype=str)
<PandasArray>
['a', 'b']
Length: 2, dtype: str32
```

This would instead return the new ExtensionArray dedicated for string data. If you really need the new array to be backed by a NumPy array, specify that in the dtype.

```
>>> pd.array(['a', 'b'], dtype=np.dtype("<U1"))
<PandasArray>
['a', 'b']
Length: 2, dtype: str32
```

Finally, Pandas has arrays that mostly overlap with NumPy

- *arrays.DatetimeArray*
- *arrays.TimedeltaArray*

When data with a `datetime64[ns]` or `timedelta64[ns]` dtype is passed, pandas will always return a `DatetimeArray` or `TimedeltaArray` rather than a `PandasArray`. This is for symmetry with the case of timezone-aware data, which NumPy does not natively support.

```
>>> pd.array(['2015', '2016'], dtype='datetime64[ns]')
<DatetimeArray>
['2015-01-01 00:00:00', '2016-01-01 00:00:00']
Length: 2, dtype: datetime64[ns]
```

```
>>> pd.array(["1H", "2H"], dtype='timedelta64[ns]')
<TimedeltaArray>
['0 days 01:00:00', '0 days 02:00:00']
Length: 2, dtype: timedelta64[ns]
```

Examples

If a dtype is not specified, pandas will infer the best dtype from the values. See the description of *dtype* for the types pandas infers for.

```
>>> pd.array([1, 2])
<IntegerArray>
[1, 2]
Length: 2, dtype: Int64
```

```
>>> pd.array([1, 2, np.nan])
<IntegerArray>
[1, 2, <NA>]
Length: 3, dtype: Int64
```

```
>>> pd.array(["a", None, "c"])
<StringArray>
['a', <NA>, 'c']
Length: 3, dtype: string
```

```
>>> pd.array([pd.Period('2000', freq="D"), pd.Period("2000", freq="D")])
<PeriodArray>
['2000-01-01', '2000-01-01']
Length: 2, dtype: period[D]
```

You can use the string alias for *dtype*

```
>>> pd.array(['a', 'b', 'a'], dtype='category')
['a', 'b', 'a']
Categories (2, object): ['a', 'b']
```

Or specify the actual dtype

```
>>> pd.array(['a', 'b', 'a'],
...          dtype=pd.CategoricalDtype(['a', 'b', 'c'], ordered=True))
['a', 'b', 'a']
Categories (3, object): ['a' < 'b' < 'c']
```

If pandas does not infer a dedicated extension type a *arrays.PandasArray* is returned.

```
>>> pd.array([1.1, 2.2])
<PandasArray>
[1.1, 2.2]
Length: 2, dtype: float64
```

As mentioned in the "Notes" section, new extension types may be added in the future (by pandas or 3rd party libraries), causing the return value to no longer be a *arrays.PandasArray*. Specify the *dtype* as a NumPy dtype if you need to ensure there's no future change in behavior.

```
>>> pd.array([1, 2], dtype=np.dtype("int32"))
<PandasArray>
[1, 2]
Length: 2, dtype: int32
```

data must be 1-dimensional. A ValueError is raised when the input has the wrong dimensionality.

```
>>> pd.array(1)
Traceback (most recent call last):
  ...
ValueError: Cannot pass scalar '1' to 'pandas.array'.
```

3.5.2 Datetime data

NumPy cannot natively represent timezone-aware datetimes. Pandas supports this with the *arrays.DatetimeArray* extension array, which can hold timezone-naive or timezone-aware values.

Timestamp, a subclass of datetime.datetime, is pandas' scalar type for timezone-naive or timezone-aware datetime data.

Timestamp([ts_input, freq, tz, unit, year, ...])	Pandas replacement for python datetime.datetime object.

pandas.Timestamp

class pandas.**Timestamp**(*ts_input=<object object>*, *freq=None*, *tz=None*, *unit=None*, *year=None*, *month=None*, *day=None*, *hour=None*, *minute=None*, *second=None*, *microsecond=None*, *nanosecond=None*, *tzinfo=None*, ***, *fold=None*)

Pandas replacement for python datetime.datetime object.

Timestamp is the pandas equivalent of python's Datetime and is interchangeable with it in most cases. It's the type used for the entries that make up a DatetimeIndex, and other timeseries oriented data structures in pandas.

Parameters

ts_input [datetime-like, str, int, float] Value to be converted to Timestamp.

freq [str, DateOffset] Offset which Timestamp will have.

tz [str, pytz.timezone, dateutil.tz.tzfile or None] Time zone for time which Timestamp will

have.

unit [str] Unit used for conversion if ts_input is of type int or float. The valid values are 'D', 'h', 'm', 's', 'ms', 'us', and 'ns'. For example, 's' means seconds and 'ms' means milliseconds.

year, month, day [int]

hour, minute, second, microsecond [int, optional, default 0]

nanosecond [int, optional, default 0] New in version 0.23.0.

tzinfo [datetime.tzinfo, optional, default None]

fold [{0, 1}, default None, keyword-only] Due to daylight saving time, one wall clock time can occur twice when shifting from summer to winter time; fold describes whether the datetime-like corresponds to the first (0) or the second time (1) the wall clock hits the ambiguous time

New in version 1.1.0.

Notes

There are essentially three calling conventions for the constructor. The primary form accepts four parameters. They can be passed by position or keyword.

The other two forms mimic the parameters from `datetime.datetime`. They can be passed by either position or keyword, but not both mixed together.

Examples

Using the primary calling convention:

This converts a datetime-like string

```
>>> pd.Timestamp('2017-01-01T12')
Timestamp('2017-01-01 12:00:00')
```

This converts a float representing a Unix epoch in units of seconds

```
>>> pd.Timestamp(1513393355.5, unit='s')
Timestamp('2017-12-16 03:02:35.500000')
```

This converts an int representing a Unix-epoch in units of seconds and for a particular timezone

```
>>> pd.Timestamp(1513393355, unit='s', tz='US/Pacific')
Timestamp('2017-12-15 19:02:35-0800', tz='US/Pacific')
```

Using the other two forms that mimic the API for `datetime.datetime`:

```
>>> pd.Timestamp(2017, 1, 1, 12)
Timestamp('2017-01-01 12:00:00')
```

```
>>> pd.Timestamp(year=2017, month=1, day=1, hour=12)
Timestamp('2017-01-01 12:00:00')
```

Attributes

asm8	Return numpy datetime64 format in nanoseconds.
dayofweek	Return day of the week.
dayofyear	Return the day of the year.
days_in_month	Return the number of days in the month.
daysinmonth	Return the number of days in the month.
freqstr	Return the total number of days in the month.
is_leap_year	Return True if year is a leap year.
is_month_end	Return True if date is last day of month.
is_month_start	Return True if date is first day of month.
is_quarter_end	Return True if date is last day of the quarter.
is_quarter_start	Return True if date is first day of the quarter.
is_year_end	Return True if date is last day of the year.
is_year_start	Return True if date is first day of the year.
quarter	Return the quarter of the year.
tz	Alias for tzinfo.
week	Return the week number of the year.
weekofyear	Return the week number of the year.

pandas.Timestamp.asm8

Timestamp.**asm8**
Return numpy datetime64 format in nanoseconds.

pandas.Timestamp.dayofweek

Timestamp.**dayofweek**
Return day of the week.

pandas.Timestamp.dayofyear

Timestamp.**dayofyear**
Return the day of the year.

pandas.Timestamp.days_in_month

Timestamp.**days_in_month**
Return the number of days in the month.

pandas.Timestamp.daysinmonth

Timestamp.**daysinmonth**
Return the number of days in the month.

pandas.Timestamp.freqstr

property Timestamp.**freqstr**
Return the total number of days in the month.

pandas.Timestamp.is_leap_year

Timestamp.**is_leap_year**
Return True if year is a leap year.

pandas.Timestamp.is_month_end

Timestamp.**is_month_end**
Return True if date is last day of month.

pandas.Timestamp.is_month_start

Timestamp.**is_month_start**
Return True if date is first day of month.

pandas.Timestamp.is_quarter_end

Timestamp.**is_quarter_end**
Return True if date is last day of the quarter.

pandas.Timestamp.is_quarter_start

Timestamp.**is_quarter_start**
Return True if date is first day of the quarter.

pandas.Timestamp.is_year_end

Timestamp.**is_year_end**
Return True if date is last day of the year.

pandas.Timestamp.is_year_start

Timestamp.**is_year_start**
Return True if date is first day of the year.

pandas.Timestamp.quarter

Timestamp.**quarter**
Return the quarter of the year.

pandas.Timestamp.tz

property Timestamp.**tz**
Alias for tzinfo.

pandas.Timestamp.week

Timestamp.**week**
Return the week number of the year.

pandas.Timestamp.weekofyear

Timestamp.**weekofyear**
Return the week number of the year.

day	
fold	
freq	
hour	
microsecond	
minute	
month	
nanosecond	
second	
tzinfo	
value	
year	

Methods

astimezone(tz)	Convert tz-aware Timestamp to another time zone.
ceil(freq[, ambiguous, nonexistent])	return a new Timestamp ceiled to this resolution.
combine(date, time)	date, time -> datetime with same date and time fields.
ctime	Return ctime() style string.
date	Return date object with same year, month and day.

continues on next page

Table 82 – continued from previous page

day_name	Return the day name of the Timestamp with specified locale.
dst	Return self.tzinfo.dst(self).
floor(freq[, ambiguous, nonexistent])	return a new Timestamp floored to this resolution.
fromisocalendar	int, int, int -> Construct a date from the ISO year, week number and weekday.
fromisoformat	string -> datetime from datetime.isoformat() output
fromordinal(ordinal[, freq, tz])	Passed an ordinal, translate and convert to a ts.
fromtimestamp(ts)	timestamp[, tz] -> tz's local time from POSIX timestamp.
isocalendar	Return a 3-tuple containing ISO year, week number, and weekday.
isoformat	[sep] -> string in ISO 8601 format, YYYY-MM-DDT[HH[:MM[:SS[.mmm[uuu]]]]][+HH:MM].
isoweekday	Return the day of the week represented by the date.
month_name	Return the month name of the Timestamp with specified locale.
normalize	Normalize Timestamp to midnight, preserving tz information.
now([tz])	Return new Timestamp object representing current time local to tz.
replace([year, month, day, hour, minute, ...])	implements datetime.replace, handles nanoseconds.
round(freq[, ambiguous, nonexistent])	Round the Timestamp to the specified resolution.
strftime	format -> strftime() style string.
strptime(string, format)	Function is not implemented.
time	Return time object with same time but with tzinfo=None.
timestamp	Return POSIX timestamp as float.
timetuple	Return time tuple, compatible with time.localtime().
timetz	Return time object with same time and tzinfo.
to_datetime64	Return a numpy.datetime64 object with 'ns' precision.
to_julian_date()	Convert TimeStamp to a Julian Date.
to_numpy	Convert the Timestamp to a NumPy datetime64.
to_period	Return an period of which this timestamp is an observation.
to_pydatetime	Convert a Timestamp object to a native Python datetime object.
today(cls[, tz])	Return the current time in the local timezone.
toordinal	Return proleptic Gregorian ordinal.
tz_convert(tz)	Convert tz-aware Timestamp to another time zone.
tz_localize(tz[, ambiguous, nonexistent])	Convert naive Timestamp to local time zone, or remove timezone from tz-aware Timestamp.
tzname	Return self.tzinfo.tzname(self).
utcfromtimestamp(ts)	Construct a naive UTC datetime from a POSIX timestamp.
utcnow()	Return a new Timestamp representing UTC day and time.
utcoffset	Return self.tzinfo.utcoffset(self).
utctimetuple	Return UTC time tuple, compatible with time.localtime().

continues on next page

Table 82 – continued from previous page

weekday	Return the day of the week represented by the date.

pandas.Timestamp.astimezone

Timestamp.**astimezone**(*tz*)

Convert tz-aware Timestamp to another time zone.

Parameters

tz [str, pytz.timezone, dateutil.tz.tzfile or None] Time zone for time which Timestamp will be converted to. None will remove timezone holding UTC time.

Returns

converted [Timestamp]

Raises

TypeError If Timestamp is tz-naive.

pandas.Timestamp.ceil

Timestamp.**ceil**(*freq*, *ambiguous='raise'*, *nonexistent='raise'*)

return a new Timestamp ceiled to this resolution.

Parameters

freq [str] Frequency string indicating the ceiling resolution.

ambiguous [bool or {'raise', 'NaT'}, default 'raise'] The behavior is as follows:

- bool contains flags to determine if time is dst or not (note that this flag is only applicable for ambiguous fall dst dates).
- 'NaT' will return NaT for an ambiguous time.
- 'raise' will raise an AmbiguousTimeError for an ambiguous time.

New in version 0.24.0.

nonexistent [{'raise', 'shift_forward', 'shift_backward, 'NaT', timedelta}, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- 'shift_forward' will shift the nonexistent time forward to the closest existing time.
- 'shift_backward' will shift the nonexistent time backward to the closest existing time.
- 'NaT' will return NaT where there are nonexistent times.
- timedelta objects will shift nonexistent times by the timedelta.
- 'raise' will raise an NonExistentTimeError if there are nonexistent times.

New in version 0.24.0.

Raises

ValueError if the freq cannot be converted.

pandas.Timestamp.combine

classmethod Timestamp.**combine**(*date*, *time*)
date, time -> datetime with same date and time fields.

pandas.Timestamp.ctime

Timestamp.**ctime**()
Return ctime() style string.

pandas.Timestamp.date

Timestamp.**date**()
Return date object with same year, month and day.

pandas.Timestamp.day_name

Timestamp.**day_name**()
Return the day name of the Timestamp with specified locale.

Parameters

locale [str, default None (English locale)] Locale determining the language in which to return the day name.

Returns

day_name [string]

New in version 0.23.0: ..

pandas.Timestamp.dst

Timestamp.**dst**()
Return self.tzinfo.dst(self).

pandas.Timestamp.floor

Timestamp.**floor**(*freq*, *ambiguous='raise'*, *nonexistent='raise'*)
return a new Timestamp floored to this resolution.

Parameters

freq [str] Frequency string indicating the flooring resolution.

ambiguous [bool or {'raise', 'NaT'}, default 'raise'] The behavior is as follows:

- bool contains flags to determine if time is dst or not (note that this flag is only applicable for ambiguous fall dst dates).
- 'NaT' will return NaT for an ambiguous time.
- 'raise' will raise an AmbiguousTimeError for an ambiguous time.

New in version 0.24.0.

nonexistent [{'raise', 'shift_forward', 'shift_backward, 'NaT', timedelta}, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- 'shift_forward' will shift the nonexistent time forward to the closest existing time.
- 'shift_backward' will shift the nonexistent time backward to the closest existing time.
- 'NaT' will return NaT where there are nonexistent times.
- timedelta objects will shift nonexistent times by the timedelta.
- 'raise' will raise an NonExistentTimeError if there are nonexistent times.

New in version 0.24.0.

Raises

ValueError if the freq cannot be converted.

pandas.Timestamp.fromisocalendar

`Timestamp.`**`fromisocalendar`**`()`

int, int, int -> Construct a date from the ISO year, week number and weekday.

This is the inverse of the date.isocalendar() function

pandas.Timestamp.fromisoformat

`Timestamp.`**`fromisoformat`**`()`

string -> datetime from datetime.isoformat() output

pandas.Timestamp.fromordinal

`classmethod` `Timestamp.`**`fromordinal`**`(`*ordinal*, *freq=None*, *tz=None*`)`

Passed an ordinal, translate and convert to a ts. Note: by definition there cannot be any tz info on the ordinal itself.

Parameters

ordinal [int] Date corresponding to a proleptic Gregorian ordinal.

freq [str, DateOffset] Offset to apply to the Timestamp.

tz [str, pytz.timezone, dateutil.tz.tzfile or None] Time zone for the Timestamp.

pandas.Timestamp.fromtimestamp

classmethod Timestamp.**fromtimestamp**(*ts*)
timestamp[, tz] -> tz's local time from POSIX timestamp.

pandas.Timestamp.isocalendar

Timestamp.**isocalendar**()
Return a 3-tuple containing ISO year, week number, and weekday.

pandas.Timestamp.isoformat

Timestamp.**isoformat**()
[sep] -> string in ISO 8601 format, YYYY-MM-DDT[HH[:MM[:SS[.mmm[uuu]]]]][+HH:MM]. sep is used to separate the year from the time, and defaults to 'T'. timespec specifies what components of the time to include (allowed values are 'auto', 'hours', 'minutes', 'seconds', 'milliseconds', and 'microseconds').

pandas.Timestamp.isoweekday

Timestamp.**isoweekday**()
Return the day of the week represented by the date. Monday == 1 … Sunday == 7

pandas.Timestamp.month_name

Timestamp.**month_name**()
Return the month name of the Timestamp with specified locale.

Parameters

locale [str, default None (English locale)] Locale determining the language in which to return the month name.

Returns

month_name [string]

New in version 0.23.0: ..

pandas.Timestamp.normalize

Timestamp.**normalize**()
Normalize Timestamp to midnight, preserving tz information.

pandas.Timestamp.now

classmethod Timestamp.**now**(*tz=None*)

Return new Timestamp object representing current time local to tz.

Parameters

tz [str or timezone object, default None] Timezone to localize to.

pandas.Timestamp.replace

Timestamp.**replace**(*year=None*, *month=None*, *day=None*, *hour=None*, *minute=None*, *second=None*, *microsecond=None*, *nanosecond=None*, *tzinfo=<class 'object'>*, *fold=0*)

implements datetime.replace, handles nanoseconds.

Parameters

year [int, optional]

month [int, optional]

day [int, optional]

hour [int, optional]

minute [int, optional]

second [int, optional]

microsecond [int, optional]

nanosecond [int, optional]

tzinfo [tz-convertible, optional]

fold [int, optional, default is 0]

Returns

Timestamp with fields replaced

pandas.Timestamp.round

Timestamp.**round**(*freq*, *ambiguous='raise'*, *nonexistent='raise'*)

Round the Timestamp to the specified resolution.

Parameters

freq [str] Frequency string indicating the rounding resolution.

ambiguous [bool or {'raise', 'NaT'}, default 'raise'] The behavior is as follows:

- bool contains flags to determine if time is dst or not (note that this flag is only applicable for ambiguous fall dst dates).
- 'NaT' will return NaT for an ambiguous time.
- 'raise' will raise an AmbiguousTimeError for an ambiguous time.

New in version 0.24.0.

nonexistent [{'raise', 'shift_forward', 'shift_backward, 'NaT', timedelta}, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- 'shift_forward' will shift the nonexistent time forward to the closest existing time.
- 'shift_backward' will shift the nonexistent time backward to the closest existing time.
- 'NaT' will return NaT where there are nonexistent times.
- timedelta objects will shift nonexistent times by the timedelta.
- 'raise' will raise an NonExistentTimeError if there are nonexistent times.

New in version 0.24.0.

Returns

a new Timestamp rounded to the given resolution of *freq*

Raises

ValueError if the freq cannot be converted

pandas.Timestamp.strftime

`Timestamp.`**`strftime`**`()`
format -> strftime() style string.

pandas.Timestamp.strptime

`classmethod` `Timestamp.`**`strptime`**`(`*string*, *format*`)`
Function is not implemented. Use pd.to_datetime().

pandas.Timestamp.time

`Timestamp.`**`time`**`()`
Return time object with same time but with tzinfo=None.

pandas.Timestamp.timestamp

`Timestamp.`**`timestamp`**`()`
Return POSIX timestamp as float.

pandas.Timestamp.timetuple

Timestamp.**timetuple**()
Return time tuple, compatible with time.localtime().

pandas.Timestamp.timetz

Timestamp.**timetz**()
Return time object with same time and tzinfo.

pandas.Timestamp.to_datetime64

Timestamp.**to_datetime64**()
Return a numpy.datetime64 object with 'ns' precision.

pandas.Timestamp.to_julian_date

Timestamp.**to_julian_date**()
Convert TimeStamp to a Julian Date. 0 Julian date is noon January 1, 4713 BC.

pandas.Timestamp.to_numpy

Timestamp.**to_numpy**()
Convert the Timestamp to a NumPy datetime64.

New in version 0.25.0.

This is an alias method for *Timestamp.to_datetime64()*. The dtype and copy parameters are available here only for compatibility. Their values will not affect the return value.

Returns

numpy.datetime64

See also:

DatetimeIndex.to_numpy Similar method for DatetimeIndex.

pandas.Timestamp.to_period

Timestamp.**to_period**()
Return an period of which this timestamp is an observation.

pandas.Timestamp.to_pydatetime

Timestamp.**to_pydatetime**()

Convert a Timestamp object to a native Python datetime object.

If warn=True, issue a warning if nanoseconds is nonzero.

pandas.Timestamp.today

classmethod Timestamp.**today**(*cls*, *tz=None*)

Return the current time in the local timezone. This differs from datetime.today() in that it can be localized to a passed timezone.

Parameters

tz [str or timezone object, default None] Timezone to localize to.

pandas.Timestamp.toordinal

Timestamp.**toordinal**()

Return proleptic Gregorian ordinal. January 1 of year 1 is day 1.

pandas.Timestamp.tz_convert

Timestamp.**tz_convert**(*tz*)

Convert tz-aware Timestamp to another time zone.

Parameters

tz [str, pytz.timezone, dateutil.tz.tzfile or None] Time zone for time which Timestamp will be converted to. None will remove timezone holding UTC time.

Returns

converted [Timestamp]

Raises

TypeError If Timestamp is tz-naive.

pandas.Timestamp.tz_localize

Timestamp.**tz_localize**(*tz*, *ambiguous='raise'*, *nonexistent='raise'*)

Convert naive Timestamp to local time zone, or remove timezone from tz-aware Timestamp.

Parameters

tz [str, pytz.timezone, dateutil.tz.tzfile or None] Time zone for time which Timestamp will be converted to. None will remove timezone holding local time.

ambiguous [bool, 'NaT', default 'raise'] When clocks moved backward due to DST, ambiguous times may arise. For example in Central European Time (UTC+01), when going from 03:00 DST to 02:00 non-DST, 02:30:00 local time occurs both at 00:30:00 UTC and at 01:30:00 UTC. In such a situation, the *ambiguous* parameter dictates how ambiguous times should be handled.

The behavior is as follows:

- bool contains flags to determine if time is dst or not (note that this flag is only applicable for ambiguous fall dst dates).
- 'NaT' will return NaT for an ambiguous time.
- 'raise' will raise an AmbiguousTimeError for an ambiguous time.

nonexistent ['shift_forward', 'shift_backward, 'NaT', timedelta, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

The behavior is as follows:

- 'shift_forward' will shift the nonexistent time forward to the closest existing time.
- 'shift_backward' will shift the nonexistent time backward to the closest existing time.
- 'NaT' will return NaT where there are nonexistent times.
- timedelta objects will shift nonexistent times by the timedelta.
- 'raise' will raise an NonExistentTimeError if there are nonexistent times.

New in version 0.24.0.

Returns

localized [Timestamp]

Raises

TypeError If the Timestamp is tz-aware and tz is not None.

pandas.Timestamp.tzname

`Timestamp.`**`tzname`**`()`
Return self.tzinfo.tzname(self).

pandas.Timestamp.utcfromtimestamp

`classmethod` `Timestamp.`**`utcfromtimestamp`**`(`*`ts`*`)`
Construct a naive UTC datetime from a POSIX timestamp.

pandas.Timestamp.utcnow

`classmethod` `Timestamp.`**`utcnow`**`()`
Return a new Timestamp representing UTC day and time.

pandas.Timestamp.utcoffset

Timestamp.**utcoffset**()
Return self.tzinfo.utcoffset(self).

pandas.Timestamp.utctimetuple

Timestamp.**utctimetuple**()
Return UTC time tuple, compatible with time.localtime().

pandas.Timestamp.weekday

Timestamp.**weekday**()
Return the day of the week represented by the date. Monday == 0 . . . Sunday == 6

Properties

Timestamp.asm8	Return numpy datetime64 format in nanoseconds.
Timestamp.day	
Timestamp.dayofweek	Return day of the week.
Timestamp.dayofyear	Return the day of the year.
Timestamp.days_in_month	Return the number of days in the month.
Timestamp.daysinmonth	Return the number of days in the month.
Timestamp.fold	
Timestamp.hour	
Timestamp.is_leap_year	Return True if year is a leap year.
Timestamp.is_month_end	Return True if date is last day of month.
Timestamp.is_month_start	Return True if date is first day of month.
Timestamp.is_quarter_end	Return True if date is last day of the quarter.
Timestamp.is_quarter_start	Return True if date is first day of the quarter.
Timestamp.is_year_end	Return True if date is last day of the year.
Timestamp.is_year_start	Return True if date is first day of the year.
Timestamp.max	
Timestamp.microsecond	
Timestamp.min	
Timestamp.minute	
Timestamp.month	
Timestamp.nanosecond	
Timestamp.quarter	Return the quarter of the year.
Timestamp.resolution	
Timestamp.second	
Timestamp.tz	Alias for tzinfo.
Timestamp.tzinfo	
Timestamp.value	
Timestamp.week	Return the week number of the year.
Timestamp.weekofyear	Return the week number of the year.
Timestamp.year	

pandas.Timestamp.day

Timestamp.**day**

pandas.Timestamp.fold

Timestamp.**fold**

pandas.Timestamp.hour

Timestamp.**hour**

pandas.Timestamp.max

Timestamp.**max = Timestamp('2262-04-11 23:47:16.854775807')**

pandas.Timestamp.microsecond

Timestamp.**microsecond**

pandas.Timestamp.min

Timestamp.**min = Timestamp('1677-09-21 00:12:43.145225')**

pandas.Timestamp.minute

Timestamp.**minute**

pandas.Timestamp.month

Timestamp.**month**

pandas.Timestamp.nanosecond

Timestamp.**nanosecond**

pandas.Timestamp.resolution

Timestamp.**resolution = Timedelta('0 days 00:00:00.000000001')**

pandas.Timestamp.second

Timestamp.**second**

pandas.Timestamp.tzinfo

Timestamp.**tzinfo**

pandas.Timestamp.value

Timestamp.**value**

pandas.Timestamp.year

Timestamp.**year**

Methods

Timestamp.astimezone(tz)	Convert tz-aware Timestamp to another time zone.
Timestamp.ceil(freq[, ambiguous, nonexistent])	return a new Timestamp ceiled to this resolution.
Timestamp.combine(date, time)	date, time -> datetime with same date and time fields.
Timestamp.ctime	Return ctime() style string.
Timestamp.date	Return date object with same year, month and day.
Timestamp.day_name	Return the day name of the Timestamp with specified locale.
Timestamp.dst	Return self.tzinfo.dst(self).
Timestamp.floor(freq[, ambiguous, nonexistent])	return a new Timestamp floored to this resolution.
Timestamp.freq	
Timestamp.freqstr	Return the total number of days in the month.
Timestamp.fromordinal(ordinal[, freq, tz])	Passed an ordinal, translate and convert to a ts.
Timestamp.fromtimestamp(ts)	timestamp[, tz] -> tz's local time from POSIX timestamp.
Timestamp.isocalendar	Return a 3-tuple containing ISO year, week number, and weekday.
Timestamp.isoformat	[sep] -> string in ISO 8601 format, YYYY-MM-DDT[HH[:MM[:SS[.mmm[uuu]]]]][+HH:MM].
Timestamp.isoweekday	Return the day of the week represented by the date.
Timestamp.month_name	Return the month name of the Timestamp with specified locale.
Timestamp.normalize	Normalize Timestamp to midnight, preserving tz information.
Timestamp.now([tz])	Return new Timestamp object representing current time local to tz.

continues on next page

Table 84 – continued from previous page

Timestamp.replace([year, month, day, hour, ...])	implements datetime.replace, handles nanoseconds.
Timestamp.round(freq[, ambiguous, nonexistent])	Round the Timestamp to the specified resolution.
Timestamp.strftime	format -> strftime() style string.
Timestamp.strptime(string, format)	Function is not implemented.
Timestamp.time	Return time object with same time but with tzinfo=None.
Timestamp.timestamp	Return POSIX timestamp as float.
Timestamp.timetuple	Return time tuple, compatible with time.localtime().
Timestamp.timetz	Return time object with same time and tzinfo.
Timestamp.to_datetime64	Return a numpy.datetime64 object with 'ns' precision.
Timestamp.to_numpy	Convert the Timestamp to a NumPy datetime64.
Timestamp.to_julian_date()	Convert TimeStamp to a Julian Date.
Timestamp.to_period	Return an period of which this timestamp is an observation.
Timestamp.to_pydatetime	Convert a Timestamp object to a native Python datetime object.
Timestamp.today(cls[, tz])	Return the current time in the local timezone.
Timestamp.toordinal	Return proleptic Gregorian ordinal.
Timestamp.tz_convert(tz)	Convert tz-aware Timestamp to another time zone.
Timestamp.tz_localize(tz[, ambiguous, ...])	Convert naive Timestamp to local time zone, or remove timezone from tz-aware Timestamp.
Timestamp.tzname	Return self.tzinfo.tzname(self).
Timestamp.utcfromtimestamp(ts)	Construct a naive UTC datetime from a POSIX timestamp.
Timestamp.utcnow()	Return a new Timestamp representing UTC day and time.
Timestamp.utcoffset	Return self.tzinfo.utcoffset(self).
Timestamp.utctimetuple	Return UTC time tuple, compatible with time.localtime().
Timestamp.weekday	Return the day of the week represented by the date.

pandas.Timestamp.freq

Timestamp.**freq**

A collection of timestamps may be stored in a *arrays.DatetimeArray*. For timezone-aware data, the `.dtype` of a `DatetimeArray` is a *DatetimeTZDtype*. For timezone-naive data, `np.dtype("datetime64[ns]")` is used.

If the data are tz-aware, then every value in the array must have the same timezone.

arrays.DatetimeArray(values[, dtype, freq, copy])	Pandas ExtensionArray for tz-naive or tz-aware datetime data.

pandas.arrays.DatetimeArray

class pandas.arrays.**DatetimeArray**(*values*, *dtype=dtype('<M8[ns]')*, *freq=None*, *copy=False*)

Pandas ExtensionArray for tz-naive or tz-aware datetime data.

New in version 0.24.0.

> **Warning:** DatetimeArray is currently experimental, and its API may change without warning. In particular, `DatetimeArray.dtype` is expected to change to always be an instance of an `ExtensionDtype` subclass.

Parameters

values [Series, Index, DatetimeArray, ndarray] The datetime data.

For DatetimeArray *values* (or a Series or Index boxing one), *dtype* and *freq* will be extracted from *values*.

dtype [numpy.dtype or DatetimeTZDtype] Note that the only NumPy dtype allowed is 'datetime64[ns]'.

freq [str or Offset, optional] The frequency.

copy [bool, default False] Whether to copy the underlying array of values.

Attributes

None	

Methods

None	

DatetimeTZDtype([unit, tz])	An ExtensionDtype for timezone-aware datetime data.

pandas.DatetimeTZDtype

class pandas.**DatetimeTZDtype**(*unit='ns'*, *tz=None*)

An ExtensionDtype for timezone-aware datetime data.

This is not an actual numpy dtype, but a duck type.

Parameters

unit [str, default "ns"] The precision of the datetime data. Currently limited to `"ns"`.

tz [str, int, or datetime.tzinfo] The timezone.

Raises

pytz.UnknownTimeZoneError When the requested timezone cannot be found.

Examples

```
>>> pd.DatetimeTZDtype(tz='UTC')
datetime64[ns, UTC]
```

```
>>> pd.DatetimeTZDtype(tz='dateutil/US/Central')
datetime64[ns, tzfile('/usr/share/zoneinfo/US/Central')]
```

Attributes

unit	The precision of the datetime data.
tz	The timezone.

pandas.DatetimeTZDtype.unit

property DatetimeTZDtype.**unit**
The precision of the datetime data.

pandas.DatetimeTZDtype.tz

property DatetimeTZDtype.**tz**
The timezone.

Methods

None	

3.5.3 Timedelta data

NumPy can natively represent timedeltas. Pandas provides *Timedelta* for symmetry with *Timestamp*.

Timedelta([value, unit])	Represents a duration, the difference between two dates or times.

pandas.Timedelta

class pandas.**Timedelta**(*value=<object object>*, *unit=None*, ***kwargs*)
Represents a duration, the difference between two dates or times.

Timedelta is the pandas equivalent of python's `datetime.timedelta` and is interchangeable with it in most cases.

Parameters

value [Timedelta, timedelta, np.timedelta64, str, or int]

unit [str, default 'ns'] Denote the unit of the input, if input is an integer.

Possible values:

- 'W', 'D', 'T', 'S', 'L', 'U', or 'N'
- 'days' or 'day'
- 'hours', 'hour', 'hr', or 'h'
- 'minutes', 'minute', 'min', or 'm'
- 'seconds', 'second', or 'sec'
- 'milliseconds', 'millisecond', 'millis', or 'milli'
- 'microseconds', 'microsecond', 'micros', or 'micro'
- 'nanoseconds', 'nanosecond', 'nanos', 'nano', or 'ns'.

****kwargs** Available kwargs: {days, seconds, microseconds, milliseconds, minutes, hours, weeks}. Values for construction in compat with datetime.timedelta. Numpy ints and floats will be coerced to python ints and floats.

Notes

The `.value` attribute is always in ns.

Attributes

asm8	Return a numpy timedelta64 array scalar view.
components	Return a components namedtuple-like.
days	Number of days.
delta	Return the timedelta in nanoseconds (ns), for internal compatibility.
microseconds	Number of microseconds (>= 0 and less than 1 second).
nanoseconds	Return the number of nanoseconds (n), where 0 <= n < 1 microsecond.
resolution_string	Return a string representing the lowest timedelta resolution.
seconds	Number of seconds (>= 0 and less than 1 day).

pandas.Timedelta.asm8

Timedelta.**asm8**

Return a numpy timedelta64 array scalar view.

Provides access to the array scalar view (i.e. a combination of the value and the units) associated with the numpy.timedelta64().view(), including a 64-bit integer representation of the timedelta in nanoseconds (Python int compatible).

Returns

numpy timedelta64 array scalar view Array scalar view of the timedelta in nanoseconds.

Examples

```
>>> td = pd.Timedelta('1 days 2 min 3 us 42 ns')
>>> td.asm8
numpy.timedelta64(86520000003042,'ns')
```

```
>>> td = pd.Timedelta('2 min 3 s')
>>> td.asm8
numpy.timedelta64(123000000000,'ns')
```

```
>>> td = pd.Timedelta('3 ms 5 us')
>>> td.asm8
numpy.timedelta64(3005000,'ns')
```

```
>>> td = pd.Timedelta(42, unit='ns')
>>> td.asm8
numpy.timedelta64(42,'ns')
```

pandas.Timedelta.components

Timedelta.**components**
Return a components namedtuple-like.

pandas.Timedelta.days

Timedelta.**days**
Number of days.

pandas.Timedelta.delta

Timedelta.**delta**
Return the timedelta in nanoseconds (ns), for internal compatibility.

Returns

int Timedelta in nanoseconds.

Examples

```
>>> td = pd.Timedelta('1 days 42 ns')
>>> td.delta
86400000000042
```

```
>>> td = pd.Timedelta('3 s')
>>> td.delta
3000000000
```

```
>>> td = pd.Timedelta('3 ms 5 us')
>>> td.delta
3005000
```

```
>>> td = pd.Timedelta(42, unit='ns')
>>> td.delta
42
```

pandas.Timedelta.microseconds

Timedelta.**microseconds**
Number of microseconds (>= 0 and less than 1 second).

pandas.Timedelta.nanoseconds

Timedelta.**nanoseconds**
Return the number of nanoseconds (n), where 0 <= n < 1 microsecond.

Returns

int Number of nanoseconds.

See also:

Timedelta.components Return all attributes with assigned values (i.e. days, hours, minutes, seconds, milliseconds, microseconds, nanoseconds).

Examples

Using string input

```
>>> td = pd.Timedelta('1 days 2 min 3 us 42 ns')
```

```
>>> td.nanoseconds
42
```

Using integer input

```
>>> td = pd.Timedelta(42, unit='ns')
>>> td.nanoseconds
42
```

pandas.Timedelta.resolution_string

Timedelta.**resolution_string**
Return a string representing the lowest timedelta resolution.

Each timedelta has a defined resolution that represents the lowest OR most granular level of precision. Each level of resolution is represented by a short string as defined below:

Resolution: Return value

- Days: 'D'
- Hours: 'H'
- Minutes: 'T'

- Seconds: 'S'
- Milliseconds: 'L'
- Microseconds: 'U'
- Nanoseconds: 'N'

Returns

str Timedelta resolution.

Examples

```
>>> td = pd.Timedelta('1 days 2 min 3 us 42 ns')
>>> td.resolution_string
'N'
```

```
>>> td = pd.Timedelta('1 days 2 min 3 us')
>>> td.resolution_string
'U'
```

```
>>> td = pd.Timedelta('2 min 3 s')
>>> td.resolution_string
'S'
```

```
>>> td = pd.Timedelta(36, unit='us')
>>> td.resolution_string
'U'
```

pandas.Timedelta.seconds

Timedelta.**seconds**
Number of seconds (>= 0 and less than 1 day).

freq	
is_populated	
value	

Methods

ceil(freq)	Return a new Timedelta ceiled to this resolution.
floor(freq)	Return a new Timedelta floored to this resolution.
isoformat	Format Timedelta as ISO 8601 Duration like `P[n]Y[n]M[n]DT[n]H[n]M[n]S`, where the `[n]` s are replaced by the values.
round(freq)	Round the Timedelta to the specified resolution.
to_numpy	Convert the Timedelta to a NumPy timedelta64.
to_pytimedelta	Convert a pandas Timedelta object into a python timedelta object.

continues on next page

Table 90 – continued from previous page

to_timedelta64	Return a numpy.timedelta64 object with 'ns' precision.
total_seconds	Total seconds in the duration.
view	Array view compatibility.

pandas.Timedelta.ceil

Timedelta.**ceil**(*freq*)

Return a new Timedelta ceiled to this resolution.

Parameters

freq [str] Frequency string indicating the ceiling resolution.

pandas.Timedelta.floor

Timedelta.**floor**(*freq*)

Return a new Timedelta floored to this resolution.

Parameters

freq [str] Frequency string indicating the flooring resolution.

pandas.Timedelta.isoformat

Timedelta.**isoformat**()

Format Timedelta as ISO 8601 Duration like `P[n]Y[n]M[n]DT[n]H[n]M[n]S`, where the `[n]` s are replaced by the values. See https://en.wikipedia.org/wiki/ISO_8601#Durations.

Returns

str

See also:

Timestamp.isoformat

Notes

The longest component is days, whose value may be larger than 365. Every component is always included, even if its value is 0. Pandas uses nanosecond precision, so up to 9 decimal places may be included in the seconds component. Trailing 0's are removed from the seconds component after the decimal. We do not 0 pad components, so it's . . . *T5H*. . . , not . . . *T05H*. . .

Examples

```
>>> td = pd.Timedelta(days=6, minutes=50, seconds=3,
...                   milliseconds=10, microseconds=10, nanoseconds=12)
```

```
>>> td.isoformat()
'P6DT0H50M3.010010012S'
>>> pd.Timedelta(hours=1, seconds=10).isoformat()
'P0DT0H0M10S'
>>> pd.Timedelta(hours=1, seconds=10).isoformat()
'P0DT0H0M10S'
>>> pd.Timedelta(days=500.5).isoformat()
'P500DT12H0MS'
```

pandas.Timedelta.round

Timedelta.**round**(*freq*)

Round the Timedelta to the specified resolution.

Parameters

freq [str] Frequency string indicating the rounding resolution.

Returns

a new Timedelta rounded to the given resolution of *freq*

Raises

ValueError if the freq cannot be converted

pandas.Timedelta.to_numpy

Timedelta.**to_numpy**()

Convert the Timedelta to a NumPy timedelta64.

New in version 0.25.0.

This is an alias method for *Timedelta.to_timedelta64()*. The dtype and copy parameters are available here only for compatibility. Their values will not affect the return value.

Returns

numpy.timedelta64

See also:

Series.to_numpy Similar method for Series.

pandas.Timedelta.to_pytimedelta

Timedelta.**to_pytimedelta**()
Convert a pandas Timedelta object into a python timedelta object.

Timedelta objects are internally saved as numpy datetime64[ns] dtype. Use to_pytimedelta() to convert to object dtype.

Returns

datetime.timedelta or numpy.array of datetime.timedelta

See also:

to_timedelta Convert argument to Timedelta type.

Notes

Any nanosecond resolution will be lost.

pandas.Timedelta.to_timedelta64

Timedelta.**to_timedelta64**()
Return a numpy.timedelta64 object with 'ns' precision.

pandas.Timedelta.total_seconds

Timedelta.**total_seconds**()
Total seconds in the duration.

pandas.Timedelta.view

Timedelta.**view**()
Array view compatibility.

Properties

Timedelta.asm8	Return a numpy timedelta64 array scalar view.
Timedelta.components	Return a components namedtuple-like.
Timedelta.days	Number of days.
Timedelta.delta	Return the timedelta in nanoseconds (ns), for internal compatibility.
Timedelta.freq	
Timedelta.is_populated	
Timedelta.max	
Timedelta.microseconds	Number of microseconds (>= 0 and less than 1 second).
Timedelta.min	
Timedelta.nanoseconds	Return the number of nanoseconds (n), where 0 <= n < 1 microsecond.

continues on next page

Table 91 – continued from previous page

Timedelta.resolution	
Timedelta.seconds	Number of seconds (>= 0 and less than 1 day).
Timedelta.value	
Timedelta.view	Array view compatibility.

pandas.Timedelta.freq

Timedelta.**freq**

pandas.Timedelta.is_populated

Timedelta.**is_populated**

pandas.Timedelta.max

Timedelta.**max = Timedelta('106751 days 23:47:16.854775807')**

pandas.Timedelta.min

Timedelta.**min = Timedelta('-106752 days +00:12:43.145224193')**

pandas.Timedelta.resolution

Timedelta.**resolution = Timedelta('0 days 00:00:00.000000001')**

pandas.Timedelta.value

Timedelta.**value**

Methods

Timedelta.ceil(freq)	Return a new Timedelta ceiled to this resolution.
Timedelta.floor(freq)	Return a new Timedelta floored to this resolution.
Timedelta.isoformat	Format Timedelta as ISO 8601 Duration like `P[n]Y[n]M[n]DT[n]H[n]M[n]S`, where the `[n]` s are replaced by the values.
Timedelta.round(freq)	Round the Timedelta to the specified resolution.
Timedelta.to_pytimedelta	Convert a pandas Timedelta object into a python timedelta object.
Timedelta.to_timedelta64	Return a numpy.timedelta64 object with 'ns' precision.
Timedelta.to_numpy	Convert the Timedelta to a NumPy timedelta64.
Timedelta.total_seconds	Total seconds in the duration.

A collection of timedeltas may be stored in a `TimedeltaArray`.

arrays.TimedeltaArray(values[, dtype, freq, ...])	Pandas ExtensionArray for timedelta data.

pandas.arrays.TimedeltaArray

class pandas.arrays.**TimedeltaArray**(*values*, *dtype=dtype('<m8[ns]')*, *freq=<object object>*, *copy=False*)

Pandas ExtensionArray for timedelta data.

New in version 0.24.0.

Warning: TimedeltaArray is currently experimental, and its API may change without warning. In particular, `TimedeltaArray.dtype` is expected to change to be an instance of an `ExtensionDtype` subclass.

Parameters

values [array-like] The timedelta data.

dtype [numpy.dtype] Currently, only `numpy.dtype("timedelta64[ns]")` is accepted.

freq [Offset, optional]

copy [bool, default False] Whether to copy the underlying array of data.

Attributes

None	

Methods

None	

3.5.4 Timespan data

Pandas represents spans of times as *Period* objects.

3.5.5 Period

Period([value, freq, ordinal, year, month, ...])	Represents a period of time.

pandas.Period

class pandas.**Period**(*value=None*, *freq=None*, *ordinal=None*, *year=None*, *month=None*, *quarter=None*, *day=None*, *hour=None*, *minute=None*, *second=None*)

Represents a period of time.

Parameters

value [Period or str, default None] The time period represented (e.g., '4Q2005').

freq [str, default None] One of pandas period strings or corresponding objects.

ordinal [int, default None] The period offset from the gregorian proleptic epoch.

year [int, default None] Year value of the period.

month [int, default 1] Month value of the period.

quarter [int, default None] Quarter value of the period.

day [int, default 1] Day value of the period.

hour [int, default 0] Hour value of the period.

minute [int, default 0] Minute value of the period.

second [int, default 0] Second value of the period.

Attributes

day	Get day of the month that a Period falls on.
dayofweek	Day of the week the period lies in, with Monday=0 and Sunday=6.
dayofyear	Return the day of the year.
days_in_month	Get the total number of days in the month that this period falls on.
daysinmonth	Get the total number of days of the month that the Period falls in.
hour	Get the hour of the day component of the Period.
minute	Get minute of the hour component of the Period.
qyear	Fiscal year the Period lies in according to its starting-quarter.
second	Get the second component of the Period.
start_time	Get the Timestamp for the start of the period.
week	Get the week of the year on the given Period.
weekday	Day of the week the period lies in, with Monday=0 and Sunday=6.

pandas.Period.day

Period.**day**

Get day of the month that a Period falls on.

Returns

int

See also:

Period.dayofweek Get the day of the week.

Period.dayofyear Get the day of the year.

Examples

```
>>> p = pd.Period("2018-03-11", freq='H')
>>> p.day
11
```

pandas.Period.dayofweek

Period.**dayofweek**

Day of the week the period lies in, with Monday=0 and Sunday=6.

If the period frequency is lower than daily (e.g. hourly), and the period spans over multiple days, the day at the start of the period is used.

If the frequency is higher than daily (e.g. monthly), the last day of the period is used.

Returns

int Day of the week.

See also:

Period.dayofweek Day of the week the period lies in.

Period.weekday Alias of Period.dayofweek.

Period.day Day of the month.

Period.dayofyear Day of the year.

Examples

```
>>> per = pd.Period('2017-12-31 22:00', 'H')
>>> per.dayofweek
6
```

For periods that span over multiple days, the day at the beginning of the period is returned.

```
>>> per = pd.Period('2017-12-31 22:00', '4H')
>>> per.dayofweek
6
>>> per.start_time.dayofweek
6
```

For periods with a frequency higher than days, the last day of the period is returned.

```
>>> per = pd.Period('2018-01', 'M')
>>> per.dayofweek
2
>>> per.end_time.dayofweek
2
```

pandas.Period.dayofyear

Period.**dayofyear**

Return the day of the year.

This attribute returns the day of the year on which the particular date occurs. The return value ranges between 1 to 365 for regular years and 1 to 366 for leap years.

Returns

int The day of year.

See also:

Period.day Return the day of the month.

Period.dayofweek Return the day of week.

PeriodIndex.dayofyear Return the day of year of all indexes.

Examples

```
>>> period = pd.Period("2015-10-23", freq='H')
>>> period.dayofyear
296
>>> period = pd.Period("2012-12-31", freq='D')
>>> period.dayofyear
366
>>> period = pd.Period("2013-01-01", freq='D')
>>> period.dayofyear
1
```

pandas.Period.days_in_month

Period.**days_in_month**

Get the total number of days in the month that this period falls on.

Returns

int

See also:

Period.daysinmonth Gets the number of days in the month.

DatetimeIndex.daysinmonth Gets the number of days in the month.

calendar.monthrange Returns a tuple containing weekday (0-6 ~ Mon-Sun) and number of days (28-31).

Examples

```
>>> p = pd.Period('2018-2-17')
>>> p.days_in_month
28
```

```
>>> pd.Period('2018-03-01').days_in_month
31
```

Handles the leap year case as well:

```
>>> p = pd.Period('2016-2-17')
>>> p.days_in_month
29
```

pandas.Period.daysinmonth

Period.**daysinmonth**

Get the total number of days of the month that the Period falls in.

Returns

int

See also:

Period.days_in_month Return the days of the month.

Period.dayofyear Return the day of the year.

Examples

```
>>> p = pd.Period("2018-03-11", freq='H')
>>> p.daysinmonth
31
```

pandas.Period.hour

Period.**hour**

Get the hour of the day component of the Period.

Returns

int The hour as an integer, between 0 and 23.

See also:

Period.second Get the second component of the Period.

Period.minute Get the minute component of the Period.

Examples

```
>>> p = pd.Period("2018-03-11 13:03:12.050000")
>>> p.hour
13
```

Period longer than a day

```
>>> p = pd.Period("2018-03-11", freq="M")
>>> p.hour
0
```

pandas.Period.minute

Period.**minute**

Get minute of the hour component of the Period.

Returns

int The minute as an integer, between 0 and 59.

See also:

Period.hour Get the hour component of the Period.

Period.second Get the second component of the Period.

Examples

```
>>> p = pd.Period("2018-03-11 13:03:12.050000")
>>> p.minute
3
```

pandas.Period.qyear

Period.**qyear**

Fiscal year the Period lies in according to its starting-quarter.

The *year* and the *qyear* of the period will be the same if the fiscal and calendar years are the same. When they are not, the fiscal year can be different from the calendar year of the period.

Returns

int The fiscal year of the period.

See also:

Period.year Return the calendar year of the period.

Examples

If the natural and fiscal year are the same, *qyear* and *year* will be the same.

```
>>> per = pd.Period('2018Q1', freq='Q')
>>> per.qyear
2018
>>> per.year
2018
```

If the fiscal year starts in April (*Q-MAR*), the first quarter of 2018 will start in April 2017. *year* will then be 2018, but *qyear* will be the fiscal year, 2018.

```
>>> per = pd.Period('2018Q1', freq='Q-MAR')
>>> per.start_time
Timestamp('2017-04-01 00:00:00')
>>> per.qyear
2018
>>> per.year
2017
```

pandas.Period.second

Period.**second**

Get the second component of the Period.

Returns

int The second of the Period (ranges from 0 to 59).

See also:

Period.hour Get the hour component of the Period.

Period.minute Get the minute component of the Period.

Examples

```
>>> p = pd.Period("2018-03-11 13:03:12.050000")
>>> p.second
12
```

pandas.Period.start_time

Period.**start_time**

Get the Timestamp for the start of the period.

Returns

Timestamp

See also:

Period.end_time Return the end Timestamp.

Period.dayofyear Return the day of year.

Period.daysinmonth Return the days in that month.

Period.dayofweek Return the day of the week.

Examples

```
>>> period = pd.Period('2012-1-1', freq='D')
>>> period
Period('2012-01-01', 'D')
```

```
>>> period.start_time
Timestamp('2012-01-01 00:00:00')
```

```
>>> period.end_time
Timestamp('2012-01-01 23:59:59.999999999')
```

pandas.Period.week

Period.**week**

Get the week of the year on the given Period.

Returns

int

See also:

Period.dayofweek Get the day component of the Period.

Period.weekday Get the day component of the Period.

Examples

```
>>> p = pd.Period("2018-03-11", "H")
>>> p.week
10
```

```
>>> p = pd.Period("2018-02-01", "D")
>>> p.week
5
```

```
>>> p = pd.Period("2018-01-06", "D")
>>> p.week
1
```

pandas.Period.weekday

Period.**weekday**

Day of the week the period lies in, with Monday=0 and Sunday=6.

If the period frequency is lower than daily (e.g. hourly), and the period spans over multiple days, the day at the start of the period is used.

If the frequency is higher than daily (e.g. monthly), the last day of the period is used.

Returns

int Day of the week.

See also:

Period.dayofweek Day of the week the period lies in.

Period.weekday Alias of Period.dayofweek.

Period.day Day of the month.

Period.dayofyear Day of the year.

Examples

```
>>> per = pd.Period('2017-12-31 22:00', 'H')
>>> per.dayofweek
6
```

For periods that span over multiple days, the day at the beginning of the period is returned.

```
>>> per = pd.Period('2017-12-31 22:00', '4H')
>>> per.dayofweek
6
>>> per.start_time.dayofweek
6
```

For periods with a frequency higher than days, the last day of the period is returned.

```
>>> per = pd.Period('2018-01', 'M')
>>> per.dayofweek
2
>>> per.end_time.dayofweek
2
```

end_time	
freq	
freqstr	
is_leap_year	
month	
ordinal	
quarter	
weekofyear	
year	

Methods

asfreq	Convert Period to desired frequency, at the start or end of the interval.
strftime	Returns the string representation of the *Period*, depending on the selected `fmt`.
to_timestamp	Return the Timestamp representation of the Period.

pandas.Period.asfreq

`Period.`**`asfreq`**`()`

Convert Period to desired frequency, at the start or end of the interval.

Parameters

freq [str] The desired frequency.

how [{'E', 'S', 'end', 'start'}, default 'end'] Start or end of the timespan.

Returns

resampled [Period]

pandas.Period.strftime

`Period.`**`strftime`**`()`

Returns the string representation of the *Period*, depending on the selected `fmt`. `fmt` must be a string containing one or several directives. The method recognizes the same directives as the `time.strftime()` function of the standard Python distribution, as well as the specific additional directives `%f`, `%F`, `%q`. (formatting & docs originally from scikits.timeries).

Directive	Meaning	Notes
%a	Locale's abbreviated weekday name.	
%A	Locale's full weekday name.	
%b	Locale's abbreviated month name.	
%B	Locale's full month name.	
%c	Locale's appropriate date and time representation.	
%d	Day of the month as a decimal number [01,31].	
%f	'Fiscal' year without a century as a decimal number [00,99]	(1)
%F	'Fiscal' year with a century as a decimal number	(2)
%H	Hour (24-hour clock) as a decimal number [00,23].	
%I	Hour (12-hour clock) as a decimal number [01,12].	
%j	Day of the year as a decimal number [001,366].	
%m	Month as a decimal number [01,12].	
%M	Minute as a decimal number [00,59].	
%p	Locale's equivalent of either AM or PM.	(3)
%q	Quarter as a decimal number [01,04]	
%S	Second as a decimal number [00,61].	(4)
%U	Week number of the year (Sunday as the first day of the week) as a decimal number [00,53]. All days in a new year preceding the first Sunday are considered to be in week 0.	(5)
%w	Weekday as a decimal number [0(Sunday),6].	
%W	Week number of the year (Monday as the first day of the week) as a decimal number [00,53]. All days in a new year preceding the first Monday are considered to be in week 0.	(5)
%x	Locale's appropriate date representation.	
%X	Locale's appropriate time representation.	
%y	Year without century as a decimal number [00,99].	
%Y	Year with century as a decimal number.	
%Z	Time zone name (no characters if no time zone exists).	
%%	A literal '%' character.	

Notes

(1) The %f directive is the same as %y if the frequency is not quarterly. Otherwise, it corresponds to the 'fiscal' year, as defined by the *qyear* attribute.

(2) The %F directive is the same as %Y if the frequency is not quarterly. Otherwise, it corresponds to the 'fiscal' year, as defined by the *qyear* attribute.

(3) The %p directive only affects the output hour field if the %I directive is used to parse the hour.

(4) The range really is 0 to 61; this accounts for leap seconds and the (very rare) double leap seconds.

(5) The %U and %W directives are only used in calculations when the day of the week and the year are specified.

Examples

```
>>> a = Period(freq='Q-JUL', year=2006, quarter=1)
>>> a.strftime('%F-Q%q')
'2006-Q1'
>>> # Output the last month in the quarter of this date
>>> a.strftime('%b-%Y')
'Oct-2005'
>>>
>>> a = Period(freq='D', year=2001, month=1, day=1)
>>> a.strftime('%d-%b-%Y')
'01-Jan-2006'
>>> a.strftime('%b. %d, %Y was a %A')
'Jan. 01, 2001 was a Monday'
```

pandas.Period.to_timestamp

Period.**to_timestamp**()

Return the Timestamp representation of the Period.

Uses the target frequency specified at the part of the period specified by *how*, which is either *Start* or *Finish*.

Parameters

freq [str or DateOffset] Target frequency. Default is 'D' if self.freq is week or longer and 'S' otherwise.

how [str, default 'S' (start)] One of 'S', 'E'. Can be aliased as case insensitive 'Start', 'Finish', 'Begin', 'End'.

Returns

Timestamp

now	

Properties

Period.day	Get day of the month that a Period falls on.
Period.dayofweek	Day of the week the period lies in, with Monday=0 and Sunday=6.
Period.dayofyear	Return the day of the year.
Period.days_in_month	Get the total number of days in the month that this period falls on.
Period.daysinmonth	Get the total number of days of the month that the Period falls in.
Period.end_time	
Period.freq	
Period.freqstr	
Period.hour	Get the hour of the day component of the Period.
Period.is_leap_year	
Period.minute	Get minute of the hour component of the Period.

continues on next page

Table 97 – continued from previous page

Period.month	
Period.ordinal	
Period.quarter	
Period.qyear	Fiscal year the Period lies in according to its starting-quarter.
Period.second	Get the second component of the Period.
Period.start_time	Get the Timestamp for the start of the period.
Period.week	Get the week of the year on the given Period.
Period.weekday	Day of the week the period lies in, with Monday=0 and Sunday=6.
Period.weekofyear	
Period.year	

pandas.Period.end_time

Period.**end_time**

pandas.Period.freq

Period.**freq**

pandas.Period.freqstr

Period.**freqstr**

pandas.Period.is_leap_year

Period.**is_leap_year**

pandas.Period.month

Period.**month**

pandas.Period.ordinal

Period.**ordinal**

pandas.Period.quarter

Period.**quarter**

pandas.Period.weekofyear

Period.**weekofyear**

pandas.Period.year

Period.**year**

Methods

Period.asfreq	Convert Period to desired frequency, at the start or end of the interval.
Period.now	
Period.strftime	Returns the string representation of the *Period*, depending on the selected `fmt`.
Period.to_timestamp	Return the Timestamp representation of the Period.

pandas.Period.now

Period.**now**()

A collection of timedeltas may be stored in a *arrays.PeriodArray*. Every period in a `PeriodArray` must have the same `freq`.

arrays.PeriodArray(values[, freq, dtype, copy])	Pandas ExtensionArray for storing Period data.

pandas.arrays.PeriodArray

class pandas.arrays.**PeriodArray**(*values*, *freq=None*, *dtype=None*, *copy=False*)

Pandas ExtensionArray for storing Period data.

Users should use `period_array()` to create new instances.

Parameters

values [Union[PeriodArray, Series[period], ndarray[int], PeriodIndex]] The data to store. These should be arrays that can be directly converted to ordinals without inference or copy (PeriodArray, ndarray[int64]), or a box around such an array (Series[period], PeriodIndex).

freq [str or DateOffset] The *freq* to use for the array. Mostly applicable when *values* is an ndarray of integers, when *freq* is required. When *values* is a PeriodArray (or box around), it's checked that `values.freq` matches *freq*.

dtype [PeriodDtype, optional] A PeriodDtype instance from which to extract a *freq*. If both *freq* and *dtype* are specified, then the frequencies must match.

copy [bool, default False] Whether to copy the ordinals before storing.

See also:

period_array Create a new PeriodArray.
PeriodIndex Immutable Index for period data.

Notes

There are two components to a PeriodArray

- ordinals : integer ndarray
- freq : pd.tseries.offsets.Offset

The values are physically stored as a 1-D ndarray of integers. These are called "ordinals" and represent some kind of offset from a base.

The *freq* indicates the span covered by each element of the array. All elements in the PeriodArray have the same *freq*.

Attributes

None	

Methods

None	

PeriodDtype([freq])	An ExtensionDtype for Period data.

pandas.PeriodDtype

class pandas.**PeriodDtype**(*freq=None*)

An ExtensionDtype for Period data.

This is not an actual numpy dtype, but a duck type.

Parameters

freq [str or DateOffset] The frequency of this PeriodDtype.

Examples

```
>>> pd.PeriodDtype(freq='D')
period[D]
```

```
>>> pd.PeriodDtype(freq=pd.offsets.MonthEnd())
period[M]
```

Attributes

freq	The frequency object of this PeriodDtype.

pandas.PeriodDtype.freq

property PeriodDtype.**freq**
The frequency object of this PeriodDtype.

Methods

None	

3.5.6 Interval data

Arbitrary intervals can be represented as *Interval* objects.

Interval	Immutable object implementing an Interval, a bounded slice-like interval.

pandas.Interval

class pandas.**Interval**
Immutable object implementing an Interval, a bounded slice-like interval.

Parameters

left [orderable scalar] Left bound for the interval.

right [orderable scalar] Right bound for the interval.

closed [{'right', 'left', 'both', 'neither'}, default 'right'] Whether the interval is closed on the left-side, right-side, both or neither. See the Notes for more detailed explanation.

See also:

IntervalIndex An Index of Interval objects that are all closed on the same side.
cut Convert continuous data into discrete bins (Categorical of Interval objects).
qcut Convert continuous data into bins (Categorical of Interval objects) based on quantiles.
Period Represents a period of time.

Notes

The parameters *left* and *right* must be from the same type, you must be able to compare them and they must satisfy `left <= right`.

A closed interval (in mathematics denoted by square brackets) contains its endpoints, i.e. the closed interval `[0, 5]` is characterized by the conditions `0 <= x <= 5`. This is what `closed='both'` stands for. An open interval (in mathematics denoted by parentheses) does not contain its endpoints, i.e. the open interval `(0, 5)` is characterized by the conditions `0 < x < 5`. This is what `closed='neither'` stands for. Intervals can also be half-open or half-closed, i.e. `[0, 5)` is described by `0 <= x < 5` (`closed='left'`) and `(0, 5]` is described by `0 < x <= 5` (`closed='right'`).

Examples

It is possible to build Intervals of different types, like numeric ones:

```
>>> iv = pd.Interval(left=0, right=5)
>>> iv
Interval(0, 5, closed='right')
```

You can check if an element belongs to it

```
>>> 2.5 in iv
True
```

You can test the bounds (`closed='right'`, so `0 < x <= 5`):

```
>>> 0 in iv
False
>>> 5 in iv
True
>>> 0.0001 in iv
True
```

Calculate its length

```
>>> iv.length
5
```

You can operate with + and * over an Interval and the operation is applied to each of its bounds, so the result depends on the type of the bound elements

```
>>> shifted_iv = iv + 3
>>> shifted_iv
Interval(3, 8, closed='right')
>>> extended_iv = iv * 10.0
>>> extended_iv
Interval(0.0, 50.0, closed='right')
```

To create a time interval you can use Timestamps as the bounds

```
>>> year_2017 = pd.Interval(pd.Timestamp('2017-01-01 00:00:00'),
...                         pd.Timestamp('2018-01-01 00:00:00'),
...                         closed='left')
>>> pd.Timestamp('2017-01-01 00:00') in year_2017
True
>>> year_2017.length
Timedelta('365 days 00:00:00')
```

And also you can create string intervals

```
>>> volume_1 = pd.Interval('Ant', 'Dog', closed='both')
>>> 'Bee' in volume_1
True
```

Attributes

closed	Whether the interval is closed on the left-side, right-side, both or neither.
closed_left	Check if the interval is closed on the left side.
closed_right	Check if the interval is closed on the right side.
is_empty	Indicates if an interval is empty, meaning it contains no points.
left	Left bound for the interval.
length	Return the length of the Interval.
mid	Return the midpoint of the Interval.
open_left	Check if the interval is open on the left side.
open_right	Check if the interval is open on the right side.
right	Right bound for the interval.

pandas.Interval.closed

Interval.**closed**
Whether the interval is closed on the left-side, right-side, both or neither.

pandas.Interval.closed_left

Interval.**closed_left**
Check if the interval is closed on the left side.

For the meaning of *closed* and *open* see *Interval*.

Returns

bool True if the Interval is closed on the left-side.

pandas.Interval.closed_right

Interval.**closed_right**
Check if the interval is closed on the right side.

For the meaning of *closed* and *open* see *Interval*.

Returns

bool True if the Interval is closed on the left-side.

pandas.Interval.is_empty

Interval.**is_empty**
Indicates if an interval is empty, meaning it contains no points.

New in version 0.25.0.

Returns

bool or ndarray A boolean indicating if a scalar *Interval* is empty, or a boolean ndarray positionally indicating if an Interval in an *IntervalArray* or *IntervalIndex* is empty.

Examples

An *Interval* that contains points is not empty:

```
>>> pd.Interval(0, 1, closed='right').is_empty
False
```

An Interval that does not contain any points is empty:

```
>>> pd.Interval(0, 0, closed='right').is_empty
True
>>> pd.Interval(0, 0, closed='left').is_empty
True
>>> pd.Interval(0, 0, closed='neither').is_empty
True
```

An Interval that contains a single point is not empty:

```
>>> pd.Interval(0, 0, closed='both').is_empty
False
```

An *IntervalArray* or *IntervalIndex* returns a boolean ndarray positionally indicating if an Interval is empty:

```
>>> ivs = [pd.Interval(0, 0, closed='neither'),
...        pd.Interval(1, 2, closed='neither')]
>>> pd.arrays.IntervalArray(ivs).is_empty
array([ True, False])
```

Missing values are not considered empty:

```
>>> ivs = [pd.Interval(0, 0, closed='neither'), np.nan]
>>> pd.IntervalIndex(ivs).is_empty
array([ True, False])
```

pandas.Interval.left

Interval.**left**
Left bound for the interval.

pandas.Interval.length

Interval.**length**
Return the length of the Interval.

pandas.Interval.mid

Interval.**mid**
Return the midpoint of the Interval.

pandas.Interval.open_left

Interval.**open_left**
Check if the interval is open on the left side.

For the meaning of *closed* and *open* see *Interval*.

Returns

bool True if the Interval is closed on the left-side.

pandas.Interval.open_right

Interval.**open_right**
Check if the interval is open on the right side.

For the meaning of *closed* and *open* see *Interval*.

Returns

bool True if the Interval is closed on the left-side.

pandas.Interval.right

Interval.**right**
Right bound for the interval.

Methods

overlaps	Check whether two Interval objects overlap.

pandas.Interval.overlaps

Interval.**overlaps**()
Check whether two Interval objects overlap.

Two intervals overlap if they share a common point, including closed endpoints. Intervals that only have an open endpoint in common do not overlap.

New in version 0.24.0.

Parameters

other [Interval] Interval to check against for an overlap.

Returns

bool True if the two intervals overlap.

See also:

`IntervalArray.overlaps` The corresponding method for IntervalArray.

`IntervalIndex.overlaps` The corresponding method for IntervalIndex.

Examples

```
>>> i1 = pd.Interval(0, 2)
>>> i2 = pd.Interval(1, 3)
>>> i1.overlaps(i2)
True
>>> i3 = pd.Interval(4, 5)
>>> i1.overlaps(i3)
False
```

Intervals that share closed endpoints overlap:

```
>>> i4 = pd.Interval(0, 1, closed='both')
>>> i5 = pd.Interval(1, 2, closed='both')
>>> i4.overlaps(i5)
True
```

Intervals that only have an open endpoint in common do not overlap:

```
>>> i6 = pd.Interval(1, 2, closed='neither')
>>> i4.overlaps(i6)
False
```

Properties

Interval.closed	Whether the interval is closed on the left-side, right-side, both or neither.
Interval.closed_left	Check if the interval is closed on the left side.
Interval.closed_right	Check if the interval is closed on the right side.
Interval.is_empty	Indicates if an interval is empty, meaning it contains no points.
Interval.left	Left bound for the interval.
Interval.length	Return the length of the Interval.
Interval.mid	Return the midpoint of the Interval.
Interval.open_left	Check if the interval is open on the left side.
Interval.open_right	Check if the interval is open on the right side.
Interval.overlaps	Check whether two Interval objects overlap.
Interval.right	Right bound for the interval.

A collection of intervals may be stored in an *arrays.IntervalArray*.

arrays.IntervalArray(data[, closed, dtype, ...])	Pandas array for interval data that are closed on the same side.

pandas.arrays.IntervalArray

class pandas.arrays.**IntervalArray**(*data*, *closed=None*, *dtype=None*, *copy=False*, *verify_integrity=True*)

Pandas array for interval data that are closed on the same side.

New in version 0.24.0.

Parameters

data [array-like (1-dimensional)] Array-like containing Interval objects from which to build the IntervalArray.

closed [{'left', 'right', 'both', 'neither'}, default 'right'] Whether the intervals are closed on the left-side, right-side, both or neither.

dtype [dtype or None, default None] If None, dtype will be inferred.

New in version 0.23.0.

copy [bool, default False] Copy the input data.

verify_integrity [bool, default True] Verify that the IntervalArray is valid.

See also:

Index The base pandas Index type.
Interval A bounded slice-like interval; the elements of an IntervalArray.
interval_range Function to create a fixed frequency IntervalIndex.
cut Bin values into discrete Intervals.
qcut Bin values into equal-sized Intervals based on rank or sample quantiles.

Notes

See the user guide for more.

Examples

A new `IntervalArray` can be constructed directly from an array-like of `Interval` objects:

```
>>> pd.arrays.IntervalArray([pd.Interval(0, 1), pd.Interval(1, 5)])
<IntervalArray>
[(0, 1], (1, 5]]
Length: 2, closed: right, dtype: interval[int64]
```

It may also be constructed using one of the constructor methods: *IntervalArray.from_arrays()*, *IntervalArray.from_breaks()*, and *IntervalArray.from_tuples()*.

Attributes

left	Return the left endpoints of each Interval in the IntervalArray as an Index.
right	Return the right endpoints of each Interval in the IntervalArray as an Index.
closed	Whether the intervals are closed on the left-side, right-side, both or neither.

continues on next page

Table 107 – continued from previous page

mid	Return the midpoint of each Interval in the IntervalArray as an Index.
length	Return an Index with entries denoting the length of each Interval in the IntervalArray.
is_empty	Indicates if an interval is empty, meaning it contains no points.
is_non_overlapping_monotonic	Return True if the IntervalArray is non-overlapping (no Intervals share points) and is either monotonic increasing or monotonic decreasing, else False.

pandas.arrays.IntervalArray.left

property IntervalArray.**left**
Return the left endpoints of each Interval in the IntervalArray as an Index.

pandas.arrays.IntervalArray.right

property IntervalArray.**right**
Return the right endpoints of each Interval in the IntervalArray as an Index.

pandas.arrays.IntervalArray.closed

property IntervalArray.**closed**
Whether the intervals are closed on the left-side, right-side, both or neither.

pandas.arrays.IntervalArray.mid

property IntervalArray.**mid**
Return the midpoint of each Interval in the IntervalArray as an Index.

pandas.arrays.IntervalArray.length

property IntervalArray.**length**
Return an Index with entries denoting the length of each Interval in the IntervalArray.

pandas.arrays.IntervalArray.is_empty

IntervalArray.**is_empty**
Indicates if an interval is empty, meaning it contains no points.

New in version 0.25.0.

Returns

bool or ndarray A boolean indicating if a scalar `Interval` is empty, or a boolean `ndarray` positionally indicating if an `Interval` in an `IntervalArray` or `IntervalIndex` is empty.

Examples

An `Interval` that contains points is not empty:

```
>>> pd.Interval(0, 1, closed='right').is_empty
False
```

An `Interval` that does not contain any points is empty:

```
>>> pd.Interval(0, 0, closed='right').is_empty
True
>>> pd.Interval(0, 0, closed='left').is_empty
True
>>> pd.Interval(0, 0, closed='neither').is_empty
True
```

An `Interval` that contains a single point is not empty:

```
>>> pd.Interval(0, 0, closed='both').is_empty
False
```

An `IntervalArray` or `IntervalIndex` returns a boolean `ndarray` positionally indicating if an `Interval` is empty:

```
>>> ivs = [pd.Interval(0, 0, closed='neither'),
...        pd.Interval(1, 2, closed='neither')]
>>> pd.arrays.IntervalArray(ivs).is_empty
array([ True, False])
```

Missing values are not considered empty:

```
>>> ivs = [pd.Interval(0, 0, closed='neither'), np.nan]
>>> pd.IntervalIndex(ivs).is_empty
array([ True, False])
```

pandas.arrays.IntervalArray.is_non_overlapping_monotonic

property IntervalArray.**is_non_overlapping_monotonic**

Return True if the IntervalArray is non-overlapping (no Intervals share points) and is either monotonic increasing or monotonic decreasing, else False.

Methods

from_arrays(left, right[, closed, copy, dtype])	Construct from two arrays defining the left and right bounds.
from_tuples(data[, closed, copy, dtype])	Construct an IntervalArray from an array-like of tuples.
from_breaks(breaks[, closed, copy, dtype])	Construct an IntervalArray from an array of splits.
contains(other)	Check elementwise if the Intervals contain the value.
overlaps(other)	Check elementwise if an Interval overlaps the values in the IntervalArray.

continues on next page

Table 108 – continued from previous page

set_closed(closed)	Return an IntervalArray identical to the current one, but closed on the specified side.
to_tuples([na_tuple])	Return an ndarray of tuples of the form (left, right).

pandas.arrays.IntervalArray.from_arrays

classmethod IntervalArray.**from_arrays**(*left*, *right*, *closed='right'*, *copy=False*, *dtype=None*)

Construct from two arrays defining the left and right bounds.

Parameters

left [array-like (1-dimensional)] Left bounds for each interval.

right [array-like (1-dimensional)] Right bounds for each interval.

closed [{'left', 'right', 'both', 'neither'}, default 'right'] Whether the intervals are closed on the left-side, right-side, both or neither.

copy [bool, default False] Copy the data.

dtype [dtype, optional] If None, dtype will be inferred.

New in version 0.23.0.

Returns

IntervalArray

Raises

ValueError When a value is missing in only one of *left* or *right*. When a value in *left* is greater than the corresponding value in *right*.

See also:

interval_range Function to create a fixed frequency IntervalIndex.

IntervalArray.from_breaks Construct an IntervalArray from an array of splits.

IntervalArray.from_tuples Construct an IntervalArray from an array-like of tuples.

Notes

Each element of *left* must be less than or equal to the *right* element at the same position. If an element is missing, it must be missing in both *left* and *right*. A TypeError is raised when using an unsupported type for *left* or *right*. At the moment, 'category', 'object', and 'string' subtypes are not supported.

```
>>> pd.arrays.IntervalArray.from_arrays([0, 1, 2], [1, 2, 3])
<IntervalArray>
[(0, 1], (1, 2], (2, 3]]
Length: 3, closed: right, dtype: interval[int64]
```

pandas.arrays.IntervalArray.from_tuples

classmethod IntervalArray.**from_tuples**(*data*, *closed='right'*, *copy=False*, *dtype=None*)

Construct an IntervalArray from an array-like of tuples.

Parameters

data [array-like (1-dimensional)] Array of tuples.

closed [{'left', 'right', 'both', 'neither'}, default 'right'] Whether the intervals are closed on the left-side, right-side, both or neither.

copy [bool, default False] By-default copy the data, this is compat only and ignored.

dtype [dtype or None, default None] If None, dtype will be inferred.

New in version 0.23.0.

Returns

IntervalArray

See also:

interval_range Function to create a fixed frequency IntervalIndex.

IntervalArray.from_arrays Construct an IntervalArray from a left and right array.

IntervalArray.from_breaks Construct an IntervalArray from an array of splits.

Examples

```
>>> pd.arrays.IntervalArray.from_tuples([(0, 1), (1, 2)])
<IntervalArray>
[(0, 1], (1, 2]]
Length: 2, closed: right, dtype: interval[int64]
```

pandas.arrays.IntervalArray.from_breaks

classmethod IntervalArray.**from_breaks**(*breaks*, *closed='right'*, *copy=False*, *dtype=None*)

Construct an IntervalArray from an array of splits.

Parameters

breaks [array-like (1-dimensional)] Left and right bounds for each interval.

closed [{'left', 'right', 'both', 'neither'}, default 'right'] Whether the intervals are closed on the left-side, right-side, both or neither.

copy [bool, default False] Copy the data.

dtype [dtype or None, default None] If None, dtype will be inferred.

New in version 0.23.0.

Returns

IntervalArray

See also:

interval_range Function to create a fixed frequency IntervalIndex.

IntervalArray.from_arrays Construct from a left and right array.

IntervalArray.from_tuples Construct from a sequence of tuples.

Examples

```
>>> pd.arrays.IntervalArray.from_breaks([0, 1, 2, 3])
<IntervalArray>
[(0, 1], (1, 2], (2, 3]]
Length: 3, closed: right, dtype: interval[int64]
```

pandas.arrays.IntervalArray.contains

IntervalArray.**contains**(*other*)

Check elementwise if the Intervals contain the value.

Return a boolean mask whether the value is contained in the Intervals of the IntervalArray.

New in version 0.25.0.

Parameters

other [scalar] The value to check whether it is contained in the Intervals.

Returns

boolean array

See also:

Interval.contains Check whether Interval object contains value.

IntervalArray.overlaps Check if an Interval overlaps the values in the IntervalArray.

Examples

```
>>> intervals = pd.arrays.IntervalArray.from_tuples([(0, 1), (1, 3), (2, 4)])
>>> intervals
<IntervalArray>
[(0, 1], (1, 3], (2, 4]]
Length: 3, closed: right, dtype: interval[int64]
```

```
>>> intervals.contains(0.5)
array([ True, False, False])
```

pandas.arrays.IntervalArray.overlaps

IntervalArray.**overlaps**(*other*)

Check elementwise if an Interval overlaps the values in the IntervalArray.

Two intervals overlap if they share a common point, including closed endpoints. Intervals that only have an open endpoint in common do not overlap.

New in version 0.24.0.

Parameters

other [IntervalArray] Interval to check against for an overlap.

Returns

ndarray Boolean array positionally indicating where an overlap occurs.

See also:

Interval.overlaps Check whether two Interval objects overlap.

Examples

```
>>> data = [(0, 1), (1, 3), (2, 4)]
>>> intervals = pd.arrays.IntervalArray.from_tuples(data)
>>> intervals
<IntervalArray>
[(0, 1], (1, 3], (2, 4]]
Length: 3, closed: right, dtype: interval[int64]
```

```
>>> intervals.overlaps(pd.Interval(0.5, 1.5))
array([ True,  True, False])
```

Intervals that share closed endpoints overlap:

```
>>> intervals.overlaps(pd.Interval(1, 3, closed='left'))
array([ True,  True, True])
```

Intervals that only have an open endpoint in common do not overlap:

```
>>> intervals.overlaps(pd.Interval(1, 2, closed='right'))
array([False,  True, False])
```

pandas.arrays.IntervalArray.set_closed

IntervalArray.**set_closed**(*closed*)

Return an IntervalArray identical to the current one, but closed on the specified side.

New in version 0.24.0.

Parameters

closed [{'left', 'right', 'both', 'neither'}] Whether the intervals are closed on the left-side, right-side, both or neither.

Returns

new_index [IntervalArray]

Examples

```
>>> index = pd.arrays.IntervalArray.from_breaks(range(4))
>>> index
<IntervalArray>
[(0, 1], (1, 2], (2, 3]]
Length: 3, closed: right, dtype: interval[int64]
>>> index.set_closed('both')
<IntervalArray>
[[0, 1], [1, 2], [2, 3]]
Length: 3, closed: both, dtype: interval[int64]
```

pandas.arrays.IntervalArray.to_tuples

IntervalArray.**to_tuples**(*na_tuple=True*)

Return an ndarray of tuples of the form (left, right).

Parameters

na_tuple [bool, default True] Returns NA as a tuple if True, `(nan, nan)`, or just as the NA value itself if False, `nan`.

New in version 0.23.0.

Returns

tuples: ndarray

IntervalDtype([subtype])	An ExtensionDtype for Interval data.

pandas.IntervalDtype

class pandas.**IntervalDtype**(*subtype=None*)

An ExtensionDtype for Interval data.

This is not an actual numpy dtype, but a duck type.

Parameters

subtype [str, np.dtype] The dtype of the Interval bounds.

Examples

```
>>> pd.IntervalDtype(subtype='int64')
interval[int64]
```

Attributes

subtype	The dtype of the Interval bounds.

pandas.IntervalDtype.subtype

property IntervalDtype.**subtype**
The dtype of the Interval bounds.

Methods

None	

3.5.7 Nullable integer

numpy.ndarray cannot natively represent integer-data with missing values. Pandas provides this through *arrays.IntegerArray*.

arrays.IntegerArray(values, mask[, copy])	Array of integer (optional missing) values.

pandas.arrays.IntegerArray

class pandas.arrays.**IntegerArray**(*values*, *mask*, *copy=False*)
Array of integer (optional missing) values.

New in version 0.24.0.

Changed in version 1.0.0: Now uses pandas.NA as the missing value rather than numpy.nan.

> **Warning:** IntegerArray is currently experimental, and its API or internal implementation may change without warning.

We represent an IntegerArray with 2 numpy arrays:
- data: contains a numpy integer array of the appropriate dtype
- mask: a boolean array holding a mask on the data, True is missing

To construct an IntegerArray from generic array-like input, use *pandas.array()* with one of the integer dtypes (see examples).

See *Nullable integer data type* for more.

Parameters

values [numpy.ndarray] A 1-d integer-dtype array.

mask [numpy.ndarray] A 1-d boolean-dtype array indicating missing values.

copy [bool, default False] Whether to copy the *values* and *mask*.

Returns

IntegerArray

Examples

Create an IntegerArray with *pandas.array()*.

```
>>> int_array = pd.array([1, None, 3], dtype=pd.Int32Dtype())
>>> int_array
<IntegerArray>
[1, <NA>, 3]
Length: 3, dtype: Int32
```

String aliases for the dtypes are also available. They are capitalized.

```
>>> pd.array([1, None, 3], dtype='Int32')
<IntegerArray>
[1, <NA>, 3]
Length: 3, dtype: Int32
```

```
>>> pd.array([1, None, 3], dtype='UInt16')
<IntegerArray>
[1, <NA>, 3]
Length: 3, dtype: UInt16
```

Attributes

None	

Methods

None	

Int8Dtype()	An ExtensionDtype for int8 integer data.
Int16Dtype()	An ExtensionDtype for int16 integer data.
Int32Dtype()	An ExtensionDtype for int32 integer data.
Int64Dtype()	An ExtensionDtype for int64 integer data.
UInt8Dtype()	An ExtensionDtype for uint8 integer data.
UInt16Dtype()	An ExtensionDtype for uint16 integer data.
UInt32Dtype()	An ExtensionDtype for uint32 integer data.
UInt64Dtype()	An ExtensionDtype for uint64 integer data.

pandas.Int8Dtype

class pandas.**Int8Dtype**
An ExtensionDtype for int8 integer data.

Changed in version 1.0.0: Now uses `pandas.NA` as its missing value, rather than `numpy.nan`.

Attributes

None	

Methods

None	

pandas.Int16Dtype

class pandas.**Int16Dtype**
An ExtensionDtype for int16 integer data.

Changed in version 1.0.0: Now uses `pandas.NA` as its missing value, rather than `numpy.nan`.

Attributes

None	

Methods

None	

pandas.Int32Dtype

class pandas.**Int32Dtype**
An ExtensionDtype for int32 integer data.

Changed in version 1.0.0: Now uses `pandas.NA` as its missing value, rather than `numpy.nan`.

Attributes

None	

Methods

None	

pandas.Int64Dtype

class pandas.**Int64Dtype**

An ExtensionDtype for int64 integer data.

Changed in version 1.0.0: Now uses `pandas.NA` as its missing value, rather than `numpy.nan`.

Attributes

None	

Methods

None	

pandas.UInt8Dtype

class pandas.**UInt8Dtype**

An ExtensionDtype for uint8 integer data.

Changed in version 1.0.0: Now uses `pandas.NA` as its missing value, rather than `numpy.nan`.

Attributes

None	

Methods

None	

pandas.UInt16Dtype

class pandas.**UInt16Dtype**
An ExtensionDtype for uint16 integer data.

Changed in version 1.0.0: Now uses `pandas.NA` as its missing value, rather than `numpy.nan`.

Attributes

None	

Methods

None	

pandas.UInt32Dtype

class pandas.**UInt32Dtype**
An ExtensionDtype for uint32 integer data.

Changed in version 1.0.0: Now uses `pandas.NA` as its missing value, rather than `numpy.nan`.

Attributes

None	

Methods

None	

pandas.UInt64Dtype

class pandas.**UInt64Dtype**
An ExtensionDtype for uint64 integer data.

Changed in version 1.0.0: Now uses `pandas.NA` as its missing value, rather than `numpy.nan`.

Attributes

None	

Methods

None	

3.5.8 Categorical data

Pandas defines a custom data type for representing data that can take only a limited, fixed set of values. The dtype of a `Categorical` can be described by a `pandas.api.types.CategoricalDtype`.

CategoricalDtype([categories, ordered])	Type for categorical data with the categories and orderedness.

pandas.CategoricalDtype

class pandas.**CategoricalDtype**(*categories=None*, *ordered=False*)

Type for categorical data with the categories and orderedness.

Parameters

categories [sequence, optional] Must be unique, and must not contain any nulls. The categories are stored in an Index, and if an index is provided the dtype of that index will be used.

ordered [bool or None, default False] Whether or not this categorical is treated as a ordered categorical. None can be used to maintain the ordered value of existing categoricals when used in operations that combine categoricals, e.g. astype, and will resolve to False if there is no existing ordered to maintain.

See also:

Categorical Represent a categorical variable in classic R / S-plus fashion.

Notes

This class is useful for specifying the type of a `Categorical` independent of the values. See *CategoricalDtype* for more.

Examples

```
>>> t = pd.CategoricalDtype(categories=['b', 'a'], ordered=True)
>>> pd.Series(['a', 'b', 'a', 'c'], dtype=t)
0      a
1      b
2      a
3    NaN
dtype: category
Categories (2, object): ['b' < 'a']
```

An empty CategoricalDtype with a specific dtype can be created by providing an empty index. As follows,

```
>>> pd.CategoricalDtype(pd.DatetimeIndex([])).categories.dtype
dtype('<M8[ns]')
```

Attributes

categories	An Index containing the unique categories allowed.
ordered	Whether the categories have an ordered relationship.

pandas.CategoricalDtype.categories

property CategoricalDtype.**categories**
An Index containing the unique categories allowed.

pandas.CategoricalDtype.ordered

property CategoricalDtype.**ordered**
Whether the categories have an ordered relationship.

Methods

None	

CategoricalDtype.categories	An Index containing the unique categories allowed.
CategoricalDtype.ordered	Whether the categories have an ordered relationship.

Categorical data can be stored in a *pandas.Categorical*

Categorical(values[, categories, ordered, ...])	Represent a categorical variable in classic R / S-plus fashion.

pandas.Categorical

class pandas.**Categorical**(*values*, *categories=None*, *ordered=None*, *dtype=None*, *fastpath=False*)
Represent a categorical variable in classic R / S-plus fashion.

Categoricals can only take on only a limited, and usually fixed, number of possible values (*categories*). In contrast to statistical categorical variables, a *Categorical* might have an order, but numerical operations (additions, divisions, ...) are not possible.

All values of the *Categorical* are either in *categories* or *np.nan*. Assigning values outside of *categories* will raise a *ValueError*. Order is defined by the order of the *categories*, not lexical order of the values.

Parameters

values [list-like] The values of the categorical. If categories are given, values not in categories will be replaced with NaN.

categories [Index-like (unique), optional] The unique categories for this categorical. If not given, the categories are assumed to be the unique values of *values* (sorted, if possible, otherwise in the order in which they appear).

ordered [bool, default False] Whether or not this categorical is treated as a ordered categorical. If True, the resulting categorical will be ordered. An ordered categorical respects, when sorted, the order of its *categories* attribute (which in turn is the *categories* argument, if provided).

dtype [CategoricalDtype] An instance of `CategoricalDtype` to use for this categorical.

Raises

ValueError If the categories do not validate.

TypeError If an explicit `ordered=True` is given but no *categories* and the *values* are not sortable.

See also:

CategoricalDtype Type for categorical data.
CategoricalIndex An Index with an underlying `Categorical`.

Notes

See the user guide for more.

Examples

```
>>> pd.Categorical([1, 2, 3, 1, 2, 3])
[1, 2, 3, 1, 2, 3]
Categories (3, int64): [1, 2, 3]
```

```
>>> pd.Categorical(['a', 'b', 'c', 'a', 'b', 'c'])
['a', 'b', 'c', 'a', 'b', 'c']
Categories (3, object): ['a', 'b', 'c']
```

Ordered *Categoricals* can be sorted according to the custom order of the categories and can have a min and max value.

```
>>> c = pd.Categorical(['a', 'b', 'c', 'a', 'b', 'c'], ordered=True,
...                    categories=['c', 'b', 'a'])
>>> c
['a', 'b', 'c', 'a', 'b', 'c']
Categories (3, object): ['c' < 'b' < 'a']
>>> c.min()
'c'
```

Attributes

categories	The categories of this categorical.
codes	The category codes of this categorical.
ordered	Whether the categories have an ordered relationship.
dtype	The `CategoricalDtype` for this instance.

pandas.Categorical.categories

property `Categorical.`**categories**

The categories of this categorical.

Setting assigns new values to each category (effectively a rename of each individual category).

The assigned value has to be a list-like object. All items must be unique and the number of items in the new categories must be the same as the number of items in the old categories.

Assigning to *categories* is a inplace operation!

Raises

ValueError If the new categories do not validate as categories or if the number of new categories is unequal the number of old categories

See also:

rename_categories Rename categories.

reorder_categories Reorder categories.

add_categories Add new categories.

remove_categories Remove the specified categories.

remove_unused_categories Remove categories which are not used.

set_categories Set the categories to the specified ones.

pandas.Categorical.codes

property `Categorical.`**codes**

The category codes of this categorical.

Codes are an array of integers which are the positions of the actual values in the categories array.

There is no setter, use the other categorical methods and the normal item setter to change values in the categorical.

Returns

ndarray[int] A non-writable view of the *codes* array.

pandas.Categorical.ordered

property Categorical.**ordered**
Whether the categories have an ordered relationship.

pandas.Categorical.dtype

property Categorical.**dtype**
The CategoricalDtype for this instance.

Methods

from_codes(codes[, categories, ordered, dtype])	Make a Categorical type from codes and categories or dtype.
__array__([dtype])	The numpy array interface.

pandas.Categorical.from_codes

classmethod Categorical.**from_codes**(*codes*, *categories=None*, *ordered=None*, *dtype=None*)
Make a Categorical type from codes and categories or dtype.

This constructor is useful if you already have codes and categories/dtype and so do not need the (computation intensive) factorization step, which is usually done on the constructor.

If your data does not follow this convention, please use the normal constructor.

Parameters

codes [array-like of int] An integer array, where each integer points to a category in categories or dtype.categories, or else is -1 for NaN.

categories [index-like, optional] The categories for the categorical. Items need to be unique. If the categories are not given here, then they must be provided in *dtype*.

ordered [bool, optional] Whether or not this categorical is treated as an ordered categorical. If not given here or in *dtype*, the resulting categorical will be unordered.

dtype [CategoricalDtype or "category", optional] If *CategoricalDtype*, cannot be used together with *categories* or *ordered*.

New in version 0.24.0: When *dtype* is provided, neither *categories* nor *ordered* should be provided.

Returns

Categorical

Examples

```
>>> dtype = pd.CategoricalDtype(['a', 'b'], ordered=True)
>>> pd.Categorical.from_codes(codes=[0, 1, 0, 1], dtype=dtype)
['a', 'b', 'a', 'b']
Categories (2, object): ['a' < 'b']
```

pandas.Categorical.__array__

Categorical.__array__(*dtype=None*)

The numpy array interface.

Returns

numpy.array A numpy array of either the specified dtype or, if dtype==None (default), the same dtype as categorical.categories.dtype.

The alternative *Categorical.from_codes()* constructor can be used when you have the categories and integer codes already:

Categorical.from_codes(codes[, categories, ...])	Make a Categorical type from codes and categories or dtype.

The dtype information is available on the Categorical

Categorical.dtype	The CategoricalDtype for this instance.
Categorical.categories	The categories of this categorical.
Categorical.ordered	Whether the categories have an ordered relationship.
Categorical.codes	The category codes of this categorical.

np.asarray(categorical) works by implementing the array interface. Be aware, that this converts the Categorical back to a NumPy array, so categories and order information is not preserved!

Categorical.__array__([dtype])	The numpy array interface.

A Categorical can be stored in a Series or DataFrame. To create a Series of dtype category, use cat = s.astype(dtype) or Series(..., dtype=dtype) where dtype is either

- the string 'category'
- an instance of CategoricalDtype.

If the Series is of dtype CategoricalDtype, Series.cat can be used to change the categorical data. See *Categorical accessor* for more.

3.5.9 Sparse data

Data where a single value is repeated many times (e.g. `0` or `NaN`) may be stored efficiently as a *arrays.SparseArray*.

arrays.SparseArray(data[, sparse_index, ...])	An ExtensionArray for storing sparse data.

pandas.arrays.SparseArray

class pandas.arrays.**SparseArray**(*data*, *sparse_index=None*, *index=None*, *fill_value=None*, *kind='integer'*, *dtype=None*, *copy=False*)

An ExtensionArray for storing sparse data.

Changed in version 0.24.0: Implements the ExtensionArray interface.

Parameters

data [array-like] A dense array of values to store in the SparseArray. This may contain *fill_value*.

sparse_index [SparseIndex, optional]

index [Index]

fill_value [scalar, optional] Elements in *data* that are *fill_value* are not stored in the SparseArray. For memory savings, this should be the most common value in *data*. By default, *fill_value* depends on the dtype of *data*:

data.dtype	na_value
float	`np.nan`
int	`0`
bool	False
datetime64	`pd.NaT`
timedelta64	`pd.NaT`

The fill value is potentially specified in three ways. In order of precedence, these are

1. The *fill_value* argument
2. `dtype.fill_value` if *fill_value* is None and *dtype* is a `SparseDtype`
3. `data.dtype.fill_value` if *fill_value* is None and *dtype* is not a `SparseDtype` and *data* is a `SparseArray`.

kind [{'integer', 'block'}, default 'integer'] The type of storage for sparse locations.

- 'block': Stores a *block* and *block_length* for each contiguous *span* of sparse values. This is best when sparse data tends to be clumped together, with large regions of `fill-value` values between sparse values.
- 'integer': uses an integer to store the location of each sparse value.

dtype [np.dtype or SparseDtype, optional] The dtype to use for the SparseArray. For numpy dtypes, this determines the dtype of `self.sp_values`. For SparseDtype, this determines `self.sp_values` and `self.fill_value`.

copy [bool, default False] Whether to explicitly copy the incoming *data* array.

Examples

```
>>> from pandas.arrays import SparseArray
>>> arr = SparseArray([0, 0, 1, 2])
>>> arr
[0, 0, 1, 2]
Fill: 0
IntIndex
Indices: array([2, 3], dtype=int32)
```

Attributes

None	

Methods

None	

SparseDtype([dtype, fill_value])	Dtype for data stored in `SparseArray`.

pandas.SparseDtype

class pandas.**SparseDtype**(*dtype=<class 'numpy.float64'>*, *fill_value=None*)

Dtype for data stored in `SparseArray`.

This dtype implements the pandas ExtensionDtype interface.

New in version 0.24.0.

Parameters

dtype [str, ExtensionDtype, numpy.dtype, type, default numpy.float64] The dtype of the underlying array storing the non-fill value values.

fill_value [scalar, optional] The scalar value not stored in the SparseArray. By default, this depends on *dtype*.

dtype	na_value
float	`np.nan`
int	`0`
bool	`False`
datetime64	`pd.NaT`
timedelta64	`pd.NaT`

The default value may be overridden by specifying a *fill_value*.

Attributes

None	

Methods

None	

The `Series.sparse` accessor may be used to access sparse-specific attributes and methods if the *Series* contains sparse values. See *Sparse accessor* for more.

3.5.10 Text data

When working with text data, where each valid element is a string or missing, we recommend using *StringDtype* (with the alias `"string"`).

arrays.StringArray(values[, copy])	Extension array for string data.

pandas.arrays.StringArray

class pandas.arrays.**StringArray**(*values*, *copy=False*)

Extension array for string data.

New in version 1.0.0.

> **Warning:** StringArray is considered experimental. The implementation and parts of the API may change without warning.

Parameters

values [array-like] The array of data.

> **Warning:** Currently, this expects an object-dtype ndarray where the elements are Python strings or `pandas.NA`. This may change without warning in the future. Use *pandas.array()* with `dtype="string"` for a stable way of creating a *StringArray* from any sequence.

copy [bool, default False] Whether to copy the array of data.

See also:

array The recommended function for creating a StringArray.
Series.str The string methods are available on Series backed by a StringArray.

Notes

StringArray returns a BooleanArray for comparison methods.

Examples

```
>>> pd.array(['This is', 'some text', None, 'data.'], dtype="string")
<StringArray>
['This is', 'some text', <NA>, 'data.']
Length: 4, dtype: string
```

Unlike arrays instantiated with `dtype="object"`, `StringArray` will convert the values to strings.

```
>>> pd.array(['1', 1], dtype="object")
<PandasArray>
['1', 1]
Length: 2, dtype: object
>>> pd.array(['1', 1], dtype="string")
<StringArray>
['1', '1']
Length: 2, dtype: string
```

However, instantiating StringArrays directly with non-strings will raise an error.

For comparison methods, *StringArray* returns a `pandas.BooleanArray`:

```
>>> pd.array(["a", None, "c"], dtype="string") == "a"
<BooleanArray>
[True, <NA>, False]
Length: 3, dtype: boolean
```

Attributes

None	

Methods

None	

StringDtype()	Extension dtype for string data.

pandas.StringDtype

class pandas.**StringDtype**
Extension dtype for string data.

New in version 1.0.0.

> **Warning:** StringDtype is considered experimental. The implementation and parts of the API may change without warning.
>
> In particular, StringDtype.na_value may change to no longer be `numpy.nan`.

Examples

```
>>> pd.StringDtype()
StringDtype
```

Attributes

None	

Methods

None	

The `Series.str` accessor is available for `Series` backed by a *arrays.StringArray*. See *String handling* for more.

3.5.11 Boolean data with missing values

The boolean dtype (with the alias `"boolean"`) provides support for storing boolean data (True, False values) with missing values, which is not possible with a bool `numpy.ndarray`.

arrays.BooleanArray(values, mask[, copy])	Array of boolean (True/False) data with missing values.

pandas.arrays.BooleanArray

class pandas.arrays.**BooleanArray**(*values*, *mask*, *copy=False*)
Array of boolean (True/False) data with missing values.

This is a pandas Extension array for boolean data, under the hood represented by 2 numpy arrays: a boolean array with the data and a boolean array with the mask (True indicating missing).

BooleanArray implements Kleene logic (sometimes called three-value logic) for logical operations. See *Kleene logical operations* for more.

To construct an BooleanArray from generic array-like input, use *pandas.array()* specifying `dtype="boolean"` (see examples below).

New in version 1.0.0.

Warning: BooleanArray is considered experimental. The implementation and parts of the API may change without warning.

Parameters

values [numpy.ndarray] A 1-d boolean-dtype array with the data.

mask [numpy.ndarray] A 1-d boolean-dtype array indicating missing values (True indicates missing).

copy [bool, default False] Whether to copy the *values* and *mask* arrays.

Returns

BooleanArray

Examples

Create an BooleanArray with *pandas.array()*:

```
>>> pd.array([True, False, None], dtype="boolean")
<BooleanArray>
[True, False, <NA>]
Length: 3, dtype: boolean
```

Attributes

None	

Methods

None	

BooleanDtype()	Extension dtype for boolean data.

pandas.BooleanDtype

class pandas.**BooleanDtype**

Extension dtype for boolean data.

New in version 1.0.0.

Warning: BooleanDtype is considered experimental. The implementation and parts of the API may change without warning.

Examples

```
>>> pd.BooleanDtype()
BooleanDtype
```

Attributes

None	

Methods

None	

3.6 Panel

Panel was removed in 0.25.0. For prior documentation, see the 0.24 documentation

3.7 Index objects

3.7.1 Index

Many of these methods or variants thereof are available on the objects that contain an index (Series/DataFrame) and those should most likely be used before calling these methods directly.

Index([data, dtype, copy, name, tupleize_cols])	Immutable ndarray implementing an ordered, sliceable set.

pandas.Index

class pandas.**Index**(*data=None*, *dtype=None*, *copy=False*, *name=None*, *tupleize_cols=True*, ***kwargs*)

Immutable ndarray implementing an ordered, sliceable set. The basic object storing axis labels for all pandas objects.

Parameters

data [array-like (1-dimensional)]

dtype [NumPy dtype (default: object)] If dtype is None, we find the dtype that best fits the data. If an actual dtype is provided, we coerce to that dtype if it's safe. Otherwise, an error will be raised.

copy [bool] Make a copy of input ndarray.

name [object] Name to be stored in the index.

tupleize_cols [bool (default: True)] When True, attempt to create a MultiIndex if possible.

See also:

RangeIndex Index implementing a monotonic integer range.
CategoricalIndex Index of *Categorical* s.
MultiIndex A multi-level, or hierarchical Index.
IntervalIndex An Index of *Interval* s.
DatetimeIndex Index of datetime64 data.
TimedeltaIndex Index of timedelta64 data.
PeriodIndex Index of Period data.
Int64Index A special case of *Index* with purely integer labels.
UInt64Index A special case of *Index* with purely unsigned integer labels.
Float64Index A special case of *Index* with purely float labels.

Notes

An Index instance can **only** contain hashable objects

Examples

```
>>> pd.Index([1, 2, 3])
Int64Index([1, 2, 3], dtype='int64')
```

```
>>> pd.Index(list('abc'))
Index(['a', 'b', 'c'], dtype='object')
```

Attributes

T	Return the transpose, which is by definition self.
array	The ExtensionArray of the data backing this Series or Index.
asi8	Integer representation of the values.
dtype	Return the dtype object of the underlying data.
has_duplicates	Check if the Index has duplicate values.
hasnans	Return if I have any nans; enables various perf speedups.
inferred_type	Return a string of the type inferred from the values.
is_all_dates	Whether or not the index values only consist of dates.
is_monotonic	Alias for is_monotonic_increasing.
is_monotonic_decreasing	Return if the index is monotonic decreasing (only equal or decreasing) values.
is_monotonic_increasing	Return if the index is monotonic increasing (only equal or increasing) values.
is_unique	Return if the index has unique values.
name	Return Index or MultiIndex name.
nbytes	Return the number of bytes in the underlying data.
ndim	Number of dimensions of the underlying data, by definition 1.
nlevels	Number of levels.
shape	Return a tuple of the shape of the underlying data.
size	Return the number of elements in the underlying data.

continues on next page

Table 129 – continued from previous page

values	Return an array representing the data in the Index.

pandas.Index.T

property Index.**T**
Return the transpose, which is by definition self.

pandas.Index.array

Index.**array**
The ExtensionArray of the data backing this Series or Index.

New in version 0.24.0.

Returns

ExtensionArray An ExtensionArray of the values stored within. For extension types, this is the actual array. For NumPy native types, this is a thin (no copy) wrapper around `numpy.ndarray`.

`.array` differs `.values` which may require converting the data to a different form.

See also:

Index.to_numpy Similar method that always returns a NumPy array.

Series.to_numpy Similar method that always returns a NumPy array.

Notes

This table lays out the different array types for each extension dtype within pandas.

dtype	array type
category	Categorical
period	PeriodArray
interval	IntervalArray
IntegerNA	IntegerArray
string	StringArray
boolean	BooleanArray
datetime64[ns, tz]	DatetimeArray

For any 3rd-party extension types, the array type will be an ExtensionArray.

For all remaining dtypes `.array` will be a `arrays.NumpyExtensionArray` wrapping the actual ndarray stored within. If you absolutely need a NumPy array (possibly with copying / coercing data), then use *Series.to_numpy()* instead.

Examples

For regular NumPy types like int, and float, a PandasArray is returned.

```
>>> pd.Series([1, 2, 3]).array
<PandasArray>
[1, 2, 3]
Length: 3, dtype: int64
```

For extension types, like Categorical, the actual ExtensionArray is returned

```
>>> ser = pd.Series(pd.Categorical(['a', 'b', 'a']))
>>> ser.array
['a', 'b', 'a']
Categories (2, object): ['a', 'b']
```

pandas.Index.asi8

property Index.**asi8**

Integer representation of the values.

Returns

ndarray An ndarray with int64 dtype.

pandas.Index.dtype

Index.**dtype**

Return the dtype object of the underlying data.

pandas.Index.has_duplicates

property Index.**has_duplicates**

Check if the Index has duplicate values.

Returns

bool Whether or not the Index has duplicate values.

Examples

```
>>> idx = pd.Index([1, 5, 7, 7])
>>> idx.has_duplicates
True
```

```
>>> idx = pd.Index([1, 5, 7])
>>> idx.has_duplicates
False
```

```
>>> idx = pd.Index(["Watermelon", "Orange", "Apple",
...                 "Watermelon"]).astype("category")
>>> idx.has_duplicates
True
```

```
>>> idx = pd.Index(["Orange", "Apple",
...                 "Watermelon"]).astype("category")
>>> idx.has_duplicates
False
```

pandas.Index.hasnans

Index.**hasnans**
Return if I have any nans; enables various perf speedups.

pandas.Index.inferred_type

Index.**inferred_type**
Return a string of the type inferred from the values.

pandas.Index.is_all_dates

Index.**is_all_dates**
Whether or not the index values only consist of dates.

pandas.Index.is_monotonic

property Index.**is_monotonic**
Alias for is_monotonic_increasing.

pandas.Index.is_monotonic_decreasing

property Index.**is_monotonic_decreasing**
Return if the index is monotonic decreasing (only equal or decreasing) values.

Examples

```
>>> Index([3, 2, 1]).is_monotonic_decreasing
True
>>> Index([3, 2, 2]).is_monotonic_decreasing
True
>>> Index([3, 1, 2]).is_monotonic_decreasing
False
```

pandas.Index.is_monotonic_increasing

property Index.**is_monotonic_increasing**
Return if the index is monotonic increasing (only equal or increasing) values.

Examples

```
>>> Index([1, 2, 3]).is_monotonic_increasing
True
>>> Index([1, 2, 2]).is_monotonic_increasing
True
>>> Index([1, 3, 2]).is_monotonic_increasing
False
```

pandas.Index.is_unique

Index.**is_unique**
Return if the index has unique values.

pandas.Index.name

property Index.**name**
Return Index or MultiIndex name.

pandas.Index.nbytes

property Index.**nbytes**
Return the number of bytes in the underlying data.

pandas.Index.ndim

property Index.**ndim**
Number of dimensions of the underlying data, by definition 1.

pandas.Index.nlevels

property Index.**nlevels**
Number of levels.

pandas.Index.shape

property Index.**shape**
Return a tuple of the shape of the underlying data.

pandas.Index.size

property Index.**size**
Return the number of elements in the underlying data.

pandas.Index.values

property Index.**values**
Return an array representing the data in the Index.

> **Warning:** We recommend using *Index.array* or *Index.to_numpy()*, depending on whether you need a reference to the underlying data or a NumPy array.

Returns

array: numpy.ndarray or ExtensionArray

See also:

Index.array Reference to the underlying data.

Index.to_numpy A NumPy array representing the underlying data.

empty	
names	

Methods

all(*args, **kwargs)	Return whether all elements are True.
any(*args, **kwargs)	Return whether any element is True.
append(other)	Append a collection of Index options together.
argmax([axis, skipna])	Return int position of the largest value in the Series.
argmin([axis, skipna])	Return int position of the smallest value in the Series.
argsort(*args, **kwargs)	Return the integer indices that would sort the index.
asof(label)	Return the label from the index, or, if not present, the previous one.
asof_locs(where, mask)	Return the locations (indices) of labels in the index.
astype(dtype[, copy])	Create an Index with values cast to dtypes.
copy([name, deep, dtype, names])	Make a copy of this object.
delete(loc)	Make new Index with passed location(-s) deleted.
difference(other[, sort])	Return a new Index with elements of index not in *other*.

continues on next page

Table 130 – continued from previous page

drop(labels[, errors])	Make new Index with passed list of labels deleted.
drop_duplicates([keep])	Return Index with duplicate values removed.
droplevel([level])	Return index with requested level(s) removed.
dropna([how])	Return Index without NA/NaN values.
duplicated([keep])	Indicate duplicate index values.
equals(other)	Determine if two Index object are equal.
factorize([sort, na_sentinel])	Encode the object as an enumerated type or categorical variable.
fillna([value, downcast])	Fill NA/NaN values with the specified value.
format([name, formatter, na_rep])	Render a string representation of the Index.
get_indexer(target[, method, limit, tolerance])	Compute indexer and mask for new index given the current index.
get_indexer_for(target, **kwargs)	Guaranteed return of an indexer even when non-unique.
get_indexer_non_unique(target)	Compute indexer and mask for new index given the current index.
get_level_values(level)	Return an Index of values for requested level.
get_loc(key[, method, tolerance])	Get integer location, slice or boolean mask for requested label.
get_slice_bound(label, side, kind)	Calculate slice bound that corresponds to given label.
get_value(series, key)	Fast lookup of value from 1-dimensional ndarray.
groupby(values)	Group the index labels by a given array of values.
holds_integer()	Whether the type is an integer type.
identical(other)	Similar to equals, but checks that object attributes and types are also equal.
insert(loc, item)	Make new Index inserting new item at location.
intersection(other[, sort])	Form the intersection of two Index objects.
is_(other)	More flexible, faster check like `is` but that works through views.
is_boolean()	Check if the Index only consists of booleans.
is_categorical()	Check if the Index holds categorical data.
is_floating()	Check if the Index is a floating type.
is_integer()	Check if the Index only consists of integers.
is_interval()	Check if the Index holds Interval objects.
is_mixed()	Check if the Index holds data with mixed data types.
is_numeric()	Check if the Index only consists of numeric data.
is_object()	Check if the Index is of the object dtype.
is_type_compatible(kind)	Whether the index type is compatible with the provided type.
isin(values[, level])	Return a boolean array where the index values are in *values*.
isna()	Detect missing values.
isnull()	Detect missing values.
item()	Return the first element of the underlying data as a python scalar.
join(other[, how, level, return_indexers, sort])	Compute join_index and indexers to conform data structures to the new index.
map(mapper[, na_action])	Map values using input correspondence (a dict, Series, or function).
max([axis, skipna])	Return the maximum value of the Index.
memory_usage([deep])	Memory usage of the values.

continues on next page

Table 130 – continued from previous page

min([axis, skipna])	Return the minimum value of the Index.
notna()	Detect existing (non-missing) values.
notnull()	Detect existing (non-missing) values.
nunique([dropna])	Return number of unique elements in the object.
putmask(mask, value)	Return a new Index of the values set with the mask.
ravel([order])	Return an ndarray of the flattened values of the underlying data.
reindex(target[, method, level, limit, ...])	Create index with target's values.
rename(name[, inplace])	Alter Index or MultiIndex name.
repeat(repeats[, axis])	Repeat elements of a Index.
searchsorted(value[, side, sorter])	Find indices where elements should be inserted to maintain order.
set_names(names[, level, inplace])	Set Index or MultiIndex name.
set_value(arr, key, value)	(DEPRECATED) Fast lookup of value from 1-dimensional ndarray.
shift([periods, freq])	Shift index by desired number of time frequency increments.
slice_indexer([start, end, step, kind])	Compute the slice indexer for input labels and step.
slice_locs([start, end, step, kind])	Compute slice locations for input labels.
sort(*args, **kwargs)	Use sort_values instead.
sort_values([return_indexer, ascending, key])	Return a sorted copy of the index.
sortlevel([level, ascending, sort_remaining])	For internal compatibility with with the Index API.
str	alias of `pandas.core.strings.StringMethods`
symmetric_difference(other[, result_name, sort])	Compute the symmetric difference of two Index objects.
take(indices[, axis, allow_fill, fill_value])	Return a new Index of the values selected by the indices.
to_flat_index()	Identity method.
to_frame([index, name])	Create a DataFrame with a column containing the Index.
to_list()	Return a list of the values.
to_native_types([slicer])	Format specified values of *self* and return them.
to_numpy([dtype, copy, na_value])	A NumPy ndarray representing the values in this Series or Index.
to_series([index, name])	Create a Series with both index and values equal to the index keys.
tolist()	Return a list of the values.
transpose(*args, **kwargs)	Return the transpose, which is by definition self.
union(other[, sort])	Form the union of two Index objects.
unique([level])	Return unique values in the index.
value_counts([normalize, sort, ascending, ...])	Return a Series containing counts of unique values.
where(cond[, other])	Replace values where the condition is False.

pandas.Index.all

Index.**all**(**args*, ***kwargs*)

Return whether all elements are True.

Parameters

***args** These parameters will be passed to numpy.all.

****kwargs** These parameters will be passed to numpy.all.

Returns

all [bool or array_like (if axis is specified)] A single element array_like may be converted to bool.

See also:

Index.any Return whether any element in an Index is True.

Series.any Return whether any element in a Series is True.

Series.all Return whether all elements in a Series are True.

Notes

Not a Number (NaN), positive infinity and negative infinity evaluate to True because these are not equal to zero.

Examples

all

True, because nonzero integers are considered True.

```
>>> pd.Index([1, 2, 3]).all()
True
```

False, because `0` is considered False.

```
>>> pd.Index([0, 1, 2]).all()
False
```

any

True, because `1` is considered True.

```
>>> pd.Index([0, 0, 1]).any()
True
```

False, because `0` is considered False.

```
>>> pd.Index([0, 0, 0]).any()
False
```

pandas.Index.any

Index.**any**(**args*, ***kwargs*)

Return whether any element is True.

Parameters

***args** These parameters will be passed to numpy.any.

****kwargs** These parameters will be passed to numpy.any.

Returns

any [bool or array_like (if axis is specified)] A single element array_like may be converted to bool.

See also:

Index.all Return whether all elements are True.

Series.all Return whether all elements are True.

Notes

Not a Number (NaN), positive infinity and negative infinity evaluate to True because these are not equal to zero.

Examples

```
>>> index = pd.Index([0, 1, 2])
>>> index.any()
True
```

```
>>> index = pd.Index([0, 0, 0])
>>> index.any()
False
```

pandas.Index.append

Index.**append**(*other*)

Append a collection of Index options together.

Parameters

other [Index or list/tuple of indices]

Returns

appended [Index]

pandas.Index.argmax

Index.**argmax**(*axis=None*, *skipna=True*, **args*, ***kwargs*)

Return int position of the largest value in the Series.

If the maximum is achieved in multiple locations, the first row position is returned.

Parameters

axis [{None}] Dummy argument for consistency with Series.

skipna [bool, default True] Exclude NA/null values when showing the result.

***args, **kwargs** Additional arguments and keywords for compatibility with NumPy.

Returns

int Row position of the maximum value.

See also:

Series.argmax Return position of the maximum value.

Series.argmin Return position of the minimum value.

numpy.ndarray.argmax Equivalent method for numpy arrays.

Series.idxmax Return index label of the maximum values.

Series.idxmin Return index label of the minimum values.

Examples

Consider dataset containing cereal calories

```
>>> s = pd.Series({'Corn Flakes': 100.0, 'Almond Delight': 110.0,
...                'Cinnamon Toast Crunch': 120.0, 'Cocoa Puff': 110.0})
>>> s
Corn Flakes              100.0
Almond Delight           110.0
Cinnamon Toast Crunch    120.0
Cocoa Puff               110.0
dtype: float64
```

```
>>> s.argmax()
2
>>> s.argmin()
0
```

The maximum cereal calories is the third element and the minimum cereal calories is the first element, since series is zero-indexed.

pandas.Index.argmin

Index.**argmin**(*axis=None*, *skipna=True*, **args*, ***kwargs*)

Return int position of the smallest value in the Series.

If the minimum is achieved in multiple locations, the first row position is returned.

Parameters

axis [{None}] Dummy argument for consistency with Series.

skipna [bool, default True] Exclude NA/null values when showing the result.

***args, **kwargs** Additional arguments and keywords for compatibility with NumPy.

Returns

int Row position of the minimum value.

See also:

Series.argmin Return position of the minimum value.

Series.argmax Return position of the maximum value.

numpy.ndarray.argmin Equivalent method for numpy arrays.

Series.idxmax Return index label of the maximum values.

Series.idxmin Return index label of the minimum values.

Examples

Consider dataset containing cereal calories

```
>>> s = pd.Series({'Corn Flakes': 100.0, 'Almond Delight': 110.0,
...                'Cinnamon Toast Crunch': 120.0, 'Cocoa Puff': 110.0})
>>> s
Corn Flakes              100.0
Almond Delight           110.0
Cinnamon Toast Crunch    120.0
Cocoa Puff               110.0
dtype: float64
```

```
>>> s.argmax()
2
>>> s.argmin()
0
```

The maximum cereal calories is the third element and the minimum cereal calories is the first element, since series is zero-indexed.

pandas.Index.argsort

Index.**argsort**(**args*, ***kwargs*)

Return the integer indices that would sort the index.

Parameters

***args** Passed to *numpy.ndarray.argsort*.

****kwargs** Passed to *numpy.ndarray.argsort*.

Returns

numpy.ndarray Integer indices that would sort the index if used as an indexer.

See also:

numpy.argsort Similar method for NumPy arrays.

Index.sort_values Return sorted copy of Index.

Examples

```
>>> idx = pd.Index(['b', 'a', 'd', 'c'])
>>> idx
Index(['b', 'a', 'd', 'c'], dtype='object')
```

```
>>> order = idx.argsort()
>>> order
array([1, 0, 3, 2])
```

```
>>> idx[order]
Index(['a', 'b', 'c', 'd'], dtype='object')
```

pandas.Index.asof

Index.**asof**(*label*)

Return the label from the index, or, if not present, the previous one.

Assuming that the index is sorted, return the passed index label if it is in the index, or return the previous index label if the passed one is not in the index.

Parameters

label [object] The label up to which the method returns the latest index label.

Returns

object The passed label if it is in the index. The previous label if the passed label is not in the sorted index or *NaN* if there is no such label.

See also:

Series.asof Return the latest value in a Series up to the passed index.

merge_asof Perform an asof merge (similar to left join but it matches on nearest key rather than equal key).

Index.get_loc An *asof* is a thin wrapper around *get_loc* with method='pad'.

Examples

Index.asof returns the latest index label up to the passed label.

```
>>> idx = pd.Index(['2013-12-31', '2014-01-02', '2014-01-03'])
>>> idx.asof('2014-01-01')
'2013-12-31'
```

If the label is in the index, the method returns the passed label.

```
>>> idx.asof('2014-01-02')
'2014-01-02'
```

If all of the labels in the index are later than the passed label, NaN is returned.

```
>>> idx.asof('1999-01-02')
nan
```

If the index is not sorted, an error is raised.

```
>>> idx_not_sorted = pd.Index(['2013-12-31', '2015-01-02',
...                            '2014-01-03'])
>>> idx_not_sorted.asof('2013-12-31')
Traceback (most recent call last):
ValueError: index must be monotonic increasing or decreasing
```

pandas.Index.asof_locs

Index.**asof_locs**(*where*, *mask*)

Return the locations (indices) of labels in the index.

As in the *asof* function, if the label (a particular entry in *where*) is not in the index, the latest index label up to the passed label is chosen and its index returned.

If all of the labels in the index are later than a label in *where*, -1 is returned.

mask is used to ignore NA values in the index during calculation.

Parameters

where [Index] An Index consisting of an array of timestamps.

mask [array-like] Array of booleans denoting where values in the original data are not NA.

Returns

numpy.ndarray An array of locations (indices) of the labels from the Index which correspond to the return values of the *asof* function for every element in *where*.

pandas.Index.astype

Index.**astype**(*dtype*, *copy=True*)

Create an Index with values cast to dtypes.

The class of a new Index is determined by dtype. When conversion is impossible, a ValueError exception is raised.

Parameters

dtype [numpy dtype or pandas type] Note that any signed integer *dtype* is treated as `'int64'`, and any unsigned integer *dtype* is treated as `'uint64'`, regardless of the size.

copy [bool, default True] By default, astype always returns a newly allocated object. If copy is set to False and internal requirements on dtype are satisfied, the original data is used to create a new Index or the original Index is returned.

Returns

Index Index with values cast to specified dtype.

pandas.Index.copy

Index.**copy**(*name=None*, *deep=False*, *dtype=None*, *names=None*)

Make a copy of this object.

Name and dtype sets those attributes on the new object.

Parameters

name [Label, optional] Set name for new object.

deep [bool, default False]

dtype [numpy dtype or pandas type, optional] Set dtype for new object.

names [list-like, optional] Kept for compatibility with MultiIndex. Should not be used.

Returns

Index Index refer to new object which is a copy of this object.

Notes

In most cases, there should be no functional difference from using `deep`, but if `deep` is passed it will attempt to deepcopy.

pandas.Index.delete

Index.**delete**(*loc*)

Make new Index with passed location(-s) deleted.

Parameters

loc [int or list of int] Location of item(-s) which will be deleted. Use a list of locations to delete more than one value at the same time.

Returns

Index New Index with passed location(-s) deleted.

See also:

`numpy.delete` Delete any rows and column from NumPy array (ndarray).

Examples

```
>>> idx = pd.Index(['a', 'b', 'c'])
>>> idx.delete(1)
Index(['a', 'c'], dtype='object')
```

```
>>> idx = pd.Index(['a', 'b', 'c'])
>>> idx.delete([0, 2])
Index(['b'], dtype='object')
```

pandas.Index.difference

Index.**difference**(*other*, *sort=None*)

Return a new Index with elements of index not in *other*.

This is the set difference of two Index objects.

Parameters

other [Index or array-like]

sort [False or None, default None] Whether to sort the resulting index. By default, the values are attempted to be sorted, but any TypeError from incomparable elements is caught by pandas.

- None : Attempt to sort the result, but catch any TypeErrors from comparing incomparable elements.
- False : Do not sort the result.

New in version 0.24.0.

Changed in version 0.24.1: Changed the default value from `True` to `None` (without change in behaviour).

Returns

difference [Index]

Examples

```
>>> idx1 = pd.Index([2, 1, 3, 4])
>>> idx2 = pd.Index([3, 4, 5, 6])
>>> idx1.difference(idx2)
Int64Index([1, 2], dtype='int64')
>>> idx1.difference(idx2, sort=False)
Int64Index([2, 1], dtype='int64')
```

pandas.Index.drop

Index.**drop**(*labels*, *errors='raise'*)

Make new Index with passed list of labels deleted.

Parameters

labels [array-like]

errors [{'ignore', 'raise'}, default 'raise'] If 'ignore', suppress error and existing labels are dropped.

Returns

dropped [Index]

Raises

KeyError If not all of the labels are found in the selected axis

pandas.Index.drop_duplicates

Index.**drop_duplicates**(*keep='first'*)

Return Index with duplicate values removed.

Parameters

keep [{'first', 'last', False}, default 'first']

- 'first' : Drop duplicates except for the first occurrence.
- 'last' : Drop duplicates except for the last occurrence.
- False : Drop all duplicates.

Returns

deduplicated [Index]

See also:

Series.drop_duplicates Equivalent method on Series.

DataFrame.drop_duplicates Equivalent method on DataFrame.

Index.duplicated Related method on Index, indicating duplicate Index values.

Examples

Generate an pandas.Index with duplicate values.

```
>>> idx = pd.Index(['lama', 'cow', 'lama', 'beetle', 'lama', 'hippo'])
```

The *keep* parameter controls which duplicate values are removed. The value 'first' keeps the first occurrence for each set of duplicated entries. The default value of keep is 'first'.

```
>>> idx.drop_duplicates(keep='first')
Index(['lama', 'cow', 'beetle', 'hippo'], dtype='object')
```

The value 'last' keeps the last occurrence for each set of duplicated entries.

```
>>> idx.drop_duplicates(keep='last')
Index(['cow', 'beetle', 'lama', 'hippo'], dtype='object')
```

The value `False` discards all sets of duplicated entries.

```
>>> idx.drop_duplicates(keep=False)
Index(['cow', 'beetle', 'hippo'], dtype='object')
```

pandas.Index.droplevel

`Index.`**`droplevel`**(*level=0*)

Return index with requested level(s) removed.

If resulting index has only 1 level left, the result will be of Index type, not MultiIndex.

New in version 0.23.1: (support for non-MultiIndex)

Parameters

level [int, str, or list-like, default 0] If a string is given, must be the name of a level If list-like, elements must be names or indexes of levels.

Returns

Index or MultiIndex

pandas.Index.dropna

`Index.`**`dropna`**(*how='any'*)

Return Index without NA/NaN values.

Parameters

how [{'any', 'all'}, default 'any'] If the Index is a MultiIndex, drop the value when any or all levels are NaN.

Returns

Index

pandas.Index.duplicated

`Index.`**`duplicated`**(*keep='first'*)

Indicate duplicate index values.

Duplicated values are indicated as `True` values in the resulting array. Either all duplicates, all except the first, or all except the last occurrence of duplicates can be indicated.

Parameters

keep [{'first', 'last', False}, default 'first'] The value or values in a set of duplicates to mark as missing.

- 'first' : Mark duplicates as `True` except for the first occurrence.
- 'last' : Mark duplicates as `True` except for the last occurrence.
- `False` : Mark all duplicates as `True`.

Returns

numpy.ndarray

See also:

Series.duplicated Equivalent method on pandas.Series.

DataFrame.duplicated Equivalent method on pandas.DataFrame.

Index.drop_duplicates Remove duplicate values from Index.

Examples

By default, for each set of duplicated values, the first occurrence is set to False and all others to True:

```
>>> idx = pd.Index(['lama', 'cow', 'lama', 'beetle', 'lama'])
>>> idx.duplicated()
array([False, False,  True, False,  True])
```

which is equivalent to

```
>>> idx.duplicated(keep='first')
array([False, False,  True, False,  True])
```

By using 'last', the last occurrence of each set of duplicated values is set on False and all others on True:

```
>>> idx.duplicated(keep='last')
array([ True, False,  True, False, False])
```

By setting keep on `False`, all duplicates are True:

```
>>> idx.duplicated(keep=False)
array([ True, False,  True, False,  True])
```

pandas.Index.equals

`Index.`**`equals`**(*other*)

Determine if two Index object are equal.

The things that are being compared are:

- The elements inside the Index object.
- The order of the elements inside the Index object.

Parameters

other [Any] The other object to compare against.

Returns

bool True if "other" is an Index and it has the same elements and order as the calling index; False otherwise.

Examples

```
>>> idx1 = pd.Index([1, 2, 3])
>>> idx1
Int64Index([1, 2, 3], dtype='int64')
>>> idx1.equals(pd.Index([1, 2, 3]))
True
```

The elements inside are compared

```
>>> idx2 = pd.Index(["1", "2", "3"])
>>> idx2
Index(['1', '2', '3'], dtype='object')
```

```
>>> idx1.equals(idx2)
False
```

The order is compared

```
>>> ascending_idx = pd.Index([1, 2, 3])
>>> ascending_idx
Int64Index([1, 2, 3], dtype='int64')
>>> descending_idx = pd.Index([3, 2, 1])
>>> descending_idx
Int64Index([3, 2, 1], dtype='int64')
>>> ascending_idx.equals(descending_idx)
False
```

The dtype is *not* compared

```
>>> int64_idx = pd.Int64Index([1, 2, 3])
>>> int64_idx
Int64Index([1, 2, 3], dtype='int64')
>>> uint64_idx = pd.UInt64Index([1, 2, 3])
>>> uint64_idx
UInt64Index([1, 2, 3], dtype='uint64')
>>> int64_idx.equals(uint64_idx)
True
```

pandas.Index.factorize

Index.**factorize**(*sort=False*, *na_sentinel=- 1*)

Encode the object as an enumerated type or categorical variable.

This method is useful for obtaining a numeric representation of an array when all that matters is identifying distinct values. *factorize* is available as both a top-level function *pandas.factorize()*, and as a method *Series.factorize()* and *Index.factorize()*.

Parameters

sort [bool, default False] Sort *uniques* and shuffle *codes* to maintain the relationship.

na_sentinel [int, default -1] Value to mark "not found".

Returns

codes [ndarray] An integer ndarray that's an indexer into *uniques*. `uniques.take(codes)` will have the same values as *values*.

uniques [ndarray, Index, or Categorical] The unique valid values. When *values* is Categorical, *uniques* is a Categorical. When *values* is some other pandas object, an *Index* is returned. Otherwise, a 1-D ndarray is returned.

Note: Even if there's a missing value in *values*, *uniques* will *not* contain an entry for it.

See also:

cut Discretize continuous-valued array.

unique Find the unique value in an array.

Examples

These examples all show factorize as a top-level method like `pd.factorize(values)`. The results are identical for methods like *`Series.factorize()`*.

```
>>> codes, uniques = pd.factorize(['b', 'b', 'a', 'c', 'b'])
>>> codes
array([0, 0, 1, 2, 0]...)
>>> uniques
array(['b', 'a', 'c'], dtype=object)
```

With `sort=True`, the *uniques* will be sorted, and *codes* will be shuffled so that the relationship is the maintained.

```
>>> codes, uniques = pd.factorize(['b', 'b', 'a', 'c', 'b'], sort=True)
>>> codes
array([1, 1, 0, 2, 1]...)
>>> uniques
array(['a', 'b', 'c'], dtype=object)
```

Missing values are indicated in *codes* with *na_sentinel* (`-1` by default). Note that missing values are never included in *uniques*.

```
>>> codes, uniques = pd.factorize(['b', None, 'a', 'c', 'b'])
>>> codes
array([ 0, -1,  1,  2,  0]...)
>>> uniques
array(['b', 'a', 'c'], dtype=object)
```

Thus far, we've only factorized lists (which are internally coerced to NumPy arrays). When factorizing pandas objects, the type of *uniques* will differ. For Categoricals, a *Categorical* is returned.

```
>>> cat = pd.Categorical(['a', 'a', 'c'], categories=['a', 'b', 'c'])
>>> codes, uniques = pd.factorize(cat)
>>> codes
array([0, 0, 1]...)
>>> uniques
['a', 'c']
Categories (3, object): ['a', 'b', 'c']
```

Notice that `'b'` is in `uniques.categories`, despite not being present in `cat.values`.

For all other pandas objects, an Index of the appropriate type is returned.

```
>>> cat = pd.Series(['a', 'a', 'c'])
>>> codes, uniques = pd.factorize(cat)
>>> codes
array([0, 0, 1]...)
>>> uniques
Index(['a', 'c'], dtype='object')
```

pandas.Index.fillna

Index.**fillna**(*value=None*, *downcast=None*)

Fill NA/NaN values with the specified value.

Parameters

value [scalar] Scalar value to use to fill holes (e.g. 0). This value cannot be a list-likes.

downcast [dict, default is None] A dict of item->dtype of what to downcast if possible, or the string 'infer' which will try to downcast to an appropriate equal type (e.g. float64 to int64 if possible).

Returns

Index

See also:

DataFrame.fillna Fill NaN values of a DataFrame.

Series.fillna Fill NaN Values of a Series.

pandas.Index.format

Index.**format**(*name=False*, *formatter=None*, *na_rep='NaN'*)

Render a string representation of the Index.

pandas.Index.get_indexer

Index.**get_indexer**(*target*, *method=None*, *limit=None*, *tolerance=None*)

Compute indexer and mask for new index given the current index. The indexer should be then used as an input to ndarray.take to align the current data to the new index.

Parameters

target [Index]

method [{None, 'pad'/'ffill', 'backfill'/'bfill', 'nearest'}, optional]

- default: exact matches only.
- pad / ffill: find the PREVIOUS index value if no exact match.
- backfill / bfill: use NEXT index value if no exact match
- nearest: use the NEAREST index value if no exact match. Tied distances are broken by preferring the larger index value.

limit [int, optional] Maximum number of consecutive labels in `target` to match for inexact matches.

tolerance [optional] Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations most satisfy the equation `abs(index[indexer] - target) <= tolerance`.

Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple, array, Series, and must be the same size as the index and its dtype must exactly match the index's type.

Returns

indexer [ndarray of int] Integers from 0 to n - 1 indicating that the index at these positions matches the corresponding target values. Missing values in the target are marked by -1.

Examples

```
>>> index = pd.Index(['c', 'a', 'b'])
>>> index.get_indexer(['a', 'b', 'x'])
array([ 1,  2, -1])
```

Notice that the return value is an array of locations in `index` and `x` is marked by -1, as it is not in `index`.

pandas.Index.get_indexer_for

`Index.`**`get_indexer_for`**(*target*, ***kwargs*)

Guaranteed return of an indexer even when non-unique.

This dispatches to get_indexer or get_indexer_non_unique as appropriate.

Returns

numpy.ndarray List of indices.

pandas.Index.get_indexer_non_unique

`Index.`**`get_indexer_non_unique`**(*target*)

Compute indexer and mask for new index given the current index. The indexer should be then used as an input to ndarray.take to align the current data to the new index.

Parameters

target [Index]

Returns

indexer [ndarray of int] Integers from 0 to n - 1 indicating that the index at these positions matches the corresponding target values. Missing values in the target are marked by -1.

missing [ndarray of int] An indexer into the target of the values not found. These correspond to the -1 in the indexer array.

pandas.Index.get_level_values

Index.**get_level_values**(*level*)

Return an Index of values for requested level.

This is primarily useful to get an individual level of values from a MultiIndex, but is provided on Index as well for compatibility.

Parameters

level [int or str] It is either the integer position or the name of the level.

Returns

Index Calling object, as there is only one level in the Index.

See also:

MultiIndex.get_level_values Get values for a level of a MultiIndex.

Notes

For Index, level should be 0, since there are no multiple levels.

Examples

```
>>> idx = pd.Index(list('abc'))
>>> idx
Index(['a', 'b', 'c'], dtype='object')
```

Get level values by supplying *level* as integer:

```
>>> idx.get_level_values(0)
Index(['a', 'b', 'c'], dtype='object')
```

pandas.Index.get_loc

Index.**get_loc**(*key*, *method=None*, *tolerance=None*)

Get integer location, slice or boolean mask for requested label.

Parameters

key [label]

method [{None, 'pad'/'ffill', 'backfill'/'bfill', 'nearest'}, optional]

- default: exact matches only.
- pad / ffill: find the PREVIOUS index value if no exact match.
- backfill / bfill: use NEXT index value if no exact match
- nearest: use the NEAREST index value if no exact match. Tied distances are broken by preferring the larger index value.

tolerance [int or float, optional] Maximum distance from index value for inexact matches. The value of the index at the matching location most satisfy the equation `abs(index[loc] - key) <= tolerance`.

Returns

loc [int if unique index, slice if monotonic index, else mask]

Examples

```
>>> unique_index = pd.Index(list('abc'))
>>> unique_index.get_loc('b')
1
```

```
>>> monotonic_index = pd.Index(list('abbc'))
>>> monotonic_index.get_loc('b')
slice(1, 3, None)
```

```
>>> non_monotonic_index = pd.Index(list('abcb'))
>>> non_monotonic_index.get_loc('b')
array([False,  True, False,  True])
```

pandas.Index.get_slice_bound

`Index.`**`get_slice_bound`**(*label*, *side*, *kind*)

Calculate slice bound that corresponds to given label.

Returns leftmost (one-past-the-rightmost if `side=='right'`) position of given label.

Parameters

label [object]

side [{'left', 'right'}]

kind [{'loc', 'getitem'} or None]

Returns

int Index of label.

pandas.Index.get_value

`Index.`**`get_value`**(*series*, *key*)

Fast lookup of value from 1-dimensional ndarray.

Only use this if you know what you're doing.

Returns

scalar or Series

pandas.Index.groupby

Index.**groupby**(*values*)

Group the index labels by a given array of values.

Parameters

values [array] Values used to determine the groups.

Returns

dict {group name -> group labels}

pandas.Index.holds_integer

Index.**holds_integer**()

Whether the type is an integer type.

pandas.Index.identical

Index.**identical**(*other*)

Similar to equals, but checks that object attributes and types are also equal.

Returns

bool If two Index objects have equal elements and same type True, otherwise False.

pandas.Index.insert

Index.**insert**(*loc*, *item*)

Make new Index inserting new item at location.

Follows Python list.append semantics for negative values.

Parameters

loc [int]

item [object]

Returns

new_index [Index]

pandas.Index.intersection

Index.**intersection**(*other*, *sort=False*)

Form the intersection of two Index objects.

This returns a new Index with elements common to the index and *other*.

Parameters

other [Index or array-like]

sort [False or None, default False] Whether to sort the resulting index.

- False : do not sort the result.

- None : sort the result, except when *self* and *other* are equal or when the values cannot be compared.

New in version 0.24.0.

Changed in version 0.24.1: Changed the default from `True` to `False`, to match the behaviour of 0.23.4 and earlier.

Returns

intersection [Index]

Examples

```
>>> idx1 = pd.Index([1, 2, 3, 4])
>>> idx2 = pd.Index([3, 4, 5, 6])
>>> idx1.intersection(idx2)
Int64Index([3, 4], dtype='int64')
```

pandas.Index.is_

`Index.`**`is_`**`(`*other*`)`

More flexible, faster check like `is` but that works through views.

Note: this is *not* the same as `Index.identical()`, which checks that metadata is also the same.

Parameters

other [object] Other object to compare against.

Returns

bool True if both have same underlying data, False otherwise.

See also:

Index.identical Works like `Index.is_` but also checks metadata.

pandas.Index.is_boolean

`Index.`**`is_boolean`**`()`

Check if the Index only consists of booleans.

Returns

bool Whether or not the Index only consists of booleans.

See also:

is_integer Check if the Index only consists of integers.

is_floating Check if the Index is a floating type.

is_numeric Check if the Index only consists of numeric data.

is_object Check if the Index is of the object dtype.

is_categorical Check if the Index holds categorical data.

is_interval Check if the Index holds Interval objects.

is_mixed Check if the Index holds data with mixed data types.

Examples

```
>>> idx = pd.Index([True, False, True])
>>> idx.is_boolean()
True
```

```
>>> idx = pd.Index(["True", "False", "True"])
>>> idx.is_boolean()
False
```

```
>>> idx = pd.Index([True, False, "True"])
>>> idx.is_boolean()
False
```

pandas.Index.is_categorical

Index.**is_categorical**()

Check if the Index holds categorical data.

Returns

bool True if the Index is categorical.

See also:

CategoricalIndex Index for categorical data.

is_boolean Check if the Index only consists of booleans.

is_integer Check if the Index only consists of integers.

is_floating Check if the Index is a floating type.

is_numeric Check if the Index only consists of numeric data.

is_object Check if the Index is of the object dtype.

is_interval Check if the Index holds Interval objects.

is_mixed Check if the Index holds data with mixed data types.

Examples

```
>>> idx = pd.Index(["Watermelon", "Orange", "Apple",
...                 "Watermelon"]).astype("category")
>>> idx.is_categorical()
True
```

```
>>> idx = pd.Index([1, 3, 5, 7])
>>> idx.is_categorical()
False
```

```
>>> s = pd.Series(["Peter", "Victor", "Elisabeth", "Mar"])
>>> s
0        Peter
1       Victor
2    Elisabeth
3          Mar
dtype: object
>>> s.index.is_categorical()
False
```

pandas.Index.is_floating

Index.**is_floating**()

Check if the Index is a floating type.

The Index may consist of only floats, NaNs, or a mix of floats, integers, or NaNs.

Returns

bool Whether or not the Index only consists of only consists of floats, NaNs, or a mix of floats, integers, or NaNs.

See also:

is_boolean Check if the Index only consists of booleans.

is_integer Check if the Index only consists of integers.

is_numeric Check if the Index only consists of numeric data.

is_object Check if the Index is of the object dtype.

is_categorical Check if the Index holds categorical data.

is_interval Check if the Index holds Interval objects.

is_mixed Check if the Index holds data with mixed data types.

Examples

```
>>> idx = pd.Index([1.0, 2.0, 3.0, 4.0])
>>> idx.is_floating()
True
```

```
>>> idx = pd.Index([1.0, 2.0, np.nan, 4.0])
>>> idx.is_floating()
True
```

```
>>> idx = pd.Index([1, 2, 3, 4, np.nan])
>>> idx.is_floating()
True
```

```
>>> idx = pd.Index([1, 2, 3, 4])
>>> idx.is_floating()
False
```

pandas.Index.is_integer

Index.**is_integer**()

Check if the Index only consists of integers.

Returns

bool Whether or not the Index only consists of integers.

See also:

is_boolean Check if the Index only consists of booleans.

is_floating Check if the Index is a floating type.

is_numeric Check if the Index only consists of numeric data.

is_object Check if the Index is of the object dtype.

is_categorical Check if the Index holds categorical data.

is_interval Check if the Index holds Interval objects.

is_mixed Check if the Index holds data with mixed data types.

Examples

```
>>> idx = pd.Index([1, 2, 3, 4])
>>> idx.is_integer()
True
```

```
>>> idx = pd.Index([1.0, 2.0, 3.0, 4.0])
>>> idx.is_integer()
False
```

```
>>> idx = pd.Index(["Apple", "Mango", "Watermelon"])
>>> idx.is_integer()
False
```

pandas.Index.is_interval

Index.**is_interval**()

Check if the Index holds Interval objects.

Returns

bool Whether or not the Index holds Interval objects.

See also:

IntervalIndex Index for Interval objects.

is_boolean Check if the Index only consists of booleans.

is_integer Check if the Index only consists of integers.

is_floating Check if the Index is a floating type.

is_numeric Check if the Index only consists of numeric data.

is_object Check if the Index is of the object dtype.

is_categorical Check if the Index holds categorical data.

is_mixed Check if the Index holds data with mixed data types.

Examples

```
>>> idx = pd.Index([pd.Interval(left=0, right=5),
...                 pd.Interval(left=5, right=10)])
>>> idx.is_interval()
True
```

```
>>> idx = pd.Index([1, 3, 5, 7])
>>> idx.is_interval()
False
```

pandas.Index.is_mixed

Index.**is_mixed**()

Check if the Index holds data with mixed data types.

Returns

bool Whether or not the Index holds data with mixed data types.

See also:

is_boolean Check if the Index only consists of booleans.

is_integer Check if the Index only consists of integers.

is_floating Check if the Index is a floating type.

is_numeric Check if the Index only consists of numeric data.

is_object Check if the Index is of the object dtype.

is_categorical Check if the Index holds categorical data.

is_interval Check if the Index holds Interval objects.

Examples

```
>>> idx = pd.Index(['a', np.nan, 'b'])
>>> idx.is_mixed()
True
```

```
>>> idx = pd.Index([1.0, 2.0, 3.0, 5.0])
>>> idx.is_mixed()
False
```

pandas.Index.is_numeric

Index.**is_numeric**()

Check if the Index only consists of numeric data.

Returns

bool Whether or not the Index only consists of numeric data.

See also:

is_boolean Check if the Index only consists of booleans.

is_integer Check if the Index only consists of integers.

is_floating Check if the Index is a floating type.

is_object Check if the Index is of the object dtype.

is_categorical Check if the Index holds categorical data.

is_interval Check if the Index holds Interval objects.

is_mixed Check if the Index holds data with mixed data types.

Examples

```
>>> idx = pd.Index([1.0, 2.0, 3.0, 4.0])
>>> idx.is_numeric()
True
```

```
>>> idx = pd.Index([1, 2, 3, 4.0])
>>> idx.is_numeric()
True
```

```
>>> idx = pd.Index([1, 2, 3, 4])
>>> idx.is_numeric()
True
```

```
>>> idx = pd.Index([1, 2, 3, 4.0, np.nan])
>>> idx.is_numeric()
True
```

```
>>> idx = pd.Index([1, 2, 3, 4.0, np.nan, "Apple"])
>>> idx.is_numeric()
False
```

pandas.Index.is_object

Index.**is_object**()

Check if the Index is of the object dtype.

Returns

bool Whether or not the Index is of the object dtype.

See also:

is_boolean Check if the Index only consists of booleans.

is_integer Check if the Index only consists of integers.

is_floating Check if the Index is a floating type.

is_numeric Check if the Index only consists of numeric data.

is_categorical Check if the Index holds categorical data.

is_interval Check if the Index holds Interval objects.

is_mixed Check if the Index holds data with mixed data types.

Examples

```
>>> idx = pd.Index(["Apple", "Mango", "Watermelon"])
>>> idx.is_object()
True
```

```
>>> idx = pd.Index(["Apple", "Mango", 2.0])
>>> idx.is_object()
True
```

```
>>> idx = pd.Index(["Watermelon", "Orange", "Apple",
...                 "Watermelon"]).astype("category")
>>> idx.is_object()
False
```

```
>>> idx = pd.Index([1.0, 2.0, 3.0, 4.0])
>>> idx.is_object()
False
```

pandas.Index.is_type_compatible

Index.**is_type_compatible**(*kind*)

Whether the index type is compatible with the provided type.

pandas.Index.isin

Index.**isin**(*values*, *level=None*)

Return a boolean array where the index values are in *values*.

Compute boolean array of whether each index value is found in the passed set of values. The length of the returned boolean array matches the length of the index.

Parameters

values [set or list-like] Sought values.

level [str or int, optional] Name or position of the index level to use (if the index is a *MultiIndex*).

Returns

is_contained [ndarray] NumPy array of boolean values.

See also:

Series.isin Same for Series.

DataFrame.isin Same method for DataFrames.

Notes

In the case of *MultiIndex* you must either specify *values* as a list-like object containing tuples that are the same length as the number of levels, or specify *level*. Otherwise it will raise a `ValueError`.

If *level* is specified:

- if it is the name of one *and only one* index level, use that level;
- otherwise it should be a number indicating level position.

Examples

```
>>> idx = pd.Index([1,2,3])
>>> idx
Int64Index([1, 2, 3], dtype='int64')
```

Check whether each index value in a list of values.

```
>>> idx.isin([1, 4])
array([ True, False, False])
```

```
>>> midx = pd.MultiIndex.from_arrays([[1,2,3],
...                                   ['red', 'blue', 'green']],
...                                   names=('number', 'color'))
>>> midx
MultiIndex([(1,   'red'),
            (2,  'blue'),
            (3, 'green')],
           names=['number', 'color'])
```

Check whether the strings in the 'color' level of the MultiIndex are in a list of colors.

```
>>> midx.isin(['red', 'orange', 'yellow'], level='color')
array([ True, False, False])
```

To check across the levels of a MultiIndex, pass a list of tuples:

```
>>> midx.isin([(1, 'red'), (3, 'red')])
array([ True, False, False])
```

For a DatetimeIndex, string values in *values* are converted to Timestamps.

```
>>> dates = ['2000-03-11', '2000-03-12', '2000-03-13']
>>> dti = pd.to_datetime(dates)
>>> dti
DatetimeIndex(['2000-03-11', '2000-03-12', '2000-03-13'],
dtype='datetime64[ns]', freq=None)
```

```
>>> dti.isin(['2000-03-11'])
array([ True, False, False])
```

pandas.Index.isna

Index.**isna**()

Detect missing values.

Return a boolean same-sized object indicating if the values are NA. NA values, such as `None`, `numpy.NaN` or `pd.NaT`, get mapped to `True` values. Everything else get mapped to `False` values. Characters such as empty strings '' or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`).

Returns

numpy.ndarray A boolean array of whether my values are NA.

See also:

Index.notna Boolean inverse of isna.

Index.dropna Omit entries with missing values.

isna Top-level isna.

Series.isna Detect missing values in Series object.

Examples

Show which entries in a pandas.Index are NA. The result is an array.

```
>>> idx = pd.Index([5.2, 6.0, np.NaN])
>>> idx
Float64Index([5.2, 6.0, nan], dtype='float64')
>>> idx.isna()
array([False, False,  True])
```

Empty strings are not considered NA values. None is considered an NA value.

```
>>> idx = pd.Index(['black', '', 'red', None])
>>> idx
Index(['black', '', 'red', None], dtype='object')
>>> idx.isna()
array([False, False, False,  True])
```

For datetimes, *NaT* (Not a Time) is considered as an NA value.

```
>>> idx = pd.DatetimeIndex([pd.Timestamp('1940-04-25'),
...                         pd.Timestamp(''), None, pd.NaT])
>>> idx
DatetimeIndex(['1940-04-25', 'NaT', 'NaT', 'NaT'],
              dtype='datetime64[ns]', freq=None)
>>> idx.isna()
array([False,  True,  True,  True])
```

pandas.Index.isnull

Index.**isnull**()

Detect missing values.

Return a boolean same-sized object indicating if the values are NA. NA values, such as `None`, `numpy.NaN` or `pd.NaT`, get mapped to `True` values. Everything else get mapped to `False` values. Characters such as empty strings '' or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`).

Returns

numpy.ndarray A boolean array of whether my values are NA.

See also:

Index.notna Boolean inverse of isna.

Index.dropna Omit entries with missing values.

isna Top-level isna.

Series.isna Detect missing values in Series object.

Examples

Show which entries in a pandas.Index are NA. The result is an array.

```
>>> idx = pd.Index([5.2, 6.0, np.NaN])
>>> idx
Float64Index([5.2, 6.0, nan], dtype='float64')
>>> idx.isna()
array([False, False,  True])
```

Empty strings are not considered NA values. None is considered an NA value.

```
>>> idx = pd.Index(['black', '', 'red', None])
>>> idx
Index(['black', '', 'red', None], dtype='object')
>>> idx.isna()
array([False, False, False,  True])
```

For datetimes, *NaT* (Not a Time) is considered as an NA value.

```
>>> idx = pd.DatetimeIndex([pd.Timestamp('1940-04-25'),
...                         pd.Timestamp(''), None, pd.NaT])
>>> idx
DatetimeIndex(['1940-04-25', 'NaT', 'NaT', 'NaT'],
              dtype='datetime64[ns]', freq=None)
>>> idx.isna()
array([False,  True,  True,  True])
```

pandas.Index.item

Index.**item**()

Return the first element of the underlying data as a python scalar.

Returns

scalar The first element of %(klass)s.

Raises

ValueError If the data is not length-1.

pandas.Index.join

Index.**join**(*other*, *how='left'*, *level=None*, *return_indexers=False*, *sort=False*)

Compute join_index and indexers to conform data structures to the new index.

Parameters

other [Index]

how [{'left', 'right', 'inner', 'outer'}]

level [int or level name, default None]

return_indexers [bool, default False]

sort [bool, default False] Sort the join keys lexicographically in the result Index. If False, the order of the join keys depends on the join type (how keyword).

Returns

join_index, (left_indexer, right_indexer)

pandas.Index.map

Index.**map**(*mapper*, *na_action=None*)

Map values using input correspondence (a dict, Series, or function).

Parameters

mapper [function, dict, or Series] Mapping correspondence.

na_action [{None, 'ignore'}] If 'ignore', propagate NA values, without passing them to the mapping correspondence.

Returns

applied [Union[Index, MultiIndex], inferred] The output of the mapping function applied to the index. If the function returns a tuple with more than one element a MultiIndex will be returned.

pandas.Index.max

Index.**max**(*axis=None*, *skipna=True*, **args*, ***kwargs*)

Return the maximum value of the Index.

Parameters

axis [int, optional] For compatibility with NumPy. Only 0 or None are allowed.

skipna [bool, default True] Exclude NA/null values when showing the result.

***args, **kwargs** Additional arguments and keywords for compatibility with NumPy.

Returns

scalar Maximum value.

See also:

Index.min Return the minimum value in an Index.

Series.max Return the maximum value in a Series.

DataFrame.max Return the maximum values in a DataFrame.

Examples

```
>>> idx = pd.Index([3, 2, 1])
>>> idx.max()
3
```

```
>>> idx = pd.Index(['c', 'b', 'a'])
>>> idx.max()
'c'
```

For a MultiIndex, the maximum is determined lexicographically.

```
>>> idx = pd.MultiIndex.from_product([('a', 'b'), (2, 1)])
>>> idx.max()
('b', 2)
```

pandas.Index.memory_usage

Index.**memory_usage**(*deep=False*)

Memory usage of the values.

Parameters

deep [bool] Introspect the data deeply, interrogate *object* dtypes for system-level memory consumption.

Returns

bytes used

See also:

`numpy.ndarray.nbytes` Total bytes consumed by the elements of the array.

Notes

Memory usage does not include memory consumed by elements that are not components of the array if deep=False or if used on PyPy

pandas.Index.min

Index.**min**(*axis=None*, *skipna=True*, **args*, ***kwargs*)

Return the minimum value of the Index.

Parameters

axis [{None}] Dummy argument for consistency with Series.

skipna [bool, default True] Exclude NA/null values when showing the result.

***args, **kwargs** Additional arguments and keywords for compatibility with NumPy.

Returns

scalar Minimum value.

See also:

`Index.max` Return the maximum value of the object.

`Series.min` Return the minimum value in a Series.

`DataFrame.min` Return the minimum values in a DataFrame.

Examples

```
>>> idx = pd.Index([3, 2, 1])
>>> idx.min()
1
```

```
>>> idx = pd.Index(['c', 'b', 'a'])
>>> idx.min()
'a'
```

For a MultiIndex, the minimum is determined lexicographically.

```
>>> idx = pd.MultiIndex.from_product([('a', 'b'), (2, 1)])
>>> idx.min()
('a', 1)
```

pandas.Index.notna

Index.**notna**()

Detect existing (non-missing) values.

Return a boolean same-sized object indicating if the values are not NA. Non-missing values get mapped to `True`. Characters such as empty strings `''` or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`). NA values, such as None or `numpy.NaN`, get mapped to `False` values.

Returns

numpy.ndarray Boolean array to indicate which entries are not NA.

See also:

Index.notnull Alias of notna.

Index.isna Inverse of notna.

notna Top-level notna.

Examples

Show which entries in an Index are not NA. The result is an array.

```
>>> idx = pd.Index([5.2, 6.0, np.NaN])
>>> idx
Float64Index([5.2, 6.0, nan], dtype='float64')
>>> idx.notna()
array([ True,  True, False])
```

Empty strings are not considered NA values. None is considered a NA value.

```
>>> idx = pd.Index(['black', '', 'red', None])
>>> idx
Index(['black', '', 'red', None], dtype='object')
>>> idx.notna()
array([ True,  True,  True, False])
```

pandas.Index.notnull

Index.**notnull**()

Detect existing (non-missing) values.

Return a boolean same-sized object indicating if the values are not NA. Non-missing values get mapped to `True`. Characters such as empty strings `''` or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`). NA values, such as None or `numpy.NaN`, get mapped to `False` values.

Returns

numpy.ndarray Boolean array to indicate which entries are not NA.

See also:

Index.notnull Alias of notna.

Index.isna Inverse of notna.

notna Top-level notna.

Examples

Show which entries in an Index are not NA. The result is an array.

```
>>> idx = pd.Index([5.2, 6.0, np.NaN])
>>> idx
Float64Index([5.2, 6.0, nan], dtype='float64')
>>> idx.notna()
array([ True,  True, False])
```

Empty strings are not considered NA values. None is considered a NA value.

```
>>> idx = pd.Index(['black', '', 'red', None])
>>> idx
Index(['black', '', 'red', None], dtype='object')
>>> idx.notna()
array([ True,  True,  True, False])
```

pandas.Index.nunique

Index.**nunique**(*dropna=True*)

Return number of unique elements in the object.

Excludes NA values by default.

Parameters

dropna [bool, default True] Don't include NaN in the count.

Returns

int

See also:

DataFrame.nunique Method nunique for DataFrame.

Series.count Count non-NA/null observations in the Series.

Examples

```
>>> s = pd.Series([1, 3, 5, 7, 7])
>>> s
0    1
1    3
2    5
3    7
4    7
dtype: int64
```

```
>>> s.nunique()
4
```

pandas.Index.putmask

Index.**putmask**(*mask*, *value*)

Return a new Index of the values set with the mask.

Returns

Index

See also:

numpy.ndarray.putmask

pandas.Index.ravel

Index.**ravel**(*order='C'*)

Return an ndarray of the flattened values of the underlying data.

Returns

numpy.ndarray Flattened array.

See also:

numpy.ndarray.ravel

pandas.Index.reindex

Index.**reindex**(*target*, *method=None*, *level=None*, *limit=None*, *tolerance=None*)

Create index with target's values.

Parameters

target [an iterable]

Returns

new_index [pd.Index] Resulting index.

indexer [np.ndarray or None] Indices of output values in original index.

pandas.Index.rename

Index.**rename**(*name*, *inplace=False*)

Alter Index or MultiIndex name.

Able to set new names without level. Defaults to returning new index. Length of names must match number of levels in MultiIndex.

Parameters

name [label or list of labels] Name(s) to set.

inplace [bool, default False] Modifies the object directly, instead of creating a new Index or MultiIndex.

Returns

Index The same type as the caller or None if inplace is True.

See also:

Index.set_names Able to set new names partially and by level.

Examples

```
>>> idx = pd.Index(['A', 'C', 'A', 'B'], name='score')
>>> idx.rename('grade')
Index(['A', 'C', 'A', 'B'], dtype='object', name='grade')
```

```
>>> idx = pd.MultiIndex.from_product([['python', 'cobra'],
...                                   [2018, 2019]],
...                                   names=['kind', 'year'])
>>> idx
MultiIndex([('python', 2018),
            ('python', 2019),
            ( 'cobra', 2018),
            ( 'cobra', 2019)],
           names=['kind', 'year'])
>>> idx.rename(['species', 'year'])
MultiIndex([('python', 2018),
            ('python', 2019),
            ( 'cobra', 2018),
            ( 'cobra', 2019)],
           names=['species', 'year'])
>>> idx.rename('species')
Traceback (most recent call last):
TypeError: Must pass list-like as `names`.
```

pandas.Index.repeat

Index.**repeat**(*repeats*, *axis=None*)

Repeat elements of a Index.

Returns a new Index where each element of the current Index is repeated consecutively a given number of times.

Parameters

repeats [int or array of ints] The number of repetitions for each element. This should be a non-negative integer. Repeating 0 times will return an empty Index.

axis [None] Must be `None`. Has no effect but is accepted for compatibility with numpy.

Returns

repeated_index [Index] Newly created Index with repeated elements.

See also:

Series.repeat Equivalent function for Series.

numpy.repeat Similar method for `numpy.ndarray`.

Examples

```
>>> idx = pd.Index(['a', 'b', 'c'])
>>> idx
Index(['a', 'b', 'c'], dtype='object')
>>> idx.repeat(2)
Index(['a', 'a', 'b', 'b', 'c', 'c'], dtype='object')
>>> idx.repeat([1, 2, 3])
Index(['a', 'b', 'b', 'c', 'c', 'c'], dtype='object')
```

pandas.Index.searchsorted

Index.**searchsorted**(*value*, *side='left'*, *sorter=None*)

Find indices where elements should be inserted to maintain order.

Find the indices into a sorted Index *self* such that, if the corresponding elements in *value* were inserted before the indices, the order of *self* would be preserved.

Note: The Index *must* be monotonically sorted, otherwise wrong locations will likely be returned. Pandas does *not* check this for you.

Parameters

value [array_like] Values to insert into *self*.

side [{'left', 'right'}, optional] If 'left', the index of the first suitable location found is given. If 'right', return the last such index. If there is no suitable index, return either 0 or N (where N is the length of *self*).

sorter [1-D array_like, optional] Optional array of integer indices that sort *self* into ascending order. They are typically the result of `np.argsort`.

Returns

int or array of int A scalar or array of insertion points with the same shape as *value*.

Changed in version 0.24.0: If *value* is a scalar, an int is now always returned. Previously, scalar inputs returned an 1-item array for *Series* and *Categorical*.

See also:

sort_values Sort by the values along either axis.

numpy.searchsorted Similar method from NumPy.

Notes

Binary search is used to find the required insertion points.

Examples

```
>>> ser = pd.Series([1, 2, 3])
>>> ser
0    1
1    2
2    3
dtype: int64
```

```
>>> ser.searchsorted(4)
3
```

```
>>> ser.searchsorted([0, 4])
array([0, 3])
```

```
>>> ser.searchsorted([1, 3], side='left')
array([0, 2])
```

```
>>> ser.searchsorted([1, 3], side='right')
array([1, 3])
```

```
>>> ser = pd.Categorical(
...     ['apple', 'bread', 'bread', 'cheese', 'milk'], ordered=True
... )
>>> ser
['apple', 'bread', 'bread', 'cheese', 'milk']
Categories (4, object): ['apple' < 'bread' < 'cheese' < 'milk']
```

```
>>> ser.searchsorted('bread')
1
```

```
>>> ser.searchsorted(['bread'], side='right')
array([3])
```

If the values are not monotonically sorted, wrong locations may be returned:

```
>>> ser = pd.Series([2, 1, 3])
>>> ser
0    2
1    1
2    3
dtype: int64
```

```
>>> ser.searchsorted(1)
0  # wrong result, correct would be 1
```

pandas.Index.set_names

Index.**set_names**(*names*, *level=None*, *inplace=False*)

Set Index or MultiIndex name.

Able to set new names partially and by level.

Parameters

names [label or list of label] Name(s) to set.

level [int, label or list of int or label, optional] If the index is a MultiIndex, level(s) to set (None for all levels). Otherwise level must be None.

inplace [bool, default False] Modifies the object directly, instead of creating a new Index or MultiIndex.

Returns

Index The same type as the caller or None if inplace is True.

See also:

Index.rename Able to set new names without level.

Examples

```
>>> idx = pd.Index([1, 2, 3, 4])
>>> idx
Int64Index([1, 2, 3, 4], dtype='int64')
>>> idx.set_names('quarter')
Int64Index([1, 2, 3, 4], dtype='int64', name='quarter')
```

```
>>> idx = pd.MultiIndex.from_product([['python', 'cobra'],
...                                   [2018, 2019]])
>>> idx
MultiIndex([('python', 2018),
            ('python', 2019),
            ( 'cobra', 2018),
            ( 'cobra', 2019)],
           )
>>> idx.set_names(['kind', 'year'], inplace=True)
>>> idx
MultiIndex([('python', 2018),
            ('python', 2019),
            ( 'cobra', 2018),
            ( 'cobra', 2019)],
           names=['kind', 'year'])
>>> idx.set_names('species', level=0)
MultiIndex([('python', 2018),
            ('python', 2019),
            ( 'cobra', 2018),
            ( 'cobra', 2019)],
           names=['species', 'year'])
```

pandas.Index.set_value

Index.**set_value**(*arr*, *key*, *value*)

Fast lookup of value from 1-dimensional ndarray.

Deprecated since version 1.0.

Notes

Only use this if you know what you're doing.

pandas.Index.shift

Index.**shift**(*periods=1*, *freq=None*)

Shift index by desired number of time frequency increments.

This method is for shifting the values of datetime-like indexes by a specified time increment a given number of times.

Parameters

periods [int, default 1] Number of periods (or increments) to shift by, can be positive or negative.

freq [pandas.DateOffset, pandas.Timedelta or str, optional] Frequency increment to shift by. If None, the index is shifted by its own *freq* attribute. Offset aliases are valid strings, e.g., 'D', 'W', 'M' etc.

Returns

pandas.Index Shifted index.

See also:

Series.shift Shift values of Series.

Notes

This method is only implemented for datetime-like index classes, i.e., DatetimeIndex, PeriodIndex and TimedeltaIndex.

Examples

Put the first 5 month starts of 2011 into an index.

```
>>> month_starts = pd.date_range('1/1/2011', periods=5, freq='MS')
>>> month_starts
DatetimeIndex(['2011-01-01', '2011-02-01', '2011-03-01', '2011-04-01',
               '2011-05-01'],
              dtype='datetime64[ns]', freq='MS')
```

Shift the index by 10 days.

```
>>> month_starts.shift(10, freq='D')
DatetimeIndex(['2011-01-11', '2011-02-11', '2011-03-11', '2011-04-11',
               '2011-05-11'],
              dtype='datetime64[ns]', freq=None)
```

The default value of *freq* is the *freq* attribute of the index, which is 'MS' (month start) in this example.

```
>>> month_starts.shift(10)
DatetimeIndex(['2011-11-01', '2011-12-01', '2012-01-01', '2012-02-01',
               '2012-03-01'],
              dtype='datetime64[ns]', freq='MS')
```

pandas.Index.slice_indexer

Index.**slice_indexer**(*start=None*, *end=None*, *step=None*, *kind=None*)

Compute the slice indexer for input labels and step.

Index needs to be ordered and unique.

Parameters

start [label, default None] If None, defaults to the beginning.

end [label, default None] If None, defaults to the end.

step [int, default None]

kind [str, default None]

Returns

indexer [slice]

Raises

KeyError [If key does not exist, or key is not unique and index is] not ordered.

Notes

This function assumes that the data is sorted, so use at your own peril

Examples

This is a method on all index types. For example you can do:

```
>>> idx = pd.Index(list('abcd'))
>>> idx.slice_indexer(start='b', end='c')
slice(1, 3, None)
```

```
>>> idx = pd.MultiIndex.from_arrays([list('abcd'), list('efgh')])
>>> idx.slice_indexer(start='b', end=('c', 'g'))
slice(1, 3, None)
```

pandas.Index.slice_locs

Index.**slice_locs**(*start=None*, *end=None*, *step=None*, *kind=None*)

Compute slice locations for input labels.

Parameters

start [label, default None] If None, defaults to the beginning.

end [label, default None] If None, defaults to the end.

step [int, defaults None] If None, defaults to 1.

kind [{'loc', 'getitem'} or None]

Returns

start, end [int]

See also:

Index.get_loc Get location for a single label.

Notes

This method only works if the index is monotonic or unique.

Examples

```
>>> idx = pd.Index(list('abcd'))
>>> idx.slice_locs(start='b', end='c')
(1, 3)
```

pandas.Index.sort

Index.**sort**(**args*, ***kwargs*)

Use sort_values instead.

pandas.Index.sort_values

Index.**sort_values**(*return_indexer=False*, *ascending=True*, *key=None*)

Return a sorted copy of the index.

Return a sorted copy of the index, and optionally return the indices that sorted the index itself.

Parameters

return_indexer [bool, default False] Should the indices that would sort the index be returned.

ascending [bool, default True] Should the index values be sorted in an ascending order.

key [callable, optional] If not None, apply the key function to the index values before sorting. This is similar to the *key* argument in the builtin `sorted()` function, with the notable difference that this *key* function should be *vectorized*. It should expect an `Index` and return an `Index` of the same shape.

New in version 1.1.0.

Returns

sorted_index [pandas.Index] Sorted copy of the index.

indexer [numpy.ndarray, optional] The indices that the index itself was sorted by.

See also:

Series.sort_values Sort values of a Series.

DataFrame.sort_values Sort values in a DataFrame.

Examples

```
>>> idx = pd.Index([10, 100, 1, 1000])
>>> idx
Int64Index([10, 100, 1, 1000], dtype='int64')
```

Sort values in ascending order (default behavior).

```
>>> idx.sort_values()
Int64Index([1, 10, 100, 1000], dtype='int64')
```

Sort values in descending order, and also get the indices *idx* was sorted by.

```
>>> idx.sort_values(ascending=False, return_indexer=True)
(Int64Index([1000, 100, 10, 1], dtype='int64'), array([3, 1, 0, 2]))
```

pandas.Index.sortlevel

Index.**sortlevel**(*level=None*, *ascending=True*, *sort_remaining=None*)

For internal compatibility with with the Index API.

Sort the Index. This is for compat with MultiIndex

Parameters

ascending [bool, default True] False to sort in descending order

level, sort_remaining are compat parameters

Returns

Index

pandas.Index.str

Index.**str**()

Vectorized string functions for Series and Index.

NAs stay NA unless handled otherwise by a particular method. Patterned after Python's string methods, with some inspiration from R's stringr package.

Examples

```
>>> s = pd.Series(["A_Str_Series"])
>>> s
0    A_Str_Series
dtype: object
```

```
>>> s.str.split("_")
0    [A, Str, Series]
dtype: object
```

```
>>> s.str.replace("_", "")
0    AStrSeries
dtype: object
```

pandas.Index.symmetric_difference

Index.**symmetric_difference**(*other*, *result_name=None*, *sort=None*)

Compute the symmetric difference of two Index objects.

Parameters

other [Index or array-like]

result_name [str]

sort [False or None, default None] Whether to sort the resulting index. By default, the values are attempted to be sorted, but any TypeError from incomparable elements is caught by pandas.

- None : Attempt to sort the result, but catch any TypeErrors from comparing incomparable elements.
- False : Do not sort the result.

New in version 0.24.0.

Changed in version 0.24.1: Changed the default value from `True` to `None` (without change in behaviour).

Returns

symmetric_difference [Index]

Notes

`symmetric_difference` contains elements that appear in either `idx1` or `idx2` but not both. Equivalent to the Index created by `idx1.difference(idx2) | idx2.difference(idx1)` with duplicates dropped.

Examples

```
>>> idx1 = pd.Index([1, 2, 3, 4])
>>> idx2 = pd.Index([2, 3, 4, 5])
>>> idx1.symmetric_difference(idx2)
Int64Index([1, 5], dtype='int64')
```

You can also use the ^ operator:

```
>>> idx1 ^ idx2
Int64Index([1, 5], dtype='int64')
```

pandas.Index.take

Index.**take**(*indices*, *axis=0*, *allow_fill=True*, *fill_value=None*, ***kwargs*)

Return a new Index of the values selected by the indices.

For internal compatibility with numpy arrays.

Parameters

indices [list] Indices to be taken.

axis [int, optional] The axis over which to select values, always 0.

allow_fill [bool, default True]

fill_value [bool, default None] If allow_fill=True and fill_value is not None, indices specified by -1 is regarded as NA. If Index doesn't hold NA, raise ValueError.

Returns

numpy.ndarray Elements of given indices.

See also:

numpy.ndarray.take

pandas.Index.to_flat_index

Index.**to_flat_index**()

Identity method.

New in version 0.24.0.

This is implemented for compatibility with subclass implementations when chaining.

Returns

pd.Index Caller.

See also:

MultiIndex.to_flat_index Subclass implementation.

pandas.Index.to_frame

Index.**to_frame**(*index=True*, *name=None*)

Create a DataFrame with a column containing the Index.

New in version 0.24.0.

Parameters

index [bool, default True] Set the index of the returned DataFrame as the original Index.

name [object, default None] The passed name should substitute for the index name (if it has one).

Returns

DataFrame DataFrame containing the original Index data.

See also:

Index.to_series Convert an Index to a Series.

Series.to_frame Convert Series to DataFrame.

Examples

```
>>> idx = pd.Index(['Ant', 'Bear', 'Cow'], name='animal')
>>> idx.to_frame()
       animal
animal
Ant       Ant
Bear     Bear
Cow       Cow
```

By default, the original Index is reused. To enforce a new Index:

```
>>> idx.to_frame(index=False)
    animal
0   Ant
1  Bear
2   Cow
```

To override the name of the resulting column, specify *name*:

```
>>> idx.to_frame(index=False, name='zoo')
    zoo
0   Ant
1  Bear
2   Cow
```

pandas.Index.to_list

Index.**to_list**()
Return a list of the values.

These are each a scalar type, which is a Python scalar (for str, int, float) or a pandas scalar (for Timestamp/Timedelta/Interval/Period)

Returns

list

See also:

numpy.ndarray.tolist Return the array as an a.ndim-levels deep nested list of Python scalars.

pandas.Index.to_native_types

Index.**to_native_types**(*slicer=None*, ***kwargs*)
Format specified values of *self* and return them.

Parameters

slicer [int, array-like] An indexer into *self* that specifies which values are used in the formatting process.

kwargs [dict] Options for specifying how the values should be formatted. These options include the following:

1) **na_rep** [str] The value that serves as a placeholder for NULL values
2) **quoting** [bool or None] Whether or not there are quoted values in *self*
3) **date_format** [str] The format used to represent date-like values.

Returns

numpy.ndarray Formatted values.

pandas.Index.to_numpy

Index.**to_numpy**(*dtype=None*, *copy=False*, *na_value=<object object>*, ***kwargs*)
A NumPy ndarray representing the values in this Series or Index.

New in version 0.24.0.

Parameters

dtype [str or numpy.dtype, optional] The dtype to pass to `numpy.asarray()`.

copy [bool, default False] Whether to ensure that the returned value is not a view on another array. Note that `copy=False` does not *ensure* that `to_numpy()` is no-copy. Rather, `copy=True` ensure that a copy is made, even if not strictly necessary.

na_value [Any, optional] The value to use for missing values. The default value depends on *dtype* and the type of the array.

New in version 1.0.0.

****kwargs** Additional keywords passed through to the `to_numpy` method of the underlying array (for extension arrays).

New in version 1.0.0.

Returns

numpy.ndarray

See also:

Series.array Get the actual data stored within.

Index.array Get the actual data stored within.

DataFrame.to_numpy Similar method for DataFrame.

Notes

The returned array will be the same up to equality (values equal in *self* will be equal in the returned array; likewise for values that are not equal). When *self* contains an ExtensionArray, the dtype may be different. For example, for a category-dtype Series, `to_numpy()` will return a NumPy array and the categorical dtype will be lost.

For NumPy dtypes, this will be a reference to the actual data stored in this Series or Index (assuming `copy=False`). Modifying the result in place will modify the data stored in the Series or Index (not that we recommend doing that).

For extension types, `to_numpy()` *may* require copying data and coercing the result to a NumPy type (possibly object), which may be expensive. When you need a no-copy reference to the underlying data, *Series.array* should be used instead.

This table lays out the different dtypes and default return types of `to_numpy()` for various dtypes within pandas.

dtype	array type
category[T]	ndarray[T] (same dtype as input)
period	ndarray[object] (Periods)
interval	ndarray[object] (Intervals)
IntegerNA	ndarray[object]
datetime64[ns]	datetime64[ns]
datetime64[ns, tz]	ndarray[object] (Timestamps)

Examples

```
>>> ser = pd.Series(pd.Categorical(['a', 'b', 'a']))
>>> ser.to_numpy()
array(['a', 'b', 'a'], dtype=object)
```

Specify the *dtype* to control how datetime-aware data is represented. Use `dtype=object` to return an ndarray of pandas *Timestamp* objects, each with the correct `tz`.

```
>>> ser = pd.Series(pd.date_range('2000', periods=2, tz="CET"))
>>> ser.to_numpy(dtype=object)
array([Timestamp('2000-01-01 00:00:00+0100', tz='CET', freq='D'),
       Timestamp('2000-01-02 00:00:00+0100', tz='CET', freq='D')],
      dtype=object)
```

Or `dtype='datetime64[ns]'` to return an ndarray of native datetime64 values. The values are converted to UTC and the timezone info is dropped.

```
>>> ser.to_numpy(dtype="datetime64[ns]")
...
array(['1999-12-31T23:00:00.000000000', '2000-01-01T23:00:00...'],
      dtype='datetime64[ns]')
```

pandas.Index.to_series

Index.**to_series**(*index=None*, *name=None*)

Create a Series with both index and values equal to the index keys.

Useful with map for returning an indexer based on an index.

Parameters

index [Index, optional] Index of resulting Series. If None, defaults to original index.

name [str, optional] Name of resulting Series. If None, defaults to name of original index.

Returns

Series The dtype will be based on the type of the Index values.

See also:

Index.to_frame Convert an Index to a DataFrame.

Series.to_frame Convert Series to DataFrame.

Examples

```
>>> idx = pd.Index(['Ant', 'Bear', 'Cow'], name='animal')
```

By default, the original Index and original name is reused.

```
>>> idx.to_series()
animal
Ant      Ant
Bear    Bear
Cow      Cow
Name: animal, dtype: object
```

To enforce a new Index, specify new labels to `index`:

```
>>> idx.to_series(index=[0, 1, 2])
0     Ant
1    Bear
2     Cow
Name: animal, dtype: object
```

To override the name of the resulting column, specify *name*:

```
>>> idx.to_series(name='zoo')
animal
Ant      Ant
Bear    Bear
Cow      Cow
Name: zoo, dtype: object
```

pandas.Index.tolist

Index.**tolist**()

Return a list of the values.

These are each a scalar type, which is a Python scalar (for str, int, float) or a pandas scalar (for Timestamp/Timedelta/Interval/Period)

Returns

list

See also:

`numpy.ndarray.tolist` Return the array as an a.ndim-levels deep nested list of Python scalars.

pandas.Index.transpose

Index.**transpose**(**args*, ***kwargs*)

Return the transpose, which is by definition self.

Returns

%(klass)s

pandas.Index.union

Index.**union**(*other*, *sort=None*)

Form the union of two Index objects.

If the Index objects are incompatible, both Index objects will be cast to dtype('object') first.

Changed in version 0.25.0.

Parameters

other [Index or array-like]

sort [bool or None, default None] Whether to sort the resulting Index.

- None : Sort the result, except when
  1. *self* and *other* are equal.
  2. *self* or *other* has length 0.
  3. Some values in *self* or *other* cannot be compared. A RuntimeWarning is issued in this case.
- False : do not sort the result.

New in version 0.24.0.

Changed in version 0.24.1: Changed the default value from `True` to `None` (without change in behaviour).

Returns

union [Index]

Examples

Union matching dtypes

```
>>> idx1 = pd.Index([1, 2, 3, 4])
>>> idx2 = pd.Index([3, 4, 5, 6])
>>> idx1.union(idx2)
Int64Index([1, 2, 3, 4, 5, 6], dtype='int64')
```

Union mismatched dtypes

```
>>> idx1 = pd.Index(['a', 'b', 'c', 'd'])
>>> idx2 = pd.Index([1, 2, 3, 4])
>>> idx1.union(idx2)
Index(['a', 'b', 'c', 'd', 1, 2, 3, 4], dtype='object')
```

pandas.Index.unique

Index.**unique**(*level=None*)

Return unique values in the index.

Unique values are returned in order of appearance, this does NOT sort.

Parameters

level [int or str, optional, default None] Only return values from specified level (for MultiIndex).

New in version 0.23.0.

Returns

Index without duplicates

See also:

unique

Series.unique

pandas.Index.value_counts

Index.**value_counts**(*normalize=False*, *sort=True*, *ascending=False*, *bins=None*, *dropna=True*)

Return a Series containing counts of unique values.

The resulting object will be in descending order so that the first element is the most frequently-occurring element. Excludes NA values by default.

Parameters

normalize [bool, default False] If True then the object returned will contain the relative frequencies of the unique values.

sort [bool, default True] Sort by frequencies.

ascending [bool, default False] Sort in ascending order.

bins [int, optional] Rather than count values, group them into half-open bins, a convenience for `pd.cut`, only works with numeric data.

dropna [bool, default True] Don't include counts of NaN.

Returns

Series

See also:

Series.count Number of non-NA elements in a Series.

DataFrame.count Number of non-NA elements in a DataFrame.

DataFrame.value_counts Equivalent method on DataFrames.

Examples

```
>>> index = pd.Index([3, 1, 2, 3, 4, np.nan])
>>> index.value_counts()
3.0    2
4.0    1
2.0    1
1.0    1
dtype: int64
```

With *normalize* set to *True*, returns the relative frequency by dividing all values by the sum of values.

```
>>> s = pd.Series([3, 1, 2, 3, 4, np.nan])
>>> s.value_counts(normalize=True)
3.0    0.4
4.0    0.2
2.0    0.2
1.0    0.2
dtype: float64
```

bins

Bins can be useful for going from a continuous variable to a categorical variable; instead of counting unique apparitions of values, divide the index in the specified number of half-open bins.

```
>>> s.value_counts(bins=3)
(2.0, 3.0]      2
(0.996, 2.0]    2
(3.0, 4.0]      1
dtype: int64
```

dropna

With *dropna* set to *False* we can also see NaN index values.

```
>>> s.value_counts(dropna=False)
3.0    2
NaN    1
4.0    1
2.0    1
1.0    1
dtype: int64
```

pandas.Index.where

Index.**where**(*cond*, *other=None*)

Replace values where the condition is False.

The replacement is taken from other.

Parameters

cond [bool array-like with the same length as self] Condition to select the values on.

other [scalar, or array-like, default None] Replacement if the condition is False.

Returns

pandas.Index A copy of self with values replaced from other where the condition is False.

See also:

Series.where Same method for Series.

DataFrame.where Same method for DataFrame.

Examples

```
>>> idx = pd.Index(['car', 'bike', 'train', 'tractor'])
>>> idx
Index(['car', 'bike', 'train', 'tractor'], dtype='object')
>>> idx.where(idx.isin(['car', 'train']), 'other')
Index(['car', 'other', 'train', 'other'], dtype='object')
```

view	

Properties

Index.values	Return an array representing the data in the Index.
Index.is_monotonic	Alias for is_monotonic_increasing.
Index.is_monotonic_increasing	Return if the index is monotonic increasing (only equal or increasing) values.
Index.is_monotonic_decreasing	Return if the index is monotonic decreasing (only equal or decreasing) values.
Index.is_unique	Return if the index has unique values.
Index.has_duplicates	Check if the Index has duplicate values.
Index.hasnans	Return if I have any nans; enables various perf speedups.
Index.dtype	Return the dtype object of the underlying data.
Index.inferred_type	Return a string of the type inferred from the values.
Index.is_all_dates	Whether or not the index values only consist of dates.
Index.shape	Return a tuple of the shape of the underlying data.
Index.name	Return Index or MultiIndex name.
Index.names	
Index.nbytes	Return the number of bytes in the underlying data.
Index.ndim	Number of dimensions of the underlying data, by definition 1.
Index.size	Return the number of elements in the underlying data.
Index.empty	
Index.T	Return the transpose, which is by definition self.
Index.memory_usage([deep])	Memory usage of the values.

pandas.Index.names

property Index.**names**

pandas.Index.empty

property Index.**empty**

Modifying and computations

Index.all(*args, **kwargs)	Return whether all elements are True.
Index.any(*args, **kwargs)	Return whether any element is True.
Index.argmin([axis, skipna])	Return int position of the smallest value in the Series.
Index.argmax([axis, skipna])	Return int position of the largest value in the Series.
Index.copy([name, deep, dtype, names])	Make a copy of this object.
Index.delete(loc)	Make new Index with passed location(-s) deleted.
Index.drop(labels[, errors])	Make new Index with passed list of labels deleted.
Index.drop_duplicates([keep])	Return Index with duplicate values removed.
Index.duplicated([keep])	Indicate duplicate index values.
Index.equals(other)	Determine if two Index object are equal.
Index.factorize([sort, na_sentinel])	Encode the object as an enumerated type or categorical variable.

continues on next page

Table 132 – continued from previous page

Index.identical(other)	Similar to equals, but checks that object attributes and types are also equal.
Index.insert(loc, item)	Make new Index inserting new item at location.
Index.is_(other)	More flexible, faster check like `is` but that works through views.
Index.is_boolean()	Check if the Index only consists of booleans.
Index.is_categorical()	Check if the Index holds categorical data.
Index.is_floating()	Check if the Index is a floating type.
Index.is_integer()	Check if the Index only consists of integers.
Index.is_interval()	Check if the Index holds Interval objects.
Index.is_mixed()	Check if the Index holds data with mixed data types.
Index.is_numeric()	Check if the Index only consists of numeric data.
Index.is_object()	Check if the Index is of the object dtype.
Index.min([axis, skipna])	Return the minimum value of the Index.
Index.max([axis, skipna])	Return the maximum value of the Index.
Index.reindex(target[, method, level, ...])	Create index with target's values.
Index.rename(name[, inplace])	Alter Index or MultiIndex name.
Index.repeat(repeats[, axis])	Repeat elements of a Index.
Index.where(cond[, other])	Replace values where the condition is False.
Index.take(indices[, axis, allow_fill, ...])	Return a new Index of the values selected by the indices.
Index.putmask(mask, value)	Return a new Index of the values set with the mask.
Index.unique([level])	Return unique values in the index.
Index.nunique([dropna])	Return number of unique elements in the object.
Index.value_counts([normalize, sort, ...])	Return a Series containing counts of unique values.

Compatibility with MultiIndex

Index.set_names(names[, level, inplace])	Set Index or MultiIndex name.
Index.droplevel([level])	Return index with requested level(s) removed.

Missing values

Index.fillna([value, downcast])	Fill NA/NaN values with the specified value.
Index.dropna([how])	Return Index without NA/NaN values.
Index.isna()	Detect missing values.
Index.notna()	Detect existing (non-missing) values.

Conversion

Index.astype(dtype[, copy])	Create an Index with values cast to dtypes.
Index.item()	Return the first element of the underlying data as a python scalar.
Index.map(mapper[, na_action])	Map values using input correspondence (a dict, Series, or function).
Index.ravel([order])	Return an ndarray of the flattened values of the underlying data.

continues on next page

Table 135 – continued from previous page

Index.to_list()	Return a list of the values.
Index.to_native_types([slicer])	Format specified values of *self* and return them.
Index.to_series([index, name])	Create a Series with both index and values equal to the index keys.
Index.to_frame([index, name])	Create a DataFrame with a column containing the Index.
Index.view([cls])	

pandas.Index.view

Index.**view**(*cls=None*)

Sorting

Index.argsort(*args, **kwargs)	Return the integer indices that would sort the index.
Index.searchsorted(value[, side, sorter])	Find indices where elements should be inserted to maintain order.
Index.sort_values([return_indexer, ...])	Return a sorted copy of the index.

Time-specific operations

Index.shift([periods, freq])	Shift index by desired number of time frequency increments.

Combining / joining / set operations

Index.append(other)	Append a collection of Index options together.
Index.join(other[, how, level, ...])	Compute join_index and indexers to conform data structures to the new index.
Index.intersection(other[, sort])	Form the intersection of two Index objects.
Index.union(other[, sort])	Form the union of two Index objects.
Index.difference(other[, sort])	Return a new Index with elements of index not in *other*.
Index.symmetric_difference(other[, ...])	Compute the symmetric difference of two Index objects.

Selecting

Index.asof(label)	Return the label from the index, or, if not present, the previous one.
Index.asof_locs(where, mask)	Return the locations (indices) of labels in the index.
Index.get_indexer(target[, method, limit, ...])	Compute indexer and mask for new index given the current index.
Index.get_indexer_for(target, **kwargs)	Guaranteed return of an indexer even when non-unique.
Index.get_indexer_non_unique(target)	Compute indexer and mask for new index given the current index.

continues on next page

Table 139 – continued from previous page

`Index.get_level_values`(level)	Return an Index of values for requested level.
`Index.get_loc`(key[, method, tolerance])	Get integer location, slice or boolean mask for requested label.
`Index.get_slice_bound`(label, side, kind)	Calculate slice bound that corresponds to given label.
`Index.get_value`(series, key)	Fast lookup of value from 1-dimensional ndarray.
`Index.isin`(values[, level])	Return a boolean array where the index values are in *values*.
`Index.slice_indexer`([start, end, step, kind])	Compute the slice indexer for input labels and step.
`Index.slice_locs`([start, end, step, kind])	Compute slice locations for input labels.

3.7.2 Numeric Index

`RangeIndex`([start, stop, step, dtype, copy, ...])	Immutable Index implementing a monotonic integer range.
`Int64Index`([data, dtype, copy, name])	Immutable ndarray implementing an ordered, sliceable set.
`UInt64Index`([data, dtype, copy, name])	Immutable ndarray implementing an ordered, sliceable set.
`Float64Index`([data, dtype, copy, name])	Immutable ndarray implementing an ordered, sliceable set.

pandas.RangeIndex

class pandas.**RangeIndex**(*start=None*, *stop=None*, *step=None*, *dtype=None*, *copy=False*, *name=None*)

Immutable Index implementing a monotonic integer range.

RangeIndex is a memory-saving special case of Int64Index limited to representing monotonic ranges. Using RangeIndex may in some instances improve computing speed.

This is the default index type used by DataFrame and Series when no explicit index is provided by the user.

Parameters

start [int (default: 0), or other RangeIndex instance] If int and "stop" is not given, interpreted as "stop" instead.

stop [int (default: 0)]

step [int (default: 1)]

name [object, optional] Name to be stored in the index.

copy [bool, default False] Unused, accepted for homogeneity with other index types.

See also:

Index The base pandas Index type.
Int64Index Index of int64 data.

Attributes

start	The value of the *start* parameter (0 if this was not supplied).
stop	The value of the *stop* parameter.
step	The value of the *step* parameter (1 if this was not supplied).

pandas.RangeIndex.start

RangeIndex.**start**
The value of the *start* parameter (0 if this was not supplied).

pandas.RangeIndex.stop

RangeIndex.**stop**
The value of the *stop* parameter.

pandas.RangeIndex.step

RangeIndex.**step**
The value of the *step* parameter (1 if this was not supplied).

Methods

from_range(data[, name, dtype])	Create RangeIndex from a range object.

pandas.RangeIndex.from_range

classmethod RangeIndex.**from_range**(*data*, *name=None*, *dtype=None*)
Create RangeIndex from a range object.

Returns

RangeIndex

pandas.Int64Index

class pandas.**Int64Index**(*data=None*, *dtype=None*, *copy=False*, *name=None*)
Immutable ndarray implementing an ordered, sliceable set. The basic object storing axis labels for all pandas objects. Int64Index is a special case of *Index* with purely integer labels. .

Parameters

data [array-like (1-dimensional)]

dtype [NumPy dtype (default: int64)]

copy [bool] Make a copy of input ndarray.

name [object] Name to be stored in the index.

See also:

Index The base pandas Index type.

Notes

An Index instance can **only** contain hashable objects.

Attributes

None	

Methods

None	

pandas.UInt64Index

class pandas.**UInt64Index**(*data=None*, *dtype=None*, *copy=False*, *name=None*)

Immutable ndarray implementing an ordered, sliceable set. The basic object storing axis labels for all pandas objects. UInt64Index is a special case of *Index* with purely unsigned integer labels. .

Parameters

data [array-like (1-dimensional)]

dtype [NumPy dtype (default: uint64)]

copy [bool] Make a copy of input ndarray.

name [object] Name to be stored in the index.

See also:

Index The base pandas Index type.

Notes

An Index instance can **only** contain hashable objects.

Attributes

None	

Methods

None	

pandas.Float64Index

class pandas.**Float64Index**(*data=None*, *dtype=None*, *copy=False*, *name=None*)

Immutable ndarray implementing an ordered, sliceable set. The basic object storing axis labels for all pandas objects. Float64Index is a special case of *Index* with purely float labels. .

Parameters

data [array-like (1-dimensional)]

dtype [NumPy dtype (default: float64)]

copy [bool] Make a copy of input ndarray.

name [object] Name to be stored in the index.

See also:

Index The base pandas Index type.

Notes

An Index instance can **only** contain hashable objects.

Attributes

None	

Methods

None	

RangeIndex.start	The value of the *start* parameter (`0` if this was not supplied).
RangeIndex.stop	The value of the *stop* parameter.
RangeIndex.step	The value of the *step* parameter (`1` if this was not supplied).
RangeIndex.from_range(data[, name, dtype])	Create RangeIndex from a range object.

3.7.3 CategoricalIndex

`CategoricalIndex`([data, categories, ...])	Index based on an underlying `Categorical`.

pandas.CategoricalIndex

class pandas.**CategoricalIndex**(*data=None*, *categories=None*, *ordered=None*, *dtype=None*, *copy=False*, *name=None*)

Index based on an underlying `Categorical`.

CategoricalIndex, like Categorical, can only take on a limited, and usually fixed, number of possible values (*categories*). Also, like Categorical, it might have an order, but numerical operations (additions, divisions, ...) are not possible.

Parameters

data [array-like (1-dimensional)] The values of the categorical. If *categories* are given, values not in *categories* will be replaced with NaN.

categories [index-like, optional] The categories for the categorical. Items need to be unique. If the categories are not given here (and also not in *dtype*), they will be inferred from the *data*.

ordered [bool, optional] Whether or not this categorical is treated as an ordered categorical. If not given here or in *dtype*, the resulting categorical will be unordered.

dtype [CategoricalDtype or "category", optional] If `CategoricalDtype`, cannot be used together with *categories* or *ordered*.

copy [bool, default False] Make a copy of input ndarray.

name [object, optional] Name to be stored in the index.

Raises

ValueError If the categories do not validate.

TypeError If an explicit `ordered=True` is given but no *categories* and the *values* are not sortable.

See also:

Index The base pandas Index type.
Categorical A categorical array.
CategoricalDtype Type for categorical data.

Notes

See the user guide for more.

Examples

```
>>> pd.CategoricalIndex(["a", "b", "c", "a", "b", "c"])
CategoricalIndex(['a', 'b', 'c', 'a', 'b', 'c'],
                 categories=['a', 'b', 'c'], ordered=False, dtype='category')
```

`CategoricalIndex` can also be instantiated from a `Categorical`:

```
>>> c = pd.Categorical(["a", "b", "c", "a", "b", "c"])
>>> pd.CategoricalIndex(c)
CategoricalIndex(['a', 'b', 'c', 'a', 'b', 'c'],
                 categories=['a', 'b', 'c'], ordered=False, dtype='category')
```

Ordered `CategoricalIndex` can have a min and max value.

```
>>> ci = pd.CategoricalIndex(
...     ["a", "b", "c", "a", "b", "c"], ordered=True, categories=["c", "b", "a"]
... )
>>> ci
CategoricalIndex(['a', 'b', 'c', 'a', 'b', 'c'],
                 categories=['c', 'b', 'a'], ordered=True, dtype='category')
>>> ci.min()
'c'
```

Attributes

codes	The category codes of this categorical.
categories	The categories of this categorical.
ordered	Whether the categories have an ordered relationship.

pandas.CategoricalIndex.codes

property CategoricalIndex.**codes**

The category codes of this categorical.

Codes are an array of integers which are the positions of the actual values in the categories array.

There is no setter, use the other categorical methods and the normal item setter to change values in the categorical.

Returns

ndarray[int] A non-writable view of the *codes* array.

pandas.CategoricalIndex.categories

property CategoricalIndex.**categories**

The categories of this categorical.

Setting assigns new values to each category (effectively a rename of each individual category).

The assigned value has to be a list-like object. All items must be unique and the number of items in the new categories must be the same as the number of items in the old categories.

Assigning to *categories* is a inplace operation!

Raises

ValueError If the new categories do not validate as categories or if the number of new categories is unequal the number of old categories

See also:

rename_categories Rename categories.

reorder_categories Reorder categories.

add_categories Add new categories.

remove_categories Remove the specified categories.

remove_unused_categories Remove categories which are not used.

set_categories Set the categories to the specified ones.

pandas.CategoricalIndex.ordered

property CategoricalIndex.**ordered**

Whether the categories have an ordered relationship.

Methods

rename_categories(*args, **kwargs)	Rename categories.
reorder_categories(*args, **kwargs)	Reorder categories as specified in new_categories.
add_categories(*args, **kwargs)	Add new categories.
remove_categories(*args, **kwargs)	Remove the specified categories.
remove_unused_categories(*args, **kwargs)	Remove categories which are not used.
set_categories(*args, **kwargs)	Set the categories to the specified new_categories.
as_ordered(*args, **kwargs)	Set the Categorical to be ordered.
as_unordered(*args, **kwargs)	Set the Categorical to be unordered.
map(mapper)	Map values using input correspondence (a dict, Series, or function).

pandas.CategoricalIndex.rename_categories

CategoricalIndex.**rename_categories**(**args*, ***kwargs*)

Rename categories.

Parameters

new_categories [list-like, dict-like or callable] New categories which will replace old categories.

- list-like: all items must be unique and the number of items in the new categories must match the existing number of categories.
- dict-like: specifies a mapping from old categories to new. Categories not contained in the mapping are passed through and extra categories in the mapping are ignored.
- callable : a callable that is called on all items in the old categories and whose return values comprise the new categories.

New in version 0.23.0..

inplace [bool, default False] Whether or not to rename the categories inplace or return a copy of this categorical with renamed categories.

Returns

cat [Categorical or None] With `inplace=False`, the new categorical is returned. With `inplace=True`, there is no return value.

Raises

ValueError If new categories are list-like and do not have the same number of items than the current categories or do not validate as categories

See also:

reorder_categories Reorder categories.

add_categories Add new categories.

remove_categories Remove the specified categories.

remove_unused_categories Remove categories which are not used.

set_categories Set the categories to the specified ones.

Examples

```
>>> c = pd.Categorical(['a', 'a', 'b'])
>>> c.rename_categories([0, 1])
[0, 0, 1]
Categories (2, int64): [0, 1]
```

For dict-like `new_categories`, extra keys are ignored and categories not in the dictionary are passed through

```
>>> c.rename_categories({'a': 'A', 'c': 'C'})
['A', 'A', 'b']
Categories (2, object): ['A', 'b']
```

You may also provide a callable to create the new categories

```
>>> c.rename_categories(lambda x: x.upper())
['A', 'A', 'B']
Categories (2, object): ['A', 'B']
```

pandas.CategoricalIndex.reorder_categories

CategoricalIndex.**reorder_categories**(**args*, ***kwargs*)

Reorder categories as specified in new_categories.

new_categories need to include all old categories and no new category items.

Parameters

new_categories [Index-like] The categories in new order.

ordered [bool, optional] Whether or not the categorical is treated as a ordered categorical. If not given, do not change the ordered information.

inplace [bool, default False] Whether or not to reorder the categories inplace or return a copy of this categorical with reordered categories.

Returns

cat [Categorical with reordered categories or None if inplace.]

Raises

ValueError If the new categories do not contain all old category items or any new ones

See also:

rename_categories Rename categories.

add_categories Add new categories.

remove_categories Remove the specified categories.

remove_unused_categories Remove categories which are not used.

set_categories Set the categories to the specified ones.

pandas.CategoricalIndex.add_categories

CategoricalIndex.**add_categories**(**args*, ***kwargs*)

Add new categories.

new_categories will be included at the last/highest place in the categories and will be unused directly after this call.

Parameters

new_categories [category or list-like of category] The new categories to be included.

inplace [bool, default False] Whether or not to add the categories inplace or return a copy of this categorical with added categories.

Returns

cat [Categorical with new categories added or None if inplace.]

Raises

ValueError If the new categories include old categories or do not validate as categories

See also:

rename_categories Rename categories.

reorder_categories Reorder categories.

remove_categories Remove the specified categories.

remove_unused_categories Remove categories which are not used.

set_categories Set the categories to the specified ones.

pandas.CategoricalIndex.remove_categories

CategoricalIndex.**remove_categories**(**args*, ***kwargs*)

Remove the specified categories.

removals must be included in the old categories. Values which were in the removed categories will be set to NaN

Parameters

removals [category or list of categories] The categories which should be removed.

inplace [bool, default False] Whether or not to remove the categories inplace or return a copy of this categorical with removed categories.

Returns

cat [Categorical with removed categories or None if inplace.]

Raises

ValueError If the removals are not contained in the categories

See also:

rename_categories Rename categories.

reorder_categories Reorder categories.

add_categories Add new categories.

remove_unused_categories Remove categories which are not used.

set_categories Set the categories to the specified ones.

pandas.CategoricalIndex.remove_unused_categories

CategoricalIndex.**remove_unused_categories**(**args*, ***kwargs*)

Remove categories which are not used.

Parameters

inplace [bool, default False] Whether or not to drop unused categories inplace or return a copy of this categorical with unused categories dropped.

Returns

cat [Categorical with unused categories dropped or None if inplace.]

See also:

rename_categories Rename categories.

reorder_categories Reorder categories.

add_categories Add new categories.

remove_categories Remove the specified categories.

set_categories Set the categories to the specified ones.

pandas.CategoricalIndex.set_categories

CategoricalIndex.**set_categories**(**args*, ***kwargs*)

Set the categories to the specified new_categories.

new_categories can include new categories (which will result in unused categories) or remove old categories (which results in values set to NaN). If *rename==True*, the categories will simple be renamed (less or more items than in old categories will result in values set to NaN or in unused categories respectively).

This method can be used to perform more than one action of adding, removing, and reordering simultaneously and is therefore faster than performing the individual steps via the more specialised methods.

On the other hand this methods does not do checks (e.g., whether the old categories are included in the new categories on a reorder), which can result in surprising changes, for example when using special string dtypes, which does not considers a S1 string equal to a single char python string.

Parameters

new_categories [Index-like] The categories in new order.

ordered [bool, default False] Whether or not the categorical is treated as a ordered categorical. If not given, do not change the ordered information.

rename [bool, default False] Whether or not the new_categories should be considered as a rename of the old categories or as reordered categories.

inplace [bool, default False] Whether or not to reorder the categories in-place or return a copy of this categorical with reordered categories.

Returns

Categorical with reordered categories or None if inplace.

Raises

ValueError If new_categories does not validate as categories

See also:

rename_categories Rename categories.

reorder_categories Reorder categories.

add_categories Add new categories.

remove_categories Remove the specified categories.

remove_unused_categories Remove categories which are not used.

pandas.CategoricalIndex.as_ordered

CategoricalIndex.**as_ordered**(**args*, ***kwargs*)

Set the Categorical to be ordered.

Parameters

inplace [bool, default False] Whether or not to set the ordered attribute in-place or return a copy of this categorical with ordered set to True.

Returns

Categorical Ordered Categorical.

pandas.CategoricalIndex.as_unordered

CategoricalIndex.**as_unordered**(**args*, ***kwargs*)

Set the Categorical to be unordered.

Parameters

inplace [bool, default False] Whether or not to set the ordered attribute in-place or return a copy of this categorical with ordered set to False.

Returns

Categorical Unordered Categorical.

pandas.CategoricalIndex.map

CategoricalIndex.**map**(*mapper*)

Map values using input correspondence (a dict, Series, or function).

Maps the values (their categories, not the codes) of the index to new categories. If the mapping correspondence is one-to-one the result is a *CategoricalIndex* which has the same order property as the original, otherwise an *Index* is returned.

If a *dict* or *Series* is used any unmapped category is mapped to *NaN*. Note that if this happens an *Index* will be returned.

Parameters

mapper [function, dict, or Series] Mapping correspondence.

Returns

pandas.CategoricalIndex or pandas.Index Mapped index.

See also:

Index.map Apply a mapping correspondence on an *Index*.

Series.map Apply a mapping correspondence on a *Series*.

Series.apply Apply more complex functions on a *Series*.

Examples

```
>>> idx = pd.CategoricalIndex(['a', 'b', 'c'])
>>> idx
CategoricalIndex(['a', 'b', 'c'], categories=['a', 'b', 'c'],
                 ordered=False, dtype='category')
>>> idx.map(lambda x: x.upper())
CategoricalIndex(['A', 'B', 'C'], categories=['A', 'B', 'C'],
                 ordered=False, dtype='category')
>>> idx.map({'a': 'first', 'b': 'second', 'c': 'third'})
CategoricalIndex(['first', 'second', 'third'], categories=['first',
                 'second', 'third'], ordered=False, dtype='category')
```

If the mapping is one-to-one the ordering of the categories is preserved:

```
>>> idx = pd.CategoricalIndex(['a', 'b', 'c'], ordered=True)
>>> idx
CategoricalIndex(['a', 'b', 'c'], categories=['a', 'b', 'c'],
                 ordered=True, dtype='category')
>>> idx.map({'a': 3, 'b': 2, 'c': 1})
CategoricalIndex([3, 2, 1], categories=[3, 2, 1], ordered=True,
                 dtype='category')
```

If the mapping is not one-to-one an *Index* is returned:

```
>>> idx.map({'a': 'first', 'b': 'second', 'c': 'first'})
Index(['first', 'second', 'first'], dtype='object')
```

If a *dict* is used, all unmapped categories are mapped to *NaN* and the result is an *Index*:

```
>>> idx.map({'a': 'first', 'b': 'second'})
Index(['first', 'second', nan], dtype='object')
```

Categorical components

CategoricalIndex.codes	The category codes of this categorical.
CategoricalIndex.categories	The categories of this categorical.
CategoricalIndex.ordered	Whether the categories have an ordered relationship.
CategoricalIndex.rename_categories(*args, ...)	Rename categories.
CategoricalIndex.reorder_categories(*args, ...)	Reorder categories as specified in new_categories.
CategoricalIndex.add_categories(*args, **kwargs)	Add new categories.
CategoricalIndex.remove_categories(*args, ...)	Remove the specified categories.
CategoricalIndex.remove_unused_categories(...)	Remove categories which are not used.
CategoricalIndex.set_categories(*args, **kwargs)	Set the categories to the specified new_categories.
CategoricalIndex.as_ordered(*args, **kwargs)	Set the Categorical to be ordered.

continues on next page

Table 147 – continued from previous page

CategoricalIndex.as_unordered(*args, **kwargs)	Set the Categorical to be unordered.

Modifying and computations

CategoricalIndex.map(mapper)	Map values using input correspondence (a dict, Series, or function).
CategoricalIndex.equals(other)	Determine if two CategoricalIndex objects contain the same elements.

pandas.CategoricalIndex.equals

CategoricalIndex.**equals**(*other*)

Determine if two CategoricalIndex objects contain the same elements.

Returns

bool If two CategoricalIndex objects have equal elements True, otherwise False.

3.7.4 IntervalIndex

IntervalIndex(data[, closed, dtype, copy, ...])	Immutable index of intervals that are closed on the same side.

pandas.IntervalIndex

class pandas.**IntervalIndex**(*data*, *closed=None*, *dtype=None*, *copy=False*, *name=None*, *verify_integrity=True*)

Immutable index of intervals that are closed on the same side.

New in version 0.20.0.

Parameters

data [array-like (1-dimensional)] Array-like containing Interval objects from which to build the IntervalIndex.

closed [{'left', 'right', 'both', 'neither'}, default 'right'] Whether the intervals are closed on the left-side, right-side, both or neither.

dtype [dtype or None, default None] If None, dtype will be inferred.

New in version 0.23.0.

copy [bool, default False] Copy the input data.

name [object, optional] Name to be stored in the index.

verify_integrity [bool, default True] Verify that the IntervalIndex is valid.

See also:

Index The base pandas Index type.
Interval A bounded slice-like interval; the elements of an IntervalIndex.
interval_range Function to create a fixed frequency IntervalIndex.

cut Bin values into discrete Intervals.
qcut Bin values into equal-sized Intervals based on rank or sample quantiles.

Notes

See the user guide for more.

Examples

A new `IntervalIndex` is typically constructed using *interval_range()*:

```
>>> pd.interval_range(start=0, end=5)
IntervalIndex([(0, 1], (1, 2], (2, 3], (3, 4], (4, 5]],
              closed='right',
              dtype='interval[int64]')
```

It may also be constructed using one of the constructor methods: *IntervalIndex.from_arrays()*, *IntervalIndex.from_breaks()*, and *IntervalIndex.from_tuples()*.

See further examples in the doc strings of `interval_range` and the mentioned constructor methods.

Attributes

left	Return the left endpoints of each Interval in the IntervalArray as an Index.
right	Return the right endpoints of each Interval in the IntervalArray as an Index.
closed	Whether the intervals are closed on the left-side, right-side, both or neither.
mid	Return the midpoint of each Interval in the IntervalArray as an Index.
length	Return an Index with entries denoting the length of each Interval in the IntervalArray.
is_empty	Indicates if an interval is empty, meaning it contains no points.
is_non_overlapping_monotonic	Return True if the IntervalArray is non-overlapping (no Intervals share points) and is either monotonic increasing or monotonic decreasing, else False.
is_overlapping	Return True if the IntervalIndex has overlapping intervals, else False.
values	Return the IntervalIndex's data as an IntervalArray.

pandas.IntervalIndex.left

property IntervalIndex.**left**
Return the left endpoints of each Interval in the IntervalArray as an Index.

pandas.IntervalIndex.right

property IntervalIndex.**right**
Return the right endpoints of each Interval in the IntervalArray as an Index.

pandas.IntervalIndex.closed

IntervalIndex.**closed**
Whether the intervals are closed on the left-side, right-side, both or neither.

pandas.IntervalIndex.mid

IntervalIndex.**mid**
Return the midpoint of each Interval in the IntervalArray as an Index.

pandas.IntervalIndex.length

property IntervalIndex.**length**
Return an Index with entries denoting the length of each Interval in the IntervalArray.

pandas.IntervalIndex.is_empty

IntervalIndex.**is_empty**
Indicates if an interval is empty, meaning it contains no points.

New in version 0.25.0.

Returns

bool or ndarray A boolean indicating if a scalar *Interval* is empty, or a boolean ndarray positionally indicating if an Interval in an *IntervalArray* or *IntervalIndex* is empty.

Examples

An *Interval* that contains points is not empty:

```
>>> pd.Interval(0, 1, closed='right').is_empty
False
```

An Interval that does not contain any points is empty:

```
>>> pd.Interval(0, 0, closed='right').is_empty
True
>>> pd.Interval(0, 0, closed='left').is_empty
True
>>> pd.Interval(0, 0, closed='neither').is_empty
True
```

An `Interval` that contains a single point is not empty:

```
>>> pd.Interval(0, 0, closed='both').is_empty
False
```

An *IntervalArray* or *IntervalIndex* returns a boolean `ndarray` positionally indicating if an `Interval` is empty:

```
>>> ivs = [pd.Interval(0, 0, closed='neither'),
...        pd.Interval(1, 2, closed='neither')]
>>> pd.arrays.IntervalArray(ivs).is_empty
array([ True, False])
```

Missing values are not considered empty:

```
>>> ivs = [pd.Interval(0, 0, closed='neither'), np.nan]
>>> pd.IntervalIndex(ivs).is_empty
array([ True, False])
```

pandas.IntervalIndex.is_non_overlapping_monotonic

`IntervalIndex.`**`is_non_overlapping_monotonic`**

Return True if the IntervalArray is non-overlapping (no Intervals share points) and is either monotonic increasing or monotonic decreasing, else False.

pandas.IntervalIndex.is_overlapping

property `IntervalIndex.`**`is_overlapping`**

Return True if the IntervalIndex has overlapping intervals, else False.

Two intervals overlap if they share a common point, including closed endpoints. Intervals that only have an open endpoint in common do not overlap.

New in version 0.24.0.

Returns

bool Boolean indicating if the IntervalIndex has overlapping intervals.

See also:

Interval.overlaps Check whether two Interval objects overlap.

IntervalIndex.overlaps Check an IntervalIndex elementwise for overlaps.

Examples

```
>>> index = pd.IntervalIndex.from_tuples([(0, 2), (1, 3), (4, 5)])
>>> index
IntervalIndex([(0, 2], (1, 3], (4, 5]],
      closed='right',
      dtype='interval[int64]')
>>> index.is_overlapping
True
```

Intervals that share closed endpoints overlap:

```
>>> index = pd.interval_range(0, 3, closed='both')
>>> index
IntervalIndex([[0, 1], [1, 2], [2, 3]],
      closed='both',
      dtype='interval[int64]')
>>> index.is_overlapping
True
```

Intervals that only have an open endpoint in common do not overlap:

```
>>> index = pd.interval_range(0, 3, closed='left')
>>> index
IntervalIndex([[0, 1), [1, 2), [2, 3)],
      closed='left',
      dtype='interval[int64]')
>>> index.is_overlapping
False
```

pandas.IntervalIndex.values

IntervalIndex.**values**
Return the IntervalIndex's data as an IntervalArray.

Methods

from_arrays(left, right[, closed, name, ...])	Construct from two arrays defining the left and right bounds.
from_tuples(data[, closed, name, copy, dtype])	Construct an IntervalIndex from an array-like of tuples.
from_breaks(breaks[, closed, name, copy, dtype])	Construct an IntervalIndex from an array of splits.
contains(*args, **kwargs)	Check elementwise if the Intervals contain the value.
overlaps(*args, **kwargs)	Check elementwise if an Interval overlaps the values in the IntervalArray.
set_closed(*args, **kwargs)	Return an IntervalArray identical to the current one, but closed on the specified side.
to_tuples(*args, **kwargs)	Return an ndarray of tuples of the form (left, right).

pandas.IntervalIndex.from_arrays

classmethod IntervalIndex.**from_arrays**(*left*, *right*, *closed='right'*, *name=None*, *copy=False*, *dtype=None*)

Construct from two arrays defining the left and right bounds.

Parameters

left [array-like (1-dimensional)] Left bounds for each interval.

right [array-like (1-dimensional)] Right bounds for each interval.

closed [{'left', 'right', 'both', 'neither'}, default 'right'] Whether the intervals are closed on the left-side, right-side, both or neither.

copy [bool, default False] Copy the data.

dtype [dtype, optional] If None, dtype will be inferred.

New in version 0.23.0.

Returns

IntervalIndex

Raises

ValueError When a value is missing in only one of *left* or *right*. When a value in *left* is greater than the corresponding value in *right*.

See also:

interval_range Function to create a fixed frequency IntervalIndex.

IntervalIndex.from_breaks Construct an IntervalIndex from an array of splits.

IntervalIndex.from_tuples Construct an IntervalIndex from an array-like of tuples.

Notes

Each element of *left* must be less than or equal to the *right* element at the same position. If an element is missing, it must be missing in both *left* and *right*. A TypeError is raised when using an unsupported type for *left* or *right*. At the moment, 'category', 'object', and 'string' subtypes are not supported.

Examples

```
>>> pd.IntervalIndex.from_arrays([0, 1, 2], [1, 2, 3])
IntervalIndex([(0, 1], (1, 2], (2, 3]],
              closed='right',
              dtype='interval[int64]')
```

pandas.IntervalIndex.from_tuples

classmethod IntervalIndex.**from_tuples**(*data*, *closed='right'*, *name=None*, *copy=False*, *dtype=None*)

Construct an IntervalIndex from an array-like of tuples.

Parameters

data [array-like (1-dimensional)] Array of tuples.

closed [{'left', 'right', 'both', 'neither'}, default 'right'] Whether the intervals are closed on the left-side, right-side, both or neither.

copy [bool, default False] By-default copy the data, this is compat only and ignored.

dtype [dtype or None, default None] If None, dtype will be inferred.

New in version 0.23.0.

Returns

IntervalIndex

See also:

interval_range Function to create a fixed frequency IntervalIndex.

IntervalIndex.from_arrays Construct an IntervalIndex from a left and right array.

IntervalIndex.from_breaks Construct an IntervalIndex from an array of splits.

Examples

```
>>> pd.IntervalIndex.from_tuples([(0, 1), (1, 2)])
IntervalIndex([(0, 1], (1, 2]],
              closed='right',
              dtype='interval[int64]')
```

pandas.IntervalIndex.from_breaks

classmethod IntervalIndex.**from_breaks**(*breaks*, *closed='right'*, *name=None*, *copy=False*, *dtype=None*)

Construct an IntervalIndex from an array of splits.

Parameters

breaks [array-like (1-dimensional)] Left and right bounds for each interval.

closed [{'left', 'right', 'both', 'neither'}, default 'right'] Whether the intervals are closed on the left-side, right-side, both or neither.

copy [bool, default False] Copy the data.

dtype [dtype or None, default None] If None, dtype will be inferred.

New in version 0.23.0.

Returns

IntervalIndex

See also:

interval_range Function to create a fixed frequency IntervalIndex.

IntervalIndex.from_arrays Construct from a left and right array.

IntervalIndex.from_tuples Construct from a sequence of tuples.

Examples

```
>>> pd.IntervalIndex.from_breaks([0, 1, 2, 3])
IntervalIndex([(0, 1], (1, 2], (2, 3]],
              closed='right',
              dtype='interval[int64]')
```

pandas.IntervalIndex.contains

IntervalIndex.**contains**(**args*, ***kwargs*)

Check elementwise if the Intervals contain the value.

Return a boolean mask whether the value is contained in the Intervals of the IntervalArray.

New in version 0.25.0.

Parameters

other [scalar] The value to check whether it is contained in the Intervals.

Returns

boolean array

See also:

Interval.contains Check whether Interval object contains value.

IntervalArray.overlaps Check if an Interval overlaps the values in the IntervalArray.

Examples

```
>>> intervals = pd.arrays.IntervalArray.from_tuples([(0, 1), (1, 3), (2, 4)])
>>> intervals
<IntervalArray>
[(0, 1], (1, 3], (2, 4]]
Length: 3, closed: right, dtype: interval[int64]
```

```
>>> intervals.contains(0.5)
array([ True, False, False])
```

pandas.IntervalIndex.overlaps

IntervalIndex.**overlaps**(**args*, ***kwargs*)

Check elementwise if an Interval overlaps the values in the IntervalArray.

Two intervals overlap if they share a common point, including closed endpoints. Intervals that only have an open endpoint in common do not overlap.

New in version 0.24.0.

Parameters

other [IntervalArray] Interval to check against for an overlap.

Returns

ndarray Boolean array positionally indicating where an overlap occurs.

See also:

Interval.overlaps Check whether two Interval objects overlap.

Examples

```
>>> data = [(0, 1), (1, 3), (2, 4)]
>>> intervals = pd.arrays.IntervalArray.from_tuples(data)
>>> intervals
<IntervalArray>
[(0, 1], (1, 3], (2, 4]]
Length: 3, closed: right, dtype: interval[int64]
```

```
>>> intervals.overlaps(pd.Interval(0.5, 1.5))
array([ True,  True, False])
```

Intervals that share closed endpoints overlap:

```
>>> intervals.overlaps(pd.Interval(1, 3, closed='left'))
array([ True,  True, True])
```

Intervals that only have an open endpoint in common do not overlap:

```
>>> intervals.overlaps(pd.Interval(1, 2, closed='right'))
array([False,  True, False])
```

pandas.IntervalIndex.set_closed

IntervalIndex.**set_closed**(**args*, ***kwargs*)

Return an IntervalArray identical to the current one, but closed on the specified side.

New in version 0.24.0.

Parameters

closed [{'left', 'right', 'both', 'neither'}] Whether the intervals are closed on the left-side, right-side, both or neither.

Returns

new_index [IntervalArray]

Examples

```
>>> index = pd.arrays.IntervalArray.from_breaks(range(4))
>>> index
<IntervalArray>
[(0, 1], (1, 2], (2, 3]]
Length: 3, closed: right, dtype: interval[int64]
>>> index.set_closed('both')
<IntervalArray>
[[0, 1], [1, 2], [2, 3]]
Length: 3, closed: both, dtype: interval[int64]
```

pandas.IntervalIndex.to_tuples

IntervalIndex.**to_tuples**(**args*, ***kwargs*)

Return an ndarray of tuples of the form (left, right).

Parameters

na_tuple [bool, default True] Returns NA as a tuple if True, `(nan, nan)`, or just as the NA value itself if False, `nan`.

New in version 0.23.0.

Returns

tuples: ndarray

IntervalIndex components

IntervalIndex.from_arrays(left, right[, ...])	Construct from two arrays defining the left and right bounds.
IntervalIndex.from_tuples(data[, closed, ...])	Construct an IntervalIndex from an array-like of tuples.
IntervalIndex.from_breaks(breaks[, closed, ...])	Construct an IntervalIndex from an array of splits.
IntervalIndex.left	Return the left endpoints of each Interval in the IntervalArray as an Index.
IntervalIndex.right	Return the right endpoints of each Interval in the IntervalArray as an Index.
IntervalIndex.mid	Return the midpoint of each Interval in the IntervalArray as an Index.
IntervalIndex.closed	Whether the intervals are closed on the left-side, right-side, both or neither.
IntervalIndex.length	Return an Index with entries denoting the length of each Interval in the IntervalArray.
IntervalIndex.values	Return the IntervalIndex's data as an IntervalArray.
IntervalIndex.is_empty	Indicates if an interval is empty, meaning it contains no points.

continues on next page

Table 152 – continued from previous page

IntervalIndex.is_non_overlapping_monotonic	Return True if the IntervalArray is non-overlapping (no Intervals share points) and is either monotonic increasing or monotonic decreasing, else False.
IntervalIndex.is_overlapping	Return True if the IntervalIndex has overlapping intervals, else False.
IntervalIndex.get_loc(key[, method, tolerance])	Get integer location, slice or boolean mask for requested label.
IntervalIndex.get_indexer(target[, method, ...])	Compute indexer and mask for new index given the current index.
IntervalIndex.set_closed(*args, **kwargs)	Return an IntervalArray identical to the current one, but closed on the specified side.
IntervalIndex.contains(*args, **kwargs)	Check elementwise if the Intervals contain the value.
IntervalIndex.overlaps(*args, **kwargs)	Check elementwise if an Interval overlaps the values in the IntervalArray.
IntervalIndex.to_tuples(*args, **kwargs)	Return an ndarray of tuples of the form (left, right).

pandas.IntervalIndex.get_loc

IntervalIndex.**get_loc**(*key*, *method=None*, *tolerance=None*)

Get integer location, slice or boolean mask for requested label.

Parameters

key [label]

method [{None}, optional]

- default: matches where the label is within an interval only.

Returns

int if unique index, slice if monotonic index, else mask

Examples

```
>>> i1, i2 = pd.Interval(0, 1), pd.Interval(1, 2)
>>> index = pd.IntervalIndex([i1, i2])
>>> index.get_loc(1)
0
```

You can also supply a point inside an interval.

```
>>> index.get_loc(1.5)
1
```

If a label is in several intervals, you get the locations of all the relevant intervals.

```
>>> i3 = pd.Interval(0, 2)
>>> overlapping_index = pd.IntervalIndex([i1, i2, i3])
>>> overlapping_index.get_loc(0.5)
array([ True, False,  True])
```

Only exact matches will be returned if an interval is provided.

```
>>> index.get_loc(pd.Interval(0, 1))
0
```

pandas.IntervalIndex.get_indexer

IntervalIndex.**get_indexer**(*target*, *method=None*, *limit=None*, *tolerance=None*)

Compute indexer and mask for new index given the current index. The indexer should be then used as an input to ndarray.take to align the current data to the new index.

Parameters

target [IntervalIndex or list of Intervals]

method [{None, 'pad'/'ffill', 'backfill'/'bfill', 'nearest'}, optional]

- default: exact matches only.
- pad / ffill: find the PREVIOUS index value if no exact match.
- backfill / bfill: use NEXT index value if no exact match
- nearest: use the NEAREST index value if no exact match. Tied distances are broken by preferring the larger index value.

limit [int, optional] Maximum number of consecutive labels in `target` to match for inexact matches.

tolerance [optional] Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations most satisfy the equation `abs(index[indexer] - target) <= tolerance`.

Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple, array, Series, and must be the same size as the index and its dtype must exactly match the index's type.

Returns

indexer [ndarray of int] Integers from 0 to n - 1 indicating that the index at these positions matches the corresponding target values. Missing values in the target are marked by -1.

Raises

NotImplementedError If any method argument other than the default of None is specified as these are not yet implemented.

Examples

```
>>> index = pd.Index(['c', 'a', 'b'])
>>> index.get_indexer(['a', 'b', 'x'])
array([ 1,  2, -1])
```

Notice that the return value is an array of locations in `index` and `x` is marked by -1, as it is not in `index`.

3.7.5 MultiIndex

MultiIndex([levels, codes, sortorder, ...])	A multi-level, or hierarchical, index object for pandas objects.

pandas.MultiIndex

class pandas.**MultiIndex**(*levels=None*, *codes=None*, *sortorder=None*, *names=None*, *dtype=None*, *copy=False*, *name=None*, *verify_integrity=True*, *_set_identity=True*)

A multi-level, or hierarchical, index object for pandas objects.

Parameters

levels [sequence of arrays] The unique labels for each level.

codes [sequence of arrays] Integers for each level designating which label at each location.

New in version 0.24.0.

sortorder [optional int] Level of sortedness (must be lexicographically sorted by that level).

names [optional sequence of objects] Names for each of the index levels. (name is accepted for compat).

copy [bool, default False] Copy the meta-data.

verify_integrity [bool, default True] Check that the levels/codes are consistent and valid.

See also:

MultiIndex.from_arrays Convert list of arrays to MultiIndex.
MultiIndex.from_product Create a MultiIndex from the cartesian product of iterables.
MultiIndex.from_tuples Convert list of tuples to a MultiIndex.
MultiIndex.from_frame Make a MultiIndex from a DataFrame.
Index The base pandas Index type.

Notes

See the user guide for more.

Examples

A new `MultiIndex` is typically constructed using one of the helper methods *`MultiIndex.from_arrays()`*, *`MultiIndex.from_product()`* and *`MultiIndex.from_tuples()`*. For example (using `.from_arrays`):

```
>>> arrays = [[1, 1, 2, 2], ['red', 'blue', 'red', 'blue']]
>>> pd.MultiIndex.from_arrays(arrays, names=('number', 'color'))
MultiIndex([(1,  'red'),
            (1, 'blue'),
            (2,  'red'),
            (2, 'blue')],
           names=['number', 'color'])
```

See further examples for how to construct a MultiIndex in the doc strings of the mentioned helper methods.

Attributes

names	Names of levels in MultiIndex.
nlevels	Integer number of levels in this MultiIndex.
levshape	A tuple with the length of each level.

pandas.MultiIndex.names

property MultiIndex.**names**
Names of levels in MultiIndex.

pandas.MultiIndex.nlevels

property MultiIndex.**nlevels**
Integer number of levels in this MultiIndex.

pandas.MultiIndex.levshape

property MultiIndex.**levshape**
A tuple with the length of each level.

levels	
codes	

Methods

from_arrays(arrays[, sortorder, names])	Convert arrays to MultiIndex.
from_tuples(tuples[, sortorder, names])	Convert list of tuples to MultiIndex.
from_product(iterables[, sortorder, names])	Make a MultiIndex from the cartesian product of multiple iterables.
from_frame(df[, sortorder, names])	Make a MultiIndex from a DataFrame.
set_levels(levels[, level, inplace, ...])	Set new levels on MultiIndex.
set_codes(codes[, level, inplace, ...])	Set new codes on MultiIndex.
to_frame([index, name])	Create a DataFrame with the levels of the MultiIndex as columns.
to_flat_index()	Convert a MultiIndex to an Index of Tuples containing the level values.
is_lexsorted()	Return True if the codes are lexicographically sorted.
sortlevel([level, ascending, sort_remaining])	Sort MultiIndex at the requested level.
droplevel([level])	Return index with requested level(s) removed.
swaplevel([i, j])	Swap level i with level j.
reorder_levels(order)	Rearrange levels using input order.
remove_unused_levels()	Create new MultiIndex from current that removes unused levels.
get_locs(seq)	Get location for a sequence of labels.

pandas.MultiIndex.from_arrays

classmethod MultiIndex.**from_arrays**(*arrays*, *sortorder=None*, *names=<object object>*)

Convert arrays to MultiIndex.

Parameters

arrays [list / sequence of array-likes] Each array-like gives one level's value for each data point. len(arrays) is the number of levels.

sortorder [int or None] Level of sortedness (must be lexicographically sorted by that level).

names [list / sequence of str, optional] Names for the levels in the index.

Returns

MultiIndex

See also:

MultiIndex.from_tuples Convert list of tuples to MultiIndex.

MultiIndex.from_product Make a MultiIndex from cartesian product of iterables.

MultiIndex.from_frame Make a MultiIndex from a DataFrame.

Examples

```
>>> arrays = [[1, 1, 2, 2], ['red', 'blue', 'red', 'blue']]
>>> pd.MultiIndex.from_arrays(arrays, names=('number', 'color'))
MultiIndex([(1,  'red'),
            (1, 'blue'),
            (2,  'red'),
            (2, 'blue')],
           names=['number', 'color'])
```

pandas.MultiIndex.from_tuples

classmethod MultiIndex.**from_tuples**(*tuples*, *sortorder=None*, *names=None*)

Convert list of tuples to MultiIndex.

Parameters

tuples [list / sequence of tuple-likes] Each tuple is the index of one row/column.

sortorder [int or None] Level of sortedness (must be lexicographically sorted by that level).

names [list / sequence of str, optional] Names for the levels in the index.

Returns

MultiIndex

See also:

MultiIndex.from_arrays Convert list of arrays to MultiIndex.

MultiIndex.from_product Make a MultiIndex from cartesian product of iterables.

MultiIndex.from_frame Make a MultiIndex from a DataFrame.

Examples

```
>>> tuples = [(1, 'red'), (1, 'blue'),
...           (2, 'red'), (2, 'blue')]
>>> pd.MultiIndex.from_tuples(tuples, names=('number', 'color'))
MultiIndex([(1,  'red'),
            (1, 'blue'),
            (2,  'red'),
            (2, 'blue')],
           names=['number', 'color'])
```

pandas.MultiIndex.from_product

classmethod MultiIndex.**from_product**(*iterables*, *sortorder=None*, *names=<object object>*)

Make a MultiIndex from the cartesian product of multiple iterables.

Parameters

iterables [list / sequence of iterables] Each iterable has unique labels for each level of the index.

sortorder [int or None] Level of sortedness (must be lexicographically sorted by that level).

names [list / sequence of str, optional] Names for the levels in the index.

Changed in version 1.0.0: If not explicitly provided, names will be inferred from the elements of iterables if an element has a name attribute

Returns

MultiIndex

See also:

MultiIndex.from_arrays Convert list of arrays to MultiIndex.

MultiIndex.from_tuples Convert list of tuples to MultiIndex.

MultiIndex.from_frame Make a MultiIndex from a DataFrame.

Examples

```
>>> numbers = [0, 1, 2]
>>> colors = ['green', 'purple']
>>> pd.MultiIndex.from_product([numbers, colors],
...                            names=['number', 'color'])
MultiIndex([(0,  'green'),
            (0, 'purple'),
            (1,  'green'),
            (1, 'purple'),
            (2,  'green'),
            (2, 'purple')],
           names=['number', 'color'])
```

pandas.MultiIndex.from_frame

classmethod MultiIndex.**from_frame**(*df*, *sortorder=None*, *names=None*)

Make a MultiIndex from a DataFrame.

New in version 0.24.0.

Parameters

df [DataFrame] DataFrame to be converted to MultiIndex.

sortorder [int, optional] Level of sortedness (must be lexicographically sorted by that level).

names [list-like, optional] If no names are provided, use the column names, or tuple of column names if the columns is a MultiIndex. If a sequence, overwrite names with the given sequence.

Returns

MultiIndex The MultiIndex representation of the given DataFrame.

See also:

MultiIndex.from_arrays Convert list of arrays to MultiIndex.

MultiIndex.from_tuples Convert list of tuples to MultiIndex.

MultiIndex.from_product Make a MultiIndex from cartesian product of iterables.

Examples

```
>>> df = pd.DataFrame([['HI', 'Temp'], ['HI', 'Precip'],
...                    ['NJ', 'Temp'], ['NJ', 'Precip']],
...                   columns=['a', 'b'])
>>> df
      a       b
0    HI    Temp
1    HI  Precip
2    NJ    Temp
3    NJ  Precip
```

```
>>> pd.MultiIndex.from_frame(df)
MultiIndex([('HI',   'Temp'),
            ('HI', 'Precip'),
            ('NJ',   'Temp'),
            ('NJ', 'Precip')],
           names=['a', 'b'])
```

Using explicit names, instead of the column names

```
>>> pd.MultiIndex.from_frame(df, names=['state', 'observation'])
MultiIndex([('HI',   'Temp'),
            ('HI', 'Precip'),
            ('NJ',   'Temp'),
            ('NJ', 'Precip')],
           names=['state', 'observation'])
```

pandas.MultiIndex.set_levels

MultiIndex.**set_levels**(*levels*, *level=None*, *inplace=False*, *verify_integrity=True*)

Set new levels on MultiIndex. Defaults to returning new index.

Parameters

levels [sequence or list of sequence] New level(s) to apply.

level [int, level name, or sequence of int/level names (default None)] Level(s) to set (None for all levels).

inplace [bool] If True, mutates in place.

verify_integrity [bool, default True] If True, checks that levels and codes are compatible.

Returns

new index (of same type and class...etc)

Examples

```
>>> idx = pd.MultiIndex.from_tuples(
...     [
...         (1, "one"),
...         (1, "two"),
...         (2, "one"),
...         (2, "two"),
...         (3, "one"),
...         (3, "two")
...     ],
...     names=["foo", "bar"]
... )
>>> idx
MultiIndex([(1, 'one'),
    (1, 'two'),
    (2, 'one'),
    (2, 'two'),
    (3, 'one'),
    (3, 'two')],
   names=['foo', 'bar'])
```

```
>>> idx.set_levels([['a', 'b', 'c'], [1, 2]])
MultiIndex([('a', 1),
            ('a', 2),
            ('b', 1),
            ('b', 2),
            ('c', 1),
            ('c', 2)],
           names=['foo', 'bar'])
>>> idx.set_levels(['a', 'b', 'c'], level=0)
MultiIndex([('a', 'one'),
            ('a', 'two'),
            ('b', 'one'),
            ('b', 'two'),
            ('c', 'one'),
            ('c', 'two')],
```

(continues on next page)

(continued from previous page)

```
           names=['foo', 'bar'])
>>> idx.set_levels(['a', 'b'], level='bar')
MultiIndex([(1, 'a'),
            (1, 'b'),
            (2, 'a'),
            (2, 'b'),
            (3, 'a'),
            (3, 'b')],
           names=['foo', 'bar'])
```

If any of the levels passed to `set_levels()` exceeds the existing length, all of the values from that argument will be stored in the MultiIndex levels, though the values will be truncated in the MultiIndex output.

```
>>> idx.set_levels([['a', 'b', 'c'], [1, 2, 3, 4]], level=[0, 1])
MultiIndex([('a', 1),
    ('a', 2),
    ('b', 1),
    ('b', 2),
    ('c', 1),
    ('c', 2)],
   names=['foo', 'bar'])
>>> idx.set_levels([['a', 'b', 'c'], [1, 2, 3, 4]], level=[0, 1]).levels
FrozenList([['a', 'b', 'c'], [1, 2, 3, 4]])
```

pandas.MultiIndex.set_codes

MultiIndex.**set_codes**(*codes*, *level=None*, *inplace=False*, *verify_integrity=True*)

Set new codes on MultiIndex. Defaults to returning new index.

New in version 0.24.0: New name for deprecated method *set_labels*.

Parameters

codes [sequence or list of sequence] New codes to apply.

level [int, level name, or sequence of int/level names (default None)] Level(s) to set (None for all levels).

inplace [bool] If True, mutates in place.

verify_integrity [bool (default True)] If True, checks that levels and codes are compatible.

Returns

new index (of same type and class...etc)

Examples

```
>>> idx = pd.MultiIndex.from_tuples(
...     [(1, "one"), (1, "two"), (2, "one"), (2, "two")], names=["foo", "bar
↪"]
... )
>>> idx
MultiIndex([(1, 'one'),
    (1, 'two'),
    (2, 'one'),
    (2, 'two')],
   names=['foo', 'bar'])
```

```
>>> idx.set_codes([[1, 0, 1, 0], [0, 0, 1, 1]])
MultiIndex([(2, 'one'),
            (1, 'one'),
            (2, 'two'),
            (1, 'two')],
           names=['foo', 'bar'])
>>> idx.set_codes([1, 0, 1, 0], level=0)
MultiIndex([(2, 'one'),
            (1, 'two'),
            (2, 'one'),
            (1, 'two')],
           names=['foo', 'bar'])
>>> idx.set_codes([0, 0, 1, 1], level='bar')
MultiIndex([(1, 'one'),
            (1, 'one'),
            (2, 'two'),
            (2, 'two')],
           names=['foo', 'bar'])
>>> idx.set_codes([[1, 0, 1, 0], [0, 0, 1, 1]], level=[0, 1])
MultiIndex([(2, 'one'),
            (1, 'one'),
            (2, 'two'),
            (1, 'two')],
           names=['foo', 'bar'])
```

pandas.MultiIndex.to_frame

`MultiIndex.`**`to_frame`**(*index=True*, *name=None*)

Create a DataFrame with the levels of the MultiIndex as columns.

Column ordering is determined by the DataFrame constructor with data as a dict.

New in version 0.24.0.

Parameters

index [bool, default True] Set the index of the returned DataFrame as the original MultiIndex.

name [list / sequence of str, optional] The passed names should substitute index level names.

Returns

DataFrame [a DataFrame containing the original MultiIndex data.]

See also:

DataFrame Two-dimensional, size-mutable, potentially heterogeneous tabular data.

pandas.MultiIndex.to_flat_index

MultiIndex.**to_flat_index**()

Convert a MultiIndex to an Index of Tuples containing the level values.

New in version 0.24.0.

Returns

pd.Index Index with the MultiIndex data represented in Tuples.

Notes

This method will simply return the caller if called by anything other than a MultiIndex.

Examples

```
>>> index = pd.MultiIndex.from_product(
...     [['foo', 'bar'], ['baz', 'qux']],
...     names=['a', 'b'])
>>> index.to_flat_index()
Index([('foo', 'baz'), ('foo', 'qux'),
       ('bar', 'baz'), ('bar', 'qux')],
      dtype='object')
```

pandas.MultiIndex.is_lexsorted

MultiIndex.**is_lexsorted**()

Return True if the codes are lexicographically sorted.

Returns

bool

Examples

In the below examples, the first level of the MultiIndex is sorted because a<b<c, so there is no need to look at the next level.

```
>>> pd.MultiIndex.from_arrays([['a', 'b', 'c'], ['d', 'e', 'f']]).is_
↪lexsorted()
True
>>> pd.MultiIndex.from_arrays([['a', 'b', 'c'], ['d', 'f', 'e']]).is_
↪lexsorted()
True
```

In case there is a tie, the lexicographical sorting looks at the next level of the MultiIndex.

```
>>> pd.MultiIndex.from_arrays([[0, 1, 1], ['a', 'b', 'c']]).is_lexsorted()
True
>>> pd.MultiIndex.from_arrays([[0, 1, 1], ['a', 'c', 'b']]).is_lexsorted()
False
>>> pd.MultiIndex.from_arrays([['a', 'a', 'b', 'b'],
...                            ['aa', 'bb', 'aa', 'bb']]).is_lexsorted()
True
>>> pd.MultiIndex.from_arrays([['a', 'a', 'b', 'b'],
...                            ['bb', 'aa', 'aa', 'bb']]).is_lexsorted()
False
```

pandas.MultiIndex.sortlevel

MultiIndex.**sortlevel**(*level=0*, *ascending=True*, *sort_remaining=True*)

Sort MultiIndex at the requested level.

The result will respect the original ordering of the associated factor at that level.

Parameters

level [list-like, int or str, default 0] If a string is given, must be a name of the level. If list-like must be names or ints of levels.

ascending [bool, default True] False to sort in descending order. Can also be a list to specify a directed ordering.

sort_remaining [sort by the remaining levels after level]

Returns

sorted_index [pd.MultiIndex] Resulting index.

indexer [np.ndarray] Indices of output values in original index.

pandas.MultiIndex.droplevel

MultiIndex.**droplevel**(*level=0*)

Return index with requested level(s) removed.

If resulting index has only 1 level left, the result will be of Index type, not MultiIndex.

New in version 0.23.1: (support for non-MultiIndex)

Parameters

level [int, str, or list-like, default 0] If a string is given, must be the name of a level If list-like, elements must be names or indexes of levels.

Returns

Index or MultiIndex

pandas.MultiIndex.swaplevel

MultiIndex.**swaplevel**(*i=-2*, *j=-1*)

Swap level i with level j.

Calling this method does not change the ordering of the values.

Parameters

i [int, str, default -2] First level of index to be swapped. Can pass level name as string. Type of parameters can be mixed.

j [int, str, default -1] Second level of index to be swapped. Can pass level name as string. Type of parameters can be mixed.

Returns

MultiIndex A new MultiIndex.

See also:

Series.swaplevel Swap levels i and j in a MultiIndex.

Dataframe.swaplevel Swap levels i and j in a MultiIndex on a particular axis.

Examples

```
>>> mi = pd.MultiIndex(levels=[['a', 'b'], ['bb', 'aa']],
...                    codes=[[0, 0, 1, 1], [0, 1, 0, 1]])
>>> mi
MultiIndex([('a', 'bb'),
            ('a', 'aa'),
            ('b', 'bb'),
            ('b', 'aa')],
           )
>>> mi.swaplevel(0, 1)
MultiIndex([('bb', 'a'),
            ('aa', 'a'),
            ('bb', 'b'),
            ('aa', 'b')],
           )
```

pandas.MultiIndex.reorder_levels

MultiIndex.**reorder_levels**(*order*)

Rearrange levels using input order. May not drop or duplicate levels.

Parameters

order [list of int or list of str] List representing new level order. Reference level by number (position) or by key (label).

Returns

MultiIndex

pandas.MultiIndex.remove_unused_levels

MultiIndex.**remove_unused_levels**()

Create new MultiIndex from current that removes unused levels.

Unused level(s) means levels that are not expressed in the labels. The resulting MultiIndex will have the same outward appearance, meaning the same .values and ordering. It will also be .equals() to the original.

Returns

MultiIndex

Examples

```
>>> mi = pd.MultiIndex.from_product([range(2), list('ab')])
>>> mi
MultiIndex([(0, 'a'),
            (0, 'b'),
            (1, 'a'),
            (1, 'b')],
           )
```

```
>>> mi[2:]
MultiIndex([(1, 'a'),
            (1, 'b')],
           )
```

The 0 from the first level is not represented and can be removed

```
>>> mi2 = mi[2:].remove_unused_levels()
>>> mi2.levels
FrozenList([[1], ['a', 'b']])
```

pandas.MultiIndex.get_locs

MultiIndex.**get_locs**(*seq*)

Get location for a sequence of labels.

Parameters

seq [label, slice, list, mask or a sequence of such] You should use one of the above for each level. If a level should not be used, set it to `slice(None)`.

Returns

numpy.ndarray NumPy array of integers suitable for passing to iloc.

See also:

MultiIndex.get_loc Get location for a label or a tuple of labels.

MultiIndex.slice_locs Get slice location given start label(s) and end label(s).

Examples

```
>>> mi = pd.MultiIndex.from_arrays([list('abb'), list('def')])
```

```
>>> mi.get_locs('b')
array([1, 2], dtype=int64)
```

```
>>> mi.get_locs([slice(None), ['e', 'f']])
array([1, 2], dtype=int64)
```

```
>>> mi.get_locs([[True, False, True], slice('e', 'f')])
array([2], dtype=int64)
```

IndexSlice	Create an object to more easily perform multi-index slicing.

pandas.IndexSlice

pandas.**IndexSlice = <pandas.core.indexing._IndexSlice object>**

Create an object to more easily perform multi-index slicing.

See also:

MultiIndex.remove_unused_levels New MultiIndex with no unused levels.

Notes

See *Defined Levels* for further info on slicing a MultiIndex.

Examples

```
>>> midx = pd.MultiIndex.from_product([['A0','A1'], ['B0','B1','B2','B3']])
>>> columns = ['foo', 'bar']
>>> dfmi = pd.DataFrame(np.arange(16).reshape((len(midx), len(columns))),
                        index=midx, columns=columns)
```

Using the default slice command:

```
>>> dfmi.loc[(slice(None), slice('B0', 'B1')), :]
           foo  bar
    A0 B0    0    1
       B1    2    3
    A1 B0    8    9
       B1   10   11
```

Using the IndexSlice class for a more intuitive command:

```
>>> idx = pd.IndexSlice
>>> dfmi.loc[idx[:, 'B0':'B1'], :]
           foo  bar
    A0 B0    0    1
       B1    2    3
```

(continues on next page)

(continued from previous page)

```
    A1 B0    8    9
       B1   10   11
```

MultiIndex constructors

MultiIndex.from_arrays(arrays[, sortorder, ...])	Convert arrays to MultiIndex.
MultiIndex.from_tuples(tuples[, sortorder, ...])	Convert list of tuples to MultiIndex.
MultiIndex.from_product(iterables[, ...])	Make a MultiIndex from the cartesian product of multiple iterables.
MultiIndex.from_frame(df[, sortorder, names])	Make a MultiIndex from a DataFrame.

MultiIndex properties

MultiIndex.names	Names of levels in MultiIndex.
MultiIndex.levels	
MultiIndex.codes	
MultiIndex.nlevels	Integer number of levels in this MultiIndex.
MultiIndex.levshape	A tuple with the length of each level.

pandas.MultiIndex.levels

MultiIndex.**levels**

pandas.MultiIndex.codes

property MultiIndex.**codes**

MultiIndex components

MultiIndex.set_levels(levels[, level, ...])	Set new levels on MultiIndex.
MultiIndex.set_codes(codes[, level, ...])	Set new codes on MultiIndex.
MultiIndex.to_flat_index()	Convert a MultiIndex to an Index of Tuples containing the level values.
MultiIndex.to_frame([index, name])	Create a DataFrame with the levels of the MultiIndex as columns.
MultiIndex.is_lexsorted()	Return True if the codes are lexicographically sorted.
MultiIndex.sortlevel([level, ascending, ...])	Sort MultiIndex at the requested level.
MultiIndex.droplevel([level])	Return index with requested level(s) removed.
MultiIndex.swaplevel([i, j])	Swap level i with level j.
MultiIndex.reorder_levels(order)	Rearrange levels using input order.
MultiIndex.remove_unused_levels()	Create new MultiIndex from current that removes unused levels.

MultiIndex selecting

MultiIndex.get_loc(key[, method])	Get location for a label or a tuple of labels.
MultiIndex.get_locs(seq)	Get location for a sequence of labels.
MultiIndex.get_loc_level(key[, level, ...])	Get location and sliced index for requested label(s)/level(s).
MultiIndex.get_indexer(target[, method, ...])	Compute indexer and mask for new index given the current index.
MultiIndex.get_level_values(level)	Return vector of label values for requested level.

pandas.MultiIndex.get_loc

MultiIndex.**get_loc**(*key*, *method=None*)

Get location for a label or a tuple of labels.

The location is returned as an integer/slice or boolean mask.

Parameters

key [label or tuple of labels (one for each level)]

method [None]

Returns

loc [int, slice object or boolean mask] If the key is past the lexsort depth, the return may be a boolean mask array, otherwise it is always a slice or int.

See also:

Index.get_loc The get_loc method for (single-level) index.
MultiIndex.slice_locs Get slice location given start label(s) and end label(s).
MultiIndex.get_locs Get location for a label/slice/list/mask or a sequence of such.

Notes

The key cannot be a slice, list of same-level labels, a boolean mask, or a sequence of such. If you want to use those, use *MultiIndex.get_locs()* instead.

Examples

```
>>> mi = pd.MultiIndex.from_arrays([list('abb'), list('def')])
```

```
>>> mi.get_loc('b')
slice(1, 3, None)
```

```
>>> mi.get_loc(('b', 'e'))
1
```

pandas.MultiIndex.get_loc_level

MultiIndex.**get_loc_level**(*key*, *level=0*, *drop_level=True*)

Get location and sliced index for requested label(s)/level(s).

Parameters

key [label or sequence of labels]

level [int/level name or list thereof, optional]

drop_level [bool, default True] If `False`, the resulting index will not drop any level.

Returns

loc [A 2-tuple where the elements are:] Element 0: int, slice object or boolean array Element 1: The resulting sliced multiindex/index. If the key contains all levels, this will be `None`.

See also:

MultiIndex.get_loc Get location for a label or a tuple of labels.
MultiIndex.get_locs Get location for a label/slice/list/mask or a sequence of such.

Examples

```
>>> mi = pd.MultiIndex.from_arrays([list('abb'), list('def')],
...                                names=['A', 'B'])
```

```
>>> mi.get_loc_level('b')
(slice(1, 3, None), Index(['e', 'f'], dtype='object', name='B'))
```

```
>>> mi.get_loc_level('e', level='B')
(array([False,  True, False]), Index(['b'], dtype='object', name='A'))
```

```
>>> mi.get_loc_level(['b', 'e'])
(1, None)
```

pandas.MultiIndex.get_indexer

MultiIndex.**get_indexer**(*target*, *method=None*, *limit=None*, *tolerance=None*)

Compute indexer and mask for new index given the current index. The indexer should be then used as an input to ndarray.take to align the current data to the new index.

Parameters

target [MultiIndex or list of tuples]

method [{None, 'pad'/'ffill', 'backfill'/'bfill', 'nearest'}, optional]

- default: exact matches only.
- pad / ffill: find the PREVIOUS index value if no exact match.
- backfill / bfill: use NEXT index value if no exact match
- nearest: use the NEAREST index value if no exact match. Tied distances are broken by preferring the larger index value.

limit [int, optional] Maximum number of consecutive labels in `target` to match for inexact matches.

tolerance [optional] Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations most satisfy the equation `abs(index[indexer] - target) <= tolerance`.

Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple, array, Series, and must be the same size as the index and its dtype must exactly match the index's type.

Returns

indexer [ndarray of int] Integers from 0 to n - 1 indicating that the index at these positions matches the corresponding target values. Missing values in the target are marked by -1.

Examples

```
>>> index = pd.Index(['c', 'a', 'b'])
>>> index.get_indexer(['a', 'b', 'x'])
array([ 1,  2, -1])
```

Notice that the return value is an array of locations in `index` and `x` is marked by -1, as it is not in `index`.

pandas.MultiIndex.get_level_values

`MultiIndex.`**`get_level_values`**(*level*)

Return vector of label values for requested level.

Length of returned vector is equal to the length of the index.

Parameters

level [int or str] `level` is either the integer position of the level in the MultiIndex, or the name of the level.

Returns

values [Index] Values is a level of this MultiIndex converted to a single *Index* (or subclass thereof).

Examples

Create a MultiIndex:

```
>>> mi = pd.MultiIndex.from_arrays((list('abc'), list('def')))
>>> mi.names = ['level_1', 'level_2']
```

Get level values by supplying level as either integer or name:

```
>>> mi.get_level_values(0)
Index(['a', 'b', 'c'], dtype='object', name='level_1')
>>> mi.get_level_values('level_2')
Index(['d', 'e', 'f'], dtype='object', name='level_2')
```

3.7.6 DatetimeIndex

`DatetimeIndex`([data, freq, tz, normalize, ...])	Immutable ndarray-like of datetime64 data.

pandas.DatetimeIndex

class pandas.**DatetimeIndex**(*data=None*, *freq=<object object>*, *tz=None*, *normalize=False*, *closed=None*, *ambiguous='raise'*, *dayfirst=False*, *yearfirst=False*, *dtype=None*, *copy=False*, *name=None*)

Immutable ndarray-like of datetime64 data.

Represented internally as int64, and which can be boxed to Timestamp objects that are subclasses of datetime and carry metadata.

Parameters

data [array-like (1-dimensional), optional] Optional datetime-like data to construct index with.

freq [str or pandas offset object, optional] One of pandas date offset strings or corresponding objects. The string 'infer' can be passed in order to set the frequency of the index as the inferred frequency upon creation.

tz [pytz.timezone or dateutil.tz.tzfile or datetime.tzinfo or str] Set the Timezone of the data.

normalize [bool, default False] Normalize start/end dates to midnight before generating date range.

closed [{'left', 'right'}, optional] Set whether to include *start* and *end* that are on the boundary. The default includes boundary points on either end.

ambiguous ['infer', bool-ndarray, 'NaT', default 'raise'] When clocks moved backward due to DST, ambiguous times may arise. For example in Central European Time (UTC+01), when going from 03:00 DST to 02:00 non-DST, 02:30:00 local time occurs both at 00:30:00 UTC and at 01:30:00 UTC. In such a situation, the *ambiguous* parameter dictates how ambiguous times should be handled.

- 'infer' will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False signifies a non-DST time (note that this flag is only applicable for ambiguous times)
- 'NaT' will return NaT where there are ambiguous times
- 'raise' will raise an AmbiguousTimeError if there are ambiguous times.

dayfirst [bool, default False] If True, parse dates in *data* with the day first order.

yearfirst [bool, default False] If True parse dates in *data* with the year first order.

dtype [numpy.dtype or DatetimeTZDtype or str, default None] Note that the only NumPy dtype allowed is 'datetime64[ns]'.

copy [bool, default False] Make a copy of input ndarray.

name [label, default None] Name to be stored in the index.

See also:

Index The base pandas Index type.
TimedeltaIndex Index of timedelta64 data.
PeriodIndex Index of Period data.
to_datetime Convert argument to datetime.

date_range Create a fixed-frequency DatetimeIndex.

Notes

To learn more about the frequency strings, please see this link.

Attributes

year	The year of the datetime.
month	The month as January=1, December=12.
day	The day of the datetime.
hour	The hours of the datetime.
minute	The minutes of the datetime.
second	The seconds of the datetime.
microsecond	The microseconds of the datetime.
nanosecond	The nanoseconds of the datetime.
date	Returns numpy array of python datetime.date objects (namely, the date part of Timestamps without timezone information).
time	Returns numpy array of datetime.time.
timetz	Returns numpy array of datetime.time also containing timezone information.
dayofyear	The ordinal day of the year.
weekofyear	(DEPRECATED) The week ordinal of the year.
week	(DEPRECATED) The week ordinal of the year.
dayofweek	The day of the week with Monday=0, Sunday=6.
weekday	The day of the week with Monday=0, Sunday=6.
quarter	The quarter of the date.
tz	Return timezone, if any.
freq	Return the frequency object if it is set, otherwise None.
freqstr	Return the frequency object as a string if its set, otherwise None.
is_month_start	Indicates whether the date is the first day of the month.
is_month_end	Indicates whether the date is the last day of the month.
is_quarter_start	Indicator for whether the date is the first day of a quarter.
is_quarter_end	Indicator for whether the date is the last day of a quarter.
is_year_start	Indicate whether the date is the first day of a year.
is_year_end	Indicate whether the date is the last day of the year.
is_leap_year	Boolean indicator if the date belongs to a leap year.
inferred_freq	Tries to return a string representing a frequency guess, generated by infer_freq.

pandas.DatetimeIndex.year

property DatetimeIndex.**year**
The year of the datetime.

Examples

```
>>> datetime_series = pd.Series(
...     pd.date_range("2000-01-01", periods=3, freq="Y")
... )
>>> datetime_series
0   2000-12-31
1   2001-12-31
2   2002-12-31
dtype: datetime64[ns]
>>> datetime_series.dt.year
0    2000
1    2001
2    2002
dtype: int64
```

pandas.DatetimeIndex.month

property DatetimeIndex.**month**
The month as January=1, December=12.

Examples

```
>>> datetime_series = pd.Series(
...     pd.date_range("2000-01-01", periods=3, freq="M")
... )
>>> datetime_series
0   2000-01-31
1   2000-02-29
2   2000-03-31
dtype: datetime64[ns]
>>> datetime_series.dt.month
0    1
1    2
2    3
dtype: int64
```

pandas.DatetimeIndex.day

property DatetimeIndex.**day**
The day of the datetime.

Examples

```
>>> datetime_series = pd.Series(
...     pd.date_range("2000-01-01", periods=3, freq="D")
... )
>>> datetime_series
0   2000-01-01
1   2000-01-02
2   2000-01-03
dtype: datetime64[ns]
>>> datetime_series.dt.day
0    1
1    2
2    3
dtype: int64
```

pandas.DatetimeIndex.hour

property DatetimeIndex.**hour**
The hours of the datetime.

Examples

```
>>> datetime_series = pd.Series(
...     pd.date_range("2000-01-01", periods=3, freq="h")
... )
>>> datetime_series
0   2000-01-01 00:00:00
1   2000-01-01 01:00:00
2   2000-01-01 02:00:00
dtype: datetime64[ns]
>>> datetime_series.dt.hour
0    0
1    1
2    2
dtype: int64
```

pandas.DatetimeIndex.minute

property DatetimeIndex.**minute**
The minutes of the datetime.

Examples

```
>>> datetime_series = pd.Series(
...     pd.date_range("2000-01-01", periods=3, freq="T")
... )
>>> datetime_series
0   2000-01-01 00:00:00
1   2000-01-01 00:01:00
2   2000-01-01 00:02:00
dtype: datetime64[ns]
>>> datetime_series.dt.minute
0    0
1    1
2    2
dtype: int64
```

pandas.DatetimeIndex.second

property DatetimeIndex.**second**
The seconds of the datetime.

Examples

```
>>> datetime_series = pd.Series(
...     pd.date_range("2000-01-01", periods=3, freq="s")
... )
>>> datetime_series
0   2000-01-01 00:00:00
1   2000-01-01 00:00:01
2   2000-01-01 00:00:02
dtype: datetime64[ns]
>>> datetime_series.dt.second
0    0
1    1
2    2
dtype: int64
```

pandas.DatetimeIndex.microsecond

property DatetimeIndex.**microsecond**
The microseconds of the datetime.

Examples

```
>>> datetime_series = pd.Series(
...     pd.date_range("2000-01-01", periods=3, freq="us")
... )
>>> datetime_series
0   2000-01-01 00:00:00.000000
1   2000-01-01 00:00:00.000001
2   2000-01-01 00:00:00.000002
dtype: datetime64[ns]
>>> datetime_series.dt.microsecond
0       0
1       1
2       2
dtype: int64
```

pandas.DatetimeIndex.nanosecond

property DatetimeIndex.**nanosecond**
The nanoseconds of the datetime.

Examples

```
>>> datetime_series = pd.Series(
...     pd.date_range("2000-01-01", periods=3, freq="ns")
... )
>>> datetime_series
0   2000-01-01 00:00:00.000000000
1   2000-01-01 00:00:00.000000001
2   2000-01-01 00:00:00.000000002
dtype: datetime64[ns]
>>> datetime_series.dt.nanosecond
0       0
1       1
2       2
dtype: int64
```

pandas.DatetimeIndex.date

property DatetimeIndex.**date**
Returns numpy array of python datetime.date objects (namely, the date part of Timestamps without timezone information).

pandas.DatetimeIndex.time

property DatetimeIndex.**time**
Returns numpy array of datetime.time. The time part of the Timestamps.

pandas.DatetimeIndex.timetz

property DatetimeIndex.**timetz**
Returns numpy array of datetime.time also containing timezone information. The time part of the Timestamps.

pandas.DatetimeIndex.dayofyear

property DatetimeIndex.**dayofyear**
The ordinal day of the year.

pandas.DatetimeIndex.weekofyear

property DatetimeIndex.**weekofyear**
The week ordinal of the year.

Deprecated since version 1.1.0.

weekofyear and week have been deprecated. Please use DatetimeIndex.isocalendar().week instead.

pandas.DatetimeIndex.week

property DatetimeIndex.**week**
The week ordinal of the year.

Deprecated since version 1.1.0.

weekofyear and week have been deprecated. Please use DatetimeIndex.isocalendar().week instead.

pandas.DatetimeIndex.dayofweek

property DatetimeIndex.**dayofweek**
The day of the week with Monday=0, Sunday=6.

Return the day of the week. It is assumed the week starts on Monday, which is denoted by 0 and ends on Sunday which is denoted by 6. This method is available on both Series with datetime values (using the *dt* accessor) or DatetimeIndex.

Returns

Series or Index Containing integers indicating the day number.

See also:

Series.dt.dayofweek Alias.

Series.dt.weekday Alias.

Series.dt.day_name Returns the name of the day of the week.

Examples

```
>>> s = pd.date_range('2016-12-31', '2017-01-08', freq='D').to_series()
>>> s.dt.dayofweek
2016-12-31    5
2017-01-01    6
2017-01-02    0
2017-01-03    1
2017-01-04    2
2017-01-05    3
2017-01-06    4
2017-01-07    5
2017-01-08    6
Freq: D, dtype: int64
```

pandas.DatetimeIndex.weekday

property DatetimeIndex.**weekday**

The day of the week with Monday=0, Sunday=6.

Return the day of the week. It is assumed the week starts on Monday, which is denoted by 0 and ends on Sunday which is denoted by 6. This method is available on both Series with datetime values (using the *dt* accessor) or DatetimeIndex.

Returns

Series or Index Containing integers indicating the day number.

See also:

Series.dt.dayofweek Alias.

Series.dt.weekday Alias.

Series.dt.day_name Returns the name of the day of the week.

Examples

```
>>> s = pd.date_range('2016-12-31', '2017-01-08', freq='D').to_series()
>>> s.dt.dayofweek
2016-12-31    5
2017-01-01    6
2017-01-02    0
2017-01-03    1
2017-01-04    2
2017-01-05    3
```

(continues on next page)

(continued from previous page)

```
2017-01-06    4
2017-01-07    5
2017-01-08    6
Freq: D, dtype: int64
```

pandas.DatetimeIndex.quarter

property DatetimeIndex.**quarter**
The quarter of the date.

pandas.DatetimeIndex.tz

property DatetimeIndex.**tz**
Return timezone, if any.

Returns

datetime.tzinfo, pytz.tzinfo.BaseTZInfo, dateutil.tz.tz.tzfile, or None Returns None when the array is tz-naive.

pandas.DatetimeIndex.freq

property DatetimeIndex.**freq**
Return the frequency object if it is set, otherwise None.

pandas.DatetimeIndex.freqstr

property DatetimeIndex.**freqstr**
Return the frequency object as a string if its set, otherwise None.

pandas.DatetimeIndex.is_month_start

property DatetimeIndex.**is_month_start**
Indicates whether the date is the first day of the month.

Returns

Series or array For Series, returns a Series with boolean values. For DatetimeIndex, returns a boolean array.

See also:

is_month_start Return a boolean indicating whether the date is the first day of the month.

is_month_end Return a boolean indicating whether the date is the last day of the month.

Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on DatetimeIndex.

```
>>> s = pd.Series(pd.date_range("2018-02-27", periods=3))
>>> s
0   2018-02-27
1   2018-02-28
2   2018-03-01
dtype: datetime64[ns]
>>> s.dt.is_month_start
0    False
1    False
2    True
dtype: bool
>>> s.dt.is_month_end
0    False
1    True
2    False
dtype: bool
```

```
>>> idx = pd.date_range("2018-02-27", periods=3)
>>> idx.is_month_start
array([False, False, True])
>>> idx.is_month_end
array([False, True, False])
```

pandas.DatetimeIndex.is_month_end

property DatetimeIndex.**is_month_end**

Indicates whether the date is the last day of the month.

Returns

Series or array For Series, returns a Series with boolean values. For DatetimeIndex, returns a boolean array.

See also:

is_month_start Return a boolean indicating whether the date is the first day of the month.

is_month_end Return a boolean indicating whether the date is the last day of the month.

Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on DatetimeIndex.

```
>>> s = pd.Series(pd.date_range("2018-02-27", periods=3))
>>> s
0   2018-02-27
1   2018-02-28
2   2018-03-01
dtype: datetime64[ns]
```

(continues on next page)

(continued from previous page)

```
>>> s.dt.is_month_start
0    False
1    False
2    True
dtype: bool
>>> s.dt.is_month_end
0    False
1    True
2    False
dtype: bool
```

```
>>> idx = pd.date_range("2018-02-27", periods=3)
>>> idx.is_month_start
array([False, False, True])
>>> idx.is_month_end
array([False, True, False])
```

pandas.DatetimeIndex.is_quarter_start

property DatetimeIndex.**is_quarter_start**

Indicator for whether the date is the first day of a quarter.

Returns

is_quarter_start [Series or DatetimeIndex] The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

See also:

quarter Return the quarter of the date.

is_quarter_end Similar property for indicating the quarter start.

Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on DatetimeIndex.

```
>>> df = pd.DataFrame({'dates': pd.date_range("2017-03-30",
...                   periods=4)})
>>> df.assign(quarter=df.dates.dt.quarter,
...           is_quarter_start=df.dates.dt.is_quarter_start)
       dates  quarter  is_quarter_start
0 2017-03-30        1             False
1 2017-03-31        1             False
2 2017-04-01        2              True
3 2017-04-02        2             False
```

```
>>> idx = pd.date_range('2017-03-30', periods=4)
>>> idx
DatetimeIndex(['2017-03-30', '2017-03-31', '2017-04-01', '2017-04-02'],
              dtype='datetime64[ns]', freq='D')
```

```
>>> idx.is_quarter_start
array([False, False,  True, False])
```

pandas.DatetimeIndex.is_quarter_end

property DatetimeIndex.**is_quarter_end**

Indicator for whether the date is the last day of a quarter.

Returns

is_quarter_end [Series or DatetimeIndex] The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

See also:

quarter Return the quarter of the date.

is_quarter_start Similar property indicating the quarter start.

Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on DatetimeIndex.

```
>>> df = pd.DataFrame({'dates': pd.date_range("2017-03-30",
...                    periods=4)})
>>> df.assign(quarter=df.dates.dt.quarter,
...           is_quarter_end=df.dates.dt.is_quarter_end)
       dates  quarter    is_quarter_end
0 2017-03-30        1             False
1 2017-03-31        1              True
2 2017-04-01        2             False
3 2017-04-02        2             False
```

```
>>> idx = pd.date_range('2017-03-30', periods=4)
>>> idx
DatetimeIndex(['2017-03-30', '2017-03-31', '2017-04-01', '2017-04-02'],
              dtype='datetime64[ns]', freq='D')
```

```
>>> idx.is_quarter_end
array([False,  True, False, False])
```

pandas.DatetimeIndex.is_year_start

property DatetimeIndex.**is_year_start**

Indicate whether the date is the first day of a year.

Returns

Series or DatetimeIndex The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

See also:

is_year_end Similar property indicating the last day of the year.

Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on DatetimeIndex.

```
>>> dates = pd.Series(pd.date_range("2017-12-30", periods=3))
>>> dates
0   2017-12-30
1   2017-12-31
2   2018-01-01
dtype: datetime64[ns]
```

```
>>> dates.dt.is_year_start
0    False
1    False
2    True
dtype: bool
```

```
>>> idx = pd.date_range("2017-12-30", periods=3)
>>> idx
DatetimeIndex(['2017-12-30', '2017-12-31', '2018-01-01'],
              dtype='datetime64[ns]', freq='D')
```

```
>>> idx.is_year_start
array([False, False,  True])
```

pandas.DatetimeIndex.is_year_end

property DatetimeIndex.**is_year_end**

Indicate whether the date is the last day of the year.

Returns

Series or DatetimeIndex The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

See also:

is_year_start Similar property indicating the start of the year.

Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on DatetimeIndex.

```
>>> dates = pd.Series(pd.date_range("2017-12-30", periods=3))
>>> dates
0   2017-12-30
1   2017-12-31
2   2018-01-01
dtype: datetime64[ns]
```

```
>>> dates.dt.is_year_end
0    False
1     True
2    False
dtype: bool
```

```
>>> idx = pd.date_range("2017-12-30", periods=3)
>>> idx
DatetimeIndex(['2017-12-30', '2017-12-31', '2018-01-01'],
              dtype='datetime64[ns]', freq='D')
```

```
>>> idx.is_year_end
array([False,  True, False])
```

pandas.DatetimeIndex.is_leap_year

property DatetimeIndex.**is_leap_year**

Boolean indicator if the date belongs to a leap year.

A leap year is a year, which has 366 days (instead of 365) including 29th of February as an intercalary day. Leap years are years which are multiples of four with the exception of years divisible by 100 but not by 400.

Returns

Series or ndarray Booleans indicating if dates belong to a leap year.

Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on DatetimeIndex.

```
>>> idx = pd.date_range("2012-01-01", "2015-01-01", freq="Y")
>>> idx
DatetimeIndex(['2012-12-31', '2013-12-31', '2014-12-31'],
              dtype='datetime64[ns]', freq='A-DEC')
>>> idx.is_leap_year
array([ True, False, False])
```

```
>>> dates_series = pd.Series(idx)
>>> dates_series
0   2012-12-31
1   2013-12-31
2   2014-12-31
dtype: datetime64[ns]
>>> dates_series.dt.is_leap_year
0     True
1    False
2    False
dtype: bool
```

pandas.DatetimeIndex.inferred_freq

DatetimeIndex.**inferred_freq**
Tries to return a string representing a frequency guess, generated by infer_freq. Returns None if it can't autodetect the frequency.

Methods

normalize(*args, **kwargs)	Convert times to midnight.
strftime(*args, **kwargs)	Convert to Index using specified date_format.
snap([freq])	Snap time stamps to nearest occurring frequency.
tz_convert(*args, **kwargs)	Convert tz-aware Datetime Array/Index from one time zone to another.
tz_localize(tz[, ambiguous, nonexistent])	Localize tz-naive Datetime Array/Index to tz-aware Datetime Array/Index.
round(*args, **kwargs)	Perform round operation on the data to the specified *freq*.
floor(*args, **kwargs)	Perform floor operation on the data to the specified *freq*.
ceil(*args, **kwargs)	Perform ceil operation on the data to the specified *freq*.
to_period(*args, **kwargs)	Cast to PeriodArray/Index at a particular frequency.
to_perioddelta(*args, **kwargs)	Calculate TimedeltaArray of difference between index values and index converted to PeriodArray at specified freq.
to_pydatetime(*args, **kwargs)	Return Datetime Array/Index as object ndarray of datetime.datetime objects.
to_series([keep_tz, index, name])	Create a Series with both index and values equal to the index keys useful with map for returning an indexer based on an index.
to_frame([index, name])	Create a DataFrame with a column containing the Index.
month_name(*args, **kwargs)	Return the month names of the DateTimeIndex with specified locale.
day_name(*args, **kwargs)	Return the day names of the DateTimeIndex with specified locale.
mean(*args, **kwargs)	Return the mean value of the Array.

pandas.DatetimeIndex.normalize

DatetimeIndex.**normalize**(**args*, ***kwargs*)
Convert times to midnight.

The time component of the date-time is converted to midnight i.e. 00:00:00. This is useful in cases, when the time does not matter. Length is unaltered. The timezones are unaffected.

This method is available on Series with datetime values under the `.dt` accessor, and directly on Datetime Array/Index.

Returns

DatetimeArray, DatetimeIndex or Series The same type as the original data. Series

will have the same name and index. DatetimeIndex will have the same name.

See also:

floor Floor the datetimes to the specified freq.

ceil Ceil the datetimes to the specified freq.

round Round the datetimes to the specified freq.

Examples

```
>>> idx = pd.date_range(start='2014-08-01 10:00', freq='H',
...                     periods=3, tz='Asia/Calcutta')
>>> idx
DatetimeIndex(['2014-08-01 10:00:00+05:30',
               '2014-08-01 11:00:00+05:30',
               '2014-08-01 12:00:00+05:30'],
                dtype='datetime64[ns, Asia/Calcutta]', freq='H')
>>> idx.normalize()
DatetimeIndex(['2014-08-01 00:00:00+05:30',
               '2014-08-01 00:00:00+05:30',
               '2014-08-01 00:00:00+05:30'],
              dtype='datetime64[ns, Asia/Calcutta]', freq=None)
```

pandas.DatetimeIndex.strftime

DatetimeIndex.**strftime**(**args*, ***kwargs*)

Convert to Index using specified date_format.

Return an Index of formatted strings specified by date_format, which supports the same string format as the python standard library. Details of the string format can be found in python string format doc.

Parameters

date_format [str] Date format string (e.g. "%Y-%m-%d").

Returns

ndarray NumPy ndarray of formatted strings.

See also:

to_datetime Convert the given argument to datetime.

DatetimeIndex.normalize Return DatetimeIndex with times to midnight.

DatetimeIndex.round Round the DatetimeIndex to the specified freq.

DatetimeIndex.floor Floor the DatetimeIndex to the specified freq.

Examples

```
>>> rng = pd.date_range(pd.Timestamp("2018-03-10 09:00"),
...                     periods=3, freq='s')
>>> rng.strftime('%B %d, %Y, %r')
Index(['March 10, 2018, 09:00:00 AM', 'March 10, 2018, 09:00:01 AM',
       'March 10, 2018, 09:00:02 AM'],
      dtype='object')
```

pandas.DatetimeIndex.snap

DatetimeIndex.**snap**(*freq='S'*)

Snap time stamps to nearest occurring frequency.

Returns

DatetimeIndex

pandas.DatetimeIndex.tz_convert

DatetimeIndex.**tz_convert**(**args*, ***kwargs*)

Convert tz-aware Datetime Array/Index from one time zone to another.

Parameters

tz [str, pytz.timezone, dateutil.tz.tzfile or None] Time zone for time. Corresponding timestamps would be converted to this time zone of the Datetime Array/Index. A *tz* of None will convert to UTC and remove the timezone information.

Returns

Array or Index

Raises

TypeError If Datetime Array/Index is tz-naive.

See also:

DatetimeIndex.tz A timezone that has a variable offset from UTC.

DatetimeIndex.tz_localize Localize tz-naive DatetimeIndex to a given time zone, or remove timezone from a tz-aware DatetimeIndex.

Examples

With the *tz* parameter, we can change the DatetimeIndex to other time zones:

```
>>> dti = pd.date_range(start='2014-08-01 09:00',
...                     freq='H', periods=3, tz='Europe/Berlin')
```

```
>>> dti
DatetimeIndex(['2014-08-01 09:00:00+02:00',
               '2014-08-01 10:00:00+02:00',
               '2014-08-01 11:00:00+02:00'],
              dtype='datetime64[ns, Europe/Berlin]', freq='H')
```

```
>>> dti.tz_convert('US/Central')
DatetimeIndex(['2014-08-01 02:00:00-05:00',
               '2014-08-01 03:00:00-05:00',
               '2014-08-01 04:00:00-05:00'],
              dtype='datetime64[ns, US/Central]', freq='H')
```

With the `tz=None`, we can remove the timezone (after converting to UTC if necessary):

```
>>> dti = pd.date_range(start='2014-08-01 09:00', freq='H',
...                     periods=3, tz='Europe/Berlin')
```

```
>>> dti
DatetimeIndex(['2014-08-01 09:00:00+02:00',
               '2014-08-01 10:00:00+02:00',
               '2014-08-01 11:00:00+02:00'],
               dtype='datetime64[ns, Europe/Berlin]', freq='H')
```

```
>>> dti.tz_convert(None)
DatetimeIndex(['2014-08-01 07:00:00',
               '2014-08-01 08:00:00',
               '2014-08-01 09:00:00'],
               dtype='datetime64[ns]', freq='H')
```

pandas.DatetimeIndex.tz_localize

DatetimeIndex.**tz_localize**(*tz*, *ambiguous='raise'*, *nonexistent='raise'*)

Localize tz-naive Datetime Array/Index to tz-aware Datetime Array/Index.

This method takes a time zone (tz) naive Datetime Array/Index object and makes this time zone aware. It does not move the time to another time zone. Time zone localization helps to switch from time zone aware to time zone unaware objects.

Parameters

tz [str, pytz.timezone, dateutil.tz.tzfile or None] Time zone to convert timestamps to. Passing `None` will remove the time zone information preserving local time.

ambiguous ['infer', 'NaT', bool array, default 'raise'] When clocks moved backward due to DST, ambiguous times may arise. For example in Central European Time (UTC+01), when going from 03:00 DST to 02:00 non-DST, 02:30:00 local time occurs both at 00:30:00 UTC and at 01:30:00 UTC. In such a situation, the *ambiguous* parameter dictates how ambiguous times should be handled.

- 'infer' will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False signifies a non-DST time (note that this flag is only applicable for ambiguous times)
- 'NaT' will return NaT where there are ambiguous times
- 'raise' will raise an AmbiguousTimeError if there are ambiguous times.

nonexistent ['shift_forward', 'shift_backward, 'NaT', timedelta, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- 'shift_forward' will shift the nonexistent time forward to the closest existing time

- 'shift_backward' will shift the nonexistent time backward to the closest existing time
- 'NaT' will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- 'raise' will raise an NonExistentTimeError if there are nonexistent times.

New in version 0.24.0.

Returns

Same type as self Array/Index converted to the specified time zone.

Raises

TypeError If the Datetime Array/Index is tz-aware and tz is not None.

See also:

DatetimeIndex.tz_convert Convert tz-aware DatetimeIndex from one time zone to another.

Examples

```
>>> tz_naive = pd.date_range('2018-03-01 09:00', periods=3)
>>> tz_naive
DatetimeIndex(['2018-03-01 09:00:00', '2018-03-02 09:00:00',
               '2018-03-03 09:00:00'],
              dtype='datetime64[ns]', freq='D')
```

Localize DatetimeIndex in US/Eastern time zone:

```
>>> tz_aware = tz_naive.tz_localize(tz='US/Eastern')
>>> tz_aware
DatetimeIndex(['2018-03-01 09:00:00-05:00',
               '2018-03-02 09:00:00-05:00',
               '2018-03-03 09:00:00-05:00'],
              dtype='datetime64[ns, US/Eastern]', freq=None)
```

With the `tz=None`, we can remove the time zone information while keeping the local time (not converted to UTC):

```
>>> tz_aware.tz_localize(None)
DatetimeIndex(['2018-03-01 09:00:00', '2018-03-02 09:00:00',
               '2018-03-03 09:00:00'],
              dtype='datetime64[ns]', freq=None)
```

Be careful with DST changes. When there is sequential data, pandas can infer the DST time:

```
>>> s = pd.to_datetime(pd.Series(['2018-10-28 01:30:00',
...                               '2018-10-28 02:00:00',
...                               '2018-10-28 02:30:00',
...                               '2018-10-28 02:00:00',
...                               '2018-10-28 02:30:00',
...                               '2018-10-28 03:00:00',
...                               '2018-10-28 03:30:00']))
>>> s.dt.tz_localize('CET', ambiguous='infer')
0   2018-10-28 01:30:00+02:00
```

(continues on next page)

(continued from previous page)

```
1   2018-10-28 02:00:00+02:00
2   2018-10-28 02:30:00+02:00
3   2018-10-28 02:00:00+01:00
4   2018-10-28 02:30:00+01:00
5   2018-10-28 03:00:00+01:00
6   2018-10-28 03:30:00+01:00
dtype: datetime64[ns, CET]
```

In some cases, inferring the DST is impossible. In such cases, you can pass an ndarray to the ambiguous parameter to set the DST explicitly

```
>>> s = pd.to_datetime(pd.Series(['2018-10-28 01:20:00',
...                               '2018-10-28 02:36:00',
...                               '2018-10-28 03:46:00']))
>>> s.dt.tz_localize('CET', ambiguous=np.array([True, True, False]))
0   2018-10-28 01:20:00+02:00
1   2018-10-28 02:36:00+02:00
2   2018-10-28 03:46:00+01:00
dtype: datetime64[ns, CET]
```

If the DST transition causes nonexistent times, you can shift these dates forward or backwards with a timedelta object or *'shift_forward'* or *'shift_backwards'*.

```
>>> s = pd.to_datetime(pd.Series(['2015-03-29 02:30:00',
...                               '2015-03-29 03:30:00']))
>>> s.dt.tz_localize('Europe/Warsaw', nonexistent='shift_forward')
0   2015-03-29 03:00:00+02:00
1   2015-03-29 03:30:00+02:00
dtype: datetime64[ns, Europe/Warsaw]
```

```
>>> s.dt.tz_localize('Europe/Warsaw', nonexistent='shift_backward')
0   2015-03-29 01:59:59.999999999+01:00
1   2015-03-29 03:30:00+02:00
dtype: datetime64[ns, Europe/Warsaw]
```

```
>>> s.dt.tz_localize('Europe/Warsaw', nonexistent=pd.Timedelta('1H'))
0   2015-03-29 03:30:00+02:00
1   2015-03-29 03:30:00+02:00
dtype: datetime64[ns, Europe/Warsaw]
```

pandas.DatetimeIndex.round

DatetimeIndex.**round**(**args*, ***kwargs*)

Perform round operation on the data to the specified *freq*.

Parameters

freq [str or Offset] The frequency level to round the index to. Must be a fixed frequency like 'S' (second) not 'ME' (month end). See *frequency aliases* for a list of possible *freq* values.

ambiguous ['infer', bool-ndarray, 'NaT', default 'raise'] Only relevant for DatetimeIndex:

- 'infer' will attempt to infer fall dst-transition hours based on order

- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- 'NaT' will return NaT where there are ambiguous times
- 'raise' will raise an AmbiguousTimeError if there are ambiguous times.

New in version 0.24.0.

nonexistent ['shift_forward', 'shift_backward', 'NaT', timedelta, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- 'shift_forward' will shift the nonexistent time forward to the closest existing time
- 'shift_backward' will shift the nonexistent time backward to the closest existing time
- 'NaT' will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- 'raise' will raise an NonExistentTimeError if there are nonexistent times.

New in version 0.24.0.

Returns

DatetimeIndex, TimedeltaIndex, or Series Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

Raises

ValueError if the *freq* cannot be converted.

Examples

DatetimeIndex

```
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
               '2018-01-01 12:01:00'],
              dtype='datetime64[ns]', freq='T')
>>> rng.round('H')
DatetimeIndex(['2018-01-01 12:00:00', '2018-01-01 12:00:00',
               '2018-01-01 12:00:00'],
              dtype='datetime64[ns]', freq=None)
```

Series

```
>>> pd.Series(rng).dt.round("H")
0   2018-01-01 12:00:00
1   2018-01-01 12:00:00
2   2018-01-01 12:00:00
dtype: datetime64[ns]
```

pandas.DatetimeIndex.floor

DatetimeIndex.**floor**(**args*, ***kwargs*)

Perform floor operation on the data to the specified *freq*.

Parameters

freq [str or Offset] The frequency level to floor the index to. Must be a fixed frequency like 'S' (second) not 'ME' (month end). See *frequency aliases* for a list of possible *freq* values.

ambiguous ['infer', bool-ndarray, 'NaT', default 'raise'] Only relevant for DatetimeIndex:

- 'infer' will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- 'NaT' will return NaT where there are ambiguous times
- 'raise' will raise an AmbiguousTimeError if there are ambiguous times.

New in version 0.24.0.

nonexistent ['shift_forward', 'shift_backward', 'NaT', timedelta, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- 'shift_forward' will shift the nonexistent time forward to the closest existing time
- 'shift_backward' will shift the nonexistent time backward to the closest existing time
- 'NaT' will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- 'raise' will raise an NonExistentTimeError if there are nonexistent times.

New in version 0.24.0.

Returns

DatetimeIndex, TimedeltaIndex, or Series Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

Raises

ValueError if the *freq* cannot be converted.

Examples

DatetimeIndex

```
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
               '2018-01-01 12:01:00'],
              dtype='datetime64[ns]', freq='T')
>>> rng.floor('H')
```

(continues on next page)

(continued from previous page)

```
DatetimeIndex(['2018-01-01 11:00:00', '2018-01-01 12:00:00',
               '2018-01-01 12:00:00'],
              dtype='datetime64[ns]', freq=None)
```

Series

```
>>> pd.Series(rng).dt.floor("H")
0   2018-01-01 11:00:00
1   2018-01-01 12:00:00
2   2018-01-01 12:00:00
dtype: datetime64[ns]
```

pandas.DatetimeIndex.ceil

DatetimeIndex.**ceil**(**args*, ***kwargs*)

Perform ceil operation on the data to the specified *freq*.

Parameters

freq [str or Offset] The frequency level to ceil the index to. Must be a fixed frequency like 'S' (second) not 'ME' (month end). See *frequency aliases* for a list of possible *freq* values.

ambiguous ['infer', bool-ndarray, 'NaT', default 'raise'] Only relevant for DatetimeIndex:

- 'infer' will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- 'NaT' will return NaT where there are ambiguous times
- 'raise' will raise an AmbiguousTimeError if there are ambiguous times.

New in version 0.24.0.

nonexistent ['shift_forward', 'shift_backward', 'NaT', timedelta, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- 'shift_forward' will shift the nonexistent time forward to the closest existing time
- 'shift_backward' will shift the nonexistent time backward to the closest existing time
- 'NaT' will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- 'raise' will raise an NonExistentTimeError if there are nonexistent times.

New in version 0.24.0.

Returns

DatetimeIndex, TimedeltaIndex, or Series Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

Raises

ValueError if the *freq* cannot be converted.

Examples

DatetimeIndex

```
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
               '2018-01-01 12:01:00'],
              dtype='datetime64[ns]', freq='T')
>>> rng.ceil('H')
DatetimeIndex(['2018-01-01 12:00:00', '2018-01-01 12:00:00',
               '2018-01-01 13:00:00'],
              dtype='datetime64[ns]', freq=None)
```

Series

```
>>> pd.Series(rng).dt.ceil("H")
0   2018-01-01 12:00:00
1   2018-01-01 12:00:00
2   2018-01-01 13:00:00
dtype: datetime64[ns]
```

pandas.DatetimeIndex.to_period

DatetimeIndex.**to_period**(**args*, ***kwargs*)

Cast to PeriodArray/Index at a particular frequency.

Converts DatetimeArray/Index to PeriodArray/Index.

Parameters

freq [str or Offset, optional] One of pandas' *offset strings* or an Offset object. Will be inferred by default.

Returns

PeriodArray/Index

Raises

ValueError When converting a DatetimeArray/Index with non-regular values, so that a frequency cannot be inferred.

See also:

PeriodIndex Immutable ndarray holding ordinal values.

DatetimeIndex.to_pydatetime Return DatetimeIndex as object.

Examples

```
>>> df = pd.DataFrame({"y": [1, 2, 3]},
...                   index=pd.to_datetime(["2000-03-31 00:00:00",
...                                         "2000-05-31 00:00:00",
...                                         "2000-08-31 00:00:00"]))
>>> df.index.to_period("M")
PeriodIndex(['2000-03', '2000-05', '2000-08'],
            dtype='period[M]', freq='M')
```

Infer the daily frequency

```
>>> idx = pd.date_range("2017-01-01", periods=2)
>>> idx.to_period()
PeriodIndex(['2017-01-01', '2017-01-02'],
            dtype='period[D]', freq='D')
```

pandas.DatetimeIndex.to_perioddelta

DatetimeIndex.**to_perioddelta**(**args*, ***kwargs*)

Calculate TimedeltaArray of difference between index values and index converted to PeriodArray at specified freq. Used for vectorized offsets.

Parameters

freq [Period frequency]

Returns

TimedeltaArray/Index

pandas.DatetimeIndex.to_pydatetime

DatetimeIndex.**to_pydatetime**(**args*, ***kwargs*)

Return Datetime Array/Index as object ndarray of datetime.datetime objects.

Returns

datetimes [ndarray]

pandas.DatetimeIndex.to_series

DatetimeIndex.**to_series**(*keep_tz=<object object>*, *index=None*, *name=None*)

Create a Series with both index and values equal to the index keys useful with map for returning an indexer based on an index.

Parameters

keep_tz [optional, defaults True] Return the data keeping the timezone.

If keep_tz is True:

If the timezone is not set, the resulting Series will have a datetime64[ns] dtype.

Otherwise the Series will have an datetime64[ns, tz] dtype; the tz will be preserved.

If keep_tz is False:

Series will have a datetime64[ns] dtype. TZ aware objects will have the tz removed.

Changed in version 1.0.0: The default value is now True. In a future version, this keyword will be removed entirely. Stop passing the argument to obtain the future behavior and silence the warning.

index [Index, optional] Index of resulting Series. If None, defaults to original index.

name [str, optional] Name of resulting Series. If None, defaults to name of original index.

Returns

Series

pandas.DatetimeIndex.to_frame

DatetimeIndex.**to_frame**(*index=True*, *name=None*)

Create a DataFrame with a column containing the Index.

New in version 0.24.0.

Parameters

index [bool, default True] Set the index of the returned DataFrame as the original Index.

name [object, default None] The passed name should substitute for the index name (if it has one).

Returns

DataFrame DataFrame containing the original Index data.

See also:

Index.to_series Convert an Index to a Series.

Series.to_frame Convert Series to DataFrame.

Examples

```
>>> idx = pd.Index(['Ant', 'Bear', 'Cow'], name='animal')
>>> idx.to_frame()
       animal
animal
Ant       Ant
Bear     Bear
Cow       Cow
```

By default, the original Index is reused. To enforce a new Index:

```
>>> idx.to_frame(index=False)
    animal
0   Ant
1  Bear
2   Cow
```

To override the name of the resulting column, specify *name*:

```
>>> idx.to_frame(index=False, name='zoo')
    zoo
0   Ant
1  Bear
2   Cow
```

pandas.DatetimeIndex.month_name

DatetimeIndex.**month_name**(**args*, ***kwargs*)

Return the month names of the DateTimeIndex with specified locale.

New in version 0.23.0.

Parameters

locale [str, optional] Locale determining the language in which to return the month name. Default is English locale.

Returns

Index Index of month names.

Examples

```
>>> idx = pd.date_range(start='2018-01', freq='M', periods=3)
>>> idx
DatetimeIndex(['2018-01-31', '2018-02-28', '2018-03-31'],
              dtype='datetime64[ns]', freq='M')
>>> idx.month_name()
Index(['January', 'February', 'March'], dtype='object')
```

pandas.DatetimeIndex.day_name

DatetimeIndex.**day_name**(**args*, ***kwargs*)

Return the day names of the DateTimeIndex with specified locale.

New in version 0.23.0.

Parameters

locale [str, optional] Locale determining the language in which to return the day name. Default is English locale.

Returns

Index Index of day names.

Examples

```
>>> idx = pd.date_range(start='2018-01-01', freq='D', periods=3)
>>> idx
DatetimeIndex(['2018-01-01', '2018-01-02', '2018-01-03'],
              dtype='datetime64[ns]', freq='D')
>>> idx.day_name()
Index(['Monday', 'Tuesday', 'Wednesday'], dtype='object')
```

pandas.DatetimeIndex.mean

DatetimeIndex.**mean**(**args*, ***kwargs*)

Return the mean value of the Array.

New in version 0.25.0.

Parameters

skipna [bool, default True] Whether to ignore any NaT elements.

Returns

scalar Timestamp or Timedelta.

See also:

numpy.ndarray.mean Returns the average of array elements along a given axis.

Series.mean Return the mean value in a Series.

Notes

mean is only defined for Datetime and Timedelta dtypes, not for Period.

Time/date components

DatetimeIndex.year	The year of the datetime.
DatetimeIndex.month	The month as January=1, December=12.
DatetimeIndex.day	The day of the datetime.
DatetimeIndex.hour	The hours of the datetime.
DatetimeIndex.minute	The minutes of the datetime.
DatetimeIndex.second	The seconds of the datetime.
DatetimeIndex.microsecond	The microseconds of the datetime.
DatetimeIndex.nanosecond	The nanoseconds of the datetime.
DatetimeIndex.date	Returns numpy array of python datetime.date objects (namely, the date part of Timestamps without timezone information).
DatetimeIndex.time	Returns numpy array of datetime.time.
DatetimeIndex.timetz	Returns numpy array of datetime.time also containing timezone information.
DatetimeIndex.dayofyear	The ordinal day of the year.
DatetimeIndex.weekofyear	(DEPRECATED) The week ordinal of the year.

continues on next page

Table 164 – continued from previous page

DatetimeIndex.week	(DEPRECATED) The week ordinal of the year.
DatetimeIndex.dayofweek	The day of the week with Monday=0, Sunday=6.
DatetimeIndex.weekday	The day of the week with Monday=0, Sunday=6.
DatetimeIndex.quarter	The quarter of the date.
DatetimeIndex.tz	Return timezone, if any.
DatetimeIndex.freq	Return the frequency object if it is set, otherwise None.
DatetimeIndex.freqstr	Return the frequency object as a string if its set, otherwise None.
DatetimeIndex.is_month_start	Indicates whether the date is the first day of the month.
DatetimeIndex.is_month_end	Indicates whether the date is the last day of the month.
DatetimeIndex.is_quarter_start	Indicator for whether the date is the first day of a quarter.
DatetimeIndex.is_quarter_end	Indicator for whether the date is the last day of a quarter.
DatetimeIndex.is_year_start	Indicate whether the date is the first day of a year.
DatetimeIndex.is_year_end	Indicate whether the date is the last day of the year.
DatetimeIndex.is_leap_year	Boolean indicator if the date belongs to a leap year.
DatetimeIndex.inferred_freq	Tries to return a string representing a frequency guess, generated by infer_freq.

Selecting

DatetimeIndex.indexer_at_time(time[, asof])	Return index locations of values at particular time of day (e.g.
DatetimeIndex.indexer_between_time(...[, ...])	Return index locations of values between particular times of day (e.g., 9:00-9:30AM).

pandas.DatetimeIndex.indexer_at_time

DatetimeIndex.**indexer_at_time**(*time*, *asof=False*)

Return index locations of values at particular time of day (e.g. 9:30AM).

Parameters

time [datetime.time or str] Time passed in either as object (datetime.time) or as string in appropriate format ("%H:%M", "%H%M", "%I:%M%p", "%I%M%p", "%H:%M:%S", "%H%M%S", "%I:%M:%S%p", "%I%M%S%p").

Returns

values_at_time [array of integers]

See also:

indexer_between_time Get index locations of values between particular times of day.
DataFrame.at_time Select values at particular time of day.

pandas.DatetimeIndex.indexer_between_time

DatetimeIndex.**indexer_between_time**(*start_time*, *end_time*, *include_start=True*, *include_end=True*)

Return index locations of values between particular times of day (e.g., 9:00-9:30AM).

Parameters

start_time, end_time [datetime.time, str] Time passed either as object (datetime.time) or as string in appropriate format ("%H:%M", "%H%M", "%I:%M%p", "%I%M%p", "%H:%M:%S", "%H%M%S", "%I:%M:%S%p","%I%M%S%p").

include_start [bool, default True]

include_end [bool, default True]

Returns

values_between_time [array of integers]

See also:

indexer_at_time Get index locations of values at particular time of day.
DataFrame.between_time Select values between particular times of day.

Time-specific operations

DatetimeIndex.normalize(*args, **kwargs)	Convert times to midnight.
DatetimeIndex.strftime(*args, **kwargs)	Convert to Index using specified date_format.
DatetimeIndex.snap([freq])	Snap time stamps to nearest occurring frequency.
DatetimeIndex.tz_convert(*args, **kwargs)	Convert tz-aware Datetime Array/Index from one time zone to another.
DatetimeIndex.tz_localize(tz[, ambiguous, ...])	Localize tz-naive Datetime Array/Index to tz-aware Datetime Array/Index.
DatetimeIndex.round(*args, **kwargs)	Perform round operation on the data to the specified *freq*.
DatetimeIndex.floor(*args, **kwargs)	Perform floor operation on the data to the specified *freq*.
DatetimeIndex.ceil(*args, **kwargs)	Perform ceil operation on the data to the specified *freq*.
DatetimeIndex.month_name(*args, **kwargs)	Return the month names of the DateTimeIndex with specified locale.
DatetimeIndex.day_name(*args, **kwargs)	Return the day names of the DateTimeIndex with specified locale.

Conversion

DatetimeIndex.to_period(*args, **kwargs)	Cast to PeriodArray/Index at a particular frequency.
DatetimeIndex.to_perioddelta(*args, **kwargs)	Calculate TimedeltaArray of difference between index values and index converted to PeriodArray at specified freq.
DatetimeIndex.to_pydatetime(*args, **kwargs)	Return Datetime Array/Index as object ndarray of datetime.datetime objects.
DatetimeIndex.to_series([keep_tz, index, name])	Create a Series with both index and values equal to the index keys useful with map for returning an indexer based on an index.

continues on next page

Table 167 – continued from previous page

`DatetimeIndex.to_frame`([index, name])	Create a DataFrame with a column containing the Index.

Methods

`DatetimeIndex.mean`(*args, **kwargs)	Return the mean value of the Array.

3.7.7 TimedeltaIndex

`TimedeltaIndex`([data, unit, freq, closed, ...])	Immutable ndarray of timedelta64 data, represented internally as int64, and which can be boxed to timedelta objects.

pandas.TimedeltaIndex

class pandas.**TimedeltaIndex**(*data=None*, *unit=None*, *freq=<object object>*, *closed=None*, *dtype=dtype('<m8[ns]')*, *copy=False*, *name=None*)

Immutable ndarray of timedelta64 data, represented internally as int64, and which can be boxed to timedelta objects.

Parameters

data [array-like (1-dimensional), optional] Optional timedelta-like data to construct index with.

unit [unit of the arg (D,h,m,s,ms,us,ns) denote the unit, optional] Which is an integer/float number.

freq [str or pandas offset object, optional] One of pandas date offset strings or corresponding objects. The string 'infer' can be passed in order to set the frequency of the index as the inferred frequency upon creation.

copy [bool] Make a copy of input ndarray.

name [object] Name to be stored in the index.

See also:

Index The base pandas Index type.
Timedelta Represents a duration between two dates or times.
DatetimeIndex Index of datetime64 data.
PeriodIndex Index of Period data.
timedelta_range Create a fixed-frequency TimedeltaIndex.

Notes

To learn more about the frequency strings, please see this link.

Attributes

days	Number of days for each element.
seconds	Number of seconds (>= 0 and less than 1 day) for each element.
microseconds	Number of microseconds (>= 0 and less than 1 second) for each element.
nanoseconds	Number of nanoseconds (>= 0 and less than 1 microsecond) for each element.
components	Return a dataframe of the components (days, hours, minutes, seconds, milliseconds, microseconds, nanoseconds) of the Timedeltas.
inferred_freq	Tries to return a string representing a frequency guess, generated by infer_freq.

pandas.TimedeltaIndex.days

property TimedeltaIndex.**days**
Number of days for each element.

pandas.TimedeltaIndex.seconds

property TimedeltaIndex.**seconds**
Number of seconds (>= 0 and less than 1 day) for each element.

pandas.TimedeltaIndex.microseconds

property TimedeltaIndex.**microseconds**
Number of microseconds (>= 0 and less than 1 second) for each element.

pandas.TimedeltaIndex.nanoseconds

property TimedeltaIndex.**nanoseconds**
Number of nanoseconds (>= 0 and less than 1 microsecond) for each element.

pandas.TimedeltaIndex.components

property TimedeltaIndex.**components**

Return a dataframe of the components (days, hours, minutes, seconds, milliseconds, microseconds, nanoseconds) of the Timedeltas.

Returns

a DataFrame

pandas.TimedeltaIndex.inferred_freq

TimedeltaIndex.**inferred_freq**

Tries to return a string representing a frequency guess, generated by infer_freq. Returns None if it can't autodetect the frequency.

Methods

to_pytimedelta(*args, **kwargs)	Return Timedelta Array/Index as object ndarray of datetime.timedelta objects.
to_series([index, name])	Create a Series with both index and values equal to the index keys.
round(*args, **kwargs)	Perform round operation on the data to the specified *freq*.
floor(*args, **kwargs)	Perform floor operation on the data to the specified *freq*.
ceil(*args, **kwargs)	Perform ceil operation on the data to the specified *freq*.
to_frame([index, name])	Create a DataFrame with a column containing the Index.
mean(*args, **kwargs)	Return the mean value of the Array.

pandas.TimedeltaIndex.to_pytimedelta

TimedeltaIndex.**to_pytimedelta**(**args*, ***kwargs*)

Return Timedelta Array/Index as object ndarray of datetime.timedelta objects.

Returns

datetimes [ndarray]

pandas.TimedeltaIndex.to_series

TimedeltaIndex.**to_series**(*index=None*, *name=None*)

Create a Series with both index and values equal to the index keys.

Useful with map for returning an indexer based on an index.

Parameters

index [Index, optional] Index of resulting Series. If None, defaults to original index.

name [str, optional] Name of resulting Series. If None, defaults to name of original index.

Returns

Series The dtype will be based on the type of the Index values.

See also:

Index.to_frame Convert an Index to a DataFrame.

Series.to_frame Convert Series to DataFrame.

Examples

```
>>> idx = pd.Index(['Ant', 'Bear', 'Cow'], name='animal')
```

By default, the original Index and original name is reused.

```
>>> idx.to_series()
animal
Ant       Ant
Bear     Bear
Cow       Cow
Name: animal, dtype: object
```

To enforce a new Index, specify new labels to `index`:

```
>>> idx.to_series(index=[0, 1, 2])
0     Ant
1    Bear
2     Cow
Name: animal, dtype: object
```

To override the name of the resulting column, specify *name*:

```
>>> idx.to_series(name='zoo')
animal
Ant       Ant
Bear     Bear
Cow       Cow
Name: zoo, dtype: object
```

pandas.TimedeltaIndex.round

`TimedeltaIndex.`**`round`**`(*args, **kwargs)`

Perform round operation on the data to the specified *freq*.

Parameters

freq [str or Offset] The frequency level to round the index to. Must be a fixed frequency like 'S' (second) not 'ME' (month end). See *frequency aliases* for a list of possible *freq* values.

ambiguous ['infer', bool-ndarray, 'NaT', default 'raise'] Only relevant for DatetimeIndex:

- 'infer' will attempt to infer fall dst-transition hours based on order

- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- 'NaT' will return NaT where there are ambiguous times
- 'raise' will raise an AmbiguousTimeError if there are ambiguous times.

New in version 0.24.0.

nonexistent ['shift_forward', 'shift_backward', 'NaT', timedelta, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- 'shift_forward' will shift the nonexistent time forward to the closest existing time
- 'shift_backward' will shift the nonexistent time backward to the closest existing time
- 'NaT' will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- 'raise' will raise an NonExistentTimeError if there are nonexistent times.

New in version 0.24.0.

Returns

DatetimeIndex, TimedeltaIndex, or Series Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

Raises

ValueError if the *freq* cannot be converted.

Examples

DatetimeIndex

```
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
               '2018-01-01 12:01:00'],
              dtype='datetime64[ns]', freq='T')
>>> rng.round('H')
DatetimeIndex(['2018-01-01 12:00:00', '2018-01-01 12:00:00',
               '2018-01-01 12:00:00'],
              dtype='datetime64[ns]', freq=None)
```

Series

```
>>> pd.Series(rng).dt.round("H")
0   2018-01-01 12:00:00
1   2018-01-01 12:00:00
2   2018-01-01 12:00:00
dtype: datetime64[ns]
```

pandas.TimedeltaIndex.floor

TimedeltaIndex.**floor**(**args*, ***kwargs*)

Perform floor operation on the data to the specified *freq*.

Parameters

freq [str or Offset] The frequency level to floor the index to. Must be a fixed frequency like 'S' (second) not 'ME' (month end). See *frequency aliases* for a list of possible *freq* values.

ambiguous ['infer', bool-ndarray, 'NaT', default 'raise'] Only relevant for DatetimeIndex:

- 'infer' will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- 'NaT' will return NaT where there are ambiguous times
- 'raise' will raise an AmbiguousTimeError if there are ambiguous times.

New in version 0.24.0.

nonexistent ['shift_forward', 'shift_backward', 'NaT', timedelta, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- 'shift_forward' will shift the nonexistent time forward to the closest existing time
- 'shift_backward' will shift the nonexistent time backward to the closest existing time
- 'NaT' will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- 'raise' will raise an NonExistentTimeError if there are nonexistent times.

New in version 0.24.0.

Returns

DatetimeIndex, TimedeltaIndex, or Series Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

Raises

ValueError if the *freq* cannot be converted.

Examples

DatetimeIndex

```
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
               '2018-01-01 12:01:00'],
              dtype='datetime64[ns]', freq='T')
>>> rng.floor('H')
```

(continues on next page)

(continued from previous page)

```
DatetimeIndex(['2018-01-01 11:00:00', '2018-01-01 12:00:00',
               '2018-01-01 12:00:00'],
              dtype='datetime64[ns]', freq=None)
```

Series

```
>>> pd.Series(rng).dt.floor("H")
0   2018-01-01 11:00:00
1   2018-01-01 12:00:00
2   2018-01-01 12:00:00
dtype: datetime64[ns]
```

pandas.TimedeltaIndex.ceil

TimedeltaIndex.**ceil**(**args*, ***kwargs*)

Perform ceil operation on the data to the specified *freq*.

Parameters

freq [str or Offset] The frequency level to ceil the index to. Must be a fixed frequency like 'S' (second) not 'ME' (month end). See *frequency aliases* for a list of possible *freq* values.

ambiguous ['infer', bool-ndarray, 'NaT', default 'raise'] Only relevant for DatetimeIndex:

- 'infer' will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- 'NaT' will return NaT where there are ambiguous times
- 'raise' will raise an AmbiguousTimeError if there are ambiguous times.

New in version 0.24.0.

nonexistent ['shift_forward', 'shift_backward', 'NaT', timedelta, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- 'shift_forward' will shift the nonexistent time forward to the closest existing time
- 'shift_backward' will shift the nonexistent time backward to the closest existing time
- 'NaT' will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- 'raise' will raise an NonExistentTimeError if there are nonexistent times.

New in version 0.24.0.

Returns

DatetimeIndex, TimedeltaIndex, or Series Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

Raises

ValueError if the *freq* cannot be converted.

Examples

DatetimeIndex

```
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
               '2018-01-01 12:01:00'],
              dtype='datetime64[ns]', freq='T')
>>> rng.ceil('H')
DatetimeIndex(['2018-01-01 12:00:00', '2018-01-01 12:00:00',
               '2018-01-01 13:00:00'],
              dtype='datetime64[ns]', freq=None)
```

Series

```
>>> pd.Series(rng).dt.ceil("H")
0   2018-01-01 12:00:00
1   2018-01-01 12:00:00
2   2018-01-01 13:00:00
dtype: datetime64[ns]
```

pandas.TimedeltaIndex.to_frame

`TimedeltaIndex.`**`to_frame`**(*index=True*, *name=None*)

Create a DataFrame with a column containing the Index.

New in version 0.24.0.

Parameters

index [bool, default True] Set the index of the returned DataFrame as the original Index.

name [object, default None] The passed name should substitute for the index name (if it has one).

Returns

DataFrame DataFrame containing the original Index data.

See also:

Index.to_series Convert an Index to a Series.

Series.to_frame Convert Series to DataFrame.

Examples

```
>>> idx = pd.Index(['Ant', 'Bear', 'Cow'], name='animal')
>>> idx.to_frame()
       animal
animal
Ant       Ant
Bear     Bear
Cow       Cow
```

By default, the original Index is reused. To enforce a new Index:

```
>>> idx.to_frame(index=False)
    animal
0   Ant
1  Bear
2   Cow
```

To override the name of the resulting column, specify *name*:

```
>>> idx.to_frame(index=False, name='zoo')
    zoo
0   Ant
1  Bear
2   Cow
```

pandas.TimedeltaIndex.mean

TimedeltaIndex.**mean**(**args*, ***kwargs*)

Return the mean value of the Array.

New in version 0.25.0.

Parameters

skipna [bool, default True] Whether to ignore any NaT elements.

Returns

scalar Timestamp or Timedelta.

See also:

numpy.ndarray.mean Returns the average of array elements along a given axis.

Series.mean Return the mean value in a Series.

Notes

mean is only defined for Datetime and Timedelta dtypes, not for Period.

Components

TimedeltaIndex.days	Number of days for each element.
TimedeltaIndex.seconds	Number of seconds (>= 0 and less than 1 day) for each element.
TimedeltaIndex.microseconds	Number of microseconds (>= 0 and less than 1 second) for each element.
TimedeltaIndex.nanoseconds	Number of nanoseconds (>= 0 and less than 1 microsecond) for each element.
TimedeltaIndex.components	Return a dataframe of the components (days, hours, minutes, seconds, milliseconds, microseconds, nanoseconds) of the Timedeltas.
TimedeltaIndex.inferred_freq	Tries to return a string representing a frequency guess, generated by infer_freq.

Conversion

TimedeltaIndex.to_pytimedelta(*args, **kwargs)	Return Timedelta Array/Index as object ndarray of datetime.timedelta objects.
TimedeltaIndex.to_series([index, name])	Create a Series with both index and values equal to the index keys.
TimedeltaIndex.round(*args, **kwargs)	Perform round operation on the data to the specified *freq*.
TimedeltaIndex.floor(*args, **kwargs)	Perform floor operation on the data to the specified *freq*.
TimedeltaIndex.ceil(*args, **kwargs)	Perform ceil operation on the data to the specified *freq*.
TimedeltaIndex.to_frame([index, name])	Create a DataFrame with a column containing the Index.

Methods

TimedeltaIndex.mean(*args, **kwargs)	Return the mean value of the Array.

3.7.8 PeriodIndex

PeriodIndex([data, ordinal, freq, tz, ...])	Immutable ndarray holding ordinal values indicating regular periods in time.

pandas.PeriodIndex

class pandas.**PeriodIndex**(*data=None*, *ordinal=None*, *freq=None*, *tz=None*, *dtype=None*, *copy=False*, *name=None*, ***fields*)

Immutable ndarray holding ordinal values indicating regular periods in time.

Index keys are boxed to Period objects which carries the metadata (eg, frequency information).

Parameters

data [array-like (1d int np.ndarray or PeriodArray), optional] Optional period-like data to construct index with.

copy [bool] Make a copy of input ndarray.

freq [str or period object, optional] One of pandas period strings or corresponding objects.

year [int, array, or Series, default None]

month [int, array, or Series, default None]

quarter [int, array, or Series, default None]

day [int, array, or Series, default None]

hour [int, array, or Series, default None]

minute [int, array, or Series, default None]

second [int, array, or Series, default None]

tz [object, default None] Timezone for converting datetime64 data to Periods.

dtype [str or PeriodDtype, default None]

See also:

Index The base pandas Index type.
Period Represents a period of time.
DatetimeIndex Index with datetime64 data.
TimedeltaIndex Index of timedelta64 data.
period_range Create a fixed-frequency PeriodIndex.

Examples

```
>>> idx = pd.PeriodIndex(year=[2000, 2002], quarter=[1, 3])
>>> idx
PeriodIndex(['2000Q1', '2002Q3'], dtype='period[Q-DEC]', freq='Q-DEC')
```

Attributes

day	The days of the period.
dayofweek	The day of the week with Monday=0, Sunday=6.
dayofyear	The ordinal day of the year.
days_in_month	The number of days in the month.
daysinmonth	The number of days in the month.
freq	Return the frequency object if it is set, otherwise None.
freqstr	Return the frequency object as a string if its set, otherwise None.
hour	The hour of the period.
is_leap_year	Logical indicating if the date belongs to a leap year.
minute	The minute of the period.
month	The month as January=1, December=12.
quarter	The quarter of the date.
second	The second of the period.
week	The week ordinal of the year.
weekday	The day of the week with Monday=0, Sunday=6.
weekofyear	The week ordinal of the year.

continues on next page

Table 176 – continued from previous page

year	The year of the period.

pandas.PeriodIndex.day

property PeriodIndex.**day**
The days of the period.

pandas.PeriodIndex.dayofweek

property PeriodIndex.**dayofweek**
The day of the week with Monday=0, Sunday=6.

pandas.PeriodIndex.dayofyear

property PeriodIndex.**dayofyear**
The ordinal day of the year.

pandas.PeriodIndex.days_in_month

property PeriodIndex.**days_in_month**
The number of days in the month.

pandas.PeriodIndex.daysinmonth

property PeriodIndex.**daysinmonth**
The number of days in the month.

pandas.PeriodIndex.freq

property PeriodIndex.**freq**
Return the frequency object if it is set, otherwise None.

pandas.PeriodIndex.freqstr

property PeriodIndex.**freqstr**
Return the frequency object as a string if its set, otherwise None.

pandas.PeriodIndex.hour

property PeriodIndex.**hour**
The hour of the period.

pandas.PeriodIndex.is_leap_year

property PeriodIndex.**is_leap_year**
Logical indicating if the date belongs to a leap year.

pandas.PeriodIndex.minute

property PeriodIndex.**minute**
The minute of the period.

pandas.PeriodIndex.month

property PeriodIndex.**month**
The month as January=1, December=12.

pandas.PeriodIndex.quarter

property PeriodIndex.**quarter**
The quarter of the date.

pandas.PeriodIndex.second

property PeriodIndex.**second**
The second of the period.

pandas.PeriodIndex.week

property PeriodIndex.**week**
The week ordinal of the year.

pandas.PeriodIndex.weekday

property PeriodIndex.**weekday**
The day of the week with Monday=0, Sunday=6.

pandas.PeriodIndex.weekofyear

property PeriodIndex.**weekofyear**
The week ordinal of the year.

pandas.PeriodIndex.year

property PeriodIndex.**year**
The year of the period.

end_time	
qyear	
start_time	

Methods

asfreq([freq, how])	Convert the Period Array/Index to the specified frequency *freq*.
strftime(*args, **kwargs)	Convert to Index using specified date_format.
to_timestamp(*args, **kwargs)	Cast to DatetimeArray/Index.

pandas.PeriodIndex.asfreq

PeriodIndex.**asfreq**(*freq=None*, *how='E'*)
Convert the Period Array/Index to the specified frequency *freq*.

Parameters

freq [str] A frequency.

how [str {'E', 'S'}] Whether the elements should be aligned to the end or start within pa period.

- 'E', 'END', or 'FINISH' for end,
- 'S', 'START', or 'BEGIN' for start.

January 31st ('END') vs. January 1st ('START') for example.

Returns

Period Array/Index Constructed with the new frequency.

Examples

```
>>> pidx = pd.period_range('2010-01-01', '2015-01-01', freq='A')
>>> pidx
PeriodIndex(['2010', '2011', '2012', '2013', '2014', '2015'],
dtype='period[A-DEC]', freq='A-DEC')
```

```
>>> pidx.asfreq('M')
PeriodIndex(['2010-12', '2011-12', '2012-12', '2013-12', '2014-12',
'2015-12'], dtype='period[M]', freq='M')
```

```
>>> pidx.asfreq('M', how='S')
PeriodIndex(['2010-01', '2011-01', '2012-01', '2013-01', '2014-01',
'2015-01'], dtype='period[M]', freq='M')
```

pandas.PeriodIndex.strftime

PeriodIndex.**strftime**(**args*, ***kwargs*)

Convert to Index using specified date_format.

Return an Index of formatted strings specified by date_format, which supports the same string format as the python standard library. Details of the string format can be found in python string format doc.

Parameters

date_format [str] Date format string (e.g. "%Y-%m-%d").

Returns

ndarray NumPy ndarray of formatted strings.

See also:

to_datetime Convert the given argument to datetime.

DatetimeIndex.normalize Return DatetimeIndex with times to midnight.

DatetimeIndex.round Round the DatetimeIndex to the specified freq.

DatetimeIndex.floor Floor the DatetimeIndex to the specified freq.

Examples

```
>>> rng = pd.date_range(pd.Timestamp("2018-03-10 09:00"),
...                     periods=3, freq='s')
>>> rng.strftime('%B %d, %Y, %r')
Index(['March 10, 2018, 09:00:00 AM', 'March 10, 2018, 09:00:01 AM',
       'March 10, 2018, 09:00:02 AM'],
      dtype='object')
```

pandas.PeriodIndex.to_timestamp

PeriodIndex.**to_timestamp**(**args*, ***kwargs*)

Cast to DatetimeArray/Index.

Parameters

freq [str or DateOffset, optional] Target frequency. The default is 'D' for week or longer, 'S' otherwise.

how [{'s', 'e', 'start', 'end'}] Whether to use the start or end of the time period being converted.

Returns

DatetimeArray/Index

Properties

PeriodIndex.day	The days of the period.
PeriodIndex.dayofweek	The day of the week with Monday=0, Sunday=6.
PeriodIndex.dayofyear	The ordinal day of the year.
PeriodIndex.days_in_month	The number of days in the month.
PeriodIndex.daysinmonth	The number of days in the month.
PeriodIndex.end_time	
PeriodIndex.freq	Return the frequency object if it is set, otherwise None.
PeriodIndex.freqstr	Return the frequency object as a string if its set, otherwise None.
PeriodIndex.hour	The hour of the period.
PeriodIndex.is_leap_year	Logical indicating if the date belongs to a leap year.
PeriodIndex.minute	The minute of the period.
PeriodIndex.month	The month as January=1, December=12.
PeriodIndex.quarter	The quarter of the date.
PeriodIndex.qyear	
PeriodIndex.second	The second of the period.
PeriodIndex.start_time	
PeriodIndex.week	The week ordinal of the year.
PeriodIndex.weekday	The day of the week with Monday=0, Sunday=6.
PeriodIndex.weekofyear	The week ordinal of the year.
PeriodIndex.year	The year of the period.

pandas.PeriodIndex.end_time

property PeriodIndex.**end_time**

pandas.PeriodIndex.qyear

property PeriodIndex.**qyear**

pandas.PeriodIndex.start_time

property PeriodIndex.**start_time**

Methods

PeriodIndex.asfreq([freq, how])	Convert the Period Array/Index to the specified frequency *freq*.
PeriodIndex.strftime(*args, **kwargs)	Convert to Index using specified date_format.
PeriodIndex.to_timestamp(*args, **kwargs)	Cast to DatetimeArray/Index.

3.8 Date offsets

3.8.1 DateOffset

DateOffset	Standard kind of date increment used for a date range.

pandas.tseries.offsets.DateOffset

class pandas.tseries.offsets.**DateOffset**

Standard kind of date increment used for a date range.

Works exactly like relativedelta in terms of the keyword args you pass in, use of the keyword n is discouraged– you would be better off specifying n in the keywords you use, but regardless it is there for you. n is needed for DateOffset subclasses.

DateOffset work as follows. Each offset specify a set of dates that conform to the DateOffset. For example, Bday defines this set to be the set of dates that are weekdays (M-F). To test if a date is in the set of a DateOffset dateOffset we can use the is_on_offset method: dateOffset.is_on_offset(date).

If a date is not on a valid date, the rollback and rollforward methods can be used to roll the date to the nearest valid date before/after the date.

DateOffsets can be created to move dates forward a given number of valid dates. For example, Bday(2) can be added to a date to move it two business days forward. If the date does not start on a valid date, first it is moved to a valid date. Thus pseudo code is:
def __add__(date): date = rollback(date) # does nothing if date is valid return date + <n number of periods>
When a date offset is created for a negative number of periods, the date is first rolled forward. The pseudo code is:
def __add__(date): date = rollforward(date) # does nothing is date is valid return date + <n number of periods>
Zero presents a problem. Should it roll forward or back? We arbitrarily have it rollforward:

date + BDay(0) == BDay.rollforward(date)

Since 0 is a bit weird, we suggest avoiding its use.

Parameters

n [int, default 1] The number of time periods the offset represents.

normalize [bool, default False] Whether to round the result of a DateOffset addition down to the previous midnight.

****kwds** Temporal parameter that add to or replace the offset value.

Parameters that **add** to the offset (like Timedelta):

- years
- months
- weeks
- days
- hours
- minutes
- seconds
- microseconds
- nanoseconds

Parameters that **replace** the offset value:

- year
- month
- day
- weekday
- hour
- minute
- second
- microsecond
- nanosecond.

See also:

`dateutil.relativedelta.relativedelta` The relativedelta type is designed to be applied to an existing datetime an can replace specific components of that datetime, or represents an interval of time.

Examples

```
>>> from pandas.tseries.offsets import DateOffset
>>> ts = pd.Timestamp('2017-01-01 09:10:11')
>>> ts + DateOffset(months=3)
Timestamp('2017-04-01 09:10:11')
```

```
>>> ts = pd.Timestamp('2017-01-01 09:10:11')
>>> ts + DateOffset(months=2)
Timestamp('2017-03-01 09:10:11')
```

Attributes

base	Returns a copy of the calling offset object with n=1 and all other attributes equal.

pandas.tseries.offsets.DateOffset.base

DateOffset.**base**

Returns a copy of the calling offset object with n=1 and all other attributes equal.

normalize	
rule_code	

Methods

__call__(*args, **kwargs)	Call self as a function.
rollback	Roll provided date backward to next offset only if not on offset.
rollforward	Roll provided date forward to next offset only if not on offset.

pandas.tseries.offsets.DateOffset.__call__

DateOffset.**__call__**(**args*, ***kwargs*)

Call self as a function.

pandas.tseries.offsets.DateOffset.rollback

DateOffset.**rollback**()

Roll provided date backward to next offset only if not on offset.

Returns

TimeStamp Rolled timestamp if not on offset, otherwise unchanged timestamp.

pandas.tseries.offsets.DateOffset.rollforward

DateOffset.**rollforward**()

Roll provided date forward to next offset only if not on offset.

Returns

TimeStamp Rolled timestamp if not on offset, otherwise unchanged timestamp.

3.8.4 CustomBusinessDay

CustomBusinessDay	DateOffset subclass representing custom business days excluding holidays.

pandas.tseries.offsets.CustomBusinessDay

class pandas.tseries.offsets.**CustomBusinessDay**

DateOffset subclass representing custom business days excluding holidays.

Parameters

n [int, default 1]

normalize [bool, default False] Normalize start/end dates to midnight before generating date range.

weekmask [str, Default 'Mon Tue Wed Thu Fri'] Weekmask of valid business days, passed to `numpy.busdaycalendar`.

holidays [list] List/array of dates to exclude from the set of valid business days, passed to `numpy.busdaycalendar`.

calendar [pd.HolidayCalendar or np.busdaycalendar]

offset [timedelta, default timedelta(0)]

Attributes

base	Returns a copy of the calling offset object with n=1 and all other attributes equal.
offset	Alias for self._offset.

pandas.tseries.offsets.CustomBusinessDay.base

`CustomBusinessDay.`**`base`**

Returns a copy of the calling offset object with n=1 and all other attributes equal.

pandas.tseries.offsets.CustomBusinessDay.offset

`CustomBusinessDay.`**`offset`**

Alias for self._offset.

3.8.8 BusinessMonthEnd

BusinessMonthEnd	DateOffset increments between the last business day of the month

pandas.tseries.offsets.BusinessMonthEnd

class pandas.tseries.offsets.**BusinessMonthEnd**

DateOffset increments between the last business day of the month

Examples

```
>>> from pandas.tseries.offset import BMonthEnd
>>> ts = pd.Timestamp('2020-05-24 05:01:15')
>>> ts + BMonthEnd()
Timestamp('2020-05-29 05:01:15')
>>> ts + BMonthEnd(2)
Timestamp('2020-06-30 05:01:15')
>>> ts + BMonthEnd(-2)
Timestamp('2020-03-31 05:01:15')
```

Attributes

base	Returns a copy of the calling offset object with n=1 and all other attributes equal.

pandas.tseries.offsets.BusinessMonthEnd.base

BusinessMonthEnd.**base**

Returns a copy of the calling offset object with n=1 and all other attributes equal.

3.8.15 WeekOfMonth

WeekOfMonth	Describes monthly dates like "the Tuesday of the 2nd week of each month".

pandas.tseries.offsets.WeekOfMonth

class pandas.tseries.offsets.**WeekOfMonth**

Describes monthly dates like "the Tuesday of the 2nd week of each month".

Parameters

n [int]

week [int {0, 1, 2, 3, ...}, default 0] A specific integer for the week of the month. e.g. 0 is 1st week of month, 1 is the 2nd week, etc.

weekday [int {0, 1, ..., 6}, default 0] A specific integer for the day of the week.

- 0 is Monday

- 1 is Tuesday
- 2 is Wednesday
- 3 is Thursday
- 4 is Friday
- 5 is Saturday
- 6 is Sunday.

Attributes

base	Returns a copy of the calling offset object with n=1 and all other attributes equal.

pandas.tseries.offsets.WeekOfMonth.base

WeekOfMonth.**base**

Returns a copy of the calling offset object with n=1 and all other attributes equal.

Methods

__call__(*args, **kwargs)	Call self as a function.
rollback	Roll provided date backward to next offset only if not on offset.
rollforward	Roll provided date forward to next offset only if not on offset.

pandas.tseries.offsets.WeekOfMonth.__call__

WeekOfMonth.**__call__**(**args*, ***kwargs*)
Call self as a function.

pandas.tseries.offsets.WeekOfMonth.rollback

WeekOfMonth.**rollback**()
Roll provided date backward to next offset only if not on offset.

Returns

TimeStamp Rolled timestamp if not on offset, otherwise unchanged timestamp.

pandas.tseries.offsets.WeekOfMonth.rollforward

WeekOfMonth.**rollforward**()
Roll provided date forward to next offset only if not on offset.

Returns

TimeStamp Rolled timestamp if not on offset, otherwise unchanged timestamp.

3.8.16 LastWeekOfMonth

LastWeekOfMonth	Describes monthly dates in last week of month like "the last Tuesday of each month".

pandas.tseries.offsets.LastWeekOfMonth

class pandas.tseries.offsets.**LastWeekOfMonth**

Describes monthly dates in last week of month like "the last Tuesday of each month".

Parameters

n [int, default 1]

weekday [int {0, 1, ..., 6}, default 0] A specific integer for the day of the week.

- 0 is Monday
- 1 is Tuesday
- 2 is Wednesday
- 3 is Thursday
- 4 is Friday
- 5 is Saturday
- 6 is Sunday.

Attributes

base	Returns a copy of the calling offset object with n=1 and all other attributes equal.

pandas.tseries.offsets.LastWeekOfMonth.base

LastWeekOfMonth.**base**

Returns a copy of the calling offset object with n=1 and all other attributes equal.

freqstr

pandas.tseries.offsets.LastWeekOfMonth.is_on_offset

LastWeekOfMonth.**is_on_offset**()

3.8.17 BQuarterEnd

BQuarterEnd	DateOffset increments between the last business day of each Quarter.

pandas.tseries.offsets.BQuarterEnd

class pandas.tseries.offsets.**BQuarterEnd**

DateOffset increments between the last business day of each Quarter.

startingMonth = 1 corresponds to dates like 1/31/2007, 4/30/2007, ... startingMonth = 2 corresponds to dates like 2/28/2007, 5/31/2007, ... startingMonth = 3 corresponds to dates like 3/30/2007, 6/29/2007, ...

Examples

```
>>> from pandas.tseries.offset import BQuarterEnd
>>> ts = pd.Timestamp('2020-05-24 05:01:15')
>>> ts + BQuarterEnd()
Timestamp('2020-06-30 05:01:15')
>>> ts + BQuarterEnd(2)
Timestamp('2020-09-30 05:01:15')
>>> ts + BQuarterEnd(1, startingMonth=2)
Timestamp('2020-05-29 05:01:15')
>>> ts + BQuarterEnd(startingMonth=2)
Timestamp('2020-05-29 05:01:15')
```

Attributes

base	Returns a copy of the calling offset object with n=1 and all other attributes equal.

pandas.tseries.offsets.BQuarterEnd.base

BQuarterEnd.**base**

Returns a copy of the calling offset object with n=1 and all other attributes equal.

freqstr	
kwds	
n	
name

3.8.18 BQuarterBegin

BQuarterBegin	DateOffset increments between the first business day of each Quarter.

pandas.tseries.offsets.BQuarterBegin

class pandas.tseries.offsets.**BQuarterBegin**

DateOffset increments between the first business day of each Quarter.

startingMonth = 1 corresponds to dates like 1/01/2007, 4/01/2007, … startingMonth = 2 corresponds to dates like 2/01/2007, 5/01/2007, … startingMonth = 3 corresponds to dates like 3/01/2007, 6/01/2007, …

Examples

```
>>> from pandas.tseries.offset import BQuarterBegin
>>> ts = pd.Timestamp('2020-05-24 05:01:15')
>>> ts + BQuarterBegin()
Timestamp('2020-06-01 05:01:15')
>>> ts + BQuarterBegin(2)
Timestamp('2020-09-01 05:01:15')
>>> ts + BQuarterBegin(startingMonth=2)
Timestamp('2020-08-03 05:01:15')
>>> ts + BQuarterBegin(-1)
Timestamp('2020-03-02 05:01:15')
```

Attributes

base	Returns a copy of the calling offset object with n=1 and all other attributes equal.

pandas.tseries.offsets.BQuarterBegin.base

BQuarterBegin.**base**

Returns a copy of the calling offset object with n=1 and all other attributes equal.

freqstr	
kwds	
n	
name	
nanos	
normalize	
rule_code	
startingMonth	

Methods

__call__(*args, **kwargs)	Call self as a function.
rollback	Roll provided date backward to next offset only if not on offset.
rollforward	Roll provided date forward to next offset only if not on offset.

pandas.tseries.offsets.BQuarterBegin.__call__

BQuarterBegin.**__call__**(**args*, ***kwargs*)
Call self as a function.

pandas.tseries.offsets.BQuarterBegin.rollback

BQuarterBegin.**rollback**()
Roll provided date backward to next offset only if not on offset.

Returns

TimeStamp Rolled timestamp if not on offset, otherwise unchanged timestamp.

pandas.tseries.offsets.BQuarterBegin.rollforward

BQuarterBegin.**rollforward**()
Roll provided date forward to next offset only if not on offset.

Returns

TimeStamp Rolled timestamp if not on offset, otherwise unchanged timestamp.

3.8.25 FY5253

FY5253	Describes 52-53 week fiscal year.

pandas.tseries.offsets.FY5253

class pandas.tseries.offsets.**FY5253**

Describes 52-53 week fiscal year. This is also known as a 4-4-5 calendar.

It is used by companies that desire that their fiscal year always end on the same day of the week.

It is a method of managing accounting periods. It is a common calendar structure for some industries, such as retail, manufacturing and parking industry.

For more information see: https://en.wikipedia.org/wiki/4-4-5_calendar

The year may either:

- end on the last X day of the Y month.
- end on the last X day closest to the last day of the Y month.

X is a specific day of the week. Y is a certain month of the year

Parameters

n [int]

weekday [int {0, 1, . . . , 6}, default 0] A specific integer for the day of the week.

- 0 is Monday
- 1 is Tuesday
- 2 is Wednesday
- 3 is Thursday
- 4 is Friday
- 5 is Saturday
- 6 is Sunday.

startingMonth [int {1, 2, . . . 12}, default 1] The month in which the fiscal year ends.

variation [str, default "nearest"] Method of employing 4-4-5 calendar.

There are two options:

- "nearest" means year end is **weekday** closest to last day of month in year.
- "last" means year end is final **weekday** of the final month in fiscal year.

Attributes

base	Returns a copy of the calling offset object with n=1 and all other attributes equal.

pandas.tseries.offsets.FY5253.base

FY5253.**base**

Returns a copy of the calling offset object with n=1 and all other attributes equal.

3.8.26 FY5253Quarter

FY5253Quarter	DateOffset increments between business quarter dates for 52-53 week fiscal year (also known as a 4-4-5 calendar).

pandas.tseries.offsets.FY5253Quarter

class pandas.tseries.offsets.**FY5253Quarter**

DateOffset increments between business quarter dates for 52-53 week fiscal year (also known as a 4-4-5 calendar).

It is used by companies that desire that their fiscal year always end on the same day of the week.

It is a method of managing accounting periods. It is a common calendar structure for some industries, such as retail, manufacturing and parking industry.

For more information see: https://en.wikipedia.org/wiki/4-4-5_calendar

The year may either:

- end on the last X day of the Y month.
- end on the last X day closest to the last day of the Y month.

X is a specific day of the week. Y is a certain month of the year

startingMonth = 1 corresponds to dates like 1/31/2007, 4/30/2007, ... startingMonth = 2 corresponds to dates like 2/28/2007, 5/31/2007, ... startingMonth = 3 corresponds to dates like 3/30/2007, 6/29/2007, ...

Parameters

n [int]

weekday [int {0, 1, ..., 6}, default 0] A specific integer for the day of the week.

- 0 is Monday
- 1 is Tuesday
- 2 is Wednesday
- 3 is Thursday
- 4 is Friday
- 5 is Saturday
- 6 is Sunday.

startingMonth [int {1, 2, ..., 12}, default 1] The month in which fiscal years end.

qtr_with_extra_week [int {1, 2, 3, 4}, default 1] The quarter number that has the leap or 14 week when needed.

variation [str, default "nearest"] Method of employing 4-4-5 calendar.

There are two options:

- "nearest" means year end is **weekday** closest to last day of month in year.
- "last" means year end is final **weekday** of the final month in fiscal year.

Attributes

base	Returns a copy of the calling offset object with n=1 and all other attributes equal.

3.8.30 Hour

Hour

Attributes

pandas.tseries.offsets.Hour

class pandas.tseries.offsets.**Hour**

Attributes

base	Returns a copy of the calling offset object with n=1 and all other attributes equal.

pandas.tseries.offsets.Hour.base

Hour.**base**
Returns a copy of the calling offset object with n=1 and all other attributes equal.

delta	
freqstr	
kwds	
n	
name	
nanos	
normalize	
rule_code	

Methods

__call__(*args, **kwargs)	Call self as a function.
rollback	Roll provided date backward to next offset only if not on offset.
rollforward	Roll provided date forward to next offset only if not on offset.

pandas.tseries.offsets.Hour.__call__

Hour.**__call__**(**args*, ***kwargs*)
Call self as a function.

pandas.tseries.offsets.Hour.rollback

Hour.**rollback**()
Roll provided date backward to next offset only if not on offset.

Returns

TimeStamp Rolled timestamp if not on offset, otherwise unchanged timestamp.

pandas.tseries.offsets.Hour.rollforward

Hour.**rollforward**()

Roll provided date forward to next offset only if not on offset.

Returns

TimeStamp Rolled timestamp if not on offset, otherwise unchanged timestamp.

apply

3.9 Frequencies

to_offset	Return DateOffset object from string or tuple representation or datetime.timedelta object.

3.9.1 pandas.tseries.frequencies.to_offset

pandas.tseries.frequencies.**to_offset**()

Return DateOffset object from string or tuple representation or datetime.timedelta object.

Parameters

freq [str, tuple, datetime.timedelta, DateOffset or None]

Returns

DateOffset or None

Raises

ValueError If freq is an invalid frequency

See also:

DateOffset Standard kind of date increment used for a date range.

Examples

```
>>> to_offset("5min")
<5 * Minutes>
```

```
>>> to_offset("1D1H")
<25 * Hours>
```

```
>>> to_offset("2W")
<2 * Weeks: weekday=6>
```

```
>>> to_offset("2B")
<2 * BusinessDays>
```

```
>>> to_offset(pd.Timedelta(days=1))
<Day>
```

```
>>> to_offset(Hour())
<Hour>
```

3.10 Window

Rolling objects are returned by `.rolling` calls: *pandas.DataFrame.rolling()*, *pandas.Series.rolling()*, etc. Expanding objects are returned by `.expanding` calls: *pandas.DataFrame.expanding()*, *pandas.Series.expanding()*, etc. ExponentialMovingWindow objects are returned by `.ewm` calls: *pandas.DataFrame.ewm()*, *pandas.Series.ewm()*, etc.

3.10.1 Standard moving window functions

Rolling.count()	The rolling count of any non-NaN observations inside the window.
Rolling.sum(*args, **kwargs)	Calculate rolling sum of given DataFrame or Series.
Rolling.mean(*args, **kwargs)	Calculate the rolling mean of the values.
Rolling.median(**kwargs)	Calculate the rolling median.
Rolling.var([ddof])	Calculate unbiased rolling variance.
Rolling.std([ddof])	Calculate rolling standard deviation.
Rolling.min(*args, **kwargs)	Calculate the rolling minimum.
Rolling.max(*args, **kwargs)	Calculate the rolling maximum.
Rolling.corr([other, pairwise])	Calculate rolling correlation.
Rolling.cov([other, pairwise, ddof])	Calculate the rolling sample covariance.
Rolling.skew(**kwargs)	Unbiased rolling skewness.
Rolling.kurt(**kwargs)	Calculate unbiased rolling kurtosis.
Rolling.apply(func[, raw, engine, ...])	Apply an arbitrary function to each rolling window.

continues on next page

Table 362 – continued from previous page

Rolling.aggregate(func, *args, **kwargs)	Aggregate using one or more operations over the specified axis.
Rolling.quantile(quantile[, interpolation])	Calculate the rolling quantile.
Window.mean(*args, **kwargs)	Calculate the window mean of the values.
Window.sum(*args, **kwargs)	Calculate window sum of given DataFrame or Series.
Window.var([ddof])	Calculate unbiased window variance.
Window.std([ddof])	Calculate window standard deviation.

pandas.core.window.rolling.Rolling.count

Rolling.**count**()

The rolling count of any non-NaN observations inside the window.

Returns

Series or DataFrame Returned object type is determined by the caller of the rolling calculation.

See also:

pandas.Series.rolling Calling object with Series data.
pandas.DataFrame.rolling Calling object with DataFrames.
pandas.DataFrame.count Count of the full DataFrame.

Examples

```
>>> s = pd.Series([2, 3, np.nan, 10])
>>> s.rolling(2).count()
0    1.0
1    2.0
2    1.0
3    1.0
dtype: float64
>>> s.rolling(3).count()
0    1.0
1    2.0
2    2.0
3    2.0
dtype: float64
>>> s.rolling(4).count()
0    1.0
1    2.0
2    2.0
3    3.0
dtype: float64
```

pandas.core.window.rolling.Rolling.sum

Rolling.**sum**(**args*, ***kwargs*)

Calculate rolling sum of given DataFrame or Series.

Parameters

***args, **kwargs** For compatibility with other rolling methods. Has no effect on the computed value.

Returns

Series or DataFrame Same type as the input, with the same index, containing the rolling sum.

See also:

pandas.Series.sum Reducing sum for Series.
pandas.DataFrame.sum Reducing sum for DataFrame.

Examples

```
>>> s = pd.Series([1, 2, 3, 4, 5])
>>> s
0    1
1    2
2    3
3    4
4    5
dtype: int64
```

```
>>> s.rolling(3).sum()
0     NaN
1     NaN
2     6.0
3     9.0
4    12.0
dtype: float64
```

```
>>> s.expanding(3).sum()
0     NaN
1     NaN
2     6.0
3    10.0
4    15.0
dtype: float64
```

```
>>> s.rolling(3, center=True).sum()
0     NaN
1     6.0
2     9.0
3    12.0
4     NaN
dtype: float64
```

For DataFrame, each rolling sum is computed column-wise.

```
>>> df = pd.DataFrame({"A": s, "B": s ** 2})
>>> df
   A   B
0  1   1
1  2   4
2  3   9
3  4  16
4  5  25
```

```
>>> df.rolling(3).sum()
      A     B
0   NaN   NaN
1   NaN   NaN
2   6.0  14.0
3   9.0  29.0
4  12.0  50.0
```

pandas.core.window.rolling.Rolling.mean

Rolling.**mean**(**args*, ***kwargs*)

Calculate the rolling mean of the values.

Parameters

***args** Under Review.

****kwargs** Under Review.

Returns

Series or DataFrame Returned object type is determined by the caller of the rolling calculation.

See also:

pandas.Series.rolling Calling object with Series data.
pandas.DataFrame.rolling Calling object with DataFrames.
pandas.Series.mean Equivalent method for Series.
pandas.DataFrame.mean Equivalent method for DataFrame.

Examples

The below examples will show rolling mean calculations with window sizes of two and three, respectively.

```
>>> s = pd.Series([1, 2, 3, 4])
>>> s.rolling(2).mean()
0    NaN
1    1.5
2    2.5
3    3.5
dtype: float64
```

```
>>> s.rolling(3).mean()
0    NaN
1    NaN
2    2.0
3    3.0
dtype: float64
```

pandas.core.window.rolling.Rolling.median

Rolling.**median**(***kwargs*)

Calculate the rolling median.

Parameters

****kwargs** For compatibility with other rolling methods. Has no effect on the computed median.

Returns

Series or DataFrame Returned type is the same as the original object.

See also:

pandas.Series.rolling Calling object with Series data.
pandas.DataFrame.rolling Calling object with DataFrames.
pandas.Series.median Equivalent method for Series.
pandas.DataFrame.median Equivalent method for DataFrame.

Examples

Compute the rolling median of a series with a window size of 3.

```
>>> s = pd.Series([0, 1, 2, 3, 4])
>>> s.rolling(3).median()
0    NaN
1    NaN
2    1.0
3    2.0
4    3.0
dtype: float64
```

pandas.core.window.rolling.Rolling.var

Rolling.**var**(*ddof=1*, **args*, ***kwargs*)

Calculate unbiased rolling variance.

Normalized by N-1 by default. This can be changed using the *ddof* argument.

Parameters

ddof [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is `N - ddof`, where `N` represents the number of elements.

***args, **kwargs** For NumPy compatibility. No additional arguments are used.

Returns

Series or DataFrame Returns the same object type as the caller of the rolling calculation.

See also:

pandas.Series.rolling Calling object with Series data.
pandas.DataFrame.rolling Calling object with DataFrames.
pandas.Series.var Equivalent method for Series.
pandas.DataFrame.var Equivalent method for DataFrame.
numpy.var Equivalent method for Numpy array.

Notes

The default *ddof* of 1 used in `Series.var()` is different than the default *ddof* of 0 in `numpy.var()`.

A minimum of 1 period is required for the rolling calculation.

Examples

```
>>> s = pd.Series([5, 5, 6, 7, 5, 5, 5])
>>> s.rolling(3).var()
0         NaN
1         NaN
2    0.333333
3    1.000000
4    1.000000
5    1.333333
6    0.000000
dtype: float64
```

```
>>> s.expanding(3).var()
0         NaN
1         NaN
2    0.333333
3    0.916667
4    0.800000
5    0.700000
6    0.619048
dtype: float64
```

pandas.core.window.rolling.Rolling.std

`Rolling.`**`std`**(*ddof=1*, **args*, ***kwargs*)

Calculate rolling standard deviation.

Normalized by N-1 by default. This can be changed using the *ddof* argument.

Parameters

ddof [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is `N - ddof`, where `N` represents the number of elements.

***args, **kwargs** For NumPy compatibility. No additional arguments are used.

Returns

Series or DataFrame Returns the same object type as the caller of the rolling calculation.

See also:

pandas.Series.rolling Calling object with Series data.
pandas.DataFrame.rolling Calling object with DataFrames.
pandas.Series.std Equivalent method for Series.
pandas.DataFrame.std Equivalent method for DataFrame.
numpy.std Equivalent method for Numpy array.

Notes

The default *ddof* of 1 used in Series.std is different than the default *ddof* of 0 in numpy.std.

A minimum of one period is required for the rolling calculation.

Examples

```
>>> s = pd.Series([5, 5, 6, 7, 5, 5, 5])
>>> s.rolling(3).std()
0         NaN
1         NaN
2    0.577350
3    1.000000
4    1.000000
5    1.154701
6    0.000000
dtype: float64
```

```
>>> s.expanding(3).std()
0         NaN
1         NaN
2    0.577350
3    0.957427
4    0.894427
5    0.836660
6    0.786796
dtype: float64
```

pandas.core.window.rolling.Rolling.min

Rolling.**min**(**args*, ***kwargs*)

Calculate the rolling minimum.

Parameters

****kwargs** Under Review.

Returns

Series or DataFrame Returned object type is determined by the caller of the rolling calculation.

See also:

pandas.Series.rolling Calling object with a Series.
pandas.DataFrame.rolling Calling object with a DataFrame.
pandas.Series.min Similar method for Series.
pandas.DataFrame.min Similar method for DataFrame.

Examples

Performing a rolling minimum with a window size of 3.

```
>>> s = pd.Series([4, 3, 5, 2, 6])
>>> s.rolling(3).min()
0    NaN
1    NaN
2    3.0
3    2.0
4    2.0
dtype: float64
```

pandas.core.window.rolling.Rolling.max

Rolling.**max**(**args*, ***kwargs*)

Calculate the rolling maximum.

Parameters

***args, **kwargs** Arguments and keyword arguments to be passed into func.

Returns

Series or DataFrame Return type is determined by the caller.

See also:

pandas.Series.rolling Calling object with Series data.
pandas.DataFrame.rolling Calling object with DataFrame data.
pandas.Series.max Similar method for Series.
pandas.DataFrame.max Similar method for DataFrame.

pandas.core.window.rolling.Rolling.corr

Rolling.**corr**(*other=None*, *pairwise=None*, ***kwargs*)

Calculate rolling correlation.

Parameters

other [Series, DataFrame, or ndarray, optional] If not supplied then will default to self.

pairwise [bool, default None] Calculate pairwise combinations of columns within a DataFrame. If *other* is not specified, defaults to *True*, otherwise defaults to *False*. Not relevant for *Series*.

****kwargs** Unused.

Returns

Series or DataFrame Returned object type is determined by the caller of the rolling calculation.

See also:

pandas.Series.rolling Calling object with Series data.
pandas.DataFrame.rolling Calling object with DataFrames.
pandas.Series.corr Equivalent method for Series.
pandas.DataFrame.corr Equivalent method for DataFrame.
cov Similar method to calculate covariance.
numpy.corrcoef NumPy Pearson's correlation calculation.

Notes

This function uses Pearson's definition of correlation (https://en.wikipedia.org/wiki/Pearson_correlation_coefficient).

When *other* is not specified, the output will be self correlation (e.g. all 1's), except for `DataFrame` inputs with *pairwise* set to *True*.

Function will return `NaN` for correlations of equal valued sequences; this is the result of a 0/0 division error.

When *pairwise* is set to *False*, only matching columns between *self* and *other* will be used.

When *pairwise* is set to *True*, the output will be a MultiIndex DataFrame with the original index on the first level, and the *other* DataFrame columns on the second level.

In the case of missing elements, only complete pairwise observations will be used.

Examples

The below example shows a rolling calculation with a window size of four matching the equivalent function call using `numpy.corrcoef()`.

```
>>> v1 = [3, 3, 3, 5, 8]
>>> v2 = [3, 4, 4, 4, 8]
>>> # numpy returns a 2X2 array, the correlation coefficient
>>> # is the number at entry [0][1]
>>> print(f"{np.corrcoef(v1[:-1], v2[:-1])[0][1]:.6f}")
0.333333
>>> print(f"{np.corrcoef(v1[1:], v2[1:])[0][1]:.6f}")
0.916949
>>> s1 = pd.Series(v1)
>>> s2 = pd.Series(v2)
>>> s1.rolling(4).corr(s2)
0         NaN
1         NaN
2         NaN
3    0.333333
4    0.916949
dtype: float64
```

The below example shows a similar rolling calculation on a DataFrame using the pairwise option.

```
>>> matrix = np.array([[51., 35.], [49., 30.], [47., 32.],    [46., 31.], [50.,␣
↪36.]])
>>> print(np.corrcoef(matrix[:-1,0], matrix[:-1,1]).round(7))
[[1.         0.6263001]
 [0.6263001  1.       ]]
>>> print(np.corrcoef(matrix[1:,0], matrix[1:,1]).round(7))
[[1.         0.5553681]
 [0.5553681  1.       ]]
>>> df = pd.DataFrame(matrix, columns=['X','Y'])
>>> df
      X     Y
0  51.0  35.0
1  49.0  30.0
2  47.0  32.0
3  46.0  31.0
4  50.0  36.0
```

(continues on next page)

(continued from previous page)

```
>>> df.rolling(4).corr(pairwise=True)
            X         Y
0 X       NaN       NaN
  Y       NaN       NaN
1 X       NaN       NaN
  Y       NaN       NaN
2 X       NaN       NaN
  Y       NaN       NaN
3 X  1.000000  0.626300
  Y  0.626300  1.000000
4 X  1.000000  0.555368
  Y  0.555368  1.000000
```

pandas.core.window.rolling.Rolling.cov

`Rolling.`**`cov`**(*other=None*, *pairwise=None*, *ddof=1*, ***kwargs*)

Calculate the rolling sample covariance.

Parameters

other [Series, DataFrame, or ndarray, optional] If not supplied then will default to self and produce pairwise output.

pairwise [bool, default None] If False then only matching columns between self and other will be used and the output will be a DataFrame. If True then all pairwise combinations will be calculated and the output will be a MultiIndexed DataFrame in the case of DataFrame inputs. In the case of missing elements, only complete pairwise observations will be used.

ddof [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is `N - ddof`, where `N` represents the number of elements.

****kwargs** Keyword arguments to be passed into func.

Returns

Series or DataFrame Return type is determined by the caller.

See also:

pandas.Series.rolling Calling object with Series data.
pandas.DataFrame.rolling Calling object with DataFrame data.
pandas.Series.cov Similar method for Series.
pandas.DataFrame.cov Similar method for DataFrame.

pandas.core.window.rolling.Rolling.skew

`Rolling.`**`skew`**(***kwargs*)

Unbiased rolling skewness.

Parameters

****kwargs** Keyword arguments to be passed into func.

Returns

Series or DataFrame Return type is determined by the caller.

See also:

pandas.Series.rolling Calling object with Series data.

pandas.DataFrame.rolling Calling object with DataFrame data.
pandas.Series.skew Similar method for Series.
pandas.DataFrame.skew Similar method for DataFrame.

pandas.core.window.rolling.Rolling.kurt

Rolling.**kurt**(***kwargs*)

Calculate unbiased rolling kurtosis.

This function uses Fisher's definition of kurtosis without bias.

Parameters

****kwargs** Under Review.

Returns

Series or DataFrame Returned object type is determined by the caller of the rolling calculation.

See also:

pandas.Series.rolling Calling object with Series data.
pandas.DataFrame.rolling Calling object with DataFrames.
pandas.Series.kurt Equivalent method for Series.
pandas.DataFrame.kurt Equivalent method for DataFrame.
scipy.stats.skew Third moment of a probability density.
scipy.stats.kurtosis Reference SciPy method.

Notes

A minimum of 4 periods is required for the rolling calculation.

Examples

The example below will show a rolling calculation with a window size of four matching the equivalent function call using *scipy.stats*.

```
>>> arr = [1, 2, 3, 4, 999]
>>> import scipy.stats
>>> print(f"{scipy.stats.kurtosis(arr[:-1], bias=False):.6f}")
-1.200000
>>> print(f"{scipy.stats.kurtosis(arr[1:], bias=False):.6f}")
3.999946
>>> s = pd.Series(arr)
>>> s.rolling(4).kurt()
0         NaN
1         NaN
2         NaN
3   -1.200000
4    3.999946
dtype: float64
```

pandas.core.window.rolling.Rolling.apply

`Rolling.apply`(*func*, *raw=False*, *engine=None*, *engine_kwargs=None*, *args=None*, *kwargs=None*)

Apply an arbitrary function to each rolling window.

Parameters

func [function] Must produce a single value from an ndarray input if `raw=True` or a single value from a Series if `raw=False`. Can also accept a Numba JIT function with `engine='numba'` specified.

Changed in version 1.0.0.

raw [bool, default None]

- `False` : passes each row or column as a Series to the function.
- `True` : the passed function will receive ndarray objects instead. If you are just applying a NumPy reduction function this will achieve much better performance.

engine [str, default None]

- `'cython'` : Runs rolling apply through C-extensions from cython.
- `'numba'` : Runs rolling apply through JIT compiled code from numba. Only available when `raw` is set to `True`.
- `None` : Defaults to `'cython'` or globally setting `compute.use_numba`

New in version 1.0.0.

engine_kwargs [dict, default None]

- For `'cython'` engine, there are no accepted `engine_kwargs`
- For `'numba'` engine, the engine can accept `nopython`, `nogil` and `parallel` dictionary keys. The values must either be `True` or `False`. The default `engine_kwargs` for the `'numba'` engine is `{'nopython': True, 'nogil': False, 'parallel': False}` and will be applied to both the `func` and the `apply` rolling aggregation.

New in version 1.0.0.

args [tuple, default None] Positional arguments to be passed into func.

kwargs [dict, default None] Keyword arguments to be passed into func.

Returns

Series or DataFrame Return type is determined by the caller.

See also:

pandas.Series.rolling Calling object with Series data.
pandas.DataFrame.rolling Calling object with DataFrame data.
pandas.Series.apply Similar method for Series.
pandas.DataFrame.apply Similar method for DataFrame.

Notes

See *Rolling apply* for extended documentation and performance considerations for the Numba engine.

pandas.core.window.rolling.Rolling.aggregate

`Rolling.`**`aggregate`**(*func*, **args*, ***kwargs*)

Aggregate using one or more operations over the specified axis.

Parameters

func [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a Series/Dataframe or when passed to Series/Dataframe.apply.

Accepted combinations are:

- function
- string function name
- list of functions and/or function names, e.g. `[np.sum, 'mean']`
- dict of axis labels -> functions, function names or list of such.

***args** Positional arguments to pass to *func*.

****kwargs** Keyword arguments to pass to *func*.

Returns

scalar, Series or DataFrame The return can be:

- scalar : when Series.agg is called with single function
- Series : when DataFrame.agg is called with a single function
- DataFrame : when DataFrame.agg is called with several functions

Return scalar, Series or DataFrame.

See also:

pandas.Series.rolling Calling object with Series data.
pandas.DataFrame.rolling Calling object with DataFrame data.

Notes

agg is an alias for *aggregate*. Use the alias.

A passed user-defined-function will be passed a Series for evaluation.

Examples

```
>>> df = pd.DataFrame({"A": [1, 2, 3], "B": [4, 5, 6], "C": [7, 8, 9]})
>>> df
   A  B  C
0  1  4  7
1  2  5  8
2  3  6  9
```

```
>>> df.rolling(2).sum()
     A     B     C
0  NaN   NaN   NaN
1  3.0   9.0  15.0
2  5.0  11.0  17.0
```

```
>>> df.rolling(2).agg({"A": "sum", "B": "min"})
     A    B
0  NaN  NaN
1  3.0  4.0
2  5.0  5.0
```

pandas.core.window.rolling.Rolling.quantile

Rolling.**quantile**(*quantile*, *interpolation='linear'*, ***kwargs*)

Calculate the rolling quantile.

Parameters

quantile [float] Quantile to compute. 0 <= quantile <= 1.

interpolation [{'linear', 'lower', 'higher', 'midpoint', 'nearest'}] New in version 0.23.0.

This optional parameter specifies the interpolation method to use, when the desired quantile lies between two data points *i* and *j*:

- linear: *i* + (*j* - *i*) * *fraction*, where *fraction* is the fractional part of the index surrounded by *i* and *j*.
- lower: *i*.
- higher: *j*.
- nearest: *i* or *j* whichever is nearest.
- midpoint: (*i* + *j*) / 2.

****kwargs** For compatibility with other rolling methods. Has no effect on the result.

Returns

Series or DataFrame Returned object type is determined by the caller of the rolling calculation.

See also:

pandas.Series.quantile Computes value at the given quantile over all data in Series.
pandas.DataFrame.quantile Computes values at the given quantile over requested axis in DataFrame.

Examples

```
>>> s = pd.Series([1, 2, 3, 4])
>>> s.rolling(2).quantile(.4, interpolation='lower')
0    NaN
1    1.0
2    2.0
3    3.0
dtype: float64
```

```
>>> s.rolling(2).quantile(.4, interpolation='midpoint')
0    NaN
1    1.5
2    2.5
3    3.5
dtype: float64
```

pandas.core.window.rolling.Window.mean

Window.**mean**(**args*, ***kwargs*)

Calculate the window mean of the values.

Parameters

***args** Under Review.

****kwargs** Under Review.

Returns

Series or DataFrame Returned object type is determined by the caller of the window calculation.

See also:

pandas.Series.window Calling object with Series data.
pandas.DataFrame.window Calling object with DataFrames.
pandas.Series.mean Equivalent method for Series.
pandas.DataFrame.mean Equivalent method for DataFrame.

Examples

The below examples will show rolling mean calculations with window sizes of two and three, respectively.

```
>>> s = pd.Series([1, 2, 3, 4])
>>> s.rolling(2).mean()
0    NaN
1    1.5
2    2.5
3    3.5
dtype: float64
```

```
>>> s.rolling(3).mean()
0    NaN
1    NaN
2    2.0
3    3.0
dtype: float64
```

pandas.core.window.rolling.Window.sum

Window.**sum**(**args*, ***kwargs*)

Calculate window sum of given DataFrame or Series.

Parameters

***args, **kwargs** For compatibility with other window methods. Has no effect on the computed value.

Returns

Series or DataFrame Same type as the input, with the same index, containing the window sum.

See also:

pandas.Series.sum Reducing sum for Series.
pandas.DataFrame.sum Reducing sum for DataFrame.

Examples

```
>>> s = pd.Series([1, 2, 3, 4, 5])
>>> s
0    1
1    2
2    3
3    4
4    5
dtype: int64
```

```
>>> s.rolling(3).sum()
0     NaN
1     NaN
2     6.0
3     9.0
4    12.0
dtype: float64
```

```
>>> s.expanding(3).sum()
0     NaN
1     NaN
2     6.0
3    10.0
4    15.0
dtype: float64
```

```
>>> s.rolling(3, center=True).sum()
0     NaN
1     6.0
2     9.0
3    12.0
4     NaN
dtype: float64
```

For DataFrame, each window sum is computed column-wise.

```
>>> df = pd.DataFrame({"A": s, "B": s ** 2})
>>> df
   A   B
0  1   1
1  2   4
2  3   9
3  4  16
4  5  25
```

```
>>> df.rolling(3).sum()
      A     B
0   NaN   NaN
1   NaN   NaN
2   6.0  14.0
3   9.0  29.0
4  12.0  50.0
```

pandas.core.window.rolling.Window.var

Window.**var**(*ddof=1*, **args*, ***kwargs*)

Calculate unbiased window variance.

New in version 1.0.0.

Normalized by N-1 by default. This can be changed using the *ddof* argument.

Parameters

ddof [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is `N - ddof`, where `N` represents the number of elements.

***args, **kwargs** For NumPy compatibility. No additional arguments are used.

Returns

Series or DataFrame Returns the same object type as the caller of the window calculation.

See also:

pandas.Series.window Calling object with Series data.
pandas.DataFrame.window Calling object with DataFrames.
pandas.Series.var Equivalent method for Series.
pandas.DataFrame.var Equivalent method for DataFrame.
numpy.var Equivalent method for Numpy array.

Notes

The default *ddof* of 1 used in `Series.var()` is different than the default *ddof* of 0 in `numpy.var()`.

A minimum of 1 period is required for the rolling calculation.

Examples

```
>>> s = pd.Series([5, 5, 6, 7, 5, 5, 5])
>>> s.rolling(3).var()
0         NaN
1         NaN
2    0.333333
3    1.000000
4    1.000000
5    1.333333
6    0.000000
dtype: float64
```

```
>>> s.expanding(3).var()
0         NaN
1         NaN
2    0.333333
3    0.916667
4    0.800000
5    0.700000
6    0.619048
dtype: float64
```

pandas.core.window.rolling.Window.std

Window.**std**(*ddof=1*, **args*, ***kwargs*)

Calculate window standard deviation.

New in version 1.0.0.

Normalized by N-1 by default. This can be changed using the *ddof* argument.

Parameters

ddof [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is `N - ddof`, where `N` represents the number of elements.

***args, **kwargs** For NumPy compatibility. No additional arguments are used.

Returns

Series or DataFrame Returns the same object type as the caller of the window calculation.

See also:

pandas.Series.window Calling object with Series data.
pandas.DataFrame.window Calling object with DataFrames.
pandas.Series.std Equivalent method for Series.
pandas.DataFrame.std Equivalent method for DataFrame.
numpy.std Equivalent method for Numpy array.

Notes

The default *ddof* of 1 used in Series.std is different than the default *ddof* of 0 in numpy.std.

A minimum of one period is required for the rolling calculation.

Examples

```
>>> s = pd.Series([5, 5, 6, 7, 5, 5, 5])
>>> s.rolling(3).std()
0         NaN
1         NaN
2    0.577350
3    1.000000
4    1.000000
5    1.154701
6    0.000000
dtype: float64
```

```
>>> s.expanding(3).std()
0         NaN
1         NaN
2    0.577350
3    0.957427
4    0.894427
5    0.836660
6    0.786796
dtype: float64
```

3.10.2 Standard expanding window functions

Expanding.count(**kwargs)	The expanding count of any non-NaN observations inside the window.
Expanding.sum(*args, **kwargs)	Calculate expanding sum of given DataFrame or Series.
Expanding.mean(*args, **kwargs)	Calculate the expanding mean of the values.
Expanding.median(**kwargs)	Calculate the expanding median.
Expanding.var([ddof])	Calculate unbiased expanding variance.
Expanding.std([ddof])	Calculate expanding standard deviation.
Expanding.min(*args, **kwargs)	Calculate the expanding minimum.
Expanding.max(*args, **kwargs)	Calculate the expanding maximum.
Expanding.corr([other, pairwise])	Calculate expanding correlation.
Expanding.cov([other, pairwise, ddof])	Calculate the expanding sample covariance.
Expanding.skew(**kwargs)	Unbiased expanding skewness.
Expanding.kurt(**kwargs)	Calculate unbiased expanding kurtosis.
Expanding.apply(func[, raw, engine, ...])	Apply an arbitrary function to each expanding window.
Expanding.aggregate(func, *args, **kwargs)	Aggregate using one or more operations over the specified axis.
Expanding.quantile(quantile[, interpolation])	Calculate the expanding quantile.

pandas.core.window.expanding.Expanding.count

Expanding.**count**(***kwargs*)

The expanding count of any non-NaN observations inside the window.

Returns

Series or DataFrame Returned object type is determined by the caller of the expanding calculation.

See also:

pandas.Series.expanding Calling object with Series data.
pandas.DataFrame.expanding Calling object with DataFrames.
pandas.DataFrame.count Count of the full DataFrame.

Examples

```
>>> s = pd.Series([2, 3, np.nan, 10])
>>> s.rolling(2).count()
0    1.0
1    2.0
2    1.0
3    1.0
dtype: float64
>>> s.rolling(3).count()
0    1.0
1    2.0
2    2.0
3    2.0
dtype: float64
>>> s.rolling(4).count()
0    1.0
1    2.0
2    2.0
3    3.0
dtype: float64
```

pandas.core.window.expanding.Expanding.sum

Expanding.**sum**(**args*, ***kwargs*)

Calculate expanding sum of given DataFrame or Series.

Parameters

***args, **kwargs** For compatibility with other expanding methods. Has no effect on the computed value.

Returns

Series or DataFrame Same type as the input, with the same index, containing the expanding sum.

See also:

pandas.Series.sum Reducing sum for Series.
pandas.DataFrame.sum Reducing sum for DataFrame.

Examples

```
>>> s = pd.Series([1, 2, 3, 4, 5])
>>> s
0    1
1    2
2    3
3    4
4    5
dtype: int64
```

```
>>> s.rolling(3).sum()
0     NaN
1     NaN
2     6.0
3     9.0
4    12.0
dtype: float64
```

```
>>> s.expanding(3).sum()
0     NaN
1     NaN
2     6.0
3    10.0
4    15.0
dtype: float64
```

```
>>> s.rolling(3, center=True).sum()
0     NaN
1     6.0
2     9.0
3    12.0
4     NaN
dtype: float64
```

For DataFrame, each expanding sum is computed column-wise.

```
>>> df = pd.DataFrame({"A": s, "B": s ** 2})
>>> df
   A   B
0  1   1
1  2   4
2  3   9
3  4  16
4  5  25
```

```
>>> df.rolling(3).sum()
      A     B
0   NaN   NaN
1   NaN   NaN
2   6.0  14.0
3   9.0  29.0
4  12.0  50.0
```

pandas.core.window.expanding.Expanding.mean

Expanding.**mean**(**args*, ***kwargs*)

Calculate the expanding mean of the values.

Parameters

***args** Under Review.

****kwargs** Under Review.

Returns

Series or DataFrame Returned object type is determined by the caller of the expanding calculation.

See also:

pandas.Series.expanding Calling object with Series data.
pandas.DataFrame.expanding Calling object with DataFrames.
pandas.Series.mean Equivalent method for Series.
pandas.DataFrame.mean Equivalent method for DataFrame.

Examples

The below examples will show rolling mean calculations with window sizes of two and three, respectively.

```
>>> s = pd.Series([1, 2, 3, 4])
>>> s.rolling(2).mean()
0    NaN
1    1.5
2    2.5
3    3.5
dtype: float64
```

```
>>> s.rolling(3).mean()
0    NaN
1    NaN
2    2.0
3    3.0
dtype: float64
```

pandas.core.window.expanding.Expanding.median

Expanding.**median**(***kwargs*)

Calculate the expanding median.

Parameters

****kwargs** For compatibility with other expanding methods. Has no effect on the computed median.

Returns

Series or DataFrame Returned type is the same as the original object.

See also:

pandas.Series.expanding Calling object with Series data.
pandas.DataFrame.expanding Calling object with DataFrames.
pandas.Series.median Equivalent method for Series.
pandas.DataFrame.median Equivalent method for DataFrame.

Examples

Compute the rolling median of a series with a window size of 3.

```
>>> s = pd.Series([0, 1, 2, 3, 4])
>>> s.rolling(3).median()
0    NaN
1    NaN
2    1.0
3    2.0
4    3.0
dtype: float64
```

pandas.core.window.expanding.Expanding.var

Expanding.**var**(*ddof=1*, **args*, ***kwargs*)

Calculate unbiased expanding variance.

Normalized by N-1 by default. This can be changed using the *ddof* argument.

Parameters

ddof [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is `N - ddof`, where `N` represents the number of elements.

***args, **kwargs** For NumPy compatibility. No additional arguments are used.

Returns

Series or DataFrame Returns the same object type as the caller of the expanding calculation.

See also:

pandas.Series.expanding Calling object with Series data.
pandas.DataFrame.expanding Calling object with DataFrames.
pandas.Series.var Equivalent method for Series.
pandas.DataFrame.var Equivalent method for DataFrame.
numpy.var Equivalent method for Numpy array.

Notes

The default *ddof* of 1 used in `Series.var()` is different than the default *ddof* of 0 in `numpy.var()`.

A minimum of 1 period is required for the rolling calculation.

Examples

```
>>> s = pd.Series([5, 5, 6, 7, 5, 5, 5])
>>> s.rolling(3).var()
0         NaN
1         NaN
2    0.333333
3    1.000000
4    1.000000
5    1.333333
6    0.000000
dtype: float64
```

```
>>> s.expanding(3).var()
0         NaN
1         NaN
2    0.333333
3    0.916667
4    0.800000
5    0.700000
6    0.619048
dtype: float64
```

pandas.core.window.expanding.Expanding.std

Expanding.**std**(*ddof=1*, **args*, ***kwargs*)

Calculate expanding standard deviation.

Normalized by N-1 by default. This can be changed using the *ddof* argument.

Parameters

ddof [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is `N - ddof`, where `N` represents the number of elements.

***args, **kwargs** For NumPy compatibility. No additional arguments are used.

Returns

Series or DataFrame Returns the same object type as the caller of the expanding calculation.

See also:

pandas.Series.expanding Calling object with Series data.
pandas.DataFrame.expanding Calling object with DataFrames.
pandas.Series.std Equivalent method for Series.
pandas.DataFrame.std Equivalent method for DataFrame.
numpy.std Equivalent method for Numpy array.

Notes

The default *ddof* of 1 used in Series.std is different than the default *ddof* of 0 in numpy.std.

A minimum of one period is required for the rolling calculation.

Examples

```
>>> s = pd.Series([5, 5, 6, 7, 5, 5, 5])
>>> s.rolling(3).std()
0         NaN
1         NaN
2    0.577350
3    1.000000
4    1.000000
5    1.154701
6    0.000000
dtype: float64
```

```
>>> s.expanding(3).std()
0         NaN
1         NaN
2    0.577350
3    0.957427
4    0.894427
5    0.836660
6    0.786796
dtype: float64
```

pandas.core.window.expanding.Expanding.min

Expanding.**min**(**args*, ***kwargs*)

Calculate the expanding minimum.

Parameters

****kwargs** Under Review.

Returns

Series or DataFrame Returned object type is determined by the caller of the expanding calculation.

See also:

pandas.Series.expanding Calling object with a Series.
pandas.DataFrame.expanding Calling object with a DataFrame.
pandas.Series.min Similar method for Series.
pandas.DataFrame.min Similar method for DataFrame.

Examples

Performing a rolling minimum with a window size of 3.

```
>>> s = pd.Series([4, 3, 5, 2, 6])
>>> s.rolling(3).min()
0    NaN
1    NaN
2    3.0
3    2.0
4    2.0
dtype: float64
```

pandas.core.window.expanding.Expanding.max

Expanding.**max**(**args*, ***kwargs*)

Calculate the expanding maximum.

Parameters

***args, **kwargs** Arguments and keyword arguments to be passed into func.

Returns

Series or DataFrame Return type is determined by the caller.

See also:

pandas.Series.expanding Calling object with Series data.

pandas.DataFrame.expanding Calling object with DataFrame data.
pandas.Series.max Similar method for Series.
pandas.DataFrame.max Similar method for DataFrame.

pandas.core.window.expanding.Expanding.corr

Expanding.**corr**(*other=None*, *pairwise=None*, ***kwargs*)

Calculate expanding correlation.

Parameters

other [Series, DataFrame, or ndarray, optional] If not supplied then will default to self.

pairwise [bool, default None] Calculate pairwise combinations of columns within a DataFrame. If *other* is not specified, defaults to *True*, otherwise defaults to *False*. Not relevant for *Series*.

****kwargs** Unused.

Returns

Series or DataFrame Returned object type is determined by the caller of the expanding calculation.

See also:

pandas.Series.expanding Calling object with Series data.
pandas.DataFrame.expanding Calling object with DataFrames.
pandas.Series.corr Equivalent method for Series.
pandas.DataFrame.corr Equivalent method for DataFrame.
cov Similar method to calculate covariance.
numpy.corrcoef NumPy Pearson's correlation calculation.

Notes

This function uses Pearson's definition of correlation (https://en.wikipedia.org/wiki/Pearson_correlation_coefficient).

When *other* is not specified, the output will be self correlation (e.g. all 1's), except for *DataFrame* inputs with *pairwise* set to *True*.

Function will return `NaN` for correlations of equal valued sequences; this is the result of a 0/0 division error.

When *pairwise* is set to *False*, only matching columns between *self* and *other* will be used.

When *pairwise* is set to *True*, the output will be a MultiIndex DataFrame with the original index on the first level, and the *other* DataFrame columns on the second level.

In the case of missing elements, only complete pairwise observations will be used.

Examples

The below example shows a rolling calculation with a window size of four matching the equivalent function call using `numpy.corrcoef()`.

```
>>> v1 = [3, 3, 3, 5, 8]
>>> v2 = [3, 4, 4, 4, 8]
>>> # numpy returns a 2X2 array, the correlation coefficient
>>> # is the number at entry [0][1]
>>> print(f"{np.corrcoef(v1[:-1], v2[:-1])[0][1]:.6f}")
0.333333
>>> print(f"{np.corrcoef(v1[1:], v2[1:])[0][1]:.6f}")
0.916949
>>> s1 = pd.Series(v1)
>>> s2 = pd.Series(v2)
>>> s1.rolling(4).corr(s2)
0         NaN
1         NaN
2         NaN
3    0.333333
4    0.916949
dtype: float64
```

The below example shows a similar rolling calculation on a DataFrame using the pairwise option.

```
>>> matrix = np.array([[51., 35.], [49., 30.], [47., 32.],    [46., 31.], [50.,␣
↪36.]])
>>> print(np.corrcoef(matrix[:-1,0], matrix[:-1,1]).round(7))
[[1.         0.6263001]
 [0.6263001  1.       ]]
>>> print(np.corrcoef(matrix[1:,0], matrix[1:,1]).round(7))
[[1.         0.5553681]
 [0.5553681  1.        ]]
>>> df = pd.DataFrame(matrix, columns=['X','Y'])
>>> df
      X     Y
0  51.0  35.0
1  49.0  30.0
2  47.0  32.0
3  46.0  31.0
4  50.0  36.0
>>> df.rolling(4).corr(pairwise=True)
            X         Y
0 X       NaN       NaN
  Y       NaN       NaN
1 X       NaN       NaN
  Y       NaN       NaN
2 X       NaN       NaN
  Y       NaN       NaN
3 X  1.000000  0.626300
  Y  0.626300  1.000000
4 X  1.000000  0.555368
  Y  0.555368  1.000000
```

pandas.core.window.expanding.Expanding.cov

Expanding.**cov**(*other=None*, *pairwise=None*, *ddof=1*, ***kwargs*)

Calculate the expanding sample covariance.

Parameters

other [Series, DataFrame, or ndarray, optional] If not supplied then will default to self and produce pairwise output.

pairwise [bool, default None] If False then only matching columns between self and other will be used and the output will be a DataFrame. If True then all pairwise combinations will be calculated and the output will be a MultiIndexed DataFrame in the case of DataFrame inputs. In the case of missing elements, only complete pairwise observations will be used.

ddof [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is `N - ddof`, where `N` represents the number of elements.

****kwargs** Keyword arguments to be passed into func.

Returns

Series or DataFrame Return type is determined by the caller.

See also:

pandas.Series.expanding Calling object with Series data.
pandas.DataFrame.expanding Calling object with DataFrame data.
pandas.Series.cov Similar method for Series.
pandas.DataFrame.cov Similar method for DataFrame.

pandas.core.window.expanding.Expanding.skew

Expanding.**skew**(***kwargs*)

Unbiased expanding skewness.

Parameters

****kwargs** Keyword arguments to be passed into func.

Returns

Series or DataFrame Return type is determined by the caller.

See also:

pandas.Series.expanding Calling object with Series data.
pandas.DataFrame.expanding Calling object with DataFrame data.
pandas.Series.skew Similar method for Series.
pandas.DataFrame.skew Similar method for DataFrame.

pandas.core.window.expanding.Expanding.kurt

Expanding.**kurt**(***kwargs*)

Calculate unbiased expanding kurtosis.

This function uses Fisher's definition of kurtosis without bias.

Parameters

****kwargs** Under Review.

Returns

Series or DataFrame Returned object type is determined by the caller of the expanding calculation.

See also:

pandas.Series.expanding	Calling object with Series data.
pandas.DataFrame.expanding	Calling object with DataFrames.
pandas.Series.kurt	Equivalent method for Series.
pandas.DataFrame.kurt	Equivalent method for DataFrame.
scipy.stats.skew	Third moment of a probability density.
scipy.stats.kurtosis	Reference SciPy method.

Notes

A minimum of 4 periods is required for the expanding calculation.

Examples

The example below will show an expanding calculation with a window size of four matching the equivalent function call using *scipy.stats*.

```
>>> arr = [1, 2, 3, 4, 999]
>>> import scipy.stats
>>> print(f"{scipy.stats.kurtosis(arr[:-1], bias=False):.6f}")
-1.200000
>>> print(f"{scipy.stats.kurtosis(arr, bias=False):.6f}")
4.999874
>>> s = pd.Series(arr)
>>> s.expanding(4).kurt()
0         NaN
1         NaN
2         NaN
3   -1.200000
4    4.999874
dtype: float64
```

pandas.core.window.expanding.Expanding.apply

Expanding.**apply**(*func*, *raw=False*, *engine=None*, *engine_kwargs=None*, *args=None*, *kwargs=None*)

Apply an arbitrary function to each expanding window.

Parameters

func [function] Must produce a single value from an ndarray input if `raw=True` or a single value from a Series if `raw=False`. Can also accept a Numba JIT function with `engine='numba'` specified.

Changed in version 1.0.0.

raw [bool, default None]

- `False` : passes each row or column as a Series to the function.
- `True` : the passed function will receive ndarray objects instead. If you are just applying a NumPy reduction function this will achieve much better performance.

engine [str, default None]

- `'cython'` : Runs rolling apply through C-extensions from cython.

- `'numba'` : Runs rolling apply through JIT compiled code from numba. Only available when `raw` is set to `True`.
- `None` : Defaults to `'cython'` or globally setting `compute.use_numba`

  New in version 1.0.0.

engine_kwargs [dict, default None]

- For `'cython'` engine, there are no accepted `engine_kwargs`
- For `'numba'` engine, the engine can accept `nopython`, `nogil` and `parallel` dictionary keys. The values must either be `True` or `False`. The default `engine_kwargs` for the `'numba'` engine is `{'nopython': True, 'nogil': False, 'parallel': False}` and will be applied to both the `func` and the `apply` rolling aggregation.

  New in version 1.0.0.

args [tuple, default None] Positional arguments to be passed into func.

kwargs [dict, default None] Keyword arguments to be passed into func.

Returns

Series or DataFrame Return type is determined by the caller.

See also:

pandas.Series.expanding Calling object with Series data.
pandas.DataFrame.expanding Calling object with DataFrame data.
pandas.Series.apply Similar method for Series.
pandas.DataFrame.apply Similar method for DataFrame.

Notes

See *Rolling apply* for extended documentation and performance considerations for the Numba engine.

pandas.core.window.expanding.Expanding.aggregate

`Expanding.`**`aggregate`**(*func*, **args*, ***kwargs*)

Aggregate using one or more operations over the specified axis.

Parameters

func [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a Series/Dataframe or when passed to Series/Dataframe.apply.

Accepted combinations are:

- function
- string function name
- list of functions and/or function names, e.g. `[np.sum, 'mean']`
- dict of axis labels -> functions, function names or list of such.

***args** Positional arguments to pass to *func*.

****kwargs** Keyword arguments to pass to *func*.

Returns

scalar, Series or DataFrame The return can be:

- scalar : when Series.agg is called with single function
- Series : when DataFrame.agg is called with a single function
- DataFrame : when DataFrame.agg is called with several functions

Return scalar, Series or DataFrame.

See also:

pandas.DataFrame.aggregate Similar DataFrame method.
pandas.Series.aggregate Similar Series method.

Notes

agg is an alias for *aggregate*. Use the alias.

A passed user-defined-function will be passed a Series for evaluation.

Examples

```
>>> df = pd.DataFrame({"A": [1, 2, 3], "B": [4, 5, 6], "C": [7, 8, 9]})
>>> df
   A  B  C
0  1  4  7
1  2  5  8
2  3  6  9
```

```
>>> df.ewm(alpha=0.5).mean()
          A         B         C
0  1.000000  4.000000  7.000000
1  1.666667  4.666667  7.666667
2  2.428571  5.428571  8.428571
```

pandas.core.window.expanding.Expanding.quantile

Expanding.**quantile**(*quantile*, *interpolation='linear'*, ***kwargs*)

Calculate the expanding quantile.

Parameters

quantile [float] Quantile to compute. 0 <= quantile <= 1.

interpolation [{'linear', 'lower', 'higher', 'midpoint', 'nearest'}] New in version 0.23.0.

This optional parameter specifies the interpolation method to use, when the desired quantile lies between two data points *i* and *j*:

- linear: *i* + *(j - i)* * *fraction*, where *fraction* is the fractional part of the index surrounded by *i* and *j*.
- lower: *i*.
- higher: *j*.
- nearest: *i* or *j* whichever is nearest.
- midpoint: (*i* + *j*) / 2.

****kwargs** For compatibility with other expanding methods. Has no effect on the result.

Returns

Series or DataFrame Returned object type is determined by the caller of the expanding calculation.

See also:

pandas.Series.quantile Computes value at the given quantile over all data in Series.
pandas.DataFrame.quantile Computes values at the given quantile over requested axis in DataFrame.

Examples

```
>>> s = pd.Series([1, 2, 3, 4])
>>> s.rolling(2).quantile(.4, interpolation='lower')
0    NaN
1    1.0
2    2.0
3    3.0
dtype: float64
```

```
>>> s.rolling(2).quantile(.4, interpolation='midpoint')
0    NaN
1    1.5
2    2.5
3    3.5
dtype: float64
```

3.10.3 Exponentially-weighted moving window functions

ExponentialMovingWindow.mean(*args, **kwargs)	Exponential weighted moving average.
ExponentialMovingWindow.std([bias])	Exponential weighted moving stddev.
ExponentialMovingWindow.var([bias])	Exponential weighted moving variance.
ExponentialMovingWindow.corr([other, pairwise])	Exponential weighted sample correlation.
ExponentialMovingWindow.cov([other, ...])	Exponential weighted sample covariance.

pandas.core.window.ewm.ExponentialMovingWindow.mean

ExponentialMovingWindow.**mean**(**args*, ***kwargs*)

Exponential weighted moving average.

Parameters

***args, **kwargs** Arguments and keyword arguments to be passed into func.

Returns

Series or DataFrame Return type is determined by the caller.

See also:

pandas.Series.ewm Calling object with Series data.
pandas.DataFrame.ewm Calling object with DataFrame data.
pandas.Series.mean Similar method for Series.
pandas.DataFrame.mean Similar method for DataFrame.

pandas.core.window.ewm.ExponentialMovingWindow.std

ExponentialMovingWindow.**std**(*bias=False*, **args*, ***kwargs*)

Exponential weighted moving stddev.

Parameters

bias [bool, default False] Use a standard estimation bias correction.

***args, **kwargs** Arguments and keyword arguments to be passed into func.

Returns

Series or DataFrame Return type is determined by the caller.

See also:

pandas.Series.ewm Calling object with Series data.
pandas.DataFrame.ewm Calling object with DataFrame data.
pandas.Series.std Similar method for Series.
pandas.DataFrame.std Similar method for DataFrame.

pandas.core.window.ewm.ExponentialMovingWindow.var

ExponentialMovingWindow.**var**(*bias=False*, **args*, ***kwargs*)

Exponential weighted moving variance.

Parameters

bias [bool, default False] Use a standard estimation bias correction.

***args, **kwargs** Arguments and keyword arguments to be passed into func.

Returns

Series or DataFrame Return type is determined by the caller.

See also:

pandas.Series.ewm Calling object with Series data.
pandas.DataFrame.ewm Calling object with DataFrame data.
pandas.Series.var Similar method for Series.
pandas.DataFrame.var Similar method for DataFrame.

pandas.core.window.ewm.ExponentialMovingWindow.corr

ExponentialMovingWindow.**corr**(*other=None*, *pairwise=None*, ***kwargs*)

Exponential weighted sample correlation.

Parameters

other [Series, DataFrame, or ndarray, optional] If not supplied then will default to self and produce pairwise output.

pairwise [bool, default None] If False then only matching columns between self and other will be used and the output will be a DataFrame. If True then all pairwise combinations will be calculated and the output will be a MultiIndex DataFrame in the case of DataFrame inputs. In the case of missing elements, only complete pairwise observations will be used.

****kwargs** Keyword arguments to be passed into func.

Returns

Series or DataFrame Return type is determined by the caller.

See also:

pandas.Series.ewm Calling object with Series data.
pandas.DataFrame.ewm Calling object with DataFrame data.
pandas.Series.corr Similar method for Series.
pandas.DataFrame.corr Similar method for DataFrame.

pandas.core.window.ewm.ExponentialMovingWindow.cov

ExponentialMovingWindow.**cov**(*other=None*, *pairwise=None*, *bias=False*, ***kwargs*)

Exponential weighted sample covariance.

Parameters

other [Series, DataFrame, or ndarray, optional] If not supplied then will default to self and produce pairwise output.

pairwise [bool, default None] If False then only matching columns between self and other will be used and the output will be a DataFrame. If True then all pairwise combinations will be calculated and the output will be a MultiIndex DataFrame in the case of DataFrame inputs. In the case of missing elements, only complete pairwise observations will be used.

bias [bool, default False] Use a standard estimation bias correction.

****kwargs** Keyword arguments to be passed into func.

Returns

Series or DataFrame Return type is determined by the caller.

See also:

pandas.Series.ewm Calling object with Series data.
pandas.DataFrame.ewm Calling object with DataFrame data.
pandas.Series.cov Similar method for Series.
pandas.DataFrame.cov Similar method for DataFrame.

3.10.4 Window indexer

Base class for defining custom window boundaries.

api.indexers.BaseIndexer([index_array, ...])	Base class for window bounds calculations.
api.indexers.FixedForwardWindowIndexer([...])	Creates window boundaries for fixed-length windows that include the current row.
api.indexers.VariableOffsetWindowIndexer([...])	Calculate window boundaries based on a non-fixed offset such as a BusinessDay

pandas.api.indexers.BaseIndexer

class pandas.api.indexers.**BaseIndexer**(*index_array=None*, *window_size=0*, ***kwargs*)
Base class for window bounds calculations.

Methods

get_window_bounds([num_values, min_periods, ...])	Computes the bounds of a window.

pandas.api.indexers.BaseIndexer.get_window_bounds

BaseIndexer.**get_window_bounds**(*num_values=0*, *min_periods=None*, *center=None*, *closed=None*)
Computes the bounds of a window.

Parameters

num_values [int, default 0] number of values that will be aggregated over

window_size [int, default 0] the number of rows in a window

min_periods [int, default None] min_periods passed from the top level rolling API

center [bool, default None] center passed from the top level rolling API

closed [str, default None] closed passed from the top level rolling API

win_type [str, default None] win_type passed from the top level rolling API

Returns

A tuple of ndarray[int64]s, indicating the boundaries of each

window

pandas.api.indexers.FixedForwardWindowIndexer

class pandas.api.indexers.**FixedForwardWindowIndexer**(*index_array=None*, *window_size=0*, ***kwargs*)
Creates window boundaries for fixed-length windows that include the current row.

Examples

```
>>> df = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]})
>>> df
     B
0  0.0
1  1.0
2  2.0
3  NaN
4  4.0
```

```
>>> indexer = pd.api.indexers.FixedForwardWindowIndexer(window_size=2)
>>> df.rolling(window=indexer, min_periods=1).sum()
     B
0  1.0
1  3.0
2  2.0
3  4.0
4  4.0
```

Methods

get_window_bounds([num_values, min_periods, ...])	Computes the bounds of a window.

pandas.api.indexers.FixedForwardWindowIndexer.get_window_bounds

FixedForwardWindowIndexer.**get_window_bounds**(*num_values=0*, *min_periods=None*, *center=None*, *closed=None*)

Computes the bounds of a window.

Parameters

num_values [int, default 0] number of values that will be aggregated over

window_size [int, default 0] the number of rows in a window

min_periods [int, default None] min_periods passed from the top level rolling API

center [bool, default None] center passed from the top level rolling API

closed [str, default None] closed passed from the top level rolling API

win_type [str, default None] win_type passed from the top level rolling API

Returns

A tuple of ndarray[int64]s, indicating the boundaries of each

window

pandas.api.indexers.VariableOffsetWindowIndexer

class pandas.api.indexers.**VariableOffsetWindowIndexer**(*index_array=None*, *window_size=0*, *index=None*, *offset=None*, ***kwargs*)

Calculate window boundaries based on a non-fixed offset such as a BusinessDay

Methods

get_window_bounds([num_values, min_periods, ...])	Computes the bounds of a window.

pandas.api.indexers.VariableOffsetWindowIndexer.get_window_bounds

VariableOffsetWindowIndexer.**get_window_bounds**(*num_values=0*, *min_periods=None*, *center=None*, *closed=None*)

Computes the bounds of a window.

Parameters

num_values [int, default 0] number of values that will be aggregated over

window_size [int, default 0] the number of rows in a window

min_periods [int, default None] min_periods passed from the top level rolling API

center [bool, default None] center passed from the top level rolling API

closed [str, default None] closed passed from the top level rolling API

win_type [str, default None] win_type passed from the top level rolling API

Returns

A tuple of ndarray[int64]s, indicating the boundaries of each

window

3.11 GroupBy

GroupBy objects are returned by groupby calls: *pandas.DataFrame.groupby()*, *pandas.Series.groupby()*, etc.

3.11.1 Indexing, iteration

GroupBy.__iter__()	Groupby iterator.
GroupBy.groups	Dict {group name -> group labels}.
GroupBy.indices	Dict {group name -> group indices}.
GroupBy.get_group(name[, obj])	Construct DataFrame from group with provided name.

pandas.core.groupby.GroupBy.__iter__

GroupBy.**__iter__**()
Groupby iterator.

Returns

Generator yielding sequence of (name, subsetted object)

for each group

pandas.core.groupby.GroupBy.groups

property GroupBy.**groups**
Dict {group name -> group labels}.

pandas.core.groupby.GroupBy.indices

property GroupBy.**indices**
Dict {group name -> group indices}.

pandas.core.groupby.GroupBy.get_group

GroupBy.**get_group**(*name*, *obj=None*)
Construct DataFrame from group with provided name.

Parameters

name [object] The name of the group to get as a DataFrame.

obj [DataFrame, default None] The DataFrame to take the DataFrame out of. If it is None, the object groupby was called on will be used.

Returns

group [same type as obj]

Grouper(*args, **kwargs)	A Grouper allows the user to specify a groupby instruction for an object.

pandas.Grouper

class pandas.**Grouper**(**args*, ***kwargs*)
A Grouper allows the user to specify a groupby instruction for an object.

This specification will select a column via the key parameter, or if the level and/or axis parameters are given, a level of the index of the target object.

If *axis* and/or *level* are passed as keywords to both *Grouper* and *groupby*, the values passed to *Grouper* take precedence.

Parameters

key [str, defaults to None] Groupby key, which selects the grouping column of the target.

level [name/number, defaults to None] The level for the target index.

freq [str / frequency object, defaults to None] This will groupby the specified frequency if the target selection (via key or level) is a datetime-like object. For full specification of

available frequencies, please see here.

axis [str, int, defaults to 0] Number/name of the axis.

sort [bool, default to False] Whether to sort the resulting labels.

closed [{'left' or 'right'}] Closed end of interval. Only when *freq* parameter is passed.

label [{'left' or 'right'}] Interval boundary to use for labeling. Only when *freq* parameter is passed.

convention [{'start', 'end', 'e', 's'}] If grouper is PeriodIndex and *freq* parameter is passed.

base [int, default 0] Only when *freq* parameter is passed. For frequencies that evenly subdivide 1 day, the "origin" of the aggregated intervals. For example, for '5min' frequency, base could range from 0 through 4. Defaults to 0.

Deprecated since version 1.1.0: The new arguments that you should use are 'offset' or 'origin'.

loffset [str, DateOffset, timedelta object] Only when *freq* parameter is passed.

Deprecated since version 1.1.0: loffset is only working for `.resample(...)` and not for Grouper (GH28302). However, loffset is also deprecated for `.resample(...)` See: *DataFrame.resample*

origin [{'epoch', 'start', 'start_day'}, Timestamp or str, default 'start_day'] The timestamp on which to adjust the grouping. The timezone of origin must match the timezone of the index. If a timestamp is not used, these values are also supported:

- 'epoch': *origin* is 1970-01-01
- 'start': *origin* is the first value of the timeseries
- 'start_day': *origin* is the first day at midnight of the timeseries

New in version 1.1.0.

offset [Timedelta or str, default is None] An offset timedelta added to the origin.

New in version 1.1.0.

Returns

A specification for a groupby instruction

Examples

Syntactic sugar for `df.groupby('A')`

```
>>> df = pd.DataFrame(
...     {
...         "Animal": ["Falcon", "Parrot", "Falcon", "Falcon", "Parrot"],
...         "Speed": [100, 5, 200, 300, 15],
...     }
... )
>>> df
   Animal  Speed
0  Falcon    100
1  Parrot      5
2  Falcon    200
3  Falcon    300
4  Parrot     15
```

(continues on next page)

(continued from previous page)

```
>>> df.groupby(pd.Grouper(key="Animal")).mean()
        Speed
Animal
Falcon    200
Parrot     10
```

Specify a resample operation on the column 'Publish date'

```
>>> df = pd.DataFrame(
...     {
...         "Publish date": [
...              pd.Timestamp("2000-01-02"),
...              pd.Timestamp("2000-01-02"),
...              pd.Timestamp("2000-01-09"),
...              pd.Timestamp("2000-01-16")
...          ],
...          "ID": [0, 1, 2, 3],
...          "Price": [10, 20, 30, 40]
...      }
... )
>>> df
  Publish date  ID  Price
0   2000-01-02   0     10
1   2000-01-02   1     20
2   2000-01-09   2     30
3   2000-01-16   3     40
>>> df.groupby(pd.Grouper(key="Publish date", freq="1W")).mean()
                ID  Price
Publish date
2000-01-02    0.5   15.0
2000-01-09    2.0   30.0
2000-01-16    3.0   40.0
```

If you want to adjust the start of the bins based on a fixed timestamp:

```
>>> start, end = '2000-10-01 23:30:00', '2000-10-02 00:30:00'
>>> rng = pd.date_range(start, end, freq='7min')
>>> ts = pd.Series(np.arange(len(rng)) * 3, index=rng)
>>> ts
2000-10-01 23:30:00     0
2000-10-01 23:37:00     3
2000-10-01 23:44:00     6
2000-10-01 23:51:00     9
2000-10-01 23:58:00    12
2000-10-02 00:05:00    15
2000-10-02 00:12:00    18
2000-10-02 00:19:00    21
2000-10-02 00:26:00    24
Freq: 7T, dtype: int64
```

```
>>> ts.groupby(pd.Grouper(freq='17min')).sum()
2000-10-01 23:14:00     0
2000-10-01 23:31:00     9
2000-10-01 23:48:00    21
2000-10-02 00:05:00    54
2000-10-02 00:22:00    24
Freq: 17T, dtype: int64
```

```
>>> ts.groupby(pd.Grouper(freq='17min', origin='epoch')).sum()
2000-10-01 23:18:00     0
2000-10-01 23:35:00    18
2000-10-01 23:52:00    27
2000-10-02 00:09:00    39
2000-10-02 00:26:00    24
Freq: 17T, dtype: int64
```

```
>>> ts.groupby(pd.Grouper(freq='17min', origin='2000-01-01')).sum()
2000-10-01 23:24:00     3
2000-10-01 23:41:00    15
2000-10-01 23:58:00    45
2000-10-02 00:15:00    45
Freq: 17T, dtype: int64
```

If you want to adjust the start of the bins with an *offset* Timedelta, the two following lines are equivalent:

```
>>> ts.groupby(pd.Grouper(freq='17min', origin='start')).sum()
2000-10-01 23:30:00     9
2000-10-01 23:47:00    21
2000-10-02 00:04:00    54
2000-10-02 00:21:00    24
Freq: 17T, dtype: int64
```

```
>>> ts.groupby(pd.Grouper(freq='17min', offset='23h30min')).sum()
2000-10-01 23:30:00     9
2000-10-01 23:47:00    21
2000-10-02 00:04:00    54
2000-10-02 00:21:00    24
Freq: 17T, dtype: int64
```

To replace the use of the deprecated *base* argument, you can now use *offset*, in this example it is equivalent to have *base=2*:

```
>>> ts.groupby(pd.Grouper(freq='17min', offset='2min')).sum()
2000-10-01 23:16:00     0
2000-10-01 23:33:00     9
2000-10-01 23:50:00    36
2000-10-02 00:07:00    39
2000-10-02 00:24:00    24
Freq: 17T, dtype: int64
```

Attributes

ax	
groups	

3.11.2 Function application

`GroupBy.apply`(func, *args, **kwargs)	Apply function *func* group-wise and combine the results together.
`GroupBy.agg`(func, *args, **kwargs)	
`SeriesGroupBy.aggregate`([func, engine, ...])	Aggregate using one or more operations over the specified axis.
`DataFrameGroupBy.aggregate`([func, engine, ...])	Aggregate using one or more operations over the specified axis.
`SeriesGroupBy.transform`(func, *args[, ...])	Call function producing a like-indexed Series on each group and return a Series having the same indexes as the original object filled with the transformed values
`DataFrameGroupBy.transform`(func, *args[, ...])	Call function producing a like-indexed DataFrame on each group and return a DataFrame having the same indexes as the original object filled with the transformed values
`GroupBy.pipe`(func, *args, **kwargs)	Apply a function *func* with arguments to this GroupBy object and return the function's result.

pandas.core.groupby.GroupBy.apply

GroupBy.**apply**(*func*, **args*, ***kwargs*)

Apply function *func* group-wise and combine the results together.

The function passed to *apply* must take a dataframe as its first argument and return a DataFrame, Series or scalar. *apply* will then take care of combining the results back together into a single dataframe or series. *apply* is therefore a highly flexible grouping method.

While *apply* is a very flexible method, its downside is that using it can be quite a bit slower than using more specific methods like *agg* or *transform*. Pandas offers a wide range of method that will be much faster than using *apply* for their specific purposes, so try to use them before reaching for *apply*.

Parameters

func [callable] A callable that takes a dataframe as its first argument, and returns a dataframe, a series or a scalar. In addition the callable may take positional and keyword arguments.

args, kwargs [tuple and dict] Optional positional and keyword arguments to pass to *func*.

Returns

applied [Series or DataFrame]

See also:

pipe Apply function to the full GroupBy object instead of to each group.
aggregate Apply aggregate function to the GroupBy object.
transform Apply function column-by-column to the GroupBy object.
Series.apply Apply a function to a Series.
DataFrame.apply Apply a function to each row or column of a DataFrame.

pandas.core.groupby.GroupBy.agg

GroupBy.**agg**(*func*, **args*, ***kwargs*)

pandas.core.groupby.SeriesGroupBy.aggregate

SeriesGroupBy.**aggregate**(*func=None*, **args*, *engine=None*, *engine_kwargs=None*, ***kwargs*)

Aggregate using one or more operations over the specified axis.

Parameters

func [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a Series or when passed to Series.apply.

Accepted combinations are:

- function
- string function name
- list of functions and/or function names, e.g. `[np.sum, 'mean']`
- dict of axis labels -> functions, function names or list of such.

Can also accept a Numba JIT function with `engine='numba'` specified.

If the `'numba'` engine is chosen, the function must be a user defined function with `values` and `index` as the first and second arguments respectively in the function signature. Each group's index will be passed to the user defined function and optionally available for use.

Changed in version 1.1.0.

***args** Positional arguments to pass to func

engine [str, default None]

- `'cython'` : Runs the function through C-extensions from cython.
- `'numba'` : Runs the function through JIT compiled code from numba.
- `None` : Defaults to `'cython'` or globally setting `compute.use_numba`

New in version 1.1.0.

engine_kwargs [dict, default None]

- For `'cython'` engine, there are no accepted `engine_kwargs`
- For `'numba'` engine, the engine can accept `nopython`, `nogil` and `parallel` dictionary keys. The values must either be `True` or `False`. The default `engine_kwargs` for the `'numba'` engine is `{'nopython': True, 'nogil': False, 'parallel': False}` and will be applied to the function

New in version 1.1.0.

****kwargs** Keyword arguments to be passed into func.

Returns

Series

See also:

`Series.groupby.apply`
`Series.groupby.transform`

Series.aggregate

Notes

When using `engine='numba'`, there will be no "fall back" behavior internally. The group data and group index will be passed as numpy arrays to the JITed user defined function, and no alternative execution attempts will be tried.

Examples

```
>>> s = pd.Series([1, 2, 3, 4])
```

```
>>> s
0    1
1    2
2    3
3    4
dtype: int64
```

```
>>> s.groupby([1, 1, 2, 2]).min()
1    1
2    3
dtype: int64
```

```
>>> s.groupby([1, 1, 2, 2]).agg('min')
1    1
2    3
dtype: int64
```

```
>>> s.groupby([1, 1, 2, 2]).agg(['min', 'max'])
   min  max
1    1    2
2    3    4
```

The output column names can be controlled by passing the desired column names and aggregations as keyword arguments.

```
>>> s.groupby([1, 1, 2, 2]).agg(
...     minimum='min',
...     maximum='max',
... )
   minimum  maximum
1        1        2
2        3        4
```

pandas.core.groupby.DataFrameGroupBy.aggregate

DataFrameGroupBy.**aggregate**(*func=None*, **args*, *engine=None*, *engine_kwargs=None*, ***kwargs*)

Aggregate using one or more operations over the specified axis.

Parameters

func [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a DataFrame or when passed to DataFrame.apply.

Accepted combinations are:

- function
- string function name
- list of functions and/or function names, e.g. `[np.sum, 'mean']`
- dict of axis labels -> functions, function names or list of such.

Can also accept a Numba JIT function with `engine='numba'` specified.

If the `'numba'` engine is chosen, the function must be a user defined function with `values` and `index` as the first and second arguments respectively in the function signature. Each group's index will be passed to the user defined function and optionally available for use.

Changed in version 1.1.0.

***args** Positional arguments to pass to func

engine [str, default None]

- `'cython'` : Runs the function through C-extensions from cython.
- `'numba'` : Runs the function through JIT compiled code from numba.
- `None` : Defaults to `'cython'` or globally setting `compute.use_numba`

New in version 1.1.0.

engine_kwargs [dict, default None]

- For `'cython'` engine, there are no accepted `engine_kwargs`
- For `'numba'` engine, the engine can accept `nopython`, `nogil` and `parallel` dictionary keys. The values must either be `True` or `False`. The default `engine_kwargs` for the `'numba'` engine is `{'nopython': True, 'nogil': False, 'parallel': False}` and will be applied to the function

New in version 1.1.0.

****kwargs** Keyword arguments to be passed into func.

Returns

DataFrame

See also:

DataFrame.groupby.apply
DataFrame.groupby.transform
DataFrame.aggregate

Notes

When using `engine='numba'`, there will be no "fall back" behavior internally. The group data and group index will be passed as numpy arrays to the JITed user defined function, and no alternative execution attempts will be tried.

Examples

```
>>> df = pd.DataFrame(
...     {
...         "A": [1, 1, 2, 2],
...         "B": [1, 2, 3, 4],
...         "C": [0.362838, 0.227877, 1.267767, -0.562860],
...     }
... )
```

```
>>> df
   A  B         C
0  1  1  0.362838
1  1  2  0.227877
2  2  3  1.267767
3  2  4 -0.562860
```

The aggregation is for each column.

```
>>> df.groupby('A').agg('min')
   B         C
A
1  1  0.227877
2  3 -0.562860
```

Multiple aggregations

```
>>> df.groupby('A').agg(['min', 'max'])
    B             C
  min max       min       max
A
1   1   2  0.227877  0.362838
2   3   4 -0.562860  1.267767
```

Select a column for aggregation

```
>>> df.groupby('A').B.agg(['min', 'max'])
   min  max
A
1    1    2
2    3    4
```

Different aggregations per column

```
>>> df.groupby('A').agg({'B': ['min', 'max'], 'C': 'sum'})
    B             C
  min max       sum
A
1   1   2  0.590715
2   3   4  0.704907
```

To control the output names with different aggregations per column, pandas supports "named aggregation"

```
>>> df.groupby("A").agg(
...     b_min=pd.NamedAgg(column="B", aggfunc="min"),
...     c_sum=pd.NamedAgg(column="C", aggfunc="sum"))
   b_min     c_sum
A
1      1  0.590715
2      3  0.704907
```

- The keywords are the *output* column names
- The values are tuples whose first element is the column to select and the second element is the aggregation to apply to that column. Pandas provides the `pandas.NamedAgg` namedtuple with the fields `['column', 'aggfunc']` to make it clearer what the arguments are. As usual, the aggregation can be a callable or a string alias.

See *Named aggregation* for more.

pandas.core.groupby.SeriesGroupBy.transform

`SeriesGroupBy.`**`transform`**(*func*, **args*, *engine=None*, *engine_kwargs=None*, ***kwargs*)

Call function producing a like-indexed Series on each group and return a Series having the same indexes as the original object filled with the transformed values

Parameters

f [function] Function to apply to each group.

Can also accept a Numba JIT function with `engine='numba'` specified.

If the `'numba'` engine is chosen, the function must be a user defined function with `values` and `index` as the first and second arguments respectively in the function signature. Each group's index will be passed to the user defined function and optionally available for use.

Changed in version 1.1.0.

***args** Positional arguments to pass to func

engine [str, default None]

- `'cython'` : Runs the function through C-extensions from cython.
- `'numba'` : Runs the function through JIT compiled code from numba.
- `None` : Defaults to `'cython'` or globally setting `compute.use_numba`

New in version 1.1.0.

engine_kwargs [dict, default None]

- For `'cython'` engine, there are no accepted `engine_kwargs`
- For `'numba'` engine, the engine can accept `nopython`, `nogil` and `parallel` dictionary keys. The values must either be `True` or `False`. The default `engine_kwargs` for the `'numba'` engine is `{'nopython': True, 'nogil': False, 'parallel': False}` and will be applied to the function

New in version 1.1.0.

****kwargs** Keyword arguments to be passed into func.

Returns

Series

See also:

`Series.groupby.apply`
`Series.groupby.aggregate`
`Series.transform`

Notes

Each group is endowed the attribute 'name' in case you need to know which group you are working on.

The current implementation imposes three requirements on f:

- f must return a value that either has the same shape as the input subframe or can be broadcast to the shape of the input subframe. For example, if *f* returns a scalar it will be broadcast to have the same shape as the input subframe.
- if this is a DataFrame, f must support application column-by-column in the subframe. If f also supports application to the entire subframe, then a fast path is used starting from the second chunk.
- f must not mutate groups. Mutation is not supported and may produce unexpected results.

When using `engine='numba'`, there will be no "fall back" behavior internally. The group data and group index will be passed as numpy arrays to the JITed user defined function, and no alternative execution attempts will be tried.

Examples

```
>>> df = pd.DataFrame({'A' : ['foo', 'bar', 'foo', 'bar',
...                           'foo', 'bar'],
...                    'B' : ['one', 'one', 'two', 'three',
...                           'two', 'two'],
...                    'C' : [1, 5, 5, 2, 5, 5],
...                    'D' : [2.0, 5., 8., 1., 2., 9.]})
>>> grouped = df.groupby('A')
>>> grouped.transform(lambda x: (x - x.mean()) / x.std())
          C         D
0 -1.154701 -0.577350
1  0.577350  0.000000
2  0.577350  1.154701
3 -1.154701 -1.000000
4  0.577350 -0.577350
5  0.577350  1.000000
```

Broadcast result of the transformation

```
>>> grouped.transform(lambda x: x.max() - x.min())
   C    D
0  4  6.0
1  3  8.0
2  4  6.0
3  3  8.0
4  4  6.0
5  3  8.0
```

pandas.core.groupby.DataFrameGroupBy.transform

DataFrameGroupBy.**transform**(*func*, **args*, *engine=None*, *engine_kwargs=None*, ***kwargs*)

Call function producing a like-indexed DataFrame on each group and return a DataFrame having the same indexes as the original object filled with the transformed values

Parameters

f [function] Function to apply to each group.

Can also accept a Numba JIT function with `engine='numba'` specified.

If the `'numba'` engine is chosen, the function must be a user defined function with `values` and `index` as the first and second arguments respectively in the function signature. Each group's index will be passed to the user defined function and optionally available for use.

Changed in version 1.1.0.

***args** Positional arguments to pass to func

engine [str, default None]

- `'cython'` : Runs the function through C-extensions from cython.
- `'numba'` : Runs the function through JIT compiled code from numba.
- `None` : Defaults to `'cython'` or globally setting `compute.use_numba`

New in version 1.1.0.

engine_kwargs [dict, default None]

- For `'cython'` engine, there are no accepted `engine_kwargs`
- For `'numba'` engine, the engine can accept `nopython`, `nogil` and `parallel` dictionary keys. The values must either be `True` or `False`. The default `engine_kwargs` for the `'numba'` engine is `{'nopython': True, 'nogil': False, 'parallel': False}` and will be applied to the function

New in version 1.1.0.

****kwargs** Keyword arguments to be passed into func.

Returns

DataFrame

See also:

DataFrame.groupby.apply
DataFrame.groupby.aggregate
DataFrame.transform

Notes

Each group is endowed the attribute 'name' in case you need to know which group you are working on.

The current implementation imposes three requirements on f:

- f must return a value that either has the same shape as the input subframe or can be broadcast to the shape of the input subframe. For example, if *f* returns a scalar it will be broadcast to have the same shape as the input subframe.
- if this is a DataFrame, f must support application column-by-column in the subframe. If f also supports application to the entire subframe, then a fast path is used starting from the second chunk.
- f must not mutate groups. Mutation is not supported and may produce unexpected results.

When using `engine='numba'`, there will be no "fall back" behavior internally. The group data and group index will be passed as numpy arrays to the JITed user defined function, and no alternative execution attempts will be tried.

Examples

```
>>> df = pd.DataFrame({'A' : ['foo', 'bar', 'foo', 'bar',
...                           'foo', 'bar'],
...                    'B' : ['one', 'one', 'two', 'three',
...                           'two', 'two'],
...                    'C' : [1, 5, 5, 2, 5, 5],
...                    'D' : [2.0, 5., 8., 1., 2., 9.]})
>>> grouped = df.groupby('A')
>>> grouped.transform(lambda x: (x - x.mean()) / x.std())
          C         D
0 -1.154701 -0.577350
1  0.577350  0.000000
2  0.577350  1.154701
3 -1.154701 -1.000000
4  0.577350 -0.577350
5  0.577350  1.000000
```

Broadcast result of the transformation

```
>>> grouped.transform(lambda x: x.max() - x.min())
   C    D
0  4  6.0
1  3  8.0
2  4  6.0
3  3  8.0
4  4  6.0
5  3  8.0
```

pandas.core.groupby.GroupBy.pipe

`GroupBy.`**`pipe`**(*func*, **args*, ***kwargs*)

Apply a function *func* with arguments to this GroupBy object and return the function's result.

New in version 0.21.0.

Use *.pipe* when you want to improve readability by chaining together functions that expect Series, DataFrames, GroupBy or Resampler objects. Instead of writing

```
>>> h(g(f(df.groupby('group')), arg1=a), arg2=b, arg3=c)
```

You can write

```
>>> (df.groupby('group')
...    .pipe(f)
...    .pipe(g, arg1=a)
...    .pipe(h, arg2=b, arg3=c))
```

which is much more readable.

Parameters

func [callable or tuple of (callable, str)] Function to apply to this GroupBy object or, alternatively, a *(callable, data_keyword)* tuple where *data_keyword* is a string indicating the keyword of *callable* that expects the GroupBy object.

args [iterable, optional] Positional arguments passed into *func*.

kwargs [dict, optional] A dictionary of keyword arguments passed into *func*.

Returns

object [the return type of *func*.]

See also:

`Series.pipe` Apply a function with arguments to a series.
`DataFrame.pipe` Apply a function with arguments to a dataframe.
`apply` Apply function to each group instead of to the full GroupBy object.

Notes

See more here

Examples

```
>>> df = pd.DataFrame({'A': 'a b a b'.split(), 'B': [1, 2, 3, 4]})
>>> df
   A  B
0  a  1
1  b  2
2  a  3
3  b  4
```

To get the difference between each groups maximum and minimum value in one pass, you can do

```
>>> df.groupby('A').pipe(lambda x: x.max() - x.min())
   B
A
a  2
b  2
```

3.11.3 Computations / descriptive stats

GroupBy.all([skipna])	Return True if all values in the group are truthful, else False.
GroupBy.any([skipna])	Return True if any value in the group is truthful, else False.
GroupBy.bfill([limit])	Backward fill the values.
GroupBy.backfill([limit])	Backward fill the values.
GroupBy.count()	Compute count of group, excluding missing values.
GroupBy.cumcount([ascending])	Number each item in each group from 0 to the length of that group - 1.
GroupBy.cummax([axis])	Cumulative max for each group.
GroupBy.cummin([axis])	Cumulative min for each group.
GroupBy.cumprod([axis])	Cumulative product for each group.
GroupBy.cumsum([axis])	Cumulative sum for each group.
GroupBy.ffill([limit])	Forward fill the values.
GroupBy.first([numeric_only, min_count])	Compute first of group values.
GroupBy.head([n])	Return first n rows of each group.
GroupBy.last([numeric_only, min_count])	Compute last of group values.
GroupBy.max([numeric_only, min_count])	Compute max of group values.
GroupBy.mean([numeric_only])	Compute mean of groups, excluding missing values.
GroupBy.median([numeric_only])	Compute median of groups, excluding missing values.
GroupBy.min([numeric_only, min_count])	Compute min of group values.
GroupBy.ngroup([ascending])	Number each group from 0 to the number of groups - 1.
GroupBy.nth(n[, dropna])	Take the nth row from each group if n is an int, or a subset of rows if n is a list of ints.
GroupBy.ohlc()	Compute open, high, low and close values of a group, excluding missing values.
GroupBy.pad([limit])	Forward fill the values.
GroupBy.prod([numeric_only, min_count])	Compute prod of group values.
GroupBy.rank([method, ascending, na_option, ...])	Provide the rank of values within each group.
GroupBy.pct_change([periods, fill_method, ...])	Calculate pct_change of each value to previous entry in group.
GroupBy.size()	Compute group sizes.
GroupBy.sem([ddof])	Compute standard error of the mean of groups, excluding missing values.
GroupBy.std([ddof])	Compute standard deviation of groups, excluding missing values.
GroupBy.sum([numeric_only, min_count])	Compute sum of group values.
GroupBy.var([ddof])	Compute variance of groups, excluding missing values.
GroupBy.tail([n])	Return last n rows of each group.

pandas.core.groupby.GroupBy.all

GroupBy.**all**(*skipna=True*)

Return True if all values in the group are truthful, else False.

Parameters

skipna [bool, default True] Flag to ignore nan values during truth testing.

Returns

bool

See also:

Series.groupby
DataFrame.groupby

pandas.core.groupby.GroupBy.any

GroupBy.**any**(*skipna=True*)

Return True if any value in the group is truthful, else False.

Parameters

skipna [bool, default True] Flag to ignore nan values during truth testing.

Returns

bool

See also:

Series.groupby
DataFrame.groupby

pandas.core.groupby.GroupBy.bfill

GroupBy.**bfill**(*limit=None*)

Backward fill the values.

Parameters

limit [int, optional] Limit of how many values to fill.

Returns

Series or DataFrame Object with missing values filled.

See also:

Series.backfill
DataFrame.backfill
Series.fillna
DataFrame.fillna

pandas.core.groupby.GroupBy.backfill

GroupBy.**backfill**(*limit=None*)

Backward fill the values.

Parameters

limit [int, optional] Limit of how many values to fill.

Returns

Series or DataFrame Object with missing values filled.

See also:

Series.backfill
DataFrame.backfill
Series.fillna
DataFrame.fillna

pandas.core.groupby.GroupBy.count

GroupBy.**count**()

Compute count of group, excluding missing values.

Returns

Series or DataFrame Count of values within each group.

See also:

Series.groupby
DataFrame.groupby

pandas.core.groupby.GroupBy.cumcount

GroupBy.**cumcount**(*ascending=True*)

Number each item in each group from 0 to the length of that group - 1.

Essentially this is equivalent to

```
self.apply(lambda x: pd.Series(np.arange(len(x)), x.index))
```

Parameters

ascending [bool, default True] If False, number in reverse, from length of group - 1 to 0.

Returns

Series Sequence number of each element within each group.

See also:

ngroup Number the groups themselves.

Examples

```
>>> df = pd.DataFrame([['a'], ['a'], ['a'], ['b'], ['b'], ['a']],
...                   columns=['A'])
>>> df
   A
0  a
1  a
2  a
3  b
4  b
5  a
>>> df.groupby('A').cumcount()
0    0
1    1
2    2
3    0
4    1
5    3
dtype: int64
>>> df.groupby('A').cumcount(ascending=False)
0    3
1    2
2    1
3    1
4    0
5    0
dtype: int64
```

pandas.core.groupby.GroupBy.cummax

GroupBy.**cummax**(*axis=0*, ***kwargs*)

Cumulative max for each group.

Returns

Series or DataFrame

See also:

Series.groupby
DataFrame.groupby

pandas.core.groupby.GroupBy.cummin

GroupBy.**cummin**(*axis=0*, ***kwargs*)

Cumulative min for each group.

Returns

Series or DataFrame

See also:

Series.groupby
DataFrame.groupby

pandas.core.groupby.GroupBy.cumprod

GroupBy.**cumprod**(*axis=0*, **args*, ***kwargs*)

Cumulative product for each group.

Returns

Series or DataFrame

See also:

Series.groupby
DataFrame.groupby

pandas.core.groupby.GroupBy.cumsum

GroupBy.**cumsum**(*axis=0*, **args*, ***kwargs*)

Cumulative sum for each group.

Returns

Series or DataFrame

See also:

Series.groupby
DataFrame.groupby

pandas.core.groupby.GroupBy.ffill

GroupBy.**ffill**(*limit=None*)

Forward fill the values.

Parameters

limit [int, optional] Limit of how many values to fill.

Returns

Series or DataFrame Object with missing values filled.

See also:

Series.pad
DataFrame.pad
Series.fillna
DataFrame.fillna

pandas.core.groupby.GroupBy.first

GroupBy.**first**(*numeric_only=False*, *min_count=- 1*)

Compute first of group values.

Parameters

numeric_only [bool, default False] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

min_count [int, default -1] The required number of valid values to perform the operation. If fewer than `min_count` non-NA values are present the result will be NA.

Returns

Series or DataFrame Computed first of values within each group.

pandas.core.groupby.GroupBy.head

GroupBy.**head**(*n=5*)

Return first n rows of each group.

Similar to `.apply(lambda x: x.head(n))`, but it returns a subset of rows from the original DataFrame with original index and order preserved (`as_index` flag is ignored).

Does not work for negative values of *n*.

Returns

Series or DataFrame

See also:

Series.groupby
DataFrame.groupby

Examples

```
>>> df = pd.DataFrame([[1, 2], [1, 4], [5, 6]],
...                   columns=['A', 'B'])
>>> df.groupby('A').head(1)
   A  B
0  1  2
2  5  6
>>> df.groupby('A').head(-1)
Empty DataFrame
Columns: [A, B]
Index: []
```

pandas.core.groupby.GroupBy.last

GroupBy.**last**(*numeric_only=False*, *min_count=- 1*)

Compute last of group values.

Parameters

numeric_only [bool, default False] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

min_count [int, default -1] The required number of valid values to perform the operation. If fewer than `min_count` non-NA values are present the result will be NA.

Returns

Series or DataFrame Computed last of values within each group.

pandas.core.groupby.GroupBy.max

GroupBy.**max**(*numeric_only=False*, *min_count=- 1*)

Compute max of group values.

Parameters

numeric_only [bool, default False] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

min_count [int, default -1] The required number of valid values to perform the operation. If fewer than `min_count` non-NA values are present the result will be NA.

Returns

Series or DataFrame Computed max of values within each group.

pandas.core.groupby.GroupBy.mean

GroupBy.**mean**(*numeric_only=True*)

Compute mean of groups, excluding missing values.

Parameters

numeric_only [bool, default True] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

Returns

pandas.Series or pandas.DataFrame

See also:

Series.groupby
DataFrame.groupby

Examples

```
>>> df = pd.DataFrame({'A': [1, 1, 2, 1, 2],
...                    'B': [np.nan, 2, 3, 4, 5],
...                    'C': [1, 2, 1, 1, 2]}, columns=['A', 'B', 'C'])
```

Groupby one column and return the mean of the remaining columns in each group.

```
>>> df.groupby('A').mean()
     B         C
A
1  3.0  1.333333
2  4.0  1.500000
```

Groupby two columns and return the mean of the remaining column.

```
>>> df.groupby(['A', 'B']).mean()
       C
A B
1 2.0  2
  4.0  1
2 3.0  1
  5.0  2
```

Groupby one column and return the mean of only particular column in the group.

```
>>> df.groupby('A')['B'].mean()
A
1    3.0
2    4.0
Name: B, dtype: float64
```

pandas.core.groupby.GroupBy.median

GroupBy.**median**(*numeric_only=True*)

Compute median of groups, excluding missing values.

For multiple groupings, the result index will be a MultiIndex

Parameters

numeric_only [bool, default True] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

Returns

Series or DataFrame Median of values within each group.

See also:

Series.groupby
DataFrame.groupby

pandas.core.groupby.GroupBy.min

GroupBy.**min**(*numeric_only=False*, *min_count=- 1*)

Compute min of group values.

Parameters

numeric_only [bool, default False] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

min_count [int, default -1] The required number of valid values to perform the operation. If fewer than `min_count` non-NA values are present the result will be NA.

Returns

Series or DataFrame Computed min of values within each group.

pandas.core.groupby.GroupBy.ngroup

GroupBy.**ngroup**(*ascending=True*)

Number each group from 0 to the number of groups - 1.

This is the enumerative complement of cumcount. Note that the numbers given to the groups match the order in which the groups would be seen when iterating over the groupby object, not the order they are first observed.

Parameters

ascending [bool, default True] If False, number in reverse, from number of group - 1 to 0.

Returns

Series Unique numbers for each group.

See also:

cumcount Number the rows in each group.

Examples

```
>>> df = pd.DataFrame({"A": list("aaabba")})
>>> df
   A
0  a
1  a
2  a
3  b
4  b
5  a
>>> df.groupby('A').ngroup()
0    0
1    0
2    0
3    1
4    1
5    0
dtype: int64
>>> df.groupby('A').ngroup(ascending=False)
0    1
1    1
2    1
3    0
4    0
5    1
dtype: int64
>>> df.groupby(["A", [1,1,2,3,2,1]]).ngroup()
0    0
1    0
2    1
3    3
4    2
5    0
dtype: int64
```

pandas.core.groupby.GroupBy.nth

GroupBy.**nth**(*n*, *dropna=None*)

Take the nth row from each group if n is an int, or a subset of rows if n is a list of ints.

If dropna, will take the nth non-null row, dropna is either 'all' or 'any'; this is equivalent to calling dropna(how=dropna) before the groupby.

Parameters

n [int or list of ints] A single nth value for the row or a list of nth values.

dropna [None or str, optional] Apply the specified dropna operation before counting which row is the nth row. Needs to be None, 'any' or 'all'.

Returns

Series or DataFrame N-th value within each group.

See also:

Series.groupby
DataFrame.groupby

Examples

```
>>> df = pd.DataFrame({'A': [1, 1, 2, 1, 2],
...                    'B': [np.nan, 2, 3, 4, 5]}, columns=['A', 'B'])
>>> g = df.groupby('A')
>>> g.nth(0)
     B
A
1  NaN
2  3.0
>>> g.nth(1)
     B
A
1  2.0
2  5.0
>>> g.nth(-1)
     B
A
1  4.0
2  5.0
>>> g.nth([0, 1])
     B
A
1  NaN
1  2.0
2  3.0
2  5.0
```

Specifying *dropna* allows count ignoring `NaN`

```
>>> g.nth(0, dropna='any')
     B
A
1  2.0
2  3.0
```

NaNs denote group exhausted when using dropna

```
>>> g.nth(3, dropna='any')
    B
A
1 NaN
2 NaN
```

Specifying *as_index=False* in *groupby* keeps the original index.

```
>>> df.groupby('A', as_index=False).nth(1)
   A    B
1  1  2.0
4  2  5.0
```

pandas.core.groupby.GroupBy.ohlc

GroupBy.**ohlc**()

Compute open, high, low and close values of a group, excluding missing values.

For multiple groupings, the result index will be a MultiIndex

Returns

DataFrame Open, high, low and close values within each group.

See also:

Series.groupby
DataFrame.groupby

pandas.core.groupby.GroupBy.pad

GroupBy.**pad**(*limit=None*)

Forward fill the values.

Parameters

limit [int, optional] Limit of how many values to fill.

Returns

Series or DataFrame Object with missing values filled.

See also:

Series.pad
DataFrame.pad
Series.fillna
DataFrame.fillna

pandas.core.groupby.GroupBy.prod

GroupBy.**prod**(*numeric_only=True*, *min_count=0*)

Compute prod of group values.

Parameters

numeric_only [bool, default True] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

min_count [int, default 0] The required number of valid values to perform the operation. If fewer than `min_count` non-NA values are present the result will be NA.

Returns

Series or DataFrame Computed prod of values within each group.

pandas.core.groupby.GroupBy.rank

GroupBy.**rank**(*method='average'*, *ascending=True*, *na_option='keep'*, *pct=False*, *axis=0*)

Provide the rank of values within each group.

Parameters

method [{'average', 'min', 'max', 'first', 'dense'}, default 'average']

- average: average rank of group.
- min: lowest rank in group.
- max: highest rank in group.
- first: ranks assigned in order they appear in the array.
- dense: like 'min', but rank always increases by 1 between groups.

ascending [bool, default True] False for ranks by high (1) to low (N).

na_option [{'keep', 'top', 'bottom'}, default 'keep']

- keep: leave NA values where they are.
- top: smallest rank if ascending.
- bottom: smallest rank if descending.

pct [bool, default False] Compute percentage rank of data within each group.

axis [int, default 0] The axis of the object over which to compute the rank.

Returns

DataFrame with ranking of values within each group

See also:

Series.groupby
DataFrame.groupby

pandas.core.groupby.GroupBy.pct_change

GroupBy.**pct_change**(*periods=1*, *fill_method='pad'*, *limit=None*, *freq=None*, *axis=0*)

Calculate pct_change of each value to previous entry in group.

Returns

Series or DataFrame Percentage changes within each group.

See also:

Series.groupby
DataFrame.groupby

pandas.core.groupby.GroupBy.size

GroupBy.**size**()

Compute group sizes.

Returns

DataFrame or Series Number of rows in each group as a Series if as_index is True or a DataFrame if as_index is False.

See also:

Series.groupby
DataFrame.groupby

pandas.core.groupby.GroupBy.sem

GroupBy.**sem**(*ddof=1*)

Compute standard error of the mean of groups, excluding missing values.

For multiple groupings, the result index will be a MultiIndex.

Parameters

ddof [int, default 1] Degrees of freedom.

Returns

Series or DataFrame Standard error of the mean of values within each group.

See also:

Series.groupby
DataFrame.groupby

pandas.core.groupby.GroupBy.std

GroupBy.**std**(*ddof=1*)

Compute standard deviation of groups, excluding missing values.

For multiple groupings, the result index will be a MultiIndex.

Parameters

ddof [int, default 1] Degrees of freedom.

Returns

Series or DataFrame Standard deviation of values within each group.

See also:

Series.groupby
DataFrame.groupby

pandas.core.groupby.GroupBy.sum

GroupBy.**sum**(*numeric_only=True*, *min_count=0*)

Compute sum of group values.

Parameters

numeric_only [bool, default True] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

min_count [int, default 0] The required number of valid values to perform the operation. If fewer than `min_count` non-NA values are present the result will be NA.

Returns

Series or DataFrame Computed sum of values within each group.

pandas.core.groupby.GroupBy.var

GroupBy.**var**(*ddof=1*)

Compute variance of groups, excluding missing values.

For multiple groupings, the result index will be a MultiIndex.

Parameters

ddof [int, default 1] Degrees of freedom.

Returns

Series or DataFrame Variance of values within each group.

See also:

Series.groupby
DataFrame.groupby

pandas.core.groupby.GroupBy.tail

GroupBy.**tail**(*n=5*)

Return last n rows of each group.

Similar to `.apply(lambda x: x.tail(n))`, but it returns a subset of rows from the original DataFrame with original index and order preserved (`as_index` flag is ignored).

Does not work for negative values of *n*.

Returns

Series or DataFrame

See also:

Series.groupby
DataFrame.groupby

Examples

```
>>> df = pd.DataFrame([['a', 1], ['a', 2], ['b', 1], ['b', 2]],
...                   columns=['A', 'B'])
>>> df.groupby('A').tail(1)
   A  B
1  a  2
3  b  2
>>> df.groupby('A').tail(-1)
Empty DataFrame
Columns: [A, B]
Index: []
```

The following methods are available in both `SeriesGroupBy` and `DataFrameGroupBy` objects, but may differ slightly, usually in that the `DataFrameGroupBy` version usually permits the specification of an axis argument, and often an argument indicating whether to restrict application to columns of a specific data type.

DataFrameGroupBy.all([skipna])	Return True if all values in the group are truthful, else False.
DataFrameGroupBy.any([skipna])	Return True if any value in the group is truthful, else False.
DataFrameGroupBy.backfill([limit])	Backward fill the values.
DataFrameGroupBy.bfill([limit])	Backward fill the values.
DataFrameGroupBy.corr	Compute pairwise correlation of columns, excluding NA/null values.
DataFrameGroupBy.count()	Compute count of group, excluding missing values.
DataFrameGroupBy.cov	Compute pairwise covariance of columns, excluding NA/null values.
DataFrameGroupBy.cumcount([ascending])	Number each item in each group from 0 to the length of that group - 1.
DataFrameGroupBy.cummax([axis])	Cumulative max for each group.
DataFrameGroupBy.cummin([axis])	Cumulative min for each group.
DataFrameGroupBy.cumprod([axis])	Cumulative product for each group.
DataFrameGroupBy.cumsum([axis])	Cumulative sum for each group.
DataFrameGroupBy.describe(**kwargs)	Generate descriptive statistics.
DataFrameGroupBy.diff	First discrete difference of element.
DataFrameGroupBy.ffill([limit])	Forward fill the values.
DataFrameGroupBy.fillna	Fill NA/NaN values using the specified method.
DataFrameGroupBy.filter(func[, dropna])	Return a copy of a DataFrame excluding filtered elements.
DataFrameGroupBy.hist	Make a histogram of the DataFrame's.
DataFrameGroupBy.idxmax	Return index of first occurrence of maximum over requested axis.
DataFrameGroupBy.idxmin	Return index of first occurrence of minimum over requested axis.
DataFrameGroupBy.mad	Return the mean absolute deviation of the values for the requested axis.
DataFrameGroupBy.nunique([dropna])	Return DataFrame with counts of unique elements in each position.
DataFrameGroupBy.pad([limit])	Forward fill the values.
DataFrameGroupBy.pct_change([periods, ...])	Calculate pct_change of each value to previous entry in group.

continues on next page

Table 373 – continued from previous page

DataFrameGroupBy.plot	Class implementing the .plot attribute for groupby objects.
DataFrameGroupBy.quantile([q, interpolation])	Return group values at the given quantile, a la numpy.percentile.
DataFrameGroupBy.rank([method, ascending, ...])	Provide the rank of values within each group.
DataFrameGroupBy.resample(rule, *args, **kwargs)	Provide resampling when using a TimeGrouper.
DataFrameGroupBy.sample([n, frac, replace, ...])	Return a random sample of items from each group.
DataFrameGroupBy.shift([periods, freq, ...])	Shift each group by periods observations.
DataFrameGroupBy.size()	Compute group sizes.
DataFrameGroupBy.skew	Return unbiased skew over requested axis.
DataFrameGroupBy.take	Return the elements in the given *positional* indices along an axis.
DataFrameGroupBy.tshift	(DEPRECATED) Shift the time index, using the index's frequency if available.

pandas.core.groupby.DataFrameGroupBy.all

DataFrameGroupBy.**all**(*skipna=True*)

Return True if all values in the group are truthful, else False.

Parameters

skipna [bool, default True] Flag to ignore nan values during truth testing.

Returns

bool

See also:

Series.groupby
DataFrame.groupby

pandas.core.groupby.DataFrameGroupBy.any

DataFrameGroupBy.**any**(*skipna=True*)

Return True if any value in the group is truthful, else False.

Parameters

skipna [bool, default True] Flag to ignore nan values during truth testing.

Returns

bool

See also:

Series.groupby
DataFrame.groupby

pandas.core.groupby.DataFrameGroupBy.backfill

DataFrameGroupBy.**backfill**(*limit=None*)

Backward fill the values.

Parameters

limit [int, optional] Limit of how many values to fill.

Returns

Series or DataFrame Object with missing values filled.

See also:

Series.backfill
DataFrame.backfill
Series.fillna
DataFrame.fillna

pandas.core.groupby.DataFrameGroupBy.bfill

DataFrameGroupBy.**bfill**(*limit=None*)

Backward fill the values.

Parameters

limit [int, optional] Limit of how many values to fill.

Returns

Series or DataFrame Object with missing values filled.

See also:

Series.backfill
DataFrame.backfill
Series.fillna
DataFrame.fillna

pandas.core.groupby.DataFrameGroupBy.corr

property DataFrameGroupBy.**corr**

Compute pairwise correlation of columns, excluding NA/null values.

Parameters

method [{'pearson', 'kendall', 'spearman'} or callable] Method of correlation:

- pearson : standard correlation coefficient
- kendall : Kendall Tau correlation coefficient
- spearman : Spearman rank correlation
- **callable: callable with input two 1d ndarrays** and returning a float. Note that the returned matrix from corr will have 1 along the diagonals and will be symmetric regardless of the callable's behavior.

  New in version 0.24.0.

min_periods [int, optional] Minimum number of observations required per pair of columns to have a valid result. Currently only available for Pearson and Spearman correlation.

Returns

DataFrame Correlation matrix.

See also:

DataFrame.corrwith Compute pairwise correlation with another DataFrame or Series.
Series.corr Compute the correlation between two Series.

Examples

```
>>> def histogram_intersection(a, b):
...     v = np.minimum(a, b).sum().round(decimals=1)
...     return v
>>> df = pd.DataFrame([(.2, .3), (.0, .6), (.6, .0), (.2, .1)],
...                   columns=['dogs', 'cats'])
>>> df.corr(method=histogram_intersection)
      dogs  cats
dogs   1.0   0.3
cats   0.3   1.0
```

pandas.core.groupby.DataFrameGroupBy.count

DataFrameGroupBy.**count**()

Compute count of group, excluding missing values.

Returns

DataFrame Count of values within each group.

pandas.core.groupby.DataFrameGroupBy.cov

property DataFrameGroupBy.**cov**

Compute pairwise covariance of columns, excluding NA/null values.

Compute the pairwise covariance among the series of a DataFrame. The returned data frame is the covariance matrix of the columns of the DataFrame.

Both NA and null values are automatically excluded from the calculation. (See the note below about bias from missing values.) A threshold can be set for the minimum number of observations for each value created. Comparisons with observations below this threshold will be returned as `NaN`.

This method is generally used for the analysis of time series data to understand the relationship between different measures across time.

Parameters

min_periods [int, optional] Minimum number of observations required per pair of columns to have a valid result.

ddof [int, default 1] Delta degrees of freedom. The divisor used in calculations is `N - ddof`, where `N` represents the number of elements.

New in version 1.1.0.

Returns

DataFrame The covariance matrix of the series of the DataFrame.

See also:

Series.cov Compute covariance with another Series.
core.window.ExponentialMovingWindow.cov Exponential weighted sample covariance.

core.window.Expanding.cov Expanding sample covariance.
core.window.Rolling.cov Rolling sample covariance.

Notes

Returns the covariance matrix of the DataFrame's time series. The covariance is normalized by N-ddof.

For DataFrames that have Series that are missing data (assuming that data is missing at random) the returned covariance matrix will be an unbiased estimate of the variance and covariance between the member Series.

However, for many applications this estimate may not be acceptable because the estimate covariance matrix is not guaranteed to be positive semi-definite. This could lead to estimate correlations having absolute values which are greater than one, and/or a non-invertible covariance matrix. See Estimation of covariance matrices for more details.

Examples

```
>>> df = pd.DataFrame([(1, 2), (0, 3), (2, 0), (1, 1)],
...                   columns=['dogs', 'cats'])
>>> df.cov()
          dogs      cats
dogs  0.666667 -1.000000
cats -1.000000  1.666667
```

```
>>> np.random.seed(42)
>>> df = pd.DataFrame(np.random.randn(1000, 5),
...                   columns=['a', 'b', 'c', 'd', 'e'])
>>> df.cov()
          a         b         c         d         e
a  0.998438 -0.020161  0.059277 -0.008943  0.014144
b -0.020161  1.059352 -0.008543 -0.024738  0.009826
c  0.059277 -0.008543  1.010670 -0.001486 -0.000271
d -0.008943 -0.024738 -0.001486  0.921297 -0.013692
e  0.014144  0.009826 -0.000271 -0.013692  0.977795
```

Minimum number of periods

This method also supports an optional `min_periods` keyword that specifies the required minimum number of non-NA observations for each column pair in order to have a valid result:

```
>>> np.random.seed(42)
>>> df = pd.DataFrame(np.random.randn(20, 3),
...                   columns=['a', 'b', 'c'])
>>> df.loc[df.index[:5], 'a'] = np.nan
>>> df.loc[df.index[5:10], 'b'] = np.nan
>>> df.cov(min_periods=12)
          a         b         c
a  0.316741       NaN -0.150812
b       NaN  1.248003  0.191417
c -0.150812  0.191417  0.895202
```

pandas.core.groupby.DataFrameGroupBy.cumcount

DataFrameGroupBy.**cumcount**(*ascending=True*)

Number each item in each group from 0 to the length of that group - 1.

Essentially this is equivalent to

```
self.apply(lambda x: pd.Series(np.arange(len(x)), x.index))
```

Parameters

ascending [bool, default True] If False, number in reverse, from length of group - 1 to 0.

Returns

Series Sequence number of each element within each group.

See also:

ngroup Number the groups themselves.

Examples

```
>>> df = pd.DataFrame([['a'], ['a'], ['a'], ['b'], ['b'], ['a']],
...                   columns=['A'])
>>> df
   A
0  a
1  a
2  a
3  b
4  b
5  a
>>> df.groupby('A').cumcount()
0    0
1    1
2    2
3    0
4    1
5    3
dtype: int64
>>> df.groupby('A').cumcount(ascending=False)
0    3
1    2
2    1
3    1
4    0
5    0
dtype: int64
```

pandas.core.groupby.DataFrameGroupBy.cummax

DataFrameGroupBy.**cummax**(*axis=0*, ***kwargs*)

Cumulative max for each group.

Returns

Series or DataFrame

See also:

Series.groupby
DataFrame.groupby

pandas.core.groupby.DataFrameGroupBy.cummin

DataFrameGroupBy.**cummin**(*axis=0*, ***kwargs*)

Cumulative min for each group.

Returns

Series or DataFrame

See also:

Series.groupby
DataFrame.groupby

pandas.core.groupby.DataFrameGroupBy.cumprod

DataFrameGroupBy.**cumprod**(*axis=0*, **args*, ***kwargs*)

Cumulative product for each group.

Returns

Series or DataFrame

See also:

Series.groupby
DataFrame.groupby

pandas.core.groupby.DataFrameGroupBy.cumsum

DataFrameGroupBy.**cumsum**(*axis=0*, **args*, ***kwargs*)

Cumulative sum for each group.

Returns

Series or DataFrame

See also:

Series.groupby
DataFrame.groupby

pandas.core.groupby.DataFrameGroupBy.describe

DataFrameGroupBy.**describe**(***kwargs*)

Generate descriptive statistics.

Descriptive statistics include those that summarize the central tendency, dispersion and shape of a dataset's distribution, excluding NaN values.

Analyzes both numeric and object series, as well as DataFrame column sets of mixed data types. The output will vary depending on what is provided. Refer to the notes below for more detail.

Parameters

percentiles [list-like of numbers, optional] The percentiles to include in the output. All should fall between 0 and 1. The default is [.25, .5, .75], which returns the 25th, 50th, and 75th percentiles.

include ['all', list-like of dtypes or None (default), optional] A white list of data types to include in the result. Ignored for Series. Here are the options:

- 'all' : All columns of the input will be included in the output.
- A list-like of dtypes : Limits the results to the provided data types. To limit the result to numeric types submit numpy.number. To limit it instead to object columns submit the numpy.object data type. Strings can also be used in the style of select_dtypes (e.g. df.describe(include=['O'])). To select pandas categorical columns, use 'category'
- None (default) : The result will include all numeric columns.

exclude [list-like of dtypes or None (default), optional,] A black list of data types to omit from the result. Ignored for Series. Here are the options:

- A list-like of dtypes : Excludes the provided data types from the result. To exclude numeric types submit numpy.number. To exclude object columns submit the data type numpy.object. Strings can also be used in the style of select_dtypes (e.g. df.describe(include=['O'])). To exclude pandas categorical columns, use 'category'
- None (default) : The result will exclude nothing.

datetime_is_numeric [bool, default False] Whether to treat datetime dtypes as numeric. This affects statistics calculated for the column. For DataFrame input, this also controls whether datetime columns are included by default.

New in version 1.1.0.

Returns

Series or DataFrame Summary statistics of the Series or Dataframe provided.

See also:

DataFrame.count Count number of non-NA/null observations.
DataFrame.max Maximum of the values in the object.
DataFrame.min Minimum of the values in the object.
DataFrame.mean Mean of the values.
DataFrame.std Standard deviation of the observations.
DataFrame.select_dtypes Subset of a DataFrame including/excluding columns based on their dtype.

Notes

For numeric data, the result's index will include `count`, `mean`, `std`, `min`, `max` as well as lower, `50` and upper percentiles. By default the lower percentile is `25` and the upper percentile is `75`. The `50` percentile is the same as the median.

For object data (e.g. strings or timestamps), the result's index will include `count`, `unique`, `top`, and `freq`. The `top` is the most common value. The `freq` is the most common value's frequency. Timestamps also include the `first` and `last` items.

If multiple object values have the highest count, then the `count` and `top` results will be arbitrarily chosen from among those with the highest count.

For mixed data types provided via a `DataFrame`, the default is to return only an analysis of numeric columns. If the dataframe consists only of object and categorical data without any numeric columns, the default is to return an analysis of both the object and categorical columns. If `include='all'` is provided as an option, the result will include a union of attributes of each type.

The *include* and *exclude* parameters can be used to limit which columns in a `DataFrame` are analyzed for the output. The parameters are ignored when analyzing a `Series`.

Examples

Describing a numeric `Series`.

```
>>> s = pd.Series([1, 2, 3])
>>> s.describe()
count    3.0
mean     2.0
std      1.0
min      1.0
25%      1.5
50%      2.0
75%      2.5
max      3.0
dtype: float64
```

Describing a categorical `Series`.

```
>>> s = pd.Series(['a', 'a', 'b', 'c'])
>>> s.describe()
count     4
unique    3
top       a
freq      2
dtype: object
```

Describing a timestamp `Series`.

```
>>> s = pd.Series([
...   np.datetime64("2000-01-01"),
...   np.datetime64("2010-01-01"),
...   np.datetime64("2010-01-01")
... ])
>>> s.describe(datetime_is_numeric=True)
count                      3
mean     2006-09-01 08:00:00
```

(continues on next page)

(continued from previous page)

```
min      2000-01-01 00:00:00
25%      2004-12-31 12:00:00
50%      2010-01-01 00:00:00
75%      2010-01-01 00:00:00
max      2010-01-01 00:00:00
dtype: object
```

Describing a `DataFrame`. By default only numeric fields are returned.

```
>>> df = pd.DataFrame({'categorical': pd.Categorical(['d','e','f']),
...                    'numeric': [1, 2, 3],
...                    'object': ['a', 'b', 'c']
...                   })
>>> df.describe()
       numeric
count      3.0
mean       2.0
std        1.0
min        1.0
25%        1.5
50%        2.0
75%        2.5
max        3.0
```

Describing all columns of a `DataFrame` regardless of data type.

```
>>> df.describe(include='all')
       categorical  numeric object
count            3      3.0      3
unique           3      NaN      3
top              f      NaN      a
freq             1      NaN      1
mean           NaN      2.0    NaN
std            NaN      1.0    NaN
min            NaN      1.0    NaN
25%            NaN      1.5    NaN
50%            NaN      2.0    NaN
75%            NaN      2.5    NaN
max            NaN      3.0    NaN
```

Describing a column from a `DataFrame` by accessing it as an attribute.

```
>>> df.numeric.describe()
count    3.0
mean     2.0
std      1.0
min      1.0
25%      1.5
50%      2.0
75%      2.5
max      3.0
Name: numeric, dtype: float64
```

Including only numeric columns in a `DataFrame` description.

```
>>> df.describe(include=[np.number])
       numeric
```

(continues on next page)

(continued from previous page)

```
count      3.0
mean       2.0
std        1.0
min        1.0
25%        1.5
50%        2.0
75%        2.5
max        3.0
```

Including only string columns in a `DataFrame` description.

```
>>> df.describe(include=[object])
       object
count       3
unique      3
top         a
freq        1
```

Including only categorical columns from a `DataFrame` description.

```
>>> df.describe(include=['category'])
       categorical
count            3
unique           3
top              f
freq             1
```

Excluding numeric columns from a `DataFrame` description.

```
>>> df.describe(exclude=[np.number])
       categorical object
count            3      3
unique           3      3
top              f      a
freq             1      1
```

Excluding object columns from a `DataFrame` description.

```
>>> df.describe(exclude=[object])
       categorical  numeric
count            3      3.0
unique           3      NaN
top              f      NaN
freq             1      NaN
mean           NaN      2.0
std            NaN      1.0
min            NaN      1.0
25%            NaN      1.5
50%            NaN      2.0
75%            NaN      2.5
max            NaN      3.0
```

pandas.core.groupby.DataFrameGroupBy.diff

property DataFrameGroupBy.**diff**

First discrete difference of element.

Calculates the difference of a Dataframe element compared with another element in the Dataframe (default is element in previous row).

Parameters

periods [int, default 1] Periods to shift for calculating difference, accepts negative values.

axis [{0 or 'index', 1 or 'columns'}, default 0] Take difference over rows (0) or columns (1).

Returns

Dataframe First differences of the Series.

See also:

Dataframe.pct_change Percent change over given number of periods.
Dataframe.shift Shift index by desired number of periods with an optional time freq.
Series.diff First discrete difference of object.

Notes

For boolean dtypes, this uses `operator.xor()` rather than `operator.sub()`. The result is calculated according to current dtype in Dataframe, however dtype of the result is always float64.

Examples

Difference with previous row

```
>>> df = pd.DataFrame({'a': [1, 2, 3, 4, 5, 6],
...                    'b': [1, 1, 2, 3, 5, 8],
...                    'c': [1, 4, 9, 16, 25, 36]})
>>> df
   a  b   c
0  1  1   1
1  2  1   4
2  3  2   9
3  4  3  16
4  5  5  25
5  6  8  36
```

```
>>> df.diff()
     a    b     c
0  NaN  NaN   NaN
1  1.0  0.0   3.0
2  1.0  1.0   5.0
3  1.0  1.0   7.0
4  1.0  2.0   9.0
5  1.0  3.0  11.0
```

Difference with previous column

```
>>> df.diff(axis=1)
    a    b     c
0 NaN  0.0   0.0
```

(continues on next page)

(continued from previous page)

```
1 NaN -1.0   3.0
2 NaN -1.0   7.0
3 NaN -1.0  13.0
4 NaN  0.0  20.0
5 NaN  2.0  28.0
```

Difference with 3rd previous row

```
>>> df.diff(periods=3)
     a    b     c
0  NaN  NaN   NaN
1  NaN  NaN   NaN
2  NaN  NaN   NaN
3  3.0  2.0  15.0
4  3.0  4.0  21.0
5  3.0  6.0  27.0
```

Difference with following row

```
>>> df.diff(periods=-1)
     a    b     c
0 -1.0  0.0  -3.0
1 -1.0 -1.0  -5.0
2 -1.0 -1.0  -7.0
3 -1.0 -2.0  -9.0
4 -1.0 -3.0 -11.0
5  NaN  NaN   NaN
```

Overflow in input dtype

```
>>> df = pd.DataFrame({'a': [1, 0]}, dtype=np.uint8)
>>> df.diff()
       a
0    NaN
1  255.0
```

pandas.core.groupby.DataFrameGroupBy.ffill

DataFrameGroupBy.**ffill**(*limit=None*)

Forward fill the values.

Parameters

limit [int, optional] Limit of how many values to fill.

Returns

Series or DataFrame Object with missing values filled.

See also:

Series.pad
DataFrame.pad
Series.fillna
DataFrame.fillna

pandas.core.groupby.DataFrameGroupBy.fillna

property DataFrameGroupBy.**fillna**

Fill NA/NaN values using the specified method.

Parameters

value [scalar, dict, Series, or DataFrame] Value to use to fill holes (e.g. 0), alternately a dict/Series/DataFrame of values specifying which value to use for each index (for a Series) or column (for a DataFrame). Values not in the dict/Series/DataFrame will not be filled. This value cannot be a list.

method [{'backfill', 'bfill', 'pad', 'ffill', None}, default None] Method to use for filling holes in reindexed Series pad / ffill: propagate last valid observation forward to next valid backfill / bfill: use next valid observation to fill gap.

axis [{0 or 'index', 1 or 'columns'}] Axis along which to fill missing values.

inplace [bool, default False] If True, fill in-place. Note: this will modify any other views on this object (e.g., a no-copy slice for a column in a DataFrame).

limit [int, default None] If method is specified, this is the maximum number of consecutive NaN values to forward/backward fill. In other words, if there is a gap with more than this number of consecutive NaNs, it will only be partially filled. If method is not specified, this is the maximum number of entries along the entire axis where NaNs will be filled. Must be greater than 0 if not None.

downcast [dict, default is None] A dict of item->dtype of what to downcast if possible, or the string 'infer' which will try to downcast to an appropriate equal type (e.g. float64 to int64 if possible).

Returns

DataFrame or None Object with missing values filled or None if `inplace=True`.

See also:

interpolate Fill NaN values using interpolation.
reindex Conform object to new index.
asfreq Convert TimeSeries to specified frequency.

Examples

```
>>> df = pd.DataFrame([[np.nan, 2, np.nan, 0],
...                    [3, 4, np.nan, 1],
...                    [np.nan, np.nan, np.nan, 5],
...                    [np.nan, 3, np.nan, 4]],
...                   columns=list('ABCD'))
>>> df
     A    B   C  D
0  NaN  2.0 NaN  0
1  3.0  4.0 NaN  1
2  NaN  NaN NaN  5
3  NaN  3.0 NaN  4
```

Replace all NaN elements with 0s.

```
>>> df.fillna(0)
    A   B   C   D
0   0.0 2.0 0.0 0
```

(continues on next page)

(continued from previous page)

```
1   3.0 4.0 0.0 1
2   0.0 0.0 0.0 5
3   0.0 3.0 0.0 4
```

We can also propagate non-null values forward or backward.

```
>>> df.fillna(method='ffill')
    A   B   C   D
0   NaN 2.0 NaN 0
1   3.0 4.0 NaN 1
2   3.0 4.0 NaN 5
3   3.0 3.0 NaN 4
```

Replace all NaN elements in column 'A', 'B', 'C', and 'D', with 0, 1, 2, and 3 respectively.

```
>>> values = {'A': 0, 'B': 1, 'C': 2, 'D': 3}
>>> df.fillna(value=values)
    A   B   C   D
0   0.0 2.0 2.0 0
1   3.0 4.0 2.0 1
2   0.0 1.0 2.0 5
3   0.0 3.0 2.0 4
```

Only replace the first NaN element.

```
>>> df.fillna(value=values, limit=1)
    A   B   C   D
0   0.0 2.0 2.0 0
1   3.0 4.0 NaN 1
2   NaN 1.0 NaN 5
3   NaN 3.0 NaN 4
```

pandas.core.groupby.DataFrameGroupBy.filter

DataFrameGroupBy.**filter**(*func*, *dropna=True*, **args*, ***kwargs*)

Return a copy of a DataFrame excluding filtered elements.

Elements from groups are filtered if they do not satisfy the boolean criterion specified by func.

Parameters

func [function] Function to apply to each subframe. Should return True or False.

dropna [Drop groups that do not pass the filter. True by default;] If False, groups that evaluate False are filled with NaNs.

Returns

filtered [DataFrame]

Notes

Each subframe is endowed the attribute 'name' in case you need to know which group you are working on.

Examples

```
>>> df = pd.DataFrame({'A' : ['foo', 'bar', 'foo', 'bar',
...                           'foo', 'bar'],
...                    'B' : [1, 2, 3, 4, 5, 6],
...                    'C' : [2.0, 5., 8., 1., 2., 9.]})
>>> grouped = df.groupby('A')
>>> grouped.filter(lambda x: x['B'].mean() > 3.)
     A  B    C
1  bar  2  5.0
3  bar  4  1.0
5  bar  6  9.0
```

pandas.core.groupby.DataFrameGroupBy.hist

property DataFrameGroupBy.**hist**

Make a histogram of the DataFrame's.

A histogram is a representation of the distribution of data. This function calls `matplotlib.pyplot.hist()`, on each series in the DataFrame, resulting in one histogram per column.

Parameters

data [DataFrame] The pandas object holding the data.

column [str or sequence] If passed, will be used to limit data to a subset of columns.

by [object, optional] If passed, then used to form histograms for separate groups.

grid [bool, default True] Whether to show axis grid lines.

xlabelsize [int, default None] If specified changes the x-axis label size.

xrot [float, default None] Rotation of x axis labels. For example, a value of 90 displays the x labels rotated 90 degrees clockwise.

ylabelsize [int, default None] If specified changes the y-axis label size.

yrot [float, default None] Rotation of y axis labels. For example, a value of 90 displays the y labels rotated 90 degrees clockwise.

ax [Matplotlib axes object, default None] The axes to plot the histogram on.

sharex [bool, default True if ax is None else False] In case subplots=True, share x axis and set some x axis labels to invisible; defaults to True if ax is None otherwise False if an ax is passed in. Note that passing in both an ax and sharex=True will alter all x axis labels for all subplots in a figure.

sharey [bool, default False] In case subplots=True, share y axis and set some y axis labels to invisible.

figsize [tuple] The size in inches of the figure to create. Uses the value in *matplotlib.rcParams* by default.

layout [tuple, optional] Tuple of (rows, columns) for the layout of the histograms.

bins [int or sequence, default 10] Number of histogram bins to be used. If an integer is given, bins + 1 bin edges are calculated and returned. If bins is a sequence, gives bin edges, including left edge of first bin and right edge of last bin. In this case, bins is returned unmodified.

backend [str, default None] Backend to use instead of the backend specified in the option `plotting.backend`. For instance, 'matplotlib'. Alternatively, to specify the `plotting.backend` for the whole session, set `pd.options.plotting.backend`.

New in version 1.0.0.

legend [bool, default False] Whether to show the legend.

New in version 1.1.0.

****kwargs** All other plotting keyword arguments to be passed to `matplotlib.pyplot.hist()`.

Returns

matplotlib.AxesSubplot or numpy.ndarray of them

See also:

`matplotlib.pyplot.hist` Plot a histogram using matplotlib.

Examples

This example draws a histogram based on the length and width of some animals, displayed in three bins

```
>>> df = pd.DataFrame({
...     'length': [1.5, 0.5, 1.2, 0.9, 3],
...     'width': [0.7, 0.2, 0.15, 0.2, 1.1]
...     }, index=['pig', 'rabbit', 'duck', 'chicken', 'horse'])
>>> hist = df.hist(bins=3)
```

pandas.core.groupby.DataFrameGroupBy.idxmax

property DataFrameGroupBy.**idxmax**

Return index of first occurrence of maximum over requested axis.

NA/null values are excluded.

Parameters

axis [{0 or 'index', 1 or 'columns'}, default 0] The axis to use. 0 or 'index' for row-wise, 1 or 'columns' for column-wise.

skipna [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

Returns

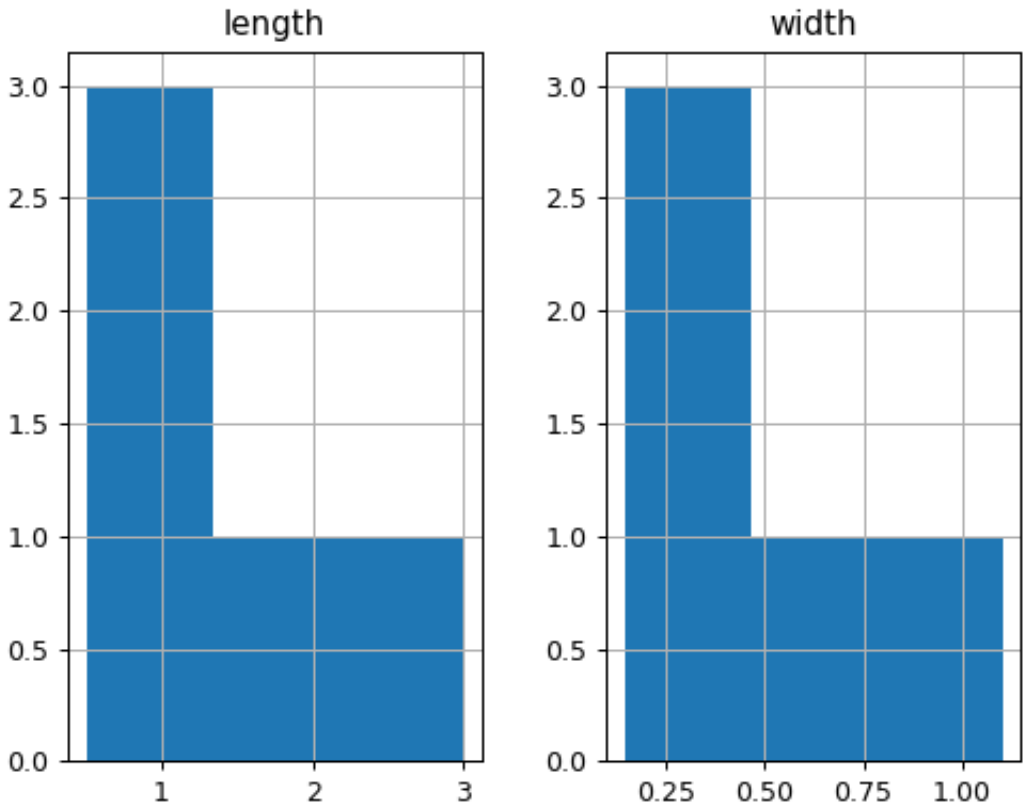
Series Indexes of maxima along the specified axis.

Raises

ValueError

- If the row/column is empty

See also:



length
width
3.0
2.5
2.0
1.5
1.0
0.5
0.0
1
2
3
0.25
0.50
0.75
1.00

Series.idxmax Return index of the maximum element.

Notes

This method is the DataFrame version of `ndarray.argmax`.

Examples

Consider a dataset containing food consumption in Argentina.

```
>>> df = pd.DataFrame({'consumption': [10.51, 103.11, 55.48],
...                    'co2_emissions': [37.2, 19.66, 1712]},
...                    index=['Pork', 'Wheat Products', 'Beef'])
```

```
>>> df
                consumption  co2_emissions
Pork                  10.51          37.20
Wheat Products       103.11          19.66
Beef                  55.48        1712.00
```

By default, it returns the index for the maximum value in each column.

```
>>> df.idxmax()
consumption     Wheat Products
co2_emissions             Beef
dtype: object
```

To return the index for the maximum value in each row, use `axis="columns"`.

```
>>> df.idxmax(axis="columns")
Pork              co2_emissions
Wheat Products     consumption
Beef              co2_emissions
dtype: object
```

pandas.core.groupby.DataFrameGroupBy.idxmin

property DataFrameGroupBy.**idxmin**

Return index of first occurrence of minimum over requested axis.

NA/null values are excluded.

Parameters

axis [{0 or 'index', 1 or 'columns'}, default 0] The axis to use. 0 or 'index' for row-wise, 1 or 'columns' for column-wise.

skipna [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

Returns

Series Indexes of minima along the specified axis.

Raises

ValueError

- If the row/column is empty

See also:

`Series.idxmin` Return index of the minimum element.

Notes

This method is the DataFrame version of `ndarray.argmin`.

Examples

Consider a dataset containing food consumption in Argentina.

```
>>> df = pd.DataFrame({'consumption': [10.51, 103.11, 55.48],
...                    'co2_emissions': [37.2, 19.66, 1712]},
...                    index=['Pork', 'Wheat Products', 'Beef'])
```

```
>>> df
                consumption  co2_emissions
Pork                  10.51         37.20
Wheat Products       103.11         19.66
Beef                  55.48       1712.00
```

By default, it returns the index for the minimum value in each column.

```
>>> df.idxmin()
consumption                Pork
co2_emissions    Wheat Products
dtype: object
```

To return the index for the minimum value in each row, use `axis="columns"`.

```
>>> df.idxmin(axis="columns")
Pork                consumption
Wheat Products    co2_emissions
Beef                consumption
dtype: object
```

pandas.core.groupby.DataFrameGroupBy.mad

property DataFrameGroupBy.**mad**

Return the mean absolute deviation of the values for the requested axis.

Parameters

axis [{index (0), columns (1)}] Axis for the function to be applied on.

skipna [bool, default None] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

Returns

Series or DataFrame (if level specified)

pandas.core.groupby.DataFrameGroupBy.nunique

DataFrameGroupBy.**nunique**(*dropna=True*)

Return DataFrame with counts of unique elements in each position.

Parameters

dropna [bool, default True] Don't include NaN in the counts.

Returns

nunique: DataFrame

Examples

```
>>> df = pd.DataFrame({'id': ['spam', 'egg', 'egg', 'spam',
...                           'ham', 'ham'],
...                    'value1': [1, 5, 5, 2, 5, 5],
...                    'value2': list('abbaxy')})
>>> df
     id  value1 value2
0  spam       1      a
1   egg       5      b
2   egg       5      b
3  spam       2      a
4   ham       5      x
5   ham       5      y
```

```
>>> df.groupby('id').nunique()
      value1  value2
id
egg        1       1
ham        1       2
spam       2       1
```

Check for rows with the same id but conflicting values:

```
>>> df.groupby('id').filter(lambda g: (g.nunique() > 1).any())
     id  value1 value2
0  spam       1      a
3  spam       2      a
4   ham       5      x
5   ham       5      y
```

pandas.core.groupby.DataFrameGroupBy.pad

DataFrameGroupBy.**pad**(*limit=None*)

Forward fill the values.

Parameters

limit [int, optional] Limit of how many values to fill.

Returns

Series or DataFrame Object with missing values filled.

See also:

Series.pad

DataFrame.pad
Series.fillna
DataFrame.fillna

pandas.core.groupby.DataFrameGroupBy.pct_change

DataFrameGroupBy.**pct_change**(*periods=1*, *fill_method='pad'*, *limit=None*, *freq=None*, *axis=0*)

Calculate pct_change of each value to previous entry in group.

Returns

Series or DataFrame Percentage changes within each group.

See also:

Series.groupby
DataFrame.groupby

pandas.core.groupby.DataFrameGroupBy.plot

property DataFrameGroupBy.**plot**

Class implementing the .plot attribute for groupby objects.

pandas.core.groupby.DataFrameGroupBy.quantile

DataFrameGroupBy.**quantile**(*q=0.5*, *interpolation='linear'*)

Return group values at the given quantile, a la numpy.percentile.

Parameters

q [float or array-like, default 0.5 (50% quantile)] Value(s) between 0 and 1 providing the quantile(s) to compute.

interpolation [{'linear', 'lower', 'higher', 'midpoint', 'nearest'}] Method to use when the desired quantile falls between two points.

Returns

Series or DataFrame Return type determined by caller of GroupBy object.

See also:

Series.quantile Similar method for Series.
DataFrame.quantile Similar method for DataFrame.
numpy.percentile NumPy method to compute qth percentile.

Examples

```
>>> df = pd.DataFrame([
...     ['a', 1], ['a', 2], ['a', 3],
...     ['b', 1], ['b', 3], ['b', 5]
... ], columns=['key', 'val'])
>>> df.groupby('key').quantile()
    val
key
a    2.0
b    3.0
```

pandas.core.groupby.DataFrameGroupBy.rank

DataFrameGroupBy.**rank**(*method='average'*, *ascending=True*, *na_option='keep'*, *pct=False*, *axis=0*)

Provide the rank of values within each group.

Parameters

method [{'average', 'min', 'max', 'first', 'dense'}, default 'average']

- average: average rank of group.
- min: lowest rank in group.
- max: highest rank in group.
- first: ranks assigned in order they appear in the array.
- dense: like 'min', but rank always increases by 1 between groups.

ascending [bool, default True] False for ranks by high (1) to low (N).

na_option [{'keep', 'top', 'bottom'}, default 'keep']

- keep: leave NA values where they are.
- top: smallest rank if ascending.
- bottom: smallest rank if descending.

pct [bool, default False] Compute percentage rank of data within each group.

axis [int, default 0] The axis of the object over which to compute the rank.

Returns

DataFrame with ranking of values within each group

See also:

Series.groupby
DataFrame.groupby

pandas.core.groupby.DataFrameGroupBy.resample

DataFrameGroupBy.**resample**(*rule*, **args*, ***kwargs*)

Provide resampling when using a TimeGrouper.

Given a grouper, the function resamples it according to a string "string" -> "frequency".

See the *frequency aliases* documentation for more details.

Parameters

rule [str or DateOffset] The offset string or object representing target grouper conversion.

***args, **kwargs** Possible arguments are *how*, *fill_method*, *limit*, *kind* and *on*, and other arguments of *TimeGrouper*.

Returns

Grouper Return a new grouper with our resampler appended.

See also:

Grouper Specify a frequency to resample with when grouping by a key.
DatetimeIndex.resample Frequency conversion and resampling of time series.

Examples

```
>>> idx = pd.date_range('1/1/2000', periods=4, freq='T')
>>> df = pd.DataFrame(data=4 * [range(2)],
...                   index=idx,
...                   columns=['a', 'b'])
>>> df.iloc[2, 0] = 5
>>> df
                     a  b
2000-01-01 00:00:00  0  1
2000-01-01 00:01:00  0  1
2000-01-01 00:02:00  5  1
2000-01-01 00:03:00  0  1
```

Downsample the DataFrame into 3 minute bins and sum the values of the timestamps falling into a bin.

```
>>> df.groupby('a').resample('3T').sum()
                          a  b
a
0   2000-01-01 00:00:00  0  2
    2000-01-01 00:03:00  0  1
5   2000-01-01 00:00:00  5  1
```

Upsample the series into 30 second bins.

```
>>> df.groupby('a').resample('30S').sum()
                     a  b
a
0   2000-01-01 00:00:00  0  1
    2000-01-01 00:00:30  0  0
    2000-01-01 00:01:00  0  1
    2000-01-01 00:01:30  0  0
    2000-01-01 00:02:00  0  0
    2000-01-01 00:02:30  0  0
    2000-01-01 00:03:00  0  1
5   2000-01-01 00:02:00  5  1
```

Resample by month. Values are assigned to the month of the period.

```
>>> df.groupby('a').resample('M').sum()
            a  b
a
0   2000-01-31  0  3
5   2000-01-31  5  1
```

Downsample the series into 3 minute bins as above, but close the right side of the bin interval.

```
>>> df.groupby('a').resample('3T', closed='right').sum()
                          a  b
a
0   1999-12-31 23:57:00  0  1
    2000-01-01 00:00:00  0  2
5   2000-01-01 00:00:00  5  1
```

Downsample the series into 3 minute bins and close the right side of the bin interval, but label each bin using the right edge instead of the left.

```
>>> df.groupby('a').resample('3T', closed='right', label='right').sum()
                         a  b
a
0   2000-01-01 00:00:00  0  1
    2000-01-01 00:03:00  0  2
5   2000-01-01 00:03:00  5  1
```

pandas.core.groupby.DataFrameGroupBy.sample

DataFrameGroupBy.**sample**(*n=None*, *frac=None*, *replace=False*, *weights=None*, *random_state=None*)

Return a random sample of items from each group.

You can use *random_state* for reproducibility.

New in version 1.1.0.

Parameters

n [int, optional] Number of items to return for each group. Cannot be used with *frac* and must be no larger than the smallest group unless *replace* is True. Default is one if *frac* is None.

frac [float, optional] Fraction of items to return. Cannot be used with *n*.

replace [bool, default False] Allow or disallow sampling of the same row more than once.

weights [list-like, optional] Default None results in equal probability weighting. If passed a list-like then values must have the same length as the underlying DataFrame or Series object and will be used as sampling probabilities after normalization within each group. Values must be non-negative with at least one positive element within each group.

random_state [int, array-like, BitGenerator, np.random.RandomState, optional] If int, array-like, or BitGenerator (NumPy>=1.17), seed for random number generator If np.random.RandomState, use as numpy RandomState object.

Returns

Series or DataFrame A new object of same type as caller containing items randomly sampled within each group from the caller object.

See also:

DataFrame.sample Generate random samples from a DataFrame object.
numpy.random.choice Generate a random sample from a given 1-D numpy array.

Examples

```
>>> df = pd.DataFrame(
...     {"a": ["red"] * 2 + ["blue"] * 2 + ["black"] * 2, "b": range(6)}
... )
>>> df
       a  b
0    red  0
1    red  1
2   blue  2
3   blue  3
4  black  4
5  black  5
```

Select one row at random for each distinct value in column a. The *random_state* argument can be used to guarantee reproducibility:

```
>>> df.groupby("a").sample(n=1, random_state=1)
       a  b
4  black  4
2   blue  2
1    red  1
```

Set *frac* to sample fixed proportions rather than counts:

```
>>> df.groupby("a")["b"].sample(frac=0.5, random_state=2)
5    5
2    2
0    0
Name: b, dtype: int64
```

Control sample probabilities within groups by setting weights:

```
>>> df.groupby("a").sample(
...     n=1,
...     weights=[1, 1, 1, 0, 0, 1],
...     random_state=1,
... )
       a  b
5  black  5
2   blue  2
0    red  0
```

pandas.core.groupby.DataFrameGroupBy.shift

DataFrameGroupBy.**shift**(*periods=1*, *freq=None*, *axis=0*, *fill_value=None*)

Shift each group by periods observations.

If freq is passed, the index will be increased using the periods and the freq.

Parameters

periods [int, default 1] Number of periods to shift.

freq [str, optional] Frequency string.

axis [axis to shift, default 0] Shift direction.

fill_value [optional] The scalar value to use for newly introduced missing values.

New in version 0.24.0.

Returns

Series or DataFrame Object shifted within each group.

See also:

Index.shift Shift values of Index.
tshift Shift the time index, using the index's frequency if available.

pandas.core.groupby.DataFrameGroupBy.size

DataFrameGroupBy.**size**()

Compute group sizes.

Returns

DataFrame or Series Number of rows in each group as a Series if as_index is True or a DataFrame if as_index is False.

See also:

Series.groupby
DataFrame.groupby

pandas.core.groupby.DataFrameGroupBy.skew

property DataFrameGroupBy.**skew**

Return unbiased skew over requested axis.

Normalized by N-1.

Parameters

axis [{index (0), columns (1)}] Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

****kwargs** Additional keyword arguments to be passed to the function.

Returns

Series or DataFrame (if level specified)

pandas.core.groupby.DataFrameGroupBy.take

property DataFrameGroupBy.**take**

Return the elements in the given *positional* indices along an axis.

This means that we are not indexing according to actual values in the index attribute of the object. We are indexing according to the actual position of the element in the object.

Parameters

indices [array-like] An array of ints indicating which positions to take.

axis [{0 or 'index', 1 or 'columns', None}, default 0] The axis on which to select elements. `0` means that we are selecting rows, `1` means that we are selecting columns.

is_copy [bool] Before pandas 1.0, `is_copy=False` can be specified to ensure that the return value is an actual copy. Starting with pandas 1.0, `take` always returns a copy, and the keyword is therefore deprecated.

Deprecated since version 1.0.0.

****kwargs** For compatibility with `numpy.take()`. Has no effect on the output.

Returns

taken [same type as caller] An array-like containing the elements taken from the object.

See also:

`DataFrame.loc` Select a subset of a DataFrame by labels.
`DataFrame.iloc` Select a subset of a DataFrame by positions.
`numpy.take` Take elements from an array along an axis.

Examples

```
>>> df = pd.DataFrame([('falcon', 'bird', 389.0),
...                    ('parrot', 'bird', 24.0),
...                    ('lion', 'mammal', 80.5),
...                    ('monkey', 'mammal', np.nan)],
...                   columns=['name', 'class', 'max_speed'],
...                   index=[0, 2, 3, 1])
>>> df
     name   class  max_speed
0  falcon    bird      389.0
2  parrot    bird       24.0
3    lion  mammal       80.5
1  monkey  mammal        NaN
```

Take elements at positions 0 and 3 along the axis 0 (default).

Note how the actual indices selected (0 and 1) do not correspond to our selected indices 0 and 3. That's because we are selecting the 0th and 3rd rows, not rows whose indices equal 0 and 3.

```
>>> df.take([0, 3])
     name   class  max_speed
0  falcon    bird      389.0
1  monkey  mammal        NaN
```

Take elements at indices 1 and 2 along the axis 1 (column selection).

```
>>> df.take([1, 2], axis=1)
    class  max_speed
0    bird      389.0
2    bird       24.0
3  mammal       80.5
1  mammal        NaN
```

We may take elements using negative integers for positive indices, starting from the end of the object, just like with Python lists.

```
>>> df.take([-1, -2])
     name   class  max_speed
1  monkey  mammal        NaN
3    lion  mammal       80.5
```

pandas.core.groupby.DataFrameGroupBy.tshift

property DataFrameGroupBy.**tshift**

Shift the time index, using the index's frequency if available.

Deprecated since version 1.1.0: Use *shift* instead.

Parameters

periods [int] Number of periods to move, can be positive or negative.

freq [DateOffset, timedelta, or str, default None] Increment to use from the tseries module or time rule expressed as a string (e.g. 'EOM').

axis [{0 or 'index', 1 or 'columns', None}, default 0] Corresponds to the axis that contains the Index.

Returns

shifted [Series/DataFrame]

Notes

If freq is not specified then tries to use the freq or inferred_freq attributes of the index. If neither of those attributes exist, a ValueError is thrown

The following methods are available only for SeriesGroupBy objects.

SeriesGroupBy.hist	Draw histogram of the input series using matplotlib.
SeriesGroupBy.nlargest	Return the largest *n* elements.
SeriesGroupBy.nsmallest	Return the smallest *n* elements.
SeriesGroupBy.nunique([dropna])	Return number of unique elements in the group.
SeriesGroupBy.unique	Return unique values of Series object.
SeriesGroupBy.value_counts([normalize, ...])	
SeriesGroupBy.is_monotonic_increasing	Alias for is_monotonic.
SeriesGroupBy.is_monotonic_decreasing	Return boolean if values in the object are monotonic_decreasing.

pandas.core.groupby.SeriesGroupBy.hist

property SeriesGroupBy.**hist**

Draw histogram of the input series using matplotlib.

Parameters

by [object, optional] If passed, then used to form histograms for separate groups.

ax [matplotlib axis object] If not passed, uses gca().

grid [bool, default True] Whether to show axis grid lines.

xlabelsize [int, default None] If specified changes the x-axis label size.

xrot [float, default None] Rotation of x axis labels.

ylabelsize [int, default None] If specified changes the y-axis label size.

yrot [float, default None] Rotation of y axis labels.

figsize [tuple, default None] Figure size in inches by default.

bins [int or sequence, default 10] Number of histogram bins to be used. If an integer is given, bins + 1 bin edges are calculated and returned. If bins is a sequence, gives bin edges, including left edge of first bin and right edge of last bin. In this case, bins is returned unmodified.

backend [str, default None] Backend to use instead of the backend specified in the option `plotting.backend`. For instance, 'matplotlib'. Alternatively, to specify the `plotting.backend` for the whole session, set `pd.options.plotting.backend`.

New in version 1.0.0.

legend [bool, default False] Whether to show the legend.

New in version 1.1.0.

****kwargs** To be passed to the actual plotting function.

Returns

matplotlib.AxesSubplot A histogram plot.

See also:

matplotlib.axes.Axes.hist Plot a histogram using matplotlib.

pandas.core.groupby.SeriesGroupBy.nlargest

property SeriesGroupBy.**nlargest**

Return the largest *n* elements.

Parameters

n [int, default 5] Return this many descending sorted values.

keep [{'first', 'last', 'all'}, default 'first'] When there are duplicate values that cannot all fit in a Series of *n* elements:

- **first** [return the first *n* occurrences in order] of appearance.
- **last** [return the last *n* occurrences in reverse] order of appearance.
- **all** [keep all occurrences. This can result in a Series of] size larger than *n*.

Returns

Series The *n* largest values in the Series, sorted in decreasing order.

See also:

Series.nsmallest Get the *n* smallest elements.
Series.sort_values Sort Series by values.
Series.head Return the first *n* rows.

Notes

Faster than `.sort_values(ascending=False).head(n)` for small *n* relative to the size of the `Series` object.

Examples

```
>>> countries_population = {"Italy": 59000000, "France": 65000000,
...                         "Malta": 434000, "Maldives": 434000,
...                         "Brunei": 434000, "Iceland": 337000,
...                         "Nauru": 11300, "Tuvalu": 11300,
...                         "Anguilla": 11300, "Montserrat": 5200}
>>> s = pd.Series(countries_population)
>>> s
Italy       59000000
France      65000000
Malta         434000
Maldives      434000
Brunei        434000
Iceland       337000
Nauru          11300
Tuvalu         11300
Anguilla       11300
Montserrat      5200
dtype: int64
```

The *n* largest elements where `n=5` by default.

```
>>> s.nlargest()
France      65000000
Italy       59000000
Malta         434000
Maldives      434000
Brunei        434000
dtype: int64
```

The *n* largest elements where `n=3`. Default *keep* value is 'first' so Malta will be kept.

```
>>> s.nlargest(3)
France    65000000
Italy     59000000
Malta       434000
dtype: int64
```

The *n* largest elements where `n=3` and keeping the last duplicates. Brunei will be kept since it is the last with value 434000 based on the index order.

```
>>> s.nlargest(3, keep='last')
France      65000000
Italy       59000000
Brunei        434000
dtype: int64
```

The *n* largest elements where `n=3` with all duplicates kept. Note that the returned Series has five elements due to the three duplicates.

```
>>> s.nlargest(3, keep='all')
France      65000000
Italy       59000000
Malta         434000
Maldives      434000
Brunei        434000
dtype: int64
```

pandas.core.groupby.SeriesGroupBy.nsmallest

property SeriesGroupBy.**nsmallest**

Return the smallest *n* elements.

Parameters

n [int, default 5] Return this many ascending sorted values.

keep [{'first', 'last', 'all'}, default 'first'] When there are duplicate values that cannot all fit in a Series of *n* elements:

- **first** [return the first *n* occurrences in order] of appearance.
- **last** [return the last *n* occurrences in reverse] order of appearance.
- **all** [keep all occurrences. This can result in a Series of] size larger than *n*.

Returns

Series The *n* smallest values in the Series, sorted in increasing order.

See also:

Series.nlargest Get the *n* largest elements.
Series.sort_values Sort Series by values.
Series.head Return the first *n* rows.

Notes

Faster than `.sort_values().head(n)` for small *n* relative to the size of the `Series` object.

Examples

```
>>> countries_population = {"Italy": 59000000, "France": 65000000,
...                         "Brunei": 434000, "Malta": 434000,
...                         "Maldives": 434000, "Iceland": 337000,
...                         "Nauru": 11300, "Tuvalu": 11300,
...                         "Anguilla": 11300, "Montserrat": 5200}
>>> s = pd.Series(countries_population)
>>> s
Italy       59000000
France      65000000
Brunei        434000
Malta         434000
Maldives      434000
Iceland       337000
Nauru          11300
Tuvalu         11300
Anguilla       11300
```

(continues on next page)

(continued from previous page)

```
Montserrat      5200
dtype: int64
```

The *n* smallest elements where `n=5` by default.

```
>>> s.nsmallest()
Montserrat    5200
Nauru        11300
Tuvalu       11300
Anguilla     11300
Iceland     337000
dtype: int64
```

The *n* smallest elements where `n=3`. Default *keep* value is 'first' so Nauru and Tuvalu will be kept.

```
>>> s.nsmallest(3)
Montserrat   5200
Nauru       11300
Tuvalu      11300
dtype: int64
```

The *n* smallest elements where `n=3` and keeping the last duplicates. Anguilla and Tuvalu will be kept since they are the last with value 11300 based on the index order.

```
>>> s.nsmallest(3, keep='last')
Montserrat   5200
Anguilla    11300
Tuvalu      11300
dtype: int64
```

The *n* smallest elements where `n=3` with all duplicates kept. Note that the returned Series has four elements due to the three duplicates.

```
>>> s.nsmallest(3, keep='all')
Montserrat   5200
Nauru       11300
Tuvalu      11300
Anguilla    11300
dtype: int64
```

pandas.core.groupby.SeriesGroupBy.nunique

`SeriesGroupBy.`**`nunique`**(*dropna=True*)

Return number of unique elements in the group.

Returns

Series Number of unique values within each group.

pandas.core.groupby.SeriesGroupBy.unique

property SeriesGroupBy.**unique**

Return unique values of Series object.

Uniques are returned in order of appearance. Hash table-based unique, therefore does NOT sort.

Returns

ndarray or ExtensionArray The unique values returned as a NumPy array. See Notes.

See also:

unique Top-level unique method for any 1-d array-like object.

Index.unique Return Index with unique values from an Index object.

Notes

Returns the unique values as a NumPy array. In case of an extension-array backed Series, a new ExtensionArray of that type with just the unique values is returned. This includes

- Categorical
- Period
- Datetime with Timezone
- Interval
- Sparse
- IntegerNA

See Examples section.

Examples

```
>>> pd.Series([2, 1, 3, 3], name='A').unique()
array([2, 1, 3])
```

```
>>> pd.Series([pd.Timestamp('2016-01-01') for _ in range(3)]).unique()
array(['2016-01-01T00:00:00.000000000'], dtype='datetime64[ns]')
```

```
>>> pd.Series([pd.Timestamp('2016-01-01', tz='US/Eastern')
...             for _ in range(3)]).unique()
<DatetimeArray>
['2016-01-01 00:00:00-05:00']
Length: 1, dtype: datetime64[ns, US/Eastern]
```

An unordered Categorical will return categories in the order of appearance.

```
>>> pd.Series(pd.Categorical(list('baabc'))).unique()
['b', 'a', 'c']
Categories (3, object): ['b', 'a', 'c']
```

An ordered Categorical preserves the category ordering.

```
>>> pd.Series(pd.Categorical(list('baabc'), categories=list('abc'),
...                          ordered=True)).unique()
['b', 'a', 'c']
Categories (3, object): ['a' < 'b' < 'c']
```

pandas.core.groupby.SeriesGroupBy.value_counts

SeriesGroupBy.**value_counts**(*normalize=False*, *sort=True*, *ascending=False*, *bins=None*, *dropna=True*)

pandas.core.groupby.SeriesGroupBy.is_monotonic_increasing

property SeriesGroupBy.**is_monotonic_increasing**

Alias for is_monotonic.

pandas.core.groupby.SeriesGroupBy.is_monotonic_decreasing

property SeriesGroupBy.**is_monotonic_decreasing**

Return boolean if values in the object are monotonic_decreasing.

Returns

bool

The following methods are available only for DataFrameGroupBy objects.

DataFrameGroupBy.corrwith	Compute pairwise correlation.
DataFrameGroupBy.boxplot([subplots, column, ...])	Make box plots from DataFrameGroupBy data.

pandas.core.groupby.DataFrameGroupBy.corrwith

property DataFrameGroupBy.**corrwith**

Compute pairwise correlation.

Pairwise correlation is computed between rows or columns of DataFrame with rows or columns of Series or DataFrame. DataFrames are first aligned along both axes before computing the correlations.

Parameters

other [DataFrame, Series] Object with which to compute correlations.

axis [{0 or 'index', 1 or 'columns'}, default 0] The axis to use. 0 or 'index' to compute column-wise, 1 or 'columns' for row-wise.

drop [bool, default False] Drop missing indices from result.

method [{'pearson', 'kendall', 'spearman'} or callable] Method of correlation:

- pearson : standard correlation coefficient
- kendall : Kendall Tau correlation coefficient
- spearman : Spearman rank correlation
- **callable: callable with input two 1d ndarrays** and returning a float.

New in version 0.24.0.

Returns

Series Pairwise correlations.

See also:

DataFrame.corr Compute pairwise correlation of columns.

pandas.core.groupby.DataFrameGroupBy.boxplot

DataFrameGroupBy.**boxplot**(*subplots=True*, *column=None*, *fontsize=None*, *rot=0*, *grid=True*, *ax=None*, *figsize=None*, *layout=None*, *sharex=False*, *sharey=True*, *backend=None*, ***kwargs*)

Make box plots from DataFrameGroupBy data.

Parameters

grouped [Grouped DataFrame]

subplots [bool]

- `False` - no subplots will be used
- `True` - create a subplot for each group.

column [column name or list of names, or vector] Can be any valid input to groupby.

fontsize [int or str]

rot [label rotation angle]

grid [Setting this to True will show the grid]

ax [Matplotlib axis object, default None]

figsize [A tuple (width, height) in inches]

layout [tuple (optional)] The layout of the plot: (rows, columns).

sharex [bool, default False] Whether x-axes will be shared among subplots.

New in version 0.23.1.

sharey [bool, default True] Whether y-axes will be shared among subplots.

New in version 0.23.1.

backend [str, default None] Backend to use instead of the backend specified in the option `plotting.backend`. For instance, 'matplotlib'. Alternatively, to specify the `plotting.backend` for the whole session, set `pd.options.plotting.backend`.

New in version 1.0.0.

****kwargs** All other plotting keyword arguments to be passed to matplotlib's boxplot function.

Returns

dict of key/value = group key/DataFrame.boxplot return value

or DataFrame.boxplot return value in case subplots=figures=False

Examples

You can create boxplots for grouped data and show them as separate subplots:

```
>>> import itertools
>>> tuples = [t for t in itertools.product(range(1000), range(4))]
>>> index = pd.MultiIndex.from_tuples(tuples, names=['lvl0', 'lvl1'])
>>> data = np.random.randn(len(index),4)
>>> df = pd.DataFrame(data, columns=list('ABCD'), index=index)
>>> grouped = df.groupby(level='lvl1')
>>> grouped.boxplot(rot=45, fontsize=12, figsize=(8,10))
```

The `subplots=False` option shows the boxplots in a single figure.

```
>>> grouped.boxplot(subplots=False, rot=45, fontsize=12)
```

3.12 Resampling

Resampler objects are returned by resample calls: *pandas.DataFrame.resample()*, *pandas.Series.resample()*.

3.12.1 Indexing, iteration

Resampler.__iter__()	Resampler iterator.
Resampler.groups	Dict {group name -> group labels}.
Resampler.indices	Dict {group name -> group indices}.
Resampler.get_group(name[, obj])	Construct DataFrame from group with provided name.

pandas.core.resample.Resampler.__iter__

Resampler.**__iter__**()

Resampler iterator.

Returns

Generator yielding sequence of (name, subsetted object)

for each group.

See also:

GroupBy.__iter__

pandas.core.resample.Resampler.groups

property Resampler.**groups**
Dict {group name -> group labels}.

pandas.core.resample.Resampler.indices

property Resampler.**indices**
Dict {group name -> group indices}.

pandas.core.resample.Resampler.get_group

Resampler.**get_group**(*name*, *obj=None*)
Construct DataFrame from group with provided name.

Parameters

name [object] The name of the group to get as a DataFrame.

obj [DataFrame, default None] The DataFrame to take the DataFrame out of. If it is None, the object groupby was called on will be used.

Returns

group [same type as obj]

3.12.2 Function application

Resampler.apply(func, *args, **kwargs)	Aggregate using one or more operations over the specified axis.
Resampler.aggregate(func, *args, **kwargs)	Aggregate using one or more operations over the specified axis.
Resampler.transform(arg, *args, **kwargs)	Call function producing a like-indexed Series on each group and return a Series with the transformed values.
Resampler.pipe(func, *args, **kwargs)	Apply a function *func* with arguments to this Resampler object and return the function's result.

pandas.core.resample.Resampler.apply

Resampler.**apply**(*func*, **args*, ***kwargs*)
Aggregate using one or more operations over the specified axis.

Parameters

func [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a DataFrame or when passed to DataFrame.apply.

Accepted combinations are:

- function
- string function name
- list of functions and/or function names, e.g. `[np.sum, 'mean']`
- dict of axis labels -> functions, function names or list of such.

***args** Positional arguments to pass to *func*.

****kwargs** Keyword arguments to pass to *func*.

Returns

scalar, Series or DataFrame The return can be:

- scalar : when Series.agg is called with single function
- Series : when DataFrame.agg is called with a single function
- DataFrame : when DataFrame.agg is called with several functions

Return scalar, Series or DataFrame.

See also:

DataFrame.groupby.aggregate
DataFrame.resample.transform
DataFrame.aggregate

Notes

agg is an alias for *aggregate*. Use the alias.

A passed user-defined-function will be passed a Series for evaluation.

Examples

```
>>> s = pd.Series([1,2,3,4,5],
                  index=pd.date_range('20130101', periods=5,freq='s'))
2013-01-01 00:00:00    1
2013-01-01 00:00:01    2
2013-01-01 00:00:02    3
2013-01-01 00:00:03    4
2013-01-01 00:00:04    5
Freq: S, dtype: int64
```

```
>>> r = s.resample('2s')
DatetimeIndexResampler [freq=<2 * Seconds>, axis=0, closed=left,
                        label=left, convention=start]
```

```
>>> r.agg(np.sum)
2013-01-01 00:00:00    3
2013-01-01 00:00:02    7
2013-01-01 00:00:04    5
Freq: 2S, dtype: int64
```

```
>>> r.agg(['sum','mean','max'])
                     sum  mean  max
2013-01-01 00:00:00    3   1.5    2
2013-01-01 00:00:02    7   3.5    4
2013-01-01 00:00:04    5   5.0    5
```

```
>>> r.agg({'result' : lambda x: x.mean() / x.std(),
           'total' : np.sum})
                     total    result
```

(continues on next page)

(continued from previous page)

```
2013-01-01 00:00:00      3  2.121320
2013-01-01 00:00:02      7  4.949747
2013-01-01 00:00:04      5       NaN
```

pandas.core.resample.Resampler.aggregate

Resampler.**aggregate**(*func*, **args*, ***kwargs*)

Aggregate using one or more operations over the specified axis.

Parameters

func [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a DataFrame or when passed to DataFrame.apply.

Accepted combinations are:

- function
- string function name
- list of functions and/or function names, e.g. `[np.sum, 'mean']`
- dict of axis labels -> functions, function names or list of such.

***args** Positional arguments to pass to *func*.

****kwargs** Keyword arguments to pass to *func*.

Returns

scalar, Series or DataFrame The return can be:

- scalar : when Series.agg is called with single function
- Series : when DataFrame.agg is called with a single function
- DataFrame : when DataFrame.agg is called with several functions

Return scalar, Series or DataFrame.

See also:

DataFrame.groupby.aggregate
DataFrame.resample.transform
DataFrame.aggregate

Notes

agg is an alias for *aggregate*. Use the alias.

A passed user-defined-function will be passed a Series for evaluation.

Examples

```
>>> s = pd.Series([1,2,3,4,5],
                  index=pd.date_range('20130101', periods=5,freq='s'))
2013-01-01 00:00:00    1
2013-01-01 00:00:01    2
2013-01-01 00:00:02    3
2013-01-01 00:00:03    4
2013-01-01 00:00:04    5
Freq: S, dtype: int64
```

```
>>> r = s.resample('2s')
DatetimeIndexResampler [freq=<2 * Seconds>, axis=0, closed=left,
                        label=left, convention=start]
```

```
>>> r.agg(np.sum)
2013-01-01 00:00:00    3
2013-01-01 00:00:02    7
2013-01-01 00:00:04    5
Freq: 2S, dtype: int64
```

```
>>> r.agg(['sum','mean','max'])
                     sum  mean  max
2013-01-01 00:00:00    3   1.5    2
2013-01-01 00:00:02    7   3.5    4
2013-01-01 00:00:04    5   5.0    5
```

```
>>> r.agg({'result' : lambda x: x.mean() / x.std(),
           'total' : np.sum})
                     total    result
2013-01-01 00:00:00      3  2.121320
2013-01-01 00:00:02      7  4.949747
2013-01-01 00:00:04      5       NaN
```

pandas.core.resample.Resampler.transform

Resampler.**transform**(*arg*, **args*, ***kwargs*)

Call function producing a like-indexed Series on each group and return a Series with the transformed values.

Parameters

arg [function] To apply to each group. Should return a Series with the same index.

Returns

transformed [Series]

Examples

```
>>> resampled.transform(lambda x: (x - x.mean()) / x.std())
```

pandas.core.resample.Resampler.pipe

Resampler.**pipe**(*func*, **args*, ***kwargs*)

Apply a function *func* with arguments to this Resampler object and return the function's result.

New in version 0.23.0.

Use *.pipe* when you want to improve readability by chaining together functions that expect Series, DataFrames, GroupBy or Resampler objects. Instead of writing

```
>>> h(g(f(df.groupby('group')), arg1=a), arg2=b, arg3=c)
```

You can write

```
>>> (df.groupby('group')
...    .pipe(f)
...    .pipe(g, arg1=a)
...    .pipe(h, arg2=b, arg3=c))
```

which is much more readable.

Parameters

func [callable or tuple of (callable, str)] Function to apply to this Resampler object or, alternatively, a *(callable, data_keyword)* tuple where *data_keyword* is a string indicating the keyword of *callable* that expects the Resampler object.

args [iterable, optional] Positional arguments passed into *func*.

kwargs [dict, optional] A dictionary of keyword arguments passed into *func*.

Returns

object [the return type of *func*.]

See also:

Series.pipe Apply a function with arguments to a series.
DataFrame.pipe Apply a function with arguments to a dataframe.
apply Apply function to each group instead of to the full Resampler object.

Notes

See more here

Examples

```
>>> df = pd.DataFrame({'A': [1, 2, 3, 4]},
...                   index=pd.date_range('2012-08-02', periods=4))
>>> df
            A
2012-08-02  1
2012-08-03  2
2012-08-04  3
2012-08-05  4
```

To get the difference between each 2-day period's maximum and minimum value in one pass, you can do

```
>>> df.resample('2D').pipe(lambda x: x.max() - x.min())
            A
2012-08-02  1
2012-08-04  1
```

3.12.3 Upsampling

Resampler.ffill([limit])	Forward fill the values.
Resampler.backfill([limit])	Backward fill the new missing values in the resampled data.
Resampler.bfill([limit])	Backward fill the new missing values in the resampled data.
Resampler.pad([limit])	Forward fill the values.
Resampler.nearest([limit])	Resample by using the nearest value.
Resampler.fillna(method[, limit])	Fill missing values introduced by upsampling.
Resampler.asfreq([fill_value])	Return the values at the new freq, essentially a reindex.
Resampler.interpolate([method, axis, limit, ...])	Interpolate values according to different methods.

pandas.core.resample.Resampler.ffill

Resampler.**ffill**(*limit=None*)

Forward fill the values.

Parameters

limit [int, optional] Limit of how many values to fill.

Returns

An upsampled Series.

See also:

Series.fillna
DataFrame.fillna

pandas.core.resample.Resampler.backfill

Resampler.**backfill**(*limit=None*)

Backward fill the new missing values in the resampled data.

In statistics, imputation is the process of replacing missing data with substituted values [1]. When resampling data, missing values may appear (e.g., when the resampling frequency is higher than the original frequency). The backward fill will replace NaN values that appeared in the resampled data with the next value in the original sequence. Missing values that existed in the original data will not be modified.

Parameters

limit [int, optional] Limit of how many values to fill.

Returns

Series, DataFrame An upsampled Series or DataFrame with backward filled NaN values.

See also:

bfill Alias of backfill.
fillna Fill NaN values using the specified method, which can be 'backfill'.
nearest Fill NaN values with nearest neighbor starting from center.
pad Forward fill NaN values.
Series.fillna Fill NaN values in the Series using the specified method, which can be 'backfill'.
DataFrame.fillna Fill NaN values in the DataFrame using the specified method, which can be 'backfill'.

Examples

Resampling a Series:

```
>>> s = pd.Series([1, 2, 3],
...               index=pd.date_range('20180101', periods=3, freq='h'))
>>> s
2018-01-01 00:00:00    1
2018-01-01 01:00:00    2
2018-01-01 02:00:00    3
Freq: H, dtype: int64
```

```
>>> s.resample('30min').backfill()
2018-01-01 00:00:00    1
2018-01-01 00:30:00    2
2018-01-01 01:00:00    2
2018-01-01 01:30:00    3
2018-01-01 02:00:00    3
Freq: 30T, dtype: int64
```

```
>>> s.resample('15min').backfill(limit=2)
2018-01-01 00:00:00    1.0
2018-01-01 00:15:00    NaN
2018-01-01 00:30:00    2.0
2018-01-01 00:45:00    2.0
2018-01-01 01:00:00    2.0
```

(continues on next page)

(continued from previous page)

Freq: 15T, dtype: float64
```

Resampling a DataFrame that has missing values:

```
>>> df = pd.DataFrame({'a': [2, np.nan, 6], 'b': [1, 3, 5]},
...                   index=pd.date_range('20180101', periods=3,
...                                       freq='h'))
>>> df
                     a  b
2018-01-01 00:00:00  2.0  1
2018-01-01 01:00:00  NaN  3
2018-01-01 02:00:00  6.0  5
```

```
>>> df.resample('30min').backfill()
                     a  b
2018-01-01 00:00:00  2.0  1
2018-01-01 00:30:00  NaN  3
2018-01-01 01:00:00  NaN  3
2018-01-01 01:30:00  6.0  5
2018-01-01 02:00:00  6.0  5
```

```
>>> df.resample('15min').backfill(limit=2)
                     a    b
2018-01-01 00:00:00  2.0  1.0
2018-01-01 00:15:00  NaN  NaN
2018-01-01 00:30:00  NaN  3.0
2018-01-01 00:45:00  NaN  3.0
2018-01-01 01:00:00  NaN  3.0
2018-01-01 01:15:00  NaN  NaN
2018-01-01 01:30:00  6.0  5.0
2018-01-01 01:45:00  6.0  5.0
2018-01-01 02:00:00  6.0  5.0
```

pandas.core.resample.Resampler.bfill

Resampler.**bfill**(*limit=None*)

Backward fill the new missing values in the resampled data.

In statistics, imputation is the process of replacing missing data with substituted values [1]. When resampling data, missing values may appear (e.g., when the resampling frequency is higher than the original frequency). The backward fill will replace NaN values that appeared in the resampled data with the next value in the original sequence. Missing values that existed in the original data will not be modified.

Parameters

limit [int, optional] Limit of how many values to fill.

Returns

Series, DataFrame An upsampled Series or DataFrame with backward filled NaN values.

See also:

bfill Alias of backfill.

fillna Fill NaN values using the specified method, which can be 'backfill'.
nearest Fill NaN values with nearest neighbor starting from center.
pad Forward fill NaN values.
Series.fillna Fill NaN values in the Series using the specified method, which can be 'backfill'.
DataFrame.fillna Fill NaN values in the DataFrame using the specified method, which can be 'backfill'.

[1]

Examples

Resampling a Series:

```
>>> s = pd.Series([1, 2, 3],
...               index=pd.date_range('20180101', periods=3, freq='h'))
>>> s
2018-01-01 00:00:00    1
2018-01-01 01:00:00    2
2018-01-01 02:00:00    3
Freq: H, dtype: int64
```

```
>>> s.resample('30min').backfill()
2018-01-01 00:00:00    1
2018-01-01 00:30:00    2
2018-01-01 01:00:00    2
2018-01-01 01:30:00    3
2018-01-01 02:00:00    3
Freq: 30T, dtype: int64
```

```
>>> s.resample('15min').backfill(limit=2)
2018-01-01 00:00:00    1.0
2018-01-01 00:15:00    NaN
2018-01-01 00:30:00    2.0
2018-01-01 00:45:00    2.0
2018-01-01 01:00:00    2.0
2018-01-01 01:15:00    NaN
2018-01-01 01:30:00    3.0
2018-01-01 01:45:00    3.0
2018-01-01 02:00:00    3.0
Freq: 15T, dtype: float64
```

Resampling a DataFrame that has missing values:

```
>>> df = pd.DataFrame({'a': [2, np.nan, 6], 'b': [1, 3, 5]},
...                   index=pd.date_range('20180101', periods=3,
...                                       freq='h'))
>>> df
                       a  b
2018-01-01 00:00:00  2.0  1
2018-01-01 01:00:00  NaN  3
2018-01-01 02:00:00  6.0  5
```

```
>>> df.resample('30min').backfill()
                     a  b
2018-01-01 00:00:00  2.0  1
2018-01-01 00:30:00  NaN  3
2018-01-01 01:00:00  NaN  3
2018-01-01 01:30:00  6.0  5
2018-01-01 02:00:00  6.0  5
```

```
>>> df.resample('15min').backfill(limit=2)
                     a    b
2018-01-01 00:00:00  2.0  1.0
2018-01-01 00:15:00  NaN  NaN
2018-01-01 00:30:00  NaN  3.0
2018-01-01 00:45:00  NaN  3.0
2018-01-01 01:00:00  NaN  3.0
2018-01-01 01:15:00  NaN  NaN
2018-01-01 01:30:00  6.0  5.0
2018-01-01 01:45:00  6.0  5.0
2018-01-01 02:00:00  6.0  5.0
```

pandas.core.resample.Resampler.pad

Resampler.**pad**(*limit=None*)

Forward fill the values.

Parameters

limit [int, optional] Limit of how many values to fill.

Returns

An upsampled Series.

See also:

Series.fillna
DataFrame.fillna

pandas.core.resample.Resampler.nearest

Resampler.**nearest**(*limit=None*)

Resample by using the nearest value.

When resampling data, missing values may appear (e.g., when the resampling frequency is higher than the original frequency). The *nearest* method will replace NaN values that appeared in the resampled data with the value from the nearest member of the sequence, based on the index value. Missing values that existed in the original data will not be modified. If *limit* is given, fill only this many values in each direction for each of the original values.

Parameters

limit [int, optional] Limit of how many values to fill.

Returns

Series or DataFrame An upsampled Series or DataFrame with NaN values filled with their nearest value.

See also:

backfill Backward fill the new missing values in the resampled data.

pad Forward fill NaN values.

Examples

```
>>> s = pd.Series([1, 2],
...               index=pd.date_range('20180101',
...                                   periods=2,
...                                   freq='1h'))
>>> s
2018-01-01 00:00:00    1
2018-01-01 01:00:00    2
Freq: H, dtype: int64
```

```
>>> s.resample('15min').nearest()
2018-01-01 00:00:00    1
2018-01-01 00:15:00    1
2018-01-01 00:30:00    2
2018-01-01 00:45:00    2
2018-01-01 01:00:00    2
Freq: 15T, dtype: int64
```

Limit the number of upsampled values imputed by the nearest:

```
>>> s.resample('15min').nearest(limit=1)
2018-01-01 00:00:00    1.0
2018-01-01 00:15:00    1.0
2018-01-01 00:30:00    NaN
2018-01-01 00:45:00    2.0
2018-01-01 01:00:00    2.0
Freq: 15T, dtype: float64
```

pandas.core.resample.Resampler.fillna

Resampler.**fillna**(*method*, *limit=None*)

Fill missing values introduced by upsampling.

In statistics, imputation is the process of replacing missing data with substituted values [1]. When resampling data, missing values may appear (e.g., when the resampling frequency is higher than the original frequency).

Missing values that existed in the original data will not be modified.

Parameters

method [{'pad', 'backfill', 'ffill', 'bfill', 'nearest'}] Method to use for filling holes in resampled data

- 'pad' or 'ffill': use previous valid observation to fill gap (forward fill).
- 'backfill' or 'bfill': use next valid observation to fill gap.
- 'nearest': use nearest valid observation to fill gap.

limit [int, optional] Limit of how many consecutive missing values to fill.

Returns

Series or DataFrame An upsampled Series or DataFrame with missing values filled.

See also:

backfill Backward fill NaN values in the resampled data.

pad Forward fill NaN values in the resampled data.
nearest Fill NaN values in the resampled data with nearest neighbor starting from center.
interpolate Fill NaN values using interpolation.
Series.fillna Fill NaN values in the Series using the specified method, which can be 'bfill' and 'ffill'.
DataFrame.fillna Fill NaN values in the DataFrame using the specified method, which can be 'bfill' and 'ffill'.

Examples

Resampling a Series:

```
>>> s = pd.Series([1, 2, 3],
...               index=pd.date_range('20180101', periods=3, freq='h'))
>>> s
2018-01-01 00:00:00    1
2018-01-01 01:00:00    2
2018-01-01 02:00:00    3
Freq: H, dtype: int64
```

Without filling the missing values you get:

```
>>> s.resample("30min").asfreq()
2018-01-01 00:00:00    1.0
2018-01-01 00:30:00    NaN
2018-01-01 01:00:00    2.0
2018-01-01 01:30:00    NaN
2018-01-01 02:00:00    3.0
Freq: 30T, dtype: float64
```

```
>>> s.resample('30min').fillna("backfill")
2018-01-01 00:00:00    1
2018-01-01 00:30:00    2
2018-01-01 01:00:00    2
2018-01-01 01:30:00    3
2018-01-01 02:00:00    3
Freq: 30T, dtype: int64
```

```
>>> s.resample('15min').fillna("backfill", limit=2)
2018-01-01 00:00:00    1.0
2018-01-01 00:15:00    NaN
2018-01-01 00:30:00    2.0
2018-01-01 00:45:00    2.0
2018-01-01 01:00:00    2.0
2018-01-01 01:15:00    NaN
2018-01-01 01:30:00    3.0
2018-01-01 01:45:00    3.0
2018-01-01 02:00:00    3.0
Freq: 15T, dtype: float64
```

```
>>> s.resample('30min').fillna("pad")
2018-01-01 00:00:00    1
2018-01-01 00:30:00    1
2018-01-01 01:00:00    2
2018-01-01 01:30:00    2
2018-01-01 02:00:00    3
Freq: 30T, dtype: int64
```

```
>>> s.resample('30min').fillna("nearest")
2018-01-01 00:00:00    1
2018-01-01 00:30:00    2
2018-01-01 01:00:00    2
2018-01-01 01:30:00    3
2018-01-01 02:00:00    3
Freq: 30T, dtype: int64
```

Missing values present before the upsampling are not affected.

```
>>> sm = pd.Series([1, None, 3],
...                index=pd.date_range('20180101', periods=3, freq='h'))
>>> sm
2018-01-01 00:00:00    1.0
2018-01-01 01:00:00    NaN
2018-01-01 02:00:00    3.0
Freq: H, dtype: float64
```

```
>>> sm.resample('30min').fillna('backfill')
2018-01-01 00:00:00    1.0
2018-01-01 00:30:00    NaN
2018-01-01 01:00:00    NaN
2018-01-01 01:30:00    3.0
2018-01-01 02:00:00    3.0
Freq: 30T, dtype: float64
```

```
>>> sm.resample('30min').fillna('pad')
2018-01-01 00:00:00    1.0
2018-01-01 00:30:00    1.0
2018-01-01 01:00:00    NaN
2018-01-01 01:30:00    NaN
2018-01-01 02:00:00    3.0
Freq: 30T, dtype: float64
```

```
>>> sm.resample('30min').fillna('nearest')
2018-01-01 00:00:00    1.0
2018-01-01 00:30:00    NaN
2018-01-01 01:00:00    NaN
2018-01-01 01:30:00    3.0
2018-01-01 02:00:00    3.0
Freq: 30T, dtype: float64
```

DataFrame resampling is done column-wise. All the same options are available.

```
>>> df = pd.DataFrame({'a': [2, np.nan, 6], 'b': [1, 3, 5]},
...                   index=pd.date_range('20180101', periods=3,
...                                       freq='h'))
>>> df
```

(continues on next page)

(continued from previous page)

```
                     a  b
2018-01-01 00:00:00  2.0  1
2018-01-01 01:00:00  NaN  3
2018-01-01 02:00:00  6.0  5
```

```
>>> df.resample('30min').fillna("bfill")
                     a  b
2018-01-01 00:00:00  2.0  1
2018-01-01 00:30:00  NaN  3
2018-01-01 01:00:00  NaN  3
2018-01-01 01:30:00  6.0  5
2018-01-01 02:00:00  6.0  5
```

pandas.core.resample.Resampler.asfreq

Resampler.**asfreq**(*fill_value=None*)

Return the values at the new freq, essentially a reindex.

Parameters

fill_value [scalar, optional] Value to use for missing values, applied during upsampling (note this does not fill NaNs that already were present).

Returns

DataFrame or Series Values at the specified freq.

See also:

Series.asfreq
DataFrame.asfreq

pandas.core.resample.Resampler.interpolate

Resampler.**interpolate**(*method='linear'*, *axis=0*, *limit=None*, *inplace=False*, *limit_direction='forward'*, *limit_area=None*, *downcast=None*, ***kwargs*)

Interpolate values according to different methods.

Please note that only `method='linear'` is supported for DataFrame/Series with a MultiIndex.

Parameters

method [str, default 'linear'] Interpolation technique to use. One of:

- 'linear': Ignore the index and treat the values as equally spaced. This is the only method supported on MultiIndexes.
- 'time': Works on daily and higher resolution data to interpolate given length of interval.
- 'index', 'values': use the actual numerical values of the index.
- 'pad': Fill in NaNs using existing values.
- 'nearest', 'zero', 'slinear', 'quadratic', 'cubic', 'spline', 'barycentric', 'polynomial': Passed to *scipy.interpolate.interp1d*. These methods use the numerical values of the index. Both 'polynomial' and 'spline' require that you also specify an *order* (int), e.g. `df.interpolate(method='polynomial', order=5)`.
- 'krogh', 'piecewise_polynomial', 'spline', 'pchip', 'akima', 'cubicspline': Wrappers around the SciPy interpolation methods of similar names. See *Notes*.

- 'from_derivatives': Refers to *scipy.interpolate.BPoly.from_derivatives* which replaces 'piecewise_polynomial' interpolation method in scipy 0.18.

axis [{{0 or 'index', 1 or 'columns', None}}, default None] Axis to interpolate along.

limit [int, optional] Maximum number of consecutive NaNs to fill. Must be greater than 0.

inplace [bool, default False] Update the data in place if possible.

limit_direction [{{'forward', 'backward', 'both'}}, Optional] Consecutive NaNs will be filled in this direction.

If limit is specified:

- If 'method' is 'pad' or 'ffill', 'limit_direction' must be 'forward'.
- If 'method' is 'backfill' or 'bfill', 'limit_direction' must be 'backwards'.

If 'limit' is not specified:

- If 'method' is 'backfill' or 'bfill', the default is 'backward'
- else the default is 'forward'

Changed in version 1.1.0: raises ValueError if *limit_direction* is 'forward' or 'both' and method is 'backfill' or 'bfill'. raises ValueError if *limit_direction* is 'backward' or 'both' and method is 'pad' or 'ffill'.

limit_area [{{*None*, 'inside', 'outside'}}, default None] If limit is specified, consecutive NaNs will be filled with this restriction.

- `None`: No fill restriction.
- 'inside': Only fill NaNs surrounded by valid values (interpolate).
- 'outside': Only fill NaNs outside valid values (extrapolate).

New in version 0.23.0.

downcast [optional, 'infer' or None, defaults to None] Downcast dtypes if possible.

****kwargs** Keyword arguments to pass on to the interpolating function.

Returns

Series or DataFrame Returns the same object type as the caller, interpolated at some or all `NaN` values.

See also:

fillna Fill missing values using different methods.
scipy.interpolate.Akima1DInterpolator Piecewise cubic polynomials (Akima interpolator).
scipy.interpolate.BPoly.from_derivatives Piecewise polynomial in the Bernstein basis.
scipy.interpolate.interp1d Interpolate a 1-D function.
scipy.interpolate.KroghInterpolator Interpolate polynomial (Krogh interpolator).
scipy.interpolate.PchipInterpolator PCHIP 1-d monotonic cubic interpolation.
scipy.interpolate.CubicSpline Cubic spline data interpolator.

Notes

The 'krogh', 'piecewise_polynomial', 'spline', 'pchip' and 'akima' methods are wrappers around the respective SciPy implementations of similar names. These use the actual numerical values of the index. For more information on their behavior, see the SciPy documentation and SciPy tutorial.

Examples

Filling in `NaN` in a *`Series`* via linear interpolation.

```
>>> s = pd.Series([0, 1, np.nan, 3])
>>> s
0    0.0
1    1.0
2    NaN
3    3.0
dtype: float64
>>> s.interpolate()
0    0.0
1    1.0
2    2.0
3    3.0
dtype: float64
```

Filling in `NaN` in a Series by padding, but filling at most two consecutive `NaN` at a time.

```
>>> s = pd.Series([np.nan, "single_one", np.nan,
...                "fill_two_more", np.nan, np.nan, np.nan,
...                4.71, np.nan])
>>> s
0              NaN
1       single_one
2              NaN
3    fill_two_more
4              NaN
5              NaN
6              NaN
7             4.71
8              NaN
dtype: object
>>> s.interpolate(method='pad', limit=2)
0              NaN
1       single_one
2       single_one
3    fill_two_more
4    fill_two_more
5    fill_two_more
6              NaN
7             4.71
8             4.71
dtype: object
```

Filling in `NaN` in a Series via polynomial interpolation or splines: Both 'polynomial' and 'spline' methods require that you also specify an `order` (int).

```
>>> s = pd.Series([0, 2, np.nan, 8])
>>> s.interpolate(method='polynomial', order=2)
0    0.000000
1    2.000000
2    4.666667
3    8.000000
dtype: float64
```

Fill the DataFrame forward (that is, going down) along each column using linear interpolation.

Note how the last entry in column 'a' is interpolated differently, because there is no entry after it to use for interpolation. Note how the first entry in column 'b' remains `NaN`, because there is no entry before it to use for interpolation.

```
>>> df = pd.DataFrame([(0.0, np.nan, -1.0, 1.0),
...                    (np.nan, 2.0, np.nan, np.nan),
...                    (2.0, 3.0, np.nan, 9.0),
...                    (np.nan, 4.0, -4.0, 16.0)],
...                   columns=list('abcd'))
>>> df
     a    b    c     d
0  0.0  NaN -1.0   1.0
1  NaN  2.0  NaN   NaN
2  2.0  3.0  NaN   9.0
3  NaN  4.0 -4.0  16.0
>>> df.interpolate(method='linear', limit_direction='forward', axis=0)
     a    b    c     d
0  0.0  NaN -1.0   1.0
1  1.0  2.0 -2.0   5.0
2  2.0  3.0 -3.0   9.0
3  2.0  4.0 -4.0  16.0
```

Using polynomial interpolation.

```
>>> df['d'].interpolate(method='polynomial', order=2)
0     1.0
1     4.0
2     9.0
3    16.0
Name: d, dtype: float64
```

3.12.4 Computations / descriptive stats

Resampler.count()	Compute count of group, excluding missing values.
Resampler.nunique([_method])	Return number of unique elements in the group.
Resampler.first([_method])	Compute first of group values.
Resampler.last([_method])	Compute last of group values.
Resampler.max([_method])	Compute max of group values.
Resampler.mean([_method])	Compute mean of groups, excluding missing values.
Resampler.median([_method])	Compute median of groups, excluding missing values.
Resampler.min([_method])	Compute min of group values.
Resampler.ohlc([_method])	Compute open, high, low and close values of a group, excluding missing values.

continues on next page

Table 379 – continued from previous page

Resampler.prod([_method, min_count])	Compute prod of group values.
Resampler.size()	Compute group sizes.
Resampler.sem([_method])	Compute standard error of the mean of groups, excluding missing values.
Resampler.std([ddof])	Compute standard deviation of groups, excluding missing values.
Resampler.sum([_method, min_count])	Compute sum of group values.
Resampler.var([ddof])	Compute variance of groups, excluding missing values.
Resampler.quantile([q])	Return value at the given quantile.

pandas.core.resample.Resampler.count

Resampler.**count**()

Compute count of group, excluding missing values.

Returns

Series or DataFrame Count of values within each group.

See also:

Series.groupby
DataFrame.groupby

pandas.core.resample.Resampler.nunique

Resampler.**nunique**(*_method='nunique'*)

Return number of unique elements in the group.

Returns

Series Number of unique values within each group.

pandas.core.resample.Resampler.first

Resampler.**first**(*_method='first'*, **args*, ***kwargs*)

Compute first of group values.

Parameters

numeric_only [bool, default False] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

min_count [int, default -1] The required number of valid values to perform the operation. If fewer than `min_count` non-NA values are present the result will be NA.

Returns

Series or DataFrame Computed first of values within each group.

pandas.core.resample.Resampler.last

Resampler.**last**(*_method='last'*, **args*, ***kwargs*)

Compute last of group values.

Parameters

numeric_only [bool, default False] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

min_count [int, default -1] The required number of valid values to perform the operation. If fewer than `min_count` non-NA values are present the result will be NA.

Returns

Series or DataFrame Computed last of values within each group.

pandas.core.resample.Resampler.max

Resampler.**max**(*_method='max'*, **args*, ***kwargs*)

Compute max of group values.

Parameters

numeric_only [bool, default False] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

min_count [int, default -1] The required number of valid values to perform the operation. If fewer than `min_count` non-NA values are present the result will be NA.

Returns

Series or DataFrame Computed max of values within each group.

pandas.core.resample.Resampler.mean

Resampler.**mean**(*_method='mean'*, **args*, ***kwargs*)

Compute mean of groups, excluding missing values.

Parameters

numeric_only [bool, default True] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

Returns

pandas.Series or pandas.DataFrame

See also:

`Series.groupby`
`DataFrame.groupby`

Examples

```
>>> df = pd.DataFrame({'A': [1, 1, 2, 1, 2],
...                    'B': [np.nan, 2, 3, 4, 5],
...                    'C': [1, 2, 1, 1, 2]}, columns=['A', 'B', 'C'])
```

Groupby one column and return the mean of the remaining columns in each group.

```
>>> df.groupby('A').mean()
     B         C
A
1  3.0  1.333333
2  4.0  1.500000
```

Groupby two columns and return the mean of the remaining column.

```
>>> df.groupby(['A', 'B']).mean()
       C
A B
1 2.0  2
  4.0  1
2 3.0  1
  5.0  2
```

Groupby one column and return the mean of only particular column in the group.

```
>>> df.groupby('A')['B'].mean()
A
1    3.0
2    4.0
Name: B, dtype: float64
```

pandas.core.resample.Resampler.median

Resampler.**median**(*_method='median', *args, **kwargs*)

Compute median of groups, excluding missing values.

For multiple groupings, the result index will be a MultiIndex

Parameters

numeric_only [bool, default True] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

Returns

Series or DataFrame Median of values within each group.

See also:

Series.groupby
DataFrame.groupby

pandas.core.resample.Resampler.min

Resampler.**min**(*_method='min'*, **args*, ***kwargs*)

Compute min of group values.

Parameters

numeric_only [bool, default False] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

min_count [int, default -1] The required number of valid values to perform the operation. If fewer than `min_count` non-NA values are present the result will be NA.

Returns

Series or DataFrame Computed min of values within each group.

pandas.core.resample.Resampler.ohlc

Resampler.**ohlc**(*_method='ohlc'*, **args*, ***kwargs*)

Compute open, high, low and close values of a group, excluding missing values.

For multiple groupings, the result index will be a MultiIndex

Returns

DataFrame Open, high, low and close values within each group.

See also:

Series.groupby
DataFrame.groupby

pandas.core.resample.Resampler.prod

Resampler.**prod**(*_method='prod'*, *min_count=0*, **args*, ***kwargs*)

Compute prod of group values.

Parameters

numeric_only [bool, default True] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

min_count [int, default 0] The required number of valid values to perform the operation. If fewer than `min_count` non-NA values are present the result will be NA.

Returns

Series or DataFrame Computed prod of values within each group.

pandas.core.resample.Resampler.size

Resampler.**size**()

Compute group sizes.

Returns

DataFrame or Series Number of rows in each group as a Series if as_index is True or a DataFrame if as_index is False.

See also:

Series.groupby
DataFrame.groupby

pandas.core.resample.Resampler.sem

Resampler.**sem**(*_method='sem'*, **args*, ***kwargs*)

Compute standard error of the mean of groups, excluding missing values.

For multiple groupings, the result index will be a MultiIndex.

Parameters

ddof [int, default 1] Degrees of freedom.

Returns

Series or DataFrame Standard error of the mean of values within each group.

See also:

Series.groupby
DataFrame.groupby

pandas.core.resample.Resampler.std

Resampler.**std**(*ddof=1*, **args*, ***kwargs*)

Compute standard deviation of groups, excluding missing values.

Parameters

ddof [int, default 1] Degrees of freedom.

Returns

DataFrame or Series Standard deviation of values within each group.

pandas.core.resample.Resampler.sum

Resampler.**sum**(*_method='sum'*, *min_count=0*, **args*, ***kwargs*)

Compute sum of group values.

Parameters

numeric_only [bool, default True] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

min_count [int, default 0] The required number of valid values to perform the operation. If fewer than `min_count` non-NA values are present the result will be NA.

Returns

Series or DataFrame Computed sum of values within each group.

pandas.core.resample.Resampler.var

Resampler.**var**(*ddof=1*, **args*, ***kwargs*)

Compute variance of groups, excluding missing values.

Parameters

ddof [int, default 1] Degrees of freedom.

Returns

DataFrame or Series Variance of values within each group.

pandas.core.resample.Resampler.quantile

Resampler.**quantile**(*q=0.5*, ***kwargs*)

Return value at the given quantile.

New in version 0.24.0.

Parameters

q [float or array-like, default 0.5 (50% quantile)]

Returns

DataFrame or Series Quantile of values within each group.

See also:

Series.quantile
DataFrame.quantile
DataFrameGroupBy.quantile

3.13 Style

`Styler` objects are returned by *pandas.DataFrame.style*.

3.13.1 Styler constructor

Styler(data[, precision, table_styles, ...])	Helps style a DataFrame or Series according to the data with HTML and CSS.
Styler.from_custom_template(searchpath, name)	Factory function for creating a subclass of `Styler`.

pandas.io.formats.style.Styler

class pandas.io.formats.style.**Styler**(*data*, *precision=None*, *table_styles=None*, *uuid=None*, *caption=None*, *table_attributes=None*, *cell_ids=True*, *na_rep=None*)

Helps style a DataFrame or Series according to the data with HTML and CSS.

Parameters

data [Series or DataFrame] Data to be styled - either a Series or DataFrame.

precision [int] Precision to round floats to, defaults to pd.options.display.precision.

table_styles [list-like, default None] List of {selector: (attr, value)} dicts; see Notes.

uuid [str, default None] A unique identifier to avoid CSS collisions; generated automatically.

caption [str, default None] Caption to attach to the table.

table_attributes [str, default None] Items that show up in the opening `<table>` tag in addition to automatic (by default) id.

cell_ids [bool, default True] If True, each cell will have an `id` attribute in their HTML tag. The `id` takes the form `T_<uuid>_row<num_row>_col<num_col>` where `<uuid>` is the unique identifier, `<num_row>` is the row number and `<num_col>` is the column number.

na_rep [str, optional] Representation for missing values. If `na_rep` is None, no special formatting is applied.

New in version 1.0.0.

See also:

`DataFrame.style` Return a Styler object containing methods for building a styled HTML representation for the DataFrame.

Notes

Most styling will be done by passing style functions into `Styler.apply` or `Styler.applymap`. Style functions should return values with strings containing CSS `'attr: value'` that will be applied to the indicated cells.

If using in the Jupyter notebook, Styler has defined a `_repr_html_` to automatically render itself. Otherwise call Styler.render to get the generated HTML.

CSS classes are attached to the generated HTML

- Index and Column names include `index_name` and `level<k>` where *k* is its level in a MultiIndex
- Index label cells include
  - `row_heading`
  - `row<n>` where *n* is the numeric position of the row
  - `level<k>` where *k* is the level in a MultiIndex
- Column label cells include * `col_heading` * `col<n>` where *n* is the numeric position of the column * `level<k>` where *k* is the level in a MultiIndex
- Blank cells include `blank`
- Data cells include `data`

Attributes

env	(Jinja2 jinja2.Environment)
template	(Jinja2 Template)
loader	(Jinja2 Loader)

Methods

apply(func[, axis, subset])	Apply a function column-wise, row-wise, or table-wise.
applymap(func[, subset])	Apply a function elementwise.
background_gradient([cmap, low, high, axis, ...])	Color the background in a gradient style.
bar([subset, axis, color, width, align, ...])	Draw bar chart in the cell backgrounds.
clear()	Reset the styler, removing any previously applied styles.
export()	Export the styles to applied to the current Styler.
format(formatter[, subset, na_rep])	Format the text display value of cells.
from_custom_template(searchpath, name)	Factory function for creating a subclass of `Styler`.
hide_columns(subset)	Hide columns from rendering.

continues on next page

Table 381 – continued from previous page

hide_index()	Hide any indices from rendering.
highlight_max([subset, color, axis])	Highlight the maximum by shading the background.
highlight_min([subset, color, axis])	Highlight the minimum by shading the background.
highlight_null([null_color, subset])	Shade the background `null_color` for missing values.
pipe(func, *args, **kwargs)	Apply `func(self, *args, **kwargs)`, and return the result.
render(**kwargs)	Render the built up styles to HTML.
set_caption(caption)	Set the caption on a Styler.
set_na_rep(na_rep)	Set the missing data representation on a Styler.
set_precision(precision)	Set the precision used to render.
set_properties([subset])	Method to set one or more non-data dependent properties or each cell.
set_table_attributes(attributes)	Set the table attributes.
set_table_styles(table_styles)	Set the table styles on a Styler.
set_uuid(uuid)	Set the uuid for a Styler.
to_excel(excel_writer[, sheet_name, na_rep, ...])	Write Styler to an Excel sheet.
use(styles)	Set the styles on the current Styler.
where(cond, value[, other, subset])	Apply a function elementwise.

pandas.io.formats.style.Styler.apply

`Styler.`**`apply`**(*func*, *axis=0*, *subset=None*, ***kwargs*)

Apply a function column-wise, row-wise, or table-wise.

Updates the HTML representation with the result.

Parameters

func [function] `func` should take a Series or DataFrame (depending on `axis`), and return an object with the same shape. Must return a DataFrame with identical index and column labels when `axis=None`.

axis [{0 or 'index', 1 or 'columns', None}, default 0] Apply to each column (`axis=0` or `'index'`), to each row (`axis=1` or `'columns'`), or to the entire DataFrame at once with `axis=None`.

subset [IndexSlice] A valid indexer to limit `data` to *before* applying the function. Consider using a pandas.IndexSlice.

****kwargs** [dict] Pass along to `func`.

Returns

self [Styler]

Notes

The output shape of `func` should match the input, i.e. if `x` is the input row, column, or table (depending on `axis`), then `func(x).shape == x.shape` should be true.

This is similar to `DataFrame.apply`, except that `axis=None` applies the function to the entire DataFrame at once, rather than column-wise or row-wise.

Examples

```
>>> def highlight_max(x):
...     return ['background-color: yellow' if v == x.max() else ''
                for v in x]
...
>>> df = pd.DataFrame(np.random.randn(5, 2))
>>> df.style.apply(highlight_max)
```

pandas.io.formats.style.Styler.applymap

Styler.**applymap**(*func*, *subset=None*, ***kwargs*)

Apply a function elementwise.

Updates the HTML representation with the result.

Parameters

func [function] `func` should take a scalar and return a scalar.

subset [IndexSlice] A valid indexer to limit `data` to *before* applying the function. Consider using a pandas.IndexSlice.

****kwargs** [dict] Pass along to `func`.

Returns

self [Styler]

See also:

Styler.where

pandas.io.formats.style.Styler.background_gradient

Styler.**background_gradient**(*cmap='PuBu'*, *low=0*, *high=0*, *axis=0*, *subset=None*, *text_color_threshold=0.408*, *vmin=None*, *vmax=None*)

Color the background in a gradient style.

The background color is determined according to the data in each column (optionally row). Requires matplotlib.

Parameters

cmap [str or colormap] Matplotlib colormap.

low [float] Compress the range by the low.

high [float] Compress the range by the high.

axis [{0 or 'index', 1 or 'columns', None}, default 0] Apply to each column (`axis=0` or `'index'`), to each row (`axis=1` or `'columns'`), or to the entire DataFrame at once with `axis=None`.

subset [IndexSlice] A valid slice for `data` to limit the style application to.

text_color_threshold [float or int] Luminance threshold for determining text color. Facilitates text visibility across varying background colors. From 0 to 1. 0 = all text is dark colored, 1 = all text is light colored.

New in version 0.24.0.

vmin [float, optional] Minimum data value that corresponds to colormap minimum value. When None (default): the minimum value of the data will be used.

New in version 1.0.0.

vmax [float, optional] Maximum data value that corresponds to colormap maximum value. When None (default): the maximum value of the data will be used.

New in version 1.0.0.

Returns

self [Styler]

Raises

ValueError If `text_color_threshold` is not a value from 0 to 1.

Notes

Set `text_color_threshold` or tune `low` and `high` to keep the text legible by not using the entire range of the color map. The range of the data is extended by `low * (x.max() - x.min())` and `high * (x.max() - x.min())` before normalizing.

pandas.io.formats.style.Styler.bar

`Styler.`**`bar`**(*subset=None*, *axis=0*, *color='#d65f5f'*, *width=100*, *align='left'*, *vmin=None*, *vmax=None*)

Draw bar chart in the cell backgrounds.

Parameters

subset [IndexSlice, optional] A valid slice for *data* to limit the style application to.

axis [{0 or 'index', 1 or 'columns', None}, default 0] Apply to each column (`axis=0` or `'index'`), to each row (`axis=1` or `'columns'`), or to the entire DataFrame at once with `axis=None`.

color [str or 2-tuple/list] If a str is passed, the color is the same for both negative and positive numbers. If 2-tuple/list is used, the first element is the color_negative and the second is the color_positive (eg: ['#d65f5f', '#5fba7d']).

width [float, default 100] A number between 0 or 100. The largest value will cover *width* percent of the cell's width.

align [{'left', 'zero',' mid'}, default 'left'] How to align the bars with the cells.

- 'left' : the min value starts at the left of the cell.
- 'zero' : a value of zero is located at the center of the cell.

- 'mid' : the center of the cell is at (max-min)/2, or if values are all negative (positive) the zero is aligned at the right (left) of the cell.

vmin [float, optional] Minimum bar value, defining the left hand limit of the bar drawing range, lower values are clipped to *vmin*. When None (default): the minimum value of the data will be used.

New in version 0.24.0.

vmax [float, optional] Maximum bar value, defining the right hand limit of the bar drawing range, higher values are clipped to *vmax*. When None (default): the maximum value of the data will be used.

New in version 0.24.0.

Returns

self [Styler]

pandas.io.formats.style.Styler.clear

`Styler.`**`clear`**`()`

Reset the styler, removing any previously applied styles.

Returns None.

pandas.io.formats.style.Styler.export

`Styler.`**`export`**`()`

Export the styles to applied to the current Styler.

Can be applied to a second style with `Styler.use`.

Returns

styles [list]

See also:

`Styler.use`

pandas.io.formats.style.Styler.format

`Styler.`**`format`**`(`*formatter*, *subset=None*, *na_rep=None*`)`

Format the text display value of cells.

Parameters

formatter [str, callable, dict or None] If `formatter` is None, the default formatter is used.

subset [IndexSlice] An argument to `DataFrame.loc` that restricts which elements `formatter` is applied to.

na_rep [str, optional] Representation for missing values. If `na_rep` is None, no special formatting is applied.

New in version 1.0.0.

Returns

self [Styler]

Notes

`formatter` is either an `a` or a dict `{column name: a}` where `a` is one of

- str: this will be wrapped in: `a.format(x)`
- callable: called with the value of an individual cell

The default display value for numeric values is the "general" (`g`) format with `pd.options.display.precision` precision.

Examples

```
>>> df = pd.DataFrame(np.random.randn(4, 2), columns=['a', 'b'])
>>> df.style.format("{:.2%}")
>>> df['c'] = ['a', 'b', 'c', 'd']
>>> df.style.format({'c': str.upper})
```

pandas.io.formats.style.Styler.from_custom_template

classmethod `Styler.`**from_custom_template**(*searchpath*, *name*)

Factory function for creating a subclass of `Styler`.

Uses a custom template and Jinja environment.

Parameters

searchpath [str or list] Path or paths of directories containing the templates.

name [str] Name of your custom template to use for rendering.

Returns

MyStyler [subclass of Styler] Has the correct `env` and `template` class attributes set.

pandas.io.formats.style.Styler.hide_columns

`Styler.`**hide_columns**(*subset*)

Hide columns from rendering.

New in version 0.23.0.

Parameters

subset [IndexSlice] An argument to `DataFrame.loc` that identifies which columns are hidden.

Returns

self [Styler]

pandas.io.formats.style.Styler.hide_index

Styler.**hide_index**()
Hide any indices from rendering.

New in version 0.23.0.

Returns

self [Styler]

pandas.io.formats.style.Styler.highlight_max

Styler.**highlight_max**(*subset=None*, *color='yellow'*, *axis=0*)
Highlight the maximum by shading the background.

Parameters

subset [IndexSlice, default None] A valid slice for `data` to limit the style application to.

color [str, default 'yellow']

axis [{0 or 'index', 1 or 'columns', None}, default 0] Apply to each column (`axis=0` or `'index'`), to each row (`axis=1` or `'columns'`), or to the entire DataFrame at once with `axis=None`.

Returns

self [Styler]

pandas.io.formats.style.Styler.highlight_min

Styler.**highlight_min**(*subset=None*, *color='yellow'*, *axis=0*)
Highlight the minimum by shading the background.

Parameters

subset [IndexSlice, default None] A valid slice for `data` to limit the style application to.

color [str, default 'yellow']

axis [{0 or 'index', 1 or 'columns', None}, default 0] Apply to each column (`axis=0` or `'index'`), to each row (`axis=1` or `'columns'`), or to the entire DataFrame at once with `axis=None`.

Returns

self [Styler]

pandas.io.formats.style.Styler.highlight_null

Styler.**highlight_null**(*null_color='red'*, *subset=None*)

Shade the background `null_color` for missing values.

Parameters

null_color [str, default 'red']

subset [label or list of labels, default None] A valid slice for `data` to limit the style application to.

New in version 1.1.0.

Returns

self [Styler]

pandas.io.formats.style.Styler.pipe

Styler.**pipe**(*func*, **args*, ***kwargs*)

Apply `func(self, *args, **kwargs)`, and return the result.

New in version 0.24.0.

Parameters

func [function] Function to apply to the Styler. Alternatively, a `(callable, keyword)` tuple where `keyword` is a string indicating the keyword of `callable` that expects the Styler.

***args** [optional] Arguments passed to *func*.

****kwargs** [optional] A dictionary of keyword arguments passed into `func`.

Returns

object [] The value returned by `func`.

See also:

DataFrame.pipe Analogous method for DataFrame.

Styler.apply Apply a function row-wise, column-wise, or table-wise to modify the dataframe's styling.

Notes

Like `DataFrame.pipe()`, this method can simplify the application of several user-defined functions to a styler. Instead of writing:

```
f(g(df.style.set_precision(3), arg1=a), arg2=b, arg3=c)
```

users can write:

```
(df.style.set_precision(3)
   .pipe(g, arg1=a)
   .pipe(f, arg2=b, arg3=c))
```

In particular, this allows users to define functions that take a styler object, along with other parameters, and return the styler after making styling changes (such as calling *Styler.apply()* or *Styler.set_properties()*). Using `.pipe`, these user-defined style "transformations" can be interleaved with calls to the built-in Styler interface.

Examples

```
>>> def format_conversion(styler):
...     return (styler.set_properties(**{'text-align': 'right'})
...                   .format({'conversion': '{:.1%}'}))
```

The user-defined `format_conversion` function above can be called within a sequence of other style modifications:

```
>>> df = pd.DataFrame({'trial': list(range(5)),
...                    'conversion': [0.75, 0.85, np.nan, 0.7, 0.72]})
>>> (df.style
...    .highlight_min(subset=['conversion'], color='yellow')
...    .pipe(format_conversion)
...    .set_caption("Results with minimum conversion highlighted."))
```

pandas.io.formats.style.Styler.render

`Styler.`**`render`**(***kwargs*)

Render the built up styles to HTML.

Parameters

****kwargs** Any additional keyword arguments are passed through to `self.template.render`. This is useful when you need to provide additional variables for a custom template.

Returns

rendered [str] The rendered HTML.

Notes

`Styler` objects have defined the `_repr_html_` method which automatically calls `self.render()` when it's the last item in a Notebook cell. When calling `Styler.render()` directly, wrap the result in `IPython.display.HTML` to view the rendered HTML in the notebook.

Pandas uses the following keys in render. Arguments passed in `**kwargs` take precedence, so think carefully if you want to override them:

- head
- cellstyle
- body
- uuid
- precision
- table_styles
- caption

- table_attributes

pandas.io.formats.style.Styler.set_caption

`Styler.set_caption(caption)`
Set the caption on a Styler.

Parameters

caption [str]

Returns

self [Styler]

pandas.io.formats.style.Styler.set_na_rep

`Styler.set_na_rep(na_rep)`
Set the missing data representation on a Styler.

New in version 1.0.0.

Parameters

na_rep [str]

Returns

self [Styler]

pandas.io.formats.style.Styler.set_precision

`Styler.set_precision(precision)`
Set the precision used to render.

Parameters

precision [int]

Returns

self [Styler]

pandas.io.formats.style.Styler.set_properties

`Styler.set_properties(subset=None, **kwargs)`
Method to set one or more non-data dependent properties or each cell.

Parameters

subset [IndexSlice] A valid slice for `data` to limit the style application to.

****kwargs** [dict] A dictionary of property, value pairs to be set for each cell.

Returns

self [Styler]

Examples

```
>>> df = pd.DataFrame(np.random.randn(10, 4))
>>> df.style.set_properties(color="white", align="right")
>>> df.style.set_properties(**{'background-color': 'yellow'})
```

pandas.io.formats.style.Styler.set_table_attributes

Styler.**set_table_attributes**(*attributes*)

Set the table attributes.

These are the items that show up in the opening <table> tag in addition to to automatic (by default) id.

Parameters

attributes [str]

Returns

self [Styler]

Examples

```
>>> df = pd.DataFrame(np.random.randn(10, 4))
>>> df.style.set_table_attributes('class="pure-table"')
# ... <table class="pure-table"> ...
```

pandas.io.formats.style.Styler.set_table_styles

Styler.**set_table_styles**(*table_styles*)

Set the table styles on a Styler.

These are placed in a <style> tag before the generated HTML table.

Parameters

table_styles [list] Each individual table_style should be a dictionary with `selector` and `props` keys. `selector` should be a CSS selector that the style will be applied to (automatically prefixed by the table's UUID) and `props` should be a list of tuples with `(attribute, value)`.

Returns

self [Styler]

Examples

```
>>> df = pd.DataFrame(np.random.randn(10, 4))
>>> df.style.set_table_styles(
...     [{'selector': 'tr:hover',
...       'props': [('background-color', 'yellow')]}]
... )
```

pandas.io.formats.style.Styler.set_uuid

Styler.**set_uuid**(*uuid*)

Set the uuid for a Styler.

Parameters

uuid [str]

Returns

self [Styler]

pandas.io.formats.style.Styler.to_excel

Styler.**to_excel**(*excel_writer*, *sheet_name='Sheet1'*, *na_rep=''*, *float_format=None*, *columns=None*, *header=True*, *index=True*, *index_label=None*, *startrow=0*, *startcol=0*, *engine=None*, *merge_cells=True*, *encoding=None*, *inf_rep='inf'*, *verbose=True*, *freeze_panes=None*)

Write Styler to an Excel sheet.

To write a single Styler to an Excel .xlsx file it is only necessary to specify a target file name. To write to multiple sheets it is necessary to create an *ExcelWriter* object with a target file name, and specify a sheet in the file to write to.

Multiple sheets may be written to by specifying unique *sheet_name*. With all data written to the file it is necessary to save the changes. Note that creating an *ExcelWriter* object with a file name that already exists will result in the contents of the existing file being erased.

Parameters

excel_writer [str or ExcelWriter object] File path or existing ExcelWriter.

sheet_name [str, default 'Sheet1'] Name of sheet which will contain DataFrame.

na_rep [str, default ''] Missing data representation.

float_format [str, optional] Format string for floating point numbers. For example `float_format="%.2f"` will format 0.1234 to 0.12.

columns [sequence or list of str, optional] Columns to write.

header [bool or list of str, default True] Write out the column names. If a list of string is given it is assumed to be aliases for the column names.

index [bool, default True] Write row names (index).

index_label [str or sequence, optional] Column label for index column(s) if desired. If not specified, and *header* and *index* are True, then the index names are used. A sequence should be given if the DataFrame uses MultiIndex.

startrow [int, default 0] Upper left cell row to dump data frame.

startcol [int, default 0] Upper left cell column to dump data frame.

engine [str, optional] Write engine to use, 'openpyxl' or 'xlsxwriter'. You can also set this via the options `io.excel.xlsx.writer`, `io.excel.xls.writer`, and `io.excel.xlsm.writer`.

merge_cells [bool, default True] Write MultiIndex and Hierarchical Rows as merged cells.

encoding [str, optional] Encoding of the resulting excel file. Only necessary for xlwt, other writers support unicode natively.

inf_rep [str, default 'inf'] Representation for infinity (there is no native representation for infinity in Excel).

verbose [bool, default True] Display more information in the error logs.

freeze_panes [tuple of int (length 2), optional] Specifies the one-based bottommost row and rightmost column that is to be frozen.

See also:

`to_csv` Write DataFrame to a comma-separated values (csv) file.

`ExcelWriter` Class for writing DataFrame objects into excel sheets.

`read_excel` Read an Excel file into a pandas DataFrame.

`read_csv` Read a comma-separated values (csv) file into DataFrame.

Notes

For compatibility with `to_csv()`, to_excel serializes lists and dicts to strings before writing.

Once a workbook has been saved it is not possible write further data without rewriting the whole workbook.

Examples

Create, write to and save a workbook:

```
>>> df1 = pd.DataFrame([['a', 'b'], ['c', 'd']],
...                    index=['row 1', 'row 2'],
...                    columns=['col 1', 'col 2'])
>>> df1.to_excel("output.xlsx")
```

To specify the sheet name:

```
>>> df1.to_excel("output.xlsx",
...              sheet_name='Sheet_name_1')
```

If you wish to write to more than one sheet in the workbook, it is necessary to specify an ExcelWriter object:

```
>>> df2 = df1.copy()
>>> with pd.ExcelWriter('output.xlsx') as writer:
...     df1.to_excel(writer, sheet_name='Sheet_name_1')
...     df2.to_excel(writer, sheet_name='Sheet_name_2')
```

ExcelWriter can also be used to append to an existing Excel file:

```
>>> with pd.ExcelWriter('output.xlsx',
...                     mode='a') as writer:
...     df.to_excel(writer, sheet_name='Sheet_name_3')
```

To set the library that is used to write the Excel file, you can pass the *engine* keyword (the default engine is automatically chosen depending on the file extension):

```
>>> df1.to_excel('output1.xlsx', engine='xlsxwriter')
```

pandas.io.formats.style.Styler.use

`Styler.use`(*styles*)

Set the styles on the current Styler.

Possibly uses styles from `Styler.export`.

Parameters

styles [list] List of style functions.

Returns

self [Styler]

See also:

Styler.export

pandas.io.formats.style.Styler.where

`Styler.where`(*cond*, *value*, *other=None*, *subset=None*, ***kwargs*)

Apply a function elementwise.

Updates the HTML representation with a style which is selected in accordance with the return value of a function.

Parameters

cond [callable] `cond` should take a scalar and return a boolean.

value [str] Applied when `cond` returns true.

other [str] Applied when `cond` returns false.

subset [IndexSlice] A valid indexer to limit `data` to *before* applying the function. Consider using a pandas.IndexSlice.

****kwargs** [dict] Pass along to `cond`.

Returns

self [Styler]

See also:

Styler.applymap

3.13.2 Styler properties

Styler.env	
Styler.template	
Styler.loader	

pandas.io.formats.style.Styler.env

Styler.**env = <jinja2.environment.Environment object>**

pandas.io.formats.style.Styler.template

Styler.**template = <Template 'html.tpl'>**

pandas.io.formats.style.Styler.loader

Styler.**loader = <jinja2.loaders.PackageLoader object>**

3.13.3 Style application

Styler.apply(func[, axis, subset])	Apply a function column-wise, row-wise, or table-wise.
Styler.applymap(func[, subset])	Apply a function elementwise.
Styler.where(cond, value[, other, subset])	Apply a function elementwise.
Styler.format(formatter[, subset, na_rep])	Format the text display value of cells.
Styler.set_precision(precision)	Set the precision used to render.
Styler.set_table_styles(table_styles)	Set the table styles on a Styler.
Styler.set_table_attributes(attributes)	Set the table attributes.
Styler.set_caption(caption)	Set the caption on a Styler.
Styler.set_properties([subset])	Method to set one or more non-data dependent properties or each cell.
Styler.set_uuid(uuid)	Set the uuid for a Styler.
Styler.set_na_rep(na_rep)	Set the missing data representation on a Styler.
Styler.clear()	Reset the styler, removing any previously applied styles.
Styler.pipe(func, *args, **kwargs)	Apply `func(self, *args, **kwargs)`, and return the result.

3.13.4 Builtin styles

Styler.highlight_max([subset, color, axis])	Highlight the maximum by shading the background.
Styler.highlight_min([subset, color, axis])	Highlight the minimum by shading the background.
Styler.highlight_null([null_color, subset])	Shade the background `null_color` for missing values.
Styler.background_gradient([cmap, low, ...])	Color the background in a gradient style.
Styler.bar([subset, axis, color, width, ...])	Draw bar chart in the cell backgrounds.

3.13.5 Style export and import

Styler.render(**kwargs)	Render the built up styles to HTML.
Styler.export()	Export the styles to applied to the current Styler.
Styler.use(styles)	Set the styles on the current Styler.
Styler.to_excel(excel_writer[, sheet_name, ...])	Write Styler to an Excel sheet.

3.14 Plotting

The following functions are contained in the *pandas.plotting* module.

andrews_curves(frame, class_column[, ax, ...])	Generate a matplotlib plot of Andrews curves, for visualising clusters of multivariate data.
autocorrelation_plot(series[, ax])	Autocorrelation plot for time series.
bootstrap_plot(series[, fig, size, samples])	Bootstrap plot on mean, median and mid-range statistics.
boxplot(data[, column, by, ax, fontsize, ...])	Make a box plot from DataFrame columns.
deregister_matplotlib_converters()	Remove pandas formatters and converters.
lag_plot(series[, lag, ax])	Lag plot for time series.
parallel_coordinates(frame, class_column[, ...])	Parallel coordinates plotting.
plot_params	Stores pandas plotting options.
radviz(frame, class_column[, ax, color, ...])	Plot a multidimensional dataset in 2D.
register_matplotlib_converters()	Register pandas formatters and converters with matplotlib.
scatter_matrix(frame[, alpha, figsize, ax, ...])	Draw a matrix of scatter plots.
table(ax, data[, rowLabels, colLabels])	Helper function to convert DataFrame and Series to matplotlib.table.

3.14.1 pandas.plotting.andrews_curves

pandas.plotting.**andrews_curves**(*frame*, *class_column*, *ax=None*, *samples=200*, *color=None*, *colormap=None*, ***kwargs*)

Generate a matplotlib plot of Andrews curves, for visualising clusters of multivariate data.

Andrews curves have the functional form:
f(t) = x_1/sqrt(2) + x_2 sin(t) + x_3 cos(t) + x_4 sin(2t) + x_5 cos(2t) + ...
Where x coefficients correspond to the values of each dimension and t is linearly spaced between -pi and +pi. Each row of frame then corresponds to a single curve.

Parameters

frame [DataFrame] Data to be plotted, preferably normalized to (0.0, 1.0).

class_column [Name of the column containing class names]

ax [matplotlib axes object, default None]

samples [Number of points to plot in each curve]

color [list or tuple, optional] Colors to use for the different classes.

colormap [str or matplotlib colormap object, default None] Colormap to select colors from. If string, load colormap with that name from matplotlib.

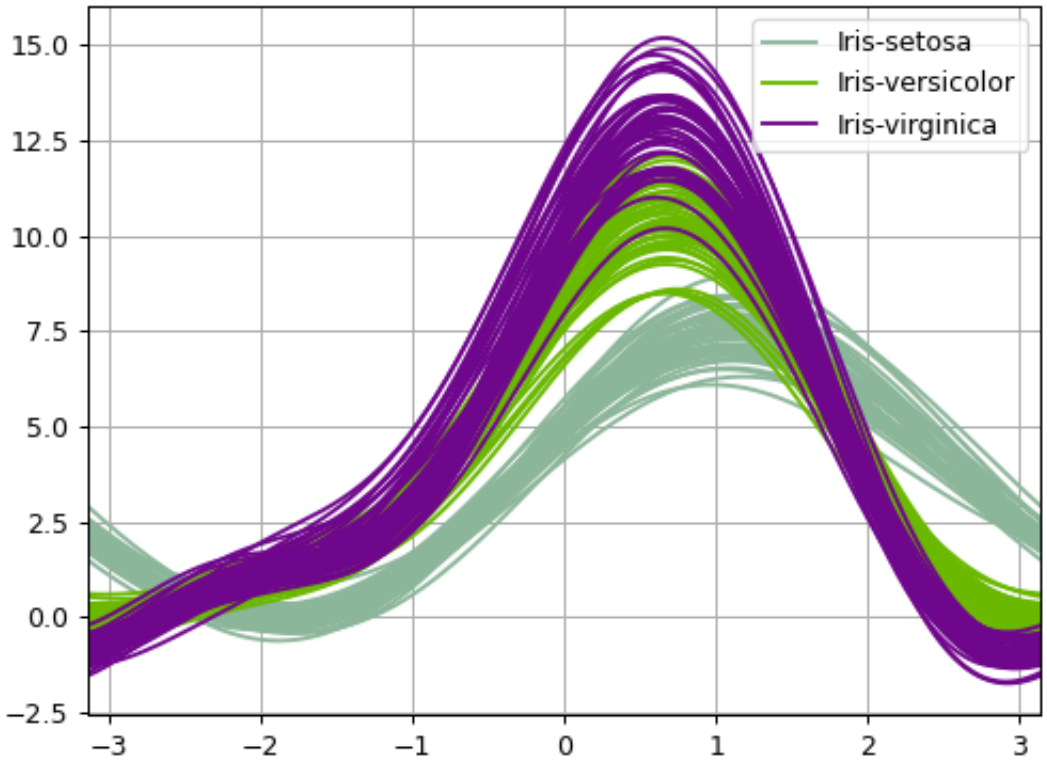
****kwargs** Options to pass to matplotlib plotting method.

Returns

class:*matplotlip.axis.Axes*

Examples

```
>>> df = pd.read_csv(
...     'https://raw.github.com/pandas-dev/'
...     'pandas/master/pandas/tests/io/data/csv/iris.csv'
... )
>>> pd.plotting.andrews_curves(df, 'Name')
```



3.14.2 pandas.plotting.autocorrelation_plot

pandas.plotting.**autocorrelation_plot**(*series*, *ax=None*, ***kwargs*)

Autocorrelation plot for time series.

Parameters

series [Time series]

ax [Matplotlib axis object, optional]

****kwargs** Options to pass to matplotlib plotting method.

Returns

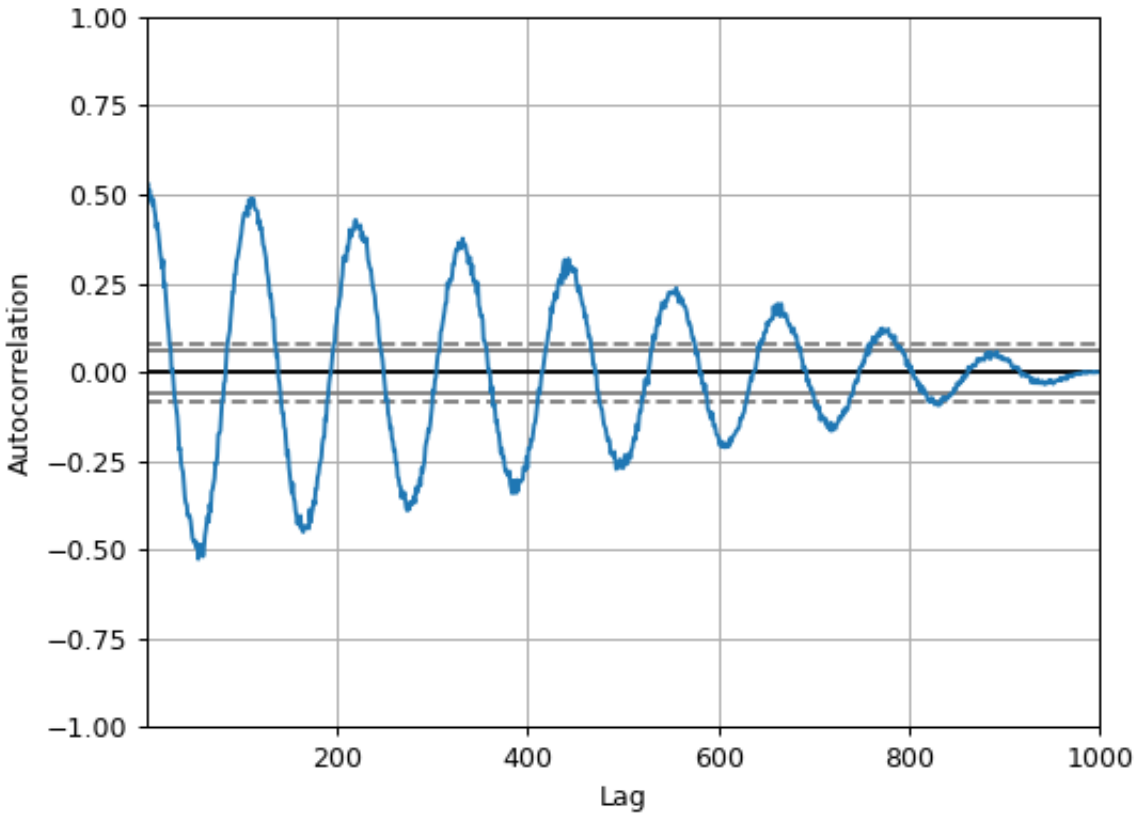
class:*matplotlib.axis.Axes*

Examples

The horizontal lines in the plot correspond to 95% and 99% confidence bands.

The dashed line is 99% confidence band.

```
>>> spacing = np.linspace(-9 * np.pi, 9 * np.pi, num=1000)
>>> s = pd.Series(0.7 * np.random.rand(1000) + 0.3 * np.sin(spacing))
>>> pd.plotting.autocorrelation_plot(s)
```



3.14.3 pandas.plotting.bootstrap_plot

pandas.plotting.**bootstrap_plot**(*series*, *fig=None*, *size=50*, *samples=500*, ***kwds*)

Bootstrap plot on mean, median and mid-range statistics.

The bootstrap plot is used to estimate the uncertainty of a statistic by relaying on random sampling with replacement [1]. This function will generate bootstrapping plots for mean, median and mid-range statistics for the given number of samples of the given size.

Parameters

series [pandas.Series] Series from where to get the samplings for the bootstrapping.

fig [matplotlib.figure.Figure, default None] If given, it will use the *fig* reference for plotting instead of creating a new one with default parameters.

size [int, default 50] Number of data points to consider during each sampling. It must be less than or equal to the length of the *series*.

samples [int, default 500] Number of times the bootstrap procedure is performed.

****kwds** Options to pass to matplotlib plotting method.

Returns

matplotlib.figure.Figure Matplotlib figure.

See also:

DataFrame.plot Basic plotting for DataFrame objects.
Series.plot Basic plotting for Series objects.

Examples

This example draws a basic bootstap plot for a Series.

```
>>> s = pd.Series(np.random.uniform(size=100))
>>> pd.plotting.bootstrap_plot(s)
```

3.14.4 pandas.plotting.boxplot

pandas.plotting.**boxplot**(*data*, *column=None*, *by=None*, *ax=None*, *fontsize=None*, *rot=0*, *grid=True*, *figsize=None*, *layout=None*, *return_type=None*, ***kwargs*)

Make a box plot from DataFrame columns.

Make a box-and-whisker plot from DataFrame columns, optionally grouped by some other columns. A box plot is a method for graphically depicting groups of numerical data through their quartiles. The box extends from the Q1 to Q3 quartile values of the data, with a line at the median (Q2). The whiskers extend from the edges of box to show the range of the data. By default, they extend no more than *1.5 * IQR (IQR = Q3 - Q1)* from the edges of the box, ending at the farthest data point within that interval. Outliers are plotted as separate dots.

For further details see Wikipedia's entry for boxplot.

Parameters

column [str or list of str, optional] Column name or list of names, or vector. Can be any valid input to *pandas.DataFrame.groupby()*.

by [str or array-like, optional] Column in the DataFrame to *pandas.DataFrame.groupby()*. One box-plot will be done per value of columns in *by*.

ax [object of class matplotlib.axes.Axes, optional] The matplotlib axes to be used by boxplot.

fontsize [float or str] Tick label font size in points or as a string (e.g., *large*).

rot [int or float, default 0] The rotation angle of labels (in degrees) with respect to the screen coordinate system.

grid [bool, default True] Setting this to True will show the grid.

figsize [A tuple (width, height) in inches] The size of the figure to create in matplotlib.

layout [tuple (rows, columns), optional] For example, (3, 5) will display the subplots using 3 columns and 5 rows, starting from the top-left.

return_type [{'axes', 'dict', 'both'} or None, default 'axes'] The kind of object to return. The default is `axes`.

- 'axes' returns the matplotlib axes the boxplot is drawn on.
- 'dict' returns a dictionary whose values are the matplotlib Lines of the boxplot.
- 'both' returns a namedtuple with the axes and dict.
- when grouping with `by`, a Series mapping columns to `return_type` is returned.

  If `return_type` is *None*, a NumPy array of axes with the same shape as `layout` is returned.

****kwargs** All other plotting keyword arguments to be passed to `matplotlib.pyplot.boxplot()`.

Returns

result See Notes.

See also:

`Series.plot.hist` Make a histogram.
`matplotlib.pyplot.boxplot` Matplotlib equivalent plot.

Notes

The return type depends on the *return_type* parameter:
- 'axes' : object of class matplotlib.axes.Axes
- 'dict' : dict of matplotlib.lines.Line2D objects
- 'both' : a namedtuple with structure (ax, lines)

For data grouped with `by`, return a Series of the above or a numpy array:
- *Series*
- `array` (for `return_type = None`)

Use `return_type='dict'` when you want to tweak the appearance of the lines after plotting. In this case a dict containing the Lines making up the boxes, caps, fliers, medians, and whiskers is returned.

Examples

Boxplots can be created for every column in the dataframe by `df.boxplot()` or indicating the columns to be used:

```
>>> np.random.seed(1234)
>>> df = pd.DataFrame(np.random.randn(10, 4),
...                   columns=['Col1', 'Col2', 'Col3', 'Col4'])
>>> boxplot = df.boxplot(column=['Col1', 'Col2', 'Col3'])
```

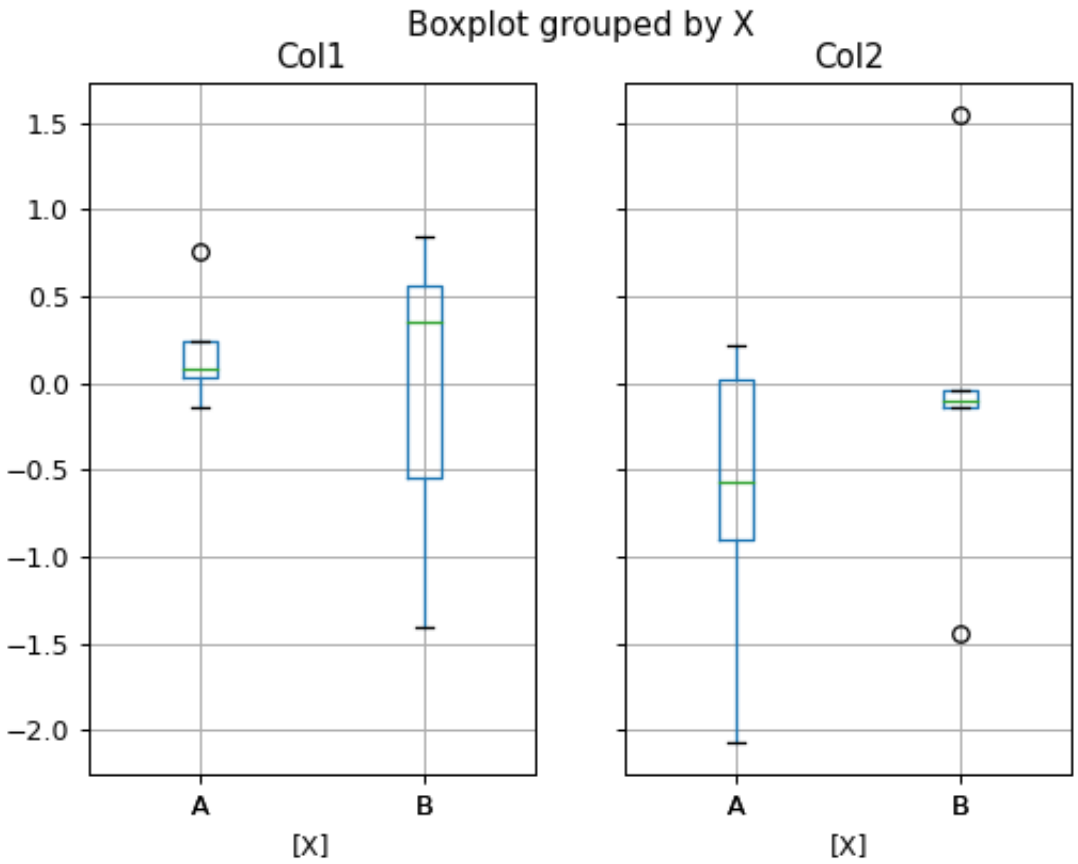
0.5
0.0
−0.5
−1.0
−1.5
−2.0
Col1
Col2
Col3

Boxplots of variables distributions grouped by the values of a third variable can be created using the option `by`. For instance:

```
>>> df = pd.DataFrame(np.random.randn(10, 2),
...                   columns=['Col1', 'Col2'])
>>> df['X'] = pd.Series(['A', 'A', 'A', 'A', 'A',
...                      'B', 'B', 'B', 'B', 'B'])
>>> boxplot = df.boxplot(by='X')
```



A list of strings (i.e. `['X', 'Y']`) can be passed to boxplot in order to group the data by combination of the variables in the x-axis:

```
>>> df = pd.DataFrame(np.random.randn(10, 3),
...                   columns=['Col1', 'Col2', 'Col3'])
>>> df['X'] = pd.Series(['A', 'A', 'A', 'A', 'A',
...                      'B', 'B', 'B', 'B', 'B'])
>>> df['Y'] = pd.Series(['A', 'B', 'A', 'B', 'A',
...                      'B', 'A', 'B', 'A', 'B'])
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], by=['X', 'Y'])
```

The layout of boxplot can be adjusted giving a tuple to `layout`:

```
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], by='X',
...                      layout=(2, 1))
```

Additional formatting can be done to the boxplot, like suppressing the grid (`grid=False`), rotating the labels

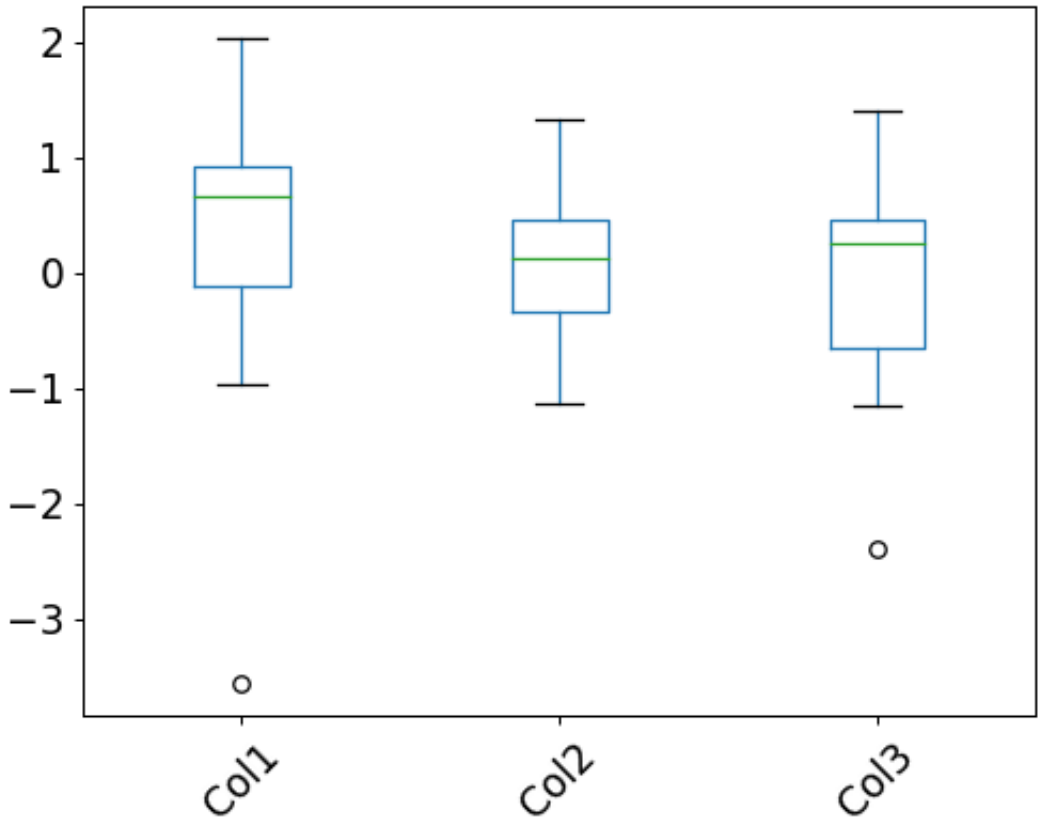
in the x-axis (i.e. `rot=45`) or changing the fontsize (i.e. `fontsize=15`):

```
>>> boxplot = df.boxplot(grid=False, rot=45, fontsize=15)
```



The parameter `return_type` can be used to select the type of element returned by *boxplot*. When `return_type='axes'` is selected, the matplotlib axes on which the boxplot is drawn are returned:

```
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], return_type='axes')
>>> type(boxplot)
<class 'matplotlib.axes._subplots.AxesSubplot'>
```

When grouping with `by`, a Series mapping columns to `return_type` is returned:

```
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], by='X',
...                      return_type='axes')
>>> type(boxplot)
<class 'pandas.core.series.Series'>
```

If `return_type` is *None*, a NumPy array of axes with the same shape as `layout` is returned:

```
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], by='X',
...                      return_type=None)
>>> type(boxplot)
<class 'numpy.ndarray'>
```

3.14.5 pandas.plotting.deregister_matplotlib_converters

pandas.plotting.**deregister_matplotlib_converters**()

Remove pandas formatters and converters.

Removes the custom converters added by `register()`. This attempts to set the state of the registry back to the state before pandas registered its own units. Converters for pandas' own types like Timestamp and Period are removed completely. Converters for types pandas overwrites, like `datetime.datetime`, are restored to their original value.

See also:

register_matplotlib_converters Register pandas formatters and converters with matplotlib.

3.14.6 pandas.plotting.lag_plot

pandas.plotting.**lag_plot**(*series*, *lag=1*, *ax=None*, ***kwds*)

Lag plot for time series.

Parameters

series [Time series]

lag [lag of the scatter plot, default 1]

ax [Matplotlib axis object, optional]

****kwds** Matplotlib scatter method keyword arguments.

Returns

class:*matplotlib.axis.Axes*

Examples

Lag plots are most commonly used to look for patterns in time series data.

Given the following time series

```
>>> np.random.seed(5)
>>> x = np.cumsum(np.random.normal(loc=1, scale=5, size=50))
>>> s = pd.Series(x)
>>> s.plot()
```

A lag plot with `lag=1` returns

```
>>> pd.plotting.lag_plot(s, lag=1)
```

3.14.7 pandas.plotting.parallel_coordinates

pandas.plotting.**parallel_coordinates**(*frame*, *class_column*, *cols=None*, *ax=None*, *color=None*, *use_columns=False*, *xticks=None*, *colormap=None*, *axvlines=True*, *axvlines_kwds=None*, *sort_labels=False*, ***kwargs*)

Parallel coordinates plotting.

Parameters

frame [DataFrame]

class_column [str] Column name containing class names.

cols [list, optional] A list of column names to use.

ax [matplotlib.axis, optional] Matplotlib axis object.

color [list or tuple, optional] Colors to use for the different classes.

use_columns [bool, optional] If true, columns will be used as xticks.

xticks [list or tuple, optional] A list of values to use for xticks.

colormap [str or matplotlib colormap, default None] Colormap to use for line colors.

axvlines [bool, optional] If true, vertical lines will be added at each xtick.

axvlines_kwds [keywords, optional] Options to be passed to axvline method for vertical lines.

sort_labels [bool, default False] Sort class_column labels, useful when assigning colors.

****kwargs** Options to pass to matplotlib plotting method.

Returns

class:*matplotlib.axis.Axes*

Examples

```
>>> df = pd.read_csv(
...     'https://raw.github.com/pandas-dev/'
...     'pandas/master/pandas/tests/io/data/csv/iris.csv'
... )
>>> pd.plotting.parallel_coordinates(
...     df, 'Name', color=('#556270', '#4ECDC4', '#C7F464')
... )
```

3.14.8 pandas.plotting.plot_params

pandas.plotting.**plot_params = {'xaxis.compat': False}**

Stores pandas plotting options.

Allows for parameter aliasing so you can just use parameter names that are the same as the plot function parameters, but is stored in a canonical format that makes it easy to breakdown into groups later.

3.14.9 pandas.plotting.radviz

pandas.plotting.**radviz**(*frame*, *class_column*, *ax=None*, *color=None*, *colormap=None*, ***kwds*)

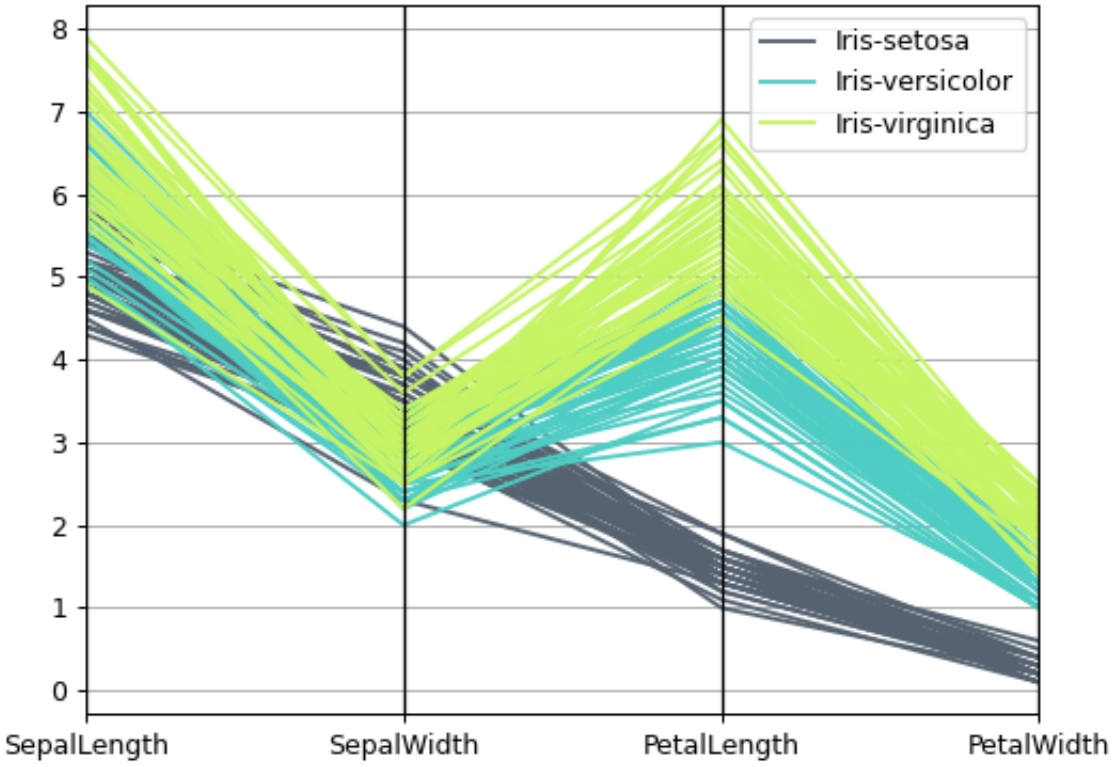
Plot a multidimensional dataset in 2D.

Each Series in the DataFrame is represented as a evenly distributed slice on a circle. Each data point is rendered in the circle according to the value on each Series. Highly correlated *Series* in the *DataFrame* are placed closer on the unit circle.

RadViz allow to project a N-dimensional data set into a 2D space where the influence of each dimension can be interpreted as a balance between the influence of all dimensions.

More info available at the original article describing RadViz.

Parameters



8
7
6
5
4
3
2
1
0
Iris-setosa
Iris-versicolor
Iris-virginica
SepalLength
SepalWidth
PetalLength
PetalWidth

frame [*DataFrame*] Object holding the data.

class_column [str] Column name containing the name of the data point category.

ax [`matplotlib.axes.Axes`, optional] A plot instance to which to add the information.

color [list[str] or tuple[str], optional] Assign a color to each category. Example: ['blue', 'green'].

colormap [str or `matplotlib.colors.Colormap`, default None] Colormap to select colors from. If string, load colormap with that name from matplotlib.

****kwds** Options to pass to matplotlib scatter plotting method.

Returns

class:*matplotlib.axes.Axes*

See also:

`plotting.andrews_curves` Plot clustering visualization.

Examples

```
>>> df = pd.DataFrame(
...     {
...         'SepalLength': [6.5, 7.7, 5.1, 5.8, 7.6, 5.0, 5.4, 4.6, 6.7, 4.6],
...         'SepalWidth': [3.0, 3.8, 3.8, 2.7, 3.0, 2.3, 3.0, 3.2, 3.3, 3.6],
...         'PetalLength': [5.5, 6.7, 1.9, 5.1, 6.6, 3.3, 4.5, 1.4, 5.7, 1.0],
...         'PetalWidth': [1.8, 2.2, 0.4, 1.9, 2.1, 1.0, 1.5, 0.2, 2.1, 0.2],
...         'Category': [
...             'virginica',
...             'virginica',
...             'setosa',
...             'virginica',
...             'virginica',
...             'versicolor',
...             'versicolor',
...             'setosa',
...             'virginica',
...             'setosa'
...         ]
...     }
... )
>>> pd.plotting.radviz(df, 'Category')
```

3.14.10 pandas.plotting.register_matplotlib_converters

`pandas.plotting.`**`register_matplotlib_converters`**`()`

Register pandas formatters and converters with matplotlib.

This function modifies the global `matplotlib.units.registry` dictionary. pandas adds custom converters for

- pd.Timestamp
- pd.Period
- np.datetime64
- datetime.datetime
- datetime.date
- datetime.time

See also:

deregister_matplotlib_converters Remove pandas formatters and converters.

3.14.11 pandas.plotting.scatter_matrix

pandas.plotting.**scatter_matrix**(*frame*, *alpha=0.5*, *figsize=None*, *ax=None*, *grid=False*, *diagonal='hist'*, *marker='.'*, *density_kwds=None*, *hist_kwds=None*, *range_padding=0.05*, ***kwargs*)

Draw a matrix of scatter plots.

Parameters

frame [DataFrame]

alpha [float, optional] Amount of transparency applied.

figsize [(float,float), optional] A tuple (width, height) in inches.

ax [Matplotlib axis object, optional]

grid [bool, optional] Setting this to True will show the grid.

diagonal [{'hist', 'kde'}] Pick between 'kde' and 'hist' for either Kernel Density Estimation or Histogram plot in the diagonal.

marker [str, optional] Matplotlib marker type, default '.'.

density_kwds [keywords] Keyword arguments to be passed to kernel density estimate plot.

hist_kwds [keywords] Keyword arguments to be passed to hist function.

range_padding [float, default 0.05] Relative extension of axis range in x and y with respect to (x_max - x_min) or (y_max - y_min).

****kwargs** Keyword arguments to be passed to scatter function.

Returns

numpy.ndarray A matrix of scatter plots.

Examples

```
>>> df = pd.DataFrame(np.random.randn(1000, 4), columns=['A','B','C','D'])
>>> pd.plotting.scatter_matrix(df, alpha=0.2)
```

3.14.12 pandas.plotting.table

pandas.plotting.**table**(*ax*, *data*, *rowLabels=None*, *colLabels=None*, ***kwargs*)

Helper function to convert DataFrame and Series to matplotlib.table.

Parameters

ax [Matplotlib axes object]

data [DataFrame or Series] Data for table contents.

****kwargs** Keyword arguments to be passed to matplotlib.table.table. If *rowLabels* or *colLabels* is not specified, data index or column name will be used.

Returns

matplotlib table object

3.15 General utility functions

3.15.1 Working with options

describe_option(pat[, _print_desc])	Prints the description for one or more registered options.
reset_option(pat)	Reset one or more options to their default value.
get_option(pat)	Retrieves the value of the specified option.
set_option(pat, value)	Sets the value of the specified option.
option_context(*args)	Context manager to temporarily set options in the *with* statement context.

pandas.describe_option

pandas.**describe_option**(*pat*, *_print_desc=False*) **= <pandas._config.config.CallableDynamicDoc object>**

Prints the description for one or more registered options.

Call with not arguments to get a listing for all registered options.

Available options:

- compute.[use_bottleneck, use_numba, use_numexpr]
- display.[chop_threshold, colheader_justify, column_space, date_dayfirst, date_yearfirst, encoding, expand_frame_repr, float_format]
- display.html.[border, table_schema, use_mathjax]
- display.[large_repr]
- display.latex.[escape, longtable, multicolumn, multicolumn_format, multirow, repr]
- display.[max_categories, max_columns, max_colwidth, max_info_columns, max_info_rows, max_rows, max_seq_items, memory_usage, min_rows, multi_sparse, notebook_repr_html, pprint_nest_depth, precision, show_dimensions]
- display.unicode.[ambiguous_as_wide, east_asian_width]
- display.[width]
- io.excel.ods.[reader, writer]
- io.excel.xls.[reader, writer]
- io.excel.xlsb.[reader]
- io.excel.xlsm.[reader, writer]
- io.excel.xlsx.[reader, writer]
- io.hdf.[default_format, dropna_table]
- io.parquet.[engine]
- mode.[chained_assignment, sim_interactive, use_inf_as_na, use_inf_as_null]
- plotting.[backend]
- plotting.matplotlib.[register_converters]

Parameters

pat [str] Regexp pattern. All matching keys will have their description displayed.

_print_desc [bool, default True] If True (default) the description(s) will be printed to stdout. Otherwise, the description(s) will be returned as a unicode string (for testing).

Returns

None by default, the description(s) as a unicode string if _print_desc

is False

Notes

The available options with its descriptions:

compute.use_bottleneck [bool] Use the bottleneck library to accelerate if it is installed, the default is True Valid values: False,True [default: True] [currently: True]

compute.use_numba [bool] Use the numba engine option for select operations if it is installed, the default is False Valid values: False,True [default: False] [currently: False]

compute.use_numexpr [bool] Use the numexpr library to accelerate computation if it is installed, the default is True Valid values: False,True [default: True] [currently: True]

display.chop_threshold [float or None] if set to a float value, all float values smaller then the given threshold will be displayed as exactly 0 by repr and friends. [default: None] [currently: None]

display.colheader_justify ['left'/'right'] Controls the justification of column headers. used by DataFrameFormatter. [default: right] [currently: right]

display.column_space No description available. [default: 12] [currently: 12]

display.date_dayfirst [boolean] When True, prints and parses dates with the day first, eg 20/01/2005 [default: False] [currently: False]

display.date_yearfirst [boolean] When True, prints and parses dates with the year first, eg 2005/01/20 [default: False] [currently: False]

display.encoding [str/unicode] Defaults to the detected encoding of the console. Specifies the encoding to be used for strings returned by to_string, these are generally strings meant to be displayed on the console. [default: utf-8] [currently: utf-8]

display.expand_frame_repr [boolean] Whether to print out the full DataFrame repr for wide DataFrames across multiple lines, *max_columns* is still respected, but the output will wrap-around across multiple "pages" if its width exceeds *display.width*. [default: True] [currently: True]

display.float_format [callable] The callable should accept a floating point number and return a string with the desired format of the number. This is used in some places like SeriesFormatter. See formats.format.EngFormatter for an example. [default: None] [currently: None]

display.html.border [int] A `border=value` attribute is inserted in the `<table>` tag for the DataFrame HTML repr. [default: 1] [currently: 1]

display.html.table_schema [boolean] Whether to publish a Table Schema representation for frontends that support it. (default: False) [default: False] [currently: False]

display.html.use_mathjax [boolean] When True, Jupyter notebook will process table contents using MathJax, rendering mathematical expressions enclosed by the dollar symbol. (default: True) [default: True] [currently: True]

display.large_repr ['truncate'/'info'] For DataFrames exceeding max_rows/max_cols, the repr (and HTML repr) can show a truncated table (the default from 0.13), or switch to the view from df.info() (the behaviour in earlier versions of pandas). [default: truncate] [currently: truncate]

display.latex.escape [bool] This specifies if the to_latex method of a Dataframe uses escapes special characters. Valid values: False,True [default: True] [currently: True]

display.latex.longtable :bool This specifies if the to_latex method of a Dataframe uses the longtable format. Valid values: False,True [default: False] [currently: False]

display.latex.multicolumn [bool] This specifies if the to_latex method of a Dataframe uses multicolumns to pretty-print MultiIndex columns. Valid values: False,True [default: True] [currently: True]

display.latex.multicolumn_format [bool] This specifies if the to_latex method of a Dataframe uses multicolumns to pretty-print MultiIndex columns. Valid values: False,True [default: l] [currently: l]

display.latex.multirow [bool] This specifies if the to_latex method of a Dataframe uses multirows to pretty-print MultiIndex rows. Valid values: False,True [default: False] [currently: False]

display.latex.repr [boolean] Whether to produce a latex DataFrame representation for jupyter environments that support it. (default: False) [default: False] [currently: False]

display.max_categories [int] This sets the maximum number of categories pandas should output when printing out a *Categorical* or a Series of dtype "category". [default: 8] [currently: 8]

display.max_columns [int] If max_cols is exceeded, switch to truncate view. Depending on *large_repr*, objects are either centrally truncated or printed as a summary view. 'None' value means unlimited.

In case python/IPython is running in a terminal and *large_repr* equals 'truncate' this can be set to 0 and pandas will auto-detect the width of the terminal and print a truncated object which fits the screen width. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: 0] [currently: 0]

display.max_colwidth [int or None] The maximum width in characters of a column in the repr of a pandas data structure. When the column overflows, a "..." placeholder is embedded in the output. A 'None' value means unlimited. [default: 50] [currently: 50]

display.max_info_columns [int] max_info_columns is used in DataFrame.info method to decide if per column information will be printed. [default: 100] [currently: 100]

display.max_info_rows [int or None] df.info() will usually show null-counts for each column. For large frames this can be quite slow. max_info_rows and max_info_cols limit this null check only to frames with smaller dimensions than specified. [default: 1690785] [currently: 1690785]

display.max_rows [int] If max_rows is exceeded, switch to truncate view. Depending on *large_repr*, objects are either centrally truncated or printed as a summary view. 'None' value means unlimited.

In case python/IPython is running in a terminal and *large_repr* equals 'truncate' this can be set to 0 and pandas will auto-detect the height of the terminal and print a truncated object which fits the screen height. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: 60] [currently: 15]

display.max_seq_items [int or None] when pretty-printing a long sequence, no more then *max_seq_items* will be printed. If items are omitted, they will be denoted by the addition of "..." to the resulting string.

If set to None, the number of items to be printed is unlimited. [default: 100] [currently: 100]

display.memory_usage [bool, string or None] This specifies if the memory usage of a DataFrame should be displayed when df.info() is called. Valid values True,False,'deep' [default: True] [currently: True]

display.min_rows [int] The numbers of rows to show in a truncated view (when *max_rows* is exceeded). Ignored when *max_rows* is set to None or 0. When set to None, follows the value of *max_rows*. [default: 10] [currently: 10]

display.multi_sparse [boolean] "sparsify" MultiIndex display (don't display repeated elements in outer levels within groups) [default: True] [currently: True]

display.notebook_repr_html [boolean] When True, IPython notebook will use html representation for pandas objects (if it is available). [default: True] [currently: True]

display.pprint_nest_depth [int] Controls the number of nested levels to process when pretty-printing [default: 3] [currently: 3]

display.precision [int] Floating point output precision (number of significant digits). This is only a suggestion [default: 6] [currently: 6]

display.show_dimensions [boolean or 'truncate'] Whether to print out dimensions at the end of DataFrame repr. If 'truncate' is specified, only print out the dimensions if the frame is truncated (e.g. not display all rows and/or columns) [default: truncate] [currently: truncate]

display.unicode.ambiguous_as_wide [boolean] Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance (default: False) [default: False] [currently: False]

display.unicode.east_asian_width [boolean] Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance (default: False) [default: False] [currently: False]

display.width [int] Width of the display in characters. In case python/IPython is running in a terminal this can be set to None and pandas will correctly auto-detect the width. Note that the IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to correctly detect the width. [default: 80] [currently: 80]

io.excel.ods.reader [string] The default Excel reader engine for 'ods' files. Available options: auto, odf. [default: auto] [currently: auto]

io.excel.ods.writer [string] The default Excel writer engine for 'ods' files. Available options: auto, odf. [default: auto] [currently: auto]

io.excel.xls.reader [string] The default Excel reader engine for 'xls' files. Available options: auto, xlrd. [default: auto] [currently: auto]

io.excel.xls.writer [string] The default Excel writer engine for 'xls' files. Available options: auto, xlwt. [default: auto] [currently: auto]

io.excel.xlsb.reader [string] The default Excel reader engine for 'xlsb' files. Available options: auto, pyxlsb. [default: auto] [currently: auto]

io.excel.xlsm.reader [string] The default Excel reader engine for 'xlsm' files. Available options: auto, xlrd, openpyxl. [default: auto] [currently: auto]

io.excel.xlsm.writer [string] The default Excel writer engine for 'xlsm' files. Available options: auto, openpyxl. [default: auto] [currently: auto]

io.excel.xlsx.reader [string] The default Excel reader engine for 'xlsx' files. Available options: auto, xlrd, openpyxl. [default: auto] [currently: auto]

io.excel.xlsx.writer [string] The default Excel writer engine for 'xlsx' files. Available options: auto, openpyxl, xlsxwriter. [default: auto] [currently: auto]

io.hdf.default_format [format] default format writing format, if None, then put will default to 'fixed' and append will default to 'table' [default: None] [currently: None]

io.hdf.dropna_table [boolean] drop ALL nan rows when appending to a table [default: False] [currently: False]

io.parquet.engine [string] The default parquet reader/writer engine. Available options: 'auto', 'pyarrow', 'fastparquet', the default is 'auto' [default: auto] [currently: auto]

mode.chained_assignment [string] Raise an exception, warn, or no action if trying to use chained assignment, The default is warn [default: warn] [currently: warn]

mode.sim_interactive [boolean] Whether to simulate interactive mode for purposes of testing [default: False] [currently: False]

mode.use_inf_as_na [boolean] True means treat None, NaN, INF, -INF as NA (old way), False means None and NaN are null, but INF, -INF are not NA (new way). [default: False] [currently: False]

mode.use_inf_as_null [boolean] use_inf_as_null had been deprecated and will be removed in a future version. Use *use_inf_as_na* instead. [default: False] [currently: False] (Deprecated, use *mode.use_inf_as_na* instead.)

plotting.backend [str] The plotting backend to use. The default value is "matplotlib", the backend provided with pandas. Other backends can be specified by providing the name of the module that implements the backend. [default: matplotlib] [currently: matplotlib]

plotting.matplotlib.register_converters [bool or 'auto'.] Whether to register converters with matplotlib's units registry for dates, times, datetimes, and Periods. Toggling to False will remove the converters, restoring any converters that pandas overwrote. [default: auto] [currently: auto]

pandas.reset_option

pandas.**reset_option**(*pat*) **= <pandas._config.config.CallableDynamicDoc object>**

Reset one or more options to their default value.

Pass "all" as argument to reset all options.

Available options:

- compute.[use_bottleneck, use_numba, use_numexpr]
- display.[chop_threshold, colheader_justify, column_space, date_dayfirst, date_yearfirst, encoding, expand_frame_repr, float_format]
- display.html.[border, table_schema, use_mathjax]
- display.[large_repr]
- display.latex.[escape, longtable, multicolumn, multicolumn_format, multirow, repr]
- display.[max_categories, max_columns, max_colwidth, max_info_columns, max_info_rows, max_rows, max_seq_items, memory_usage, min_rows, multi_sparse, notebook_repr_html, pprint_nest_depth, precision, show_dimensions]
- display.unicode.[ambiguous_as_wide, east_asian_width]
- display.[width]

- io.excel.ods.[reader, writer]
- io.excel.xls.[reader, writer]
- io.excel.xlsb.[reader]
- io.excel.xlsm.[reader, writer]
- io.excel.xlsx.[reader, writer]
- io.hdf.[default_format, dropna_table]
- io.parquet.[engine]
- mode.[chained_assignment, sim_interactive, use_inf_as_na, use_inf_as_null]
- plotting.[backend]
- plotting.matplotlib.[register_converters]

Parameters

pat [str/regex] If specified only options matching *prefix** will be reset. Note: partial matches are supported for convenience, but unless you use the full option name (e.g. x.y.z.option_name), your code may break in future versions if new options with similar names are introduced.

Returns

None

Notes

The available options with its descriptions:

compute.use_bottleneck [bool] Use the bottleneck library to accelerate if it is installed, the default is True Valid values: False,True [default: True] [currently: True]

compute.use_numba [bool] Use the numba engine option for select operations if it is installed, the default is False Valid values: False,True [default: False] [currently: False]

compute.use_numexpr [bool] Use the numexpr library to accelerate computation if it is installed, the default is True Valid values: False,True [default: True] [currently: True]

display.chop_threshold [float or None] if set to a float value, all float values smaller then the given threshold will be displayed as exactly 0 by repr and friends. [default: None] [currently: None]

display.colheader_justify ['left'/'right'] Controls the justification of column headers. used by DataFrameFormatter. [default: right] [currently: right]

display.column_space No description available. [default: 12] [currently: 12]

display.date_dayfirst [boolean] When True, prints and parses dates with the day first, eg 20/01/2005 [default: False] [currently: False]

display.date_yearfirst [boolean] When True, prints and parses dates with the year first, eg 2005/01/20 [default: False] [currently: False]

display.encoding [str/unicode] Defaults to the detected encoding of the console. Specifies the encoding to be used for strings returned by to_string, these are generally strings meant to be displayed on the console. [default: utf-8] [currently: utf-8]

display.expand_frame_repr [boolean] Whether to print out the full DataFrame repr for wide DataFrames across multiple lines, *max_columns* is still respected, but the output will wrap-around across multiple "pages" if its width exceeds *display.width*. [default: True] [currently: True]

display.float_format [callable] The callable should accept a floating point number and return a string with the desired format of the number. This is used in some places like SeriesFormatter. See formats.format.EngFormatter for an example. [default: None] [currently: None]

display.html.border [int] A `border=value` attribute is inserted in the `<table>` tag for the DataFrame HTML repr. [default: 1] [currently: 1]

display.html.table_schema [boolean] Whether to publish a Table Schema representation for frontends that support it. (default: False) [default: False] [currently: False]

display.html.use_mathjax [boolean] When True, Jupyter notebook will process table contents using MathJax, rendering mathematical expressions enclosed by the dollar symbol. (default: True) [default: True]

[currently: True]

display.large_repr ['truncate'/'info'] For DataFrames exceeding max_rows/max_cols, the repr (and HTML repr) can show a truncated table (the default from 0.13), or switch to the view from df.info() (the behaviour in earlier versions of pandas). [default: truncate] [currently: truncate]

display.latex.escape [bool] This specifies if the to_latex method of a Dataframe uses escapes special characters. Valid values: False,True [default: True] [currently: True]

display.latex.longtable :bool This specifies if the to_latex method of a Dataframe uses the longtable format. Valid values: False,True [default: False] [currently: False]

display.latex.multicolumn [bool] This specifies if the to_latex method of a Dataframe uses multicolumns to pretty-print MultiIndex columns. Valid values: False,True [default: True] [currently: True]

display.latex.multicolumn_format [bool] This specifies if the to_latex method of a Dataframe uses multicolumns to pretty-print MultiIndex columns. Valid values: False,True [default: l] [currently: l]

display.latex.multirow [bool] This specifies if the to_latex method of a Dataframe uses multirows to pretty-print MultiIndex rows. Valid values: False,True [default: False] [currently: False]

display.latex.repr [boolean] Whether to produce a latex DataFrame representation for jupyter environments that support it. (default: False) [default: False] [currently: False]

display.max_categories [int] This sets the maximum number of categories pandas should output when printing out a *Categorical* or a Series of dtype "category". [default: 8] [currently: 8]

display.max_columns [int] If max_cols is exceeded, switch to truncate view. Depending on *large_repr*, objects are either centrally truncated or printed as a summary view. 'None' value means unlimited.

In case python/IPython is running in a terminal and *large_repr* equals 'truncate' this can be set to 0 and pandas will auto-detect the width of the terminal and print a truncated object which fits the screen width. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: 0] [currently: 0]

display.max_colwidth [int or None] The maximum width in characters of a column in the repr of a pandas data structure. When the column overflows, a "..." placeholder is embedded in the output. A 'None' value means unlimited. [default: 50] [currently: 50]

display.max_info_columns [int] max_info_columns is used in DataFrame.info method to decide if per column information will be printed. [default: 100] [currently: 100]

display.max_info_rows [int or None] df.info() will usually show null-counts for each column. For large frames this can be quite slow. max_info_rows and max_info_cols limit this null check only to frames with smaller dimensions than specified. [default: 1690785] [currently: 1690785]

display.max_rows [int] If max_rows is exceeded, switch to truncate view. Depending on *large_repr*, objects are either centrally truncated or printed as a summary view. 'None' value means unlimited.

In case python/IPython is running in a terminal and *large_repr* equals 'truncate' this can be set to 0 and pandas will auto-detect the height of the terminal and print a truncated object which fits the screen height. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: 60] [currently: 15]

display.max_seq_items [int or None] when pretty-printing a long sequence, no more then *max_seq_items* will be printed. If items are omitted, they will be denoted by the addition of "..." to the resulting string.

If set to None, the number of items to be printed is unlimited. [default: 100] [currently: 100]

display.memory_usage [bool, string or None] This specifies if the memory usage of a DataFrame should be displayed when df.info() is called. Valid values True,False,'deep' [default: True] [currently: True]

display.min_rows [int] The numbers of rows to show in a truncated view (when *max_rows* is exceeded). Ignored when *max_rows* is set to None or 0. When set to None, follows the value of *max_rows*. [default: 10] [currently: 10]

display.multi_sparse [boolean] "sparsify" MultiIndex display (don't display repeated elements in outer levels within groups) [default: True] [currently: True]

display.notebook_repr_html [boolean] When True, IPython notebook will use html representation for pandas objects (if it is available). [default: True] [currently: True]

display.pprint_nest_depth [int] Controls the number of nested levels to process when pretty-printing [default: 3] [currently: 3]

display.precision [int] Floating point output precision (number of significant digits). This is only a suggestion [default: 6] [currently: 6]

display.show_dimensions [boolean or 'truncate'] Whether to print out dimensions at the end of DataFrame repr. If 'truncate' is specified, only print out the dimensions if the frame is truncated (e.g. not display all rows and/or columns) [default: truncate] [currently: truncate]

display.unicode.ambiguous_as_wide [boolean] Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance (default: False) [default: False] [currently: False]

display.unicode.east_asian_width [boolean] Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance (default: False) [default: False] [currently: False]

display.width [int] Width of the display in characters. In case python/IPython is running in a terminal this can be set to None and pandas will correctly auto-detect the width. Note that the IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to correctly detect the width. [default: 80] [currently: 80]

io.excel.ods.reader [string] The default Excel reader engine for 'ods' files. Available options: auto, odf. [default: auto] [currently: auto]

io.excel.ods.writer [string] The default Excel writer engine for 'ods' files. Available options: auto, odf. [default: auto] [currently: auto]

io.excel.xls.reader [string] The default Excel reader engine for 'xls' files. Available options: auto, xlrd. [default: auto] [currently: auto]

io.excel.xls.writer [string] The default Excel writer engine for 'xls' files. Available options: auto, xlwt. [default: auto] [currently: auto]

io.excel.xlsb.reader [string] The default Excel reader engine for 'xlsb' files. Available options: auto, pyxlsb. [default: auto] [currently: auto]

io.excel.xlsm.reader [string] The default Excel reader engine for 'xlsm' files. Available options: auto, xlrd, openpyxl. [default: auto] [currently: auto]

io.excel.xlsm.writer [string] The default Excel writer engine for 'xlsm' files. Available options: auto, openpyxl. [default: auto] [currently: auto]

io.excel.xlsx.reader [string] The default Excel reader engine for 'xlsx' files. Available options: auto, xlrd, openpyxl. [default: auto] [currently: auto]

io.excel.xlsx.writer [string] The default Excel writer engine for 'xlsx' files. Available options: auto, openpyxl, xlsxwriter. [default: auto] [currently: auto]

io.hdf.default_format [format] default format writing format, if None, then put will default to 'fixed' and append will default to 'table' [default: None] [currently: None]

io.hdf.dropna_table [boolean] drop ALL nan rows when appending to a table [default: False] [currently: False]

io.parquet.engine [string] The default parquet reader/writer engine. Available options: 'auto', 'pyarrow', 'fastparquet', the default is 'auto' [default: auto] [currently: auto]

mode.chained_assignment [string] Raise an exception, warn, or no action if trying to use chained assignment, The default is warn [default: warn] [currently: warn]

mode.sim_interactive [boolean] Whether to simulate interactive mode for purposes of testing [default: False] [currently: False]

mode.use_inf_as_na [boolean] True means treat None, NaN, INF, -INF as NA (old way), False means None and NaN are null, but INF, -INF are not NA (new way). [default: False] [currently: False]

mode.use_inf_as_null [boolean] use_inf_as_null had been deprecated and will be removed in a future version. Use *use_inf_as_na* instead. [default: False] [currently: False] (Deprecated, use *mode.use_inf_as_na* instead.)

plotting.backend [str] The plotting backend to use. The default value is "matplotlib", the backend provided with pandas. Other backends can be specified by providing the name of the module that implements the backend. [default: matplotlib] [currently: matplotlib]

plotting.matplotlib.register_converters [bool or 'auto'.] Whether to register converters with matplotlib's units registry for dates, times, datetimes, and Periods. Toggling to False will remove the converters, restoring any converters that pandas overwrote. [default: auto] [currently: auto]

pandas.get_option

pandas.**get_option**(*pat*) **= <pandas._config.config.CallableDynamicDoc object>**

Retrieves the value of the specified option.

Available options:

- compute.[use_bottleneck, use_numba, use_numexpr]
- display.[chop_threshold, colheader_justify, column_space, date_dayfirst, date_yearfirst, encoding, expand_frame_repr, float_format]
- display.html.[border, table_schema, use_mathjax]
- display.[large_repr]
- display.latex.[escape, longtable, multicolumn, multicolumn_format, multirow, repr]
- display.[max_categories, max_columns, max_colwidth, max_info_columns, max_info_rows, max_rows, max_seq_items, memory_usage, min_rows, multi_sparse, notebook_repr_html, pprint_nest_depth, precision, show_dimensions]
- display.unicode.[ambiguous_as_wide, east_asian_width]

- io.excel.xlsm.[reader, writer]
- io.excel.xlsx.[reader, writer]
- io.hdf.[default_format, dropna_table]
- io.parquet.[engine]
- mode.[chained_assignment, sim_interactive, use_inf_as_na, use_inf_as_null]
- plotting.[backend]
- plotting.matplotlib.[register_converters]

Parameters

pat [str] Regexp which should match a single option. Note: partial matches are supported for convenience, but unless you use the full option name (e.g. x.y.z.option_name), your code may break in future versions if new options with similar names are introduced.

Returns

result [the value of the option]

Raises

OptionError [if no such option exists]

Notes

The available options with its descriptions:

compute.use_bottleneck [bool] Use the bottleneck library to accelerate if it is installed, the default is True Valid values: False,True [default: True] [currently: True]

compute.use_numba [bool] Use the numba engine option for select operations if it is installed, the default is False Valid values: False,True [default: False] [currently: False]

compute.use_numexpr [bool] Use the numexpr library to accelerate computation if it is installed, the default is True Valid values: False,True [default: True] [currently: True]

display.chop_threshold [float or None] if set to a float value, all float values smaller then the given threshold will be displayed as exactly 0 by repr and friends. [default: None] [currently: None]

display.colheader_justify ['left'/'right'] Controls the justification of column headers. used by DataFrameFormatter. [default: right] [currently: right]

display.column_space No description available. [default: 12] [currently: 12]

display.date_dayfirst [boolean] When True, prints and parses dates with the day first, eg 20/01/2005 [default: False] [currently: False]

display.date_yearfirst [boolean] When True, prints and parses dates with the year first, eg 2005/01/20 [default: False] [currently: False]

display.encoding [str/unicode] Defaults to the detected encoding of the console. Specifies the encoding to be used for strings returned by to_string, these are generally strings meant to be displayed on the console. [default: utf-8] [currently: utf-8]

display.expand_frame_repr [boolean] Whether to print out the full DataFrame repr for wide DataFrames across multiple lines, *max_columns* is still respected, but the output will wrap-around across multiple "pages" if its width exceeds *display.width*. [default: True] [currently: True]

display.float_format [callable] The callable should accept a floating point number and return a string with the desired format of the number. This is used in some places like SeriesFormatter. See formats.format.EngFormatter for an example. [default: None] [currently: None]

display.html.border [int] A `border=value` attribute is inserted in the `<table>` tag for the DataFrame HTML repr. [default: 1] [currently: 1]

display.html.table_schema [boolean] Whether to publish a Table Schema representation for frontends that support it. (default: False) [default: False] [currently: False]

display.html.use_mathjax [boolean] When True, Jupyter notebook will process table contents using MathJax, rendering mathematical expressions enclosed by the dollar symbol. (default: True) [default: True] [currently: True]

display.large_repr ['truncate'/'info'] For DataFrames exceeding max_rows/max_cols, the repr (and HTML repr) can show a truncated table (the default from 0.13), or switch to the view from df.info() (the behaviour in earlier versions of pandas). [default: truncate] [currently: truncate]

display.latex.escape [bool] This specifies if the to_latex method of a Dataframe uses escapes special characters. Valid values: False,True [default: True] [currently: True]

display.latex.longtable :bool This specifies if the to_latex method of a Dataframe uses the longtable format. Valid values: False,True [default: False] [currently: False]

display.latex.multicolumn [bool] This specifies if the to_latex method of a Dataframe uses multicolumns to pretty-print MultiIndex columns. Valid values: False,True [default: True] [currently: True]

display.latex.multicolumn_format [bool] This specifies if the to_latex method of a Dataframe uses multicolumns to pretty-print MultiIndex columns. Valid values: False,True [default: l] [currently: l]

display.latex.multirow [bool] This specifies if the to_latex method of a Dataframe uses multirows to pretty-print MultiIndex rows. Valid values: False,True [default: False] [currently: False]

display.latex.repr [boolean] Whether to produce a latex DataFrame representation for jupyter environments that support it. (default: False) [default: False] [currently: False]

display.max_categories [int] This sets the maximum number of categories pandas should output when printing out a *Categorical* or a Series of dtype "category". [default: 8] [currently: 8]

display.max_columns [int] If max_cols is exceeded, switch to truncate view. Depending on *large_repr*, objects are either centrally truncated or printed as a summary view. 'None' value means unlimited.

In case python/IPython is running in a terminal and *large_repr* equals 'truncate' this can be set to 0 and pandas will auto-detect the width of the terminal and print a truncated object which fits the screen width. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: 0] [currently: 0]

display.max_colwidth [int or None] The maximum width in characters of a column in the repr of a pandas data structure. When the column overflows, a "..." placeholder is embedded in the output. A 'None' value means unlimited. [default: 50] [currently: 50]

display.max_info_columns [int] max_info_columns is used in DataFrame.info method to decide if per column information will be printed. [default: 100] [currently: 100]

display.max_info_rows [int or None] df.info() will usually show null-counts for each column. For large frames this can be quite slow. max_info_rows and max_info_cols limit this null check only to frames with smaller dimensions than specified. [default: 1690785] [currently: 1690785]

display.max_rows [int] If max_rows is exceeded, switch to truncate view. Depending on *large_repr*, objects are either centrally truncated or printed as a summary view. 'None' value means unlimited.

In case python/IPython is running in a terminal and *large_repr* equals 'truncate' this can be set to 0 and pandas will auto-detect the height of the terminal and print a truncated object which fits the screen height. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: 60] [currently: 15]

display.max_seq_items [int or None] when pretty-printing a long sequence, no more then *max_seq_items* will be printed. If items are omitted, they will be denoted by the addition of "..." to the resulting string.

If set to None, the number of items to be printed is unlimited. [default: 100] [currently: 100]

display.memory_usage [bool, string or None] This specifies if the memory usage of a DataFrame should be displayed when df.info() is called. Valid values True,False,'deep' [default: True] [currently: True]

display.min_rows [int] The numbers of rows to show in a truncated view (when *max_rows* is exceeded). Ignored when *max_rows* is set to None or 0. When set to None, follows the value of *max_rows*. [default: 10] [currently: 10]

display.multi_sparse [boolean] "sparsify" MultiIndex display (don't display repeated elements in outer levels within groups) [default: True] [currently: True]

display.notebook_repr_html [boolean] When True, IPython notebook will use html representation for pandas objects (if it is available). [default: True] [currently: True]

display.pprint_nest_depth [int] Controls the number of nested levels to process when pretty-printing [default: 3] [currently: 3]

display.precision [int] Floating point output precision (number of significant digits). This is only a suggestion [default: 6] [currently: 6]

display.show_dimensions [boolean or 'truncate'] Whether to print out dimensions at the end of DataFrame repr. If 'truncate' is specified, only print out the dimensions if the frame is truncated (e.g. not display all rows and/or columns) [default: truncate] [currently: truncate]

display.unicode.ambiguous_as_wide [boolean] Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance (default: False) [default: False] [currently: False]

display.unicode.east_asian_width [boolean] Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance (default: False) [default: False] [currently: False]

display.width [int] Width of the display in characters. In case python/IPython is running in a terminal this can be set to None and pandas will correctly auto-detect the width. Note that the IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to correctly detect the width. [default: 80] [currently: 80]

io.excel.ods.reader [string] The default Excel reader engine for 'ods' files. Available options: auto, odf. [default: auto] [currently: auto]

io.excel.ods.writer [string] The default Excel writer engine for 'ods' files. Available options: auto, odf. [default: auto] [currently: auto]

io.excel.xls.reader [string] The default Excel reader engine for 'xls' files. Available options: auto, xlrd. [default: auto] [currently: auto]

io.excel.xls.writer [string] The default Excel writer engine for 'xls' files. Available options: auto, xlwt. [default: auto] [currently: auto]

io.excel.xlsb.reader [string] The default Excel reader engine for 'xlsb' files. Available options: auto, pyxlsb. [default: auto] [currently: auto]

io.excel.xlsm.reader [string] The default Excel reader engine for 'xlsm' files. Available options: auto, xlrd, openpyxl. [default: auto] [currently: auto]

io.excel.xlsm.writer [string] The default Excel writer engine for 'xlsm' files. Available options: auto, openpyxl. [default: auto] [currently: auto]

io.excel.xlsx.reader [string] The default Excel reader engine for 'xlsx' files. Available options: auto, xlrd, openpyxl. [default: auto] [currently: auto]

io.excel.xlsx.writer [string] The default Excel writer engine for 'xlsx' files. Available options: auto, openpyxl, xlsxwriter. [default: auto] [currently: auto]

io.hdf.default_format [format] default format writing format, if None, then put will default to 'fixed' and append will default to 'table' [default: None] [currently: None]

io.hdf.dropna_table [boolean] drop ALL nan rows when appending to a table [default: False] [currently: False]

io.parquet.engine [string] The default parquet reader/writer engine. Available options: 'auto', 'pyarrow', 'fastparquet', the default is 'auto' [default: auto] [currently: auto]

mode.chained_assignment [string] Raise an exception, warn, or no action if trying to use chained assignment, The default is warn [default: warn] [currently: warn]

mode.sim_interactive [boolean] Whether to simulate interactive mode for purposes of testing [default: False] [currently: False]

mode.use_inf_as_na [boolean] True means treat None, NaN, INF, -INF as NA (old way), False means None and NaN are null, but INF, -INF are not NA (new way). [default: False] [currently: False]

mode.use_inf_as_null [boolean] use_inf_as_null had been deprecated and will be removed in a future version. Use *use_inf_as_na* instead. [default: False] [currently: False] (Deprecated, use *mode.use_inf_as_na* instead.)

plotting.backend [str] The plotting backend to use. The default value is "matplotlib", the backend provided with pandas. Other backends can be specified by providing the name of the module that implements the backend. [default: matplotlib] [currently: matplotlib]

plotting.matplotlib.register_converters [bool or 'auto'.] Whether to register converters with matplotlib's units registry for dates, times, datetimes, and Periods. Toggling to False will remove the converters, restoring any converters that pandas overwrote. [default: auto] [currently: auto]

pandas.set_option

pandas.**set_option**(*pat*, *value*) **= <pandas._config.config.CallableDynamicDoc object>**

Sets the value of the specified option.

Available options:

- compute.[use_bottleneck, use_numba, use_numexpr]
- display.[chop_threshold, colheader_justify, column_space, date_dayfirst, date_yearfirst, encoding, expand_frame_repr, float_format]
- display.html.[border, table_schema, use_mathjax]
- display.[large_repr]
- display.latex.[escape, longtable, multicolumn, multicolumn_format, multirow, repr]
- display.[max_categories, max_columns, max_colwidth, max_info_columns, max_info_rows, max_rows, max_seq_items, memory_usage, min_rows, multi_sparse, notebook_repr_html, pprint_nest_depth, precision, show_dimensions]
- display.unicode.[ambiguous_as_wide, east_asian_width]
- display.[width]
- io.excel.ods.[reader, writer]
- io.excel.xls.[reader, writer]
- io.excel.xlsb.[reader]
- io.excel.xlsm.[reader, writer]
- io.excel.xlsx.[reader, writer]
- io.hdf.[default_format, dropna_table]
- io.parquet.[engine]
- mode.[chained_assignment, sim_interactive, use_inf_as_na, use_inf_as_null]
- plotting.[backend]
- plotting.matplotlib.[register_converters]

Parameters

pat [str] Regexp which should match a single option. Note: partial matches are supported for convenience, but unless you use the full option name (e.g. x.y.z.option_name), your code may break in future versions if new options with similar names are introduced.

value [object] New value of option.

Returns

None

Raises

OptionError if no such option exists

Notes

The available options with its descriptions:

compute.use_bottleneck [bool] Use the bottleneck library to accelerate if it is installed, the default is True Valid values: False,True [default: True] [currently: True]

compute.use_numba [bool] Use the numba engine option for select operations if it is installed, the default is False Valid values: False,True [default: False] [currently: False]

compute.use_numexpr [bool] Use the numexpr library to accelerate computation if it is installed, the default is True Valid values: False,True [default: True] [currently: True]

display.chop_threshold [float or None] if set to a float value, all float values smaller then the given threshold will be displayed as exactly 0 by repr and friends. [default: None] [currently: None]

display.colheader_justify ['left'/'right'] Controls the justification of column headers. used by DataFrameFormatter. [default: right] [currently: right]

display.column_space No description available. [default: 12] [currently: 12]

display.date_dayfirst [boolean] When True, prints and parses dates with the day first, eg 20/01/2005 [default: False] [currently: False]

display.date_yearfirst [boolean] When True, prints and parses dates with the year first, eg 2005/01/20 [default: False] [currently: False]

display.encoding [str/unicode] Defaults to the detected encoding of the console. Specifies the encoding to be used for strings returned by to_string, these are generally strings meant to be displayed on the console. [default: utf-8] [currently: utf-8]

display.expand_frame_repr [boolean] Whether to print out the full DataFrame repr for wide DataFrames across multiple lines, *max_columns* is still respected, but the output will wrap-around across multiple "pages" if its width exceeds *display.width*. [default: True] [currently: True]

display.float_format [callable] The callable should accept a floating point number and return a string with the desired format of the number. This is used in some places like SeriesFormatter. See formats.format.EngFormatter for an example. [default: None] [currently: None]

display.html.border [int] A `border=value` attribute is inserted in the `<table>` tag for the DataFrame HTML repr. [default: 1] [currently: 1]

display.html.table_schema [boolean] Whether to publish a Table Schema representation for frontends that support it. (default: False) [default: False] [currently: False]

display.html.use_mathjax [boolean] When True, Jupyter notebook will process table contents using MathJax, rendering mathematical expressions enclosed by the dollar symbol. (default: True) [default: True] [currently: True]

display.large_repr ['truncate'/'info'] For DataFrames exceeding max_rows/max_cols, the repr (and HTML repr) can show a truncated table (the default from 0.13), or switch to the view from df.info() (the behaviour in earlier versions of pandas). [default: truncate] [currently: truncate]

display.latex.escape [bool] This specifies if the to_latex method of a Dataframe uses escapes special characters. Valid values: False,True [default: True] [currently: True]

display.latex.longtable :bool This specifies if the to_latex method of a Dataframe uses the longtable format. Valid values: False,True [default: False] [currently: False]

display.latex.multicolumn [bool] This specifies if the to_latex method of a Dataframe uses multicolumns to pretty-print MultiIndex columns. Valid values: False,True [default: True] [currently: True]

display.latex.multicolumn_format [bool] This specifies if the to_latex method of a Dataframe uses multicolumns to pretty-print MultiIndex columns. Valid values: False,True [default: l] [currently: l]

display.latex.multirow [bool] This specifies if the to_latex method of a Dataframe uses multirows to pretty-print MultiIndex rows. Valid values: False,True [default: False] [currently: False]

display.latex.repr [boolean] Whether to produce a latex DataFrame representation for jupyter environments that support it. (default: False) [default: False] [currently: False]

display.max_categories [int] This sets the maximum number of categories pandas should output when printing out a *Categorical* or a Series of dtype "category". [default: 8] [currently: 8]

display.max_columns [int] If max_cols is exceeded, switch to truncate view. Depending on *large_repr*, objects are either centrally truncated or printed as a summary view. 'None' value means unlimited.

In case python/IPython is running in a terminal and *large_repr* equals 'truncate' this can be set to 0 and pandas will auto-detect the width of the terminal and print a truncated object which fits the screen width. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: 0] [currently: 0]

display.max_colwidth [int or None] The maximum width in characters of a column in the repr of a pandas data structure. When the column overflows, a "..." placeholder is embedded in the output. A 'None' value means unlimited. [default: 50] [currently: 50]

display.max_info_columns [int] max_info_columns is used in DataFrame.info method to decide if per column information will be printed. [default: 100] [currently: 100]

display.max_info_rows [int or None] df.info() will usually show null-counts for each column. For large frames this can be quite slow. max_info_rows and max_info_cols limit this null check only to frames with smaller dimensions than specified. [default: 1690785] [currently: 1690785]

display.max_rows [int] If max_rows is exceeded, switch to truncate view. Depending on *large_repr*, objects are either centrally truncated or printed as a summary view. 'None' value means unlimited.

In case python/IPython is running in a terminal and *large_repr* equals 'truncate' this can be set to 0 and pandas will auto-detect the height of the terminal and print a truncated object which fits the screen height. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: 60] [currently: 15]

display.max_seq_items [int or None] when pretty-printing a long sequence, no more then *max_seq_items* will be printed. If items are omitted, they will be denoted by the addition of "..." to the resulting string.

If set to None, the number of items to be printed is unlimited. [default: 100] [currently: 100]

display.memory_usage [bool, string or None] This specifies if the memory usage of a DataFrame should be displayed when df.info() is called. Valid values True,False,'deep' [default: True] [currently: True]

display.min_rows [int] The numbers of rows to show in a truncated view (when *max_rows* is exceeded). Ignored when *max_rows* is set to None or 0. When set to None, follows the value of *max_rows*. [default: 10] [currently: 10]

display.multi_sparse [boolean] "sparsify" MultiIndex display (don't display repeated elements in outer levels within groups) [default: True] [currently: True]

display.notebook_repr_html [boolean] When True, IPython notebook will use html representation for pandas objects (if it is available). [default: True] [currently: True]

display.pprint_nest_depth [int] Controls the number of nested levels to process when pretty-printing [default: 3] [currently: 3]

display.precision [int] Floating point output precision (number of significant digits). This is only a suggestion [default: 6] [currently: 6]

display.show_dimensions [boolean or 'truncate'] Whether to print out dimensions at the end of DataFrame repr. If 'truncate' is specified, only print out the dimensions if the frame is truncated (e.g. not display all rows and/or columns) [default: truncate] [currently: truncate]

display.unicode.ambiguous_as_wide [boolean] Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance (default: False) [default: False] [currently: False]

display.unicode.east_asian_width [boolean] Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance (default: False) [default: False] [currently: False]

display.width [int] Width of the display in characters. In case python/IPython is running in a terminal this can

be set to None and pandas will correctly auto-detect the width. Note that the IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to correctly detect the width. [default: 80] [currently: 80]

io.excel.ods.reader [string] The default Excel reader engine for 'ods' files. Available options: auto, odf. [default: auto] [currently: auto]

io.excel.ods.writer [string] The default Excel writer engine for 'ods' files. Available options: auto, odf. [default: auto] [currently: auto]

io.excel.xls.reader [string] The default Excel reader engine for 'xls' files. Available options: auto, xlrd. [default: auto] [currently: auto]

io.excel.xls.writer [string] The default Excel writer engine for 'xls' files. Available options: auto, xlwt. [default: auto] [currently: auto]

io.excel.xlsb.reader [string] The default Excel reader engine for 'xlsb' files. Available options: auto, pyxlsb. [default: auto] [currently: auto]

io.excel.xlsm.reader [string] The default Excel reader engine for 'xlsm' files. Available options: auto, xlrd, openpyxl. [default: auto] [currently: auto]

io.excel.xlsm.writer [string] The default Excel writer engine for 'xlsm' files. Available options: auto, openpyxl. [default: auto] [currently: auto]

io.excel.xlsx.reader [string] The default Excel reader engine for 'xlsx' files. Available options: auto, xlrd, openpyxl. [default: auto] [currently: auto]

io.excel.xlsx.writer [string] The default Excel writer engine for 'xlsx' files. Available options: auto, openpyxl, xlsxwriter. [default: auto] [currently: auto]

io.hdf.default_format [format] default format writing format, if None, then put will default to 'fixed' and append will default to 'table' [default: None] [currently: None]

io.hdf.dropna_table [boolean] drop ALL nan rows when appending to a table [default: False] [currently: False]

io.parquet.engine [string] The default parquet reader/writer engine. Available options: 'auto', 'pyarrow', 'fastparquet', the default is 'auto' [default: auto] [currently: auto]

mode.chained_assignment [string] Raise an exception, warn, or no action if trying to use chained assignment, The default is warn [default: warn] [currently: warn]

mode.sim_interactive [boolean] Whether to simulate interactive mode for purposes of testing [default: False] [currently: False]

mode.use_inf_as_na [boolean] True means treat None, NaN, INF, -INF as NA (old way), False means None and NaN are null, but INF, -INF are not NA (new way). [default: False] [currently: False]

mode.use_inf_as_null [boolean] use_inf_as_null had been deprecated and will be removed in a future version. Use *use_inf_as_na* instead. [default: False] [currently: False] (Deprecated, use *mode.use_inf_as_na* instead.)

plotting.backend [str] The plotting backend to use. The default value is "matplotlib", the backend provided with pandas. Other backends can be specified by providing the name of the module that implements the backend. [default: matplotlib] [currently: matplotlib]

plotting.matplotlib.register_converters [bool or 'auto'.] Whether to register converters with matplotlib's units registry for dates, times, datetimes, and Periods. Toggling to False will remove the converters, restoring any converters that pandas overwrote. [default: auto] [currently: auto]

pandas.option_context

class pandas.**option_context**(**args*)

Context manager to temporarily set options in the *with* statement context.

You need to invoke as `option_context(pat, val, [(pat, val), ...])`.

Examples

```
>>> with option_context('display.max_rows', 10, 'display.max_columns', 5):
...     ...
```

Methods

__call__(func)	Call self as a function.

pandas.option_context.__call__

option_context.**__call__**(*func*)

Call self as a function.

3.15.2 Testing functions

testing.assert_frame_equal(left, right[, ...])	Check that left and right DataFrame are equal.
testing.assert_series_equal(left, right[, ...])	Check that left and right Series are equal.
testing.assert_index_equal(left, right[, ...])	Check that left and right Index are equal.
testing.assert_extension_array_equal(left, right)	Check that left and right ExtensionArrays are equal.

pandas.testing.assert_frame_equal

pandas.testing.**assert_frame_equal**(*left*, *right*, *check_dtype=True*, *check_index_type='equiv'*, *check_column_type='equiv'*, *check_frame_type=True*, *check_less_precise=<object object>*, *check_names=True*, *by_blocks=False*, *check_exact=False*, *check_datetimelike_compat=False*, *check_categorical=True*, *check_like=False*, *check_freq=True*, *rtol=1e-05*, *atol=1e-08*, *obj='DataFrame'*)

Check that left and right DataFrame are equal.

This function is intended to compare two DataFrames and output any differences. Is is mostly intended for use in unit tests. Additional parameters allow varying the strictness of the equality checks performed.

Parameters

left [DataFrame] First DataFrame to compare.

right [DataFrame] Second DataFrame to compare.

check_dtype [bool, default True] Whether to check the DataFrame dtype is identical.

check_index_type [bool or {'equiv'}, default 'equiv'] Whether to check the Index class, dtype and inferred_type are identical.

check_column_type [bool or {'equiv'}, default 'equiv'] Whether to check the columns class, dtype and inferred_type are identical. Is passed as the `exact` argument of *`assert_index_equal()`*.

check_frame_type [bool, default True] Whether to check the DataFrame class is identical.

check_less_precise [bool or int, default False] Specify comparison precision. Only used when check_exact is False. 5 digits (False) or 3 digits (True) after decimal points are compared. If int, then specify the digits to compare.

When comparing two numbers, if the first number has magnitude less than 1e-5, we compare the two numbers directly and check whether they are equivalent within the specified precision. Otherwise, we compare the **ratio** of the second number to the first number and check whether it is equivalent to 1 within the specified precision.

Deprecated since version 1.1.0: Use *rtol* and *atol* instead to define relative/absolute tolerance, respectively. Similar to `math.isclose()`.

check_names [bool, default True] Whether to check that the *names* attribute for both the *index* and *column* attributes of the DataFrame is identical.

by_blocks [bool, default False] Specify how to compare internal data. If False, compare by columns. If True, compare by blocks.

check_exact [bool, default False] Whether to compare number exactly.

check_datetimelike_compat [bool, default False] Compare datetime-like which is comparable ignoring dtype.

check_categorical [bool, default True] Whether to compare internal Categorical exactly.

check_like [bool, default False] If True, ignore the order of index & columns. Note: index labels must match their respective rows (same as in columns) - same labels must be with the same data.

check_freq [bool, default True] Whether to check the *freq* attribute on a DatetimeIndex or TimedeltaIndex.

rtol [float, default 1e-5] Relative tolerance. Only used when check_exact is False.

New in version 1.1.0.

atol [float, default 1e-8] Absolute tolerance. Only used when check_exact is False.

New in version 1.1.0.

obj [str, default 'DataFrame'] Specify object name being compared, internally used to show appropriate assertion message.

See also:

`assert_series_equal` Equivalent method for asserting Series equality.
`DataFrame.equals` Check DataFrame equality.

Examples

This example shows comparing two DataFrames that are equal but with columns of differing dtypes.

```
>>> from pandas._testing import assert_frame_equal
>>> df1 = pd.DataFrame({'a': [1, 2], 'b': [3, 4]})
>>> df2 = pd.DataFrame({'a': [1, 2], 'b': [3.0, 4.0]})
```

df1 equals itself.

```
>>> assert_frame_equal(df1, df1)
```

df1 differs from df2 as column 'b' is of a different type.

```
>>> assert_frame_equal(df1, df2)
Traceback (most recent call last):
...
AssertionError: Attributes of DataFrame.iloc[:, 1] (column name="b") are different
```

Attribute "dtype" are different [left]: int64 [right]: float64

Ignore differing dtypes in columns with check_dtype.

```
>>> assert_frame_equal(df1, df2, check_dtype=False)
```

pandas.testing.assert_series_equal

pandas.testing.**assert_series_equal**(*left*, *right*, *check_dtype=True*, *check_index_type='equiv'*, *check_series_type=True*, *check_less_precise=<object object>*, *check_names=True*, *check_exact=False*, *check_datetimelike_compat=False*, *check_categorical=True*, *check_category_order=True*, *check_freq=True*, *rtol=1e-05*, *atol=1e-08*, *obj='Series'*)

Check that left and right Series are equal.

Parameters

left [Series]

right [Series]

check_dtype [bool, default True] Whether to check the Series dtype is identical.

check_index_type [bool or {'equiv'}, default 'equiv'] Whether to check the Index class, dtype and inferred_type are identical.

check_series_type [bool, default True] Whether to check the Series class is identical.

check_less_precise [bool or int, default False] Specify comparison precision. Only used when check_exact is False. 5 digits (False) or 3 digits (True) after decimal points are compared. If int, then specify the digits to compare.

When comparing two numbers, if the first number has magnitude less than 1e-5, we compare the two numbers directly and check whether they are equivalent within the specified precision. Otherwise, we compare the **ratio** of the second number to the first number and check whether it is equivalent to 1 within the specified precision.

Deprecated since version 1.1.0: Use *rtol* and *atol* instead to define relative/absolute tolerance, respectively. Similar to `math.isclose()`.

check_names [bool, default True] Whether to check the Series and Index names attribute.

check_exact [bool, default False] Whether to compare number exactly.

check_datetimelike_compat [bool, default False] Compare datetime-like which is comparable ignoring dtype.

check_categorical [bool, default True] Whether to compare internal Categorical exactly.

check_category_order [bool, default True] Whether to compare category order of internal Categoricals.

New in version 1.0.2.

check_freq [bool, default True] Whether to check the *freq* attribute on a DatetimeIndex or TimedeltaIndex.

rtol [float, default 1e-5] Relative tolerance. Only used when check_exact is False.

New in version 1.1.0.

atol [float, default 1e-8] Absolute tolerance. Only used when check_exact is False.

New in version 1.1.0.

obj [str, default 'Series'] Specify object name being compared, internally used to show appropriate assertion message.

pandas.testing.assert_index_equal

pandas.testing.**assert_index_equal**(*left*, *right*, *exact='equiv'*, *check_names=True*, *check_less_precise=<object object>*, *check_exact=True*, *check_categorical=True*, *rtol=1e-05*, *atol=1e-08*, *obj='Index'*)

Check that left and right Index are equal.

Parameters

left [Index]

right [Index]

exact [bool or {'equiv'}, default 'equiv'] Whether to check the Index class, dtype and inferred_type are identical. If 'equiv', then RangeIndex can be substituted for Int64Index as well.

check_names [bool, default True] Whether to check the names attribute.

check_less_precise [bool or int, default False] Specify comparison precision. Only used when check_exact is False. 5 digits (False) or 3 digits (True) after decimal points are compared. If int, then specify the digits to compare.

Deprecated since version 1.1.0: Use *rtol* and *atol* instead to define relative/absolute tolerance, respectively. Similar to `math.isclose()`.

check_exact [bool, default True] Whether to compare number exactly.

check_categorical [bool, default True] Whether to compare internal Categorical exactly.

rtol [float, default 1e-5] Relative tolerance. Only used when check_exact is False.

New in version 1.1.0.

atol [float, default 1e-8] Absolute tolerance. Only used when check_exact is False.

New in version 1.1.0.

obj [str, default 'Index'] Specify object name being compared, internally used to show appropriate assertion message.

pandas.testing.assert_extension_array_equal

pandas.testing.**assert_extension_array_equal**(*left*, *right*, *check_dtype=True*, *index_values=None*, *check_less_precise=<object object>*, *check_exact=False*, *rtol=1e-05*, *atol=1e-08*)

Check that left and right ExtensionArrays are equal.

Parameters

left, right [ExtensionArray] The two arrays to compare.

check_dtype [bool, default True] Whether to check if the ExtensionArray dtypes are identical.

index_values [numpy.ndarray, default None] Optional index (shared by both left and right), used in output.

check_less_precise [bool or int, default False] Specify comparison precision. Only used when check_exact is False. 5 digits (False) or 3 digits (True) after decimal points are compared. If int, then specify the digits to compare.

Deprecated since version 1.1.0: Use *rtol* and *atol* instead to define relative/absolute tolerance, respectively. Similar to `math.isclose()`.

check_exact [bool, default False] Whether to compare number exactly.

rtol [float, default 1e-5] Relative tolerance. Only used when check_exact is False.

New in version 1.1.0.

atol [float, default 1e-8] Absolute tolerance. Only used when check_exact is False.

New in version 1.1.0.

Notes

Missing values are checked separately from valid values. A mask of missing values is computed for each and checked to match. The remaining all-valid values are cast to object dtype and checked.

3.15.3 Exceptions and warnings

errors.AccessorRegistrationWarning	Warning for attribute conflicts in accessor registration.
errors.DtypeWarning	Warning raised when reading different dtypes in a column from a file.
errors.EmptyDataError	Exception that is thrown in *pd.read_csv* (by both the C and Python engines) when empty data or header is encountered.
errors.InvalidIndexError	Exception raised when attemping to use an invalid index key.
errors.MergeError	Error raised when problems arise during merging due to problems with input data.

continues on next page

Table 390 – continued from previous page

errors.NullFrequencyError	Error raised when a null *freq* attribute is used in an operation that needs a non-null frequency, particularly *DatetimeIndex.shift*, *TimedeltaIndex.shift*, *PeriodIndex.shift*.
errors.NumbaUtilError	Error raised for unsupported Numba engine routines.
errors.OutOfBoundsDatetime	
errors.OutOfBoundsTimedelta	Raised when encountering a timedelta value that cannot be represented as a timedelta64[ns].
errors.ParserError	Exception that is raised by an error encountered in parsing file contents.
errors.ParserWarning	Warning raised when reading a file that doesn't use the default 'c' parser.
errors.PerformanceWarning	Warning raised when there is a possible performance impact.
errors.UnsortedIndexError	Error raised when attempting to get a slice of a MultiIndex, and the index has not been lexsorted.
errors.UnsupportedFunctionCall	Exception raised when attempting to call a numpy function on a pandas object, but that function is not supported by the object e.g.

pandas.errors.AccessorRegistrationWarning

exception pandas.errors.**AccessorRegistrationWarning**
Warning for attribute conflicts in accessor registration.

pandas.errors.DtypeWarning

exception pandas.errors.**DtypeWarning**
Warning raised when reading different dtypes in a column from a file.

Raised for a dtype incompatibility. This can happen whenever *read_csv* or *read_table* encounter non-uniform dtypes in a column(s) of a given CSV file.

See also:

read_csv Read CSV (comma-separated) file into a DataFrame.
read_table Read general delimited file into a DataFrame.

Notes

This warning is issued when dealing with larger files because the dtype checking happens per chunk read.

Despite the warning, the CSV file is read with mixed types in a single column which will be an object type. See the examples below to better understand this issue.

Examples

This example creates and reads a large CSV file with a column that contains *int* and *str*.

```
>>> df = pd.DataFrame({'a': (['1'] * 100000 + ['X'] * 100000 +
...                          ['1'] * 100000),
...                    'b': ['b'] * 300000})
>>> df.to_csv('test.csv', index=False)
>>> df2 = pd.read_csv('test.csv')
... # DtypeWarning: Columns (0) have mixed types
```

Important to notice that `df2` will contain both *str* and *int* for the same input, '1'.

```
>>> df2.iloc[262140, 0]
'1'
>>> type(df2.iloc[262140, 0])
<class 'str'>
>>> df2.iloc[262150, 0]
1
>>> type(df2.iloc[262150, 0])
<class 'int'>
```

One way to solve this issue is using the *dtype* parameter in the *read_csv* and *read_table* functions to explicit the conversion:

```
>>> df2 = pd.read_csv('test.csv', sep=',', dtype={'a': str})
```

No warning was issued.

```
>>> import os
>>> os.remove('test.csv')
```

pandas.errors.EmptyDataError

exception pandas.errors.**EmptyDataError**

Exception that is thrown in *pd.read_csv* (by both the C and Python engines) when empty data or header is encountered.

pandas.errors.InvalidIndexError

exception pandas.errors.**InvalidIndexError**

Exception raised when attemping to use an invalid index key.

New in version 1.1.0.

pandas.errors.MergeError

exception pandas.errors.**MergeError**
Error raised when problems arise during merging due to problems with input data. Subclass of *ValueError*.

pandas.errors.NullFrequencyError

exception pandas.errors.**NullFrequencyError**
Error raised when a null *freq* attribute is used in an operation that needs a non-null frequency, particularly *DatetimeIndex.shift*, *TimedeltaIndex.shift*, *PeriodIndex.shift*.

pandas.errors.NumbaUtilError

exception pandas.errors.**NumbaUtilError**
Error raised for unsupported Numba engine routines.

pandas.errors.OutOfBoundsDatetime

exception pandas.errors.**OutOfBoundsDatetime**

pandas.errors.OutOfBoundsTimedelta

exception pandas.errors.**OutOfBoundsTimedelta**
Raised when encountering a timedelta value that cannot be represented as a timedelta64[ns].

pandas.errors.ParserError

exception pandas.errors.**ParserError**
Exception that is raised by an error encountered in parsing file contents.

This is a generic error raised for errors encountered when functions like *read_csv* or *read_html* are parsing contents of a file.

See also:

read_csv Read CSV (comma-separated) file into a DataFrame.
read_html Read HTML table into a DataFrame.

pandas.errors.ParserWarning

exception pandas.errors.**ParserWarning**
Warning raised when reading a file that doesn't use the default 'c' parser.

Raised by *pd.read_csv* and *pd.read_table* when it is necessary to change parsers, generally from the default 'c' parser to 'python'.

It happens due to a lack of support or functionality for parsing a particular attribute of a CSV file with the requested engine.

Currently, 'c' unsupported options include the following parameters:

1. *sep* other than a single character (e.g. regex separators)
2. *skipfooter* higher than 0
3. *sep=None* with *delim_whitespace=False*

The warning can be avoided by adding *engine='python'* as a parameter in *pd.read_csv* and *pd.read_table* methods.

See also:

pd.read_csv Read CSV (comma-separated) file into DataFrame.
pd.read_table Read general delimited file into DataFrame.

Examples

Using a *sep* in *pd.read_csv* other than a single character:

```
>>> import io
>>> csv = '''a;b;c
...           1;1,8
...           1;2,1'''
>>> df = pd.read_csv(io.StringIO(csv), sep='[;,]')
... # ParserWarning: Falling back to the 'python' engine...
```

Adding *engine='python'* to *pd.read_csv* removes the Warning:

```
>>> df = pd.read_csv(io.StringIO(csv), sep='[;,]', engine='python')
```

pandas.errors.PerformanceWarning

exception pandas.errors.**PerformanceWarning**
Warning raised when there is a possible performance impact.

pandas.errors.UnsortedIndexError

exception pandas.errors.**UnsortedIndexError**
Error raised when attempting to get a slice of a MultiIndex, and the index has not been lexsorted. Subclass of *KeyError*.

pandas.errors.UnsupportedFunctionCall

exception pandas.errors.**UnsupportedFunctionCall**
Exception raised when attempting to call a numpy function on a pandas object, but that function is not supported by the object e.g. `np.cumsum(groupby_object)`.

3.15.4 Data types related functionality

api.types.union_categoricals(to_union[, ...])	Combine list-like of Categorical-like, unioning categories.
api.types.infer_dtype	Efficiently infer the type of a passed val, or list-like array of values.
api.types.pandas_dtype(dtype)	Convert input into a pandas only dtype object or a numpy dtype object.

pandas.api.types.union_categoricals

pandas.api.types.**union_categoricals**(*to_union*, *sort_categories=False*, *ignore_order=False*)

Combine list-like of Categorical-like, unioning categories.

All categories must have the same dtype.

Parameters

to_union [list-like] Categorical, CategoricalIndex, or Series with dtype='category'.

sort_categories [bool, default False] If true, resulting categories will be lexsorted, otherwise they will be ordered as they appear in the data.

ignore_order [bool, default False] If true, the ordered attribute of the Categoricals will be ignored. Results in an unordered categorical.

Returns

Categorical

Raises

TypeError

- all inputs do not have the same dtype
- all inputs do not have the same ordered property
- all inputs are ordered and their categories are not identical
- sort_categories=True and Categoricals are ordered

ValueError Empty list of categoricals passed

Notes

To learn more about categories, see link

Examples

```
>>> from pandas.api.types import union_categoricals
```

If you want to combine categoricals that do not necessarily have the same categories, *union_categoricals* will combine a list-like of categoricals. The new categories will be the union of the categories being combined.

```
>>> a = pd.Categorical(["b", "c"])
>>> b = pd.Categorical(["a", "b"])
>>> union_categoricals([a, b])
['b', 'c', 'a', 'b']
Categories (3, object): ['b', 'c', 'a']
```

By default, the resulting categories will be ordered as they appear in the *categories* of the data. If you want the categories to be lexsorted, use *sort_categories=True* argument.

```
>>> union_categoricals([a, b], sort_categories=True)
['b', 'c', 'a', 'b']
Categories (3, object): ['a', 'b', 'c']
```

union_categoricals also works with the case of combining two categoricals of the same categories and order information (e.g. what you could also *append* for).

```
>>> a = pd.Categorical(["a", "b"], ordered=True)
>>> b = pd.Categorical(["a", "b", "a"], ordered=True)
>>> union_categoricals([a, b])
['a', 'b', 'a', 'b', 'a']
Categories (2, object): ['a' < 'b']
```

Raises *TypeError* because the categories are ordered and not identical.

```
>>> a = pd.Categorical(["a", "b"], ordered=True)
>>> b = pd.Categorical(["a", "b", "c"], ordered=True)
>>> union_categoricals([a, b])
Traceback (most recent call last):
    ...
TypeError: to union ordered Categoricals, all categories must be the same
```

New in version 0.20.0

Ordered categoricals with different categories or orderings can be combined by using the *ignore_ordered=True* argument.

```
>>> a = pd.Categorical(["a", "b", "c"], ordered=True)
>>> b = pd.Categorical(["c", "b", "a"], ordered=True)
>>> union_categoricals([a, b], ignore_order=True)
['a', 'b', 'c', 'c', 'b', 'a']
Categories (3, object): ['a', 'b', 'c']
```

union_categoricals also works with a *CategoricalIndex*, or *Series* containing categorical data, but note that the resulting array will always be a plain *Categorical*

```
>>> a = pd.Series(["b", "c"], dtype='category')
>>> b = pd.Series(["a", "b"], dtype='category')
>>> union_categoricals([a, b])
['b', 'c', 'a', 'b']
Categories (3, object): ['b', 'c', 'a']
```

pandas.api.types.infer_dtype

pandas.api.types.**infer_dtype**()

Efficiently infer the type of a passed val, or list-like array of values. Return a string describing the type.

Parameters

value [scalar, list, ndarray, or pandas type]

skipna [bool, default True] Ignore NaN values when inferring the type.

Returns

str Describing the common type of the input data.

Results can include:

- **string**
- **bytes**
- **floating**
- **integer**
- **mixed-integer**

- **mixed-integer-float**
- **decimal**
- **complex**
- **categorical**
- **boolean**
- **datetime64**
- **datetime**
- **date**
- **timedelta64**
- **timedelta**
- **time**
- **period**
- **mixed**

Raises

TypeError If ndarray-like but cannot infer the dtype

Notes

- 'mixed' is the catchall for anything that is not otherwise specialized
- 'mixed-integer-float' are floats and integers
- 'mixed-integer' are integers mixed with non-integers

Examples

```
>>> infer_dtype(['foo', 'bar'])
'string'
```

```
>>> infer_dtype(['a', np.nan, 'b'], skipna=True)
'string'
```

```
>>> infer_dtype(['a', np.nan, 'b'], skipna=False)
'mixed'
```

```
>>> infer_dtype([b'foo', b'bar'])
'bytes'
```

```
>>> infer_dtype([1, 2, 3])
'integer'
```

```
>>> infer_dtype([1, 2, 3.5])
'mixed-integer-float'
```

```
>>> infer_dtype([1.0, 2.0, 3.5])
'floating'
```

```
>>> infer_dtype(['a', 1])
'mixed-integer'
```

```
>>> infer_dtype([Decimal(1), Decimal(2.0)])
'decimal'
```

```
>>> infer_dtype([True, False])
'boolean'
```

```
>>> infer_dtype([True, False, np.nan])
'mixed'
```

```
>>> infer_dtype([pd.Timestamp('20130101')])
'datetime'
```

```
>>> infer_dtype([datetime.date(2013, 1, 1)])
'date'
```

```
>>> infer_dtype([np.datetime64('2013-01-01')])
'datetime64'
```

```
>>> infer_dtype([datetime.timedelta(0, 1, 1)])
'timedelta'
```

```
>>> infer_dtype(pd.Series(list('aabc')).astype('category'))
'categorical'
```

pandas.api.types.pandas_dtype

pandas.api.types.**pandas_dtype**(*dtype*)

Convert input into a pandas only dtype object or a numpy dtype object.

Parameters

dtype [object to be converted]

Returns

np.dtype or a pandas dtype

Raises

TypeError if not a dtype

Dtype introspection

api.types.is_bool_dtype(arr_or_dtype)	Check whether the provided array or dtype is of a boolean dtype.
api.types.is_categorical_dtype(arr_or_dtype)	Check whether an array-like or dtype is of the Categorical dtype.
api.types.is_complex_dtype(arr_or_dtype)	Check whether the provided array or dtype is of a complex dtype.

continues on next page

Table 392 – continued from previous page

api.types.is_datetime64_any_dtype(arr_or_dtype)	Check whether the provided array or dtype is of the datetime64 dtype.
api.types.is_datetime64_dtype(arr_or_dtype)	Check whether an array-like or dtype is of the datetime64 dtype.
api.types.is_datetime64_ns_dtype(arr_or_dtype)	Check whether the provided array or dtype is of the datetime64[ns] dtype.
api.types.is_datetime64tz_dtype(arr_or_dtype)	Check whether an array-like or dtype is of a DatetimeTZDtype dtype.
api.types.is_extension_type(arr)	(DEPRECATED) Check whether an array-like is of a pandas extension class instance.
api.types.is_extension_array_dtype(arr_or_dtype)	Check if an object is a pandas extension array type.
api.types.is_float_dtype(arr_or_dtype)	Check whether the provided array or dtype is of a float dtype.
api.types.is_int64_dtype(arr_or_dtype)	Check whether the provided array or dtype is of the int64 dtype.
api.types.is_integer_dtype(arr_or_dtype)	Check whether the provided array or dtype is of an integer dtype.
api.types.is_interval_dtype(arr_or_dtype)	Check whether an array-like or dtype is of the Interval dtype.
api.types.is_numeric_dtype(arr_or_dtype)	Check whether the provided array or dtype is of a numeric dtype.
api.types.is_object_dtype(arr_or_dtype)	Check whether an array-like or dtype is of the object dtype.
api.types.is_period_dtype(arr_or_dtype)	Check whether an array-like or dtype is of the Period dtype.
api.types.is_signed_integer_dtype(arr_or_dtype)	Check whether the provided array or dtype is of a signed integer dtype.
api.types.is_string_dtype(arr_or_dtype)	Check whether the provided array or dtype is of the string dtype.
api.types.is_timedelta64_dtype(arr_or_dtype)	Check whether an array-like or dtype is of the timedelta64 dtype.
api.types.is_timedelta64_ns_dtype(arr_or_dtype)	Check whether the provided array or dtype is of the timedelta64[ns] dtype.
api.types.is_unsigned_integer_dtype(arr_or_dtype)	Check whether the provided array or dtype is of an unsigned integer dtype.
api.types.is_sparse(arr)	Check whether an array-like is a 1-D pandas sparse array.

pandas.api.types.is_bool_dtype

pandas.api.types.**is_bool_dtype**(*arr_or_dtype*)

Check whether the provided array or dtype is of a boolean dtype.

Parameters

arr_or_dtype [array-like] The array or dtype to check.

Returns

boolean Whether or not the array or dtype is of a boolean dtype.

Notes

An ExtensionArray is considered boolean when the `_is_boolean` attribute is set to True.

Examples

```
>>> is_bool_dtype(str)
False
>>> is_bool_dtype(int)
False
>>> is_bool_dtype(bool)
True
>>> is_bool_dtype(np.bool_)
True
>>> is_bool_dtype(np.array(['a', 'b']))
False
>>> is_bool_dtype(pd.Series([1, 2]))
False
>>> is_bool_dtype(np.array([True, False]))
True
>>> is_bool_dtype(pd.Categorical([True, False]))
True
>>> is_bool_dtype(pd.arrays.SparseArray([True, False]))
True
```

pandas.api.types.is_categorical_dtype

pandas.api.types.**is_categorical_dtype**(*arr_or_dtype*)

Check whether an array-like or dtype is of the Categorical dtype.

Parameters

arr_or_dtype [array-like] The array-like or dtype to check.

Returns

boolean Whether or not the array-like or dtype is of the Categorical dtype.

Examples

```
>>> is_categorical_dtype(object)
False
>>> is_categorical_dtype(CategoricalDtype())
True
>>> is_categorical_dtype([1, 2, 3])
False
>>> is_categorical_dtype(pd.Categorical([1, 2, 3]))
True
>>> is_categorical_dtype(pd.CategoricalIndex([1, 2, 3]))
True
```

pandas.api.types.is_complex_dtype

pandas.api.types.**is_complex_dtype**(*arr_or_dtype*)

Check whether the provided array or dtype is of a complex dtype.

Parameters

arr_or_dtype [array-like] The array or dtype to check.

Returns

boolean Whether or not the array or dtype is of a complex dtype.

Examples

```
>>> is_complex_dtype(str)
False
>>> is_complex_dtype(int)
False
>>> is_complex_dtype(np.complex_)
True
>>> is_complex_dtype(np.array(['a', 'b']))
False
>>> is_complex_dtype(pd.Series([1, 2]))
False
>>> is_complex_dtype(np.array([1 + 1j, 5]))
True
```

pandas.api.types.is_datetime64_any_dtype

pandas.api.types.**is_datetime64_any_dtype**(*arr_or_dtype*)

Check whether the provided array or dtype is of the datetime64 dtype.

Parameters

arr_or_dtype [array-like] The array or dtype to check.

Returns

bool Whether or not the array or dtype is of the datetime64 dtype.

Examples

```
>>> is_datetime64_any_dtype(str)
False
>>> is_datetime64_any_dtype(int)
False
>>> is_datetime64_any_dtype(np.datetime64)  # can be tz-naive
True
>>> is_datetime64_any_dtype(DatetimeTZDtype("ns", "US/Eastern"))
True
>>> is_datetime64_any_dtype(np.array(['a', 'b']))
False
>>> is_datetime64_any_dtype(np.array([1, 2]))
False
>>> is_datetime64_any_dtype(np.array([], dtype="datetime64[ns]"))
```

(continues on next page)

(continued from previous page)

```
True
>>> is_datetime64_any_dtype(pd.DatetimeIndex([1, 2, 3], dtype="datetime64[ns]"))
True
```

pandas.api.types.is_datetime64_dtype

pandas.api.types.**is_datetime64_dtype**(*arr_or_dtype*)

Check whether an array-like or dtype is of the datetime64 dtype.

Parameters

arr_or_dtype [array-like] The array-like or dtype to check.

Returns

boolean Whether or not the array-like or dtype is of the datetime64 dtype.

Examples

```
>>> is_datetime64_dtype(object)
False
>>> is_datetime64_dtype(np.datetime64)
True
>>> is_datetime64_dtype(np.array([], dtype=int))
False
>>> is_datetime64_dtype(np.array([], dtype=np.datetime64))
True
>>> is_datetime64_dtype([1, 2, 3])
False
```

pandas.api.types.is_datetime64_ns_dtype

pandas.api.types.**is_datetime64_ns_dtype**(*arr_or_dtype*)

Check whether the provided array or dtype is of the datetime64[ns] dtype.

Parameters

arr_or_dtype [array-like] The array or dtype to check.

Returns

bool Whether or not the array or dtype is of the datetime64[ns] dtype.

Examples

```
>>> is_datetime64_ns_dtype(str)
False
>>> is_datetime64_ns_dtype(int)
False
>>> is_datetime64_ns_dtype(np.datetime64)  # no unit
False
>>> is_datetime64_ns_dtype(DatetimeTZDtype("ns", "US/Eastern"))
True
>>> is_datetime64_ns_dtype(np.array(['a', 'b']))
```

(continues on next page)

(continued from previous page)

```
False
>>> is_datetime64_ns_dtype(np.array([1, 2]))
False
>>> is_datetime64_ns_dtype(np.array([], dtype="datetime64"))  # no unit
False
>>> is_datetime64_ns_dtype(np.array([], dtype="datetime64[ps]"))  # wrong unit
False
>>> is_datetime64_ns_dtype(pd.DatetimeIndex([1, 2, 3], dtype="datetime64[ns]"))
True
```

pandas.api.types.is_datetime64tz_dtype

pandas.api.types.**is_datetime64tz_dtype**(*arr_or_dtype*)

Check whether an array-like or dtype is of a DatetimeTZDtype dtype.

Parameters

arr_or_dtype [array-like] The array-like or dtype to check.

Returns

boolean Whether or not the array-like or dtype is of a DatetimeTZDtype dtype.

Examples

```
>>> is_datetime64tz_dtype(object)
False
>>> is_datetime64tz_dtype([1, 2, 3])
False
>>> is_datetime64tz_dtype(pd.DatetimeIndex([1, 2, 3]))  # tz-naive
False
>>> is_datetime64tz_dtype(pd.DatetimeIndex([1, 2, 3], tz="US/Eastern"))
True
```

```
>>> dtype = DatetimeTZDtype("ns", tz="US/Eastern")
>>> s = pd.Series([], dtype=dtype)
>>> is_datetime64tz_dtype(dtype)
True
>>> is_datetime64tz_dtype(s)
True
```

pandas.api.types.is_extension_type

pandas.api.types.**is_extension_type**(*arr*)

Check whether an array-like is of a pandas extension class instance.

Deprecated since version 1.0.0: Use `is_extension_array_dtype` instead.

Extension classes include categoricals, pandas sparse objects (i.e. classes represented within the pandas library and not ones external to it like scipy sparse matrices), and datetime-like arrays.

Parameters

arr [array-like] The array-like to check.

Returns

boolean Whether or not the array-like is of a pandas extension class instance.

Examples

```
>>> is_extension_type([1, 2, 3])
False
>>> is_extension_type(np.array([1, 2, 3]))
False
>>>
>>> cat = pd.Categorical([1, 2, 3])
>>>
>>> is_extension_type(cat)
True
>>> is_extension_type(pd.Series(cat))
True
>>> is_extension_type(pd.arrays.SparseArray([1, 2, 3]))
True
>>> from scipy.sparse import bsr_matrix
>>> is_extension_type(bsr_matrix([1, 2, 3]))
False
>>> is_extension_type(pd.DatetimeIndex([1, 2, 3]))
False
>>> is_extension_type(pd.DatetimeIndex([1, 2, 3], tz="US/Eastern"))
True
>>>
>>> dtype = DatetimeTZDtype("ns", tz="US/Eastern")
>>> s = pd.Series([], dtype=dtype)
>>> is_extension_type(s)
True
```

pandas.api.types.is_extension_array_dtype

pandas.api.types.**is_extension_array_dtype**(*arr_or_dtype*)

Check if an object is a pandas extension array type.

See the *Use Guide* for more.

Parameters

arr_or_dtype [object] For array-like input, the `.dtype` attribute will be extracted.

Returns

bool Whether the *arr_or_dtype* is an extension array type.

Notes

This checks whether an object implements the pandas extension array interface. In pandas, this includes:

- Categorical
- Sparse
- Interval
- Period
- DatetimeArray
- TimedeltaArray

Third-party libraries may implement arrays or types satisfying this interface as well.

Examples

```
>>> from pandas.api.types import is_extension_array_dtype
>>> arr = pd.Categorical(['a', 'b'])
>>> is_extension_array_dtype(arr)
True
>>> is_extension_array_dtype(arr.dtype)
True
```

```
>>> arr = np.array(['a', 'b'])
>>> is_extension_array_dtype(arr.dtype)
False
```

pandas.api.types.is_float_dtype

pandas.api.types.**is_float_dtype**(*arr_or_dtype*)

Check whether the provided array or dtype is of a float dtype.

This function is internal and should not be exposed in the public API.

Parameters

arr_or_dtype [array-like] The array or dtype to check.

Returns

boolean Whether or not the array or dtype is of a float dtype.

Examples

```
>>> is_float_dtype(str)
False
>>> is_float_dtype(int)
False
>>> is_float_dtype(float)
True
>>> is_float_dtype(np.array(['a', 'b']))
False
>>> is_float_dtype(pd.Series([1, 2]))
False
>>> is_float_dtype(pd.Index([1, 2.]))
True
```

pandas.api.types.is_int64_dtype

pandas.api.types.**is_int64_dtype**(*arr_or_dtype*)

Check whether the provided array or dtype is of the int64 dtype.

Parameters

arr_or_dtype [array-like] The array or dtype to check.

Returns

boolean Whether or not the array or dtype is of the int64 dtype.

Notes

Depending on system architecture, the return value of *is_int64_dtype(int)* will be True if the OS uses 64-bit integers and False if the OS uses 32-bit integers.

Examples

```
>>> is_int64_dtype(str)
False
>>> is_int64_dtype(np.int32)
False
>>> is_int64_dtype(np.int64)
True
>>> is_int64_dtype('int8')
False
>>> is_int64_dtype('Int8')
False
>>> is_int64_dtype(pd.Int64Dtype)
True
>>> is_int64_dtype(float)
False
>>> is_int64_dtype(np.uint64)  # unsigned
False
>>> is_int64_dtype(np.array(['a', 'b']))
False
>>> is_int64_dtype(np.array([1, 2], dtype=np.int64))
True
>>> is_int64_dtype(pd.Index([1, 2.]))  # float
False
>>> is_int64_dtype(np.array([1, 2], dtype=np.uint32))  # unsigned
False
```

pandas.api.types.is_integer_dtype

pandas.api.types.**is_integer_dtype**(*arr_or_dtype*)

Check whether the provided array or dtype is of an integer dtype.

Unlike in *in_any_int_dtype*, timedelta64 instances will return False.

Changed in version 0.24.0: The nullable Integer dtypes (e.g. pandas.Int64Dtype) are also considered as integer by this function.

Parameters

arr_or_dtype [array-like] The array or dtype to check.

Returns

boolean Whether or not the array or dtype is of an integer dtype and not an instance of timedelta64.

Examples

```
>>> is_integer_dtype(str)
False
>>> is_integer_dtype(int)
True
>>> is_integer_dtype(float)
False
>>> is_integer_dtype(np.uint64)
True
>>> is_integer_dtype('int8')
True
>>> is_integer_dtype('Int8')
True
>>> is_integer_dtype(pd.Int8Dtype)
True
>>> is_integer_dtype(np.datetime64)
False
>>> is_integer_dtype(np.timedelta64)
False
>>> is_integer_dtype(np.array(['a', 'b']))
False
>>> is_integer_dtype(pd.Series([1, 2]))
True
>>> is_integer_dtype(np.array([], dtype=np.timedelta64))
False
>>> is_integer_dtype(pd.Index([1, 2.]))  # float
False
```

pandas.api.types.is_interval_dtype

pandas.api.types.**is_interval_dtype**(*arr_or_dtype*)

Check whether an array-like or dtype is of the Interval dtype.

Parameters

arr_or_dtype [array-like] The array-like or dtype to check.

Returns

boolean Whether or not the array-like or dtype is of the Interval dtype.

Examples

```
>>> is_interval_dtype(object)
False
>>> is_interval_dtype(IntervalDtype())
True
>>> is_interval_dtype([1, 2, 3])
False
>>>
>>> interval = pd.Interval(1, 2, closed="right")
>>> is_interval_dtype(interval)
False
>>> is_interval_dtype(pd.IntervalIndex([interval]))
True
```

pandas.api.types.is_numeric_dtype

pandas.api.types.**is_numeric_dtype**(*arr_or_dtype*)

Check whether the provided array or dtype is of a numeric dtype.

Parameters

arr_or_dtype [array-like] The array or dtype to check.

Returns

boolean Whether or not the array or dtype is of a numeric dtype.

Examples

```
>>> is_numeric_dtype(str)
False
>>> is_numeric_dtype(int)
True
>>> is_numeric_dtype(float)
True
>>> is_numeric_dtype(np.uint64)
True
>>> is_numeric_dtype(np.datetime64)
False
>>> is_numeric_dtype(np.timedelta64)
False
>>> is_numeric_dtype(np.array(['a', 'b']))
False
>>> is_numeric_dtype(pd.Series([1, 2]))
True
>>> is_numeric_dtype(pd.Index([1, 2.]))
True
>>> is_numeric_dtype(np.array([], dtype=np.timedelta64))
False
```

pandas.api.types.is_object_dtype

pandas.api.types.**is_object_dtype**(*arr_or_dtype*)

Check whether an array-like or dtype is of the object dtype.

Parameters

arr_or_dtype [array-like] The array-like or dtype to check.

Returns

boolean Whether or not the array-like or dtype is of the object dtype.

Examples

```
>>> is_object_dtype(object)
True
>>> is_object_dtype(int)
False
>>> is_object_dtype(np.array([], dtype=object))
True
>>> is_object_dtype(np.array([], dtype=int))
False
>>> is_object_dtype([1, 2, 3])
False
```

pandas.api.types.is_period_dtype

pandas.api.types.**is_period_dtype**(*arr_or_dtype*)

Check whether an array-like or dtype is of the Period dtype.

Parameters

arr_or_dtype [array-like] The array-like or dtype to check.

Returns

boolean Whether or not the array-like or dtype is of the Period dtype.

Examples

```
>>> is_period_dtype(object)
False
>>> is_period_dtype(PeriodDtype(freq="D"))
True
>>> is_period_dtype([1, 2, 3])
False
>>> is_period_dtype(pd.Period("2017-01-01"))
False
>>> is_period_dtype(pd.PeriodIndex([], freq="A"))
True
```

pandas.api.types.is_signed_integer_dtype

pandas.api.types.**is_signed_integer_dtype**(*arr_or_dtype*)

Check whether the provided array or dtype is of a signed integer dtype.

Unlike in *in_any_int_dtype*, timedelta64 instances will return False.

Changed in version 0.24.0: The nullable Integer dtypes (e.g. pandas.Int64Dtype) are also considered as integer by this function.

Parameters

arr_or_dtype [array-like] The array or dtype to check.

Returns

boolean Whether or not the array or dtype is of a signed integer dtype and not an instance of timedelta64.

Examples

```
>>> is_signed_integer_dtype(str)
False
>>> is_signed_integer_dtype(int)
True
>>> is_signed_integer_dtype(float)
False
>>> is_signed_integer_dtype(np.uint64)  # unsigned
False
>>> is_signed_integer_dtype('int8')
True
>>> is_signed_integer_dtype('Int8')
True
>>> is_signed_integer_dtype(pd.Int8Dtype)
True
>>> is_signed_integer_dtype(np.datetime64)
False
>>> is_signed_integer_dtype(np.timedelta64)
False
>>> is_signed_integer_dtype(np.array(['a', 'b']))
False
>>> is_signed_integer_dtype(pd.Series([1, 2]))
True
>>> is_signed_integer_dtype(np.array([], dtype=np.timedelta64))
False
>>> is_signed_integer_dtype(pd.Index([1, 2.]))  # float
False
>>> is_signed_integer_dtype(np.array([1, 2], dtype=np.uint32))  # unsigned
False
```

pandas.api.types.is_string_dtype

pandas.api.types.**is_string_dtype**(*arr_or_dtype*)

Check whether the provided array or dtype is of the string dtype.

Parameters

arr_or_dtype [array-like] The array or dtype to check.

Returns

boolean Whether or not the array or dtype is of the string dtype.

Examples

```
>>> is_string_dtype(str)
True
>>> is_string_dtype(object)
True
>>> is_string_dtype(int)
False
>>>
>>> is_string_dtype(np.array(['a', 'b']))
True
```

(continues on next page)

(continued from previous page)

```
>>> is_string_dtype(pd.Series([1, 2]))
False
```

pandas.api.types.is_timedelta64_dtype

pandas.api.types.**is_timedelta64_dtype**(*arr_or_dtype*)

Check whether an array-like or dtype is of the timedelta64 dtype.

Parameters

arr_or_dtype [array-like] The array-like or dtype to check.

Returns

boolean Whether or not the array-like or dtype is of the timedelta64 dtype.

Examples

```
>>> is_timedelta64_dtype(object)
False
>>> is_timedelta64_dtype(np.timedelta64)
True
>>> is_timedelta64_dtype([1, 2, 3])
False
>>> is_timedelta64_dtype(pd.Series([], dtype="timedelta64[ns]"))
True
>>> is_timedelta64_dtype('0 days')
False
```

pandas.api.types.is_timedelta64_ns_dtype

pandas.api.types.**is_timedelta64_ns_dtype**(*arr_or_dtype*)

Check whether the provided array or dtype is of the timedelta64[ns] dtype.

This is a very specific dtype, so generic ones like *np.timedelta64* will return False if passed into this function.

Parameters

arr_or_dtype [array-like] The array or dtype to check.

Returns

boolean Whether or not the array or dtype is of the timedelta64[ns] dtype.

Examples

```
>>> is_timedelta64_ns_dtype(np.dtype('m8[ns]'))
True
>>> is_timedelta64_ns_dtype(np.dtype('m8[ps]'))  # Wrong frequency
False
>>> is_timedelta64_ns_dtype(np.array([1, 2], dtype='m8[ns]'))
True
>>> is_timedelta64_ns_dtype(np.array([1, 2], dtype=np.timedelta64))
False
```

pandas.api.types.is_unsigned_integer_dtype

pandas.api.types.**is_unsigned_integer_dtype**(*arr_or_dtype*)

Check whether the provided array or dtype is of an unsigned integer dtype.

Changed in version 0.24.0: The nullable Integer dtypes (e.g. pandas.UInt64Dtype) are also considered as integer by this function.

Parameters

arr_or_dtype [array-like] The array or dtype to check.

Returns

boolean Whether or not the array or dtype is of an unsigned integer dtype.

Examples

```
>>> is_unsigned_integer_dtype(str)
False
>>> is_unsigned_integer_dtype(int)  # signed
False
>>> is_unsigned_integer_dtype(float)
False
>>> is_unsigned_integer_dtype(np.uint64)
True
>>> is_unsigned_integer_dtype('uint8')
True
>>> is_unsigned_integer_dtype('UInt8')
True
>>> is_unsigned_integer_dtype(pd.UInt8Dtype)
True
>>> is_unsigned_integer_dtype(np.array(['a', 'b']))
False
>>> is_unsigned_integer_dtype(pd.Series([1, 2]))  # signed
False
>>> is_unsigned_integer_dtype(pd.Index([1, 2.]))  # float
False
>>> is_unsigned_integer_dtype(np.array([1, 2], dtype=np.uint32))
True
```

pandas.api.types.is_sparse

pandas.api.types.**is_sparse**(*arr*)

Check whether an array-like is a 1-D pandas sparse array.

Check that the one-dimensional array-like is a pandas sparse array. Returns True if it is a pandas sparse array, not another type of sparse array.

Parameters

arr [array-like] Array-like to check.

Returns

bool Whether or not the array-like is a pandas sparse array.

Examples

Returns *True* if the parameter is a 1-D pandas sparse array.

```
>>> is_sparse(pd.arrays.SparseArray([0, 0, 1, 0]))
True
>>> is_sparse(pd.Series(pd.arrays.SparseArray([0, 0, 1, 0])))
True
```

Returns *False* if the parameter is not sparse.

```
>>> is_sparse(np.array([0, 0, 1, 0]))
False
>>> is_sparse(pd.Series([0, 1, 0, 0]))
False
```

Returns *False* if the parameter is not a pandas sparse array.

```
>>> from scipy.sparse import bsr_matrix
>>> is_sparse(bsr_matrix([0, 1, 0, 0]))
False
```

Returns *False* if the parameter has more than one dimension.

Iterable introspection

api.types.is_dict_like(obj)	Check if the object is dict-like.
api.types.is_file_like(obj)	Check if the object is a file-like object.
api.types.is_list_like	Check if the object is list-like.
api.types.is_named_tuple(obj)	Check if the object is a named tuple.
api.types.is_iterator	Check if the object is an iterator.

pandas.api.types.is_dict_like

pandas.api.types.**is_dict_like**(*obj*)

Check if the object is dict-like.

Parameters

obj [The object to check]

Returns

is_dict_like [bool] Whether *obj* has dict-like properties.

Examples

```
>>> is_dict_like({1: 2})
True
>>> is_dict_like([1, 2, 3])
False
>>> is_dict_like(dict)
False
>>> is_dict_like(dict())
True
```

pandas.api.types.is_file_like

pandas.api.types.**is_file_like**(*obj*)

Check if the object is a file-like object.

For objects to be considered file-like, they must be an iterator AND have either a *read* and/or *write* method as an attribute.

Note: file-like objects must be iterable, but iterable objects need not be file-like.

Parameters

obj [The object to check]

Returns

is_file_like [bool] Whether *obj* has file-like properties.

Examples

```
>>> import io
>>> buffer = io.StringIO("data")
>>> is_file_like(buffer)
True
>>> is_file_like([1, 2, 3])
False
```

pandas.api.types.is_list_like

pandas.api.types.**is_list_like**()

Check if the object is list-like.

Objects that are considered list-like are for example Python lists, tuples, sets, NumPy arrays, and Pandas Series.

Strings and datetime objects, however, are not considered list-like.

Parameters

obj [object] Object to check.

allow_sets [bool, default True] If this parameter is False, sets will not be considered list-like.

New in version 0.24.0.

Returns

bool Whether *obj* has list-like properties.

Examples

```
>>> is_list_like([1, 2, 3])
True
>>> is_list_like({1, 2, 3})
True
>>> is_list_like(datetime(2017, 1, 1))
False
>>> is_list_like("foo")
False
>>> is_list_like(1)
False
>>> is_list_like(np.array([2]))
True
>>> is_list_like(np.array(2))
False
```

pandas.api.types.is_named_tuple

pandas.api.types.**is_named_tuple**(*obj*)

Check if the object is a named tuple.

Parameters

obj [The object to check]

Returns

is_named_tuple [bool] Whether *obj* is a named tuple.

Examples

```
>>> from collections import namedtuple
>>> Point = namedtuple("Point", ["x", "y"])
>>> p = Point(1, 2)
>>>
>>> is_named_tuple(p)
True
>>> is_named_tuple((1, 2))
False
```

pandas.api.types.is_iterator

pandas.api.types.**is_iterator**()

Check if the object is an iterator.

This is intended for generators, not list-like objects.

Parameters

obj [The object to check]

Returns

is_iter [bool] Whether *obj* is an iterator.

Examples

```
>>> is_iterator((x for x in []))
True
>>> is_iterator([1, 2, 3])
False
>>> is_iterator(datetime(2017, 1, 1))
False
>>> is_iterator("foo")
False
>>> is_iterator(1)
False
```

Scalar introspection

api.types.is_bool	**Returns**
api.types.is_categorical(arr)	Check whether an array-like is a Categorical instance.
api.types.is_complex	**Returns**
api.types.is_float	**Returns**
api.types.is_hashable(obj)	Return True if hash(obj) will succeed, False otherwise.
api.types.is_integer	**Returns**
api.types.is_interval	
api.types.is_number(obj)	Check if the object is a number.
api.types.is_re(obj)	Check if the object is a regex pattern instance.
api.types.is_re_compilable(obj)	Check if the object can be compiled into a regex pattern instance.
api.types.is_scalar	**Parameters**

pandas.api.types.is_bool

pandas.api.types.**is_bool**()

Returns

bool

pandas.api.types.is_categorical

pandas.api.types.**is_categorical**(*arr*)

Check whether an array-like is a Categorical instance.

Parameters

arr [array-like] The array-like to check.

Returns

boolean Whether or not the array-like is of a Categorical instance.

Examples

```
>>> is_categorical([1, 2, 3])
False
```

Categoricals, Series Categoricals, and CategoricalIndex will return True.

```
>>> cat = pd.Categorical([1, 2, 3])
>>> is_categorical(cat)
True
>>> is_categorical(pd.Series(cat))
True
>>> is_categorical(pd.CategoricalIndex([1, 2, 3]))
True
```

pandas.api.types.is_complex

pandas.api.types.**is_complex**()

Returns

bool

pandas.api.types.is_float

pandas.api.types.**is_float**()

Returns

bool

pandas.api.types.is_hashable

pandas.api.types.**is_hashable**(*obj*)

Return True if hash(obj) will succeed, False otherwise.

Some types will pass a test against collections.abc.Hashable but fail when they are actually hashed with hash().

Distinguish between these and other types by trying the call to hash() and seeing if they raise TypeError.

Returns

bool

Examples

```
>>> import collections
>>> a = ([],)
>>> isinstance(a, collections.abc.Hashable)
True
>>> is_hashable(a)
False
```

pandas.api.types.is_integer

pandas.api.types.**is_integer**()

Returns

bool

pandas.api.types.is_interval

pandas.api.types.**is_interval**()

pandas.api.types.is_number

pandas.api.types.**is_number**(*obj*)

Check if the object is a number.

Returns True when the object is a number, and False if is not.

Parameters

obj [any type] The object to check if is a number.

Returns

is_number [bool] Whether *obj* is a number or not.

See also:

api.types.is_integer Checks a subgroup of numbers.

Examples

```
>>> pd.api.types.is_number(1)
True
>>> pd.api.types.is_number(7.15)
True
```

Booleans are valid because they are int subclass.

```
>>> pd.api.types.is_number(False)
True
```

```
>>> pd.api.types.is_number("foo")
False
>>> pd.api.types.is_number("5")
False
```

pandas.api.types.is_re

pandas.api.types.**is_re**(*obj*)

Check if the object is a regex pattern instance.

Parameters

obj [The object to check]

Returns

is_regex [bool] Whether *obj* is a regex pattern.

Examples

```
>>> is_re(re.compile(".*"))
True
>>> is_re("foo")
False
```

pandas.api.types.is_re_compilable

pandas.api.types.**is_re_compilable**(*obj*)

Check if the object can be compiled into a regex pattern instance.

Parameters

obj [The object to check]

Returns

is_regex_compilable [bool] Whether *obj* can be compiled as a regex pattern.

Examples

```
>>> is_re_compilable(".*")
True
>>> is_re_compilable(1)
False
```

pandas.api.types.is_scalar

pandas.api.types.**is_scalar**()

Parameters

val [object] This includes:

- numpy array scalar (e.g. np.int64)
- Python builtin numerics
- Python builtin byte arrays and strings
- None
- datetime.datetime
- datetime.timedelta

- Period
- decimal.Decimal
- Interval
- DateOffset
- Fraction
- Number.

Returns

bool Return True if given object is scalar.

Examples

```
>>> dt = datetime.datetime(2018, 10, 3)
>>> pd.api.types.is_scalar(dt)
True
```

```
>>> pd.api.types.is_scalar([2, 3])
False
```

```
>>> pd.api.types.is_scalar({0: 1, 2: 3})
False
```

```
>>> pd.api.types.is_scalar((0, 2))
False
```

pandas supports PEP 3141 numbers:

```
>>> from fractions import Fraction
>>> pd.api.types.is_scalar(Fraction(3, 5))
True
```

3.15.5 Bug report function

show_versions([as_json])	Provide useful information, important for bug reports.

pandas.show_versions

pandas.**show_versions**(*as_json=False*)

Provide useful information, important for bug reports.

It comprises info about hosting operation system, pandas version, and versions of other installed relative packages.

Parameters

as_json [str or bool, default False]

- If False, outputs info in a human readable form to the console.
- If str, it will be considered as a path to a file. Info will be written to that file in JSON format.

- If True, outputs info in JSON format to the console.

3.16 Extensions

These are primarily intended for library authors looking to extend pandas objects.

api.extensions.register_extension_dtype(cls)	Register an ExtensionType with pandas as class decorator.
api.extensions.register_dataframe_accessor(name)	Register a custom accessor on DataFrame objects.
api.extensions.register_series_accessor(name)	Register a custom accessor on Series objects.
api.extensions.register_index_accessor(name)	Register a custom accessor on Index objects.
api.extensions.ExtensionDtype()	A custom data type, to be paired with an ExtensionArray.

3.16.1 pandas.api.extensions.register_extension_dtype

pandas.api.extensions.**register_extension_dtype**(*cls*)

Register an ExtensionType with pandas as class decorator.

New in version 0.24.0.

This enables operations like `.astype(name)` for the name of the ExtensionDtype.

Returns

callable A class decorator.

Examples

```
>>> from pandas.api.extensions import register_extension_dtype
>>> from pandas.api.extensions import ExtensionDtype
>>> @register_extension_dtype
... class MyExtensionDtype(ExtensionDtype):
...     name = "myextension"
```

3.16.2 pandas.api.extensions.register_dataframe_accessor

pandas.api.extensions.**register_dataframe_accessor**(*name*)

Register a custom accessor on DataFrame objects.

Parameters

name [str] Name under which the accessor should be registered. A warning is issued if this name conflicts with a preexisting attribute.

Returns

callable A class decorator.

See also:

register_dataframe_accessor Register a custom accessor on DataFrame objects.
register_series_accessor Register a custom accessor on Series objects.
register_index_accessor Register a custom accessor on Index objects.

Notes

When accessed, your accessor will be initialized with the pandas object the user is interacting with. So the signature must be

```
def __init__(self, pandas_object):  # noqa: E999
    ...
```

For consistency with pandas methods, you should raise an `AttributeError` if the data passed to your accessor has an incorrect dtype.

```
>>> pd.Series(['a', 'b']).dt
Traceback (most recent call last):
...
AttributeError: Can only use .dt accessor with datetimelike values
```

Examples

In your library code:

```
import pandas as pd

@pd.api.extensions.register_dataframe_accessor("geo")
class GeoAccessor:
    def __init__(self, pandas_obj):
        self._obj = pandas_obj

    @property
    def center(self):
        # return the geographic center point of this DataFrame
        lat = self._obj.latitude
        lon = self._obj.longitude
        return (float(lon.mean()), float(lat.mean()))

    def plot(self):
        # plot this array's data on a map, e.g., using Cartopy
        pass
```

Back in an interactive IPython session:

```
In [1]: ds = pd.DataFrame({"longitude": np.linspace(0, 10),
   ...:                    "latitude": np.linspace(0, 20)})
In [2]: ds.geo.center
Out[2]: (5.0, 10.0)
In [3]: ds.geo.plot()  # plots data on a map
```

3.16.3 pandas.api.extensions.register_series_accessor

pandas.api.extensions.**register_series_accessor**(*name*)

Register a custom accessor on Series objects.

Parameters

name [str] Name under which the accessor should be registered. A warning is issued if this name conflicts with a preexisting attribute.

Returns

callable A class decorator.

See also:

register_dataframe_accessor Register a custom accessor on DataFrame objects.
register_series_accessor Register a custom accessor on Series objects.
register_index_accessor Register a custom accessor on Index objects.

Notes

When accessed, your accessor will be initialized with the pandas object the user is interacting with. So the signature must be

```
def __init__(self, pandas_object):  # noqa: E999
    ...
```

For consistency with pandas methods, you should raise an `AttributeError` if the data passed to your accessor has an incorrect dtype.

```
>>> pd.Series(['a', 'b']).dt
Traceback (most recent call last):
...
AttributeError: Can only use .dt accessor with datetimelike values
```

Examples

In your library code:

```
import pandas as pd

@pd.api.extensions.register_dataframe_accessor("geo")
class GeoAccessor:
    def __init__(self, pandas_obj):
        self._obj = pandas_obj

    @property
    def center(self):
        # return the geographic center point of this DataFrame
        lat = self._obj.latitude
        lon = self._obj.longitude
        return (float(lon.mean()), float(lat.mean()))

    def plot(self):
        # plot this array's data on a map, e.g., using Cartopy
        pass
```

Back in an interactive IPython session:

```
In [1]: ds = pd.DataFrame({"longitude": np.linspace(0, 10),
   ...:                    "latitude": np.linspace(0, 20)})
In [2]: ds.geo.center
Out[2]: (5.0, 10.0)
In [3]: ds.geo.plot()  # plots data on a map
```

3.16.4 pandas.api.extensions.register_index_accessor

pandas.api.extensions.**register_index_accessor**(*name*)

Register a custom accessor on Index objects.

Parameters

name [str] Name under which the accessor should be registered. A warning is issued if this name conflicts with a preexisting attribute.

Returns

callable A class decorator.

See also:

register_dataframe_accessor Register a custom accessor on DataFrame objects.
register_series_accessor Register a custom accessor on Series objects.
register_index_accessor Register a custom accessor on Index objects.

Notes

When accessed, your accessor will be initialized with the pandas object the user is interacting with. So the signature must be

```
def __init__(self, pandas_object):  # noqa: E999
    ...
```

For consistency with pandas methods, you should raise an `AttributeError` if the data passed to your accessor has an incorrect dtype.

```
>>> pd.Series(['a', 'b']).dt
Traceback (most recent call last):
...
AttributeError: Can only use .dt accessor with datetimelike values
```

Examples

In your library code:

```
import pandas as pd

@pd.api.extensions.register_dataframe_accessor("geo")
class GeoAccessor:
    def __init__(self, pandas_obj):
        self._obj = pandas_obj

    @property
    def center(self):
        # return the geographic center point of this DataFrame
```

(continues on next page)

(continued from previous page)

```
        lat = self._obj.latitude
        lon = self._obj.longitude
        return (float(lon.mean()), float(lat.mean()))

    def plot(self):
        # plot this array's data on a map, e.g., using Cartopy
        pass
```

Back in an interactive IPython session:

```
In [1]: ds = pd.DataFrame({"longitude": np.linspace(0, 10),
   ...:                    "latitude": np.linspace(0, 20)})
In [2]: ds.geo.center
Out[2]: (5.0, 10.0)
In [3]: ds.geo.plot()  # plots data on a map
```

3.16.5 pandas.api.extensions.ExtensionDtype

class pandas.api.extensions.**ExtensionDtype**

A custom data type, to be paired with an ExtensionArray.

New in version 0.23.0.

See also:

extensions.register_extension_dtype
extensions.ExtensionArray

Notes

The interface includes the following abstract methods that must be implemented by subclasses:

- type
- name

The following attributes and methods influence the behavior of the dtype in pandas operations

- _is_numeric
- _is_boolean
- _get_common_dtype

Optionally one can override construct_array_type for construction with the name of this dtype via the Registry. See `extensions.register_extension_dtype()`.

- construct_array_type

The *na_value* class attribute can be used to set the default NA value for this type. `numpy.nan` is used by default.

ExtensionDtypes are required to be hashable. The base class provides a default implementation, which relies on the `_metadata` class attribute. `_metadata` should be a tuple containing the strings that define your data type. For example, with `PeriodDtype` that's the `freq` attribute.

If you have a parametrized dtype you should set the ``_metadata`` class property.

Ideally, the attributes in `_metadata` will match the parameters to your `ExtensionDtype.__init__` (if any). If any of the attributes in `_metadata` don't implement the standard `__eq__` or `__hash__`, the default implementations here will not work.

Changed in version 0.24.0: Added `_metadata`, `__hash__`, and changed the default definition of `__eq__`.

For interaction with Apache Arrow (pyarrow), a `__from_arrow__` method can be implemented: this method receives a pyarrow Array or ChunkedArray as only argument and is expected to return the appropriate pandas ExtensionArray for this dtype and the passed values:

```
class ExtensionDtype:

    def __from_arrow__(
        self, array: Union[pyarrow.Array, pyarrow.ChunkedArray]
    ) -> ExtensionArray:
        ...
```

This class does not inherit from 'abc.ABCMeta' for performance reasons. Methods and properties required by the interface raise `pandas.errors.AbstractMethodError` and no `register` method is provided for registering virtual subclasses.

Attributes

kind	A character code (one of 'biufcmMOSUV'), default 'O'
na_value	Default NA value to use for this type.
name	A string identifying the data type.
names	Ordered list of field names, or None if there are no fields.
type	The scalar type for the array, e.g.

pandas.api.extensions.ExtensionDtype.kind

property ExtensionDtype.**kind**

A character code (one of 'biufcmMOSUV'), default 'O'

This should match the NumPy dtype used when the array is converted to an ndarray, which is probably 'O' for object if the extension type cannot be represented as a built-in NumPy type.

See also:

numpy.dtype.kind

pandas.api.extensions.ExtensionDtype.na_value

property ExtensionDtype.**na_value**

Default NA value to use for this type.

This is used in e.g. ExtensionArray.take. This should be the user-facing "boxed" version of the NA value, not the physical NA value for storage. e.g. for JSONArray, this is an empty dictionary.

pandas.api.extensions.ExtensionDtype.name

property ExtensionDtype.**name**
A string identifying the data type.

Will be used for display in, e.g. `Series.dtype`

pandas.api.extensions.ExtensionDtype.names

property ExtensionDtype.**names**
Ordered list of field names, or None if there are no fields.

This is for compatibility with NumPy arrays, and may be removed in the future.

pandas.api.extensions.ExtensionDtype.type

property ExtensionDtype.**type**
The scalar type for the array, e.g. `int`

It's expected `ExtensionArray[item]` returns an instance of `ExtensionDtype.type` for scalar `item`, assuming that value is valid (not NA). NA values do not need to be instances of *type*.

Methods

construct_array_type()	Return the array type associated with this dtype.
construct_from_string(string)	Construct this type from a string.
is_dtype(dtype)	Check if we match 'dtype'.

pandas.api.extensions.ExtensionDtype.construct_array_type

classmethod ExtensionDtype.**construct_array_type**()
Return the array type associated with this dtype.

Returns

type

pandas.api.extensions.ExtensionDtype.construct_from_string

classmethod ExtensionDtype.**construct_from_string**(*string*)
Construct this type from a string.

This is useful mainly for data types that accept parameters. For example, a period dtype accepts a frequency parameter that can be set as `period[H]` (where H means hourly frequency).

By default, in the abstract class, just the name of the type is expected. But subclasses can overwrite this method to accept parameters.

Parameters

string [str] The name of the type, for example `category`.

Returns

ExtensionDtype Instance of the dtype.

Raises

TypeError If a class cannot be constructed from this 'string'.

Examples

For extension dtypes with arguments the following may be an adequate implementation.

```
>>> @classmethod
... def construct_from_string(cls, string):
...     pattern = re.compile(r"^my_type\[(?P<arg_name>.+)\]$")
...     match = pattern.match(string)
...     if match:
...         return cls(**match.groupdict())
...     else:
...         raise TypeError(
...             f"Cannot construct a '{cls.__name__}' from '{string}'"
...         )
```

pandas.api.extensions.ExtensionDtype.is_dtype

classmethod ExtensionDtype.**is_dtype**(*dtype*)

Check if we match 'dtype'.

Parameters

dtype [object] The object to check.

Returns

bool

Notes

The default implementation is True if

1. `cls.construct_from_string(dtype)` is an instance of `cls`.
2. `dtype` is an object and is an instance of `cls`
3. `dtype` has a `dtype` attribute, and any of the above conditions is true for `dtype.dtype`.

api.extensions.ExtensionArray()	Abstract base class for custom 1-D array types.
arrays.PandasArray(values[, copy])	A pandas ExtensionArray for NumPy data.

3.16.6 pandas.api.extensions.ExtensionArray

class pandas.api.extensions.**ExtensionArray**

Abstract base class for custom 1-D array types.

pandas will recognize instances of this class as proper arrays with a custom type and will not attempt to coerce them to objects. They may be stored directly inside a `DataFrame` or `Series`.

New in version 0.23.0.

Notes

The interface includes the following abstract methods that must be implemented by subclasses:

- _from_sequence
- _from_factorized
- __getitem__
- __len__
- __eq__
- dtype
- nbytes
- isna
- take
- copy
- _concat_same_type

A default repr displaying the type, (truncated) data, length, and dtype is provided. It can be customized or replaced by by overriding:

- __repr__ : A default repr for the ExtensionArray.
- _formatter : Print scalars inside a Series or DataFrame.

Some methods require casting the ExtensionArray to an ndarray of Python objects with `self.astype(object)`, which may be expensive. When performance is a concern, we highly recommend overriding the following methods:

- fillna
- dropna
- unique
- factorize / _values_for_factorize
- argsort / _values_for_argsort
- searchsorted

The remaining methods implemented on this class should be performant, as they only compose abstract methods. Still, a more efficient implementation may be available, and these methods can be overridden.

One can implement methods to handle array reductions.

- _reduce

One can implement methods to handle parsing from strings that will be used in methods such as `pandas.io.parsers.read_csv`.

- _from_sequence_of_strings

This class does not inherit from 'abc.ABCMeta' for performance reasons. Methods and properties required by the interface raise `pandas.errors.AbstractMethodError` and no `register` method is provided for registering virtual subclasses.

ExtensionArrays are limited to 1 dimension.

They may be backed by none, one, or many NumPy arrays. For example, `pandas.Categorical` is an extension array backed by two arrays, one for codes and one for categories. An array of IPv6 address may be backed by a NumPy structured array with two fields, one for the lower 64 bits and one for the upper 64 bits. Or they may be backed by some other storage type, like Python lists. Pandas makes no assumptions on how the data are stored, just that it can be converted to a NumPy array. The ExtensionArray interface does not impose any rules on how this data is stored. However, currently, the backing data cannot be stored in attributes called `.values` or `._values` to ensure full compatibility with pandas internals. But other names as `.data`, `._data`, `._items`, ... can be freely used.

If implementing NumPy's `__array_ufunc__` interface, pandas expects that

1. You defer by returning `NotImplemented` when any Series are present in *inputs*. Pandas will extract the arrays and call the ufunc again.
2. You define a `_HANDLED_TYPES` tuple as an attribute on the class. Pandas inspect this to determine whether the ufunc is valid for the types present.

See *NumPy universal functions* for more.

By default, ExtensionArrays are not hashable. Immutable subclasses may override this behavior.

Attributes

dtype	An instance of 'ExtensionDtype'.
nbytes	The number of bytes needed to store this object in memory.
ndim	Extension Arrays are only allowed to be 1-dimensional.
shape	Return a tuple of the array dimensions.

pandas.api.extensions.ExtensionArray.dtype

property ExtensionArray.**dtype**
An instance of 'ExtensionDtype'.

pandas.api.extensions.ExtensionArray.nbytes

property ExtensionArray.**nbytes**
The number of bytes needed to store this object in memory.

pandas.api.extensions.ExtensionArray.ndim

property ExtensionArray.**ndim**
Extension Arrays are only allowed to be 1-dimensional.

pandas.api.extensions.ExtensionArray.shape

property ExtensionArray.**shape**
Return a tuple of the array dimensions.

Methods

argsort([ascending, kind])	Return the indices that would sort this array.
astype(dtype[, copy])	Cast to a NumPy array with 'dtype'.
copy()	Return a copy of the array.
dropna()	Return ExtensionArray without NA values.
factorize([na_sentinel])	Encode the extension array as an enumerated type.
fillna([value, method, limit])	Fill NA/NaN values using the specified method.
equals(other)	Return if another array is equivalent to this array.
isna()	A 1-D array indicating if each value is missing.
ravel([order])	Return a flattened view on this array.
repeat(repeats[, axis])	Repeat elements of a ExtensionArray.
searchsorted(value[, side, sorter])	Find indices where elements should be inserted to maintain order.
shift([periods, fill_value])	Shift values by desired number.

continues on next page

Table 401 – continued from previous page

take(indices[, allow_fill, fill_value])	Take elements from an array.
unique()	Compute the ExtensionArray of unique values.
view([dtype])	Return a view on the array.
_concat_same_type(to_concat)	Concatenate multiple array of this dtype.
_formatter([boxed])	Formatting function for scalar values.
_from_factorized(values, original)	Reconstruct an ExtensionArray after factorization.
_from_sequence(scalars[, dtype, copy])	Construct a new ExtensionArray from a sequence of scalars.
_from_sequence_of_strings(strings[, dtype, copy])	Construct a new ExtensionArray from a sequence of strings.
_reduce(name[, skipna])	Return a scalar result of performing the reduction operation.
_values_for_argsort()	Return values for sorting.
_values_for_factorize()	Return an array and missing value suitable for factorization.

pandas.api.extensions.ExtensionArray.argsort

ExtensionArray.**argsort**(*ascending=True*, *kind='quicksort'*, **args*, ***kwargs*)

Return the indices that would sort this array.

Parameters

ascending [bool, default True] Whether the indices should result in an ascending or descending sort.

kind [{'quicksort', 'mergesort', 'heapsort'}, optional] Sorting algorithm.

***args, **kwargs:** Passed through to `numpy.argsort()`.

Returns

ndarray Array of indices that sort `self`. If NaN values are contained, NaN values are placed at the end.

See also:

numpy.argsort Sorting implementation used internally.

pandas.api.extensions.ExtensionArray.astype

ExtensionArray.**astype**(*dtype*, *copy=True*)

Cast to a NumPy array with 'dtype'.

Parameters

dtype [str or dtype] Typecode or data-type to which the array is cast.

copy [bool, default True] Whether to copy the data, even if not necessary. If False, a copy is made only if the old dtype does not match the new dtype.

Returns

array [ndarray] NumPy ndarray with 'dtype' for its dtype.

pandas.api.extensions.ExtensionArray.copy

ExtensionArray.**copy**()
Return a copy of the array.

Returns

ExtensionArray

pandas.api.extensions.ExtensionArray.dropna

ExtensionArray.**dropna**()
Return ExtensionArray without NA values.

Returns

valid [ExtensionArray]

pandas.api.extensions.ExtensionArray.factorize

ExtensionArray.**factorize**(*na_sentinel=- 1*)
Encode the extension array as an enumerated type.

Parameters

na_sentinel [int, default -1] Value to use in the *codes* array to indicate missing values.

Returns

codes [ndarray] An integer NumPy array that's an indexer into the original ExtensionArray.

uniques [ExtensionArray] An ExtensionArray containing the unique values of *self*.

Note: uniques will *not* contain an entry for the NA value of the ExtensionArray if there are any missing values present in *self*.

See also:

factorize Top-level factorize method that dispatches here.

Notes

pandas.factorize() offers a *sort* keyword as well.

pandas.api.extensions.ExtensionArray.fillna

ExtensionArray.**fillna**(*value=None*, *method=None*, *limit=None*)

Fill NA/NaN values using the specified method.

Parameters

value [scalar, array-like] If a scalar value is passed it is used to fill all missing values. Alternatively, an array-like 'value' can be given. It's expected that the array-like have the same length as 'self'.

method [{'backfill', 'bfill', 'pad', 'ffill', None}, default None] Method to use for filling holes in reindexed Series pad / ffill: propagate last valid observation forward to next valid backfill / bfill: use NEXT valid observation to fill gap.

limit [int, default None] If method is specified, this is the maximum number of consecutive NaN values to forward/backward fill. In other words, if there is a gap with more than this number of consecutive NaNs, it will only be partially filled. If method is not specified, this is the maximum number of entries along the entire axis where NaNs will be filled.

Returns

ExtensionArray With NA/NaN filled.

pandas.api.extensions.ExtensionArray.equals

ExtensionArray.**equals**(*other*)

Return if another array is equivalent to this array.

Equivalent means that both arrays have the same shape and dtype, and all values compare equal. Missing values in the same location are considered equal (in contrast with normal equality).

Parameters

other [ExtensionArray] Array to compare to this Array.

Returns

boolean Whether the arrays are equivalent.

pandas.api.extensions.ExtensionArray.isna

ExtensionArray.**isna**()

A 1-D array indicating if each value is missing.

Returns

na_values [Union[np.ndarray, ExtensionArray]] In most cases, this should return a NumPy ndarray. For exceptional cases like `SparseArray`, where returning an ndarray would be expensive, an ExtensionArray may be returned.

Notes

If returning an ExtensionArray, then

- `na_values._is_boolean` should be True
- *na_values* should implement *ExtensionArray._reduce()*
- `na_values.any` and `na_values.all` should be implemented

pandas.api.extensions.ExtensionArray.ravel

`ExtensionArray.`**`ravel`**(*order='C'*)

Return a flattened view on this array.

Parameters

order [{None, 'C', 'F', 'A', 'K'}, default 'C']

Returns

ExtensionArray

Notes

- Because ExtensionArrays are 1D-only, this is a no-op.
- The "order" argument is ignored, is for compatibility with NumPy.

pandas.api.extensions.ExtensionArray.repeat

`ExtensionArray.`**`repeat`**(*repeats*, *axis=None*)

Repeat elements of a ExtensionArray.

Returns a new ExtensionArray where each element of the current ExtensionArray is repeated consecutively a given number of times.

Parameters

repeats [int or array of ints] The number of repetitions for each element. This should be a non-negative integer. Repeating 0 times will return an empty ExtensionArray.

axis [None] Must be `None`. Has no effect but is accepted for compatibility with numpy.

Returns

repeated_array [ExtensionArray] Newly created ExtensionArray with repeated elements.

See also:

`Series.repeat` Equivalent function for Series.

`Index.repeat` Equivalent function for Index.

`numpy.repeat` Similar method for `numpy.ndarray`.

`ExtensionArray.take` Take arbitrary positions.

Examples

```
>>> cat = pd.Categorical(['a', 'b', 'c'])
>>> cat
['a', 'b', 'c']
Categories (3, object): ['a', 'b', 'c']
>>> cat.repeat(2)
['a', 'a', 'b', 'b', 'c', 'c']
Categories (3, object): ['a', 'b', 'c']
>>> cat.repeat([1, 2, 3])
['a', 'b', 'b', 'c', 'c', 'c']
Categories (3, object): ['a', 'b', 'c']
```

pandas.api.extensions.ExtensionArray.searchsorted

ExtensionArray.**searchsorted**(*value*, *side='left'*, *sorter=None*)

Find indices where elements should be inserted to maintain order.

New in version 0.24.0.

Find the indices into a sorted array *self* (a) such that, if the corresponding elements in *value* were inserted before the indices, the order of *self* would be preserved.

Assuming that *self* is sorted:

side	returned index *i* satisfies
left	`self[i-1] < value <= self[i]`
right	`self[i-1] <= value < self[i]`

Parameters

value [array_like] Values to insert into *self*.

side [{'left', 'right'}, optional] If 'left', the index of the first suitable location found is given. If 'right', return the last such index. If there is no suitable index, return either 0 or N (where N is the length of *self*).

sorter [1-D array_like, optional] Optional array of integer indices that sort array a into ascending order. They are typically the result of argsort.

Returns

array of ints Array of insertion points with the same shape as *value*.

See also:

`numpy.searchsorted` Similar method from NumPy.

pandas.api.extensions.ExtensionArray.shift

ExtensionArray.**shift**(*periods=1*, *fill_value=None*)

Shift values by desired number.

Newly introduced missing values are filled with `self.dtype.na_value`.

New in version 0.24.0.

Parameters

periods [int, default 1] The number of periods to shift. Negative values are allowed for shifting backwards.

fill_value [object, optional] The scalar value to use for newly introduced missing values. The default is `self.dtype.na_value`.

New in version 0.24.0.

Returns

ExtensionArray Shifted.

Notes

If `self` is empty or `periods` is 0, a copy of `self` is returned.

If `periods > len(self)`, then an array of size len(self) is returned, with all values filled with `self.dtype.na_value`.

pandas.api.extensions.ExtensionArray.take

ExtensionArray.**take**(*indices*, *allow_fill=False*, *fill_value=None*)

Take elements from an array.

Parameters

indices [sequence of int] Indices to be taken.

allow_fill [bool, default False] How to handle negative values in *indices*.

- False: negative values in *indices* indicate positional indices from the right (the default). This is similar to `numpy.take()`.
- True: negative values in *indices* indicate missing values. These values are set to *fill_value*. Any other other negative values raise a `ValueError`.

fill_value [any, optional] Fill value to use for NA-indices when *allow_fill* is True. This may be `None`, in which case the default NA value for the type, `self.dtype.na_value`, is used.

For many ExtensionArrays, there will be two representations of *fill_value*: a user-facing "boxed" scalar, and a low-level physical NA value. *fill_value* should be the user-facing version, and the implementation should handle translating that to the physical version for processing the take if necessary.

Returns

ExtensionArray

Raises

IndexError When the indices are out of bounds for the array.

ValueError When *indices* contains negative values other than `-1` and *allow_fill* is True.

See also:

`numpy.take`

`api.extensions.take`

Notes

ExtensionArray.take is called by `Series.__getitem__`, `.loc`, `iloc`, when *indices* is a sequence of values. Additionally, it's called by `Series.reindex()`, or any other method that causes realignment, with a *fill_value*.

Examples

Here's an example implementation, which relies on casting the extension array to object dtype. This uses the helper method `pandas.api.extensions.take()`.

```
def take(self, indices, allow_fill=False, fill_value=None):
    from pandas.core.algorithms import take

    # If the ExtensionArray is backed by an ndarray, then
    # just pass that here instead of coercing to object.
    data = self.astype(object)

    if allow_fill and fill_value is None:
        fill_value = self.dtype.na_value

    # fill value should always be translated from the scalar
    # type for the array, to the physical storage type for
    # the data, before passing to take.

    result = take(data, indices, fill_value=fill_value,
                  allow_fill=allow_fill)
    return self._from_sequence(result, dtype=self.dtype)
```

pandas.api.extensions.ExtensionArray.unique

ExtensionArray.**unique**()

Compute the ExtensionArray of unique values.

Returns

uniques [ExtensionArray]

pandas.api.extensions.ExtensionArray.view

ExtensionArray.**view**(*dtype=None*)
Return a view on the array.

Parameters

dtype [str, np.dtype, or ExtensionDtype, optional] Default None.

Returns

ExtensionArray or np.ndarray A view on the *ExtensionArray*'s data.

pandas.api.extensions.ExtensionArray._concat_same_type

classmethod ExtensionArray.**_concat_same_type**(*to_concat*)
Concatenate multiple array of this dtype.

Parameters

to_concat [sequence of this type]

Returns

ExtensionArray

pandas.api.extensions.ExtensionArray._formatter

ExtensionArray.**_formatter**(*boxed=False*)
Formatting function for scalar values.

This is used in the default '__repr__'. The returned formatting function receives instances of your scalar type.

Parameters

boxed [bool, default False] An indicated for whether or not your array is being printed within a Series, DataFrame, or Index (True), or just by itself (False). This may be useful if you want scalar values to appear differently within a Series versus on its own (e.g. quoted or not).

Returns

Callable[[Any], str] A callable that gets instances of the scalar type and returns a string. By default, `repr()` is used when `boxed=False` and `str()` is used when `boxed=True`.

pandas.api.extensions.ExtensionArray._from_factorized

classmethod ExtensionArray.**_from_factorized**(*values*, *original*)
Reconstruct an ExtensionArray after factorization.

Parameters

values [ndarray] An integer ndarray with the factorized values.

original [ExtensionArray] The original ExtensionArray that factorize was called on.

See also:

factorize

ExtensionArray.factorize

pandas.api.extensions.ExtensionArray._from_sequence

classmethod ExtensionArray.**_from_sequence**(*scalars*, *dtype=None*, *copy=False*)
Construct a new ExtensionArray from a sequence of scalars.

Parameters

scalars [Sequence] Each element will be an instance of the scalar type for this array, `cls.dtype.type` or be converted into this type in this method.

dtype [dtype, optional] Construct for this particular dtype. This should be a Dtype compatible with the ExtensionArray.

copy [bool, default False] If True, copy the underlying data.

Returns

ExtensionArray

pandas.api.extensions.ExtensionArray._from_sequence_of_strings

classmethod ExtensionArray.**_from_sequence_of_strings**(*strings*, *dtype=None*, *copy=False*)
Construct a new ExtensionArray from a sequence of strings.

New in version 0.24.0.

Parameters

strings [Sequence] Each element will be an instance of the scalar type for this array, `cls.dtype.type`.

dtype [dtype, optional] Construct for this particular dtype. This should be a Dtype compatible with the ExtensionArray.

copy [bool, default False] If True, copy the underlying data.

Returns

ExtensionArray

pandas.api.extensions.ExtensionArray._reduce

ExtensionArray.**_reduce**(*name*, *skipna=True*, ***kwargs*)
Return a scalar result of performing the reduction operation.

Parameters

name [str] Name of the function, supported values are: { any, all, min, max, sum, mean, median, prod, std, var, sem, kurt, skew }.

skipna [bool, default True] If True, skip NaN values.

****kwargs** Additional keyword arguments passed to the reduction function. Currently, *ddof* is the only supported kwarg.

Returns

scalar

Raises

TypeError [subclass does not define reductions]

pandas.api.extensions.ExtensionArray._values_for_argsort

ExtensionArray.**_values_for_argsort**()
Return values for sorting.

Returns

ndarray The transformed values should maintain the ordering between values within the array.

See also:

ExtensionArray.argsort

pandas.api.extensions.ExtensionArray._values_for_factorize

ExtensionArray.**_values_for_factorize**()
Return an array and missing value suitable for factorization.

Returns

values [ndarray] An array suitable for factorization. This should maintain order and be a supported dtype (Float64, Int64, UInt64, String, Object). By default, the extension array is cast to object dtype.

na_value [object] The value in *values* to consider missing. This will be treated as NA in the factorization routines, so it will be coded as *na_sentinel* and not included in *uniques*. By default, `np.nan` is used.

Notes

The values returned by this method are also used in *pandas.util.hash_pandas_object()*.

3.16.7 pandas.arrays.PandasArray

class pandas.arrays.**PandasArray**(*values*, *copy=False*)
A pandas ExtensionArray for NumPy data.

New in version 0.24.0.

This is mostly for internal compatibility, and is not especially useful on its own.

Parameters

values [ndarray] The NumPy ndarray to wrap. Must be 1-dimensional.

copy [bool, default False] Whether to copy *values*.

Attributes

None	

Methods

None	

Additionally, we have some utility methods for ensuring your object behaves correctly.

api.indexers.check_array_indexer(array, indexer)	Check if *indexer* is a valid array indexer for *array*.

3.16.8 pandas.api.indexers.check_array_indexer

pandas.api.indexers.**check_array_indexer**(*array*, *indexer*)

Check if *indexer* is a valid array indexer for *array*.

For a boolean mask, *array* and *indexer* are checked to have the same length. The dtype is validated, and if it is an integer or boolean ExtensionArray, it is checked if there are missing values present, and it is converted to the appropriate numpy array. Other dtypes will raise an error.

Non-array indexers (integer, slice, Ellipsis, tuples, ..) are passed through as is.

New in version 1.0.0.

Parameters

array [array-like] The array that is being indexed (only used for the length).

indexer [array-like or list-like] The array-like that's used to index. List-like input that is not yet a numpy array or an ExtensionArray is converted to one. Other input types are passed through as is.

Returns

numpy.ndarray The validated indexer as a numpy array that can be used to index.

Raises

IndexError When the lengths don't match.

ValueError When *indexer* cannot be converted to a numpy ndarray to index (e.g. presence of missing values).

See also:

api.types.is_bool_dtype Check if *key* is of boolean dtype.

Examples

When checking a boolean mask, a boolean ndarray is returned when the arguments are all valid.

```
>>> mask = pd.array([True, False])
>>> arr = pd.array([1, 2])
>>> pd.api.indexers.check_array_indexer(arr, mask)
array([ True, False])
```

An IndexError is raised when the lengths don't match.

```
>>> mask = pd.array([True, False, True])
>>> pd.api.indexers.check_array_indexer(arr, mask)
Traceback (most recent call last):
...
IndexError: Boolean index has wrong length: 3 instead of 2.
```

NA values in a boolean array are treated as False.

```
>>> mask = pd.array([True, pd.NA])
>>> pd.api.indexers.check_array_indexer(arr, mask)
array([ True, False])
```

A numpy boolean mask will get passed through (if the length is correct):

```
>>> mask = np.array([True, False])
>>> pd.api.indexers.check_array_indexer(arr, mask)
array([ True, False])
```

Similarly for integer indexers, an integer ndarray is returned when it is a valid indexer, otherwise an error is (for integer indexers, a matching length is not required):

```
>>> indexer = pd.array([0, 2], dtype="Int64")
>>> arr = pd.array([1, 2, 3])
>>> pd.api.indexers.check_array_indexer(arr, indexer)
array([0, 2])
```

```
>>> indexer = pd.array([0, pd.NA], dtype="Int64")
>>> pd.api.indexers.check_array_indexer(arr, indexer)
Traceback (most recent call last):
...
ValueError: Cannot index with an integer indexer containing NA values
```

For non-integer/boolean dtypes, an appropriate error is raised:

```
>>> indexer = np.array([0., 2.], dtype="float64")
>>> pd.api.indexers.check_array_indexer(arr, indexer)
Traceback (most recent call last):
...
IndexError: arrays used as indices must be of integer or boolean type
```

The sentinel `pandas.api.extensions.no_default` is used as the default value in some methods. Use an `is` comparison to check if the user provides a non-default value.

CHAPTER

FOUR

DEVELOPMENT

4.1 Contributing to pandas

Table of contents:

4.1.1 Where to start?

All contributions, bug reports, bug fixes, documentation improvements, enhancements, and ideas are welcome.

If you are brand new to pandas or open-source development, we recommend going through the GitHub "issues" tab to find issues that interest you. There are a number of issues listed under Docs and good first issue where you could start out. Once you've found an interesting issue, you can return here to get your development environment setup.

When you start working on an issue, it's a good idea to assign the issue to yourself, so nobody else duplicates the work on it. GitHub restricts assigning issues to maintainers of the project only. In most projects, and until recently in pandas, contributors added a comment letting others know they are working on an issue. While this is ok, you need to check each issue individually, and it's not possible to find the unassigned ones.

For this reason, we implemented a workaround consisting of adding a comment with the exact text *take*. When you do

it, a GitHub action will automatically assign you the issue (this will take seconds, and may require refreshing the page to see it). By doing this, it's possible to filter the list of issues and find only the unassigned ones.

So, a good way to find an issue to start contributing to pandas is to check the list of unassigned good first issues and assign yourself one you like by writing a comment with the exact text *take*.

If for whatever reason you are not able to continue working with the issue, please try to unassign it, so other people know it's available again. You can check the list of assigned issues, since people may not be working in them anymore. If you want to work on one that is assigned, feel free to kindly ask the current assignee if you can take it (please allow at least a week of inactivity before considering work in the issue discontinued).

Feel free to ask questions on the mailing list or on Gitter.

4.1.2 Bug reports and enhancement requests

Bug reports are an important part of making pandas more stable. Having a complete bug report will allow others to reproduce the bug and provide insight into fixing. See this stackoverflow article and this blogpost for tips on writing a good bug report.

Trying the bug-producing code out on the *master* branch is often a worthwhile exercise to confirm the bug still exists. It is also worth searching existing bug reports and pull requests to see if the issue has already been reported and/or fixed.

Bug reports must:

1. Include a short, self-contained Python snippet reproducing the problem. You can format the code nicely by using GitHub Flavored Markdown:

```
```python
>>> from pandas import DataFrame
>>> df = DataFrame(...)
...
```
```

2. Include the full version string of pandas and its dependencies. You can use the built-in function:

```
>>> import pandas as pd
>>> pd.show_versions()
```

3. Explain why the current behavior is wrong/not desired and what you expect instead.

The issue will then show up to the pandas community and be open to comments/ideas from others.

4.1.3 Working with the code

Now that you have an issue you want to fix, enhancement to add, or documentation to improve, you need to learn how to work with GitHub and the pandas code base.

Version control, Git, and GitHub

To the new user, working with Git is one of the more daunting aspects of contributing to pandas. It can very quickly become overwhelming, but sticking to the guidelines below will help keep the process straightforward and mostly trouble free. As always, if you are having difficulties please feel free to ask for help.

The code is hosted on GitHub. To contribute you will need to sign up for a free GitHub account. We use Git for version control to allow many people to work together on the project.

Some great resources for learning Git:

- the GitHub help pages.
- the NumPy's documentation.
- Matthew Brett's Pydagogue.

Getting started with Git

GitHub has instructions for installing git, setting up your SSH key, and configuring git. All these steps need to be completed before you can work seamlessly between your local repository and GitHub.

Forking

You will need your own fork to work on the code. Go to the pandas project page and hit the `Fork` button. You will want to clone your fork to your machine:

```
git clone https://github.com/your-user-name/pandas.git pandas-yourname
cd pandas-yourname
git remote add upstream https://github.com/pandas-dev/pandas.git
```

This creates the directory *pandas-yourname* and connects your repository to the upstream (main project) *pandas* repository.

Note that performing a shallow clone (with `--depth==N`, for some `N` greater or equal to 1) might break some tests and features as `pd.show_versions()` as the version number cannot be computed anymore.

Creating a development environment

To test out code changes, you'll need to build pandas from source, which requires a C compiler and Python environment. If you're making documentation changes, you can skip to *Contributing to the documentation* but you won't be able to build the documentation locally before pushing your changes.

Using a Docker container

Instead of manually setting up a development environment, you can use Docker to automatically create the environment with just several commands. Pandas provides a *DockerFile* in the root directory to build a Docker image with a full pandas development environment.

Even easier, you can use the DockerFile to launch a remote session with Visual Studio Code, a popular free IDE, using the *.devcontainer.json* file. See https://code.visualstudio.com/docs/remote/containers for details.

Installing a C compiler

Pandas uses C extensions (mostly written using Cython) to speed up certain operations. To install pandas from source, you need to compile these C extensions, which means you need a C compiler. This process depends on which platform you're using.

Windows

You will need Build Tools for Visual Studio 2017.

> **Warning:** You DO NOT need to install Visual Studio 2019. You only need "Build Tools for Visual Studio 2019" found by scrolling down to "All downloads" -> "Tools for Visual Studio 2019".

Mac OS

Information about compiler installation can be found here: https://devguide.python.org/setup/#macos

Unix

Some Linux distributions will come with a pre-installed C compiler. To find out which compilers (and versions) are installed on your system:

```
# for Debian/Ubuntu:
dpkg --list | grep compiler
# for Red Hat/RHEL/CentOS/Fedora:
yum list installed | grep -i --color compiler
```

GCC (GNU Compiler Collection), is a widely used compiler, which supports C and a number of other languages. If GCC is listed as an installed compiler nothing more is required. If no C compiler is installed (or you wish to install a newer version) you can install a compiler (GCC in the example code below) with:

```
# for recent Debian/Ubuntu:
sudo apt install build-essential
# for Red Had/RHEL/CentOS/Fedora
yum groupinstall "Development Tools"
```

For other Linux distributions, consult your favourite search engine for compiler installation instructions.

Let us know if you have any difficulties by opening an issue or reaching out on Gitter.

Creating a Python environment

Now that you have a C compiler, create an isolated pandas development environment:

- Install either Anaconda or miniconda
- Make sure your conda is up to date (`conda update conda`)
- Make sure that you have *cloned the repository*
- `cd` to the pandas source directory

We'll now kick off a three-step process:

1. Install the build dependencies
2. Build and install pandas
3. Install the optional dependencies

```
# Create and activate the build environment
conda env create -f environment.yml
conda activate pandas-dev

# or with older versions of Anaconda:
source activate pandas-dev

# Build and install pandas
python setup.py build_ext --inplace -j 4
python -m pip install -e . --no-build-isolation --no-use-pep517
```

At this point you should be able to import pandas from your locally built version:

```
$ python  # start an interpreter
>>> import pandas
>>> print(pandas.__version__)
0.22.0.dev0+29.g4ad6d4d74
```

This will create the new environment, and not touch any of your existing environments, nor any existing Python installation.

To view your environments:

```
conda info -e
```

To return to your root environment:

```
conda deactivate
```

See the full conda docs here.

Creating a Python environment (pip)

If you aren't using conda for your development environment, follow these instructions. You'll need to have at least Python 3.6.1 installed on your system.

Unix/Mac OS with virtualenv

```
# Create a virtual environment
# Use an ENV_DIR of your choice. We'll use ~/virtualenvs/pandas-dev
# Any parent directories should already exist
python3 -m venv ~/virtualenvs/pandas-dev

# Activate the virtualenv
. ~/virtualenvs/pandas-dev/bin/activate

# Install the build dependencies
python -m pip install -r requirements-dev.txt

# Build and install pandas
python setup.py build_ext --inplace -j 4
python -m pip install -e . --no-build-isolation --no-use-pep517
```

Unix/Mac OS with pyenv

Consult the docs for setting up pyenv here.

```
# Create a virtual environment
# Use an ENV_DIR of your choice. We'll use ~/Users/<yourname>/.pyenv/versions/pandas-
↪dev

pyenv virtualenv <version> <name-to-give-it>

# For instance:
pyenv virtualenv 3.7.6 pandas-dev

# Activate the virtualenv
pyenv activate pandas-dev

# Now install the build dependencies in the cloned pandas repo
python -m pip install -r requirements-dev.txt

# Build and install pandas
python setup.py build_ext --inplace -j 4
python -m pip install -e . --no-build-isolation --no-use-pep517
```

Windows

Below is a brief overview on how to set-up a virtual environment with Powershell under Windows. For details please refer to the official virtualenv user guide

Use an ENV_DIR of your choice. We'll use ~\virtualenvs\pandas-dev where '~' is the folder pointed to by either $env:USERPROFILE (Powershell) or %USERPROFILE% (cmd.exe) environment variable. Any parent directories should already exist.

```
# Create a virtual environment
python -m venv $env:USERPROFILE\virtualenvs\pandas-dev

# Activate the virtualenv. Use activate.bat for cmd.exe
~\virtualenvs\pandas-dev\Scripts\Activate.ps1

# Install the build dependencies
python -m pip install -r requirements-dev.txt

# Build and install pandas
python setup.py build_ext --inplace -j 4
python -m pip install -e . --no-build-isolation --no-use-pep517
```

Creating a branch

You want your master branch to reflect only production-ready code, so create a feature branch for making your changes. For example:

```
git branch shiny-new-feature
git checkout shiny-new-feature
```

The above can be simplified to:

```
git checkout -b shiny-new-feature
```

This changes your working directory to the shiny-new-feature branch. Keep any changes in this branch specific to one bug or feature so it is clear what the branch brings to pandas. You can have many shiny-new-features and switch in between them using the git checkout command.

When creating this branch, make sure your master branch is up to date with the latest upstream master version. To update your local master branch, you can do:

```
git checkout master
git pull upstream master --ff-only
```

When you want to update the feature branch with changes in master after you created the branch, check the section on *updating a PR*.

4.1.4 Contributing to the documentation

Contributing to the documentation benefits everyone who uses pandas. We encourage you to help us improve the documentation, and you don't have to be an expert on pandas to do so! In fact, there are sections of the docs that are worse off after being written by experts. If something in the docs doesn't make sense to you, updating the relevant section after you figure it out is a great way to ensure it will help the next person.

Documentation:

- *About the pandas documentation*
- *Updating a pandas docstring*
- *How to build the pandas documentation*
  - *Requirements*
  - *Building the documentation*
  - *Building master branch documentation*

About the pandas documentation

The documentation is written in **reStructuredText**, which is almost like writing in plain English, and built using Sphinx. The Sphinx Documentation has an excellent introduction to reST. Review the Sphinx docs to perform more complex changes to the documentation as well.

Some other important things to know about the docs:

- The pandas documentation consists of two parts: the docstrings in the code itself and the docs in this folder `doc/`.

  The docstrings provide a clear explanation of the usage of the individual functions, while the documentation in this folder consists of tutorial-like overviews per topic together with some other information (what's new, installation, etc).

- The docstrings follow a pandas convention, based on the **Numpy Docstring Standard**. Follow the *pandas docstring guide* for detailed instructions on how to write a correct docstring.

pandas docstring guide

About docstrings and standards

A Python docstring is a string used to document a Python module, class, function or method, so programmers can understand what it does without having to read the details of the implementation.

Also, it is a common practice to generate online (html) documentation automatically from docstrings. Sphinx serves this purpose.

The next example gives an idea of what a docstring looks like:

```
def add(num1, num2):
    """
    Add up two integer numbers.

    This function simply wraps the `+` operator, and does not
    do anything interesting, except for illustrating what
    the docstring of a very simple function looks like.

    Parameters
    ----------
    num1 : int
        First number to add
    num2 : int
        Second number to add

    Returns
    -------
    int
        The sum of `num1` and `num2`

    See Also
    --------
    subtract : Subtract one integer from another

    Examples
    --------
    >>> add(2, 2)
    4
    >>> add(25, 0)
    25
    >>> add(10, -10)
    0
    """
    return num1 + num2
```

Some standards regarding docstrings exist, which make them easier to read, and allow them be easily exported to other formats such as html or pdf.

The first conventions every Python docstring should follow are defined in PEP-257.

As PEP-257 is quite broad, other more specific standards also exist. In the case of pandas, the numpy docstring convention is followed. These conventions are explained in this document:

- numpydoc docstring guide (which is based in the original Guide to NumPy/SciPy documentation)

numpydoc is a Sphinx extension to support the numpy docstring convention.

The standard uses reStructuredText (reST). reStructuredText is a markup language that allows encoding styles in plain text files. Documentation about reStructuredText can be found in:

- Sphinx reStructuredText primer
- Quick reStructuredText reference
- Full reStructuredText specification

pandas has some helpers for sharing docstrings between related classes, see *Sharing docstrings*.

The rest of this document will summarize all the above guidelines, and will provide additional conventions specific to the pandas project.

Writing a docstring

General rules

Docstrings must be defined with three double-quotes. No blank lines should be left before or after the docstring. The text starts in the next line after the opening quotes. The closing quotes have their own line (meaning that they are not at the end of the last sentence).

On rare occasions reST styles like bold text or italics will be used in docstrings, but is it common to have inline code, which is presented between backticks. The following are considered inline code:

- The name of a parameter
- Python code, a module, function, built-in, type, literal... (e.g. `os`, `list`, `numpy.abs`, `datetime.date`, `True`)
- A pandas class (in the form `:class:`pandas.Series``)
- A pandas method (in the form `:meth:`pandas.Series.sum``)
- A pandas function (in the form `:func:`pandas.to_datetime``)

Note: To display only the last component of the linked class, method or function, prefix it with ~. For example, `:class:`~pandas.Series`` will link to `pandas.Series` but only display the last part, `Series` as the link text. See Sphinx cross-referencing syntax for details.

Good:

```
def add_values(arr):
    """
    Add the values in `arr`.

    This is equivalent to Python `sum` of :meth:`pandas.Series.sum`.

    Some sections are omitted here for simplicity.
    """
    return sum(arr)
```

Bad:

```
def func():

    """Some function.

```

(continues on next page)

(continued from previous page)

```
    With several mistakes in the docstring.

    It has a blank like after the signature `def func():`.

    The text 'Some function' should go in the line after the
    opening quotes of the docstring, not in the same line.

    There is a blank line between the docstring and the first line
    of code `foo = 1`.

    The closing quotes should be in the next line, not in this one."""

    foo = 1
    bar = 2
    return foo + bar
```

Section 1: short summary

The short summary is a single sentence that expresses what the function does in a concise way.

The short summary must start with a capital letter, end with a dot, and fit in a single line. It needs to express what the object does without providing details. For functions and methods, the short summary must start with an infinitive verb.

Good:

```
def astype(dtype):
    """
    Cast Series type.

    This section will provide further details.
    """
    pass
```

Bad:

```
def astype(dtype):
    """
    Casts Series type.

    Verb in third-person of the present simple, should be infinitive.
    """
    pass
```

```
def astype(dtype):
    """
    Method to cast Series type.

    Does not start with verb.
    """
    pass
```

```
def astype(dtype):
    """
```

(continues on next page)

(continued from previous page)

```
    Cast Series type

    Missing dot at the end.
    """
    pass
```

```
def astype(dtype):
    """
    Cast Series type from its current type to the new type defined in
    the parameter dtype.

    Summary is too verbose and doesn't fit in a single line.
    """
    pass
```

Section 2: extended summary

The extended summary provides details on what the function does. It should not go into the details of the parameters, or discuss implementation notes, which go in other sections.

A blank line is left between the short summary and the extended summary. Every paragraph in the extended summary ends with a dot.

The extended summary should provide details on why the function is useful and their use cases, if it is not too generic.

```
def unstack():
    """
    Pivot a row index to columns.

    When using a MultiIndex, a level can be pivoted so each value in
    the index becomes a column. This is especially useful when a subindex
    is repeated for the main index, and data is easier to visualize as a
    pivot table.

    The index level will be automatically removed from the index when added
    as columns.
    """
    pass
```

Section 3: parameters

The details of the parameters will be added in this section. This section has the title "Parameters", followed by a line with a hyphen under each letter of the word "Parameters". A blank line is left before the section title, but not after, and not between the line with the word "Parameters" and the one with the hyphens.

After the title, each parameter in the signature must be documented, including **args* and ***kwargs*, but not *self*.

The parameters are defined by their name, followed by a space, a colon, another space, and the type (or types). Note that the space between the name and the colon is important. Types are not defined for **args* and ***kwargs*, but must be defined for all other parameters. After the parameter definition, it is required to have a line with the parameter description, which is indented, and can have multiple lines. The description must start with a capital letter, and finish with a dot.

For keyword arguments with a default value, the default will be listed after a comma at the end of the type. The exact form of the type in this case will be "int, default 0". In some cases it may be useful to explain what the default argument means, which can be added after a comma "int, default -1, meaning all cpus".

In cases where the default value is *None*, meaning that the value will not be used. Instead of "str, default None", it is preferred to write "str, optional". When *None* is a value being used, we will keep the form "str, default None". For example, in *df.to_csv(compression=None)*, *None* is not a value being used, but means that compression is optional, and no compression is being used if not provided. In this case we will use *str, optional*. Only in cases like *func(value=None)* and *None* is being used in the same way as *0* or *foo* would be used, then we will specify "str, int or None, default None".

Good:

```
class Series:
    def plot(self, kind, color='blue', **kwargs):
        """
        Generate a plot.

        Render the data in the Series as a matplotlib plot of the
        specified kind.

        Parameters
        ----------
        kind : str
            Kind of matplotlib plot.
        color : str, default 'blue'
            Color name or rgb code.
        **kwargs
            These parameters will be passed to the matplotlib plotting
            function.
        """
        pass
```

Bad:

```
class Series:
    def plot(self, kind, **kwargs):
        """
        Generate a plot.

        Render the data in the Series as a matplotlib plot of the
        specified kind.

        Note the blank line between the parameters title and the first
        parameter. Also, note that after the name of the parameter `kind`
        and before the colon, a space is missing.

        Also, note that the parameter descriptions do not start with a
        capital letter, and do not finish with a dot.

        Finally, the `**kwargs` parameter is missing.

        Parameters
        ----------

        kind: str
            kind of matplotlib plot
        """
```

(continues on next page)

(continued from previous page)

```
        pass
```

Parameter types

When specifying the parameter types, Python built-in data types can be used directly (the Python type is preferred to the more verbose string, integer, boolean, etc):

- int
- float
- str
- bool

For complex types, define the subtypes. For *dict* and *tuple*, as more than one type is present, we use the brackets to help read the type (curly brackets for *dict* and normal brackets for *tuple*):

- list of int
- dict of {str : int}
- tuple of (str, int, int)
- tuple of (str,)
- set of str

In case where there are just a set of values allowed, list them in curly brackets and separated by commas (followed by a space). If the values are ordinal and they have an order, list them in this order. Otherwise, list the default value first, if there is one:

- {0, 10, 25}
- {'simple', 'advanced'}
- {'low', 'medium', 'high'}
- {'cat', 'dog', 'bird'}

If the type is defined in a Python module, the module must be specified:

- datetime.date
- datetime.datetime
- decimal.Decimal

If the type is in a package, the module must be also specified:

- numpy.ndarray
- scipy.sparse.coo_matrix

If the type is a pandas type, also specify pandas except for Series and DataFrame:

- Series
- DataFrame
- pandas.Index
- pandas.Categorical
- pandas.arrays.SparseArray

If the exact type is not relevant, but must be compatible with a numpy array, array-like can be specified. If Any type that can be iterated is accepted, iterable can be used:

- array-like
- iterable

If more than one type is accepted, separate them by commas, except the last two types, that need to be separated by the word 'or':

- int or float
- float, decimal.Decimal or None
- str or list of str

If `None` is one of the accepted values, it always needs to be the last in the list.

For axis, the convention is to use something like:

- axis : {0 or 'index', 1 or 'columns', None}, default None

Section 4: returns or yields

If the method returns a value, it will be documented in this section. Also if the method yields its output.

The title of the section will be defined in the same way as the "Parameters". With the names "Returns" or "Yields" followed by a line with as many hyphens as the letters in the preceding word.

The documentation of the return is also similar to the parameters. But in this case, no name will be provided, unless the method returns or yields more than one value (a tuple of values).

The types for "Returns" and "Yields" are the same as the ones for the "Parameters". Also, the description must finish with a dot.

For example, with a single value:

```
def sample():
    """
    Generate and return a random number.

    The value is sampled from a continuous uniform distribution between
    0 and 1.

    Returns
    -------
    float
        Random number generated.
    """
    return np.random.random()
```

With more than one value:

```
import string

def random_letters():
    """
    Generate and return a sequence of random letters.

    The length of the returned string is also random, and is also
    returned.
```

(continues on next page)

(continued from previous page)

```
    Returns
    -------
    length : int
        Length of the returned string.
    letters : str
        String of random letters.
    """
    length = np.random.randint(1, 10)
    letters = ''.join(np.random.choice(string.ascii_lowercase)
                      for i in range(length))
    return length, letters
```

If the method yields its value:

```
def sample_values():
    """
    Generate an infinite sequence of random numbers.

    The values are sampled from a continuous uniform distribution between
    0 and 1.

    Yields
    ------
    float
        Random number generated.
    """
    while True:
        yield np.random.random()
```

Section 5: see also

This section is used to let users know about pandas functionality related to the one being documented. In rare cases, if no related methods or functions can be found at all, this section can be skipped.

An obvious example would be the *head()* and *tail()* methods. As *tail()* does the equivalent as *head()* but at the end of the *Series* or *DataFrame* instead of at the beginning, it is good to let the users know about it.

To give an intuition on what can be considered related, here there are some examples:

- `loc` and `iloc`, as they do the same, but in one case providing indices and in the other positions
- `max` and `min`, as they do the opposite
- `iterrows`, `itertuples` and `items`, as it is easy that a user looking for the method to iterate over columns ends up in the method to iterate over rows, and vice-versa
- `fillna` and `dropna`, as both methods are used to handle missing values
- `read_csv` and `to_csv`, as they are complementary
- `merge` and `join`, as one is a generalization of the other
- `astype` and `pandas.to_datetime`, as users may be reading the documentation of `astype` to know how to cast as a date, and the way to do it is with `pandas.to_datetime`
- `where` is related to `numpy.where`, as its functionality is based on it

When deciding what is related, you should mainly use your common sense and think about what can be useful for the users reading the documentation, especially the less experienced ones.

When relating to other libraries (mainly `numpy`), use the name of the module first (not an alias like `np`). If the function is in a module which is not the main one, like `scipy.sparse`, list the full module (e.g. `scipy.sparse.coo_matrix`).

This section has a header, "See Also" (note the capital S and A), followed by the line with hyphens and preceded by a blank line.

After the header, we will add a line for each related method or function, followed by a space, a colon, another space, and a short description that illustrates what this method or function does, why is it relevant in this context, and what the key differences are between the documented function and the one being referenced. The description must also end with a dot.

Note that in "Returns" and "Yields", the description is located on the line after the type. In this section, however, it is located on the same line, with a colon in between. If the description does not fit on the same line, it can continue onto other lines which must be further indented.

For example:

```
class Series:
    def head(self):
        """
        Return the first 5 elements of the Series.

        This function is mainly useful to preview the values of the
        Series without displaying the whole of it.

        Returns
        -------
        Series
            Subset of the original series with the 5 first values.

        See Also
        --------
        Series.tail : Return the last 5 elements of the Series.
        Series.iloc : Return a slice of the elements in the Series,
            which can also be used to return the first or last n.
        """
        return self.iloc[:5]
```

Section 6: notes

This is an optional section used for notes about the implementation of the algorithm, or to document technical aspects of the function behavior.

Feel free to skip it, unless you are familiar with the implementation of the algorithm, or you discover some counter-intuitive behavior while writing the examples for the function.

This section follows the same format as the extended summary section.

Section 7: examples

This is one of the most important sections of a docstring, despite being placed in the last position, as often people understand concepts better by example than through accurate explanations.

Examples in docstrings, besides illustrating the usage of the function or method, must be valid Python code, that returns the given output in a deterministic way, and that can be copied and run by users.

Examples are presented as a session in the Python terminal. >>> is used to present code. ... is used for code continuing from the previous line. Output is presented immediately after the last line of code generating the output (no blank lines in between). Comments describing the examples can be added with blank lines before and after them.

The way to present examples is as follows:

1. Import required libraries (except `numpy` and `pandas`)
2. Create the data required for the example
3. Show a very basic example that gives an idea of the most common use case
4. Add examples with explanations that illustrate how the parameters can be used for extended functionality

A simple example could be:

```
class Series:

    def head(self, n=5):
        """
        Return the first elements of the Series.

        This function is mainly useful to preview the values of the
        Series without displaying all of it.

        Parameters
        ----------
        n : int
            Number of values to return.

        Return
        ------
        pandas.Series
            Subset of the original series with the n first values.

        See Also
        --------
        tail : Return the last n elements of the Series.

        Examples
        --------
        >>> s = pd.Series(['Ant', 'Bear', 'Cow', 'Dog', 'Falcon',
        ...                'Lion', 'Monkey', 'Rabbit', 'Zebra'])
        >>> s.head()
        0   Ant
        1   Bear
        2   Cow
        3   Dog
        4   Falcon
        dtype: object
```

(continues on next page)

(continued from previous page)

```
        With the `n` parameter, we can change the number of returned rows:

        >>> s.head(n=3)
        0   Ant
        1   Bear
        2   Cow
        dtype: object
        """
        return self.iloc[:n]
```

The examples should be as concise as possible. In cases where the complexity of the function requires long examples, is recommended to use blocks with headers in bold. Use double star `**` to make a text bold, like in `**this example**`.

Conventions for the examples

Code in examples is assumed to always start with these two lines which are not shown:

```
import numpy as np
import pandas as pd
```

Any other module used in the examples must be explicitly imported, one per line (as recommended in **PEP 8#imports**) and avoiding aliases. Avoid excessive imports, but if needed, imports from the standard library go first, followed by third-party libraries (like matplotlib).

When illustrating examples with a single `Series` use the name `s`, and if illustrating with a single `DataFrame` use the name `df`. For indices, `idx` is the preferred name. If a set of homogeneous `Series` or `DataFrame` is used, name them `s1`, `s2`, `s3...` or `df1`, `df2`, `df3...` If the data is not homogeneous, and more than one structure is needed, name them with something meaningful, for example `df_main` and `df_to_join`.

Data used in the example should be as compact as possible. The number of rows is recommended to be around 4, but make it a number that makes sense for the specific example. For example in the `head` method, it requires to be higher than 5, to show the example with the default values. If doing the `mean`, we could use something like `[1, 2, 3]`, so it is easy to see that the value returned is the mean.

For more complex examples (grouping for example), avoid using data without interpretation, like a matrix of random numbers with columns A, B, C, D... And instead use a meaningful example, which makes it easier to understand the concept. Unless required by the example, use names of animals, to keep examples consistent. And numerical properties of them.

When calling the method, keywords arguments `head(n=3)` are preferred to positional arguments `head(3)`.

Good:

```
class Series:

    def mean(self):
        """
        Compute the mean of the input.

        Examples
        --------
        >>> s = pd.Series([1, 2, 3])
        >>> s.mean()
        2
        """
```

(continues on next page)

(continued from previous page)

```
        pass

    def fillna(self, value):
        """
        Replace missing values by `value`.

        Examples
        --------
        >>> s = pd.Series([1, np.nan, 3])
        >>> s.fillna(0)
        [1, 0, 3]
        """
        pass

    def groupby_mean(self):
        """
        Group by index and return mean.

        Examples
        --------
        >>> s = pd.Series([380., 370., 24., 26],
        ...               name='max_speed',
        ...               index=['falcon', 'falcon', 'parrot', 'parrot'])
        >>> s.groupby_mean()
        index
        falcon    375.0
        parrot     25.0
        Name: max_speed, dtype: float64
        """
        pass

    def contains(self, pattern, case_sensitive=True, na=numpy.nan):
        """
        Return whether each value contains `pattern`.

        In this case, we are illustrating how to use sections, even
        if the example is simple enough and does not require them.

        Examples
        --------
        >>> s = pd.Series('Antelope', 'Lion', 'Zebra', np.nan)
        >>> s.contains(pattern='a')
        0    False
        1    False
        2     True
        3      NaN
        dtype: bool

        **Case sensitivity**

        With `case_sensitive` set to `False` we can match `a` with both
        `a` and `A`:

        >>> s.contains(pattern='a', case_sensitive=False)
        0     True
        1    False
```

(continues on next page)

(continued from previous page)

```
        2     True
        3      NaN
        dtype: bool

        **Missing values**

        We can fill missing values in the output using the `na` parameter:

        >>> s.contains(pattern='a', na=False)
        0    False
        1    False
        2     True
        3    False
        dtype: bool
        """
        pass
```

Bad:

```
def method(foo=None, bar=None):
    """
    A sample DataFrame method.

    Do not import numpy and pandas.

    Try to use meaningful data, when it makes the example easier
    to understand.

    Try to avoid positional arguments like in `df.method(1)`. They
    can be all right if previously defined with a meaningful name,
    like in `present_value(interest_rate)`, but avoid them otherwise.

    When presenting the behavior with different parameters, do not place
    all the calls one next to the other. Instead, add a short sentence
    explaining what the example shows.

    Examples
    --------
    >>> import numpy as np
    >>> import pandas as pd
    >>> df = pd.DataFrame(np.random.randn(3, 3),
    ...                   columns=('a', 'b', 'c'))
    >>> df.method(1)
    21
    >>> df.method(bar=14)
    123
    """
    pass
```

Tips for getting your examples pass the doctests

Getting the examples pass the doctests in the validation script can sometimes be tricky. Here are some attention points:

- Import all needed libraries (except for pandas and numpy, those are already imported as `import pandas as pd` and `import numpy as np`) and define all variables you use in the example.
- Try to avoid using random data. However random data might be OK in some cases, like if the function you are documenting deals with probability distributions, or if the amount of data needed to make the function result meaningful is too much, such that creating it manually is very cumbersome. In those cases, always use a fixed random seed to make the generated examples predictable. Example:

```
>>> np.random.seed(42)
>>> df = pd.DataFrame({'normal': np.random.normal(100, 5, 20)})
```

- If you have a code snippet that wraps multiple lines, you need to use '...' on the continued lines:

```
>>> df = pd.DataFrame([[1, 2, 3], [4, 5, 6]], index=['a', 'b', 'c'],
...                   columns=['A', 'B'])
```

- If you want to show a case where an exception is raised, you can do:

```
>>> pd.to_datetime(["712-01-01"])
Traceback (most recent call last):
OutOfBoundsDatetime: Out of bounds nanosecond timestamp: 712-01-01 00:00:00
```

  It is essential to include the "Traceback (most recent call last):", but for the actual error only the error name is sufficient.

- If there is a small part of the result that can vary (e.g. a hash in an object representation), you can use `...` to represent this part.

  If you want to show that `s.plot()` returns a matplotlib AxesSubplot object, this will fail the doctest

```
>>> s.plot()
<matplotlib.axes._subplots.AxesSubplot at 0x7efd0c0b0690>
```

  However, you can do (notice the comment that needs to be added)

```
>>> s.plot()
<matplotlib.axes._subplots.AxesSubplot at ...>
```

Plots in examples

There are some methods in pandas returning plots. To render the plots generated by the examples in the documentation, the `.. plot::` directive exists.

To use it, place the next code after the "Examples" header as shown below. The plot will be generated automatically when building the documentation.

```
class Series:
    def plot(self):
        """
        Generate a plot with the `Series` data.

```

(continues on next page)

(continued from previous page)

```
        Examples
        --------

        .. plot::
            :context: close-figs

            >>> s = pd.Series([1, 2, 3])
            >>> s.plot()
        """
        pass
```

Sharing docstrings

pandas has a system for sharing docstrings, with slight variations, between classes. This helps us keep docstrings consistent, while keeping things clear for the user reading. It comes at the cost of some complexity when writing.

Each shared docstring will have a base template with variables, like `{klass}`. The variables filled in later on using the `doc` decorator. Finally, docstrings can also be appended to with the `doc` decorator.

In this example, we'll create a parent docstring normally (this is like `pandas.core.generic.NDFrame`. Then we'll have two children (like `pandas.core.series.Series` and `pandas.core.frame.DataFrame`). We'll substitute the class names in this docstring.

```
class Parent:
    @doc(klass="Parent")
    def my_function(self):
        """Apply my function to {klass}."""
        ...

class ChildA(Parent):
    @doc(Parent.my_function, klass="ChildA")
    def my_function(self):
        ...

class ChildB(Parent):
    @doc(Parent.my_function, klass="ChildB")
    def my_function(self):
        ...
```

The resulting docstrings are

```
>>> print(Parent.my_function.__doc__)
Apply my function to Parent.
>>> print(ChildA.my_function.__doc__)
Apply my function to ChildA.
>>> print(ChildB.my_function.__doc__)
Apply my function to ChildB.
```

Notice:

1. We "append" the parent docstring to the children docstrings, which are initially empty.

Our files will often contain a module-level `_shared_doc_kwargs` with some common substitution values (things like `klass`, `axes`, etc).

You can substitute and append in one shot with something like

```
@doc(template, **_shared_doc_kwargs)
def my_function(self):
    ...
```

where `template` may come from a module-level `_shared_docs` dictionary mapping function names to docstrings. Wherever possible, we prefer using `doc`, since the docstring-writing processes is slightly closer to normal.

See `pandas.core.generic.NDFrame.fillna` for an example template, and `pandas.core.series.Series.fillna` and `pandas.core.generic.frame.fillna` for the filled versions.

- The tutorials make heavy use of the ipython directive sphinx extension. This directive lets you put code in the documentation which will be run during the doc build. For example:

```
.. ipython:: python

    x = 2
    x**3
```

will be rendered as:

```
In [1]: x = 2

In [2]: x**3
Out[2]: 8
```

Almost all code examples in the docs are run (and the output saved) during the doc build. This approach means that code examples will always be up to date, but it does make the doc building a bit more complex.

- Our API documentation files in `doc/source/reference` house the auto-generated documentation from the docstrings. For classes, there are a few subtleties around controlling which methods and attributes have pages auto-generated.

  We have two autosummary templates for classes.

  1. `_templates/autosummary/class.rst`. Use this when you want to automatically generate a page for every public method and attribute on the class. The `Attributes` and `Methods` sections will be automatically added to the class' rendered documentation by numpydoc. See `DataFrame` for an example.
  2. `_templates/autosummary/class_without_autosummary`. Use this when you want to pick a subset of methods / attributes to auto-generate pages for. When using this template, you should include an `Attributes` and `Methods` section in the class docstring. See `CategoricalIndex` for an example.

  Every method should be included in a `toctree` in one of the documentation files in `doc/source/reference`, else Sphinx will emit a warning.

Note: The `.rst` files are used to automatically generate Markdown and HTML versions of the docs. For this reason, please do not edit `CONTRIBUTING.md` directly, but instead make any changes to `doc/source/development/contributing.rst`. Then, to generate `CONTRIBUTING.md`, use pandoc with the following command:

```
pandoc doc/source/development/contributing.rst -t markdown_github > CONTRIBUTING.md
```

The utility script `scripts/validate_docstrings.py` can be used to get a csv summary of the API documentation. And also validate common errors in the docstring of a specific class, function or method. The summary

also compares the list of methods documented in the files in `doc/source/reference` (which is used to generate the API Reference page) and the actual public methods. This will identify methods documented in `doc/source/reference` that are not actually class methods, and existing methods that are not documented in `doc/source/reference`.

Updating a pandas docstring

When improving a single function or method's docstring, it is not necessarily needed to build the full documentation (see next section). However, there is a script that checks a docstring (for example for the `DataFrame.mean` method):

```
python scripts/validate_docstrings.py pandas.DataFrame.mean
```

This script will indicate some formatting errors if present, and will also run and test the examples included in the docstring. Check the *pandas docstring guide* for a detailed guide on how to format the docstring.

The examples in the docstring ('doctests') must be valid Python code, that in a deterministic way returns the presented output, and that can be copied and run by users. This can be checked with the script above, and is also tested on Travis. A failing doctest will be a blocker for merging a PR. Check the *examples* section in the docstring guide for some tips and tricks to get the doctests passing.

When doing a PR with a docstring update, it is good to post the output of the validation script in a comment on github.

How to build the pandas documentation

Requirements

First, you need to have a development environment to be able to build pandas (see the docs on *creating a development environment above*).

Building the documentation

So how do you build the docs? Navigate to your local `doc/` directory in the console and run:

```
python make.py html
```

Then you can find the HTML output in the folder `doc/build/html/`.

The first time you build the docs, it will take quite a while because it has to run all the code examples and build all the generated docstring pages. In subsequent evocations, sphinx will try to only build the pages that have been modified.

If you want to do a full clean build, do:

```
python make.py clean
python make.py html
```

You can tell `make.py` to compile only a single section of the docs, greatly reducing the turn-around time for checking your changes.

```
# omit autosummary and API section
python make.py clean
python make.py --no-api

# compile the docs with only a single section, relative to the "source" folder.
# For example, compiling only this guide (doc/source/development/contributing.rst)
```

(continues on next page)

(continued from previous page)

```
python make.py clean
python make.py --single development/contributing.rst

# compile the reference docs for a single function
python make.py clean
python make.py --single pandas.DataFrame.join
```

For comparison, a full documentation build may take 15 minutes, but a single section may take 15 seconds. Subsequent builds, which only process portions you have changed, will be faster.

You can also specify to use multiple cores to speed up the documentation build:

```
python make.py html --num-jobs 4
```

Open the following file in a web browser to see the full documentation you just built:

```
doc/build/html/index.html
```

And you'll have the satisfaction of seeing your new and improved documentation!

Building master branch documentation

When pull requests are merged into the pandas `master` branch, the main parts of the documentation are also built by Travis-CI. These docs are then hosted here, see also the *Continuous Integration* section.

4.1.5 Contributing to the code base

Code Base:

Code standards

Writing good code is not just about what you write. It is also about *how* you write it. During *Continuous Integration* testing, several tools will be run to check your code for stylistic errors. Generating any warnings will cause the test to fail. Thus, good style is a requirement for submitting code to pandas.

There is a tool in pandas to help contributors verify their changes before contributing them to the project:

```
./ci/code_checks.sh
```

The script verifies the linting of code files, it looks for common mistake patterns (like missing spaces around sphinx directives that make the documentation not being rendered properly) and it also validates the doctests. It is possible to run the checks independently by using the parameters `lint`, `patterns` and `doctests` (e.g. `./ci/code_checks.sh lint`).

In addition, because a lot of people use our library, it is important that we do not make sudden changes to the code that could have the potential to break a lot of user code as a result, that is, we need it to be as *backwards compatible* as possible to avoid mass breakages.

Additional standards are outlined on the *pandas code style guide*

Optional dependencies

Optional dependencies (e.g. matplotlib) should be imported with the private helper `pandas.compat._optional.import_optional_dependency`. This ensures a consistent error message when the dependency is not met.

All methods using an optional dependency should include a test asserting that an `ImportError` is raised when the optional dependency is not found. This test should be skipped if the library is present.

All optional dependencies should be documented in *Optional dependencies* and the minimum required version should be set in the `pandas.compat._optional.VERSIONS` dict.

C (cpplint)

pandas uses the Google standard. Google provides an open source style checker called `cpplint`, but we use a fork of it that can be found here. Here are *some* of the more common `cpplint` issues:

- we restrict line-length to 80 characters to promote readability
- every header file must include a header guard to avoid name collisions if re-included

Continuous Integration will run the cpplint tool and report any stylistic errors in your code. Therefore, it is helpful before submitting code to run the check yourself:

```
cpplint --extensions=c,h --headers=h --filter=-readability/casting,-runtime/int,-
↪build/include_subdir modified-c-file
```

You can also run this command on an entire directory if necessary:

```
cpplint --extensions=c,h --headers=h --filter=-readability/casting,-runtime/int,-
↪build/include_subdir --recursive modified-c-directory
```

To make your commits compliant with this standard, you can install the ClangFormat tool, which can be downloaded here. To configure, in your home directory, run the following command:

```
clang-format style=google -dump-config  > .clang-format
```

Then modify the file to ensure that any indentation width parameters are at least four. Once configured, you can run the tool as follows:

```
clang-format modified-c-file
```

This will output what your file will look like if the changes are made, and to apply them, run the following command:

```
clang-format -i modified-c-file
```

To run the tool on an entire directory, you can run the following analogous commands:

```
clang-format modified-c-directory/*.c modified-c-directory/*.h
clang-format -i modified-c-directory/*.c modified-c-directory/*.h
```

Do note that this tool is best-effort, meaning that it will try to correct as many errors as possible, but it may not correct *all* of them. Thus, it is recommended that you run `cpplint` to double check and make any other style fixes manually.

Python (PEP8 / black)

pandas follows the PEP8 standard and uses Black and Flake8 to ensure a consistent code format throughout the project.

Continuous Integration will run those tools and report any stylistic errors in your code. Therefore, it is helpful before submitting code to run the check yourself:

```
black pandas
git diff upstream/master -u -- "*.py" | flake8 --diff
```

to auto-format your code. Additionally, many editors have plugins that will apply `black` as you edit files.

You should use a `black` version >= 19.10b0 as previous versions are not compatible with the pandas codebase.

If you wish to run these checks automatically, we encourage you to use *pre-commits* instead.

One caveat about `git diff upstream/master -u -- "*.py" | flake8 --diff`: this command will catch any stylistic errors in your changes specifically, but be beware it may not catch all of them. For example, if you delete the only usage of an imported function, it is stylistically incorrect to import an unused function. However, style-checking the diff will not catch this because the actual import is not part of the diff. Thus, for completeness, you should run this command, though it may take longer:

```
git diff upstream/master --name-only -- "*.py" | xargs -r flake8
```

Note that on OSX, the `-r` flag is not available, so you have to omit it and run this slightly modified command:

```
git diff upstream/master --name-only -- "*.py" | xargs flake8
```

Windows does not support the `xargs` command (unless installed for example via the MinGW toolchain), but one can imitate the behaviour as follows:

```
for /f %i in ('git diff upstream/master --name-only -- "*.py"') do flake8 %i
```

This will get all the files being changed by the PR (and ending with `.py`), and run `flake8` on them, one after the other.

Note that these commands can be run analogously with `black`.

Import formatting

pandas uses isort to standardise import formatting across the codebase.

A guide to import layout as per pep8 can be found here.

A summary of our current import sections (in order):

- Future
- Python Standard Library
- Third Party
- `pandas._libs`, `pandas.compat`, `pandas.util._*`, `pandas.errors` (largely not dependent on `pandas.core`)
- `pandas.core.dtypes` (largely not dependent on the rest of `pandas.core`)
- Rest of `pandas.core.*`
- Non-core `pandas.io`, `pandas.plotting`, `pandas.tseries`
- Local application/library specific imports

Imports are alphabetically sorted within these sections.

As part of *Continuous Integration* checks we run:

```
isort --check-only pandas
```

to check that imports are correctly formatted as per the *setup.cfg*.

If you see output like the below in *Continuous Integration* checks:

```
Check import format using isort
ERROR: /home/travis/build/pandas-dev/pandas/pandas/io/pytables.py Imports are␣
↪incorrectly sorted
Check import format using isort DONE
The command "ci/code_checks.sh" exited with 1
```

You should run:

```
isort pandas/io/pytables.py
```

to automatically format imports correctly. This will modify your local copy of the files.

Alternatively, you can run a command similar to what was suggested for `black` and `flake8` *right above*:

```
git diff upstream/master --name-only -- "*.py" | xargs -r isort
```

Where similar caveats apply if you are on OSX or Windows.

You can then verify the changes look ok, then git *commit* and *push*.

Pre-commit

You can run many of these styling checks manually as we have described above. However, we encourage you to use pre-commit hooks instead to automatically run `black`, `flake8`, `isort` when you make a git commit. This can be done by installing `pre-commit`:

```
pip install pre-commit
```

and then running:

```
pre-commit install
```

from the root of the pandas repository. Now all of the styling checks will be run each time you commit changes without your needing to run each one manually. In addition, using this pre-commit hook will also allow you to more easily remain up-to-date with our code checks as they change.

Note that if needed, you can skip these checks with `git commit --no-verify`.

Backwards compatibility

Please try to maintain backward compatibility. pandas has lots of users with lots of existing code, so don't break it if at all possible. If you think breakage is required, clearly state why as part of the pull request. Also, be careful when changing method signatures and add deprecation warnings where needed. Also, add the deprecated sphinx directive to the deprecated functions or methods.

If a function with the same arguments as the one being deprecated exist, you can use the `pandas.util._decorators.deprecate`:

```
from pandas.util._decorators import deprecate

deprecate('old_func', 'new_func', '1.1.0')
```

Otherwise, you need to do it manually:

```
import warnings

def old_func():
    """Summary of the function.

    .. deprecated:: 1.1.0
       Use new_func instead.
    """
    warnings.warn('Use new_func instead.', FutureWarning, stacklevel=2)
    new_func()

def new_func():
    pass
```

You'll also need to

1. Write a new test that asserts a warning is issued when calling with the deprecated argument
2. Update all of pandas existing tests and code to use the new argument

See *Testing warnings* for more.

Type hints

pandas strongly encourages the use of **PEP 484** style type hints. New development should contain type hints and pull requests to annotate existing code are accepted as well!

Style guidelines

Types imports should follow the `from typing import ...` convention. So rather than

```
import typing

primes: typing.List[int] = []
```

You should write

```
from typing import List, Optional, Union

primes: List[int] = []
```

`Optional` should be used where applicable, so instead of

```
maybe_primes: List[Union[int, None]] = []
```

You should write

```
maybe_primes: List[Optional[int]] = []
```

In some cases in the code base classes may define class variables that shadow builtins. This causes an issue as described in Mypy 1775. The defensive solution here is to create an unambiguous alias of the builtin and use that without your annotation. For example, if you come across a definition like

```
class SomeClass1:
    str = None
```

The appropriate way to annotate this would be as follows

```
str_type = str

class SomeClass2:
    str: str_type = None
```

In some cases you may be tempted to use `cast` from the typing module when you know better than the analyzer. This occurs particularly when using custom inference functions. For example

```
from typing import cast

from pandas.core.dtypes.common import is_number

```

(continues on next page)

(continued from previous page)

```
def cannot_infer_bad(obj: Union[str, int, float]):

    if is_number(obj):
        ...
    else:  # Reasonably only str objects would reach this but...
        obj = cast(str, obj)  # Mypy complains without this!
        return obj.upper()
```

The limitation here is that while a human can reasonably understand that `is_number` would catch the `int` and `float` types mypy cannot make that same inference just yet (see mypy #5206. While the above works, the use of `cast` is **strongly discouraged**. Where applicable a refactor of the code to appease static analysis is preferable

```
def cannot_infer_good(obj: Union[str, int, float]):

    if isinstance(obj, str):
        return obj.upper()
    else:
        ...
```

With custom types and inference this is not always possible so exceptions are made, but every effort should be exhausted to avoid `cast` before going down such paths.

pandas-specific types

Commonly used types specific to pandas will appear in pandas._typing and you should use these where applicable. This module is private for now but ultimately this should be exposed to third party libraries who want to implement type checking against pandas.

For example, quite a few functions in pandas accept a `dtype` argument. This can be expressed as a string like `"object"`, a `numpy.dtype` like `np.int64` or even a pandas `ExtensionDtype` like `pd.CategoricalDtype`. Rather than burden the user with having to constantly annotate all of those options, this can simply be imported and reused from the pandas._typing module

```
from pandas._typing import Dtype

def as_type(dtype: Dtype) -> ...:
    ...
```

This module will ultimately house types for repeatedly used concepts like “path-like”, “array-like”, “numeric”, etc... and can also hold aliases for commonly appearing parameters like *axis*. Development of this module is active so be sure to refer to the source for the most up to date list of available types.

Validating type hints

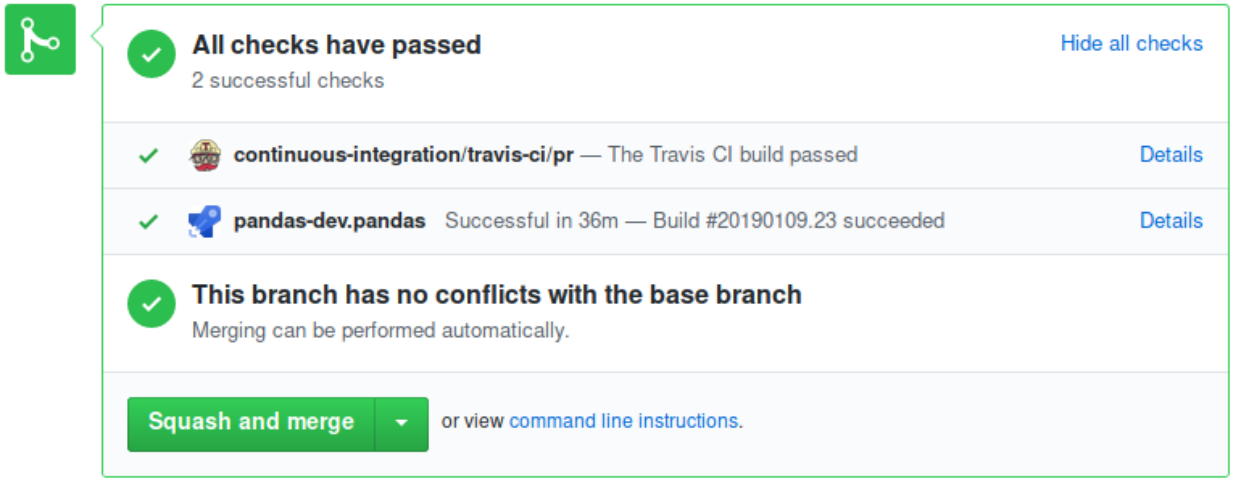
pandas uses mypy to statically analyze the code base and type hints. After making any change you can ensure your type hints are correct by running

```
mypy pandas
```

Testing with continuous integration

The pandas test suite will run automatically on Travis-CI and Azure Pipelines continuous integration services, once your pull request is submitted. However, if you wish to run the test suite on a branch prior to submitting the pull request, then the continuous integration services need to be hooked to your GitHub repository. Instructions are here for Travis-CI and Azure Pipelines.

A pull-request will be considered for merging when you have an all 'green' build. If any tests are failing, then you will get a red 'X', where you can click through to see the individual failed tests. This is an example of a green build.



Note: Each time you push to *your* fork, a *new* run of the tests will be triggered on the CI. You can enable the auto-cancel feature, which removes any non-currently-running tests for that same pull-request, for Travis-CI here.

Test-driven development/code writing

pandas is serious about testing and strongly encourages contributors to embrace test-driven development (TDD). This development process "relies on the repetition of a very short development cycle: first the developer writes an (initially failing) automated test case that defines a desired improvement or new function, then produces the minimum amount of code to pass that test." So, before actually writing any code, you should write your tests. Often the test can be taken from the original GitHub issue. However, it is always worth considering additional use cases and writing corresponding tests.

Adding tests is one of the most common requests after code is pushed to pandas. Therefore, it is worth getting in the habit of writing tests ahead of time so this is never an issue.

Like many packages, pandas uses pytest and the convenient extensions in numpy.testing.

Note: The earliest supported pytest version is 5.0.1.

Writing tests

All tests should go into the `tests` subdirectory of the specific package. This folder contains many current examples of tests, and we suggest looking to these for inspiration. If your test requires working with files or network connectivity, there is more information on the testing page of the wiki.

The `pandas._testing` module has many special `assert` functions that make it easier to make statements about whether Series or DataFrame objects are equivalent. The easiest way to verify that your code is correct is to explicitly construct the result you expect, then compare the actual result to the expected correct result:

```
def test_pivot(self):
    data = {
        'index' : ['A', 'B', 'C', 'C', 'B', 'A'],
        'columns' : ['One', 'One', 'One', 'Two', 'Two', 'Two'],
        'values' : [1., 2., 3., 3., 2., 1.]
    }

    frame = DataFrame(data)
    pivoted = frame.pivot(index='index', columns='columns', values='values')

    expected = DataFrame({
        'One' : {'A' : 1., 'B' : 2., 'C' : 3.},
        'Two' : {'A' : 1., 'B' : 2., 'C' : 3.}
    })

    assert_frame_equal(pivoted, expected)
```

Please remember to add the Github Issue Number as a comment to a new test. E.g. "# brief comment, see GH#28907"

Transitioning to `pytest`

pandas existing test structure is *mostly* class-based, meaning that you will typically find tests wrapped in a class.

```
class TestReallyCoolFeature:
    pass
```

Going forward, we are moving to a more *functional* style using the pytest framework, which offers a richer testing framework that will facilitate testing and developing. Thus, instead of writing test classes, we will write test functions like this:

```
def test_really_cool_feature():
    pass
```

Using `pytest`

Here is an example of a self-contained set of tests that illustrate multiple features that we like to use.

- functional style: tests are like `test_*` and *only* take arguments that are either fixtures or parameters
- `pytest.mark` can be used to set metadata on test functions, e.g. `skip` or `xfail`.
- using `parametrize`: allow testing of multiple cases
- to set a mark on a parameter, `pytest.param(..., marks=...)` syntax should be used
- `fixture`, code for object construction, on a per-test basis

- using bare `assert` for scalars and truth-testing
- `tm.assert_series_equal` (and its counter part `tm.assert_frame_equal`), for pandas object comparisons.
- the typical pattern of constructing an `expected` and comparing versus the `result`

We would name this file `test_cool_feature.py` and put in an appropriate place in the `pandas/tests/` structure.

```
import pytest
import numpy as np
import pandas as pd

@pytest.mark.parametrize('dtype', ['int8', 'int16', 'int32', 'int64'])
def test_dtypes(dtype):
    assert str(np.dtype(dtype)) == dtype

@pytest.mark.parametrize(
    'dtype', ['float32', pytest.param('int16', marks=pytest.mark.skip),
              pytest.param('int32', marks=pytest.mark.xfail(
                  reason='to show how it works'))])
def test_mark(dtype):
    assert str(np.dtype(dtype)) == 'float32'

@pytest.fixture
def series():
    return pd.Series([1, 2, 3])

@pytest.fixture(params=['int8', 'int16', 'int32', 'int64'])
def dtype(request):
    return request.param

def test_series(series, dtype):
    result = series.astype(dtype)
    assert result.dtype == dtype

    expected = pd.Series([1, 2, 3], dtype=dtype)
    tm.assert_series_equal(result, expected)
```

A test run of this yields

```
((pandas) bash-3.2$ pytest  test_cool_feature.py  -v
=========================== test session starts ===========================
platform darwin -- Python 3.6.2, pytest-3.6.0, py-1.4.31, pluggy-0.4.0
collected 11 items

tester.py::test_dtypes[int8] PASSED
tester.py::test_dtypes[int16] PASSED
tester.py::test_dtypes[int32] PASSED
tester.py::test_dtypes[int64] PASSED
tester.py::test_mark[float32] PASSED
tester.py::test_mark[int16] SKIPPED
tester.py::test_mark[int32] xfail
```

(continues on next page)

(continued from previous page)

```
tester.py::test_series[int8] PASSED
tester.py::test_series[int16] PASSED
tester.py::test_series[int32] PASSED
tester.py::test_series[int64] PASSED
```

Tests that we have `parametrized` are now accessible via the test name, for example we could run these with `-k int8` to sub-select *only* those tests which match `int8`.

```
((pandas) bash-3.2$ pytest  test_cool_feature.py  -v -k int8
============================ test session starts ============================
platform darwin -- Python 3.6.2, pytest-3.6.0, py-1.4.31, pluggy-0.4.0
collected 11 items

test_cool_feature.py::test_dtypes[int8] PASSED
test_cool_feature.py::test_series[int8] PASSED
```

Using `hypothesis`

Hypothesis is a library for property-based testing. Instead of explicitly parametrizing a test, you can describe *all* valid inputs and let Hypothesis try to find a failing input. Even better, no matter how many random examples it tries, Hypothesis always reports a single minimal counterexample to your assertions - often an example that you would never have thought to test.

See Getting Started with Hypothesis for more of an introduction, then refer to the Hypothesis documentation for details.

```
import json
from hypothesis import given, strategies as st

any_json_value = st.deferred(lambda: st.one_of(
    st.none(), st.booleans(), st.floats(allow_nan=False), st.text(),
    st.lists(any_json_value), st.dictionaries(st.text(), any_json_value)
))

@given(value=any_json_value)
def test_json_roundtrip(value):
    result = json.loads(json.dumps(value))
    assert value == result
```

This test shows off several useful features of Hypothesis, as well as demonstrating a good use-case: checking properties that should hold over a large or complicated domain of inputs.

To keep the Pandas test suite running quickly, parametrized tests are preferred if the inputs or logic are simple, with Hypothesis tests reserved for cases with complex logic or where there are too many combinations of options or subtle interactions to test (or think of!) all of them.

Testing warnings

By default, one of pandas CI workers will fail if any unhandled warnings are emitted.

If your change involves checking that a warning is actually emitted, use `tm.assert_produces_warning(ExpectedWarning)`.

```
import pandas._testing as tm

df = pd.DataFrame()
with tm.assert_produces_warning(FutureWarning):
    df.some_operation()
```

We prefer this to the `pytest.warns` context manager because ours checks that the warning's stacklevel is set correctly. The stacklevel is what ensure the *user's* file name and line number is printed in the warning, rather than something internal to pandas. It represents the number of function calls from user code (e.g. `df.some_operation()`) to the function that actually emits the warning. Our linter will fail the build if you use `pytest.warns` in a test.

If you have a test that would emit a warning, but you aren't actually testing the warning itself (say because it's going to be removed in the future, or because we're matching a 3rd-party library's behavior), then use `pytest.mark.filterwarnings` to ignore the error.

```
@pytest.mark.filterwarnings("ignore:msg:category")
def test_thing(self):
    ...
```

If the test generates a warning of class `category` whose message starts with `msg`, the warning will be ignored and the test will pass.

If you need finer-grained control, you can use Python's usual warnings module to control whether a warning is ignored / raised at different places within a single test.

```
with warnings.catch_warnings():
    warnings.simplefilter("ignore", FutureWarning)
    # Or use warnings.filterwarnings(...)
```

Alternatively, consider breaking up the unit test.

Running the test suite

The tests can then be run directly inside your Git clone (without having to install pandas) by typing:

```
pytest pandas
```

The tests suite is exhaustive and takes around 20 minutes to run. Often it is worth running only a subset of tests first around your changes before running the entire suite.

The easiest way to do this is with:

```
pytest pandas/path/to/test.py -k regex_matching_test_name
```

Or with one of the following constructs:

```
pytest pandas/tests/[test-module].py
pytest pandas/tests/[test-module].py::[TestClass]
pytest pandas/tests/[test-module].py::[TestClass]::[test_method]
```

Using pytest-xdist, one can speed up local testing on multicore machines. To use this feature, you will need to install *pytest-xdist* via:

```
pip install pytest-xdist
```

Two scripts are provided to assist with this. These scripts distribute testing across 4 threads.

On Unix variants, one can type:

```
test_fast.sh
```

On Windows, one can type:

```
test_fast.bat
```

This can significantly reduce the time it takes to locally run tests before submitting a pull request.

For more, see the pytest documentation.

Furthermore one can run

```
pd.test()
```

with an imported pandas to run tests similarly.

Running the performance test suite

Performance matters and it is worth considering whether your code has introduced performance regressions. pandas is in the process of migrating to asv benchmarks to enable easy monitoring of the performance of critical pandas operations. These benchmarks are all found in the `pandas/asv_bench` directory, and the test results can be found here.

To use all features of asv, you will need either `conda` or `virtualenv`. For more details please check the asv installation webpage.

To install asv:

```
pip install git+https://github.com/spacetelescope/asv
```

If you need to run a benchmark, change your directory to `asv_bench/` and run:

```
asv continuous -f 1.1 upstream/master HEAD
```

You can replace `HEAD` with the name of the branch you are working on, and report benchmarks that changed by more than 10%. The command uses `conda` by default for creating the benchmark environments. If you want to use virtualenv instead, write:

```
asv continuous -f 1.1 -E virtualenv upstream/master HEAD
```

The `-E virtualenv` option should be added to all `asv` commands that run benchmarks. The default value is defined in `asv.conf.json`.

Running the full test suite can take up to one hour and use up to 3GB of RAM. Usually it is sufficient to paste only a subset of the results into the pull request to show that the committed changes do not cause unexpected performance regressions. You can run specific benchmarks using the `-b` flag, which takes a regular expression. For example, this will only run tests from a `pandas/asv_bench/benchmarks/groupby.py` file:

```
asv continuous -f 1.1 upstream/master HEAD -b ^groupby
```

If you want to only run a specific group of tests from a file, you can do it using `.` as a separator. For example:

```
asv continuous -f 1.1 upstream/master HEAD -b groupby.GroupByMethods
```

will only run the `GroupByMethods` benchmark defined in `groupby.py`.

You can also run the benchmark suite using the version of `pandas` already installed in your current Python environment. This can be useful if you do not have virtualenv or conda, or are using the `setup.py develop` approach discussed above; for the in-place build you need to set `PYTHONPATH`, e.g. `PYTHONPATH="$PWD/.." asv [remaining arguments]`. You can run benchmarks using an existing Python environment by:

```
asv run -e -E existing
```

or, to use a specific Python interpreter,:

```
asv run -e -E existing:python3.6
```

This will display stderr from the benchmarks, and use your local `python` that comes from your `$PATH`.

Information on how to write a benchmark and how to use asv can be found in the asv documentation.

Documenting your code

Changes should be reflected in the release notes located in `doc/source/whatsnew/vx.y.z.rst`. This file contains an ongoing change log for each release. Add an entry to this file to document your fix, enhancement or (unavoidable) breaking change. Make sure to include the GitHub issue number when adding your entry (using `:issue:`1234`` where `1234` is the issue/pull request number).

If your code is an enhancement, it is most likely necessary to add usage examples to the existing documentation. This can be done following the section regarding documentation *above*. Further, to let users know when this feature was added, the `versionadded` directive is used. The sphinx syntax for that is:

```
.. versionadded:: 1.1.0
```

This will put the text *New in version 1.1.0* wherever you put the sphinx directive. This should also be put in the docstring when adding a new function or method (example) or a new keyword argument (example).

4.1.6 Contributing your changes to pandas

Committing your code

Keep style fixes to a separate commit to make your pull request more readable.

Once you've made changes, you can see them by typing:

```
git status
```

If you have created a new file, it is not being tracked by git. Add it by typing:

```
git add path/to/file-to-be-added.py
```

Doing 'git status' again should give something like:

```
# On branch shiny-new-feature
#
#       modified:   /relative/path/to/file-you-added.py
#
```

Finally, commit your changes to your local repository with an explanatory message. pandas uses a convention for commit message prefixes and layout. Here are some common prefixes along with general guidelines for when to use them:

- ENH: Enhancement, new functionality
- BUG: Bug fix
- DOC: Additions/updates to documentation
- TST: Additions/updates to tests
- BLD: Updates to the build process/scripts
- PERF: Performance improvement
- TYP: Type annotations
- CLN: Code cleanup

The following defines how a commit message should be structured. Please reference the relevant GitHub issues in your commit message using GH1234 or #1234. Either style is fine, but the former is generally preferred:

- a subject line with < *80* chars.
- One blank line.
- Optionally, a commit message body.

Now you can commit your changes in your local repository:

```
git commit -m
```

Pushing your changes

When you want your changes to appear publicly on your GitHub page, push your forked feature branch's commits:

```
git push origin shiny-new-feature
```

Here `origin` is the default name given to your remote repository on GitHub. You can see the remote repositories:

```
git remote -v
```

If you added the upstream repository as described above you will see something like:

```
origin  git@github.com:yourname/pandas.git (fetch)
origin  git@github.com:yourname/pandas.git (push)
upstream        git://github.com/pandas-dev/pandas.git (fetch)
upstream        git://github.com/pandas-dev/pandas.git (push)
```

Now your code is on GitHub, but it is not yet a part of the pandas project. For that to happen, a pull request needs to be submitted on GitHub.

Review your code

When you're ready to ask for a code review, file a pull request. Before you do, once again make sure that you have followed all the guidelines outlined in this document regarding code style, tests, performance tests, and documentation. You should also double check your branch changes against the branch it was based on:

1. Navigate to your repository on GitHub – https://github.com/your-user-name/pandas
2. Click on `Branches`
3. Click on the `Compare` button for your feature branch
4. Select the `base` and `compare` branches, if necessary. This will be `master` and `shiny-new-feature`, respectively.

Finally, make the pull request

If everything looks good, you are ready to make a pull request. A pull request is how code from a local repository becomes available to the GitHub community and can be looked at and eventually merged into the master version. This pull request and its associated changes will eventually be committed to the master branch and available in the next release. To submit a pull request:

1. Navigate to your repository on GitHub
2. Click on the `Pull Request` button
3. You can then click on `Commits` and `Files Changed` to make sure everything looks okay one last time
4. Write a description of your changes in the `Preview Discussion` tab
5. Click `Send Pull Request`.

This request then goes to the repository maintainers, and they will review the code.

Updating your pull request

Based on the review you get on your pull request, you will probably need to make some changes to the code. In that case, you can make them in your branch, add a new commit to that branch, push it to GitHub, and the pull request will be automatically updated. Pushing them to GitHub again is done by:

```
git push origin shiny-new-feature
```

This will automatically update your pull request with the latest code and restart the *Continuous Integration* tests.

Another reason you might need to update your pull request is to solve conflicts with changes that have been merged into the master branch since you opened your pull request.

To do this, you need to "merge upstream master" in your branch:

```
git checkout shiny-new-feature
git fetch upstream
git merge upstream/master
```

If there are no conflicts (or they could be fixed automatically), a file with a default commit message will open, and you can simply save and quit this file.

If there are merge conflicts, you need to solve those conflicts. See for example at https://help.github.com/articles/resolving-a-merge-conflict-using-the-command-line/ for an explanation on how to do this. Once the conflicts are merged and the files where the conflicts were solved are added, you can run `git commit` to save those fixes.

If you have uncommitted changes at the moment you want to update the branch with master, you will need to `stash` them prior to updating (see the stash docs). This will effectively store your changes and they can be reapplied after updating.

After the feature branch has been update locally, you can now update your pull request by pushing to the branch on GitHub:

```
git push origin shiny-new-feature
```

Delete your merged branch (optional)

Once your feature branch is accepted into upstream, you'll probably want to get rid of the branch. First, merge upstream master into your branch so git knows it is safe to delete your branch:

```
git fetch upstream
git checkout master
git merge upstream/master
```

Then you can do:

```
git branch -d shiny-new-feature
```

Make sure you use a lower-case `-d`, or else git won't warn you if your feature branch has not actually been merged.

The branch will still exist on GitHub, so to delete it there do:

```
git push origin --delete shiny-new-feature
```

4.1.7 Tips for a successful pull request

If you have made it to the *Review your code* phase, one of the core contributors may take a look. Please note however that a handful of people are responsible for reviewing all of the contributions, which can often lead to bottlenecks.

To improve the chances of your pull request being reviewed, you should:

- **Reference an open issue** for non-trivial changes to clarify the PR's purpose
- **Ensure you have appropriate tests**. These should be the first part of any PR
- **Keep your pull requests as simple as possible**. Larger PRs take longer to review
- **Ensure that CI is in a green state**. Reviewers may not even look otherwise
- **Keep** *Updating your pull request*, either by request or every few days

4.2 pandas code style guide

Table of contents:

pandas follows the PEP8 standard and uses Black and Flake8 to ensure a consistent code format throughout the project. For details see the *contributing guide to pandas*.

4.2.1 Patterns

Using foo.__class__

pandas uses 'type(foo)' instead 'foo.__class__' as it is making the code more readable. For example:

Good:

```
foo = "bar"
type(foo)
```

Bad:

```
foo = "bar"
foo.__class__
```

4.2.2 String formatting

Concatenated strings

Using f-strings

pandas uses f-strings formatting instead of '%' and '.format()' string formatters.

The convention of using f-strings on a string that is concatenated over several lines, is to prefix only the lines containing values which need to be interpreted.

For example:

Good:

```
foo = "old_function"
bar = "new_function"

my_warning_message = (
    f"Warning, {foo} is deprecated, "
    "please use the new and way better "
    f"{bar}"
)
```

Bad:

```
foo = "old_function"
bar = "new_function"

my_warning_message = (
    f"Warning, {foo} is deprecated, "
    f"please use the new and way better "
    f"{bar}"
)
```

White spaces

Only put white space at the end of the previous line, so there is no whitespace at the beginning of the concatenated string.

For example:

Good:

```
example_string = (
    "Some long concatenated string, "
    "with good placement of the "
    "whitespaces"
)
```

Bad:

```
example_string = (
    "Some long concatenated string,"
    " with bad placement of the"
    " whitespaces"
)
```

Representation function (aka 'repr()')

pandas uses 'repr()' instead of '%r' and '!r'.

The use of 'repr()' will only happen when the value is not an obvious string.

For example:

Good:

```
value = str
f"Unknown received value, got: {repr(value)}"
```

Good:

```
value = str
f"Unknown received type, got: '{type(value).__name__}'"
```

4.2.3 Imports (aim for absolute)

In Python 3, absolute imports are recommended. Using absolute imports, doing something like `import string` will import the string module rather than `string.py` in the same directory. As much as possible, you should try to write out absolute imports that show the whole import chain from top-level pandas.

Explicit relative imports are also supported in Python 3 but it is not recommended to use them. Implicit relative imports should never be used and are removed in Python 3.

For example:

```
# preferred
import pandas.core.common as com

# not preferred
from .common import test_base

# wrong
from common import test_base
```

4.2.4 Miscellaneous

Reading from a url

Good:

```
from pandas.io.common import urlopen
with urlopen('http://www.google.com') as url:
    raw_text = url.read()
```

4.3 pandas maintenance

This guide is for pandas' maintainers. It may also be interesting to contributors looking to understand the pandas development process and what steps are necessary to become a maintainer.

The main contributing guide is available at *Contributing to pandas*.

4.3.1 Roles

pandas uses two levels of permissions: **triage** and **core** team members.

Triage members can label and close issues and pull requests.

Core team members can label and close issues and pull request, and can merge pull requests.

GitHub publishes the full list of permissions.

4.3.2 Tasks

pandas is largely a volunteer project, so these tasks shouldn't be read as "expectations" of triage and maintainers. Rather, they're general descriptions of what it means to be a maintainer.

- Triage newly filed issues (see *Issue triage*)
- Review newly opened pull requests
- Respond to updates on existing issues and pull requests
- Drive discussion and decisions on stalled issues and pull requests
- Provide experience / wisdom on API design questions to ensure consistency and maintainability
- Project organization (run / attend developer meetings, represent pandas)

https://matthewrocklin.com/blog/2019/05/18/maintainer may be interesting background reading.

4.3.3 Issue triage

Here's a typical workflow for triaging a newly opened issue.

1. **Thank the reporter for opening an issue**

   The issue tracker is many people's first interaction with the pandas project itself, beyond just using the library. As such, we want it to be a welcoming, pleasant experience.

2. **Is the necessary information provided?**

   Ideally reporters would fill out the issue template, but many don't. If crucial information (like the version of pandas they used), is missing feel free to ask for that and label the issue with "Needs info". The report should follow the guidelines in *Bug reports and enhancement requests*. You may want to link to that if they didn't follow the template.

   Make sure that the title accurately reflects the issue. Edit it yourself if it's not clear.

3. **Is this a duplicate issue?**

   We have many open issues. If a new issue is clearly a duplicate, label the new issue as "Duplicate" assign the milestone "No Action", and close the issue with a link to the original issue. Make sure to still thank the reporter, and encourage them to chime in on the original issue, and perhaps try to fix it.

   If the new issue provides relevant information, such as a better or slightly different example, add it to the original issue as a comment or an edit to the original post.

4. **Is the issue minimal and reproducible**?

   For bug reports, we ask that the reporter provide a minimal reproducible example. See https://matthewrocklin.com/blog/work/2018/02/28/minimal-bug-reports for a good explanation. If the example is not reproducible, or if it's *clearly* not minimal, feel free to ask the reporter if they can provide and example or simplify the provided one. Do acknowledge that writing minimal reproducible examples is hard work. If the reporter is struggling, you can try to write one yourself and we'll edit the original post to include it.

   If a reproducible example can't be provided, add the "Needs info" label.

   If a reproducible example is provided, but you see a simplification, edit the original post with your simpler reproducible example.

5. **Is this a clearly defined feature request?**

   Generally, pandas prefers to discuss and design new features in issues, before a pull request is made. Encourage the submitter to include a proposed API for the new feature. Having them write a full docstring is a good way to pin down specifics.

We'll need a discussion from several pandas maintainers before deciding whether the proposal is in scope for pandas.

6. **Is this a usage question?**

   We prefer that usage questions are asked on StackOverflow with the pandas tag. https://stackoverflow.com/questions/tagged/pandas

   If it's easy to answer, feel free to link to the relevant documentation section, let them know that in the future this kind of question should be on StackOverflow, and close the issue.

7. **What labels and milestones should I add?**

   Apply the relevant labels. This is a bit of an art, and comes with experience. Look at similar issues to get a feel for how things are labeled.

   If the issue is clearly defined and the fix seems relatively straightforward, label the issue as "Good first issue".

   Typically, new issues will be assigned the "Contributions welcome" milestone, unless it's know that this issue should be addressed in a specific release (say because it's a large regression).

4.3.4 Closing issues

Be delicate here: many people interpret closing an issue as us saying that the conversation is over. It's typically best to give the reporter some time to respond or self-close their issue if it's determined that the behavior is not a bug, or the feature is out of scope. Sometimes reporters just go away though, and we'll close the issue after the conversation has died.

4.3.5 Reviewing pull requests

Anybody can review a pull request: regular contributors, triagers, or core-team members. Here are some guidelines to check.

- Tests should be in a sensible location.
- New public APIs should be included somewhere in `doc/source/reference/`.
- New / changed API should use the `versionadded` or `versionchanged` directives in the docstring.
- User-facing changes should have a whatsnew in the appropriate file.
- Regression tests should reference the original GitHub issue number like `# GH-1234`.

4.3.6 Cleaning up old issues

Every open issue in pandas has a cost. Open issues make finding duplicates harder, and can make it harder to know what needs to be done in pandas. That said, closing issues isn't a goal on its own. Our goal is to make pandas the best it can be, and that's best done by ensuring that the quality of our open issues is high.

Occasionally, bugs are fixed but the issue isn't linked to in the Pull Request. In these cases, comment that "This has been fixed, but could use a test." and label the issue as "Good First Issue" and "Needs Test".

If an older issue doesn't follow our issue template, edit the original post to include a minimal example, the actual output, and the expected output. Uniformity in issue reports is valuable.

If an older issue lacks a reproducible example, label it as "Needs Info" and ask them to provide one (or write one yourself if possible). If one isn't provide reasonably soon, close it according to the policies in *Closing issues*.

4.3.7 Cleaning up old pull requests

Occasionally, contributors are unable to finish off a pull request. If some time has passed (two weeks, say) since the last review requesting changes, gently ask if they're still interested in working on this. If another two weeks or so passes with no response, thank them for their work and close the pull request. Comment on the original issue that "There's a stalled PR at #1234 that may be helpful.", and perhaps label the issue as "Good first issue" if the PR was relatively close to being accepted.

Additionally, core-team members can push to contributors branches. This can be helpful for pushing an important PR across the line, or for fixing a small merge conflict.

4.3.8 Becoming a pandas maintainer

The full process is outlined in our governance documents. In summary, we're happy to give triage permissions to anyone who shows interest by being helpful on the issue tracker.

The current list of core-team members is at https://github.com/pandas-dev/pandas-governance/blob/master/people.md

4.4 Internals

This section will provide a look into some of pandas internals. It's primarily intended for developers of pandas itself.

4.4.1 Indexing

In pandas there are a few objects implemented which can serve as valid containers for the axis labels:

- `Index`: the generic "ordered set" object, an ndarray of object dtype assuming nothing about its contents. The labels must be hashable (and likely immutable) and unique. Populates a dict of label to location in Cython to do `O(1)` lookups.
- `Int64Index`: a version of `Index` highly optimized for 64-bit integer data, such as time stamps
- `Float64Index`: a version of `Index` highly optimized for 64-bit float data
- `MultiIndex`: the standard hierarchical index object
- `DatetimeIndex`: An Index object with `Timestamp` boxed elements (impl are the int64 values)
- `TimedeltaIndex`: An Index object with `Timedelta` boxed elements (impl are the in64 values)
- `PeriodIndex`: An Index object with Period elements

There are functions that make the creation of a regular index easy:

- `date_range`: fixed frequency date range generated from a time rule or DateOffset. An ndarray of Python datetime objects
- `period_range`: fixed frequency date range generated from a time rule or DateOffset. An ndarray of `Period` objects, representing timespans

The motivation for having an `Index` class in the first place was to enable different implementations of indexing. This means that it's possible for you, the user, to implement a custom `Index` subclass that may be better suited to a particular application than the ones provided in pandas.

From an internal implementation point of view, the relevant methods that an `Index` must define are one or more of the following (depending on how incompatible the new object internals are with the `Index` functions):

- `get_loc`: returns an "indexer" (an integer, or in some cases a slice object) for a label

- `slice_locs`: returns the "range" to slice between two labels
- `get_indexer`: Computes the indexing vector for reindexing / data alignment purposes. See the source / docstrings for more on this
- `get_indexer_non_unique`: Computes the indexing vector for reindexing / data alignment purposes when the index is non-unique. See the source / docstrings for more on this
- `reindex`: Does any pre-conversion of the input index then calls `get_indexer`
- `union`, `intersection`: computes the union or intersection of two Index objects
- `insert`: Inserts a new label into an Index, yielding a new object
- `delete`: Delete a label, yielding a new object
- `drop`: Deletes a set of labels
- `take`: Analogous to ndarray.take

MultiIndex

Internally, the `MultiIndex` consists of a few things: the **levels**, the integer **codes** (until version 0.24 named *labels*), and the level **names**:

```
In [1]: index = pd.MultiIndex.from_product([range(3), ['one', 'two']],
   ...:                                    names=['first', 'second'])
   ...:

In [2]: index
Out[2]:
MultiIndex([(0, 'one'),
            (0, 'two'),
            (1, 'one'),
            (1, 'two'),
            (2, 'one'),
            (2, 'two')],
           names=['first', 'second'])

In [3]: index.levels
Out[3]: FrozenList([[0, 1, 2], ['one', 'two']])

In [4]: index.codes
Out[4]: FrozenList([[0, 0, 1, 1, 2, 2], [0, 1, 0, 1, 0, 1]])

In [5]: index.names
Out[5]: FrozenList(['first', 'second'])
```

You can probably guess that the codes determine which unique element is identified with that location at each layer of the index. It's important to note that sortedness is determined **solely** from the integer codes and does not check (or care) whether the levels themselves are sorted. Fortunately, the constructors `from_tuples` and `from_arrays` ensure that this is true, but if you compute the levels and codes yourself, please be careful.

Values

pandas extends NumPy's type system with custom types, like `Categorical` or datetimes with a timezone, so we have multiple notions of "values". For 1-D containers (`Index` classes and `Series`) we have the following convention:

- `cls._values` refers is the "best possible" array. This could be an `ndarray` or `ExtensionArray`.

So, for example, `Series[category]._values` is a `Categorical`.

4.4.2 Subclassing pandas data structures

This section has been moved to *Subclassing pandas data structures*.

4.5 Extending pandas

While pandas provides a rich set of methods, containers, and data types, your needs may not be fully satisfied. pandas offers a few options for extending pandas.

4.5.1 Registering custom accessors

Libraries can use the decorators *pandas.api.extensions.register_dataframe_accessor()*, *pandas.api.extensions.register_series_accessor()*, and *pandas.api.extensions.register_index_accessor()*, to add additional "namespaces" to pandas objects. All of these follow a similar convention: you decorate a class, providing the name of attribute to add. The class's `__init__` method gets the object being decorated. For example:

```
@pd.api.extensions.register_dataframe_accessor("geo")
class GeoAccessor:
    def __init__(self, pandas_obj):
        self._validate(pandas_obj)
        self._obj = pandas_obj

    @staticmethod
    def _validate(obj):
        # verify there is a column latitude and a column longitude
        if 'latitude' not in obj.columns or 'longitude' not in obj.columns:
            raise AttributeError("Must have 'latitude' and 'longitude'.")

    @property
    def center(self):
        # return the geographic center point of this DataFrame
        lat = self._obj.latitude
        lon = self._obj.longitude
        return (float(lon.mean()), float(lat.mean()))

    def plot(self):
        # plot this array's data on a map, e.g., using Cartopy
        pass
```

Now users can access your methods using the `geo` namespace:

```
>>> ds = pd.DataFrame({'longitude': np.linspace(0, 10),
...                    'latitude': np.linspace(0, 20)})
>>> ds.geo.center
(5.0, 10.0)
>>> ds.geo.plot()
# plots data on a map
```

This can be a convenient way to extend pandas objects without subclassing them. If you write a custom accessor, make a pull request adding it to our ecosystem page.

We highly recommend validating the data in your accessor's *__init__*. In our `GeoAccessor`, we validate that the data contains the expected columns, raising an `AttributeError` when the validation fails. For a `Series` accessor, you should validate the `dtype` if the accessor applies only to certain dtypes.

4.5.2 Extension types

New in version 0.23.0.

Warning: The *pandas.api.extensions.ExtensionDtype* and *pandas.api.extensions.ExtensionArray* APIs are new and experimental. They may change between versions without warning.

pandas defines an interface for implementing data types and arrays that *extend* NumPy's type system. pandas itself uses the extension system for some types that aren't built into NumPy (categorical, period, interval, datetime with timezone).

Libraries can define a custom array and data type. When pandas encounters these objects, they will be handled properly (i.e. not converted to an ndarray of objects). Many methods like *pandas.isna()* will dispatch to the extension type's implementation.

If you're building a library that implements the interface, please publicize it on ecosystem.extensions.

The interface consists of two classes.

ExtensionDtype

A *pandas.api.extensions.ExtensionDtype* is similar to a `numpy.dtype` object. It describes the data type. Implementors are responsible for a few unique items like the name.

One particularly important item is the `type` property. This should be the class that is the scalar type for your data. For example, if you were writing an extension array for IP Address data, this might be `ipaddress.IPv4Address`.

See the extension dtype source for interface definition.

New in version 0.24.0.

`pandas.api.extension.ExtensionDtype` can be registered to pandas to allow creation via a string dtype name. This allows one to instantiate `Series` and `.astype()` with a registered string name, for example `'category'` is a registered string accessor for the `CategoricalDtype`.

See the extension dtype dtypes for more on how to register dtypes.

ExtensionArray

This class provides all the array-like functionality. ExtensionArrays are limited to 1 dimension. An ExtensionArray is linked to an ExtensionDtype via the `dtype` attribute.

pandas makes no restrictions on how an extension array is created via its `__new__` or `__init__`, and puts no restrictions on how you store your data. We do require that your array be convertible to a NumPy array, even if this is relatively expensive (as it is for `Categorical`).

They may be backed by none, one, or many NumPy arrays. For example, `pandas.Categorical` is an extension array backed by two arrays, one for codes and one for categories. An array of IPv6 addresses may be backed by a NumPy structured array with two fields, one for the lower 64 bits and one for the upper 64 bits. Or they may be backed by some other storage type, like Python lists.

See the extension array source for the interface definition. The docstrings and comments contain guidance for properly implementing the interface.

ExtensionArray operator support

New in version 0.24.0.

By default, there are no operators defined for the class *ExtensionArray*. There are two approaches for providing operator support for your ExtensionArray:

1. Define each of the operators on your `ExtensionArray` subclass.
2. Use an operator implementation from pandas that depends on operators that are already defined on the underlying elements (scalars) of the ExtensionArray.

Note: Regardless of the approach, you may want to set `__array_priority__` if you want your implementation to be called when involved in binary operations with NumPy arrays.

For the first approach, you define selected operators, e.g., `__add__`, `__le__`, etc. that you want your `ExtensionArray` subclass to support.

The second approach assumes that the underlying elements (i.e., scalar type) of the `ExtensionArray` have the individual operators already defined. In other words, if your `ExtensionArray` named `MyExtensionArray` is implemented so that each element is an instance of the class `MyExtensionElement`, then if the operators are defined for `MyExtensionElement`, the second approach will automatically define the operators for `MyExtensionArray`.

A mixin class, `ExtensionScalarOpsMixin` supports this second approach. If developing an `ExtensionArray` subclass, for example `MyExtensionArray`, can simply include `ExtensionScalarOpsMixin` as a parent class of `MyExtensionArray`, and then call the methods `_add_arithmetic_ops()` and/or `_add_comparison_ops()` to hook the operators into your `MyExtensionArray` class, as follows:

```
from pandas.api.extensions import ExtensionArray, ExtensionScalarOpsMixin

class MyExtensionArray(ExtensionArray, ExtensionScalarOpsMixin):
    pass

MyExtensionArray._add_arithmetic_ops()
MyExtensionArray._add_comparison_ops()
```

Note: Since `pandas` automatically calls the underlying operator on each element one-by-one, this might not be as performant as implementing your own version of the associated operators directly on the `ExtensionArray`.

For arithmetic operations, this implementation will try to reconstruct a new `ExtensionArray` with the result of the element-wise operation. Whether or not that succeeds depends on whether the operation returns a result that's valid for the `ExtensionArray`. If an `ExtensionArray` cannot be reconstructed, an ndarray containing the scalars returned instead.

For ease of implementation and consistency with operations between pandas and NumPy ndarrays, we recommend *not* handling Series and Indexes in your binary ops. Instead, you should detect these cases and return `NotImplemented`. When pandas encounters an operation like `op(Series, ExtensionArray)`, pandas will

1. unbox the array from the `Series` (`Series.array`)
2. call `result = op(values, ExtensionArray)`
3. re-box the result in a `Series`

NumPy universal functions

Series implements `__array_ufunc__`. As part of the implementation, pandas unboxes the `ExtensionArray` from the *Series*, applies the ufunc, and re-boxes it if necessary.

If applicable, we highly recommend that you implement `__array_ufunc__` in your extension array to avoid coercion to an ndarray. See the numpy documentation for an example.

As part of your implementation, we require that you defer to pandas when a pandas container (*Series*, *DataFrame*, *Index*) is detected in `inputs`. If any of those is present, you should return `NotImplemented`. pandas will take care of unboxing the array from the container and re-calling the ufunc with the unwrapped input.

Testing extension arrays

We provide a test suite for ensuring that your extension arrays satisfy the expected behavior. To use the test suite, you must provide several pytest fixtures and inherit from the base test class. The required fixtures are found in https://github.com/pandas-dev/pandas/blob/master/pandas/tests/extension/conftest.py.

To use a test, subclass it:

```
from pandas.tests.extension import base

class TestConstructors(base.BaseConstructorsTests):
    pass
```

See https://github.com/pandas-dev/pandas/blob/master/pandas/tests/extension/base/__init__.py for a list of all the tests available.

Compatibility with Apache Arrow

An `ExtensionArray` can support conversion to / from `pyarrow` arrays (and thus support for example serialization to the Parquet file format) by implementing two methods: `ExtensionArray.__arrow_array__` and `ExtensionDtype.__from_arrow__`.

The `ExtensionArray.__arrow_array__` ensures that `pyarrow` knowns how to convert the specific extension array into a `pyarrow.Array` (also when included as a column in a pandas DataFrame):

```
class MyExtensionArray(ExtensionArray):
    ...

    def __arrow_array__(self, type=None):
        # convert the underlying array values to a pyarrow Array
        import pyarrow
        return pyarrow.array(..., type=type)
```

The `ExtensionDtype.__from_arrow__` method then controls the conversion back from pyarrow to a pandas ExtensionArray. This method receives a pyarrow `Array` or `ChunkedArray` as only argument and is expected to return the appropriate pandas `ExtensionArray` for this dtype and the passed values:

```
class ExtensionDtype:
    ...

    def __from_arrow__(self, array: pyarrow.Array/ChunkedArray) -> ExtensionArray:
        ...
```

See more in the Arrow documentation.

Those methods have been implemented for the nullable integer and string extension dtypes included in pandas, and ensure roundtrip to pyarrow and the Parquet file format.

4.5.3 Subclassing pandas data structures

Warning: There are some easier alternatives before considering subclassing `pandas` data structures.

1. Extensible method chains with *pipe*
2. Use *composition*. See here.
3. Extending by *registering an accessor*
4. Extending by *extension type*

This section describes how to subclass `pandas` data structures to meet more specific needs. There are two points that need attention:

1. Override constructor properties.
2. Define original properties

Note: You can find a nice example in geopandas project.

Override constructor properties

Each data structure has several *constructor properties* for returning a new data structure as the result of an operation. By overriding these properties, you can retain subclasses through `pandas` data manipulations.

There are 3 constructor properties to be defined:

- `_constructor`: Used when a manipulation result has the same dimensions as the original.
- `_constructor_sliced`: Used when a manipulation result has one lower dimension(s) as the original, such as `DataFrame` single columns slicing.
- `_constructor_expanddim`: Used when a manipulation result has one higher dimension as the original, such as `Series.to_frame()`.

Following table shows how `pandas` data structures define constructor properties by default.

Property Attributes	`Series`	`DataFrame`
`_constructor`	`Series`	`DataFrame`
`_constructor_sliced`	`NotImplementedError`	`Series`
`_constructor_expanddim`	`DataFrame`	`NotImplementedError`

Below example shows how to define `SubclassedSeries` and `SubclassedDataFrame` overriding constructor properties.

```
class SubclassedSeries(pd.Series):

    @property
    def _constructor(self):
        return SubclassedSeries

    @property
    def _constructor_expanddim(self):
        return SubclassedDataFrame

class SubclassedDataFrame(pd.DataFrame):

    @property
    def _constructor(self):
        return SubclassedDataFrame

    @property
    def _constructor_sliced(self):
        return SubclassedSeries
```

```
>>> s = SubclassedSeries([1, 2, 3])
>>> type(s)
<class '__main__.SubclassedSeries'>

>>> to_framed = s.to_frame()
>>> type(to_framed)
<class '__main__.SubclassedDataFrame'>

>>> df = SubclassedDataFrame({'A': [1, 2, 3], 'B': [4, 5, 6], 'C': [7, 8, 9]})
>>> df
   A  B  C
0  1  4  7
```

(continues on next page)

(continued from previous page)

```
1  2  5  8
2  3  6  9

>>> type(df)
<class '__main__.SubclassedDataFrame'>

>>> sliced1 = df[['A', 'B']]
>>> sliced1
   A  B
0  1  4
1  2  5
2  3  6

>>> type(sliced1)
<class '__main__.SubclassedDataFrame'>

>>> sliced2 = df['A']
>>> sliced2
0    1
1    2
2    3
Name: A, dtype: int64

>>> type(sliced2)
<class '__main__.SubclassedSeries'>
```

Define original properties

To let original data structures have additional properties, you should let `pandas` know what properties are added. `pandas` maps unknown properties to data names overriding `__getattribute__`. Defining original properties can be done in one of 2 ways:

1. Define `_internal_names` and `_internal_names_set` for temporary properties which WILL NOT be passed to manipulation results.
2. Define `_metadata` for normal properties which will be passed to manipulation results.

Below is an example to define two original properties, "internal_cache" as a temporary property and "added_property" as a normal property

```
class SubclassedDataFrame2(pd.DataFrame):

    # temporary properties
    _internal_names = pd.DataFrame._internal_names + ['internal_cache']
    _internal_names_set = set(_internal_names)

    # normal properties
    _metadata = ['added_property']

    @property
    def _constructor(self):
        return SubclassedDataFrame2
```

```
>>> df = SubclassedDataFrame2({'A': [1, 2, 3], 'B': [4, 5, 6], 'C': [7, 8, 9]})
>>> df
```

(continues on next page)

(continued from previous page)

```
   A  B  C
0  1  4  7
1  2  5  8
2  3  6  9

>>> df.internal_cache = 'cached'
>>> df.added_property = 'property'

>>> df.internal_cache
cached
>>> df.added_property
property

# properties defined in _internal_names is reset after manipulation
>>> df[['A', 'B']].internal_cache
AttributeError: 'SubclassedDataFrame2' object has no attribute 'internal_cache'

# properties defined in _metadata are retained
>>> df[['A', 'B']].added_property
property
```

4.5.4 Plotting backends

Starting in 0.25 pandas can be extended with third-party plotting backends. The main idea is letting users select a plotting backend different than the provided one based on Matplotlib. For example:

```
>>> pd.set_option('plotting.backend', 'backend.module')
>>> pd.Series([1, 2, 3]).plot()
```

This would be more or less equivalent to:

```
>>> import backend.module
>>> backend.module.plot(pd.Series([1, 2, 3]))
```

The backend module can then use other visualization tools (Bokeh, Altair,...) to generate the plots.

Libraries implementing the plotting backend should use entry points to make their backend discoverable to pandas. The key is `"pandas_plotting_backends"`. For example, pandas registers the default "matplotlib" backend as follows.

```
# in setup.py
setup(  # noqa: F821
    ...,
    entry_points={
        "pandas_plotting_backends": [
            "matplotlib = pandas:plotting._matplotlib",
        ],
    },
)
```

More information on how to implement a third-party plotting backend can be found at https://github.com/pandas-dev/pandas/blob/master/pandas/plotting/__init__.py#L1.

4.6 Developer

This section will focus on downstream applications of pandas.

4.6.1 Storing pandas DataFrame objects in Apache Parquet format

The Apache Parquet format provides key-value metadata at the file and column level, stored in the footer of the Parquet file:

```
5: optional list<KeyValue> key_value_metadata
```

where `KeyValue` is

```
struct KeyValue {
  1: required string key
  2: optional string value
}
```

So that a `pandas.DataFrame` can be faithfully reconstructed, we store a `pandas` metadata key in the `FileMetaData` with the value stored as :

```
{'index_columns': [<descr0>, <descr1>, ...],
 'column_indexes': [<ci0>, <ci1>, ..., <ciN>],
 'columns': [<c0>, <c1>, ...],
 'pandas_version': $VERSION,
 'creator': {
   'library': $LIBRARY,
   'version': $LIBRARY_VERSION
 }}
```

The "descriptor" values `<descr0>` in the `'index_columns'` field are strings (referring to a column) or dictionaries with values as described below.

The `<c0>`/`<ci0>` and so forth are dictionaries containing the metadata for each column, *including the index columns*. This has JSON form:

```
{'name': column_name,
 'field_name': parquet_column_name,
 'pandas_type': pandas_type,
 'numpy_type': numpy_type,
 'metadata': metadata}
```

See below for the detailed specification for these.

Index metadata descriptors

`RangeIndex` can be stored as metadata only, not requiring serialization. The descriptor format for these as is follows:

```
index = pd.RangeIndex(0, 10, 2)
{'kind': 'range',
 'name': index.name,
 'start': index.start,
 'stop': index.stop,
 'step': index.step}
```

Other index types must be serialized as data columns along with the other DataFrame columns. The metadata for these is a string indicating the name of the field in the data columns, for example `'__index_level_0__'`.

If an index has a non-None `name` attribute, and there is no other column with a name matching that value, then the `index.name` value can be used as the descriptor. Otherwise (for unnamed indexes and ones with names colliding with other column names) a disambiguating name with pattern matching `__index_level_\d+__` should be used. In cases of named indexes as data columns, `name` attribute is always stored in the column descriptors as above.

Column metadata

`pandas_type` is the logical type of the column, and is one of:

- Boolean: `'bool'`
- Integers: `'int8', 'int16', 'int32', 'int64', 'uint8', 'uint16', 'uint32', 'uint64'`
- Floats: `'float16', 'float32', 'float64'`
- Date and Time Types: `'datetime', 'datetimetz', 'timedelta'`
- String: `'unicode', 'bytes'`
- Categorical: `'categorical'`
- Other Python objects: `'object'`

The `numpy_type` is the physical storage type of the column, which is the result of `str(dtype)` for the underlying NumPy array that holds the data. So for `datetimetz` this is `datetime64[ns]` and for categorical, it may be any of the supported integer categorical types.

The `metadata` field is `None` except for:

- `datetimetz`: `{'timezone': zone, 'unit': 'ns'}`, e.g. `{'timezone', 'America/New_York', 'unit': 'ns'}`. The `'unit'` is optional, and if omitted it is assumed to be nanoseconds.
- `categorical`: `{'num_categories': K, 'ordered': is_ordered, 'type': $TYPE}`
  - Here `'type'` is optional, and can be a nested pandas type specification here (but not categorical)
- `unicode`: `{'encoding': encoding}`
  - The encoding is optional, and if not present is UTF-8
- `object`: `{'encoding': encoding}`. Objects can be serialized and stored in `BYTE_ARRAY` Parquet columns. The encoding can be one of:
  - `'pickle'`
  - `'bson'`
  - `'json'`
- `timedelta`: `{'unit': 'ns'}`. The `'unit'` is optional, and if omitted it is assumed to be nanoseconds. This metadata is optional altogether

For types other than these, the `'metadata'` key can be omitted. Implementations can assume `None` if the key is not present.

As an example of fully-formed metadata:

```
{'index_columns': ['__index_level_0__'],
 'column_indexes': [
     {'name': None,
      'field_name': 'None',
      'pandas_type': 'unicode',
      'numpy_type': 'object',
      'metadata': {'encoding': 'UTF-8'}}
 ],
 'columns': [
     {'name': 'c0',
      'field_name': 'c0',
      'pandas_type': 'int8',
      'numpy_type': 'int8',
      'metadata': None},
     {'name': 'c1',
      'field_name': 'c1',
      'pandas_type': 'bytes',
      'numpy_type': 'object',
      'metadata': None},
     {'name': 'c2',
      'field_name': 'c2',
      'pandas_type': 'categorical',
      'numpy_type': 'int16',
      'metadata': {'num_categories': 1000, 'ordered': False}},
     {'name': 'c3',
      'field_name': 'c3',
      'pandas_type': 'datetimetz',
      'numpy_type': 'datetime64[ns]',
      'metadata': {'timezone': 'America/Los_Angeles'}},
     {'name': 'c4',
      'field_name': 'c4',
      'pandas_type': 'object',
      'numpy_type': 'object',
      'metadata': {'encoding': 'pickle'}},
     {'name': None,
      'field_name': '__index_level_0__',
      'pandas_type': 'int64',
      'numpy_type': 'int64',
      'metadata': None}
 ],
 'pandas_version': '0.20.0',
 'creator': {
   'library': 'pyarrow',
   'version': '0.13.0'
 }}
```

4.7 Policies

4.7.1 Version policy

Changed in version 1.0.0.

pandas uses a loose variant of semantic versioning (SemVer) to govern deprecations, API compatibility, and version numbering.

A pandas release number is made up of `MAJOR.MINOR.PATCH`.

API breaking changes should only occur in **major** releases. Theses changes will be documented, with clear guidance on what is changing, why it's changing, and how to migrate existing code to the new behavior.

Whenever possible, a deprecation path will be provided rather than an outright breaking change.

pandas will introduce deprecations in **minor** releases. These deprecations will preserve the existing behavior while emitting a warning that provide guidance on:

- How to achieve similar behavior if an alternative is available
- The pandas version in which the deprecation will be enforced.

We will not introduce new deprecations in patch releases.

Deprecations will only be enforced in **major** releases. For example, if a behavior is deprecated in pandas 1.2.0, it will continue to work, with a warning, for all releases in the 1.x series. The behavior will change and the deprecation removed in the next next major release (2.0.0).

Note: pandas will sometimes make *behavior changing* bug fixes, as part of minor or patch releases. Whether or not a change is a bug fix or an API-breaking change is a judgement call. We'll do our best, and we invite you to participate in development discussion on the issue tracker or mailing list.

These policies do not apply to features marked as **experimental** in the documentation. pandas may change the behavior of experimental features at any time.

4.7.2 Python support

pandas will only drop support for specific Python versions (e.g. 3.6.x, 3.7.x) in pandas **major** releases.

4.8 Roadmap

This page provides an overview of the major themes in pandas' development. Each of these items requires a relatively large amount of effort to implement. These may be achieved more quickly with dedicated funding or interest from contributors.

An item being on the roadmap does not mean that it will *necessarily* happen, even with unlimited funding. During the implementation period we may discover issues preventing the adoption of the feature.

Additionally, an item *not* being on the roadmap does not exclude it from inclusion in pandas. The roadmap is intended for larger, fundamental changes to the project that are likely to take months or years of developer time. Smaller-scoped items will continue to be tracked on our issue tracker.

See *Roadmap evolution* for proposing changes to this document.

4.8.1 Extensibility

pandas *Extension types* allow for extending NumPy types with custom data types and array storage. pandas uses extension types internally, and provides an interface for 3rd-party libraries to define their own custom data types.

Many parts of pandas still unintentionally convert data to a NumPy array. These problems are especially pronounced for nested data.

We'd like to improve the handling of extension arrays throughout the library, making their behavior more consistent with the handling of NumPy arrays. We'll do this by cleaning up pandas' internals and adding new methods to the extension array interface.

4.8.2 String data type

Currently, pandas stores text data in an `object` -dtype NumPy array. The current implementation has two primary drawbacks: First, `object` -dtype is not specific to strings: any Python object can be stored in an `object` -dtype array, not just strings. Second: this is not efficient. The NumPy memory model isn't especially well-suited to variable width text data.

To solve the first issue, we propose a new extension type for string data. This will initially be opt-in, with users explicitly requesting `dtype="string"`. The array backing this string dtype may initially be the current implementation: an `object` -dtype NumPy array of Python strings.

To solve the second issue (performance), we'll explore alternative in-memory array libraries (for example, Apache Arrow). As part of the work, we may need to implement certain operations expected by pandas users (for example the algorithm used in, `Series.str.upper`). That work may be done outside of pandas.

4.8.3 Apache Arrow interoperability

Apache Arrow is a cross-language development platform for in-memory data. The Arrow logical types are closely aligned with typical pandas use cases.

We'd like to provide better-integrated support for Arrow memory and data types within pandas. This will let us take advantage of its I/O capabilities and provide for better interoperability with other languages and libraries using Arrow.

4.8.4 Block manager rewrite

We'd like to replace pandas current internal data structures (a collection of 1 or 2-D arrays) with a simpler collection of 1-D arrays.

pandas internal data model is quite complex. A DataFrame is made up of one or more 2-dimensional "blocks", with one or more blocks per dtype. This collection of 2-D arrays is managed by the BlockManager.

The primary benefit of the BlockManager is improved performance on certain operations (construction from a 2D array, binary operations, reductions across the columns), especially for wide DataFrames. However, the BlockManager substantially increases the complexity and maintenance burden of pandas.

By replacing the BlockManager we hope to achieve

- Substantially simpler code
- Easier extensibility with new logical types
- Better user control over memory use and layout
- Improved micro-performance
- Option to provide a C / Cython API to pandas' internals

See these design documents for more.

4.8.5 Decoupling of indexing and internals

The code for getting and setting values in pandas' data structures needs refactoring. In particular, we must clearly separate code that converts keys (e.g., the argument to `DataFrame.loc`) to positions from code that uses these positions to get or set values. This is related to the proposed BlockManager rewrite. Currently, the BlockManager sometimes uses label-based, rather than position-based, indexing. We propose that it should only work with positional indexing, and the translation of keys to positions should be entirely done at a higher level.

Indexing is a complicated API with many subtleties. This refactor will require care and attention. More details are discussed at https://github.com/pandas-dev/pandas/wiki/(Tentative)-rules-for-restructuring-indexing-code

4.8.6 Numba-accelerated operations

Numba is a JIT compiler for Python code. We'd like to provide ways for users to apply their own Numba-jitted functions where pandas accepts user-defined functions (for example, `Series.apply()`, `DataFrame.apply()`, `DataFrame.applymap()`, and in groupby and window contexts). This will improve the performance of user-defined-functions in these operations by staying within compiled code.

4.8.7 Documentation improvements

We'd like to improve the content, structure, and presentation of the pandas documentation. Some specific goals include

- Overhaul the HTML theme with a modern, responsive design (GH15556)
- Improve the "Getting Started" documentation, designing and writing learning paths for users different backgrounds (e.g. brand new to programming, familiar with other languages like R, already familiar with Python).
- Improve the overall organization of the documentation and specific subsections of the documentation to make navigation and finding content easier.

4.8.8 Performance monitoring

pandas uses airspeed velocity to monitor for performance regressions. ASV itself is a fabulous tool, but requires some additional work to be integrated into an open source project's workflow.

The asv-runner organization, currently made up of pandas maintainers, provides tools built on top of ASV. We have a physical machine for running a number of project's benchmarks, and tools managing the benchmark runs and reporting on results.

We'd like to fund improvements and maintenance of these tools to

- Be more stable. Currently, they're maintained on the nights and weekends when a maintainer has free time.
- Tune the system for benchmarks to improve stability, following https://pyperf.readthedocs.io/en/latest/system.html
- Build a GitHub bot to request ASV runs *before* a PR is merged. Currently, the benchmarks are only run nightly.

4.8.9 Roadmap evolution

pandas continues to evolve. The direction is primarily determined by community interest. Everyone is welcome to review existing items on the roadmap and to propose a new item.

Each item on the roadmap should be a short summary of a larger design proposal. The proposal should include

1. Short summary of the changes, which would be appropriate for inclusion in the roadmap if accepted.
2. Motivation for the changes.
3. An explanation of why the change is in scope for pandas.
4. Detailed design: Preferably with example-usage (even if not implemented yet) and API documentation
5. API Change: Any API changes that may result from the proposal.

That proposal may then be submitted as a GitHub issue, where the pandas maintainers can review and comment on the design. The pandas mailing list should be notified of the proposal.

When there's agreement that an implementation would be welcome, the roadmap should be updated to include the summary and a link to the discussion issue.

4.9 Developer meetings

We hold regular developer meetings on the second Wednesday of each month at 18:00 UTC. These meetings and their minutes are open to the public. All are welcome to join.

4.9.1 Minutes

The minutes of past meetings are available in this Google Document.

4.9.2 Calendar

This calendar shows all the developer meetings.

You can subscribe to this calendar with the following links:

- iCal
- Google calendar

Additionally, we'll sometimes have one-off meetings on specific topics. These will be published on the same calendar.

CHAPTER

FIVE

RELEASE NOTES

This is the list of changes to pandas between each release. For full details, see the commit logs. For install and upgrade instructions, see *Installation*.

5.1 Version 1.1

5.1.1 What's new in 1.1.1 (August 20, 2020)

These are the changes in pandas 1.1.1. See *Release notes* for a full changelog including other versions of pandas.

Fixed regressions

- Fixed regression in `CategoricalIndex.format()` where, when stringified scalars had different lengths, the shorter string would be right-filled with spaces, so it had the same length as the longest string (GH35439)
- Fixed regression in *`Series.truncate()`* when trying to truncate a single-element series (GH35544)
- Fixed regression where *`DataFrame.to_numpy()`* would raise a `RuntimeError` for mixed dtypes when converting to `str` (GH35455)
- Fixed regression where *`read_csv()`* would raise a `ValueError` when `pandas.options.mode.use_inf_as_na` was set to `True` (GH35493)
- Fixed regression where *`pandas.testing.assert_series_equal()`* would raise an error when non-numeric dtypes were passed with `check_exact=True` (GH35446)
- Fixed regression in `.groupby(..).rolling(..)` where column selection was ignored (GH35486)
- Fixed regression where *`DataFrame.interpolate()`* would raise a `TypeError` when the *`DataFrame`* was empty (GH35598)
- Fixed regression in *`DataFrame.shift()`* with `axis=1` and heterogeneous dtypes (GH35488)
- Fixed regression in *`DataFrame.diff()`* with read-only data (GH35559)
- Fixed regression in `.groupby(..).rolling(..)` where a segfault would occur with `center=True` and an odd number of values (GH35552)
- Fixed regression in *`DataFrame.apply()`* where functions that altered the input in-place only operated on a single row (GH35462)
- Fixed regression in *`DataFrame.reset_index()`* would raise a `ValueError` on empty *`DataFrame`* with a *`MultiIndex`* with a `datetime64` dtype level (GH35606, GH35657)

- Fixed regression where *pandas.merge_asof()* would raise a `UnboundLocalError` when `left_index`, `right_index` and `tolerance` were set (GH35558)
- Fixed regression in `.groupby(..).rolling(..)` where a custom `BaseIndexer` would be ignored (GH35557)
- Fixed regression in *DataFrame.replace()* and *Series.replace()* where compiled regular expressions would be ignored during replacement (GH35680)
- Fixed regression in *aggregate()* where a list of functions would produce the wrong results if at least one of the functions did not aggregate (GH35490)
- Fixed memory usage issue when instantiating large *pandas.arrays.StringArray* (GH35499)

Bug fixes

- Bug in *Styler* whereby `cell_ids` argument had no effect due to other recent changes (GH35588) (GH35663)
- Bug in *pandas.testing.assert_series_equal()* and *pandas.testing.assert_frame_equal()* where extension dtypes were not ignored when `check_dtypes` was set to `False` (GH35715)
- Bug in *to_timedelta()* fails when `arg` is a *Series* with `Int64` dtype containing null values (GH35574)
- Bug in `.groupby(..).rolling(..)` where passing `closed` with column selection would raise a `ValueError` (GH35549)
- Bug in *DataFrame* constructor failing to raise `ValueError` in some cases when `data` and `index` have mismatched lengths (GH33437)

Contributors

A total of 20 people contributed patches to this release. People with a "+" by their names contributed a patch for the first time.

5.1.2 What's new in 1.1.0 (July 28, 2020)

These are the changes in pandas 1.1.0. See *Release notes* for a full changelog including other versions of pandas.

Enhancements

KeyErrors raised by loc specify missing labels

Previously, if labels were missing for a `.loc` call, a KeyError was raised stating that this was no longer supported.

Now the error message also includes a list of the missing labels (max 10 items, display width 80 characters). See GH34272.

All dtypes can now be converted to `StringDtype`

Previously, declaring or converting to *`StringDtype`* was in general only possible if the data was already only `str` or nan-like (GH31204). *`StringDtype`* now works in all situations where `astype(str)` or `dtype=str` work:

For example, the below now works:

```
In [1]: ser = pd.Series([1, "abc", np.nan], dtype="string")

In [2]: ser
Out[2]:
0       1
1     abc
2    <NA>
Length: 3, dtype: string

In [3]: ser[0]
Out[3]: '1'

In [4]: pd.Series([1, 2, np.nan], dtype="Int64").astype("string")
Out[4]:
0       1
1       2
2    <NA>
Length: 3, dtype: string
```

Non-monotonic PeriodIndex Partial String Slicing

PeriodIndex now supports partial string slicing for non-monotonic indexes, mirroring *DatetimeIndex* behavior (GH31096)

For example:

```
In [5]: dti = pd.date_range("2014-01-01", periods=30, freq="30D")

In [6]: pi = dti.to_period("D")

In [7]: ser_monotonic = pd.Series(np.arange(30), index=pi)

In [8]: shuffler = list(range(0, 30, 2)) + list(range(1, 31, 2))

In [9]: ser = ser_monotonic[shuffler]

In [10]: ser
Out[10]:
2014-01-01     0
2014-03-02     2
2014-05-01     4
2014-06-30     6
2014-08-29     8
              ..
2015-09-23    21
2015-11-22    23
2016-01-21    25
2016-03-21    27
2016-05-20    29
Freq: D, Length: 30, dtype: int64
```

```
In [11]: ser["2014"]
Out[11]:
2014-01-01     0
2014-03-02     2
2014-05-01     4
2014-06-30     6
2014-08-29     8
2014-10-28    10
2014-12-27    12

2014-05-31     5
2014-07-30     7
2014-09-28     9
2014-11-27    11
Freq: D, Length: 13, dtype: int64

In [12]: ser.loc["May 2015"]
Out[12]:
2015-05-26    17
Freq: D, Length: 1, dtype: int64
```

Comparing two *DataFrame* or two *Series* and summarizing the differences

We've added *DataFrame.compare()* and *Series.compare()* for comparing two *DataFrame* or two *Series* (GH30429)

```
In [13]: df = pd.DataFrame(
   ....:     {
   ....:         "col1": ["a", "a", "b", "b", "a"],
   ....:         "col2": [1.0, 2.0, 3.0, np.nan, 5.0],
   ....:         "col3": [1.0, 2.0, 3.0, 4.0, 5.0]
   ....:     },
   ....:     columns=["col1", "col2", "col3"],
   ....: )
   ....:

In [14]: df
Out[14]:
  col1  col2  col3
0    a   1.0   1.0
1    a   2.0   2.0
2    b   3.0   3.0
3    b   NaN   4.0
4    a   5.0   5.0

[5 rows x 3 columns]
```

```
In [15]: df2 = df.copy()

In [16]: df2.loc[0, 'col1'] = 'c'

In [17]: df2.loc[2, 'col3'] = 4.0

In [18]: df2
Out[18]:
  col1  col2  col3
0    c   1.0   1.0
1    a   2.0   2.0
2    b   3.0   4.0
3    b   NaN   4.0
4    a   5.0   5.0

[5 rows x 3 columns]
```

```
In [19]: df.compare(df2)
Out[19]:
  col1       col3
  self other self other
0    a     c  NaN   NaN
2  NaN   NaN  3.0   4.0

[2 rows x 4 columns]
```

See *User Guide* for more details.

Allow NA in groupby key

With *groupby* , we've added a `dropna` keyword to *DataFrame.groupby()* and *Series.groupby()* in order to allow `NA` values in group keys. Users can define `dropna` to `False` if they want to include `NA` values in groupby keys. The default is set to `True` for `dropna` to keep backwards compatibility (GH3729)

```
In [20]: df_list = [[1, 2, 3], [1, None, 4], [2, 1, 3], [1, 2, 2]]

In [21]: df_dropna = pd.DataFrame(df_list, columns=["a", "b", "c"])

In [22]: df_dropna
Out[22]:
   a    b  c
0  1  2.0  3
1  1  NaN  4
2  2  1.0  3
3  1  2.0  2

[4 rows x 3 columns]
```

```
# Default `dropna` is set to True, which will exclude NaNs in keys
In [23]: df_dropna.groupby(by=["b"], dropna=True).sum()
Out[23]:
     a  c
b
1.0  2  3
2.0  2  5

[2 rows x 2 columns]

# In order to allow NaN in keys, set `dropna` to False
In [24]: df_dropna.groupby(by=["b"], dropna=False).sum()
Out[24]:
     a  c
b
1.0  2  3
2.0  2  5
NaN  1  4

[3 rows x 2 columns]
```

The default setting of `dropna` argument is `True` which means `NA` are not included in group keys.

Sorting with keys

We've added a `key` argument to the *DataFrame* and *Series* sorting methods, including *DataFrame.sort_values()*, *DataFrame.sort_index()*, *Series.sort_values()*, and *Series.sort_index()*. The `key` can be any callable function which is applied column-by-column to each column used for sorting, before sorting is performed (GH27237). See *sort_values with keys* and *sort_index with keys* for more information.

```
In [25]: s = pd.Series(['C', 'a', 'B'])

In [26]: s
Out[26]:
```

(continues on next page)

(continued from previous page)

```
0    C
1    a
2    B
Length: 3, dtype: object
```

```
In [27]: s.sort_values()
Out[27]:
2    B
0    C
1    a
Length: 3, dtype: object
```

Note how this is sorted with capital letters first. If we apply the *Series.str.lower()* method, we get

```
In [28]: s.sort_values(key=lambda x: x.str.lower())
Out[28]:
1    a
2    B
0    C
Length: 3, dtype: object
```

When applied to a *DataFrame*, they key is applied per-column to all columns or a subset if *by* is specified, e.g.

```
In [29]: df = pd.DataFrame({'a': ['C', 'C', 'a', 'a', 'B', 'B'],
   ....:                    'b': [1, 2, 3, 4, 5, 6]})
   ....:

In [30]: df
Out[30]:
   a  b
0  C  1
1  C  2
2  a  3
3  a  4
4  B  5
5  B  6

[6 rows x 2 columns]
```

```
In [31]: df.sort_values(by=['a'], key=lambda col: col.str.lower())
Out[31]:
   a  b
2  a  3
3  a  4
4  B  5
5  B  6
0  C  1
1  C  2

[6 rows x 2 columns]
```

For more details, see examples and documentation in *DataFrame.sort_values()*, *Series.sort_values()*, and *sort_index()*.

Fold argument support in Timestamp constructor

`Timestamp`: now supports the keyword-only fold argument according to PEP 495 similar to parent `datetime.datetime` class. It supports both accepting fold as an initialization argument and inferring fold from other constructor arguments (GH25057, GH31338). Support is limited to `dateutil` timezones as `pytz` doesn't support fold.

For example:

```
In [32]: ts = pd.Timestamp("2019-10-27 01:30:00+00:00")

In [33]: ts.fold
Out[33]: 0
```

```
In [34]: ts = pd.Timestamp(year=2019, month=10, day=27, hour=1, minute=30,
   ....:                   tz="dateutil/Europe/London", fold=1)
   ....:

In [35]: ts
Out[35]: Timestamp('2019-10-27 01:30:00+0000', tz='dateutil//usr/share/zoneinfo/
↪Europe/London')
```

For more on working with fold, see *Fold subsection* in the user guide.

Parsing timezone-aware format with different timezones in to_datetime

to_datetime() now supports parsing formats containing timezone names (`%Z`) and UTC offsets (`%z`) from different timezones then converting them to UTC by setting `utc=True`. This would return a *DatetimeIndex* with timezone at UTC as opposed to an *Index* with `object` dtype if `utc=True` is not set (GH32792).

For example:

```
In [36]: tz_strs = ["2010-01-01 12:00:00 +0100", "2010-01-01 12:00:00 -0100",
   ....:            "2010-01-01 12:00:00 +0300", "2010-01-01 12:00:00 +0400"]
   ....:

In [37]: pd.to_datetime(tz_strs, format='%Y-%m-%d %H:%M:%S %z', utc=True)
Out[37]:
DatetimeIndex(['2010-01-01 11:00:00+00:00', '2010-01-01 13:00:00+00:00',
               '2010-01-01 09:00:00+00:00', '2010-01-01 08:00:00+00:00'],
              dtype='datetime64[ns, UTC]', freq=None)

In [38]: pd.to_datetime(tz_strs, format='%Y-%m-%d %H:%M:%S %z')
Out[38]:
Index([2010-01-01 12:00:00+01:00, 2010-01-01 12:00:00-01:00,
       2010-01-01 12:00:00+03:00, 2010-01-01 12:00:00+04:00],
      dtype='object')
```

Grouper and resample now supports the arguments origin and offset

Grouper and *DataFrame.resample()* now supports the arguments `origin` and `offset`. It let the user control the timestamp on which to adjust the grouping. (GH31809)

The bins of the grouping are adjusted based on the beginning of the day of the time series starting point. This works well with frequencies that are multiples of a day (like *30D*) or that divides a day (like *90s* or *1min*). But it can create inconsistencies with some frequencies that do not meet this criteria. To change this behavior you can now specify a fixed timestamp with the argument `origin`.

Two arguments are now deprecated (more information in the documentation of *DataFrame.resample()*):

- `base` should be replaced by `offset`.
- `loffset` should be replaced by directly adding an offset to the index *DataFrame* after being resampled.

Small example of the use of `origin`:

```
In [39]: start, end = '2000-10-01 23:30:00', '2000-10-02 00:30:00'

In [40]: middle = '2000-10-02 00:00:00'

In [41]: rng = pd.date_range(start, end, freq='7min')

In [42]: ts = pd.Series(np.arange(len(rng)) * 3, index=rng)

In [43]: ts
Out[43]:
2000-10-01 23:30:00     0
2000-10-01 23:37:00     3
2000-10-01 23:44:00     6
2000-10-01 23:51:00     9
2000-10-01 23:58:00    12
2000-10-02 00:05:00    15
2000-10-02 00:12:00    18
2000-10-02 00:19:00    21
2000-10-02 00:26:00    24
Freq: 7T, Length: 9, dtype: int64
```

Resample with the default behavior `'start_day'` (origin is `2000-10-01 00:00:00`):

```
In [44]: ts.resample('17min').sum()
Out[44]:
2000-10-01 23:14:00     0
2000-10-01 23:31:00     9
2000-10-01 23:48:00    21
2000-10-02 00:05:00    54
2000-10-02 00:22:00    24
Freq: 17T, Length: 5, dtype: int64

In [45]: ts.resample('17min', origin='start_day').sum()
Out[45]:
2000-10-01 23:14:00     0
2000-10-01 23:31:00     9
2000-10-01 23:48:00    21
2000-10-02 00:05:00    54
2000-10-02 00:22:00    24
Freq: 17T, Length: 5, dtype: int64
```

Resample using a fixed origin:

```
In [46]: ts.resample('17min', origin='epoch').sum()
Out[46]:
2000-10-01 23:18:00     0
2000-10-01 23:35:00    18
2000-10-01 23:52:00    27
2000-10-02 00:09:00    39
2000-10-02 00:26:00    24
Freq: 17T, Length: 5, dtype: int64

In [47]: ts.resample('17min', origin='2000-01-01').sum()
Out[47]:
2000-10-01 23:24:00     3
2000-10-01 23:41:00    15
2000-10-01 23:58:00    45
2000-10-02 00:15:00    45
Freq: 17T, Length: 4, dtype: int64
```

If needed you can adjust the bins with the argument `offset` (a *Timedelta*) that would be added to the default `origin`.

For a full example, see: *Use origin or offset to adjust the start of the bins*.

fsspec now used for filesystem handling

For reading and writing to filesystems other than local and reading from HTTP(S), the optional dependency `fsspec` will be used to dispatch operations (GH33452). This will give unchanged functionality for S3 and GCS storage, which were already supported, but also add support for several other storage implementations such as Azure Datalake and Blob, SSH, FTP, dropbox and github. For docs and capabilities, see the fsspec docs.

The existing capability to interface with S3 and GCS will be unaffected by this change, as `fsspec` will still bring in the same packages as before.

Other enhancements

- Compatibility with matplotlib 3.3.0 (GH34850)
- `IntegerArray.astype()` now supports `datetime64` dtype (GH32538)
- `IntegerArray` now implements the `sum` operation (GH33172)
- Added *pandas.errors.InvalidIndexError* (GH34570).
- Added *DataFrame.value_counts()* (GH5377)
- Added a *pandas.api.indexers.FixedForwardWindowIndexer()* class to support forward-looking windows during `rolling` operations.
- Added a *pandas.api.indexers.VariableOffsetWindowIndexer()* class to support `rolling` operations with non-fixed offsets (GH34994)
- *describe()* now includes a `datetime_is_numeric` keyword to control how datetime columns are summarized (GH30164, GH34798)
- *Styler* may now render CSS more efficiently where multiple cells have the same styling (GH30876)
- *highlight_null()* now accepts `subset` argument (GH31345)
- When writing directly to a sqlite connection *DataFrame.to_sql()* now supports the `multi` method (GH29921)

- `pandas.errors.OptionError` is now exposed in `pandas.errors` (GH27553)
- Added `api.extensions.ExtensionArray.argmax()` and `api.extensions.ExtensionArray.argmin()` (GH24382)
- *`timedelta_range()`* will now infer a frequency when passed `start`, `stop`, and `periods` (GH32377)
- Positional slicing on a *`IntervalIndex`* now supports slices with `step > 1` (GH31658)
- *`Series.str`* now has a *fullmatch* method that matches a regular expression against the entire string in each row of the *`Series`*, similar to *re.fullmatch* (GH32806).
- *`DataFrame.sample()`* will now also allow array-like and BitGenerator objects to be passed to `random_state` as seeds (GH32503)
- *`Index.union()`* will now raise `RuntimeWarning` for *`MultiIndex`* objects if the object inside are unsortable. Pass `sort=False` to suppress this warning (GH33015)
- Added `Series.dt.isocalendar()` and `DatetimeIndex.isocalendar()` that returns a *`DataFrame`* with year, week, and day calculated according to the ISO 8601 calendar (GH33206, GH34392).
- The *`DataFrame.to_feather()`* method now supports additional keyword arguments (e.g. to set the compression) that are added in pyarrow 0.17 (GH33422).
- The *`cut()`* will now accept parameter `ordered` with default `ordered=True`. If `ordered=False` and no labels are provided, an error will be raised (GH33141)
- *`DataFrame.to_csv()`*, *`DataFrame.to_pickle()`*, and *`DataFrame.to_json()`* now support passing a dict of compression arguments when using the `gzip` and `bz2` protocols. This can be used to set a custom compression level, e.g., `df.to_csv(path, compression={'method': 'gzip', 'compresslevel': 1}` (GH33196)
- *`melt()`* has gained an `ignore_index` (default `True`) argument that, if set to `False`, prevents the method from dropping the index (GH17440).
- *`Series.update()`* now accepts objects that can be coerced to a *`Series`*, such as `dict` and `list`, mirroring the behavior of *`DataFrame.update()`* (GH33215)
- *`transform()`* and *`aggregate()`* have gained `engine` and `engine_kwargs` arguments that support executing functions with `Numba` (GH32854, GH33388)
- *`interpolate()`* now supports SciPy interpolation method `scipy.interpolate.CubicSpline` as method `cubicspline` (GH33670)
- `DataFrameGroupBy` and `SeriesGroupBy` now implement the `sample` method for doing random sampling within groups (GH31775)
- *`DataFrame.to_numpy()`* now supports the `na_value` keyword to control the NA sentinel in the output array (GH33820)
- Added `api.extension.ExtensionArray.equals` to the extension array interface, similar to *`Series.equals()`* (GH27081)
- The minimum supported dta version has increased to 105 in *`read_stata()`* and `StataReader` (GH26667).
- *`to_stata()`* supports compression using the `compression` keyword argument. Compression can either be inferred or explicitly set using a string or a dictionary containing both the method and any additional arguments that are passed to the compression library. Compression was also added to the low-level Stata-file writers `StataWriter`, `StataWriter117`, and `StataWriterUTF8` (GH26599).
- *`HDFStore.put()`* now accepts a `track_times` parameter. This parameter is passed to the `create_table` method of `PyTables` (GH32682).

- *Series.plot()* and *DataFrame.plot()* now accepts *xlabel* and *ylabel* parameters to present labels on x and y axis (GH9093).
- Made `pandas.core.window.rolling.Rolling` and `pandas.core.window.expanding.Expanding` iterableGH11704)
- Made `option_context` a `contextlib.ContextDecorator`, which allows it to be used as a decorator over an entire function (GH34253).
- *DataFrame.to_csv()* and *Series.to_csv()* now accept an `errors` argument (GH22610)
- `transform()` now allows `func` to be `pad`, `backfill` and `cumcount` (GH31269).
- *read_json()* now accepts an `nrows` parameter. (GH33916).
- *DataFrame.hist()*, *Series.hist()*, *core.groupby.DataFrameGroupBy.hist()*, and *core.groupby.SeriesGroupBy.hist()* have gained the `legend` argument. Set to True to show a legend in the histogram. (GH6279)
- *concat()* and *append()* now preserve extension dtypes, for example combining a nullable integer column with a numpy integer column will no longer result in object dtype but preserve the integer dtype (GH33607, GH34339, GH34095).
- *read_gbq()* now allows to disable progress bar (GH33360).
- *read_gbq()* now supports the `max_results` kwarg from `pandas-gbq` (GH34639).
- *DataFrame.cov()* and *Series.cov()* now support a new parameter `ddof` to support delta degrees of freedom as in the corresponding numpy methods (GH34611).
- *DataFrame.to_html()* and *DataFrame.to_string()*'s `col_space` parameter now accepts a list or dict to change only some specific columns' width (GH28917).
- *DataFrame.to_excel()* can now also write OpenOffice spreadsheet (.ods) files (GH27222)
- *explode()* now accepts `ignore_index` to reset the index, similar to `pd.concat()` or *DataFrame.sort_values()* (GH34932).
- *DataFrame.to_markdown()* and *Series.to_markdown()* now accept `index` argument as an alias for tabulate's `showindex` (GH32667)
- *read_csv()* now accepts string values like "0", "0.0", "1", "1.0" as convertible to the nullable Boolean dtype (GH34859)
- `pandas.core.window.ExponentialMovingWindow` now supports a `times` argument that allows `mean` to be calculated with observations spaced by the timestamps in `times` (GH34839)
- *DataFrame.agg()* and *Series.agg()* now accept named aggregation for renaming the output columns/indexes. (GH26513)
- `compute.use_numba` now exists as a configuration option that utilizes the numba engine when available (GH33966, GH35374)
- *Series.plot()* now supports asymmetric error bars. Previously, if *Series.plot()* received a "2xN" array with error values for *yerr* and/or *xerr*, the left/lower values (first row) were mirrored, while the right/upper values (second row) were ignored. Now, the first row represents the left/lower error values and the second row the right/upper error values. (GH9536)

Notable bug fixes

These are bug fixes that might have notable behavior changes.

`MultiIndex.get_indexer` interprets `method` argument correctly

This restores the behavior of *`MultiIndex.get_indexer()`* with `method='backfill'` or `method='pad'` to the behavior before pandas 0.23.0. In particular, MultiIndexes are treated as a list of tuples and padding or backfilling is done with respect to the ordering of these lists of tuples (GH29896).

As an example of this, given:

```
In [48]: df = pd.DataFrame({
   ....:     'a': [0, 0, 0, 0],
   ....:     'b': [0, 2, 3, 4],
   ....:     'c': ['A', 'B', 'C', 'D'],
   ....: }).set_index(['a', 'b'])
   ....:

In [49]: mi_2 = pd.MultiIndex.from_product([[0], [-1, 0, 1, 3, 4, 5]])
```

The differences in reindexing `df` with `mi_2` and using `method='backfill'` can be seen here:

pandas >= 0.23, < 1.1.0:

```
In [1]: df.reindex(mi_2, method='backfill')
Out[1]:
      c
0 -1  A
   0  A
   1  D
   3  A
   4  A
   5  C
```

pandas <0.23, >= 1.1.0

```
In [50]: df.reindex(mi_2, method='backfill')
Out[50]:
        c
0 -1    A
   0    A
   1    B
   3    C
   4    D
   5  NaN

[6 rows x 1 columns]
```

And the differences in reindexing `df` with `mi_2` and using `method='pad'` can be seen here:

pandas >= 0.23, < 1.1.0

```
In [1]: df.reindex(mi_2, method='pad')
Out[1]:
        c
0 -1  NaN
```

(continues on next page)

(continued from previous page)

```
   0  NaN
   1    D
   3  NaN
   4    A
   5    C
```

pandas < 0.23, >= 1.1.0

```
In [51]: df.reindex(mi_2, method='pad')
Out[51]:
        c
0 -1  NaN
   0    A
   1    A
   3    C
   4    D
   5    D

[6 rows x 1 columns]
```

Failed Label-Based Lookups Always Raise KeyError

Label lookups `series[key]`, `series.loc[key]` and `frame.loc[key]` used to raise either `KeyError` or `TypeError` depending on the type of key and type of *`Index`*. These now consistently raise `KeyError` (GH31867)

```
In [52]: ser1 = pd.Series(range(3), index=[0, 1, 2])

In [53]: ser2 = pd.Series(range(3), index=pd.date_range("2020-02-01", periods=3))
```

Previous behavior:

```
In [3]: ser1[1.5]
...
TypeError: cannot do label indexing on Int64Index with these indexers [1.5] of type␣
↪float

In [4] ser1["foo"]
...
KeyError: 'foo'

In [5]: ser1.loc[1.5]
...
TypeError: cannot do label indexing on Int64Index with these indexers [1.5] of type␣
↪float

In [6]: ser1.loc["foo"]
...
KeyError: 'foo'

In [7]: ser2.loc[1]
...
TypeError: cannot do label indexing on DatetimeIndex with these indexers [1] of type␣
↪int

In [8]: ser2.loc[pd.Timestamp(0)]
```

(continues on next page)

(continued from previous page)

```
...
KeyError: Timestamp('1970-01-01 00:00:00')
```

New behavior:

```
In [3]: ser1[1.5]
...
KeyError: 1.5

In [4] ser1["foo"]
...
KeyError: 'foo'

In [5]: ser1.loc[1.5]
...
KeyError: 1.5

In [6]: ser1.loc["foo"]
...
KeyError: 'foo'

In [7]: ser2.loc[1]
...
KeyError: 1

In [8]: ser2.loc[pd.Timestamp(0)]
...
KeyError: Timestamp('1970-01-01 00:00:00')
```

Similarly, *DataFrame.at()* and *Series.at()* will raise a `TypeError` instead of a `ValueError` if an incompatible key is passed, and `KeyError` if a missing key is passed, matching the behavior of `.loc[]` (GH31722)

Failed Integer Lookups on MultiIndex Raise KeyError

Indexing with integers with a *MultiIndex* that has an integer-dtype first level incorrectly failed to raise `KeyError` when one or more of those integer keys is not present in the first level of the index (GH33539)

```
In [54]: idx = pd.Index(range(4))

In [55]: dti = pd.date_range("2000-01-03", periods=3)

In [56]: mi = pd.MultiIndex.from_product([idx, dti])

In [57]: ser = pd.Series(range(len(mi)), index=mi)
```

Previous behavior:

```
In [5]: ser[[5]]
Out[5]: Series([], dtype: int64)
```

New behavior:

```
In [5]: ser[[5]]
...
KeyError: '[5] not in index'
```

`DataFrame.merge()` preserves right frame's row order

`DataFrame.merge()` now preserves the right frame's row order when executing a right merge (GH27453)

```
In [58]: left_df = pd.DataFrame({'animal': ['dog', 'pig'],
   ....:                         'max_speed': [40, 11]})
   ....:

In [59]: right_df = pd.DataFrame({'animal': ['quetzal', 'pig'],
   ....:                          'max_speed': [80, 11]})
   ....:

In [60]: left_df
Out[60]:
  animal  max_speed
0    dog         40
1    pig         11

[2 rows x 2 columns]

In [61]: right_df
Out[61]:
    animal  max_speed
0  quetzal         80
1      pig         11

[2 rows x 2 columns]
```

Previous behavior:

```
>>> left_df.merge(right_df, on=['animal', 'max_speed'], how="right")
    animal  max_speed
0      pig         11
1  quetzal         80
```

New behavior:

```
In [62]: left_df.merge(right_df, on=['animal', 'max_speed'], how="right")
Out[62]:
    animal  max_speed
0  quetzal         80
1      pig         11

[2 rows x 2 columns]
```

Assignment to multiple columns of a DataFrame when some columns do not exist

Assignment to multiple columns of a *`DataFrame`* when some of the columns do not exist would previously assign the values to the last column. Now, new columns will be constructed with the right values. (GH13658)

```
In [63]: df = pd.DataFrame({'a': [0, 1, 2], 'b': [3, 4, 5]})

In [64]: df
Out[64]:
   a  b
```

(continues on next page)

(continued from previous page)

```
0  0  3
1  1  4
2  2  5

[3 rows x 2 columns]
```

Previous behavior:

```
In [3]: df[['a', 'c']] = 1
In [4]: df
Out[4]:
   a  b
0  1  1
1  1  1
2  1  1
```

New behavior:

```
In [65]: df[['a', 'c']] = 1

In [66]: df
Out[66]:
   a  b  c
0  1  3  1
1  1  4  1
2  1  5  1

[3 rows x 3 columns]
```

Consistency across groupby reductions

Using *DataFrame.groupby()* with `as_index=True` and the aggregation `nunique` would include the grouping column(s) in the columns of the result. Now the grouping column(s) only appear in the index, consistent with other reductions. (GH32579)

```
In [67]: df = pd.DataFrame({"a": ["x", "x", "y", "y"], "b": [1, 1, 2, 3]})

In [68]: df
Out[68]:
   a  b
0  x  1
1  x  1
2  y  2
3  y  3

[4 rows x 2 columns]
```

Previous behavior:

```
In [3]: df.groupby("a", as_index=True).nunique()
Out[4]:
   a  b
a
x  1  1
y  1  2
```

New behavior:

```
In [69]: df.groupby("a", as_index=True).nunique()
Out[69]:
   b
a
x  1
y  2

[2 rows x 1 columns]
```

Using *DataFrame.groupby()* with `as_index=False` and the function `idxmax`, `idxmin`, `mad`, `nunique`, `sem`, `skew`, or `std` would modify the grouping column. Now the grouping column remains unchanged, consistent with other reductions. (GH21090, GH10355)

Previous behavior:

```
In [3]: df.groupby("a", as_index=False).nunique()
Out[4]:
   a  b
0  1  1
1  1  2
```

New behavior:

```
In [70]: df.groupby("a", as_index=False).nunique()
Out[70]:
   a  b
0  x  1
1  y  2

[2 rows x 2 columns]
```

The method *size()* would previously ignore `as_index=False`. Now the grouping columns are returned as columns, making the result a *DataFrame* instead of a *Series*. (GH32599)

Previous behavior:

```
In [3]: df.groupby("a", as_index=False).size()
Out[4]:
a
x    2
y    2
dtype: int64
```

New behavior:

```
In [71]: df.groupby("a", as_index=False).size()
Out[71]:
   a  size
0  x     2
1  y     2

[2 rows x 2 columns]
```

`agg()` lost results with `as_index=False` when relabeling columns

Previously `agg()` lost the result columns, when the `as_index` option was set to `False` and the result columns were relabeled. In this case the result values were replaced with the previous index (GH32240).

```
In [72]: df = pd.DataFrame({"key": ["x", "y", "z", "x", "y", "z"],
   ....:                    "val": [1.0, 0.8, 2.0, 3.0, 3.6, 0.75]})
   ....:

In [73]: df
Out[73]:
  key   val
0   x  1.00
1   y  0.80
2   z  2.00
3   x  3.00
4   y  3.60
5   z  0.75

[6 rows x 2 columns]
```

Previous behavior:

```
In [2]: grouped = df.groupby("key", as_index=False)
In [3]: result = grouped.agg(min_val=pd.NamedAgg(column="val", aggfunc="min"))
In [4]: result
Out[4]:
    min_val
 0   x
 1   y
 2   z
```

New behavior:

```
In [74]: grouped = df.groupby("key", as_index=False)

In [75]: result = grouped.agg(min_val=pd.NamedAgg(column="val", aggfunc="min"))

In [76]: result
Out[76]:
  key  min_val
0   x     1.00
1   y     0.80
2   z     0.75

[3 rows x 2 columns]
```

apply and applymap on `DataFrame` evaluates first row/column only once

```
In [77]: df = pd.DataFrame({'a': [1, 2], 'b': [3, 6]})

In [78]: def func(row):
   ....:     print(row)
   ....:     return row
   ....:
```

Previous behavior:

```
In [4]: df.apply(func, axis=1)
a    1
b    3
Name: 0, dtype: int64
a    1
b    3
Name: 0, dtype: int64
a    2
b    6
Name: 1, dtype: int64
Out[4]:
   a  b
0  1  3
1  2  6
```

New behavior:

```
In [79]: df.apply(func, axis=1)
a    1
b    3
Name: 0, Length: 2, dtype: int64
a    2
b    6
Name: 1, Length: 2, dtype: int64
Out[79]:
   a  b
0  1  3
1  2  6

[2 rows x 2 columns]
```

Increased minimum versions for dependencies

Some minimum supported versions of dependencies were updated (GH33718, GH29766, GH29723, pytables >= 3.4.3). If installed, we now require:

Package	Minimum Version	Required	Changed
numpy	1.15.4	X	X
pytz	2015.4	X	
python-dateutil	2.7.3	X	X
bottleneck	1.2.1		
numexpr	2.6.2		
pytest (dev)	4.0.2		

For optional libraries the general recommendation is to use the latest version. The following table lists the lowest version per library that is currently being tested throughout the development of pandas. Optional libraries below the lowest tested version may still work, but are not considered supported.

Package	Minimum Version	Changed
beautifulsoup4	4.6.0	
fastparquet	0.3.2	
fsspec	0.7.4	
gcsfs	0.6.0	X
lxml	3.8.0	
matplotlib	2.2.2	
numba	0.46.0	
openpyxl	2.5.7	
pyarrow	0.13.0	
pymysql	0.7.1	
pytables	3.4.3	X
s3fs	0.4.0	X
scipy	1.2.0	X
sqlalchemy	1.1.4	
xarray	0.8.2	
xlrd	1.1.0	
xlsxwriter	0.9.8	
xlwt	1.2.0	
pandas-gbq	1.2.0	X

See *Dependencies* and *Optional dependencies* for more.

Development Changes

- The minimum version of Cython is now the most recent bug-fix version (0.29.16) (GH33334).

Deprecations

- Lookups on a *`Series`* with a single-item list containing a slice (e.g. `ser[[slice(0, 4)]]`) are deprecated and will raise in a future version. Either convert the list to a tuple, or pass the slice directly instead (GH31333)
- *`DataFrame.mean()`* and *`DataFrame.median()`* with `numeric_only=None` will include `datetime64` and `datetime64tz` columns in a future version (GH29941)
- Setting values with `.loc` using a positional slice is deprecated and will raise in a future version. Use `.loc` with labels or `.iloc` with positions instead (GH31840)
- *`DataFrame.to_dict()`* has deprecated accepting short names for `orient` and will raise in a future version (GH32515)
- `Categorical.to_dense()` is deprecated and will be removed in a future version, use `np.asarray(cat)` instead (GH32639)
- The `fastpath` keyword in the `SingleBlockManager` constructor is deprecated and will be removed in a future version (GH33092)
- Providing `suffixes` as a `set` in *`pandas.merge()`* is deprecated. Provide a tuple instead (GH33740, GH34741).

- Indexing a *Series* with a multi-dimensional indexer like `[:, None]` to return an `ndarray` now raises a `FutureWarning`. Convert to a NumPy array before indexing instead (GH27837)
- *Index.is_mixed()* is deprecated and will be removed in a future version, check `index.inferred_type` directly instead (GH32922)
- Passing any arguments but the first one to *read_html()* as positional arguments is deprecated. All other arguments should be given as keyword arguments (GH27573).
- Passing any arguments but `path_or_buf` (the first one) to *read_json()* as positional arguments is deprecated. All other arguments should be given as keyword arguments (GH27573).
- Passing any arguments but the first two to *read_excel()* as positional arguments is deprecated. All other arguments should be given as keyword arguments (GH27573).
- *pandas.api.types.is_categorical()* is deprecated and will be removed in a future version; use *pandas.api.types.is_categorical_dtype()* instead (GH33385)
- *Index.get_value()* is deprecated and will be removed in a future version (GH19728)
- *Series.dt.week()* and *Series.dt.weekofyear()* are deprecated and will be removed in a future version, use `Series.dt.isocalendar().week()` instead (GH33595)
- *DatetimeIndex.week()* and `DatetimeIndex.weekofyear` are deprecated and will be removed in a future version, use `DatetimeIndex.isocalendar().week` instead (GH33595)
- `DatetimeArray.week()` and `DatetimeArray.weekofyear` are deprecated and will be removed in a future version, use `DatetimeArray.isocalendar().week` instead (GH33595)
- `DateOffset.__call__()` is deprecated and will be removed in a future version, use `offset + other` instead (GH34171)
- *apply_index()* is deprecated and will be removed in a future version. Use `offset + other` instead (GH34580)
- *DataFrame.tshift()* and *Series.tshift()* are deprecated and will be removed in a future version, use *DataFrame.shift()* and *Series.shift()* instead (GH11631)
- Indexing an *Index* object with a float key is deprecated, and will raise an `IndexError` in the future. You can manually convert to an integer key instead (GH34191).
- The `squeeze` keyword in *groupby()* is deprecated and will be removed in a future version (GH32380)
- The `tz` keyword in *Period.to_timestamp()* is deprecated and will be removed in a future version; use `per.to_timestamp(...).tz_localize(tz)` instead (GH34522)
- *DatetimeIndex.to_perioddelta()* is deprecated and will be removed in a future version. Use `index - index.to_period(freq).to_timestamp()` instead (GH34853)
- *DataFrame.melt()* accepting a `value_name` that already exists is deprecated, and will be removed in a future version (GH34731)
- The `center` keyword in the *DataFrame.expanding()* function is deprecated and will be removed in a future version (GH20647)

Performance improvements

- Performance improvement in *Timedelta* constructor (GH30543)
- Performance improvement in *Timestamp* constructor (GH30543)
- Performance improvement in flex arithmetic ops between *DataFrame* and *Series* with `axis=0` (GH31296)
- Performance improvement in arithmetic ops between *DataFrame* and *Series* with `axis=1` (GH33600)
- The internal index method `_shallow_copy()` now copies cached attributes over to the new index, avoiding creating these again on the new index. This can speed up many operations that depend on creating copies of existing indexes (GH28584, GH32640, GH32669)
- Significant performance improvement when creating a *DataFrame* with sparse values from `scipy.sparse` matrices using the *DataFrame.sparse.from_spmatrix()* constructor (GH32821, GH32825, GH32826, GH32856, GH32858).
- Performance improvement for groupby methods `first()` and `last()` (GH34178)
- Performance improvement in *factorize()* for nullable (integer and Boolean) dtypes (GH33064).
- Performance improvement when constructing *Categorical* objects (GH33921)
- Fixed performance regression in *pandas.qcut()* and *pandas.cut()* (GH33921)
- Performance improvement in reductions (`sum`, `prod`, `min`, `max`) for nullable (integer and Boolean) dtypes (GH30982, GH33261, GH33442).
- Performance improvement in arithmetic operations between two *DataFrame* objects (GH32779)
- Performance improvement in `pandas.core.groupby.RollingGroupby` (GH34052)
- Performance improvement in arithmetic operations (`sub`, `add`, `mul`, `div`) for *MultiIndex* (GH34297)
- Performance improvement in `DataFrame[bool_indexer]` when `bool_indexer` is a `list` (GH33924)
- Significant performance improvement of *io.formats.style.Styler.render()* with styles added with various ways such as *io.formats.style.Styler.apply()*, *io.formats.style.Styler.applymap()* or *io.formats.style.Styler.bar()* (GH19917)

Bug fixes

Categorical

- Passing an invalid `fill_value` to `Categorical.take()` raises a `ValueError` instead of `TypeError` (GH33660)
- Combining a *Categorical* with integer categories and which contains missing values with a float dtype column in operations such as *concat()* or *append()* will now result in a float column instead of an object dtype column (GH33607)
- Bug where *merge()* was unable to join on non-unique categorical indices (GH28189)
- Bug when passing categorical data to *Index* constructor along with `dtype=object` incorrectly returning a *CategoricalIndex* instead of object-dtype *Index* (GH32167)
- Bug where *Categorical* comparison operator `__ne__` would incorrectly evaluate to `False` when either element was missing (GH32276)
- `Categorical.fillna()` now accepts *Categorical* `other` argument (GH32420)
- Repr of *Categorical* was not distinguishing between `int` and `str` (GH33676)

Datetimelike

- Passing an integer dtype other than `int64` to `np.array(period_index, dtype=...)` will now raise `TypeError` instead of incorrectly using `int64` (GH32255)
- *`Series.to_timestamp()`* now raises a `TypeError` if the axis is not a *`PeriodIndex`*. Previously an `AttributeError` was raised (GH33327)
- *`Series.to_period()`* now raises a `TypeError` if the axis is not a *`DatetimeIndex`*. Previously an `AttributeError` was raised (GH33327)
- *`Period`* no longer accepts tuples for the `freq` argument (GH34658)
- Bug in *`Timestamp`* where constructing a *`Timestamp`* from ambiguous epoch time and calling constructor again changed the *`Timestamp.value()`* property (GH24329)
- `DatetimeArray.searchsorted()`, `TimedeltaArray.searchsorted()`, `PeriodArray.searchsorted()` not recognizing non-pandas scalars and incorrectly raising `ValueError` instead of `TypeError` (GH30950)
- Bug in *`Timestamp`* where constructing *`Timestamp`* with dateutil timezone less than 128 nanoseconds before daylight saving time switch from winter to summer would result in nonexistent time (GH31043)
- Bug in *`Period.to_timestamp()`*, *`Period.start_time()`* with microsecond frequency returning a timestamp one nanosecond earlier than the correct time (GH31475)
- *`Timestamp`* raised a confusing error message when year, month or day is missing (GH31200)
- Bug in *`DatetimeIndex`* constructor incorrectly accepting `bool`-dtype inputs (GH32668)
- Bug in `DatetimeIndex.searchsorted()` not accepting a `list` or *`Series`* as its argument (GH32762)
- Bug where *`PeriodIndex()`* raised when passed a *`Series`* of strings (GH26109)
- Bug in *`Timestamp`* arithmetic when adding or subtracting an `np.ndarray` with `timedelta64` dtype (GH33296)
- Bug in *`DatetimeIndex.to_period()`* not inferring the frequency when called with no arguments (GH33358)
- Bug in *`DatetimeIndex.tz_localize()`* incorrectly retaining `freq` in some cases where the original `freq` is no longer valid (GH30511)
- Bug in `DatetimeIndex.intersection()` losing `freq` and timezone in some cases (GH33604)
- Bug in `DatetimeIndex.get_indexer()` where incorrect output would be returned for mixed datetime-like targets (GH33741)
- Bug in *`DatetimeIndex`* addition and subtraction with some types of `DateOffset` objects incorrectly retaining an invalid `freq` attribute (GH33779)
- Bug in *`DatetimeIndex`* where setting the `freq` attribute on an index could silently change the `freq` attribute on another index viewing the same data (GH33552)
- *`DataFrame.min()`* and *`DataFrame.max()`* were not returning consistent results with *`Series.min()`* and *`Series.max()`* when called on objects initialized with empty `pd.to_datetime()`
- Bug in `DatetimeIndex.intersection()` and `TimedeltaIndex.intersection()` with results not having the correct `name` attribute (GH33904)
- Bug in `DatetimeArray.__setitem__()`, `TimedeltaArray.__setitem__()`, `PeriodArray.__setitem__()` incorrectly allowing values with `int64` dtype to be silently cast (GH33717)

- Bug in subtracting *TimedeltaIndex* from *Period* incorrectly raising `TypeError` in some cases where it should succeed and `IncompatibleFrequency` in some cases where it should raise `TypeError` (GH33883)
- Bug in constructing a *Series* or *Index* from a read-only NumPy array with non-ns resolution which converted to object dtype instead of coercing to `datetime64[ns]` dtype when within the timestamp bounds (GH34843).
- The `freq` keyword in *Period*, *date_range()*, *period_range()*, `pd.tseries.frequencies.to_offset()` no longer allows tuples, pass as string instead (GH34703)
- Bug in *DataFrame.append()* when appending a *Series* containing a scalar tz-aware *Timestamp* to an empty *DataFrame* resulted in an object column instead of `datetime64[ns, tz]` dtype (GH35038)
- `OutOfBoundsDatetime` issues an improved error message when timestamp is out of implementation bounds. (GH32967)
- Bug in `AbstractHolidayCalendar.holidays()` when no rules were defined (GH31415)
- Bug in `Tick` comparisons raising `TypeError` when comparing against timedelta-like objects (GH34088)
- Bug in `Tick` multiplication raising `TypeError` when multiplying by a float (GH34486)

Timedelta

- Bug in constructing a *Timedelta* with a high precision integer that would round the *Timedelta* components (GH31354)
- Bug in dividing `np.nan` or `None` by *Timedelta* incorrectly returning `NaT` (GH31869)
- *Timedelta* now understands `µs` as an identifier for microsecond (GH32899)
- *Timedelta* string representation now includes nanoseconds, when nanoseconds are non-zero (GH9309)
- Bug in comparing a *Timedelta* object against an `np.ndarray` with `timedelta64` dtype incorrectly viewing all entries as unequal (GH33441)
- Bug in *timedelta_range()* that produced an extra point on a edge case (GH30353, GH33498)
- Bug in *DataFrame.resample()* that produced an extra point on a edge case (GH30353, GH13022, GH33498)
- Bug in *DataFrame.resample()* that ignored the `loffset` argument when dealing with timedelta (GH7687, GH33498)
- Bug in *Timedelta* and *pandas.to_timedelta()* that ignored the `unit` argument for string input (GH12136)

Timezones

- Bug in *to_datetime()* with `infer_datetime_format=True` where timezone names (e.g. `UTC`) would not be parsed correctly (GH33133)

Numeric

- Bug in *DataFrame.floordiv()* with `axis=0` not treating division-by-zero like *Series.floordiv()* (GH31271)
- Bug in *to_numeric()* with string argument `"uint64"` and `errors="coerce"` silently fails (GH32394)
- Bug in *to_numeric()* with `downcast="unsigned"` fails for empty data (GH32493)
- Bug in *DataFrame.mean()* with `numeric_only=False` and either `datetime64` dtype or `PeriodDtype` column incorrectly raising `TypeError` (GH32426)
- Bug in *DataFrame.count()* with `level="foo"` and index level `"foo"` containing NaNs causes segmentation fault (GH21824)
- Bug in *DataFrame.diff()* with `axis=1` returning incorrect results with mixed dtypes (GH32995)
- Bug in *DataFrame.corr()* and *DataFrame.cov()* raising when handling nullable integer columns with `pandas.NA` (GH33803)
- Bug in arithmetic operations between *DataFrame* objects with non-overlapping columns with duplicate labels causing an infinite loop (GH35194)
- Bug in *DataFrame* and *Series* addition and subtraction between object-dtype objects and `datetime64` dtype objects (GH33824)
- Bug in *Index.difference()* giving incorrect results when comparing a *Float64Index* and object *Index* (GH35217)
- Bug in *DataFrame* reductions (e.g. `df.min()`, `df.max()`) with `ExtensionArray` dtypes (GH34520, GH32651)
- *Series.interpolate()* and *DataFrame.interpolate()* now raise a ValueError if `limit_direction` is `'forward'` or `'both'` and `method` is `'backfill'` or `'bfill'` or `limit_direction` is `'backward'` or `'both'` and `method` is `'pad'` or `'ffill'` (GH34746)

Conversion

- Bug in *Series* construction from NumPy array with big-endian `datetime64` dtype (GH29684)
- Bug in *Timedelta* construction with large nanoseconds keyword value (GH32402)
- Bug in *DataFrame* construction where sets would be duplicated rather than raising (GH32582)
- The *DataFrame* constructor no longer accepts a list of *DataFrame* objects. Because of changes to NumPy, *DataFrame* objects are now consistently treated as 2D objects, so a list of *DataFrame* objects is considered 3D, and no longer acceptable for the *DataFrame* constructor (GH32289).
- Bug in *DataFrame* when initiating a frame with lists and assign `columns` with nested list for `MultiIndex` (GH32173)
- Improved error message for invalid construction of list when creating a new index (GH35190)

Strings

- Bug in the *astype()* method when converting "string" dtype data to nullable integer dtype (GH32450).
- Fixed issue where taking `min` or `max` of a `StringArray` or `Series` with `StringDtype` type would raise. (GH31746)
- Bug in *Series.str.cat()* returning `NaN` output when other had *Index* type (GH33425)
- `pandas.api.dtypes.is_string_dtype()` no longer incorrectly identifies categorical series as string.

Interval

- Bug in `IntervalArray` incorrectly allowing the underlying data to be changed when setting values (GH32782)

Indexing

- *DataFrame.xs()* now raises a `TypeError` if a `level` keyword is supplied and the axis is not a *MultiIndex*. Previously an `AttributeError` was raised (GH33610)
- Bug in slicing on a *DatetimeIndex* with a partial-timestamp dropping high-resolution indices near the end of a year, quarter, or month (GH31064)
- Bug in `PeriodIndex.get_loc()` treating higher-resolution strings differently from `PeriodIndex.get_value()` (GH31172)
- Bug in *Series.at()* and *DataFrame.at()* not matching `.loc` behavior when looking up an integer in a *Float64Index* (GH31329)
- Bug in `PeriodIndex.is_monotonic()` incorrectly returning `True` when containing leading `NaT` entries (GH31437)
- Bug in `DatetimeIndex.get_loc()` raising `KeyError` with converted-integer key instead of the user-passed key (GH31425)
- Bug in *Series.xs()* incorrectly returning `Timestamp` instead of `datetime64` in some object-dtype cases (GH31630)
- Bug in *DataFrame.iat()* incorrectly returning `Timestamp` instead of `datetime` in some object-dtype cases (GH32809)
- Bug in *DataFrame.at()* when either columns or index is non-unique (GH33041)
- Bug in *Series.loc()* and *DataFrame.loc()* when indexing with an integer key on a object-dtype *Index* that is not all-integers (GH31905)
- Bug in `DataFrame.iloc.__setitem__()` on a *DataFrame* with duplicate columns incorrectly setting values for all matching columns (GH15686, GH22036)
- Bug in *DataFrame.loc()* and *Series.loc()* with a *DatetimeIndex*, *TimedeltaIndex*, or *PeriodIndex* incorrectly allowing lookups of non-matching datetime-like dtypes (GH32650)
- Bug in `Series.__getitem__()` indexing with non-standard scalars, e.g. `np.dtype` (GH32684)
- Bug in *Index* constructor where an unhelpful error message was raised for NumPy scalars (GH33017)
- Bug in *DataFrame.lookup()* incorrectly raising an `AttributeError` when `frame.index` or `frame.columns` is not unique; this will now raise a `ValueError` with a helpful error message (GH33041)

- Bug in *Interval* where a *Timedelta* could not be added or subtracted from a *Timestamp* interval (GH32023)
- Bug in *DataFrame.copy()* not invalidating _item_cache after copy caused post-copy value updates to not be reflected (GH31784)
- Fixed regression in *DataFrame.loc()* and *Series.loc()* throwing an error when a `datetime64[ns, tz]` value is provided (GH32395)
- Bug in `Series.__getitem__()` with an integer key and a *MultiIndex* with leading integer level failing to raise `KeyError` if the key is not present in the first level (GH33355)
- Bug in *DataFrame.iloc()* when slicing a single column *DataFrame* with `ExtensionDtype` (e.g. `df.iloc[:, :1]`) returning an invalid result (GH32957)
- Bug in `DatetimeIndex.insert()` and `TimedeltaIndex.insert()` causing index `freq` to be lost when setting an element into an empty *Series* (GH33573)
- Bug in `Series.__setitem__()` with an *IntervalIndex* and a list-like key of integers (GH33473)
- Bug in `Series.__getitem__()` allowing missing labels with `np.ndarray`, *Index*, *Series* indexers but not `list`, these now all raise `KeyError` (GH33646)
- Bug in *DataFrame.truncate()* and *Series.truncate()* where index was assumed to be monotone increasing (GH33756)
- Indexing with a list of strings representing datetimes failed on *DatetimeIndex* or *PeriodIndex* (GH11278)
- Bug in *Series.at()* when used with a *MultiIndex* would raise an exception on valid inputs (GH26989)
- Bug in *DataFrame.loc()* with dictionary of values changes columns with dtype of `int` to `float` (GH34573)
- Bug in *Series.loc()* when used with a *MultiIndex* would raise an `IndexingError` when accessing a `None` value (GH34318)
- Bug in *DataFrame.reset_index()* and *Series.reset_index()* would not preserve data types on an empty *DataFrame* or *Series* with a *MultiIndex* (GH19602)
- Bug in *Series* and *DataFrame* indexing with a `time` key on a *DatetimeIndex* with `NaT` entries (GH35114)

Missing

- Calling `fillna()` on an empty *Series* now correctly returns a shallow copied object. The behaviour is now consistent with *Index*, *DataFrame* and a non-empty *Series* (GH32543).
- Bug in *Series.replace()* when argument `to_replace` is of type dict/list and is used on a *Series* containing `<NA>` was raising a `TypeError`. The method now handles this by ignoring `<NA>` values when doing the comparison for the replacement (GH32621)
- Bug in *any()* and *all()* incorrectly returning `<NA>` for all `False` or all `True` values using the nulllable Boolean dtype and with `skipna=False` (GH33253)
- Clarified documentation on interpolate with `method=akima`. The `der` parameter must be scalar or `None` (GH33426)
- *DataFrame.interpolate()* uses the correct axis convention now. Previously interpolating along columns lead to interpolation along indices and vice versa. Furthermore interpolating with methods `pad`, `ffill`, `bfill` and `backfill` are identical to using these methods with *DataFrame.fillna()* (GH12918, GH29146)

- Bug in *DataFrame.interpolate()* when called on a *DataFrame* with column names of string type was throwing a ValueError. The method is now independent of the type of the column names (GH33956)
- Passing NA into a format string using format specs will now work. For example "{:.1f}".format(pd.NA) would previously raise a ValueError, but will now return the string "<NA>" (GH34740)
- Bug in *Series.map()* not raising on invalid na_action (GH32815)

MultiIndex

- DataFrame.swaplevels() now raises a TypeError if the axis is not a *MultiIndex*. Previously an AttributeError was raised (GH31126)
- Bug in Dataframe.loc() when used with a *MultiIndex*. The returned values were not in the same order as the given inputs (GH22797)

```
In [80]: df = pd.DataFrame(np.arange(4),
   ....:                   index=[["a", "a", "b", "b"], [1, 2, 1, 2]])
   ....:

# Rows are now ordered as the requested keys
In [81]: df.loc[(['b', 'a'], [2, 1]), :]
Out[81]:
     0
b 2  3
  1  2
a 2  1
  1  0

[4 rows x 1 columns]
```

- Bug in MultiIndex.intersection() was not guaranteed to preserve order when sort=False. (GH31325)
- Bug in *DataFrame.truncate()* was dropping *MultiIndex* names. (GH34564)

```
In [82]: left = pd.MultiIndex.from_arrays([["b", "a"], [2, 1]])

In [83]: right = pd.MultiIndex.from_arrays([["a", "b", "c"], [1, 2, 3]])

# Common elements are now guaranteed to be ordered by the left side
In [84]: left.intersection(right, sort=False)
Out[84]:
MultiIndex([('b', 2),
            ('a', 1)],
           )
```

- Bug when joining two *MultiIndex* without specifying level with different columns. Return-indexers parameter was ignored. (GH34074)

I/O

- Passing a `set` as `names` argument to *`pandas.read_csv()`*, *`pandas.read_table()`*, or *`pandas.read_fwf()`* will raise `ValueError: Names should be an ordered collection.` (GH34946)
- Bug in print-out when `display.precision` is zero. (GH20359)
- Bug in *`read_json()`* where integer overflow was occurring when json contains big number strings. (GH30320)
- *`read_csv()`* will now raise a `ValueError` when the arguments `header` and `prefix` both are not `None`. (GH27394)
- Bug in *`DataFrame.to_json()`* was raising `NotFoundError` when `path_or_buf` was an S3 URI (GH28375)
- Bug in *`DataFrame.to_parquet()`* overwriting pyarrow's default for `coerce_timestamps`; following pyarrow's default allows writing nanosecond timestamps with `version="2.0"` (GH31652).
- Bug in *`read_csv()`* was raising `TypeError` when `sep=None` was used in combination with `comment` keyword (GH31396)
- Bug in `HDFStore` that caused it to set to `int64` the dtype of a `datetime64` column when reading a *`DataFrame`* in Python 3 from fixed format written in Python 2 (GH31750)
- *`read_sas()`* now handles dates and datetimes larger than *`Timestamp.max`* returning them as `datetime.datetime` objects (GH20927)
- Bug in *`DataFrame.to_json()`* where `Timedelta` objects would not be serialized correctly with `date_format="iso"` (GH28256)
- *`read_csv()`* will raise a `ValueError` when the column names passed in `parse_dates` are missing in the `Dataframe` (GH31251)
- Bug in *`read_excel()`* where a UTF-8 string with a high surrogate would cause a segmentation violation (GH23809)
- Bug in *`read_csv()`* was causing a file descriptor leak on an empty file (GH31488)
- Bug in *`read_csv()`* was causing a segfault when there were blank lines between the header and data rows (GH28071)
- Bug in *`read_csv()`* was raising a misleading exception on a permissions issue (GH23784)
- Bug in *`read_csv()`* was raising an `IndexError` when `header=None` and two extra data columns
- Bug in *`read_sas()`* was raising an `AttributeError` when reading files from Google Cloud Storage (GH33069)
- Bug in *`DataFrame.to_sql()`* where an `AttributeError` was raised when saving an out of bounds date (GH26761)
- Bug in *`read_excel()`* did not correctly handle multiple embedded spaces in OpenDocument text cells. (GH32207)
- Bug in *`read_json()`* was raising `TypeError` when reading a `list` of Booleans into a *`Series`*. (GH31464)
- Bug in `pandas.io.json.json_normalize()` where location specified by `record_path` doesn't point to an array. (GH26284)
- *`pandas.read_hdf()`* has a more explicit error message when loading an unsupported HDF file (GH9539)
- Bug in `read_feather()` was raising an `ArrowIOError` when reading an s3 or http file path (GH29055)

- Bug in *to_excel()* could not handle the column name `render` and was raising an `KeyError` (GH34331)
- Bug in `execute()` was raising a `ProgrammingError` for some DB-API drivers when the SQL statement contained the `%` character and no parameters were present (GH34211)
- Bug in `StataReader()` which resulted in categorical variables with different dtypes when reading data using an iterator. (GH31544)
- *HDFStore.keys()* has now an optional `include` parameter that allows the retrieval of all native HDF5 table names (GH29916)
- `TypeError` exceptions raised by *read_csv()* and *read_table()* were showing as `parser_f` when an unexpected keyword argument was passed (GH25648)
- Bug in *read_excel()* for ODS files removes 0.0 values (GH27222)
- Bug in `ujson.encode()` was raising an `OverflowError` with numbers larger than `sys.maxsize` (GH34395)
- Bug in `HDFStore.append_to_multiple()` was raising a `ValueError` when the `min_itemsize` parameter is set (GH11238)
- Bug in `create_table()` now raises an error when `column` argument was not specified in `data_columns` on input (GH28156)
- *read_json()* now could read line-delimited json file from a file url while `lines` and `chunksize` are set.
- Bug in *DataFrame.to_sql()* when reading DataFrames with `-np.inf` entries with MySQL now has a more explicit `ValueError` (GH34431)
- Bug where capitalised files extensions were not decompressed by read_* functions (GH35164)
- Bug in *read_excel()* that was raising a `TypeError` when `header=None` and `index_col` is given as a `list` (GH31783)
- Bug in *read_excel()* where datetime values are used in the header in a *MultiIndex* (GH34748)
- *read_excel()* no longer takes `**kwds` arguments. This means that passing in the keyword argument `chunksize` now raises a `TypeError` (previously raised a `NotImplementedError`), while passing in the keyword argument `encoding` now raises a `TypeError` (GH34464)
- Bug in *DataFrame.to_records()* was incorrectly losing timezone information in timezone-aware `datetime64` columns (GH32535)

Plotting

- *DataFrame.plot()* for line/bar now accepts color by dictionary (GH8193).
- Bug in *DataFrame.plot.hist()* where weights are not working for multiple columns (GH33173)
- Bug in *DataFrame.boxplot()* and `DataFrame.plot.boxplot()` lost color attributes of `medianprops`, `whiskerprops`, `capprops` and `boxprops` (GH30346)
- Bug in *DataFrame.hist()* where the order of `column` argument was ignored (GH29235)
- Bug in *DataFrame.plot.scatter()* that when adding multiple plots with different `cmap`, colorbars always use the first `cmap` (GH33389)
- Bug in *DataFrame.plot.scatter()* was adding a colorbar to the plot even if the argument `c` was assigned to a column containing color names (GH34316)
- Bug in *pandas.plotting.bootstrap_plot()* was causing cluttered axes and overlapping labels (GH34905)

- Bug in *DataFrame.plot.scatter()* caused an error when plotting variable marker sizes (GH32904)

Groupby/resample/rolling

- Using a *pandas.api.indexers.BaseIndexer* with `count`, `min`, `max`, `median`, `skew`, `cov`, `corr` will now return correct results for any monotonic *pandas.api.indexers.BaseIndexer* descendant (GH32865)
- `DataFrameGroupby.mean()` and `SeriesGroupby.mean()` (and similarly for `median()`, `std()` and `var()`) now raise a `TypeError` if a non-accepted keyword argument is passed into it. Previously an `UnsupportedFunctionCall` was raised (`AssertionError` if `min_count` passed into `median()`) (GH31485)
- Bug in `GroupBy.apply()` raises `ValueError` when the `by` axis is not sorted, has duplicates, and the applied `func` does not mutate passed in objects (GH30667)
- Bug in `DataFrameGroupBy.transform()` produces an incorrect result with transformation functions (GH30918)
- Bug in `Groupby.transform()` was returning the wrong result when grouping by multiple keys of which some were categorical and others not (GH32494)
- Bug in `GroupBy.count()` causes segmentation fault when grouped-by columns contain NaNs (GH32841)
- Bug in *DataFrame.groupby()* and *Series.groupby()* produces inconsistent type when aggregating Boolean *Series* (GH32894)
- Bug in `DataFrameGroupBy.sum()` and `SeriesGroupBy.sum()` where a large negative number would be returned when the number of non-null values was below `min_count` for nullable integer dtypes (GH32861)
- Bug in `SeriesGroupBy.quantile()` was raising on nullable integers (GH33136)
- Bug in *DataFrame.resample()* where an `AmbiguousTimeError` would be raised when the resulting timezone aware *DatetimeIndex* had a DST transition at midnight (GH25758)
- Bug in *DataFrame.groupby()* where a `ValueError` would be raised when grouping by a categorical column with read-only categories and `sort=False` (GH33410)
- Bug in `GroupBy.agg()`, `GroupBy.transform()`, and `GroupBy.resample()` where subclasses are not preserved (GH28330)
- Bug in `SeriesGroupBy.agg()` where any column name was accepted in the named aggregation of `SeriesGroupBy` previously. The behaviour now allows only `str` and callables else would raise `TypeError`. (GH34422)
- Bug in *DataFrame.groupby()* lost the name of the *Index* when one of the `agg` keys referenced an empty list (GH32580)
- Bug in `Rolling.apply()` where `center=True` was ignored when `engine='numba'` was specified (GH34784)
- Bug in `DataFrame.ewm.cov()` was throwing `AssertionError` for *MultiIndex* inputs (GH34440)
- Bug in *core.groupby.DataFrameGroupBy.quantile()* raised `TypeError` for non-numeric types rather than dropping the columns (GH27892)
- Bug in *core.groupby.DataFrameGroupBy.transform()* when `func='nunique'` and columns are of type `datetime64`, the result would also be of type `datetime64` instead of `int64` (GH35109)
- Bug in *DataFrame.groupby()* raising an `AttributeError` when selecting a column and aggregating with `as_index=False` (GH35246).

- Bug in `DataFrameGroupBy.first()` and `DataFrameGroupBy.last()` that would raise an unnecessary `ValueError` when grouping on multiple `Categoricals` (GH34951)

Reshaping

- Bug effecting all numeric and Boolean reduction methods not returning subclassed data type. (GH25596)
- Bug in *DataFrame.pivot_table()* when only `MultiIndexed` columns is set (GH17038)
- Bug in *DataFrame.unstack()* and *Series.unstack()* can take tuple names in `MultiIndexed` data (GH19966)
- Bug in *DataFrame.pivot_table()* when `margin` is `True` and only `column` is defined (GH31016)
- Fixed incorrect error message in *DataFrame.pivot()* when `columns` is set to `None`. (GH30924)
- Bug in *crosstab()* when inputs are two *Series* and have tuple names, the output will keep a dummy *MultiIndex* as columns. (GH18321)
- *DataFrame.pivot()* can now take lists for `index` and `columns` arguments (GH21425)
- Bug in *concat()* where the resulting indices are not copied when `copy=True` (GH29879)
- Bug in `SeriesGroupBy.aggregate()` was resulting in aggregations being overwritten when they shared the same name (GH30880)
- Bug where *Index.astype()* would lose the `name` attribute when converting from `Float64Index` to `Int64Index`, or when casting to an `ExtensionArray` dtype (GH32013)
- *Series.append()* will now raise a `TypeError` when passed a *DataFrame* or a sequence containing *DataFrame* (GH31413)
- *DataFrame.replace()* and *Series.replace()* will raise a `TypeError` if `to_replace` is not an expected type. Previously the `replace` would fail silently (GH18634)
- Bug on inplace operation of a *Series* that was adding a column to the *DataFrame* from where it was originally dropped from (using `inplace=True`) (GH30484)
- Bug in *DataFrame.apply()* where callback was called with *Series* parameter even though `raw=True` requested. (GH32423)
- Bug in *DataFrame.pivot_table()* losing timezone information when creating a *MultiIndex* level from a column with timezone-aware dtype (GH32558)
- Bug in *concat()* where when passing a non-dict mapping as `objs` would raise a `TypeError` (GH32863)
- *DataFrame.agg()* now provides more descriptive `SpecificationError` message when attempting to aggregate a non-existent column (GH32755)
- Bug in *DataFrame.unstack()* when *MultiIndex* columns and *MultiIndex* rows were used (GH32624, GH24729 and GH28306)
- Appending a dictionary to a *DataFrame* without passing `ignore_index=True` will raise `TypeError: Can only append a dict if ignore_index=True` instead of `TypeError: Can only append a :class:`Series` if ignore_index=True or if the :class:`Series` has a name` (GH30871)
- Bug in *DataFrame.corrwith()*, *DataFrame.memory_usage()*, *DataFrame.dot()*, *DataFrame.idxmin()*, *DataFrame.idxmax()*, *DataFrame.duplicated()*, *DataFrame.isin()*, *DataFrame.count()*, *Series.explode()*, *Series.asof()* and *DataFrame.asof()* not returning subclassed types. (GH31331)

- Bug in *concat()* was not allowing for concatenation of *DataFrame* and *Series* with duplicate keys (GH33654)
- Bug in *cut()* raised an error when the argument `labels` contains duplicates (GH33141)
- Ensure only named functions can be used in *eval()* (GH32460)
- Bug in `Dataframe.aggregate()` and *Series.aggregate()* was causing a recursive loop in some cases (GH34224)
- Fixed bug in *melt()* where melting *MultiIndex* columns with `col_level > 0` would raise a `KeyError` on `id_vars` (GH34129)
- Bug in *Series.where()* with an empty *Series* and empty `cond` having non-bool dtype (GH34592)
- Fixed regression where *DataFrame.apply()* would raise `ValueError` for elements with `S` dtype (GH34529)

Sparse

- Creating a `SparseArray` from timezone-aware dtype will issue a warning before dropping timezone information, instead of doing so silently (GH32501)
- Bug in `arrays.SparseArray.from_spmatrix()` wrongly read scipy sparse matrix (GH31991)
- Bug in *Series.sum()* with `SparseArray` raised a `TypeError` (GH25777)
- Bug where *DataFrame* containing an all-sparse `SparseArray` filled with `NaN` when indexed by a list-like (GH27781, GH29563)
- The repr of *SparseDtype* now includes the repr of its `fill_value` attribute. Previously it used `fill_value`'s string representation (GH34352)
- Bug where empty *DataFrame* could not be cast to *SparseDtype* (GH33113)
- Bug in *arrays.SparseArray()* was returning the incorrect type when indexing a sparse dataframe with an iterable (GH34526, GH34540)

ExtensionArray

- Fixed bug where *Series.value_counts()* would raise on empty input of `Int64` dtype (GH33317)
- Fixed bug in *concat()* when concatenating *DataFrame* objects with non-overlapping columns resulting in object-dtype columns rather than preserving the extension dtype (GH27692, GH33027)
- Fixed bug where `StringArray.isna()` would return `False` for NA values when `pandas.options.mode.use_inf_as_na` was set to `True` (GH33655)
- Fixed bug in *Series* construction with EA dtype and index but no data or scalar data fails (GH26469)
- Fixed bug that caused `Series.__repr__()` to crash for extension types whose elements are multidimensional arrays (GH33770).
- Fixed bug where *Series.update()* would raise a `ValueError` for `ExtensionArray` dtypes with missing values (GH33980)
- Fixed bug where `StringArray.memory_usage()` was not implemented (GH33963)
- Fixed bug where `DataFrameGroupBy()` would ignore the `min_count` argument for aggregations on nullable Boolean dtypes (GH34051)
- Fixed bug where the constructor of *DataFrame* with `dtype='string'` would fail (GH27953, GH33623)

- Bug where *DataFrame* column set to scalar extension type was considered an object type rather than the extension type (GH34832)
- Fixed bug in `IntegerArray.astype()` to correctly copy the mask as well (GH34931).

Other

- Set operations on an object-dtype *Index* now always return object-dtype results (GH31401)
- Fixed *pandas.testing.assert_series_equal()* to correctly raise if the `left` argument is a different subclass with `check_series_type=True` (GH32670).
- Getting a missing attribute in a *DataFrame.query()* or *DataFrame.eval()* string raises the correct `AttributeError` (GH32408)
- Fixed bug in *pandas.testing.assert_series_equal()* where dtypes were checked for `Interval` and `ExtensionArray` operands when `check_dtype` was `False` (GH32747)
- Bug in `DataFrame.__dir__()` caused a segfault when using unicode surrogates in a column name (GH25509)
- Bug in *DataFrame.equals()* and *Series.equals()* in allowing subclasses to be equal (GH34402).

5.2 Version 1.0

5.2.1 What's new in 1.0.5 (June 17, 2020)

These are the changes in pandas 1.0.5. See *Release notes* for a full changelog including other versions of pandas.

Fixed regressions

- Fix regression in *read_parquet()* when reading from file-like objects (GH34467).
- Fix regression in reading from public S3 buckets (GH34626).

Note this disables the ability to read Parquet files from directories on S3 again (GH26388, GH34632), which was added in the 1.0.4 release, but is now targeted for pandas 1.1.0.

- Fixed regression in *replace()* raising an `AssertionError` when replacing values in an extension dtype with values of a different dtype (GH34530)

Bug fixes

- Fixed building from source with Python 3.8 fetching the wrong version of NumPy (GH34666)

Contributors

A total of 8 people contributed patches to this release. People with a "+" by their names contributed a patch for the first time.

5.2.2 What's new in 1.0.4 (May 28, 2020)

These are the changes in pandas 1.0.4. See *Release notes* for a full changelog including other versions of pandas.

Fixed regressions

- Fix regression where *Series.isna()* and *DataFrame.isna()* would raise for categorical dtype when `pandas.options.mode.use_inf_as_na` was set to `True` (GH33594)
- Fix regression in `GroupBy.first()` and `GroupBy.last()` where None is not preserved in object dtype (GH32800)
- Fix regression in DataFrame reductions using `numeric_only=True` and ExtensionArrays (GH33256).
- Fix performance regression in `memory_usage(deep=True)` for object dtype (GH33012)
- Fix regression where `Categorical.replace()` would replace with `NaN` whenever the new value and replacement value were equal (GH33288)
- Fix regression where an ordered *Categorical* containing only `NaN` values would raise rather than returning `NaN` when taking the minimum or maximum (GH33450)

- Fix regression in `DataFrameGroupBy.agg()` with dictionary input losing `ExtensionArray` dtypes (GH32194)
- Fix to preserve the ability to index with the "nearest" method with xarray's CFTimeIndex, an *`Index`* subclass (pydata/xarray#3751, GH32905).
- Fix regression in *`DataFrame.describe()`* raising `TypeError: unhashable type: 'dict'` (GH32409)
- Fix regression in *`DataFrame.replace()`* casts columns to `object` dtype if items in `to_replace` not in values (GH32988)
- Fix regression in *`Series.groupby()`* would raise `ValueError` when grouping by *`PeriodIndex`* level (GH34010)
- Fix regression in `GroupBy.rolling.apply()` ignores args and kwargs parameters (GH33433)
- Fix regression in error message with `np.min` or `np.max` on unordered *`Categorical`* (GH33115)
- Fix regression in *`DataFrame.loc()`* and *`Series.loc()`* throwing an error when a `datetime64[ns, tz]` value is provided (GH32395)

Bug fixes

- Bug in `SeriesGroupBy.first()`, `SeriesGroupBy.last()`, `SeriesGroupBy.min()`, and `SeriesGroupBy.max()` returning floats when applied to nullable Booleans (GH33071)
- Bug in `Rolling.min()` and `Rolling.max()`: Growing memory usage after multiple calls when using a fixed window (GH30726)
- Bug in *`to_parquet()`* was not raising `PermissionError` when writing to a private s3 bucket with invalid creds. (GH27679)
- Bug in *`to_csv()`* was silently failing when writing to an invalid s3 bucket. (GH32486)
- Bug in *`read_parquet()`* was raising a `FileNotFoundError` when passed an s3 directory path. (GH26388)
- Bug in *`to_parquet()`* was throwing an `AttributeError` when writing a partitioned parquet file to s3 (GH27596)
- Bug in `GroupBy.quantile()` causes the quantiles to be shifted when the `by` axis contains `NaN` (GH33200, GH33569)

5.2.3 What's new in 1.0.3 (March 17, 2020)

These are the changes in pandas 1.0.3. See *Release notes* for a full changelog including other versions of pandas.

Fixed regressions

- Fixed regression in `resample.agg` when the underlying data is non-writeable (GH31710)
- Fixed regression in *DataFrame* exponentiation with reindexing (GH32685)

Bug fixes

Contributors

A total of 5 people contributed patches to this release. People with a "+" by their names contributed a patch for the first time.

- jbrockmendel

5.2.4 What's new in 1.0.2 (March 12, 2020)

These are the changes in pandas 1.0.2. See *Release notes* for a full changelog including other versions of pandas.

Fixed regressions

Groupby

- Fixed regression in *groupby(..).agg()* which was failing on frames with *MultiIndex* columns and a custom function (GH31777)
- Fixed regression in `groupby(..).rolling(..).apply()` (`RollingGroupby`) where the `raw` parameter was ignored (GH31754)
- Fixed regression in *rolling(..).corr()* when using a time offset (GH31789)
- Fixed regression in *groupby(..).nunique()* which was modifying the original values if `NaN` values were present (GH31950)
- Fixed regression in `DataFrame.groupby` raising a `ValueError` from an internal operation (GH31802)
- Fixed regression in *groupby(..).agg()* calling a user-provided function an extra time on an empty input (GH31760)

I/O

- Fixed regression in *read_csv()* in which the `encoding` option was not recognized with certain file-like objects (GH31819)
- Fixed regression in *DataFrame.to_excel()* when the `columns` keyword argument is passed (GH31677)
- Fixed regression in `ExcelFile` where the stream passed into the function was closed by the destructor. (GH31467)
- Fixed regression where *read_pickle()* raised a `UnicodeDecodeError` when reading a py27 pickle with *MultiIndex* column (GH31988).

Reindexing/alignment

- Fixed regression in *Series.align()* when `other` is a *DataFrame* and `method` is not `None` (GH31785)
- Fixed regression in *DataFrame.reindex()* and *Series.reindex()* when reindexing with (tz-aware) index and `method=nearest` (GH26683)
- Fixed regression in *DataFrame.reindex_like()* on a *DataFrame* subclass raised an `AssertionError` (GH31925)
- Fixed regression in *DataFrame* arithmetic operations with mis-matched columns (GH31623)

Other

- Fixed regression in joining on *DatetimeIndex* or *TimedeltaIndex* to preserve `freq` in simple cases (GH32166)
- Fixed regression in *Series.shift()* with `datetime64` dtype when passing an integer `fill_value` (GH32591)
- Fixed regression in the repr of an object-dtype *Index* with bools and missing values (GH32146)

Indexing with Nullable Boolean Arrays

Previously indexing with a nullable Boolean array containing `NA` would raise a `ValueError`, however this is now permitted with `NA` being treated as `False`. (GH31503)

```
In [1]: s = pd.Series([1, 2, 3, 4])

In [2]: mask = pd.array([True, True, False, None], dtype="boolean")

In [3]: s
Out[3]:
0    1
1    2
2    3
3    4
Length: 4, dtype: int64

In [4]: mask
Out[4]:
<BooleanArray>
[True, True, False, <NA>]
Length: 4, dtype: boolean
```

pandas 1.0.0-1.0.1

```
>>> s[mask]
Traceback (most recent call last):
...
ValueError: cannot mask with array containing NA / NaN values
```

pandas 1.0.2

```
In [5]: s[mask]
Out[5]:
0    1
1    2
Length: 2, dtype: int64
```

Bug fixes

Datetimelike

- Bug in *Series.astype()* not copying for tz-naive and tz-aware `datetime64` dtype (GH32490)
- Bug where *to_datetime()* would raise when passed `pd.NA` (GH32213)
- Improved error message when subtracting two *Timestamp* that result in an out-of-bounds *Timedelta* (GH31774)

Categorical

- Fixed bug where *Categorical.from_codes()* improperly raised a `ValueError` when passed nullable integer codes. (GH31779)
- Fixed bug where *Categorical()* constructor would raise a `TypeError` when given a numpy array containing `pd.NA`. (GH31927)
- Bug in *Categorical* that would ignore or crash when calling *Series.replace()* with a list-like `to_replace` (GH31720)

I/O

- Using `pd.NA` with *`DataFrame.to_json()`* now correctly outputs a null value instead of an empty object (GH31615)
- Bug in *`pandas.json_normalize()`* when value in meta path is not iterable (GH31507)
- Fixed pickling of `pandas.NA`. Previously a new object was returned, which broke computations relying on `NA` being a singleton (GH31847)
- Fixed bug in parquet roundtrip with nullable unsigned integer dtypes (GH31896).

Experimental dtypes

- Fixed bug in *`DataFrame.convert_dtypes()`* for columns that were already using the `"string"` dtype (GH31731).
- Fixed bug in *`DataFrame.convert_dtypes()`* for series with mix of integers and strings (GH32117)
- Fixed bug in *`DataFrame.convert_dtypes()`* where `BooleanDtype` columns were converted to `Int64` (GH32287)
- Fixed bug in setting values using a slice indexer with string dtype (GH31772)
- Fixed bug where *`pandas.core.groupby.GroupBy.first()`* and *`pandas.core.groupby.GroupBy.last()`* would raise a `TypeError` when groups contained `pd.NA` in a column of object dtype (GH32123)
- Fixed bug where `DataFrameGroupBy.mean()`, `DataFrameGroupBy.median()`, `DataFrameGroupBy.var()`, and `DataFrameGroupBy.std()` would raise a `TypeError` on `Int64` dtype columns (GH32219)

Strings

- Using `pd.NA` with *`Series.str.repeat()`* now correctly outputs a null value instead of raising error for vector inputs (GH31632)

Rolling

- Fixed rolling operations with variable window (defined by time duration) on decreasing time index (GH32385).

5.2.5 What's new in 1.0.1 (February 5, 2020)

These are the changes in pandas 1.0.1. See *Release notes* for a full changelog including other versions of pandas.

Fixed regressions

- Fixed regression in *DataFrame* setting values with a slice (e.g. `df[-4:] = 1`) indexing by label instead of position (GH31469)
- Fixed regression when indexing a `Series` or `DataFrame` indexed by `DatetimeIndex` with a slice containing a `datetime.date` (GH31501)
- Fixed regression in `DataFrame.__setitem__` raising an `AttributeError` with a *MultiIndex* and a non-monotonic indexer (GH31449)
- Fixed regression in *Series* multiplication when multiplying a numeric *Series* with >10000 elements with a timedelta-like scalar (GH31457)
- Fixed regression in `.groupby().agg()` raising an `AssertionError` for some reductions like `min` on object-dtype columns (GH31522)
- Fixed regression in `.groupby()` aggregations with categorical dtype using Cythonized reduction functions (e.g. `first`) (GH31450)
- Fixed regression in `GroupBy.apply()` if called with a function which returned a non-pandas non-scalar object (e.g. a list or numpy array) (GH31441)
- Fixed regression in *DataFrame.groupby()* whereby taking the minimum or maximum of a column with period dtype would raise a `TypeError`. (GH31471)
- Fixed regression in *DataFrame.groupby()* with an empty DataFrame grouping by a level of a MultiIndex (GH31670).
- Fixed regression in *DataFrame.apply()* with object dtype and non-reducing function (GH31505)

- Fixed regression in *to_datetime()* when parsing non-nanosecond resolution datetimes (GH31491)
- Fixed regression in *to_csv()* where specifying an na_rep might truncate the values written (GH31447)
- Fixed regression in *Categorical* construction with numpy.str_ categories (GH31499)
- Fixed regression in *DataFrame.loc()* and *DataFrame.iloc()* when selecting a row containing a single datetime64 or timedelta64 column (GH31649)
- Fixed regression where setting pd.options.display.max_colwidth was not accepting negative integer. In addition, this behavior has been deprecated in favor of using None (GH31532)
- Fixed regression in objTOJSON.c fix return-type warning (GH31463)
- Fixed regression in *qcut()* when passed a nullable integer. (GH31389)
- Fixed regression in assigning to a *Series* using a nullable integer dtype (GH31446)
- Fixed performance regression when indexing a DataFrame or Series with a *MultiIndex* for the index using a list of labels (GH31648)
- Fixed regression in *read_csv()* used in file like object RawIOBase is not recognize encoding option (GH31575)

Deprecations

- Support for negative integer for pd.options.display.max_colwidth is deprecated in favor of using None (GH31532)

Bug fixes

Datetimelike

- Fixed bug in *to_datetime()* raising when cache=True and out-of-bound values are present (GH31491)

Numeric

- Bug in dtypes being lost in DataFrame.__invert__ (~ operator) with mixed dtypes (GH31183) and for extension-array backed Series and DataFrame (GH23087)

Plotting

- Plotting tz-aware timeseries no longer gives UserWarning (GH31205)

Interval

- Bug in *Series.shift()* with interval dtype raising a TypeError when shifting an interval array of integers or datetimes (GH34195)

5.2.6 What's new in 1.0.0 (January 29, 2020)

These are the changes in pandas 1.0.0. See *Release notes* for a full changelog including other versions of pandas.

Note: The pandas 1.0 release removed a lot of functionality that was deprecated in previous releases (see *below* for an overview). It is recommended to first upgrade to pandas 0.25 and to ensure your code is working without warnings, before upgrading to pandas 1.0.

New deprecation policy

Starting with Pandas 1.0.0, pandas will adopt a variant of SemVer to version releases. Briefly,

- Deprecations will be introduced in minor releases (e.g. 1.1.0, 1.2.0, 2.1.0, ...)
- Deprecations will be enforced in major releases (e.g. 1.0.0, 2.0.0, 3.0.0, ...)
- API-breaking changes will be made only in major releases (except for experimental features)

See *Version policy* for more.

Enhancements

Using Numba in `rolling.apply` and `expanding.apply`

We've added an `engine` keyword to *`apply()`* and *`apply()`* that allows the user to execute the routine using Numba instead of Cython. Using the Numba engine can yield significant performance gains if the apply function can operate on numpy arrays and the data set is larger (1 million rows or greater). For more details, see *rolling apply documentation* (GH28987, GH30936)

Defining custom windows for rolling operations

We've added a *pandas.api.indexers.BaseIndexer()* class that allows users to define how window bounds are created during `rolling` operations. Users can define their own `get_window_bounds` method on a *pandas.api.indexers.BaseIndexer()* subclass that will generate the start and end indices used for each window during the rolling aggregation. For more details and example usage, see the *custom window rolling documentation*

Converting to markdown

We've added *to_markdown()* for creating a markdown table (GH11052)

```
In [1]: df = pd.DataFrame({"A": [1, 2, 3], "B": [1, 2, 3]}, index=['a', 'a', 'b'])

In [2]: print(df.to_markdown())
|    |   A |   B |
|:---|----:|----:|
| a  |   1 |   1 |
| a  |   2 |   2 |
| b  |   3 |   3 |
```

Experimental new features

Experimental NA scalar to denote missing values

A new `pd.NA` value (singleton) is introduced to represent scalar missing values. Up to now, pandas used several values to represent missing data: `np.nan` is used for this for float data, `np.nan` or `None` for object-dtype data and `pd.NaT` for datetime-like data. The goal of `pd.NA` is to provide a "missing" indicator that can be used consistently across data types. `pd.NA` is currently used by the nullable integer and boolean data types and the new string data type (GH28095).

Warning: Experimental: the behaviour of `pd.NA` can still change without warning.

For example, creating a Series using the nullable integer dtype:

```
In [3]: s = pd.Series([1, 2, None], dtype="Int64")

In [4]: s
Out[4]:
0       1
1       2
2    <NA>
Length: 3, dtype: Int64

In [5]: s[2]
Out[5]: <NA>
```

Compared to `np.nan`, `pd.NA` behaves differently in certain operations. In addition to arithmetic operations, `pd.NA` also propagates as "missing" or "unknown" in comparison operations:

```
In [6]: np.nan > 1
Out[6]: False
```

(continues on next page)

(continued from previous page)

```
In [7]: pd.NA > 1
Out[7]: <NA>
```

For logical operations, `pd.NA` follows the rules of the three-valued logic (or *Kleene logic*). For example:

```
In [8]: pd.NA | True
Out[8]: True
```

For more, see *NA section* in the user guide on missing data.

Dedicated string data type

We've added *`StringDtype`*, an extension type dedicated to string data. Previously, strings were typically stored in object-dtype NumPy arrays. (GH29975)

Warning: `StringDtype` is currently considered experimental. The implementation and parts of the API may change without warning.

The `'string'` extension type solves several issues with object-dtype NumPy arrays:

1. You can accidentally store a *mixture* of strings and non-strings in an `object` dtype array. A `StringArray` can only store strings.
2. `object` dtype breaks dtype-specific operations like *`DataFrame.select_dtypes()`*. There isn't a clear way to select *just* text while excluding non-text, but still object-dtype columns.
3. When reading code, the contents of an `object` dtype array is less clear than `string`.

```
In [9]: pd.Series(['abc', None, 'def'], dtype=pd.StringDtype())
Out[9]:
0     abc
1    <NA>
2     def
Length: 3, dtype: string
```

You can use the alias `"string"` as well.

```
In [10]: s = pd.Series(['abc', None, 'def'], dtype="string")

In [11]: s
Out[11]:
0     abc
1    <NA>
2     def
Length: 3, dtype: string
```

The usual string accessor methods work. Where appropriate, the return type of the Series or columns of a DataFrame will also have string dtype.

```
In [12]: s.str.upper()
Out[12]:
0     ABC
1    <NA>
```

(continues on next page)

(continued from previous page)

```
2     DEF
Length: 3, dtype: string

In [13]: s.str.split('b', expand=True).dtypes
Out[13]:
0    string
1    string
Length: 2, dtype: object
```

String accessor methods returning integers will return a value with *Int64Dtype*

```
In [14]: s.str.count("a")
Out[14]:
0       1
1    <NA>
2       0
Length: 3, dtype: Int64
```

We recommend explicitly using the `string` data type when working with strings. See *Text data types* for more.

Boolean data type with missing values support

We've added *BooleanDtype* / *BooleanArray*, an extension type dedicated to boolean data that can hold missing values. The default `bool` data type based on a bool-dtype NumPy array, the column can only hold `True` or `False`, and not missing values. This new *BooleanArray* can store missing values as well by keeping track of this in a separate mask. (GH29555, GH30095, GH31131)

```
In [15]: pd.Series([True, False, None], dtype=pd.BooleanDtype())
Out[15]:
0     True
1    False
2     <NA>
Length: 3, dtype: boolean
```

You can use the alias `"boolean"` as well.

```
In [16]: s = pd.Series([True, False, None], dtype="boolean")

In [17]: s
Out[17]:
0     True
1    False
2     <NA>
Length: 3, dtype: boolean
```

`convert_dtypes` method to ease use of supported extension dtypes

In order to encourage use of the extension dtypes `StringDtype`, `BooleanDtype`, `Int64Dtype`, `Int32Dtype`, etc., that support `pd.NA`, the methods *`DataFrame.convert_dtypes()`* and *`Series.convert_dtypes()`* have been introduced. (GH29752) (GH30929)

Example:

```
In [18]: df = pd.DataFrame({'x': ['abc', None, 'def'],
   ....:                    'y': [1, 2, np.nan],
   ....:                    'z': [True, False, True]})
   ....:

In [19]: df
Out[19]:
      x    y      z
0   abc  1.0   True
1  None  2.0  False
2   def  NaN   True

[3 rows x 3 columns]

In [20]: df.dtypes
Out[20]:
x     object
y    float64
z       bool
Length: 3, dtype: object
```

```
In [21]: converted = df.convert_dtypes()

In [22]: converted
Out[22]:
      x     y      z
0   abc     1   True
1  <NA>     2  False
2   def  <NA>   True

[3 rows x 3 columns]

In [23]: converted.dtypes
Out[23]:
x     string
y      Int64
z    boolean
Length: 3, dtype: object
```

This is especially useful after reading in data using readers such as *`read_csv()`* and *`read_excel()`*. See *here* for a description.

Other enhancements

- *DataFrame.to_string()* added the max_colwidth parameter to control when wide columns are truncated (GH9784)
- Added the na_value argument to *Series.to_numpy()*, *Index.to_numpy()* and *DataFrame.to_numpy()* to control the value used for missing data (GH30322)
- *MultiIndex.from_product()* infers level names from inputs if not explicitly provided (GH27292)
- *DataFrame.to_latex()* now accepts caption and label arguments (GH25436)
- DataFrames with *nullable integer*, the *new string dtype* and period data type can now be converted to pyarrow (>=0.15.0), which means that it is supported in writing to the Parquet file format when using the pyarrow engine (GH28368). Full roundtrip to parquet (writing and reading back in with *to_parquet()* / *read_parquet()*) is supported starting with pyarrow >= 0.16 (GH20612).
- to_parquet() now appropriately handles the schema argument for user defined schemas in the pyarrow engine. (GH30270)
- *DataFrame.to_json()* now accepts an indent integer argument to enable pretty printing of JSON output (GH12004)
- *read_stata()* can read Stata 119 dta files. (GH28250)
- Implemented pandas.core.window.Window.var() and pandas.core.window.Window.std() functions (GH26597)
- Added encoding argument to *DataFrame.to_string()* for non-ascii text (GH28766)
- Added encoding argument to *DataFrame.to_html()* for non-ascii text (GH28663)
- Styler.background_gradient() now accepts vmin and vmax arguments (GH12145)
- Styler.format() added the na_rep parameter to help format the missing values (GH21527, GH28358)
- *read_excel()* now can read binary Excel (.xlsb) files by passing engine='pyxlsb'. For more details and example usage, see the *Binary Excel files documentation*. Closes GH8540.
- The partition_cols argument in *DataFrame.to_parquet()* now accepts a string (GH27117)
- *pandas.read_json()* now parses NaN, Infinity and -Infinity (GH12213)
- DataFrame constructor preserve *ExtensionArray* dtype with *ExtensionArray* (GH11363)
- *DataFrame.sort_values()* and *Series.sort_values()* have gained ignore_index keyword to be able to reset index after sorting (GH30114)
- *DataFrame.sort_index()* and *Series.sort_index()* have gained ignore_index keyword to reset index (GH30114)
- *DataFrame.drop_duplicates()* has gained ignore_index keyword to reset index (GH30114)
- Added new writer for exporting Stata dta files in versions 118 and 119, StataWriterUTF8. These files formats support exporting strings containing Unicode characters. Format 119 supports data sets with more than 32,767 variables (GH23573, GH30959)
- *Series.map()* now accepts collections.abc.Mapping subclasses as a mapper (GH29733)
- Added an experimental *attrs* for storing global metadata about a dataset (GH29062)
- *Timestamp.fromisocalendar()* is now compatible with python 3.8 and above (GH28115)
- *DataFrame.to_pickle()* and *read_pickle()* now accept URL (GH30163)

Backwards incompatible API changes

Avoid using names from `MultiIndex.levels`

As part of a larger refactor to *`MultiIndex`* the level names are now stored separately from the levels (GH27242). We recommend using *`MultiIndex.names`* to access the names, and *`Index.set_names()`* to update the names.

For backwards compatibility, you can still *access* the names via the levels.

```
In [24]: mi = pd.MultiIndex.from_product([[1, 2], ['a', 'b']], names=['x', 'y'])

In [25]: mi.levels[0].name
Out[25]: 'x'
```

However, it is no longer possible to *update* the names of the `MultiIndex` via the level.

```
In [26]: mi.levels[0].name = "new name"
---------------------------------------------------------------------------
RuntimeError                              Traceback (most recent call last)
<ipython-input-26-65f4400a0c97> in <module>
----> 1 mi.levels[0].name = "new name"

/pandas-release/pandas/pandas/core/indexes/base.py in name(self, value)
   1178         if self._no_setting_name:
   1179             # Used in MultiIndex.levels to avoid silently ignoring name␣
↪updates.
-> 1180             raise RuntimeError(
   1181                 "Cannot set name on a level of a MultiIndex. Use "
   1182                 "'MultiIndex.set_names' instead."

RuntimeError: Cannot set name on a level of a MultiIndex. Use 'MultiIndex.set_names'␣
↪instead.

In [27]: mi.names
Out[27]: FrozenList(['x', 'y'])
```

To update, use `MultiIndex.set_names`, which returns a new `MultiIndex`.

```
In [28]: mi2 = mi.set_names("new name", level=0)

In [29]: mi2.names
Out[29]: FrozenList(['new name', 'y'])
```

New repr for `IntervalArray`

`pandas.arrays.IntervalArray` adopts a new `__repr__` in accordance with other array classes (GH25022)

pandas 0.25.x

```
In [1]: pd.arrays.IntervalArray.from_tuples([(0, 1), (2, 3)])
Out[2]:
IntervalArray([(0, 1], (2, 3]],
              closed='right',
              dtype='interval[int64]')
```

pandas 1.0.0

```
In [30]: pd.arrays.IntervalArray.from_tuples([(0, 1), (2, 3)])
Out[30]:
<IntervalArray>
[(0, 1], (2, 3]]
Length: 2, closed: right, dtype: interval[int64]
```

`DataFrame.rename` now only accepts one positional argument

`DataFrame.rename()` would previously accept positional arguments that would lead to ambiguous or undefined behavior. From pandas 1.0, only the very first argument, which maps labels to their new names along the default axis, is allowed to be passed by position (GH29136).

pandas 0.25.x

```
>>> df = pd.DataFrame([[1]])
>>> df.rename({0: 1}, {0: 2})
FutureWarning: ...Use named arguments to resolve ambiguity...
   2
1  1
```

pandas 1.0.0

```
>>> df.rename({0: 1}, {0: 2})
Traceback (most recent call last):
...
TypeError: rename() takes from 1 to 2 positional arguments but 3 were given
```

Note that errors will now be raised when conflicting or potentially ambiguous arguments are provided.

pandas 0.25.x

```
>>> df.rename({0: 1}, index={0: 2})
   0
1  1

>>> df.rename(mapper={0: 1}, index={0: 2})
   0
2  1
```

pandas 1.0.0

```
>>> df.rename({0: 1}, index={0: 2})
Traceback (most recent call last):
...
TypeError: Cannot specify both 'mapper' and any of 'index' or 'columns'

>>> df.rename(mapper={0: 1}, index={0: 2})
Traceback (most recent call last):
...
TypeError: Cannot specify both 'mapper' and any of 'index' or 'columns'
```

You can still change the axis along which the first positional argument is applied by supplying the `axis` keyword argument.

```
In [31]: df.rename({0: 1})
Out[31]:
```

(continues on next page)

(continued from previous page)

```
   0
1  1

[1 rows x 1 columns]

In [32]: df.rename({0: 1}, axis=1)
Out[32]:
   1
0  1

[1 rows x 1 columns]
```

If you would like to update both the index and column labels, be sure to use the respective keywords.

```
In [33]: df.rename(index={0: 1}, columns={0: 2})
Out[33]:
   2
1  1

[1 rows x 1 columns]
```

Extended verbose info output for `DataFrame`

`DataFrame.info()` now shows line numbers for the columns summary (GH17304)

pandas 0.25.x

```
>>> df = pd.DataFrame({"int_col": [1, 2, 3],
...                    "text_col": ["a", "b", "c"],
...                    "float_col": [0.0, 0.1, 0.2]})
>>> df.info(verbose=True)
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 3 entries, 0 to 2
Data columns (total 3 columns):
int_col      3 non-null int64
text_col     3 non-null object
float_col    3 non-null float64
dtypes: float64(1), int64(1), object(1)
memory usage: 152.0+ bytes
```

pandas 1.0.0

```
In [34]: df = pd.DataFrame({"int_col": [1, 2, 3],
   ....:                    "text_col": ["a", "b", "c"],
   ....:                    "float_col": [0.0, 0.1, 0.2]})
   ....:

In [35]: df.info(verbose=True)
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 3 entries, 0 to 2
Data columns (total 3 columns):
 #   Column     Non-Null Count  Dtype
---  ------     --------------  -----
 0   int_col    3 non-null      int64
 1   text_col   3 non-null      object
```

(continues on next page)

(continued from previous page)

```
 2   float_col  3 non-null      float64
dtypes: float64(1), int64(1), object(1)
memory usage: 200.0+ bytes
```

`pandas.array()` inference changes

`pandas.array()` now infers pandas' new extension types in several cases (GH29791):

1. String data (including missing values) now returns a *`arrays.StringArray`*.
2. Integer data (including missing values) now returns a *`arrays.IntegerArray`*.
3. Boolean data (including missing values) now returns the new *`arrays.BooleanArray`*

pandas 0.25.x

```
>>> pd.array(["a", None])
<PandasArray>
['a', None]
Length: 2, dtype: object

>>> pd.array([1, None])
<PandasArray>
[1, None]
Length: 2, dtype: object
```

pandas 1.0.0

```
In [36]: pd.array(["a", None])
Out[36]:
<StringArray>
['a', <NA>]
Length: 2, dtype: string

In [37]: pd.array([1, None])
Out[37]:
<IntegerArray>
[1, <NA>]
Length: 2, dtype: Int64
```

As a reminder, you can specify the `dtype` to disable all inference.

`arrays.IntegerArray` now uses `pandas.NA`

`arrays.IntegerArray` now uses `pandas.NA` rather than `numpy.nan` as its missing value marker (GH29964).

pandas 0.25.x

```
>>> a = pd.array([1, 2, None], dtype="Int64")
>>> a
<IntegerArray>
[1, 2, NaN]
Length: 3, dtype: Int64

>>> a[2]
nan
```

pandas 1.0.0

```
In [38]: a = pd.array([1, 2, None], dtype="Int64")

In [39]: a
Out[39]:
<IntegerArray>
[1, 2, <NA>]
Length: 3, dtype: Int64

In [40]: a[2]
Out[40]: <NA>
```

This has a few API-breaking consequences.

Converting to a NumPy ndarray

When converting to a NumPy array missing values will be `pd.NA`, which cannot be converted to a float. So calling `np.asarray(integer_array, dtype="float")` will now raise.

pandas 0.25.x

```
>>> np.asarray(a, dtype="float")
array([ 1.,  2., nan])
```

pandas 1.0.0

```
In [41]: np.asarray(a, dtype="float")
---------------------------------------------------------------------------
ValueError                                Traceback (most recent call last)
<ipython-input-41-4578f04da2b3> in <module>
----> 1 np.asarray(a, dtype="float")

/opt/conda/envs/pandas/lib/python3.8/site-packages/numpy/core/_asarray.py in␣
↪asarray(a, dtype, order)
     83
     84     """
---> 85     return array(a, dtype, copy=False, order=order)
     86
     87

/pandas-release/pandas/pandas/core/arrays/masked.py in __array__(self, dtype)
    217         We return an object array here to preserve our scalar values
    218         """
--> 219         return self.to_numpy(dtype=dtype)
    220
    221     def __arrow_array__(self, type=None):

/pandas-release/pandas/pandas/core/arrays/masked.py in to_numpy(self, dtype, copy, na_
↪value)
    198                 and na_value is libmissing.NA
    199             ):
--> 200                 raise ValueError(
    201                     f"cannot convert to '{dtype}'-dtype NumPy array "
    202                     "with missing values. Specify an appropriate 'na_value' "

ValueError: cannot convert to 'float64'-dtype NumPy array with missing values.␣
↪Specify an appropriate 'na_value' for this dtype.
```

Use `arrays.IntegerArray.to_numpy()` with an explicit `na_value` instead.

```
In [42]: a.to_numpy(dtype="float", na_value=np.nan)
Out[42]: array([ 1.,  2., nan])
```

Reductions can return ``pd.NA``

When performing a reduction such as a sum with `skipna=False`, the result will now be `pd.NA` instead of `np.nan` in presence of missing values (GH30958).

pandas 0.25.x

```
>>> pd.Series(a).sum(skipna=False)
nan
```

pandas 1.0.0

```
In [43]: pd.Series(a).sum(skipna=False)
Out[43]: <NA>
```

value_counts returns a nullable integer dtype

`Series.value_counts()` with a nullable integer dtype now returns a nullable integer dtype for the values.

pandas 0.25.x

```
>>> pd.Series([2, 1, 1, None], dtype="Int64").value_counts().dtype
dtype('int64')
```

pandas 1.0.0

```
In [44]: pd.Series([2, 1, 1, None], dtype="Int64").value_counts().dtype
Out[44]: Int64Dtype()
```

See *Experimental NA scalar to denote missing values* for more on the differences between `pandas.NA` and `numpy.nan`.

`arrays.IntegerArray` comparisons return `arrays.BooleanArray`

Comparison operations on a *`arrays.IntegerArray`* now returns a *`arrays.BooleanArray`* rather than a NumPy array (GH29964).

pandas 0.25.x

```
>>> a = pd.array([1, 2, None], dtype="Int64")
>>> a
<IntegerArray>
[1, 2, NaN]
Length: 3, dtype: Int64

>>> a > 1
array([False,  True, False])
```

pandas 1.0.0

```
In [45]: a = pd.array([1, 2, None], dtype="Int64")

In [46]: a > 1
Out[46]:
```

(continues on next page)

(continued from previous page)

```
<BooleanArray>
[False, True, <NA>]
Length: 3, dtype: boolean
```

Note that missing values now propagate, rather than always comparing unequal like `numpy.nan`. See *Experimental NA scalar to denote missing values* for more.

By default `Categorical.min()` now returns the minimum instead of np.nan

When *Categorical* contains `np.nan`, `Categorical.min()` no longer return `np.nan` by default (skipna=True) (GH25303)

pandas 0.25.x

```
In [1]: pd.Categorical([1, 2, np.nan], ordered=True).min()
Out[1]: nan
```

pandas 1.0.0

```
In [47]: pd.Categorical([1, 2, np.nan], ordered=True).min()
Out[47]: 1
```

Default dtype of empty `pandas.Series`

Initialising an empty *pandas.Series* without specifying a dtype will raise a *DeprecationWarning* now (GH17261). The default dtype will change from `float64` to `object` in future releases so that it is consistent with the behaviour of *DataFrame* and *Index*.

pandas 1.0.0

```
In [1]: pd.Series()
Out[2]:
DeprecationWarning: The default dtype for empty Series will be 'object' instead of
↪'float64' in a future version. Specify a dtype explicitly to silence this warning.
Series([], dtype: float64)
```

Result dtype inference changes for resample operations

The rules for the result dtype in *DataFrame.resample()* aggregations have changed for extension types (GH31359). Previously, pandas would attempt to convert the result back to the original dtype, falling back to the usual inference rules if that was not possible. Now, pandas will only return a result of the original dtype if the scalar values in the result are instances of the extension dtype's scalar type.

```
In [48]: df = pd.DataFrame({"A": ['a', 'b']}, dtype='category',
   ....:                   index=pd.date_range('2000', periods=2))
   ....:

In [49]: df
Out[49]:
              A
2000-01-01  a
```

(continues on next page)

(continued from previous page)

```
2000-01-02  b

[2 rows x 1 columns]
```

pandas 0.25.x

```
>>> df.resample("2D").agg(lambda x: 'a').A.dtype
CategoricalDtype(categories=['a', 'b'], ordered=False)
```

pandas 1.0.0

```
In [50]: df.resample("2D").agg(lambda x: 'a').A.dtype
Out[50]: dtype('O')
```

This fixes an inconsistency between `resample` and `groupby`. This also fixes a potential bug, where the **values** of the result might change depending on how the results are cast back to the original dtype.

pandas 0.25.x

```
>>> df.resample("2D").agg(lambda x: 'c')

     A
0  NaN
```

pandas 1.0.0

```
In [51]: df.resample("2D").agg(lambda x: 'c')
Out[51]:
            A
2000-01-01  c

[1 rows x 1 columns]
```

Increased minimum version for Python

Pandas 1.0.0 supports Python 3.6.1 and higher (GH29212).

Increased minimum versions for dependencies

Some minimum supported versions of dependencies were updated (GH29766, GH29723). If installed, we now require:

Package	Minimum Version	Required	Changed
numpy	1.13.3	X	
pytz	2015.4	X	
python-dateutil	2.6.1	X	
bottleneck	1.2.1		
numexpr	2.6.2		
pytest (dev)	4.0.2		

For optional libraries the general recommendation is to use the latest version. The following table lists the lowest version per library that is currently being tested throughout the development of pandas. Optional libraries below the lowest tested version may still work, but are not considered supported.

Package	Minimum Version	Changed
beautifulsoup4	4.6.0	
fastparquet	0.3.2	X
gcsfs	0.2.2	
lxml	3.8.0	
matplotlib	2.2.2	
numba	0.46.0	X
openpyxl	2.5.7	X
pyarrow	0.13.0	X
pymysql	0.7.1	
pytables	3.4.2	
s3fs	0.3.0	X
scipy	0.19.0	
sqlalchemy	1.1.4	
xarray	0.8.2	
xlrd	1.1.0	
xlsxwriter	0.9.8	
xlwt	1.2.0	

See *Dependencies* and *Optional dependencies* for more.

Build changes

Pandas has added a pyproject.toml file and will no longer include cythonized files in the source distribution uploaded to PyPI (GH28341, GH20775). If you're installing a built distribution (wheel) or via conda, this shouldn't have any effect on you. If you're building pandas from source, you should no longer need to install Cython into your build environment before calling `pip install pandas`.

Other API changes

- `core.groupby.GroupBy.transform` now raises on invalid operation names (GH27489)
- *`pandas.api.types.infer_dtype()`* will now return "integer-na" for integer and `np.nan` mix (GH27283)
- *`MultiIndex.from_arrays()`* will no longer infer names from arrays if `names=None` is explicitly provided (GH27292)
- In order to improve tab-completion, Pandas does not include most deprecated attributes when introspecting a pandas object using `dir` (e.g. `dir(df)`). To see which attributes are excluded, see an object's `_deprecations` attribute, for example `pd.DataFrame._deprecations` (GH28805).
- The returned dtype of *`unique()`* now matches the input dtype. (GH27874)
- Changed the default configuration value for `options.matplotlib.register_converters` from `True` to `"auto"` (GH18720). Now, pandas custom formatters will only be applied to plots created by pandas, through *`plot()`*. Previously, pandas' formatters would be applied to all plots created *after* a *`plot()`*. See *units registration* for more.
- *`Series.dropna()`* has dropped its `**kwargs` argument in favor of a single `how` parameter. Supplying anything else than `how` to `**kwargs` raised a `TypeError` previously (GH29388)
- When testing pandas, the new minimum required version of pytest is 5.0.1 (GH29664)

- `Series.str.__iter__()` was deprecated and will be removed in future releases (GH28277).
- Added `<NA>` to the list of default NA values for *`read_csv()`* (GH30821)

Documentation improvements

- Added new section on *Scaling to large datasets* (GH28315).
- Added sub-section on *Query MultiIndex* for HDF5 datasets (GH28791).

Deprecations

- *`Series.item()`* and *`Index.item()`* have been _undeprecated_ (GH29250)
- `Index.set_value` has been deprecated. For a given index `idx`, array `arr`, value in `idx` of `idx_val` and a new value of `val`, `idx.set_value(arr, idx_val, val)` is equivalent to `arr[idx.get_loc(idx_val)] = val`, which should be used instead (GH28621).
- `is_extension_type()` is deprecated, `is_extension_array_dtype()` should be used instead (GH29457)
- *`eval()`* keyword argument "truediv" is deprecated and will be removed in a future version (GH29812)
- `DateOffset.isAnchored()` and `DatetOffset.onOffset()` are deprecated and will be removed in a future version, use `DateOffset.is_anchored()` and `DateOffset.is_on_offset()` instead (GH30340)
- `pandas.tseries.frequencies.get_offset` is deprecated and will be removed in a future version, use `pandas.tseries.frequencies.to_offset` instead (GH4205)
- `Categorical.take_nd()` and `CategoricalIndex.take_nd()` are deprecated, use `Categorical.take()` and `CategoricalIndex.take()` instead (GH27745)
- The parameter `numeric_only` of `Categorical.min()` and `Categorical.max()` is deprecated and replaced with `skipna` (GH25303)
- The parameter `label` in `lreshape()` has been deprecated and will be removed in a future version (GH29742)
- `pandas.core.index` has been deprecated and will be removed in a future version, the public classes are available in the top-level namespace (GH19711)
- *`pandas.json_normalize()`* is now exposed in the top-level namespace. Usage of `json_normalize` as `pandas.io.json.json_normalize` is now deprecated and it is recommended to use `json_normalize` as *`pandas.json_normalize()`* instead (GH27586).
- The `numpy` argument of *`pandas.read_json()`* is deprecated (GH28512).
- *`DataFrame.to_stata()`*, *`DataFrame.to_feather()`*, and *`DataFrame.to_parquet()`* argument "fname" is deprecated, use "path" instead (GH23574)
- The deprecated internal attributes `_start`, `_stop` and `_step` of *`RangeIndex`* now raise a `FutureWarning` instead of a `DeprecationWarning` (GH26581)
- The `pandas.util.testing` module has been deprecated. Use the public API in `pandas.testing` documented at *Testing functions* (GH16232).
- `pandas.SparseArray` has been deprecated. Use `pandas.arrays.SparseArray` (*`arrays.SparseArray`*) instead. (GH30642)

- The parameter `is_copy` of *`Series.take()`* and *`DataFrame.take()`* has been deprecated and will be removed in a future version. (GH27357)
- Support for multi-dimensional indexing (e.g. `index[:, None]`) on a *`Index`* is deprecated and will be removed in a future version, convert to a numpy array before indexing instead (GH30588)
- The `pandas.np` submodule is now deprecated. Import numpy directly instead (GH30296)
- The `pandas.datetime` class is now deprecated. Import from `datetime` instead (GH30610)
- *`diff`* will raise a `TypeError` rather than implicitly losing the dtype of extension types in the future. Convert to the correct dtype before calling `diff` instead (GH31025)

Selecting Columns from a Grouped DataFrame

When selecting columns from a `DataFrameGroupBy` object, passing individual keys (or a tuple of keys) inside single brackets is deprecated, a list of items should be used instead. (GH23566) For example:

```
df = pd.DataFrame({
    "A": ["foo", "bar", "foo", "bar", "foo", "bar", "foo", "foo"],
    "B": np.random.randn(8),
    "C": np.random.randn(8),
})
g = df.groupby('A')

# single key, returns SeriesGroupBy
g['B']

# tuple of single key, returns SeriesGroupBy
g[('B',)]

# tuple of multiple keys, returns DataFrameGroupBy, raises FutureWarning
g[('B', 'C')]

# multiple keys passed directly, returns DataFrameGroupBy, raises FutureWarning
# (implicitly converts the passed strings into a single tuple)
g['B', 'C']

# proper way, returns DataFrameGroupBy
g[['B', 'C']]
```

Removal of prior version deprecations/changes

Removed SparseSeries and SparseDataFrame

`SparseSeries`, `SparseDataFrame` and the `DataFrame.to_sparse` method have been removed (GH28425). We recommend using a `Series` or `DataFrame` with sparse values instead. See *Migrating* for help with migrating existing code.

Matplotlib unit registration

Previously, pandas would register converters with matplotlib as a side effect of importing pandas (GH18720). This changed the output of plots made via matplotlib plots after pandas was imported, even if you were using matplotlib directly rather than *`plot()`*.

To use pandas formatters with a matplotlib plot, specify

```
>>> import pandas as pd
>>> pd.options.plotting.matplotlib.register_converters = True
```

Note that plots created by *DataFrame.plot()* and *Series.plot()* *do* register the converters automatically. The only behavior change is when plotting a date-like object via `matplotlib.pyplot.plot` or `matplotlib.Axes.plot`. See *Custom formatters for timeseries plots* for more.

Other removals

- Removed the previously deprecated keyword "index" from *read_stata()*, `StataReader`, and `StataReader.read()`, use "index_col" instead (GH17328)
- Removed `StataReader.data` method, use `StataReader.read()` instead (GH9493)
- Removed `pandas.plotting._matplotlib.tsplot`, use *Series.plot()* instead (GH19980)
- `pandas.tseries.converter.register` has been moved to *pandas.plotting.register_matplotlib_converters()* (GH18307)
- *Series.plot()* no longer accepts positional arguments, pass keyword arguments instead (GH30003)
- *DataFrame.hist()* and *Series.hist()* no longer allows `figsize="default"`, specify figure size by passinig a tuple instead (GH30003)
- Floordiv of integer-dtyped array by *Timedelta* now raises `TypeError` (GH21036)
- *TimedeltaIndex* and *DatetimeIndex* no longer accept non-nanosecond dtype strings like "timedelta64" or "datetime64", use "timedelta64[ns]" and "datetime64[ns]" instead (GH24806)
- Changed the default "skipna" argument in *pandas.api.types.infer_dtype()* from `False` to `True` (GH24050)
- Removed `Series.ix` and `DataFrame.ix` (GH26438)
- Removed `Index.summary` (GH18217)
- Removed the previously deprecated keyword "fastpath" from the *Index* constructor (GH23110)
- Removed `Series.get_value`, `Series.set_value`, `DataFrame.get_value`, `DataFrame.set_value` (GH17739)
- Removed `Series.compound` and `DataFrame.compound` (GH26405)
- Changed the default "inplace" argument in *DataFrame.set_index()* and *Series.set_axis()* from `None` to `False` (GH27600)
- Removed `Series.cat.categorical`, `Series.cat.index`, `Series.cat.name` (GH24751)
- Removed the previously deprecated keyword "box" from *to_datetime()* and *to_timedelta()*; in addition these now always returns *DatetimeIndex*, *TimedeltaIndex*, *Index*, *Series*, or *DataFrame* (GH24486)
- *to_timedelta()*, *Timedelta*, and *TimedeltaIndex* no longer allow "M", "y", or "Y" for the "unit" argument (GH23264)
- Removed the previously deprecated keyword "time_rule" from (non-public) `offsets.generate_range`, which has been moved to `core.arrays._ranges.generate_range()` (GH24157)
- *DataFrame.loc()* or *Series.loc()* with listlike indexers and missing labels will no longer reindex (GH17295)
- *DataFrame.to_excel()* and *Series.to_excel()* with non-existent columns will no longer reindex (GH17295)
- Removed the previously deprecated keyword "join_axes" from *concat()*; use `reindex_like` on the result instead (GH22318)
- Removed the previously deprecated keyword "by" from *DataFrame.sort_index()*, use *DataFrame.sort_values()* instead (GH10726)

- Removed support for nested renaming in *DataFrame.aggregate()*, *Series.aggregate()*, *core.groupby.DataFrameGroupBy.aggregate()*, *core.groupby.SeriesGroupBy.aggregate()*, *core.window.rolling.Rolling.aggregate()* (GH18529)
- Passing `datetime64` data to *TimedeltaIndex* or `timedelta64` data to `DatetimeIndex` now raises `TypeError` (GH23539, GH23937)
- Passing `int64` values to *DatetimeIndex* and a timezone now interprets the values as nanosecond timestamps in UTC, not wall times in the given timezone (GH24559)
- A tuple passed to *DataFrame.groupby()* is now exclusively treated as a single key (GH18314)
- Removed `Index.contains`, use `key in index` instead (GH30103)
- Addition and subtraction of `int` or integer-arrays is no longer allowed in *Timestamp*, *DatetimeIndex*, *TimedeltaIndex*, use `obj + n * obj.freq` instead of `obj + n` (GH22535)
- Removed `Series.ptp` (GH21614)
- Removed `Series.from_array` (GH18258)
- Removed `DataFrame.from_items` (GH18458)
- Removed `DataFrame.as_matrix`, `Series.as_matrix` (GH18458)
- Removed `Series.asobject` (GH18477)
- Removed `DataFrame.as_blocks`, `Series.as_blocks`, `DataFrame.blocks`, `Series.blocks` (GH17656)
- *pandas.Series.str.cat()* now defaults to aligning `others`, using `join='left'` (GH27611)
- *pandas.Series.str.cat()* does not accept list-likes *within* list-likes anymore (GH27611)
- *Series.where()* with `Categorical` dtype (or *DataFrame.where()* with `Categorical` column) no longer allows setting new categories (GH24114)
- Removed the previously deprecated keywords "start", "end", and "periods" from the *DatetimeIndex*, *TimedeltaIndex*, and *PeriodIndex* constructors; use *date_range()*, *timedelta_range()*, and *period_range()* instead (GH23919)
- Removed the previously deprecated keyword "verify_integrity" from the *DatetimeIndex* and *TimedeltaIndex* constructors (GH23919)
- Removed the previously deprecated keyword "fastpath" from `pandas.core.internals.blocks.make_block` (GH19265)
- Removed the previously deprecated keyword "dtype" from `Block.make_block_same_class()` (GH19434)
- Removed `ExtensionArray._formatting_values`. Use `ExtensionArray._formatter` instead. (GH23601)
- Removed `MultiIndex.to_hierarchical` (GH21613)
- Removed `MultiIndex.labels`, use *MultiIndex.codes* instead (GH23752)
- Removed the previously deprecated keyword "labels" from the *MultiIndex* constructor, use "codes" instead (GH23752)
- Removed `MultiIndex.set_labels`, use *MultiIndex.set_codes()* instead (GH23752)
- Removed the previously deprecated keyword "labels" from *MultiIndex.set_codes()*, `MultiIndex.copy()`, `MultiIndex.drop()`, use "codes" instead (GH23752)
- Removed support for legacy HDF5 formats (GH29787)

- Passing a dtype alias (e.g. 'datetime64[ns, UTC]') to *DatetimeTZDtype* is no longer allowed, use `DatetimeTZDtype.construct_from_string()` instead (GH23990)
- Removed the previously deprecated keyword "skip_footer" from *read_excel()*; use "skipfooter" instead (GH18836)
- *read_excel()* no longer allows an integer value for the parameter `usecols`, instead pass a list of integers from 0 to `usecols` inclusive (GH23635)
- Removed the previously deprecated keyword "convert_datetime64" from *DataFrame.to_records()* (GH18902)
- Removed `IntervalIndex.from_intervals` in favor of the *IntervalIndex* constructor (GH19263)
- Changed the default "keep_tz" argument in *DatetimeIndex.to_series()* from `None` to `True` (GH23739)
- Removed `api.types.is_period` and `api.types.is_datetimetz` (GH23917)
- Ability to read pickles containing *Categorical* instances created with pre-0.16 version of pandas has been removed (GH27538)
- Removed `pandas.tseries.plotting.tsplot` (GH18627)
- Removed the previously deprecated keywords "reduce" and "broadcast" from *DataFrame.apply()* (GH18577)
- Removed the previously deprecated `assert_raises_regex` function in `pandas._testing` (GH29174)
- Removed the previously deprecated `FrozenNDArray` class in `pandas.core.indexes.frozen` (GH29335)
- Removed the previously deprecated keyword "nthreads" from *read_feather()*, use "use_threads" instead (GH23053)
- Removed `Index.is_lexsorted_for_tuple` (GH29305)
- Removed support for nested renaming in *DataFrame.aggregate()*, *Series.aggregate()*, *core.groupby.DataFrameGroupBy.aggregate()*, *core.groupby.SeriesGroupBy.aggregate()*, *core.window.rolling.Rolling.aggregate()* (GH29608)
- Removed `Series.valid`; use *Series.dropna()* instead (GH18800)
- Removed `DataFrame.is_copy`, `Series.is_copy` (GH18812)
- Removed `DataFrame.get_ftype_counts`, `Series.get_ftype_counts` (GH18243)
- Removed `DataFrame.ftypes`, `Series.ftypes`, `Series.ftype` (GH26744)
- Removed `Index.get_duplicates`, use `idx[idx.duplicated()].unique()` instead (GH20239)
- Removed `Series.clip_upper`, `Series.clip_lower`, `DataFrame.clip_upper`, `DataFrame.clip_lower` (GH24203)
- Removed the ability to alter *DatetimeIndex.freq*, `TimedeltaIndex.freq`, or *PeriodIndex.freq* (GH20772)
- Removed `DatetimeIndex.offset` (GH20730)
- Removed `DatetimeIndex.asobject`, `TimedeltaIndex.asobject`, `PeriodIndex.asobject`, use `astype(object)` instead (GH29801)
- Removed the previously deprecated keyword "order" from *factorize()* (GH19751)
- Removed the previously deprecated keyword "encoding" from *read_stata()* and *DataFrame.to_stata()* (GH21400)

- Changed the default "sort" argument in *concat()* from None to False (GH20613)
- Removed the previously deprecated keyword "raise_conflict" from *DataFrame.update()*, use "errors" instead (GH23585)
- Removed the previously deprecated keyword "n" from DatetimeIndex.shift(), TimedeltaIndex.shift(), PeriodIndex.shift(), use "periods" instead (GH22458)
- Removed the previously deprecated keywords "how", "fill_method", and "limit" from *DataFrame.resample()* (GH30139)
- Passing an integer to *Series.fillna()* or *DataFrame.fillna()* with timedelta64[ns] dtype now raises TypeError (GH24694)
- Passing multiple axes to *DataFrame.dropna()* is no longer supported (GH20995)
- Removed Series.nonzero, use to_numpy().nonzero() instead (GH24048)
- Passing floating dtype codes to *Categorical.from_codes()* is no longer supported, pass codes.astype(np.int64) instead (GH21775)
- Removed the previously deprecated keyword "pat" from *Series.str.partition()* and *Series.str.rpartition()*, use "sep" instead (GH23767)
- Removed Series.put (GH27106)
- Removed Series.real, Series.imag (GH27106)
- Removed Series.to_dense, DataFrame.to_dense (GH26684)
- Removed Index.dtype_str, use str(index.dtype) instead (GH27106)
- Categorical.ravel() returns a *Categorical* instead of a ndarray (GH27199)
- The 'outer' method on Numpy ufuncs, e.g. np.subtract.outer operating on *Series* objects is no longer supported, and will raise NotImplementedError (GH27198)
- Removed Series.get_dtype_counts and DataFrame.get_dtype_counts (GH27145)
- Changed the default "fill_value" argument in Categorical.take() from True to False (GH20841)
- Changed the default value for the *raw* argument in Series.rolling().apply(), DataFrame.rolling().apply(), Series.expanding().apply(), and DataFrame.expanding().apply() from None to False (GH20584)
- Removed deprecated behavior of *Series.argmin()* and *Series.argmax()*, use *Series.idxmin()* and *Series.idxmax()* for the old behavior (GH16955)
- Passing a tz-aware datetime.datetime or *Timestamp* into the *Timestamp* constructor with the tz argument now raises a ValueError (GH23621)
- Removed Series.base, Index.base, Categorical.base, Series.flags, Index.flags, PeriodArray.flags, Series.strides, Index.strides, Series.itemsize, Index.itemsize, Series.data, Index.data (GH20721)
- Changed *Timedelta.resolution()* to match the behavior of the standard library datetime.timedelta.resolution, for the old behavior, use *Timedelta.resolution_string()* (GH26839)
- Removed Timestamp.weekday_name, DatetimeIndex.weekday_name, and Series.dt.weekday_name (GH18164)
- Removed the previously deprecated keyword "errors" in *Timestamp.tz_localize()*, *DatetimeIndex.tz_localize()*, and *Series.tz_localize()* (GH22644)
- Changed the default "ordered" argument in *CategoricalDtype* from None to False (GH26336)

- *Series.set_axis()* and *DataFrame.set_axis()* now require "labels" as the first argument and "axis" as an optional named parameter (GH30089)
- Removed `to_msgpack`, `read_msgpack`, `DataFrame.to_msgpack`, `Series.to_msgpack` (GH27103)
- Removed `Series.compress` (GH21930)
- Removed the previously deprecated keyword "fill_value" from `Categorical.fillna()`, use "value" instead (GH19269)
- Removed the previously deprecated keyword "data" from `andrews_curves()`, use "frame" instead (GH6956)
- Removed the previously deprecated keyword "data" from `parallel_coordinates()`, use "frame" instead (GH6956)
- Removed the previously deprecated keyword "colors" from `parallel_coordinates()`, use "color" instead (GH6956)
- Removed the previously deprecated keywords "verbose" and "private_key" from *read_gbq()* (GH30200)
- Calling `np.array` and `np.asarray` on tz-aware *Series* and *DatetimeIndex* will now return an object array of tz-aware *Timestamp* (GH24596)
-

Performance improvements

- Performance improvement in *DataFrame* arithmetic and comparison operations with scalars (GH24990, GH29853)
- Performance improvement in indexing with a non-unique *IntervalIndex* (GH27489)
- Performance improvement in `MultiIndex.is_monotonic` (GH27495)
- Performance improvement in *cut()* when `bins` is an *IntervalIndex* (GH27668)
- Performance improvement when initializing a *DataFrame* using a `range` (GH30171)
- Performance improvement in *DataFrame.corr()* when `method` is `"spearman"` (GH28139)
- Performance improvement in *DataFrame.replace()* when provided a list of values to replace (GH28099)
- Performance improvement in *DataFrame.select_dtypes()* by using vectorization instead of iterating over a loop (GH28317)
- Performance improvement in `Categorical.searchsorted()` and `CategoricalIndex.searchsorted()` (GH28795)
- Performance improvement when comparing a *Categorical* with a scalar and the scalar is not found in the categories (GH29750)
- Performance improvement when checking if values in a *Categorical* are equal, equal or larger or larger than a given scalar. The improvement is not present if checking if the *Categorical* is less than or less than or equal than the scalar (GH29820)
- Performance improvement in *Index.equals()* and `MultiIndex.equals()` (GH29134)
- Performance improvement in *infer_dtype()* when `skipna` is `True` (GH28814)

Bug fixes

Categorical

- Added test to assert the `fillna()` raises the correct `ValueError` message when the value isn't a value from categories (GH13628)
- Bug in `Categorical.astype()` where `NaN` values were handled incorrectly when casting to int (GH28406)
- *`DataFrame.reindex()`* with a *`CategoricalIndex`* would fail when the targets contained duplicates, and wouldn't fail if the source contained duplicates (GH28107)
- Bug in `Categorical.astype()` not allowing for casting to extension dtypes (GH28668)
- Bug where *`merge()`* was unable to join on categorical and extension dtype columns (GH28668)
- `Categorical.searchsorted()` and `CategoricalIndex.searchsorted()` now work on unordered categoricals also (GH21667)
- Added test to assert roundtripping to parquet with *`DataFrame.to_parquet()`* or *`read_parquet()`* will preserve Categorical dtypes for string types (GH27955)
- Changed the error message in `Categorical.remove_categories()` to always show the invalid removals as a set (GH28669)
- Using date accessors on a categorical dtyped *`Series`* of datetimes was not returning an object of the same type as if one used the `str.()` / `dt.()` on a *`Series`* of that type. E.g. when accessing *`Series.dt.tz_localize()`* on a *`Categorical`* with duplicate entries, the accessor was skipping duplicates (GH27952)
- Bug in *`DataFrame.replace()`* and *`Series.replace()`* that would give incorrect results on categorical data (GH26988)
- Bug where calling `Categorical.min()` or `Categorical.max()` on an empty Categorical would raise a numpy exception (GH30227)
- The following methods now also correctly output values for unobserved categories when called through `groupby(..., observed=False)` (GH17605) * `core.groupby.SeriesGroupBy.count()` * `core.groupby.SeriesGroupBy.size()` * *`core.groupby.SeriesGroupBy.nunique()`* * `core.groupby.SeriesGroupBy.nth()`

Datetimelike

- Bug in `Series.__setitem__()` incorrectly casting `np.timedelta64("NaT")` to `np.datetime64("NaT")` when inserting into a *`Series`* with datetime64 dtype (GH27311)
- Bug in *`Series.dt()`* property lookups when the underlying data is read-only (GH27529)
- Bug in `HDFStore.__getitem__` incorrectly reading tz attribute created in Python 2 (GH26443)
- Bug in *`to_datetime()`* where passing arrays of malformed `str` with errors="coerce" could incorrectly lead to raising `ValueError` (GH28299)
- Bug in *`core.groupby.SeriesGroupBy.nunique()`* where `NaT` values were interfering with the count of unique values (GH27951)
- Bug in *`Timestamp`* subtraction when subtracting a *`Timestamp`* from a `np.datetime64` object incorrectly raising `TypeError` (GH28286)

- Addition and subtraction of integer or integer-dtype arrays with *Timestamp* will now raise `NullFrequencyError` instead of `ValueError` (GH28268)
- Bug in *Series* and *DataFrame* with integer dtype failing to raise `TypeError` when adding or subtracting a `np.datetime64` object (GH28080)
- Bug in *Series.astype()*, *Index.astype()*, and *DataFrame.astype()* failing to handle `NaT` when casting to an integer dtype (GH28492)
- Bug in `Week` with `weekday` incorrectly raising `AttributeError` instead of `TypeError` when adding or subtracting an invalid type (GH28530)
- Bug in *DataFrame* arithmetic operations when operating with a *Series* with dtype *'timedelta64[ns]'* (GH28049)
- Bug in `core.groupby.generic.SeriesGroupBy.apply()` raising `ValueError` when a column in the original DataFrame is a datetime and the column labels are not standard integers (GH28247)
- Bug in `pandas._config.localization.get_locales()` where the `locales -a` encodes the locales list as windows-1252 (GH23638, GH24760, GH27368)
- Bug in *Series.var()* failing to raise `TypeError` when called with `timedelta64[ns]` dtype (GH28289)
- Bug in *DatetimeIndex.strftime()* and *Series.dt.strftime()* where `NaT` was converted to the string `'NaT'` instead of `np.nan` (GH29578)
- Bug in masking datetime-like arrays with a boolean mask of an incorrect length not raising an `IndexError` (GH30308)
- Bug in *Timestamp.resolution* being a property instead of a class attribute (GH29910)
- Bug in *pandas.to_datetime()* when called with `None` raising `TypeError` instead of returning `NaT` (GH30011)
- Bug in *pandas.to_datetime()* failing for *deques* when using `cache=True` (the default) (GH29403)
- Bug in *Series.item()* with `datetime64` or `timedelta64` dtype, `DatetimeIndex.item()`, and `TimedeltaIndex.item()` returning an integer instead of a *Timestamp* or *Timedelta* (GH30175)
- Bug in *DatetimeIndex* addition when adding a non-optimized `DateOffset` incorrectly dropping timezone information (GH30336)
- Bug in *DataFrame.drop()* where attempting to drop non-existent values from a DatetimeIndex would yield a confusing error message (GH30399)
- Bug in *DataFrame.append()* would remove the timezone-awareness of new data (GH30238)
- Bug in *Series.cummin()* and *Series.cummax()* with timezone-aware dtype incorrectly dropping its timezone (GH15553)
- Bug in `DatetimeArray`, `TimedeltaArray`, and `PeriodArray` where inplace addition and subtraction did not actually operate inplace (GH24115)
- Bug in *pandas.to_datetime()* when called with `Series` storing `IntegerArray` raising `TypeError` instead of returning `Series` (GH30050)
- Bug in *date_range()* with custom business hours as `freq` and given number of `periods` (GH30593)
- Bug in *PeriodIndex* comparisons with incorrectly casting integers to *Period* objects, inconsistent with the *Period* comparison behavior (GH30722)
- Bug in `DatetimeIndex.insert()` raising a `ValueError` instead of a `TypeError` when trying to insert a timezone-aware *Timestamp* into a timezone-naive *DatetimeIndex*, or vice-versa (GH30806)

Timedelta

- Bug in subtracting a *TimedeltaIndex* or TimedeltaArray from a np.datetime64 object (GH29558)
-
-

Timezones

-
-

Numeric

- Bug in *DataFrame.quantile()* with zero-column *DataFrame* incorrectly raising (GH23925)
- *DataFrame* flex inequality comparisons methods (*DataFrame.lt()*, *DataFrame.le()*, *DataFrame.gt()*, *DataFrame.ge()*) with object-dtype and complex entries failing to raise TypeError like their *Series* counterparts (GH28079)
- Bug in *DataFrame* logical operations (&, |, ^) not matching *Series* behavior by filling NA values (GH28741)
- Bug in *DataFrame.interpolate()* where specifying axis by name references variable before it is assigned (GH29142)
- Bug in *Series.var()* not computing the right value with a nullable integer dtype series not passing through ddof argument (GH29128)
- Improved error message when using *frac* > 1 and *replace* = False (GH27451)
- Bug in numeric indexes resulted in it being possible to instantiate an *Int64Index*, *UInt64Index*, or *Float64Index* with an invalid dtype (e.g. datetime-like) (GH29539)
- Bug in *UInt64Index* precision loss while constructing from a list with values in the np.uint64 range (GH29526)
- Bug in NumericIndex construction that caused indexing to fail when integers in the np.uint64 range were used (GH28023)
- Bug in NumericIndex construction that caused *UInt64Index* to be casted to *Float64Index* when integers in the np.uint64 range were used to index a *DataFrame* (GH28279)
- Bug in *Series.interpolate()* when using method=`index` with an unsorted index, would previously return incorrect results. (GH21037)
- Bug in *DataFrame.round()* where a *DataFrame* with a *CategoricalIndex* of *IntervalIndex* columns would incorrectly raise a TypeError (GH30063)
- Bug in *Series.pct_change()* and *DataFrame.pct_change()* when there are duplicated indices (GH30463)
- Bug in *DataFrame* cumulative operations (e.g. cumsum, cummax) incorrect casting to object-dtype (GH19296)
- Bug in *diff* losing the dtype for extension types (GH30889)
- Bug in *DataFrame.diff* raising an IndexError when one of the columns was a nullable integer dtype (GH30967)

Conversion

-
-

Strings

- Calling *Series.str.isalnum()* (and other "ismethods") on an empty Series would return an object dtype instead of bool (GH29624)
-

Interval

- Bug in *IntervalIndex.get_indexer()* where a *Categorical* or *CategoricalIndex* target would incorrectly raise a TypeError (GH30063)
- Bug in pandas.core.dtypes.cast.infer_dtype_from_scalar where passing pandas_dtype=True did not infer *IntervalDtype* (GH30337)
- Bug in *Series* constructor where constructing a Series from a list of *Interval* objects resulted in object dtype instead of *IntervalDtype* (GH23563)
- Bug in *IntervalDtype* where the kind attribute was incorrectly set as None instead of "O" (GH30568)
- Bug in *IntervalIndex*, *IntervalArray*, and *Series* with interval data where equality comparisons were incorrect (GH24112)

Indexing

- Bug in assignment using a reverse slicer (GH26939)
- Bug in *DataFrame.explode()* would duplicate frame in the presence of duplicates in the index (GH28010)
- Bug in reindexing a *PeriodIndex()* with another type of index that contained a *Period* (GH28323) (GH28337)
- Fix assignment of column via *.loc* with numpy non-ns datetime type (GH27395)
- Bug in Float64Index.astype() where np.inf was not handled properly when casting to an integer dtype (GH28475)
- *Index.union()* could fail when the left contained duplicates (GH28257)
- Bug when indexing with .loc where the index was a *CategoricalIndex* with non-string categories didn't work (GH17569, GH30225)
- *Index.get_indexer_non_unique()* could fail with TypeError in some cases, such as when searching for ints in a string index (GH28257)
- Bug in Float64Index.get_loc() incorrectly raising TypeError instead of KeyError (GH29189)
- Bug in *DataFrame.loc()* with incorrect dtype when setting Categorical value in 1-row DataFrame (GH25495)
- *MultiIndex.get_loc()* can't find missing values when input includes missing values (GH19132)

- Bug in `Series.__setitem__()` incorrectly assigning values with boolean indexer when the length of new data matches the number of `True` values and new data is not a `Series` or an `np.array` (GH30567)
- Bug in indexing with a *`PeriodIndex`* incorrectly accepting integers representing years, use e.g. `ser.loc["2007"]` instead of `ser.loc[2007]` (GH30763)

Missing

-
-

MultiIndex

- Constructor for *`MultiIndex`* verifies that the given `sortorder` is compatible with the actual `lexsort_depth` if `verify_integrity` parameter is `True` (the default) (GH28735)
- Series and MultiIndex *.drop* with *MultiIndex* raise exception if labels not in given in level (GH8594)
-

I/O

- *`read_csv()`* now accepts binary mode file buffers when using the Python csv engine (GH23779)
- Bug in *`DataFrame.to_json()`* where using a Tuple as a column or index value and using `orient="columns"` or `orient="index"` would produce invalid JSON (GH20500)
- Improve infinity parsing. *`read_csv()`* now interprets `Infinity`, `+Infinity`, `-Infinity` as floating point values (GH10065)
- Bug in *`DataFrame.to_csv()`* where values were truncated when the length of `na_rep` was shorter than the text input data. (GH25099)
- Bug in *`DataFrame.to_string()`* where values were truncated using display options instead of outputting the full content (GH9784)
- Bug in *`DataFrame.to_json()`* where a datetime column label would not be written out in ISO format with `orient="table"` (GH28130)
- Bug in *`DataFrame.to_parquet()`* where writing to GCS would fail with *engine='fastparquet'* if the file did not already exist (GH28326)
- Bug in *`read_hdf()`* closing stores that it didn't open when Exceptions are raised (GH28699)
- Bug in `DataFrame.read_json()` where using `orient="index"` would not maintain the order (GH28557)
- Bug in *`DataFrame.to_html()`* where the length of the `formatters` argument was not verified (GH28469)
- Bug in `DataFrame.read_excel()` with `engine='ods'` when `sheet_name` argument references a non-existent sheet (GH27676)
- Bug in *`pandas.io.formats.style.Styler()`* formatting for floating values not displaying decimals correctly (GH13257)
- Bug in *`DataFrame.to_html()`* when using `formatters=<list>` and `max_cols` together. (GH25955)

- Bug in `Styler.background_gradient()` not able to work with dtype `Int64` (GH28869)
- Bug in *DataFrame.to_clipboard()* which did not work reliably in ipython (GH22707)
- Bug in *read_json()* where default encoding was not set to `utf-8` (GH29565)
- Bug in `PythonParser` where str and bytes were being mixed when dealing with the decimal field (GH29650)
- *read_gbq()* now accepts `progress_bar_type` to display progress bar while the data downloads. (GH29857)
- Bug in `pandas.io.json.json_normalize()` where a missing value in the location specified by *record_path* would raise a `TypeError` (GH30148)
- *read_excel()* now accepts binary data (GH15914)
- Bug in *read_csv()* in which encoding handling was limited to just the string *utf-16* for the C engine (GH24130)

Plotting

- Bug in *Series.plot()* not able to plot boolean values (GH23719)
- Bug in *DataFrame.plot()* not able to plot when no rows (GH27758)
- Bug in *DataFrame.plot()* producing incorrect legend markers when plotting multiple series on the same axis (GH18222)
- Bug in *DataFrame.plot()* when `kind='box'` and data contains datetime or timedelta data. These types are now automatically dropped (GH22799)
- Bug in *DataFrame.plot.line()* and *DataFrame.plot.area()* produce wrong xlim in x-axis (GH27686, GH25160, GH24784)
- Bug where *DataFrame.boxplot()* would not accept a `color` parameter like *DataFrame.plot.box()* (GH26214)
- Bug in the `xticks` argument being ignored for *DataFrame.plot.bar()* (GH14119)
- *set_option()* now validates that the plot backend provided to `'plotting.backend'` implements the backend when the option is set, rather than when a plot is created (GH28163)
- *DataFrame.plot()* now allow a `backend` keyword argument to allow changing between backends in one session (GH28619).
- Bug in color validation incorrectly raising for non-color styles (GH29122).
- Allow *DataFrame.plot.scatter()* to plot `objects` and `datetime` type data (GH18755, GH30391)
- Bug in *DataFrame.hist()*, `xrot=0` does not work with `by` and subplots (GH30288).

Groupby/resample/rolling

- Bug in `core.groupby.DataFrameGroupBy.apply()` only showing output from a single group when function returns an *Index* (GH28652)
- Bug in *DataFrame.groupby()* with multiple groups where an `IndexError` would be raised if any group contained all NA values (GH20519)
- Bug in *pandas.core.resample.Resampler.size()* and *pandas.core.resample.Resampler.count()* returning wrong dtype when used with an empty *Series* or *DataFrame* (GH28427)

- Bug in *DataFrame.rolling()* not allowing for rolling over datetimes when `axis=1` (GH28192)
- Bug in *DataFrame.rolling()* not allowing rolling over multi-index levels (GH15584).
- Bug in *DataFrame.rolling()* not allowing rolling on monotonic decreasing time indexes (GH19248).
- Bug in *DataFrame.groupby()* not offering selection by column name when `axis=1` (GH27614)
- Bug in `core.groupby.DataFrameGroupby.agg()` not able to use lambda function with named aggregation (GH27519)
- Bug in *DataFrame.groupby()* losing column name information when grouping by a categorical column (GH28787)
- Remove error raised due to duplicated input functions in named aggregation in *DataFrame.groupby()* and *Series.groupby()*. Previously error will be raised if the same function is applied on the same column and now it is allowed if new assigned names are different. (GH28426)
- *core.groupby.SeriesGroupBy.value_counts()* will be able to handle the case even when the *Grouper* makes empty groups (GH28479)
- Bug in *core.window.rolling.Rolling.quantile()* ignoring `interpolation` keyword argument when used within a groupby (GH28779)
- Bug in *DataFrame.groupby()* where `any`, `all`, `nunique` and transform functions would incorrectly handle duplicate column labels (GH21668)
- Bug in `core.groupby.DataFrameGroupBy.agg()` with timezone-aware datetime64 column incorrectly casting results to the original dtype (GH29641)
- Bug in *DataFrame.groupby()* when using axis=1 and having a single level columns index (GH30208)
- Bug in *DataFrame.groupby()* when using nunique on axis=1 (GH30253)
- Bug in `GroupBy.quantile()` with multiple list-like q value and integer column names (GH30289)
- Bug in `GroupBy.pct_change()` and `core.groupby.SeriesGroupBy.pct_change()` causes `TypeError` when `fill_method` is `None` (GH30463)
- Bug in `Rolling.count()` and `Expanding.count()` argument where `min_periods` was ignored (GH26996)

Reshaping

- Bug in *DataFrame.apply()* that caused incorrect output with empty *DataFrame* (GH28202, GH21959)
- Bug in *DataFrame.stack()* not handling non-unique indexes correctly when creating MultiIndex (GH28301)
- Bug in *pivot_table()* not returning correct type `float` when `margins=True` and `aggfunc='mean'` (GH24893)
- Bug *merge_asof()* could not use `datetime.timedelta` for `tolerance` kwarg (GH28098)
- Bug in *merge()*, did not append suffixes correctly with MultiIndex (GH28518)
- *qcut()* and *cut()* now handle boolean input (GH20303)
- Fix to ensure all int dtypes can be used in *merge_asof()* when using a tolerance value. Previously every non-int64 type would raise an erroneous `MergeError` (GH28870).
- Better error message in *get_dummies()* when *columns* isn't a list-like value (GH28383)

- Bug in *Index.join()* that caused infinite recursion error for mismatched MultiIndex name orders. (GH25760, GH28956)
- Bug *Series.pct_change()* where supplying an anchored frequency would throw a ValueError (GH28664)
- Bug where *DataFrame.equals()* returned True incorrectly in some cases when two DataFrames had the same columns in different orders (GH28839)
- Bug in *DataFrame.replace()* that caused non-numeric replacer's dtype not respected (GH26632)
- Bug in *melt()* where supplying mixed strings and numeric values for id_vars or value_vars would incorrectly raise a ValueError (GH29718)
- Dtypes are now preserved when transposing a DataFrame where each column is the same extension dtype (GH30091)
- Bug in *merge_asof()* merging on a tz-aware left_index and right_on a tz-aware column (GH29864)
- Improved error message and docstring in *cut()* and *qcut()* when *labels=True* (GH13318)
- Bug in missing *fill_na* parameter to *DataFrame.unstack()* with list of levels (GH30740)

Sparse

- Bug in SparseDataFrame arithmetic operations incorrectly casting inputs to float (GH28107)
- Bug in DataFrame.sparse returning a Series when there was a column named sparse rather than the accessor (GH30758)
- Fixed operator.xor() with a boolean-dtype SparseArray. Now returns a sparse result, rather than object dtype (GH31025)

ExtensionArray

- Bug in *arrays.PandasArray* when setting a scalar string (GH28118, GH28150).
- Bug where nullable integers could not be compared to strings (GH28930)
- Bug where *DataFrame* constructor raised ValueError with list-like data and dtype specified (GH30280)

Other

- Trying to set the display.precision, display.max_rows or display.max_columns using *set_option()* to anything but a None or a positive int will raise a ValueError (GH23348)
- Using *DataFrame.replace()* with overlapping keys in a nested dictionary will no longer raise, now matching the behavior of a flat dictionary (GH27660)
- *DataFrame.to_csv()* and *Series.to_csv()* now support dicts as compression argument with key 'method' being the compression method and others as additional compression options when the compression method is 'zip'. (GH26023)
- Bug in *Series.diff()* where a boolean series would incorrectly raise a TypeError (GH17294)
- *Series.append()* will no longer raise a TypeError when passed a tuple of Series (GH28410)
- Fix corrupted error message when calling pandas.libs._json.encode() on a 0d array (GH18878)

- Backtick quoting in *DataFrame.query()* and *DataFrame.eval()* can now also be used to use invalid identifiers like names that start with a digit, are python keywords, or are using single character operators. (GH27017)
- Bug in pd.core.util.hashing.hash_pandas_object where arrays containing tuples were incorrectly treated as non-hashable (GH28969)
- Bug in *DataFrame.append()* that raised IndexError when appending with empty list (GH28769)
- Fix AbstractHolidayCalendar to return correct results for years after 2030 (now goes up to 2200) (GH27790)
- Fixed *IntegerArray* returning inf rather than NaN for operations dividing by 0 (GH27398)
- Fixed pow operations for *IntegerArray* when the other value is 0 or 1 (GH29997)
- Bug in *Series.count()* raises if use_inf_as_na is enabled (GH29478)
- Bug in *Index* where a non-hashable name could be set without raising TypeError (GH29069)
- Bug in *DataFrame* constructor when passing a 2D ndarray and an extension dtype (GH12513)
- Bug in *DataFrame.to_csv()* when supplied a series with a dtype="string" and a na_rep, the na_rep was being truncated to 2 characters. (GH29975)
- Bug where *DataFrame.itertuples()* would incorrectly determine whether or not namedtuples could be used for dataframes of 255 columns (GH28282)
- Handle nested NumPy object arrays in *testing.assert_series_equal()* for ExtensionArray implementations (GH30841)
- Bug in *Index* constructor incorrectly allowing 2-dimensional input arrays (GH13601, GH27125)

5.3 Version 0.25

5.3.1 What's new in 0.25.3 (October 31, 2019)

These are the changes in pandas 0.25.3. See *Release notes* for a full changelog including other versions of pandas.

Bug fixes

Groupby/resample/rolling

- Bug in `DataFrameGroupBy.quantile()` where NA values in the grouping could cause segfaults or incorrect results (GH28882)

Contributors

A total of 2 people contributed patches to this release. People with a "+" by their names contributed a patch for the first time.

- Will Ayd
- William Ayd

5.3.2 What's new in 0.25.2 (October 15, 2019)

These are the changes in pandas 0.25.2. See *Release notes* for a full changelog including other versions of pandas.

Note: Pandas 0.25.2 adds compatibility for Python 3.8 (GH28147).

Bug fixes

Indexing

- Fix regression in `DataFrame.reindex()` not following the `limit` argument (GH28631).
- Fix regression in `RangeIndex.get_indexer()` for decreasing `RangeIndex` where target values may be improperly identified as missing/present (GH28678)

I/O

- Fix regression in notebook display where <th> tags were missing for DataFrame.index values (GH28204).
- Regression in to_csv() where writing a Series or DataFrame indexed by an IntervalIndex would incorrectly raise a TypeError (GH28210)
- Fix to_csv() with ExtensionArray with list-like values (GH28840).

Groupby/resample/rolling

- Bug incorrectly raising an IndexError when passing a list of quantiles to *pandas.core.groupby.DataFrameGroupBy.quantile()* (GH28113).
- Bug in pandas.core.groupby.GroupBy.shift(), *pandas.core.groupby.GroupBy.bfill()* and *pandas.core.groupby.GroupBy.ffill()* where timezone information would be dropped (GH19995, GH27992)

Other

- Compatibility with Python 3.8 in DataFrame.query() (GH27261)
- Fix to ensure that tab-completion in an IPython console does not raise warnings for deprecated attributes (GH27900).

Contributors

A total of 6 people contributed patches to this release. People with a "+" by their names contributed a patch for the first time.

- Felix Divo +
- Jeremy Schendel
- Joris Van den Bossche
- MeeseeksMachine
- Tom Augspurger
- jbrockmendel

5.3.3 What's new in 0.25.1 (August 21, 2019)

These are the changes in pandas 0.25.1. See *Release notes* for a full changelog including other versions of pandas.

I/O and LZMA

Some users may unknowingly have an incomplete Python installation lacking the *lzma* module from the standard library. In this case, *import pandas* failed due to an *ImportError* (GH27575). Pandas will now warn, rather than raising an *ImportError* if the *lzma* module is not present. Any subsequent attempt to use *lzma* methods will raise a *RuntimeError*. A possible fix for the lack of the *lzma* module is to ensure you have the necessary libraries and then re-install Python. For example, on MacOS installing Python with *pyenv* may lead to an incomplete Python installation due to unmet system dependencies at compilation time (like *xz*). Compilation will succeed, but Python might fail at run time. The issue can be solved by installing the necessary dependencies and then re-installing Python.

Bug fixes

Categorical

- Bug in `Categorical.fillna()` that would replace all values, not just those that are `NaN` (GH26215)

Datetimelike

- Bug in `to_datetime()` where passing a timezone-naive `DatetimeArray` or `DatetimeIndex` and `utc=True` would incorrectly return a timezone-naive result (GH27733)
- Bug in `Period.to_timestamp()` where a `Period` outside the `Timestamp` implementation bounds (roughly 1677-09-21 to 2262-04-11) would return an incorrect `Timestamp` instead of raising `OutOfBoundsDatetime` (GH19643)
- Bug in iterating over `DatetimeIndex` when the underlying data is read-only (GH28055)

Timezones

- Bug in `Index` where a numpy object array with a timezone aware `Timestamp` and `np.nan` would not return a `DatetimeIndex` (GH27011)

Numeric

- Bug in `Series.interpolate()` when using a timezone aware `DatetimeIndex` (GH27548)
- Bug when printing negative floating point complex numbers would raise an `IndexError` (GH27484)
- Bug where `DataFrame` arithmetic operators such as `DataFrame.mul()` with a `Series` with axis=1 would raise an `AttributeError` on `DataFrame` larger than the minimum threshold to invoke numexpr (GH27636)
- Bug in `DataFrame` arithmetic where missing values in results were incorrectly masked with `NaN` instead of `Inf` (GH27464)

Conversion

- Improved the warnings for the deprecated methods `Series.real()` and `Series.imag()` (GH27610)

Interval

- Bug in `IntervalIndex` where *dir(obj)* would raise `ValueError` (GH27571)

Indexing

- Bug in partial-string indexing returning a NumPy array rather than a `Series` when indexing with a scalar like `.loc['2015']` (GH27516)
- Break reference cycle involving `Index` and other index classes to allow garbage collection of index objects without running the GC. (GH27585, GH27840)
- Fix regression in assigning values to a single column of a DataFrame with a `MultiIndex` columns (GH27841).
- Fix regression in `.ix` fallback with an `IntervalIndex` (GH27865).

Missing

- Bug in *pandas.isnull()* or *pandas.isna()* when the input is a type e.g. `type(pandas.Series())` (GH27482)

I/O

- Avoid calling `S3File.s3` when reading parquet, as this was removed in s3fs version 0.3.0 (GH27756)
- Better error message when a negative header is passed in *pandas.read_csv()* (GH27779)
- Follow the `min_rows` display option (introduced in v0.25.0) correctly in the HTML repr in the notebook (GH27991).

Plotting

- Added a `pandas_plotting_backends` entrypoint group for registering plot backends. See *Plotting backends* for more (GH26747).
- Fixed the re-instatement of Matplotlib datetime converters after calling *pandas.plotting.deregister_matplotlib_converters()* (GH27481).
- Fix compatibility issue with matplotlib when passing a pandas `Index` to a plot call (GH27775).

Groupby/resample/rolling

- Fixed regression in `pands.core.groupby.DataFrameGroupBy.quantile()` raising when multiple quantiles are given (GH27526)
- Bug in *pandas.core.groupby.DataFrameGroupBy.transform()* where applying a timezone conversion lambda function would drop timezone information (GH27496)
- Bug in *pandas.core.groupby.GroupBy.nth()* where `observed=False` was being ignored for Categorical groupers (GH26385)
- Bug in windowing over read-only arrays (GH27766)
- Fixed segfault in *pandas.core.groupby.DataFrameGroupBy.quantile* when an invalid quantile was passed (GH27470)

Reshaping

- A `KeyError` is now raised if `.unstack()` is called on a `Series` or `DataFrame` with a flat `Index` passing a name which is not the correct one (GH18303)
- Bug `merge_asof()` could not merge `Timedelta` objects when passing *tolerance* kwarg (GH27642)
- Bug in `DataFrame.crosstab()` when `margins` set to `True` and `normalize` is not `False`, an error is raised. (GH27500)
- `DataFrame.join()` now suppresses the `FutureWarning` when the sort parameter is specified (GH21952)
- Bug in `DataFrame.join()` raising with readonly arrays (GH27943)

Sparse

- Bug in reductions for `Series` with Sparse dtypes (GH27080)

Other

- Bug in `Series.replace()` and `DataFrame.replace()` when replacing timezone-aware timestamps using a dict-like replacer (GH27720)
- Bug in `Series.rename()` when using a custom type indexer. Now any value that isn't callable or dict-like is treated as a scalar. (GH27814)

Contributors

A total of 5 people contributed patches to this release. People with a "+" by their names contributed a patch for the first time.

- Jeff Reback
- Joris Van den Bossche
- MeeseeksMachine +
- Tom Augspurger
- jbrockmendel

5.3.4 What's new in 0.25.0 (July 18, 2019)

Warning: Starting with the 0.25.x series of releases, pandas only supports Python 3.5.3 and higher. See Dropping Python 2.7 for more details.

Warning: The minimum supported Python version will be bumped to 3.6 in a future release.

Warning: *Panel* has been fully removed. For N-D labeled data structures, please use xarray

Warning: `read_pickle()` and `read_msgpack()` are only guaranteed backwards compatible back to pandas version 0.20.3 (GH27082)

These are the changes in pandas 0.25.0. See *Release notes* for a full changelog including other versions of pandas.

Enhancements

Groupby aggregation with relabeling

Pandas has added special groupby behavior, known as "named aggregation", for naming the output columns when applying multiple aggregation functions to specific columns (GH18366, GH26512).

```
In [1]: animals = pd.DataFrame({'kind': ['cat', 'dog', 'cat', 'dog'],
   ...:                         'height': [9.1, 6.0, 9.5, 34.0],
   ...:                         'weight': [7.9, 7.5, 9.9, 198.0]})
   ...:

In [2]: animals
Out[2]:
  kind  height  weight
0  cat     9.1     7.9
1  dog     6.0     7.5
2  cat     9.5     9.9
3  dog    34.0   198.0

[4 rows x 3 columns]

In [3]: animals.groupby("kind").agg(
   ...:     min_height=pd.NamedAgg(column='height', aggfunc='min'),
   ...:     max_height=pd.NamedAgg(column='height', aggfunc='max'),
   ...:     average_weight=pd.NamedAgg(column='weight', aggfunc=np.mean),
   ...: )
   ...:
Out[3]:
      min_height  max_height  average_weight
kind
cat          9.1         9.5            8.90
dog          6.0        34.0          102.75
```

(continues on next page)

(continued from previous page)

```
[2 rows x 3 columns]
```

Pass the desired columns names as the `**kwargs` to `.agg`. The values of `**kwargs` should be tuples where the first element is the column selection, and the second element is the aggregation function to apply. Pandas provides the `pandas.NamedAgg` namedtuple to make it clearer what the arguments to the function are, but plain tuples are accepted as well.

```
In [4]: animals.groupby("kind").agg(
   ...:     min_height=('height', 'min'),
   ...:     max_height=('height', 'max'),
   ...:     average_weight=('weight', np.mean),
   ...: )
   ...:
Out[4]:
      min_height  max_height  average_weight
kind
cat          9.1         9.5            8.90
dog          6.0        34.0          102.75

[2 rows x 3 columns]
```
