>>> df.asof(pd.DatetimeIndex(['2018-02-27 09:03:30',
...                           '2018-02-27 09:04:30']))
...
           a    b
2018-02-27 09:03:30 NaN NaN
2018-02-27 09:04:30 NaN NaN
```

Take a single column into consideration

```
>>> df.asof(pd.DatetimeIndex(['2018-02-27 09:03:30',
...                           '2018-02-27 09:04:30']),
...         subset=['a'])
...
           a    b
2018-02-27 09:03:30  30.0 NaN
2018-02-27 09:04:30  40.0 NaN
```

pandas.Series.astype

`Series.astype(dtype, copy=True, errors='raise')`

Cast a pandas object to a specified dtype `dtype`.

Parameters

dtype [data type, or dict of column name -> data type] Use a `numpy.dtype` or Python type to cast entire pandas object to the same type. Alternatively, use `{col: dtype, ...}`, where `col` is a column label and `dtype` is a `numpy.dtype` or Python type to cast one or more of the DataFrame's columns to column-specific types.

copy [bool, default True] Return a copy when `copy=True` (be very careful setting `copy=False` as changes to values then may propagate to other pandas objects).

errors [{'raise', 'ignore'}, default 'raise'] Control raising of exceptions on invalid data for provided dtype.

- `raise` : allow exceptions to be raised
- `ignore` : suppress exceptions. On error return original object.

Returns

casted [same type as caller]

See also:

[`to_datetime`](#) Convert argument to datetime.

[`to_timedelta`](#) Convert argument to timedelta.

[`to_numeric`](#) Convert argument to a numeric type.

[`numpy.ndarray.astype`](#) Cast a numpy array to a specified type.

Notes

Deprecated since version 1.3.0: Using `astype` to convert from timezone-naive dtype to timezone-aware dtype is deprecated and will raise in a future version. Use [`Series.dt.tz_localize\(\)`](#) instead.

Examples

Create a DataFrame:

```
>>> d = {'col1': [1, 2], 'col2': [3, 4]}
>>> df = pd.DataFrame(data=d)
>>> df.dtypes
col1    int64
col2    int64
dtype: object
```

Cast all columns to int32:

```
>>> df.astype('int32').dtypes
col1    int32
col2    int32
dtype: object
```

Cast col1 to int32 using a dictionary:

```
>>> df.astype({'col1': 'int32'}).dtypes
col1    int32
col2    int64
dtype: object
```

Create a series:

```
>>> ser = pd.Series([1, 2], dtype='int32')
>>> ser
0    1
1    2
dtype: int32
>>> ser.astype('int64')
0    1
1    2
dtype: int64
```

Convert to categorical type:

```
>>> ser.astype('category')
0    1
1    2
dtype: category
Categories (2, int64): [1, 2]
```

Convert to ordered categorical type with custom ordering:

```
>>> from pandas.api.types import CategoricalDtype
>>> cat_dtype = CategoricalDtype(
...     categories=[2, 1], ordered=True)
>>> ser.astype(cat_dtype)
0    1
1    2
dtype: category
Categories (2, int64): [2 < 1]
```

Note that using copy=False and changing data on a new pandas object may propagate changes:

```
>>> s1 = pd.Series([1, 2])
>>> s2 = s1.astype('int64', copy=False)
>>> s2[0] = 10
>>> s1 # note that s1[0] has changed too
0    10
1     2
dtype: int64
```

Create a series of dates:

```
>>> ser_date = pd.Series(pd.date_range('20200101', periods=3))
>>> ser_date
0    2020-01-01
1    2020-01-02
```

(continues on next page)

(continued from previous page)

```
2    2020-01-03
dtype: datetime64[ns]
```

pandas.Series.at_time

`Series.at_time(time, asof=False, axis=None)`

Select values at particular time of day (e.g., 9:30AM).

Parameters

time [datetime.time or str]

axis [{0 or 'index', 1 or 'columns'}, default 0]

Returns

Series or DataFrame

Raises

TypeError If the index is not a *DatetimeIndex*

See also:

[*between_time*](#) Select values between particular times of the day.

[*first*](#) Select initial periods of time series based on a date offset.

[*last*](#) Select final periods of time series based on a date offset.

[*DatetimeIndex.indexer_at_time*](#) Get just the index locations for values at particular time of the day.

Examples

```
>>> i = pd.date_range('2018-04-09', periods=4, freq='12H')
>>> ts = pd.DataFrame({'A': [1, 2, 3, 4]}, index=i)
>>> ts
              A
2018-04-09 00:00:00  1
2018-04-09 12:00:00  2
2018-04-10 00:00:00  3
2018-04-10 12:00:00  4
```

```
>>> ts.at_time('12:00')
              A
2018-04-09 12:00:00  2
2018-04-10 12:00:00  4
```

pandas.Series.autocorr**Series.autocorr**(*lag=1*)

Compute the lag-N autocorrelation.

This method computes the Pearson correlation between the Series and its shifted self.

Parameters**lag** [int, default 1] Number of lags to apply before performing autocorrelation.**Returns****float** The Pearson correlation between self and self.shift(lag).**See also:****Series.corr** Compute the correlation between two Series.**Series.shift** Shift index by desired number of periods.**DataFrame.corr** Compute pairwise correlation of columns.**DataFrame.corrwith** Compute pairwise correlation between rows or columns of two DataFrame objects.**Notes**

If the Pearson correlation is not well defined return 'NaN'.

Examples

```
>>> s = pd.Series([0.25, 0.5, 0.2, -0.05])
>>> s.autocorr()
0.10355...
>>> s.autocorr(lag=2)
-0.99999...
```

If the Pearson correlation is not well defined, then 'NaN' is returned.

```
>>> s = pd.Series([1, 0, 0, 0])
>>> s.autocorr()
nan
```

pandas.Series.backfill**Series.backfill**(*axis=None, inplace=False, limit=None, downcast=None*)Synonym for **DataFrame.fillna()** with *method='bfill'*.**Returns****Series/DataFrame or None** Object with missing values filled or None if *inplace=True*.

pandas.Series.between

`Series.between(left, right, inclusive='both')`

Return boolean Series equivalent to `left <= series <= right`.

This function returns a boolean vector containing *True* wherever the corresponding Series element is between the boundary values *left* and *right*. NA values are treated as *False*.

Parameters

left [scalar or list-like] Left boundary.

right [scalar or list-like] Right boundary.

inclusive [{"both", "neither", "left", "right"}] Include boundaries. Whether to set each bound as closed or open.

Changed in version 1.3.0.

Returns

Series Series representing whether each element is between left and right (inclusive).

See also:

[*Series.gt*](#) Greater than of series and other.

[*Series.lt*](#) Less than of series and other.

Notes

This function is equivalent to `(left <= ser) & (ser <= right)`

Examples

```
>>> s = pd.Series([2, 0, 4, 8, np.nan])
```

Boundary values are included by default:

```
>>> s.between(1, 4)
0    True
1    False
2    True
3    False
4    False
dtype: bool
```

With *inclusive* set to "neither" boundary values are excluded:

```
>>> s.between(1, 4, inclusive="neither")
0    True
1    False
2    False
3    False
4    False
dtype: bool
```

left and *right* can be any scalar value:

```
>>> s = pd.Series(['Alice', 'Bob', 'Carol', 'Eve'])
>>> s.between('Anna', 'Daniel')
0    False
1     True
2     True
3    False
dtype: bool
```

pandas.Series.between_time

`Series.between_time(start_time, end_time, include_start=True, include_end=True, axis=None)`

Select values between particular times of the day (e.g., 9:00-9:30 AM).

By setting `start_time` to be later than `end_time`, you can get the times that are *not* between the two times.

Parameters

start_time [datetime.time or str] Initial time as a time filter limit.

end_time [datetime.time or str] End time as a time filter limit.

include_start [bool, default True] Whether the start time needs to be included in the result.

include_end [bool, default True] Whether the end time needs to be included in the result.

axis [{0 or 'index', 1 or 'columns'}, default 0] Determine range time on index or columns value.

Returns

Series or DataFrame Data from the original object filtered to the specified dates range.

Raises

TypeError If the index is not a *DatetimeIndex*

See also:

at_time Select values at a particular time of the day.

first Select initial periods of time series based on a date offset.

last Select final periods of time series based on a date offset.

DatetimeIndex.indexer_between_time Get just the index locations for values between particular times of the day.

Examples

```
>>> i = pd.date_range('2018-04-09', periods=4, freq='1D20min')
>>> ts = pd.DataFrame({'A': [1, 2, 3, 4]}, index=i)
>>> ts
```

| | A |
|---------------------|---|
| 2018-04-09 00:00:00 | 1 |
| 2018-04-10 00:20:00 | 2 |
| 2018-04-11 00:40:00 | 3 |
| 2018-04-12 01:00:00 | 4 |

```
>>> ts.between_time('0:15', '0:45')
```

| | A |
|---------------------|---|
| 2018-04-10 00:20:00 | 2 |
| 2018-04-11 00:40:00 | 3 |

You get the times that are *not* between two times by setting `start_time` later than `end_time`:

```
>>> ts.between_time('0:45', '0:15')
```

| | A |
|---------------------|---|
| 2018-04-09 00:00:00 | 1 |
| 2018-04-12 01:00:00 | 4 |

pandas.Series.bfill

`Series.bfill(axis=None, inplace=False, limit=None, downcast=None)`

Synonym for `DataFrame.fillna()` with `method='bfill'`.

Returns

Series/DataFrame or None Object with missing values filled or None if `inplace=True`.

pandas.Series.bool

`Series.bool()`

Return the bool of a single element Series or DataFrame.

This must be a boolean scalar value, either True or False. It will raise a `ValueError` if the Series or DataFrame does not have exactly 1 element, or that element is not boolean (integer values 0 and 1 will also raise an exception).

Returns

bool The value in the Series or DataFrame.

See also:

Series.astype Change the data type of a Series, including to boolean.

DataFrame.astype Change the data type of a DataFrame, including to boolean.

numpy.bool_ NumPy boolean data type, used by pandas for boolean values.

Examples

The method will only work for single element objects with a boolean value:

```
>>> pd.Series([True]).bool()
True
>>> pd.Series([False]).bool()
False
```

```
>>> pd.DataFrame({'col': [True]}).bool()
True
>>> pd.DataFrame({'col': [False]}).bool()
False
```

pandas.Series.cat

Series.cat()

Accessor object for categorical properties of the Series values.

Be aware that assigning to *categories* is a inplace operation, while all methods return new categorical data per default (but can be called with *inplace=True*).

Parameters

data [Series or CategoricalIndex]

Examples

```
>>> s = pd.Series(list("abbccc")).astype("category")
>>> s
0    a
1    b
2    b
3    c
4    c
5    c
dtype: category
Categories (3, object): ['a', 'b', 'c']
```

```
>>> s.cat.categories
Index(['a', 'b', 'c'], dtype='object')
```

```
>>> s.cat.rename_categories(list("cba"))
0    c
1    b
2    b
3    a
4    a
5    a
dtype: category
Categories (3, object): ['c', 'b', 'a']
```

```
>>> s.cat.reorder_categories(list("cba"))
0    a
1    b
2    b
3    c
4    c
5    c
dtype: category
Categories (3, object): ['c', 'b', 'a']
```

```
>>> s.cat.add_categories(["d", "e"])
0    a
1    b
2    b
3    c
4    c
5    c
dtype: category
Categories (5, object): ['a', 'b', 'c', 'd', 'e']
```

```
>>> s.cat.remove_categories(["a", "c"])
0    NaN
1     b
2     b
3    NaN
4    NaN
5    NaN
dtype: category
Categories (1, object): ['b']
```

```
>>> s1 = s.cat.add_categories(["d", "e"])
>>> s1.cat.remove_unused_categories()
0    a
1    b
2    b
3    c
4    c
5    c
dtype: category
Categories (3, object): ['a', 'b', 'c']
```

```
>>> s.cat.set_categories(list("abcde"))
0    a
1    b
2    b
3    c
4    c
5    c
dtype: category
Categories (5, object): ['a', 'b', 'c', 'd', 'e']
```

```
>>> s.cat.as_ordered()
0    a
1    b
2    b
3    c
4    c
5    c
dtype: category
Categories (3, object): ['a' < 'b' < 'c']
```

```
>>> s.cat.as_unordered()
0    a
1    b
2    b
3    c
4    c
5    c
dtype: category
Categories (3, object): ['a', 'b', 'c']
```

pandas.Series.clip

Series.clip(*lower=None, upper=None, axis=None, inplace=False, *args, **kwargs*)

Trim values at input threshold(s).

Assigns values outside boundary to boundary values. Thresholds can be singular values or array like, and in the latter case the clipping is performed element-wise in the specified axis.

Parameters

lower [float or array-like, default None] Minimum threshold value. All values below this threshold will be set to it. A missing threshold (e.g *NA*) will not clip the value.

upper [float or array-like, default None] Maximum threshold value. All values above this threshold will be set to it. A missing threshold (e.g *NA*) will not clip the value.

axis [int or str axis name, optional] Align object with lower and upper along the given axis.

inplace [bool, default False] Whether to perform the operation in place on the data.

***args, **kwargs** Additional keywords have no effect but might be accepted for compatibility with numpy.

Returns

Series or DataFrame or None Same type as calling object with the values outside the clip boundaries replaced or None if `inplace=True`.

See also:

[*Series.clip*](#) Trim values at input threshold in series.

[*DataFrame.clip*](#) Trim values at input threshold in dataframe.

[*numpy.clip*](#) Clip (limit) the values in an array.

Examples

```
>>> data = {'col_0': [9, -3, 0, -1, 5], 'col_1': [-2, -7, 6, 8, -5]}
>>> df = pd.DataFrame(data)
>>> df
   col_0  col_1
0      9    -2
1     -3    -7
2      0     6
3     -1     8
4      5    -5
```

Clips per column using lower and upper thresholds:

```
>>> df.clip(-4, 6)
   col_0  col_1
0      6    -2
1     -3    -4
2      0     6
3     -1     6
4      5    -4
```

Clips using specific lower and upper thresholds per column element:

```
>>> t = pd.Series([2, -4, -1, 6, 3])
>>> t
0     2
1    -4
2    -1
3     6
4     3
dtype: int64
```

```
>>> df.clip(t, t + 4, axis=0)
   col_0  col_1
0      6     2
1     -3    -4
2      0     3
3      6     8
4      5     3
```

Clips using specific lower threshold per column element, with missing values:

```
>>> t = pd.Series([2, -4, np.NaN, 6, 3])
>>> t
0     2.0
1    -4.0
2     NaN
3     6.0
4     3.0
dtype: float64
```

```
>>> df.clip(t, axis=0)
col_0  col_1
0      9      2
1     -3     -4
2      0      6
3      6      8
4      5      3
```

pandas.Series.combine

`Series.combine(other, func, fill_value=None)`

Combine the Series with a Series or scalar according to *func*.

Combine the Series and *other* using *func* to perform elementwise selection for combined Series. *fill_value* is assumed when value is missing at some index from one of the two objects being combined.

Parameters

other [Series or scalar] The value(s) to be combined with the *Series*.

func [function] Function that takes two scalars as inputs and returns an element.

fill_value [scalar, optional] The value to assume when an index is missing from one Series or the other. The default specifies to use the appropriate NaN value for the underlying dtype of the Series.

Returns

Series The result of combining the Series with the other object.

See also:

[`Series.combine_first`](#) Combine Series values, choosing the calling Series' values first.

Examples

Consider 2 Datasets `s1` and `s2` containing highest clocked speeds of different birds.

```
>>> s1 = pd.Series({'falcon': 330.0, 'eagle': 160.0})
>>> s1
falcon    330.0
eagle     160.0
dtype: float64
>>> s2 = pd.Series({'falcon': 345.0, 'eagle': 200.0, 'duck': 30.0})
>>> s2
falcon    345.0
eagle     200.0
duck       30.0
dtype: float64
```

Now, to combine the two datasets and view the highest speeds of the birds across the two datasets

```
>>> s1.combine(s2, max)
duck      NaN
eagle    200.0
```

(continues on next page)

(continued from previous page)

```
falcon    345.0
dtype: float64
```

In the previous example, the resulting value for duck is missing, because the maximum of a NaN and a float is a NaN. So, in the example, we set `fill_value=0`, so the maximum value returned will be the value from some dataset.

```
>>> s1.combine(s2, max, fill_value=0)
duck      30.0
eagle     200.0
falcon    345.0
dtype: float64
```

pandas.Series.combine_first

Series.combine_first(*other*)

Update null elements with value in the same location in ‘other’.

Combine two Series objects by filling null values in one Series with non-null values from the other Series. Result index will be the union of the two indexes.

Parameters

other [Series] The value(s) to be used for filling null values.

Returns

Series The result of combining the provided Series with the other object.

See also:

[Series.combine](#) Perform element-wise operation on two Series using a given function.

Examples

```
>>> s1 = pd.Series([1, np.nan])
>>> s2 = pd.Series([3, 4, 5])
>>> s1.combine_first(s2)
0    1.0
1    4.0
2    5.0
dtype: float64
```

Null values still persist if the location of that null value does not exist in *other*

```
>>> s1 = pd.Series({'falcon': np.nan, 'eagle': 160.0})
>>> s2 = pd.Series({'eagle': 200.0, 'duck': 30.0})
>>> s1.combine_first(s2)
duck      30.0
eagle     160.0
falcon     NaN
dtype: float64
```

pandas.Series.compare

`Series.compare(other, align_axis=1, keep_shape=False, keep_equal=False)`

Compare to another Series and show the differences.

New in version 1.1.0.

Parameters

other [Series] Object to compare with.

align_axis [{0 or 'index', 1 or 'columns'}, default 1] Determine which axis to align the comparison on.

- **0, or 'index'** [Resulting differences are stacked vertically] with rows drawn alternately from self and other.
- **1, or 'columns'** [Resulting differences are aligned horizontally] with columns drawn alternately from self and other.

keep_shape [bool, default False] If true, all rows and columns are kept. Otherwise, only the ones with different values are kept.

keep_equal [bool, default False] If true, the result keeps values that are equal. Otherwise, equal values are shown as NaNs.

Returns

Series or DataFrame If axis is 0 or 'index' the result will be a Series. The resulting index will be a MultiIndex with 'self' and 'other' stacked alternately at the inner level.

If axis is 1 or 'columns' the result will be a DataFrame. It will have two columns namely 'self' and 'other'.

See also:

[`DataFrame.compare`](#) Compare with another DataFrame and show differences.

Notes

Matching NaNs will not appear as a difference.

Examples

```
>>> s1 = pd.Series(["a", "b", "c", "d", "e"])
>>> s2 = pd.Series(["a", "a", "c", "b", "e"])
```

Align the differences on columns

```
>>> s1.compare(s2)
  self other
1    b     a
3    d     b
```

Stack the differences on indices

```
>>> s1.compare(s2, align_axis=0)
1  self    b
   other   a
3  self    d
   other   b
dtype: object
```

Keep all original rows

```
>>> s1.compare(s2, keep_shape=True)
   self other
0  NaN  NaN
1   b    a
2  NaN  NaN
3   d    b
4  NaN  NaN
```

Keep all original rows and also all original values

```
>>> s1.compare(s2, keep_shape=True, keep_equal=True)
   self other
0    a    a
1    b    a
2    c    c
3    d    b
4    e    e
```

pandas.Series.convert_dtypes

`Series.convert_dtypes(infer_objects=True, convert_string=True, convert_integer=True, convert_boolean=True, convert_floating=True)`

Convert columns to best possible dtypes using dtypes supporting `pd.NA`.

New in version 1.0.0.

Parameters

infer_objects [bool, default True] Whether object dtypes should be converted to the best possible types.

convert_string [bool, default True] Whether object dtypes should be converted to `StringDtype()`.

convert_integer [bool, default True] Whether, if possible, conversion can be done to integer extension types.

convert_boolean [bool, defaults True] Whether object dtypes should be converted to `BooleanDtypes()`.

convert_floating [bool, defaults True] Whether, if possible, conversion can be done to floating extension types. If `convert_integer` is also True, preference will be give to integer dtypes if the floats can be faithfully casted to integers.

New in version 1.2.0.

Returns

Series or DataFrame Copy of input object with new dtype.

See also:

infer_objects Infer dtypes of objects.

to_datetime Convert argument to datetime.

to_timedelta Convert argument to timedelta.

to_numeric Convert argument to a numeric type.

Notes

By default, `convert_dtypes` will attempt to convert a Series (or each Series in a DataFrame) to dtypes that support `pd.NA`. By using the options `convert_string`, `convert_integer`, `convert_boolean` and `convert_numeric`, it is possible to turn off individual conversions to `StringDtype`, the integer extension types, `BooleanDtype` or floating extension types, respectively.

For object-dtyped columns, if `infer_objects` is `True`, use the inference rules as during normal Series/DataFrame construction. Then, if possible, convert to `StringDtype`, `BooleanDtype` or an appropriate integer or floating extension type, otherwise leave as object.

If the dtype is integer, convert to an appropriate integer extension type.

If the dtype is numeric, and consists of all integers, convert to an appropriate integer extension type. Otherwise, convert to an appropriate floating extension type.

Changed in version 1.2: Starting with pandas 1.2, this method also converts float columns to the nullable floating extension type.

In the future, as new dtypes are added that support `pd.NA`, the results of this method will change to support those new dtypes.

Examples

```
>>> df = pd.DataFrame(
...     {
...         "a": pd.Series([1, 2, 3], dtype=np.dtype("int32")),
...         "b": pd.Series(["x", "y", "z"], dtype=np.dtype("O")),
...         "c": pd.Series([True, False, np.nan], dtype=np.dtype("O")),
...         "d": pd.Series(["h", "i", np.nan], dtype=np.dtype("O")),
...         "e": pd.Series([10, np.nan, 20], dtype=np.dtype("float")),
...         "f": pd.Series([np.nan, 100.5, 200], dtype=np.dtype("float")),
...     }
... )
```

Start with a DataFrame with default dtypes.

```
>>> df
   a  b    c    d    e    f
0  1  x  True  h  10.0  NaN
1  2  y False  i   NaN  100.5
2  3  z   NaN NaN  20.0  200.0
```

```
>>> df.dtypes
a      int32
b      object
c      object
d      object
e      float64
f      float64
dtype: object
```

Convert the DataFrame to use best possible dtypes.

```
>>> dfn = df.convert_dtypes()
>>> dfn
   a  b      c      d      e      f
0  1  x  True      h     10  <NA>
1  2  y False      i  <NA>  100.5
2  3  z  <NA> <NA>    20  200.0
```

```
>>> dfn.dtypes
a      Int32
b      string
c      boolean
d      string
e      Int64
f      Float64
dtype: object
```

Start with a Series of strings and missing data represented by `np.nan`.

```
>>> s = pd.Series(["a", "b", np.nan])
>>> s
0      a
1      b
2     NaN
dtype: object
```

Obtain a Series with dtype `StringDtype`.

```
>>> s.convert_dtypes()
0      a
1      b
2     <NA>
dtype: string
```

pandas.Series.copy

`Series.copy(deep=True)`

Make a copy of this object's indices and data.

When `deep=True` (default), a new object will be created with a copy of the calling object's data and indices. Modifications to the data or indices of the copy will not be reflected in the original object (see notes below).

When `deep=False`, a new object will be created without copying the calling object's data or index (only references to the data and index are copied). Any changes to the data of the original will be reflected in the shallow copy (and vice versa).

Parameters

deep [bool, default True] Make a deep copy, including a copy of the data and the indices. With `deep=False` neither the indices nor the data are copied.

Returns

copy [Series or DataFrame] Object type matches caller.

Notes

When `deep=True`, data is copied but actual Python objects will not be copied recursively, only the reference to the object. This is in contrast to `copy.deepcopy` in the Standard Library, which recursively copies object data (see examples below).

While `Index` objects are copied when `deep=True`, the underlying numpy array is not copied for performance reasons. Since `Index` is immutable, the underlying data can be safely shared and a copy is not needed.

Examples

```
>>> s = pd.Series([1, 2], index=["a", "b"])
>>> s
a    1
b    2
dtype: int64
```

```
>>> s_copy = s.copy()
>>> s_copy
a    1
b    2
dtype: int64
```

Shallow copy versus default (deep) copy:

```
>>> s = pd.Series([1, 2], index=["a", "b"])
>>> deep = s.copy()
>>> shallow = s.copy(deep=False)
```

Shallow copy shares data and index with original.

```
>>> s is shallow
False
>>> s.values is shallow.values and s.index is shallow.index
True
```

Deep copy has own copy of data and index.

```
>>> s is deep
False
>>> s.values is deep.values or s.index is deep.index
False
```

Updates to the data shared by shallow copy and original is reflected in both; deep copy remains unchanged.

```
>>> s[0] = 3
>>> shallow[1] = 4
>>> s
a    3
b    4
dtype: int64
>>> shallow
a    3
b    4
dtype: int64
>>> deep
a    1
b    2
dtype: int64
```

Note that when copying an object containing Python objects, a deep copy will copy the data, but will not do so recursively. Updating a nested data object will be reflected in the deep copy.

```
>>> s = pd.Series([[1, 2], [3, 4]])
>>> deep = s.copy()
>>> s[0][0] = 10
>>> s
0    [10, 2]
1     [3, 4]
dtype: object
>>> deep
0    [10, 2]
1     [3, 4]
dtype: object
```

pandas.Series.corr

`Series.corr(other, method='pearson', min_periods=None)`

Compute correlation with *other* Series, excluding missing values.

Parameters

other [Series] Series with which to compute the correlation.

method [{ 'pearson', 'kendall', 'spearman' } or callable] Method used to compute correlation:

- pearson : Standard correlation coefficient
- kendall : Kendall Tau correlation coefficient
- spearman : Spearman rank correlation
- callable: Callable with input two 1d ndarrays and returning a float.

Warning: Note that the returned matrix from `corr` will have 1 along the diagonals and will be symmetric regardless of the callable's behavior.

min_periods [int, optional] Minimum number of observations needed to have a valid result.

Returns

float Correlation with other.

See also:

[`DataFrame.corr`](#) Compute pairwise correlation between columns.

[`DataFrame.corrwith`](#) Compute pairwise correlation with another DataFrame or Series.

Examples

```
>>> def histogram_intersection(a, b):
...     v = np.minimum(a, b).sum().round(decimals=1)
...     return v
>>> s1 = pd.Series([.2, .0, .6, .2])
>>> s2 = pd.Series([.3, .6, .0, .1])
>>> s1.corr(s2, method=histogram_intersection)
0.3
```

pandas.Series.count

`Series.count` (*level=None*)

Return number of non-NA/null observations in the Series.

Parameters

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a smaller Series.

Returns

int or Series (if level specified) Number of non-null values in the Series.

See also:

[`DataFrame.count`](#) Count non-NA cells for each column or row.

Examples

```
>>> s = pd.Series([0.0, 1.0, np.nan])
>>> s.count()
2
```

pandas.Series.cov

`Series.cov` (*other, min_periods=None, ddof=1*)

Compute covariance with Series, excluding missing values.

Parameters

other [Series] Series with which to compute the covariance.

min_periods [int, optional] Minimum number of observations needed to have a valid result.

ddof [int, default 1] Delta degrees of freedom. The divisor used in calculations is $N - \text{ddof}$, where N represents the number of elements.

New in version 1.1.0.

Returns

float Covariance between Series and other normalized by $N-1$ (unbiased estimator).

See also:

[`DataFrame.cov`](#) Compute pairwise covariance of columns.

Examples

```
>>> s1 = pd.Series([0.90010907, 0.13484424, 0.62036035])
>>> s2 = pd.Series([0.12528585, 0.26962463, 0.51111198])
>>> s1.cov(s2)
-0.01685762652715874
```

pandas.Series.cummax

`Series.cummax`(*axis=None*, *skipna=True*, *args, **kwargs)

Return cumulative maximum over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative maximum.

Parameters

axis [{0 or 'index', 1 or 'columns'}, default 0] The index or the name of the axis. 0 is equivalent to None or 'index'.

skipna [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

***args, **kwargs** Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

scalar or Series Return cumulative maximum of scalar or Series.

See also:

core.window.Expanding.max Similar functionality but ignores NaN values.

Series.max Return the maximum over Series axis.

Series.cummax Return cumulative maximum over Series axis.

Series.cummin Return cumulative minimum over Series axis.

Series.cumsun Return cumulative sum over Series axis.

Series.cumprod Return cumulative product over Series axis.

Examples

Series

```
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0    2.0
1    NaN
2    5.0
3   -1.0
4    0.0
dtype: float64
```

By default, NA values are ignored.

```
>>> s.cummax()
0    2.0
1    NaN
2    5.0
3    5.0
4    5.0
dtype: float64
```

To include NA values in the operation, use `skipna=False`

```
>>> s.cummax(skipna=False)
0    2.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

DataFrame

```
>>> df = pd.DataFrame([[2.0, 1.0],
...                    [3.0, np.nan],
...                    [1.0, 0.0]],
...                    columns=list('AB'))
>>> df
   A    B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```

By default, iterates over rows and finds the maximum in each column. This is equivalent to `axis=None` or `axis='index'`.

```
>>> df.cummax()
   A    B
0  2.0  1.0
1  3.0  NaN
2  3.0  1.0
```

To iterate over columns and find the maximum in each row, use `axis=1`

```
>>> df.cummax(axis=1)
   A    B
0  2.0  2.0
1  3.0  NaN
2  1.0  1.0
```

pandas.Series.cummin

`Series.cummin(axis=None, skipna=True, *args, **kwargs)`

Return cumulative minimum over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative minimum.

Parameters

axis [{0 or 'index', 1 or 'columns'}, default 0] The index or the name of the axis. 0 is equivalent to None or 'index'.

skipna [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

***args, **kwargs** Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

scalar or Series Return cumulative minimum of scalar or Series.

See also:

core.window.Expanding.min Similar functionality but ignores NaN values.

Series.min Return the minimum over Series axis.

Series.cummax Return cumulative maximum over Series axis.

Series.cummin Return cumulative minimum over Series axis.

Series.cumsum Return cumulative sum over Series axis.

Series.cumprod Return cumulative product over Series axis.

Examples

Series

```
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0    2.0
1    NaN
2    5.0
3   -1.0
4    0.0
dtype: float64
```

By default, NA values are ignored.

```
>>> s.cummin()
0    2.0
1    NaN
2    2.0
3   -1.0
4   -1.0
dtype: float64
```

To include NA values in the operation, use `skipna=False`

```
>>> s.cummin(skipna=False)
0    2.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

DataFrame

```
>>> df = pd.DataFrame([[2.0, 1.0],
...                   [3.0, np.nan],
...                   [1.0, 0.0]],
...                   columns=list('AB'))
>>> df
   A    B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```

By default, iterates over rows and finds the minimum in each column. This is equivalent to `axis=None` or `axis='index'`.

```
>>> df.cummin()
   A    B
0  2.0  1.0
1  2.0  NaN
2  1.0  0.0
```

To iterate over columns and find the minimum in each row, use `axis=1`

```
>>> df.cummin(axis=1)
   A    B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```

pandas.Series.cumprod

`Series.cumprod(axis=None, skipna=True, *args, **kwargs)`

Return cumulative product over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative product.

Parameters

axis [{0 or 'index', 1 or 'columns'}, default 0] The index or the name of the axis. 0 is equivalent to None or 'index'.

skipna [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

***args, **kwargs** Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

scalar or Series Return cumulative product of scalar or Series.

See also:

core.window.Expanding.prod Similar functionality but ignores NaN values.

Series.prod Return the product over Series axis.

Series.cummax Return cumulative maximum over Series axis.

Series.cummin Return cumulative minimum over Series axis.

Series.cumsum Return cumulative sum over Series axis.

Series.cumprod Return cumulative product over Series axis.

Examples

Series

```
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0    2.0
1    NaN
2    5.0
3   -1.0
4    0.0
dtype: float64
```

By default, NA values are ignored.

```
>>> s.cumprod()
0    2.0
1    NaN
2   10.0
3  -10.0
4   -0.0
dtype: float64
```

To include NA values in the operation, use `skipna=False`

```
>>> s.cumprod(skipna=False)
0    2.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

DataFrame

```
>>> df = pd.DataFrame([[2.0, 1.0],
...                    [3.0, np.nan],
...                    [1.0, 0.0]],
...                   columns=list('AB'))
>>> df
```

(continues on next page)

(continued from previous page)

```

      A    B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0

```

By default, iterates over rows and finds the product in each column. This is equivalent to `axis=None` or `axis='index'`.

```

>>> df.cumprod()
      A    B
0  2.0  1.0
1  6.0  NaN
2  6.0  0.0

```

To iterate over columns and find the product in each row, use `axis=1`

```

>>> df.cumprod(axis=1)
      A    B
0  2.0  2.0
1  3.0  NaN
2  1.0  0.0

```

pandas.Series.cumsum

`Series.cumsum(axis=None, skipna=True, *args, **kwargs)`

Return cumulative sum over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative sum.

Parameters

axis [{0 or 'index', 1 or 'columns'}, default 0] The index or the name of the axis. 0 is equivalent to None or 'index'.

skipna [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

***args, **kwargs** Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

scalar or Series Return cumulative sum of scalar or Series.

See also:

core.window.Expanding.sum Similar functionality but ignores NaN values.

Series.sum Return the sum over Series axis.

Series.cummax Return cumulative maximum over Series axis.

Series.cummin Return cumulative minimum over Series axis.

Series.cumsum Return cumulative sum over Series axis.

Series.cumprod Return cumulative product over Series axis.

Examples

Series

```
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0    2.0
1    NaN
2    5.0
3   -1.0
4    0.0
dtype: float64
```

By default, NA values are ignored.

```
>>> s.cumsum()
0    2.0
1    NaN
2    7.0
3    6.0
4    6.0
dtype: float64
```

To include NA values in the operation, use `skipna=False`

```
>>> s.cumsum(skipna=False)
0    2.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

DataFrame

```
>>> df = pd.DataFrame([[2.0, 1.0],
...                   [3.0, np.nan],
...                   [1.0, 0.0]],
...                   columns=list('AB'))
>>> df
   A    B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```

By default, iterates over rows and finds the sum in each column. This is equivalent to `axis=None` or `axis='index'`.

```
>>> df.cumsum()
   A    B
0  2.0  1.0
1  5.0  NaN
2  6.0  1.0
```

To iterate over columns and find the sum in each row, use `axis=1`

```
>>> df.cumsum(axis=1)
   A    B
0  2.0  3.0
1  3.0  NaN
2  1.0  1.0
```

pandas.Series.describe

Series.describe(*percentiles=None, include=None, exclude=None, datetime_is_numeric=False*)
Generate descriptive statistics.

Descriptive statistics include those that summarize the central tendency, dispersion and shape of a dataset's distribution, excluding NaN values.

Analyzes both numeric and object series, as well as DataFrame column sets of mixed data types. The output will vary depending on what is provided. Refer to the notes below for more detail.

Parameters

percentiles [list-like of numbers, optional] The percentiles to include in the output. All should fall between 0 and 1. The default is `[.25, .5, .75]`, which returns the 25th, 50th, and 75th percentiles.

include ['all', list-like of dtypes or None (default), optional] A white list of data types to include in the result. Ignored for Series. Here are the options:

- 'all' : All columns of the input will be included in the output.
- A list-like of dtypes : Limits the results to the provided data types. To limit the result to numeric types submit `numpy.number`. To limit it instead to object columns submit the `numpy.object` data type. Strings can also be used in the style of `select_dtypes` (e.g. `df.describe(include=['O'])`). To select pandas categorical columns, use 'category'
- None (default) : The result will include all numeric columns.

exclude [list-like of dtypes or None (default), optional,] A black list of data types to omit from the result. Ignored for Series. Here are the options:

- A list-like of dtypes : Excludes the provided data types from the result. To exclude numeric types submit `numpy.number`. To exclude object columns submit the data type `numpy.object`. Strings can also be used in the style of `select_dtypes` (e.g. `df.describe(include=['O'])`). To exclude pandas categorical columns, use 'category'
- None (default) : The result will exclude nothing.

datetime_is_numeric [bool, default False] Whether to treat datetime dtypes as numeric. This affects statistics calculated for the column. For DataFrame input, this also controls whether datetime columns are included by default.

New in version 1.1.0.

Returns

Series or DataFrame Summary statistics of the Series or Dataframe provided.

See also:

[**DataFrame.count**](#) Count number of non-NA/null observations.

DataFrame.max Maximum of the values in the object.

DataFrame.min Minimum of the values in the object.

DataFrame.mean Mean of the values.

DataFrame.std Standard deviation of the observations.

DataFrame.select_dtypes Subset of a DataFrame including/excluding columns based on their dtype.

Notes

For numeric data, the result's index will include `count`, `mean`, `std`, `min`, `max` as well as lower, 50 and upper percentiles. By default the lower percentile is 25 and the upper percentile is 75. The 50 percentile is the same as the median.

For object data (e.g. strings or timestamps), the result's index will include `count`, `unique`, `top`, and `freq`. The `top` is the most common value. The `freq` is the most common value's frequency. Timestamps also include the `first` and `last` items.

If multiple object values have the highest count, then the `count` and `top` results will be arbitrarily chosen from among those with the highest count.

For mixed data types provided via a DataFrame, the default is to return only an analysis of numeric columns. If the dataframe consists only of object and categorical data without any numeric columns, the default is to return an analysis of both the object and categorical columns. If `include='all'` is provided as an option, the result will include a union of attributes of each type.

The `include` and `exclude` parameters can be used to limit which columns in a DataFrame are analyzed for the output. The parameters are ignored when analyzing a Series.

Examples

Describing a numeric Series.

```
>>> s = pd.Series([1, 2, 3])
>>> s.describe()
count      3.0
mean       2.0
std        1.0
min        1.0
25%        1.5
50%        2.0
75%        2.5
max        3.0
dtype: float64
```

Describing a categorical Series.

```
>>> s = pd.Series(['a', 'a', 'b', 'c'])
>>> s.describe()
count      4
unique     3
top        a
freq       2
dtype: object
```

Describing a timestamp Series.

```
>>> s = pd.Series([
...     np.datetime64("2000-01-01"),
...     np.datetime64("2010-01-01"),
...     np.datetime64("2010-01-01")
... ])
>>> s.describe(datetime_is_numeric=True)
count          3
mean    2006-09-01 08:00:00
min     2000-01-01 00:00:00
25%    2004-12-31 12:00:00
50%    2010-01-01 00:00:00
75%    2010-01-01 00:00:00
max     2010-01-01 00:00:00
dtype: object
```

Describing a DataFrame. By default only numeric fields are returned.

```
>>> df = pd.DataFrame({'categorical': pd.Categorical(['d', 'e', 'f']),
...                    'numeric': [1, 2, 3],
...                    'object': ['a', 'b', 'c']}
... )
>>> df.describe()
numeric
count    3.0
mean     2.0
std      1.0
min      1.0
25%     1.5
50%     2.0
75%     2.5
max      3.0
```

Describing all columns of a DataFrame regardless of data type.

```
>>> df.describe(include='all')
categorical  numeric  object
count        3        3.0    3
unique        3        NaN    3
top           f        NaN    a
freq          1        NaN    1
mean         NaN        2.0   NaN
std          NaN        1.0   NaN
min          NaN        1.0   NaN
25%          NaN        1.5   NaN
50%          NaN        2.0   NaN
75%          NaN        2.5   NaN
max          NaN        3.0   NaN
```

Describing a column from a DataFrame by accessing it as an attribute.

```
>>> df.numeric.describe()
count    3.0
```

(continues on next page)

(continued from previous page)

```

mean      2.0
std       1.0
min       1.0
25%      1.5
50%      2.0

pandas.Series.diff

Series.diff(*periods=1*)

First discrete difference of element.

Calculates the difference of a Series element compared with another element in the Series (default is element in previous row).

Parameters

periods [int, default 1] Periods to shift for calculating difference, accepts negative values.

Returns

Series First differences of the Series.

See also:

[*Series.pct_change*](#) Percent change over given number of periods.

[*Series.shift*](#) Shift index by desired number of periods with an optional time freq.

[*DataFrame.diff*](#) First discrete difference of object.

Notes

For boolean dtypes, this uses `operator.xor()` rather than `operator.sub()`. The result is calculated according to current dtype in Series, however dtype of the result is always float64.

Examples

Difference with previous row

```

>>> s = pd.Series([1, 1, 2, 3, 5, 8])
>>> s.diff()
0    NaN
1    0.0
2    1.0
3    1.0
4    2.0
5    3.0
dtype: float64

```

Difference with 3rd previous row

```
>>> s.diff( periods=3)
0    NaN
1    NaN
2    NaN
3    2.0
4    4.0
5    6.0
dtype: float64
```

Difference with following row

```
>>> s.diff( periods=-1)
0    0.0
1   -1.0
2   -1.0
3   -2.0
4   -3.0
5    NaN
dtype: float64
```

Overflow in input dtype

```
>>> s = pd.Series([1, 0], dtype=np.uint8)
>>> s.diff()
0    NaN
1   255.0
dtype: float64
```

pandas.Series.div

Series.div(*other*, *level=None*, *fill_value=None*, *axis=0*)

Return Floating division of series and other, element-wise (binary operator *truediv*).

Equivalent to `series / other`, but with support to substitute a `fill_value` for missing data in either one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level.

Returns

Series The result of the operation.

See also:

[*Series.rtruediv*](#) Reverse of the Floating division operator, see [Python documentation](#) for more details.

Examples

```

>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.divide(b, fill_value=0)
a    1.0
b    inf
c    inf
d    0.0
e    NaN
dtype: float64

```

pandas.Series.divide

`Series.divide`(*other*, *level=None*, *fill_value=None*, *axis=0*)

Return Floating division of series and other, element-wise (binary operator *truediv*).

Equivalent to `series / other`, but with support to substitute a `fill_value` for missing data in either one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level.

Returns

Series The result of the operation.

See also:

[`Series.rtruediv`](#) Reverse of the Floating division operator, see [Python documentation](#) for more details.

Examples

```

>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.divide(b, fill_value=0)
a    1.0
b    inf
c    inf
d    0.0
e    NaN
dtype: float64

```

pandas.Series.divmod

`Series.divmod(other, level=None, fill_value=None, axis=0)`

Return Integer division and modulo of series and other, element-wise (binary operator *divmod*).

Equivalent to `divmod(series, other)`, but with support to substitute a `fill_value` for missing data in either one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level.

Returns

2-Tuple of Series The result of the operation.

See also:

[*Series.rdivmod*](#) Reverse of the Integer division and modulo operator, see [Python documentation](#) for more details.

Examples

```

>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.divmod(b, fill_value=0)
(a    1.0
 b    NaN
 c    NaN
 d    0.0
 e    NaN
 dtype: float64,
 a    0.0
 b    NaN
 c    NaN
 d    0.0
 e    NaN
 dtype: float64)

```

pandas.Series.dot

Series.dot(*other*)

Compute the dot product between the Series and the columns of *other*.

This method computes the dot product between the Series and another one, or the Series and each columns of a DataFrame, or the Series and each columns of an array.

It can also be called using *self @ other* in Python ≥ 3.5 .

Parameters

other [Series, DataFrame or array-like] The other object to compute the dot product with its columns.

Returns

scalar, Series or numpy.ndarray Return the dot product of the Series and *other* if *other* is a Series, the Series of the dot product of Series and each rows of *other* if *other* is a DataFrame or a numpy.ndarray between the Series and each columns of the numpy array.

See also:

[DataFrame.dot](#) Compute the matrix product with the DataFrame.

Series.mul Multiplication of series and other, element-wise.

Notes

The Series and other has to share the same index if other is a Series or a DataFrame.

Examples

```
>>> s = pd.Series([0, 1, 2, 3])
>>> other = pd.Series([-1, 2, -3, 4])
>>> s.dot(other)
8
>>> s @ other
8
>>> df = pd.DataFrame([[0, 1], [-2, 3], [4, -5], [6, 7]])
>>> s.dot(df)
0    24
1    14
dtype: int64
>>> arr = np.array([[0, 1], [-2, 3], [4, -5], [6, 7]])
>>> s.dot(arr)
array([24, 14])
```

pandas.Series.drop

Series.drop(*labels=None, axis=0, index=None, columns=None, level=None, inplace=False, errors='raise'*)

Return Series with specified index labels removed.

Remove elements of a Series based on specifying the index labels. When using a multi-index, labels on different levels can be removed by specifying the level.

Parameters

labels [single label or list-like] Index labels to drop.

axis [0, default 0] Redundant for application on Series.

index [single label or list-like] Redundant for application on Series, but 'index' can be used instead of 'labels'.

columns [single label or list-like] No change is made to the Series; use 'index' or 'labels' instead.

level [int or level name, optional] For MultiIndex, level for which the labels will be removed.

inplace [bool, default False] If True, do operation inplace and return None.

errors [{'ignore', 'raise'}, default 'raise'] If 'ignore', suppress error and only existing labels are dropped.

Returns

Series or None Series with specified index labels removed or None if `inplace=True`.

Raises

KeyError If none of the labels are found in the index.

See also:

[*Series.reindex*](#) Return only specified index labels of Series.

[*Series.dropna*](#) Return series without null values.

[*Series.drop_duplicates*](#) Return Series with duplicate values removed.

[*DataFrame.drop*](#) Drop specified labels from rows or columns.

Examples

```
>>> s = pd.Series(data=np.arange(3), index=['A', 'B', 'C'])
>>> s
A    0
B    1
C    2
dtype: int64
```

Drop labels B en C

```
>>> s.drop(labels=['B', 'C'])
A    0
dtype: int64
```

Drop 2nd level label in MultiIndex Series

```
>>> midx = pd.MultiIndex(levels=[['lama', 'cow', 'falcon'],
...                             ['speed', 'weight', 'length']],
...                      codes=[[0, 0, 0, 1, 1, 1, 2, 2, 2],
...                             [0, 1, 2, 0, 1, 2, 0, 1, 2]])
>>> s = pd.Series([45, 200, 1.2, 30, 250, 1.5, 320, 1, 0.3],
...               index=midx)
>>> s
lama    speed    45.0
        weight   200.0
        length    1.2
cow     speed    30.0
        weight   250.0
        length    1.5
falcon  speed   320.0
        weight    1.0
        length    0.3
dtype: float64
```

```
>>> s.drop(labels='weight', level=1)
lama    speed    45.0
        length    1.2
cow     speed    30.0
        length    1.5
falcon  speed   320.0
        length    0.3
dtype: float64
```

pandas.Series.drop_duplicates**Series.drop_duplicates**(*keep='first', inplace=False*)

Return Series with duplicate values removed.

Parameters**keep** [{ 'first', 'last', False }, default 'first'] Method to handle dropping duplicates:

- 'first' : Drop duplicates except for the first occurrence.
- 'last' : Drop duplicates except for the last occurrence.
- False : Drop all duplicates.

inplace [bool, default False] If True, performs operation inplace and returns None.**Returns****Series or None** Series with duplicates dropped or None if `inplace=True`.**See also:*****Index.drop_duplicates*** Equivalent method on Index.***DataFrame.drop_duplicates*** Equivalent method on DataFrame.***Series.duplicated*** Related method on Series, indicating duplicate Series values.**Examples**

Generate a Series with duplicated entries.

```
>>> s = pd.Series(['lama', 'cow', 'lama', 'beetle', 'lama', 'hippo'],
...               name='animal')
>>> s
0    lama
1     cow
2    lama
3  beetle
4    lama
5   hippo
Name: animal, dtype: object
```

With the 'keep' parameter, the selection behaviour of duplicated values can be changed. The value 'first' keeps the first occurrence for each set of duplicated entries. The default value of keep is 'first'.

```
>>> s.drop_duplicates()
0    lama
1     cow
3  beetle
5   hippo
Name: animal, dtype: object
```

The value 'last' for parameter 'keep' keeps the last occurrence for each set of duplicated entries.

```
>>> s.drop_duplicates(keep='last')
1      cow
3     beetle
4      lama
5     hippo
Name: animal, dtype: object
```

The value `False` for parameter `'keep'` discards all sets of duplicated entries. Setting the value of `'inplace'` to `True` performs the operation inplace and returns `None`.

```
>>> s.drop_duplicates(keep=False, inplace=True)
>>> s
1      cow
3     beetle
5     hippo
Name: animal, dtype: object
```

pandas.Series.droplevel

`Series.droplevel` (*level*, *axis=0*)

Return Series/DataFrame with requested index / column level(s) removed.

Parameters

level [int, str, or list-like] If a string is given, must be the name of a level. If list-like, elements must be names or positional indexes of levels.

axis [{0 or 'index', 1 or 'columns'}, default 0] Axis along which the level(s) is removed:

- 0 or 'index': remove level(s) in column.
- 1 or 'columns': remove level(s) in row.

Returns

Series/DataFrame Series/DataFrame with requested index / column level(s) removed.

Examples

```
>>> df = pd.DataFrame([
...     [1, 2, 3, 4],
...     [5, 6, 7, 8],
...     [9, 10, 11, 12]
... ]).set_index([0, 1]).rename_axis(['a', 'b'])
```

```
>>> df.columns = pd.MultiIndex.from_tuples([
...     ('c', 'e'), ('d', 'f')
... ], names=['level_1', 'level_2'])
```

```
>>> df
level_1  c  d
level_2  e  f
a b
```

(continues on next page)

(continued from previous page)

```

1 2      3  4
5 6      7  8
9 10     11 12

```

```

>>> df.droplevel('a')
level_1  c  d
level_2  e  f
b
2        3  4
6        7  8
10       11 12

```

```

>>> df.droplevel('level_2', axis=1)
level_1  c  d
a b
1 2      3  4
5 6      7  8
9 10     11 12

```

pandas.Series.dropna

`Series.dropna(axis=0, inplace=False, how=None)`

Return a new Series with missing values removed.

See the [User Guide](#) for more on which values are considered missing, and how to work with missing data.

Parameters

axis [{0 or 'index'}, default 0] There is only one axis to drop values from.

inplace [bool, default False] If True, do operation inplace and return None.

how [str, optional] Not in use. Kept for compatibility.

Returns

Series or None Series with NA entries dropped from it or None if `inplace=True`.

See also:

[Series.isna](#) Indicate missing values.

[Series.notna](#) Indicate existing (non-missing) values.

[Series.fillna](#) Replace missing values.

[DataFrame.dropna](#) Drop rows or columns which contain NA values.

[Index.dropna](#) Drop missing indices.

Examples

```
>>> ser = pd.Series([1., 2., np.nan])
>>> ser
0    1.0
1    2.0
2    NaN
dtype: float64
```

Drop NA values from a Series.

```
>>> ser.dropna()
0    1.0
1    2.0
dtype: float64
```

Keep the Series with valid entries in the same variable.

```
>>> ser.dropna(inplace=True)
>>> ser
0    1.0
1    2.0
dtype: float64
```

Empty strings are not considered NA values. None is considered an NA value.

```
>>> ser = pd.Series([np.NaN, 2, pd.NaT, '', None, 'I stay'])
>>> ser
0    NaN
1     2
2    NaT
3
4    None
5    I stay
dtype: object
>>> ser.dropna()
1     2
3
5    I stay
dtype: object
```

pandas.Series.dt**Series.dt()**

Accessor object for datetimelike properties of the Series values.

Examples

```
>>> seconds_series = pd.Series(pd.date_range("2000-01-01", periods=3, freq="s
↳"))
>>> seconds_series
0    2000-01-01 00:00:00
1    2000-01-01 00:00:01
2    2000-01-01 00:00:02
dtype: datetime64[ns]
>>> seconds_series.dt.second
0    0
1    1
2    2
dtype: int64
```

```
>>> hours_series = pd.Series(pd.date_range("2000-01-01", periods=3, freq="h"))
>>> hours_series
0    2000-01-01 00:00:00
1    2000-01-01 01:00:00
2    2000-01-01 02:00:00
dtype: datetime64[ns]
>>> hours_series.dt.hour
0    0
1    1
2    2
dtype: int64
```

```
>>> quarters_series = pd.Series(pd.date_range("2000-01-01", periods=3, freq="q
↳"))
>>> quarters_series
0    2000-03-31
1    2000-06-30
2    2000-09-30
dtype: datetime64[ns]
>>> quarters_series.dt.quarter
0    1
1    2
2    3
dtype: int64
```

Returns a Series indexed like the original Series. Raises `TypeError` if the Series does not contain datetime-like values.

pandas.Series.duplicated**Series.duplicated**(*keep='first'*)

Indicate duplicate Series values.

Duplicated values are indicated as `True` values in the resulting Series. Either all duplicates, all except the first or all except the last occurrence of duplicates can be indicated.

Parameters**keep** [{ 'first', 'last', False }, default 'first'] Method to handle dropping duplicates:

- 'first' : Mark duplicates as `True` except for the first occurrence.
- 'last' : Mark duplicates as `True` except for the last occurrence.
- False : Mark all duplicates as `True`.

Returns**Series[bool]** Series indicating whether each value has occurred in the preceding values.**See also:****Index.duplicated** Equivalent method on pandas.Index.**DataFrame.duplicated** Equivalent method on pandas.DataFrame.**Series.drop_duplicates** Remove duplicate values from Series.**Examples**

By default, for each set of duplicated values, the first occurrence is set on `False` and all others on `True`:

```
>>> animals = pd.Series(['lama', 'cow', 'lama', 'beetle', 'lama'])
>>> animals.duplicated()
0    False
1    False
2     True
3    False
4     True
dtype: bool
```

which is equivalent to

```
>>> animals.duplicated(keep='first')
0    False
1    False
2     True
3    False
4     True
dtype: bool
```

By using 'last', the last occurrence of each set of duplicated values is set on `False` and all others on `True`:

```
>>> animals.duplicated(keep='last')
0     True
1    False
```

(continues on next page)

(continued from previous page)

```

2    True
3    False
4    False
dtype: bool

```

By setting `keep` on `False`, all duplicates are `True`:

```

>>> animals.duplicated(keep=False)
0    True
1    False
2    True
3    False
4    True
dtype: bool

```

pandas.Series.eq

`Series.eq(other, level=None, fill_value=None, axis=0)`

Return Equal to of series and other, element-wise (binary operator *eq*).

Equivalent to `series == other`, but with support to substitute a `fill_value` for missing data in either one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level.

Returns

Series The result of the operation.

Examples

```

>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0

```

(continues on next page)

(continued from previous page)

```
e    NaN
dtype: float64
>>> a.eq(b, fill_value=0)
a    True
b    False
c    False
d    False
e    False
dtype: bool
```

pandas.Series.equals

Series.equals(*other*)

Test whether two objects contain the same elements.

This function allows two Series or DataFrames to be compared against each other to see if they have the same shape and elements. NaNs in the same location are considered equal.

The row/column index do not need to have the same type, as long as the values are considered equal. Corresponding columns must be of the same dtype.

Parameters

other [Series or DataFrame] The other Series or DataFrame to be compared with the first.

Returns

bool True if all elements are the same in both objects, False otherwise.

See also:

Series.eq Compare two Series objects of the same length and return a Series where each element is True if the element in each Series is equal, False otherwise.

DataFrame.eq Compare two DataFrame objects of the same shape and return a DataFrame where each element is True if the respective element in each DataFrame is equal, False otherwise.

testing.assert_series_equal Raises an AssertionError if left and right are not equal. Provides an easy interface to ignore inequality in dtypes, indexes and precision among others.

testing.assert_frame_equal Like assert_series_equal, but targets DataFrames.

numpy.array_equal Return True if two arrays have the same shape and elements, False otherwise.

Examples

```
>>> df = pd.DataFrame({'1': [10], '2': [20]})
>>> df
   1  2
0 10 20
```

DataFrames `df` and `exactly_equal` have the same types and values for their elements and column labels, which will return True.

```
>>> exactly_equal = pd.DataFrame({1: [10], 2: [20]})
>>> exactly_equal
   1  2
0 10 20
>>> df.equals(exactly_equal)
True
```

DataFrames `df` and `different_column_type` have the same element types and values, but have different types for the column labels, which will still return `True`.

```
>>> different_column_type = pd.DataFrame({1.0: [10], 2.0: [20]})
>>> different_column_type
   1.0  2.0
0  10  20
>>> df.equals(different_column_type)
True
```

DataFrames `df` and `different_data_type` have different types for the same values for their elements, and will return `False` even though their column labels are the same values and types.

```
>>> different_data_type = pd.DataFrame({1: [10.0], 2: [20.0]})
>>> different_data_type
   1    2
0 10.0 20.0

False
```

pandas.Series.ewm

`Series.ewm`(*com=None, span=None, halflife=None, alpha=None, min_periods=0, adjust=True, ignore_na=False, axis=0, times=None*)

Provide exponential weighted (EW) functions.

Available EW functions: `mean()`, `var()`, `std()`, `corr()`, `cov()`.

Exactly one parameter: `com`, `span`, `halflife`, or `alpha` must be provided.

Parameters

com [float, optional] Specify decay in terms of center of mass, $\alpha = 1/(1 + com)$, for $com \geq 0$.

span [float, optional] Specify decay in terms of span, $\alpha = 2/(span + 1)$, for $span \geq 1$.

halflife [float, str, timedelta, optional] Specify decay in terms of half-life, $\alpha = 1 - \exp(-\ln(2)/halflife)$, for $halflife > 0$.

If `times` is specified, the time unit (str or timedelta) over which an observation decays to half its value. Only applicable to `mean()` and `halflife` value will not apply to the other functions.

New in version 1.1.0.

alpha [float, optional] Specify smoothing factor α directly, $0 < \alpha \leq 1$.

min_periods [int, default 0] Minimum number of observations in window required to have a value (otherwise result is NA).

adjust [bool, default True] Divide by decaying adjustment factor in beginning periods to account for imbalance in relative weightings (viewing EWMA as a moving average).

- When `adjust=True` (default), the EW function is calculated using weights $w_i = (1 - \alpha)^i$. For example, the EW moving average of the series $[x_0, x_1, \dots, x_t]$ would be:

$$y_t = \frac{x_t + (1 - \alpha)x_{t-1} + (1 - \alpha)^2x_{t-2} + \dots + (1 - \alpha)^t x_0}{1 + (1 - \alpha) + (1 - \alpha)^2 + \dots + (1 - \alpha)^t}$$

- When `adjust=False`, the exponentially weighted function is calculated recursively:

$$y_0 = x_0$$
$$y_t = (1 - \alpha)y_{t-1} + \alpha x_t,$$

ignore_na [bool, default False] Ignore missing values when calculating weights; specify True to reproduce pre-0.15.0 behavior.

- When `ignore_na=False` (default), weights are based on absolute positions. For example, the weights of x_0 and x_2 used in calculating the final weighted average of $[x_0, \text{None}, x_2]$ are $(1 - \alpha)^2$ and 1 if `adjust=True`, and $(1 - \alpha)^2$ and α if `adjust=False`.
- When `ignore_na=True` (reproducing pre-0.15.0 behavior), weights are based on relative positions. For example, the weights of x_0 and x_2 used in calculating the final weighted average of $[x_0, \text{None}, x_2]$ are $1 - \alpha$ and 1 if `adjust=True`, and $1 - \alpha$ and α if `adjust=False`.

axis [{0, 1}, default 0] The axis to use. The value 0 identifies the rows, and 1 identifies the columns.

times [str, np.ndarray, Series, default None] New in version 1.1.0.

Times corresponding to the observations. Must be monotonically increasing and `datetime64[ns]` dtype.

If str, the name of the column in the DataFrame representing the times.

If 1-D array like, a sequence with the same shape as the observations.

Only applicable to `mean()`.

Returns

DataFrame A Window sub-classed for the particular operation.

See also:

rolling Provides rolling window calculations.

expanding Provides expanding transformations.

Notes

More details can be found at: *Exponentially weighted windows*.

Examples

```
>>> df = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]})
>>> df
   B
0  0.0
1  1.0
2  2.0
3  NaN
4  4.0
```

```
>>> df.ewm(com=0.5).mean()
   B
0  0.000000
1  0.750000
2  1.615385
3  1.615385
4  3.670213
```

Specifying times with a timedelta halflife when computing mean.

```
>>> times = ['2020-01-01', '2020-01-03', '2020-01-10', '2020-01-15', '2020-01-
→17']
>>> df.ewm(halflife='4 days', times=pd.DatetimeIndex(times)).mean()
   B
0  0.000000
1  0.585786
2  1.523889
3  1.523889
4  3.233686
```

pandas.Series.expanding

Series.**expanding**(*min_periods=1, center=None, axis=0, method='single'*)

Provide expanding transformations.

Parameters

min_periods [int, default 1] Minimum number of observations in window required to have a value (otherwise result is NA).

center [bool, default False] Set the labels at the center of the window.

axis [int or str, default 0]

method [str {'single', 'table'}, default 'single'] Execute the rolling operation per single column or row ('single') or over the entire object ('table').

This argument is only implemented when specifying `engine='numba'` in the method call.

New in version 1.3.0.

Returns

a **Window** sub-classed for the particular operation

See also:

rolling Provides rolling window calculations.

ewm Provides exponential weighted functions.

Notes

By default, the result is set to the right edge of the window. This can be changed to the center of the window by setting `center=True`.

Examples

```
>>> df = pd.DataFrame({"B": [0, 1, 2, np.nan, 4]})
>>> df
   B
0  0.0
1  1.0
2  2.0
3  NaN
4  4.0
```

```
>>> df.expanding(2).sum()
   B
0  NaN
1  1.0
2  3.0
3  3.0
4  7.0
```

pandas.Series.explode

`Series.explode(ignore_index=False)`

Transform each element of a list-like to a row.

New in version 0.25.0.

Parameters

ignore_index [bool, default False] If True, the resulting index will be labeled 0, 1, ..., n - 1.

New in version 1.1.0.

Returns

Series Exploded lists to rows; index will be duplicated for these rows.

See also:

Series.str.split Split string values on specified separator.

Series.unstack Unstack, a.k.a. pivot, Series with MultiIndex to produce DataFrame.

DataFrame.melt Unpivot a DataFrame from wide format to long format.

DataFrame.explode Explode a DataFrame from list-like columns to long format.

Notes

This routine will explode list-likes including lists, tuples, sets, Series, and np.ndarray. The result dtype of the subset rows will be object. Scalars will be returned unchanged, and empty list-likes will result in a np.nan for that row. In addition, the ordering of elements in the output will be non-deterministic when exploding sets.

Examples

```
>>> s = pd.Series([[1, 2, 3], 'foo', [], [3, 4]])
>>> s
0    [1, 2, 3]
1         foo
2          []
3     [3, 4]
dtype: object
```

```
>>> s.explode()
0     1
0     2
0     3
1    foo
2   NaN
3     3
3     4
dtype: object
```

pandas.Series.factorize

Series.factorize (*sort=False, na_sentinel=-1*)

Encode the object as an enumerated type or categorical variable.

This method is useful for obtaining a numeric representation of an array when all that matters is identifying distinct values. *factorize* is available as both a top-level function [pandas.factorize\(\)](#), and as a method [Series.factorize\(\)](#) and [Index.factorize\(\)](#).

Parameters

sort [bool, default False] Sort *uniques* and shuffle *codes* to maintain the relationship.

na_sentinel [int or None, default -1] Value to mark “not found”. If None, will not drop the NaN from the uniques of the values.

Changed in version 1.1.2.

Returns

codes [ndarray] An integer ndarray that's an indexer into *uniques*. `uniques.take(codes)` will have the same values as *values*.

uniques [ndarray, Index, or Categorical] The unique valid values. When *values* is Categorical, *uniques* is a Categorical. When *values* is some other pandas object, an *Index* is returned. Otherwise, a 1-D ndarray is returned.

Note: Even if there's a missing value in *values*, *uniques* will *not* contain an entry for it.

See also:

cut Discretize continuous-valued array.

unique Find the unique value in an array.

Examples

These examples all show `factorize` as a top-level method like `pd.factorize(values)`. The results are identical for methods like `Series.factorize()`.

```
>>> codes, uniques = pd.factorize(['b', 'b', 'a', 'c', 'b'])
>>> codes
array([0, 0, 1, 2, 0]...)
>>> uniques
array(['b', 'a', 'c'], dtype=object)
```

With `sort=True`, the *uniques* will be sorted, and *codes* will be shuffled so that the relationship is the maintained.

```
>>> codes, uniques = pd.factorize(['b', 'b', 'a', 'c', 'b'], sort=True)
>>> codes
array([1, 1, 0, 2, 1]...)
>>> uniques
array(['a', 'b', 'c'], dtype=object)
```

Missing values are indicated in *codes* with *na_sentinel* (-1 by default). Note that missing values are never included in *uniques*.

```
>>> codes, uniques = pd.factorize(['b', None, 'a', 'c', 'b'])
>>> codes
array([ 0, -1,  1,  2,  0]...)
>>> uniques
array(['b', 'a', 'c'], dtype=object)
```

Thus far, we've only factorized lists (which are internally coerced to NumPy arrays). When factorizing pandas objects, the type of *uniques* will differ. For Categoricals, a *Categorical* is returned.

```
>>> cat = pd.Categorical(['a', 'a', 'c'], categories=['a', 'b', 'c'])
>>> codes, uniques = pd.factorize(cat)
>>> codes
array([0, 0, 1]...)
>>> uniques
```

(continues on next page)

(continued from previous page)

```
['a', 'c']
Categories (3, object): ['a', 'b', 'c']
```

Notice that 'b' is in `uniques.categories`, despite not being present in `cat.values`.

For all other pandas objects, an Index of the appropriate type is returned.

```
>>> cat = pd.Series(['a', 'a', 'c'])
>>> codes, uniques = pd.factorize(cat)
>>> codes
array([0, 0, 1]...)
>>> uniques
Index(['a', 'c'], dtype='object')
```

If NaN is in the values, and we want to include NaN in the uniques of the values, it can be achieved by setting `na_sentinel=None`.

```
>>> values = np.array([1, 2, 1, np.nan])
>>> codes, uniques = pd.factorize(values) # default: na_sentinel=-1
>>> codes
array([ 0,  1,  0, -1])
>>> uniques
array([1., 2.]
```

```
>>> codes, uniques = pd.factorize(values, na_sentinel=None)
>>> codes
array([0, 1, 0, 2])
>>> uniques
array([ 1.,  2., nan])
```

pandas.Series.fill

`Series.fill`(*axis=None, inplace=False, limit=None, downcast=None*)
Synonym for `DataFrame.fillna()` with `method='ffill'`.

Returns

Series/DataFrame or None Object with missing values filled or None if `inplace=True`.

pandas.Series.fillna

`Series.fillna`(*value=None, method=None, axis=None, inplace=False, limit=None, downcast=None*)
Fill NA/NaN values using the specified method.

Parameters

value [scalar, dict, Series, or DataFrame] Value to use to fill holes (e.g. 0), alternately a dict/Series/DataFrame of values specifying which value to use for each index (for a Series) or column (for a DataFrame). Values not in the dict/Series/DataFrame will not be filled. This value cannot be a list.

method [{ 'backfill', 'bfill', 'pad', 'ffill', None }, default None] Method to use for filling holes in reindexed Series `pad` / `ffill`: propagate last valid observation forward to next valid `backfill` / `bfill`: use next valid observation to fill gap.

axis [{0 or 'index'}] Axis along which to fill missing values.

inplace [bool, default False] If True, fill in-place. Note: this will modify any other views on this object (e.g., a no-copy slice for a column in a DataFrame).

limit [int, default None] If method is specified, this is the maximum number of consecutive NaN values to forward/backward fill. In other words, if there is a gap with more than this number of consecutive NaNs, it will only be partially filled. If method is not specified, this is the maximum number of entries along the entire axis where NaNs will be filled. Must be greater than 0 if not None.

downcast [dict, default is None] A dict of item->dtype of what to downcast if possible, or the string 'infer' which will try to downcast to an appropriate equal type (e.g. float64 to int64 if possible).

Returns

Series or None Object with missing values filled or None if `inplace=True`.

See also:

[*interpolate*](#) Fill NaN values using interpolation.

[*reindex*](#) Conform object to new index.

[*asfreq*](#) Convert TimeSeries to specified frequency.

Examples

```
>>> df = pd.DataFrame([[np.nan, 2, np.nan, 0],
...                   [3, 4, np.nan, 1],
...                   [np.nan, np.nan, np.nan, 5],
...                   [np.nan, 3, np.nan, 4]],
...                   columns=list("ABCD"))
>>> df
   A    B    C  D
0 NaN  2.0 NaN  0
1  3.0  4.0 NaN  1
2 NaN  NaN NaN  5
3 NaN  3.0 NaN  4
```

Replace all NaN elements with 0s.

```
>>> df.fillna(0)
   A    B    C  D
0  0.0  2.0  0.0  0
1  3.0  4.0  0.0  1
2  0.0  0.0  0.0  5
3  0.0  3.0  0.0  4
```

We can also propagate non-null values forward or backward.

```
>>> df.fillna(method="ffill")
   A    B    C  D
0 NaN  2.0 NaN  0
1  3.0  4.0 NaN  1
```

(continues on next page)

(continued from previous page)

```
2  3.0 4.0 NaN 5
3  3.0 3.0 NaN 4
```

Replace all NaN elements in column 'A', 'B', 'C', and 'D', with 0, 1, 2, and 3 respectively.

```
>>> values = {"A": 0, "B": 1, "C": 2, "D": 3}
>>> df.fillna(value=values)
   A  B  C  D
0  0.0 2.0 2.0 0
1  3.0 4.0 2.0 1
2  0.0 1.0 2.0 5
3  0.0 3.0 2.0 4
```

Only replace the first NaN element.

```
>>> df.fillna(value=values, limit=1)
   A  B  C  D
0  0.0 2.0 2.0 0
1  3.0 4.0 NaN 1
2  NaN 1.0 NaN 5
3  NaN 3.0 NaN 4
```

When filling using a DataFrame, replacement happens along the same column names and same indices

```
>>> df2 = pd.DataFrame(np.zeros((4, 4)), columns=list("ABCE"))
>>> df.fillna(df2)
   A  B  C  D
0  0.0 2.0 0.0 0
1  3.0 4.0 0.0 1
2  0.0 0.0 0.0 5
3  0.0 3.0 0.0 4
```

pandas.Series.filter

Series.filter(*items=None, like=None, regex=None, axis=None*)

Subset the dataframe rows or columns according to the specified index labels.

Note that this routine does not filter a dataframe on its contents. The filter is applied to the labels of the index.

Parameters

items [list-like] Keep labels from axis which are in items.

like [str] Keep labels from axis for which "like in label == True".

regex [str (regular expression)] Keep labels from axis for which `re.search(regex, label) == True`.

axis [{0 or 'index', 1 or 'columns', None}, default None] The axis to filter on, expressed either as an index (int) or axis name (str). By default this is the info axis, 'index' for Series, 'columns' for DataFrame.

Returns

same type as input object

See also:

[*DataFrame.loc*](#) Access a group of rows and columns by label(s) or a boolean array.

Notes

The `items`, `like`, and `regex` parameters are enforced to be mutually exclusive.

`axis` defaults to the info axis that is used when indexing with `[]`.

Examples

```
>>> df = pd.DataFrame(np.array([[1, 2, 3], [4, 5, 6]]),
...                   index=['mouse', 'rabbit'],
...                   columns=['one', 'two', 'three'])
>>> df
```

| | one | two | three |
|--------|-----|-----|-------|
| mouse | 1 | 2 | 3 |
| rabbit | 4 | 5 | 6 |

```
>>> # select columns by name
>>> df.filter(items=['one', 'three'])
```

| | one | three |
|--------|-----|-------|
| mouse | 1 | 3 |
| rabbit | 4 | 6 |

```
>>> # select columns by regular expression
>>> df.filter(regex='e$', axis=1)
```

| | one | three |
|--------|-----|-------|
| mouse | 1 | 3 |
| rabbit | 4 | 6 |

```
>>> # select rows containing 'bbi'
>>> df.filter(like='bbi', axis=0)
```

| | one | two | three |
|--------|-----|-----|-------|
| rabbit | 4 | 5 | 6 |

pandas.Series.first

`Series.first(offset)`

Select initial periods of time series data based on a date offset.

When having a DataFrame with dates as index, this function can select the first few rows based on a date offset.

Parameters

offset [str, DateOffset or dateutil.relativedelta] The offset length of the data that will be selected. For instance, '1M' will display all the rows having their index within the first month.

Returns

Series or DataFrame A subset of the caller.

Raises

TypeError If the index is not a *DatetimeIndex*

See also:

last Select final periods of time series based on a date offset.

at_time Select values at a particular time of the day.

between_time Select values between particular times of the day.

Examples

```
>>> i = pd.date_range('2018-04-09', periods=4, freq='2D')
>>> ts = pd.DataFrame({'A': [1, 2, 3, 4]}, index=i)
>>> ts
```

| | A |
|------------|---|
| 2018-04-09 | 1 |
| 2018-04-11 | 2 |
| 2018-04-13 | 3 |
| 2018-04-15 | 4 |

Get the rows for the first 3 days:

```
>>> ts.first('3D')
```

| | A |
|------------|---|
| 2018-04-09 | 1 |
| 2018-04-11 | 2 |

Notice the data for 3 first calendar days were returned, not the first 3 days observed in the dataset, and therefore data for 2018-04-13 was not returned.

pandas.Series.first_valid_index

Series.first_valid_index()

Return index for first non-NA value or None, if no NA value is found.

Returns

scalar [type of index]

Notes

If all elements are non-NA/null, returns None. Also returns None for empty Series/DataFrame.

pandas.Series.floordiv

`Series.floordiv`(*other*, *level=None*, *fill_value=None*, *axis=0*)

Return Integer division of series and other, element-wise (binary operator *floordiv*).

Equivalent to `series // other`, but with support to substitute a *fill_value* for missing data in either one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level.

Returns

Series The result of the operation.

See also:

[*Series.rfloordiv*](#) Reverse of the Integer division operator, see [Python documentation](#) for more details.

Examples

```
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.floordiv(b, fill_value=0)
a    1.0
b    NaN
c    NaN
d    0.0
e    NaN
dtype: float64
```

pandas.Series.ge

`Series.ge`(*other*, *level=None*, *fill_value=None*, *axis=0*)

Return Greater than or equal to of series and other, element-wise (binary operator *ge*).

Equivalent to `series >= other`, but with support to substitute a *fill_value* for missing data in either one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level.

Returns

Series The result of the operation.

Examples

```
>>> a = pd.Series([1, 1, 1, np.nan, 1], index=['a', 'b', 'c', 'd', 'e'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
e    1.0
dtype: float64
>>> b = pd.Series([0, 1, 2, np.nan, 1], index=['a', 'b', 'c', 'd', 'f'])
>>> b
a    0.0
b    1.0
c    2.0
d    NaN
f    1.0
dtype: float64
>>> a.ge(b, fill_value=0)
a    True
b    True
c    False
d    False
e    True
f    False
dtype: bool
```

pandas.Series.get

`Series.get(key, default=None)`

Get item from object for given key (ex: DataFrame column).

Returns default value if not found.

Parameters

key [object]

Returns

value [same type as items contained in object]

pandas.Series.groupby

`Series.groupby(by=None, axis=0, level=None, as_index=True, sort=True, group_keys=True, squeeze=NoDefault.no_default, observed=False, dropna=True)`

Group Series using a mapper or by a Series of columns.

A groupby operation involves some combination of splitting the object, applying a function, and combining the results. This can be used to group large amounts of data and compute operations on these groups.

Parameters

by [mapping, function, label, or list of labels] Used to determine the groups for the groupby. If `by` is a function, it's called on each value of the object's index. If a dict or Series is passed, the Series or dict VALUES will be used to determine the groups (the Series' values are first aligned; see `.align()` method). If an ndarray is passed, the values are used as-is to determine the groups. A label or list of labels may be passed to group by the columns in `self`. Notice that a tuple is interpreted as a (single) key.

axis [{0 or 'index', 1 or 'columns'}, default 0] Split along rows (0) or columns (1).

level [int, level name, or sequence of such, default None] If the axis is a MultiIndex (hierarchical), group by a particular level or levels.

as_index [bool, default True] For aggregated output, return object with group labels as the index. Only relevant for DataFrame input. `as_index=False` is effectively "SQL-style" grouped output.

sort [bool, default True] Sort group keys. Get better performance by turning this off. Note this does not influence the order of observations within each group. Groupby preserves the order of rows within each group.

group_keys [bool, default True] When calling `apply`, add group keys to index to identify pieces.

squeeze [bool, default False] Reduce the dimensionality of the return type if possible, otherwise return a consistent type.

Deprecated since version 1.1.0.

observed [bool, default False] This only applies if any of the groupers are Categoricals. If True: only show observed values for categorical groupers. If False: show all values for categorical groupers.

dropna [bool, default True] If True, and if group keys contain NA values, NA values together with row/column will be dropped. If False, NA values will also be treated as the key in groups

New in version 1.1.0.

Returns

SeriesGroupBy Returns a groupby object that contains information about the groups.

See also:

[*resample*](#) Convenience method for frequency conversion and resampling of time series.

Notes

See the [user guide](#) for more.

Examples

```
>>> ser = pd.Series([390., 350., 30., 20.],
...                 index=['Falcon', 'Falcon', 'Parrot', 'Parrot'], name="Max_
↳Speed")
>>> ser
Falcon    390.0
Falcon    350.0
Parrot     30.0
Parrot     20.0
Name: Max Speed, dtype: float64
>>> ser.groupby(["a", "b", "a", "b"]).mean()
a    210.0
b    185.0
Name: Max Speed, dtype: float64
>>> ser.groupby(level=0).mean()
Falcon    370.0
Parrot     25.0
Name: Max Speed, dtype: float64
>>> ser.groupby(ser > 100).mean()
Max Speed
False     25.0
True     370.0
Name: Max Speed, dtype: float64
```

Grouping by Indexes

We can groupby different levels of a hierarchical index using the *level* parameter:

```
>>> arrays = [['Falcon', 'Falcon', 'Parrot', 'Parrot'],
...           ['Captive', 'Wild', 'Captive', 'Wild']]
>>> index = pd.MultiIndex.from_arrays(arrays, names=('Animal', 'Type'))
>>> ser = pd.Series([390., 350., 30., 20.], index=index, name="Max Speed")
>>> ser
Animal  Type
Falcon  Captive    390.0
        Wild      350.0
Parrot  Captive    30.0
        Wild      20.0
Name: Max Speed, dtype: float64
```

(continues on next page)

(continued from previous page)

```
>>> ser.groupby(level=0).mean()
Animal
Falcon    370.0
Parrot     25.0
Name: Max Speed, dtype: float64
>>> ser.groupby(level="Type").mean()
Type
Captive    210.0
Wild       185.0
Name: Max Speed, dtype: float64
```

We can also choose to include *NA* in group keys or not by defining *dropna* parameter, the default setting is *True*:

```
>>> ser = pd.Series([1, 2, 3, 3], index=["a", 'a', 'b', np.nan])
>>> ser.groupby(level=0).sum()
a      3
b      3
dtype: int64
```

```
>>> ser.groupby(level=0, dropna=False).sum()
a      3
b      3
NaN    3
dtype: int64
```

```
>>> arrays = ['Falcon', 'Falcon', 'Parrot', 'Parrot']
>>> ser = pd.Series([390., 350., 30., 20.], index=arrays, name="Max Speed")
>>> ser.groupby(["a", "b", "a", np.nan]).mean()
a      210.0
b      350.0
Name: Max Speed, dtype: float64
```

```
>>> ser.groupby(["a", "b", "a", np.nan], dropna=False).mean()
a      210.0
b      350.0
NaN     20.0
Name: Max Speed, dtype: float64
```

pandas.Series.gt

Series.gt(*other*, *level=None*, *fill_value=None*, *axis=0*)

Return Greater than of series and other, element-wise (binary operator *gt*).

Equivalent to `series > other`, but with support to substitute a *fill_value* for missing data in either one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before

computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level.

Returns

Series The result of the operation.

Examples

```
>>> a = pd.Series([1, 1, 1, np.nan, 1], index=['a', 'b', 'c', 'd', 'e'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
e    1.0
dtype: float64
>>> b = pd.Series([0, 1, 2, np.nan, 1], index=['a', 'b', 'c', 'd', 'f'])
>>> b
a    0.0
b    1.0
c    2.0
d    NaN
f    1.0
dtype: float64
>>> a.gt(b, fill_value=0)
a    True
b    False
c    False
d    False
e    True
f    False
dtype: bool
```

pandas.Series.head

Series.head(*n*=5)

Return the first *n* rows.

This function returns the first *n* rows for the object based on position. It is useful for quickly testing if your object has the right type of data in it.

For negative values of *n*, this function returns all rows except the last *n* rows, equivalent to `df[: -n]`.

Parameters

n [int, default 5] Number of rows to select.

Returns

same type as caller The first *n* rows of the caller object.

See also:

`DataFrame.tail` Returns the last n rows.

Examples

```
>>> df = pd.DataFrame({'animal': ['alligator', 'bee', 'falcon', 'lion',  
...                               'monkey', 'parrot', 'shark', 'whale', 'zebra']})  
>>> df  
   animal  
0 alligator  
1      bee  
2   falcon  
3     lion  
4   monkey  
5   parrot  
6    shark  
7    whale  
8    zebra
```

Viewing the first 5 lines

```
>>> df.head()  
   animal  
0 alligator  
1      bee  
2   falcon  
3     lion  
4   monkey
```

Viewing the first n lines (three in this case)

```
>>> df.head(3)  
   animal  
0 alligator  
1      bee  
2   falcon
```

For negative values of n

```
>>> df.head(-3)  
   animal  
0 alligator  
1      bee  
2   falcon  
3     lion  
4   monkey  
5   parrot
```

pandas.Series.hist

`Series.hist`(*by=None, ax=None, grid=True, xlabelsize=None, xrot=None, ylabelsize=None, yrot=None, figsize=None, bins=10, backend=None, legend=False, **kwargs*)

Draw histogram of the input series using matplotlib.

Parameters

by [object, optional] If passed, then used to form histograms for separate groups.

ax [matplotlib axis object] If not passed, uses `gca()`.

grid [bool, default True] Whether to show axis grid lines.

xlabelsize [int, default None] If specified changes the x-axis label size.

xrot [float, default None] Rotation of x axis labels.

ylabelsize [int, default None] If specified changes the y-axis label size.

yrot [float, default None] Rotation of y axis labels.

figsize [tuple, default None] Figure size in inches by default.

bins [int or sequence, default 10] Number of histogram bins to be used. If an integer is given, `bins + 1` bin edges are calculated and returned. If `bins` is a sequence, gives bin edges, including left edge of first bin and right edge of last bin. In this case, `bins` is returned unmodified.

backend [str, default None] Backend to use instead of the backend specified in the option `plotting.backend`. For instance, `'matplotlib'`. Alternatively, to specify the `plotting.backend` for the whole session, set `pd.options.plotting.backend`.

New in version 1.0.0.

legend [bool, default False] Whether to show the legend.

New in version 1.1.0.

****kwargs** To be passed to the actual plotting function.

Returns

`matplotlib.AxesSubplot` A histogram plot.

See also:

[matplotlib.axes.Axes.hist](#) Plot a histogram using matplotlib.

pandas.Series.idxmax

`Series.idxmax`(*axis=0, skipna=True, *args, **kwargs*)

Return the row label of the maximum value.

If multiple values equal the maximum, the first row label with that value is returned.

Parameters

axis [int, default 0] For compatibility with `DataFrame.idxmax`. Redundant for application on Series.

skipna [bool, default True] Exclude NA/null values. If the entire Series is NA, the result will be NA.

***args, **kwargs** Additional arguments and keywords have no effect but might be accepted for compatibility with NumPy.

Returns

Index Label of the maximum value.

Raises

ValueError If the Series is empty.

See also:

numpy.argmax Return indices of the maximum values along the given axis.

DataFrame.idxmax Return index of first occurrence of maximum over requested axis.

Series.idxmin Return index *label* of the first occurrence of minimum of values.

Notes

This method is the Series version of `ndarray.argmax`. This method returns the label of the maximum, while `ndarray.argmax` returns the position. To get the position, use `series.values.argmax()`.

Examples

```
>>> s = pd.Series(data=[1, None, 4, 3, 4],
...                index=['A', 'B', 'C', 'D', 'E'])
>>> s
A    1.0
B    NaN
C    4.0
D    3.0
E    4.0
dtype: float64
```

```
>>> s.idxmax()
'C'
```

If *skipna* is False and there is an NA value in the data, the function returns `nan`.

```
>>> s.idxmax(skipna=False)
nan
```

pandas.Series.idxmin

Series.idxmin(*axis=0, skipna=True, *args, **kwargs*)

Return the row label of the minimum value.

If multiple values equal the minimum, the first row label with that value is returned.

Parameters

axis [int, default 0] For compatibility with `DataFrame.idxmin`. Redundant for application on Series.

skipna [bool, default True] Exclude NA/null values. If the entire Series is NA, the result will be NA.

***args, **kwargs** Additional arguments and keywords have no effect but might be accepted for compatibility with NumPy.

Returns

Index Label of the minimum value.

Raises

ValueError If the Series is empty.

See also:

[`numpy.argmax`](#) Return indices of the minimum values along the given axis.

[`DataFrame.idxmin`](#) Return index of first occurrence of minimum over requested axis.

[`Series.idxmax`](#) Return index *label* of the first occurrence of maximum of values.

Notes

This method is the Series version of `ndarray.argmax`. This method returns the label of the minimum, while `ndarray.argmax` returns the position. To get the position, use `series.values.argmax()`.

Examples

```
>>> s = pd.Series(data=[1, None, 4, 1],
...               index=['A', 'B', 'C', 'D'])
>>> s
A    1.0
B    NaN
C    4.0
D    1.0
dtype: float64
```

```
>>> s.idxmin()
'A'
```

If *skipna* is False and there is an NA value in the data, the function returns `nan`.

```
>>> s.idxmin(skipna=False)
nan
```

pandas.Series.infer_objects

Series.infer_objects()

Attempt to infer better dtypes for object columns.

Attempts soft conversion of object-dtyped columns, leaving non-object and unconvertible columns unchanged. The inference rules are the same as during normal Series/DataFrame construction.

Returns

converted [same type as input object]

See also:

[`to_datetime`](#) Convert argument to datetime.

[`to_timedelta`](#) Convert argument to timedelta.

[`to_numeric`](#) Convert argument to numeric type.

[`convert_dtypes`](#) Convert argument to best possible dtype.

Examples

```
>>> df = pd.DataFrame({"A": ["a", 1, 2, 3]})
>>> df = df.iloc[1:]
>>> df
   A
1  1
2  2
3  3
```

```
>>> df.dtypes
A    object
dtype: object
```

```
>>> df.infer_objects().dtypes
A    int64
dtype: object
```

pandas.Series.interpolate

Series.**interpolate**(*method='linear', axis=0, limit=None, inplace=False, limit_direction=None, limit_area=None, downcast=None, **kwargs*)

Fill NaN values using an interpolation method.

Please note that only `method='linear'` is supported for DataFrame/Series with a MultiIndex.

Parameters

method [str, default 'linear'] Interpolation technique to use. One of:

- 'linear': Ignore the index and treat the values as equally spaced. This is the only method supported on MultiIndexes.
- 'time': Works on daily and higher resolution data to interpolate given length of interval.

- ‘index’, ‘values’: use the actual numerical values of the index.
- ‘pad’: Fill in NaNs using existing values.
- ‘nearest’, ‘zero’, ‘slinear’, ‘quadratic’, ‘cubic’, ‘spline’, ‘barycentric’, ‘polynomial’: Passed to `scipy.interpolate.interp1d`. These methods use the numerical values of the index. Both ‘polynomial’ and ‘spline’ require that you also specify an *order* (int), e.g. `df.interpolate(method='polynomial', order=5)`.
- ‘krogh’, ‘piecewise_polynomial’, ‘spline’, ‘pchip’, ‘akima’, ‘cubicspline’: Wrappers around the SciPy interpolation methods of similar names. See *Notes*.
- ‘from_derivatives’: Refers to `scipy.interpolate.BPoly.from_derivatives` which replaces ‘piecewise_polynomial’ interpolation method in scipy 0.18.

axis [{0 or ‘index’, 1 or ‘columns’, None}], default None] Axis to interpolate along.

limit [int, optional] Maximum number of consecutive NaNs to fill. Must be greater than 0.

inplace [bool, default False] Update the data in place if possible.

limit_direction [{‘forward’, ‘backward’, ‘both’}], Optional] Consecutive NaNs will be filled in this direction.

If limit is specified:

- If ‘method’ is ‘pad’ or ‘ffill’, ‘limit_direction’ must be ‘forward’.
- If ‘method’ is ‘backfill’ or ‘bfill’, ‘limit_direction’ must be ‘backwards’.

If ‘limit’ is not specified:

- If ‘method’ is ‘backfill’ or ‘bfill’, the default is ‘backward’
- else the default is ‘forward’

Changed in version 1.1.0: raises `ValueError` if *limit_direction* is ‘forward’ or ‘both’ and method is ‘backfill’ or ‘bfill’. raises `ValueError` if *limit_direction* is ‘backward’ or ‘both’ and method is ‘pad’ or ‘ffill’.

limit_area [{None, ‘inside’, ‘outside’}], default None] If limit is specified, consecutive NaNs will be filled with this restriction.

- None: No fill restriction.
- ‘inside’: Only fill NaNs surrounded by valid values (interpolate).
- ‘outside’: Only fill NaNs outside valid values (extrapolate).

downcast [optional, ‘infer’ or None, defaults to None] Downcast dtypes if possible.

kwargs [optional] Keyword arguments to pass on to the interpolating function.

Returns

Series or DataFrame or None Returns the same object type as the caller, interpolated at some or all NaN values or None if `inplace=True`.

See also:

[*fillna*](#) Fill missing values using different methods.

[`scipy.interpolate.Akima1DInterpolator`](#) Piecewise cubic polynomials (Akima interpolator).

[`scipy.interpolate.BPoly.from_derivatives`](#) Piecewise polynomial in the Bernstein basis.

`scipy.interpolate.interp1d` Interpolate a 1-D function.

`scipy.interpolate.KroghInterpolator` Interpolate polynomial (Krogh interpolator).

`scipy.interpolate.PchipInterpolator` PCHIP 1-d monotonic cubic interpolation.

`scipy.interpolate.CubicSpline` Cubic spline data interpolator.

Notes

The ‘krogh’, ‘piecewise_polynomial’, ‘spline’, ‘pchip’ and ‘akima’ methods are wrappers around the respective SciPy implementations of similar names. These use the actual numerical values of the index. For more information on their behavior, see the [SciPy documentation](#) and [SciPy tutorial](#).

Examples

Filling in NaN in a *Series* via linear interpolation.

```
>>> s = pd.Series([0, 1, np.nan, 3])
>>> s
0    0.0
1    1.0
2    NaN
3    3.0
dtype: float64
>>> s.interpolate()
0    0.0
1    1.0
2    2.0
3    3.0
dtype: float64
```

Filling in NaN in a Series by padding, but filling at most two consecutive NaN at a time.

```
>>> s = pd.Series([np.nan, "single_one", np.nan,
...               "fill_two_more", np.nan, np.nan, np.nan,
...               4.71, np.nan])
>>> s
0          NaN
1    single_one
2          NaN
3    fill_two_more
4          NaN
5          NaN
6          NaN
7          4.71
8          NaN
dtype: object
>>> s.interpolate(method='pad', limit=2)
0          NaN
1    single_one
2    single_one
3    fill_two_more
4    fill_two_more
```

(continues on next page)

(continued from previous page)

```

5    fill_two_more
6                NaN
7                4.71
8                4.71
dtype: object

```

Filling in NaN in a Series via polynomial interpolation or splines: Both ‘polynomial’ and ‘spline’ methods require that you also specify an order (int).

```

>>> s = pd.Series([0, 2, np.nan, 8])
>>> s.interpolate(method='polynomial', order=2)
0    0.000000
1    2.000000
2    4.666667
3    8.000000
dtype: float64

```

Fill the DataFrame forward (that is, going down) along each column using linear interpolation.

Note how the last entry in column ‘a’ is interpolated differently, because there is no entry after it to use for interpolation. Note how the first entry in column ‘b’ remains NaN, because there is no entry before it to use for interpolation.

```

>>> df = pd.DataFrame([(0.0, np.nan, -1.0, 1.0),
...                   (np.nan, 2.0, np.nan, np.nan),
...                   (2.0, 3.0, np.nan, 9.0),
...                   (np.nan, 4.0, -4.0, 16.0)],
...                   columns=list('abcd'))
>>> df
   a    b    c    d
0  0.0 NaN -1.0  1.0
1  NaN  2.0 NaN  NaN
2  2.0  3.0 NaN  9.0
3  NaN  4.0 -4.0 16.0
>>> df.interpolate(method='linear', limit_direction='forward', axis=0)
   a    b    c    d
0  0.0 NaN -1.0  1.0
1  1.0  2.0 -2.0  5.0
2  2.0  3.0 -3.0  9.0
3  2.0  4.0 -4.0 16.0

```

Using polynomial interpolation.

```

>>> df['d'].interpolate(method='polynomial', order=2)
0    1.0
1    4.0
2    9.0
3   16.0
Name: d, dtype: float64

```

pandas.Series.isin**Series.isin(values)**Whether elements in Series are contained in *values*.Return a boolean Series showing whether each element in the Series matches an element in the passed sequence of *values* exactly.**Parameters****values** [set or list-like] The sequence of values to test. Passing in a single string will raise a `TypeError`. Instead, turn a single string into a list of one element.**Returns****Series** Series of booleans indicating if each element is in values.**Raises****TypeError**

- If *values* is a string

See also:**DataFrame.isin** Equivalent method on DataFrame.**Examples**

```
>>> s = pd.Series(['lama', 'cow', 'lama', 'beetle', 'lama',
...               'hippo'], name='animal')
>>> s.isin(['cow', 'lama'])
0    True
1    True
2    True
3    False
4    True
5    False
Name: animal, dtype: bool
```

Passing a single string as `s.isin('lama')` will raise an error. Use a list of one element instead:

```
>>> s.isin(['lama'])
0    True
1    False
2    True
3    False
4    True
5    False
Name: animal, dtype: bool
```

Strings and integers are distinct and are therefore not comparable:

```
>>> pd.Series([1]).isin(['1'])
0    False
dtype: bool
>>> pd.Series([1.1]).isin(['1.1'])
```

(continues on next page)

(continued from previous page)

```
0    False
dtype: bool
```

pandas.Series.isna

Series.isna()

Detect missing values.

Return a boolean same-sized object indicating if the values are NA. NA values, such as None or numpy. NaN, gets mapped to True values. Everything else gets mapped to False values. Characters such as empty strings '' or numpy.inf are not considered NA values (unless you set pandas.options.mode.use_inf_as_na = True).

Returns

Series Mask of bool values for each element in Series that indicates whether an element is an NA value.

See also:

Series.isnull Alias of isna.

Series.notna Boolean inverse of isna.

Series.dropna Omit axes labels with missing values.

isna Top-level isna.

Examples

Show which entries in a DataFrame are NA.

```
>>> df = pd.DataFrame(dict(age=[5, 6, np.NaN],
...                          born=[pd.NaT, pd.Timestamp('1939-05-27'),
...                               pd.Timestamp('1940-04-25')],
...                          name=['Alfred', 'Batman', ''],
...                          toy=[None, 'Batmobile', 'Joker']))
>>> df
   age      born  name      toy
0  5.0      NaT  Alfred    None
1  6.0  1939-05-27  Batman  Batmobile
2  NaN  1940-04-25         Joker
```

```
>>> df.isna()
   age  born  name  toy
0  False  True  False  True
1  False  False  False  False
2   True  False  False  False
```

Show which entries in a Series are NA.

```
>>> ser = pd.Series([5, 6, np.NaN])
>>> ser
```

(continues on next page)

(continued from previous page)

```
0    5.0
1    6.0
2    NaN
dtype: float64
```

```
>>> ser.isna()
0    False
1    False
2     True
dtype: bool
```

pandas.Series.isnull

Series.isnull()

Detect missing values.

Return a boolean same-sized object indicating if the values are NA. NA values, such as `None` or `numpy.NaN`, gets mapped to `True` values. Everything else gets mapped to `False` values. Characters such as empty strings `' '` or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`).

Returns

Series Mask of bool values for each element in Series that indicates whether an element is an NA value.

See also:

Series.isnull Alias of `isna`.

Series.notna Boolean inverse of `isna`.

Series.dropna Omit axes labels with missing values.

isna Top-level `isna`.

Examples

Show which entries in a DataFrame are NA.

```
>>> df = pd.DataFrame(dict(age=[5, 6, np.NaN],
...                          born=[pd.NaT, pd.Timestamp('1939-05-27'),
...                                pd.Timestamp('1940-04-25')],
...                          name=['Alfred', 'Batman', ''],
...                          toy=[None, 'Batmobile', 'Joker']))
>>> df
   age      born      name      toy
0  5.0      NaT  Alfred     None
1  6.0  1939-05-27  Batman  Batmobile
2  NaN  1940-04-25           Joker
```

```
>>> df.isna()
   age  born  name  toy
0  False  True  False  True
1  False  False  False  False
2   True  False  False  False
```

Show which entries in a Series are NA.

```
>>> ser = pd.Series([5, 6, np.NaN])
>>> ser
0    5.0
1    6.0
2    NaN
dtype: float64
```

```
>>> ser.isna()
0    False
1    False
2     True
dtype: bool
```

pandas.Series.item

Series.item()

Return the first element of the underlying data as a Python scalar.

Returns

scalar The first element of %(klass)s.

Raises

ValueError If the data is not length-1.

pandas.Series.items

Series.items()

Lazily iterate over (index, value) tuples.

This method returns an iterable tuple (index, value). This is convenient if you want to create a lazy iterator.

Returns

iterable Iterable of tuples containing the (index, value) pairs from a Series.

See also:

[*DataFrame.items*](#) Iterate over (column name, Series) pairs.

[*DataFrame.iterrows*](#) Iterate over DataFrame rows as (index, Series) pairs.

Examples

```
>>> s = pd.Series(['A', 'B', 'C'])
>>> for index, value in s.items():
...     print(f"Index : {index}, Value : {value}")
Index : 0, Value : A
Index : 1, Value : B
Index : 2, Value : C
```

pandas.Series.iteritems

Series.iteritems()

Lazily iterate over (index, value) tuples.

This method returns an iterable tuple (index, value). This is convenient if you want to create a lazy iterator.

Returns

iterable Iterable of tuples containing the (index, value) pairs from a Series.

See also:

[*DataFrame.items*](#) Iterate over (column name, Series) pairs.

[*DataFrame.iterrows*](#) Iterate over DataFrame rows as (index, Series) pairs.

Examples

```
>>> s = pd.Series(['A', 'B', 'C'])
>>> for index, value in s.items():
...     print(f"Index : {index}, Value : {value}")
Index : 0, Value : A
Index : 1, Value : B
Index : 2, Value : C
```

pandas.Series.keys

Series.keys()

Return alias for index.

Returns

Index Index of the Series.

pandas.Series.kurt

`Series.kurt` (*axis=None, skipna=None, level=None, numeric_only=None, **kwargs*)

Return unbiased kurtosis over requested axis.

Kurtosis obtained using Fisher's definition of kurtosis (kurtosis of normal == 0.0). Normalized by N-1.

Parameters

axis [{index (0)}] Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

****kwargs** Additional keyword arguments to be passed to the function.

Returns

scalar or Series (if level specified)

pandas.Series.kurtosis

`Series.kurtosis` (*axis=None, skipna=None, level=None, numeric_only=None, **kwargs*)

Return unbiased kurtosis over requested axis.

Kurtosis obtained using Fisher's definition of kurtosis (kurtosis of normal == 0.0). Normalized by N-1.

Parameters

axis [{index (0)}] Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

****kwargs** Additional keyword arguments to be passed to the function.

Returns

scalar or Series (if level specified)

pandas.Series.last

`Series.last` (*offset*)

Select final periods of time series data based on a date offset.

For a DataFrame with a sorted DatetimeIndex, this function selects the last few rows based on a date offset.

Parameters

offset [str, DateOffset, dateutil.relativedelta] The offset length of the data that will be selected. For instance, '3D' will display all the rows having their index within the last 3 days.

Returns

Series or DataFrame A subset of the caller.

Raises

TypeError If the index is not a *DatetimeIndex*

See also:

first Select initial periods of time series based on a date offset.

at_time Select values at a particular time of the day.

between_time Select values between particular times of the day.

Examples

```
>>> i = pd.date_range('2018-04-09', periods=4, freq='2D')
>>> ts = pd.DataFrame({'A': [1, 2, 3, 4]}, index=i)
>>> ts
```

| | A |
|------------|---|
| 2018-04-09 | 1 |
| 2018-04-11 | 2 |
| 2018-04-13 | 3 |
| 2018-04-15 | 4 |

Get the rows for the last 3 days:

```
>>> ts.last('3D')
```

| | A |
|------------|---|
| 2018-04-13 | 3 |
| 2018-04-15 | 4 |

Notice the data for 3 last calendar days were returned, not the last 3 observed days in the dataset, and therefore data for 2018-04-11 was not returned.

pandas.Series.last_valid_index

Series.last_valid_index()

Return index for last non-NA value or None, if no NA value is found.

Returns

scalar [type of index]

Notes

If all elements are non-NA/null, returns None. Also returns None for empty Series/DataFrame.

pandas.Series.le

`Series.le(other, level=None, fill_value=None, axis=0)`

Return Less than or equal to of series and other, element-wise (binary operator *le*).

Equivalent to `series <= other`, but with support to substitute a `fill_value` for missing data in either one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level.

Returns

Series The result of the operation.

Examples

```

>>> a = pd.Series([1, 1, 1, np.nan, 1], index=['a', 'b', 'c', 'd', 'e'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
e    1.0
dtype: float64
>>> b = pd.Series([0, 1, 2, np.nan, 1], index=['a', 'b', 'c', 'd', 'f'])
>>> b
a    0.0
b    1.0
c    2.0
d    NaN
f    1.0
dtype: float64
>>> a.le(b, fill_value=0)
a    False
b     True
c     True
d    False
e    False
f     True
dtype: bool

```

pandas.Series.lt

`Series.lt(other, level=None, fill_value=None, axis=0)`

Return Less than of series and other, element-wise (binary operator *lt*).

Equivalent to `series < other`, but with support to substitute a `fill_value` for missing data in either one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level.

Returns

Series The result of the operation.

Examples

```

>>> a = pd.Series([1, 1, 1, np.nan, 1], index=['a', 'b', 'c', 'd', 'e'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
e    1.0
dtype: float64
>>> b = pd.Series([0, 1, 2, np.nan, 1], index=['a', 'b', 'c', 'd', 'f'])
>>> b
a    0.0
b    1.0
c    2.0
d    NaN
f    1.0
dtype: float64
>>> a.lt(b, fill_value=0)
a    False
b    False
c     True
d    False
e    False
f     True
dtype: bool

```

pandas.Series.mad**Series.mad**(*axis=None, skipna=None, level=None*)

Return the mean absolute deviation of the values over the requested axis.

Parameters**axis** [{index (0)}] Axis for the function to be applied on.**skipna** [bool, default None] Exclude NA/null values when computing the result.**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.**Returns****scalar or Series (if level specified)****pandas.Series.map****Series.map**(*arg, na_action=None*)

Map values of Series according to input correspondence.

Used for substituting each value in a Series with another value, that may be derived from a function, a dict or a *Series*.**Parameters****arg** [function, collections.abc.Mapping subclass or Series] Mapping correspondence.**na_action** [{None, 'ignore'}, default None] If 'ignore', propagate NaN values, without passing them to the mapping correspondence.**Returns****Series** Same index as caller.**See also:***Series.apply* For applying more complex functions on a Series.*DataFrame.apply* Apply a function row-/column-wise.*DataFrame.applymap* Apply a function elementwise on a whole DataFrame.**Notes**When *arg* is a dictionary, values in Series that are not in the dictionary (as keys) are converted to NaN. However, if the dictionary is a dict subclass that defines `__missing__` (i.e. provides a method for default values), then this default is used rather than NaN.

Examples

```
>>> s = pd.Series(['cat', 'dog', np.nan, 'rabbit'])
>>> s
0      cat
1      dog
2      NaN
3  rabbit
dtype: object
```

`map` accepts a dict or a Series. Values that are not found in the dict are converted to NaN, unless the dict has a default value (e.g. `defaultdict`):

```
>>> s.map({'cat': 'kitten', 'dog': 'puppy'})
0  kitten
1  puppy
2     NaN
3     NaN
dtype: object
```

It also accepts a function:

```
>>> s.map('I am a {}'.format)
0      I am a cat
1      I am a dog
2      I am a nan
3  I am a rabbit
dtype: object
```

To avoid applying the function to missing values (and keep them as NaN) `na_action='ignore'` can be used:

```
>>> s.map('I am a {}'.format, na_action='ignore')
0      I am a cat
1      I am a dog
2           NaN
3  I am a rabbit
dtype: object
```

pandas.Series.mask

`Series.mask(cond, other=nan, inplace=False, axis=None, level=None, errors='raise', try_cast=NoDefault.no_default)`

Replace values where the condition is True.

Parameters

cond [bool Series/DataFrame, array-like, or callable] Where `cond` is False, keep the original value. Where True, replace with corresponding value from `other`. If `cond` is callable, it is computed on the Series/DataFrame and should return boolean Series/DataFrame or array. The callable must not change input Series/DataFrame (though pandas doesn't check it).

other [scalar, Series/DataFrame, or callable] Entries where *cond* is True are replaced with corresponding value from *other*. If *other* is callable, it is computed on the Series/DataFrame and should return scalar or Series/DataFrame. The callable must not change input Series/DataFrame (though pandas doesn't check it).

inplace [bool, default False] Whether to perform the operation in place on the data.

axis [int, default None] Alignment axis if needed.

level [int, default None] Alignment level if needed.

errors [str, {'raise', 'ignore'}, default 'raise'] Note that currently this parameter won't affect the results and will always coerce to a suitable dtype.

- 'raise' : allow exceptions to be raised.
- 'ignore' : suppress exceptions. On error return original object.

try_cast [bool, default None] Try to cast the result back to the input type (if possible).

Deprecated since version 1.3.0: Manually cast back if necessary.

Returns

Same type as caller or None if **inplace=True**.

See also:

[DataFrame.where\(\)](#) Return an object of same shape as self.

Notes

The mask method is an application of the if-then idiom. For each element in the calling DataFrame, if *cond* is False the element is used; otherwise the corresponding element from the DataFrame *other* is used.

The signature for [DataFrame.where\(\)](#) differs from [numpy.where\(\)](#). Roughly `df1.where(m, df2)` is equivalent to `np.where(m, df1, df2)`.

For further details and examples see the mask documentation in [indexing](#).

Examples

```
>>> s = pd.Series(range(5))
>>> s.where(s > 0)
0    NaN
1    1.0
2    2.0
3    3.0
4    4.0
dtype: float64
>>> s.mask(s > 0)
0    0.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

```
>>> s.where(s > 1, 10)
0    10
1    10
2     2
3     3
4     4
dtype: int64
>>> s.mask(s > 1, 10)
0     0
1     1
2    10
3    10
4    10
dtype: int64
```

```
>>> df = pd.DataFrame(np.arange(10).reshape(-1, 2), columns=['A', 'B'])
>>> df
   A  B
0  0  1
1  2  3
2  4  5
3  6  7
4  8  9
>>> m = df % 3 == 0
>>> df.where(m, -df)
   A  B
0  0 -1
1 -2  3
2 -4 -5
3  6 -7
4 -8  9
>>> df.where(m, -df) == np.where(m, df, -df)
   A  B
0  True  True
1  True  True
2  True  True
3  True  True
4  True  True
>>> df.where(m, -df) == df.mask(~m, -df)
   A  B
0  True  True
1  True  True
2  True  True
3  True  True
4  True  True
```

pandas.Series.max

`Series.max(axis=None, skipna=None, level=None, numeric_only=None, **kwargs)`

Return the maximum of the values over the requested axis.

If you want the *index* of the maximum, use `idxmax`. This is the equivalent of the `numpy.ndarray` method `argmax`.

Parameters

axis [{index (0)}] Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

****kwargs** Additional keyword arguments to be passed to the function.

Returns

scalar or Series (if level specified)

See also:

[*Series.sum*](#) Return the sum.

[*Series.min*](#) Return the minimum.

[*Series.max*](#) Return the maximum.

[*Series.idxmin*](#) Return the index of the minimum.

[*Series.idxmax*](#) Return the index of the maximum.

[*DataFrame.sum*](#) Return the sum over the requested axis.

[*DataFrame.min*](#) Return the minimum over the requested axis.

[*DataFrame.max*](#) Return the maximum over the requested axis.

[*DataFrame.idxmin*](#) Return the index of the minimum over the requested axis.

[*DataFrame.idxmax*](#) Return the index of the maximum over the requested axis.

Examples

```
>>> idx = pd.MultiIndex.from_arrays([
...     ['warm', 'warm', 'cold', 'cold'],
...     ['dog', 'falcon', 'fish', 'spider']],
...     names=['blooded', 'animal'])
>>> s = pd.Series([4, 2, 0, 8], name='legs', index=idx)
>>> s
blooded  animal
warm     dog      4
         falcon   2
cold     fish     0
         spider   8
Name: legs, dtype: int64
```

```
>>> s.max()
8
```

pandas.Series.mean

`Series.mean(axis=None, skipna=None, level=None, numeric_only=None, **kwargs)`

Return the mean of the values over the requested axis.

Parameters

axis [int or index (0)] Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

****kwargs** Additional keyword arguments to be passed to the function.

Returns

scalar or Series (if level specified)

pandas.Series.median

`Series.median(axis=None, skipna=None, level=None, numeric_only=None, **kwargs)`

Return the median of the values over the requested axis.

Parameters

axis [int or index (0)] Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

****kwargs** Additional keyword arguments to be passed to the function.

Returns

scalar or Series (if level specified)

pandas.Series.memory_usage

`Series.memory_usage(index=True, deep=False)`

Return the memory usage of the Series.

The memory usage can optionally include the contribution of the index and of elements of *object* dtype.

Parameters

index [bool, default True] Specifies whether to include the memory usage of the Series index.

deep [bool, default False] If True, introspect the data deeply by interrogating *object* dtypes for system-level memory consumption, and include it in the returned value.

Returns

int Bytes of memory consumed.

See also:

`numpy.ndarray.nbytes` Total bytes consumed by the elements of the array.

`DataFrame.memory_usage` Bytes consumed by a DataFrame.

Examples

```
>>> s = pd.Series(range(3))
>>> s.memory_usage()
152
```

Not including the index gives the size of the rest of the data, which is necessarily smaller:

```
>>> s.memory_usage(index=False)
24
```

The memory footprint of *object* values is ignored by default:

```
>>> s = pd.Series(["a", "b"])
>>> s.values
array(['a', 'b'], dtype=object)
>>> s.memory_usage()
144
>>> s.memory_usage(deep=True)
244
```

pandas.Series.min

`Series.min(axis=None, skipna=None, level=None, numeric_only=None, **kwargs)`

Return the minimum of the values over the requested axis.

If you want the *index* of the minimum, use `idxmin`. This is the equivalent of the `numpy.ndarray` method `argmin`.

Parameters

axis [{index (0)}] Axis for the function to be applied on.

- skipna** [bool, default True] Exclude NA/null values when computing the result.
- level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.
- numeric_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.
- **kwargs** Additional keyword arguments to be passed to the function.

Returns

scalar or Series (if level specified)

See also:

- Series.sum** Return the sum.
- Series.min** Return the minimum.
- Series.max** Return the maximum.
- Series.idxmin** Return the index of the minimum.
- Series.idxmax** Return the index of the maximum.
- DataFrame.sum** Return the sum over the requested axis.
- DataFrame.min** Return the minimum over the requested axis.
- DataFrame.max** Return the maximum over the requested axis.
- DataFrame.idxmin** Return the index of the minimum over the requested axis.
- DataFrame.idxmax** Return the index of the maximum over the requested axis.

Examples

```
>>> idx = pd.MultiIndex.from_arrays([\n...     ['warm', 'warm', 'cold', 'cold'],\n...     ['dog', 'falcon', 'fish', 'spider']],\n...     names=['blooded', 'animal'])\n>>> s = pd.Series([4, 2, 0, 8], name='legs', index=idx)\n>>> s\nblooded  animal\nwarm     dog      4\n         falcon   2\ncold     fish     0\n         spider   8\nName: legs, dtype: int64
```

```
>>> s.min()\n0
```

pandas.Series.mod

`Series.mod`(*other*, *level=None*, *fill_value=None*, *axis=0*)

Return Modulo of series and other, element-wise (binary operator *mod*).

Equivalent to `series % other`, but with support to substitute a *fill_value* for missing data in either one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level.

Returns

Series The result of the operation.

See also:

[*Series.rmod*](#) Reverse of the Modulo operator, see [Python documentation](#) for more details.

Examples

```
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.mod(b, fill_value=0)
a    0.0
b    NaN
c    NaN
d    0.0
e    NaN
dtype: float64
```

pandas.Series.mode

`Series.mode(dropna=True)`

Return the mode(s) of the Series.

The mode is the value that appears most often. There can be multiple modes.

Always returns Series even if only one value is returned.

Parameters

dropna [bool, default True] Don't consider counts of NaN/NaT.

Returns

Series Modes of the Series in sorted order.

pandas.Series.mul

`Series.mul(other, level=None, fill_value=None, axis=0)`

Return Multiplication of series and other, element-wise (binary operator *mul*).

Equivalent to `series * other`, but with support to substitute a `fill_value` for missing data in either one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level.

Returns

Series The result of the operation.

See also:

[*Series.rmul*](#) Reverse of the Multiplication operator, see [Python documentation](#) for more details.

Examples

```
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
```

(continues on next page)

(continued from previous page)

```

d    1.0
e    NaN
dtype: float64
>>> a.multiply(b, fill_value=0)
a    1.0
b    0.0
c    0.0
d    0.0
e    NaN
dtype: float64

```

pandas.Series.multiply

Series.multiply(*other, level=None, fill_value=None, axis=0*)

Return Multiplication of series and other, element-wise (binary operator *mul*).

Equivalent to `series * other`, but with support to substitute a `fill_value` for missing data in either one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level.

Returns

Series The result of the operation.

See also:

[*Series.rmul*](#) Reverse of the Multiplication operator, see [Python documentation](#) for more details.

Examples

```

>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0

```

(continues on next page)

(continued from previous page)

```

e    NaN
dtype: float64
>>> a.multiply(b, fill_value=0)
a    1.0
b    0.0
c    0.0
d    0.0
e    NaN
dtype: float64

```

pandas.Series.ne

Series.ne(*other*, *level=None*, *fill_value=None*, *axis=0*)

Return Not equal to of series and other, element-wise (binary operator *ne*).

Equivalent to `series != other`, but with support to substitute a `fill_value` for missing data in either one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level.

Returns

Series The result of the operation.

Examples

```

>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.ne(b, fill_value=0)
a    False
b     True

```

(continues on next page)

(continued from previous page)

```
c    True
d    True
e    True
dtype: bool
```

pandas.Series.nlargest

`Series.nlargest(n=5, keep='first')`

Return the largest n elements.

Parameters

n [int, default 5] Return this many descending sorted values.

keep [{ 'first', 'last', 'all' }, default 'first'] When there are duplicate values that cannot all fit in a Series of n elements:

- **first** [return the first n occurrences in order] of appearance.
- **last** [return the last n occurrences in reverse] order of appearance.
- **all** [keep all occurrences. This can result in a Series of] size larger than n .

Returns

Series The n largest values in the Series, sorted in decreasing order.

See also:

[`Series.nsmallest`](#) Get the n smallest elements.

[`Series.sort_values`](#) Sort Series by values.

[`Series.head`](#) Return the first n rows.

Notes

Faster than `.sort_values(ascending=False).head(n)` for small n relative to the size of the Series object.

Examples

```
>>> countries_population = {"Italy": 59000000, "France": 65000000,
...                          "Malta": 434000, "Maldives": 434000,
...                          "Brunei": 434000, "Iceland": 337000,
...                          "Nauru": 11300, "Tuvalu": 11300,
...                          "Anguilla": 11300, "Montserrat": 5200}
>>> s = pd.Series(countries_population)
>>> s
Italy          59000000
France         65000000
Malta           434000
Maldives       434000
Brunei          434000
```

(continues on next page)

(continued from previous page)

```
Iceland      337000
Nauru        11300
Tuvalu       11300
Anguilla     11300
Montserrat   5200
dtype: int64
```

The n largest elements where $n=5$ by default.

```
>>> s.nlargest()
France      65000000
Italy       59000000
Malta       434000
Maldives    434000
Brunei      434000
dtype: int64
```

The n largest elements where $n=3$. Default *keep* value is 'first' so Malta will be kept.

```
>>> s.nlargest(3)
France      65000000
Italy       59000000
Malta       434000
dtype: int64
```

The n largest elements where $n=3$ and keeping the last duplicates. Brunei will be kept since it is the last with value 434000 based on the index order.

```
>>> s.nlargest(3, keep='last')
France      65000000
Italy       59000000
Brunei      434000
dtype: int64
```

The n largest elements where $n=3$ with all duplicates kept. Note that the returned Series has five elements due to the three duplicates.

```
>>> s.nlargest(3, keep='all')
France      65000000
Italy       59000000
Malta       434000
Maldives    434000
Brunei      434000
dtype: int64
```

pandas.Series.notna**Series.notna()**

Detect existing (non-missing) values.

Return a boolean same-sized object indicating if the values are not NA. Non-missing values get mapped to True. Characters such as empty strings '' or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`). NA values, such as `None` or `numpy.NaN`, get mapped to False values.

Returns

Series Mask of bool values for each element in Series that indicates whether an element is not an NA value.

See also:

Series.notnull Alias of `notna`.

Series.isna Boolean inverse of `notna`.

Series.dropna Omit axes labels with missing values.

notna Top-level `notna`.

Examples

Show which entries in a DataFrame are not NA.

```
>>> df = pd.DataFrame(dict(age=[5, 6, np.NaN],
...                          born=[pd.NaT, pd.Timestamp('1939-05-27'),
...                                pd.Timestamp('1940-04-25')],
...                          name=['Alfred', 'Batman', ''],
...                          toy=[None, 'Batmobile', 'Joker']))
>>> df
   age      born  name      toy
0  5.0      NaT  Alfred    None
1  6.0  1939-05-27  Batman  Batmobile
2  NaN  1940-04-25          Joker
```

```
>>> df.notna()
   age  born  name  toy
0  True  False  True  False
1  True   True  True   True
2  False   True  True   True
```

Show which entries in a Series are not NA.

```
>>> ser = pd.Series([5, 6, np.NaN])
>>> ser
0    5.0
1    6.0
2    NaN
dtype: float64
```

```
>>> ser.notna()
0     True
1     True
2    False
dtype: bool
```

pandas.Series.notnull

Series.notnull()

Detect existing (non-missing) values.

Return a boolean same-sized object indicating if the values are not NA. Non-missing values get mapped to True. Characters such as empty strings '' or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`). NA values, such as `None` or `numpy.NaN`, get mapped to False values.

Returns

Series Mask of bool values for each element in Series that indicates whether an element is not an NA value.

See also:

Series.notnull Alias of `notna`.

Series.isna Boolean inverse of `notna`.

Series.dropna Omit axes labels with missing values.

notna Top-level `notna`.

Examples

Show which entries in a DataFrame are not NA.

```
>>> df = pd.DataFrame(dict(age=[5, 6, np.NaN],
...                        born=[pd.NaT, pd.Timestamp('1939-05-27'),
...                              pd.Timestamp('1940-04-25')],
...                        name=['Alfred', 'Batman', ''],
...                        toy=[None, 'Batmobile', 'Joker']))
>>> df
   age      born  name      toy
0  5.0      NaT  Alfred  None
1  6.0  1939-05-27  Batman  Batmobile
2  NaN  1940-04-25      Joker
```

```
>>> df.notna()
   age  born  name  toy
0  True  False  True  False
1  True   True  True   True
2  False   True  True   True
```

Show which entries in a Series are not NA.

```
>>> ser = pd.Series([5, 6, np.NaN])
>>> ser
0    5.0
1    6.0
2    NaN
dtype: float64
```

```
>>> ser.notna()
0    True
1    True
2    False
dtype: bool
```

pandas.Series.nsmallest

`Series.nsmallest` ($n=5$, $keep='first'$)

Return the smallest n elements.

Parameters

n [int, default 5] Return this many ascending sorted values.

keep [{‘first’, ‘last’, ‘all’}, default ‘first’] When there are duplicate values that cannot all fit in a Series of n elements:

- **first** [return the first n occurrences in order] of appearance.
- **last** [return the last n occurrences in reverse] order of appearance.
- **all** [keep all occurrences. This can result in a Series of] size larger than n .

Returns

Series The n smallest values in the Series, sorted in increasing order.

See also:

[`Series.nlargest`](#) Get the n largest elements.

[`Series.sort_values`](#) Sort Series by values.

[`Series.head`](#) Return the first n rows.

Notes

Faster than `.sort_values().head(n)` for small n relative to the size of the Series object.

Examples

```
>>> countries_population = {"Italy": 590000000, "France": 650000000,
...                          "Brunei": 434000, "Malta": 434000,
...                          "Maldives": 434000, "Iceland": 337000,
...                          "Nauru": 11300, "Tuvalu": 11300,
...                          "Anguilla": 11300, "Montserrat": 5200}
>>> s = pd.Series(countries_population)
>>> s
Italy          590000000
France         650000000
Brunei          434000
Malta           434000
Maldives        434000
Iceland         337000
Nauru            11300
Tuvalu          11300
Anguilla        11300
Montserrat       5200
dtype: int64
```

The n smallest elements where $n=5$ by default.

```
>>> s.nsmallest()
Montserrat     5200
Nauru          11300
Tuvalu         11300
Anguilla       11300
Iceland        337000
dtype: int64
```

The n smallest elements where $n=3$. Default *keep* value is 'first' so Nauru and Tuvalu will be kept.

```
>>> s.nsmallest(3)
Montserrat     5200
Nauru          11300
Tuvalu         11300
dtype: int64
```

The n smallest elements where $n=3$ and keeping the last duplicates. Anguilla and Tuvalu will be kept since they are the last with value 11300 based on the index order.

```
>>> s.nsmallest(3, keep='last')
Montserrat     5200
Anguilla       11300
Tuvalu         11300
dtype: int64
```

The n smallest elements where $n=3$ with all duplicates kept. Note that the returned Series has four elements due to the three duplicates.

```
>>> s.nsmallest(3, keep='all')
Montserrat     5200
Nauru          11300
```

(continues on next page)

(continued from previous page)

```
Tuvalu      11300
Anguilla    11300
dtype: int64
```

pandas.Series.nunique

`Series.nunique(dropna=True)`

Return number of unique elements in the object.

Excludes NA values by default.

Parameters

dropna [bool, default True] Don't include NaN in the count.

Returns

int

See also:

[`DataFrame.nunique`](#) Method `nunique` for `DataFrame`.

[`Series.count`](#) Count non-NA/null observations in the `Series`.

Examples

```
>>> s = pd.Series([1, 3, 5, 7, 7])
>>> s
0    1
1    3
2    5
3    7
4    7
dtype: int64
```

```
>>> s.nunique()
4
```

pandas.Series.pad

`Series.pad(axis=None, inplace=False, limit=None, downcast=None)`

Synonym for [`DataFrame.fillna\(\)`](#) with `method='ffill'`.

Returns

Series/DataFrame or None Object with missing values filled or None if `inplace=True`.

pandas.Series.pct_change

`Series.pct_change(periods=1, fill_method='pad', limit=None, freq=None, **kwargs)`

Percentage change between the current and a prior element.

Computes the percentage change from the immediately previous row by default. This is useful in comparing the percentage of change in a time series of elements.

Parameters

periods [int, default 1] Periods to shift for forming percent change.

fill_method [str, default 'pad'] How to handle NAs before computing percent changes.

limit [int, default None] The number of consecutive NAs to fill before stopping.

freq [DateOffset, timedelta, or str, optional] Increment to use from time series API (e.g. 'M' or BDay()).

****kwargs** Additional keyword arguments are passed into *DataFrame.shift* or *Series.shift*.

Returns

chg [Series or DataFrame] The same type as the calling object.

See also:

[*Series.diff*](#) Compute the difference of two elements in a Series.

[*DataFrame.diff*](#) Compute the difference of two elements in a DataFrame.

[*Series.shift*](#) Shift the index by some number of periods.

[*DataFrame.shift*](#) Shift the index by some number of periods.

Examples

Series

```
>>> s = pd.Series([90, 91, 85])
>>> s
0    90
1    91
2    85
dtype: int64
```

```
>>> s.pct_change()
0         NaN
1    0.011111
2   -0.065934
dtype: float64
```

```
>>> s.pct_change(periods=2)
0         NaN
1         NaN
2   -0.055556
dtype: float64
```

See the percentage change in a Series where filling NAs with last valid observation forward to next valid.

```
>>> s = pd.Series([90, 91, None, 85])
>>> s
0    90.0
1    91.0
2     NaN
3    85.0
dtype: float64
```

```
>>> s.pct_change(fill_method='ffill')
0         NaN
1    0.011111
2    0.000000
3   -0.065934
dtype: float64
```

DataFrame

Percentage change in French franc, Deutsche Mark, and Italian lira from 1980-01-01 to 1980-03-01.

```
>>> df = pd.DataFrame({
...     'FR': [4.0405, 4.0963, 4.3149],
...     'GR': [1.7246, 1.7482, 1.8519],
...     'IT': [804.74, 810.01, 860.13]},
...     index=['1980-01-01', '1980-02-01', '1980-03-01'])
>>> df
```

| | FR | GR | IT |
|------------|--------|--------|--------|
| 1980-01-01 | 4.0405 | 1.7246 | 804.74 |
| 1980-02-01 | 4.0963 | 1.7482 | 810.01 |
| 1980-03-01 | 4.3149 | 1.8519 | 860.13 |

```
>>> df.pct_change()
```

| | FR | GR | IT |
|------------|----------|----------|----------|
| 1980-01-01 | NaN | NaN | NaN |
| 1980-02-01 | 0.013810 | 0.013684 | 0.006549 |
| 1980-03-01 | 0.053365 | 0.059318 | 0.061876 |

Percentage of change in GOOG and APPL stock volume. Shows computing the percentage change between columns.

```
>>> df = pd.DataFrame({
...     '2016': [1769950, 30586265],
...     '2015': [1500923, 40912316],
...     '2014': [1371819, 41403351]},
...     index=['GOOG', 'APPL'])
>>> df
```

| | 2016 | 2015 | 2014 |
|------|----------|----------|----------|
| GOOG | 1769950 | 1500923 | 1371819 |
| APPL | 30586265 | 40912316 | 41403351 |

```
>>> df.pct_change(axis='columns', periods=-1)
```

| | 2016 | 2015 | 2014 |
|------|-----------|-----------|------|
| GOOG | 0.179241 | 0.094112 | NaN |
| APPL | -0.252395 | -0.011860 | NaN |

pandas.Series.pipe

`Series.pipe(func, *args, **kwargs)`
Apply `func(self, *args, **kwargs)`.

Parameters

func [function] Function to apply to the Series/DataFrame. `args`, and `kwargs` are passed into `func`. Alternatively a (callable, data_keyword) tuple where `data_keyword` is a string indicating the keyword of callable that expects the Series/DataFrame.

args [iterable, optional] Positional arguments passed into `func`.

kwargs [mapping, optional] A dictionary of keyword arguments passed into `func`.

Returns

object [the return type of `func`.]

See also:

[`DataFrame.apply`](#) Apply a function along input axis of DataFrame.

[`DataFrame.applymap`](#) Apply a function elementwise on a whole DataFrame.

[`Series.map`](#) Apply a mapping correspondence on a [`Series`](#).

Notes

Use `.pipe` when chaining together functions that expect Series, DataFrames or GroupBy objects. Instead of writing

```
>>> func(g(h(df), arg1=a), arg2=b, arg3=c)
```

You can write

```
>>> (df.pipe(h)
...   .pipe(g, arg1=a)
...   .pipe(func, arg2=b, arg3=c)
... )
```

If you have a function that takes the data as (say) the second argument, pass a tuple indicating which keyword expects the data. For example, suppose `f` takes its data as `arg2`:

```
>>> (df.pipe(h)
...   .pipe(g, arg1=a)
...   .pipe((func, 'arg2'), arg1=a, arg3=c)
... )
```

pandas.Series.plot**Series.plot**(*args, **kwargs)

Make plots of Series or DataFrame.

Uses the backend specified by the option `plotting.backend`. By default, matplotlib is used.**Parameters****data** [Series or DataFrame] The object for which the method is called.**x** [label or position, default None] Only used if data is a DataFrame.**y** [label, position or list of label, positions, default None] Allows plotting of one column versus another. Only used if data is a DataFrame.**kind** [str] The kind of plot to produce:

- 'line' : line plot (default)
- 'bar' : vertical bar plot
- 'barh' : horizontal bar plot
- 'hist' : histogram
- 'box' : boxplot
- 'kde' : Kernel Density Estimation plot
- 'density' : same as 'kde'
- 'area' : area plot
- 'pie' : pie plot
- 'scatter' : scatter plot (DataFrame only)
- 'hexbin' : hexbin plot (DataFrame only)

ax [matplotlib axes object, default None] An axes of the current figure.**subplots** [bool, default False] Make separate subplots for each column.**sharex** [bool, default True if ax is None else False] In case `subplots=True`, share x axis and set some x axis labels to invisible; defaults to True if ax is None otherwise False if an ax is passed in; Be aware, that passing in both an ax and `sharex=True` will alter all x axis labels for all axis in a figure.**sharey** [bool, default False] In case `subplots=True`, share y axis and set some y axis labels to invisible.**layout** [tuple, optional] (rows, columns) for the layout of subplots.**figsize** [a tuple (width, height) in inches] Size of a figure object.**use_index** [bool, default True] Use index as ticks for x axis.**title** [str or list] Title to use for the plot. If a string is passed, print the string at the top of the figure. If a list is passed and `subplots` is True, print each item in the list above the corresponding subplot.**grid** [bool, default None (matlab style default)] Axis grid lines.**legend** [bool or {'reverse'}] Place legend on axis subplots.**style** [list or dict] The matplotlib line style per column.

- logx** [bool or 'sym', default False] Use log scaling or symlog scaling on x axis. .. version-changed:: 0.25.0
- logy** [bool or 'sym' default False] Use log scaling or symlog scaling on y axis. .. version-changed:: 0.25.0
- loglog** [bool or 'sym', default False] Use log scaling or symlog scaling on both x and y axes. .. versionchanged:: 0.25.0
- xticks** [sequence] Values to use for the xticks.
- yticks** [sequence] Values to use for the yticks.
- xlim** [2-tuple/list] Set the x limits of the current axes.
- ylim** [2-tuple/list] Set the y limits of the current axes.
- xlabel** [label, optional] Name to use for the xlabel on x-axis. Default uses index name as xlabel, or the x-column name for planar plots.
New in version 1.1.0.
Changed in version 1.2.0: Now applicable to planar plots (*scatter*, *hexbin*).
- ylabel** [label, optional] Name to use for the ylabel on y-axis. Default will show no ylabel, or the y-column name for planar plots.
New in version 1.1.0.
Changed in version 1.2.0: Now applicable to planar plots (*scatter*, *hexbin*).
- rot** [int, default None] Rotation for ticks (xticks for vertical, yticks for horizontal plots).
- fontsize** [int, default None] Font size for xticks and yticks.
- colormap** [str or matplotlib colormap object, default None] Colormap to select colors from. If string, load colormap with that name from matplotlib.
- colorbar** [bool, optional] If True, plot colorbar (only relevant for 'scatter' and 'hexbin' plots).
- position** [float] Specify relative alignments for bar plot layout. From 0 (left/bottom-end) to 1 (right/top-end). Default is 0.5 (center).
- table** [bool, Series or DataFrame, default False] If True, draw a table using the data in the DataFrame and the data will be transposed to meet matplotlib's default layout. If a Series or DataFrame is passed, use passed data to draw a table.
- yerr** [DataFrame, Series, array-like, dict and str] See *Plotting with Error Bars* for detail.
- xerr** [DataFrame, Series, array-like, dict and str] Equivalent to yerr.
- stacked** [bool, default False in line and bar plots, and True in area plot] If True, create stacked plot.
- sort_columns** [bool, default False] Sort column names to determine plot ordering.
- secondary_y** [bool or sequence, default False] Whether to plot on the secondary y-axis if a list/tuple, which columns to plot on secondary y-axis.
- mark_right** [bool, default True] When using a secondary_y axis, automatically mark the column labels with "(right)" in the legend.
- include_bool** [bool, default is False] If True, boolean values can be plotted.

backend [str, default None] Backend to use instead of the backend specified in the option `plotting.backend`. For instance, 'matplotlib'. Alternatively, to specify the `plotting.backend` for the whole session, set `pd.options.plotting.backend`.

New in version 1.0.0.

****kwargs** Options to pass to matplotlib plotting method.

Returns

matplotlib.axes.Axes or numpy.ndarray of them If the backend is not the default matplotlib one, the return value will be the object returned by the backend.

Notes

- See matplotlib documentation online for more on this subject
- If *kind* = 'bar' or 'barh', you can specify relative alignments for bar plot layout by *position* keyword. From 0 (left/bottom-end) to 1 (right/top-end). Default is 0.5 (center)

pandas.Series.pop

`Series.pop(item)`

Return item and drops from series. Raise `KeyError` if not found.

Parameters

item [label] Index of the element that needs to be removed.

Returns

Value that is popped from series.

Examples

```
>>> ser = pd.Series([1,2,3])
```

```
>>> ser.pop(0)
1
```

```
>>> ser
1    2
2    3
dtype: int64
```

pandas.Series.pow

`Series.pow`(*other*, *level=None*, *fill_value=None*, *axis=0*)

Return Exponential power of series and other, element-wise (binary operator *pow*).

Equivalent to `series ** other`, but with support to substitute a *fill_value* for missing data in either one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level.

Returns

Series The result of the operation.

See also:

[*Series.rpow*](#) Reverse of the Exponential power operator, see [Python documentation](#) for more details.

Examples

```
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.pow(b, fill_value=0)
a    1.0
b    1.0
c    1.0
d    0.0
e    NaN
dtype: float64
```

pandas.Series.prod

`Series.prod(axis=None, skipna=None, level=None, numeric_only=None, min_count=0, **kwargs)`
 Return the product of the values over the requested axis.

Parameters

- axis** [{index (0)}] Axis for the function to be applied on.
- skipna** [bool, default True] Exclude NA/null values when computing the result.
- level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.
- numeric_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.
- min_count** [int, default 0] The required number of valid values to perform the operation. If fewer than `min_count` non-NA values are present the result will be NA.
- **kwargs** Additional keyword arguments to be passed to the function.

Returns

scalar or Series (if level specified)

See also:

- [`Series.sum`](#) Return the sum.
- [`Series.min`](#) Return the minimum.
- [`Series.max`](#) Return the maximum.
- [`Series.idxmin`](#) Return the index of the minimum.
- [`Series.idxmax`](#) Return the index of the maximum.
- [`DataFrame.sum`](#) Return the sum over the requested axis.
- [`DataFrame.min`](#) Return the minimum over the requested axis.
- [`DataFrame.max`](#) Return the maximum over the requested axis.
- [`DataFrame.idxmin`](#) Return the index of the minimum over the requested axis.
- [`DataFrame.idxmax`](#) Return the index of the maximum over the requested axis.

Examples

By default, the product of an empty or all-NA Series is 1

```
>>> pd.Series([], dtype="float64").prod()
1.0
```

This can be controlled with the `min_count` parameter

```
>>> pd.Series([], dtype="float64").prod(min_count=1)
nan
```

Thanks to the `skipna` parameter, `min_count` handles all-NA and empty series identically.

```
>>> pd.Series([np.nan]).prod()
1.0
```

```
>>> pd.Series([np.nan]).prod(min_count=1)
nan
```

pandas.Series.product

Series.product(*axis=None, skipna=None, level=None, numeric_only=None, min_count=0, **kwargs*)
Return the product of the values over the requested axis.

Parameters

axis [{index (0)}] Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

min_count [int, default 0] The required number of valid values to perform the operation. If fewer than `min_count` non-NA values are present the result will be NA.

****kwargs** Additional keyword arguments to be passed to the function.

Returns

scalar or Series (if level specified)

See also:

[*Series.sum*](#) Return the sum.

[*Series.min*](#) Return the minimum.

[*Series.max*](#) Return the maximum.

[*Series.idxmin*](#) Return the index of the minimum.

[*Series.idxmax*](#) Return the index of the maximum.

[*DataFrame.sum*](#) Return the sum over the requested axis.

[*DataFrame.min*](#) Return the minimum over the requested axis.

[*DataFrame.max*](#) Return the maximum over the requested axis.

[*DataFrame.idxmin*](#) Return the index of the minimum over the requested axis.

[*DataFrame.idxmax*](#) Return the index of the maximum over the requested axis.

Examples

By default, the product of an empty or all-NA Series is 1

```
>>> pd.Series([], dtype="float64").prod()
1.0
```

This can be controlled with the `min_count` parameter

```
>>> pd.Series([], dtype="float64").prod(min_count=1)
nan
```

Thanks to the `skipna` parameter, `min_count` handles all-NA and empty series identically.

```
>>> pd.Series([np.nan]).prod()
1.0
```

```
>>> pd.Series([np.nan]).prod(min_count=1)
nan
```

pandas.Series.quantile

`Series.quantile(q=0.5, interpolation='linear')`

Return value at the given quantile.

Parameters

q [float or array-like, default 0.5 (50% quantile)] The quantile(s) to compute, which can lie in range: $0 \leq q \leq 1$.

interpolation [{ 'linear', 'lower', 'higher', 'midpoint', 'nearest' }] This optional parameter specifies the interpolation method to use, when the desired quantile lies between two data points i and j :

- linear: $i + (j - i) * \text{fraction}$, where *fraction* is the fractional part of the index surrounded by i and j .
- lower: i .
- higher: j .
- nearest: i or j whichever is nearest.
- midpoint: $(i + j) / 2$.

Returns

float or Series If `q` is an array, a Series will be returned where the index is `q` and the values are the quantiles, otherwise a float will be returned.

See also:

core.window.Rolling.quantile Calculate the rolling quantile.

numpy.percentile Returns the q -th percentile(s) of the array elements.

Examples

```

>>> s = pd.Series([1, 2, 3, 4])
>>> s.quantile(.5)
2.5
>>> s.quantile([.25, .5, .75])
0.25    1.75
0.50    2.50
0.75    3.25
dtype: float64

```

pandas.Series.radd

`Series.radd(other, level=None, fill_value=None, axis=0)`

Return Addition of series and other, element-wise (binary operator *radd*).

Equivalent to `other + series`, but with support to substitute a `fill_value` for missing data in either one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level.

Returns

Series The result of the operation.

See also:

[*Series.add*](#) Element-wise Addition, see [Python documentation](#) for more details.

Examples

```

>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN

```

(continues on next page)

(continued from previous page)

```

dtype: float64
>>> a.add(b, fill_value=0)
a    2.0
b    1.0
c    1.0
d    1.0
e    NaN
dtype: float64

```

pandas.Series.rank

`Series.rank`(*axis=0, method='average', numeric_only=None, na_option='keep', ascending=True, pct=False*)

Compute numerical data ranks (1 through n) along axis.

By default, equal values are assigned a rank that is the average of the ranks of those values.

Parameters

axis [{0 or 'index', 1 or 'columns'}], default 0] Index to direct ranking.

method [{'average', 'min', 'max', 'first', 'dense'}], default 'average'] How to rank the group of records that have the same value (i.e. ties):

- average: average rank of the group
- min: lowest rank in the group
- max: highest rank in the group
- first: ranks assigned in order they appear in the array
- dense: like 'min', but rank always increases by 1 between groups.

numeric_only [bool, optional] For DataFrame objects, rank only numeric columns if set to True.

na_option [{'keep', 'top', 'bottom'}], default 'keep'] How to rank NaN values:

- keep: assign NaN rank to NaN values
- top: assign lowest rank to NaN values
- bottom: assign highest rank to NaN values

ascending [bool, default True] Whether or not the elements should be ranked in ascending order.

pct [bool, default False] Whether or not to display the returned rankings in percentile form.

Returns

same type as caller Return a Series or DataFrame with data ranks as values.

See also:

[*core.groupby.GroupBy.rank*](#) Rank of values within each group.

Examples

```
>>> df = pd.DataFrame(data={'Animal': ['cat', 'penguin', 'dog',
...                                  'spider', 'snake'],
...                        'Number_legs': [4, 2, 4, 8, np.nan]})
>>> df
   Animal  Number_legs
0     cat           4.0
1  penguin           2.0
2     dog           4.0
3  spider           8.0
4  snake           NaN
```

The following example shows how the method behaves with the above parameters:

- `default_rank`: this is the default behaviour obtained without using any parameter.
- `max_rank`: setting `method = 'max'` the records that have the same values are ranked using the highest rank (e.g.: since 'cat' and 'dog' are both in the 2nd and 3rd position, rank 3 is assigned.)
- `NA_bottom`: choosing `na_option = 'bottom'`, if there are records with NaN values they are placed at the bottom of the ranking.
- `pct_rank`: when setting `pct = True`, the ranking is expressed as percentile rank.

```
>>> df['default_rank'] = df['Number_legs'].rank()
>>> df['max_rank'] = df['Number_legs'].rank(method='max')
>>> df['NA_bottom'] = df['Number_legs'].rank(na_option='bottom')
>>> df['pct_rank'] = df['Number_legs'].rank(pct=True)
>>> df
   Animal  Number_legs  default_rank  max_rank  NA_bottom  pct_rank
0     cat           4.0           2.5         3.0         2.5      0.625
1  penguin           2.0           1.0         1.0         1.0      0.250
2     dog           4.0           2.5         3.0         2.5      0.625
3  spider           8.0           4.0         4.0         4.0      1.000
4  snake           NaN           NaN         NaN         5.0       NaN
```

pandas.Series.ravel

`Series.ravel` (*order='C'*)

Return the flattened underlying data as an ndarray.

Returns

numpy.ndarray or ndarray-like Flattened data of the Series.

See also:

[numpy.ndarray.ravel](#) Return a flattened array.

pandas.Series.rdiv

`Series.rdiv`(*other*, *level=None*, *fill_value=None*, *axis=0*)

Return Floating division of series and other, element-wise (binary operator *rtruediv*).

Equivalent to `other / series`, but with support to substitute a `fill_value` for missing data in either one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level.

Returns

Series The result of the operation.

See also:

[`Series.truediv`](#) Element-wise Floating division, see [Python documentation](#) for more details.

Examples

```
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.divide(b, fill_value=0)
a    1.0
b    inf
c    inf
d    0.0
e    NaN
dtype: float64
```

pandas.Series.rdivmod

`Series.rdivmod(other, level=None, fill_value=None, axis=0)`

Return Integer division and modulo of series and other, element-wise (binary operator *rdivmod*).

Equivalent to `other divmod series`, but with support to substitute a `fill_value` for missing data in either one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level.

Returns

2-Tuple of Series The result of the operation.

See also:

[*Series.divmod*](#) Element-wise Integer division and modulo, see [Python documentation](#) for more details.

Examples

```
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.divmod(b, fill_value=0)
(a    1.0
 b    NaN
 c    NaN
 d    0.0
 e    NaN
 dtype: float64,
 a    0.0
 b    NaN
 c    NaN
 d    0.0
```

(continues on next page)

(continued from previous page)

```
e    NaN
dtype: float64)
```

pandas.Series.reindex

Series.reindex(*index=None, **kwargs*)

Conform Series to new index with optional filling logic.

Places NA/NaN in locations having no value in the previous index. A new object is produced unless the new index is equivalent to the current one and `copy=False`.

Parameters

index [array-like, optional] New labels / index to conform to, should be specified using keywords. Preferably an Index object to avoid duplicating data.

method [{None, 'backfill'/'bfill', 'pad'/'ffill', 'nearest'}] Method to use for filling holes in reindexed DataFrame. Please note: this is only applicable to DataFrames/Series with a monotonically increasing/decreasing index.

- None (default): don't fill gaps
- pad / ffill: Propagate last valid observation forward to next valid.
- backfill / bfill: Use next valid observation to fill gap.
- nearest: Use nearest valid observations to fill gap.

copy [bool, default True] Return a new object, even if the passed indexes are the same.

level [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level.

fill_value [scalar, default np.NaN] Value to use for missing values. Defaults to NaN, but can be any "compatible" value.

limit [int, default None] Maximum number of consecutive elements to forward or backward fill.

tolerance [optional] Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations must satisfy the equation $\text{abs}(\text{index}[\text{indexer}] - \text{target}) \leq \text{tolerance}$.

Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple, array, Series, and must be the same size as the index and its dtype must exactly match the index's type.

Returns

Series with changed index.

See also:

[*DataFrame.set_index*](#) Set row labels.

[*DataFrame.reset_index*](#) Remove row labels or move them to new columns.

[*DataFrame.reindex_like*](#) Change to same indices as other DataFrame.

Examples

DataFrame.reindex supports two calling conventions

- (index=index_labels, columns=column_labels, ...)
- (labels, axis={'index', 'columns'}, ...)

We *highly* recommend using keyword arguments to clarify your intent.

Create a dataframe with some fictional data.

```
>>> index = ['Firefox', 'Chrome', 'Safari', 'IE10', 'Konqueror']
>>> df = pd.DataFrame({'http_status': [200, 200, 404, 404, 301],
...                    'response_time': [0.04, 0.02, 0.07, 0.08, 1.0]},
...                    index=index)
>>> df
```

| | http_status | response_time |
|-----------|-------------|---------------|
| Firefox | 200 | 0.04 |
| Chrome | 200 | 0.02 |
| Safari | 404 | 0.07 |
| IE10 | 404 | 0.08 |
| Konqueror | 301 | 1.00 |

Create a new index and reindex the dataframe. By default values in the new index that do not have corresponding records in the dataframe are assigned NaN.

```
>>> new_index = ['Safari', 'Iceweasel', 'Comodo Dragon', 'IE10',
...              'Chrome']
>>> df.reindex(new_index)
```

| | http_status | response_time |
|---------------|-------------|---------------|
| Safari | 404.0 | 0.07 |
| Iceweasel | NaN | NaN |
| Comodo Dragon | NaN | NaN |
| IE10 | 404.0 | 0.08 |
| Chrome | 200.0 | 0.02 |

We can fill in the missing values by passing a value to the keyword `fill_value`. Because the index is not monotonically increasing or decreasing, we cannot use arguments to the keyword method to fill the NaN values.

```
>>> df.reindex(new_index, fill_value=0)
```

| | http_status | response_time |
|---------------|-------------|---------------|
| Safari | 404 | 0.07 |
| Iceweasel | 0 | 0.00 |
| Comodo Dragon | 0 | 0.00 |
| IE10 | 404 | 0.08 |
| Chrome | 200 | 0.02 |

```
>>> df.reindex(new_index, fill_value='missing')
```

| | http_status | response_time |
|---------------|-------------|---------------|
| Safari | 404 | 0.07 |
| Iceweasel | missing | missing |
| Comodo Dragon | missing | missing |
| IE10 | 404 | 0.08 |
| Chrome | 200 | 0.02 |

We can also reindex the columns.

```
>>> df.reindex(columns=['http_status', 'user_agent'])
```

| | http_status | user_agent |
|-----------|-------------|------------|
| Firefox | 200 | NaN |
| Chrome | 200 | NaN |
| Safari | 404 | NaN |
| IE10 | 404 | NaN |
| Konqueror | 301 | NaN |

Or we can use “axis-style” keyword arguments

```
>>> df.reindex(['http_status', 'user_agent'], axis="columns")
```

| | http_status | user_agent |
|-----------|-------------|------------|
| Firefox | 200 | NaN |
| Chrome | 200 | NaN |
| Safari | 404 | NaN |
| IE10 | 404 | NaN |
| Konqueror | 301 | NaN |

To further illustrate the filling functionality in `reindex`, we will create a dataframe with a monotonically increasing index (for example, a sequence of dates).

```
>>> date_index = pd.date_range('1/1/2010', periods=6, freq='D')
>>> df2 = pd.DataFrame({"prices": [100, 101, np.nan, 100, 89, 88]},
...                    index=date_index)
>>> df2
```

| | prices |
|------------|--------|
| 2010-01-01 | 100.0 |
| 2010-01-02 | 101.0 |
| 2010-01-03 | NaN |
| 2010-01-04 | 100.0 |
| 2010-01-05 | 89.0 |
| 2010-01-06 | 88.0 |

Suppose we decide to expand the dataframe to cover a wider date range.

```
>>> date_index2 = pd.date_range('12/29/2009', periods=10, freq='D')
>>> df2.reindex(date_index2)
```

| | prices |
|------------|--------|
| 2009-12-29 | NaN |
| 2009-12-30 | NaN |
| 2009-12-31 | NaN |
| 2010-01-01 | 100.0 |
| 2010-01-02 | 101.0 |
| 2010-01-03 | NaN |
| 2010-01-04 | 100.0 |
| 2010-01-05 | 89.0 |
| 2010-01-06 | 88.0 |
| 2010-01-07 | NaN |

The index entries that did not have a value in the original data frame (for example, ‘2009-12-29’) are by default filled with NaN. If desired, we can fill in the missing values using one of several options.

For example, to back-propagate the last valid value to fill the NaN values, pass `bfill` as an argument to

the `method` keyword.

```
>>> df2.reindex(date_index2, method='bfill')
           prices
2009-12-29    100.0
2009-12-30    100.0
2009-12-31    100.0
2010-01-01    100.0
2010-01-02    101.0
2010-01-03     NaN
2010-01-04    100.0
2010-01-05     89.0
2010-01-06     88.0
2010-01-07     NaN
```

Please note that the NaN value present in the original dataframe (at index value 2010-01-03) will not be filled by any of the value propagation schemes. This is because filling while reindexing does not look at dataframe values, but only compares the original and desired indexes. If you do want to fill in the NaN values present in the original dataframe, use the `fillna()` method.

See the [user guide](#) for more.

pandas.Series.reindex_like

`Series.reindex_like`(*other*, *method=None*, *copy=True*, *limit=None*, *tolerance=None*)

Return an object with matching indices as other object.

Conform the object to the same index on all axes. Optional filling logic, placing NaN in locations having no value in the previous index. A new object is produced unless the new index is equivalent to the current one and `copy=False`.

Parameters

other [Object of the same data type] Its row and column indices are used to define the new indices of this object.

method [{None, 'backfill'/'bfill', 'pad'/'ffill', 'nearest'}] Method to use for filling holes in reindexed DataFrame. Please note: this is only applicable to DataFrames/Series with a monotonically increasing/decreasing index.

- None (default): don't fill gaps
- pad / ffill: propagate last valid observation forward to next valid
- backfill / bfill: use next valid observation to fill gap
- nearest: use nearest valid observations to fill gap.

copy [bool, default True] Return a new object, even if the passed indexes are the same.

limit [int, default None] Maximum number of consecutive labels to fill for inexact matches.

tolerance [optional] Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations must satisfy the equation `abs(index[indexer] - target) <= tolerance`.

Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple,

array, Series, and must be the same size as the index and its dtype must exactly match the index's type.

Returns

Series or DataFrame Same type as caller, but with changed indices on each axis.

See also:

[*DataFrame.set_index*](#) Set row labels.

[*DataFrame.reset_index*](#) Remove row labels or move them to new columns.

[*DataFrame.reindex*](#) Change to new indices or expand indices.

Notes

Same as calling `.reindex(index=other.index, columns=other.columns, ...)`.

Examples

```
>>> df1 = pd.DataFrame([[24.3, 75.7, 'high'],
...                     [31, 87.8, 'high'],
...                     [22, 71.6, 'medium'],
...                     [35, 95, 'medium']],
...                     columns=['temp_celsius', 'temp_fahrenheit',
...                               'windspeed'],
...                     index=pd.date_range(start='2014-02-12',
...                                         end='2014-02-15', freq='D'))
```

```
>>> df1
      temp_celsius  temp_fahrenheit  windspeed
2014-02-12         24.3             75.7      high
2014-02-13         31.0             87.8      high
2014-02-14         22.0             71.6    medium
2014-02-15         35.0             95.0    medium
```

```
>>> df2 = pd.DataFrame([[28, 'low'],
...                     [30, 'low'],
...                     [35.1, 'medium']],
...                     columns=['temp_celsius', 'windspeed'],
...                     index=pd.DatetimeIndex(['2014-02-12', '2014-02-13',
...                                             '2014-02-15']))
```

```
>>> df2
      temp_celsius  windspeed
2014-02-12         28.0      low
2014-02-13         30.0      low
2014-02-15         35.1    medium
```

```
>>> df2.reindex_like(df1)
      temp_celsius  temp_fahrenheit  windspeed
2014-02-12         28.0             NaN      low
```

(continues on next page)

(continued from previous page)

| | | | |
|------------|------|-----|--------|
| 2014-02-13 | 30.0 | NaN | low |
| 2014-02-14 | NaN | NaN | NaN |
| 2014-02-15 | 35.1 | NaN | medium |

pandas.Series.rename

`Series.rename(index=None, *, axis=None, copy=True, inplace=False, level=None, errors='ignore')`

Alter Series index labels or name.

Function / dict values must be unique (1-to-1). Labels not contained in a dict / Series will be left as-is. Extra labels listed don't throw an error.

Alternatively, change `Series.name` with a scalar value.

See the *user guide* for more.

Parameters

axis [{0 or "index"}] Unused. Accepted for compatibility with DataFrame method only.

index [scalar, hashable sequence, dict-like or function, optional] Functions or dict-like are transformations to apply to the index. Scalar or hashable sequence-like will alter the `Series.name` attribute.

****kwargs** Additional keyword arguments passed to the function. Only the "inplace" keyword is used.

Returns

Series or None Series with index labels or name altered or None if `inplace=True`.

See also:

[`DataFrame.rename`](#) Corresponding DataFrame method.

[`Series.rename_axis`](#) Set the name of the axis.

Examples

```
>>> s = pd.Series([1, 2, 3])
>>> s
0    1
1    2
2    3
dtype: int64
>>> s.rename("my_name") # scalar, changes Series.name
0    1
1    2
2    3
Name: my_name, dtype: int64
>>> s.rename(lambda x: x ** 2) # function, changes labels
0    1
1    2
4    3
dtype: int64
```

(continues on next page)

(continued from previous page)

```
>>> s.rename({1: 3, 2: 5}) # mapping, changes labels
0    1
3    2
5    3
dtype: int64
```

pandas.Series.rename_axis

`Series.rename_axis`(*mapper=None, index=None, columns=None, axis=None, copy=True, inplace=False*)
Set the name of the axis for the index or columns.

Parameters

mapper [scalar, list-like, optional] Value to set the axis name attribute.

index, columns [scalar, list-like, dict-like or function, optional] A scalar, list-like, dict-like or functions transformations to apply to that axis' values. Note that the `columns` parameter is not allowed if the object is a Series. This parameter only apply for DataFrame type objects.

Use either `mapper` and `axis` to specify the axis to target with `mapper`, or `index` and/or `columns`.

axis [{0 or 'index', 1 or 'columns'}, default 0] The axis to rename.

copy [bool, default True] Also copy underlying data.

inplace [bool, default False] Modifies the object directly, instead of creating a new Series or DataFrame.

Returns

Series, DataFrame, or None The same type as the caller or None if `inplace=True`.

See also:

[`Series.rename`](#) Alter Series index labels or name.

[`DataFrame.rename`](#) Alter DataFrame index labels or name.

[`Index.rename`](#) Set new names on index.

Notes

`DataFrame.rename_axis` supports two calling conventions

- (`index=index_mapper, columns=columns_mapper, ...`)
- (`mapper, axis={'index', 'columns'}, ...`)

The first calling convention will only modify the names of the index and/or the names of the Index object that is the columns. In this case, the parameter `copy` is ignored.

The second calling convention will modify the names of the corresponding index if `mapper` is a list or a scalar. However, if `mapper` is dict-like or a function, it will use the deprecated behavior of modifying the axis *labels*.

We *highly* recommend using keyword arguments to clarify your intent.

Examples

Series

```
>>> s = pd.Series(["dog", "cat", "monkey"])
>>> s
0      dog
1      cat
2  monkey
dtype: object
>>> s.rename_axis("animal")
animal
0      dog
1      cat
2  monkey
dtype: object
```

DataFrame

```
>>> df = pd.DataFrame({"num_legs": [4, 4, 2],
...                    "num_arms": [0, 0, 2]},
...                   ["dog", "cat", "monkey"])
>>> df
   num_legs  num_arms
dog         4         0
cat         4         0
monkey      2         2
>>> df = df.rename_axis("animal")
>>> df
   num_legs  num_arms
animal
dog         4         0
cat         4         0
monkey      2         2
>>> df = df.rename_axis("limbs", axis="columns")
>>> df
limbs  num_legs  num_arms
animal
dog         4         0
cat         4         0
monkey      2         2
```

MultiIndex

```
>>> df.index = pd.MultiIndex.from_product(['mammal'],
...                                       ['dog', 'cat', 'monkey']),
...                                       names=['type', 'name'])
>>> df
limbs      num_legs  num_arms
type name
mammal dog         4         0
       cat         4         0
       monkey      2         2
```

```
>>> df.rename_axis(index={'type': 'class'})
limbs      num_legs  num_arms
class name
mammal dog          4         0
        cat          4         0
        monkey       2         2
```

```
>>> df.rename_axis(columns=str.upper)
LIMBS      num_legs  num_arms
type name
mammal dog          4         0
        cat          4         0
        monkey       2         2
```

pandas.Series.reorder_levels

`Series.reorder_levels(order)`

Rearrange index levels using input order.

May not drop or duplicate levels.

Parameters

order [list of int representing new level order] Reference level by number or key.

Returns

type of caller (new object)

pandas.Series.repeat

`Series.repeat(repeats, axis=None)`

Repeat elements of a Series.

Returns a new Series where each element of the current Series is repeated consecutively a given number of times.

Parameters

repeats [int or array of ints] The number of repetitions for each element. This should be a non-negative integer. Repeating 0 times will return an empty Series.

axis [None] Must be None. Has no effect but is accepted for compatibility with numpy.

Returns

Series Newly created Series with repeated elements.

See also:

[`Index.repeat`](#) Equivalent function for Index.

[`numpy.repeat`](#) Similar method for `numpy.ndarray`.

Examples

```

>>> s = pd.Series(['a', 'b', 'c'])
>>> s
0    a
1    b
2    c
dtype: object
>>> s.repeat(2)
0    a
0    a
1    b
1    b
2    c
2    c
dtype: object
>>> s.repeat([1, 2, 3])
0    a
1    b
1    b
2    c
2    c
2    c
dtype: object

```

pandas.Series.replace

`Series.replace(to_replace=None, value=None, inplace=False, limit=None, regex=False, method='pad')`
 Replace values given in *to_replace* with *value*.

Values of the Series are replaced with other values dynamically.

This differs from updating with `.loc` or `.iloc`, which require you to specify a location to update with some value.

Parameters

to_replace [str, regex, list, dict, Series, int, float, or None] How to find the values that will be replaced.

- numeric, str or regex:
 - **numeric:** numeric values equal to *to_replace* will be replaced with *value*
 - **str:** string exactly matching *to_replace* will be replaced with *value*
 - **regex:** regexs matching *to_replace* will be replaced with *value*
- list of str, regex, or numeric:
 - **First, if *to_replace* and *value* are both lists, they must** be the same length.
 - **Second, if *regex=True* then all of the strings in both** lists will be interpreted as regexs otherwise they will match directly. This doesn't matter much for *value* since there are only a few possible substitution regexes you can use.
 - str, regex and numeric rules apply as above.
- dict:

- **Dicts can be used to specify different replacement values** for different existing values. For example, `{'a': 'b', 'y': 'z'}` replaces the value 'a' with 'b' and 'y' with 'z'. To use a dict in this way the *value* parameter should be *None*.
- **For a DataFrame a dict can specify that different values** should be replaced in different columns. For example, `{'a': 1, 'b': 'z'}` looks for the value 1 in column 'a' and the value 'z' in column 'b' and replaces these values with whatever is specified in *value*. The *value* parameter should not be *None* in this case. You can treat this as a special case of passing two lists except that you are specifying the column to search in.
- **For a DataFrame nested dictionaries, e.g.,** `{'a': {'b': np.nan}}`, are read as follows: look in column 'a' for the value 'b' and replace it with NaN. The *value* parameter should be *None* to use a nested dict in this way. You can nest regular expressions as well. Note that column names (the top-level dictionary keys in a nested dictionary) **cannot** be regular expressions.
- None:
 - **This means that the *regex* argument must be a string**, compiled regular expression, or list, dict, ndarray or Series of such elements. If *value* is also *None* then this **must** be a nested dictionary or Series.

See the examples section for examples of each of these.

value [scalar, dict, list, str, regex, default None] Value to replace any values matching *to_replace* with. For a DataFrame a dict of values can be used to specify which value to use for each column (columns not in the dict will not be filled). Regular expressions, strings and lists or dicts of such objects are also allowed.

inplace [bool, default False] If True, performs operation inplace and returns None.

limit [int, default None] Maximum size gap to forward or backward fill.

regex [bool or same types as *to_replace*, default False] Whether to interpret *to_replace* and/or *value* as regular expressions. If this is True then *to_replace* must be a string. Alternatively, this could be a regular expression or a list, dict, or array of regular expressions in which case *to_replace* must be None.

method [{ 'pad', 'ffill', 'bfill', None}] The method to use when for replacement, when *to_replace* is a scalar, list or tuple and *value* is None.

Changed in version 0.23.0: Added to DataFrame.

Returns

Series Object after replacement.

Raises

AssertionError

- If *regex* is not a bool and *to_replace* is not None.

TypeError

- If *to_replace* is not a scalar, array-like, dict, or None
- If *to_replace* is a dict and *value* is not a list, dict, ndarray, or Series
- If *to_replace* is None and *regex* is not compilable into a regular expression or is a list, dict, ndarray, or Series.

- When replacing multiple `bool` or `datetime64` objects and the arguments to `to_replace` does not match the type of the value being replaced

ValueError

- If a list or an ndarray is passed to `to_replace` and `value` but they are not the same length.

See also:

`Series.fillna` Fill NA values.

`Series.where` Replace values based on boolean condition.

`Series.str.replace` Simple string replacement.

Notes

- **Regex substitution is performed under the hood with `re.sub`.** The rules for substitution for `re.sub` are the same.
- **Regular expressions will only substitute on strings, meaning you** cannot provide, for example, a regular expression matching floating point numbers and expect the columns in your frame that have a numeric dtype to be matched. However, if those floating point numbers *are* strings, then you can do this.
- **This method has a lot of options. You are encouraged to experiment** and play with this method to gain intuition about how it works.
- **When dict is used as the `to_replace` value, it is like** key(s) in the dict are the `to_replace` part and value(s) in the dict are the value parameter.

Examples

Scalar `to_replace` and `value``

```
>>> s = pd.Series([0, 1, 2, 3, 4])
>>> s.replace(0, 5)
0    5
1    1
2    2
3    3
4    4
dtype: int64
```

```
>>> df = pd.DataFrame({'A': [0, 1, 2, 3, 4],
...                   'B': [5, 6, 7, 8, 9],
...                   'C': ['a', 'b', 'c', 'd', 'e']})
>>> df.replace(0, 5)
   A  B  C
0  5  5  a
1  1  6  b
2  2  7  c
3  3  8  d
4  4  9  e
```

List-like `to_replace`

```
>>> df.replace([0, 1, 2, 3], 4)
   A  B  C
0  4  5  a
1  4  6  b
2  4  7  c
3  4  8  d
4  4  9  e
```

```
>>> df.replace([0, 1, 2, 3], [4, 3, 2, 1])
   A  B  C
0  4  5  a
1  3  6  b
2  2  7  c
3  1  8  d
4  4  9  e
```

```
>>> s.replace([1, 2], method='bfill')
0    0
1    3
2    3
3    3
4    4
dtype: int64
```

dict-like `to_replace`

```
>>> df.replace({0: 10, 1: 100})
   A  B  C
0  10  5  a
1 100  6  b
2   2  7  c
3   3  8  d
4   4  9  e
```

```
>>> df.replace({'A': 0, 'B': 5}, 100)
   A  B  C
0 100 100 a
1   1   6 b
2   2   7 c
3   3   8 d
4   4   9 e
```

```
>>> df.replace({'A': {0: 100, 4: 400}})
   A  B  C
0 100  5  a
1   1  6  b
2   2  7  c
3   3  8  d
4 400  9  e
```

Regular expression `to_replace`

```
>>> df = pd.DataFrame({'A': ['bat', 'foo', 'bait'],
...                    'B': ['abc', 'bar', 'xyz']})
>>> df.replace(to_replace=r'^ba.$', value='new', regex=True)
   A  B
0  new abc
1  foo new
2  bait xyz
```

```
>>> df.replace({'A': r'^ba.$'}, {'A': 'new'}, regex=True)
   A  B
0  new abc
1  foo bar
2  bait xyz
```

```
>>> df.replace(regex=r'^ba.$', value='new')
   A  B
0  new abc
1  foo new
2  bait xyz
```

```
>>> df.replace(regex={r'^ba.$': 'new', 'foo': 'xyz'})
   A  B
0  new abc
1  xyz new
2  bait xyz
```

```
>>> df.replace(regex=[r'^ba.$', 'foo'], value='new')
   A  B
0  new abc
1  new new
2  bait xyz
```

Compare the behavior of `s.replace({'a': None})` and `s.replace('a', None)` to understand the peculiarities of the `to_replace` parameter:

```
>>> s = pd.Series([10, 'a', 'a', 'b', 'a'])
```

When one uses a dict as the `to_replace` value, it is like the value(s) in the dict are equal to the `value` parameter. `s.replace({'a': None})` is equivalent to `s.replace(to_replace={'a': None}, value=None, method=None)`:

```
>>> s.replace({'a': None})
0    10
1    None
2    None
3     b
4    None
dtype: object
```

When `value=None` and `to_replace` is a scalar, list or tuple, `replace` uses the method parameter (default 'pad') to do the replacement. So this is why the 'a' values are being replaced by 10 in rows 1 and 2 and 'b' in row 4 in this case. The command `s.replace('a', None)` is actually equivalent to `s.replace(to_replace='a', value=None, method='pad')`:

```
>>> s.replace('a', None)
0    10
1    10
2    10
3     b
4     b
dtype: object
```

pandas.Series.resample

`Series.resample`(*rule*, *axis=0*, *closed=None*, *label=None*, *convention='start'*, *kind=None*, *loffset=None*, *base=None*, *on=None*, *level=None*, *origin='start_day'*, *offset=None*)

Resample time-series data.

Convenience method for frequency conversion and resampling of time series. The object must have a datetime-like index (*DatetimeIndex*, *PeriodIndex*, or *TimedeltaIndex*), or the caller must pass the label of a datetime-like series/index to the *on/level* keyword parameter.

Parameters

rule [DateOffset, Timedelta or str] The offset string or object representing target conversion.

axis [{0 or 'index', 1 or 'columns'}, default 0] Which axis to use for up- or down-sampling. For *Series* this will default to 0, i.e. along the rows. Must be *DatetimeIndex*, *TimedeltaIndex* or *PeriodIndex*.

closed [{ 'right', 'left' }, default None] Which side of bin interval is closed. The default is 'left' for all frequency offsets except for 'M', 'A', 'Q', 'BM', 'BA', 'BQ', and 'W' which all have a default of 'right'.

label [{ 'right', 'left' }, default None] Which bin edge label to label bucket with. The default is 'left' for all frequency offsets except for 'M', 'A', 'Q', 'BM', 'BA', 'BQ', and 'W' which all have a default of 'right'.

convention [{ 'start', 'end', 's', 'e' }, default 'start'] For *PeriodIndex* only, controls whether to use the start or end of *rule*.

kind [{ 'timestamp', 'period' }, optional, default None] Pass 'timestamp' to convert the resulting index to a *DatetimeIndex* or 'period' to convert it to a *PeriodIndex*. By default the input representation is retained.

loffset [timedelta, default None] Adjust the resampled time labels.

Deprecated since version 1.1.0: You should add the *loffset* to the *df.index* after the resample. See below.

base [int, default 0] For frequencies that evenly subdivide 1 day, the "origin" of the aggregated intervals. For example, for '5min' frequency, *base* could range from 0 through 4. Defaults to 0.

Deprecated since version 1.1.0: The new arguments that you should use are 'offset' or 'origin'.

on [str, optional] For a *DataFrame*, column to use instead of index for resampling. Column must be datetime-like.

level [str or int, optional] For a *MultiIndex*, level (name or number) to use for resampling. *level* must be datetime-like.

origin [{‘epoch’, ‘start’, ‘start_day’, ‘end’, ‘end_day’}, Timestamp] or str, default ‘start_day’ The timestamp on which to adjust the grouping. The timezone of origin must match the timezone of the index. If a timestamp is not used, these values are also supported:

- ‘epoch’: *origin* is 1970-01-01
- ‘start’: *origin* is the first value of the timeseries
- ‘start_day’: *origin* is the first day at midnight of the timeseries

New in version 1.1.0.

- ‘end’: *origin* is the last value of the timeseries
- ‘end_day’: *origin* is the ceiling midnight of the last day

New in version 1.3.0.

offset [Timedelta or str, default is None] An offset timedelta added to the origin.

New in version 1.1.0.

Returns

pandas.core.Resampler Resampler object.

See also:

[*Series.resample*](#) Resample a Series.

[*DataFrame.resample*](#) Resample a DataFrame.

[*groupby*](#) Group Series by mapping, function, label, or list of labels.

[*asfreq*](#) Reindex a Series with the given frequency without grouping.

Notes

See the [user guide](#) for more.

To learn more about the offset strings, please see [this link](#).

Examples

Start by creating a series with 9 one minute timestamps.

```
>>> index = pd.date_range('1/1/2000', periods=9, freq='T')
>>> series = pd.Series(range(9), index=index)
>>> series
2000-01-01 00:00:00    0
2000-01-01 00:01:00    1
2000-01-01 00:02:00    2
2000-01-01 00:03:00    3
2000-01-01 00:04:00    4
2000-01-01 00:05:00    5
2000-01-01 00:06:00    6
2000-01-01 00:07:00    7
2000-01-01 00:08:00    8
Freq: T, dtype: int64
```

Downsample the series into 3 minute bins and sum the values of the timestamps falling into a bin.

```
>>> series.resample('3T').sum()
2000-01-01 00:00:00    3
2000-01-01 00:03:00   12
2000-01-01 00:06:00   21
Freq: 3T, dtype: int64
```

Downsample the series into 3 minute bins as above, but label each bin using the right edge instead of the left. Please note that the value in the bucket used as the label is not included in the bucket, which it labels. For example, in the original series the bucket 2000-01-01 00:03:00 contains the value 3, but the summed value in the resampled bucket with the label 2000-01-01 00:03:00 does not include 3 (if it did, the summed value would be 6, not 3). To include this value close the right side of the bin interval as illustrated in the example below this one.

```
>>> series.resample('3T', label='right').sum()
2000-01-01 00:03:00    3
2000-01-01 00:06:00   12
2000-01-01 00:09:00   21
Freq: 3T, dtype: int64
```

Downsample the series into 3 minute bins as above, but close the right side of the bin interval.

```
>>> series.resample('3T', label='right', closed='right').sum()
2000-01-01 00:00:00    0
2000-01-01 00:03:00    6
2000-01-01 00:06:00   15
2000-01-01 00:09:00   15
Freq: 3T, dtype: int64
```

Upsample the series into 30 second bins.

```
>>> series.resample('30S').asfreq()[0:5]  # Select first 5 rows
2000-01-01 00:00:00    0.0
2000-01-01 00:00:30   NaN
2000-01-01 00:01:00    1.0
2000-01-01 00:01:30   NaN
2000-01-01 00:02:00    2.0
Freq: 30S, dtype: float64
```

Upsample the series into 30 second bins and fill the NaN values using the pad method.

```
>>> series.resample('30S').pad()[0:5]
2000-01-01 00:00:00    0
2000-01-01 00:00:30    0
2000-01-01 00:01:00    1
2000-01-01 00:01:30    1
2000-01-01 00:02:00    2
Freq: 30S, dtype: int64
```

Upsample the series into 30 second bins and fill the NaN values using the bfill method.

```
>>> series.resample('30S').bfill()[0:5]
2000-01-01 00:00:00    0
```

(continues on next page)

(continued from previous page)

```

2000-01-01 00:00:30    1
2000-01-01 00:01:00    1
2000-01-01 00:01:30    2
2000-01-01 00:02:00    2
Freq: 30S, dtype: int64

```

Pass a custom function via `apply`

```

>>> def custom_resampler(arraylike):
...     return np.sum(arraylike) + 5
...
>>> series.resample('3T').apply(custom_resampler)
2000-01-01 00:00:00    8
2000-01-01 00:03:00   17
2000-01-01 00:06:00   26
Freq: 3T, dtype: int64

```

For a Series with a PeriodIndex, the keyword *convention* can be used to control whether to use the start or end of *rule*.

Resample a year by quarter using 'start' *convention*. Values are assigned to the first quarter of the period.

```

>>> s = pd.Series([1, 2], index=pd.period_range('2012-01-01',
...                                             freq='A',
...                                             periods=2))
>>> s
2012    1
2013    2
Freq: A-DEC, dtype: int64
>>> s.resample('Q', convention='start').asfreq()
2012Q1    1.0
2012Q2    NaN
2012Q3    NaN
2012Q4    NaN
2013Q1    2.0
2013Q2    NaN
2013Q3    NaN
2013Q4    NaN
Freq: Q-DEC, dtype: float64

```

Resample quarters by month using 'end' *convention*. Values are assigned to the last month of the period.

```

>>> q = pd.Series([1, 2, 3, 4], index=pd.period_range('2018-01-01',
...                                                  freq='Q',
...                                                  periods=4))
>>> q
2018Q1    1
2018Q2    2
2018Q3    3
2018Q4    4
Freq: Q-DEC, dtype: int64
>>> q.resample('M', convention='end').asfreq()
2018-03    1.0

```

(continues on next page)

(continued from previous page)

```

2018-04    NaN
2018-05    NaN
2018-06    2.0
2018-07    NaN
2018-08    NaN
2018-09    3.0
2018-10    NaN
2018-11    NaN
2018-12    4.0
Freq: M, dtype: float64

```

For DataFrame objects, the keyword *on* can be used to specify the column instead of the index for resampling.

```

>>> d = {'price': [10, 11, 9, 13, 14, 18, 17, 19],
...      'volume': [50, 60, 40, 100, 50, 100, 40, 50]}
>>> df = pd.DataFrame(d)
>>> df['week_starting'] = pd.date_range('01/01/2018',
...                                     periods=8,
...                                     freq='W')
>>> df
   price  volume week_starting
0     10     50  2018-01-07
1     11     60  2018-01-14
2      9     40  2018-01-21
3     13    100  2018-01-28
4     14     50  2018-02-04
5     18    100  2018-02-11
6     17     40  2018-02-18
7     19     50  2018-02-25
>>> df.resample('M', on='week_starting').mean()
           price  volume
week_starting
2018-01-31    10.75    62.5
2018-02-28    17.00    60.0

```

For a DataFrame with MultiIndex, the keyword *level* can be used to specify on which level the resampling needs to take place.

```

>>> days = pd.date_range('1/1/2000', periods=4, freq='D')
>>> d2 = {'price': [10, 11, 9, 13, 14, 18, 17, 19],
...      'volume': [50, 60, 40, 100, 50, 100, 40, 50]}
>>> df2 = pd.DataFrame(
...     d2,
...     index=pd.MultiIndex.from_product(
...         [days, ['morning', 'afternoon']]
...     )
... )
>>> df2
           price  volume
2000-01-01 morning     10     50
           afternoon    11     60

```

(continues on next page)

(continued from previous page)

```

2000-01-02 morning      9      40
              afternoon 13     100
2000-01-03 morning     14      50
              afternoon 18     100
2000-01-04 morning     17      40
              afternoon 19      50
>>> df2.resample('D', level=0).sum()
              price  volume
2000-01-01         21     110
2000-01-02         22     140
2000-01-03         32     150
2000-01-04         36      90

```

If you want to adjust the start of the bins based on a fixed timestamp:

```

>>> start, end = '2000-10-01 23:30:00', '2000-10-02 00:30:00'
>>> rng = pd.date_range(start, end, freq='7min')
>>> ts = pd.Series(np.arange(len(rng)) * 3, index=rng)
>>> ts
2000-10-01 23:30:00      0
2000-10-01 23:37:00      3
2000-10-01 23:44:00      6
2000-10-01 23:51:00      9
2000-10-01 23:58:00     12
2000-10-02 00:05:00     15
2000-10-02 00:12:00     18
2000-10-02 00:19:00     21
2000-10-02 00:26:00     24
Freq: 7T, dtype: int64

```

```

>>> ts.resample('17min').sum()
2000-10-01 23:14:00      0
2000-10-01 23:31:00      9
2000-10-01 23:48:00     21
2000-10-02 00:05:00     54
2000-10-02 00:22:00     24
Freq: 17T, dtype: int64

```

```

>>> ts.resample('17min', origin='epoch').sum()
2000-10-01 23:18:00      0
2000-10-01 23:35:00     18
2000-10-01 23:52:00     27
2000-10-02 00:09:00     39
2000-10-02 00:26:00     24
Freq: 17T, dtype: int64

```

```

>>> ts.resample('17min', origin='2000-01-01').sum()
2000-10-01 23:24:00      3
2000-10-01 23:41:00     15
2000-10-01 23:58:00     45
2000-10-02 00:15:00     45
Freq: 17T, dtype: int64

```

If you want to adjust the start of the bins with an *offset* Timedelta, the two following lines are equivalent:

```
>>> ts.resample('17min', origin='start').sum()
2000-10-01 23:30:00    9
2000-10-01 23:47:00   21
2000-10-02 00:04:00   54
2000-10-02 00:21:00   24
Freq: 17T, dtype: int64
```

```
>>> ts.resample('17min', offset='23h30min').sum()
2000-10-01 23:30:00    9
2000-10-01 23:47:00   21
2000-10-02 00:04:00   54
2000-10-02 00:21:00   24
Freq: 17T, dtype: int64
```

If you want to take the largest Timestamp as the end of the bins:

```
>>> ts.resample('17min', origin='end').sum()
2000-10-01 23:35:00    0
2000-10-01 23:52:00   18
2000-10-02 00:09:00   27
2000-10-02 00:26:00   63
Freq: 17T, dtype: int64
```

In contrast with the *start_day*, you can use *end_day* to take the ceiling midnight of the largest Timestamp as the end of the bins and drop the bins not containing data:

```
>>> ts.resample('17min', origin='end_day').sum()
2000-10-01 23:38:00    3
2000-10-01 23:55:00   15
2000-10-02 00:12:00   45
2000-10-02 00:29:00   45
Freq: 17T, dtype: int64
```

To replace the use of the deprecated *base* argument, you can now use *offset*, in this example it is equivalent to have *base=2*:

```
>>> ts.resample('17min', offset='2min').sum()
2000-10-01 23:16:00    0
2000-10-01 23:33:00    9
2000-10-01 23:50:00   36
2000-10-02 00:07:00   39
2000-10-02 00:24:00   24
Freq: 17T, dtype: int64
```

To replace the use of the deprecated *loffset* argument:

```
>>> from pandas.tseries.frequencies import to_offset
>>> loffset = '19min'
>>> ts_out = ts.resample('17min').sum()
>>> ts_out.index = ts_out.index + to_offset(loffset)
>>> ts_out
2000-10-01 23:33:00    0
```

(continues on next page)

(continued from previous page)

```

2000-10-01 23:50:00    9
2000-10-02 00:07:00   21
2000-10-02 00:24:00   54
2000-10-02 00:41:00   24
Freq: 17T, dtype: int64

```

pandas.Series.reset_index

`Series.reset_index(level=None, drop=False, name=None, inplace=False)`

Generate a new DataFrame or Series with the index reset.

This is useful when the index needs to be treated as a column, or when the index is meaningless and needs to be reset to the default before another operation.

Parameters

level [int, str, tuple, or list, default optional] For a Series with a MultiIndex, only remove the specified levels from the index. Removes all levels by default.

drop [bool, default False] Just reset the index, without inserting it as a column in the new DataFrame.

name [object, optional] The name to use for the column containing the original Series values. Uses `self.name` by default. This argument is ignored when `drop` is True.

inplace [bool, default False] Modify the Series in place (do not create a new object).

Returns

Series or DataFrame or None When `drop` is False (the default), a DataFrame is returned. The newly created columns will come first in the DataFrame, followed by the original Series values. When `drop` is True, a *Series* is returned. In either case, if `inplace=True`, no value is returned.

See also:

[`DataFrame.reset_index`](#) Analogous function for DataFrame.

Examples

```

>>> s = pd.Series([1, 2, 3, 4], name='foo',
...               index=pd.Index(['a', 'b', 'c', 'd'], name='idx'))

```

Generate a DataFrame with default index.

```

>>> s.reset_index()
   idx  foo
0    a    1
1    b    2
2    c    3
3    d    4

```

To specify the name of the new column use *name*.

```
>>> s.reset_index(name='values')
   idx  values
0    a      1
1    b      2
2    c      3
3    d      4
```

To generate a new Series with the default set *drop* to True.

```
>>> s.reset_index(drop=True)
0    1
1    2
2    3
3    4
Name: foo, dtype: int64
```

To update the Series in place, without generating a new one set *inplace* to True. Note that it also requires *drop=True*.

```
>>> s.reset_index(inplace=True, drop=True)
>>> s
0    1
1    2
2    3
3    4
Name: foo, dtype: int64
```

The *level* parameter is interesting for Series with a multi-level index.

```
>>> arrays = [np.array(['bar', 'bar', 'baz', 'baz']),
...           np.array(['one', 'two', 'one', 'two'])]
>>> s2 = pd.Series(
...     range(4), name='foo',
...     index=pd.MultiIndex.from_arrays(arrays,
...                                     names=['a', 'b']))
```

To remove a specific level from the Index, use *level*.

```
>>> s2.reset_index(level='a')
   a  foo
b
one bar    0
two bar    1
one baz    2
two baz    3
```

If *level* is not set, all levels are removed from the Index.

```
>>> s2.reset_index()
   a  b  foo
0  bar one  0
1  bar two  1
2  baz one  2
3  baz two  3
```

pandas.Series.rfloordiv

`Series.rfloordiv`(*other*, *level=None*, *fill_value=None*, *axis=0*)

Return Integer division of series and other, element-wise (binary operator *rfloordiv*).

Equivalent to `other // series`, but with support to substitute a *fill_value* for missing data in either one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

Series The result of the operation.

See also:

[*Series.floordiv*](#) Element-wise Integer division, see [Python documentation](#) for more details.

Examples

```
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.floordiv(b, fill_value=0)
a    1.0
b    NaN
c    NaN
d    0.0
e    NaN
dtype: float64
```

pandas.Series.rmod

`Series.rmod(other, level=None, fill_value=None, axis=0)`

Return Modulo of series and other, element-wise (binary operator *rmod*).

Equivalent to `other % series`, but with support to substitute a `fill_value` for missing data in either one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

Series The result of the operation.

See also:

[Series.mod](#) Element-wise Modulo, see [Python documentation](#) for more details.

Examples

```
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.mod(b, fill_value=0)
a    0.0
b    NaN
c    NaN
d    0.0
e    NaN
dtype: float64
```

pandas.Series.rmul

`Series.rmul` (*other*, *level=None*, *fill_value=None*, *axis=0*)

Return Multiplication of series and other, element-wise (binary operator *rmul*).

Equivalent to `other * series`, but with support to substitute a `fill_value` for missing data in either one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

Series The result of the operation.

See also:

[*Series.mul*](#) Element-wise Multiplication, see [Python documentation](#) for more details.

Examples

```
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.multiply(b, fill_value=0)
a    1.0
b    0.0
c    0.0
d    0.0
e    NaN
dtype: float64
```

pandas.Series.rolling

`Series.rolling(window, min_periods=None, center=False, win_type=None, on=None, axis=0, closed=None, method='single')`

Provide rolling window calculations.

Parameters

window [int, offset, or BaseIndexer subclass] Size of the moving window. This is the number of observations used for calculating the statistic. Each window will be a fixed size.

If its an offset then this will be the time period of each window. Each window will be a variable sized based on the observations included in the time-period. This is only valid for datetimelike indexes.

If a BaseIndexer subclass is passed, calculates the window boundaries based on the defined `get_window_bounds` method. Additional rolling keyword arguments, namely `min_periods`, `center`, and `closed` will be passed to `get_window_bounds`.

min_periods [int, default None] Minimum number of observations in window required to have a value (otherwise result is NA). For a window that is specified by an offset, `min_periods` will default to 1. Otherwise, `min_periods` will default to the size of the window.

center [bool, default False] Set the labels at the center of the window.

win_type [str, default None] Provide a window type. If None, all points are evenly weighted. See the notes below for further information.

on [str, optional] For a DataFrame, a datetime-like column or Index level on which to calculate the rolling window, rather than the DataFrame's index. Provided integer column is ignored and excluded from result since an integer index is not used to calculate the rolling window.

axis [int or str, default 0]

closed [str, default None] Make the interval closed on the 'right', 'left', 'both' or 'neither' endpoints. Defaults to 'right'.

Changed in version 1.2.0: The closed parameter with fixed windows is now supported.

method [str {'single', 'table'}, default 'single'] Execute the rolling operation per single column or row ('single') or over the entire object ('table').

This argument is only implemented when specifying `engine='numba'` in the method call.

New in version 1.3.0.

Returns

a Window or Rolling sub-classed for the particular operation

See also:

[*expanding*](#) Provides expanding transformations.

[*ewm*](#) Provides exponential weighted functions.

Notes

By default, the result is set to the right edge of the window. This can be changed to the center of the window by setting `center=True`.

To learn more about the offsets & frequency strings, please see [this link](#).

If `win_type=None`, all points are evenly weighted; otherwise, `win_type` can accept a string of any `scipy.signal` window function.

Certain Scipy window types require additional parameters to be passed in the aggregation function. The additional parameters must match the keywords specified in the Scipy window type method signature. Please see the third example below on how to add the additional parameters.

Examples

```
>>> df = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]})
>>> df
   B
0  0.0
1  1.0
2  2.0
3  NaN
4  4.0
```

Rolling sum with a window length of 2, using the 'triang' window type.

```
>>> df.rolling(2, win_type='triang').sum()
   B
0  NaN
1  0.5
2  1.5
3  NaN
4  NaN
```

Rolling sum with a window length of 2, using the 'gaussian' window type (note how we need to specify `std`).

```
>>> df.rolling(2, win_type='gaussian').sum(std=3)
   B
0  NaN
1  0.986207
2  2.958621
3  NaN
4  NaN
```

Rolling sum with a window length of 2, `min_periods` defaults to the window length.

```
>>> df.rolling(2).sum()
   B
0  NaN
1  1.0
2  3.0
3  NaN
4  NaN
```

Same as above, but explicitly set the `min_periods`

```
>>> df.rolling(2, min_periods=1).sum()
      B
0  0.0
1  1.0
2  3.0
3  2.0
4  4.0
```

Same as above, but with forward-looking windows

```
>>> indexer = pd.api.indexers.FixedForwardWindowIndexer(window_size=2)
>>> df.rolling(window=indexer, min_periods=1).sum()
      B
0  1.0
1  3.0
2  2.0
3  4.0
4  4.0
```

A ragged (meaning not-a-regular frequency), time-indexed DataFrame

```
>>> df = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]},
...                   index = [pd.Timestamp('20130101 09:00:00'),
...                             pd.Timestamp('20130101 09:00:02'),
...                             pd.Timestamp('20130101 09:00:03'),
...                             pd.Timestamp('20130101 09:00:05'),
...                             pd.Timestamp('20130101 09:00:06')])
```

```
>>> df
              B
2013-01-01 09:00:00  0.0
2013-01-01 09:00:02  1.0
2013-01-01 09:00:03  2.0
2013-01-01 09:00:05  NaN
2013-01-01 09:00:06  4.0
```

Contrasting to an integer rolling window, this will roll a variable length window corresponding to the time period. The default for `min_periods` is 1.

```
>>> df.rolling('2s').sum()
              B
2013-01-01 09:00:00  0.0
2013-01-01 09:00:02  1.0
2013-01-01 09:00:03  3.0
2013-01-01 09:00:05  NaN
2013-01-01 09:00:06  4.0
```

pandas.Series.round

`Series.round(decimals=0, *args, **kwargs)`

Round each value in a Series to the given number of decimals.

Parameters

decimals [int, default 0] Number of decimal places to round to. If decimals is negative, it specifies the number of positions to the left of the decimal point.

***args, **kwargs** Additional arguments and keywords have no effect but might be accepted for compatibility with NumPy.

Returns

Series Rounded values of the Series.

See also:

[`numpy.around`](#) Round values of an np.array.

[`DataFrame.round`](#) Round values of a DataFrame.

Examples

```
>>> s = pd.Series([0.1, 1.3, 2.7])
>>> s.round()
0    0.0
1    1.0
2    3.0
dtype: float64
```

pandas.Series.rpow

`Series.rpow(other, level=None, fill_value=None, axis=0)`

Return Exponential power of series and other, element-wise (binary operator *rpow*).

Equivalent to `other ** series`, but with support to substitute a `fill_value` for missing data in either one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

Series The result of the operation.

See also:

[`Series.pow`](#) Element-wise Exponential power, see [Python documentation](#) for more details.

Examples

```

>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.pow(b, fill_value=0)
a    1.0
b    1.0
c    1.0
d    0.0
e    NaN
dtype: float64

```

pandas.Series.rsub

`Series.rsub(other, level=None, fill_value=None, axis=0)`

Return Subtraction of series and other, element-wise (binary operator *rsub*).

Equivalent to `other - series`, but with support to substitute a `fill_value` for missing data in either one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

Series The result of the operation.

See also:

[Series.sub](#) Element-wise Subtraction, see [Python documentation](#) for more details.

Examples

```

>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.subtract(b, fill_value=0)
a    0.0
b    1.0
c    1.0
d   -1.0
e    NaN
dtype: float64

```

pandas.Series.rtruediv

`Series.rtruediv`(*other*, *level=None*, *fill_value=None*, *axis=0*)

Return Floating division of series and other, element-wise (binary operator *rtruediv*).

Equivalent to `other / series`, but with support to substitute a `fill_value` for missing data in either one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

Series The result of the operation.

See also:

[*Series.truediv*](#) Element-wise Floating division, see [Python documentation](#) for more details.

Examples

```

>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.divide(b, fill_value=0)
a    1.0
b    inf
c    inf
d    0.0
e    NaN
dtype: float64

```

pandas.Series.sample

`Series.sample`(*n=None, frac=None, replace=False, weights=None, random_state=None, axis=None, ignore_index=False*)

Return a random sample of items from an axis of object.

You can use *random_state* for reproducibility.

Parameters

n [int, optional] Number of items from axis to return. Cannot be used with *frac*. Default = 1 if *frac* = None.

frac [float, optional] Fraction of axis items to return. Cannot be used with *n*.

replace [bool, default False] Allow or disallow sampling of the same row more than once.

weights [str or ndarray-like, optional] Default 'None' results in equal probability weighting. If passed a Series, will align with target object on index. Index values in weights not found in sampled object will be ignored and index values in sampled object not in weights will be assigned weights of zero. If called on a DataFrame, will accept the name of a column when *axis* = 0. Unless weights are a Series, weights must be same length as axis being sampled. If weights do not sum to 1, they will be normalized to sum to 1. Missing values in the weights column will be treated as zero. Infinite values not allowed.

random_state [int, array-like, BitGenerator, np.random.RandomState, optional] If int, array-like, or BitGenerator (NumPy>=1.17), seed for random number generator If np.random.RandomState, use as numpy RandomState object.

Changed in version 1.1.0: array-like and BitGenerator (for NumPy>=1.17) object now passed to `np.random.RandomState()` as seed

axis [{0 or 'index', 1 or 'columns', None}, default None] Axis to sample. Accepts axis number or name. Default is stat axis for given data type (0 for Series and DataFrames).

ignore_index [bool, default False] If True, the resulting index will be labeled 0, 1, ..., n - 1.

New in version 1.3.0.

Returns

Series or DataFrame A new object of same type as caller containing *n* items randomly sampled from the caller object.

See also:

DataFrameGroupBy.sample Generates random samples from each group of a DataFrame object.

SeriesGroupBy.sample Generates random samples from each group of a Series object.

numpy.random.choice Generates a random sample from a given 1-D numpy array.

Notes

If *frac* > 1, *replacement* should be set to *True*.

Examples

```
>>> df = pd.DataFrame({'num_legs': [2, 4, 8, 0],
...                    'num_wings': [2, 0, 0, 0],
...                    'num_specimen_seen': [10, 2, 1, 8]},
...                    index=['falcon', 'dog', 'spider', 'fish'])
>>> df
```

| | num_legs | num_wings | num_specimen_seen |
|--------|----------|-----------|-------------------|
| falcon | 2 | 2 | 10 |
| dog | 4 | 0 | 2 |
| spider | 8 | 0 | 1 |
| fish | 0 | 0 | 8 |

Extract 3 random elements from the Series `df['num_legs']`: Note that we use *random_state* to ensure the reproducibility of the examples.

```
>>> df['num_legs'].sample(n=3, random_state=1)
fish      0
spider    8
falcon    2
Name: num_legs, dtype: int64
```

A random 50% sample of the DataFrame with replacement:

```
>>> df.sample(frac=0.5, replace=True, random_state=1)
   num_legs  num_wings  num_specimen_seen
```

(continues on next page)

(continued from previous page)

| | | | |
|------|---|---|---|
| dog | 4 | 0 | 2 |
| fish | 0 | 0 | 8 |

An upsample sample of the DataFrame with replacement: Note that *replace* parameter has to be *True* for *frac* parameter > 1.

```
>>> df.sample(frac=2, replace=True, random_state=1)
      num_legs  num_wings  num_specimen_seen
dog           4          0                  2
fish          0          0                  8
falcon        2          2                 10
falcon        2          2                 10
fish          0          0                  8
dog           4          0                  2
fish          0          0                  8
dog           4          0                  2
```

Using a DataFrame column as weights. Rows with larger value in the *num_specimen_seen* column are more likely to be sampled.

```
>>> df.sample(n=2, weights='num_specimen_seen', random_state=1)
      num_legs  num_wings  num_specimen_seen
falcon        2          2                 10
fish          0          0                  8
```

pandas.Series.searchsorted

`Series.searchsorted(value, side='left', sorter=None)`

Find indices where elements should be inserted to maintain order.

Find the indices into a sorted Series *self* such that, if the corresponding elements in *value* were inserted before the indices, the order of *self* would be preserved.

Note: The Series *must* be monotonically sorted, otherwise wrong locations will likely be returned. Pandas does *not* check this for you.

Parameters

value [array-like] Values to insert into *self*.

side [{ 'left', 'right' }, optional] If 'left', the index of the first suitable location found is given. If 'right', return the last such index. If there is no suitable index, return either 0 or N (where N is the length of *self*).

sorter [1-D array-like, optional] Optional array of integer indices that sort *self* into ascending order. They are typically the result of `np.argsort`.

Returns

int or array of int A scalar or array of insertion points with the same shape as *value*.

See also:

`sort_values` Sort by the values along either axis.

`numpy.searchsorted` Similar method from NumPy.

Notes

Binary search is used to find the required insertion points.

Examples

```
>>> ser = pd.Series([1, 2, 3])
>>> ser
0    1
1    2
2    3
dtype: int64
```

```
>>> ser.searchsorted(4)
3
```

```
>>> ser.searchsorted([0, 4])
array([0, 3])
```

```
>>> ser.searchsorted([1, 3], side='left')
array([0, 2])
```

```
>>> ser.searchsorted([1, 3], side='right')
array([1, 3])
```

```
>>> ser = pd.Series(pd.to_datetime(['3/11/2000', '3/12/2000', '3/13/2000']))
>>> ser
0    2000-03-11
1    2000-03-12
2    2000-03-13
dtype: datetime64[ns]
```

```
>>> ser.searchsorted('3/14/2000')
3
```

```
>>> ser = pd.Categorical(
...     ['apple', 'bread', 'bread', 'cheese', 'milk'], ordered=True
... )
>>> ser
['apple', 'bread', 'bread', 'cheese', 'milk']
Categories (4, object): ['apple' < 'bread' < 'cheese' < 'milk']
```

```
>>> ser.searchsorted('bread')
1
```

```
>>> ser.searchsorted(['bread'], side='right')
array([3])
```

If the values are not monotonically sorted, wrong locations may be returned:

```
>>> ser = pd.Series([2, 1, 3])
>>> ser
0    2
1    1
2    3
dtype: int64
```

```
>>> ser.searchsorted(1)
0 # wrong result, correct would be 1
```

pandas.Series.sem

`Series.sem(axis=None, skipna=None, level=None, ddof=1, numeric_only=None, **kwargs)`

Return unbiased standard error of the mean over requested axis.

Normalized by N-1 by default. This can be changed using the `ddof` argument

Parameters

axis [{index (0)}]

skipna [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

ddof [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is $N - \text{ddof}$, where N represents the number of elements.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

Returns

scalar or Series (if level specified)

Notes

To have the same behaviour as *numpy.std*, use `ddof=0` (instead of the default `ddof=1`)

pandas.Series.set_axis

`Series.set_axis(labels, axis=0, inplace=False)`

Assign desired index to given axis.

Indexes for row labels can be changed by assigning a list-like or Index.

Parameters

labels [list-like, Index] The values for the new index.

axis [{0 or 'index'}, default 0] The axis to update. The value 0 identifies the rows.

inplace [bool, default False] Whether to return a new Series instance.

Returns

renamed [Series or None] An object of type Series or None if `inplace=True`.

See also:

[`Series.rename_axis`](#) Alter the name of the index.

Examples

```
>>> s = pd.Series([1, 2, 3])
>>> s
0    1
1    2
2    3
dtype: int64
```

```
>>> s.set_axis(['a', 'b', 'c'], axis=0)
a    1
b    2
c    3
dtype: int64
```

pandas.Series.set_flags

`Series.set_flags(*, copy=False, allows_duplicate_labels=None)`

Return a new object with updated flags.

Parameters

allows_duplicate_labels [bool, optional] Whether the returned object allows duplicate labels.

Returns

Series or DataFrame The same type as the caller.

See also:

[`DataFrame.attrs`](#) Global metadata applying to this dataset.

[`DataFrame.flags`](#) Global flags applying to this object.

Notes

This method returns a new object that's a view on the same data as the input. Mutating the input or the output values will be reflected in the other.

This method is intended to be used in method chains.

“Flags” differ from “metadata”. Flags reflect properties of the pandas object (the Series or DataFrame). Metadata refer to properties of the dataset, and should be stored in `DataFrame.attrs`.

Examples

```
>>> df = pd.DataFrame({"A": [1, 2]})
>>> df.flags.allows_duplicate_labels
True
>>> df2 = df.set_flags(allows_duplicate_labels=False)
>>> df2.flags.allows_duplicate_labels
False
```

pandas.Series.shift

`Series.shift(periods=1, freq=None, axis=0, fill_value=None)`

Shift index by desired number of periods with an optional time *freq*.

When *freq* is not passed, shift the index without realigning the data. If *freq* is passed (in this case, the index must be date or datetime, or it will raise a `NotImplementedError`), the index will be increased using the periods and the *freq*. *freq* can be inferred when specified as “infer” as long as either *freq* or *inferred_freq* attribute is set in the index.

Parameters

periods [int] Number of periods to shift. Can be positive or negative.

freq [DateOffset, tseries.offsets, timedelta, or str, optional] Offset to use from the tseries module or time rule (e.g. ‘EOM’). If *freq* is specified then the index values are shifted but the data is not realigned. That is, use *freq* if you would like to extend the index when shifting and preserve the original data. If *freq* is specified as “infer” then it will be inferred from the *freq* or *inferred_freq* attributes of the index. If neither of those attributes exist, a `ValueError` is thrown.

axis [{0 or ‘index’, 1 or ‘columns’, None}, default None] Shift direction.

fill_value [object, optional] The scalar value to use for newly introduced missing values. the default depends on the dtype of *self*. For numeric data, `np.nan` is used. For datetime, timedelta, or period data, etc. `NaT` is used. For extension dtypes, `self.dtype.na_value` is used.

Changed in version 1.1.0.

Returns

Series Copy of input object, shifted.

See also:

[`Index.shift`](#) Shift values of Index.

[`DatetimeIndex.shift`](#) Shift values of DatetimeIndex.

PeriodIndex.shift Shift values of PeriodIndex.

tshift Shift the time index, using the index's frequency if available.

Examples

```
>>> df = pd.DataFrame({"Col1": [10, 20, 15, 30, 45],
...                    "Col2": [13, 23, 18, 33, 48],
...                    "Col3": [17, 27, 22, 37, 52]},
...                   index=pd.date_range("2020-01-01", "2020-01-05"))
>>> df
```

| | Col1 | Col2 | Col3 |
|------------|------|------|------|
| 2020-01-01 | 10 | 13 | 17 |
| 2020-01-02 | 20 | 23 | 27 |
| 2020-01-03 | 15 | 18 | 22 |
| 2020-01-04 | 30 | 33 | 37 |
| 2020-01-05 | 45 | 48 | 52 |

```
>>> df.shift(periods=3)
```

| | Col1 | Col2 | Col3 |
|------------|------|------|------|
| 2020-01-01 | NaN | NaN | NaN |
| 2020-01-02 | NaN | NaN | NaN |
| 2020-01-03 | NaN | NaN | NaN |
| 2020-01-04 | 10.0 | 13.0 | 17.0 |
| 2020-01-05 | 20.0 | 23.0 | 27.0 |

```
>>> df.shift(periods=1, axis="columns")
```

| | Col1 | Col2 | Col3 |
|------------|------|------|------|

| 2020-01-01 | 0 | 0 | 0 |
| 2020-01-02 | 0 | 0 | 0 |
| 2020-01-03 | 0 | 0 | 0 |
| 2020-01-04 | 10 | 13 | 17 |
| 2020-01-05 | 20 | 23 | 27 |

```
>>> df.shift(periods=3, freq="D")
```

| | Col1 | Col2 | Col3 |
|------------|------|------|------|
| 2020-01-04 | 10 | 13 | 17 |
| 2020-01-05 | 20 | 23 | 27 |
| 2020-01-06 | 15 | 18 | 22 |
| 2020-01-07 | 30 | 33 | 37 |
| 2020-01-08 | 45 | 48 | 52 |

```
>>> df.shift(periods=3, freq="infer")
      Col1  Col2  Col3
2020-01-04    10    13    17
2020-01-05    20    23    27
2020-01-06    15    18    22
2020-01-07    30    33    37
2020-01-08    45    48    52
```

pandas.Series.skew

`Series.skew(axis=None, skipna=None, level=None, numeric_only=None, **kwargs)`

Return unbiased skew over requested axis.

Normalized by N-1.

Parameters

axis [{index (0)}] Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

****kwargs** Additional keyword arguments to be passed to the function.

Returns

scalar or Series (if level specified)

pandas.Series.slice_shift

`Series.slice_shift(periods=1, axis=0)`

Equivalent to *shift* without copying data. The shifted data will not include the dropped periods and the shifted axis will be smaller than the original.

Deprecated since version 1.2.0: *slice_shift* is deprecated, use `DataFrame/Series.shift` instead.

Parameters

periods [int] Number of periods to move, can be positive or negative.

Returns

shifted [same type as caller]

Notes

While the *slice_shift* is faster than *shift*, you may pay for it later during alignment.

pandas.Series.sort_index

`Series.sort_index(axis=0, level=None, ascending=True, inplace=False, kind='quicksort', na_position='last', sort_remaining=True, ignore_index=False, key=None)`

Sort Series by index labels.

Returns a new Series sorted by label if *inplace* argument is `False`, otherwise updates the original series and returns `None`.

Parameters

axis [int, default 0] Axis to direct sorting. This can only be 0 for Series.

level [int, optional] If not `None`, sort on values in specified index level(s).

ascending [bool or list-like of bools, default `True`] Sort ascending vs. descending. When the index is a `MultiIndex` the sort direction can be controlled for each level individually.

inplace [bool, default `False`] If `True`, perform operation in-place.

kind [{`'quicksort'`, `'mergesort'`, `'heapsort'`, `'stable'`}, default `'quicksort'`] Choice of sorting algorithm. See also `numpy.sort()` for more information. `'mergesort'` and `'stable'` are the only stable algorithms. For `DataFrames`, this option is only applied when sorting on a single column or label.

na_position [{`'first'`, `'last'`}, default `'last'`] If `'first'` puts `NaNs` at the beginning, `'last'` puts `NaNs` at the end. Not implemented for `MultiIndex`.

sort_remaining [bool, default `True`] If `True` and sorting by level and index is multilevel, sort by other levels too (in order) after sorting by specified level.

ignore_index [bool, default `False`] If `True`, the resulting axis will be labeled 0, 1, ..., n - 1.

New in version 1.0.0.

key [callable, optional] If not `None`, apply the key function to the index values before sorting. This is similar to the *key* argument in the builtin `sorted()` function, with the notable difference that this *key* function should be *vectorized*. It should expect an `Index` and return an `Index` of the same shape.

New in version 1.1.0.

Returns

Series or None The original Series sorted by the labels or `None` if `inplace=True`.

See also:

[`DataFrame.sort_index`](#) Sort `DataFrame` by the index.

[`DataFrame.sort_values`](#) Sort `DataFrame` by the value.

[`Series.sort_values`](#) Sort Series by the value.

Examples

```
>>> s = pd.Series(['a', 'b', 'c', 'd'], index=[3, 2, 1, 4])
>>> s.sort_index()
1    c
2    b
3    a
4    d
dtype: object
```

Sort Descending

```
>>> s.sort_index(ascending=False)
4    d
3    a
2    b
1    c
dtype: object
```

Sort Inplace

```
>>> s.sort_index(inplace=True)
>>> s
1    c
2    b
3    a
4    d
dtype: object
```

By default NaNs are put at the end, but use *na_position* to place them at the beginning

```
>>> s = pd.Series(['a', 'b', 'c', 'd'], index=[3, 2, 1, np.nan])
>>> s.sort_index(na_position='first')
NaN    d
1.0    c
2.0    b
3.0    a
dtype: object
```

Specify index level to sort

```
>>> arrays = [np.array(['qux', 'qux', 'foo', 'foo',
...                    'baz', 'baz', 'bar', 'bar']),
...           np.array(['two', 'one', 'two', 'one',
...                    'two', 'one', 'two', 'one'])]
>>> s = pd.Series([1, 2, 3, 4, 5, 6, 7, 8], index=arrays)
>>> s.sort_index(level=1)
bar one    8
baz one    6
foo one    4
qux one    2
bar two    7
baz two    5
foo two    3
```

(continues on next page)

(continued from previous page)

```
qux two 1
dtype: int64
```

Does not sort by remaining levels when sorting by levels

```
>>> s.sort_index(level=1, sort_remaining=False)
qux one 2
foo one 4
baz one 6
bar one 8
qux two 1
foo two 3
baz two 5
bar two 7
dtype: int64
```

Apply a key function before sorting

```
>>> s = pd.Series([1, 2, 3, 4], index=['A', 'b', 'C', 'd'])
>>> s.sort_index(key=lambda x : x.str.lower())
A 1
b 2
C 3
d 4
dtype: int64
```

pandas.Series.sort_values

`Series.sort_values` (*axis=0, ascending=True, inplace=False, kind='quicksort', na_position='last', ignore_index=False, key=None*)

Sort by the values.

Sort a Series in ascending or descending order by some criterion.

Parameters

axis [{0 or 'index'}, default 0] Axis to direct sorting. The value 'index' is accepted for compatibility with `DataFrame.sort_values`.

ascending [bool or list of bools, default True] If True, sort values in ascending order, otherwise descending.

inplace [bool, default False] If True, perform operation in-place.

kind [{ 'quicksort', 'mergesort', 'heapsort', 'stable' }, default 'quicksort'] Choice of sorting algorithm. See also `numpy.sort()` for more information. 'mergesort' and 'stable' are the only stable algorithms.

na_position [{ 'first' or 'last' }, default 'last'] Argument 'first' puts NaNs at the beginning, 'last' puts NaNs at the end.

ignore_index [bool, default False] If True, the resulting axis will be labeled 0, 1, ..., n - 1.

New in version 1.0.0.

key [callable, optional] If not None, apply the key function to the series values before sorting. This is similar to the *key* argument in the builtin `sorted()` function, with the notable difference that this *key* function should be *vectorized*. It should expect a Series and return an array-like.

New in version 1.1.0.

Returns

Series or None Series ordered by values or None if `inplace=True`.

See also:

[`Series.sort_index`](#) Sort by the Series indices.

[`DataFrame.sort_values`](#) Sort DataFrame by the values along either axis.

[`DataFrame.sort_index`](#) Sort DataFrame by indices.

Examples

```
>>> s = pd.Series([np.nan, 1, 3, 10, 5])
>>> s
0      NaN
1      1.0
2      3.0
3     10.0
4      5.0
dtype: float64
```

Sort values ascending order (default behaviour)

```
>>> s.sort_values(ascending=True)
1      1.0
2      3.0
4      5.0
3     10.0
0      NaN
dtype: float64
```

Sort values descending order

```
>>> s.sort_values(ascending=False)
3     10.0
4      5.0
2      3.0
1      1.0
0      NaN
dtype: float64
```

Sort values inplace

```
>>> s.sort_values(ascending=False, inplace=True)
>>> s
3     10.0
4      5.0
```

(continues on next page)

(continued from previous page)

```
2    3.0
1    1.0
0    NaN
dtype: float64
```

Sort values putting NAs first

```
>>> s.sort_values(na_position='first')
0    NaN
1    1.0
2    3.0
4    5.0
3   10.0
dtype: float64
```

Sort a series of strings

```
>>> s = pd.Series(['z', 'b', 'd', 'a', 'c'])
>>> s
0    z
1    b
2    d
3    a
4    c
dtype: object
```

```
>>> s.sort_values()
3    a
1    b
4    c
2    d
0    z
dtype: object
```

Sort using a key function. Your *key* function will be given the Series of values and should return an array-like.

```
>>> s = pd.Series(['a', 'B', 'c', 'D', 'e'])
>>> s.sort_values()
1    B
3    D
0    a
2    c
4    e
dtype: object
>>> s.sort_values(key=lambda x: x.str.lower())
0    a
1    B
2    c
3    D
4    e
dtype: object
```

NumPy ufuncs work well here. For example, we can sort by the sin of the value

```
>>> s = pd.Series([-4, -2, 0, 2, 4])
>>> s.sort_values(key=np.sin)
1    -2
4     4
2     0
0    -4
3     2
dtype: int64
```

More complicated user-defined functions can be used, as long as they expect a Series and return an array-like

```
>>> s.sort_values(key=lambda x: (np.tan(x.cumsum()))))
0    -4
3     2
4     4
1    -2
2     0
dtype: int64
```

pandas.Series.sparse

Series.sparse()

Accessor for SparseSparse from other sparse matrix data types.

pandas.Series.squeeze

Series.squeeze(axis=None)

Squeeze 1 dimensional axis objects into scalars.

Series or DataFrames with a single element are squeezed to a scalar. DataFrames with a single column or a single row are squeezed to a Series. Otherwise the object is unchanged.

This method is most useful when you don't know if your object is a Series or DataFrame, but you do know it has just a single column. In that case you can safely call *squeeze* to ensure you have a Series.

Parameters

axis [{0 or 'index', 1 or 'columns', None}, default None] A specific axis to squeeze. By default, all length-1 axes are squeezed.

Returns

DataFrame, Series, or scalar The projection after squeezing *axis* or all the axes.

See also:

[Series.iloc](#) Integer-location based indexing for selecting scalars.

[DataFrame.iloc](#) Integer-location based indexing for selecting Series.

[Series.to_frame](#) Inverse of DataFrame.squeeze for a single-column DataFrame.

Examples

```
>>> primes = pd.Series([2, 3, 5, 7])
```

Slicing might produce a Series with a single value:

```
>>> even_primes = primes[primes % 2 == 0]
>>> even_primes
0    2
dtype: int64
```

```
>>> even_primes.squeeze()
2
```

Squeezing objects with more than one value in every axis does nothing:

```
>>> odd_primes = primes[primes % 2 == 1]
>>> odd_primes
1    3
2    5
3    7
dtype: int64
```

```
>>> odd_primes.squeeze()
1    3
2    5
3    7
dtype: int64
```

Squeezing is even more effective when used with DataFrames.

```
>>> df = pd.DataFrame([[1, 2], [3, 4]], columns=['a', 'b'])
>>> df
   a  b
0  1  2
1  3  4
```

Slicing a single column will produce a DataFrame with the columns having only one value:

```
>>> df_a = df[['a']]
>>> df_a
   a
0  1
1  3
```

So the columns can be squeezed down, resulting in a Series:

```
>>> df_a.squeeze('columns')
0    1
1    3
Name: a, dtype: int64
```

Slicing a single row from a single column will produce a single scalar DataFrame:

```
>>> df_0a = df.loc[df.index < 1, ['a']]
>>> df_0a
   a
0  1
```

Squeezing the rows produces a single scalar Series:

```
>>> df_0a.squeeze('rows')
a    1
Name: 0, dtype: int64
```

Squeezing all axes will project directly into a scalar:

```
>>> df_0a.squeeze()
1
```

pandas.Series.std

Series.std(*axis=None, skipna=None, level=None, ddof=1, numeric_only=None, **kwargs*)

Return sample standard deviation over requested axis.

Normalized by N-1 by default. This can be changed using the *ddof* argument

Parameters

axis [{{index (0)}}]

skipna [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

ddof [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is N - ddof, where N represents the number of elements.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

Returns

scalar or Series (if level specified)

Notes

To have the same behaviour as *numpy.std*, use *ddof=0* (instead of the default *ddof=1*)

pandas.Series.str

Series.str()

Vectorized string functions for Series and Index.

NAs stay NA unless handled otherwise by a particular method. Patterned after Python's string methods, with some inspiration from R's stringr package.

Examples

```
>>> s = pd.Series(["A_Str_Series"])
>>> s
0    A_Str_Series
dtype: object
```

```
>>> s.str.split("_")
0    [A, Str, Series]
dtype: object
```

```
>>> s.str.replace("_", "")
0    AStrSeries
dtype: object
```

pandas.Series.sub

Series.sub(*other*, *level=None*, *fill_value=None*, *axis=0*)

Return Subtraction of series and other, element-wise (binary operator *sub*).

Equivalent to `series - other`, but with support to substitute a `fill_value` for missing data in either one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

Series The result of the operation.

See also:

[Series.rsub](#) Reverse of the Subtraction operator, see [Python documentation](#) for more details.

Examples

```

>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.subtract(b, fill_value=0)
a    0.0
b    1.0
c    1.0
d   -1.0
e    NaN
dtype: float64

```

pandas.Series.subtract

`Series.subtract` (*other*, *level=None*, *fill_value=None*, *axis=0*)

Return Subtraction of series and other, element-wise (binary operator *sub*).

Equivalent to `series - other`, but with support to substitute a `fill_value` for missing data in either one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

Series The result of the operation.

See also:

[*Series.rsub*](#) Reverse of the Subtraction operator, see [Python documentation](#) for more details.

Examples

```

>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.subtract(b, fill_value=0)
a    0.0
b    1.0
c    1.0
d   -1.0
e    NaN
dtype: float64

```

pandas.Series.sum

`Series.sum(axis=None, skipna=None, level=None, numeric_only=None, min_count=0, **kwargs)`
 Return the sum of the values over the requested axis.

This is equivalent to the method `numpy.sum`.

Parameters

axis [{index (0)}] Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

min_count [int, default 0] The required number of valid values to perform the operation. If fewer than `min_count` non-NA values are present the result will be NA.

****kwargs** Additional keyword arguments to be passed to the function.

Returns

scalar or Series (if level specified)

See also:

[`Series.sum`](#) Return the sum.

[`Series.min`](#) Return the minimum.

Series.max Return the maximum.

Series.idxmin Return the index of the minimum.

Series.idxmax Return the index of the maximum.

DataFrame.sum Return the sum over the requested axis.

DataFrame.min Return the minimum over the requested axis.

DataFrame.max Return the maximum over the requested axis.

DataFrame.idxmin Return the index of the minimum over the requested axis.

DataFrame.idxmax Return the index of the maximum over the requested axis.

Examples

```
>>> idx = pd.MultiIndex.from_arrays([
...     ['warm', 'warm', 'cold', 'cold'],
...     ['dog', 'falcon', 'fish', 'spider']],
...     names=['blooded', 'animal'])
>>> s = pd.Series([4, 2, 0, 8], name='legs', index=idx)
>>> s
blooded animal
warm      dog      4
          falcon   2
cold     fish      0
          spider   8
Name: legs, dtype: int64
```

```
>>> s.sum()
14
```

By default, the sum of an empty or all-NA Series is 0.

```
>>> pd.Series([], dtype="float64").sum() # min_count=0 is the default
0.0
```

This can be controlled with the `min_count` parameter. For example, if you'd like the sum of an empty series to be NaN, pass `min_count=1`.

```
>>> pd.Series([], dtype="float64").sum(min_count=1)
nan
```

Thanks to the `skipna` parameter, `min_count` handles all-NA and empty series identically.

```
>>> pd.Series([np.nan]).sum()
0.0
```

```
>>> pd.Series([np.nan]).sum(min_count=1)
nan
```

pandas.Series.swapaxes`Series.swapaxes(axis1, axis2, copy=True)`

Interchange axes and swap values axes appropriately.

Returns`y` [same as input]**pandas.Series.swaplevel**`Series.swaplevel(i=-2, j=-1, copy=True)`Swap levels `i` and `j` in a *MultiIndex*.

Default is to swap the two innermost levels of the index.

Parameters`i, j` [int or str] Levels of the indices to be swapped. Can pass level name as string.`copy` [bool, default True] Whether to copy underlying data.**Returns****Series** Series with levels swapped in MultiIndex.**Examples**

```
>>> s = pd.Series(
...     ["A", "B", "A", "C"],
...     index=[
...         ["Final exam", "Final exam", "Coursework", "Coursework"],
...         ["History", "Geography", "History", "Geography"],
...         ["January", "February", "March", "April"],
...     ],
... )
>>> s
Final exam  History    January    A
            Geography  February    B
Coursework  History    March      A
            Geography  April      C
dtype: object
```

In the following example, we will swap the levels of the indices. Here, we will swap the levels column-wise, but levels can be swapped row-wise in a similar manner. Note that column-wise is the default behaviour. By not supplying any arguments for `i` and `j`, we swap the last and second to last indices.

```
>>> s.swaplevel()
Final exam  January    History    A
            February   Geography    B
Coursework  March      History    A
            April      Geography    C
dtype: object
```

By supplying one argument, we can choose which index to swap the last index with. We can for example swap the first index with the last one as follows.

```
>>> s.swaplevel(0)
January      History      Final exam      A
February     Geography     Final exam      B
March        History      Coursework      A
April        Geography     Coursework      C
dtype: object
```

We can also define explicitly which indices we want to swap by supplying values for both *i* and *j*. Here, we for example swap the first and second indices.

```
>>> s.swaplevel(0, 1)
History      Final exam      January      A
Geography    Final exam      February     B
History      Coursework      March        A
Geography    Coursework      April        C
dtype: object
```

pandas.Series.tail

Series.tail(*n*=5)

Return the last *n* rows.

This function returns last *n* rows from the object based on position. It is useful for quickly verifying data, for example, after sorting or appending rows.

For negative values of *n*, this function returns all rows except the first *n* rows, equivalent to `df[n:]`.

Parameters

n [int, default 5] Number of rows to select.

Returns

type of caller The last *n* rows of the caller object.

See also:

[`DataFrame.head`](#) The first *n* rows of the caller object.

Examples

```
>>> df = pd.DataFrame({'animal': ['alligator', 'bee', 'falcon', 'lion',
...                               'monkey', 'parrot', 'shark', 'whale', 'zebra']})
>>> df
   animal
0 alligator
1      bee
2   falcon
3     lion
4  monkey
5  parrot
6   shark
7   whale
8   zebra
```

Viewing the last 5 lines

```
>>> df.tail()
  animal
4  monkey
5  parrot
6   shark
7   whale
8   zebra
```

Viewing the last n lines (three in this case)

```
>>> df.tail(3)
  animal
6  shark
7  whale
8  zebra
```

For negative values of n

```
>>> df.tail(-3)
  animal
3   lion
4  monkey
5  parrot
6   shark
7   whale
8   zebra
```

pandas.Series.take

`Series.take(indices, axis=0, is_copy=None, **kwargs)`

Return the elements in the given *positional* indices along an axis.

This means that we are not indexing according to actual values in the index attribute of the object. We are indexing according to the actual position of the element in the object.

Parameters

indices [array-like] An array of ints indicating which positions to take.

axis [{0 or 'index', 1 or 'columns', None}, default 0] The axis on which to select elements. 0 means that we are selecting rows, 1 means that we are selecting columns.

is_copy [bool] Before pandas 1.0, `is_copy=False` can be specified to ensure that the return value is an actual copy. Starting with pandas 1.0, `take` always returns a copy, and the keyword is therefore deprecated.

Deprecated since version 1.0.0.

****kwargs** For compatibility with `numpy.take()`. Has no effect on the output.

Returns

taken [same type as caller] An array-like containing the elements taken from the object.

See also:

DataFrame.loc Select a subset of a DataFrame by labels.

DataFrame.iloc Select a subset of a DataFrame by positions.

numpy.take Take elements from an array along an axis.

Examples

```
>>> df = pd.DataFrame([('falcon', 'bird', 389.0),
...                    ('parrot', 'bird', 24.0),
...                    ('lion', 'mammal', 80.5),
...                    ('monkey', 'mammal', np.nan)],
...                    columns=['name', 'class', 'max_speed'],
...                    index=[0, 2, 3, 1])
>>> df
   name  class  max_speed
0  falcon  bird    389.0
2  parrot  bird     24.0
3   lion  mammal    80.5
1  monkey  mammal     NaN
```

Take elements at positions 0 and 3 along the axis 0 (default).

Note how the actual indices selected (0 and 1) do not correspond to our selected indices 0 and 3. That's because we are selecting the 0th and 3rd rows, not rows whose indices equal 0 and 3.

```
>>> df.take([0, 3])
   name  class  max_speed
0  falcon  bird    389.0
1  monkey  mammal     NaN
```

Take elements at indices 1 and 2 along the axis 1 (column selection).

```
>>> df.take([1, 2], axis=1)
   class  max_speed
0   bird    389.0
2   bird     24.0
3  mammal     80.5
1  mammal     NaN
```

We may take elements using negative integers for positive indices, starting from the end of the object, just like with Python lists.

```
>>> df.take([-1, -2])
   name  class  max_speed
1  monkey  mammal     NaN
3   lion  mammal    80.5
```

pandas.Series.to_clipboard

`Series.to_clipboard(excel=True, sep=None, **kwargs)`

Copy object to the system clipboard.

Write a text representation of object to the system clipboard. This can be pasted into Excel, for example.

Parameters

excel [bool, default True] Produce output in a csv format for easy pasting into excel.

- True, use the provided separator for csv pasting.
- False, write a string representation of the object to the clipboard.

sep [str, default '\t'] Field delimiter.

****kwargs** These parameters will be passed to `DataFrame.to_csv`.

See also:

[`DataFrame.to_csv`](#) Write a DataFrame to a comma-separated values (csv) file.

[`read_clipboard`](#) Read text from clipboard and pass to `read_table`.

Notes

Requirements for your platform.

- Linux : `xclip`, or `xsel` (with `PyQt4` modules)
- Windows : none
- OS X : none

Examples

Copy the contents of a DataFrame to the clipboard.

```
>>> df = pd.DataFrame([[1, 2, 3], [4, 5, 6]], columns=['A', 'B', 'C'])
```

```
>>> df.to_clipboard(sep=',')
... # Wrote the following to the system clipboard:
... # ,A,B,C
... # 0,1,2,3
... # 1,4,5,6
```

We can omit the index by passing the keyword `index` and setting it to false.

```
>>> df.to_clipboard(sep=',', index=False)
... # Wrote the following to the system clipboard:
... # A,B,C
... # 1,2,3
... # 4,5,6
```

pandas.Series.to_csv

`Series.to_csv(path_or_buf=None, sep=',', na_rep='', float_format=None, columns=None, header=True, index=True, index_label=None, mode='w', encoding=None, compression='infer', quoting=None, quotechar='"', line_terminator=None, chunksize=None, date_format=None, doublequote=True, escapechar=None, decimal='.', errors='strict', storage_options=None)`

Write object to a comma-separated values (csv) file.

Parameters

path_or_buf [str or file handle, default None] File path or object, if None is provided the result is returned as a string. If a non-binary file object is passed, it should be opened with `newline=""`, disabling universal newlines. If a binary file object is passed, `mode` might need to contain a `'b'`.

Changed in version 1.2.0: Support for binary file objects was introduced.

sep [str, default ','] String of length 1. Field delimiter for the output file.

na_rep [str, default ''] Missing data representation.

float_format [str, default None] Format string for floating point numbers.

columns [sequence, optional] Columns to write.

header [bool or list of str, default True] Write out the column names. If a list of strings is given it is assumed to be aliases for the column names.

index [bool, default True] Write row names (index).

index_label [str or sequence, or False, default None] Column label for index column(s) if desired. If None is given, and `header` and `index` are True, then the index names are used. A sequence should be given if the object uses MultiIndex. If False do not print fields for index names. Use `index_label=False` for easier importing in R.

mode [str] Python write mode, default 'w'.

encoding [str, optional] A string representing the encoding to use in the output file, defaults to 'utf-8'. `encoding` is not supported if `path_or_buf` is a non-binary file object.

compression [str or dict, default 'infer'] If str, represents compression mode. If dict, value at 'method' is the compression mode. Compression mode may be any of the following possible values: {'infer', 'gzip', 'bz2', 'zip', 'xz', None}. If compression mode is 'infer' and `path_or_buf` is path-like, then detect compression mode from the following extensions: '.gz', '.bz2', '.zip' or '.xz'. (otherwise no compression). If dict given and mode is one of {'zip', 'gzip', 'bz2'}, or inferred as one of the above, other entries passed as additional compression options.

Changed in version 1.0.0: May now be a dict with key 'method' as compression mode and other entries as additional compression options if compression mode is 'zip'.

Changed in version 1.1.0: Passing compression options as keys in dict is supported for compression modes 'gzip' and 'bz2' as well as 'zip'.

Changed in version 1.2.0: Compression is supported for binary file objects.

Changed in version 1.2.0: Previous versions forwarded dict entries for 'gzip' to `gzip.open` instead of `gzip.GzipFile` which prevented setting `mtime`.

quoting [optional constant from csv module] Defaults to `csv.QUOTE_MINIMAL`. If you have set a *float_format* then floats are converted to strings and thus `csv.QUOTE_NONNUMERIC` will treat them as non-numeric.

quotechar [str, default `"`] String of length 1. Character used to quote fields.

line_terminator [str, optional] The newline character or character sequence to use in the output file. Defaults to `os.linesep`, which depends on the OS in which this method is called (`'\n'` for linux, `'\r\n'` for Windows, i.e.).

chunksize [int or None] Rows to write at a time.

date_format [str, default None] Format string for datetime objects.

doublequote [bool, default True] Control quoting of *quotechar* inside a field.

escapechar [str, default None] String of length 1. Character used to escape *sep* and *quotechar* when appropriate.

decimal [str, default `'.'`] Character recognized as decimal separator. E.g. use `'.'` for European data.

errors [str, default `'strict'`] Specifies how encoding and decoding errors are to be handled. See the `errors` argument for `open()` for a full list of options.

New in version 1.1.0.

storage_options [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to `urllib` as header options. For other URLs (e.g. starting with `"s3://"`, and `"gcs://"`) the key-value pairs are forwarded to `fsspec`. Please see `fsspec` and `urllib` for more details.

New in version 1.2.0.

Returns

None or str If `path_or_buf` is None, returns the resulting csv format as a string. Otherwise returns None.

See also:

[`read_csv`](#) Load a CSV file into a DataFrame.

[`to_excel`](#) Write DataFrame to an Excel file.

Examples

```
>>> df = pd.DataFrame({'name': ['Raphael', 'Donatello'],
...                   'mask': ['red', 'purple'],
...                   'weapon': ['sai', 'bo staff']})
>>> df.to_csv(index=False)
'name,mask,weapon\nRaphael,red,sai\nDonatello,purple,bo staff\n'
```

Create `'out.zip'` containing `'out.csv'`

```
>>> compression_opts = dict(method='zip',
...                          archive_name='out.csv')
>>> df.to_csv('out.zip', index=False,
...           compression=compression_opts)
```

pandas.Series.to_dict

`Series.to_dict(into=<class 'dict'>)`

Convert Series to {label -> value} dict or dict-like object.

Parameters

into [class, default dict] The collections.abc.Mapping subclass to use as the return object. Can be the actual class or an empty instance of the mapping type you want. If you want a collections.defaultdict, you must pass it initialized.

Returns

collections.abc.Mapping Key-value representation of Series.

Examples

```

>>> s = pd.Series([1, 2, 3, 4])
>>> s.to_dict()
{0: 1, 1: 2, 2: 3, 3: 4}
>>> from collections import OrderedDict, defaultdict
>>> s.to_dict(OrderedDict)
OrderedDict([(0, 1), (1, 2), (2, 3), (3, 4)])
>>> dd = defaultdict(list)
>>> s.to_dict(dd)
defaultdict(<class 'list'>, {0: 1, 1: 2, 2: 3, 3: 4})

```

pandas.Series.to_excel

`Series.to_excel(excel_writer, sheet_name='Sheet1', na_rep="", float_format=None, columns=None, header=True, index=True, index_label=None, startrow=0, startcol=0, engine=None, merge_cells=True, encoding=None, inf_rep='inf', verbose=True, freeze_panes=None, storage_options=None)`

Write object to an Excel sheet.

To write a single object to an Excel .xlsx file it is only necessary to specify a target file name. To write to multiple sheets it is necessary to create an *ExcelWriter* object with a target file name, and specify a sheet in the file to write to.

Multiple sheets may be written to by specifying unique *sheet_name*. With all data written to the file it is necessary to save the changes. Note that creating an *ExcelWriter* object with a file name that already exists will result in the contents of the existing file being erased.

Parameters

excel_writer [path-like, file-like, or ExcelWriter object] File path or existing ExcelWriter.

sheet_name [str, default 'Sheet1'] Name of sheet which will contain DataFrame.

na_rep [str, default ''] Missing data representation.

float_format [str, optional] Format string for floating point numbers. For example `float_format="% .2f"` will format 0.1234 to 0.12.

columns [sequence or list of str, optional] Columns to write.

header [bool or list of str, default True] Write out the column names. If a list of string is given it is assumed to be aliases for the column names.

index [bool, default True] Write row names (index).

index_label [str or sequence, optional] Column label for index column(s) if desired. If not specified, and *header* and *index* are True, then the index names are used. A sequence should be given if the DataFrame uses MultiIndex.

startrow [int, default 0] Upper left cell row to dump data frame.

startcol [int, default 0] Upper left cell column to dump data frame.

engine [str, optional] Write engine to use, 'openpyxl' or 'xlsxwriter'. You can also set this via the options `io.excel.xlsx.writer`, `io.excel.xls.writer`, and `io.excel.xlsm.writer`.

Deprecated since version 1.2.0: As the `xlwt` package is no longer maintained, the `xlwt` engine will be removed in a future version of pandas.

merge_cells [bool, default True] Write MultiIndex and Hierarchical Rows as merged cells.

encoding [str, optional] Encoding of the resulting excel file. Only necessary for `xlwt`, other writers support unicode natively.

inf_rep [str, default 'inf'] Representation for infinity (there is no native representation for infinity in Excel).

verbose [bool, default True] Display more information in the error logs.

freeze_panes [tuple of int (length 2), optional] Specifies the one-based bottommost row and rightmost column that is to be frozen.

storage_options [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to `urllib` as header options. For other URLs (e.g. starting with "s3://", and "gcs://") the key-value pairs are forwarded to `fsspec`. Please see `fsspec` and `urllib` for more details.

New in version 1.2.0.

See also:

`to_csv` Write DataFrame to a comma-separated values (csv) file.

`ExcelWriter` Class for writing DataFrame objects into excel sheets.

`read_excel` Read an Excel file into a pandas DataFrame.

`read_csv` Read a comma-separated values (csv) file into DataFrame.

Notes

For compatibility with `to_csv()`, `to_excel` serializes lists and dicts to strings before writing.

Once a workbook has been saved it is not possible to write further data without rewriting the whole workbook.

Examples

Create, write to and save a workbook:

```
>>> df1 = pd.DataFrame([[ 'a', 'b'], [ 'c', 'd']],
...                     index=[ 'row 1', 'row 2'],
...                     columns=[ 'col 1', 'col 2'])
>>> df1.to_excel("output.xlsx")
```

To specify the sheet name:

```
>>> df1.to_excel("output.xlsx",
...              sheet_name='Sheet_name_1')
```

If you wish to write to more than one sheet in the workbook, it is necessary to specify an `ExcelWriter` object:

```
>>> df2 = df1.copy()
>>> with pd.ExcelWriter('output.xlsx') as writer:
...     df1.to_excel(writer, sheet_name='Sheet_name_1')
...     df2.to_excel(writer, sheet_name='Sheet_name_2')
```

`ExcelWriter` can also be used to append to an existing Excel file:

```
>>> with pd.ExcelWriter('output.xlsx',
...                     mode='a') as writer:
...     df.to_excel(writer, sheet_name='Sheet_name_3')
```

To set the library that is used to write the Excel file, you can pass the `engine` keyword (the default engine is automatically chosen depending on the file extension):

```
>>> df1.to_excel('output1.xlsx', engine='xlsxwriter')
```

pandas.Series.to_frame

`Series.to_frame(name=None)`

Convert Series to DataFrame.

Parameters

name [object, default None] The passed name should substitute for the series name (if it has one).

Returns

DataFrame DataFrame representation of Series.

Examples

```
>>> s = pd.Series(["a", "b", "c"],
...               name="vals")
>>> s.to_frame()
   vals
0     a
1     b
2     c
```

pandas.Series.to_hdf

`Series.to_hdf`(*path_or_buf*, *key*, *mode*='a', *complevel*=None, *complib*=None, *append*=False, *format*=None, *index*=True, *min_itemsize*=None, *nan_rep*=None, *dropna*=None, *data_columns*=None, *errors*='strict', *encoding*='UTF-8')

Write the contained data to an HDF5 file using HDFStore.

Hierarchical Data Format (HDF) is self-describing, allowing an application to interpret the structure and contents of a file with no outside information. One HDF file can hold a mix of related objects which can be accessed as a group or as individual objects.

In order to add another DataFrame or Series to an existing HDF file please use append mode and a different a key.

Warning: One can store a subclass of DataFrame or Series to HDF5, but the type of the subclass is lost upon storing.

For more information see the *user guide*.

Parameters

path_or_buf [str or pandas.HDFStore] File path or HDFStore object.

key [str] Identifier for the group in the store.

mode [{ 'a', 'w', 'r+' }, default 'a'] Mode to open file:

- 'w': write, a new file is created (an existing file with the same name would be deleted).
- 'a': append, an existing file is opened for reading and writing, and if the file does not exist it is created.
- 'r+': similar to 'a', but the file must already exist.

complevel [{0-9}, optional] Specifies a compression level for data. A value of 0 disables compression.

complib [{ 'zlib', 'lzo', 'bzip2', 'blosc' }, default 'zlib'] Specifies the compression library to be used. As of v0.20.2 these additional compressors for Blosc are supported (default if no compressor specified: 'blosc:blosclz'): { 'blosc:blosclz', 'blosc:lz4', 'blosc:lz4hc', 'blosc:snappy', 'blosc:zlib', 'blosc:zstd' }. Specifying a compression library which is not available issues a ValueError.

append [bool, default False] For Table formats, append the input data to the existing.

format [{ 'fixed', 'table', None }, default 'fixed'] Possible values:

- ‘fixed’: Fixed format. Fast writing/reading. Not-appendable, nor searchable.
- ‘table’: Table format. Write as a PyTables Table structure which may perform worse but allow more flexible operations like searching / selecting subsets of the data.
- If None, `pd.get_option('io.hdf.default_format')` is checked, followed by fall-back to “fixed”

errors [str, default ‘strict’] Specifies how encoding and decoding errors are to be handled. See the errors argument for `open()` for a full list of options.

encoding [str, default “UTF-8”]

min_itemsize [dict or int, optional] Map column names to minimum string sizes for columns.

nan_rep [Any, optional] How to represent null values as str. Not allowed with `append=True`.

data_columns [list of columns or True, optional] List of columns to create as indexed data columns for on-disk queries, or True to use all columns. By default only the axes of the object are indexed. See [Query via data columns](#). Applicable only to `format='table'`.

See also:

[read_hdf](#) Read from HDF file.

[DataFrame.to_parquet](#) Write a DataFrame to the binary parquet format.

[DataFrame.to_sql](#) Write to a SQL table.

[DataFrame.to_feather](#) Write out feather-format for DataFrames.

[DataFrame.to_csv](#) Write out to a csv file.

Examples

```
>>> df = pd.DataFrame({'A': [1, 2, 3], 'B': [4, 5, 6]},
...                   index=['a', 'b', 'c'])
>>> df.to_hdf('data.h5', key='df', mode='w')
```

We can add another object to the same file:

```
>>> s = pd.Series([1, 2, 3, 4])
>>> s.to_hdf('data.h5', key='s')
```

Reading from HDF file:

```
>>> pd.read_hdf('data.h5', 'df')
A  B
a  1  4
b  2  5
c  3  6
>>> pd.read_hdf('data.h5', 's')
0    1
1    2
```

(continues on next page)

(continued from previous page)

```
2    3
3    4
dtype: int64
```

Deleting file with data:

```
>>> import os
>>> os.remove('data.h5')
```

pandas.Series.to_json

`Series.to_json(path_or_buf=None, orient=None, date_format=None, double_precision=10, force_ascii=True, date_unit='ms', default_handler=None, lines=False, compression='infer', index=True, indent=None, storage_options=None)`

Convert the object to a JSON string.

Note NaN's and None will be converted to null and datetime objects will be converted to UNIX timestamps.

Parameters

path_or_buf [str or file handle, optional] File path or object. If not specified, the result is returned as a string.

orient [str] Indication of expected JSON string format.

- Series:
 - default is 'index'
 - allowed values are: {'split', 'records', 'index', 'table'}.
- DataFrame:
 - default is 'columns'
 - allowed values are: {'split', 'records', 'index', 'columns', 'values', 'table'}.
- The format of the JSON string:
 - 'split' : dict like {'index' -> [index], 'columns' -> [columns], 'data' -> [values]}
 - 'records' : list like [{column -> value}, ... , {column -> value}]
 - 'index' : dict like {index -> {column -> value}}
 - 'columns' : dict like {column -> {index -> value}}
 - 'values' : just the values array
 - 'table' : dict like {'schema': {schema}, 'data': {data}}

Describing the data, where data component is like `orient='records'`.

date_format [{None, 'epoch', 'iso'}] Type of date conversion. 'epoch' = epoch milliseconds, 'iso' = ISO8601. The default depends on the *orient*. For `orient='table'`, the default is 'iso'. For all other orients, the default is 'epoch'.

double_precision [int, default 10] The number of decimal places to use when encoding floating point values.

force_ascii [bool, default True] Force encoded string to be ASCII.

date_unit [str, default 'ms' (milliseconds)] The time unit to encode to, governs timestamp and ISO8601 precision. One of 's', 'ms', 'us', 'ns' for second, millisecond, microsecond, and nanosecond respectively.

default_handler [callable, default None] Handler to call if object cannot otherwise be converted to a suitable format for JSON. Should receive a single argument which is the object to convert and return a serialisable object.

lines [bool, default False] If 'orient' is 'records' write out line-delimited json format. Will throw ValueError if incorrect 'orient' since others are not list-like.

compression [{ 'infer', 'gzip', 'bz2', 'zip', 'xz', None}] A string representing the compression to use in the output file, only used when the first argument is a filename. By default, the compression is inferred from the filename.

index [bool, default True] Whether to include the index values in the JSON string. Not including the index (`index=False`) is only supported when orient is 'split' or 'table'.

indent [int, optional] Length of whitespace used to indent each record.

New in version 1.0.0.

storage_options [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to `urllib` as header options. For other URLs (e.g. starting with "s3://", and "gcs://") the key-value pairs are forwarded to `fsspec`. Please see `fsspec` and `urllib` for more details.

New in version 1.2.0.

Returns

None or str If `path_or_buf` is None, returns the resulting json format as a string. Otherwise returns None.

See also:

read_json Convert a JSON string to pandas object.

Notes

The behavior of `indent=0` varies from the `stdlib`, which does not indent the output but does insert newlines. Currently, `indent=0` and the default `indent=None` are equivalent in pandas, though this may change in a future release.

`orient='table'` contains a 'pandas_version' field under 'schema'. This stores the version of *pandas* used in the latest revision of the schema.

Examples

```
>>> import json
>>> df = pd.DataFrame(
...     [ ["a", "b"], ["c", "d"] ],
...     index=["row 1", "row 2"],
...     columns=["col 1", "col 2"],
... )
```

```
>>> result = df.to_json(orient="split")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
{
  "columns": [
    "col 1",
    "col 2"
  ],
  "index": [
    "row 1",
    "row 2"
  ],
  "data": [
    [
      "a",
      "b"
    ],
    [
      "c",
      "d"
    ]
  ]
}
```

Encoding/decoding a Dataframe using 'records' formatted JSON. Note that index labels are not preserved with this encoding.

```
>>> result = df.to_json(orient="records")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
[
  {
    "col 1": "a",
    "col 2": "b"
  },
  {
    "col 1": "c",
    "col 2": "d"
  }
]
```

Encoding/decoding a Dataframe using 'index' formatted JSON:

```
>>> result = df.to_json(orient="index")
```

(continues on next page)

(continued from previous page)

```
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
{
  "row 1": {
    "col 1": "a",
    "col 2": "b"
  },
  "row 2": {
    "col 1": "c",
    "col 2": "d"
  }
}
```

Encoding/decoding a Dataframe using 'columns' formatted JSON:

```
>>> result = df.to_json(orient="columns")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
{
  "col 1": {
    "row 1": "a",
    "row 2": "c"
  },
  "col 2": {
    "row 1": "b",
    "row 2": "d"
  }
}
```

Encoding/decoding a Dataframe using 'values' formatted JSON:

```
>>> result = df.to_json(orient="values")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
[
  [
    "a",
    "b"
  ],
  [
    "c",
    "d"
  ]
]
```

Encoding with Table Schema:

```
>>> result = df.to_json(orient="table")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
{
  "schema": {
    "fields": [
```

(continues on next page)

(continued from previous page)

```

        {
            "name": "index",
            "type": "string"
        },
        {
            "name": "col 1",
            "type": "string"
        },
        {
            "name": "col 2",
            "type": "string"
        }
    ],
    "primaryKey": [
        "index"
    ],
    "pandas_version": "0.20.0"
},
"data": [
    {
        "index": "row 1",
        "col 1": "a",
        "col 2": "b"
    },
    {
        "index": "row 2",
        "col 1": "c",
        "col 2": "d"
    }
]
}

```

pandas.Series.to_latex

`Series.to_latex`(*buf=None, columns=None, col_space=None, header=True, index=True, na_rep='NaN', formatters=None, float_format=None, sparsify=None, index_names=True, bold_rows=False, column_format=None, longtable=None, escape=None, encoding=None, decimal='.', multicolumn=None, multicolumn_format=None, multirow=None, caption=None, label=None, position=None*)

Render object to a LaTeX tabular, longtable, or nested table/tabular.

Requires `\usepackage{booktabs}`. The output can be copy/pasted into a main LaTeX document or read from an external file with `\input{table.tex}`.

Changed in version 1.0.0: Added caption and label arguments.

Changed in version 1.2.0: Added position argument, changed meaning of caption argument.

Parameters

buf [str, Path or StringIO-like, optional, default None] Buffer to write to. If None, the output is returned as a string.

columns [list of label, optional] The subset of columns to write. Writes all columns by default.

col_space [int, optional] The minimum width of each column.

header [bool or list of str, default True] Write out the column names. If a list of strings is given, it is assumed to be aliases for the column names.

index [bool, default True] Write row names (index).

na_rep [str, default 'NaN'] Missing data representation.

formatters [list of functions or dict of {str: function}, optional] Formatter functions to apply to columns' elements by position or name. The result of each function must be a unicode string. List must be of length equal to the number of columns.

float_format [one-parameter function or str, optional, default None] Formatter for floating point numbers. For example `float_format="% .2f"` and `float_format="{:0.2f}"`. `format` will both result in 0.1234 being formatted as 0.12.

sparsify [bool, optional] Set to False for a DataFrame with a hierarchical index to print every multiindex key at each row. By default, the value will be read from the config module.

index_names [bool, default True] Prints the names of the indexes.

bold_rows [bool, default False] Make the row labels bold in the output.

column_format [str, optional] The columns format as specified in [LaTeX table format](#) e.g. 'rcl' for 3 columns. By default, 'l' will be used for all columns except columns of numbers, which default to 'r'.

longtable [bool, optional] By default, the value will be read from the pandas config module. Use a longtable environment instead of tabular. Requires adding a `usepackage{longtable}` to your LaTeX preamble.

escape [bool, optional] By default, the value will be read from the pandas config module. When set to False prevents from escaping latex special characters in column names.

encoding [str, optional] A string representing the encoding to use in the output file, defaults to 'utf-8'.

decimal [str, default '.'] Character recognized as decimal separator, e.g. ',' in Europe.

multicolumn [bool, default True] Use multicolumn to enhance MultiIndex columns. The default will be read from the config module.

multicolumn_format [str, default 'l'] The alignment for multicolumns, similar to `column_format` The default will be read from the config module.

multirow [bool, default False] Use multirow to enhance MultiIndex rows. Requires adding a `usepackage{multirow}` to your LaTeX preamble. Will print centered labels (instead of top-aligned) across the contained rows, separating groups via clines. The default will be read from the pandas config module.

caption [str or tuple, optional] Tuple (full_caption, short_caption), which results in `\caption[short_caption]{full_caption}`; if a single string is passed, no short caption will be set.

New in version 1.0.0.

Changed in version 1.2.0: Optionally allow caption to be a tuple (full_caption, short_caption).

label [str, optional] The LaTeX label to be placed inside `\label{}` in the output. This is used with `\ref{}` in the main `.tex` file.

New in version 1.0.0.

position [str, optional] The LaTeX positional argument for tables, to be placed after `\begin{}` in the output.

New in version 1.2.0.

Returns

str or None If `buf` is `None`, returns the result as a string. Otherwise returns `None`.

See also:

[`DataFrame.to_string`](#) Render a DataFrame to a console-friendly tabular output.

[`DataFrame.to_html`](#) Render a DataFrame as an HTML table.

Examples

```
>>> df = pd.DataFrame(dict(name=['Raphael', 'Donatello'],
...                          mask=['red', 'purple'],
...                          weapon=['sai', 'bo staff']))
>>> print(df.to_latex(index=False))
\begin{tabular}{lll}
\toprule
name & mask & weapon \\
\midrule
Raphael & red & sai \\
Donatello & purple & bo staff \\
\bottomrule
\end{tabular}
```

[`pandas.Series.to_list`](#)

`Series.to_list()`

Return a list of the values.

These are each a scalar type, which is a Python scalar (for str, int, float) or a pandas scalar (for Timestamp/Timedelta/Interval/Period)

Returns

list

See also:

[`numpy.ndarray.tolist`](#) Return the array as an `n`-dim-levels deep nested list of Python scalars.

pandas.Series.to_markdown

`Series.to_markdown(buf=None, mode='wt', index=True, storage_options=None, **kwargs)`
 Print Series in Markdown-friendly format.

New in version 1.0.0.

Parameters

buf [str, Path or StringIO-like, optional, default None] Buffer to write to. If None, the output is returned as a string.

mode [str, optional] Mode in which file is opened, “wt” by default.

index [bool, optional, default True] Add index (row) labels.

New in version 1.1.0.

storage_options [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to `urllib` as header options. For other URLs (e.g. starting with “s3://”, and “gcs://”) the key-value pairs are forwarded to `fsspec`. Please see `fsspec` and `urllib` for more details.

New in version 1.2.0.

****kwargs** These parameters will be passed to `tabulate`.

Returns

str Series in Markdown-friendly format.

Notes

Requires the `tabulate` package.

Examples

```
>>> s = pd.Series(["elk", "pig", "dog", "quetzal"], name="animal")
>>> print(s.to_markdown())
|   | animal |
|---:|:-----|
| 0 | elk     |
| 1 | pig     |
| 2 | dog     |
| 3 | quetzal |
```

Output markdown with a tabulate option.

```
>>> print(s.to_markdown(tablefmt="grid"))
+----+-----+
|   | animal |
+====+=====+
| 0 | elk     |
+----+-----+
| 1 | pig     |
+----+-----+
```

(continues on next page)

(continued from previous page)

```

| 2 | dog      |
+---+-----+
| 3 | quetzal  |
+---+-----+

```

pandas.Series.to_numpy

`Series.to_numpy(dtype=None, copy=False, na_value=NoDefault.no_default, **kwargs)`

A NumPy ndarray representing the values in this Series or Index.

Parameters

dtype [str or numpy.dtype, optional] The dtype to pass to `numpy.asarray()`.

copy [bool, default False] Whether to ensure that the returned value is not a view on another array. Note that `copy=False` does not *ensure* that `to_numpy()` is no-copy. Rather, `copy=True` ensure that a copy is made, even if not strictly necessary.

na_value [Any, optional] The value to use for missing values. The default value depends on *dtype* and the type of the array.

New in version 1.0.0.

****kwargs** Additional keywords passed through to the `to_numpy` method of the underlying array (for extension arrays).

New in version 1.0.0.

Returns

`numpy.ndarray`

See also:

[*Series.array*](#) Get the actual data stored within.

[*Index.array*](#) Get the actual data stored within.

[*DataFrame.to_numpy*](#) Similar method for DataFrame.

Notes

The returned array will be the same up to equality (values equal in *self* will be equal in the returned array; likewise for values that are not equal). When *self* contains an `ExtensionArray`, the dtype may be different. For example, for a category-dtype Series, `to_numpy()` will return a NumPy array and the categorical dtype will be lost.

For NumPy dtypes, this will be a reference to the actual data stored in this Series or Index (assuming `copy=False`). Modifying the result in place will modify the data stored in the Series or Index (not that we recommend doing that).

For extension types, `to_numpy()` *may* require copying data and coercing the result to a NumPy type (possibly object), which may be expensive. When you need a no-copy reference to the underlying data, [*Series.array*](#) should be used instead.

This table lays out the different dtypes and default return types of `to_numpy()` for various dtypes within pandas.

| dtype | array type |
|--------------------|----------------------------------|
| category[T] | ndarray[T] (same dtype as input) |
| period | ndarray[object] (Periods) |
| interval | ndarray[object] (Intervals) |
| IntegerNA | ndarray[object] |
| datetime64[ns] | datetime64[ns] |
| datetime64[ns, tz] | ndarray[object] (Timestamps) |

Examples

```
>>> ser = pd.Series(pd.Categorical(['a', 'b', 'a']))
>>> ser.to_numpy()
array(['a', 'b', 'a'], dtype=object)
```

Specify the *dtype* to control how datetime-aware data is represented. Use *dtype=object* to return an ndarray of pandas *Timestamp* objects, each with the correct *tz*.

```
>>> ser = pd.Series(pd.date_range('2000', periods=2, tz="CET"))
>>> ser.to_numpy(dtype=object)
array([Timestamp('2000-01-01 00:00:00+0100', tz='CET'),
       Timestamp('2000-01-02 00:00:00+0100', tz='CET')],
      dtype=object)
```

Or *dtype='datetime64[ns]'* to return an ndarray of native *datetime64* values. The values are converted to UTC and the timezone info is dropped.

```
>>> ser.to_numpy(dtype="datetime64[ns]")
...
array(['1999-12-31T23:00:00.000000000', '2000-01-01T23:00:00...'],
      dtype='datetime64[ns]')
```

pandas.Series.to_period

Series.to_period(*freq=None, copy=True*)

Convert Series from DatetimeIndex to PeriodIndex.

Parameters

freq [str, default None] Frequency associated with the PeriodIndex.

copy [bool, default True] Whether or not to return a copy.

Returns

Series Series with index converted to PeriodIndex.

pandas.Series.to_pickle

`Series.to_pickle(path, compression='infer', protocol=5, storage_options=None)`
Pickle (serialize) object to file.

Parameters

path [str] File path where the pickled object will be stored.

compression [{ 'infer', 'gzip', 'bz2', 'zip', 'xz', None }, default 'infer'] A string representing the compression to use in the output file. By default, infers from the file extension in specified path. Compression mode may be any of the following possible values: { 'infer', 'gzip', 'bz2', 'zip', 'xz', None }. If compression mode is 'infer' and path_or_buf is path-like, then detect compression mode from the following extensions: '.gz', '.bz2', '.zip' or '.xz'. (otherwise no compression). If dict given and mode is 'zip' or inferred as 'zip', other entries passed as additional compression options.

protocol [int] Int which indicates which protocol should be used by the pickler, default HIGHEST_PROTOCOL (see [1] paragraph 12.1.2). The possible values are 0, 1, 2, 3, 4, 5. A negative value for the protocol parameter is equivalent to setting its value to HIGHEST_PROTOCOL.

storage_options [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to `urllib` as header options. For other URLs (e.g. starting with "s3://", and "gcs://") the key-value pairs are forwarded to `fsspec`. Please see `fsspec` and `urllib` for more details.

New in version 1.2.0.

[`read_pickle`](#) Load pickled pandas object (or any object) from file.

[`DataFrame.to_hdf`](#) Write DataFrame to an HDF5 file.

[`DataFrame.to_sql`](#) Write DataFrame to a SQL database.

[`DataFrame.to_parquet`](#) Write a DataFrame to the binary parquet format.

Examples

```
>>> original_df = pd.DataFrame({"foo": range(5), "bar": range(5, 10)})
>>> original_df
   foo  bar
0    0    5
1    1    6
2    2    7
3    3    8
4    4    9
>>> original_df.to_pickle("./dummy.pkl")
```

```
>>> unpickled_df = pd.read_pickle("./dummy.pkl")
>>> unpickled_df
   foo  bar
```

(continues on next page)

(continued from previous page)

```

0    0    5
1    1    6
2    2    7
3    3    8
4    4    9

```

```

>>> import os
>>> os.remove("./dummy.pkl")

```

pandas.Series.to_sql

`Series.to_sql(name, con, schema=None, if_exists='fail', index=True, index_label=None, chunksize=None, dtype=None, method=None)`

Write records stored in a DataFrame to a SQL database.

Databases supported by SQLAlchemy [1] are supported. Tables can be newly created, appended to, or overwritten.

Parameters

name [str] Name of SQL table.

con [sqlalchemy.engine.(Engine or Connection) or sqlite3.Connection] Using SQLAlchemy makes it possible to use any DB supported by that library. Legacy support is provided for sqlite3.Connection objects. The user is responsible for engine disposal and connection closure for the SQLAlchemy connectable See [here](#).

schema [str, optional] Specify the schema (if database flavor supports this). If None, use default schema.

if_exists [{ 'fail', 'replace', 'append' }, default 'fail'] How to behave if the table already exists.

- fail: Raise a ValueError.
- replace: Drop the table before inserting new values.
- append: Insert new values to the existing table.

index [bool, default True] Write DataFrame index as a column. Uses *index_label* as the column name in the table.

index_label [str or sequence, default None] Column label for index column(s). If None is given (default) and *index* is True, then the index names are used. A sequence should be given if the DataFrame uses MultiIndex.

chunksize [int, optional] Specify the number of rows in each batch to be written at a time. By default, all rows will be written at once.

dtype [dict or scalar, optional] Specifying the datatype for columns. If a dictionary is used, the keys should be the column names and the values should be the SQLAlchemy types or strings for the sqlite3 legacy mode. If a scalar is provided, it will be applied to all columns.

method [{None, 'multi', callable}, optional] Controls the SQL insertion clause used:

- None : Uses standard SQL INSERT clause (one per row).
- 'multi': Pass multiple values in a single INSERT clause.

- callable with signature (pd_table, conn, keys, data_iter).

Details and a sample callable implementation can be found in the section *insert method*.

Raises

ValueError When the table already exists and *if_exists* is 'fail' (the default).

See also:

[read_sql](#) Read a DataFrame from a table.

Notes

Timezone aware datetime columns will be written as `Timestamp` with `timezone` type with SQLAlchemy if supported by the database. Otherwise, the datetimes will be stored as timezone unaware timestamps local to the original timezone.

References

[1], [2]

Examples

Create an in-memory SQLite database.

```
>>> from sqlalchemy import create_engine
>>> engine = create_engine('sqlite://', echo=False)
```

Create a table from scratch with 3 rows.

```
>>> df = pd.DataFrame({'name' : ['User 1', 'User 2', 'User 3']})
>>> df
   name
0  User 1
1  User 2
2  User 3
```

```
>>> df.to_sql('users', con=engine)
>>> engine.execute("SELECT * FROM users").fetchall()
[(0, 'User 1'), (1, 'User 2'), (2, 'User 3')]
```

An `sqlalchemy.engine.Connection` can also be passed to `con`:

```
>>> with engine.begin() as connection:
...     df1 = pd.DataFrame({'name' : ['User 4', 'User 5']})
...     df1.to_sql('users', con=connection, if_exists='append')
```

This is allowed to support operations that require that the same DBAPI connection is used for the entire operation.

```
>>> df2 = pd.DataFrame({'name' : ['User 6', 'User 7']})
>>> df2.to_sql('users', con=engine, if_exists='append')
>>> engine.execute("SELECT * FROM users").fetchall()
[(0, 'User 1'), (1, 'User 2'), (2, 'User 3'),
 (0, 'User 4'), (1, 'User 5'), (0, 'User 6'),
 (1, 'User 7')]
```

Overwrite the table with just df2.

```
>>> df2.to_sql('users', con=engine, if_exists='replace',
...           index_label='id')
>>> engine.execute("SELECT * FROM users").fetchall()
[(0, 'User 6'), (1, 'User 7')]
```

Specify the dtype (especially useful for integers with missing values). Notice that while pandas is forced to store the data as floating point, the database supports nullable integers. When fetching the data with Python, we get back integer scalars.

```
>>> df = pd.DataFrame({"A": [1, None, 2]})
>>> df
   A
0  1.0
1  NaN
2  2.0
```

```
>>> from sqlalchemy.types import Integer
>>> df.to_sql('integers', con=engine, index=False,
...         dtype={"A": Integer()})
```

```
>>> engine.execute("SELECT * FROM integers").fetchall()
[(1,), (None,), (2,)]
```

pandas.Series.to_string

`Series.to_string(buf=None, na_rep='NaN', float_format=None, header=True, index=True, length=False, dtype=False, name=False, max_rows=None, min_rows=None)`

Render a string representation of the Series.

Parameters

- buf** [StringIO-like, optional] Buffer to write to.
- na_rep** [str, optional] String representation of NaN to use, default 'NaN'.
- float_format** [one-parameter function, optional] Formatter function to apply to columns' elements if they are floats, default None.
- header** [bool, default True] Add the Series header (index name).
- index** [bool, optional] Add index (row) labels, default True.
- length** [bool, default False] Add the Series length.
- dtype** [bool, default False] Add the Series dtype.
- name** [bool, default False] Add the Series name if not None.

max_rows [int, optional] Maximum number of rows to show before truncating. If None, show all.

min_rows [int, optional] The number of rows to display in a truncated repr (when number of rows is above *max_rows*).

Returns

str or None String representation of Series if buf=None, otherwise None.

pandas.Series.to_timestamp

`Series.to_timestamp(freq=None, how='start', copy=True)`
Cast to DatetimeIndex of Timestamps, at *beginning* of period.

Parameters

freq [str, default frequency of PeriodIndex] Desired frequency.

how [{'s', 'e', 'start', 'end'}] Convention for converting period to timestamp; start of period vs. end.

copy [bool, default True] Whether or not to return a copy.

Returns

Series with DatetimeIndex

pandas.Series.to_xarray

`Series.to_xarray()`
Return an xarray object from the pandas object.

Returns

xarray.DataArray or xarray.Dataset Data in the pandas structure converted to Dataset if the object is a DataFrame, or a DataArray if the object is a Series.

See also:

[*DataFrame.to_hdf*](#) Write DataFrame to an HDF5 file.

[*DataFrame.to_parquet*](#) Write a DataFrame to the binary parquet format.

Notes

See the `xarray` docs

Examples

```
>>> df = pd.DataFrame([('falcon', 'bird', 389.0, 2),
...                    ('parrot', 'bird', 24.0, 2),
...                    ('lion', 'mammal', 80.5, 4),
...                    ('monkey', 'mammal', np.nan, 4)],
...                   columns=['name', 'class', 'max_speed',
...                             'num_legs'])
>>> df
   name  class  max_speed  num_legs
0  falcon   bird    389.0         2
1  parrot   bird     24.0         2
2   lion  mammal     80.5         4
3  monkey  mammal      NaN         4
```

```
>>> df.to_xarray()
<xarray.Dataset>
Dimensions:  (index: 4)
Coordinates:
  * index    (index) int64 0 1 2 3
Data variables:
  name      (index) object 'falcon' 'parrot' 'lion' 'monkey'
  class     (index) object 'bird' 'bird' 'mammal' 'mammal'
  max_speed (index) float64 389.0 24.0 80.5 nan
  num_legs  (index) int64 2 2 4 4
```

```
>>> df['max_speed'].to_xarray()
<xarray.DataArray 'max_speed' (index: 4)>
array([389. , 24. , 80.5,  nan])
Coordinates:
  * index    (index) int64 0 1 2 3
```

```
>>> dates = pd.to_datetime(['2018-01-01', '2018-01-01',
...                          '2018-01-02', '2018-01-02'])
>>> df_multiindex = pd.DataFrame({'date': dates,
...                               'animal': ['falcon', 'parrot',
...                                         'falcon', 'parrot'],
...                               'speed': [350, 18, 361, 15]})
>>> df_multiindex = df_multiindex.set_index(['date', 'animal'])
```

```
>>> df_multiindex
           speed
date  animal
2018-01-01 falcon    350
           parrot     18
2018-01-02 falcon    361
           parrot     15
```

```
>>> df_multiindex.to_xarray()
<xarray.Dataset>
Dimensions:  (animal: 2, date: 2)
Coordinates:
```

(continues on next page)

(continued from previous page)

```
* date      (date) datetime64[ns] 2018-01-01 2018-01-02
* animal    (animal) object 'falcon' 'parrot'
Data variables:
  speed     (date, animal) int64 350 18 361 15
```

pandas.Series.tolist

Series.tolist()

Return a list of the values.

These are each a scalar type, which is a Python scalar (for str, int, float) or a pandas scalar (for Timestamp/Timedelta/Interval/Period)

Returns

list

See also:

[numpy.ndarray.tolist](#) Return the array as an a.ndim-levels deep nested list of Python scalars.

pandas.Series.transform

Series.transform(func, axis=0, *args, **kwargs)

Call func on self producing a Series with transformed values.

Produced Series will have same axis length as self.

Parameters

func [function, str, list-like or dict-like] Function to use for transforming the data. If a function, must either work when passed a Series or when passed to Series.apply. If func is both list-like and dict-like, dict-like behavior takes precedence.

Accepted combinations are:

- function
- string function name
- list-like of functions and/or function names, e.g. [np.exp, 'sqrt']
- dict-like of axis labels -> functions, function names or list-like of such.

axis [{0 or 'index'}] Parameter needed for compatibility with DataFrame.

***args** Positional arguments to pass to *func*.

****kwargs** Keyword arguments to pass to *func*.

Returns

Series A Series that must have the same length as self.

Raises

ValueError [If the returned Series has a different length than self.]

See also:

Series.agg Only perform aggregating type operations.

Series.apply Invoke function on a Series.

Notes

Functions that mutate the passed object can produce unexpected behavior or errors and are not supported. See *Mutating with User Defined Function (UDF) methods* for more details.

Examples

```
>>> df = pd.DataFrame({'A': range(3), 'B': range(1, 4)})
>>> df
   A  B
0  0  1
1  1  2
2  2  3
>>> df.transform(lambda x: x + 1)
   A  B
0  1  2
1  2  3
2  3  4
```

Even though the resulting Series must have the same length as the input Series, it is possible to provide several input functions:

```
>>> s = pd.Series(range(3))
>>> s
0    0
1    1
2    2
dtype: int64
>>> s.transform([np.sqrt, np.exp])
      sqrt      exp
0  0.000000  1.000000
1  1.000000  2.718282
2  1.414214  7.389056
```

You can call transform on a GroupBy object:

```
>>> df = pd.DataFrame({
...     "Date": [
...         "2015-05-08", "2015-05-07", "2015-05-06", "2015-05-05",
...         "2015-05-08", "2015-05-07", "2015-05-06", "2015-05-05"],
...     "Data": [5, 8, 6, 1, 50, 100, 60, 120],
... })
>>> df
   Date  Data
0 2015-05-08    5
1 2015-05-07    8
2 2015-05-06    6
3 2015-05-05    1
```

(continues on next page)

(continued from previous page)

```
4 2015-05-08    50
5 2015-05-07   100
6 2015-05-06    60
7 2015-05-05   120
>>> df.groupby('Date')['Data'].transform('sum')
0     55
1    108
2     66
3    121
4     55
5    108
6     66
7    121
Name: Data, dtype: int64
```

```
>>> df = pd.DataFrame({
...     "c": [1, 1, 1, 2, 2, 2, 2],
...     "type": ["m", "n", "o", "m", "m", "n", "n"]
... })
>>> df
   c type
0  1   m
1  1   n
2  1   o
3  2   m
4  2   m
5  2   n
6  2   n
>>> df['size'] = df.groupby('c')['type'].transform(len)
>>> df
   c type size
0  1   m     3
1  1   n     3
2  1   o     3
3  2   m     4
4  2   m     4
5  2   n     4
6  2   n     4
```

pandas.Series.transpose

`Series.transpose(*args, **kwargs)`

Return the transpose, which is by definition self.

Returns

`%c(klass)s`

pandas.Series.truediv

`Series.truediv`(*other*, *level=None*, *fill_value=None*, *axis=0*)

Return Floating division of series and other, element-wise (binary operator *truediv*).

Equivalent to `series / other`, but with support to substitute a *fill_value* for missing data in either one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

Series The result of the operation.

See also:

[*Series.rtruediv*](#) Reverse of the Floating division operator, see [Python documentation](#) for more details.

Examples

```
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.divide(b, fill_value=0)
a    1.0
b    inf
c    inf
d    0.0
e    NaN
dtype: float64
```

pandas.Series.truncate

`Series.truncate`(*before=None, after=None, axis=None, copy=True*)

Truncate a Series or DataFrame before and after some index value.

This is a useful shorthand for boolean indexing based on index values above or below certain thresholds.

Parameters

before [date, str, int] Truncate all rows before this index value.

after [date, str, int] Truncate all rows after this index value.

axis [{0 or 'index', 1 or 'columns'}, optional] Axis to truncate. Truncates the index (rows) by default.

copy [bool, default is True,] Return a copy of the truncated section.

Returns

type of caller The truncated Series or DataFrame.

See also:

[`DataFrame.loc`](#) Select a subset of a DataFrame by label.

[`DataFrame.iloc`](#) Select a subset of a DataFrame by position.

Notes

If the index being truncated contains only datetime values, *before* and *after* may be specified as strings instead of Timestamps.

Examples

```
>>> df = pd.DataFrame({'A': ['a', 'b', 'c', 'd', 'e'],
...                   'B': ['f', 'g', 'h', 'i', 'j'],
...                   'C': ['k', 'l', 'm', 'n', 'o']},
...                   index=[1, 2, 3, 4, 5])
>>> df
   A  B  C
1  a  f  k
2  b  g  l
3  c  h  m
4  d  i  n
5  e  j  o
```

```
>>> df.truncate(before=2, after=4)
   A  B  C
2  b  g  l
3  c  h  m
4  d  i  n
```

The columns of a DataFrame can be truncated.

```
>>> df.truncate(before="A", after="B", axis="columns")
   A  B
1  a  f
2  b  g
3  c  h
4  d  i
5  e  j
```

For Series, only rows can be truncated.

```
>>> df['A'].truncate(before=2, after=4)
2    b
3    c
4    d
Name: A, dtype: object
```

The index values in truncate can be datetimes or string dates.

```
>>> dates = pd.date_range('2016-01-01', '2016-02-01', freq='s')
>>> df = pd.DataFrame(index=dates, data={'A': 1})
>>> df.tail()
                A
2016-01-31 23:59:56  1
2016-01-31 23:59:57  1
2016-01-31 23:59:58  1
2016-01-31 23:59:59  1
2016-02-01 00:00:00  1
```

```
>>> df.truncate(before=pd.Timestamp('2016-01-05'),
...             after=pd.Timestamp('2016-01-10')).tail()
                A
2016-01-09 23:59:56  1
2016-01-09 23:59:57  1
2016-01-09 23:59:58  1
2016-01-09 23:59:59  1
2016-01-10 00:00:00  1
```

Because the index is a DatetimeIndex containing only dates, we can specify *before* and *after* as strings. They will be coerced to Timestamps before truncation.

```
>>> df.truncate('2016-01-05', '2016-01-10').tail()
                A
2016-01-09 23:59:56  1
2016-01-09 23:59:57  1
2016-01-09 23:59:58  1
2016-01-09 23:59:59  1
2016-01-10 00:00:00  1
```

Note that `truncate` assumes a 0 value for any unspecified time component (midnight). This differs from partial string slicing, which returns any partially matching dates.

```
>>> df.loc['2016-01-05':'2016-01-10', :].tail()
                A
```

(continues on next page)

(continued from previous page)

```

2016-01-10 23:59:56 1
2016-01-10 23:59:57 1
2016-01-10 23:59:58 1
2016-01-10 23:59:59 1

```

pandas.Series.tshift

`Series.tshift`(*periods=1, freq=None, axis=0*)

Shift the time index, using the index's frequency if available.

Deprecated since version 1.1.0: Use *shift* instead.

Parameters

periods [int] Number of periods to move, can be positive or negative.

freq [DateOffset, timedelta, or str, default None] Increment to use from the tseries module or time rule expressed as a string (e.g. 'EOM').

axis [{0 or 'index', 1 or 'columns', None}, default 0] Corresponds to the axis that contains the Index.

Returns

shifted [Series/DataFrame]

Notes

If *freq* is not specified then tries to use the *freq* or *inferred_freq* attributes of the index. If neither of those attributes exist, a `ValueError` is thrown

pandas.Series.tz_convert

`Series.tz_convert`(*tz, axis=0, level=None, copy=True*)

Convert tz-aware axis to target time zone.

Parameters

tz [str or tzinfo object]

axis [the axis to convert]

level [int, str, default None] If axis is a MultiIndex, convert a specific level. Otherwise must be None.

copy [bool, default True] Also make a copy of the underlying data.

Returns

{**klass**} Object with time zone converted axis.

Raises

TypeError If the axis is tz-naive.

pandas.Series.tz_localize

Series.tz_localize(*tz*, *axis=0*, *level=None*, *copy=True*, *ambiguous='raise'*, *nonexistent='raise'*)

Localize tz-naive index of a Series or DataFrame to target time zone.

This operation localizes the Index. To localize the values in a timezone-naive Series, use `Series.dt.tz_localize()`.

Parameters

tz [str or tzinfo]

axis [the axis to localize]

level [int, str, default None] If axis is a MultiIndex, localize a specific level. Otherwise must be None.

copy [bool, default True] Also make a copy of the underlying data.

ambiguous ['infer', bool-ndarray, 'NaT', default 'raise'] When clocks moved backward due to DST, ambiguous times may arise. For example in Central European Time (UTC+01), when going from 03:00 DST to 02:00 non-DST, 02:30:00 local time occurs both at 00:30:00 UTC and at 01:30:00 UTC. In such a situation, the *ambiguous* parameter dictates how ambiguous times should be handled.

- 'infer' will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- 'NaT' will return NaT where there are ambiguous times
- 'raise' will raise an AmbiguousTimeError if there are ambiguous times.

nonexistent [str, default 'raise'] A nonexistent time does not exist in a particular time-zone where clocks moved forward due to DST. Valid values are:

- 'shift_forward' will shift the nonexistent time forward to the closest existing time
- 'shift_backward' will shift the nonexistent time backward to the closest existing time
- 'NaT' will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- 'raise' will raise a NonExistentTimeError if there are nonexistent times.

Returns

Series or DataFrame Same type as the input.

Raises

TypeError If the TimeSeries is tz-aware and tz is not None.

Examples

Localize local times:

```
>>> s = pd.Series([1],
...                 index=pd.DatetimeIndex(['2018-09-15 01:30:00']))
>>> s.tz_localize('CET')
2018-09-15 01:30:00+02:00    1
dtype: int64
```

Be careful with DST changes. When there is sequential data, pandas can infer the DST time:

```
>>> s = pd.Series(range(7),
...                 index=pd.DatetimeIndex(['2018-10-28 01:30:00',
...                                         '2018-10-28 02:00:00',
...                                         '2018-10-28 02:30:00',
...                                         '2018-10-28 02:00:00',
...                                         '2018-10-28 02:30:00',
...                                         '2018-10-28 03:00:00',
...                                         '2018-10-28 03:30:00']))
>>> s.tz_localize('CET', ambiguous='infer')
2018-10-28 01:30:00+02:00    0
2018-10-28 02:00:00+02:00    1
2018-10-28 02:30:00+02:00    2
2018-10-28 02:00:00+01:00    3
2018-10-28 02:30:00+01:00    4
2018-10-28 03:00:00+01:00    5
2018-10-28 03:30:00+01:00    6
dtype: int64
```

In some cases, inferring the DST is impossible. In such cases, you can pass an ndarray to the `ambiguous` parameter to set the DST explicitly

```
>>> s = pd.Series(range(3),
...                 index=pd.DatetimeIndex(['2018-10-28 01:20:00',
...                                         '2018-10-28 02:36:00',
...                                         '2018-10-28 03:46:00']))
>>> s.tz_localize('CET', ambiguous=np.array([True, True, False]))
2018-10-28 01:20:00+02:00    0
2018-10-28 02:36:00+02:00    1
2018-10-28 03:46:00+01:00    2
dtype: int64
```

If the DST transition causes nonexistent times, you can shift these dates forward or backward with a `timedelta` object or `'shift_forward'` or `'shift_backward'`.

```
>>> s = pd.Series(range(2),
...                 index=pd.DatetimeIndex(['2015-03-29 02:30:00',
...                                         '2015-03-29 03:30:00']))
>>> s.tz_localize('Europe/Warsaw', nonexistent='shift_forward')
2015-03-29 03:00:00+02:00    0
2015-03-29 03:30:00+02:00    1
dtype: int64
>>> s.tz_localize('Europe/Warsaw', nonexistent='shift_backward')
```

(continues on next page)

(continued from previous page)

```

2015-03-29 01:59:59.999999999+01:00    0
2015-03-29 03:30:00+02:00          1
dtype: int64
>>> s.tz_localize('Europe/Warsaw', nonexistent=pd.Timedelta('1H'))
2015-03-29 03:30:00+02:00    0
2015-03-29 03:30:00+02:00    1
dtype: int64

```

pandas.Series.unique

Series.unique()

Return unique values of Series object.

Uniques are returned in order of appearance. Hash table-based unique, therefore does NOT sort.

Returns

ndarray or ExtensionArray The unique values returned as a NumPy array. See Notes.

See also:

unique Top-level unique method for any 1-d array-like object.

Index.unique Return Index with unique values from an Index object.

Notes

Returns the unique values as a NumPy array. In case of an extension-array backed Series, a new *ExtensionArray* of that type with just the unique values is returned. This includes

- Categorical
- Period
- Datetime with Timezone
- Interval
- Sparse
- IntegerNA

See Examples section.

Examples

```
>>> pd.Series([2, 1, 3, 3], name='A').unique()
array([2, 1, 3])
```

```
>>> pd.Series([pd.Timestamp('2016-01-01') for _ in range(3)]).unique()
array(['2016-01-01T00:00:00.000000000'], dtype='datetime64[ns]')
```

```
>>> pd.Series([pd.Timestamp('2016-01-01', tz='US/Eastern')
...             for _ in range(3)]).unique()
<DatetimeArray>
['2016-01-01 00:00:00-05:00']
Length: 1, dtype: datetime64[ns, US/Eastern]
```

An Categorical will return categories in the order of appearance and with the same dtype.

```
>>> pd.Series(pd.Categorical(list('baabc'))).unique()
['b', 'a', 'c']
Categories (3, object): ['a', 'b', 'c']
>>> pd.Series(pd.Categorical(list('baabc'), categories=list('abc'),
...                           ordered=True)).unique()
['b', 'a', 'c']
Categories (3, object): ['a' < 'b' < 'c']
```

pandas.Series.unstack

`Series.unstack(level=-1, fill_value=None)`

Unstack, also known as pivot, Series with MultiIndex to produce DataFrame.

Parameters

level [int, str, or list of these, default last level] Level(s) to unstack, can pass level name.

fill_value [scalar value, default None] Value to use when replacing NaN values.

Returns

DataFrame Unstacked Series.

Examples

```
>>> s = pd.Series([1, 2, 3, 4],
...                index=pd.MultiIndex.from_product([['one', 'two'],
...                                                  ['a', 'b']]))
>>> s
one a    1
   b    2
two a    3
   b    4
dtype: int64
```

```
>>> s.unstack(level=-1)
   a  b
one 1  2
two 3  4
```

```
>>> s.unstack(level=0)
   one  two
a    1    3
b    2    4
```

pandas.Series.update**Series.update(*other*)**

Modify Series in place using values from passed Series.

Uses non-NA values from passed Series to make updates. Aligns on index.

Parameters

other [Series, or object coercible into Series]

Examples

```
>>> s = pd.Series([1, 2, 3])
>>> s.update(pd.Series([4, 5, 6]))
>>> s
0    4
1    5
2    6
dtype: int64
```

```
>>> s = pd.Series(['a', 'b', 'c'])
>>> s.update(pd.Series(['d', 'e'], index=[0, 2]))
>>> s
0    d
1    b
2    e
dtype: object
```

```
>>> s = pd.Series([1, 2, 3])
>>> s.update(pd.Series([4, 5, 6, 7, 8]))
>>> s
0    4
1    5
2    6
dtype: int64
```

If *other* contains NaNs the corresponding values are not updated in the original Series.

```
>>> s = pd.Series([1, 2, 3])
>>> s.update(pd.Series([4, np.nan, 6]))
>>> s
0    4
1    2
2    6
dtype: int64
```

other can also be a non-Series object type that is coercible into a Series

```
>>> s = pd.Series([1, 2, 3])
>>> s.update([4, np.nan, 6])
>>> s
0    4
```

(continues on next page)

(continued from previous page)

```
1    2
2    6
dtype: int64
```

```
>>> s = pd.Series([1, 2, 3])
>>> s.update({1: 9})
>>> s
0    1
1    9
2    3
dtype: int64
```

pandas.Series.value_counts

`Series.value_counts`(*normalize=False, sort=True, ascending=False, bins=None, dropna=True*)

Return a Series containing counts of unique values.

The resulting object will be in descending order so that the first element is the most frequently-occurring element. Excludes NA values by default.

Parameters

normalize [bool, default False] If True then the object returned will contain the relative frequencies of the unique values.

sort [bool, default True] Sort by frequencies.

ascending [bool, default False] Sort in ascending order.

bins [int, optional] Rather than count values, group them into half-open bins, a convenience for `pd.cut`, only works with numeric data.

dropna [bool, default True] Don't include counts of NaN.

Returns

Series

See also:

[`Series.count`](#) Number of non-NA elements in a Series.

[`DataFrame.count`](#) Number of non-NA elements in a DataFrame.

[`DataFrame.value_counts`](#) Equivalent method on DataFrames.

Examples

```
>>> index = pd.Index([3, 1, 2, 3, 4, np.nan])
>>> index.value_counts()
3.0    2
1.0    1
2.0    1
4.0    1
dtype: int64
```

With *normalize* set to *True*, returns the relative frequency by dividing all values by the sum of values.

```
>>> s = pd.Series([3, 1, 2, 3, 4, np.nan])
>>> s.value_counts(normalize=True)
3.0    0.4
1.0    0.2
2.0    0.2
4.0    0.2
dtype: float64
```

bins

Bins can be useful for going from a continuous variable to a categorical variable; instead of counting unique apparitions of values, divide the index in the specified number of half-open bins.

```
>>> s.value_counts(bins=3)
(0.996, 2.0]    2
(2.0, 3.0]     2
(3.0, 4.0]     1
dtype: int64
```

dropna

With *dropna* set to *False* we can also see NaN index values.

```
>>> s.value_counts(dropna=False)
3.0    2
1.0    1
2.0    1
4.0    1
NaN    1
dtype: int64
```

pandas.Series.var

`Series.var` (*axis=None, skipna=None, level=None, ddof=1, numeric_only=None, **kwargs*)

Return unbiased variance over requested axis.

Normalized by N-1 by default. This can be changed using the *ddof* argument

Parameters

axis [{index (0)}]

skipna [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

ddof [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is $N - \text{ddof}$, where N represents the number of elements.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

Returns

scalar or Series (if level specified)

Notes

To have the same behaviour as *numpy.std*, use *ddof=0* (instead of the default *ddof=1*)

pandas.Series.view

`Series.view(dtype=None)`

Create a new view of the Series.

This function will return a new Series with a view of the same underlying values in memory, optionally reinterpreted with a new data type. The new data type must preserve the same size in bytes as to not cause index misalignment.

Parameters

dtype [data type] Data type object or one of their string representations.

Returns

Series A new Series object as a view of the same data in memory.

See also:

[numpy.ndarray.view](#) Equivalent numpy function to create a new view of the same data in memory.

Notes

Series are instantiated with `dtype=float64` by default. While `numpy.ndarray.view()` will return a view with the same data type as the original array, `Series.view()` (without specified `dtype`) will try using `float64` and may fail if the original data type size in bytes is not the same.

Examples

```
>>> s = pd.Series([-2, -1, 0, 1, 2], dtype='int8')
>>> s
0    -2
1    -1
2     0
3     1
4     2
dtype: int8
```

The 8 bit signed integer representation of `-1` is `0b11111111`, but the same bytes represent `255` if read as an 8 bit unsigned integer:

```
>>> us = s.view('uint8')
>>> us
0    254
1    255
2     0
3     1
```

(continues on next page)

(continued from previous page)

```
4      2
dtype: uint8
```

The views share the same underlying values:

```
>>> us[0] = 128
>>> s
0    -128
1     -1
2      0
3      1
4      2
dtype: int8
```

pandas.Series.where

`Series.where(cond, other=nan, inplace=False, axis=None, level=None, errors='raise', try_cast=NoDefault.no_default)`

Replace values where the condition is False.

Parameters

cond [bool Series/DataFrame, array-like, or callable] Where *cond* is True, keep the original value. Where False, replace with corresponding value from *other*. If *cond* is callable, it is computed on the Series/DataFrame and should return boolean Series/DataFrame or array. The callable must not change input Series/DataFrame (though pandas doesn't check it).

other [scalar, Series/DataFrame, or callable] Entries where *cond* is False are replaced with corresponding value from *other*. If *other* is callable, it is computed on the Series/DataFrame and should return scalar or Series/DataFrame. The callable must not change input Series/DataFrame (though pandas doesn't check it).

inplace [bool, default False] Whether to perform the operation in place on the data.

axis [int, default None] Alignment axis if needed.

level [int, default None] Alignment level if needed.

errors [str, {'raise', 'ignore'}, default 'raise'] Note that currently this parameter won't affect the results and will always coerce to a suitable dtype.

- 'raise' : allow exceptions to be raised.
- 'ignore' : suppress exceptions. On error return original object.

try_cast [bool, default None] Try to cast the result back to the input type (if possible).

Deprecated since version 1.3.0: Manually cast back if necessary.

Returns

Same type as caller or None if **inplace=True**.

See also:

[`DataFrame.mask\(\)`](#) Return an object of same shape as self.

Notes

The `where` method is an application of the if-then idiom. For each element in the calling `DataFrame`, if `cond` is `True` the element is used; otherwise the corresponding element from the `DataFrame other` is used.

The signature for `DataFrame.where()` differs from `numpy.where()`. Roughly `df1.where(m, df2)` is equivalent to `np.where(m, df1, df2)`.

For further details and examples see the `where` documentation in [indexing](#).

Examples

```
>>> s = pd.Series(range(5))
>>> s.where(s > 0)
0    NaN
1    1.0
2    2.0
3    3.0
4    4.0
dtype: float64
>>> s.mask(s > 0)
0    0.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

```
>>> s.where(s > 1, 10)
0    10
1    10
2     2
3     3
4     4
dtype: int64
>>> s.mask(s > 1, 10)
0     0
1     1
2    10
3    10
4    10
dtype: int64
```

```
>>> df = pd.DataFrame(np.arange(10).reshape(-1, 2), columns=['A', 'B'])
>>> df
   A  B
0  0  1
1  2  3
2  4  5
3  6  7
4  8  9
>>> m = df % 3 == 0
```

(continues on next page)

(continued from previous page)

```

>>> df.where(m, -df)
   A  B
0  0 -1
1 -2  3
2 -4 -5
3  6 -7
4 -8  9
>>> df.where(m, -df) == np.where(m, df, -df)
   A  B
0  True  True
1  True  True
2  True  True
3  True  True
4  True  True
>>> df.where(m, -df) == df.mask(~m, -df)
   A  B
0  True  True
1  True  True
2  True  True
3  True  True
4  True  True

```

pandas.Series.xs

`Series.xs(key, axis=0, level=None, drop_level=True)`

Return cross-section from the Series/DataFrame.

This method takes a *key* argument to select data at a particular level of a MultiIndex.

Parameters

- key** [label or tuple of label] Label contained in the index, or partially in a MultiIndex.
- axis** [{0 or 'index', 1 or 'columns'}, default 0] Axis to retrieve cross-section on.
- level** [object, defaults to first n levels (n=1 or len(key))] In case of a key partially contained in a MultiIndex, indicate which levels are used. Levels can be referred by label or position.
- drop_level** [bool, default True] If False, returns object with same levels as self.

Returns

Series or DataFrame Cross-section from the original Series or DataFrame corresponding to the selected index levels.

See also:

[`DataFrame.loc`](#) Access a group of rows and columns by label(s) or a boolean array.

[`DataFrame.iloc`](#) Purely integer-location based indexing for selection by position.

Notes

`xs` can not be used to set values.

MultiIndex Slicers is a generic way to get/set values on any level or levels. It is a superset of `xs` functionality, see *MultiIndex Slicers*.

Examples

```
>>> d = {'num_legs': [4, 4, 2, 2],
...      'num_wings': [0, 0, 2, 2],
...      'class': ['mammal', 'mammal', 'mammal', 'bird'],
...      'animal': ['cat', 'dog', 'bat', 'penguin'],
...      'locomotion': ['walks', 'walks', 'flies', 'walks']}
```

```
>>> df = pd.DataFrame(data=d)
>>> df = df.set_index(['class', 'animal', 'locomotion'])
>>> df
```

| class | animal | locomotion | num_legs | num_wings |
|--------|---------|------------|----------|-----------|
| mammal | cat | walks | 4 | 0 |
| | dog | walks | 4 | 0 |
| | bat | flies | 2 | 2 |
| bird | penguin | walks | 2 | 2 |

Get values at specified index

```
>>> df.xs('mammal')
```

| animal | locomotion | num_legs | num_wings |
|--------|------------|----------|-----------|
| cat | walks | 4 | 0 |
| dog | walks | 4 | 0 |
| bat | flies | 2 | 2 |

Get values at several indexes

```
>>> df.xs(('mammal', 'dog'))
```

| locomotion | num_legs | num_wings |
|------------|----------|-----------|
| walks | 4 | 0 |

Get values at specified index and level

```
>>> df.xs('cat', level=1)
```

| class | locomotion | num_legs | num_wings |
|--------|------------|----------|-----------|
| mammal | walks | 4 | 0 |

Get values at several indexes and levels

```
>>> df.xs(('bird', 'walks'),
...      level=[0, 'locomotion'])
```

| animal | num_legs | num_wings |
|---------|----------|-----------|
| penguin | 2 | 2 |

Get values at specified column and axis

```
>>> df.xs('num_wings', axis=1)
class  animal  locomotion
mammal  cat      walks      0
        dog      walks      0
        bat      flies      2
bird    penguin  walks      2
Name: num_wings, dtype: int64
```

3.3.2 Attributes

Axes

| | |
|--|--|
| <i>Series.index</i> | The index (axis labels) of the Series. |
| <i>Series.array</i> | The ExtensionArray of the data backing this Series or Index. |
| <i>Series.values</i> | Return Series as ndarray or ndarray-like depending on the dtype. |
| <i>Series.dtype</i> | Return the dtype object of the underlying data. |
| <i>Series.shape</i> | Return a tuple of the shape of the underlying data. |
| <i>Series.nbytes</i> | Return the number of bytes in the underlying data. |
| <i>Series.ndim</i> | Number of dimensions of the underlying data, by definition 1. |
| <i>Series.size</i> | Return the number of elements in the underlying data. |
| <i>Series.T</i> | Return the transpose, which is by definition self. |
| <i>Series.memory_usage</i> ([index, deep]) | Return the memory usage of the Series. |
| <i>Series.hasnans</i> | Return if I have any nans; enables various perf speedups. |
| <i>Series.empty</i> | Indicator whether DataFrame is empty. |
| <i>Series.dtypes</i> | Return the dtype object of the underlying data. |
| <i>Series.name</i> | Return the name of the Series. |
| <i>Series.flags</i> | Get the properties associated with this pandas object. |
| <i>Series.set_flags</i> (*[, copy, ...]) | Return a new object with updated flags. |

pandas.Series.empty

property Series.empty

Indicator whether DataFrame is empty.

True if DataFrame is entirely empty (no items), meaning any of the axes are of length 0.

Returns

bool If DataFrame is empty, return True, if not return False.

See also:

Series.dropna Return series without null values.

DataFrame.dropna Return DataFrame with labels on given axis omitted where (all or any) data are missing.

Notes

If DataFrame contains only NaNs, it is still not considered empty. See the example below.

Examples

An example of an actual empty DataFrame. Notice the index is empty:

```

>>> df_empty = pd.DataFrame({'A' : []})
>>> df_empty
Empty DataFrame
Columns: [A]
Index: []
>>> df_empty.empty
True

```

If we only have NaNs in our DataFrame, it is not considered empty! We will need to drop the NaNs to make the DataFrame empty:

```

>>> df = pd.DataFrame({'A' : [np.nan]})
>>> df
   A
0 NaN
>>> df.empty
False
>>> df.dropna().empty
True

```

3.3.3 Conversion

| | |
|--|--|
| <code>Series.astype(dtype[, copy, errors])</code> | Cast a pandas object to a specified dtype dtype. |
| <code>Series.convert_dtypes([infer_objects, ...])</code> | Convert columns to best possible dtypes using dtypes supporting pd.NA. |
| <code>Series.infer_objects()</code> | Attempt to infer better dtypes for object columns. |
| <code>Series.copy([deep])</code> | Make a copy of this object's indices and data. |
| <code>Series.bool()</code> | Return the bool of a single element Series or DataFrame. |
| <code>Series.to_numpy([dtype, copy, na_value])</code> | A NumPy ndarray representing the values in this Series or Index. |
| <code>Series.to_period([freq, copy])</code> | Convert Series from DatetimeIndex to PeriodIndex. |
| <code>Series.to_timestamp([freq, how, copy])</code> | Cast to DatetimeIndex of Timestamps, at <i>beginning</i> of period. |
| <code>Series.to_list()</code> | Return a list of the values. |
| <code>Series.__array__(dtype)</code> | Return the values as a NumPy array. |

pandas.Series.__array__

`Series.__array__(dtype=None)`

Return the values as a NumPy array.

Users should not call this directly. Rather, it is invoked by `numpy.array()` and `numpy.asarray()`.

Parameters

dtype [str or `numpy.dtype`, optional] The dtype to use for the resulting NumPy array. By default, the dtype is inferred from the data.

Returns

numpy.ndarray The values in the series converted to a `numpy.ndarray` with the specified *dtype*.

See also:

[`array`](#) Create a new array from data.

[`Series.array`](#) Zero-copy view to the array backing the Series.

[`Series.to_numpy`](#) Series method for similar behavior.

Examples

```
>>> ser = pd.Series([1, 2, 3])
>>> np.asarray(ser)
array([1, 2, 3])
```

For timezone-aware data, the timezones may be retained with `dtype='object'`

```
>>> tzser = pd.Series(pd.date_range('2000', periods=2, tz="CET"))
>>> np.asarray(tzser, dtype="object")
array([Timestamp('2000-01-01 00:00:00+0100', tz='CET'),
       Timestamp('2000-01-02 00:00:00+0100', tz='CET')],
      dtype=object)
```

Or the values may be localized to UTC and the tzinfo discarded with `dtype='datetime64[ns]'`

```
>>> np.asarray(tzser, dtype="datetime64[ns]")
array(['1999-12-31T23:00:00.000000000', ...],
      dtype='datetime64[ns]')
```

3.3.4 Indexing, iteration

| | |
|---|--|
| <code>Series.get(key[, default])</code> | Get item from object for given key (ex: DataFrame column). |
| <code>Series.at</code> | Access a single value for a row/column label pair. |
| <code>Series.iat</code> | Access a single value for a row/column pair by integer position. |
| <code>Series.loc</code> | Access a group of rows and columns by label(s) or a boolean array. |
| <code>Series.iloc</code> | Purely integer-location based indexing for selection by position. |

continues on next page

Table 37 – continued from previous page

| | |
|--|---|
| <code>Series.__iter__()</code> | Return an iterator of the values. |
| <code>Series.items()</code> | Lazily iterate over (index, value) tuples. |
| <code>Series.iteritems()</code> | Lazily iterate over (index, value) tuples. |
| <code>Series.keys()</code> | Return alias for index. |
| <code>Series.pop(item)</code> | Return item and drops from series. |
| <code>Series.item()</code> | Return the first element of the underlying data as a Python scalar. |
| <code>Series.xs(key[, axis, level, drop_level])</code> | Return cross-section from the Series/DataFrame. |

pandas.Series.__iter__**Series.__iter__()**

Return an iterator of the values.

These are each a scalar type, which is a Python scalar (for str, int, float) or a pandas scalar (for Timestamp/Timedelta/Interval/Period)

Returns**iterator**

For more information on `.at`, `.iat`, `.loc`, and `.iloc`, see the *indexing documentation*.

3.3.5 Binary operator functions

| | |
|--|--|
| <code>Series.add(other[, level, fill_value, axis])</code> | Return Addition of series and other, element-wise (binary operator <i>add</i>). |
| <code>Series.sub(other[, level, fill_value, axis])</code> | Return Subtraction of series and other, element-wise (binary operator <i>sub</i>). |
| <code>Series.mul(other[, level, fill_value, axis])</code> | Return Multiplication of series and other, element-wise (binary operator <i>mul</i>). |
| <code>Series.div(other[, level, fill_value, axis])</code> | Return Floating division of series and other, element-wise (binary operator <i>truediv</i>). |
| <code>Series.truediv(other[, level, fill_value, axis])</code> | Return Floating division of series and other, element-wise (binary operator <i>truediv</i>). |
| <code>Series.floordiv(other[, level, fill_value, axis])</code> | Return Integer division of series and other, element-wise (binary operator <i>floordiv</i>). |
| <code>Series.mod(other[, level, fill_value, axis])</code> | Return Modulo of series and other, element-wise (binary operator <i>mod</i>). |
| <code>Series.pow(other[, level, fill_value, axis])</code> | Return Exponential power of series and other, element-wise (binary operator <i>pow</i>). |
| <code>Series.radd(other[, level, fill_value, axis])</code> | Return Addition of series and other, element-wise (binary operator <i>radd</i>). |
| <code>Series.rsub(other[, level, fill_value, axis])</code> | Return Subtraction of series and other, element-wise (binary operator <i>rsub</i>). |
| <code>Series.rmul(other[, level, fill_value, axis])</code> | Return Multiplication of series and other, element-wise (binary operator <i>rmul</i>). |
| <code>Series.rdiv(other[, level, fill_value, axis])</code> | Return Floating division of series and other, element-wise (binary operator <i>rtruediv</i>). |
| <code>Series.rtruediv(other[, level, fill_value, axis])</code> | Return Floating division of series and other, element-wise (binary operator <i>rtruediv</i>). |

continues on next page

Table 38 – continued from previous page

| | |
|---|---|
| <code>Series.rfloordiv</code> (other[, level, fill_value, ...]) | Return Integer division of series and other, element-wise (binary operator <i>rfloordiv</i>). |
| <code>Series.rmod</code> (other[, level, fill_value, axis]) | Return Modulo of series and other, element-wise (binary operator <i>rmod</i>). |
| <code>Series.rpow</code> (other[, level, fill_value, axis]) | Return Exponential power of series and other, element-wise (binary operator <i>rpow</i>). |
| <code>Series.combine</code> (other, func[, fill_value]) | Combine the Series with a Series or scalar according to <i>func</i> . |
| <code>Series.combine_first</code> (other) | Update null elements with value in the same location in 'other'. |
| <code>Series.round</code> ([decimals]) | Round each value in a Series to the given number of decimals. |
| <code>Series.lt</code> (other[, level, fill_value, axis]) | Return Less than of series and other, element-wise (binary operator <i>lt</i>). |
| <code>Series.gt</code> (other[, level, fill_value, axis]) | Return Greater than of series and other, element-wise (binary operator <i>gt</i>). |
| <code>Series.le</code> (other[, level, fill_value, axis]) | Return Less than or equal to of series and other, element-wise (binary operator <i>le</i>). |
| <code>Series.ge</code> (other[, level, fill_value, axis]) | Return Greater than or equal to of series and other, element-wise (binary operator <i>ge</i>). |
| <code>Series.ne</code> (other[, level, fill_value, axis]) | Return Not equal to of series and other, element-wise (binary operator <i>ne</i>). |
| <code>Series.eq</code> (other[, level, fill_value, axis]) | Return Equal to of series and other, element-wise (binary operator <i>eq</i>). |
| <code>Series.product</code> ([axis, skipna, level, ...]) | Return the product of the values over the requested axis. |
| <code>Series.dot</code> (other) | Compute the dot product between the Series and the columns of other. |

3.3.6 Function application, GroupBy & window

| | |
|--|--|
| <code>Series.apply</code> (func[, convert_dtype, args]) | Invoke function on values of Series. |
| <code>Series.agg</code> ([func, axis]) | Aggregate using one or more operations over the specified axis. |
| <code>Series.aggregate</code> ([func, axis]) | Aggregate using one or more operations over the specified axis. |
| <code>Series.transform</code> (func[, axis]) | Call <i>func</i> on self producing a Series with transformed values. |
| <code>Series.map</code> (arg[, na_action]) | Map values of Series according to input correspondence. |
| <code>Series.groupby</code> ([by, axis, level, as_index, ...]) | Group Series using a mapper or by a Series of columns. |
| <code>Series.rolling</code> (window[, min_periods, ...]) | Provide rolling window calculations. |
| <code>Series.expanding</code> ([min_periods, center, ...]) | Provide expanding transformations. |
| <code>Series.ewm</code> ([com, span, halflife, alpha, ...]) | Provide exponential weighted (EW) functions. |
| <code>Series.pipe</code> (func, *args, **kwargs) | Apply <i>func</i> (self, *args, **kwargs). |

3.3.7 Computations / descriptive stats

| | |
|---|--|
| <code>Series.abs()</code> | Return a Series/DataFrame with absolute numeric value of each element. |
| <code>Series.all([axis, bool_only, skipna, level])</code> | Return whether all elements are True, potentially over an axis. |
| <code>Series.any([axis, bool_only, skipna, level])</code> | Return whether any element is True, potentially over an axis. |
| <code>Series.autocorr([lag])</code> | Compute the lag-N autocorrelation. |
| <code>Series.between(left, right[, inclusive])</code> | Return boolean Series equivalent to <code>left <= series <= right</code> . |
| <code>Series.clip([lower, upper, axis, inplace])</code> | Trim values at input threshold(s). |
| <code>Series.corr(other[, method, min_periods])</code> | Compute correlation with <i>other</i> Series, excluding missing values. |
| <code>Series.count([level])</code> | Return number of non-NA/null observations in the Series. |
| <code>Series.cov(other[, min_periods, ddof])</code> | Compute covariance with Series, excluding missing values. |
| <code>Series.cummax([axis, skipna])</code> | Return cumulative maximum over a DataFrame or Series axis. |
| <code>Series.cummin([axis, skipna])</code> | Return cumulative minimum over a DataFrame or Series axis. |
| <code>Series.cumprod([axis, skipna])</code> | Return cumulative product over a DataFrame or Series axis. |
| <code>Series.cumsum([axis, skipna])</code> | Return cumulative sum over a DataFrame or Series axis. |
| <code>Series.describe([percentiles, include, ...])</code> | Generate descriptive statistics. |
| <code>Series.diff([periods])</code> | First discrete difference of element. |
| <code>Series.factorize([sort, na_sentinel])</code> | Encode the object as an enumerated type or categorical variable. |
| <code>Series.kurt([axis, skipna, level, numeric_only])</code> | Return unbiased kurtosis over requested axis. |
| <code>Series.mad([axis, skipna, level])</code> | Return the mean absolute deviation of the values over the requested axis. |
| <code>Series.max([axis, skipna, level, numeric_only])</code> | Return the maximum of the values over the requested axis. |
| <code>Series.mean([axis, skipna, level, numeric_only])</code> | Return the mean of the values over the requested axis. |
| <code>Series.median([axis, skipna, level, ...])</code> | Return the median of the values over the requested axis. |
| <code>Series.min([axis, skipna, level, numeric_only])</code> | Return the minimum of the values over the requested axis. |
| <code>Series.mode([dropna])</code> | Return the mode(s) of the Series. |
| <code>Series.nlargest([n, keep])</code> | Return the largest <i>n</i> elements. |
| <code>Series.nsmallest([n, keep])</code> | Return the smallest <i>n</i> elements. |
| <code>Series.pct_change([periods, fill_method, ...])</code> | Percentage change between the current and a prior element. |
| <code>Series.prod([axis, skipna, level, ...])</code> | Return the product of the values over the requested axis. |
| <code>Series.quantile([q, interpolation])</code> | Return value at the given quantile. |
| <code>Series.rank([axis, method, numeric_only, ...])</code> | Compute numerical data ranks (1 through n) along axis. |
| <code>Series.sem([axis, skipna, level, ddof, ...])</code> | Return unbiased standard error of the mean over requested axis. |
| <code>Series.skew([axis, skipna, level, numeric_only])</code> | Return unbiased skew over requested axis. |
| <code>Series.std([axis, skipna, level, ddof, ...])</code> | Return sample standard deviation over requested axis. |
| <code>Series.sum([axis, skipna, level, ...])</code> | Return the sum of the values over the requested axis. |

continues on next page

Table 40 – continued from previous page

| | |
|--|--|
| <code>Series.var</code> ([axis, skipna, level, ddof, ...]) | Return unbiased variance over requested axis. |
| <code>Series.kurtosis</code> ([axis, skipna, level, ...]) | Return unbiased kurtosis over requested axis. |
| <code>Series.unique</code> () | Return unique values of Series object. |
| <code>Series.nunique</code> ([dropna]) | Return number of unique elements in the object. |
| <code>Series.is_unique</code> | Return boolean if values in the object are unique. |
| <code>Series.is_monotonic</code> | Return boolean if values in the object are monotonic_increasing. |
| <code>Series.is_monotonic_increasing</code> | Alias for <code>is_monotonic</code> . |
| <code>Series.is_monotonic_decreasing</code> | Return boolean if values in the object are monotonic_decreasing. |
| <code>Series.value_counts</code> ([normalize, sort, ...]) | Return a Series containing counts of unique values. |

3.3.8 Reindexing / selection / label manipulation

| | |
|---|---|
| <code>Series.align</code> (other[, join, axis, level, ...]) | Align two objects on their axes with the specified join method. |
| <code>Series.drop</code> ([labels, axis, index, columns, ...]) | Return Series with specified index labels removed. |
| <code>Series.droplevel</code> (level[, axis]) | Return Series/DataFrame with requested index / column level(s) removed. |
| <code>Series.drop_duplicates</code> ([keep, inplace]) | Return Series with duplicate values removed. |
| <code>Series.duplicated</code> ([keep]) | Indicate duplicate Series values. |
| <code>Series.equals</code> (other) | Test whether two objects contain the same elements. |
| <code>Series.first</code> (offset) | Select initial periods of time series data based on a date offset. |
| <code>Series.head</code> ([n]) | Return the first <i>n</i> rows. |
| <code>Series.idxmax</code> ([axis, skipna]) | Return the row label of the maximum value. |
| <code>Series.idxmin</code> ([axis, skipna]) | Return the row label of the minimum value. |
| <code>Series.isin</code> (values) | Whether elements in Series are contained in <i>values</i> . |
| <code>Series.last</code> (offset) | Select final periods of time series data based on a date offset. |
| <code>Series.reindex</code> ([index]) | Conform Series to new index with optional filling logic. |
| <code>Series.reindex_like</code> (other[, method, copy, ...]) | Return an object with matching indices as other object. |
| <code>Series.rename</code> ([index, axis, copy, inplace, ...]) | Alter Series index labels or name. |
| <code>Series.rename_axis</code> ([mapper, index, columns, ...]) | Set the name of the axis for the index or columns. |
| <code>Series.reset_index</code> ([level, drop, name, inplace]) | Generate a new DataFrame or Series with the index reset. |
| <code>Series.sample</code> ([n, frac, replace, weights, ...]) | Return a random sample of items from an axis of object. |
| <code>Series.set_axis</code> (labels[, axis, inplace]) | Assign desired index to given axis. |
| <code>Series.take</code> (indices[, axis, is_copy]) | Return the elements in the given <i>positional</i> indices along an axis. |
| <code>Series.tail</code> ([n]) | Return the last <i>n</i> rows. |
| <code>Series.truncate</code> ([before, after, axis, copy]) | Truncate a Series or DataFrame before and after some index value. |
| <code>Series.where</code> (cond[, other, inplace, axis, ...]) | Replace values where the condition is False. |
| <code>Series.mask</code> (cond[, other, inplace, axis, ...]) | Replace values where the condition is True. |
| <code>Series.add_prefix</code> (prefix) | Prefix labels with string <i>prefix</i> . |
| <code>Series.add_suffix</code> (suffix) | Suffix labels with string <i>suffix</i> . |
| <code>Series.filter</code> ([items, like, regex, axis]) | Subset the dataframe rows or columns according to the specified index labels. |

3.3.9 Missing data handling

| | |
|--|--|
| <code>Series.backfill([axis, inplace, limit, downcast])</code> | Synonym for <code>DataFrame.fillna()</code> with <code>method='bfill'</code> . |
| <code>Series.bfill([axis, inplace, limit, downcast])</code> | Synonym for <code>DataFrame.fillna()</code> with <code>method='bfill'</code> . |
| <code>Series.dropna([axis, inplace, how])</code> | Return a new Series with missing values removed. |
| <code>Series.ffill([axis, inplace, limit, downcast])</code> | Synonym for <code>DataFrame.fillna()</code> with <code>method='ffill'</code> . |
| <code>Series.fillna([value, method, axis, ...])</code> | Fill NA/NaN values using the specified method. |
| <code>Series.interpolate([method, axis, limit, ...])</code> | Fill NaN values using an interpolation method. |
| <code>Series.isna()</code> | Detect missing values. |
| <code>Series.isnull()</code> | Detect missing values. |
| <code>Series.notna()</code> | Detect existing (non-missing) values. |
| <code>Series.notnull()</code> | Detect existing (non-missing) values. |
| <code>Series.pad([axis, inplace, limit, downcast])</code> | Synonym for <code>DataFrame.fillna()</code> with <code>method='ffill'</code> . |
| <code>Series.replace([to_replace, value, inplace, ...])</code> | Replace values given in <code>to_replace</code> with <code>value</code> . |

3.3.10 Reshaping, sorting

| | |
|---|--|
| <code>Series.argsort([axis, kind, order])</code> | Return the integer indices that would sort the Series values. |
| <code>Series.argmin([axis, skipna])</code> | Return int position of the smallest value in the Series. |
| <code>Series.argmax([axis, skipna])</code> | Return int position of the largest value in the Series. |
| <code>Series.reorder_levels(order)</code> | Rearrange index levels using input order. |
| <code>Series.sort_values([axis, ascending, ...])</code> | Sort by the values. |
| <code>Series.sort_index([axis, level, ascending, ...])</code> | Sort Series by index labels. |
| <code>Series.swaplevel([i, j, copy])</code> | Swap levels <code>i</code> and <code>j</code> in a <i>MultiIndex</i> . |
| <code>Series.unstack([level, fill_value])</code> | Unstack, also known as pivot, Series with MultiIndex to produce DataFrame. |
| <code>Series.explode([ignore_index])</code> | Transform each element of a list-like to a row. |
| <code>Series.searchsorted(value[, side, sorter])</code> | Find indices where elements should be inserted to maintain order. |
| <code>Series.ravel([order])</code> | Return the flattened underlying data as an ndarray. |
| <code>Series.repeat(repeats[, axis])</code> | Repeat elements of a Series. |
| <code>Series.squeeze([axis])</code> | Squeeze 1 dimensional axis objects into scalars. |
| <code>Series.view([dtype])</code> | Create a new view of the Series. |

3.3.11 Combining / comparing / joining / merging

| | |
|--|---|
| <code>Series.append(to_append[, ignore_index, ...])</code> | Concatenate two or more Series. |
| <code>Series.compare(other[, align_axis, ...])</code> | Compare to another Series and show the differences. |
| <code>Series.update(other)</code> | Modify Series in place using values from passed Series. |

3.3.12 Time Series-related

| | |
|--|--|
| <code>Series.asfreq(freq[, method, how, ...])</code> | Convert time series to specified frequency. |
| <code>Series.asof(when[, subset])</code> | Return the last row(s) without any NaNs before <i>when</i> . |
| <code>Series.shift([periods, freq, axis, fill_value])</code> | Shift index by desired number of periods with an optional time <i>freq</i> . |
| <code>Series.first_valid_index()</code> | Return index for first non-NA value or None, if no NA value is found. |
| <code>Series.last_valid_index()</code> | Return index for last non-NA value or None, if no NA value is found. |
| <code>Series.resample(rule[, axis, closed, label, ...])</code> | Resample time-series data. |
| <code>Series.tz_convert(tz[, axis, level, copy])</code> | Convert tz-aware axis to target time zone. |
| <code>Series.tz_localize(tz[, axis, level, copy, ...])</code> | Localize tz-naive index of a Series or DataFrame to target time zone. |
| <code>Series.at_time(time[, asof, axis])</code> | Select values at particular time of day (e.g., 9:30AM). |
| <code>Series.between_time(start_time, end_time[, ...])</code> | Select values between particular times of the day (e.g., 9:00-9:30 AM). |
| <code>Series.tshift([periods, freq, axis])</code> | (DEPRECATED) Shift the time index, using the index's frequency if available. |
| <code>Series.slice_shift([periods, axis])</code> | (DEPRECATED) Equivalent to <i>shift</i> without copying data. |

3.3.13 Accessors

pandas provides dtype-specific methods under various accessors. These are separate namespaces within *Series* that only apply to specific data types.

| Data Type | Accessor |
|-----------------------------|---------------|
| Datetime, Timedelta, Period | <i>dt</i> |
| String | <i>str</i> |
| Categorical | <i>cat</i> |
| Sparse | <i>sparse</i> |

Datetimelike properties

`Series.dt` can be used to access the values of the series as datetimelike and return several properties. These can be accessed like `Series.dt.<property>`.

Datetime properties

| | |
|-------------------------------|--|
| <code>Series.dt.date</code> | Returns numpy array of python <code>datetime.date</code> objects (namely, the date part of Timestamps without timezone information). |
| <code>Series.dt.time</code> | Returns numpy array of <code>datetime.time</code> . |
| <code>Series.dt.timetz</code> | Returns numpy array of <code>datetime.time</code> also containing timezone information. |
| <code>Series.dt.year</code> | The year of the datetime. |

continues on next page

Table 46 – continued from previous page

| | |
|---|---|
| <code>Series.dt.month</code> | The month as January=1, December=12. |
| <code>Series.dt.day</code> | The day of the datetime. |
| <code>Series.dt.hour</code> | The hours of the datetime. |
| <code>Series.dt.minute</code> | The minutes of the datetime. |
| <code>Series.dt.second</code> | The seconds of the datetime. |
| <code>Series.dt.microsecond</code> | The microseconds of the datetime. |
| <code>Series.dt.nanosecond</code> | The nanoseconds of the datetime. |
| <code>Series.dt.week</code> | (DEPRECATED) The week ordinal of the year. |
| <code>Series.dt.weekofyear</code> | (DEPRECATED) The week ordinal of the year. |
| <code>Series.dt.dayofweek</code> | The day of the week with Monday=0, Sunday=6. |
| <code>Series.dt.day_of_week</code> | The day of the week with Monday=0, Sunday=6. |
| <code>Series.dt.weekday</code> | The day of the week with Monday=0, Sunday=6. |
| <code>Series.dt.dayofyear</code> | The ordinal day of the year. |
| <code>Series.dt.day_of_year</code> | The ordinal day of the year. |
| <code>Series.dt.quarter</code> | The quarter of the date. |
| <code>Series.dt.is_month_start</code> | Indicates whether the date is the first day of the month. |
| <code>Series.dt.is_month_end</code> | Indicates whether the date is the last day of the month. |
| <code>Series.dt.is_quarter_start</code> | Indicator for whether the date is the first day of a quarter. |
| <code>Series.dt.is_quarter_end</code> | Indicator for whether the date is the last day of a quarter. |
| <code>Series.dt.is_year_start</code> | Indicate whether the date is the first day of a year. |
| <code>Series.dt.is_year_end</code> | Indicate whether the date is the last day of the year. |
| <code>Series.dt.is_leap_year</code> | Boolean indicator if the date belongs to a leap year. |
| <code>Series.dt.daysinmonth</code> | The number of days in the month. |
| <code>Series.dt.days_in_month</code> | The number of days in the month. |
| <code>Series.dt.tz</code> | Return timezone, if any. |
| <code>Series.dt.freq</code> | Return the frequency object for this PeriodArray. |

pandas.Series.dt.date**Series.dt.date**

Returns numpy array of python datetime.date objects (namely, the date part of Timestamps without timezone information).

pandas.Series.dt.time**Series.dt.time**

Returns numpy array of datetime.time. The time part of the Timestamps.

pandas.Series.dt.timetz**Series.dt.timetz**

Returns numpy array of datetime.time also containing timezone information. The time part of the Timestamps.

pandas.Series.dt.year

Series.dt.year

The year of the datetime.

Examples

```
>>> datetime_series = pd.Series(
...     pd.date_range("2000-01-01", periods=3, freq="Y")
... )
>>> datetime_series
0    2000-12-31
1    2001-12-31
2    2002-12-31
dtype: datetime64[ns]
>>> datetime_series.dt.year
0     2000
1     2001
2     2002
dtype: int64
```

pandas.Series.dt.month

Series.dt.month

The month as January=1, December=12.

Examples

```
>>> datetime_series = pd.Series(
...     pd.date_range("2000-01-01", periods=3, freq="M")
... )
>>> datetime_series
0    2000-01-31
1    2000-02-29
2    2000-03-31
dtype: datetime64[ns]
>>> datetime_series.dt.month
0     1
1     2
2     3
dtype: int64
```

pandas.Series.dt.day

Series.dt.day

The day of the datetime.

Examples

```
>>> datetime_series = pd.Series(
...     pd.date_range("2000-01-01", periods=3, freq="D")
... )
>>> datetime_series
0    2000-01-01
1    2000-01-02
2    2000-01-03
dtype: datetime64[ns]
>>> datetime_series.dt.day
0     1
1     2
2     3
dtype: int64
```

pandas.Series.dt.hour

Series.dt.hour

The hours of the datetime.

Examples

```
>>> datetime_series = pd.Series(
...     pd.date_range("2000-01-01", periods=3, freq="h")
... )
>>> datetime_series
0    2000-01-01 00:00:00
1    2000-01-01 01:00:00
2    2000-01-01 02:00:00
dtype: datetime64[ns]
>>> datetime_series.dt.hour
0     0
1     1
2     2
dtype: int64
```

pandas.Series.dt.minute

Series.dt.minute

The minutes of the datetime.

Examples

```
>>> datetime_series = pd.Series(
...     pd.date_range("2000-01-01", periods=3, freq="T")
... )
>>> datetime_series
0    2000-01-01 00:00:00
1    2000-01-01 00:01:00
2    2000-01-01 00:02:00
dtype: datetime64[ns]
>>> datetime_series.dt.minute
0    0
1    1
2    2
dtype: int64
```

pandas.Series.dt.second

Series.dt.second

The seconds of the datetime.

Examples

```
>>> datetime_series = pd.Series(
...     pd.date_range("2000-01-01", periods=3, freq="s")
... )
>>> datetime_series
0    2000-01-01 00:00:00
1    2000-01-01 00:00:01
2    2000-01-01 00:00:02
dtype: datetime64[ns]
>>> datetime_series.dt.second
0    0
1    1
2    2
dtype: int64
```

pandas.Series.dt.microsecond

Series.dt.microsecond

The microseconds of the datetime.

Examples

```
>>> datetime_series = pd.Series(
...     pd.date_range("2000-01-01", periods=3, freq="us")
... )
>>> datetime_series
0    2000-01-01 00:00:00.000000
1    2000-01-01 00:00:00.000001
2    2000-01-01 00:00:00.000002
dtype: datetime64[ns]
>>> datetime_series.dt.microsecond
0      0
1      1
2      2
dtype: int64
```

pandas.Series.dt.nanosecond

Series.dt.nanosecond

The nanoseconds of the datetime.

Examples

```
>>> datetime_series = pd.Series(
...     pd.date_range("2000-01-01", periods=3, freq="ns")
... )
>>> datetime_series
0    2000-01-01 00:00:00.000000000
1    2000-01-01 00:00:00.000000001
2    2000-01-01 00:00:00.000000002
dtype: datetime64[ns]
>>> datetime_series.dt.nanosecond
0      0
1      1
2      2
dtype: int64
```

pandas.Series.dt.week

Series.dt.week

The week ordinal of the year.

Deprecated since version 1.1.0.

Series.dt.weekofyear and Series.dt.week have been deprecated. Please use Series.dt.isocalendar().week instead.

pandas.Series.dt.weekofyear

Series.dt.weekofyear

The week ordinal of the year.

Deprecated since version 1.1.0.

Series.dt.weekofyear and Series.dt.week have been deprecated. Please use Series.dt.isocalendar().week instead.

pandas.Series.dt.dayofweek

Series.dt.dayofweek

The day of the week with Monday=0, Sunday=6.

Return the day of the week. It is assumed the week starts on Monday, which is denoted by 0 and ends on Sunday which is denoted by 6. This method is available on both Series with datetime values (using the *dt* accessor) or DatetimeIndex.

Returns

Series or Index Containing integers indicating the day number.

See also:

[Series.dt.dayofweek](#) Alias.

[Series.dt.weekday](#) Alias.

[Series.dt.day_name](#) Returns the name of the day of the week.

Examples

```

>>> s = pd.date_range('2016-12-31', '2017-01-08', freq='D').to_series()
>>> s.dt.dayofweek
2016-12-31    5
2017-01-01    6
2017-01-02    0
2017-01-03    1
2017-01-04    2
2017-01-05    3
2017-01-06    4
2017-01-07    5
2017-01-08    6
Freq: D, dtype: int64

```

pandas.Series.dt.day_of_week

Series.dt.day_of_week

The day of the week with Monday=0, Sunday=6.

Return the day of the week. It is assumed the week starts on Monday, which is denoted by 0 and ends on Sunday which is denoted by 6. This method is available on both Series with datetime values (using the *dt* accessor) or DatetimeIndex.

Returns

Series or Index Containing integers indicating the day number.

See also:

[*Series.dt.dayofweek*](#) Alias.

[*Series.dt.weekday*](#) Alias.

[*Series.dt.day_name*](#) Returns the name of the day of the week.

Examples

```
>>> s = pd.date_range('2016-12-31', '2017-01-08', freq='D').to_series()
>>> s.dt.dayofweek
2016-12-31    5
2017-01-01    6
2017-01-02    0
2017-01-03    1
2017-01-04    2
2017-01-05    3
2017-01-06    4
2017-01-07    5
2017-01-08    6
Freq: D, dtype: int64
```

pandas.Series.dt.weekday

Series.dt.weekday

The day of the week with Monday=0, Sunday=6.

Return the day of the week. It is assumed the week starts on Monday, which is denoted by 0 and ends on Sunday which is denoted by 6. This method is available on both Series with datetime values (using the *dt* accessor) or DatetimeIndex.

Returns

Series or Index Containing integers indicating the day number.

See also:

[*Series.dt.dayofweek*](#) Alias.

[*Series.dt.weekday*](#) Alias.

[*Series.dt.day_name*](#) Returns the name of the day of the week.

Examples

```

>>> s = pd.date_range('2016-12-31', '2017-01-08', freq='D').to_series()
>>> s.dt.dayofweek
2016-12-31    5
2017-01-01    6
2017-01-02    0
2017-01-03    1
2017-01-04    2
2017-01-05    3
2017-01-06    4
2017-01-07    5
2017-01-08    6
Freq: D, dtype: int64

```

pandas.Series.dt.dayofyear

Series.dt.dayofyear

The ordinal day of the year.

pandas.Series.dt.day_of_year

Series.dt.day_of_year

The ordinal day of the year.

pandas.Series.dt.quarter

Series.dt.quarter

The quarter of the date.

pandas.Series.dt.is_month_start

Series.dt.is_month_start

Indicates whether the date is the first day of the month.

Returns

Series or array For Series, returns a Series with boolean values. For DatetimeIndex, returns a boolean array.

See also:

[*is_month_start*](#) Return a boolean indicating whether the date is the first day of the month.

[*is_month_end*](#) Return a boolean indicating whether the date is the last day of the month.

Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on DatetimeIndex.

```
>>> s = pd.Series(pd.date_range("2018-02-27", periods=3))
>>> s
0    2018-02-27
1    2018-02-28
2    2018-03-01
dtype: datetime64[ns]
>>> s.dt.is_month_start
0    False
1    False
2     True
dtype: bool
>>> s.dt.is_month_end
0    False
1     True
2    False
dtype: bool
```

```
>>> idx = pd.date_range("2018-02-27", periods=3)
>>> idx.is_month_start
array([False, False,  True])
>>> idx.is_month_end
array([False,  True, False])
```

pandas.Series.dt.is_month_end

Series.dt.is_month_end

Indicates whether the date is the last day of the month.

Returns

Series or array For Series, returns a Series with boolean values. For DatetimeIndex, returns a boolean array.

See also:

[`is_month_start`](#) Return a boolean indicating whether the date is the first day of the month.

[`is_month_end`](#) Return a boolean indicating whether the date is the last day of the month.

Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on DatetimeIndex.

```
>>> s = pd.Series(pd.date_range("2018-02-27", periods=3))
>>> s
0    2018-02-27
1    2018-02-28
2    2018-03-01
dtype: datetime64[ns]
>>> s.dt.is_month_start
0    False
```

(continues on next page)

(continued from previous page)

```

1    False
2     True
dtype: bool
>>> s.dt.is_month_end
0    False
1     True
2    False
dtype: bool

```

```

>>> idx = pd.date_range("2018-02-27", periods=3)
>>> idx.is_month_start
array([False, False, True])
>>> idx.is_month_end
array([False, True, False])

```

pandas.Series.dt.is_quarter_start

Series.dt.is_quarter_start

Indicator for whether the date is the first day of a quarter.

Returns

is_quarter_start [Series or DatetimeIndex] The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

See also:

[quarter](#) Return the quarter of the date.

[is_quarter_end](#) Similar property for indicating the quarter start.

Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on DatetimeIndex.

```

>>> df = pd.DataFrame({'dates': pd.date_range("2017-03-30",
...                                           periods=4)})
>>> df.assign(quarter=df.dates.dt.quarter,
...           is_quarter_start=df.dates.dt.is_quarter_start)
   dates      quarter  is_quarter_start
0 2017-03-30         1                False
1 2017-03-31         1                False
2 2017-04-01         2                 True
3 2017-04-02         2                False

```

```

>>> idx = pd.date_range('2017-03-30', periods=4)
>>> idx
DatetimeIndex(['2017-03-30', '2017-03-31', '2017-04-01', '2017-04-02'],
              dtype='datetime64[ns]', freq='D')

```

```

>>> idx.is_quarter_start
array([False, False,  True, False])

```

pandas.Series.dt.is_quarter_end

Series.dt.is_quarter_end

Indicator for whether the date is the last day of a quarter.

Returns

is_quarter_end [Series or DatetimeIndex] The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

See also:

[*quarter*](#) Return the quarter of the date.

[*is_quarter_start*](#) Similar property indicating the quarter start.

Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on `DatetimeIndex`.

```
>>> df = pd.DataFrame({'dates': pd.date_range("2017-03-30",
...                                         periods=4)})
>>> df.assign(quarter=df.dates.dt.quarter,
...           is_quarter_end=df.dates.dt.is_quarter_end)
   dates    quarter  is_quarter_end
0 2017-03-30         1             False
1 2017-03-31         1              True
2 2017-04-01         2             False
3 2017-04-02         2             False
```

```
>>> idx = pd.date_range('2017-03-30', periods=4)
>>> idx
DatetimeIndex(['2017-03-30', '2017-03-31', '2017-04-01', '2017-04-02'],
              dtype='datetime64[ns]', freq='D')
```

```
>>> idx.is_quarter_end
array([False,  True,  False,  False])
```

pandas.Series.dt.is_year_start

Series.dt.is_year_start

Indicate whether the date is the first day of a year.

Returns

Series or DatetimeIndex The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

See also:

[*is_year_end*](#) Similar property indicating the last day of the year.

Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on `DatetimeIndex`.

```
>>> dates = pd.Series(pd.date_range("2017-12-30", periods=3))
>>> dates
0    2017-12-30
1    2017-12-31
2    2018-01-01
dtype: datetime64[ns]
```

```
>>> dates.dt.is_year_start
0    False
1    False
2     True
dtype: bool
```

```
>>> idx = pd.date_range("2017-12-30", periods=3)
>>> idx
DatetimeIndex(['2017-12-30', '2017-12-31', '2018-01-01'],
              dtype='datetime64[ns]', freq='D')
```

```
>>> idx.is_year_start
array([False,  False,  True])
```

pandas.Series.dt.is_year_end

Series.dt.is_year_end

Indicate whether the date is the last day of the year.

Returns

Series or DatetimeIndex The same type as the original data with boolean values. Series will have the same name and index. `DatetimeIndex` will have the same name.

See also:

[`is_year_start`](#) Similar property indicating the start of the year.

Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on `DatetimeIndex`.

```
>>> dates = pd.Series(pd.date_range("2017-12-30", periods=3))
>>> dates
0    2017-12-30
1    2017-12-31
2    2018-01-01
dtype: datetime64[ns]
```

```
>>> dates.dt.is_year_end
0    False
1     True
```

(continues on next page)

(continued from previous page)

```
2    False
dtype: bool
```

```
>>> idx = pd.date_range("2017-12-30", periods=3)
>>> idx
DatetimeIndex(['2017-12-30', '2017-12-31', '2018-01-01'],
              dtype='datetime64[ns]', freq='D')
```

```
>>> idx.is_year_end
array([False,  True,  False])
```

pandas.Series.dt.is_leap_year

Series.dt.is_leap_year

Boolean indicator if the date belongs to a leap year.

A leap year is a year, which has 366 days (instead of 365) including 29th of February as an intercalary day. Leap years are years which are multiples of four with the exception of years divisible by 100 but not by 400.

Returns

Series or ndarray Booleans indicating if dates belong to a leap year.

Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on `DatetimeIndex`.

```
>>> idx = pd.date_range("2012-01-01", "2015-01-01", freq="Y")
>>> idx
DatetimeIndex(['2012-12-31', '2013-12-31', '2014-12-31'],
              dtype='datetime64[ns]', freq='A-DEC')
>>> idx.is_leap_year
array([ True,  False,  False])
```

```
>>> dates_series = pd.Series(idx)
>>> dates_series
0    2012-12-31
1    2013-12-31
2    2014-12-31
dtype: datetime64[ns]
>>> dates_series.dt.is_leap_year
0     True
1    False
2    False
dtype: bool
```

pandas.Series.dt.daysinmonth**Series.dt.daysinmonth**

The number of days in the month.

pandas.Series.dt.days_in_month**Series.dt.days_in_month**

The number of days in the month.

pandas.Series.dt.tz**Series.dt.tz**

Return timezone, if any.

Returns

datetime.tzinfo, pytz.tzinfo.BaseTZInfo, dateutil.tz.tz.tzfile, or None Returns None when the array is tz-naive.

pandas.Series.dt.freq**Series.dt.freq****Datetime methods**

| | |
|--|--|
| <i>Series.dt.to_period</i> (*args, **kwargs) | Cast to PeriodArray/Index at a particular frequency. |
| <i>Series.dt.to_pydatetime</i> () | Return the data as an array of native Python datetime objects. |
| <i>Series.dt.tz_localize</i> (*args, **kwargs) | Localize tz-naive Datetime Array/Index to tz-aware Datetime Array/Index. |
| <i>Series.dt.tz_convert</i> (*args, **kwargs) | Convert tz-aware Datetime Array/Index from one time zone to another. |
| <i>Series.dt.normalize</i> (*args, **kwargs) | Convert times to midnight. |
| <i>Series.dt.strftime</i> (*args, **kwargs) | Convert to Index using specified date_format. |
| <i>Series.dt.round</i> (*args, **kwargs) | Perform round operation on the data to the specified <i>freq</i> . |
| <i>Series.dt.floor</i> (*args, **kwargs) | Perform floor operation on the data to the specified <i>freq</i> . |
| <i>Series.dt.ceil</i> (*args, **kwargs) | Perform ceil operation on the data to the specified <i>freq</i> . |
| <i>Series.dt.month_name</i> (*args, **kwargs) | Return the month names of the DateTimeIndex with specified locale. |
| <i>Series.dt.day_name</i> (*args, **kwargs) | Return the day names of the DateTimeIndex with specified locale. |

pandas.Series.dt.to_period

`Series.dt.to_period(*args, **kwargs)`

Cast to PeriodArray/Index at a particular frequency.

Converts DatetimeArray/Index to PeriodArray/Index.

Parameters

freq [str or Offset, optional] One of pandas' *offset strings* or an Offset object. Will be inferred by default.

Returns

PeriodArray/Index

Raises

ValueError When converting a DatetimeArray/Index with non-regular values, so that a frequency cannot be inferred.

See also:

[PeriodIndex](#) Immutable ndarray holding ordinal values.

[DatetimeIndex.to_pydatetime](#) Return DatetimeIndex as object.

Examples

```
>>> df = pd.DataFrame({"y": [1, 2, 3]},
...                    index=pd.to_datetime(["2000-03-31 00:00:00",
...                                          "2000-05-31 00:00:00",
...                                          "2000-08-31 00:00:00"]))
>>> df.index.to_period("M")
PeriodIndex(['2000-03', '2000-05', '2000-08'],
            dtype='period[M]')
```

Infer the daily frequency

```
>>> idx = pd.date_range("2017-01-01", periods=2)
>>> idx.to_period()
PeriodIndex(['2017-01-01', '2017-01-02'],
            dtype='period[D]')
```

pandas.Series.dt.to_pydatetime

`Series.dt.to_pydatetime()`

Return the data as an array of native Python datetime objects.

Timezone information is retained if present.

Warning: Python's datetime uses microsecond resolution, which is lower than pandas (nanosecond). The values are truncated.

Returns

numpy.ndarray Object dtype array containing native Python datetime objects.

See also:

`datetime.datetime` Standard library value for a datetime.

Examples

```
>>> s = pd.Series(pd.date_range('20180310', periods=2))
>>> s
0    2018-03-10
1    2018-03-11
dtype: datetime64[ns]
```

```
>>> s.dt.to_pydatetime()
array([datetime.datetime(2018, 3, 10, 0, 0),
       datetime.datetime(2018, 3, 11, 0, 0)], dtype=object)
```

pandas' nanosecond precision is truncated to microseconds.

```
>>> s = pd.Series(pd.date_range('20180310', periods=2, freq='ns'))
>>> s
0    2018-03-10 00:00:00.000000000
1    2018-03-10 00:00:00.000000001
dtype: datetime64[ns]
```

```
>>> s.dt.to_pydatetime()
array([datetime.datetime(2018, 3, 10, 0, 0),
       datetime.datetime(2018, 3, 10, 0, 0)], dtype=object)
```

pandas.Series.dt.tz_localize

`Series.dt.tz_localize(*args, **kwargs)`

Localize tz-naive Datetime Array/Index to tz-aware Datetime Array/Index.

This method takes a time zone (tz) naive Datetime Array/Index object and makes this time zone aware. It does not move the time to another time zone.

This method can also be used to do the inverse – to create a time zone unaware object from an aware object. To that end, pass `tz=None`.

Parameters

tz [str, pytz.timezone, dateutil.tz.tzfile or None] Time zone to convert timestamps to. Passing None will remove the time zone information preserving local time.

ambiguous ['infer', 'NaT', bool array, default 'raise'] When clocks moved backward due to DST, ambiguous times may arise. For example in Central European Time (UTC+01), when going from 03:00 DST to 02:00 non-DST, 02:30:00 local time occurs both at 00:30:00 UTC and at 01:30:00 UTC. In such a situation, the *ambiguous* parameter dictates how ambiguous times should be handled.

- 'infer' will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False signifies a non-DST time (note that this flag is only applicable for ambiguous times)
- 'NaT' will return NaT where there are ambiguous times
- 'raise' will raise an `AmbiguousTimeError` if there are ambiguous times.

nonexistent ['shift_forward', 'shift_backward', 'NaT', timedelta, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- 'shift_forward' will shift the nonexistent time forward to the closest existing time
- 'shift_backward' will shift the nonexistent time backward to the closest existing time
- 'NaT' will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- 'raise' will raise an `NonExistentTimeError` if there are nonexistent times.

Returns

Same type as self Array/Index converted to the specified time zone.

Raises

TypeError If the Datetime Array/Index is tz-aware and tz is not None.

See also:

[`DatetimeIndex.tz_convert`](#) Convert tz-aware `DatetimeIndex` from one time zone to another.

Examples

```
>>> tz_naive = pd.date_range('2018-03-01 09:00', periods=3)
>>> tz_naive
DatetimeIndex(['2018-03-01 09:00:00', '2018-03-02 09:00:00',
              '2018-03-03 09:00:00'],
              dtype='datetime64[ns]', freq='D')
```

Localize `DatetimeIndex` in US/Eastern time zone:

```
>>> tz_aware = tz_naive.tz_localize(tz='US/Eastern')
>>> tz_aware
DatetimeIndex(['2018-03-01 09:00:00-05:00',
              '2018-03-02 09:00:00-05:00',
              '2018-03-03 09:00:00-05:00'],
              dtype='datetime64[ns, US/Eastern]', freq=None)
```

With the `tz=None`, we can remove the time zone information while keeping the local time (not converted to UTC):

```
>>> tz_aware.tz_localize(None)
DatetimeIndex(['2018-03-01 09:00:00', '2018-03-02 09:00:00',
              '2018-03-03 09:00:00'],
              dtype='datetime64[ns]', freq=None)
```

Be careful with DST changes. When there is sequential data, pandas can infer the DST time:

```
>>> s = pd.to_datetime(pd.Series(['2018-10-28 01:30:00',
...                               '2018-10-28 02:00:00',
...                               '2018-10-28 02:30:00',
...                               '2018-10-28 02:00:00',
...                               '2018-10-28 02:30:00',
...                               ]))
```

(continues on next page)

(continued from previous page)

```

...                                     '2018-10-28 03:00:00',
...                                     '2018-10-28 03:30:00'])])
>>> s.dt.tz_localize('CET', ambiguous='infer')
0    2018-10-28 01:30:00+02:00
1    2018-10-28 02:00:00+02:00
2    2018-10-28 02:30:00+02:00
3    2018-10-28 02:00:00+01:00
4    2018-10-28 02:30:00+01:00
5    2018-10-28 03:00:00+01:00
6    2018-10-28 03:30:00+01:00
dtype: datetime64[ns, CET]

```

In some cases, inferring the DST is impossible. In such cases, you can pass an ndarray to the ambiguous parameter to set the DST explicitly

```

>>> s = pd.to_datetime(pd.Series(['2018-10-28 01:20:00',
...                               '2018-10-28 02:36:00',
...                               '2018-10-28 03:46:00']))
>>> s.dt.tz_localize('CET', ambiguous=np.array([True, True, False]))
0    2018-10-28 01:20:00+02:00
1    2018-10-28 02:36:00+02:00
2    2018-10-28 03:46:00+01:00
dtype: datetime64[ns, CET]

```

If the DST transition causes nonexistent times, you can shift these dates forward or backwards with a timedelta object or `'shift_forward'` or `'shift_backwards'`.

```

>>> s = pd.to_datetime(pd.Series(['2015-03-29 02:30:00',
...                               '2015-03-29 03:30:00']))
>>> s.dt.tz_localize('Europe/Warsaw', nonexistent='shift_forward')
0    2015-03-29 03:00:00+02:00
1    2015-03-29 03:30:00+02:00
dtype: datetime64[ns, Europe/Warsaw]

```

```

>>> s.dt.tz_localize('Europe/Warsaw', nonexistent='shift_backward')
0    2015-03-29 01:59:59.999999999+01:00
1    2015-03-29 03:30:00+02:00
dtype: datetime64[ns, Europe/Warsaw]

```

```

>>> s.dt.tz_localize('Europe/Warsaw', nonexistent=pd.Timedelta('1H'))
0    2015-03-29 03:30:00+02:00
1    2015-03-29 03:30:00+02:00
dtype: datetime64[ns, Europe/Warsaw]

```

pandas.Series.dt.tz_convert

`Series.dt.tz_convert(*args, **kwargs)`

Convert tz-aware Datetime Array/Index from one time zone to another.

Parameters

tz [str, pytz.timezone, dateutil.tz.tzfile or None] Time zone for time. Corresponding timestamps would be converted to this time zone of the Datetime Array/Index. A *tz* of None will convert to UTC and remove the timezone information.

Returns

Array or Index

Raises

TypeError If Datetime Array/Index is tz-naive.

See also:

DatetimeIndex.tz A timezone that has a variable offset from UTC.

DatetimeIndex.tz_localize Localize tz-naive DatetimeIndex to a given time zone, or remove timezone from a tz-aware DatetimeIndex.

Examples

With the *tz* parameter, we can change the DatetimeIndex to other time zones:

```
>>> dti = pd.date_range(start='2014-08-01 09:00',
...                       freq='H', periods=3, tz='Europe/Berlin')
```

```
>>> dti
DatetimeIndex(['2014-08-01 09:00:00+02:00',
               '2014-08-01 10:00:00+02:00',
               '2014-08-01 11:00:00+02:00'],
              dtype='datetime64[ns, Europe/Berlin]', freq='H')
```

```
>>> dti.tz_convert('US/Central')
DatetimeIndex(['2014-08-01 02:00:00-05:00',
               '2014-08-01 03:00:00-05:00',
               '2014-08-01 04:00:00-05:00'],
              dtype='datetime64[ns, US/Central]', freq='H')
```

With the *tz=None*, we can remove the timezone (after converting to UTC if necessary):

```
>>> dti = pd.date_range(start='2014-08-01 09:00', freq='H',
...                       periods=3, tz='Europe/Berlin')
```

```
>>> dti
DatetimeIndex(['2014-08-01 09:00:00+02:00',
               '2014-08-01 10:00:00+02:00',
               '2014-08-01 11:00:00+02:00'],
              dtype='datetime64[ns, Europe/Berlin]', freq='H')
```

```
>>> dti.tz_convert(None)
DatetimeIndex(['2014-08-01 07:00:00',
              '2014-08-01 08:00:00',
              '2014-08-01 09:00:00'],
              dtype='datetime64[ns]', freq='H')
```

pandas.Series.dt.normalize

`Series.dt.normalize(*args, **kwargs)`

Convert times to midnight.

The time component of the date-time is converted to midnight i.e. 00:00:00. This is useful in cases, when the time does not matter. Length is unaltered. The timezones are unaffected.

This method is available on Series with datetime values under the `.dt` accessor, and directly on Datetime Array/Index.

Returns

DatetimeArray, DatetimeIndex or Series The same type as the original data. Series will have the same name and index. DatetimeIndex will have the same name.

See also:

floor Floor the datetimes to the specified freq.

ceil Ceil the datetimes to the specified freq.

round Round the datetimes to the specified freq.

Examples

```
>>> idx = pd.date_range(start='2014-08-01 10:00', freq='H',
...                    periods=3, tz='Asia/Calcutta')
>>> idx
DatetimeIndex(['2014-08-01 10:00:00+05:30',
              '2014-08-01 11:00:00+05:30',
              '2014-08-01 12:00:00+05:30'],
              dtype='datetime64[ns, Asia/Calcutta]', freq='H')
>>> idx.normalize()
DatetimeIndex(['2014-08-01 00:00:00+05:30',
              '2014-08-01 00:00:00+05:30',
              '2014-08-01 00:00:00+05:30'],
              dtype='datetime64[ns, Asia/Calcutta]', freq=None)
```

pandas.Series.dt.strftime

`Series.dt.strftime(*args, **kwargs)`

Convert to Index using specified `date_format`.

Return an Index of formatted strings specified by `date_format`, which supports the same string format as the python standard library. Details of the string format can be found in [python string format doc](#).

Parameters

date_format [str] Date format string (e.g. “%Y-%m-%d”).

Returns

ndarray NumPy ndarray of formatted strings.

See also:

`to_datetime` Convert the given argument to datetime.

`DatetimeIndex.normalize` Return DatetimeIndex with times to midnight.

`DatetimeIndex.round` Round the DatetimeIndex to the specified freq.

`DatetimeIndex.floor` Floor the DatetimeIndex to the specified freq.

Examples

```
>>> rng = pd.date_range(pd.Timestamp("2018-03-10 09:00"),
...                     periods=3, freq='s')
>>> rng.strftime('%B %d, %Y, %r')
Index(['March 10, 2018, 09:00:00 AM', 'March 10, 2018, 09:00:01 AM',
       'March 10, 2018, 09:00:02 AM'],
      dtype='object')
```

pandas.Series.dt.round

`Series.dt.round(*args, **kwargs)`

Perform round operation on the data to the specified *freq*.

Parameters

freq [str or Offset] The frequency level to round the index to. Must be a fixed frequency like 'S' (second) not 'ME' (month end). See [frequency aliases](#) for a list of possible *freq* values.

ambiguous ['infer', bool-ndarray, 'NaT', default 'raise'] Only relevant for DatetimeIndex:

- 'infer' will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- 'NaT' will return NaT where there are ambiguous times
- 'raise' will raise an `AmbiguousTimeError` if there are ambiguous times.

nonexistent ['shift_forward', 'shift_backward', 'NaT', timedelta, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- 'shift_forward' will shift the nonexistent time forward to the closest existing time
- 'shift_backward' will shift the nonexistent time backward to the closest existing time
- 'NaT' will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- 'raise' will raise an `NonExistentTimeError` if there are nonexistent times.

Returns

DatetimeIndex, TimedeltaIndex, or Series Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

Raises

ValueError if the *freq* cannot be converted.

Examples

DatetimeIndex

```
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
              '2018-01-01 12:01:00'],
              dtype='datetime64[ns]', freq='T')
>>> rng.round('H')
DatetimeIndex(['2018-01-01 12:00:00', '2018-01-01 12:00:00',
              '2018-01-01 12:00:00'],
              dtype='datetime64[ns]', freq=None)
```

Series

```
>>> pd.Series(rng).dt.round("H")
0    2018-01-01 12:00:00
1    2018-01-01 12:00:00
2    2018-01-01 12:00:00
dtype: datetime64[ns]
```

pandas.Series.dt.floor

`Series.dt.floor(*args, **kwargs)`

Perform floor operation on the data to the specified *freq*.

Parameters

freq [str or Offset] The frequency level to floor the index to. Must be a fixed frequency like 'S' (second) not 'ME' (month end). See *frequency aliases* for a list of possible *freq* values.

ambiguous ['infer', bool-ndarray, 'NaT', default 'raise'] Only relevant for DatetimeIndex:

- 'infer' will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- 'NaT' will return NaT where there are ambiguous times
- 'raise' will raise an AmbiguousTimeError if there are ambiguous times.

nonexistent ['shift_forward', 'shift_backward', 'NaT', timedelta, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- 'shift_forward' will shift the nonexistent time forward to the closest existing time
- 'shift_backward' will shift the nonexistent time backward to the closest existing time
- 'NaT' will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta

- ‘raise’ will raise an `NonExistentTimeError` if there are nonexistent times.

Returns

DatetimeIndex, TimedeltaIndex, or Series Index of the same type for a `DatetimeIndex` or `TimedeltaIndex`, or a `Series` with the same index for a `Series`.

Raises

ValueError if the *freq* cannot be converted.

Examples

DatetimeIndex

```
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
              '2018-01-01 12:01:00'],
              dtype='datetime64[ns]', freq='T')
>>> rng.floor('H')
DatetimeIndex(['2018-01-01 11:00:00', '2018-01-01 12:00:00',
              '2018-01-01 12:00:00'],
              dtype='datetime64[ns]', freq=None)
```

Series

```
>>> pd.Series(rng).dt.floor("H")
0    2018-01-01 11:00:00
1    2018-01-01 12:00:00
2    2018-01-01 12:00:00
dtype: datetime64[ns]
```

pandas.Series.dt.ceil

`Series.dt.ceil(*args, **kwargs)`

Perform ceil operation on the data to the specified *freq*.

Parameters

freq [str or Offset] The frequency level to ceil the index to. Must be a fixed frequency like ‘S’ (second) not ‘ME’ (month end). See *frequency aliases* for a list of possible *freq* values.

ambiguous [‘infer’, bool-ndarray, ‘NaT’, default ‘raise’] Only relevant for `DatetimeIndex`:

- ‘infer’ will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- ‘NaT’ will return NaT where there are ambiguous times
- ‘raise’ will raise an `AmbiguousTimeError` if there are ambiguous times.

nonexistent [‘shift_forward’, ‘shift_backward’, ‘NaT’, timedelta, default ‘raise’] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- ‘shift_forward’ will shift the nonexistent time forward to the closest existing time

- 'shift_backward' will shift the nonexistent time backward to the closest existing time
- 'NaT' will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- 'raise' will raise an NonExistentTimeError if there are nonexistent times.

Returns

DatetimeIndex, TimedeltaIndex, or Series Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

Raises

ValueError if the *freq* cannot be converted.

Examples**DatetimeIndex**

```
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
              '2018-01-01 12:01:00'],
              dtype='datetime64[ns]', freq='T')
>>> rng.ceil('H')
DatetimeIndex(['2018-01-01 12:00:00', '2018-01-01 12:00:00',
              '2018-01-01 13:00:00'],
              dtype='datetime64[ns]', freq=None)
```

Series

```
>>> pd.Series(rng).dt.ceil("H")
0    2018-01-01 12:00:00
1    2018-01-01 12:00:00
2    2018-01-01 13:00:00
dtype: datetime64[ns]
```

pandas.Series.dt.month_name

Series.dt.month_name(*args, **kwargs)

Return the month names of the DateTimeIndex with specified locale.

Parameters

locale [str, optional] Locale determining the language in which to return the month name. Default is English locale.

Returns

Index Index of month names.

Examples

```
>>> idx = pd.date_range(start='2018-01', freq='M', periods=3)
>>> idx
DatetimeIndex(['2018-01-31', '2018-02-28', '2018-03-31'],
              dtype='datetime64[ns]', freq='M')
>>> idx.month_name()
Index(['January', 'February', 'March'], dtype='object')
```

pandas.Series.dt.day_name

`Series.dt.day_name(*args, **kwargs)`

Return the day names of the DateTimeIndex with specified locale.

Parameters

locale [str, optional] Locale determining the language in which to return the day name. Default is English locale.

Returns

Index Index of day names.

Examples

```
>>> idx = pd.date_range(start='2018-01-01', freq='D', periods=3)
>>> idx
DatetimeIndex(['2018-01-01', '2018-01-02', '2018-01-03'],
              dtype='datetime64[ns]', freq='D')
>>> idx.day_name()
Index(['Monday', 'Tuesday', 'Wednesday'], dtype='object')
```

| | |
|-------------------------------------|---|
| <code>Series.dt.days</code> | Number of days for each element. |
| <code>Series.dt.seconds</code> | Number of seconds (≥ 0 and less than 1 day) for each element. |
| <code>Series.dt.microseconds</code> | Number of microseconds (≥ 0 and less than 1 second) for each element. |
| <code>Series.dt.nanoseconds</code> | Number of nanoseconds (≥ 0 and less than 1 microsecond) for each element. |
| <code>Series.dt.components</code> | Return a Dataframe of the components of the Timedeltas. |

pandas.Series.dt.days

`Series.dt.days`
 Number of days for each element.

pandas.Series.dt.seconds

`Series.dt.seconds`
 Number of seconds (≥ 0 and less than 1 day) for each element.

pandas.Series.dt.microseconds

`Series.dt.microseconds`
 Number of microseconds (≥ 0 and less than 1 second) for each element.

pandas.Series.dt.nanoseconds

Series.dt.nanoseconds

Number of nanoseconds (≥ 0 and less than 1 microsecond) for each element.

pandas.Series.dt.components

Series.dt.components

Return a DataFrame of the components of the Timedeltas.

Returns

DataFrame

Examples

```

>>> s = pd.Series(pd.to_timedelta(np.arange(5), unit='s'))
>>> s
0    0 days 00:00:00
1    0 days 00:00:01
2    0 days 00:00:02
3    0 days 00:00:03
4    0 days 00:00:04
dtype: timedelta64[ns]
>>> s.dt.components
   days  hours  minutes  seconds  milliseconds  microseconds  nanoseconds
0     0     0         0         0             0             0             0
1     0     0         0         1             0             0             0
2     0     0         0         2             0             0             0
3     0     0         0         3             0             0             0
4     0     0         0         4             0             0             0

```

Timedelta methods

| | |
|---|--|
| <code>Series.dt.to_pytimedelta()</code> | Return an array of native <i>datetime.timedelta</i> objects. |
| <code>Series.dt.total_seconds(*args, **kwargs)</code> | Return total duration of each element expressed in seconds. |

pandas.Series.dt.to_pytimedelta

Series.dt.to_pytimedelta()

Return an array of native *datetime.timedelta* objects.

Python's standard *datetime* library uses a different representation *timedelta*'s. This method converts a Series of pandas Timedeltas to *datetime.timedelta* format with the same length as the original Series.

Returns

numpy.ndarray Array of 1D containing data with *datetime.timedelta* type.

See also:

datetime.timedelta A duration expressing the difference between two date, time, or datetime.

Examples

```
>>> s = pd.Series(pd.to_timedelta(np.arange(5), unit="d"))
>>> s
0    0 days
1    1 days
2    2 days
3    3 days
4    4 days
dtype: timedelta64[ns]
```

```
>>> s.dt.to_pytimedelta()
array([datetime.timedelta(0), datetime.timedelta(days=1),
       datetime.timedelta(days=2), datetime.timedelta(days=3),
       datetime.timedelta(days=4)], dtype=object)
```

pandas.Series.dt.total_seconds

`Series.dt.total_seconds(*args, **kwargs)`

Return total duration of each element expressed in seconds.

This method is available directly on `TimedeltaArray`, `TimedeltaIndex` and on `Series` containing `timedelta` values under the `.dt` namespace.

Returns

seconds `[[ndarray, Float64Index, Series]]` When the calling object is a `TimedeltaArray`, the return type is `ndarray`. When the calling object is a `TimedeltaIndex`, the return type is a `Float64Index`. When the calling object is a `Series`, the return type is `Series` of type `float64` whose index is the same as the original.

See also:

[datetime.timedelta.total_seconds](#) Standard library version of this method.

[TimedeltaIndex.components](#) Return a `DataFrame` with components of each `Timedelta`.

Examples

Series

```
>>> s = pd.Series(pd.to_timedelta(np.arange(5), unit='d'))
>>> s
0    0 days
1    1 days
2    2 days
3    3 days
4    4 days
dtype: timedelta64[ns]
```

```
>>> s.dt.total_seconds()
0         0.0
1    86400.0
2   172800.0
3   259200.0
```

(continues on next page)

(continued from previous page)

```
4    345600.0
dtype: float64
```

TimedeltaIndex

```
>>> idx = pd.to_timedelta(np.arange(5), unit='d')
>>> idx
TimedeltaIndex(['0 days', '1 days', '2 days', '3 days', '4 days'],
                dtype='timedelta64[ns]', freq=None)
```

```
>>> idx.total_seconds()
Float64Index([0.0, 86400.0, 172800.0, 259200.000000000003, 345600.0],
              dtype='float64')
```

String handling

`Series.str` can be used to access the values of the series as strings and apply several methods to it. These can be accessed like `Series.str.<function/property>`.

| | |
|--|---|
| <code>Series.str.capitalize()</code> | Convert strings in the Series/Index to be capitalized. |
| <code>Series.str.casefold()</code> | Convert strings in the Series/Index to be casefolded. |
| <code>Series.str.cat</code> ([others, sep, na_rep, join]) | Concatenate strings in the Series/Index with given separator. |
| <code>Series.str.center</code> (width[, fillchar]) | Pad left and right side of strings in the Series/Index. |
| <code>Series.str.contains</code> (pat[, case, flags, na, ...]) | Test if pattern or regex is contained within a string of a Series or Index. |
| <code>Series.str.count</code> (pat[, flags]) | Count occurrences of pattern in each string of the Series/Index. |
| <code>Series.str.decode</code> (encoding[, errors]) | Decode character string in the Series/Index using indicated encoding. |
| <code>Series.str.encode</code> (encoding[, errors]) | Encode character string in the Series/Index using indicated encoding. |
| <code>Series.str.endswith</code> (pat[, na]) | Test if the end of each string element matches a pattern. |
| <code>Series.str.extract</code> (pat[, flags, expand]) | Extract capture groups in the regex <i>pat</i> as columns in a DataFrame. |
| <code>Series.str.extractall</code> (pat[, flags]) | Extract capture groups in the regex <i>pat</i> as columns in DataFrame. |
| <code>Series.str.find</code> (sub[, start, end]) | Return lowest indexes in each strings in the Series/Index. |
| <code>Series.str.findall</code> (pat[, flags]) | Find all occurrences of pattern or regular expression in the Series/Index. |
| <code>Series.str.fullmatch</code> (pat[, case, flags, na]) | Determine if each string entirely matches a regular expression. |
| <code>Series.str.get</code> (i) | Extract element from each component at specified position. |
| <code>Series.str.index</code> (sub[, start, end]) | Return lowest indexes in each string in Series/Index. |
| <code>Series.str.join</code> (sep) | Join lists contained as elements in the Series/Index with passed delimiter. |
| <code>Series.str.len</code> () | Compute the length of each element in the Series/Index. |
| <code>Series.str.ljust</code> (width[, fillchar]) | Pad right side of strings in the Series/Index. |
| <code>Series.str.lower</code> () | Convert strings in the Series/Index to lowercase. |

continues on next page

Table 51 – continued from previous page

| | |
|--|---|
| <code>Series.str.lstrip([to_strip])</code> | Remove leading characters. |
| <code>Series.str.match(pat[, case, flags, na])</code> | Determine if each string starts with a match of a regular expression. |
| <code>Series.str.normalize(form)</code> | Return the Unicode normal form for the strings in the Series/Index. |
| <code>Series.str.pad(width[, side, fillchar])</code> | Pad strings in the Series/Index up to width. |
| <code>Series.str.partition([sep, expand])</code> | Split the string at the first occurrence of <i>sep</i> . |
| <code>Series.str.repeat(repeats)</code> | Duplicate each string in the Series or Index. |
| <code>Series.str.replace(pat, repl[, n, case, ...])</code> | Replace each occurrence of pattern/regex in the Series/Index. |
| <code>Series.str.rfind(sub[, start, end])</code> | Return highest indexes in each strings in the Series/Index. |
| <code>Series.str.rindex(sub[, start, end])</code> | Return highest indexes in each string in Series/Index. |
| <code>Series.str.rjust(width[, fillchar])</code> | Pad left side of strings in the Series/Index. |
| <code>Series.str.rpartition([sep, expand])</code> | Split the string at the last occurrence of <i>sep</i> . |
| <code>Series.str.rstrip([to_strip])</code> | Remove trailing characters. |
| <code>Series.str.slice([start, stop, step])</code> | Slice substrings from each element in the Series or Index. |
| <code>Series.str.slice_replace([start, stop, repl])</code> | Replace a positional slice of a string with another value. |
| <code>Series.str.split([pat, n, expand])</code> | Split strings around given separator/delimiter. |
| <code>Series.str.rsplit([pat, n, expand])</code> | Split strings around given separator/delimiter. |
| <code>Series.str.startswith(pat[, na])</code> | Test if the start of each string element matches a pattern. |
| <code>Series.str.strip([to_strip])</code> | Remove leading and trailing characters. |
| <code>Series.str.swapcase()</code> | Convert strings in the Series/Index to be swapcased. |
| <code>Series.str.title()</code> | Convert strings in the Series/Index to titlecase. |
| <code>Series.str.translate(table)</code> | Map all characters in the string through the given mapping table. |
| <code>Series.str.upper()</code> | Convert strings in the Series/Index to uppercase. |
| <code>Series.str.wrap(width, **kwargs)</code> | Wrap strings in Series/Index at specified line width. |
| <code>Series.str.zfill(width)</code> | Pad strings in the Series/Index by prepending '0' characters. |
| <code>Series.str.isalnum()</code> | Check whether all characters in each string are alphanumeric. |
| <code>Series.str.isalpha()</code> | Check whether all characters in each string are alphabetic. |
| <code>Series.str.isdigit()</code> | Check whether all characters in each string are digits. |
| <code>Series.str.isspace()</code> | Check whether all characters in each string are whitespace. |
| <code>Series.str.islower()</code> | Check whether all characters in each string are lowercase. |
| <code>Series.str.isupper()</code> | Check whether all characters in each string are uppercase. |
| <code>Series.str.istitle()</code> | Check whether all characters in each string are titlecase. |
| <code>Series.str.isnumeric()</code> | Check whether all characters in each string are numeric. |
| <code>Series.str.isdecimal()</code> | Check whether all characters in each string are decimal. |
| <code>Series.str.get_dummies([sep])</code> | Return DataFrame of dummy/indicator variables for Series. |

pandas.Series.str.capitalize**Series.str.capitalize()**

Convert strings in the Series/Index to be capitalized.

Equivalent to `str.capitalize()`.

Returns

Series or Index of object

See also:

Series.str.lower Converts all characters to lowercase.

Series.str.upper Converts all characters to uppercase.

Series.str.title Converts first character of each word to uppercase and remaining to lowercase.

Series.str.capitalize Converts first character to uppercase and remaining to lowercase.

Series.str.swapcase Converts uppercase to lowercase and lowercase to uppercase.

Series.str.casefold Removes all case distinctions in the string.

Examples

```
>>> s = pd.Series(['lower', 'CAPITALS', 'this is a sentence', 'SwApCaSe'])
>>> s
0          lower
1        CAPITALS
2  this is a sentence
3        SwApCaSe
dtype: object
```

```
>>> s.str.lower()
0          lower
1        capitals
2  this is a sentence
3        swapcase
dtype: object
```

```
>>> s.str.upper()
0          LOWER
1        CAPITALS
2  THIS IS A SENTENCE
3        SWAPCASE
dtype: object
```

```
>>> s.str.title()
0          Lower
1        Capitals
2  This Is A Sentence
3        Swapcase
dtype: object
```

```
>>> s.str.capitalize()
0          Lower
1        Capitals
```

(continues on next page)

(continued from previous page)

```
2    This is a sentence
3           Swapcase
dtype: object
```

```
>>> s.str.swapcase()
0           LOWER
1           capitals
2    THIS IS A SENTENCE
3           sWaPcAsE
dtype: object
```

pandas.Series.str.casefold

Series.str.casefold()

Convert strings in the Series/Index to be casefolded.

New in version 0.25.0.

Equivalent to `str.casefold()`.

Returns

Series or Index of object

See also:

Series.str.lower Converts all characters to lowercase.

Series.str.upper Converts all characters to uppercase.

Series.str.title Converts first character of each word to uppercase and remaining to lowercase.

Series.str.capitalize Converts first character to uppercase and remaining to lowercase.

Series.str.swapcase Converts uppercase to lowercase and lowercase to uppercase.

Series.str.casefold Removes all case distinctions in the string.

Examples

```
>>> s = pd.Series(['lower', 'CAPITALS', 'this is a sentence', 'SwApCaSe'])
>>> s
0           lower
1           CAPITALS
2    this is a sentence
3           SwApCaSe
dtype: object
```

```
>>> s.str.lower()
0           lower
1           capitals
2    this is a sentence
3           swapcase
dtype: object
```

```
>>> s.str.upper()
0           LOWER
1           CAPITALS
```

(continues on next page)

(continued from previous page)

```
2    THIS IS A SENTENCE
3                SWAPCASE
dtype: object
```

```
>>> s.str.title()
0                Lower
1                Capitals
2    This Is A Sentence
3                Swapcase
dtype: object
```

```
>>> s.str.capitalize()
0                Lower
1                Capitals
2    This is a sentence
3                Swapcase
dtype: object
```

```
>>> s.str.swapcase()
0                LOWER
1                capitals
2    THIS IS A SENTENCE
3                sWaPcAsE
dtype: object
```

pandas.Series.str.cat

`Series.str.cat` (*others=None, sep=None, na_rep=None, join='left'*)

Concatenate strings in the Series/Index with given separator.

If *others* is specified, this function concatenates the Series/Index and elements of *others* element-wise. If *others* is not passed, then all values in the Series/Index are concatenated into a single string with a given *sep*.

Parameters

others [Series, Index, DataFrame, np.ndarray or list-like] Series, Index, DataFrame, np.ndarray (one- or two-dimensional) and other list-likes of strings must have the same length as the calling Series/Index, with the exception of indexed objects (i.e. Series/Index/DataFrame) if *join* is not None.

If *others* is a list-like that contains a combination of Series, Index or np.ndarray (1-dim), then all elements will be unpacked and must satisfy the above criteria individually.

If *others* is None, the method returns the concatenation of all strings in the calling Series/Index.

sep [str, default ''] The separator between the different elements/columns. By default the empty string '' is used.

na_rep [str or None, default None] Representation that is inserted for all missing values:

- If *na_rep* is None, and *others* is None, missing values in the Series/Index are omitted from the result.

- If *na_rep* is None, and *others* is not None, a row containing a missing value in any of the columns (before concatenation) will have a missing value in the result.

join [{‘left’, ‘right’, ‘outer’, ‘inner’}, default ‘left’] Determines the join-style between the calling Series/Index and any Series/Index/DataFrame in *others* (objects without an index need to match the length of the calling Series/Index). To disable alignment, use *.values* on any Series/Index/DataFrame in *others*.

New in version 0.23.0.

Changed in version 1.0.0: Changed default of *join* from None to ‘left’.

Returns

str, Series or Index If *others* is None, *str* is returned, otherwise a *Series/Index* (same type as caller) of objects is returned.

See also:

split Split each string in the Series/Index.

join Join lists contained as elements in the Series/Index.

Examples

When not passing *others*, all values are concatenated into a single string:

```
>>> s = pd.Series(['a', 'b', np.nan, 'd'])
>>> s.str.cat(sep=' ')
'a b d'
```

By default, NA values in the Series are ignored. Using *na_rep*, they can be given a representation:

```
>>> s.str.cat(sep=' ', na_rep='?')
'a b ? d'
```

If *others* is specified, corresponding values are concatenated with the separator. Result will be a Series of strings.

```
>>> s.str.cat(['A', 'B', 'C', 'D'], sep=',')
0    a,A
1    b,B
2    NaN
3    d,D
dtype: object
```

Missing values will remain missing in the result, but can again be represented using *na_rep*

```
>>> s.str.cat(['A', 'B', 'C', 'D'], sep=',', na_rep='-')
0    a,A
1    b,B
2    -,C
3    d,D
dtype: object
```

If *sep* is not specified, the values are concatenated without separation.

```
>>> s.str.cat(['A', 'B', 'C', 'D'], na_rep='-')
0    aA
```

(continues on next page)

(continued from previous page)

```

1    bB
2    -C
3    dD
dtype: object

```

Series with different indexes can be aligned before concatenation. The *join*-keyword works as in other methods.

```

>>> t = pd.Series(['d', 'a', 'e', 'c'], index=[3, 0, 4, 2])
>>> s.str.cat(t, join='left', na_rep='-')
0    aa
1    b-
2    -c
3    dd
dtype: object
>>>
>>> s.str.cat(t, join='outer', na_rep='-')
0    aa
1    b-
2    -c
3    dd
4    -e
dtype: object
>>>
>>> s.str.cat(t, join='inner', na_rep='-')
0    aa
2    -c
3    dd
dtype: object
>>>
>>> s.str.cat(t, join='right', na_rep='-')
3    dd
0    aa
4    -e
2    -c
dtype: object

```

For more examples, see [here](#).

pandas.Series.str.center

`Series.str.center(width, fillchar='')`

Pad left and right side of strings in the Series/Index.

Equivalent to `str.center()`.

Parameters

width [int] Minimum width of resulting string; additional characters will be filled with `fillchar`.

fillchar [str] Additional character for filling, default is whitespace.

Returns

filled [Series/Index of objects.]

pandas.Series.str.contains

`Series.str.contains(pat, case=True, flags=0, na=None, regex=True)`

Test if pattern or regex is contained within a string of a Series or Index.

Return boolean Series or Index based on whether a given pattern or regex is contained within a string of a Series or Index.

Parameters

pat [str] Character sequence or regular expression.

case [bool, default True] If True, case sensitive.

flags [int, default 0 (no flags)] Flags to pass through to the re module, e.g. re.IGNORECASE.

na [scalar, optional] Fill value for missing values. The default depends on dtype of the array. For object-dtype, `numpy.nan` is used. For `StringDtype`, `pandas.NA` is used.

regex [bool, default True] If True, assumes the pat is a regular expression.

If False, treats the pat as a literal string.

Returns

Series or Index of boolean values A Series or Index of boolean values indicating whether the given pattern is contained within the string of each element of the Series or Index.

See also:

[`match`](#) Analogous, but stricter, relying on `re.match` instead of `re.search`.

[`Series.str.startswith`](#) Test if the start of each string element matches a pattern.

[`Series.str.endswith`](#) Same as `startswith`, but tests the end of string.

Examples

Returning a Series of booleans using only a literal pattern.

```

>>> s1 = pd.Series(['Mouse', 'dog', 'house and parrot', '23', np.NaN])
>>> s1.str.contains('og', regex=False)
0    False
1     True
2    False
3    False
4     NaN
dtype: object

```

Returning an Index of booleans using only a literal pattern.

```

>>> ind = pd.Index(['Mouse', 'dog', 'house and parrot', '23.0', np.NaN])
>>> ind.str.contains('23', regex=False)
Index([False, False, False, True, nan], dtype='object')

```

Specifying case sensitivity using `case`.

```

>>> s1.str.contains('oG', case=True, regex=True)
0    False
1    False
2    False
3    False

```

(continues on next page)

(continued from previous page)

```
4      NaN
dtype: object
```

Specifying *na* to be *False* instead of *NaN* replaces NaN values with *False*. If Series or Index does not contain NaN values the resultant dtype will be *bool*, otherwise, an *object* dtype.

```
>>> s1.str.contains('og', na=False, regex=True)
0      False
1       True
2      False
3      False
4      False
dtype: bool
```

Returning 'house' or 'dog' when either expression occurs in a string.

```
>>> s1.str.contains('house|dog', regex=True)
0      False
1       True
2       True
3      False
4       NaN
dtype: object
```

Ignoring case sensitivity using *flags* with regex.

```
>>> import re
>>> s1.str.contains('PARROT', flags=re.IGNORECASE, regex=True)
0      False
1      False
2       True
3      False
4       NaN
dtype: object
```

Returning any digit using regular expression.

```
>>> s1.str.contains('\d', regex=True)
0      False
1      False
2      False
3       True
4       NaN
dtype: object
```

Ensure *pat* is not a literal pattern when *regex* is set to *True*. Note in the following example one might expect only *s2[1]* and *s2[3]* to return *True*. However, *'0'* as a regex matches any character followed by a 0.

```
>>> s2 = pd.Series(['40', '40.0', '41', '41.0', '35'])
>>> s2.str.contains('.0', regex=True)
0      True
1      True
2      False
```

(continues on next page)

(continued from previous page)

```
3    True
4    False
dtype: bool
```

pandas.Series.str.count

`Series.str.count(pat, flags=0)`

Count occurrences of pattern in each string of the Series/Index.

This function is used to count the number of times a particular regex pattern is repeated in each of the string elements of the *Series*.

Parameters

pat [str] Valid regular expression.

flags [int, default 0, meaning no flags] Flags for the *re* module. For a complete list, [see here](#).

****kwargs** For compatibility with other string methods. Not used.

Returns

Series or Index Same type as the calling object containing the integer counts.

See also:

re Standard library module for regular expressions.

str.count Standard library version, without regular expression support.

Notes

Some characters need to be escaped when passing in *pat*. eg. '\$' has a special meaning in regex and must be escaped when finding this literal character.

Examples

```
>>> s = pd.Series(['A', 'B', 'Aaba', 'Baca', np.nan, 'CABA', 'cat'])
>>> s.str.count('a')
0    0.0
1    0.0
2    2.0
3    2.0
4    NaN
5    0.0
6    1.0
dtype: float64
```

Escape '\$' to find the literal dollar sign.

```
>>> s = pd.Series(['$', 'B', 'Aab$', '$$ca', 'C$B$', 'cat'])
>>> s.str.count('\$')
0    1
1    0
2    1
```

(continues on next page)

(continued from previous page)

```
3    2
4    2
5    0
dtype: int64
```

This is also available on Index

```
>>> pd.Index(['A', 'A', 'Aaba', 'cat']).str.count('a')
Int64Index([0, 0, 2, 1], dtype='int64')
```

pandas.Series.str.decode

`Series.str.decode(encoding, errors='strict')`

Decode character string in the Series/Index using indicated encoding.

Equivalent to `str.decode()` in python2 and `bytes.decode()` in python3.

Parameters

encoding [str]

errors [str, optional]

Returns

Series or Index

pandas.Series.str.encode

`Series.str.encode(encoding, errors='strict')`

Encode character string in the Series/Index using indicated encoding.

Equivalent to `str.encode()`.

Parameters

encoding [str]

errors [str, optional]

Returns

encoded [Series/Index of objects]

pandas.Series.str.endswith

`Series.str.endswith(pat, na=None)`

Test if the end of each string element matches a pattern.

Equivalent to `str.endswith()`.

Parameters

pat [str] Character sequence. Regular expressions are not accepted.

na [object, default NaN] Object shown if element tested is not a string. The default depends on dtype of the array. For object-dtype, `numpy.nan` is used. For `StringDtype`, `pandas.NA` is used.

Returns

Series or Index of bool A Series of booleans indicating whether the given pattern matches the end of each string element.

See also:

[`str.endswith`](#) Python standard library string method.

[`Series.str.startswith`](#) Same as `endswith`, but tests the start of string.

[`Series.str.contains`](#) Tests if string element contains a pattern.

Examples

```
>>> s = pd.Series(['bat', 'bear', 'caT', np.nan])
>>> s
0    bat
1    bear
2    caT
3    NaN
dtype: object
```

```
>>> s.str.endswith('t')
0    True
1    False
2    False
3    NaN
dtype: object
```

Specifying *na* to be *False* instead of *NaN*.

```
>>> s.str.endswith('t', na=False)
0    True
1    False
2    False
3    False
dtype: bool
```

pandas.Series.str.extract

`Series.str.extract(pat, flags=0, expand=True)`

Extract capture groups in the regex *pat* as columns in a DataFrame.

For each subject string in the Series, extract groups from the first match of regular expression *pat*.

Parameters

pat [str] Regular expression pattern with capturing groups.

flags [int, default 0 (no flags)] Flags from the `re` module, e.g. `re.IGNORECASE`, that modify regular expression matching for things like case, spaces, etc. For more details, see [re](#).

expand [bool, default True] If True, return DataFrame with one column per capture group. If False, return a Series/Index if there is one capture group or DataFrame if there are multiple capture groups.

Returns

DataFrame or Series or Index A DataFrame with one row for each subject string, and one column for each group. Any capture group names in regular expression pat will be used for column names; otherwise capture group numbers will be used. The dtype of each result column is always object, even when no match is found. If `expand=False` and pat has only one capture group, then return a Series (if subject is a Series) or Index (if subject is an Index).

See also:

[`extractall`](#) Returns all matches (not just the first match).

Examples

A pattern with two groups will return a DataFrame with two columns. Non-matches will be NaN.

```
>>> s = pd.Series(['a1', 'b2', 'c3'])
>>> s.str.extract(r'([ab])(\d)')
   0  1
0  a  1
1  b  2
2 NaN NaN
```

A pattern may contain optional groups.

```
>>> s.str.extract(r'([ab])?(\d)')
   0  1
0  a  1
1  b  2
2 NaN 3
```

Named groups will become column names in the result.

```
>>> s.str.extract(r'(?P<letter>[ab])(?P<digit>\d)')
letter digit
0      a      1
1      b      2
2     NaN     NaN
```

A pattern with one group will return a DataFrame with one column if `expand=True`.

```
>>> s.str.extract(r'[ab](\d)', expand=True)
   0
0  1
1  2
2 NaN
```

A pattern with one group will return a Series if `expand=False`.

```
>>> s.str.extract(r'[ab](\d)', expand=False)
0      1
1      2
2     NaN
dtype: object
```

pandas.Series.str.extractall

`Series.str.extractall(pat, flags=0)`

Extract capture groups in the regex *pat* as columns in DataFrame.

For each subject string in the Series, extract groups from all matches of regular expression *pat*. When each subject string in the Series has exactly one match, `extractall(pat).xs(0, level='match')` is the same as `extract(pat)`.

Parameters

pat [str] Regular expression pattern with capturing groups.

flags [int, default 0 (no flags)] A re module flag, for example `re.IGNORECASE`. These allow to modify regular expression matching for things like case, spaces, etc. Multiple flags can be combined with the bitwise OR operator, for example `re.IGNORECASE | re.MULTILINE`.

Returns

DataFrame A DataFrame with one row for each match, and one column for each group. Its rows have a `MultiIndex` with first levels that come from the subject Series. The last level is named 'match' and indexes the matches in each item of the Series. Any capture group names in regular expression *pat* will be used for column names; otherwise capture group numbers will be used.

See also:

[extract](#) Returns first match only (not all matches).

Examples

A pattern with one group will return a DataFrame with one column. Indices with no matches will not appear in the result.

```
>>> s = pd.Series(["a1a2", "b1", "c1"], index=["A", "B", "C"])
>>> s.str.extractall(r"[ab](\d)")
      0
match
A 0    1
  1    2
B 0    1
```

Capture group names are used for column names of the result.

```
>>> s.str.extractall(r"[ab](?P<digit>\d)")
      digit
match
A 0         1
  1         2
B 0         1
```

A pattern with two groups will return a DataFrame with two columns.

```
>>> s.str.extractall(r"(?P<letter>[ab])(?P<digit>\d)")
      letter digit
match
A 0         a    1
```

(continues on next page)

(continued from previous page)

| | | |
|-----|---|---|
| 1 | a | 2 |
| B 0 | b | 1 |

Optional groups that do not match are NaN in the result.

```
>>> s.str.extractall(r"(?P<letter>[ab])?(?P<digit>\d)")
      letter digit
match
A 0      a      1
  1      a      2
B 0      b      1
C 0      NaN     1
```

pandas.Series.str.find

`Series.str.find(sub, start=0, end=None)`

Return lowest indexes in each strings in the Series/Index.

Each of returned indexes corresponds to the position where the substring is fully contained between [start:end]. Return -1 on failure. Equivalent to standard `str.find()`.

Parameters

sub [str] Substring being searched.

start [int] Left edge index.

end [int] Right edge index.

Returns

Series or Index of int.

See also:

[`rfind`](#) Return highest indexes in each strings.

pandas.Series.str.findall

`Series.str.findall(pat, flags=0)`

Find all occurrences of pattern or regular expression in the Series/Index.

Equivalent to applying `re.findall()` to all the elements in the Series/Index.

Parameters

pat [str] Pattern or regular expression.

flags [int, default 0] Flags from `re` module, e.g. `re.IGNORECASE` (default is 0, which means no flags).

Returns

Series/Index of lists of strings All non-overlapping matches of pattern or regular expression in each string of this Series/Index.

See also:

[`count`](#) Count occurrences of pattern or regular expression in each string of the Series/Index.

[`extractall`](#) For each string in the Series, extract groups from all matches of regular expression and return a DataFrame with one row for each match and one column for each group.

re.findall The equivalent re function to all non-overlapping matches of pattern or regular expression in string, as a list of strings.

Examples

```
>>> s = pd.Series(['Lion', 'Monkey', 'Rabbit'])
```

The search for the pattern 'Monkey' returns one match:

```
>>> s.str.findall('Monkey')
0      []
1  [Monkey]
2      []
dtype: object
```

On the other hand, the search for the pattern 'MONKEY' doesn't return any match:

```
>>> s.str.findall('MONKEY')
0      []
1      []
2      []
dtype: object
```

Flags can be added to the pattern or regular expression. For instance, to find the pattern 'MONKEY' ignoring the case:

```
>>> import re
>>> s.str.findall('MONKEY', flags=re.IGNORECASE)
0      []
1  [Monkey]
2      []
dtype: object
```

When the pattern matches more than one string in the Series, all matches are returned:

```
>>> s.str.findall('on')
0  [on]
1  [on]
2   []
dtype: object
```

Regular expressions are supported too. For instance, the search for all the strings ending with the word 'on' is shown next:

```
>>> s.str.findall('on$')
0  [on]
1   []
2   []
dtype: object
```

If the pattern is found more than once in the same string, then a list of multiple strings is returned:

```
>>> s.str.findall('b')
0      []
1      []
2     [b, b]
dtype: object
```

pandas.Series.str.fullmatch

`Series.str.fullmatch(pat, case=True, flags=0, na=None)`

Determine if each string entirely matches a regular expression.

New in version 1.1.0.

Parameters

pat [str] Character sequence or regular expression.

case [bool, default True] If True, case sensitive.

flags [int, default 0 (no flags)] Regex module flags, e.g. `re.IGNORECASE`.

na [scalar, optional] Fill value for missing values. The default depends on dtype of the array. For object-dtype, `numpy.nan` is used. For `StringDtype`, `pandas.NA` is used.

Returns

Series/Index/array of boolean values

See also:

match Similar, but also returns *True* when only a *prefix* of the string matches the regular expression.

extract Extract matched groups.

pandas.Series.str.get

`Series.str.get(i)`

Extract element from each component at specified position.

Extract element from lists, tuples, or strings in each element in the Series/Index.

Parameters

i [int] Position of element to extract.

Returns

Series or Index

Examples

```
>>> s = pd.Series(["String",
...              (1, 2, 3),
...              ["a", "b", "c"],
...              123,
...              -456,
...              {1: "Hello", "2": "World"}])
>>> s
0      String
```

(continues on next page)

(continued from previous page)

```

1          (1, 2, 3)
2          [a, b, c]
3          123
4          -456
5    {1: 'Hello', '2': 'World'}
dtype: object

```

```

>>> s.str.get(1)
0          t
1          2
2          b
3         NaN
4         NaN
5        Hello
dtype: object

```

```

>>> s.str.get(-1)
0          g
1          3
2          c
3         NaN
4         NaN
5         None
dtype: object

```

pandas.Series.str.index

`Series.str.index(sub, start=0, end=None)`

Return lowest indexes in each string in Series/Index.

Each of the returned indexes corresponds to the position where the substring is fully contained between [start:end]. This is the same as `str.find` except instead of returning -1, it raises a `ValueError` when the substring is not found. Equivalent to standard `str.index`.

Parameters

sub [str] Substring being searched.

start [int] Left edge index.

end [int] Right edge index.

Returns

Series or Index of object

See also:

[`rindex`](#) Return highest indexes in each strings.

pandas.Series.str.join

Series.str.join(*sep*)

Join lists contained as elements in the Series/Index with passed delimiter.

If the elements of a Series are lists themselves, join the content of these lists using the delimiter passed to the function. This function is an equivalent to `str.join()`.

Parameters

sep [str] Delimiter to use between list entries.

Returns

Series/Index: object The list entries concatenated by intervening occurrences of the delimiter.

Raises

AttributeError If the supplied Series contains neither strings nor lists.

See also:

[str.join](#) Standard library version of this method.

[Series.str.split](#) Split strings around given separator/delimiter.

Notes

If any of the list items is not a string object, the result of the join will be *NaN*.

Examples

Example with a list that contains non-string elements.

```

>>> s = pd.Series([[ 'lion', 'elephant', 'zebra' ],
...                [1.1, 2.2, 3.3],
...                [ 'cat', np.nan, 'dog' ],
...                [ 'cow', 4.5, 'goat' ],
...                [ 'duck', [ 'swan', 'fish' ], 'guppy' ]])
>>> s
0      [lion, elephant, zebra]
1      [1.1, 2.2, 3.3]
2      [cat, nan, dog]
3      [cow, 4.5, goat]
4      [duck, [swan, fish], guppy]
dtype: object

```

Join all lists using a '-'. The lists containing object(s) of types other than str will produce a NaN.

```

>>> s.str.join('-')
0      lion-elephant-zebra
1      NaN
2      NaN
3      NaN
4      NaN
dtype: object

```

pandas.Series.str.len

Series.str.len()

Compute the length of each element in the Series/Index.

The element may be a sequence (such as a string, tuple or list) or a collection (such as a dictionary).

Returns

Series or Index of int A Series or Index of integer values indicating the length of each element in the Series or Index.

See also:

str.len Python built-in function returning the length of an object.

Series.size Returns the length of the Series.

Examples

Returns the length (number of characters) in a string. Returns the number of entries for dictionaries, lists or tuples.

```

>>> s = pd.Series(['dog',
...                '',
...                5,
...                {'foo': 'bar'},
...                [2, 3, 5, 7],
...                ('one', 'two', 'three')])
>>> s
0          dog
1
2          5
3    {'foo': 'bar'}
4    [2, 3, 5, 7]
5    (one, two, three)
dtype: object
>>> s.str.len()
0    3.0
1    0.0
2    NaN
3    1.0
4    4.0
5    3.0
dtype: float64

```

pandas.Series.str.ljust

Series.str.ljust(*width*, *fillchar*='')

Pad right side of strings in the Series/Index.

Equivalent to `str.ljust()`.

Parameters

width [int] Minimum width of resulting string; additional characters will be filled with `fillchar`.

fillchar [str] Additional character for filling, default is whitespace.

Returns

filled [Series/Index of objects.]

pandas.Series.str.lower**Series.str.lower()**

Convert strings in the Series/Index to lowercase.

Equivalent to `str.lower()`.**Returns****Series or Index of object****See also:****Series.str.lower** Converts all characters to lowercase.**Series.str.upper** Converts all characters to uppercase.**Series.str.title** Converts first character of each word to uppercase and remaining to lowercase.**Series.str.capitalize** Converts first character to uppercase and remaining to lowercase.**Series.str.swapcase** Converts uppercase to lowercase and lowercase to uppercase.**Series.str.casefold** Removes all case distinctions in the string.**Examples**

```
>>> s = pd.Series(['lower', 'CAPITALS', 'this is a sentence', 'SwApCaSe'])
>>> s
0          lower
1        CAPITALS
2  this is a sentence
3        SwApCaSe
dtype: object
```

```
>>> s.str.lower()
0          lower
1        capitals
2  this is a sentence
3        swapcase
dtype: object
```

```
>>> s.str.upper()
0          LOWER
1        CAPITALS
2  THIS IS A SENTENCE
3        SWAPCASE
dtype: object
```

```
>>> s.str.title()
0          Lower
1        Capitals
2  This Is A Sentence
3        Swapcase
dtype: object
```

```
>>> s.str.capitalize()
0          Lower
1        Capitals
2  This is a sentence
3        Swapcase
dtype: object
```

```
>>> s.str.swapcase()
0          LOWER
1        capitals
2  THIS IS A SENTENCE
3        sWaPcAsE
dtype: object
```

pandas.Series.str.lstrip

`Series.str.lstrip(to_strip=None)`

Remove leading characters.

Strip whitespaces (including newlines) or a set of specified characters from each string in the Series/Index from left side. Equivalent to `str.lstrip()`.

Parameters

to_strip [str or None, default None] Specifying the set of characters to be removed. All combinations of this set of characters will be stripped. If None then whitespaces are removed.

Returns

Series or Index of object

See also:

[*Series.str.strip*](#) Remove leading and trailing characters in Series/Index.

[*Series.str.lstrip*](#) Remove leading characters in Series/Index.

[*Series.str.rstrip*](#) Remove trailing characters in Series/Index.

Examples

```
>>> s = pd.Series(['1. Ant. ', '2. Bee!\n', '3. Cat?\t', np.nan])
>>> s
0    1. Ant.
1    2. Bee!\n
2    3. Cat?\t
3         NaN
dtype: object
```

```
>>> s.str.strip()
0    1. Ant.
1    2. Bee!
2    3. Cat?
3         NaN
dtype: object
```

```
>>> s.str.lstrip('123.')
0    Ant.
1    Bee!\n
2    Cat?\t
3         NaN
dtype: object
```

```
>>> s.str.rstrip('.!? \n\t')
0    1. Ant
1    2. Bee
2    3. Cat
3         NaN
dtype: object
```

```
>>> s.str.strip('123.!? \n\t')
0    Ant
1    Bee
2    Cat
3    NaN
dtype: object
```

pandas.Series.str.match

`Series.str.match(pat, case=True, flags=0, na=None)`

Determine if each string starts with a match of a regular expression.

Parameters

pat [str] Character sequence or regular expression.

case [bool, default True] If True, case sensitive.

flags [int, default 0 (no flags)] Regex module flags, e.g. `re.IGNORECASE`.

na [scalar, optional] Fill value for missing values. The default depends on dtype of the array. For object-dtype, `numpy.nan` is used. For `StringDtype`, `pandas.NA` is used.

Returns

Series/Index/array of boolean values

See also:

fullmatch Stricter matching that requires the entire string to match.

contains Analogous, but less strict, relying on `re.search` instead of `re.match`.

extract Extract matched groups.

pandas.Series.str.normalize

`Series.str.normalize(form)`

Return the Unicode normal form for the strings in the Series/Index.

For more information on the forms, see the `unicodedata.normalize()`.

Parameters

form [{ 'NFC', 'NFKC', 'NFD', 'NFKD' }] Unicode form.

Returns

normalized [Series/Index of objects]

pandas.Series.str.pad

`Series.str.pad(width, side='left', fillchar='')`

Pad strings in the Series/Index up to width.

Parameters

width [int] Minimum width of resulting string; additional characters will be filled with character defined in *fillchar*.

side [{ 'left', 'right', 'both' }, default 'left'] Side from which to fill resulting string.

fillchar [str, default ' '] Additional character for filling, default is whitespace.

Returns

Series or Index of object Returns Series or Index with minimum number of char in object.

See also:

Series.str.rjust Fills the left side of strings with an arbitrary character. Equivalent to `Series.str.pad(side='left')`.

Series.str.ljust Fills the right side of strings with an arbitrary character. Equivalent to `Series.str.pad(side='right')`.

Series.str.center Fills both sides of strings with an arbitrary character. Equivalent to `Series.str.pad(side='both')`.

Series.str.zfill Pad strings in the Series/Index by prepending '0' character. Equivalent to `Series.str.pad(side='left', fillchar='0')`.

Examples

```
>>> s = pd.Series(["caribou", "tiger"])
>>> s
0    caribou
1     tiger
dtype: object
```

```
>>> s.str.pad(width=10)
0      caribou
1       tiger
dtype: object
```

```
>>> s.str.pad(width=10, side='right', fillchar='-')
0    caribou---
1    tiger-----
dtype: object
```

```
>>> s.str.pad(width=10, side='both', fillchar='-')
0    -caribou--
1    --tiger---
dtype: object
```

pandas.Series.str.partition

`Series.str.partition(sep=' ', expand=True)`

Split the string at the first occurrence of *sep*.

This method splits the string at the first occurrence of *sep*, and returns 3 elements containing the part before the separator, the separator itself, and the part after the separator. If the separator is not found, return 3 elements containing the string itself, followed by two empty strings.

Parameters

sep [str, default whitespace] String to split on.

expand [bool, default True] If True, return DataFrame/MultiIndex expanding dimensionality. If False, return Series/Index.

Returns

DataFrame/MultiIndex or Series/Index of objects

See also:

[*rpartition*](#) Split the string at the last occurrence of *sep*.

[*Series.str.split*](#) Split strings around given separators.

[*str.partition*](#) Standard library version.

Examples

```
>>> s = pd.Series(['Linda van der Berg', 'George Pitt-Rivers'])
>>> s
0    Linda van der Berg
1    George Pitt-Rivers
dtype: object
```

```
>>> s.str.partition()
      0 1          2
0  Linda  van der Berg
1  George  Pitt-Rivers
```

To partition by the last space instead of the first one:

```
>>> s.str.rpartition()
      0 1          2
0  Linda van der      Berg
1      George  Pitt-Rivers
```

To partition by something different than a space:

```
>>> s.str.partition('-')
          0 1      2
0  Linda van der Berg
1   George Pitt - Rivers
```

To return a Series containing tuples instead of a DataFrame:

```
>>> s.str.partition('-', expand=False)
0   (Linda van der Berg, , )
1   (George Pitt, -, Rivers)
dtype: object
```

Also available on indices:

```
>>> idx = pd.Index(['X 123', 'Y 999'])
>>> idx
Index(['X 123', 'Y 999'], dtype='object')
```

Which will create a MultiIndex:

```
>>> idx.str.partition()
MultiIndex([(X', ' ', '123'),
            (Y', ' ', '999')],
           )
```

Or an index with tuples with `expand=False`:

```
>>> idx.str.partition(expand=False)
Index([(X', ' ', '123'), (Y', ' ', '999')], dtype='object')
```

pandas.Series.str.repeat

`Series.str.repeat(repeats)`

Duplicate each string in the Series or Index.

Parameters

repeats [int or sequence of int] Same value for all (int) or different value per (sequence).

Returns

Series or Index of object Series or Index of repeated string objects specified by input parameter repeats.

Examples

```
>>> s = pd.Series(['a', 'b', 'c'])
>>> s
0    a
1    b
2    c
dtype: object
```

Single int repeats string in Series

```
>>> s.str.repeat(repeats=2)
0    aa
1    bb
2    cc
dtype: object
```

Sequence of int repeats corresponding string in Series

```
>>> s.str.repeat(repeats=[1, 2, 3])
0    a
1    bb
2    ccc
dtype: object
```

pandas.Series.str.replace

`Series.str.replace(pat, repl, n=-1, case=None, flags=0, regex=None)`

Replace each occurrence of pattern/regex in the Series/Index.

Equivalent to `str.replace()` or `re.sub()`, depending on the regex value.

Parameters

pat [str or compiled regex] String can be a character sequence or regular expression.

repl [str or callable] Replacement string or a callable. The callable is passed the regex match object and must return a replacement string to be used. See `re.sub()`.

n [int, default -1 (all)] Number of replacements to make from start.

case [bool, default None] Determines if replace is case sensitive:

- If True, case sensitive (the default if *pat* is a string)
- Set to False for case insensitive
- Cannot be set if *pat* is a compiled regex.

flags [int, default 0 (no flags)] Regex module flags, e.g. `re.IGNORECASE`. Cannot be set if *pat* is a compiled regex.

regex [bool, default True] Determines if the passed-in pattern is a regular expression:

- If True, assumes the passed-in pattern is a regular expression.
- If False, treats the pattern as a literal string
- Cannot be set to False if *pat* is a compiled regex or *repl* is a callable.

New in version 0.23.0.

Returns

Series or Index of object A copy of the object with all matching occurrences of *pat* replaced by *repl*.

Raises**ValueError**

- if *regex* is False and *repl* is a callable or *pat* is a compiled regex
- if *pat* is a compiled regex and *case* or *flags* is set

Notes

When *pat* is a compiled regex, all flags should be included in the compiled regex. Use of *case*, *flags*, or *regex=False* with a compiled regex will raise an error.

Examples

When *pat* is a string and *regex* is True (the default), the given *pat* is compiled as a regex. When *repl* is a string, it replaces matching regex patterns as with `re.sub()`. NaN value(s) in the Series are left as is:

```
>>> pd.Series(['foo', 'fuz', np.nan]).str.replace('f.', 'ba', regex=True)
0    bao
1    baz
2    NaN
dtype: object
```

When *pat* is a string and *regex* is False, every *pat* is replaced with *repl* as with `str.replace()`:

```
>>> pd.Series(['f.o', 'fuz', np.nan]).str.replace('f.', 'ba', regex=False)
0    bao
1    fuz
2    NaN
dtype: object
```

When *repl* is a callable, it is called on every *pat* using `re.sub()`. The callable should expect one positional argument (a regex object) and return a string.

To get the idea:

```
>>> pd.Series(['foo', 'fuz', np.nan]).str.replace('f', repr, regex=True)
0    <re.Match object; span=(0, 1), match='f'>oo
1    <re.Match object; span=(0, 1), match='f'>uz
2                                     NaN
dtype: object
```

Reverse every lowercase alphabetic word:

```
>>> repl = lambda m: m.group(0)[::-1]
>>> ser = pd.Series(['foo 123', 'bar baz', np.nan])
>>> ser.str.replace(r'[a-z]+', repl, regex=True)
0    oof 123
1    rab zab
```

(continues on next page)

(continued from previous page)

```
2      NaN
dtype: object
```

Using regex groups (extract second group and swap case):

```
>>> pat = r"(?P<one>\w+) (?P<two>\w+) (?P<three>\w+)"
>>> repl = lambda m: m.group('two').swapcase()
>>> ser = pd.Series(['One Two Three', 'Foo Bar Baz'])
>>> ser.str.replace(pat, repl, regex=True)
0      tWO
1      bAR
dtype: object
```

Using a compiled regex with flags

```
>>> import re
>>> regex_pat = re.compile(r'FUZ', flags=re.IGNORECASE)
>>> pd.Series(['foo', 'fuz', np.nan]).str.replace(regex_pat, 'bar', regex=True)
0      foo
1      bar
2      NaN
dtype: object
```

pandas.Series.str.rfind

`Series.str.rfind(sub, start=0, end=None)`

Return highest indexes in each strings in the Series/Index.

Each of returned indexes corresponds to the position where the substring is fully contained between [start:end]. Return -1 on failure. Equivalent to standard `str.rfind()`.

Parameters

sub [str] Substring being searched.

start [int] Left edge index.

end [int] Right edge index.

Returns

Series or Index of int.

See also:

[`find`](#) Return lowest indexes in each strings.

pandas.Series.str.rindex

`Series.str.rindex(sub, start=0, end=None)`

Return highest indexes in each string in Series/Index.

Each of the returned indexes corresponds to the position where the substring is fully contained between [start:end]. This is the same as `str.rfind` except instead of returning -1, it raises a `ValueError` when the substring is not found. Equivalent to standard `str.rindex`.

Parameters

sub [str] Substring being searched.

start [int] Left edge index.

end [int] Right edge index.

Returns

Series or Index of object

See also:

[*index*](#) Return lowest indexes in each strings.

pandas.Series.str.rjust

`Series.str.rjust(width, fillchar='')`

Pad left side of strings in the Series/Index.

Equivalent to `str.rjust()`.

Parameters

width [int] Minimum width of resulting string; additional characters will be filled with `fillchar`.

fillchar [str] Additional character for filling, default is whitespace.

Returns

filled [Series/Index of objects.]

pandas.Series.str.rpartition

`Series.str.rpartition(sep=' ', expand=True)`

Split the string at the last occurrence of `sep`.

This method splits the string at the last occurrence of `sep`, and returns 3 elements containing the part before the separator, the separator itself, and the part after the separator. If the separator is not found, return 3 elements containing two empty strings, followed by the string itself.

Parameters

sep [str, default whitespace] String to split on.

expand [bool, default True] If True, return DataFrame/MultiIndex expanding dimensionality. If False, return Series/Index.

Returns

DataFrame/MultiIndex or Series/Index of objects

See also:

[*partition*](#) Split the string at the first occurrence of `sep`.

`Series.str.split` Split strings around given separators.
`str.partition` Standard library version.

Examples

```
>>> s = pd.Series(['Linda van der Berg', 'George Pitt-Rivers'])
>>> s
0    Linda van der Berg
1    George Pitt-Rivers
dtype: object
```

```
>>> s.str.partition()
      0 1      2
0  Linda  van der Berg
1  George  Pitt-Rivers
```

To partition by the last space instead of the first one:

```
>>> s.str.rpartition()
      0 1      2
0  Linda van der      Berg
1      George  Pitt-Rivers
```

To partition by something different than a space:

```
>>> s.str.partition('-')
      0 1      2
0  Linda van der Berg
1      George Pitt - Rivers
```

To return a Series containing tuples instead of a DataFrame:

```
>>> s.str.partition('-', expand=False)
0    (Linda van der Berg, , )
1    (George Pitt, -, Rivers)
dtype: object
```

Also available on indices:

```
>>> idx = pd.Index(['X 123', 'Y 999'])
>>> idx
Index(['X 123', 'Y 999'], dtype='object')
```

Which will create a MultiIndex:

```
>>> idx.str.partition()
MultiIndex([(('X', ' ', '123'),
             ('Y', ' ', '999'))],
           )
```

Or an index with tuples with `expand=False`:

```
>>> idx.str.partition(expand=False)
Index([(('X', ' ', '123'), ('Y', ' ', '999'))], dtype='object')
```

pandas.Series.str.rstrip

`Series.str.rstrip(to_strip=None)`

Remove trailing characters.

Strip whitespaces (including newlines) or a set of specified characters from each string in the Series/Index from right side. Equivalent to `str.rstrip()`.

Parameters

to_strip [str or None, default None] Specifying the set of characters to be removed. All combinations of this set of characters will be stripped. If None then whitespaces are removed.

Returns

Series or Index of object

See also:

[*Series.str.strip*](#) Remove leading and trailing characters in Series/Index.

[*Series.str.lstrip*](#) Remove leading characters in Series/Index.

[*Series.str.rstrip*](#) Remove trailing characters in Series/Index.

Examples

```
>>> s = pd.Series(['1. Ant. ', '2. Bee!\n', '3. Cat?\t', np.nan])
>>> s
0    1. Ant.
1    2. Bee!\n
2    3. Cat?\t
3         NaN
dtype: object
```

```
>>> s.str.strip()
0    1. Ant.
1    2. Bee!
2    3. Cat?
3         NaN
dtype: object
```

```
>>> s.str.lstrip('123.')
0    Ant.
1    Bee!\n
2    Cat?\t
3         NaN
dtype: object
```

```
>>> s.str.rstrip('!?\n\t')
0    1. Ant
1    2. Bee
2    3. Cat
3         NaN
dtype: object
```

```
>>> s.str.strip('123.!? \n\t')
0    Ant
1    Bee
2    Cat
3    NaN
dtype: object
```

pandas.Series.str.slice

`Series.str.slice(start=None, stop=None, step=None)`

Slice substrings from each element in the Series or Index.

Parameters

start [int, optional] Start position for slice operation.

stop [int, optional] Stop position for slice operation.

step [int, optional] Step size for slice operation.

Returns

Series or Index of object Series or Index from sliced substring from original string object.

See also:

[`Series.str.slice_replace`](#) Replace a slice with a string.

[`Series.str.get`](#) Return element at position. Equivalent to `Series.str.slice(start=i, stop=i+1)` with *i* being the position.

Examples

```
>>> s = pd.Series(["koala", "dog", "chameleon"])
>>> s
0    koala
1     dog
2  chameleon
dtype: object
```

```
>>> s.str.slice(start=1)
0    oala
1     og
2  hameleon
dtype: object
```

```
>>> s.str.slice(start=-1)
0     a
1     g
2     n
dtype: object
```

```
>>> s.str.slice(stop=2)
0    ko
1    do
```

(continues on next page)

(continued from previous page)

```
2    ch
dtype: object
```

```
>>> s.str.slice(step=2)
0    kaa
1    dg
2    caeen
dtype: object
```

```
>>> s.str.slice(start=0, stop=5, step=3)
0    kl
1    d
2    cm
dtype: object
```

Equivalent behaviour to:

```
>>> s.str[0:5:3]
0    kl
1    d
2    cm
dtype: object
```

pandas.Series.str.slice_replace

`Series.str.slice_replace(start=None, stop=None, repl=None)`

Replace a positional slice of a string with another value.

Parameters

- start** [int, optional] Left index position to use for the slice. If not specified (None), the slice is unbounded on the left, i.e. slice from the start of the string.
- stop** [int, optional] Right index position to use for the slice. If not specified (None), the slice is unbounded on the right, i.e. slice until the end of the string.
- repl** [str, optional] String for replacement. If not specified (None), the sliced region is replaced with an empty string.

Returns

Series or Index Same type as the original object.

See also:

[Series.str.slice](#) Just slicing without replacement.

Examples

```
>>> s = pd.Series(['a', 'ab', 'abc', 'abdc', 'abcde'])
>>> s
0      a
1     ab
2    abc
3   abdc
4  abcde
dtype: object
```

Specify just *start*, meaning replace *start* until the end of the string with *repl*.

```
>>> s.str.slice_replace(1, repl='X')
0    aX
1    aX
2    aX
3    aX
4    aX
dtype: object
```

Specify just *stop*, meaning the start of the string to *stop* is replaced with *repl*, and the rest of the string is included.

```
>>> s.str.slice_replace(stop=2, repl='X')
0      X
1      X
2     Xc
3    Xdc
4   Xcde
dtype: object
```

Specify *start* and *stop*, meaning the slice from *start* to *stop* is replaced with *repl*. Everything before or after *start* and *stop* is included as is.

```
>>> s.str.slice_replace(start=1, stop=3, repl='X')
0    aX
1    aX
2    aX
3   aXc
4  aXde
dtype: object
```

pandas.Series.str.split

`Series.str.split(pat=None, n=-1, expand=False)`

Split strings around given separator/delimiter.

Splits the string in the Series/Index from the beginning, at the specified delimiter string. Equivalent to `str.split()`.

Parameters

pat [str, optional] String or regular expression to split on. If not specified, split on whitespace.

n [int, default -1 (all)] Limit number of splits in output. *None*, 0 and -1 will be interpreted as return all splits.

expand [bool, default False] Expand the split strings into separate columns.

- If *True*, return DataFrame/MultiIndex expanding dimensionality.
- If *False*, return Series/Index, containing lists of strings.

Returns

Series, Index, DataFrame or MultiIndex Type matches caller unless `expand=True` (see Notes).

See also:

Series.str.split Split strings around given separator/delimiter.

Series.str.rsplit Splits string around given separator/delimiter, starting from the right.

Series.str.join Join lists contained as elements in the Series/Index with passed delimiter.

str.split Standard library version for split.

str.rsplit Standard library version for rsplit.

Notes

The handling of the *n* keyword depends on the number of found splits:

- If found splits > *n*, make first *n* splits only
- If found splits <= *n*, make all splits
- If for a certain row the number of found splits < *n*, append *None* for padding up to *n* if `expand=True`

If using `expand=True`, Series and Index callers return DataFrame and MultiIndex objects, respectively.

Examples

```
>>> s = pd.Series(
...     [
...         "this is a regular sentence",
...         "https://docs.python.org/3/tutorial/index.html",
...         np.nan
...     ]
... )
>>> s
0          this is a regular sentence
1  https://docs.python.org/3/tutorial/index.html
2                                     NaN
dtype: object
```

In the default setting, the string is split by whitespace.

```
>>> s.str.split()
0          [this, is, a, regular, sentence]
1  [https://docs.python.org/3/tutorial/index.html]
2                                     NaN
dtype: object
```

Without the *n* parameter, the outputs of *rsplit* and *split* are identical.

```
>>> s.str.rsplit()
0          [this, is, a, regular, sentence]
1  [https://docs.python.org/3/tutorial/index.html]
2                                          NaN
dtype: object
```

The *n* parameter can be used to limit the number of splits on the delimiter. The outputs of *split* and *rsplit* are different.

```
>>> s.str.split(n=2)
0          [this, is, a regular sentence]
1  [https://docs.python.org/3/tutorial/index.html]
2                                          NaN
dtype: object
```

```
>>> s.str.rsplit(n=2)
0          [this is a, regular, sentence]
1  [https://docs.python.org/3/tutorial/index.html]
2                                          NaN
dtype: object
```

The *pat* parameter can be used to split by other characters.

```
>>> s.str.split(pat="/")
0          [this is a regular sentence]
1  [https:, , docs.python.org, 3, tutorial, index...]
2                                          NaN
dtype: object
```

When using *expand=True*, the split elements will expand out into separate columns. If NaN is present, it is propagated throughout the columns during the split.

```
>>> s.str.split(expand=True)
           0      1      2      3      4
0          this  is   a  regular  sentence
1  https://docs.python.org/3/tutorial/index.html  None  None  None  None
2          NaN  NaN  NaN  NaN  NaN
```

For slightly more complex use cases like splitting the html document name from a url, a combination of parameter settings can be used.

```
>>> s.str.rsplit("/", n=1, expand=True)
           0      1
0          this is a regular sentence  None
1  https://docs.python.org/3/tutorial  index.html
2          NaN  NaN
```

Remember to escape special characters when explicitly using regular expressions.

```
>>> s = pd.Series(["1+1=2"])
>>> s
0    1+1=2
dtype: object
```

(continues on next page)

(continued from previous page)

```
>>> s.str.split(r"\+|= ", expand=True)
      0    1    2
0     1    1    2
```

pandas.Series.str.rsplit

`Series.str.rsplit(pat=None, n=-1, expand=False)`

Split strings around given separator/delimiter.

Splits the string in the Series/Index from the end, at the specified delimiter string. Equivalent to `str.rsplit()`.

Parameters

pat [str, optional] String or regular expression to split on. If not specified, split on whitespace.

n [int, default -1 (all)] Limit number of splits in output. `None`, 0 and -1 will be interpreted as return all splits.

expand [bool, default False] Expand the split strings into separate columns.

- If `True`, return `DataFrame/MultiIndex` expanding dimensionality.
- If `False`, return `Series/Index`, containing lists of strings.

Returns

Series, Index, DataFrame or MultiIndex Type matches caller unless `expand=True` (see Notes).

See also:

[`Series.str.split`](#) Split strings around given separator/delimiter.

[`Series.str.rsplit`](#) Splits string around given separator/delimiter, starting from the right.

[`Series.str.join`](#) Join lists contained as elements in the Series/Index with passed delimiter.

[`str.split`](#) Standard library version for split.

[`str.rsplit`](#) Standard library version for rsplit.

Notes

The handling of the `n` keyword depends on the number of found splits:

- If found splits > `n`, make first `n` splits only
- If found splits <= `n`, make all splits
- If for a certain row the number of found splits < `n`, append `None` for padding up to `n` if `expand=True`

If using `expand=True`, Series and Index callers return `DataFrame` and `MultiIndex` objects, respectively.

Examples

```
>>> s = pd.Series(
...     [
...         "this is a regular sentence",
...         "https://docs.python.org/3/tutorial/index.html",
...         np.nan
...     ]
... )
>>> s
```

(continues on next page)

(continued from previous page)

```

0           this is a regular sentence
1  https://docs.python.org/3/tutorial/index.html
2                                           NaN
dtype: object

```

In the default setting, the string is split by whitespace.

```

>>> s.str.split()
0           [this, is, a, regular, sentence]
1  [https://docs.python.org/3/tutorial/index.html]
2                                           NaN
dtype: object

```

Without the *n* parameter, the outputs of *rsplit* and *split* are identical.

```

>>> s.str.rsplit()
0           [this, is, a, regular, sentence]
1  [https://docs.python.org/3/tutorial/index.html]
2                                           NaN
dtype: object

```

The *n* parameter can be used to limit the number of splits on the delimiter. The outputs of *split* and *rsplit* are different.

```

>>> s.str.split(n=2)
0           [this, is, a regular sentence]
1  [https://docs.python.org/3/tutorial/index.html]
2                                           NaN
dtype: object

```

```

>>> s.str.rsplit(n=2)
0           [this is a, regular, sentence]
1  [https://docs.python.org/3/tutorial/index.html]
2                                           NaN
dtype: object

```

The *pat* parameter can be used to split by other characters.

```

>>> s.str.split(pat="/")
0           [this is a regular sentence]
1  [https:, , docs.python.org, 3, tutorial, index...]
2                                           NaN
dtype: object

```

When using `expand=True`, the split elements will expand out into separate columns. If NaN is present, it is propagated throughout the columns during the split.

```

>>> s.str.split(expand=True)
0           0      1      2      3      4
0           this  is   a  regular  sentence
1  https://docs.python.org/3/tutorial/index.html  None  None  None  None
2           NaN  NaN  NaN  NaN  NaN

```

For slightly more complex use cases like splitting the html document name from a url, a combination of parameter settings can be used.

```
>>> s.str.rsplit("/", n=1, expand=True)
      0      1
0      this is a regular sentence      None
1  https://docs.python.org/3/tutorial  index.html
2                                     NaN      NaN
```

Remember to escape special characters when explicitly using regular expressions.

```
>>> s = pd.Series(["1+1=2"])
>>> s
0    1+1=2
dtype: object
>>> s.str.split(r"\+|= ", expand=True)
      0      1      2
0    1    1    2
```

pandas.Series.str.startswith

`Series.str.startswith(pat, na=None)`

Test if the start of each string element matches a pattern.

Equivalent to `str.startswith()`.

Parameters

pat [str] Character sequence. Regular expressions are not accepted.

na [object, default NaN] Object shown if element tested is not a string. The default depends on dtype of the array. For object-dtype, `numpy.nan` is used. For `StringDtype`, `pandas.NA` is used.

Returns

Series or Index of bool A Series of booleans indicating whether the given pattern matches the start of each string element.

See also:

[`str.startswith`](#) Python standard library string method.

[`Series.str.endswith`](#) Same as `startswith`, but tests the end of string.

[`Series.str.contains`](#) Tests if string element contains a pattern.

Examples

```
>>> s = pd.Series(['bat', 'Bear', 'cat', np.nan])
>>> s
0    bat
1    Bear
2    cat
3    NaN
dtype: object
```

```
>>> s.str.startswith('b')
0    True
1    False
2    False
3     NaN
dtype: object
```

Specifying *na* to be *False* instead of *NaN*.

```
>>> s.str.startswith('b', na=False)
0    True
1    False
2    False
3    False
dtype: bool
```

pandas.Series.str.strip

`Series.str.strip(to_strip=None)`

Remove leading and trailing characters.

Strip whitespaces (including newlines) or a set of specified characters from each string in the Series/Index from left and right sides. Equivalent to `str.strip()`.

Parameters

to_strip [str or None, default None] Specifying the set of characters to be removed. All combinations of this set of characters will be stripped. If None then whitespaces are removed.

Returns

Series or Index of object

See also:

[Series.str.strip](#) Remove leading and trailing characters in Series/Index.

[Series.str.lstrip](#) Remove leading characters in Series/Index.

[Series.str.rstrip](#) Remove trailing characters in Series/Index.

Examples

```
>>> s = pd.Series(['1. Ant. ', '2. Bee!\n', '3. Cat?\t', np.nan])
>>> s
0    1. Ant.
1    2. Bee!\n
2    3. Cat?\t
3         NaN
dtype: object
```

```
>>> s.str.strip()
0    1. Ant.
1    2. Bee!
2    3. Cat?
```

(continues on next page)

(continued from previous page)

```
3      NaN
dtype: object
```

```
>>> s.str.lstrip('123.')
0      Ant.
1      Bee!\n
2      Cat?\t
3      NaN
dtype: object
```

```
>>> s.str.rstrip('.!? \n\t')
0      1. Ant
1      2. Bee
2      3. Cat
3      NaN
dtype: object
```

```
>>> s.str.strip('123.!? \n\t')
0      Ant
1      Bee
2      Cat
3      NaN
dtype: object
```

pandas.Series.str.swapcase

Series.str.swapcase()

Convert strings in the Series/Index to be swapcased.

Equivalent to `str.swapcase()`.

Returns

Series or Index of object

See also:

Series.str.lower Converts all characters to lowercase.

Series.str.upper Converts all characters to uppercase.

Series.str.title Converts first character of each word to uppercase and remaining to lowercase.

Series.str.capitalize Converts first character to uppercase and remaining to lowercase.

Series.str.swapcase Converts uppercase to lowercase and lowercase to uppercase.

Series.str.casefold Removes all case distinctions in the string.

Examples

```
>>> s = pd.Series(['lower', 'CAPITALS', 'this is a sentence', 'SwApCaSe'])
>>> s
0          lower
1      CAPITALS
2  this is a sentence
3      SwApCaSe
dtype: object
```

```
>>> s.str.lower()
0          lower
1      capitals
2  this is a sentence
3      swapcase
dtype: object
```

```
>>> s.str.upper()
0          LOWER
1      CAPITALS
2  THIS IS A SENTENCE
3      SWAPCASE
dtype: object
```

```
>>> s.str.title()
0          Lower
1      Capitals
2  This Is A Sentence
3      Swapcase
dtype: object
```

```
>>> s.str.capitalize()
0          Lower
1      Capitals
2  This is a sentence
3      Swapcase
dtype: object
```

```
>>> s.str.swapcase()
0          LOWER
1      capitals
2  THIS IS A SENTENCE
3      sWApCaSe
dtype: object
```

pandas.Series.str.title**Series.str.title()**

Convert strings in the Series/Index to titlecase.

Equivalent to `str.title()`.

Returns

Series or Index of object

See also:

Series.str.lower Converts all characters to lowercase.

Series.str.upper Converts all characters to uppercase.

Series.str.title Converts first character of each word to uppercase and remaining to lowercase.

Series.str.capitalize Converts first character to uppercase and remaining to lowercase.

Series.str.swapcase Converts uppercase to lowercase and lowercase to uppercase.

Series.str.casefold Removes all case distinctions in the string.

Examples

```
>>> s = pd.Series(['lower', 'CAPITALS', 'this is a sentence', 'SwApCaSe'])
>>> s
0          lower
1        CAPITALS
2  this is a sentence
3        SwApCaSe
dtype: object
```

```
>>> s.str.lower()
0          lower
1        capitals
2  this is a sentence
3        swapcase
dtype: object
```

```
>>> s.str.upper()
0          LOWER
1        CAPITALS
2  THIS IS A SENTENCE
3        SWAPCASE
dtype: object
```

```
>>> s.str.title()
0          Lower
1        Capitals
2  This Is A Sentence
3        Swapcase
dtype: object
```

```
>>> s.str.capitalize()
0          Lower
1        Capitals
```

(continues on next page)

(continued from previous page)

```
2    This is a sentence

```
>>> s.str.swapcase()
0                LOWER
1                capitals
2    THIS IS A SENTENCE
3                sWaPcAsE
dtype: object
```

pandas.Series.str.translate

`Series.str.translate(table)`

Map all characters in the string through the given mapping table.

Equivalent to standard `str.translate()`.

Parameters

table [dict] Table is a mapping of Unicode ordinals to Unicode ordinals, strings, or None. Unmapped characters are left untouched. Characters mapped to None are deleted. `str.maketrans()` is a helper function for making translation tables.

Returns

Series or Index

pandas.Series.str.upper

`Series.str.upper()`

Convert strings in the Series/Index to uppercase.

Equivalent to `str.upper()`.

Returns

Series or Index of object

See also:

`Series.str.lower` Converts all characters to lowercase.

`Series.str.upper` Converts all characters to uppercase.

`Series.str.title` Converts first character of each word to uppercase and remaining to lowercase.

`Series.str.capitalize` Converts first character to uppercase and remaining to lowercase.

`Series.str.swapcase` Converts uppercase to lowercase and lowercase to uppercase.

`Series.str.casefold` Removes all case distinctions in the string.

Examples

```
>>> s = pd.Series(['lower', 'CAPITALS', 'this is a sentence', 'SwApCaSe'])
>>> s
0          lower
1      CAPITALS
2  this is a sentence
3      SwApCaSe
dtype: object
```

```
>>> s.str.lower()
0          lower
1      capitals
2  this is a sentence
3      swapcase
dtype: object
```

```
>>> s.str.upper()
0          LOWER
1      CAPITALS
2  THIS IS A SENTENCE
3      SWAPCASE
dtype: object
```

```
>>> s.str.title()
0          Lower
1      Capitals
2  This Is A Sentence
3      Swapcase
dtype: object
```

```
>>> s.str.capitalize()
0          Lower
1      Capitals
2  This is a sentence
3      Swapcase
dtype: object
```

```
>>> s.str.swapcase()
0          LOWER
1      capitals
2  THIS IS A SENTENCE
3      sWApCaSe
dtype: object
```

pandas.Series.str.wrap

`Series.str.wrap(width, **kwargs)`

Wrap strings in Series/Index at specified line width.

This method has the same keyword parameters and defaults as `textwrap.TextWrapper`.

Parameters

width [int] Maximum line width.

expand_tabs [bool, optional] If True, tab characters will be expanded to spaces (default: True).

replace_whitespace [bool, optional] If True, each whitespace character (as defined by `string.whitespace`) remaining after tab expansion will be replaced by a single space (default: True).

drop_whitespace [bool, optional] If True, whitespace that, after wrapping, happens to end up at the beginning or end of a line is dropped (default: True).

break_long_words [bool, optional] If True, then words longer than width will be broken in order to ensure that no lines are longer than width. If it is false, long words will not be broken, and some lines may be longer than width (default: True).

break_on_hyphens [bool, optional] If True, wrapping will occur preferably on whitespace and right after hyphens in compound words, as it is customary in English. If false, only whitespaces will be considered as potentially good places for line breaks, but you need to set `break_long_words` to false if you want truly inescapable words (default: True).

Returns

Series or Index

Notes

Internally, this method uses a `textwrap.TextWrapper` instance with default settings. To achieve behavior matching R's `stringr` library `str_wrap` function, use the arguments:

- `expand_tabs = False`
- `replace_whitespace = True`
- `drop_whitespace = True`
- `break_long_words = False`
- `break_on_hyphens = False`

Examples

```
>>> s = pd.Series(['line to be wrapped', 'another line to be wrapped'])
>>> s.str.wrap(12)
0      line to be\nwrapped
1  another line\nto be\nwrapped
dtype: object
```

pandas.Series.str.zfill

`Series.str.zfill(width)`

Pad strings in the Series/Index by prepending '0' characters.

Strings in the Series/Index are padded with '0' characters on the left of the string to reach a total string length *width*. Strings in the Series/Index with length greater or equal to *width* are unchanged.

Parameters

width [int] Minimum length of resulting string; strings with length less than *width* be prepended with '0' characters.

Returns

Series/Index of objects.

See also:

[*Series.str.rjust*](#) Fills the left side of strings with an arbitrary character.

[*Series.str.ljust*](#) Fills the right side of strings with an arbitrary character.

[*Series.str.pad*](#) Fills the specified sides of strings with an arbitrary character.

[*Series.str.center*](#) Fills both sides of strings with an arbitrary character.

Notes

Differs from `str.zfill()` which has special handling for '+'/'-' in the string.

Examples

```
>>> s = pd.Series(['-1', '1', '1000', 10, np.nan])
>>> s
0      -1
1       1
2    1000
3       10
4      NaN
dtype: object
```

Note that 10 and NaN are not strings, therefore they are converted to NaN. The minus sign in '-1' is treated as a regular character and the zero is added to the left of it (`str.zfill()` would have moved it to the left). 1000 remains unchanged as it is longer than *width*.

```
>>> s.str.zfill(3)
0     0-1
1     001
2    1000
3     NaN
4     NaN
dtype: object
```

pandas.Series.str.isalnum

Series.str.isalnum()

Check whether all characters in each string are alphanumeric.

This is equivalent to running the Python string method `str.isalnum()` for each element of the Series/Index. If a string has zero characters, `False` is returned for that check.

Returns

Series or Index of bool Series or Index of boolean values with the same length as the original Series/Index.

See also:

Series.str.isalpha Check whether all characters are alphabetic.
Series.str.isnumeric Check whether all characters are numeric.
Series.str.isalnum Check whether all characters are alphanumeric.
Series.str.isdigit Check whether all characters are digits.
Series.str.isdecimal Check whether all characters are decimal.
Series.str.isspace Check whether all characters are whitespace.
Series.str.islower Check whether all characters are lowercase.
Series.str.isupper Check whether all characters are uppercase.
Series.str.istitle Check whether all characters are titlecase.

Examples

Checks for Alphabetic and Numeric Characters

```
>>> s1 = pd.Series(['one', 'one1', '1', ''])
```

```
>>> s1.str.isalpha()
0    True
1   False
2   False
3   False
dtype: bool
```

```
>>> s1.str.isnumeric()
0   False
1   False
2    True
3   False
dtype: bool
```

```
>>> s1.str.isalnum()
0    True
1    True
2    True
3   False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```
>>> s2 = pd.Series(['A B', '1.5', '3,000'])
>>> s2.str.isalnum()
0    False
1    False
2    False
dtype: bool
```

More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```
>>> s3 = pd.Series(['23', '³', '', ''])
```

The `s3.str.isdecimal` method checks for characters used to form numbers in base 10.

```
>>> s3.str.isdecimal()
0     True
1    False
2    False
3    False
dtype: bool
```

The `s.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```
>>> s3.str.isdigit()
0     True
1     True
2    False
3    False
dtype: bool
```

The `s.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```
>>> s3.str.isnumeric()
0     True
1     True
2     True
3    False
dtype: bool
```

Checks for Whitespace

```
>>> s4 = pd.Series([' ', '\t\r\n ', ''])
>>> s4.str.isspace()
0     True
1     True
2    False
dtype: bool
```

Checks for Character Case

```
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])
```

```
>>> s5.str.islower()
0    True
1    False
2    False
3    False
dtype: bool
```

```
>>> s5.str.isupper()
0    False
1    False
2     True
3    False
dtype: bool
```

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```
>>> s5.str.istitle()
0    False
1     True
2    False
3    False
dtype: bool
```

pandas.Series.str.isalpha

Series.str.isalpha()

Check whether all characters in each string are alphabetic.

This is equivalent to running the Python string method `str.isalpha()` for each element of the Series/Index. If a string has zero characters, `False` is returned for that check.

Returns

Series or Index of bool Series or Index of boolean values with the same length as the original Series/Index.

See also:

- `Series.str.isalpha` Check whether all characters are alphabetic.
- `Series.str.isnumeric` Check whether all characters are numeric.
- `Series.str.isalnum` Check whether all characters are alphanumeric.
- `Series.str.isdigit` Check whether all characters are digits.
- `Series.str.isdecimal` Check whether all characters are decimal.
- `Series.str.isspace` Check whether all characters are whitespace.
- `Series.str.islower` Check whether all characters are lowercase.
- `Series.str.isupper` Check whether all characters are uppercase.
- `Series.str.istitle` Check whether all characters are titlecase.

Examples

Checks for Alphabetic and Numeric Characters

```
>>> s1 = pd.Series(['one', 'one1', '1', ''])
```

```
>>> s1.str.isalpha()
0    True
1   False
2   False
3   False
dtype: bool
```

```
>>> s1.str.isnumeric()
0   False
1   False
2    True
3   False
dtype: bool
```

```
>>> s1.str.isalnum()
0    True
1    True
2    True
3   False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```
>>> s2 = pd.Series(['A B', '1.5', '3,000'])
>>> s2.str.isalnum()
0   False
1   False
2   False
dtype: bool
```

More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```
>>> s3 = pd.Series(['23', '3', '', ''])
```

The `s3.str.isdecimal` method checks for characters used to form numbers in base 10.

```
>>> s3.str.isdecimal()
0    True
1   False
2   False
3   False
dtype: bool
```

The `s.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```
>>> s3.str.isdigit()
0    True
1    True
2   False
3   False
dtype: bool
```

The `s.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```
>>> s3.str.isnumeric()
0    True
1    True
2    True
3   False
dtype: bool
```

Checks for Whitespace

```
>>> s4 = pd.Series([' ', '\t\r\n ', ''])
>>> s4.str.isspace()
0    True
1    True
2   False
dtype: bool
```

Checks for Character Case

```
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])
```

```
>>> s5.str.islower()
0    True
1   False
2   False
3   False
dtype: bool
```

```
>>> s5.str.isupper()
0   False
1   False
2    True
3   False
dtype: bool
```

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```
>>> s5.str.istitle()
0   False
1    True
2   False
```

(continues on next page)

(continued from previous page)

```
3    False
dtype: bool
```

pandas.Series.str.isdigit

Series.str.isdigit()

Check whether all characters in each string are digits.

This is equivalent to running the Python string method `str.isdigit()` for each element of the Series/Index. If a string has zero characters, False is returned for that check.

Returns

Series or Index of bool Series or Index of boolean values with the same length as the original Series/Index.

See also:

Series.str.isalpha Check whether all characters are alphabetic.
Series.str.isnumeric Check whether all characters are numeric.
Series.str.isalnum Check whether all characters are alphanumeric.
Series.str.isdigit Check whether all characters are digits.
Series.str.isdecimal Check whether all characters are decimal.
Series.str.isspace Check whether all characters are whitespace.
Series.str.islower Check whether all characters are lowercase.
Series.str.isupper Check whether all characters are uppercase.
Series.str.istitle Check whether all characters are titlecase.

Examples

Checks for Alphabetic and Numeric Characters

```
>>> s1 = pd.Series(['one', 'one1', '1', ''])
```

```
>>> s1.str.isalpha()
0    True
1    False
2    False
3    False
dtype: bool
```

```
>>> s1.str.isnumeric()
0    False
1    False
2     True
3    False
dtype: bool
```

```
>>> s1.str.isalnum()
0    True
1    True
2    True
```

(continues on next page)

(continued from previous page)

```
3    False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```
>>> s2 = pd.Series(['A B', '1.5', '3,000'])
>>> s2.str.isalnum()
0    False
1    False
2    False
dtype: bool
```

More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```
>>> s3 = pd.Series(['23', '³', ' ', ''])
```

The `s3.str.isdecimal` method checks for characters used to form numbers in base 10.

```
>>> s3.str.isdecimal()
0     True
1    False
2    False
3    False
dtype: bool
```

The `s.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```
>>> s3.str.isdigit()
0     True
1     True
2    False
3    False
dtype: bool
```

The `s.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```
>>> s3.str.isnumeric()
0     True
1     True
2     True
3    False
dtype: bool
```

Checks for Whitespace

```
>>> s4 = pd.Series([' ', '\t\r\n ', ''])
>>> s4.str.isspace()
0     True
1     True
```

(continues on next page)

(continued from previous page)

```
2    False
dtype: bool
```

Checks for Character Case

```
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])
```

```
>>> s5.str.islower()
0     True
1    False
2    False
3    False
dtype: bool
```

```
>>> s5.str.isupper()
0    False
1    False
2     True
3    False
dtype: bool
```

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```
>>> s5.str.istitle()
0    False
1     True
2    False
3    False
dtype: bool
```

pandas.Series.str.isspace**Series.str.isspace()**

Check whether all characters in each string are whitespace.

This is equivalent to running the Python string method `str.isspace()` for each element of the Series/Index. If a string has zero characters, False is returned for that check.

Returns

Series or Index of bool Series or Index of boolean values with the same length as the original Series/Index.

See also:

Series.str.isalpha Check whether all characters are alphabetic.
Series.str.isnumeric Check whether all characters are numeric.
Series.str.isalnum Check whether all characters are alphanumeric.

Series.str.isspace Check whether all characters are whitespace.
Series.str.islower Check whether all characters are lowercase.
Series.str.isupper Check whether all characters are uppercase.

`Series.str.istitle` Check whether all characters are titlecase.

Examples

Checks for Alphabetic and Numeric Characters

```
>>> s1 = pd.Series(['one', 'one1', '1', ''])
```

```
>>> s1.str.isalpha()
0    True
1   False
2   False
3   False
dtype: bool
```

```
>>> s1.str.isnumeric()
0   False
1   False
2    True
3   False
dtype: bool
```

```
>>> s1.str.isalnum()
0    True
1    True
2    True
3   False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```
>>> s2 = pd.Series(['A B', '1.5', '3,000'])
>>> s2.str.isalnum()
0   False
1   False
2   False
dtype: bool
```

More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```
>>> s3 = pd.Series(['23', '3', '', ''])
```

The `s3.str.isdecimal` method checks for characters used to form numbers in base 10.

```
>>> s3.str.isdecimal()
0    True
1   False
2   False
3   False
dtype: bool
```

The `s.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```
>>> s3.str.isdigit()
0    True
1    True
2   False
3   False
dtype: bool
```

The `s.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```
>>> s3.str.isnumeric()
0    True
1    True
2    True
3   False
dtype: bool

Checks for Whitespace

```
>>> s4 = pd.Series([' ', '\t\r\n ', ''])
>>> s4.str.isspace()
0    True
1    True
2   False
dtype: bool
```

Checks for Character Case

```
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])
```

```
>>> s5.str.islower()
0    True
1   False
2   False
3   False
dtype: bool
```

```
>>> s5.str.isupper()
0   False
1   False
2    True
3   False
dtype: bool
```

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```
>>> s5.str.istitle()
0   False
1    True
```

(continues on next page)

(continued from previous page)

```
2    False
3    False
dtype: bool
```

pandas.Series.str.islower

Series.str.islower()

Check whether all characters in each string are lowercase.

This is equivalent to running the Python string method `str.islower()` for each element of the Series/Index. If a string has zero characters, `False` is returned for that check.

Returns

Series or Index of bool Series or Index of boolean values with the same length as the original Series/Index.

See also:

Series.str.isalpha Check whether all characters are alphabetic.
Series.str.isnumeric Check whether all characters are numeric.
Series.str.isalnum Check whether all characters are alphanumeric.
Series.str.isdigit Check whether all characters are digits.
Series.str.isdecimal Check whether all characters are decimal.
Series.str.isspace Check whether all characters are whitespace.
Series.str.islower Check whether all characters are lowercase.
Series.str.isupper Check whether all characters are uppercase.
Series.str.istitle Check whether all characters are titlecase.

Examples

Checks for Alphabetic and Numeric Characters

```
>>> s1 = pd.Series(['one', 'one1', '1', ''])
```

```
>>> s1.str.isalpha()
0    True
1    False
2    False
3    False
dtype: bool
```

```
>>> s1.str.isnumeric()
0    False
1    False
2    True
3    False
dtype: bool
```

```
>>> s1.str.isalnum()
0    True
1    True
2    True
```

(continues on next page)

(continued from previous page)

```
3    False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```
>>> s2 = pd.Series(['A B', '1.5', '3,000'])
>>> s2.str.isalnum()
0    False
1    False
2    False
dtype: bool
```

More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```
>>> s3 = pd.Series(['23', '3', '', ''])
```

The `s3.str.isdecimal` method checks for characters used to form numbers in base 10.

```
>>> s3.str.isdecimal()
0     True
1    False
2    False
3    False
dtype: bool
```

The `s.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```
>>> s3.str.isdigit()
0     True
1     True
2    False
3    False
dtype: bool
```

The `s.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```
>>> s3.str.isnumeric()
0     True
1     True
2     True
3    False
dtype: bool
```

Checks for Whitespace

```
>>> s4 = pd.Series([' ', '\t\r\n ', ''])
>>> s4.str.isspace()
0     True
1     True
```

(continues on next page)

(continued from previous page)

```
2    False
dtype: bool
```

Checks for Character Case

```
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])
```

```
>>> s5.str.islower()
0     True
1    False
2    False
3    False
dtype: bool
```

```
>>> s5.str.isupper()
0    False
1    False
2     True
3    False
dtype: bool
```

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```
>>> s5.str.istitle()
0    False
1     True
2    False
3    False
dtype: bool
```

pandas.Series.str.isupper

Series.str.isupper()

Check whether all characters in each string are uppercase.

This is equivalent to running the Python string method `str.isupper()` for each element of the Series/Index. If a string has zero characters, False is returned for that check.

Returns

Series or Index of bool Series or Index of boolean values with the same length as the original Series/Index.

See also:

- [*Series.str.isalpha*](#) Check whether all characters are alphabetic.
- [*Series.str.isnumeric*](#) Check whether all characters are numeric.
- [*Series.str.isalnum*](#) Check whether all characters are alphanumeric.
- [*Series.str.isdigit*](#) Check whether all characters are digits.
- [*Series.str.isdecimal*](#) Check whether all characters are decimal.
- [*Series.str.isspace*](#) Check whether all characters are whitespace.
- [*Series.str.islower*](#) Check whether all characters are lowercase.
- [*Series.str.isupper*](#) Check whether all characters are uppercase.

`Series.str.istitle` Check whether all characters are titlecase.

Examples

Checks for Alphabetic and Numeric Characters

```
>>> s1 = pd.Series(['one', 'one1', '1', ''])
```

```
>>> s1.str.isalpha()
0    True
1    False
2    False
3    False
dtype: bool
```

```
>>> s1.str.isnumeric()
0    False
1    False
2     True
3    False
dtype: bool
```

```
>>> s1.str.isalnum()
0    True
1    True
2    True
3    False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```
>>> s2 = pd.Series(['A B', '1.5', '3,000'])
>>> s2.str.isalnum()
0    False
1    False
2    False
dtype: bool
```

More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```
>>> s3 = pd.Series(['23', '3', '', ''])
```

The `s3.str.isdecimal` method checks for characters used to form numbers in base 10.

```
>>> s3.str.isdecimal()
0    True
1    False
2    False
3    False
dtype: bool
```

The `s.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```
>>> s3.str.isdigit()
0    True
1    True
2   False
3   False
dtype: bool
```

The `s.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```
>>> s3.str.isnumeric()
0    True
1    True
2    True
3   False
dtype: bool
```

Checks for Whitespace

```
>>> s4 = pd.Series([' ', '\t\r\n ', ''])
>>> s4.str.isspace()
0    True
1    True
2   False
dtype: bool
```

Checks for Character Case

```
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])
```

```
>>> s5.str.islower()
0    True
1   False
2   False
3   False
dtype: bool
```

```
>>> s5.str.isupper()
0   False
1   False
2    True
3   False
dtype: bool
```

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be any sequence of non-numeric characters separated by whitespace characters.

```
>>> s5.str.istitle()
0   False
1    True
```

(continues on next page)

(continued from previous page)

```
2    False
3    False
dtype: bool
```

pandas.Series.str.istitle

Series.str.istitle()

Check whether all characters in each string are titlecase.

This is equivalent to running the Python string method `str.istitle()` for each element of the Series/Index. If a string has zero characters, `False` is returned for that check.

Returns

Series or Index of bool Series or Index of boolean values with the same length as the original Series/Index.

See also:

Series.str.isalpha Check whether all characters are alphabetic.
Series.str.isnumeric Check whether all characters are numeric.
Series.str.isalnum Check whether all characters are alphanumeric.
Series.str.isdigit Check whether all characters are digits.
Series.str.isdecimal Check whether all characters are decimal.
Series.str.isspace Check whether all characters are whitespace.
Series.str.islower Check whether all characters are lowercase.
Series.str.isupper Check whether all characters are uppercase.
Series.str.istitle Check whether all characters are titlecase.

Examples

Checks for Alphabetic and Numeric Characters

```
>>> s1 = pd.Series(['one', 'one1', '1', ''])
```

```
>>> s1.str.isalpha()
0    True
1    False
2    False
3    False
dtype: bool
```

```
>>> s1.str.isnumeric()
0    False
1    False
2    True
3    False
dtype: bool
```

```
>>> s1.str.isalnum()
0    True
1    True
2    True
```

(continues on next page)

(continued from previous page)

```
3    False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```
>>> s2 = pd.Series(['A B', '1.5', '3,000'])
>>> s2.str.isalnum()
0    False
1    False
2    False
dtype: bool
```

More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```
>>> s3 = pd.Series(['23', '³', ' ', ''])
```

The `s3.str.isdecimal` method checks for characters used to form numbers in base 10.

```
>>> s3.str.isdecimal()
0     True
1    False
2    False
3    False
dtype: bool
```

The `s.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```
>>> s3.str.isdigit()
0     True
1     True
2    False
3    False
dtype: bool
```

The `s.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```
>>> s3.str.isnumeric()
0     True
1     True
2     True
3    False
dtype: bool
```

Checks for Whitespace

```
>>> s4 = pd.Series([' ', '\t\r\n ', ''])
>>> s4.str.isspace()
0     True
1     True
```

(continues on next page)

(continued from previous page)

```
2    False
dtype: bool
```

Checks for Character Case

```
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])
```

```
>>> s5.str.islower()
0     True
1    False
2    False
3    False
dtype: bool
```

```
>>> s5.str.isupper()
0    False
1    False
2     True
3    False
dtype: bool
```

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```
>>> s5.str.istitle()
0    False
1     True
2    False
3    False
dtype: bool
```

pandas.Series.str.isnumeric

Series.str.isnumeric()

Check whether all characters in each string are numeric.

This is equivalent to running the Python string method `str.isnumeric()` for each element of the Series/Index. If a string has zero characters, `False` is returned for that check.

Returns

Series or Index of bool Series or Index of boolean values with the same length as the original Series/Index.

See also:

- [*Series.str.isalpha*](#) Check whether all characters are alphabetic.
- [*Series.str.isnumeric*](#) Check whether all characters are numeric.

- [*Series.str.isdecimal*](#) Check whether all characters are decimal.
- [*Series.str.isspace*](#) Check whether all characters are whitespace.
- [*Series.str.islower*](#) Check whether all characters are lowercase.
- [*Series.str.isupper*](#) Check whether all characters are uppercase.

`Series.str.istitle` Check whether all characters are titlecase.

Examples

Checks for Alphabetic and Numeric Characters

```
>>> s1 = pd.Series(['one', 'one1', '1', ''])
```

```
>>> s1.str.isalpha()
0    True
1   False
2   False
3   False
dtype: bool
```

```
>>> s1.str.isnumeric()
0   False
1   False
2    True
3   False
dtype: bool
```

```
>>> s1.str.isalnum()
0    True
1    True
2    True
3   False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```
>>> s2 = pd.Series(['A B', '1.5', '3,000'])
>>> s2.str.isalnum()
0   False
1   False
2   False
dtype: bool
```

More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```
>>> s3 = pd.Series(['23', '3', '', ''])
```

The `s3.str.isdecimal` method checks for characters used to form numbers in base 10.

```
>>> s3.str.isdecimal()
0    True
1   False
2   False
3   False
dtype: bool
```

The `s.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```
>>> s3.str.isdigit()
0    True
1    True
2   False
3   False
dtype: bool

dtype: bool
```

pandas.Series.str.isdecimal

Series.str.isdecimal()

Check whether all characters in each string are decimal.

This is equivalent to running the Python string method `str.isdecimal()` for each element of the Series/Index. If a string has zero characters, False is returned for that check.

Returns

Series or Index of bool Series or Index of boolean values with the same length as the original Series/Index.

See also:

Series.str.isalpha Check whether all characters are alphabetic.
Series.str.isnumeric Check whether all characters are numeric.
Series.str.isalnum Check whether all characters are alphanumeric.
Series.str.isdigit Check whether all characters are digits.
Series.str.isdecimal Check whether all characters are decimal.
Series.str.isspace Check whether all characters are whitespace.
Series.str.islower Check whether all characters are lowercase.
Series.str.isupper Check whether all characters are uppercase.
Series.str.istitle Check whether all characters are titlecase.

Examples

Checks for Alphabetic and Numeric Characters

```
>>> s1 = pd.Series(['one', 'one1', '1', ''])
```

```
>>> s1.str.isalpha()
0    True
1    False
2    False
3    False
dtype: bool
```

```
>>> s1.str.isnumeric()
0    False
1    False
2    True
3    False
dtype: bool
```

```
>>> s1.str.isalnum()
0    True
1    True
2    True
```

(continues on next page)

(continued from previous page)

```
3    False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```
>>> s2 = pd.Series(['A B', '1.5', '3,000'])
>>> s2.str.isalnum()
0    False
1    False
2    False
dtype: bool
```

More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```
>>> s3 = pd.Series(['23', '3', '', ''])
```

The `s3.str.isdecimal` method checks for characters used to form numbers in base 10.

```
>>> s3.str.isdecimal()
0     True
1    False
2    False
3    False
dtype: bool
```

The `s.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```
>>> s3.str.isdigit()
0     True
1     True
2    False
3    False
dtype: bool
```

The `s.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```
>>> s3.str.isnumeric()
0     True
1     True
2     True
3    False
dtype: bool
```

Checks for Whitespace

```
>>> s4 = pd.Series([' ', '\t\r\n ', ''])
>>> s4.str.isspace()
0     True
1     True
```

(continues on next page)

(continued from previous page)

```
2    False
dtype: bool
```

Checks for Character Case

```
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])
```

```
>>> s5.str.islower()
0    True
1    False
2    False
3    False
dtype: bool
```

```
>>> s5.str.isupper()
0    False
1    False
2     True
3    False
dtype: bool
```

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```
>>> s5.str.istitle()
0    False
1     True
2    False
3    False
dtype: bool
```

pandas.Series.str.get_dummies

`Series.str.get_dummies(sep='')`

Return DataFrame of dummy/indicator variables for Series.

Each string in Series is split by `sep` and returned as a DataFrame of dummy/indicator variables.

Parameters

sep [str, default “|”] String to split on.

Returns

DataFrame Dummy variables corresponding to values of the Series.

See also:

[`get_dummies`](#) Convert categorical variable into dummy/indicator variables.

Examples

```
>>> pd.Series(['a|b', 'a', 'a|c']).str.get_dummies()
   a  b  c
0  1  1  0
1  1  0  0
2  1  0  1
```

```
>>> pd.Series(['a|b', np.nan, 'a|c']).str.get_dummies()
   a  b  c
0  1  1  0
1  0  0  0
2  1  0  1
```

Categorical accessor

Categorical-dtype specific methods and attributes are available under the `Series.cat` accessor.

| | |
|------------------------------------|--|
| <code>Series.cat.categories</code> | The categories of this categorical. |
| <code>Series.cat.ordered</code> | Whether the categories have an ordered relationship. |
| <code>Series.cat.codes</code> | Return Series of codes as well as the index. |

pandas.Series.cat.categories

`Series.cat.categories`

The categories of this categorical.

`Setting` assigns new values to each category (effectively a rename of each individual category).

The assigned value has to be a list-like object. All items must be unique and the number of items in the new categories must be the same as the number of items in the old categories.

Assigning to `categories` is a inplace operation!

Raises

ValueError If the new categories do not validate as categories or if the number of new categories is unequal the number of old categories

See also:

`rename_categories` Rename categories.

`reorder_categories` Reorder categories.

`add_categories` Add new categories.

`remove_categories` Remove the specified categories.

`remove_unused_categories` Remove categories which are not used.

`set_categories` Set the categories to the specified ones.

pandas.Series.cat.ordered

Series.cat.ordered

Whether the categories have an ordered relationship.

pandas.Series.cat.codes

Series.cat.codes

Return Series of codes as well as the index.

| | |
|--|---|
| <code>Series.cat.rename_categories(*args, **kwargs)</code> | Rename categories. |
| <code>Series.cat.reorder_categories(*args, **kwargs)</code> | Reorder categories as specified in <code>new_categories</code> . |
| <code>Series.cat.add_categories(*args, **kwargs)</code> | Add new categories. |
| <code>Series.cat.remove_categories(*args, **kwargs)</code> | Remove the specified categories. |
| <code>Series.cat.remove_unused_categories(*args, ...)</code> | Remove categories which are not used. |
| <code>Series.cat.set_categories(*args, **kwargs)</code> | Set the categories to the specified <code>new_categories</code> . |
| <code>Series.cat.as_ordered(*args, **kwargs)</code> | Set the Categorical to be ordered. |
| <code>Series.cat.as_unordered(*args, **kwargs)</code> | Set the Categorical to be unordered. |

pandas.Series.cat.rename_categories

Series.cat.rename_categories(*args, **kwargs)

Rename categories.

Parameters

new_categories [list-like, dict-like or callable] New categories which will replace old categories.

- list-like: all items must be unique and the number of items in the new categories must match the existing number of categories.
- dict-like: specifies a mapping from old categories to new. Categories not contained in the mapping are passed through and extra categories in the mapping are ignored.
- callable : a callable that is called on all items in the old categories and whose return values comprise the new categories.

inplace [bool, default False] Whether or not to rename the categories inplace or return a copy of this categorical with renamed categories.

Deprecated since version 1.3.0.

Returns

cat [Categorical or None] Categorical with removed categories or None if `inplace=True`.

Raises

ValueError If new categories are list-like and do not have the same number of items than the current categories or do not validate as categories

See also:

[`reorder_categories`](#) Reorder categories.

[`add_categories`](#) Add new categories.

remove_categories Remove the specified categories.
remove_unused_categories Remove categories which are not used.
set_categories Set the categories to the specified ones.

Examples

```
>>> c = pd.Categorical(['a', 'a', 'b'])
>>> c.rename_categories([0, 1])
[0, 0, 1]
Categories (2, int64): [0, 1]
```

For dict-like `new_categories`, extra keys are ignored and categories not in the dictionary are passed through

```
>>> c.rename_categories({'a': 'A', 'c': 'C'})
['A', 'A', 'b']
Categories (2, object): ['A', 'b']
```

You may also provide a callable to create the new categories

```
>>> c.rename_categories(lambda x: x.upper())
['A', 'A', 'B']
Categories (2, object): ['A', 'B']
```

pandas.Series.cat.reorder_categories

`Series.cat.reorder_categories(*args, **kwargs)`
 Reorder categories as specified in `new_categories`.

`new_categories` need to include all old categories and no new category items.

Parameters

- `new_categories`** [Index-like] The categories in new order.
- `ordered`** [bool, optional] Whether or not the categorical is treated as a ordered categorical. If not given, do not change the ordered information.
- `inplace`** [bool, default False] Whether or not to reorder the categories inplace or return a copy of this categorical with reordered categories.
 Deprecated since version 1.3.0.

Returns

`cat` [Categorical or None] Categorical with removed categories or None if `inplace=True`.

Raises

`ValueError` If the new categories do not contain all old category items or any new ones

See also:

rename_categories Rename categories.
add_categories Add new categories.
remove_categories Remove the specified categories.
remove_unused_categories Remove categories which are not used.
set_categories Set the categories to the specified ones.

pandas.Series.cat.add_categories

`Series.cat.add_categories(*args, **kwargs)`

Add new categories.

new_categories will be included at the last/highest place in the categories and will be unused directly after this call.

Parameters

new_categories [category or list-like of category] The new categories to be included.

inplace [bool, default False] Whether or not to add the categories inplace or return a copy of this categorical with added categories.

Deprecated since version 1.3.0.

Returns

cat [Categorical or None] Categorical with new categories added or None if `inplace=True`.

Raises

ValueError If the new categories include old categories or do not validate as categories

See also:

[*rename_categories*](#) Rename categories.

[*reorder_categories*](#) Reorder categories.

[*remove_categories*](#) Remove the specified categories.

[*remove_unused_categories*](#) Remove categories which are not used.

[*set_categories*](#) Set the categories to the specified ones.

pandas.Series.cat.remove_categories

`Series.cat.remove_categories(*args, **kwargs)`

Remove the specified categories.

removals must be included in the old categories. Values which were in the removed categories will be set to NaN

Parameters

removals [category or list of categories] The categories which should be removed.

inplace [bool, default False] Whether or not to remove the categories inplace or return a copy of this categorical with removed categories.

Deprecated since version 1.3.0.

Returns

cat [Categorical or None] Categorical with removed categories or None if `inplace=True`.

Raises

ValueError If the removals are not contained in the categories

See also:

[*rename_categories*](#) Rename categories.

[*reorder_categories*](#) Reorder categories.

[*add_categories*](#) Add new categories.

[*remove_unused_categories*](#) Remove categories which are not used.

[*set_categories*](#) Set the categories to the specified ones.

pandas.Series.cat.remove_unused_categories

`Series.cat.remove_unused_categories(*args, **kwargs)`

Remove categories which are not used.

Parameters

inplace [bool, default False] Whether or not to drop unused categories inplace or return a copy of this categorical with unused categories dropped.

Deprecated since version 1.2.0.

Returns

cat [Categorical or None] Categorical with unused categories dropped or None if `inplace=True`.

See also:

[*rename_categories*](#) Rename categories.

[*reorder_categories*](#) Reorder categories.

[*add_categories*](#) Add new categories.

[*remove_categories*](#) Remove the specified categories.

[*set_categories*](#) Set the categories to the specified ones.

pandas.Series.cat.set_categories

`Series.cat.set_categories(*args, **kwargs)`

Set the categories to the specified `new_categories`.

`new_categories` can include new categories (which will result in unused categories) or remove old categories (which results in values set to NaN). If `rename==True`, the categories will simply be renamed (less or more items than in old categories will result in values set to NaN or in unused categories respectively).

This method can be used to perform more than one action of adding, removing, and reordering simultaneously and is therefore faster than performing the individual steps via the more specialised methods.

On the other hand this method does not do checks (e.g., whether the old categories are included in the new categories on a reorder), which can result in surprising changes, for example when using special string dtypes, which does not consider a S1 string equal to a single char python string.

Parameters

new_categories [Index-like] The categories in new order.

ordered [bool, default False] Whether or not the categorical is treated as an ordered categorical. If not given, do not change the ordered information.

rename [bool, default False] Whether or not the `new_categories` should be considered as a rename of the old categories or as reordered categories.

inplace [bool, default False] Whether or not to reorder the categories in-place or return a copy of this categorical with reordered categories.

Deprecated since version 1.3.0.

Returns

Categorical with reordered categories or None if inplace.

Raises

ValueError If `new_categories` does not validate as categories

See also:

rename_categories Rename categories.
reorder_categories Reorder categories.
add_categories Add new categories.
remove_categories Remove the specified categories.
remove_unused_categories Remove categories which are not used.

pandas.Series.cat.as_ordered

Series.cat.as_ordered(*args, **kwargs)

Set the Categorical to be ordered.

Parameters

inplace [bool, default False] Whether or not to set the ordered attribute in-place or return a copy of this categorical with ordered set to True.

Returns

Categorical or None Ordered Categorical or None if inplace=True.

pandas.Series.cat.as_unordered

Series.cat.as_unordered(*args, **kwargs)

Set the Categorical to be unordered.

Parameters

inplace [bool, default False] Whether or not to set the ordered attribute in-place or return a copy of this categorical with ordered set to False.

Returns

Categorical or None Unordered Categorical or None if inplace=True.

Sparse accessor

Sparse-dtype specific methods and attributes are provided under the Series.sparse accessor.

| | |
|---------------------------------|--|
| <i>Series.sparse.npoints</i> | The number of non- <i>fill_value</i> points. |
| <i>Series.sparse.density</i> | The percent of non- <i>fill_value</i> points, as decimal. |
| <i>Series.sparse.fill_value</i> | Elements in <i>data</i> that are <i>fill_value</i> are not stored. |
| <i>Series.sparse.sp_values</i> | An ndarray containing the non- <i>fill_value</i> values. |

pandas.Series.sparse.npoints

Series.sparse.npoints

The number of non- *fill_value* points.

Examples

```
>>> s = SparseArray([0, 0, 1, 1, 1], fill_value=0)
>>> s.npoints
3
```

pandas.Series.sparse.density

Series.sparse.density

The percent of non- *fill_value* points, as decimal.

Examples

```
>>> s = SparseArray([0, 0, 1, 1, 1], fill_value=0)
>>> s.density
0.6
```

pandas.Series.sparse.fill_value

Series.sparse.fill_value

Elements in *data* that are *fill_value* are not stored.

For memory savings, this should be the most common value in the array.

pandas.Series.sparse.sp_values

Series.sparse.sp_values

An ndarray containing the non- *fill_value* values.

Examples

```
>>> s = SparseArray([0, 0, 1, 0, 2], fill_value=0)
>>> s.sp_values
array([1, 2])
```

| | |
|---|--|
| <code>Series.sparse.from_coo(A[, dense_index])</code> | Create a Series with sparse values from a <code>scipy.sparse.coo_matrix</code> . |
| <code>Series.sparse.to_coo([row_levels, ...])</code> | Create a <code>scipy.sparse.coo_matrix</code> from a Series with <code>MultiIndex</code> . |

pandas.Series.sparse.from_coo**classmethod** `Series.sparse.from_coo(A, dense_index=False)`Create a Series with sparse values from a `scipy.sparse.coo_matrix`.**Parameters****A** [`scipy.sparse.coo_matrix`]**dense_index** [bool, default False] If False (default), the `SparseSeries` index consists of only the coords of the non-null entries of the original `coo_matrix`. If True, the `SparseSeries` index consists of the full sorted (row, col) coordinates of the `coo_matrix`.**Returns****s** [`Series`] A Series with sparse values.**Examples**

```
>>> from scipy import sparse
```

```
>>> A = sparse.coo_matrix(
...     ([3.0, 1.0, 2.0], ([1, 0, 0], [0, 2, 3])), shape=(3, 4)
... )
>>> A
<3x4 sparse matrix of type '<class 'numpy.float64''>'
with 3 stored elements in COOrdinate format>
```

```
>>> A.todense()
matrix([[0., 0., 1., 2.],
        [3., 0., 0., 0.],
        [0., 0., 0., 0.]])
```

```
>>> ss = pd.Series.sparse.from_coo(A)
>>> ss
0 2 1.0
 3 2.0
1 0 3.0
dtype: Sparse[float64, nan]
```

pandas.Series.sparse.to_coo**Series.sparse.to_coo(row_levels=(0), column_levels=(1), sort_labels=False)**Create a `scipy.sparse.coo_matrix` from a Series with MultiIndex.Use `row_levels` and `column_levels` to determine the row and column coordinates respectively. `row_levels` and `column_levels` are the names (labels) or numbers of the levels. `{row_levels, column_levels}` must be a partition of the MultiIndex level names (or numbers).**Parameters****row_levels** [tuple/list]**column_levels** [tuple/list]

sort_labels [bool, default False] Sort the row and column labels before forming the sparse matrix.

Returns

y [scipy.sparse.coo_matrix]

rows [list (row labels)]

columns [list (column labels)]

Examples

```
>>> s = pd.Series([3.0, np.nan, 1.0, 3.0, np.nan, np.nan])
>>> s.index = pd.MultiIndex.from_tuples(
...     [
...         (1, 2, "a", 0),
...         (1, 2, "a", 1),
...         (1, 1, "b", 0),
...         (1, 1, "b", 1),
...         (2, 1, "b", 0),
...         (2, 1, "b", 1)
...     ],
...     names=["A", "B", "C", "D"],
... )
>>> s
A B C D
1 2 a 0  3.0
      1  NaN
   1 b 0  1.0
      1  3.0
2 1 b 0  NaN
      1  NaN
dtype: float64
```

```
>>> ss = s.astype("Sparse")
>>> ss
A B C D
1 2 a 0  3.0
      1  NaN
   1 b 0  1.0
      1  3.0
2 1 b 0  NaN
      1  NaN
dtype: Sparse[float64, nan]
```

```
>>> A, rows, columns = ss.sparse.to_coo(
...     row_levels=["A", "B"], column_levels=["C", "D"], sort_labels=True
... )
>>> A
<3x4 sparse matrix of type '<class 'numpy.float64''>'
with 3 stored elements in COOrdinate format>
>>> A.todense()
matrix([[0., 0., 1., 3.]
```

(continues on next page)

(continued from previous page)

```
[3., 0., 0., 0.],
[0., 0., 0., 0.]])
```

```
>>> rows
[(1, 1), (1, 2), (2, 1)]
>>> columns
[('a', 0), ('a', 1), ('b', 0), ('b', 1)]
```

Flags

Flags refer to attributes of the pandas object. Properties of the dataset (like the date it was recorded, the URL it was accessed from, etc.) should be stored in `Series.attrs`.

| | |
|---|-------------------------------------|
| <code>Flags(obj, *, allows_duplicate_labels)</code> | Flags that apply to pandas objects. |
|---|-------------------------------------|

pandas.Flags

class pandas.Flags(*obj*, *, *allows_duplicate_labels*)

Flags that apply to pandas objects.

New in version 1.2.0.

Parameters

obj [Series or DataFrame] The object these flags are associated with.

allows_duplicate_labels [bool, default True] Whether to allow duplicate labels in this object. By default, duplicate labels are permitted. Setting this to `False` will cause an `errors.DuplicateLabelError` to be raised when `index` (or `columns` for DataFrame) is not unique, or any subsequent operation on introduces duplicates. See *Disallowing Duplicate Labels* for more.

Warning: This is an experimental feature. Currently, many methods fail to propagate the `allows_duplicate_labels` value. In future versions it is expected that every method taking or returning one or more DataFrame or Series objects will propagate `allows_duplicate_labels`.

Notes

Attributes can be set in two ways

```
>>> df = pd.DataFrame()
>>> df.flags
<Flags(allows_duplicate_labels=True)>
>>> df.flags.allows_duplicate_labels = False
>>> df.flags
<Flags(allows_duplicate_labels=False)>
```

```
>>> df.flags['allows_duplicate_labels'] = True
>>> df.flags
<Flags(allows_duplicate_labels=True)>
```

Attributes

| | |
|--------------------------------|--|
| <i>allows_duplicate_labels</i> | Whether this object allows duplicate labels. |
|--------------------------------|--|

pandas.Flags.allows_duplicate_labels

property Flags.allows_duplicate_labels

Whether this object allows duplicate labels.

Setting `allows_duplicate_labels=False` ensures that the index (and columns of a DataFrame) are unique. Most methods that accept and return a Series or DataFrame will propagate the value of `allows_duplicate_labels`.

See *Duplicate Labels* for more.

See also:

DataFrame.attrs Set global metadata on this object.

DataFrame.set_flags Set global flags on this object.

Examples

```
>>> df = pd.DataFrame({"A": [1, 2]}, index=['a', 'a'])
>>> df.allows_duplicate_labels
True
>>> df.allows_duplicate_labels = False
Traceback (most recent call last):
...
pandas.errors.DuplicateLabelError: Index has duplicates.
      positions
label
a          [0, 1]
```

Metadata

Series.attrs is a dictionary for storing global metadata for this Series.

Warning: `Series.attrs` is considered experimental and may change without warning.

| | |
|---------------------|--|
| <i>Series.attrs</i> | Dictionary of global attributes of this dataset. |
|---------------------|--|

3.3.14 Plotting

`Series.plot` is both a callable method and a namespace attribute for specific plotting methods of the form `Series.plot.<kind>`.

| | |
|--|---|
| <code>Series.plot([kind, ax, figsize, ...])</code> | Series plotting accessor and method |
| <code>Series.plot.area([x, y])</code> | Draw a stacked area plot. |
| <code>Series.plot.bar([x, y])</code> | Vertical bar plot. |
| <code>Series.plot.barh([x, y])</code> | Make a horizontal bar plot. |
| <code>Series.plot.box([by])</code> | Make a box plot of the DataFrame columns. |
| <code>Series.plot.density([bw_method, ind])</code> | Generate Kernel Density Estimate plot using Gaussian kernels. |
| <code>Series.plot.hist([by, bins])</code> | Draw one histogram of the DataFrame's columns. |
| <code>Series.plot.kde([bw_method, ind])</code> | Generate Kernel Density Estimate plot using Gaussian kernels. |
| <code>Series.plot.line([x, y])</code> | Plot Series or DataFrame as lines. |
| <code>Series.plot.pie(**kwargs)</code> | Generate a pie plot. |

pandas.Series.plot.area

`Series.plot.area(x=None, y=None, **kwargs)`

Draw a stacked area plot.

An area plot displays quantitative data visually. This function wraps the matplotlib area function.

Parameters

- x** [label or position, optional] Coordinates for the X axis. By default uses the index.
- y** [label or position, optional] Column to plot. By default uses all columns.
- stacked** [bool, default True] Area plots are stacked by default. Set to False to create a unstacked plot.
- **kwargs** Additional keyword arguments are documented in `DataFrame.plot()`.

Returns

`matplotlib.axes.Axes` or `numpy.ndarray` Area plot, or array of area plots if `subplots` is True.

See also:

`DataFrame.plot` Make plots of DataFrame using matplotlib / pylab.

Examples

Draw an area plot based on basic business metrics:

```
>>> df = pd.DataFrame({
...     'sales': [3, 2, 3, 9, 10, 6],
...     'signups': [5, 5, 6, 12, 14, 13],
...     'visits': [20, 42, 28, 62, 81, 50],
... }, index=pd.date_range(start='2018/01/01', end='2018/07/01',
...                          freq='M'))
>>> ax = df.plot.area()
```

Area plots are stacked by default. To produce an unstacked plot, pass `stacked=False`:

```
>>> ax = df.plot.area(stacked=False)
```

Draw an area plot for a single column:

```
>>> ax = df.plot.area(y='sales')
```

Draw with a different x:

```
>>> df = pd.DataFrame({
...     'sales': [3, 2, 3],
...     'visits': [20, 42, 28],
...     'day': [1, 2, 3],
... })
>>> ax = df.plot.area(x='day')
```

pandas.Series.plot.bar

`Series.plot.bar` ($x=None$, $y=None$, ****kwargs**)

Vertical bar plot.

A bar plot is a plot that presents categorical data with rectangular bars with lengths proportional to the values that they represent. A bar plot shows comparisons among discrete categories. One axis of the plot shows the specific categories being compared, and the other axis represents a measured value.

Parameters

- x** [label or position, optional] Allows plotting of one column versus another. If not specified, the index of the DataFrame is used.
- y** [label or position, optional] Allows plotting of one column versus another. If not specified, all numerical columns are used.
- color** [str, array-like, or dict, optional] The color for each of the DataFrame's columns. Possible values are:
 - **A single color string referred to by name, RGB or RGBA code**, for instance 'red' or '#a98d19'.
 - **A sequence of color strings referred to by name, RGB or RGBA code**, which will be used for each column recursively. For instance ['green','yellow'] each column's bar will be filled in green or yellow, alternatively. If there is only a single column to be plotted, then only the first color from the color list will be used.
 - **A dict of the form {column name [color]}**, so that each column will be colored accordingly. For example, if your columns are called *a* and *b*, then passing {'a': 'green', 'b': 'red'} will color bars for column *a* in green and bars for column *b* in red.

New in version 1.1.0.

****kwargs** Additional keyword arguments are documented in `DataFrame.plot()`.

Returns

matplotlib.axes.Axes or np.ndarray of them An ndarray is returned with one `matplotlib.axes.Axes` per column when `subplots=True`.

See also:

`DataFrame.plot.barh` Horizontal bar plot.

`DataFrame.plot` Make plots of a DataFrame.

`matplotlib.pyplot.bar` Make a bar plot with matplotlib.

Examples

Basic plot.

```
>>> df = pd.DataFrame({'lab':['A', 'B', 'C'], 'val':[10, 30, 20]})
>>> ax = df.plot.bar(x='lab', y='val', rot=0)
```

Plot a whole dataframe to a bar plot. Each column is assigned a distinct color, and each row is nested in a group along the horizontal axis.

```

>>> speed = [0.1, 17.5, 40, 48, 52, 69, 88]
>>> lifespan = [2, 8, 70, 1.5, 25, 12, 28]
>>> index = ['snail', 'pig', 'elephant',
...         'rabbit', 'giraffe', 'coyote', 'horse']
>>> df = pd.DataFrame({'speed': speed,
...                   'lifespan': lifespan}, index=index)
>>> ax = df.plot.bar(rot=0)

```

Plot stacked bar charts for the DataFrame

```

>>> ax = df.plot.bar(stacked=True)

```

Instead of nesting, the figure can be split by column with `subplots=True`. In this case, a `numpy.ndarray` of `matplotlib.axes.Axes` are returned.

```

>>> axes = df.plot.bar(rot=0, subplots=True)
>>> axes[1].legend(loc=2)

```

If you don't like the default colours, you can specify how you'd like each column to be colored.

```

>>> axes = df.plot.bar(
...     rot=0, subplots=True, color={"speed": "red", "lifespan": "green"}
... )

```

(continues on next page)

(continued from previous page)

```
>>> axes[1].legend(loc=2)
```

Plot a single column.

```
>>> ax = df.plot.bar(y='speed', rot=0)
```

Plot only selected categories for the DataFrame.

```
>>> ax = df.plot.bar(x='lifespan', rot=0)
```

pandas.Series.plot.barh

`Series.plot.barh`(*x=None*, *y=None*, ***kwargs*)

Make a horizontal bar plot.

A horizontal bar plot is a plot that presents quantitative data with rectangular bars with lengths proportional to the values that they represent. A bar plot shows comparisons among discrete categories. One axis of the plot shows the specific categories being compared, and the other axis represents a measured value.

Parameters

x [label or position, optional] Allows plotting of one column versus another. If not specified, the index of the DataFrame is used.

y [label or position, optional] Allows plotting of one column versus another. If not specified, all numerical columns are used.

color [str, array-like, or dict, optional] The color for each of the DataFrame's columns. Possible values are:

- **A single color string referred to by name, RGB or RGBA code**, for instance 'red' or '#a98d19'.
- **A sequence of color strings referred to by name, RGB or RGBA code**, which will be used for each column recursively. For instance ['green','yellow'] each column's bar will be filled in green or yellow, alternatively. If there is only a single column to be plotted, then only the first color from the color list will be used.
- **A dict of the form {column name [color]}**, so that each column will be colored accordingly. For example, if your columns are called *a* and *b*, then passing {'a': 'green', 'b': 'red'} will color bars for column *a* in green and bars for column *b* in red.

New in version 1.1.0.

****kwargs** Additional keyword arguments are documented in `DataFrame.plot()`.

Returns

matplotlib.axes.Axes or np.ndarray of them An ndarray is returned with one `matplotlib.axes.Axes` per column when `subplots=True`.

See also:

`DataFrame.plot.bar` Vertical bar plot.

`DataFrame.plot` Make plots of DataFrame using matplotlib.

`matplotlib.axes.Axes.bar` Plot a vertical bar plot using matplotlib.

Examples

Basic example

```
>>> df = pd.DataFrame({'lab': ['A', 'B', 'C'], 'val': [10, 30, 20]})
>>> ax = df.plot.barh(x='lab', y='val')
```

Plot a whole DataFrame to a horizontal bar plot

```
>>> speed = [0.1, 17.5, 40, 48, 52, 69, 88]
>>> lifespan = [2, 8, 70, 1.5, 25, 12, 28]
>>> index = ['snail', 'pig', 'elephant',
...         'rabbit', 'giraffe', 'coyote', 'horse']
>>> df = pd.DataFrame({'speed': speed,
...                   'lifespan': lifespan}, index=index)
>>> ax = df.plot.barh()
```

Plot stacked barh charts for the DataFrame

```
>>> ax = df.plot.barh(stacked=True)
```

We can specify colors for each column

```
>>> ax = df.plot.barh(color={"speed": "red", "lifespan": "green"})
```

Plot a column of the DataFrame to a horizontal bar plot

```
>>> speed = [0.1, 17.5, 40, 48, 52, 69, 88]
>>> lifespan = [2, 8, 70, 1.5, 25, 12, 28]
>>> index = ['snail', 'pig', 'elephant',
...         'rabbit', 'giraffe', 'coyote', 'horse']
>>> df = pd.DataFrame({'speed': speed,
...                   'lifespan': lifespan}, index=index)
>>> ax = df.plot.barh(y='speed')
```

Plot DataFrame versus the desired column

```
>>> speed = [0.1, 17.5, 40, 48, 52, 69, 88]
>>> lifespan = [2, 8, 70, 1.5, 25, 12, 28]
>>> index = ['snail', 'pig', 'elephant',
...         'rabbit', 'giraffe', 'coyote', 'horse']
>>> df = pd.DataFrame({'speed': speed,
...                   'lifespan': lifespan}, index=index)
>>> ax = df.plot.barh(x='lifespan')
```

pandas.Series.plot.box

`Series.plot.box`(*by=None, **kwargs*)

Make a box plot of the DataFrame columns.

A box plot is a method for graphically depicting groups of numerical data through their quartiles. The box extends from the Q1 to Q3 quartile values of the data, with a line at the median (Q2). The whiskers extend from the edges of box to show the range of the data. The position of the whiskers is set by default to $1.5 \times \text{IQR}$ ($\text{IQR} = \text{Q3} - \text{Q1}$) from the edges of the box. Outlier points are those past the end of the whiskers.

For further details see Wikipedia's entry for [boxplot](#).

A consideration when using this chart is that the box and the whiskers can overlap, which is very common when plotting small sets of data.

Parameters

by [str or sequence] Column in the DataFrame to group by.

****kwargs** Additional keywords are documented in `DataFrame.plot()`.

Returns

`matplotlib.axes.Axes` or `numpy.ndarray` of them

See also:

[DataFrame.boxplot](#) Another method to draw a box plot.

[Series.plot.box](#) Draw a box plot from a Series object.

[matplotlib.pyplot.boxplot](#) Draw a box plot in matplotlib.

Examples

Draw a box plot from a DataFrame with four columns of randomly generated data.

```
>>> data = np.random.randn(25, 4)
>>> df = pd.DataFrame(data, columns=list('ABCD'))
>>> ax = df.plot.box()
```

pandas.Series.plot.density

`Series.plot.density`(*bw_method=None, ind=None, **kwargs*)

Generate Kernel Density Estimate plot using Gaussian kernels.

In statistics, [kernel density estimation](#) (KDE) is a non-parametric way to estimate the probability density function (PDF) of a random variable. This function uses Gaussian kernels and includes automatic bandwidth determination.

Parameters

bw_method [str, scalar or callable, optional] The method used to calculate the estimator bandwidth. This can be 'scott', 'silverman', a scalar constant or a callable. If None (default), 'scott' is used. See `scipy.stats.gaussian_kde` for more information.

ind [NumPy array or int, optional] Evaluation points for the estimated PDF. If None (default), 1000 equally spaced points are used. If *ind* is a NumPy array, the KDE is evaluated at the points passed. If *ind* is an integer, *ind* number of equally spaced points are used.

****kwargs** Additional keyword arguments are documented in `pandas.%<this-datatype>.plot()`.

Returns

`matplotlib.axes.Axes` or `numpy.ndarray` of them

See also:

`scipy.stats.gaussian_kde` Representation of a kernel-density estimate using Gaussian kernels. This is the function used internally to estimate the PDF.

Examples

Given a Series of points randomly sampled from an unknown distribution, estimate its PDF using KDE with automatic bandwidth determination and plot the results, evaluating them at 1000 equally spaced points (default):

```
>>> s = pd.Series([1, 2, 2.5, 3, 3.5, 4, 5])
>>> ax = s.plot.kde()
```

A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:

```
>>> ax = s.plot.kde(bw_method=0.3)
```

```
>>> ax = s.plot.kde(bw_method=3)
```

Finally, the *ind* parameter determines the evaluation points for the plot of the estimated PDF:

```
>>> ax = s.plot.kde(ind=[1, 2, 3, 4, 5])
```

For DataFrame, it works in the same way:

```
>>> df = pd.DataFrame({
...     'x': [1, 2, 2.5, 3, 3.5, 4, 5],
...     'y': [4, 4, 4.5, 5, 5.5, 6, 6],
... })
>>> ax = df.plot.kde()
```

A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:

```
>>> ax = df.plot.kde(bw_method=0.3)
```

```
>>> ax = df.plot.kde(bw_method=3)
```

Finally, the *ind* parameter determines the evaluation points for the plot of the estimated PDF:

```
>>> ax = df.plot.kde(ind=[1, 2, 3, 4, 5, 6])
```

pandas.Series.plot.hist

`Series.plot.hist`(*by=None, bins=10, **kwargs*)

Draw one histogram of the DataFrame's columns.

A histogram is a representation of the distribution of data. This function groups the values of all given Series in the DataFrame into bins and draws all bins in one `matplotlib.axes.Axes`. This is useful when the DataFrame's Series are in a similar scale.

Parameters

by [str or sequence, optional] Column in the DataFrame to group by.

bins [int, default 10] Number of histogram bins to be used.

****kwargs** Additional keyword arguments are documented in `DataFrame.plot()`.

Returns

class:matplotlib.AxesSubplot Return a histogram plot.

See also:

[`DataFrame.hist`](#) Draw histograms per DataFrame's Series.

[`Series.hist`](#) Draw a histogram with Series' data.

Examples

When we draw a dice 6000 times, we expect to get each value around 1000 times. But when we draw two dices and sum the result, the distribution is going to be quite different. A histogram illustrates those distributions.

```
>>> df = pd.DataFrame(
...     np.random.randint(1, 7, 6000),
...     columns = ['one'])
>>> df['two'] = df['one'] + np.random.randint(1, 7, 6000)
>>> ax = df.plot.hist(bins=12, alpha=0.5)
```

pandas.Series.plot.kde

`Series.plot.kde`(*bw_method=None, ind=None, **kwargs*)

Generate Kernel Density Estimate plot using Gaussian kernels.

In statistics, [kernel density estimation](#) (KDE) is a non-parametric way to estimate the probability density function (PDF) of a random variable. This function uses Gaussian kernels and includes automatic bandwidth determination.

Parameters

bw_method [str, scalar or callable, optional] The method used to calculate the estimator bandwidth. This can be 'scott', 'silverman', a scalar constant or a callable. If None (default), 'scott' is used. See `scipy.stats.gaussian_kde` for more information.

ind [NumPy array or int, optional] Evaluation points for the estimated PDF. If None (default), 1000 equally spaced points are used. If *ind* is a NumPy array, the KDE is evaluated at the points passed. If *ind* is an integer, *ind* number of equally spaced points are used.

****kwargs** Additional keyword arguments are documented in `pandas.%(this-datatype)s.plot()`.

Returns

matplotlib.axes.Axes or numpy.ndarray of them

See also:

`scipy.stats.gaussian_kde` Representation of a kernel-density estimate using Gaussian kernels. This is the function used internally to estimate the PDF.

Examples

Given a Series of points randomly sampled from an unknown distribution, estimate its PDF using KDE with automatic bandwidth determination and plot the results, evaluating them at 1000 equally spaced points (default):

```
>>> s = pd.Series([1, 2, 2.5, 3, 3.5, 4, 5])
>>> ax = s.plot.kde()
```

A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:

```
>>> ax = s.plot.kde(bw_method=0.3)
```

```
>>> ax = s.plot.kde(bw_method=3)
```

Finally, the `ind` parameter determines the evaluation points for the plot of the estimated PDF:

```
>>> ax = s.plot.kde(ind=[1, 2, 3, 4, 5])
```

For DataFrame, it works in the same way:

```
>>> df = pd.DataFrame({
...     'x': [1, 2, 2.5, 3, 3.5, 4, 5],
...     'y': [4, 4, 4.5, 5, 5.5, 6, 6],
... })
>>> ax = df.plot.kde()
```

A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:

```
>>> ax = df.plot.kde(bw_method=0.3)
```

```
>>> ax = df.plot.kde(bw_method=3)
```

Finally, the *ind* parameter determines the evaluation points for the plot of the estimated PDF:

```
>>> ax = df.plot.kde(ind=[1, 2, 3, 4, 5, 6])
```

pandas.Series.plot.line

`Series.plot.line(x=None, y=None, **kwargs)`

Plot Series or DataFrame as lines.

This function is useful to plot lines using DataFrame's values as coordinates.

Parameters

- x** [label or position, optional] Allows plotting of one column versus another. If not specified, the index of the DataFrame is used.
- y** [label or position, optional] Allows plotting of one column versus another. If not specified, all numerical columns are used.
- color** [str, array-like, or dict, optional] The color for each of the DataFrame's columns. Possible values are:
 - **A single color string referred to by name, RGB or RGBA code**, for instance 'red' or '#a98d19'.
 - **A sequence of color strings referred to by name, RGB or RGBA code**, which will be used for each column recursively. For instance ['green','yellow'] each column's line will be filled in green or yellow, alternatively. If there is only a single column to be plotted, then only the first color from the color list will be used.
 - **A dict of the form {column name [color]}**, so that each column will be colored accordingly. For example, if your columns are called *a* and *b*, then passing {'a': 'green', 'b': 'red'} will color lines for column *a* in green and lines for column *b* in red.

New in version 1.1.0.

****kwargs** Additional keyword arguments are documented in `DataFrame.plot()`.

Returns

matplotlib.axes.Axes or np.ndarray of them An ndarray is returned with one `matplotlib.axes.Axes` per column when `subplots=True`.

See also:

`matplotlib.pyplot.plot` Plot y versus x as lines and/or markers.

Examples

```
>>> s = pd.Series([1, 3, 2])
>>> s.plot.line()
```

The following example shows the populations for some animals over the years.

```
>>> df = pd.DataFrame({
...     'pig': [20, 18, 489, 675, 1776],
...     'horse': [4, 25, 281, 600, 1900]
...     }, index=[1990, 1997, 2003, 2009, 2014])
>>> lines = df.plot.line()
```

An example with subplots, so an array of axes is returned.

```
>>> axes = df.plot.line(subplots=True)
>>> type(axes)
<class 'numpy.ndarray'>
```

Let's repeat the same example, but specifying colors for each column (in this case, for each animal).

```
>>> axes = df.plot.line(
...     subplots=True, color={"pig": "pink", "horse": "#742802"}
... )
```

The following example shows the relationship between both populations.

```
>>> lines = df.plot.line(x='pig', y='horse')
```

pandas.Series.plot.pie

`Series.plot.pie(**kwargs)`

Generate a pie plot.

A pie plot is a proportional representation of the numerical data in a column. This function wraps `matplotlib.pyplot.pie()` for the specified column. If no column reference is passed and `subplots=True` a pie plot is drawn for each numerical column independently.

Parameters

`y` [int or label, optional] Label or position of the column to plot. If not provided, `subplots=True` argument must be passed.

`**kwargs` Keyword arguments to pass on to `DataFrame.plot()`.

Returns

matplotlib.axes.Axes or np.ndarray of them A NumPy array is returned when `subplots` is `True`.

See also:

[Series.plot.pie](#) Generate a pie plot for a Series.

[DataFrame.plot](#) Make plots of a DataFrame.

Examples

In the example below we have a DataFrame with the information about planet's mass and radius. We pass the 'mass' column to the pie function to get a pie plot.

```
>>> df = pd.DataFrame({'mass': [0.330, 4.87, 5.97],
...                   'radius': [2439.7, 6051.8, 6378.1]},
...                   index=['Mercury', 'Venus', 'Earth'])
>>> plot = df.plot.pie(y='mass', figsize=(5, 5))
```

```
>>> plot = df.plot.pie(subplots=True, figsize=(11, 6))
```

| | |
|---|--|
| <code>Series.hist([by, ax, grid, xlabelsize, ...])</code> | Draw histogram of the input series using matplotlib. |
|---|--|

3.3.15 Serialization / IO / conversion

| | |
|---|--|
| <code>Series.to_pickle(path[, compression, ...])</code> | Pickle (serialize) object to file. |
| <code>Series.to_csv([path_or_buf, sep, na_rep, ...])</code> | Write object to a comma-separated values (csv) file. |
| <code>Series.to_dict([into])</code> | Convert Series to {label -> value} dict or dict-like object. |
| <code>Series.to_excel(excel_writer[, sheet_name, ...])</code> | Write object to an Excel sheet. |
| <code>Series.to_frame([name])</code> | Convert Series to DataFrame. |
| <code>Series.to_xarray()</code> | Return an xarray object from the pandas object. |
| <code>Series.to_hdf(path_or_buf, key[, mode, ...])</code> | Write the contained data to an HDF5 file using HDFStore. |
| <code>Series.to_sql(name, con[, schema, ...])</code> | Write records stored in a DataFrame to a SQL database. |
| <code>Series.to_json([path_or_buf, orient, ...])</code> | Convert the object to a JSON string. |
| <code>Series.to_string([buf, na_rep, ...])</code> | Render a string representation of the Series. |
| <code>Series.to_clipboard([excel, sep])</code> | Copy object to the system clipboard. |

Table 62 – continued from previous page

| | |
|---|---|
| <code>Series.to_latex</code> ([buf, columns, col_space, ...]) | Render object to a LaTeX tabular, longtable, or nested table/tabular. |
| <code>Series.to_markdown</code> ([buf, mode, index, ...]) | Print Series in Markdown-friendly format. |

3.4 DataFrame

3.4.1 Constructor

| | |
|--|--|
| <code>DataFrame</code> ([data, index, columns, dtype, copy]) | Two-dimensional, size-mutable, potentially heterogeneous tabular data. |
|--|--|

`pandas.DataFrame`

class `pandas.DataFrame`(*data=None, index=None, columns=None, dtype=None, copy=None*)

Two-dimensional, size-mutable, potentially heterogeneous tabular data.

Data structure also contains labeled axes (rows and columns). Arithmetic operations align on both row and column labels. Can be thought of as a dict-like container for Series objects. The primary pandas data structure.

Parameters

data [ndarray (structured or homogeneous), Iterable, dict, or DataFrame] Dict can contain Series, arrays, constants, dataclass or list-like objects. If data is a dict, column order follows insertion-order.

Changed in version 0.25.0: If data is a list of dicts, column order follows insertion-order.

index [Index or array-like] Index to use for resulting frame. Will default to RangeIndex if no indexing information part of input data and no index provided.

columns [Index or array-like] Column labels to use for resulting frame when data does not have them, defaulting to RangeIndex(0, 1, 2, ..., n). If data contains column labels, will perform column selection instead.

dtype [dtype, default None] Data type to force. Only a single dtype is allowed. If None, infer.

copy [bool or None, default None] Copy data from inputs. For dict data, the default of None behaves like `copy=True`. For DataFrame or 2d ndarray input, the default of None behaves like `copy=False`.

Changed in version 1.3.0.

See also:

`DataFrame.from_records` Constructor from tuples, also record arrays.

`DataFrame.from_dict` From dicts of Series, arrays, or dicts.

`read_csv` Read a comma-separated values (csv) file into DataFrame.

`read_table` Read general delimited file into DataFrame.

`read_clipboard` Read text from clipboard into DataFrame.

Examples

Constructing DataFrame from a dictionary.

```
>>> d = {'col1': [1, 2], 'col2': [3, 4]}
>>> df = pd.DataFrame(data=d)
>>> df
   col1  col2
0     1     3
1     2     4
```

Notice that the inferred dtype is int64.

```
>>> df.dtypes
col1    int64
col2    int64
dtype: object
```

To enforce a single dtype:

```
>>> df = pd.DataFrame(data=d, dtype=np.int8)
>>> df.dtypes
col1    int8
col2    int8
dtype: object
```

Constructing DataFrame from numpy ndarray:

```
>>> df2 = pd.DataFrame(np.array([[1, 2, 3], [4, 5, 6], [7, 8, 9]]),
...                    columns=['a', 'b', 'c'])
>>> df2
   a  b  c
0  1  2  3
1  4  5  6
2  7  8  9
```

Constructing DataFrame from a numpy ndarray that has labeled columns:

```
>>> data = np.array([(1, 2, 3), (4, 5, 6), (7, 8, 9)],
...                 dtype=[("a", "i4"), ("b", "i4"), ("c", "i4")])
>>> df3 = pd.DataFrame(data, columns=['c', 'a'])
...
>>> df3
   c  a
0  3  1
1  6  4
2  9  7
```

Constructing DataFrame from dataclass:

```
>>> from dataclasses import make_dataclass
>>> Point = make_dataclass("Point", [("x", int), ("y", int)])
>>> pd.DataFrame([Point(0, 0), Point(0, 3), Point(2, 3)])
   x  y
```

(continues on next page)

(continued from previous page)

```

0 0 0
1 0 3
2 2 3

```

Attributes

| | |
|----------------|--|
| <i>at</i> | Access a single value for a row/column label pair. |
| <i>attrs</i> | Dictionary of global attributes of this dataset. |
| <i>axes</i> | Return a list representing the axes of the DataFrame. |
| <i>columns</i> | The column labels of the DataFrame. |
| <i>dtypes</i> | Return the dtypes in the DataFrame. |
| <i>empty</i> | Indicator whether DataFrame is empty. |
| <i>flags</i> | Get the properties associated with this pandas object. |
| <i>iat</i> | Access a single value for a row/column pair by integer position. |
| <i>iloc</i> | Purely integer-location based indexing for selection by position. |
| <i>index</i> | The index (row labels) of the DataFrame. |
| <i>loc</i> | Access a group of rows and columns by label(s) or a boolean array. |
| <i>ndim</i> | Return an int representing the number of axes / array dimensions. |
| <i>shape</i> | Return a tuple representing the dimensionality of the DataFrame. |
| <i>size</i> | Return an int representing the number of elements in this object. |
| <i>style</i> | Returns a Styler object. |
| <i>values</i> | Return a Numpy representation of the DataFrame. |

pandas.DataFrame.at

property DataFrame.at

Access a single value for a row/column label pair.

Similar to `loc`, in that both provide label-based lookups. Use `at` if you only need to get or set a single value in a DataFrame or Series.

Raises

KeyError If 'label' does not exist in DataFrame.

See also:

DataFrame.iat Access a single value for a row/column pair by integer position.

DataFrame.loc Access a group of rows and columns by label(s).

Series.at Access a single value using a label.

Examples

```
>>> df = pd.DataFrame([[0, 2, 3], [0, 4, 1], [10, 20, 30]],
...                    index=[4, 5, 6], columns=['A', 'B', 'C'])
>>> df
   A  B  C
4  0  2  3
5  0  4  1
6 10 20 30
```

Get value at specified row/column pair

```
>>> df.at[4, 'B']
2
```

Set value at specified row/column pair

```
>>> df.at[4, 'B'] = 10
>>> df.at[4, 'B']
10
```

Get value within a Series

```
>>> df.loc[5].at['B']
4
```

pandas.DataFrame.attrs

property DataFrame.attrs

Dictionary of global attributes of this dataset.

Warning: attrs is experimental and may change without warning.

See also:

[*DataFrame.flags*](#) Global flags applying to this object.

pandas.DataFrame.axes

property DataFrame.axes

Return a list representing the axes of the DataFrame.

It has the row axis labels and column axis labels as the only members. They are returned in that order.

Examples

```
>>> df = pd.DataFrame({'col1': [1, 2], 'col2': [3, 4]})
>>> df.axes
[RangeIndex(start=0, stop=2, step=1), Index(['col1', 'col2'],
dtype='object')]
```

pandas.DataFrame.columns

DataFrame.columns

The column labels of the DataFrame.

pandas.DataFrame.dtypes

property DataFrame.dtypes

Return the dtypes in the DataFrame.

This returns a Series with the data type of each column. The result's index is the original DataFrame's columns. Columns with mixed types are stored with the object dtype. See *the User Guide* for more.

Returns

pandas.Series The data type of each column.

Examples

```
>>> df = pd.DataFrame({'float': [1.0],
...                   'int': [1],
...                   'datetime': [pd.Timestamp('20180310')],
...                   'string': ['foo']})
>>> df.dtypes
float          float64
int            int64
datetime      datetime64[ns]
string        object
dtype: object
```

pandas.DataFrame.empty

property DataFrame.empty

Indicator whether DataFrame is empty.

True if DataFrame is entirely empty (no items), meaning any of the axes are of length 0.

Returns

bool If DataFrame is empty, return True, if not return False.

See also:

Series.dropna Return series without null values.

DataFrame.dropna Return DataFrame with labels on given axis omitted where (all or any) data are missing.

Notes

If DataFrame contains only NaNs, it is still not considered empty. See the example below.

Examples

An example of an actual empty DataFrame. Notice the index is empty:

```
>>> df_empty = pd.DataFrame({'A' : []})
>>> df_empty
Empty DataFrame
Columns: [A]
Index: []
>>> df_empty.empty
True
```

If we only have NaNs in our DataFrame, it is not considered empty! We will need to drop the NaNs to make the DataFrame empty:

```
>>> df = pd.DataFrame({'A' : [np.nan]})
>>> df
   A
0 NaN
>>> df.empty
False
>>> df.dropna().empty
True
```

pandas.DataFrame.flags

property DataFrame.flags

Get the properties associated with this pandas object.

The available flags are

- *Flags.allows_duplicate_labels*

See also:

Flags Flags that apply to pandas objects.

DataFrame.attrs Global metadata applying to this dataset.

Notes

“Flags” differ from “metadata”. Flags reflect properties of the pandas object (the Series or DataFrame). Metadata refer to properties of the dataset, and should be stored in `DataFrame.attrs`.

Examples

```
>>> df = pd.DataFrame({"A": [1, 2]})
>>> df.flags
<Flags(allows_duplicate_labels=True)>
```

Flags can be get or set using `.`

```
>>> df.flags.allows_duplicate_labels
True
>>> df.flags.allows_duplicate_labels = False
```

Or by slicing with a key

```
>>> df.flags["allows_duplicate_labels"]
False
>>> df.flags["allows_duplicate_labels"] = True
```

pandas.DataFrame.iat

property DataFrame.iat

Access a single value for a row/column pair by integer position.

Similar to `iloc`, in that both provide integer-based lookups. Use `iat` if you only need to get or set a single value in a DataFrame or Series.

Raises

IndexError When integer position is out of bounds.

See also:

DataFrame.at Access a single value for a row/column label pair.

DataFrame.loc Access a group of rows and columns by label(s).

DataFrame.iloc Access a group of rows and columns by integer position(s).

Examples

```
>>> df = pd.DataFrame([[0, 2, 3], [0, 4, 1], [10, 20, 30]],
...                   columns=['A', 'B', 'C'])
>>> df
   A  B  C
0  0  2  3
1  0  4  1
2 10 20 30
```

Get value at specified row/column pair

```
>>> df.iat[1, 2]
1
```

Set value at specified row/column pair

```
>>> df.iat[1, 2] = 10
>>> df.iat[1, 2]
10
```

Get value within a series

```
>>> df.loc[0].iat[1]
2
```

pandas.DataFrame.iat

property DataFrame.iat

Purely integer-location based indexing for selection by position.

`.iat[]` is primarily integer position based (from 0 to `length-1` of the axis), but may also be used with a boolean array.

Allowed inputs are:

- An integer, e.g. 5.
- A list or array of integers, e.g. [4, 3, 0].
- A slice object with ints, e.g. 1:7.
- A boolean array.
- A callable function with one argument (the calling Series or DataFrame) and that returns valid output for indexing (one of the above). This is useful in method chains, when you don't have a reference to the calling object, but would like to base your selection on some value.

`.iat` will raise `IndexError` if a requested indexer is out-of-bounds, except *slice* indexers which allow out-of-bounds indexing (this conforms with python/numpy *slice* semantics).

See more at [Selection by Position](#).

See also:

[DataFrame.iat](#) Fast integer location scalar accessor.

[DataFrame.loc](#) Purely label-location based indexer for selection by label.

[Series.iat](#) Purely integer-location based indexing for selection by position.

Examples

```
>>> mydict = [{'a': 1, 'b': 2, 'c': 3, 'd': 4},
...           {'a': 100, 'b': 200, 'c': 300, 'd': 400},
...           {'a': 1000, 'b': 2000, 'c': 3000, 'd': 4000 }]
>>> df = pd.DataFrame(mydict)
>>> df
```

| | a | b | c | d |
|---|------|------|------|------|
| 0 | 1 | 2 | 3 | 4 |
| 1 | 100 | 200 | 300 | 400 |
| 2 | 1000 | 2000 | 3000 | 4000 |

Indexing just the rows

With a scalar integer.

```
>>> type(df.iloc[0])
<class 'pandas.core.series.Series'>
>>> df.iloc[0]
```

| | a | b | c | d |
|---|---|---|---|---|
| 0 | 1 | 2 | 3 | 4 |

Name: 0, dtype: int64

With a list of integers.

```
>>> df.iloc[[0]]
```

| | a | b | c | d |
|---|---|---|---|---|
| 0 | 1 | 2 | 3 | 4 |

```
>>> type(df.iloc[[0]])
<class 'pandas.core.frame.DataFrame'>
```

```
>>> df.iloc[[0, 1]]
```

| | a | b | c | d |
|---|-----|-----|-----|-----|
| 0 | 1 | 2 | 3 | 4 |
| 1 | 100 | 200 | 300 | 400 |

With a *slice* object.

```
>>> df.iloc[:3]
```

| | a | b | c | d |
|---|------|------|------|------|
| 0 | 1 | 2 | 3 | 4 |
| 1 | 100 | 200 | 300 | 400 |
| 2 | 1000 | 2000 | 3000 | 4000 |

With a boolean mask the same length as the index.

```
>>> df.iloc[[True, False, True]]
```

| | a | b | c | d |
|---|------|------|------|------|
| 0 | 1 | 2 | 3 | 4 |
| 2 | 1000 | 2000 | 3000 | 4000 |

With a callable, useful in method chains. The *x* passed to the lambda is the DataFrame being sliced. This selects the rows whose index label even.

```
>>> df.iloc[lambda x: x.index % 2 == 0]
   a    b    c    d
0   1    2    3    4
2 1000 2000 3000 4000
```

Indexing both axes

You can mix the indexer types for the index and columns. Use `:` to select the entire axis.

With scalar integers.

```
>>> df.iloc[0, 1]
2
```

With lists of integers.

```
>>> df.iloc[[0, 2], [1, 3]]
   b    d
0   2    4
2 2000 4000
```

With *slice* objects.

```
>>> df.iloc[1:3, 0:3]
   a    b    c
1  100  200  300
2 1000 2000 3000
```

With a boolean array whose length matches the columns.

```
>>> df.iloc[:, [True, False, True, False]]
   a    c
0   1    3
1  100  300
2 1000 3000
```

With a callable function that expects the Series or DataFrame.

```
>>> df.iloc[:, lambda df: [0, 2]]
   a    c
0   1    3
1  100  300
2 1000 3000
```

pandas.DataFrame.index

DataFrame.index

The index (row labels) of the DataFrame.

pandas.DataFrame.loc

property DataFrame.loc

Access a group of rows and columns by label(s) or a boolean array.

.loc[] is primarily label based, but may also be used with a boolean array.

Allowed inputs are:

- A single label, e.g. 5 or 'a', (note that 5 is interpreted as a *label* of the index, and **never** as an integer position along the index).
- A list or array of labels, e.g. ['a', 'b', 'c'].
- A slice object with labels, e.g. 'a':'f'.

Warning: Note that contrary to usual python slices, **both** the start and the stop are included

- A boolean array of the same length as the axis being sliced, e.g. [True, False, True].
- An alignable boolean Series. The index of the key will be aligned before masking.
- An alignable Index. The Index of the returned selection will be the input.
- A callable function with one argument (the calling Series or DataFrame) and that returns valid output for indexing (one of the above)

See more at [Selection by Label](#).

Raises

KeyError If any items are not found.

IndexingError If an indexed key is passed and its index is unalignable to the frame index.

See also:

DataFrame.at Access a single value for a row/column label pair.

DataFrame.iloc Access group of rows and columns by integer position(s).

DataFrame.xs Returns a cross-section (row(s) or column(s)) from the Series/DataFrame.

Series.loc Access group of values using labels.

Examples

Getting values

```
>>> df = pd.DataFrame([[1, 2], [4, 5], [7, 8]],
...                   index=['cobra', 'viper', 'sidewinder'],
...                   columns=['max_speed', 'shield'])
>>> df
      max_speed  shield
cobra          1      2
viper          4      5
sidewinder     7      8
```

Single label. Note this returns the row as a Series.

```
>>> df.loc['viper']
max_speed    4
shield       5
Name: viper, dtype: int64
```

List of labels. Note using `[[[]]]` returns a DataFrame.

```
>>> df.loc[['viper', 'sidewinder']]
      max_speed  shield
viper         4      5
sidewinder    7      8
```

Single label for row and column

```
>>> df.loc['cobra', 'shield']
2
```

Slice with labels for row and single label for column. As mentioned above, note that both the start and stop of the slice are included.

```
>>> df.loc['cobra':'viper', 'max_speed']
cobra    1
viper    4
Name: max_speed, dtype: int64
```

Boolean list with the same length as the row axis

```
>>> df.loc[[False, False, True]]
      max_speed  shield
sidewinder    7      8
```

Alignable boolean Series:

```
>>> df.loc[pd.Series([False, True, False],
...                  index=['viper', 'sidewinder', 'cobra'])]
      max_speed  shield
sidewinder    7      8
```

Index (same behavior as `df.reindex`)

```
>>> df.loc[pd.Index(["cobra", "viper"], name="foo")]
      max_speed  shield
foo
cobra         1      2
viper         4      5
```

Conditional that returns a boolean Series

```
>>> df.loc[df['shield'] > 6]
      max_speed  shield
sidewinder    7      8
```

Conditional that returns a boolean Series with column labels specified

```
>>> df.loc[df['shield'] > 6, ['max_speed']]
      max_speed
sidewinder      7
```

Callable that returns a boolean Series

```
>>> df.loc[lambda df: df['shield'] == 8]
      max_speed  shield
sidewinder      7      8
```

Setting values

Set value for all items matching the list of labels

```
>>> df.loc[['viper', 'sidewinder'], ['shield']] = 50
>>> df
      max_speed  shield
cobra           1      2
viper           4     50
sidewinder       7     50
```

Set value for an entire row

```
>>> df.loc['cobra'] = 10
>>> df
      max_speed  shield
cobra         10     10
viper          4     50
sidewinder      7     50
```

Set value for an entire column

```
>>> df.loc[:, 'max_speed'] = 30
>>> df
      max_speed  shield
cobra         30     10
viper         30     50
sidewinder    30     50
```

Set value for rows matching callable condition

```
>>> df.loc[df['shield'] > 35] = 0
>>> df
      max_speed  shield
cobra         30     10
viper          0      0
sidewinder     0      0
```

Getting values on a DataFrame with an index that has integer labels

Another example using integers for the index

```
>>> df = pd.DataFrame([[1, 2], [4, 5], [7, 8]],
...                   index=[7, 8, 9], columns=['max_speed', 'shield'])
>>> df
```

(continues on next page)

(continued from previous page)

| | max_speed | shield |
|---|-----------|--------|
| 7 | 1 | 2 |
| 8 | 4 | 5 |
| 9 | 7 | 8 |

Slice with integer labels for rows. As mentioned above, note that both the start and stop of the slice are included.

```
>>> df.loc[7:9]
   max_speed  shield
7          1      2
8          4      5
9          7      8
```

Getting values with a MultiIndex

A number of examples using a DataFrame with a MultiIndex

```
>>> tuples = [
...   ('cobra', 'mark i'), ('cobra', 'mark ii'),
...   ('sidewinder', 'mark i'), ('sidewinder', 'mark ii'),
...   ('viper', 'mark ii'), ('viper', 'mark iii')
... ]
>>> index = pd.MultiIndex.from_tuples(tuples)
>>> values = [[12, 2], [0, 4], [10, 20],
...           [1, 4], [7, 1], [16, 36]]
>>> df = pd.DataFrame(values, columns=['max_speed', 'shield'], index=index)
>>> df
           max_speed  shield
cobra  mark i         12      2
       mark ii          0      4
sidewinder mark i         10     20
          mark ii          1      4
viper    mark ii          7      1
          mark iii         16     36
```

Single label. Note this returns a DataFrame with a single index.

```
>>> df.loc['cobra']
           max_speed  shield
mark i           12      2
mark ii            0      4
```

Single index tuple. Note this returns a Series.

```
>>> df.loc[('cobra', 'mark ii')]
max_speed    0
shield       4
Name: (cobra, mark ii), dtype: int64
```

Single label for row and column. Similar to passing in a tuple, this returns a Series.

```
>>> df.loc['cobra', 'mark i']
max_speed    12
```

(continues on next page)

(continued from previous page)

```
shield      2
Name: (cobra, mark i), dtype: int64
```

Single tuple. Note using `[[]]` returns a DataFrame.

```
>>> df.loc[(['cobra', 'mark ii'])]
      max_speed  shield
cobra mark ii      0      4
```

Single tuple for the index with a single label for the column

```
>>> df.loc[('cobra', 'mark i'), 'shield']
2
```

Slice from index tuple to single label

```
>>> df.loc[('cobra', 'mark i'):('viper')]
      max_speed  shield
cobra      mark i      12      2
           mark ii      0      4
sidewinder mark i      10     20
           mark ii      1      4
viper      mark ii      7      1
           mark iii     16     36
```

Slice from index tuple to index tuple

```
>>> df.loc[('cobra', 'mark i'):('viper', 'mark ii')]
      max_speed  shield
cobra      mark i      12      2
           mark ii      0      4
sidewinder mark i      10     20
           mark ii      1      4
viper      mark ii      7      1
```

pandas.DataFrame.ndim

property DataFrame.ndim

Return an int representing the number of axes / array dimensions.

Return 1 if Series. Otherwise return 2 if DataFrame.

See also:

ndarray.ndim Number of array dimensions.

Examples

```
>>> s = pd.Series({'a': 1, 'b': 2, 'c': 3})
>>> s.ndim
1
```

```
>>> df = pd.DataFrame({'col1': [1, 2], 'col2': [3, 4]})
>>> df.ndim
2
```

pandas.DataFrame.shape

property DataFrame.shape

Return a tuple representing the dimensionality of the DataFrame.

See also:

ndarray.shape Tuple of array dimensions.

Examples

```
>>> df = pd.DataFrame({'col1': [1, 2], 'col2': [3, 4]})
>>> df.shape
(2, 2)
```

```
>>> df = pd.DataFrame({'col1': [1, 2], 'col2': [3, 4],
...                   'col3': [5, 6]})
>>> df.shape
(2, 3)
```

pandas.DataFrame.size

property DataFrame.size

Return an int representing the number of elements in this object.

Return the number of rows if Series. Otherwise return the number of rows times number of columns if DataFrame.

See also:

ndarray.size Number of elements in the array.

Examples

```
>>> s = pd.Series({'a': 1, 'b': 2, 'c': 3})
>>> s.size
3
```

```
>>> df = pd.DataFrame({'col1': [1, 2], 'col2': [3, 4]})
>>> df.size
4
```

pandas.DataFrame.style

property DataFrame.style

Returns a Styler object.

Contains methods for building a styled HTML representation of the DataFrame.

See also:

[*io.formats.style.Styler*](#) Helps style a DataFrame or Series according to the data with HTML and CSS.

pandas.DataFrame.values

property DataFrame.values

Return a Numpy representation of the DataFrame.

Warning: We recommend using [*DataFrame.to_numpy\(\)*](#) instead.

Only the values in the DataFrame will be returned, the axes labels will be removed.

Returns

numpy.ndarray The values of the DataFrame.

See also:

[*DataFrame.to_numpy*](#) Recommended alternative to this method.

[*DataFrame.index*](#) Retrieve the index labels.

[*DataFrame.columns*](#) Retrieving the column names.

Notes

The dtype will be a lower-common-denominator dtype (implicit upcasting); that is to say if the dtypes (even of numeric types) are mixed, the one that accommodates all will be chosen. Use this with care if you are not dealing with the blocks.

e.g. If the dtypes are float16 and float32, dtype will be upcast to float32. If dtypes are int32 and uint8, dtype will be upcast to int32. By `numpy.find_common_type()` convention, mixing int64 and uint64 will result in a float64 dtype.

Examples

A DataFrame where all columns are the same type (e.g., int64) results in an array of the same type.

```
>>> df = pd.DataFrame({'age': [ 3, 29],
...                    'height': [94, 170],
...                    'weight': [31, 115]})
>>> df
   age  height  weight
0    3     94     31
1   29    170    115
>>> df.dtypes
age          int64
height       int64
weight       int64
dtype: object
>>> df.values
array([[ 3, 94, 31],
       [29, 170, 115]])
```

A DataFrame with mixed type columns(e.g., str/object, int64, float32) results in an ndarray of the broadest type that accommodates these mixed types (e.g., object).

```
>>> df2 = pd.DataFrame([('parrot', 24.0, 'second'),
...                    ('lion', 80.5, 1),
...                    ('monkey', np.nan, None)],
...                    columns=('name', 'max_speed', 'rank'))
>>> df2.dtypes
name          object
max_speed     float64
rank          object
dtype: object
>>> df2.values
array([[ 'parrot', 24.0, 'second'],
       [ 'lion', 80.5, 1],
       [ 'monkey', nan, None]], dtype=object)
```

T

Methods

| | |
|--|--|
| <code>abs()</code> | Return a Series/DataFrame with absolute numeric value of each element. |
| <code>add(other[, axis, level, fill_value])</code> | Get Addition of dataframe and other, element-wise (binary operator <i>add</i>). |
| <code>add_prefix(prefix)</code> | Prefix labels with string <i>prefix</i> . |
| <code>add_suffix(suffix)</code> | Suffix labels with string <i>suffix</i> . |
| <code>agg([func, axis])</code> | Aggregate using one or more operations over the specified axis. |
| <code>aggregate([func, axis])</code> | Aggregate using one or more operations over the specified axis. |
| <code>align(other[, join, axis, level, copy, ...])</code> | Align two objects on their axes with the specified join method. |
| <code>all([axis, bool_only, skipna, level])</code> | Return whether all elements are True, potentially over an axis. |
| <code>any([axis, bool_only, skipna, level])</code> | Return whether any element is True, potentially over an axis. |
| <code>append(other[, ignore_index, ...])</code> | Append rows of <i>other</i> to the end of caller, returning a new object. |
| <code>apply(func[, axis, raw, result_type, args])</code> | Apply a function along an axis of the DataFrame. |
| <code>applymap(func[, na_action])</code> | Apply a function to a Dataframe elementwise. |
| <code>asfreq(freq[, method, how, normalize, ...])</code> | Convert time series to specified frequency. |
| <code>asof(when[, subset])</code> | Return the last row(s) without any NaNs before <i>where</i> . |
| <code>assign(**kwargs)</code> | Assign new columns to a DataFrame. |
| <code>astype(dtype[, copy, errors])</code> | Cast a pandas object to a specified dtype <i>dtype</i> . |
| <code>at_time(time[, asof, axis])</code> | Select values at particular time of day (e.g., 9:30AM). |
| <code>backfill([axis, inplace, limit, downcast])</code> | Synonym for <code>DataFrame.fillna()</code> with <code>method='bfill'</code> . |
| <code>between_time(start_time, end_time[, ...])</code> | Select values between particular times of the day (e.g., 9:00-9:30 AM). |
| <code>bfill([axis, inplace, limit, downcast])</code> | Synonym for <code>DataFrame.fillna()</code> with <code>method='bfill'</code> . |
| <code>bool()</code> | Return the bool of a single element Series or DataFrame. |
| <code>boxplot([column, by, ax, fontsize, rot, ...])</code> | Make a box plot from DataFrame columns. |
| <code>clip([lower, upper, axis, inplace])</code> | Trim values at input threshold(s). |
| <code>combine(other, func[, fill_value, overwrite])</code> | Perform column-wise combine with another DataFrame. |
| <code>combine_first(other)</code> | Update null elements with value in the same location in <i>other</i> . |
| <code>compare(other[, align_axis, keep_shape, ...])</code> | Compare to another DataFrame and show the differences. |
| <code>convert_dtypes([infer_objects, ...])</code> | Convert columns to best possible dtypes using dtypes supporting <code>pd.NA</code> . |
| <code>copy([deep])</code> | Make a copy of this object's indices and data. |
| <code>corr([method, min_periods])</code> | Compute pairwise correlation of columns, excluding NA/null values. |
| <code>corrwith(other[, axis, drop, method])</code> | Compute pairwise correlation. |
| <code>count([axis, level, numeric_only])</code> | Count non-NA cells for each column or row. |

continues on next page

Table 65 – continued from previous page

| | |
|--|---|
| <code>cov</code> ([min_periods, ddof]) | Compute pairwise covariance of columns, excluding NA/null values. |
| <code>cummax</code> ([axis, skipna]) | Return cumulative maximum over a DataFrame or Series axis. |
| <code>cummin</code> ([axis, skipna]) | Return cumulative minimum over a DataFrame or Series axis. |
| <code>cumprod</code> ([axis, skipna]) | Return cumulative product over a DataFrame or Series axis. |
| <code>cumsum</code> ([axis, skipna]) | Return cumulative sum over a DataFrame or Series axis. |
| <code>describe</code> ([percentiles, include, exclude, ...]) | Generate descriptive statistics. |
| <code>diff</code> ([periods, axis]) | First discrete difference of element. |
| <code>div</code> (other[, axis, level, fill_value]) | Get Floating division of dataframe and other, element-wise (binary operator <i>truediv</i>). |
| <code>divide</code> (other[, axis, level, fill_value]) | Get Floating division of dataframe and other, element-wise (binary operator <i>truediv</i>). |
| <code>dot</code> (other) | Compute the matrix multiplication between the DataFrame and other. |
| <code>drop</code> ([labels, axis, index, columns, level, ...]) | Drop specified labels from rows or columns. |
| <code>drop_duplicates</code> ([subset, keep, inplace, ...]) | Return DataFrame with duplicate rows removed. |
| <code>droplevel</code> (level[, axis]) | Return Series/DataFrame with requested index / column level(s) removed. |
| <code>dropna</code> ([axis, how, thresh, subset, inplace]) | Remove missing values. |
| <code>duplicated</code> ([subset, keep]) | Return boolean Series denoting duplicate rows. |
| <code>eq</code> (other[, axis, level]) | Get Equal to of dataframe and other, element-wise (binary operator <i>eq</i>). |
| <code>equals</code> (other) | Test whether two objects contain the same elements. |
| <code>eval</code> (expr[, inplace]) | Evaluate a string describing operations on DataFrame columns. |
| <code>ewm</code> ([com, span, halflife, alpha, ...]) | Provide exponential weighted (EW) functions. |
| <code>expanding</code> ([min_periods, center, axis, method]) | Provide expanding transformations. |
| <code>explode</code> (column[, ignore_index]) | Transform each element of a list-like to a row, replicating index values. |
| <code>ffill</code> ([axis, inplace, limit, downcast]) | Synonym for <code>DataFrame.fillna()</code> with <code>method='ffill'</code> . |
| <code>fillna</code> ([value, method, axis, inplace, ...]) | Fill NA/NaN values using the specified method. |
| <code>filter</code> ([items, like, regex, axis]) | Subset the dataframe rows or columns according to the specified index labels. |
| <code>first</code> (offset) | Select initial periods of time series data based on a date offset. |
| <code>first_valid_index</code> () | Return index for first non-NA value or None, if no NA value is found. |
| <code>floordiv</code> (other[, axis, level, fill_value]) | Get Integer division of dataframe and other, element-wise (binary operator <i>floordiv</i>). |
| <code>from_dict</code> (data[, orient, dtype, columns]) | Construct DataFrame from dict of array-like or dicts. |
| <code>from_records</code> (data[, index, exclude, ...]) | Convert structured or record ndarray to DataFrame. |
| <code>ge</code> (other[, axis, level]) | Get Greater than or equal to of dataframe and other, element-wise (binary operator <i>ge</i>). |
| <code>get</code> (key[, default]) | Get item from object for given key (ex: DataFrame column). |

continues on next page

Table 65 – continued from previous page

| | |
|---|--|
| <code>groupby</code> ([by, axis, level, as_index, sort, ...]) | Group DataFrame using a mapper or by a Series of columns. |
| <code>gt</code> (other[, axis, level]) | Get Greater than of dataframe and other, element-wise (binary operator <i>gt</i>). |
| <code>head</code> ([n]) | Return the first <i>n</i> rows. |
| <code>hist</code> ([column, by, grid, xlabelsize, xrot, ...]) | Make a histogram of the DataFrame's columns. |
| <code>idxmax</code> ([axis, skipna]) | Return index of first occurrence of maximum over requested axis. |
| <code>idxmin</code> ([axis, skipna]) | Return index of first occurrence of minimum over requested axis. |
| <code>infer_objects</code> () | Attempt to infer better dtypes for object columns. |
| <code>info</code> ([verbose, buf, max_cols, memory_usage, ...]) | Print a concise summary of a DataFrame. |
| <code>insert</code> (loc, column, value[, allow_duplicates]) | Insert column into DataFrame at specified location. |
| <code>interpolate</code> ([method, axis, limit, inplace, ...]) | Fill NaN values using an interpolation method. |
| <code>isin</code> (values) | Whether each element in the DataFrame is contained in values. |
| <code>isna</code> () | Detect missing values. |
| <code>isnull</code> () | Detect missing values. |
| <code>items</code> () | Iterate over (column name, Series) pairs. |
| <code>iteritems</code> () | Iterate over (column name, Series) pairs. |
| <code>iterrows</code> () | Iterate over DataFrame rows as (index, Series) pairs. |
| <code>itertuples</code> ([index, name]) | Iterate over DataFrame rows as namedtuples. |
| <code>join</code> (other[, on, how, lsuffix, rsuffix, sort]) | Join columns of another DataFrame. |
| <code>keys</code> () | Get the 'info axis' (see Indexing for more). |
| <code>kurt</code> ([axis, skipna, level, numeric_only]) | Return unbiased kurtosis over requested axis. |
| <code>kurtosis</code> ([axis, skipna, level, numeric_only]) | Return unbiased kurtosis over requested axis. |
| <code>last</code> (offset) | Select final periods of time series data based on a date offset. |
| <code>last_valid_index</code> () | Return index for last non-NA value or None, if no NA value is found. |
| <code>le</code> (other[, axis, level]) | Get Less than or equal to of dataframe and other, element-wise (binary operator <i>le</i>). |
| <code>lookup</code> (row_labels, col_labels) | (DEPRECATED) Label-based "fancy indexing" function for DataFrame. |
| <code>lt</code> (other[, axis, level]) | Get Less than of dataframe and other, element-wise (binary operator <i>lt</i>). |
| <code>mad</code> ([axis, skipna, level]) | Return the mean absolute deviation of the values over the requested axis. |
| <code>mask</code> (cond[, other, inplace, axis, level, ...]) | Replace values where the condition is True. |
| <code>max</code> ([axis, skipna, level, numeric_only]) | Return the maximum of the values over the requested axis. |
| <code>mean</code> ([axis, skipna, level, numeric_only]) | Return the mean of the values over the requested axis. |
| <code>median</code> ([axis, skipna, level, numeric_only]) | Return the median of the values over the requested axis. |
| <code>melt</code> ([id_vars, value_vars, var_name, ...]) | Unpivot a DataFrame from wide to long format, optionally leaving identifiers set. |
| <code>memory_usage</code> ([index, deep]) | Return the memory usage of each column in bytes. |
| <code>merge</code> (right[, how, on, left_on, right_on, ...]) | Merge DataFrame or named Series objects with a database-style join. |
| <code>min</code> ([axis, skipna, level, numeric_only]) | Return the minimum of the values over the requested axis. |

continues on next page

Table 65 – continued from previous page

| | |
|---|--|
| <code>mod</code> (other[, axis, level, fill_value]) | Get Modulo of dataframe and other, element-wise (binary operator <i>mod</i>). |
| <code>mode</code> ([axis, numeric_only, dropna]) | Get the mode(s) of each element along the selected axis. |
| <code>mul</code> (other[, axis, level, fill_value]) | Get Multiplication of dataframe and other, element-wise (binary operator <i>mul</i>). |
| <code>multiply</code> (other[, axis, level, fill_value]) | Get Multiplication of dataframe and other, element-wise (binary operator <i>mul</i>). |
| <code>ne</code> (other[, axis, level]) | Get Not equal to of dataframe and other, element-wise (binary operator <i>ne</i>). |
| <code>nlargest</code> (n, columns[, keep]) | Return the first <i>n</i> rows ordered by <i>columns</i> in descending order. |
| <code>notna</code> () | Detect existing (non-missing) values. |
| <code>notnull</code> () | Detect existing (non-missing) values. |
| <code>nsmallest</code> (n, columns[, keep]) | Return the first <i>n</i> rows ordered by <i>columns</i> in ascending order. |
| <code>nunique</code> ([axis, dropna]) | Count number of distinct elements in specified axis. |
| <code>pad</code> ([axis, inplace, limit, downcast]) | Synonym for <code>DataFrame.fillna()</code> with <code>method='ffill'</code> . |
| <code>pct_change</code> ([periods, fill_method, limit, freq]) | Percentage change between the current and a prior element. |
| <code>pipe</code> (func, *args, **kwargs) | Apply <code>func(self, *args, **kwargs)</code> . |
| <code>pivot</code> ([index, columns, values]) | Return reshaped DataFrame organized by given index / column values. |
| <code>pivot_table</code> ([values, index, columns, ...]) | Create a spreadsheet-style pivot table as a DataFrame. |
| <code>plot</code> | alias of <code>pandas.plotting._core.PlotAccessor</code> |
| <code>pop</code> (item) | Return item and drop from frame. |
| <code>pow</code> (other[, axis, level, fill_value]) | Get Exponential power of dataframe and other, element-wise (binary operator <i>pow</i>). |
| <code>prod</code> ([axis, skipna, level, numeric_only, ...]) | Return the product of the values over the requested axis. |
| <code>product</code> ([axis, skipna, level, numeric_only, ...]) | Return the product of the values over the requested axis. |
| <code>quantile</code> ([q, axis, numeric_only, interpolation]) | Return values at the given quantile over requested axis. |
| <code>query</code> (expr[, inplace]) | Query the columns of a DataFrame with a boolean expression. |
| <code>radd</code> (other[, axis, level, fill_value]) | Get Addition of dataframe and other, element-wise (binary operator <i>radd</i>). |
| <code>rank</code> ([axis, method, numeric_only, ...]) | Compute numerical data ranks (1 through n) along axis. |
| <code>rdiv</code> (other[, axis, level, fill_value]) | Get Floating division of dataframe and other, element-wise (binary operator <i>rtruediv</i>). |
| <code>reindex</code> ([labels, index, columns, axis, ...]) | Conform Series/DataFrame to new index with optional filling logic. |
| <code>reindex_like</code> (other[, method, copy, limit, ...]) | Return an object with matching indices as other object. |
| <code>rename</code> ([mapper, index, columns, axis, copy, ...]) | Alter axes labels. |
| <code>rename_axis</code> ([mapper, index, columns, axis, ...]) | Set the name of the axis for the index or columns. |
| <code>reorder_levels</code> (order[, axis]) | Rearrange index levels using input order. |

continues on next page

Table 65 – continued from previous page

| | |
|---|--|
| <code>replace</code> ([<i>to_replace</i> , <i>value</i> , <i>inplace</i> , <i>limit</i> , ...]) | Replace values given in <i>to_replace</i> with <i>value</i> . |
| <code>resample</code> (<i>rule</i> [, <i>axis</i> , <i>closed</i> , <i>label</i> , ...]) | Resample time-series data. |
| <code>reset_index</code> ([<i>level</i> , <i>drop</i> , <i>inplace</i> , ...]) | Reset the index, or a level of it. |
| <code>rfloordiv</code> (<i>other</i> [, <i>axis</i> , <i>level</i> , <i>fill_value</i>]) | Get Integer division of dataframe and other, element-wise (binary operator <i>rfloordiv</i>). |
| <code>rmod</code> (<i>other</i> [, <i>axis</i> , <i>level</i> , <i>fill_value</i>]) | Get Modulo of dataframe and other, element-wise (binary operator <i>rmod</i>). |
| <code>rmul</code> (<i>other</i> [, <i>axis</i> , <i>level</i> , <i>fill_value</i>]) | Get Multiplication of dataframe and other, element-wise (binary operator <i>rmul</i>). |
| <code>rolling</code> (<i>window</i> [, <i>min_periods</i> , <i>center</i> , ...]) | Provide rolling window calculations. |
| <code>round</code> ([<i>decimals</i>]) | Round a DataFrame to a variable number of decimal places. |
| <code>rpow</code> (<i>other</i> [, <i>axis</i> , <i>level</i> , <i>fill_value</i>]) | Get Exponential power of dataframe and other, element-wise (binary operator <i>rpow</i>). |
| <code>rsub</code> (<i>other</i> [, <i>axis</i> , <i>level</i> , <i>fill_value</i>]) | Get Subtraction of dataframe and other, element-wise (binary operator <i>rsub</i>). |
| <code>rtruediv</code> (<i>other</i> [, <i>axis</i> , <i>level</i> , <i>fill_value</i>]) | Get Floating division of dataframe and other, element-wise (binary operator <i>rtruediv</i>). |
| <code>sample</code> ([<i>n</i> , <i>frac</i> , <i>replace</i> , <i>weights</i> , ...]) | Return a random sample of items from an axis of object. |
| <code>select_dtypes</code> ([<i>include</i> , <i>exclude</i>]) | Return a subset of the DataFrame's columns based on the column dtypes. |
| <code>sem</code> ([<i>axis</i> , <i>skipna</i> , <i>level</i> , <i>ddof</i> , <i>numeric_only</i>]) | Return unbiased standard error of the mean over requested axis. |
| <code>set_axis</code> (<i>labels</i> [, <i>axis</i> , <i>inplace</i>]) | Assign desired index to given axis. |
| <code>set_flags</code> (*[, <i>copy</i> , <i>allows_duplicate_labels</i>]) | Return a new object with updated flags. |
| <code>set_index</code> (<i>keys</i> [, <i>drop</i> , <i>append</i> , <i>inplace</i> , ...]) | Set the DataFrame index using existing columns. |
| <code>shift</code> ([<i>periods</i> , <i>freq</i> , <i>axis</i> , <i>fill_value</i>]) | Shift index by desired number of periods with an optional time <i>freq</i> . |
| <code>skew</code> ([<i>axis</i> , <i>skipna</i> , <i>level</i> , <i>numeric_only</i>]) | Return unbiased skew over requested axis. |
| <code>slice_shift</code> ([<i>periods</i> , <i>axis</i>]) | (DEPRECATED) Equivalent to <i>shift</i> without copying data. |
| <code>sort_index</code> ([<i>axis</i> , <i>level</i> , <i>ascending</i> , ...]) | Sort object by labels (along an axis). |
| <code>sort_values</code> (<i>by</i> [, <i>axis</i> , <i>ascending</i> , <i>inplace</i> , ...]) | Sort by the values along either axis. |
| <code>sparse</code> | alias of <code>pandas.core.arrays.sparse.accessor.SparseFrameAccessor</code> |
| <code>squeeze</code> ([<i>axis</i>]) | Squeeze 1 dimensional axis objects into scalars. |
| <code>stack</code> ([<i>level</i> , <i>dropna</i>]) | Stack the prescribed level(s) from columns to index. |
| <code>std</code> ([<i>axis</i> , <i>skipna</i> , <i>level</i> , <i>ddof</i> , <i>numeric_only</i>]) | Return sample standard deviation over requested axis. |
| <code>sub</code> (<i>other</i> [, <i>axis</i> , <i>level</i> , <i>fill_value</i>]) | Get Subtraction of dataframe and other, element-wise (binary operator <i>sub</i>). |
| <code>subtract</code> (<i>other</i> [, <i>axis</i> , <i>level</i> , <i>fill_value</i>]) | Get Subtraction of dataframe and other, element-wise (binary operator <i>sub</i>). |
| <code>sum</code> ([<i>axis</i> , <i>skipna</i> , <i>level</i> , <i>numeric_only</i> , ...]) | Return the sum of the values over the requested axis. |
| <code>swapaxes</code> (<i>axis1</i> , <i>axis2</i> [, <i>copy</i>]) | Interchange axes and swap values axes appropriately. |
| <code>swaplevel</code> ([<i>i</i> , <i>j</i> , <i>axis</i>]) | Swap levels <i>i</i> and <i>j</i> in a <i>MultiIndex</i> . |
| <code>tail</code> ([<i>n</i>]) | Return the last <i>n</i> rows. |
| <code>take</code> (<i>indices</i> [, <i>axis</i> , <i>is_copy</i>]) | Return the elements in the given <i>positional</i> indices along an axis. |
| <code>to_clipboard</code> ([<i>excel</i> , <i>sep</i>]) | Copy object to the system clipboard. |

continues on next page

Table 65 – continued from previous page

| | |
|---|---|
| <code>to_csv</code> ([path_or_buf, sep, na_rep, ...]) | Write object to a comma-separated values (csv) file. |
| <code>to_dict</code> ([orient, into]) | Convert the DataFrame to a dictionary. |
| <code>to_excel</code> (excel_writer[, sheet_name, na_rep, ...]) | Write object to an Excel sheet. |
| <code>to_feather</code> (path, **kwargs) | Write a DataFrame to the binary Feather format. |
| <code>to_gbq</code> (destination_table[, project_id, ...]) | Write a DataFrame to a Google BigQuery table. |
| <code>to_hdf</code> (path_or_buf, key[, mode, complevel, ...]) | Write the contained data to an HDF5 file using HDF-Store. |
| <code>to_html</code> ([buf, columns, col_space, header, ...]) | Render a DataFrame as an HTML table. |
| <code>to_json</code> ([path_or_buf, orient, date_format, ...]) | Convert the object to a JSON string. |
| <code>to_latex</code> ([buf, columns, col_space, header, ...]) | Render object to a LaTeX tabular, longtable, or nested table/tabular. |
| <code>to_markdown</code> ([buf, mode, index, storage_options]) | Print DataFrame in Markdown-friendly format. |
| <code>to_numpy</code> ([dtype, copy, na_value]) | Convert the DataFrame to a NumPy array. |
| <code>to_parquet</code> ([path, engine, compression, ...]) | Write a DataFrame to the binary parquet format. |
| <code>to_period</code> ([freq, axis, copy]) | Convert DataFrame from DatetimeIndex to PeriodIndex. |
| <code>to_pickle</code> (path[, compression, protocol, ...]) | Pickle (serialize) object to file. |
| <code>to_records</code> ([index, column_dtypes, index_dtypes]) | Convert DataFrame to a NumPy record array. |
| <code>to_sql</code> (name, con[, schema, if_exists, ...]) | Write records stored in a DataFrame to a SQL database. |
| <code>to_stata</code> (path[, convert_dates, write_index, ...]) | Export DataFrame object to Stata dta format. |
| <code>to_string</code> ([buf, columns, col_space, header, ...]) | Render a DataFrame to a console-friendly tabular output. |
| <code>to_timestamp</code> ([freq, how, axis, copy]) | Cast to DatetimeIndex of timestamps, at <i>beginning</i> of period. |
| <code>to_xarray</code> () | Return an xarray object from the pandas object. |
| <code>to_xml</code> ([path_or_buffer, index, root_name, ...]) | Render a DataFrame to an XML document. |
| <code>transform</code> (func[, axis]) | Call func on self producing a DataFrame with transformed values. |
| <code>transpose</code> (*args[, copy]) | Transpose index and columns. |
| <code>truediv</code> (other[, axis, level, fill_value]) | Get Floating division of dataframe and other, element-wise (binary operator <i>truediv</i>). |
| <code>truncate</code> ([before, after, axis, copy]) | Truncate a Series or DataFrame before and after some index value. |
| <code>tshift</code> ([periods, freq, axis]) | (DEPRECATED) Shift the time index, using the index's frequency if available. |
| <code>tz_convert</code> (tz[, axis, level, copy]) | Convert tz-aware axis to target time zone. |
| <code>tz_localize</code> (tz[, axis, level, copy, ...]) | Localize tz-naive index of a Series or DataFrame to target time zone. |
| <code>unstack</code> ([level, fill_value]) | Pivot a level of the (necessarily hierarchical) index labels. |
| <code>update</code> (other[, join, overwrite, ...]) | Modify in place using non-NA values from another DataFrame. |
| <code>value_counts</code> ([subset, normalize, sort, ...]) | Return a Series containing counts of unique rows in the DataFrame. |
| <code>var</code> ([axis, skipna, level, ddof, numeric_only]) | Return unbiased variance over requested axis. |
| <code>where</code> (cond[, other, inplace, axis, level, ...]) | Replace values where the condition is False. |
| <code>xs</code> (key[, axis, level, drop_level]) | Return cross-section from the Series/DataFrame. |

pandas.DataFrame.abs**DataFrame.abs()**

Return a Series/DataFrame with absolute numeric value of each element.

This function only applies to elements that are all numeric.

Returns

abs Series/DataFrame containing the absolute value of each element.

See also:

numpy.absolute Calculate the absolute value element-wise.

Notes

For complex inputs, $1.2 + 1j$, the absolute value is $\sqrt{a^2 + b^2}$.

Examples

Absolute numeric values in a Series.

```
>>> s = pd.Series([-1.10, 2, -3.33, 4])
>>> s.abs()
0    1.10
1    2.00
2    3.33
3    4.00
dtype: float64
```

Absolute numeric values in a Series with complex numbers.

```
>>> s = pd.Series([1.2 + 1j])
>>> s.abs()
0    1.56205
dtype: float64
```

Absolute numeric values in a Series with a Timedelta element.

```
>>> s = pd.Series([pd.Timedelta('1 days')])
>>> s.abs()
0    1 days
dtype: timedelta64[ns]
```

Select rows with data closest to certain value using `argsort` (from [StackOverflow](#)).

```
>>> df = pd.DataFrame({
...     'a': [4, 5, 6, 7],
...     'b': [10, 20, 30, 40],
...     'c': [100, 50, -30, -50]
... })
>>> df
   a  b  c
```

(continues on next page)

(continued from previous page)

```

0    4    10   100
1    5    20    50
2    6    30   -30
3    7    40   -50
>>> df.loc[(df.c - 43).abs().argsort()]
      a    b    c
1    5    20   50
0    4    10  100
2    6    30  -30
3    7    40  -50

```

pandas.DataFrame.add

DataFrame.**add**(*other*, *axis*='columns', *level*=None, *fill_value*=None)

Get Addition of dataframe and other, element-wise (binary operator *add*).

Equivalent to `dataframe + other`, but with support to substitute a `fill_value` for missing data in one of the inputs. With reverse version, *radd*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: +, -, *, /, //, %, **.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

See also:

[*DataFrame.add*](#) Add DataFrames.

[*DataFrame.sub*](#) Subtract DataFrames.

[*DataFrame.mul*](#) Multiply DataFrames.

[*DataFrame.div*](#) Divide DataFrames (float division).

[*DataFrame.truediv*](#) Divide DataFrames (float division).

[*DataFrame.floordiv*](#) Divide DataFrames (integer division).

[*DataFrame.mod*](#) Calculate modulo (remainder after division).

[*DataFrame.pow*](#) Calculate exponential power.

Notes

Mismatched indices will be unioned together.

Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                    index=['circle', 'triangle', 'rectangle'])
>>> df
```

| | angles | degrees |
|-----------|--------|---------|
| circle | 0 | 360 |
| triangle | 3 | 180 |
| rectangle | 4 | 360 |

Add a scalar with operator version which return the same results.

```
>>> df + 1
```

| | angles | degrees |
|-----------|--------|---------|
| circle | 1 | 361 |
| triangle | 4 | 181 |
| rectangle | 5 | 361 |

```
>>> df.add(1)
```

| | angles | degrees |
|-----------|--------|---------|
| circle | 1 | 361 |
| triangle | 4 | 181 |
| rectangle | 5 | 361 |

Divide by constant with reverse version.

```
>>> df.div(10)
```

| | angles | degrees |
|-----------|--------|---------|
| circle | 0.0 | 36.0 |
| triangle | 0.3 | 18.0 |
| rectangle | 0.4 | 36.0 |

```
>>> df.rdiv(10)
```

| | angles | degrees |
|-----------|----------|----------|
| circle | inf | 0.027778 |
| triangle | 3.333333 | 0.055556 |
| rectangle | 2.500000 | 0.027778 |

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
```

| | angles | degrees |
|-----------|--------|---------|
| circle | -1 | 358 |
| triangle | 2 | 178 |
| rectangle | 3 | 358 |

```
>>> df.sub([1, 2], axis='columns')
      angles  degrees
circle     -1     358
triangle    2     178
rectangle   3     358
```

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...        axis='index')
      angles  degrees
circle     -1     359
triangle    2     179
rectangle   3     359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                       index=['circle', 'triangle', 'rectangle'])
>>> other
      angles
circle      0
triangle    3
rectangle   4
```

```
>>> df * other
      angles  degrees
circle      0      NaN
triangle     9      NaN
rectangle   16      NaN
```

```
>>> df.mul(other, fill_value=0)
      angles  degrees
circle      0      0.0
triangle     9      0.0
rectangle   16      0.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                              'degrees': [360, 180, 360, 360, 540, 720]},
...                              index=[[ 'A', 'A', 'A', 'B', 'B', 'B'],
...                                     ['circle', 'triangle', 'rectangle',
...                                      'square', 'pentagon', 'hexagon']])
>>> df_multindex
      angles  degrees
A circle      0     360
  triangle    3     180
  rectangle   4     360
B square      4     360
  pentagon    5     540
  hexagon     6     720
```

```

>>> df.div(df_multindex, level=1, fill_value=0)
      angles  degrees
A circle   NaN     1.0
  triangle   1.0     1.0
  rectangle   1.0     1.0
B square    0.0     0.0
  pentagon   0.0     0.0
  hexagon    0.0     0.0

```

pandas.DataFrame.add_prefix

`DataFrame.add_prefix(prefix)`

Prefix labels with string *prefix*.

For Series, the row labels are prefixed. For DataFrame, the column labels are prefixed.

Parameters

prefix [str] The string to add before each label.

Returns

Series or DataFrame New Series or DataFrame with updated labels.

See also:

[*Series.add_suffix*](#) Suffix row labels with string *suffix*.

[*DataFrame.add_suffix*](#) Suffix column labels with string *suffix*.

Examples

```

>>> s = pd.Series([1, 2, 3, 4])
>>> s
0    1
1    2
2    3
3    4
dtype: int64

```

```

>>> s.add_prefix('item_')
item_0    1
item_1    2
item_2    3
item_3    4
dtype: int64

```

```

>>> df = pd.DataFrame({'A': [1, 2, 3, 4], 'B': [3, 4, 5, 6]})
>>> df
   A  B
0  1  3
1  2  4

```

(continues on next page)

(continued from previous page)

```
2 3 5
3 4 6
```

```
>>> df.add_prefix('col_')
   col_A  col_B
0      1     3
1      2     4
2      3     5
3      4     6
```

pandas.DataFrame.add_suffix

`DataFrame.add_suffix(suffix)`

Suffix labels with string *suffix*.

For Series, the row labels are suffixed. For DataFrame, the column labels are suffixed.

Parameters

suffix [str] The string to add after each label.

Returns

Series or DataFrame New Series or DataFrame with updated labels.

See also:

[*Series.add_prefix*](#) Prefix row labels with string *prefix*.

[*DataFrame.add_prefix*](#) Prefix column labels with string *prefix*.

Examples

```
>>> s = pd.Series([1, 2, 3, 4])
>>> s
0    1
1    2
2    3
3    4
dtype: int64
```

```
>>> s.add_suffix('_item')
0_item    1
1_item    2
2_item    3
3_item    4
dtype: int64
```

```
>>> df = pd.DataFrame({'A': [1, 2, 3, 4], 'B': [3, 4, 5, 6]})
>>> df
   A  B
0  1  3
```

(continues on next page)

(continued from previous page)

```
1 2 4
2 3 5
3 4 6
```

```
>>> df.add_suffix('_col')
   A_col  B_col
0      1     3
1      2     4
2      3     5
3      4     6
```

pandas.DataFrame.agg

`DataFrame.agg(func=None, axis=0, *args, **kwargs)`

Aggregate using one or more operations over the specified axis.

Parameters

func [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a DataFrame or when passed to DataFrame.apply.

Accepted combinations are:

- function
- string function name
- list of functions and/or function names, e.g. `[np.sum, 'mean']`
- dict of axis labels -> functions, function names or list of such.

axis [{0 or 'index', 1 or 'columns'}, default 0] If 0 or 'index': apply function to each column. If 1 or 'columns': apply function to each row.

***args** Positional arguments to pass to *func*.

****kwargs** Keyword arguments to pass to *func*.

Returns

scalar, Series or DataFrame The return can be:

- scalar : when Series.agg is called with single function
- Series : when DataFrame.agg is called with a single function
- DataFrame : when DataFrame.agg is called with several functions

Return scalar, Series or DataFrame.

The aggregation operations are always performed over an axis, either the index (default) or the column axis. This behavior is different from numpy aggregation functions (*mean*, *median*, *prod*, *sum*, *std*, *var*), where the default is to compute the aggregation of the flattened array, e.g., `numpy.mean(arr_2d)` as opposed to `numpy.mean(arr_2d, axis=0)`.

agg is an alias for *aggregate*. Use the alias.

See also:

DataFrame.apply Perform any type of operations.

DataFrame.transform Perform transformation type operations.

core.groupby.GroupBy Perform operations over groups.

core.resample.Resampler Perform operations over resampled bins.

core.window.Rolling Perform operations over rolling window.

core.window.Expanding Perform operations over expanding window.

core.window.ExponentialMovingWindow Perform operation over exponential weighted window.

Notes

agg is an alias for *aggregate*. Use the alias.

Functions that mutate the passed object can produce unexpected behavior or errors and are not supported. See *Mutating with User Defined Function (UDF) methods* for more details.

A passed user-defined-function will be passed a Series for evaluation.

Examples

```
>>> df = pd.DataFrame([[1, 2, 3],
...                    [4, 5, 6],
...                    [7, 8, 9],
...                    [np.nan, np.nan, np.nan]],
...                   columns=['A', 'B', 'C'])
```

Aggregate these functions over the rows.

```
>>> df.agg(['sum', 'min'])
      A      B      C
sum  12.0  15.0  18.0
min   1.0   2.0   3.0
```

Different aggregations per column.

```
>>> df.agg({'A' : ['sum', 'min'], 'B' : ['min', 'max']})
      A      B
sum  12.0  NaN
min   1.0   2.0
max   NaN   8.0
```

Aggregate different functions over the columns and rename the index of the resulting DataFrame.

```
>>> df.agg(x=('A', max), y=('B', min), z=('C', np.mean))
      A      B      C
x   7.0  NaN  NaN
y  NaN  2.0  NaN
z  NaN  NaN  6.0
```

Aggregate over the columns.

```
>>> df.agg("mean", axis="columns")
0    2.0
1    5.0
2    8.0
3    NaN
dtype: float64
```

pandas.DataFrame.aggregate

`DataFrame.aggregate(func=None, axis=0, *args, **kwargs)`

Aggregate using one or more operations over the specified axis.

Parameters

func [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a DataFrame or when passed to DataFrame.apply.

Accepted combinations are:

- function
- string function name
- list of functions and/or function names, e.g. `[np.sum, 'mean']`
- dict of axis labels -> functions, function names or list of such.

axis [{0 or 'index', 1 or 'columns'}, default 0] If 0 or 'index': apply function to each column. If 1 or 'columns': apply function to each row.

***args** Positional arguments to pass to *func*.

****kwargs** Keyword arguments to pass to *func*.

Returns

scalar, Series or DataFrame The return can be:

- scalar : when Series.agg is called with single function
- Series : when DataFrame.agg is called with a single function
- DataFrame : when DataFrame.agg is called with several functions

Return scalar, Series or DataFrame.

The aggregation operations are always performed over an axis, either the index (default) or the column axis. This behavior is different from *numpy* aggregation functions (*mean*, *median*, *prod*, *sum*, *std*, *var*), where the default is to compute the aggregation of the flattened array, e.g., `numpy.mean(arr_2d)` as opposed to `numpy.mean(arr_2d, axis=0)`.

agg is an alias for *aggregate*. Use the alias.

See also:

[*DataFrame.apply*](#) Perform any type of operations.

DataFrame.transform Perform transformation type operations.

core.groupby.GroupBy Perform operations over groups.

core.resample.Resampler Perform operations over resampled bins.

core.window.Rolling Perform operations over rolling window.

core.window.Expanding Perform operations over expanding window.

core.window.ExponentialMovingWindow Perform operation over exponential weighted window.

Notes

agg is an alias for *aggregate*. Use the alias.

Functions that mutate the passed object can produce unexpected behavior or errors and are not supported. See *Mutating with User Defined Function (UDF) methods* for more details.

A passed user-defined-function will be passed a Series for evaluation.

Examples

```
>>> df = pd.DataFrame([[1, 2, 3],
...                    [4, 5, 6],
...                    [7, 8, 9],
...                    [np.nan, np.nan, np.nan]],
...                   columns=['A', 'B', 'C'])
```

Aggregate these functions over the rows.

```
>>> df.agg(['sum', 'min'])
      A      B      C
sum  12.0  15.0  18.0
min   1.0   2.0   3.0
```

Different aggregations per column.

```
>>> df.agg({'A' : ['sum', 'min'], 'B' : ['min', 'max']})
      A      B
sum  12.0  NaN
min   1.0   2.0
max   NaN   8.0
```

Aggregate different functions over the columns and rename the index of the resulting DataFrame.

```
>>> df.agg(x=('A', max), y=('B', min), z=('C', np.mean))
      A      B      C
x  7.0  NaN  NaN
y  NaN  2.0  NaN
z  NaN  NaN  6.0
```

Aggregate over the columns.

```
>>> df.agg("mean", axis="columns")
0    2.0
1    5.0
2    8.0
3    NaN
dtype: float64
```

pandas.DataFrame.align

`DataFrame.align`(*other*, *join*='outer', *axis*=None, *level*=None, *copy*=True, *fill_value*=None, *method*=None, *limit*=None, *fill_axis*=0, *broadcast_axis*=None)

Align two objects on their axes with the specified join method.

Join method is specified for each axis Index.

Parameters

other [DataFrame or Series]

join [{ 'outer', 'inner', 'left', 'right' }, default 'outer']

axis [allowed axis of the other object, default None] Align on index (0), columns (1), or both (None).

level [int or level name, default None] Broadcast across a level, matching Index values on the passed MultiIndex level.

copy [bool, default True] Always returns new objects. If *copy*=False and no reindexing is required then original objects are returned.

fill_value [scalar, default np.NaN] Value to use for missing values. Defaults to NaN, but can be any “compatible” value.

method [{ 'backfill', 'bfill', 'pad', 'ffill', None }, default None] Method to use for filling holes in reindexed Series:

- *pad* / *ffill*: propagate last valid observation forward to next valid.
- *backfill* / *bfill*: use NEXT valid observation to fill gap.

limit [int, default None] If method is specified, this is the maximum number of consecutive NaN values to forward/backward fill. In other words, if there is a gap with more than this number of consecutive NaNs, it will only be partially filled. If method is not specified, this is the maximum number of entries along the entire axis where NaNs will be filled. Must be greater than 0 if not None.

fill_axis [{0 or 'index', 1 or 'columns'}, default 0] Filling axis, method and limit.

broadcast_axis [{0 or 'index', 1 or 'columns'}, default None] Broadcast values along this axis, if aligning two objects of different dimensions.

Returns

(left, right) [(DataFrame, type of other)] Aligned objects.

pandas.DataFrame.all

`DataFrame.all(axis=0, bool_only=None, skipna=True, level=None, **kwargs)`

Return whether all elements are True, potentially over an axis.

Returns True unless there at least one element within a series or along a Dataframe axis that is False or equivalent (e.g. zero or empty).

Parameters

axis [{0 or 'index', 1 or 'columns', None}, default 0] Indicate which axis or axes should be reduced.

- 0 / 'index' : reduce the index, return a Series whose index is the original column labels.
- 1 / 'columns' : reduce the columns, return a Series whose index is the original index.
- None : reduce all axes, return a scalar.

bool_only [bool, default None] Include only boolean columns. If None, will attempt to use everything, then use only boolean data. Not implemented for Series.

skipna [bool, default True] Exclude NA/null values. If the entire row/column is NA and skipna is True, then the result will be True, as for an empty row/column. If skipna is False, then NA are treated as True, because these are not equal to zero.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

****kwargs** [any, default None] Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

Series or DataFrame If level is specified, then, DataFrame is returned; otherwise, Series is returned.

See also:

[*Series.all*](#) Return True if all elements are True.

[*DataFrame.any*](#) Return True if one (or more) elements are True.

Examples**Series**

```
>>> pd.Series([True, True]).all()
True
>>> pd.Series([True, False]).all()
False
>>> pd.Series([], dtype="float64").all()
True
>>> pd.Series([np.nan]).all()
True
>>> pd.Series([np.nan]).all(skipna=False)
True
```

DataFrames

Create a dataframe from a dictionary.

```
>>> df = pd.DataFrame({'col1': [True, True], 'col2': [True, False]})
>>> df
   col1  col2
0  True   True
1  True  False
```

Default behaviour checks if column-wise values all return True.

```
>>> df.all()
col1     True
col2    False
dtype: bool
```

Specify `axis='columns'` to check if row-wise values all return True.

```
>>> df.all(axis='columns')
0     True
1    False
dtype: bool
```

Or `axis=None` for whether every value is True.

```
>>> df.all(axis=None)
False
```

pandas.DataFrame.any

`DataFrame.any(axis=0, bool_only=None, skipna=True, level=None, **kwargs)`

Return whether any element is True, potentially over an axis.

Returns False unless there is at least one element within a series or along a Dataframe axis that is True or equivalent (e.g. non-zero or non-empty).

Parameters

axis [{0 or 'index', 1 or 'columns', None}, default 0] Indicate which axis or axes should be reduced.

- 0 / 'index' : reduce the index, return a Series whose index is the original column labels.
- 1 / 'columns' : reduce the columns, return a Series whose index is the original index.
- None : reduce all axes, return a scalar.

bool_only [bool, default None] Include only boolean columns. If None, will attempt to use everything, then use only boolean data. Not implemented for Series.

skipna [bool, default True] Exclude NA/null values. If the entire row/column is NA and skipna is True, then the result will be False, as for an empty row/column. If skipna is False, then NA are treated as True, because these are not equal to zero.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

****kwargs** [any, default None] Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

Series or DataFrame If level is specified, then, DataFrame is returned; otherwise, Series is returned.

See also:

[numpy.any](#) Numpy version of this method.

[Series.any](#) Return whether any element is True.

[Series.all](#) Return whether all elements are True.

[DataFrame.any](#) Return whether any element is True over requested axis.

[DataFrame.all](#) Return whether all elements are True over requested axis.

Examples

Series

For Series input, the output is a scalar indicating whether any element is True.

```
>>> pd.Series([False, False]).any()
False
>>> pd.Series([True, False]).any()
True
>>> pd.Series([], dtype="float64").any()
False
>>> pd.Series([np.nan]).any()
False
>>> pd.Series([np.nan]).any(skipna=False)
True
```

DataFrame

Whether each column contains at least one True element (the default).

```
>>> df = pd.DataFrame({"A": [1, 2], "B": [0, 2], "C": [0, 0]})
>>> df
   A  B  C
0  1  0  0
1  2  2  0
```

```
>>> df.any()
A     True
B     True
C     False
dtype: bool
```

Aggregating over the columns.

```
>>> df = pd.DataFrame({"A": [True, False], "B": [1, 2]})
>>> df
   A  B
0  True  1
1  False 2
```

```
>>> df.any(axis='columns')
0    True
1    True
dtype: bool
```

```
>>> df = pd.DataFrame({"A": [True, False], "B": [1, 0]})
>>> df
   A  B
0  True  1
1  False 0
```

```
>>> df.any(axis='columns')
0    True
1    False
dtype: bool
```

Aggregating over the entire DataFrame with `axis=None`.

```
>>> df.any(axis=None)
True
```

`any` for an empty DataFrame is an empty Series.

```
>>> pd.DataFrame([]).any()
Series([], dtype: bool)
```

pandas.DataFrame.append

`DataFrame.append(other, ignore_index=False, verify_integrity=False, sort=False)`

Append rows of *other* to the end of caller, returning a new object.

Columns in *other* that are not in the caller are added as new columns.

Parameters

other [DataFrame or Series/dict-like object, or list of these] The data to append.

ignore_index [bool, default False] If True, the resulting axis will be labeled 0, 1, ..., n - 1.

verify_integrity [bool, default False] If True, raise `ValueError` on creating index with duplicates.

sort [bool, default False] Sort columns if the columns of *self* and *other* are not aligned.

Changed in version 1.0.0: Changed to not sort by default.

Returns

DataFrame A new DataFrame consisting of the rows of caller and the rows of *other*.

See also:

`concat` General function to concatenate DataFrame or Series objects.

Notes

If a list of dict/series is passed and the keys are all contained in the DataFrame's index, the order of the columns in the resulting DataFrame will be unchanged.

Iteratively appending rows to a DataFrame can be more computationally intensive than a single concatenate. A better solution is to append those rows to a list and then concatenate the list with the original DataFrame all at once.

Examples

```
>>> df = pd.DataFrame([[1, 2], [3, 4]], columns=list('AB'), index=['x', 'y'])
>>> df
   A  B
x  1  2
y  3  4
>>> df2 = pd.DataFrame([[5, 6], [7, 8]], columns=list('AB'), index=['x', 'y'])
>>> df.append(df2)
   A  B
x  1  2
y  3  4
x  5  6
y  7  8
```

With `ignore_index` set to True:

```
>>> df.append(df2, ignore_index=True)
   A  B
0  1  2
1  3  4
2  5  6
3  7  8
```

The following, while not recommended methods for generating DataFrames, show two ways to generate a DataFrame from multiple data sources.

Less efficient:

```
>>> df = pd.DataFrame(columns=['A'])
>>> for i in range(5):
...     df = df.append({'A': i}, ignore_index=True)
>>> df
   A
0  0
1  1
2  2
3  3
4  4
```

More efficient:

```
>>> pd.concat([pd.DataFrame([i], columns=['A']) for i in range(5)],
...            ignore_index=True)
   A
0  0
1  1
2  2
3  3
4  4
```

pandas.DataFrame.apply

`DataFrame.apply(func, axis=0, raw=False, result_type=None, args=(), **kwargs)`

Apply a function along an axis of the DataFrame.

Objects passed to the function are Series objects whose index is either the DataFrame's index (`axis=0`) or the DataFrame's columns (`axis=1`). By default (`result_type=None`), the final return type is inferred from the return type of the applied function. Otherwise, it depends on the `result_type` argument.

Parameters

func [function] Function to apply to each column or row.

axis [{0 or 'index', 1 or 'columns'}, default 0] Axis along which the function is applied:

- 0 or 'index': apply function to each column.
- 1 or 'columns': apply function to each row.

raw [bool, default False] Determines if row or column is passed as a Series or ndarray object:

- False : passes each row or column as a Series to the function.
- True : the passed function will receive ndarray objects instead. If you are just applying a NumPy reduction function this will achieve much better performance.

result_type [{'expand', 'reduce', 'broadcast', None}, default None] These only act when `axis=1` (columns):

- 'expand' : list-like results will be turned into columns.
- 'reduce' : returns a Series if possible rather than expanding list-like results. This is the opposite of 'expand'.
- 'broadcast' : results will be broadcast to the original shape of the DataFrame, the original index and columns will be retained.

The default behaviour (None) depends on the return value of the applied function: list-like results will be returned as a Series of those. However if the apply function returns a Series these are expanded to columns.

args [tuple] Positional arguments to pass to `func` in addition to the array/series.

****kwargs** Additional keyword arguments to pass as keywords arguments to `func`.

Returns

Series or DataFrame Result of applying `func` along the given axis of the DataFrame.

See also:

DataFrame.applymap For elementwise operations.

DataFrame.agg Only perform aggregating type operations.

DataFrame.transform Only perform transforming type operations.

Notes

Functions that mutate the passed object can produce unexpected behavior or errors and are not supported. See *Mutating with User Defined Function (UDF) methods* for more details.

Examples

```
>>> df = pd.DataFrame([[4, 9]] * 3, columns=['A', 'B'])
>>> df
   A  B
0  4  9
1  4  9
2  4  9
```

Using a numpy universal function (in this case the same as `np.sqrt(df)`):

```
>>> df.apply(np.sqrt)
   A  B
0  2.0  3.0
1  2.0  3.0
2  2.0  3.0
```

Using a reducing function on either axis

```
>>> df.apply(np.sum, axis=0)
A    12
B    27
dtype: int64
```

```
>>> df.apply(np.sum, axis=1)
0    13
1    13
2    13
dtype: int64
```

Returning a list-like will result in a Series

```
>>> df.apply(lambda x: [1, 2], axis=1)
0    [1, 2]
1    [1, 2]
2    [1, 2]
dtype: object
```

Passing `result_type='expand'` will expand list-like results to columns of a DataFrame

```
>>> df.apply(lambda x: [1, 2], axis=1, result_type='expand')
0  1
```

(continues on next page)

(continued from previous page)

```

0  1  2
1  1  2
2  1  2

```

Returning a Series inside the function is similar to passing `result_type='expand'`. The resulting column names will be the Series index.

```

>>> df.apply(lambda x: pd.Series([1, 2], index=['foo', 'bar']), axis=1)
   foo bar
0    1   2
1    1   2
2    1   2

```

Passing `result_type='broadcast'` will ensure the same shape result, whether list-like or scalar is returned by the function, and broadcast it along the axis. The resulting column names will be the originals.

```

>>> df.apply(lambda x: [1, 2], axis=1, result_type='broadcast')
   A  B
0  1  2
1  1  2
2  1  2

```

pandas.DataFrame.applymap

`DataFrame.applymap(func, na_action=None, **kwargs)`

Apply a function to a Dataframe elementwise.

This method applies a function that accepts and returns a scalar to every element of a DataFrame.

Parameters

func [callable] Python function, returns a single value from a single value.

na_action [{None, 'ignore'}, default None] If 'ignore', propagate NaN values, without passing them to func.

New in version 1.2.

****kwargs** Additional keyword arguments to pass as keywords arguments to *func*.

New in version 1.3.0.

Returns

DataFrame Transformed DataFrame.

See also:

[*DataFrame.apply*](#) Apply a function along input axis of DataFrame.

Examples

```
>>> df = pd.DataFrame([[1, 2.12], [3.356, 4.567]])
>>> df
   0      1
0  1.000  2.120
1  3.356  4.567
```

```
>>> df.applymap(lambda x: len(str(x)))
   0  1
0  3  4
1  5  5
```

Like `Series.map`, NA values can be ignored:

```
>>> df_copy = df.copy()
>>> df_copy.iloc[0, 0] = pd.NA
>>> df_copy.applymap(lambda x: len(str(x)), na_action='ignore')
   0  1
0  <NA>  4
1  5  5
```

Note that a vectorized version of *func* often exists, which will be much faster. You could square each number elementwise.

```
>>> df.applymap(lambda x: x**2)
   0      1
0  1.000000  4.494400
1  11.262736  20.857489
```

But it's better to avoid `applymap` in that case.

```
>>> df ** 2
   0      1
0  1.000000  4.494400
1  11.262736  20.857489
```

pandas.DataFrame.asfreq

`DataFrame.asfreq(freq, method=None, how=None, normalize=False, fill_value=None)`

Convert time series to specified frequency.

Returns the original data conformed to a new index with the specified frequency.

If the index of this `DataFrame` is a `PeriodIndex`, the new index is the result of transforming the original index with `PeriodIndex.asfreq` (so the original index will map one-to-one to the new index).

Otherwise, the new index will be equivalent to `pd.date_range(start, end, freq=freq)` where `start` and `end` are, respectively, the first and last entries in the original index (see `pandas.date_range()`). The values corresponding to any timesteps in the new index which were not present in the original index will be null (NaN), unless a method for filling such unknowns is provided (see the `method` parameter below).

The `resample()` method is more appropriate if an operation on each group of timesteps (such as an aggregate) is necessary to represent the data at the new frequency.

Parameters

freq [DateOffset or str] Frequency DateOffset or string.

method [{ 'backfill'/'bfill', 'pad'/'fill' }, default None] Method to use for filling holes in reindexed Series (note this does not fill NaNs that already were present):

- 'pad' / 'fill': propagate last valid observation forward to next valid
- 'backfill' / 'bfill': use NEXT valid observation to fill.

how [{ 'start', 'end' }, default end] For PeriodIndex only (see PeriodIndex.asfreq).

normalize [bool, default False] Whether to reset output index to midnight.

fill_value [scalar, optional] Value to use for missing values, applied during upsampling (note this does not fill NaNs that already were present).

Returns

DataFrame DataFrame object reindexed to the specified frequency.

See also:

[*reindex*](#) Conform DataFrame to new index with optional filling logic.

Notes

To learn more about the frequency strings, please see [this link](#).

Examples

Start by creating a series with 4 one minute timestamps.

```
>>> index = pd.date_range('1/1/2000', periods=4, freq='T')
>>> series = pd.Series([0.0, None, 2.0, 3.0], index=index)
>>> df = pd.DataFrame({'s': series})
>>> df
```

| | s |
|---------------------|-----|
| 2000-01-01 00:00:00 | 0.0 |
| 2000-01-01 00:01:00 | NaN |
| 2000-01-01 00:02:00 | 2.0 |
| 2000-01-01 00:03:00 | 3.0 |

Upsample the series into 30 second bins.

```
>>> df.asfreq(freq='30S')
```

| | s |
|---------------------|-----|
| 2000-01-01 00:00:00 | 0.0 |
| 2000-01-01 00:00:30 | NaN |
| 2000-01-01 00:01:00 | NaN |
| 2000-01-01 00:01:30 | NaN |
| 2000-01-01 00:02:00 | 2.0 |
| 2000-01-01 00:02:30 | NaN |
| 2000-01-01 00:03:00 | 3.0 |

Upsample again, providing a fill value.

```
>>> df.asfreq(freq='30S', fill_value=9.0)
      S
2000-01-01 00:00:00    0.0
2000-01-01 00:00:30    9.0
2000-01-01 00:01:00   NaN
2000-01-01 00:01:30    9.0
2000-01-01 00:02:00    2.0
2000-01-01 00:02:30    9.0
2000-01-01 00:03:00    3.0
```

Upsample again, providing a method.

```
>>> df.asfreq(freq='30S', method='bfill')
      S
2000-01-01 00:00:00    0.0
2000-01-01 00:00:30   NaN
2000-01-01 00:01:00   NaN
2000-01-01 00:01:30    2.0
2000-01-01 00:02:00    2.0
2000-01-01 00:02:30    3.0
2000-01-01 00:03:00    3.0
```

pandas.DataFrame.asof

`DataFrame.asof(`*where*`,` *subset*`=None)`

Return the last row(s) without any NaNs before *where*.

The last row (for each element in *where*, if list) without any NaN is taken. In case of a `DataFrame`, the last row without NaN considering only the subset of columns (if not *None*)

If there is no good value, NaN is returned for a Series or a Series of NaN values for a DataFrame

Parameters

where [date or array-like of dates] Date(s) before which the last row(s) are returned.

subset [str or array-like of str, default *None*] For DataFrame, if not *None*, only use these columns to check for NaNs.

Returns

scalar, Series, or DataFrame The return can be:

- scalar : when *self* is a Series and *where* is a scalar
- Series: when *self* is a Series and *where* is an array-like, or when *self* is a DataFrame and *where* is a scalar
- DataFrame : when *self* is a DataFrame and *where* is an array-like

Return scalar, Series, or DataFrame.

See also:

[`merge_asof`](#) Perform an asof merge. Similar to left join.

Notes

Dates are assumed to be sorted. Raises if this is not the case.

Examples

A Series and a scalar *where*.

```
>>> s = pd.Series([1, 2, np.nan, 4], index=[10, 20, 30, 40])
>>> s
10    1.0
20    2.0
30    NaN
40    4.0
dtype: float64
```

```
>>> s.asof(20)
2.0
```

For a sequence *where*, a Series is returned. The first value is NaN, because the first element of *where* is before the first index value.

```
>>> s.asof([5, 20])
5     NaN
20    2.0
dtype: float64
```

Missing values are not considered. The following is 2.0, not NaN, even though NaN is at the index location for 30.

```
>>> s.asof(30)
2.0
```

Take all columns into consideration

```
>>> df = pd.DataFrame({'a': [10, 20, 30, 40, 50],
...                    'b': [None, None, None, None, 500]},
...                    index=pd.DatetimeIndex(['2018-02-27 09:01:00',
...                                             '2018-02-27 09:02:00',
...                                             '2018-02-27 09:03:00',
...                                             '2018-02-27 09:04:00',
...                                             '2018-02-27 09:05:00']))
>>> df.asof(pd.DatetimeIndex(['2018-02-27 09:03:30',
...                           '2018-02-27 09:04:30']))
           a  b
2018-02-27 09:03:30 NaN NaN
2018-02-27 09:04:30 NaN NaN
```

Take a single column into consideration

```
>>> df.asof(pd.DatetimeIndex(['2018-02-27 09:03:30',
...                           '2018-02-27 09:04:30']),
...         subset=['a'])
```

(continues on next page)

(continued from previous page)

| | a | b |
|---------------------|------|-----|
| 2018-02-27 09:03:30 | 30.0 | NaN |
| 2018-02-27 09:04:30 | 40.0 | NaN |

pandas.DataFrame.assign

`DataFrame.assign(**kwargs)`

Assign new columns to a DataFrame.

Returns a new object with all original columns in addition to new ones. Existing columns that are re-assigned will be overwritten.

Parameters

****kwargs** [dict of {str: callable or Series}] The column names are keywords. If the values are callable, they are computed on the DataFrame and assigned to the new columns. The callable must not change input DataFrame (though pandas doesn't check it). If the values are not callable, (e.g. a Series, scalar, or array), they are simply assigned.

Returns

DataFrame A new DataFrame with the new columns in addition to all the existing columns.

Notes

Assigning multiple columns within the same `assign` is possible. Later items in `**kwargs` may refer to newly created or modified columns in `df`; items are computed and assigned into `df` in order.

Examples

```
>>> df = pd.DataFrame({'temp_c': [17.0, 25.0]},
...                   index=['Portland', 'Berkeley'])
>>> df
```

| | temp_c |
|----------|--------|
| Portland | 17.0 |
| Berkeley | 25.0 |

Where the value is a callable, evaluated on `df`:

```
>>> df.assign(temp_f=lambda x: x.temp_c * 9 / 5 + 32)
```

| | temp_c | temp_f |
|----------|--------|--------|
| Portland | 17.0 | 62.6 |
| Berkeley | 25.0 | 77.0 |

Alternatively, the same behavior can be achieved by directly referencing an existing Series or sequence:

```
>>> df.assign(temp_f=df['temp_c'] * 9 / 5 + 32)
```

| | temp_c | temp_f |
|----------|--------|--------|
| Portland | 17.0 | 62.6 |
| Berkeley | 25.0 | 77.0 |

You can create multiple columns within the same assign where one of the columns depends on another one defined within the same assign:

```
>>> df.assign(temp_f=lambda x: x['temp_c'] * 9 / 5 + 32,
...           temp_k=lambda x: (x['temp_f'] + 459.67) * 5 / 9)
   temp_c  temp_f  temp_k
Portland  17.0   62.6  290.15
Berkeley  25.0   77.0  298.15
```

pandas.DataFrame.astype

`DataFrame.astype(dtype, copy=True, errors='raise')`

Cast a pandas object to a specified dtype dtype.

Parameters

dtype [data type, or dict of column name -> data type] Use a `numpy.dtype` or Python type to cast entire pandas object to the same type. Alternatively, use `{col: dtype, ...}`, where `col` is a column label and `dtype` is a `numpy.dtype` or Python type to cast one or more of the DataFrame's columns to column-specific types.

copy [bool, default True] Return a copy when `copy=True` (be very careful setting `copy=False` as changes to values then may propagate to other pandas objects).

errors [{ 'raise', 'ignore' }, default 'raise'] Control raising of exceptions on invalid data for provided dtype.

- `raise` : allow exceptions to be raised
- `ignore` : suppress exceptions. On error return original object.

Returns

casted [same type as caller]

See also:

[`to_datetime`](#) Convert argument to datetime.

[`to_timedelta`](#) Convert argument to timedelta.

[`to_numeric`](#) Convert argument to a numeric type.

[`numpy.ndarray.astype`](#) Cast a numpy array to a specified type.

Notes

Deprecated since version 1.3.0: Using `astype` to convert from timezone-naive dtype to timezone-aware dtype is deprecated and will raise in a future version. Use `Series.dt.tz_localize()` instead.

Examples

Create a DataFrame:

```
>>> d = {'col1': [1, 2], 'col2': [3, 4]}
>>> df = pd.DataFrame(data=d)
>>> df.dtypes
col1    int64
col2    int64
dtype: object
```

Cast all columns to int32:

```
>>> df.astype('int32').dtypes
col1    int32
col2    int32
dtype: object
```

Cast col1 to int32 using a dictionary:

```
>>> df.astype({'col1': 'int32'}).dtypes
col1    int32
col2    int64
dtype: object
```

Create a series:

```
>>> ser = pd.Series([1, 2], dtype='int32')
>>> ser
0    1
1    2
dtype: int32
>>> ser.astype('int64')
0    1
1    2
dtype: int64
```

Convert to categorical type:

```
>>> ser.astype('category')
0    1
1    2
dtype: category
Categories (2, int64): [1, 2]
```

Convert to ordered categorical type with custom ordering:

```
>>> from pandas.api.types import CategoricalDtype
>>> cat_dtype = CategoricalDtype(
...     categories=[2, 1], ordered=True)
>>> ser.astype(cat_dtype)
0    1
1    2
dtype: category
Categories (2, int64): [2 < 1]
```

Note that using `copy=False` and changing data on a new pandas object may propagate changes:

```
>>> s1 = pd.Series([1, 2])
>>> s2 = s1.astype('int64', copy=False)
>>> s2[0] = 10
>>> s1 # note that s1[0] has changed too
0    10
1     2
dtype: int64
```

Create a series of dates:

```
>>> ser_date = pd.Series(pd.date_range('20200101', periods=3))
>>> ser_date
0    2020-01-01
1    2020-01-02
2    2020-01-03
dtype: datetime64[ns]
```

pandas.DataFrame.at_time

`DataFrame.at_time`(*time*, *asof=False*, *axis=None*)

Select values at particular time of day (e.g., 9:30AM).

Parameters

time [datetime.time or str]

axis [{0 or 'index', 1 or 'columns'}, default 0]

Returns

Series or DataFrame

Raises

TypeError If the index is not a *DatetimeIndex*

See also:

between_time Select values between particular times of the day.

first Select initial periods of time series based on a date offset.

last Select final periods of time series based on a date offset.

DatetimeIndex.indexer_at_time Get just the index locations for values at particular time of the day.

Examples

```
>>> i = pd.date_range('2018-04-09', periods=4, freq='12H')
>>> ts = pd.DataFrame({'A': [1, 2, 3, 4]}, index=i)
>>> ts
```

| | A |
|---------------------|---|
| 2018-04-09 00:00:00 | 1 |
| 2018-04-09 12:00:00 | 2 |
| 2018-04-10 00:00:00 | 3 |
| 2018-04-10 12:00:00 | 4 |

```
>>> ts.at_time('12:00')
```

| | A |
|---------------------|---|
| 2018-04-09 12:00:00 | 2 |
| 2018-04-10 12:00:00 | 4 |

pandas.DataFrame.backfill

`DataFrame.backfill(axis=None, inplace=False, limit=None, downcast=None)`
 Synonym for `DataFrame.fillna()` with `method='bfill'`.

Returns

Series/DataFrame or None Object with missing values filled or None if `inplace=True`.

pandas.DataFrame.between_time

`DataFrame.between_time(start_time, end_time, include_start=True, include_end=True, axis=None)`
 Select values between particular times of the day (e.g., 9:00-9:30 AM).

By setting `start_time` to be later than `end_time`, you can get the times that are *not* between the two times.

Parameters

start_time [datetime.time or str] Initial time as a time filter limit.

end_time [datetime.time or str] End time as a time filter limit.

include_start [bool, default True] Whether the start time needs to be included in the result.

include_end [bool, default True] Whether the end time needs to be included in the result.

axis [{0 or 'index', 1 or 'columns'}, default 0] Determine range time on index or columns value.

Returns

Series or DataFrame Data from the original object filtered to the specified dates range.

Raises

TypeError If the index is not a `DatetimeIndex`

See also:

at_time Select values at a particular time of the day.

first Select initial periods of time series based on a date offset.

last Select final periods of time series based on a date offset.

DatetimeIndex.indexer_between_time Get just the index locations for values between particular times of the day.

Examples

```
>>> i = pd.date_range('2018-04-09', periods=4, freq='1D20min')
>>> ts = pd.DataFrame({'A': [1, 2, 3, 4]}, index=i)
>>> ts
```

| | A |
|---------------------|---|
| 2018-04-09 00:00:00 | 1 |
| 2018-04-10 00:20:00 | 2 |
| 2018-04-11 00:40:00 | 3 |
| 2018-04-12 01:00:00 | 4 |

```
>>> ts.between_time('0:15', '0:45')
```

| | A |
|---------------------|---|
| 2018-04-10 00:20:00 | 2 |
| 2018-04-11 00:40:00 | 3 |

You get the times that are *not* between two times by setting `start_time` later than `end_time`:

```
>>> ts.between_time('0:45', '0:15')
```

| | A |
|---------------------|---|
| 2018-04-09 00:00:00 | 1 |
| 2018-04-12 01:00:00 | 4 |

pandas.DataFrame.bfill

`DataFrame.bfill(axis=None, inplace=False, limit=None, downcast=None)`

Synonym for `DataFrame.fillna()` with `method='bfill'`.

Returns

Series/DataFrame or None Object with missing values filled or None if `inplace=True`.

pandas.DataFrame.bool

`DataFrame.bool()`

Return the bool of a single element Series or DataFrame.

This must be a boolean scalar value, either True or False. It will raise a `ValueError` if the Series or DataFrame does not have exactly 1 element, or that element is not boolean (integer values 0 and 1 will also raise an exception).

Returns

bool The value in the Series or DataFrame.

See also:

`Series.astype` Change the data type of a Series, including to boolean.

`DataFrame.astype` Change the data type of a DataFrame, including to boolean.

`numpy.bool_` NumPy boolean data type, used by pandas for boolean values.

Examples

The method will only work for single element objects with a boolean value:

```
>>> pd.Series([True]).bool()
True
>>> pd.Series([False]).bool()
False
```

```
>>> pd.DataFrame({'col': [True]}).bool()
True
>>> pd.DataFrame({'col': [False]}).bool()
False
```

pandas.DataFrame.boxplot

DataFrame.boxplot(*column=None, by=None, ax=None, fontsize=None, rot=0, grid=True, figsize=None, layout=None, return_type=None, backend=None, **kwargs*)

Make a box plot from DataFrame columns.

Make a box-and-whisker plot from DataFrame columns, optionally grouped by some other columns. A box plot is a method for graphically depicting groups of numerical data through their quartiles. The box extends from the Q1 to Q3 quartile values of the data, with a line at the median (Q2). The whiskers extend from the edges of box to show the range of the data. By default, they extend no more than $1.5 * IQR$ ($IQR = Q3 - Q1$) from the edges of the box, ending at the farthest data point within that interval. Outliers are plotted as separate dots.

For further details see Wikipedia's entry for [boxplot](#).

Parameters

column [str or list of str, optional] Column name or list of names, or vector. Can be any valid input to `pandas.DataFrame.groupby()`.

by [str or array-like, optional] Column in the DataFrame to `pandas.DataFrame.groupby()`. One box-plot will be done per value of columns in *by*.

ax [object of class `matplotlib.axes.Axes`, optional] The matplotlib axes to be used by boxplot.

fontsize [float or str] Tick label font size in points or as a string (e.g., *large*).

rot [int or float, default 0] The rotation angle of labels (in degrees) with respect to the screen coordinate system.

grid [bool, default True] Setting this to True will show the grid.

figsize [A tuple (width, height) in inches] The size of the figure to create in matplotlib.

layout [tuple (rows, columns), optional] For example, (3, 5) will display the subplots using 3 columns and 5 rows, starting from the top-left.

return_type [{ 'axes', 'dict', 'both' } or None, default 'axes'] The kind of object to return. The default is axes.

- 'axes' returns the matplotlib axes the boxplot is drawn on.
- 'dict' returns a dictionary whose values are the matplotlib Lines of the boxplot.
- 'both' returns a namedtuple with the axes and dict.
- when grouping with `by`, a Series mapping columns to `return_type` is returned.

If `return_type` is `None`, a NumPy array of axes with the same shape as `layout` is returned.

backend [str, default None] Backend to use instead of the backend specified in the option `plotting.backend`. For instance, 'matplotlib'. Alternatively, to specify the `plotting.backend` for the whole session, set `pd.options.plotting.backend`.

New in version 1.0.0.

****kwargs** All other plotting keyword arguments to be passed to `matplotlib.pyplot.boxplot()`.

Returns

result See Notes.

See also:

[`Series.plot.hist`](#) Make a histogram.

[`matplotlib.pyplot.boxplot`](#) Matplotlib equivalent plot.

Notes

The return type depends on the `return_type` parameter:

- 'axes' : object of class `matplotlib.axes.Axes`
- 'dict' : dict of `matplotlib.lines.Line2D` objects
- 'both' : a namedtuple with structure (ax, lines)

For data grouped with `by`, return a Series of the above or a numpy array:

- [`Series`](#)
- `array` (for `return_type = None`)

Use `return_type='dict'` when you want to tweak the appearance of the lines after plotting. In this case a dict containing the Lines making up the boxes, caps, fliers, medians, and whiskers is returned.

Examples

Boxplots can be created for every column in the dataframe by `df.boxplot()` or indicating the columns to be used:

```
>>> np.random.seed(1234)
>>> df = pd.DataFrame(np.random.randn(10, 4),
...                    columns=['Col1', 'Col2', 'Col3', 'Col4'])
>>> boxplot = df.boxplot(column=['Col1', 'Col2', 'Col3'])
```

Boxplots of variables distributions grouped by the values of a third variable can be created using the option `by`. For instance:

```
>>> df = pd.DataFrame(np.random.randn(10, 2),
...                    columns=['Col1', 'Col2'])
>>> df['X'] = pd.Series(['A', 'A', 'A', 'A', 'A',
...                      'B', 'B', 'B', 'B', 'B'])
>>> boxplot = df.boxplot(by='X')
```

A list of strings (i.e. `['X', 'Y']`) can be passed to `boxplot` in order to group the data by combination of the variables in the x-axis:

```
>>> df = pd.DataFrame(np.random.randn(10, 3),
...                    columns=['Col1', 'Col2', 'Col3'])
```

(continues on next page)

(continued from previous page)

```

>>> df['X'] = pd.Series(['A', 'A', 'A', 'A', 'A',
...                      'B', 'B', 'B', 'B', 'B'])
>>> df['Y'] = pd.Series(['A', 'B', 'A', 'B', 'A',
...                      'B', 'A', 'B', 'A', 'B'])
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], by=['X', 'Y'])

```

The layout of boxplot can be adjusted giving a tuple to layout:

```

>>> boxplot = df.boxplot(column=['Col1', 'Col2'], by='X',
...                       layout=(2, 1))

```

Additional formatting can be done to the boxplot, like suppressing the grid (`grid=False`), rotating the labels in the x-axis (i.e. `rot=45`) or changing the fontsize (i.e. `fontsize=15`):

```

>>> boxplot = df.boxplot(grid=False, rot=45, fontsize=15)

```

The parameter `return_type` can be used to select the type of element returned by `boxplot`. When `return_type='axes'` is selected, the matplotlib axes on which the boxplot is drawn are returned:

```

>>> boxplot = df.boxplot(column=['Col1', 'Col2'], return_type='axes')
>>> type(boxplot)
<class 'matplotlib.axes._subplots.AxesSubplot'>

```

When grouping with `by`, a Series mapping columns to `return_type` is returned:

```
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], by='X',
...                       return_type='axes')
>>> type(boxplot)
<class 'pandas.core.series.Series'>
```

If `return_type` is `None`, a NumPy array of axes with the same shape as `layout` is returned:

```
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], by='X',
...                       return_type=None)
>>> type(boxplot)
<class 'numpy.ndarray'>
```

pandas.DataFrame.clip

`DataFrame.clip(lower=None, upper=None, axis=None, inplace=False, *args, **kwargs)`
Trim values at input threshold(s).

Assigns values outside boundary to boundary values. Thresholds can be singular values or array like, and in the latter case the clipping is performed element-wise in the specified axis.

Parameters

lower [float or array-like, default None] Minimum threshold value. All values below this threshold will be set to it. A missing threshold (e.g `NA`) will not clip the value.

upper [float or array-like, default None] Maximum threshold value. All values above this threshold will be set to it. A missing threshold (e.g `NA`) will not clip the value.

axis [int or str axis name, optional] Align object with lower and upper along the given axis.

inplace [bool, default False] Whether to perform the operation in place on the data.

***args, **kwargs** Additional keywords have no effect but might be accepted for compatibility with numpy.

Returns

Series or DataFrame or None Same type as calling object with the values outside the clip boundaries replaced or `None` if `inplace=True`.

See also:

[`Series.clip`](#) Trim values at input threshold in series.

[`DataFrame.clip`](#) Trim values at input threshold in dataframe.

[`numpy.clip`](#) Clip (limit) the values in an array.

Examples

```
>>> data = {'col_0': [9, -3, 0, -1, 5], 'col_1': [-2, -7, 6, 8, -5]}
>>> df = pd.DataFrame(data)
>>> df
   col_0  col_1
0      9    -2
1     -3    -7
2      0     6
3     -1     8
4      5    -5
```

Clips per column using lower and upper thresholds:

```
>>> df.clip(-4, 6)
   col_0  col_1
0      6    -2
1     -3    -4
2      0     6
3     -1     6
4      5    -4
```

Clips using specific lower and upper thresholds per column element:

```
>>> t = pd.Series([2, -4, -1, 6, 3])
>>> t
0    2
1   -4
2   -1
3    6
4    3
dtype: int64
```

```
>>> df.clip(t, t + 4, axis=0)
   col_0  col_1
0      6     2
1     -3    -4
2      0     3
3      6     8
4      5     3
```

Clips using specific lower threshold per column element, with missing values:

```
>>> t = pd.Series([2, -4, np.NaN, 6, 3])
>>> t
0    2.0
1   -4.0
2    NaN
3    6.0
4    3.0
dtype: float64
```

```
>>> df.clip(t, axis=0)
col_0  col_1
0      9      2
1     -3     -4
2      0      6
3      6      8
4      5      3
```

pandas.DataFrame.combine

`DataFrame.combine(other, func, fill_value=None, overwrite=True)`

Perform column-wise combine with another DataFrame.

Combines a DataFrame with *other* DataFrame using *func* to element-wise combine columns. The row and column indexes of the resulting DataFrame will be the union of the two.

Parameters

other [DataFrame] The DataFrame to merge column-wise.

func [function] Function that takes two series as inputs and return a Series or a scalar. Used to merge the two dataframes column by columns.

fill_value [scalar value, default None] The value to fill NaNs with prior to passing any column to the merge func.

overwrite [bool, default True] If True, columns in *self* that do not exist in *other* will be overwritten with NaNs.

Returns

DataFrame Combination of the provided DataFrames.

See also:

[`DataFrame.combine_first`](#) Combine two DataFrame objects and default to non-null values in frame calling the method.

Examples

Combine using a simple function that chooses the smaller column.

```
>>> df1 = pd.DataFrame({'A': [0, 0], 'B': [4, 4]})
>>> df2 = pd.DataFrame({'A': [1, 1], 'B': [3, 3]})
>>> take_smaller = lambda s1, s2: s1 if s1.sum() < s2.sum() else s2
>>> df1.combine(df2, take_smaller)
   A  B
0  0  3
1  0  3
```

Example using a true element-wise combine function.

```
>>> df1 = pd.DataFrame({'A': [5, 0], 'B': [2, 4]})
>>> df2 = pd.DataFrame({'A': [1, 1], 'B': [3, 3]})
>>> df1.combine(df2, np.minimum)
```

(continues on next page)

(continued from previous page)

```

  A  B
0  1  2
1  0  3

```

Using `fill_value` fills Nones prior to passing the column to the merge function.

```

>>> df1 = pd.DataFrame({'A': [0, 0], 'B': [None, 4]})
>>> df2 = pd.DataFrame({'A': [1, 1], 'B': [3, 3]})
>>> df1.combine(df2, take_smaller, fill_value=-5)
  A  B
0  0 -5.0
1  0  4.0

```

However, if the same element in both dataframes is None, that None is preserved

```

>>> df1 = pd.DataFrame({'A': [0, 0], 'B': [None, 4]})
>>> df2 = pd.DataFrame({'A': [1, 1], 'B': [None, 3]})
>>> df1.combine(df2, take_smaller, fill_value=-5)
  A  B
0  0 -5.0
1  0  3.0

```

Example that demonstrates the use of `overwrite` and behavior when the axis differ between the dataframes.

```

>>> df1 = pd.DataFrame({'A': [0, 0], 'B': [4, 4]})
>>> df2 = pd.DataFrame({'B': [3, 3], 'C': [-10, 1], }, index=[1, 2])
>>> df1.combine(df2, take_smaller)
  A  B  C
0 NaN NaN NaN
1 NaN 3.0 -10.0
2 NaN 3.0  1.0

```

```

>>> df1.combine(df2, take_smaller, overwrite=False)
  A  B  C
0 0.0 NaN NaN
1 0.0 3.0 -10.0
2 NaN 3.0  1.0

```

Demonstrating the preference of the passed in dataframe.

```

>>> df2 = pd.DataFrame({'B': [3, 3], 'C': [1, 1], }, index=[1, 2])
>>> df2.combine(df1, take_smaller)
  A  B  C
0 0.0 NaN NaN
1 0.0 3.0 NaN
2 NaN 3.0 NaN

```

```

>>> df2.combine(df1, take_smaller, overwrite=False)
  A  B  C
0 0.0 NaN NaN
1 0.0 3.0 1.0
2 NaN 3.0 1.0

```

pandas.DataFrame.combine_first

DataFrame.**combine_first**(*other*)

Update null elements with value in the same location in *other*.

Combine two DataFrame objects by filling null values in one DataFrame with non-null values from other DataFrame. The row and column indexes of the resulting DataFrame will be the union of the two.

Parameters

other [DataFrame] Provided DataFrame to use to fill null values.

Returns

DataFrame The result of combining the provided DataFrame with the other object.

See also:

[DataFrame.combine](#) Perform series-wise operation on two DataFrames using a given function.

Examples

```
>>> df1 = pd.DataFrame({'A': [None, 0], 'B': [None, 4]})
>>> df2 = pd.DataFrame({'A': [1, 1], 'B': [3, 3]})
>>> df1.combine_first(df2)
   A  B
0  1.0 3.0
1  0.0 4.0
```

Null values still persist if the location of that null value does not exist in *other*

```
>>> df1 = pd.DataFrame({'A': [None, 0], 'B': [4, None]})
>>> df2 = pd.DataFrame({'B': [3, 3], 'C': [1, 1]}, index=[1, 2])
>>> df1.combine_first(df2)
   A  B  C
0  NaN 4.0 NaN
1  0.0 3.0 1.0
2  NaN 3.0 1.0
```

pandas.DataFrame.compare

DataFrame.**compare**(*other*, *align_axis=1*, *keep_shape=False*, *keep_equal=False*)

Compare to another DataFrame and show the differences.

New in version 1.1.0.

Parameters

other [DataFrame] Object to compare with.

align_axis [{0 or 'index', 1 or 'columns'}, default 1] Determine which axis to align the comparison on.

- **0**, or **'index'** [Resulting differences are stacked vertically] with rows drawn alternately from self and other.

- **1, or 'columns'** [Resulting differences are aligned horizontally] with columns drawn alternately from self and other.

keep_shape [bool, default False] If true, all rows and columns are kept. Otherwise, only the ones with different values are kept.

keep_equal [bool, default False] If true, the result keeps values that are equal. Otherwise, equal values are shown as NaNs.

Returns

DataFrame DataFrame that shows the differences stacked side by side.

The resulting index will be a MultiIndex with 'self' and 'other' stacked alternately at the inner level.

Raises

ValueError When the two DataFrames don't have identical labels or shape.

See also:

[*Series.compare*](#) Compare with another Series and show differences.

[*DataFrame.equals*](#) Test whether two objects contain the same elements.

Notes

Matching NaNs will not appear as a difference.

Can only compare identically-labeled (i.e. same shape, identical row and column labels) DataFrames

Examples

```
>>> df = pd.DataFrame(
...     {
...         "col1": ["a", "a", "b", "b", "a"],
...         "col2": [1.0, 2.0, 3.0, np.nan, 5.0],
...         "col3": [1.0, 2.0, 3.0, 4.0, 5.0]
...     },
...     columns=["col1", "col2", "col3"],
... )
>>> df
   col1  col2  col3
0    a    1.0    1.0
1    a    2.0    2.0
2    b    3.0    3.0
3    b    NaN    4.0
4    a    5.0    5.0
```

```
>>> df2 = df.copy()
>>> df2.loc[0, 'col1'] = 'c'
>>> df2.loc[2, 'col3'] = 4.0
>>> df2
   col1  col2  col3
0    c    1.0    1.0
```

(continues on next page)

(continued from previous page)

| | | | |
|---|---|-----|-----|
| 1 | a | 2.0 | 2.0 |
| 2 | b | 3.0 | 4.0 |
| 3 | b | NaN | 4.0 |
| 4 | a | 5.0 | 5.0 |

Align the differences on columns

```
>>> df.compare(df2)
   col1      col3
   self other self other
0    a      c  NaN   NaN
2  NaN  NaN  3.0   4.0
```

Stack the differences on rows

```
>>> df.compare(df2, align_axis=0)
      col1 col3
0 self   a  NaN
  other  c  NaN
2 self  NaN  3.0
  other NaN  4.0
```

Keep the equal values

```
>>> df.compare(df2, keep_equal=True)
   col1      col3
   self other self other
0    a      c  1.0   1.0
2    b      b  3.0   4.0
```

Keep all original rows and columns

```
>>> df.compare(df2, keep_shape=True)
   col1      col2      col3
   self other self other self other
0    a      c  NaN   NaN  NaN   NaN
1  NaN  NaN  NaN   NaN  NaN   NaN
2  NaN  NaN  NaN   NaN  3.0   4.0
3  NaN  NaN  NaN   NaN  NaN   NaN
4  NaN  NaN  NaN   NaN  NaN   NaN
```

Keep all original rows and columns and also all original values

```
>>> df.compare(df2, keep_shape=True, keep_equal=True)
   col1      col2      col3
   self other self other self other
0    a      c  1.0   1.0  1.0   1.0
1    a      a  2.0   2.0  2.0   2.0
2    b      b  3.0   3.0  3.0   4.0
3    b      b  NaN   NaN  4.0   4.0
4    a      a  5.0   5.0  5.0   5.0
```

pandas.DataFrame.convert_dtypes

`DataFrame.convert_dtypes`(*infer_objects=True, convert_string=True, convert_integer=True, convert_boolean=True, convert_floating=True*)

Convert columns to best possible dtypes using dtypes supporting `pd.NA`.

New in version 1.0.0.

Parameters

infer_objects [bool, default True] Whether object dtypes should be converted to the best possible types.

convert_string [bool, default True] Whether object dtypes should be converted to `StringDtype()`.

convert_integer [bool, default True] Whether, if possible, conversion can be done to integer extension types.

convert_boolean [bool, defaults True] Whether object dtypes should be converted to `BooleanDtypes()`.

convert_floating [bool, defaults True] Whether, if possible, conversion can be done to floating extension types. If *convert_integer* is also True, preference will be give to integer dtypes if the floats can be faithfully casted to integers.

New in version 1.2.0.

Returns

Series or DataFrame Copy of input object with new dtype.

See also:

[*infer_objects*](#) Infer dtypes of objects.

[*to_datetime*](#) Convert argument to datetime.

[*to_timedelta*](#) Convert argument to timedelta.

[*to_numeric*](#) Convert argument to a numeric type.

Notes

By default, `convert_dtypes` will attempt to convert a `Series` (or each `Series` in a `DataFrame`) to dtypes that support `pd.NA`. By using the options `convert_string`, `convert_integer`, `convert_boolean` and `convert_floating`, it is possible to turn off individual conversions to `StringDtype`, the integer extension types, `BooleanDtype` or floating extension types, respectively.

For object-dtyped columns, if `infer_objects` is `True`, use the inference rules as during normal `Series/DataFrame` construction. Then, if possible, convert to `StringDtype`, `BooleanDtype` or an appropriate integer or floating extension type, otherwise leave as `object`.

If the dtype is integer, convert to an appropriate integer extension type.

If the dtype is numeric, and consists of all integers, convert to an appropriate integer extension type. Otherwise, convert to an appropriate floating extension type.

Changed in version 1.2: Starting with pandas 1.2, this method also converts float columns to the nullable floating extension type.

In the future, as new dtypes are added that support `pd.NA`, the results of this method will change to support those new dtypes.

Examples

```
>>> df = pd.DataFrame(
...     {
...         "a": pd.Series([1, 2, 3], dtype=np.dtype("int32")),
...         "b": pd.Series(["x", "y", "z"], dtype=np.dtype("O")),
...         "c": pd.Series([True, False, np.nan], dtype=np.dtype("O")),
...         "d": pd.Series(["h", "i", np.nan], dtype=np.dtype("O")),
...         "e": pd.Series([10, np.nan, 20], dtype=np.dtype("float")),
...         "f": pd.Series([np.nan, 100.5, 200], dtype=np.dtype("float")),
...     }
... )
```

Start with a DataFrame with default dtypes.

```
>>> df
   a  b    c    d    e    f
0  1  x  True  h  10.0  NaN
1  2  y False  i   NaN  100.5
2  3  z   NaN NaN  20.0  200.0
```

```
>>> df.dtypes
a      int32
b      object
c      object
d      object
e     float64
f     float64
dtype: object
```

Convert the DataFrame to use best possible dtypes.

```
>>> dfn = df.convert_dtypes()
>>> dfn
   a  b    c    d    e    f
0  1  x  True  h    10  <NA>
1  2  y False  i  <NA>  100.5
2  3  z  <NA> <NA>   20  200.0
```

```
>>> dfn.dtypes
a      Int32
b      string
c      boolean
d      string
e      Int64
f      Float64
dtype: object
```

Start with a Series of strings and missing data represented by `np.nan`.

```
>>> s = pd.Series(["a", "b", np.nan])
>>> s
0      a
1      b
2     NaN
dtype: object
```

Obtain a Series with dtype StringDtype.

```
>>> s.convert_dtypes()
0      a
1      b
2     <NA>
dtype: string
```

pandas.DataFrame.copy

DataFrame.copy(*deep=True*)

Make a copy of this object's indices and data.

When *deep=True* (default), a new object will be created with a copy of the calling object's data and indices. Modifications to the data or indices of the copy will not be reflected in the original object (see notes below).

When *deep=False*, a new object will be created without copying the calling object's data or index (only references to the data and index are copied). Any changes to the data of the original will be reflected in the shallow copy (and vice versa).

Parameters

deep [bool, default True] Make a deep copy, including a copy of the data and the indices. With *deep=False* neither the indices nor the data are copied.

Returns

copy [Series or DataFrame] Object type matches caller.

Notes

When *deep=True*, data is copied but actual Python objects will not be copied recursively, only the reference to the object. This is in contrast to *copy.deepcopy* in the Standard Library, which recursively copies object data (see examples below).

While Index objects are copied when *deep=True*, the underlying numpy array is not copied for performance reasons. Since Index is immutable, the underlying data can be safely shared and a copy is not needed.

Examples

```
>>> s = pd.Series([1, 2], index=["a", "b"])
>>> s
a    1
b    2
dtype: int64
```

```
>>> s_copy = s.copy()
>>> s_copy
a    1
b    2
dtype: int64
```

Shallow copy versus default (deep) copy:

```
>>> s = pd.Series([1, 2], index=["a", "b"])
>>> deep = s.copy()
>>> shallow = s.copy(deep=False)
```

Shallow copy shares data and index with original.

```
>>> s is shallow
False
>>> s.values is shallow.values and s.index is shallow.index
True
```

Deep copy has own copy of data and index.

```
>>> s is deep
False
>>> s.values is deep.values or s.index is deep.index
False
```

Updates to the data shared by shallow copy and original is reflected in both; deep copy remains unchanged.

```
>>> s[0] = 3
>>> shallow[1] = 4
>>> s
a    3
b    4
dtype: int64
>>> shallow
a    3
b    4
dtype: int64
>>> deep
a    1
b    2
dtype: int64
```

Note that when copying an object containing Python objects, a deep copy will copy the data, but will not do so recursively. Updating a nested data object will be reflected in the deep copy.

```

>>> s = pd.Series([[1, 2], [3, 4]])
>>> deep = s.copy()
>>> s[0][0] = 10
>>> s
0    [10, 2]
1    [3, 4]
dtype: object
>>> deep
0    [10, 2]
1    [3, 4]
dtype: object

```

pandas.DataFrame.corr

`DataFrame.corr` (*method='pearson', min_periods=1*)

Compute pairwise correlation of columns, excluding NA/null values.

Parameters

method [{ 'pearson', 'kendall', 'spearman' } or callable] Method of correlation:

- `pearson` : standard correlation coefficient
- `kendall` : Kendall Tau correlation coefficient
- `spearman` : Spearman rank correlation
- **callable**: **callable with input two 1d ndarrays** and returning a float. Note that the returned matrix from `corr` will have 1 along the diagonals and will be symmetric regardless of the callable's behavior.

min_periods [int, optional] Minimum number of observations required per pair of columns to have a valid result. Currently only available for Pearson and Spearman correlation.

Returns

DataFrame Correlation matrix.

See also:

[`DataFrame.corrwith`](#) Compute pairwise correlation with another DataFrame or Series.

[`Series.corr`](#) Compute the correlation between two Series.

Examples

```

>>> def histogram_intersection(a, b):
...     v = np.minimum(a, b).sum().round(decimals=1)
...     return v
>>> df = pd.DataFrame([(0.2, .3), (.0, .6), (.6, .0), (.2, .1)],
...                   columns=['dogs', 'cats'])
>>> df.corr(method=histogram_intersection)
      dogs  cats
dogs  1.0  0.3
cats  0.3  1.0

```

pandas.DataFrame.corrwith

`DataFrame.corrwith(other, axis=0, drop=False, method='pearson')`

Compute pairwise correlation.

Pairwise correlation is computed between rows or columns of `DataFrame` with rows or columns of `Series` or `DataFrame`. `DataFrames` are first aligned along both axes before computing the correlations.

Parameters

other [`DataFrame`, `Series`] Object with which to compute correlations.

axis [{0 or 'index', 1 or 'columns'}, default 0] The axis to use. 0 or 'index' to compute column-wise, 1 or 'columns' for row-wise.

drop [bool, default False] Drop missing indices from result.

method [{'pearson', 'kendall', 'spearman'} or callable] Method of correlation:

- `pearson` : standard correlation coefficient
- `kendall` : Kendall Tau correlation coefficient
- `spearman` : Spearman rank correlation
- **callable**: callable with input two 1d ndarrays and returning a float.

Returns

Series Pairwise correlations.

See also:

[`DataFrame.corr`](#) Compute pairwise correlation of columns.

pandas.DataFrame.count

`DataFrame.count(axis=0, level=None, numeric_only=False)`

Count non-NA cells for each column or row.

The values `None`, `NaN`, `NaT`, and optionally `numpy.inf` (depending on `pandas.options.mode.use_inf_as_na`) are considered NA.

Parameters

axis [{0 or 'index', 1 or 'columns'}, default 0] If 0 or 'index' counts are generated for each column. If 1 or 'columns' counts are generated for each row.

level [int or str, optional] If the axis is a `MultiIndex` (hierarchical), count along a particular `level`, collapsing into a `DataFrame`. A `str` specifies the level name.

numeric_only [bool, default False] Include only `float`, `int` or `boolean` data.

Returns

Series or DataFrame For each column/row the number of non-NA/null entries. If `level` is specified returns a `DataFrame`.

See also:

[`Series.count`](#) Number of non-NA elements in a `Series`.

[`DataFrame.value_counts`](#) Count unique combinations of columns.

DataFrame.shape Number of DataFrame rows and columns (including NA elements).

DataFrame.isna Boolean same-sized DataFrame showing places of NA elements.

Examples

Constructing DataFrame from a dictionary:

```
>>> df = pd.DataFrame({"Person":
...                     ["John", "Myla", "Lewis", "John", "Myla"],
...                     "Age": [24., np.nan, 21., 33, 26],
...                     "Single": [False, True, True, True, False]})
>>> df
   Person  Age  Single
0   John  24.0  False
1   Myla   NaN   True
2  Lewis  21.0   True
3   John  33.0   True
4   Myla  26.0  False
```

Notice the uncounted NA values:

```
>>> df.count()
Person    5
Age       4
Single    5
dtype: int64
```

Counts for each row:

```
>>> df.count(axis='columns')
0    3
1    2
2    3
3    3
4    3
dtype: int64
```

pandas.DataFrame.cov

DataFrame.cov(*min_periods=None, ddof=1*)

Compute pairwise covariance of columns, excluding NA/null values.

Compute the pairwise covariance among the series of a DataFrame. The returned data frame is the [covariance matrix](#) of the columns of the DataFrame.

Both NA and null values are automatically excluded from the calculation. (See the note below about bias from missing values.) A threshold can be set for the minimum number of observations for each value created. Comparisons with observations below this threshold will be returned as NaN.

This method is generally used for the analysis of time series data to understand the relationship between different measures across time.

Parameters

min_periods [int, optional] Minimum number of observations required per pair of columns to have a valid result.

ddof [int, default 1] Delta degrees of freedom. The divisor used in calculations is $N - \text{ddof}$, where N represents the number of elements.

New in version 1.1.0.

Returns

DataFrame The covariance matrix of the series of the DataFrame.

See also:

[Series.cov](#) Compute covariance with another Series.

[core.window.ExponentialMovingWindow.cov](#) Exponential weighted sample covariance.

[core.window.Expanding.cov](#) Expanding sample covariance.

[core.window.Rolling.cov](#) Rolling sample covariance.

Notes

Returns the covariance matrix of the DataFrame's time series. The covariance is normalized by $N - \text{ddof}$.

For DataFrames that have Series that are missing data (assuming that data is [missing at random](#)) the returned covariance matrix will be an unbiased estimate of the variance and covariance between the member Series.

However, for many applications this estimate may not be acceptable because the estimate covariance matrix is not guaranteed to be positive semi-definite. This could lead to estimate correlations having absolute values which are greater than one, and/or a non-invertible covariance matrix. See [Estimation of covariance matrices](#) for more details.

Examples

```
>>> df = pd.DataFrame([(1, 2), (0, 3), (2, 0), (1, 1)],
...                    columns=['dogs', 'cats'])
>>> df.cov()
           dogs      cats
dogs  0.666667 -1.000000
cats -1.000000  1.666667
```

```
>>> np.random.seed(42)
>>> df = pd.DataFrame(np.random.randn(1000, 5),
...                    columns=['a', 'b', 'c', 'd', 'e'])
>>> df.cov()
           a          b          c          d          e
a  0.998438 -0.020161  0.059277 -0.008943  0.014144
b -0.020161  1.059352 -0.008543 -0.024738  0.009826
c  0.059277 -0.008543  1.010670 -0.001486 -0.000271
d -0.008943 -0.024738 -0.001486  0.921297 -0.013692
e  0.014144  0.009826 -0.000271 -0.013692  0.977795
```

Minimum number of periods

This method also supports an optional `min_periods` keyword that specifies the required minimum number of non-NA observations for each column pair in order to have a valid result:

```

>>> np.random.seed(42)
>>> df = pd.DataFrame(np.random.randn(20, 3),
...                   columns=['a', 'b', 'c'])
>>> df.loc[df.index[:5], 'a'] = np.nan
>>> df.loc[df.index[5:10], 'b'] = np.nan
>>> df.cov(min_periods=12)

```

| | a | b | c |
|---|-----------|----------|-----------|
| a | 0.316741 | NaN | -0.150812 |
| b | NaN | 1.248003 | 0.191417 |
| c | -0.150812 | 0.191417 | 0.895202 |

pandas.DataFrame.cummax

`DataFrame.cummax`(*axis=None, skipna=True, *args, **kwargs*)

Return cumulative maximum over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative maximum.

Parameters

axis [{0 or 'index', 1 or 'columns'}, default 0] The index or the name of the axis. 0 is equivalent to None or 'index'.

skipna [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

***args, **kwargs** Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

Series or DataFrame Return cumulative maximum of Series or DataFrame.

See also:

core.window.Expanding.max Similar functionality but ignores NaN values.

DataFrame.max Return the maximum over DataFrame axis.

DataFrame.cummax Return cumulative maximum over DataFrame axis.

DataFrame.cummin Return cumulative minimum over DataFrame axis.

DataFrame.cumsum Return cumulative sum over DataFrame axis.

DataFrame.cumprod Return cumulative product over DataFrame axis.

Examples

Series

```
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0    2.0
1    NaN
2    5.0
3   -1.0
4    0.0
dtype: float64
```

By default, NA values are ignored.

```
>>> s.cummax()
0    2.0
1    NaN
2    5.0
3    5.0
4    5.0
dtype: float64
```

To include NA values in the operation, use `skipna=False`

```
>>> s.cummax(skipna=False)
0    2.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

DataFrame

```
>>> df = pd.DataFrame([[2.0, 1.0],
...                   [3.0, np.nan],
...                   [1.0, 0.0]],
...                   columns=list('AB'))
>>> df
   A    B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```

By default, iterates over rows and finds the maximum in each column. This is equivalent to `axis=None` or `axis='index'`.

```
>>> df.cummax()
   A    B
0  2.0  1.0
1  3.0  NaN
2  3.0  1.0
```

To iterate over columns and find the maximum in each row, use `axis=1`

```
>>> df.cummax(axis=1)
   A    B
0  2.0  2.0
1  3.0  NaN
2  1.0  1.0
```

pandas.DataFrame.cummin

`DataFrame.cummin`(*axis=None, skipna=True, *args, **kwargs*)

Return cumulative minimum over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative minimum.

Parameters

axis [{0 or 'index', 1 or 'columns'}, default 0] The index or the name of the axis. 0 is equivalent to None or 'index'.

skipna [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

***args, **kwargs** Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

Series or DataFrame Return cumulative minimum of Series or DataFrame.

See also:

core.window.Expanding.min Similar functionality but ignores NaN values.

DataFrame.min Return the minimum over DataFrame axis.

DataFrame.cummax Return cumulative maximum over DataFrame axis.

DataFrame.cummin Return cumulative minimum over DataFrame axis.

DataFrame.cumsum Return cumulative sum over DataFrame axis.

DataFrame.cumprod Return cumulative product over DataFrame axis.

Examples

Series

```
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0    2.0
1    NaN
2    5.0
3   -1.0
4    0.0
dtype: float64
```

By default, NA values are ignored.

```
>>> s.cummin()
0    2.0
1    NaN
2    2.0
3   -1.0
4   -1.0
dtype: float64
```

To include NA values in the operation, use `skipna=False`

```
>>> s.cummin(skipna=False)
0    2.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

DataFrame

```
>>> df = pd.DataFrame([[2.0, 1.0],
...                   [3.0, np.nan],
...                   [1.0, 0.0]],
...                   columns=list('AB'))
>>> df
   A    B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```

By default, iterates over rows and finds the minimum in each column. This is equivalent to `axis=None` or `axis='index'`.

```
>>> df.cummin()
   A    B
0  2.0  1.0
1  2.0  NaN
2  1.0  0.0
```

To iterate over columns and find the minimum in each row, use `axis=1`

```
>>> df.cummin(axis=1)
   A    B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```

pandas.DataFrame.cumprod

DataFrame.**cumprod**(axis=None, skipna=True, *args, **kwargs)

Return cumulative product over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative product.

Parameters

axis [{0 or 'index', 1 or 'columns'}, default 0] The index or the name of the axis. 0 is equivalent to None or 'index'.

skipna [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

***args, **kwargs** Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

Series or DataFrame Return cumulative product of Series or DataFrame.

See also:

core.window.Expanding.prod Similar functionality but ignores NaN values.

DataFrame.prod Return the product over DataFrame axis.

DataFrame.cummax Return cumulative maximum over DataFrame axis.

DataFrame.cummin Return cumulative minimum over DataFrame axis.

DataFrame.cumsun Return cumulative sum over DataFrame axis.

DataFrame.cumprod Return cumulative product over DataFrame axis.

Examples

Series

```
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0    2.0
1    NaN
2    5.0
3   -1.0
4    0.0
dtype: float64
```

By default, NA values are ignored.

```
>>> s.cumprod()
0    2.0
1    NaN
2   10.0
3  -10.0
4   -0.0
dtype: float64
```

To include NA values in the operation, use `skipna=False`

```
>>> s.cumprod(skipna=False)
0    2.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

DataFrame

```
>>> df = pd.DataFrame([[2.0, 1.0],
...                   [3.0, np.nan],
...                   [1.0, 0.0]],
...                   columns=list('AB'))
>>> df
   A    B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```

By default, iterates over rows and finds the product in each column. This is equivalent to `axis=None` or `axis='index'`.

```
>>> df.cumprod()
   A    B
0  2.0  1.0
1  6.0  NaN
2  6.0  0.0
```

To iterate over columns and find the product in each row, use `axis=1`

```
>>> df.cumprod(axis=1)
   A    B
0  2.0  2.0
1  3.0  NaN
2  1.0  0.0
```

pandas.DataFrame.cumsum

`DataFrame.cumsum(axis=None, skipna=True, *args, **kwargs)`

Return cumulative sum over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative sum.

Parameters

axis [{0 or 'index', 1 or 'columns'}, default 0] The index or the name of the axis. 0 is equivalent to None or 'index'.

skipna [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

***args, **kwargs** Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

Series or DataFrame Return cumulative sum of Series or DataFrame.

See also:

core.window.Expanding.sum Similar functionality but ignores NaN values.

DataFrame.sum Return the sum over DataFrame axis.

DataFrame.cummax Return cumulative maximum over DataFrame axis.

DataFrame.cummin Return cumulative minimum over DataFrame axis.

DataFrame.cumsum Return cumulative sum over DataFrame axis.

DataFrame.cumprod Return cumulative product over DataFrame axis.

Examples

Series

```
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0    2.0
1    NaN
2    5.0
3   -1.0
4    0.0
dtype: float64
```

By default, NA values are ignored.

```
>>> s.cumsum()
0    2.0
1    NaN
2    7.0
3    6.0
4    6.0
dtype: float64
```

To include NA values in the operation, use `skipna=False`

```
>>> s.cumsum(skipna=False)
0    2.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

DataFrame

```
>>> df = pd.DataFrame([[2.0, 1.0],
...                    [3.0, np.nan],
...                    [1.0, 0.0]],
...                    columns=list('AB'))
>>> df
```

(continues on next page)

(continued from previous page)

```

      A    B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0

```

By default, iterates over rows and finds the sum in each column. This is equivalent to `axis=None` or `axis='index'`.

```

>>> df.cumsum()
      A    B
0  2.0  1.0
1  5.0  NaN
2  6.0  1.0

```

To iterate over columns and find the sum in each row, use `axis=1`

```

>>> df.cumsum(axis=1)
      A    B
0  2.0  3.0
1  3.0  NaN
2  1.0  1.0

```

pandas.DataFrame.describe

DataFrame.describe(*percentiles=None, include=None, exclude=None, datetime_is_numeric=False*)
Generate descriptive statistics.

Descriptive statistics include those that summarize the central tendency, dispersion and shape of a dataset's distribution, excluding NaN values.

Analyzes both numeric and object series, as well as DataFrame column sets of mixed data types. The output will vary depending on what is provided. Refer to the notes below for more detail.

Parameters

percentiles [list-like of numbers, optional] The percentiles to include in the output. All should fall between 0 and 1. The default is `[.25, .5, .75]`, which returns the 25th, 50th, and 75th percentiles.

include ['all', list-like of dtypes or None (default), optional] A white list of data types to include in the result. Ignored for `Series`. Here are the options:

- 'all' : All columns of the input will be included in the output.
- A list-like of dtypes : Limits the results to the provided data types. To limit the result to numeric types submit `numpy.number`. To limit it instead to object columns submit the `numpy.object` data type. Strings can also be used in the style of `select_dtypes` (e.g. `df.describe(include=['O'])`). To select pandas categorical columns, use 'category'
- None (default) : The result will include all numeric columns.

exclude [list-like of dtypes or None (default), optional,] A black list of data types to omit from the result. Ignored for `Series`. Here are the options:

- A list-like of dtypes : Excludes the provided data types from the result. To exclude numeric types submit `numpy.number`. To exclude object columns

submit the data type `numpy.object`. Strings can also be used in the style of `select_dtypes` (e.g. `df.describe(include=['O'])`). To exclude pandas categorical columns, use `'category'`

- `None` (default) : The result will exclude nothing.

`datetime_is_numeric` [bool, default False] Whether to treat datetime dtypes as numeric. This affects statistics calculated for the column. For DataFrame input, this also controls whether datetime columns are included by default.

New in version 1.1.0.

Returns

Series or DataFrame Summary statistics of the Series or Dataframe provided.

See also:

`DataFrame.count` Count number of non-NA/null observations.

`DataFrame.max` Maximum of the values in the object.

`DataFrame.min` Minimum of the values in the object.

`DataFrame.mean` Mean of the values.

`DataFrame.std` Standard deviation of the observations.

`DataFrame.select_dtypes` Subset of a DataFrame including/excluding columns based on their dtype.

Notes

For numeric data, the result's index will include `count`, `mean`, `std`, `min`, `max` as well as `lower`, `50` and `upper` percentiles. By default the lower percentile is 25 and the upper percentile is 75. The `50` percentile is the same as the median.

For object data (e.g. strings or timestamps), the result's index will include `count`, `unique`, `top`, and `freq`. The `top` is the most common value. The `freq` is the most common value's frequency. Timestamps also include the `first` and `last` items.

If multiple object values have the highest count, then the `count` and `top` results will be arbitrarily chosen from among those with the highest count.

For mixed data types provided via a `DataFrame`, the default is to return only an analysis of numeric columns. If the dataframe consists only of object and categorical data without any numeric columns, the default is to return an analysis of both the object and categorical columns. If `include='all'` is provided as an option, the result will include a union of attributes of each type.

The `include` and `exclude` parameters can be used to limit which columns in a `DataFrame` are analyzed for the output. The parameters are ignored when analyzing a `Series`.

Examples

Describing a numeric Series.

```
>>> s = pd.Series([1, 2, 3])
>>> s.describe()
count      3.0
mean       2.0
std        1.0
min        1.0
25%        1.5
50%        2.0
75%        2.5
max        3.0
dtype: float64
```

Describing a categorical Series.

```
>>> s = pd.Series(['a', 'a', 'b', 'c'])
>>> s.describe()
count      4
unique     3
top        a
freq       2
dtype: object
```

Describing a timestamp Series.

```
>>> s = pd.Series([
...     np.datetime64("2000-01-01"),
...     np.datetime64("2010-01-01"),
...     np.datetime64("2010-01-01")
... ])
>>> s.describe(datetime_is_numeric=True)
count      3
mean       2006-09-01 08:00:00
min        2000-01-01 00:00:00
25%        2004-12-31 12:00:00
50%        2010-01-01 00:00:00
75%        2010-01-01 00:00:00
max        2010-01-01 00:00:00
dtype: object
```

Describing a DataFrame. By default only numeric fields are returned.

```
>>> df = pd.DataFrame({'categorical': pd.Categorical(['d', 'e', 'f']),
...                    'numeric': [1, 2, 3],
...                    'object': ['a', 'b', 'c']
...                    })
>>> df.describe()
           numeric
count          3.0
mean           2.0
std            1.0
```

(continues on next page)

(continued from previous page)

| | |
|-----|-----|
| min | 1.0 |
| 25% | 1.5 |
| 50% | 2.0 |
| 75% | 2.5 |
| max | 3.0 |

Describing all columns of a DataFrame regardless of data type.

```
>>> df.describe(include='all')
      categorical  numeric  object
count           3        3.0      3
unique           3        NaN      3
top              f        NaN      a
freq            1        NaN      1
mean            NaN        2.0     NaN
std             NaN        1.0     NaN

50%            NaN        2.0     NaN
75%            NaN        2.5     NaN
max            NaN        3.0     NaN
```

Describing a column from a DataFrame by accessing it as an attribute.

```
>>> df.numeric.describe()
count    3.0
mean     2.0
std      1.0
min      1.0
25%     1.5
50%     2.0
75%     2.5
max      3.0
Name: numeric, dtype: float64
```

Including only numeric columns in a DataFrame description.

```
>>> df.describe(include=[np.number])
      numeric
count     3.0
mean     2.0
std      1.0
min      1.0
25%     1.5
50%     2.0
75%     2.5
max      3.0
```

Including only string columns in a DataFrame description.

```
>>> df.describe(include=[object])
      object
count     3
```

(continues on next page)

(continued from previous page)

| | |
|--------|---|
| unique | 3 |
| top | a |
| freq | 1 |

Including only categorical columns from a DataFrame description.

```
>>> df.describe(include=['category'])
      categorical
count          3
unique          3
top            d
freq           1
```

Excluding numeric columns from a DataFrame description.

```
>>> df.describe(exclude=[np.number])
      categorical object
count          3      3
unique          3      3
top            f      a
freq           1      1
```

Excluding object columns from a DataFrame description.

```
>>> df.describe(exclude=[object])
      categorical  numeric
count           3      3.0
unique          3      NaN

50%            NaN      2.0
75%            NaN      2.5
max            NaN      3.0
```

pandas.DataFrame.diff

`DataFrame.diff(periods=1, axis=0)`

First discrete difference of element.

Calculates the difference of a Dataframe element compared with another element in the Dataframe (default is element in previous row).

Parameters

periods [int, default 1] Periods to shift for calculating difference, accepts negative values.

axis [{0 or 'index', 1 or 'columns'}, default 0] Take difference over rows (0) or columns (1).

Returns

Dataframe First differences of the Series.

See also:

Dataframe.pct_change Percent change over given number of periods.

Dataframe.shift Shift index by desired number of periods with an optional time freq.

Series.diff First discrete difference of object.

Notes

For boolean dtypes, this uses `operator.xor()` rather than `operator.sub()`. The result is calculated according to current dtype in Dataframe, however dtype of the result is always float64.

Examples

Difference with previous row

```
>>> df = pd.DataFrame({'a': [1, 2, 3, 4, 5, 6],
...                    'b': [1, 1, 2, 3, 5, 8],
...                    'c': [1, 4, 9, 16, 25, 36]})
>>> df
   a  b  c
0  1  1  1
1  2  1  4
2  3  2  9
3  4  3 16
4  5  5 25
5  6  8 36
```

```
>>> df.diff()
   a  b  c
0 NaN NaN NaN
1 1.0 0.0 3.0
2 1.0 1.0 5.0
3 1.0 1.0 7.0
4 1.0 2.0 9.0
5 1.0 3.0 11.0
```

Difference with previous column

```
>>> df.diff(axis=1)
   a  b  c
0 NaN 0  0
1 NaN -1  3
2 NaN -1  7
3 NaN -1 13
4 NaN  0 20
5 NaN  2 28
```

Difference with 3rd previous row

```
>>> df.diff(periods=3)
      a    b    c
0  NaN  NaN  NaN
1  NaN  NaN  NaN
2  NaN  NaN  NaN
3  3.0  2.0  15.0
4  3.0  4.0  21.0
5  3.0  6.0  27.0
```

Difference with following row

```
>>> df.diff(periods=-1)
      a    b    c
0 -1.0  0.0 -3.0
1 -1.0 -1.0 -5.0
2 -1.0 -1.0 -7.0
3 -1.0 -2.0 -9.0
4 -1.0 -3.0 -11.0
5  NaN  NaN  NaN
```

Overflow in input dtype

```
>>> df = pd.DataFrame({'a': [1, 0]}, dtype=np.uint8)
>>> df.diff()
      a
0  NaN
1 255.0
```

pandas.DataFrame.div

`DataFrame.div(other, axis='columns', level=None, fill_value=None)`

Get Floating division of dataframe and other, element-wise (binary operator *truediv*).

Equivalent to `dataframe / other`, but with support to substitute a `fill_value` for missing data in one of the inputs. With reverse version, *rtruediv*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

See also:*DataFrame.add* Add DataFrames.*DataFrame.sub* Subtract DataFrames.*DataFrame.mul* Multiply DataFrames.*DataFrame.div* Divide DataFrames (float division).*DataFrame.truediv* Divide DataFrames (float division).*DataFrame.floordiv* Divide DataFrames (integer division).*DataFrame.mod* Calculate modulo (remainder after division).*DataFrame.pow* Calculate exponential power.**Notes**

Mismatched indices will be unioned together.

Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                    index=['circle', 'triangle', 'rectangle'])
>>> df
```

| | angles | degrees |
|-----------|--------|---------|
| circle | 0 | 360 |
| triangle | 3 | 180 |
| rectangle | 4 | 360 |

Add a scalar with operator version which return the same results.

```
>>> df + 1
```

| | angles | degrees |
|-----------|--------|---------|
| circle | 1 | 361 |
| triangle | 4 | 181 |
| rectangle | 5 | 361 |

```
>>> df.add(1)
```

| | angles | degrees |
|-----------|--------|---------|
| circle | 1 | 361 |
| triangle | 4 | 181 |
| rectangle | 5 | 361 |

Divide by constant with reverse version.

```
>>> df.div(10)
```

| | angles | degrees |
|-----------|--------|---------|
| circle | 0.0 | 36.0 |
| triangle | 0.3 | 18.0 |
| rectangle | 0.4 | 36.0 |

```
>>> df.rdiv(10)
      angles  degrees
circle      inf  0.027778
triangle  3.333333  0.055556
rectangle  2.500000  0.027778
```

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
      angles  degrees
circle      -1    358
triangle     2    178
rectangle     3    358
```

```
>>> df.sub([1, 2], axis='columns')
      angles  degrees
circle      -1    358
triangle     2    178
rectangle     3    358
```

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...        axis='index')
      angles  degrees
circle      -1    359
triangle     2    179
rectangle     3    359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                       index=['circle', 'triangle', 'rectangle'])
>>> other
      angles
circle      0
triangle     3
rectangle     4
```

```
>>> df * other
      angles  degrees
circle      0     NaN
triangle     9     NaN
rectangle   16     NaN
```

```
>>> df.mul(other, fill_value=0)
      angles  degrees
circle      0     0.0
triangle     9     0.0
rectangle   16     0.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                               'degrees': [360, 180, 360, 360, 540, 720]},
...                               index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                       ['circle', 'triangle', 'rectangle',
...                                       'square', 'pentagon', 'hexagon']])
```

```
>>> df_multindex
```

| | angles | degrees |
|-----------|--------|---------|
| A circle | 0 | 360 |
| triangle | 3 | 180 |
| rectangle | 4 | 360 |
| B square | 4 | 360 |
| pentagon | 5 | 540 |
| hexagon | 6 | 720 |

```
>>> df.div(df_multindex, level=1, fill_value=0)
```

| | angles | degrees |
|-----------|--------|---------|
| A circle | NaN | 1.0 |
| triangle | 1.0 | 1.0 |
| rectangle | 1.0 | 1.0 |
| B square | 0.0 | 0.0 |
| pentagon | 0.0 | 0.0 |
| hexagon | 0.0 | 0.0 |

pandas.DataFrame.divide

DataFrame.divide(*other*, *axis*='columns', *level*=None, *fill_value*=None)

Get Floating division of dataframe and other, element-wise (binary operator *truediv*).

Equivalent to `dataframe / other`, but with support to substitute a `fill_value` for missing data in one of the inputs. With reverse version, *rtruediv*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: +, -, *, /, //, %, **.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

See also:

[*DataFrame.add*](#) Add DataFrames.

DataFrame.sub Subtract DataFrames.

DataFrame.mul Multiply DataFrames.

DataFrame.div Divide DataFrames (float division).

  hexagon    0.0     0.0

```

pandas.DataFrame.dot

DataFrame.dot(*other*)

Compute the matrix multiplication between the DataFrame and other.

This method computes the matrix product between the DataFrame and the values of an other Series, DataFrame or a numpy array.

It can also be called using `self @ other` in Python ≥ 3.5 .

Parameters

other [Series, DataFrame or array-like] The other object to compute the matrix product with.

Returns

Series or DataFrame If other is a Series, return the matrix product between self and other as a Series. If other is a DataFrame or a numpy.array, return the matrix product of self and other in a DataFrame of a np.array.

See also:

[Series.dot](#) Similar method for Series.

Notes

The dimensions of DataFrame and other must be compatible in order to compute the matrix multiplication. In addition, the column names of DataFrame and the index of other must contain the same values, as they will be aligned prior to the multiplication.

The dot method for Series computes the inner product, instead of the matrix product here.

Examples

Here we multiply a DataFrame with a Series.

```
>>> df = pd.DataFrame([[0, 1, -2, -1], [1, 1, 1, 1]])
>>> s = pd.Series([1, 1, 2, 1])
>>> df.dot(s)
0    -4
1     5
dtype: int64
```

Here we multiply a DataFrame with another DataFrame.

```
>>> other = pd.DataFrame([[0, 1], [1, 2], [-1, -1], [2, 0]])
>>> df.dot(other)
0    1
0    1  4
1    2  2
```

Note that the dot method give the same result as @

```
>>> df @ other
0    1
0    1  4
1    2  2
```

The dot method works also if other is an np.array.

```
>>> arr = np.array([[0, 1], [1, 2], [-1, -1], [2, 0]])
>>> df.dot(arr)
0    1
0    1  4
1    2  2
```

Note how shuffling of the objects does not change the result.

```
>>> s2 = s.reindex([1, 0, 2, 3])
>>> df.dot(s2)
0    -4
1     5
dtype: int64
```

pandas.DataFrame.drop

`DataFrame.drop(labels=None, axis=0, index=None, columns=None, level=None, inplace=False, errors='raise')`

Drop specified labels from rows or columns.

Remove rows or columns by specifying label names and corresponding axis, or by specifying directly index or column names. When using a multi-index, labels on different levels can be removed by specifying the level. See the *user guide* <*advanced.shown_levels*> for more information about the now unused levels.

Parameters

labels [single label or list-like] Index or column labels to drop.

axis [{0 or 'index', 1 or 'columns'}, default 0] Whether to drop labels from the index (0 or 'index') or columns (1 or 'columns').

index [single label or list-like] Alternative to specifying axis (`labels`, `axis=0` is equivalent to `index=labels`).

columns [single label or list-like] Alternative to specifying axis (`labels`, `axis=1` is equivalent to `columns=labels`).

level [int or level name, optional] For MultiIndex, level from which the labels will be removed.

inplace [bool, default False] If False, return a copy. Otherwise, do operation inplace and return None.

errors [{'ignore', 'raise'}, default 'raise'] If 'ignore', suppress error and only existing labels are dropped.

Returns

DataFrame or None DataFrame without the removed index or column labels or None if `inplace=True`.

Raises

KeyError If any of the labels is not found in the selected axis.

See also:

[*DataFrame.loc*](#) Label-location based indexer for selection by label.

[*DataFrame.dropna*](#) Return DataFrame with labels on given axis omitted where (all or any) data are missing.

[*DataFrame.drop_duplicates*](#) Return DataFrame with duplicate rows removed, optionally only considering certain columns.

[*Series.drop*](#) Return Series with specified index labels removed.

Examples

```
>>> df = pd.DataFrame(np.arange(12).reshape(3, 4),
...                    columns=['A', 'B', 'C', 'D'])
>>> df
   A  B  C  D
0  0  1  2  3
1  4  5  6  7
2  8  9 10 11
```

Drop columns

```
>>> df.drop(['B', 'C'], axis=1)
   A  D
0  0  3
1  4  7
2  8 11
```

```
>>> df.drop(columns=['B', 'C'])
   A  D
0  0  3
1  4  7
2  8 11
```

Drop a row by index

```
>>> df.drop([0, 1])
   A  B  C  D
2  8  9 10 11
```

Drop columns and/or rows of MultiIndex DataFrame

```
>>> midx = pd.MultiIndex(levels=[['lama', 'cow', 'falcon'],
...                             ['speed', 'weight', 'length']],
...                      codes=[[0, 0, 0, 1, 1, 1, 2, 2, 2],
...                             [0, 1, 2, 0, 1, 2, 0, 1, 2]])
>>> df = pd.DataFrame(index=midx, columns=['big', 'small'],
...                   data=[[45, 30], [200, 100], [1.5, 1], [30, 20],
...                          [250, 150], [1.5, 0.8], [320, 250],
...                          [1, 0.8], [0.3, 0.2]])
>>> df
           big  small
lama  speed  45.0  30.0
      weight 200.0 100.0
      length  1.5   1.0
cow    speed  30.0  20.0
      weight 250.0 150.0
      length  1.5   0.8
falcon speed 320.0 250.0
      weight  1.0   0.8
      length  0.3   0.2
```

```
>>> df.drop(index='cow', columns='small')
           big
lama  speed  45.0
      weight 200.0
      length  1.5
falcon speed 320.0
      weight  1.0
      length  0.3
```

```
>>> df.drop(index='length', level=1)
           big    small
lama  speed  45.0   30.0
      weight 200.0  100.0
cow    speed  30.0   20.0
      weight 250.0  150.0
falcon speed 320.0  250.0
      weight  1.0   0.8
```

pandas.DataFrame.drop_duplicates

DataFrame.drop_duplicates(*subset=None, keep='first', inplace=False, ignore_index=False*)

Return DataFrame with duplicate rows removed.

Considering certain columns is optional. Indexes, including time indexes are ignored.

Parameters

subset [column label or sequence of labels, optional] Only consider certain columns for identifying duplicates, by default use all of the columns.

keep [{ 'first', 'last', False }, default 'first'] Determines which duplicates (if any) to keep. - **first** : Drop duplicates except for the first occurrence. - **last** : Drop duplicates except for the last occurrence. - **False** : Drop all duplicates.

inplace [bool, default False] Whether to drop duplicates in place or to return a copy.

ignore_index [bool, default False] If True, the resulting axis will be labeled 0, 1, ..., n - 1.

New in version 1.0.0.

Returns

DataFrame or None DataFrame with duplicates removed or None if **inplace=True**.

See also:

[**DataFrame.value_counts**](#) Count unique combinations of columns.

Examples

Consider dataset containing ramen rating.

```
>>> df = pd.DataFrame({
...     'brand': ['Yum Yum', 'Yum Yum', 'Indomie', 'Indomie', 'Indomie'],
...     'style': ['cup', 'cup', 'cup', 'pack', 'pack'],
...     'rating': [4, 4, 3.5, 15, 5]
... })
>>> df
   brand style  rating
0  Yum Yum  cup    4.0
1  Yum Yum  cup    4.0
2  Indomie  cup    3.5
3  Indomie  pack   15.0
4  Indomie  pack    5.0
```

By default, it removes duplicate rows based on all columns.

```
>>> df.drop_duplicates()
   brand style  rating
0  Yum Yum  cup    4.0
2  Indomie  cup    3.5
3  Indomie  pack   15.0
4  Indomie  pack    5.0
```

To remove duplicates on specific column(s), use `subset`.

```
>>> df.drop_duplicates(subset=['brand'])
   brand style  rating
0  Yum Yum  cup    4.0
2  Indomie  cup    3.5
```

To remove duplicates and keep last occurrences, use `keep`.

```
>>> df.drop_duplicates(subset=['brand', 'style'], keep='last')
   brand style  rating
1  Yum Yum  cup    4.0
2  Indomie  cup    3.5
4  Indomie  pack    5.0
```

pandas.DataFrame.droplevel

`DataFrame.droplevel(level, axis=0)`

Return Series/DataFrame with requested index / column level(s) removed.

Parameters

level [int, str, or list-like] If a string is given, must be the name of a level. If list-like, elements must be names or positional indexes of levels.

axis [{0 or 'index', 1 or 'columns'}, default 0] Axis along which the level(s) is removed:

- 0 or 'index': remove level(s) in column.
- 1 or 'columns': remove level(s) in row.

Returns

Series/DataFrame Series/DataFrame with requested index / column level(s) removed.

Examples

```
>>> df = pd.DataFrame([
...     [1, 2, 3, 4],
...     [5, 6, 7, 8],
...     [9, 10, 11, 12]
... ]).set_index([0, 1]).rename_axis(['a', 'b'])
```

```
>>> df.columns = pd.MultiIndex.from_tuples([
...     ('c', 'e'), ('d', 'f')
... ], names=['level_1', 'level_2'])
```

```
>>> df
level_1  c  d
level_2  e  f
a b
1 2      3  4
5 6      7  8
9 10     11 12
```

```
>>> df.droplevel('a')
level_1  c  d
level_2  e  f
b
2      3  4
6      7  8
10     11 12
```

```
>>> df.droplevel('level_2', axis=1)
level_1  c  d
a b
1 2      3  4
5 6      7  8
9 10     11 12
```

pandas.DataFrame.dropna

DataFrame.dropna(*axis=0*, *how='any'*, *thresh=None*, *subset=None*, *inplace=False*)

Remove missing values.

See the [User Guide](#) for more on which values are considered missing, and how to work with missing data.

Parameters

axis [{0 or 'index', 1 or 'columns'}, default 0] Determine if rows or columns which contain missing values are removed.

- 0, or 'index' : Drop rows which contain missing values.

- 1, or 'columns' : Drop columns which contain missing value.

Changed in version 1.0.0: Pass tuple or list to drop on multiple axes. Only a single axis is allowed.

how [{ 'any', 'all' }, default 'any'] Determine if row or column is removed from DataFrame, when we have at least one NA or all NA.

- 'any' : If any NA values are present, drop that row or column.
- 'all' : If all values are NA, drop that row or column.

thresh [int, optional] Require that many non-NA values.

subset [array-like, optional] Labels along other axis to consider, e.g. if you are dropping rows these would be a list of columns to include.

inplace [bool, default False] If True, do operation inplace and return None.

Returns

DataFrame or None DataFrame with NA entries dropped from it or None if `inplace=True`.

See also:

[*DataFrame.isna*](#) Indicate missing values.

[*DataFrame.notna*](#) Indicate existing (non-missing) values.

[*DataFrame.fillna*](#) Replace missing values.

[*Series.dropna*](#) Drop missing values.

[*Index.dropna*](#) Drop missing indices.

Examples

```
>>> df = pd.DataFrame({"name": ['Alfred', 'Batman', 'Catwoman'],
...                    "toy": [np.nan, 'Batmobile', 'Bullwhip'],
...                    "born": [pd.NaT, pd.Timestamp("1940-04-25"),
...                              pd.NaT]})
>>> df
```

| | name | toy | born |
|---|----------|-----------|------------|
| 0 | Alfred | NaN | NaT |
| 1 | Batman | Batmobile | 1940-04-25 |
| 2 | Catwoman | Bullwhip | NaT |

Drop the rows where at least one element is missing.

```
>>> df.dropna()
```

| | name | toy | born |
|---|--------|-----------|------------|
| 1 | Batman | Batmobile | 1940-04-25 |

Drop the columns where at least one element is missing.

```
>>> df.dropna(axis='columns')
```

| | name |
|---|--------|
| 0 | Alfred |

(continues on next page)

(continued from previous page)

```
1  Batman
2  Catwoman
```

Drop the rows where all elements are missing.

```
>>> df.dropna(how='all')
   name      toy      born
0  Alfred    NaN      NaT
1  Batman  Batmobile  1940-04-25
2  Catwoman  Bullwhip      NaT
```

Keep only the rows with at least 2 non-NA values.

```
>>> df.dropna(thresh=2)
   name      toy      born
1  Batman  Batmobile  1940-04-25
2  Catwoman  Bullwhip      NaT
```

Define in which columns to look for missing values.

```
>>> df.dropna(subset=['name', 'toy'])
   name      toy      born
1  Batman  Batmobile  1940-04-25
2  Catwoman  Bullwhip      NaT
```

Keep the DataFrame with valid entries in the same variable.

```
>>> df.dropna(inplace=True)
>>> df
   name      toy      born
1  Batman  Batmobile  1940-04-25
```

pandas.DataFrame.duplicated

`DataFrame.duplicated(subset=None, keep='first')`

Return boolean Series denoting duplicate rows.

Considering certain columns is optional.

Parameters

subset [column label or sequence of labels, optional] Only consider certain columns for identifying duplicates, by default use all of the columns.

keep [{ 'first', 'last', False }, default 'first'] Determines which duplicates (if any) to mark.

- **first** : Mark duplicates as True except for the first occurrence.
- **last** : Mark duplicates as True except for the last occurrence.
- **False** : Mark all duplicates as True.

Returns

Series Boolean series for each duplicated rows.

See also:

Index.duplicated Equivalent method on index.

Series.duplicated Equivalent method on Series.

Series.drop_duplicates Remove duplicate values from Series.

DataFrame.drop_duplicates Remove duplicate values from DataFrame.

Examples

Consider dataset containing ramen rating.

```
>>> df = pd.DataFrame({
...     'brand': ['Yum Yum', 'Yum Yum', 'Indomie', 'Indomie', 'Indomie'],
...     'style': ['cup', 'cup', 'cup', 'pack', 'pack'],
...     'rating': [4, 4, 3.5, 15, 5]
... })
>>> df
   brand style  rating
0  Yum Yum  cup     4.0
1  Yum Yum  cup     4.0
2  Indomie  cup     3.5
3  Indomie  pack    15.0
4  Indomie  pack     5.0
```

By default, for each set of duplicated values, the first occurrence is set on False and all others on True.

```
>>> df.duplicated()
0    False
1     True
2    False
3    False
4    False
dtype: bool
```

By using 'last', the last occurrence of each set of duplicated values is set on False and all others on True.

```
>>> df.duplicated(keep='last')
0     True
1    False
2    False
3    False
4    False
dtype: bool
```

By setting keep on False, all duplicates are True.

```
>>> df.duplicated(keep=False)
0     True
1     True
2    False
3    False
4    False
dtype: bool
```

To find duplicates on specific column(s), use subset.

```
>>> df.duplicated(subset=['brand'])
0    False
1     True
2    False
3     True
4     True
dtype: bool
```

pandas.DataFrame.eq

`DataFrame.eq`(*other*, *axis*='columns', *level*=None)

Get Equal to of dataframe and other, element-wise (binary operator *eq*).

Among flexible wrappers (*eq*, *ne*, *le*, *lt*, *ge*, *gt*) to comparison operators.

Equivalent to `==`, `!=`, `<=`, `<`, `>=`, `>` with support to choose axis (rows or columns) and level for comparison.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}, default 'columns'] Whether to compare by the index (0 or 'index') or columns (1 or 'columns').

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

DataFrame of bool Result of the comparison.

See also:

[*DataFrame.eq*](#) Compare DataFrames for equality elementwise.

[*DataFrame.ne*](#) Compare DataFrames for inequality elementwise.

[*DataFrame.le*](#) Compare DataFrames for less than inequality or equality elementwise.

[*DataFrame.lt*](#) Compare DataFrames for strictly less than inequality elementwise.

[*DataFrame.ge*](#) Compare DataFrames for greater than inequality or equality elementwise.

[*DataFrame.gt*](#) Compare DataFrames for strictly greater than inequality elementwise.

Notes

Mismatched indices will be unioned together. *NaN* values are considered different (i.e. *NaN != NaN*).

Examples

```
>>> df = pd.DataFrame({'cost': [250, 150, 100],
...                    'revenue': [100, 250, 300]},
...                    index=['A', 'B', 'C'])
>>> df
   cost  revenue
A   250     100
B   150     250
C   100     300
```

Comparison with a scalar, using either the operator or method:

```
>>> df == 100
   cost  revenue
A  False     True
B  False     False
C   True     False
```

```
>>> df.eq(100)
   cost  revenue
A  False     True
B  False     False
C   True     False
```

When *other* is a *Series*, the columns of a DataFrame are aligned with the index of *other* and broadcast:

```
>>> df != pd.Series([100, 250], index=["cost", "revenue"])
   cost  revenue
A   True     True
B   True     False
C  False     True
```

Use the method to control the broadcast axis:

```
>>> df.ne(pd.Series([100, 300], index=["A", "D"]), axis='index')
   cost  revenue
A   True     False
B   True     True
C   True     True
D   True     True
```

When comparing to an arbitrary sequence, the number of columns must match the number elements in *other*:

```
>>> df == [250, 100]
   cost  revenue
A   True     True
B  False     False
C  False     False
```

Use the method to control the axis:

```
>>> df.eq([250, 250, 100], axis='index')
      cost  revenue
A   True   False
B   False  True
C   True   False
```

Compare to a DataFrame of different shape.

```
>>> other = pd.DataFrame({'revenue': [300, 250, 100, 150]},
...                       index=['A', 'B', 'C', 'D'])
>>> other
      revenue
A         300
B         250
C         100
D         150
```

```
>>> df.gt(other)
      cost  revenue
A   False  False
B   False  False
C   False  True
D   False  False
```

Compare to a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'cost': [250, 150, 100, 150, 300, 220],
...                              'revenue': [100, 250, 300, 200, 175, 225]},
...                              index=[['Q1', 'Q1', 'Q1', 'Q2', 'Q2', 'Q2'],
...                                      ['A', 'B', 'C', 'A', 'B', 'C']])
>>> df_multindex
      cost  revenue
Q1 A   250     100
   B   150     250
   C   100     300
Q2 A   150     200
   B   300     175
   C   220     225
```

```
>>> df.le(df_multindex, level=1)
      cost  revenue
Q1 A   True     True
   B   True     True
   C   True     True
Q2 A   False    True
   B   True     False
   C   True     False
```

pandas.DataFrame.equals

`DataFrame.equals` (*other*)

Test whether two objects contain the same elements.

This function allows two Series or DataFrames to be compared against each other to see if they have the same shape and elements. NaNs in the same location are considered equal.

The row/column index do not need to have the same type, as long as the values are considered equal. Corresponding columns must be of the same dtype.

Parameters

other [Series or DataFrame] The other Series or DataFrame to be compared with the first.

Returns

bool True if all elements are the same in both objects, False otherwise.

See also:

Series.eq Compare two Series objects of the same length and return a Series where each element is True if the element in each Series is equal, False otherwise.

DataFrame.eq Compare two DataFrame objects of the same shape and return a DataFrame where each element is True if the respective element in each DataFrame is equal, False otherwise.

testing.assert_series_equal Raises an AssertionError if left and right are not equal. Provides an easy interface to ignore inequality in dtypes, indexes and precision among others.

testing.assert_frame_equal Like `assert_series_equal`, but targets DataFrames.

numpy.array_equal Return True if two arrays have the same shape and elements, False otherwise.

Examples

```
>>> df = pd.DataFrame({'1': [10], '2': [20]})
>>> df
   1  2
0 10 20
```

DataFrames `df` and `exactly_equal` have the same types and values for their elements and column labels, which will return True.

```
>>> exactly_equal = pd.DataFrame({'1': [10], '2': [20]})
>>> exactly_equal
   1  2
0 10 20
>>> df.equals(exactly_equal)
True
```

DataFrames `df` and `different_column_type` have the same element types and values, but have different types for the column labels, which will still return True.

```
>>> different_column_type = pd.DataFrame({'1.0': [10], '2.0': [20]})
>>> different_column_type
  1.0  2.0
```

(continues on next page)

(continued from previous page)

```
0    10    20
>>> df.equals(different_column_type)
True
```

DataFrames `df` and `different_data_type` have different types for the same values for their elements, and will return `False` even though their column labels are the same values and types.

```
>>> different_data_type = pd.DataFrame({1: [10.0], 2: [20.0]})
>>> different_data_type
   1    2
0  10.0 20.0
>>> df.equals(different_data_type)
False
```

pandas.DataFrame.eval

`DataFrame.eval`(*expr*, *inplace=False*, ***kwargs*)

Evaluate a string describing operations on DataFrame columns.

Operates on columns only, not specific rows or elements. This allows *eval* to run arbitrary code, which can make you vulnerable to code injection if you pass user input to this function.

Parameters

expr [str] The expression string to evaluate.

inplace [bool, default False] If the expression contains an assignment, whether to perform the operation inplace and mutate the existing DataFrame. Otherwise, a new DataFrame is returned.

****kwargs** See the documentation for `eval()` for complete details on the keyword arguments accepted by `query()`.

Returns

ndarray, scalar, pandas object, or None The result of the evaluation or `None` if `inplace=True`.

See also:

[`DataFrame.query`](#) Evaluates a boolean expression to query the columns of a frame.

[`DataFrame.assign`](#) Can evaluate an expression or function to create new values for a column.

[`eval`](#) Evaluate a Python expression as a string using various backends.

Notes

For more details see the API documentation for `eval()`. For detailed examples see *enhancing performance with eval*.

Examples

```
>>> df = pd.DataFrame({'A': range(1, 6), 'B': range(10, 0, -2)})
>>> df
   A  B
0  1 10
1  2  8
2  3  6
3  4  4
4  5  2
>>> df.eval('A + B')
0    11
1    10
2     9
3     8
4     7
dtype: int64
```

Assignment is allowed though by default the original DataFrame is not modified.

```
>>> df.eval('C = A + B')
   A  B  C
0  1 10 11
1  2  8 10
2  3  6  9
3  4  4  8
4  5  2  7
>>> df
   A  B
0  1 10
1  2  8
2  3  6
3  4  4
4  5  2
```

Use `inplace=True` to modify the original DataFrame.

```
>>> df.eval('C = A + B', inplace=True)
>>> df
   A  B  C
0  1 10 11
1  2  8 10
2  3  6  9
3  4  4  8
4  5  2  7
```

Multiple columns can be assigned to using multi-line expressions:

```

>>> df.eval(
...     """
...     C = A + B
...     D = A - B
...     """
... )
   A  B  C  D
0  1 10 11 -9
1  2  8 10 -6
2  3  6  9 -3
3  4  4  8  0
4  5  2  7  3

```

pandas.DataFrame.ewm

`DataFrame.ewm`(*com=None, span=None, halflife=None, alpha=None, min_periods=0, adjust=True, ignore_na=False, axis=0, times=None*)

Provide exponential weighted (EW) functions.

Available EW functions: `mean()`, `var()`, `std()`, `corr()`, `cov()`.

Exactly one parameter: `com`, `span`, `halflife`, or `alpha` must be provided.

Parameters

com [float, optional] Specify decay in terms of center of mass, $\alpha = 1/(1 + com)$, for $com \geq 0$.

span [float, optional] Specify decay in terms of span, $\alpha = 2/(span + 1)$, for $span \geq 1$.

halflife [float, str, timedelta, optional] Specify decay in terms of half-life, $\alpha = 1 - \exp(-\ln(2)/halflife)$, for $halflife > 0$.

If `times` is specified, the time unit (str or timedelta) over which an observation decays to half its value. Only applicable to `mean()` and `halflife` value will not apply to the other functions.

New in version 1.1.0.

alpha [float, optional] Specify smoothing factor α directly, $0 < \alpha \leq 1$.

min_periods [int, default 0] Minimum number of observations in window required to have a value (otherwise result is NA).

adjust [bool, default True] Divide by decaying adjustment factor in beginning periods to account for imbalance in relative weightings (viewing EWMA as a moving average).

- When `adjust=True` (default), the EW function is calculated using weights $w_i = (1 - \alpha)^i$. For example, the EW moving average of the series $[x_0, x_1, \dots, x_t]$ would be:

$$y_t = \frac{x_t + (1 - \alpha)x_{t-1} + (1 - \alpha)^2x_{t-2} + \dots + (1 - \alpha)^tx_0}{1 + (1 - \alpha) + (1 - \alpha)^2 + \dots + (1 - \alpha)^t}$$

- When `adjust=False`, the exponentially weighted function is calculated recursively:

$$y_0 = x_0$$

$$y_t = (1 - \alpha)y_{t-1} + \alpha x_t,$$

ignore_na [bool, default False] Ignore missing values when calculating weights; specify True to reproduce pre-0.15.0 behavior.

- When `ignore_na=False` (default), weights are based on absolute positions. For example, the weights of x_0 and x_2 used in calculating the final weighted average of $[x_0, \text{None}, x_2]$ are $(1 - \alpha)^2$ and 1 if `adjust=True`, and $(1 - \alpha)^2$ and α if `adjust=False`.
- When `ignore_na=True` (reproducing pre-0.15.0 behavior), weights are based on relative positions. For example, the weights of x_0 and x_2 used in calculating the final weighted average of $[x_0, \text{None}, x_2]$ are $1 - \alpha$ and 1 if `adjust=True`, and $1 - \alpha$ and α if `adjust=False`.

axis [{0, 1}, default 0] The axis to use. The value 0 identifies the rows, and 1 identifies the columns.

times [str, np.ndarray, Series, default None] New in version 1.1.0.

Times corresponding to the observations. Must be monotonically increasing and `datetime64[ns]` dtype.

If str, the name of the column in the DataFrame representing the times.

If 1-D array like, a sequence with the same shape as the observations.

Only applicable to `mean()`.

Returns

DataFrame A Window sub-classed for the particular operation.

See also:

[*rolling*](#) Provides rolling window calculations.

[*expanding*](#) Provides expanding transformations.

Notes

More details can be found at: [Exponentially weighted windows](#).

Examples

```
>>> df = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]})
>>> df
   B
0  0.0
1  1.0
2  2.0
3  NaN
4  4.0
```

```
>>> df.ewm(com=0.5).mean()
   B
0  0.000000
1  0.750000
2  1.615385
```

(continues on next page)

(continued from previous page)

```
3  1.615385
4  3.670213
```

Specifying times with a timedelta halflife when computing mean.

```
>>> times = ['2020-01-01', '2020-01-03', '2020-01-10', '2020-01-15', '2020-01-
→17']
>>> df.ewm(halflife='4 days', times=pd.DatetimeIndex(times)).mean()
      B
0  0.000000
1  0.585786
2  1.523889
3  1.523889
4  3.233686
```

pandas.DataFrame.expanding

DataFrame.**expanding**(*min_periods=1*, *center=None*, *axis=0*, *method='single'*)

Provide expanding transformations.

Parameters

min_periods [int, default 1] Minimum number of observations in window required to have a value (otherwise result is NA).

center [bool, default False] Set the labels at the center of the window.

axis [int or str, default 0]

method [str { 'single', 'table' }, default 'single'] Execute the rolling operation per single column or row ('single') or over the entire object ('table').

This argument is only implemented when specifying `engine='numba'` in the method call.

New in version 1.3.0.

Returns

a Window sub-classed for the particular operation

See also:

[*rolling*](#) Provides rolling window calculations.

[*ewm*](#) Provides exponential weighted functions.

Notes

By default, the result is set to the right edge of the window. This can be changed to the center of the window by setting `center=True`.

Examples

```
>>> df = pd.DataFrame({"B": [0, 1, 2, np.nan, 4]})
>>> df
   B
0  0.0
1  1.0
2  2.0
3  NaN
4  4.0
```

```
>>> df.expanding(2).sum()
   B
0  NaN
1  1.0
2  3.0
3  3.0
4  7.0
```

pandas.DataFrame.explode

`DataFrame.explode`(*column*, *ignore_index=False*)

Transform each element of a list-like to a row, replicating index values.

New in version 0.25.0.

Parameters

column [str or tuple or list thereof] Column(s) to explode. For multiple columns, specify a non-empty list with each element be str or tuple, and all specified columns their list-like data on same row of the frame must have matching length.

New in version 1.3.0: Multi-column explode

ignore_index [bool, default False] If True, the resulting index will be labeled 0, 1, ..., n - 1.

New in version 1.1.0.

Returns

DataFrame Exploded lists to rows of the subset columns; index will be duplicated for these rows.

Raises

ValueError :

- If columns of the frame are not unique.
- If specified columns to explode is empty list.

- If specified columns to explode have not matching count of elements rowwise in the frame.

See also:

DataFrame.unstack Pivot a level of the (necessarily hierarchical) index labels.

DataFrame.melt Unpivot a DataFrame from wide format to long format.

Series.explode Explode a DataFrame from list-like columns to long format.

Notes

This routine will explode list-likes including lists, tuples, sets, Series, and np.ndarray. The result dtype of the subset rows will be object. Scalars will be returned unchanged, and empty list-likes will result in a np.nan for that row. In addition, the ordering of rows in the output will be non-deterministic when exploding sets.

Examples

```
>>> df = pd.DataFrame({'A': [[0, 1, 2], 'foo', [], [3, 4]],
...                   'B': 1,
...                   'C': [['a', 'b', 'c'], np.nan, [], ['d', 'e']]})
>>> df
```

| | A | B | C |
|---|-----------|---|-----------|
| 0 | [0, 1, 2] | 1 | [a, b, c] |
| 1 | foo | 1 | NaN |
| 2 | [] | 1 | [] |
| 3 | [3, 4] | 1 | [d, e] |

Single-column explode.

```
>>> df.explode('A')
```

| | A | B | C |
|---|-----|---|-----------|
| 0 | 0 | 1 | [a, b, c] |
| 0 | 1 | 1 | [a, b, c] |
| 0 | 2 | 1 | [a, b, c] |
| 1 | foo | 1 | NaN |
| 2 | NaN | 1 | [] |
| 3 | 3 | 1 | [d, e] |
| 3 | 4 | 1 | [d, e] |

Multi-column explode.

```
>>> df.explode(list('AC'))
```

| | A | B | C |
|---|-----|---|-----|
| 0 | 0 | 1 | a |
| 0 | 1 | 1 | b |
| 0 | 2 | 1 | c |
| 1 | foo | 1 | NaN |
| 2 | NaN | 1 | NaN |
| 3 | 3 | 1 | d |
| 3 | 4 | 1 | e |

pandas.DataFrame.ffill

`DataFrame.fffll` (*axis=None, inplace=False, limit=None, downcast=None*)

Synonym for `DataFrame.fillna()` with `method='ffill'`.

Returns

Series/DataFrame or None Object with missing values filled or None if `inplace=True`.

pandas.DataFrame.fillna

`DataFrame.fillna` (*value=None, method=None, axis=None, inplace=False, limit=None, downcast=None*)

Fill NA/NaN values using the specified method.

Parameters

value [scalar, dict, Series, or DataFrame] Value to use to fill holes (e.g. 0), alternately a dict/Series/DataFrame of values specifying which value to use for each index (for a Series) or column (for a DataFrame). Values not in the dict/Series/DataFrame will not be filled. This value cannot be a list.

method [{ 'backfill', 'bfill', 'pad', 'ffill', None }, default None] Method to use for filling holes in reindexed Series `pad / ffill`: propagate last valid observation forward to next valid `backfill / bfill`: use next valid observation to fill gap.

axis [{0 or 'index', 1 or 'columns' }] Axis along which to fill missing values.

inplace [bool, default False] If True, fill in-place. Note: this will modify any other views on this object (e.g., a no-copy slice for a column in a DataFrame).

limit [int, default None] If method is specified, this is the maximum number of consecutive NaN values to forward/backward fill. In other words, if there is a gap with more than this number of consecutive NaNs, it will only be partially filled. If method is not specified, this is the maximum number of entries along the entire axis where NaNs will be filled. Must be greater than 0 if not None.

downcast [dict, default is None] A dict of item->dtype of what to downcast if possible, or the string 'infer' which will try to downcast to an appropriate equal type (e.g. float64 to int64 if possible).

Returns

DataFrame or None Object with missing values filled or None if `inplace=True`.

See also:

interpolate Fill NaN values using interpolation.

reindex Conform object to new index.

asfreq Convert TimeSeries to specified frequency.

Examples

```
>>> df = pd.DataFrame([[np.nan, 2, np.nan, 0],
...                    [3, 4, np.nan, 1],
...                    [np.nan, np.nan, np.nan, 5],
...                    [np.nan, 3, np.nan, 4]],
...                    columns=list("ABCD"))
>>> df
   A    B    C    D
0 NaN  2.0 NaN  0
1 3.0  4.0 NaN  1
2 NaN  NaN NaN  5
3 NaN  3.0 NaN  4
```

Replace all NaN elements with 0s.

```
>>> df.fillna(0)
   A    B    C    D
0 0.0  2.0  0.0  0
1 3.0  4.0  0.0  1
2 0.0  0.0  0.0  5
3 0.0  3.0  0.0  4
```

We can also propagate non-null values forward or backward.

```
>>> df.fillna(method="ffill")
   A    B    C    D
0 NaN  2.0 NaN  0
1 3.0  4.0 NaN  1
2 3.0  4.0 NaN  5
3 3.0  3.0 NaN  4
```

Replace all NaN elements in column 'A', 'B', 'C', and 'D', with 0, 1, 2, and 3 respectively.

```
>>> values = {"A": 0, "B": 1, "C": 2, "D": 3}
>>> df.fillna(value=values)
   A    B    C    D
0 0.0  2.0  2.0  0
1 3.0  4.0  2.0  1
2 0.0  1.0  2.0  5
3 0.0  3.0  2.0  4
```

Only replace the first NaN element.

```
>>> df.fillna(value=values, limit=1)
   A    B    C    D
0 0.0  2.0  2.0  0
1 3.0  4.0 NaN  1
2 NaN  1.0 NaN  5
3 NaN  3.0 NaN  4
```

When filling using a DataFrame, replacement happens along the same column names and same indices

```

>>> df2 = pd.DataFrame(np.zeros((4, 4)), columns=list("ABCE"))
>>> df.fillna(df2)
   A    B    C    D
0  0.0  2.0  0.0  0
1  3.0  4.0  0.0  1
2  0.0  0.0  0.0  5
3  0.0  3.0  0.0  4

```

pandas.DataFrame.filter

DataFrame.filter (*items=None, like=None, regex=None, axis=None*)

Subset the dataframe rows or columns according to the specified index labels.

Note that this routine does not filter a dataframe on its contents. The filter is applied to the labels of the index.

Parameters

items [list-like] Keep labels from axis which are in items.

like [str] Keep labels from axis for which “like in label == True”.

regex [str (regular expression)] Keep labels from axis for which `re.search(regex, label) == True`.

axis [{0 or 'index', 1 or 'columns', None}, default None] The axis to filter on, expressed either as an index (int) or axis name (str). By default this is the info axis, 'index' for Series, 'columns' for DataFrame.

Returns

same type as input object

See also:

[*DataFrame.loc*](#) Access a group of rows and columns by label(s) or a boolean array.

Notes

The `items`, `like`, and `regex` parameters are enforced to be mutually exclusive.

`axis` defaults to the info axis that is used when indexing with `[]`.

Examples

```

>>> df = pd.DataFrame(np.array([[1, 2, 3], [4, 5, 6]]),
...                   index=['mouse', 'rabbit'],
...                   columns=['one', 'two', 'three'])
>>> df
   one  two  three
mouse  1   2     3
rabbit  4   5     6

```

```
>>> # select columns by name
>>> df.filter(items=['one', 'three'])
      one  three
mouse   1     3
rabbit  4     6
```

```
>>> # select columns by regular expression
>>> df.filter(regex='e$', axis=1)
      one  three
mouse   1     3
rabbit  4     6
```

```
>>> # select rows containing 'bbi'
>>> df.filter(like='bbi', axis=0)
      one  two  three
rabbit  4   5     6
```

pandas.DataFrame.first

`DataFrame.first`(*offset*)

Select initial periods of time series data based on a date offset.

When having a DataFrame with dates as index, this function can select the first few rows based on a date offset.

Parameters

offset [str, DateOffset or dateutil.relativedelta] The offset length of the data that will be selected. For instance, '1M' will display all the rows having their index within the first month.

Returns

Series or DataFrame A subset of the caller.

Raises

TypeError If the index is not a *DatetimeIndex*

See also:

[*last*](#) Select final periods of time series based on a date offset.

[*at_time*](#) Select values at a particular time of the day.

[*between_time*](#) Select values between particular times of the day.

Examples

```
>>> i = pd.date_range('2018-04-09', periods=4, freq='2D')
>>> ts = pd.DataFrame({'A': [1, 2, 3, 4]}, index=i)
>>> ts
           A
2018-04-09  1
2018-04-11  2
2018-04-13  3
2018-04-15  4
```

Get the rows for the first 3 days:

```
>>> ts.first('3D')
           A
2018-04-09  1
2018-04-11  2
```

Notice the data for 3 first calendar days were returned, not the first 3 days observed in the dataset, and therefore data for 2018-04-13 was not returned.

pandas.DataFrame.first_valid_index

`DataFrame.first_valid_index()`

Return index for first non-NA value or None, if no NA value is found.

Returns

scalar [type of index]

Notes

If all elements are non-NA/null, returns None. Also returns None for empty Series/DataFrame.

pandas.DataFrame.floordiv

`DataFrame.floordiv(other, axis='columns', level=None, fill_value=None)`

Get Integer division of dataframe and other, element-wise (binary operator *floordiv*).

Equivalent to `dataframe // other`, but with support to substitute a `fill_value` for missing data in one of the inputs. With reverse version, *rfloordiv*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

See also:

DataFrame.add Add DataFrames.

DataFrame.sub Subtract DataFrames.

DataFrame.mul Multiply DataFrames.

DataFrame.div Divide DataFrames (float division).

DataFrame.truediv Divide DataFrames (float division).

DataFrame.floordiv Divide DataFrames (integer division).

DataFrame.mod Calculate modulo (remainder after division).

DataFrame.pow Calculate exponential power.

Notes

Mismatched indices will be unioned together.

Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                    index=['circle', 'triangle', 'rectangle'])
>>> df
```

| | angles | degrees |
|-----------|--------|---------|
| circle | 0 | 360 |
| triangle | 3 | 180 |
| rectangle | 4 | 360 |

Add a scalar with operator version which return the same results.

```
>>> df + 1
```

| | angles | degrees |
|-----------|--------|---------|
| circle | 1 | 361 |
| triangle | 4 | 181 |
| rectangle | 5 | 361 |

```
>>> df.add(1)
```

| | angles | degrees |
|-----------|--------|---------|
| circle | 1 | 361 |
| triangle | 4 | 181 |
| rectangle | 5 | 361 |

Divide by constant with reverse version.

```
>>> df.div(10)
      angles  degrees
circle     0.0    36.0
triangle   0.3    18.0
rectangle  0.4    36.0
```

```
>>> df.rdiv(10)
      angles  degrees
circle      inf  0.027778
triangle  3.333333  0.055556
rectangle  2.500000  0.027778
```

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
      angles  degrees
circle     -1    358
triangle    2    178
rectangle   3    358
```

```
>>> df.sub([1, 2], axis='columns')
      angles  degrees
circle     -1    358
triangle    2    178
rectangle   3    358
```

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...        axis='index')
      angles  degrees
circle     -1    359
triangle    2    179
rectangle   3    359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                       index=['circle', 'triangle', 'rectangle'])
>>> other
      angles
circle      0
triangle    3
rectangle   4
```

```
>>> df * other
      angles  degrees
circle      0     NaN
triangle     9     NaN
rectangle   16     NaN
```

```
>>> df.mul(other, fill_value=0)
      angles  degrees
circle      0     0.0
```

(continues on next page)

(continued from previous page)

| | | |
|-----------|----|-----|
| triangle | 9 | 0.0 |
| rectangle | 16 | 0.0 |

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                               'degrees': [360, 180, 360, 360, 540, 720]},
...                               index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                       ['circle', 'triangle', 'rectangle',
...                                       'square', 'pentagon', 'hexagon']])
>>> df_multindex
```

| | angles | degrees |
|-----------|--------|---------|
| A circle | 0 | 360 |
| triangle | 3 | 180 |
| rectangle | 4 | 360 |
| B square | 4 | 360 |
| pentagon | 5 | 540 |
| hexagon | 6 | 720 |

```
>>> df.div(df_multindex, level=1, fill_value=0)
```

| | angles | degrees |
|-----------|--------|---------|
| A circle | NaN | 1.0 |
| triangle | 1.0 | 1.0 |
| rectangle | 1.0 | 1.0 |
| B square | 0.0 | 0.0 |
| pentagon | 0.0 | 0.0 |
| hexagon | 0.0 | 0.0 |

pandas.DataFrame.from_dict

classmethod `DataFrame.from_dict`(*data*, *orient='columns'*, *dtype=None*, *columns=None*)

Construct DataFrame from dict of array-like or dicts.

Creates DataFrame object from dictionary by columns or by index allowing dtype specification.

Parameters

data [dict] Of the form {field : array-like} or {field : dict}.

orient [{‘columns’, ‘index’}, default ‘columns’] The “orientation” of the data. If the keys of the passed dict should be the columns of the resulting DataFrame, pass ‘columns’ (default). Otherwise if the keys should be rows, pass ‘index’.

dtype [dtype, default None] Data type to force, otherwise infer.

columns [list, default None] Column labels to use when orient=‘index’. Raises a ValueError if used with orient=‘columns’.

Returns

DataFrame

See also:

[*DataFrame.from_records*](#) DataFrame from structured ndarray, sequence of tuples or dicts, or DataFrame.

DataFrame DataFrame object creation using constructor.

Examples

By default the keys of the dict become the DataFrame columns:

```
>>> data = {'col_1': [3, 2, 1, 0], 'col_2': ['a', 'b', 'c', 'd']}
>>> pd.DataFrame.from_dict(data)
   col_1 col_2
0      3    a
1      2    b
2      1    c
3      0    d
```

Specify `orient='index'` to create the DataFrame using dictionary keys as rows:

```
>>> data = {'row_1': [3, 2, 1, 0], 'row_2': ['a', 'b', 'c', 'd']}
>>> pd.DataFrame.from_dict(data, orient='index')
      0 1 2 3
row_1 3 2 1 0
row_2 a b c d
```

When using the 'index' orientation, the column names can be specified manually:

```
>>> pd.DataFrame.from_dict(data, orient='index',
...                          columns=['A', 'B', 'C', 'D'])
      A B C D
row_1 3 2 1 0
row_2 a b c d
```

pandas.DataFrame.from_records

classmethod DataFrame.**from_records**(data, index=None, exclude=None, columns=None, coerce_float=False, nrows=None)

Convert structured or record ndarray to DataFrame.

Creates a DataFrame object from a structured ndarray, sequence of tuples or dicts, or DataFrame.

Parameters

data [structured ndarray, sequence of tuples or dicts, or DataFrame] Structured input data.

index [str, list of fields, array-like] Field of array to use as the index, alternately a specific set of input labels to use.

exclude [sequence, default None] Columns or fields to exclude.

columns [sequence, default None] Column names to use. If the passed data do not have names associated with them, this argument provides names for the columns. Otherwise this argument indicates the order of the columns in the result (any names not found in the data will become all-NA columns).

coerce_float [bool, default False] Attempt to convert values of non-string, non-numeric objects (like decimal.Decimal) to floating point, useful for SQL result sets.

nrows [int, default None] Number of rows to read if data is an iterator.

Returns

DataFrame

See also:

[*DataFrame.from_dict*](#) DataFrame from dict of array-like or dicts.

[*DataFrame*](#) DataFrame object creation using constructor.

Examples

Data can be provided as a structured ndarray:

```
>>> data = np.array([(3, 'a'), (2, 'b'), (1, 'c'), (0, 'd')],
...                  dtype=[('col_1', 'i4'), ('col_2', 'U1')])
>>> pd.DataFrame.from_records(data)
   col_1 col_2
0       3    a
1       2    b
2       1    c
3       0    d
```

Data can be provided as a list of dicts:

```
>>> data = [{'col_1': 3, 'col_2': 'a'},
...         {'col_1': 2, 'col_2': 'b'},
...         {'col_1': 1, 'col_2': 'c'},
...         {'col_1': 0, 'col_2': 'd'}]
>>> pd.DataFrame.from_records(data)
   col_1 col_2
0       3    a
1       2    b
2       1    c
3       0    d
```

Data can be provided as a list of tuples with corresponding columns:

```
>>> data = [(3, 'a'), (2, 'b'), (1, 'c'), (0, 'd')]
>>> pd.DataFrame.from_records(data, columns=['col_1', 'col_2'])
   col_1 col_2
0       3    a
1       2    b
2       1    c
3       0    d
```

pandas.DataFrame.ge

`DataFrame.ge`(*other*, axis='columns', level=None)

Get Greater than or equal to of dataframe and other, element-wise (binary operator *ge*).

Among flexible wrappers (*eq*, *ne*, *le*, *lt*, *ge*, *gt*) to comparison operators.

Equivalent to `==`, `!=`, `<=`, `<`, `>=`, `>` with support to choose axis (rows or columns) and level for comparison.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}, default 'columns'] Whether to compare by the index (0 or 'index') or columns (1 or 'columns').

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

DataFrame of bool Result of the comparison.

See also:

[`DataFrame.eq`](#) Compare DataFrames for equality elementwise.

[`DataFrame.ne`](#) Compare DataFrames for inequality elementwise.

[`DataFrame.le`](#) Compare DataFrames for less than inequality or equality elementwise.

[`DataFrame.lt`](#) Compare DataFrames for strictly less than inequality elementwise.

[`DataFrame.ge`](#) Compare DataFrames for greater than inequality or equality elementwise.

[`DataFrame.gt`](#) Compare DataFrames for strictly greater than inequality elementwise.

Notes

Mismatched indices will be unioned together. *NaN* values are considered different (i.e. *NaN != NaN*).

Examples

```

>>> df = pd.DataFrame({'cost': [250, 150, 100],
...                    'revenue': [100, 250, 300]},
...                    index=['A', 'B', 'C'])
>>> df
   cost  revenue
A   250     100
B   150     250
C   100     300

```

Comparison with a scalar, using either the operator or method:

```
>>> df == 100
      cost revenue
A  False      True
B  False      False
C   True      False
```

```
>>> df.eq(100)
      cost revenue
A  False      True
B  False      False
C   True      False
```

When *other* is a *Series*, the columns of a DataFrame are aligned with the index of *other* and broadcast:

```
>>> df != pd.Series([100, 250], index=["cost", "revenue"])
      cost revenue
A   True      True
B   True      False
C  False      True
```

Use the method to control the broadcast axis:

```
>>> df.ne(pd.Series([100, 300], index=["A", "D"]), axis='index')
      cost revenue
A   True      False
B   True      True
C   True      True
D   True      True
```

When comparing to an arbitrary sequence, the number of columns must match the number elements in *other*:

```
>>> df == [250, 100]
      cost revenue
A   True      True
B  False      False
C  False      False
```

Use the method to control the axis:

```
>>> df.eq([250, 250, 100], axis='index')
      cost revenue
A   True      False
B  False      True
C   True      False
```

Compare to a DataFrame of different shape.

```
>>> other = pd.DataFrame({'revenue': [300, 250, 100, 150]},
...                       index=['A', 'B', 'C', 'D'])
>>> other
      revenue
A          300
```

(continues on next page)

(continued from previous page)

| | |
|---|-----|
| B | 250 |
| C | 100 |
| D | 150 |

```
>>> df.gt(other)
      cost  revenue
A  False   False
B  False   False
C  False    True
D  False   False
```

Compare to a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'cost': [250, 150, 100, 150, 300, 220],
...                               'revenue': [100, 250, 300, 200, 175, 225]},
...                               index=[['Q1', 'Q1', 'Q1', 'Q2', 'Q2', 'Q2'],
...                                       ['A', 'B', 'C', 'A', 'B', 'C']])
>>> df_multindex
      cost  revenue
Q1 A   250     100
   B   150     250
   C   100     300
Q2 A   150     200
   B   300     175
   C   220     225
```

```
>>> df.le(df_multindex, level=1)
      cost  revenue
Q1 A   True    True
   B   True    True
   C   True    True
Q2 A  False    True
   B   True    False
   C   True    False
```

pandas.DataFrame.get

`DataFrame.get(key, default=None)`

Get item from object for given key (ex: DataFrame column).

Returns default value if not found.

Parameters

key [object]

Returns

value [same type as items contained in object]

pandas.DataFrame.groupby

`DataFrame.groupby`(*by=None, axis=0, level=None, as_index=True, sort=True, group_keys=True, squeeze=NoDefault.no_default, observed=False, dropna=True*)

Group DataFrame using a mapper or by a Series of columns.

A groupby operation involves some combination of splitting the object, applying a function, and combining the results. This can be used to group large amounts of data and compute operations on these groups.

Parameters

by [mapping, function, label, or list of labels] Used to determine the groups for the groupby. If *by* is a function, it's called on each value of the object's index. If a dict or Series is passed, the Series or dict VALUES will be used to determine the groups (the Series' values are first aligned; see `.align()` method). If an ndarray is passed, the values are used as-is to determine the groups. A label or list of labels may be passed to group by the columns in `self`. Notice that a tuple is interpreted as a (single) key.

axis [{0 or 'index', 1 or 'columns'}, default 0] Split along rows (0) or columns (1).

level [int, level name, or sequence of such, default None] If the axis is a MultiIndex (hierarchical), group by a particular level or levels.

as_index [bool, default True] For aggregated output, return object with group labels as the index. Only relevant for DataFrame input. `as_index=False` is effectively "SQL-style" grouped output.

sort [bool, default True] Sort group keys. Get better performance by turning this off. Note this does not influence the order of observations within each group. Groupby preserves the order of rows within each group.

group_keys [bool, default True] When calling `apply`, add group keys to index to identify pieces.

squeeze [bool, default False] Reduce the dimensionality of the return type if possible, otherwise return a consistent type.

Deprecated since version 1.1.0.

observed [bool, default False] This only applies if any of the groupers are Categoricals. If True: only show observed values for categorical groupers. If False: show all values for categorical groupers.

dropna [bool, default True] If True, and if group keys contain NA values, NA values together with row/column will be dropped. If False, NA values will also be treated as the key in groups

New in version 1.1.0.

Returns

DataFrameGroupBy Returns a groupby object that contains information about the groups.

See also:

[*resample*](#) Convenience method for frequency conversion and resampling of time series.

Notes

See the [user guide](#) for more.

Examples

```
>>> df = pd.DataFrame({'Animal': ['Falcon', 'Falcon',
...                               'Parrot', 'Parrot'],
...                   'Max Speed': [380., 370., 24., 26.]})
>>> df
   Animal  Max Speed
0  Falcon    380.0
1  Falcon    370.0
2  Parrot     24.0
3  Parrot     26.0
>>> df.groupby(['Animal']).mean()
      Max Speed
Animal
Falcon    375.0
Parrot     25.0
```

Hierarchical Indexes

We can groupby different levels of a hierarchical index using the *level* parameter:

```
>>> arrays = [['Falcon', 'Falcon', 'Parrot', 'Parrot'],
...           ['Captive', 'Wild', 'Captive', 'Wild']]
>>> index = pd.MultiIndex.from_arrays(arrays, names=('Animal', 'Type'))
>>> df = pd.DataFrame({'Max Speed': [390., 350., 30., 20.]},
...                   index=index)
>>> df
      Max Speed
Animal Type
Falcon Captive    390.0
       Wild       350.0
Parrot Captive     30.0
       Wild        20.0
>>> df.groupby(level=0).mean()
      Max Speed
Animal
Falcon    370.0
Parrot     25.0
>>> df.groupby(level="Type").mean()
      Max Speed
Type
Captive    210.0
Wild       185.0
```

We can also choose to include NA in group keys or not by setting *dropna* parameter, the default setting is *True*:

```
>>> l = [[1, 2, 3], [1, None, 4], [2, 1, 3], [1, 2, 2]]
>>> df = pd.DataFrame(l, columns=["a", "b", "c"])
```

```
>>> df.groupby(by=["b"]).sum()
      a    c
b
1.0  2    3
2.0  2    5
```

```
>>> df.groupby(by=["b"], dropna=False).sum()
      a    c
b
1.0  2    3
2.0  2    5
NaN  1    4
```

```
>>> l = [{"a", 12, 12}, [None, 12.3, 33.], ["b", 12.3, 123], ["a", 1, 1]]
>>> df = pd.DataFrame(l, columns=["a", "b", "c"])
```

```
>>> df.groupby(by="a").sum()
      b      c
a
a  13.0  13.0
b  12.3  123.0
```

```
>>> df.groupby(by="a", dropna=False).sum()
      b      c
a
a  13.0  13.0
b  12.3  123.0
NaN 12.3  33.0
```

pandas.DataFrame.gt

DataFrame.gt (*other*, *axis='columns'*, *level=None*)

Get Greater than of dataframe and other, element-wise (binary operator *gt*).

Among flexible wrappers (*eq*, *ne*, *le*, *lt*, *ge*, *gt*) to comparison operators.

Equivalent to `==`, `!=`, `<=`, `<`, `>=`, `>` with support to choose axis (rows or columns) and level for comparison.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}], default 'columns' Whether to compare by the index (0 or 'index') or columns (1 or 'columns').

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

DataFrame of bool Result of the comparison.

See also:

DataFrame.eq Compare DataFrames for equality elementwise.

DataFrame.ne Compare DataFrames for inequality elementwise.

DataFrame.le Compare DataFrames for less than inequality or equality elementwise.

DataFrame.lt Compare DataFrames for strictly less than inequality elementwise.

DataFrame.ge Compare DataFrames for greater than inequality or equality elementwise.

DataFrame.gt Compare DataFrames for strictly greater than inequality elementwise.

Notes

Mismatched indices will be unioned together. *NaN* values are considered different (i.e. *NaN != NaN*).

Examples

```
>>> df = pd.DataFrame({'cost': [250, 150, 100],
...                    'revenue': [100, 250, 300]},
...                    index=['A', 'B', 'C'])
>>> df
   cost  revenue
A   250     100
B   150     250
C   100     300
```

Comparison with a scalar, using either the operator or method:

```
>>> df == 100
   cost  revenue
A  False     True
B  False     False
C   True     False
```

```
>>> df.eq(100)
   cost  revenue
A  False     True
B  False     False
C   True     False
```

When *other* is a *Series*, the columns of a DataFrame are aligned with the index of *other* and broadcast:

```
>>> df != pd.Series([100, 250], index=["cost", "revenue"])
   cost  revenue
A   True     True
B   True     False
C  False     True
```

Use the method to control the broadcast axis:

```
>>> df.ne(pd.Series([100, 300], index=["A", "D"]), axis='index')
   cost  revenue
A   True     False
```

(continues on next page)

(continued from previous page)

```
B True True
C True True
D True True
```

When comparing to an arbitrary sequence, the number of columns must match the number elements in *other*:

```
>>> df == [250, 100]
      cost revenue
A  True     True
B False    False
C False    False
```

Use the method to control the axis:

```
>>> df.eq([250, 250, 100], axis='index')
      cost revenue
A  True     False
B False     True
C  True     False
```

Compare to a DataFrame of different shape.

```
>>> other = pd.DataFrame({'revenue': [300, 250, 100, 150]},
...                       index=['A', 'B', 'C', 'D'])
>>> other
      revenue
A         300
B         250
C         100
D         150
```

```
>>> df.gt(other)
      cost revenue
A False    False
B False    False
C False     True
D False    False
```

Compare to a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'cost': [250, 150, 100, 150, 300, 220],
...                              'revenue': [100, 250, 300, 200, 175, 225]},
...                              index=[['Q1', 'Q1', 'Q1', 'Q2', 'Q2', 'Q2'],
...                                      ['A', 'B', 'C', 'A', 'B', 'C']])
>>> df_multindex
      cost revenue
Q1 A    250     100
   B    150     250
   C    100     300
Q2 A    150     200
   B    300     175
   C    220     225
```

```
>>> df.le(df_multindex, level=1)
      cost  revenue
Q1 A   True    True
   B   True    True
   C   True    True
Q2 A  False    True
   B   True   False
   C   True   False
```

pandas.DataFrame.head

`DataFrame.head(n=5)`

Return the first n rows.

This function returns the first n rows for the object based on position. It is useful for quickly testing if your object has the right type of data in it.

For negative values of n , this function returns all rows except the last n rows, equivalent to `df[: -n]`.

Parameters

n [int, default 5] Number of rows to select.

Returns

same type as caller The first n rows of the caller object.

See also:

[`DataFrame.tail`](#) Returns the last n rows.

Examples

```
>>> df = pd.DataFrame({'animal': ['alligator', 'bee', 'falcon', 'lion',
...                               'monkey', 'parrot', 'shark', 'whale', 'zebra']})
>>> df
   animal
0 alligator
1     bee
2   falcon
3     lion
4   monkey
5   parrot
6   shark
7   whale
8   zebra
```

Viewing the first 5 lines

```
>>> df.head()
   animal
0 alligator
1     bee
2   falcon
```

(continues on next page)

(continued from previous page)

```
3    lion
4    monkey
```

Viewing the first n lines (three in this case)

```
>>> df.head(3)
   animal
0  alligator
1     bee
2    falcon
```

For negative values of n

```
>>> df.head(-3)
   animal
0  alligator
1     bee
2    falcon
3     lion
4    monkey
5    parrot
```

pandas.DataFrame.hist

DataFrame.hist(*column=None, by=None, grid=True, xlabelsize=None, xrot=None, ylabelsize=None, yrot=None, ax=None, sharex=False, sharey=False, figsize=None, layout=None, bins=10, backend=None, legend=False, **kwargs*)

Make a histogram of the DataFrame's columns.

A [histogram](#) is a representation of the distribution of data. This function calls `matplotlib.pyplot.hist()`, on each series in the DataFrame, resulting in one histogram per column.

Parameters

data [DataFrame] The pandas object holding the data.

column [str or sequence, optional] If passed, will be used to limit data to a subset of columns.

by [object, optional] If passed, then used to form histograms for separate groups.

grid [bool, default True] Whether to show axis grid lines.

xlabelsize [int, default None] If specified changes the x-axis label size.

xrot [float, default None] Rotation of x axis labels. For example, a value of 90 displays the x labels rotated 90 degrees clockwise.

ylabelsize [int, default None] If specified changes the y-axis label size.

yrot [float, default None] Rotation of y axis labels. For example, a value of 90 displays the y labels rotated 90 degrees clockwise.

ax [Matplotlib axes object, default None] The axes to plot the histogram on.

sharex [bool, default True if ax is None else False] In case `subplots=True`, share x axis and set some x axis labels to invisible; defaults to True if ax is None otherwise False

if an ax is passed in. Note that passing in both an ax and sharex=True will alter all x axis labels for all subplots in a figure.

sharey [bool, default False] In case subplots=True, share y axis and set some y axis labels to invisible.

figsize [tuple, optional] The size in inches of the figure to create. Uses the value in *matplotlib.rcParams* by default.

layout [tuple, optional] Tuple of (rows, columns) for the layout of the histograms.

bins [int or sequence, default 10] Number of histogram bins to be used. If an integer is given, bins + 1 bin edges are calculated and returned. If bins is a sequence, gives bin edges, including left edge of first bin and right edge of last bin. In this case, bins is returned unmodified.

backend [str, default None] Backend to use instead of the backend specified in the option `plotting.backend`. For instance, 'matplotlib'. Alternatively, to specify the `plotting.backend` for the whole session, set `pd.options.plotting.backend`.

New in version 1.0.0.

legend [bool, default False] Whether to show the legend.

New in version 1.1.0.

****kwargs** All other plotting keyword arguments to be passed to `matplotlib.pyplot.hist()`.

Returns

`matplotlib.AxesSubplot` or `numpy.ndarray` of them

See also:

[matplotlib.pyplot.hist](#) Plot a histogram using matplotlib.

Examples

This example draws a histogram based on the length and width of some animals, displayed in three bins

```
>>> df = pd.DataFrame({
...     'length': [1.5, 0.5, 1.2, 0.9, 3],
...     'width': [0.7, 0.2, 0.15, 0.2, 1.1]
...     }, index=['pig', 'rabbit', 'duck', 'chicken', 'horse'])
>>> hist = df.hist(bins=3)
```

`pandas.DataFrame.idxmax`

`DataFrame.idxmax(axis=0, skipna=True)`

Return index of first occurrence of maximum over requested axis.

NA/null values are excluded.

Parameters

axis [{0 or 'index', 1 or 'columns'}, default 0] The axis to use. 0 or 'index' for row-wise, 1 or 'columns' for column-wise.

skipna [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

Returns

Series Indexes of maxima along the specified axis.

Raises

ValueError

- If the row/column is empty

See also:

[*Series.idxmax*](#) Return index of the maximum element.

Notes

This method is the DataFrame version of `ndarray.argmax`.

Examples

Consider a dataset containing food consumption in Argentina.

```
>>> df = pd.DataFrame({'consumption': [10.51, 103.11, 55.48],
...                    'co2_emissions': [37.2, 19.66, 1712]},
...                    index=['Pork', 'Wheat Products', 'Beef'])
```

```
>>> df
      consumption  co2_emissions
Pork             10.51           37.20
Wheat Products   103.11           19.66
Beef              55.48          1712.00
```

By default, it returns the index for the maximum value in each column.

```
>>> df.idxmax()
consumption    Wheat Products
co2_emissions           Beef
dtype: object
```

To return the index for the maximum value in each row, use `axis="columns"`.

```
>>> df.idxmax(axis="columns")
Pork             co2_emissions
Wheat Products   consumption
Beef              co2_emissions
dtype: object
```

pandas.DataFrame.idxmin

`DataFrame.idxmin(axis=0, skipna=True)`

Return index of first occurrence of minimum over requested axis.

NA/null values are excluded.

Parameters

axis [{0 or 'index', 1 or 'columns'}, default 0] The axis to use. 0 or 'index' for row-wise, 1 or 'columns' for column-wise.

skipna [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

Returns

Series Indexes of minima along the specified axis.

Raises**ValueError**

- If the row/column is empty

See also:

[`Series.idxmin`](#) Return index of the minimum element.

Notes

This method is the DataFrame version of `ndarray.argmax`.

Examples

Consider a dataset containing food consumption in Argentina.

```
>>> df = pd.DataFrame({'consumption': [10.51, 103.11, 55.48],
...                    'co2_emissions': [37.2, 19.66, 1712]},
...                    index=['Pork', 'Wheat Products', 'Beef'])
```

```
>>> df
      consumption  co2_emissions
Pork             10.51           37.20
Wheat Products   103.11           19.66
Beef              55.48          1712.00
```

By default, it returns the index for the minimum value in each column.

```
>>> df.idxmin()
consumption           Pork
co2_emissions  Wheat Products
dtype: object
```

To return the index for the minimum value in each row, use `axis="columns"`.

```
>>> df.idxmin(axis="columns")
Pork                consumption
Wheat Products     co2_emissions
Beef                consumption
dtype: object
```

pandas.DataFrame.infer_objects

DataFrame.infer_objects()

Attempt to infer better dtypes for object columns.

Attempts soft conversion of object-dtyped columns, leaving non-object and unconvertible columns unchanged. The inference rules are the same as during normal Series/DataFrame construction.

Returns

converted [same type as input object]

See also:

[*to_datetime*](#) Convert argument to datetime.

[*to_timedelta*](#) Convert argument to timedelta.

[*to_numeric*](#) Convert argument to numeric type.

[*convert_dtypes*](#) Convert argument to best possible dtype.

Examples

```
>>> df = pd.DataFrame({"A": ["a", 1, 2, 3]})
>>> df = df.iloc[1:]
>>> df
   A
1  1
2  2
3  3
```

```
>>> df.dtypes
A    object
dtype: object
```

```
>>> df.infer_objects().dtypes
A    int64
dtype: object
```

pandas.DataFrame.info

`DataFrame.info(verbose=None, buf=None, max_cols=None, memory_usage=None, show_counts=None, null_counts=None)`

Print a concise summary of a DataFrame.

This method prints information about a DataFrame including the index dtype and columns, non-null values and memory usage.

Parameters

data [DataFrame] DataFrame to print information about.

verbose [bool, optional] Whether to print the full summary. By default, the setting in `pandas.options.display.max_info_columns` is followed.

buf [writable buffer, defaults to `sys.stdout`] Where to send the output. By default, the output is printed to `sys.stdout`. Pass a writable buffer if you need to further process the output.

max_cols [int, optional] When to switch from the verbose to the truncated output. If the DataFrame has more than `max_cols` columns, the truncated output is used. By default, the setting in `pandas.options.display.max_info_columns` is used.

memory_usage [bool, str, optional] Specifies whether total memory usage of the DataFrame elements (including the index) should be displayed. By default, this follows the `pandas.options.display.memory_usage` setting.

True always show memory usage. False never shows memory usage. A value of 'deep' is equivalent to "True with deep introspection". Memory usage is shown in human-readable units (base-2 representation). Without deep introspection a memory estimation is made based in column dtype and number of rows assuming values consume the same memory amount for corresponding dtypes. With deep memory introspection, a real memory usage calculation is performed at the cost of computational resources.

show_counts [bool, optional] Whether to show the non-null counts. By default, this is shown only if the DataFrame is smaller than `pandas.options.display.max_info_rows` and `pandas.options.display.max_info_columns`. A value of True always shows the counts, and False never shows the counts.

null_counts [bool, optional] Deprecated since version 1.2.0: Use `show_counts` instead.

Returns

None This method prints a summary of a DataFrame and returns None.

See also:

[*DataFrame.describe*](#) Generate descriptive statistics of DataFrame columns.

[*DataFrame.memory_usage*](#) Memory usage of DataFrame columns.

Examples

```
>>> int_values = [1, 2, 3, 4, 5]
>>> text_values = ['alpha', 'beta', 'gamma', 'delta', 'epsilon']
>>> float_values = [0.0, 0.25, 0.5, 0.75, 1.0]
>>> df = pd.DataFrame({"int_col": int_values, "text_col": text_values,
...                    "float_col": float_values})
>>> df
   int_col text_col  float_col
0         1   alpha         0.00
1         2   beta         0.25
2         3  gamma         0.50
3         4  delta         0.75
4         5 epsilon         1.00
```

Prints information of all columns:

```
>>> df.info(verbose=True)
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 5 entries, 0 to 4
Data columns (total 3 columns):
#   Column      Non-Null Count  Dtype
---  -
0   int_col     5 non-null      int64
1   text_col    5 non-null      object
2   float_col   5 non-null      float64
dtypes: float64(1), int64(1), object(1)
memory usage: 248.0+ bytes
```

Prints a summary of columns count and its dtypes but not per column information:

```
>>> df.info(verbose=False)
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 5 entries, 0 to 4
Columns: 3 entries, int_col to float_col
dtypes: float64(1), int64(1), object(1)
memory usage: 248.0+ bytes
```

Pipe output of DataFrame.info to buffer instead of sys.stdout, get buffer content and writes to a text file:

```
>>> import io
>>> buffer = io.StringIO()
>>> df.info(buf=buffer)
>>> s = buffer.getvalue()
>>> with open("df_info.txt", "w",
...         encoding="utf-8") as f:
...     f.write(s)
260
```

The `memory_usage` parameter allows deep introspection mode, specially useful for big DataFrames and fine-tune memory optimization:

```
>>> random_strings_array = np.random.choice(['a', 'b', 'c'], 10 ** 6)
>>> df = pd.DataFrame({
```

(continues on next page)

(continued from previous page)

```

...     'column_1': np.random.choice(['a', 'b', 'c'], 10 ** 6),
...     'column_2': np.random.choice(['a', 'b', 'c'], 10 ** 6),
...     'column_3': np.random.choice(['a', 'b', 'c'], 10 ** 6)
... })
>>> df.info()
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 1000000 entries, 0 to 999999
Data columns (total 3 columns):
#   Column      Non-Null Count  Dtype
---  ---
0   column_1    1000000 non-null  object
1   column_2    1000000 non-null  object
2   column_3    1000000 non-null  object
dtypes: object(3)
memory usage: 22.9+ MB

```

```

>>> df.info(memory_usage='deep')
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 1000000 entries, 0 to 999999
Data columns (total 3 columns):
#   Column      Non-Null Count  Dtype
---  ---
0   column_1    1000000 non-null  object
1   column_2    1000000 non-null  object
2   column_3    1000000 non-null  object
dtypes: object(3)
memory usage: 165.9 MB

```

pandas.DataFrame.insert

`DataFrame.insert` (*loc*, *column*, *value*, *allow_duplicates=False*)

Insert column into DataFrame at specified location.

Raises a `ValueError` if *column* is already contained in the DataFrame, unless *allow_duplicates* is set to `True`.

Parameters

loc [int] Insertion index. Must verify $0 \leq \text{loc} \leq \text{len}(\text{columns})$.

column [str, number, or hashable object] Label of the inserted column.

value [int, Series, or array-like]

allow_duplicates [bool, optional]

See also:

[*Index.insert*](#) Insert new item by index.

Examples

```
>>> df = pd.DataFrame({'col1': [1, 2], 'col2': [3, 4]})
>>> df
   col1  col2
0     1     3
1     2     4
>>> df.insert(1, "newcol", [99, 99])
>>> df
   col1  newcol  col2
0     1      99     3
1     2      99     4
>>> df.insert(0, "col1", [100, 100], allow_duplicates=True)
>>> df
   col1  col1  newcol  col2
0  100     1      99     3
1  100     2      99     4
```

Notice that pandas uses index alignment in case of *value* from type *Series*:

```
>>> df.insert(0, "col0", pd.Series([5, 6], index=[1, 2]))
>>> df
   col0  col1  col1  newcol  col2
0   NaN  100     1      99     3
1   5.0  100     2      99     4
```

pandas.DataFrame.interpolate

`DataFrame.interpolate`(*method='linear', axis=0, limit=None, inplace=False, limit_direction=None, limit_area=None, downcast=None, **kwargs*)

Fill NaN values using an interpolation method.

Please note that only `method='linear'` is supported for DataFrame/Series with a MultiIndex.

Parameters

method [str, default 'linear'] Interpolation technique to use. One of:

- 'linear': Ignore the index and treat the values as equally spaced. This is the only method supported on MultiIndexes.
- 'time': Works on daily and higher resolution data to interpolate given length of interval.
- 'index', 'values': use the actual numerical values of the index.
- 'pad': Fill in NaNs using existing values.
- 'nearest', 'zero', 'slinear', 'quadratic', 'cubic', 'spline', 'barycentric', 'polynomial': Passed to `scipy.interpolate.interpld`. These methods use the numerical values of the index. Both 'polynomial' and 'spline' require that you also specify an *order* (int), e.g. `df.interpolate(method='polynomial', order=5)`.
- 'krogh', 'piecewise_polynomial', 'spline', 'pchip', 'akima', 'cubic_spline': Wrappers around the SciPy interpolation methods of similar names. See *Notes*.

- ‘from_derivatives’: Refers to `scipy.interpolate.BPoly.from_derivatives` which replaces ‘piecewise_polynomial’ interpolation method in scipy 0.18.

axis [{{0 or ‘index’, 1 or ‘columns’, None}}, default None] Axis to interpolate along.

limit [int, optional] Maximum number of consecutive NaNs to fill. Must be greater than 0.

inplace [bool, default False] Update the data in place if possible.

limit_direction [{{‘forward’, ‘backward’, ‘both’}}, Optional] Consecutive NaNs will be filled in this direction.

If limit is specified:

- If ‘method’ is ‘pad’ or ‘ffill’, ‘limit_direction’ must be ‘forward’.
- If ‘method’ is ‘backfill’ or ‘bfill’, ‘limit_direction’ must be ‘backwards’.

If ‘limit’ is not specified:

- If ‘method’ is ‘backfill’ or ‘bfill’, the default is ‘backward’
- else the default is ‘forward’

Changed in version 1.1.0: raises `ValueError` if `limit_direction` is ‘forward’ or ‘both’ and method is ‘backfill’ or ‘bfill’. raises `ValueError` if `limit_direction` is ‘backward’ or ‘both’ and method is ‘pad’ or ‘ffill’.

limit_area [{{None, ‘inside’, ‘outside’}}, default None] If limit is specified, consecutive NaNs will be filled with this restriction.

- None: No fill restriction.
- ‘inside’: Only fill NaNs surrounded by valid values (interpolate).
- ‘outside’: Only fill NaNs outside valid values (extrapolate).

downcast [optional, ‘infer’ or None, defaults to None] Downcast dtypes if possible.

`***kwargs` [optional] Keyword arguments to pass on to the interpolating function.

Returns

Series or DataFrame or None Returns the same object type as the caller, interpolated at some or all NaN values or None if `inplace=True`.

See also:

`fillna` Fill missing values using different methods.

`scipy.interpolate.Akima1DInterpolator` Piecewise cubic polynomials (Akima interpolator).

`scipy.interpolate.BPoly.from_derivatives` Piecewise polynomial in the Bernstein basis.

`scipy.interpolate.interp1d` Interpolate a 1-D function.

`scipy.interpolate.KroghInterpolator` Interpolate polynomial (Krogh interpolator).

`scipy.interpolate.PchipInterpolator` PCHIP 1-d monotonic cubic interpolation.

`scipy.interpolate.CubicSpline` Cubic spline data interpolator.

Notes

The ‘krogh’, ‘piecewise_polynomial’, ‘spline’, ‘pchip’ and ‘akima’ methods are wrappers around the respective SciPy implementations of similar names. These use the actual numerical values of the index. For more information on their behavior, see the [SciPy documentation](#) and [SciPy tutorial](#).

Examples

Filling in NaN in a *Series* via linear interpolation.

```
>>> s = pd.Series([0, 1, np.nan, 3])
>>> s
0    0.0
1    1.0
2    NaN
3    3.0
dtype: float64
>>> s.interpolate()
0    0.0
1    1.0
2    2.0
3    3.0
dtype: float64
```

Filling in NaN in a Series by padding, but filling at most two consecutive NaN at a time.

```
>>> s = pd.Series([np.nan, "single_one", np.nan,
...               "fill_two_more", np.nan, np.nan, np.nan,
...               4.71, np.nan])
>>> s
0          NaN
1    single_one
2          NaN
3    fill_two_more
4          NaN
5          NaN
6          NaN
7         4.71
8          NaN
dtype: object
>>> s.interpolate(method='pad', limit=2)
0          NaN
1    single_one
2    single_one
3    fill_two_more
4    fill_two_more
5    fill_two_more
6          NaN
7         4.71
8         4.71
dtype: object
```

Filling in NaN in a Series via polynomial interpolation or splines: Both ‘polynomial’ and ‘spline’ methods require that you also specify an order (int).

```
>>> s = pd.Series([0, 2, np.nan, 8])
>>> s.interpolate(method='polynomial', order=2)
0    0.000000
1    2.000000
2    4.666667
3    8.000000
dtype: float64
```

Fill the DataFrame forward (that is, going down) along each column using linear interpolation.

Note how the last entry in column 'a' is interpolated differently, because there is no entry after it to use for interpolation. Note how the first entry in column 'b' remains NaN, because there is no entry before it to use for interpolation.

```
>>> df = pd.DataFrame([(0.0, np.nan, -1.0, 1.0),
...                   (np.nan, 2.0, np.nan, np.nan),
...                   (2.0, 3.0, np.nan, 9.0),
...                   (np.nan, 4.0, -4.0, 16.0)],
...                   columns=list('abcd'))
>>> df
   a    b    c    d
0  0.0 NaN -1.0  1.0
1  NaN  2.0 NaN  NaN
2  2.0  3.0 NaN  9.0
3  NaN  4.0 -4.0 16.0
>>> df.interpolate(method='linear', limit_direction='forward', axis=0)
   a    b    c    d
0  0.0 NaN -1.0  1.0
1  1.0  2.0 -2.0  5.0
2  2.0  3.0 -3.0  9.0
3  2.0  4.0 -4.0 16.0
```

Using polynomial interpolation.

```
>>> df['d'].interpolate(method='polynomial', order=2)
0    1.0
1    4.0
2    9.0
3   16.0
Name: d, dtype: float64
```

pandas.DataFrame.isin

`DataFrame.isin(values)`

Whether each element in the DataFrame is contained in values.

Parameters

values [iterable, Series, DataFrame or dict] The result will only be true at a location if all the labels match. If *values* is a Series, that's the index. If *values* is a dict, the keys must be the column names, which must match. If *values* is a DataFrame, then both the index and column labels must match.

Returns

DataFrame DataFrame of booleans showing whether each element in the DataFrame is contained in values.

See also:

[*DataFrame.eq*](#) Equality test for DataFrame.

[*Series.isin*](#) Equivalent method on Series.

[*Series.str.contains*](#) Test if pattern or regex is contained within a string of a Series or Index.

Examples

```
>>> df = pd.DataFrame({'num_legs': [2, 4], 'num_wings': [2, 0]},
...                    index=['falcon', 'dog'])
>>> df
```

| | num_legs | num_wings |
|--------|----------|-----------|
| falcon | 2 | 2 |
| dog | 4 | 0 |

When values is a list check whether every value in the DataFrame is present in the list (which animals have 0 or 2 legs or wings)

```
>>> df.isin([0, 2])
```

| | num_legs | num_wings |
|--------|----------|-----------|
| falcon | True | True |
| dog | False | True |

When values is a dict, we can pass values to check for each column separately:

```
>>> df.isin({'num_wings': [0, 3]})
```

| | num_legs | num_wings |
|--------|----------|-----------|
| falcon | False | False |
| dog | False | True |

When values is a Series or DataFrame the index and column must match. Note that 'falcon' does not match based on the number of legs in df2.

```
>>> other = pd.DataFrame({'num_legs': [8, 2], 'num_wings': [0, 2]},
...                      index=['spider', 'falcon'])
>>> df.isin(other)
```

| | num_legs | num_wings |
|--------|----------|-----------|
| falcon | True | True |
| dog | False | False |

pandas.DataFrame.isna**DataFrame.isna()**

Detect missing values.

Return a boolean same-sized object indicating if the values are NA. NA values, such as None or numpy.NaN, gets mapped to True values. Everything else gets mapped to False values. Characters such as empty strings '' or numpy.inf are not considered NA values (unless you set pandas.options.mode.use_inf_as_na = True).

Returns

DataFrame Mask of bool values for each element in DataFrame that indicates whether an element is an NA value.

See also:*DataFrame.isnull* Alias of isna.*DataFrame.notna* Boolean inverse of isna.*DataFrame.dropna* Omit axes labels with missing values.*isna* Top-level isna.**Examples**

Show which entries in a DataFrame are NA.

```
>>> df = pd.DataFrame(dict(age=[5, 6, np.NaN],
...                          born=[pd.NaT, pd.Timestamp('1939-05-27'),
...                                pd.Timestamp('1940-04-25')],
...                          name=['Alfred', 'Batman', ''],
...                          toy=[None, 'Batmobile', 'Joker']))
>>> df
   age      born  name      toy
0  5.0      NaT  Alfred  None
1  6.0 1939-05-27  Batman  Batmobile
2  NaN 1940-04-25           Joker
```

```
>>> df.isna()
   age  born  name  toy
0  False  True  False  True
1  False  False  False  False
2   True  False  False  False
```

Show which entries in a Series are NA.

```
>>> ser = pd.Series([5, 6, np.NaN])
>>> ser
0    5.0
1    6.0
2    NaN
dtype: float64
```

```
>>> ser.isna()
0    False
1    False
2     True
dtype: bool
```

pandas.DataFrame.isnull

DataFrame.isnull()

Detect missing values.

Return a boolean same-sized object indicating if the values are NA. NA values, such as `None` or `numpy.NaN`, gets mapped to `True` values. Everything else gets mapped to `False` values. Characters such as empty strings `' '` or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`).

Returns

DataFrame Mask of bool values for each element in DataFrame that indicates whether an element is an NA value.

See also:

[*DataFrame.isnull*](#) Alias of `isna`.

[*DataFrame.notna*](#) Boolean inverse of `isna`.

[*DataFrame.dropna*](#) Omit axes labels with missing values.

[*isna*](#) Top-level `isna`.

Examples

Show which entries in a DataFrame are NA.

```
>>> df = pd.DataFrame(dict(age=[5, 6, np.NaN],
...                        born=[pd.NaT, pd.Timestamp('1939-05-27'),
...                              pd.Timestamp('1940-04-25')],
...                        name=['Alfred', 'Batman', ''],
...                        toy=[None, 'Batmobile', 'Joker']))
>>> df
   age    born  name    toy
0  5.0     NaT Alfred  None
1  6.0 1939-05-27 Batman Batmobile
2  NaN 1940-04-25      Joker
```

```
>>> df.isna()
   age  born  name  toy
0 False  True False  True
1 False False False False
2  True False False False
```

Show which entries in a Series are NA.

```
>>> ser = pd.Series([5, 6, np.NaN])
>>> ser
0    5.0
1    6.0
2    NaN
dtype: float64
```

```
>>> ser.isna()
0    False
1    False
2     True
dtype: bool
```

pandas.DataFrame.items

DataFrame.items()

Iterate over (column name, Series) pairs.

Iterates over the DataFrame columns, returning a tuple with the column name and the content as a Series.

Yields

label [object] The column names for the DataFrame being iterated over.

content [Series] The column entries belonging to each label, as a Series.

See also:

DataFrame.iterrows Iterate over DataFrame rows as (index, Series) pairs.

DataFrame.itertuples Iterate over DataFrame rows as namedtuples of the values.

Examples

```
>>> df = pd.DataFrame({'species': ['bear', 'bear', 'marsupial'],
...                   'population': [1864, 22000, 80000]},
...                   index=['panda', 'polar', 'koala'])
>>> df
   species  population
panda   bear      1864
polar   bear     22000
koala  marsupial  80000
>>> for label, content in df.items():
...     print(f'label: {label}')
...     print(f'content: {content}', sep='\n')
...
label: species
content:
panda      bear
polar      bear
koala  marsupial
Name: species, dtype: object
label: population
```

(continues on next page)

(continued from previous page)

```

content:
panda      1864
polar     22000
koala     80000
Name: population, dtype: int64

```

pandas.DataFrame.iteritems

DataFrame.iteritems()

Iterate over (column name, Series) pairs.

Iterates over the DataFrame columns, returning a tuple with the column name and the content as a Series.

Yields

label [object] The column names for the DataFrame being iterated over.

content [Series] The column entries belonging to each label, as a Series.

See also:

[*DataFrame.iterrows*](#) Iterate over DataFrame rows as (index, Series) pairs.

[*DataFrame.itertuples*](#) Iterate over DataFrame rows as namedtuples of the values.

Examples

```

>>> df = pd.DataFrame({'species': ['bear', 'bear', 'marsupial'],
...                    'population': [1864, 22000, 80000]},
...                    index=['panda', 'polar', 'koala'])
>>> df
   species  population
panda   bear         1864
polar   bear        22000
koala  marsupial    80000
>>> for label, content in df.items():
...     print(f'label: {label}')
...     print(f'content: {content}', sep='\n')
...
label: species
content:
panda      bear
polar      bear
koala  marsupial
Name: species, dtype: object
label: population
content:
panda      1864
polar     22000
koala     80000
Name: population, dtype: int64

```

pandas.DataFrame.iterrows

DataFrame.iterrows()

Iterate over DataFrame rows as (index, Series) pairs.

Yields

index [label or tuple of label] The index of the row. A tuple for a *MultiIndex*.

data [Series] The data of the row as a Series.

See also:

[*DataFrame.itertuples*](#) Iterate over DataFrame rows as namedtuples of the values.

[*DataFrame.items*](#) Iterate over (column name, Series) pairs.

Notes

1. Because `iterrows` returns a Series for each row, it does **not** preserve dtypes across the rows (dtypes are preserved across columns for DataFrames). For example,

```
>>> df = pd.DataFrame([[1, 1.5]], columns=['int', 'float'])
>>> row = next(df.iterrows())[1]
>>> row
int      1.0
float    1.5
Name: 0, dtype: float64
>>> print(row['int'].dtype)
float64
>>> print(df['int'].dtype)
int64
```

To preserve dtypes while iterating over the rows, it is better to use `itertuples()` which returns namedtuples of the values and which is generally faster than `iterrows`.

2. You should **never modify** something you are iterating over. This is not guaranteed to work in all cases. Depending on the data types, the iterator returns a copy and not a view, and writing to it will have no effect.

pandas.DataFrame.itertuples

DataFrame.itertuples(*index=True, name='Pandas'*)

Iterate over DataFrame rows as namedtuples.

Parameters

index [bool, default True] If True, return the index as the first element of the tuple.

name [str or None, default "Pandas"] The name of the returned namedtuples or None to return regular tuples.

Returns

iterator An object to iterate over namedtuples for each row in the DataFrame with the first field possibly being the index and following fields being the column values.

See also:

DataFrame.iterrows Iterate over DataFrame rows as (index, Series) pairs.

DataFrame.items Iterate over (column name, Series) pairs.

Notes

The column names will be renamed to positional names if they are invalid Python identifiers, repeated, or start with an underscore. On python versions < 3.7 regular tuples are returned for DataFrames with a large number of columns (>254).

Examples

```
>>> df = pd.DataFrame({'num_legs': [4, 2], 'num_wings': [0, 2]},
...                    index=['dog', 'hawk'])
>>> df
   num_legs  num_wings
dog         4         0
hawk        2         2
>>> for row in df.itertuples():
...     print(row)
...
Pandas(Index='dog', num_legs=4, num_wings=0)
Pandas(Index='hawk', num_legs=2, num_wings=2)
```

By setting the *index* parameter to `False` we can remove the index as the first element of the tuple:

```
>>> for row in df.itertuples(index=False):
...     print(row)
...
Pandas(num_legs=4, num_wings=0)
Pandas(num_legs=2, num_wings=2)
```

With the *name* parameter set we set a custom name for the yielded namedtuples:

```
>>> for row in df.itertuples(name='Animal'):
...     print(row)
...
Animal(Index='dog', num_legs=4, num_wings=0)
Animal(Index='hawk', num_legs=2, num_wings=2)
```

pandas.DataFrame.join

DataFrame.join(*other*, *on=None*, *how='left'*, *lsuffix=""*, *rsuffix=""*, *sort=False*)

Join columns of another DataFrame.

Join columns with *other* DataFrame either on index or on a key column. Efficiently join multiple DataFrame objects by index at once by passing a list.

Parameters

other [DataFrame, Series, or list of DataFrame] Index should be similar to one of the columns in this one. If a Series is passed, its name attribute must be set, and that will be used as the column name in the resulting joined DataFrame.

on [str, list of str, or array-like, optional] Column or index level name(s) in the caller to join on the index in *other*, otherwise joins index-on-index. If multiple values given, the *other* DataFrame must have a MultiIndex. Can pass an array as the join key if it is not already contained in the calling DataFrame. Like an Excel VLOOKUP operation.

how [{ 'left', 'right', 'outer', 'inner' }, default 'left'] How to handle the operation of the two objects.

- left: use calling frame's index (or column if on is specified)
- right: use *other*'s index.
- outer: form union of calling frame's index (or column if on is specified) with *other*'s index, and sort it. lexicographically.
- inner: form intersection of calling frame's index (or column if on is specified) with *other*'s index, preserving the order of the calling's one.

lsuffix [str, default ''] Suffix to use from left frame's overlapping columns.

rsuffix [str, default ''] Suffix to use from right frame's overlapping columns.

sort [bool, default False] Order result DataFrame lexicographically by the join key. If False, the order of the join key depends on the join type (how keyword).

Returns

DataFrame A dataframe containing columns from both the caller and *other*.

See also:

[*DataFrame.merge*](#) For column(s)-on-column(s) operations.

Notes

Parameters *on*, *lsuffix*, and *rsuffix* are not supported when passing a list of *DataFrame* objects.

Support for specifying index levels as the *on* parameter was added in version 0.23.0.

Examples

```
>>> df = pd.DataFrame({'key': ['K0', 'K1', 'K2', 'K3', 'K4', 'K5'],
...                   'A': ['A0', 'A1', 'A2', 'A3', 'A4', 'A5']})
```

```
>>> df
   key  A
0  K0  A0
1  K1  A1
2  K2  A2
3  K3  A3
4  K4  A4
5  K5  A5
```

```
>>> other = pd.DataFrame({'key': ['K0', 'K1', 'K2'],
...                      'B': ['B0', 'B1', 'B2']})
```

```
>>> other
   key  B
0  K0  B0
1  K1  B1
2  K2  B2
```

Join DataFrames using their indexes.

```
>>> df.join(other, lsuffix='_caller', rsuffix='_other')
   key_caller  A key_other  B
0          K0  A0         K0  B0
1          K1  A1         K1  B1
2          K2  A2         K2  B2
3          K3  A3         NaN NaN
4          K4  A4         NaN NaN
5          K5  A5         NaN NaN
```

If we want to join using the key columns, we need to set key to be the index in both *df* and *other*. The joined DataFrame will have key as its index.

```
>>> df.set_index('key').join(other.set_index('key'))
   A  B
key
K0  A0  B0
K1  A1  B1
K2  A2  B2
K3  A3  NaN
K4  A4  NaN
K5  A5  NaN
```

Another option to join using the key columns is to use the *on* parameter. `DataFrame.join` always uses *other*'s index but we can use any column in *df*. This method preserves the original DataFrame's index in the result.

```
>>> df.join(other.set_index('key'), on='key')
   key  A  B
0  K0  A0  B0
1  K1  A1  B1
2  K2  A2  B2
3  K3  A3  NaN
4  K4  A4  NaN
5  K5  A5  NaN
```

pandas.DataFrame.keys

DataFrame.keys()

Get the 'info axis' (see Indexing for more).

This is index for Series, columns for DataFrame.

Returns

Index Info axis.

pandas.DataFrame.kurt

DataFrame.**kurt**(*axis=None, skipna=None, level=None, numeric_only=None, **kwargs*)

Return unbiased kurtosis over requested axis.

Kurtosis obtained using Fisher's definition of kurtosis (kurtosis of normal == 0.0). Normalized by N-1.

Parameters

axis [{index (0), columns (1)}] Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

****kwargs** Additional keyword arguments to be passed to the function.

Returns

Series or DataFrame (if level specified)

pandas.DataFrame.kurtosis

DataFrame.**kurtosis**(*axis=None, skipna=None, level=None, numeric_only=None, **kwargs*)

Return unbiased kurtosis over requested axis.

Kurtosis obtained using Fisher's definition of kurtosis (kurtosis of normal == 0.0). Normalized by N-1.

Parameters

axis [{index (0), columns (1)}] Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

****kwargs** Additional keyword arguments to be passed to the function.

Returns

Series or DataFrame (if level specified)

pandas.DataFrame.last

`DataFrame.last(offset)`

Select final periods of time series data based on a date offset.

For a `DataFrame` with a sorted `DatetimeIndex`, this function selects the last few rows based on a date offset.

Parameters

offset [str, DateOffset, dateutil.relativedelta] The offset length of the data that will be selected. For instance, '3D' will display all the rows having their index within the last 3 days.

Returns

Series or DataFrame A subset of the caller.

Raises

TypeError If the index is not a `DatetimeIndex`

See also:

first Select initial periods of time series based on a date offset.

at_time Select values at a particular time of the day.

between_time Select values between particular times of the day.

Examples

```

>>> i = pd.date_range('2018-04-09', periods=4, freq='2D')
>>> ts = pd.DataFrame({'A': [1, 2, 3, 4]}, index=i)
>>> ts

```

| | A |
|------------|---|
| 2018-04-09 | 1 |
| 2018-04-11 | 2 |
| 2018-04-13 | 3 |
| 2018-04-15 | 4 |

Get the rows for the last 3 days:

```

>>> ts.last('3D')

```

| | A |
|------------|---|
| 2018-04-13 | 3 |
| 2018-04-15 | 4 |

Notice the data for 3 last calendar days were returned, not the last 3 observed days in the dataset, and therefore data for 2018-04-11 was not returned.

`pandas.DataFrame.last_valid_index`

`DataFrame.last_valid_index()`

Return index for last non-NA value or None, if no NA value is found.

Returns

scalar [type of index]

Notes

If all elements are non-NA/null, returns None. Also returns None for empty Series/DataFrame.

`pandas.DataFrame.le`

`DataFrame.le(other, axis='columns', level=None)`

Get Less than or equal to of dataframe and other, element-wise (binary operator *le*).

Among flexible wrappers (*eq*, *ne*, *le*, *lt*, *ge*, *gt*) to comparison operators.

Equivalent to `==`, `!=`, `<=`, `<`, `>=`, `>` with support to choose axis (rows or columns) and level for comparison.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}, default 'columns'] Whether to compare by the index (0 or 'index') or columns (1 or 'columns').

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

DataFrame of bool Result of the comparison.

See also:

[`DataFrame.eq`](#) Compare DataFrames for equality elementwise.

[`DataFrame.ne`](#) Compare DataFrames for inequality elementwise.

[`DataFrame.le`](#) Compare DataFrames for less than inequality or equality elementwise.

[`DataFrame.lt`](#) Compare DataFrames for strictly less than inequality elementwise.

[`DataFrame.ge`](#) Compare DataFrames for greater than inequality or equality elementwise.

[`DataFrame.gt`](#) Compare DataFrames for strictly greater than inequality elementwise.

Notes

Mismatched indices will be unioned together. *NaN* values are considered different (i.e. *NaN* != *NaN*).

Examples

```
>>> df = pd.DataFrame({'cost': [250, 150, 100],
...                    'revenue': [100, 250, 300]},
...                    index=['A', 'B', 'C'])
>>> df
   cost  revenue
A   250     100
B   150     250
C   100     300
```

Comparison with a scalar, using either the operator or method:

```
>>> df == 100
   cost  revenue
A  False     True
B  False     False
C   True     False
```

```
>>> df.eq(100)
   cost  revenue
A  False     True
B  False     False
C   True     False
```

When *other* is a *Series*, the columns of a DataFrame are aligned with the index of *other* and broadcast:

```
>>> df != pd.Series([100, 250], index=["cost", "revenue"])
   cost  revenue
A   True     True
B   True     False
C  False     True
```

Use the method to control the broadcast axis:

```
>>> df.ne(pd.Series([100, 300], index=["A", "D"]), axis='index')
   cost  revenue
A   True     False
B   True     True
C   True     True
D   True     True
```

When comparing to an arbitrary sequence, the number of columns must match the number elements in *other*:

```
>>> df == [250, 100]
   cost  revenue
A   True     True
```

(continues on next page)

(continued from previous page)

```
B False False
C False False
```

Use the method to control the axis:

```
>>> df.eq([250, 250, 100], axis='index')
      cost revenue
A   True   False
B  False    True
C   True   False
```

Compare to a DataFrame of different shape.

```
>>> other = pd.DataFrame({'revenue': [300, 250, 100, 150]},
...                       index=['A', 'B', 'C', 'D'])
>>> other
      revenue
A         300
B         250
C         100
D         150
```

```
>>> df.gt(other)
      cost revenue
A  False   False
B  False   False
C  False    True
D  False   False
```

Compare to a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'cost': [250, 150, 100, 150, 300, 220],
...                              'revenue': [100, 250, 300, 200, 175, 225]},
...                              index=[['Q1', 'Q1', 'Q1', 'Q2', 'Q2', 'Q2'],
...                                      ['A', 'B', 'C', 'A', 'B', 'C']])
>>> df_multindex
      cost revenue
Q1 A   250     100
   B   150     250
   C   100     300
Q2 A   150     200
   B   300     175
   C   220     225
```

```
>>> df.le(df_multindex, level=1)
      cost revenue
Q1 A   True     True
   B   True     True
   C   True     True
Q2 A  False     True
   B   True     False
   C   True     False
```

pandas.DataFrame.lookup

`DataFrame.lookup(row_labels, col_labels)`

Label-based “fancy indexing” function for DataFrame. Given equal-length arrays of row and column labels, return an array of the values corresponding to each (row, col) pair.

Deprecated since version 1.2.0: `DataFrame.lookup` is deprecated, use `DataFrame.melt` and `DataFrame.loc` instead. For further details see *Looking up values by index/column labels*.

Parameters

row_labels [sequence] The row labels to use for lookup.

col_labels [sequence] The column labels to use for lookup.

Returns

numpy.ndarray The found values.

pandas.DataFrame.lt

`DataFrame.lt(other, axis='columns', level=None)`

Get Less than of dataframe and other, element-wise (binary operator *lt*).

Among flexible wrappers (*eq*, *ne*, *le*, *lt*, *ge*, *gt*) to comparison operators.

Equivalent to `==`, `!=`, `<=`, `<`, `>=`, `>` with support to choose axis (rows or columns) and level for comparison.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}], default 'columns'] Whether to compare by the index (0 or 'index') or columns (1 or 'columns').

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

DataFrame of bool Result of the comparison.

See also:

[*DataFrame.eq*](#) Compare DataFrames for equality elementwise.

[*DataFrame.ne*](#) Compare DataFrames for inequality elementwise.

[*DataFrame.le*](#) Compare DataFrames for less than inequality or equality elementwise.

[*DataFrame.lt*](#) Compare DataFrames for strictly less than inequality elementwise.

[*DataFrame.ge*](#) Compare DataFrames for greater than inequality or equality elementwise.

[*DataFrame.gt*](#) Compare DataFrames for strictly greater than inequality elementwise.

Notes

Mismatched indices will be unioned together. *NaN* values are considered different (i.e. *NaN* != *NaN*).

Examples

```
>>> df = pd.DataFrame({'cost': [250, 150, 100],
...                    'revenue': [100, 250, 300]},
...                    index=['A', 'B', 'C'])
>>> df
   cost  revenue
A   250     100
B   150     250
C   100     300
```

Comparison with a scalar, using either the operator or method:

```
>>> df == 100
   cost  revenue
A  False     True
B  False    False
C   True    False
```

```
>>> df.eq(100)
   cost  revenue
A  False     True
B  False    False
C   True    False
```

When *other* is a *Series*, the columns of a DataFrame are aligned with the index of *other* and broadcast:

```
>>> df != pd.Series([100, 250], index=["cost", "revenue"])
   cost  revenue
A   True     True
B   True    False
C  False     True
```

Use the method to control the broadcast axis:

```
>>> df.ne(pd.Series([100, 300], index=["A", "D"]), axis='index')
   cost  revenue
A   True    False
B   True     True
C   True     True
D   True     True
```

When comparing to an arbitrary sequence, the number of columns must match the number elements in *other*:

```
>>> df == [250, 100]
   cost  revenue
A   True     True
```

(continues on next page)

(continued from previous page)

```
B False False
C False False
```

Use the method to control the axis:

```
>>> df.eq([250, 250, 100], axis='index')
      cost revenue
A   True   False
B  False    True
C   True   False
```

Compare to a DataFrame of different shape.

```
>>> other = pd.DataFrame({'revenue': [300, 250, 100, 150]},
...                       index=['A', 'B', 'C', 'D'])
>>> other
      revenue
A         300
B         250
C         100
D         150
```

```
>>> df.gt(other)
      cost revenue
A  False   False
B  False   False
C  False    True
D  False   False
```

Compare to a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'cost': [250, 150, 100, 150, 300, 220],
...                              'revenue': [100, 250, 300, 200, 175, 225]},
...                              index=[['Q1', 'Q1', 'Q1', 'Q2', 'Q2', 'Q2'],
...                                      ['A', 'B', 'C', 'A', 'B', 'C']])
>>> df_multindex
      cost revenue
Q1 A   250     100
   B   150     250
   C   100     300
Q2 A   150     200
   B   300     175
   C   220     225
```

```
>>> df.le(df_multindex, level=1)
      cost revenue
Q1 A   True    True
   B   True    True
   C   True    True
Q2 A  False    True
   B   True   False
   C   True   False
```

pandas.DataFrame.mad

DataFrame.**mad**(*axis=None, skipna=None, level=None*)

Return the mean absolute deviation of the values over the requested axis.

Parameters

axis [{index (0), columns (1)}] Axis for the function to be applied on.

skipna [bool, default None] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

Returns

Series or DataFrame (if level specified)

pandas.DataFrame.mask

DataFrame.**mask**(*cond, other=nan, inplace=False, axis=None, level=None, errors='raise', try_cast=NoDefault.no_default*)

Replace values where the condition is True.

Parameters

cond [bool Series/DataFrame, array-like, or callable] Where *cond* is False, keep the original value. Where True, replace with corresponding value from *other*. If *cond* is callable, it is computed on the Series/DataFrame and should return boolean Series/DataFrame or array. The callable must not change input Series/DataFrame (though pandas doesn't check it).

other [scalar, Series/DataFrame, or callable] Entries where *cond* is True are replaced with corresponding value from *other*. If *other* is callable, it is computed on the Series/DataFrame and should return scalar or Series/DataFrame. The callable must not change input Series/DataFrame (though pandas doesn't check it).

inplace [bool, default False] Whether to perform the operation in place on the data.

axis [int, default None] Alignment axis if needed.

level [int, default None] Alignment level if needed.

errors [str, {'raise', 'ignore'}, default 'raise'] Note that currently this parameter won't affect the results and will always coerce to a suitable dtype.

- 'raise' : allow exceptions to be raised.
- 'ignore' : suppress exceptions. On error return original object.

try_cast [bool, default None] Try to cast the result back to the input type (if possible).

Deprecated since version 1.3.0: Manually cast back if necessary.

Returns

Same type as caller or None if inplace=True.

See also:

[DataFrame.where\(\)](#) Return an object of same shape as self.

Notes

The mask method is an application of the if-then idiom. For each element in the calling DataFrame, if `cond` is `False` the element is used; otherwise the corresponding element from the DataFrame `other` is used.

The signature for `DataFrame.where()` differs from `numpy.where()`. Roughly `df1.where(m, df2)` is equivalent to `np.where(m, df1, df2)`.

For further details and examples see the mask documentation in [indexing](#).

Examples

```
>>> s = pd.Series(range(5))
>>> s.where(s > 0)
0    NaN
1    1.0
2    2.0
3    3.0
4    4.0
dtype: float64
>>> s.mask(s > 0)
0    0.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

```
>>> s.where(s > 1, 10)
0    10
1    10
2     2
3     3
4     4
dtype: int64
>>> s.mask(s > 1, 10)
0     0

```

pandas.DataFrame.max

`DataFrame.max`(*axis=None, skipna=None, level=None, numeric_only=None, **kwargs*)

Return the maximum of the values over the requested axis.

If you want the *index* of the maximum, use `idxmax`. This is the equivalent of the numpy `ndarray` method `argmax`.

Parameters

axis [{index (0), columns (1)}] Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

****kwargs** Additional keyword arguments to be passed to the function.

Returns

Series or DataFrame (if level specified)

See also:

[`Series.sum`](#) Return the sum.

[`Series.min`](#) Return the minimum.

[`Series.max`](#) Return the maximum.

[`Series.idxmin`](#) Return the index of the minimum.

Series.idxmax Return the index of the maximum.

DataFrame.sum Return the sum over the requested axis.

DataFrame.min Return the minimum over the requested axis.

DataFrame.max Return the maximum over the requested axis.

DataFrame.idxmin Return the index of the minimum over the requested axis.

DataFrame.idxmax Return the index of the maximum over the requested axis.

Examples

```
>>> idx = pd.MultiIndex.from_arrays([
...     ['warm', 'warm', 'cold', 'cold'],
...     ['dog', 'falcon', 'fish', 'spider']],
...     names=['blooded', 'animal'])
>>> s = pd.Series([4, 2, 0, 8], name='legs', index=idx)
>>> s
blooded  animal
warm     dog      4
         falcon   2
cold     fish     0
         spider   8
Name: legs, dtype: int64
```

```
>>> s.max()
8
```

pandas.DataFrame.mean

DataFrame.mean(*axis=None, skipna=None, level=None, numeric_only=None, **kwargs*)

Return the mean of the values over the requested axis.

Parameters

axis [{index (0), columns (1)}] Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

****kwargs** Additional keyword arguments to be passed to the function.

Returns

Series or DataFrame (if level specified)

pandas.DataFrame.median

DataFrame.**median**(*axis=None, skipna=None, level=None, numeric_only=None, **kwargs*)

Return the median of the values over the requested axis.

Parameters

axis [{index (0), columns (1)}] Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

****kwargs** Additional keyword arguments to be passed to the function.

Returns

Series or DataFrame (if level specified)

pandas.DataFrame.melt

DataFrame.**melt**(*id_vars=None, value_vars=None, var_name=None, value_name='value', col_level=None, ignore_index=True*)

Unpivot a DataFrame from wide to long format, optionally leaving identifiers set.

This function is useful to massage a DataFrame into a format where one or more columns are identifier variables (*id_vars*), while all other columns, considered measured variables (*value_vars*), are “unpivoted” to the row axis, leaving just two non-identifier columns, ‘variable’ and ‘value’.

Parameters

id_vars [tuple, list, or ndarray, optional] Column(s) to use as identifier variables.

value_vars [tuple, list, or ndarray, optional] Column(s) to unpivot. If not specified, uses all columns that are not set as *id_vars*.

var_name [scalar] Name to use for the ‘variable’ column. If None it uses `frame.columns.name` or ‘variable’.

value_name [scalar, default ‘value’] Name to use for the ‘value’ column.

col_level [int or str, optional] If columns are a MultiIndex then use this level to melt.

ignore_index [bool, default True] If True, original index is ignored. If False, the original index is retained. Index labels will be repeated as necessary.

New in version 1.1.0.

Returns

DataFrame Unpivoted DataFrame.

See also:

melt Identical method.

pivot_table Create a spreadsheet-style pivot table as a DataFrame.

DataFrame.pivot Return reshaped DataFrame organized by given index / column values.

`DataFrame.explode` Explode a DataFrame from list-like columns to long format.

Examples

```
>>> df = pd.DataFrame({'A': {0: 'a', 1: 'b', 2: 'c'},
...                   'B': {0: 1, 1: 3, 2: 5},
...                   'C': {0: 2, 1: 4, 2: 6}})
>>> df
   A  B  C
0  a  1  2
1  b  3  4
2  c  5  6
```

```
>>> df.melt(id_vars=['A'], value_vars=['B'])
   A variable  value
0  a         B      1
1  b         B      3
2  c         B      5
```

```
>>> df.melt(id_vars=['A'], value_vars=['B', 'C'])
   A variable  value
0  a         B      1
1  b         B      3
2  c         B      5
3  a         C      2
4  b         C      4
5  c         C      6
```

The names of 'variable' and 'value' columns can be customized:

```
>>> df.melt(id_vars=['A'], value_vars=['B'],
...         var_name='myVarname', value_name='myValname')
   A myVarname myValname
0  a         B          1
1  b         B          3
2  c         B          5
```

Original index values can be kept around:

```
>>> df.melt(id_vars=['A'], value_vars=['B', 'C'], ignore_index=False)
   A variable  value
0  a         B      1
1  b         B      3
2  c         B      5
0  a         C      2
1  b         C      4
2  c         C      6
```

If you have multi-index columns:

```
>>> df.columns = [list('ABC'), list('DEF')]
>>> df
```

(continues on next page)

(continued from previous page)

```

A B C
D E F
0 a 1 2
1 b 3 4
2 c 5 6

```

```

>>> df.melt(col_level=0, id_vars=['A'], value_vars=['B'])
  A variable  value
0 a         B      1
1 b         B      3
2 c         B      5

```

```

>>> df.melt(id_vars=['A', 'D'], value_vars=['B', 'E'])
(A, D) variable_0 variable_1  value
0     a           B           E      1
1     b           B           E      3
2     c           B           E      5

```

pandas.DataFrame.memory_usage

`DataFrame.memory_usage(index=True, deep=False)`

Return the memory usage of each column in bytes.

The memory usage can optionally include the contribution of the index and elements of *object* dtype.

This value is displayed in `DataFrame.info` by default. This can be suppressed by setting `pandas.options.display.memory_usage` to `False`.

Parameters

index [bool, default True] Specifies whether to include the memory usage of the `DataFrame`'s index in returned Series. If `index=True`, the memory usage of the index is the first item in the output.

deep [bool, default False] If True, introspect the data deeply by interrogating *object* dtypes for system-level memory consumption, and include it in the returned values.

Returns

Series A Series whose index is the original column names and whose values is the memory usage of each column in bytes.

See also:

[`numpy.ndarray.nbytes`](#) Total bytes consumed by the elements of an ndarray.

[`Series.memory_usage`](#) Bytes consumed by a Series.

[`Categorical`](#) Memory-efficient array for string values with many repeated values.

[`DataFrame.info`](#) Concise summary of a DataFrame.

Examples

```
>>> dtypes = ['int64', 'float64', 'complex128', 'object', 'bool']
>>> data = dict([(t, np.ones(shape=5000, dtype=int).astype(t))
...             for t in dtypes])
>>> df = pd.DataFrame(data)
>>> df.head()
   int64  float64      complex128  object  bool
0      1    1.0      1.0+0.0j      1  True
1      1    1.0      1.0+0.0j      1  True
2      1    1.0      1.0+0.0j      1  True
3      1    1.0      1.0+0.0j      1  True
4      1    1.0      1.0+0.0j      1  True
```

```
>>> df.memory_usage()
Index          128
int64         40000
float64       40000
complex128    80000
object        40000
bool          5000
dtype: int64
```

```
>>> df.memory_usage(index=False)
int64         40000
float64       40000
complex128    80000
object        40000
bool          5000
dtype: int64
```

The memory footprint of *object* dtype columns is ignored by default:

```
>>> df.memory_usage(deep=True)
Index          128
int64         40000
float64       40000
complex128    80000
object       180000
bool          5000
dtype: int64
```

Use a Categorical for efficient storage of an object-dtype column with many repeated values.

```
>>> df['object'].astype('category').memory_usage(deep=True)
5244
```

pandas.DataFrame.merge

```
DataFrame.merge(right, how='inner', on=None, left_on=None, right_on=None, left_index=False,
                right_index=False, sort=False, suffixes=('_x', '_y'), copy=True, indicator=False,
                validate=None)
```

Merge DataFrame or named Series objects with a database-style join.

A named Series object is treated as a DataFrame with a single named column.

The join is done on columns or indexes. If joining columns on columns, the DataFrame indexes *will be ignored*. Otherwise if joining indexes on indexes or indexes on a column or columns, the index will be passed on. When performing a cross merge, no column specifications to merge on are allowed.

Parameters

right [DataFrame or named Series] Object to merge with.

how [{‘left’, ‘right’, ‘outer’, ‘inner’, ‘cross’}, default ‘inner’] Type of merge to be performed.

- left: use only keys from left frame, similar to a SQL left outer join; preserve key order.
- right: use only keys from right frame, similar to a SQL right outer join; preserve key order.
- outer: use union of keys from both frames, similar to a SQL full outer join; sort keys lexicographically.
- inner: use intersection of keys from both frames, similar to a SQL inner join; preserve the order of the left keys.
- cross: creates the cartesian product from both frames, preserves the order of the left keys.

New in version 1.2.0.

on [label or list] Column or index level names to join on. These must be found in both DataFrames. If *on* is None and not merging on indexes then this defaults to the intersection of the columns in both DataFrames.

left_on [label or list, or array-like] Column or index level names to join on in the left DataFrame. Can also be an array or list of arrays of the length of the left DataFrame. These arrays are treated as if they are columns.

right_on [label or list, or array-like] Column or index level names to join on in the right DataFrame. Can also be an array or list of arrays of the length of the right DataFrame. These arrays are treated as if they are columns.

left_index [bool, default False] Use the index from the left DataFrame as the join key(s). If it is a MultiIndex, the number of keys in the other DataFrame (either the index or a number of columns) must match the number of levels.

right_index [bool, default False] Use the index from the right DataFrame as the join key. Same caveats as *left_index*.

sort [bool, default False] Sort the join keys lexicographically in the result DataFrame. If False, the order of the join keys depends on the join type (how keyword).

suffixes [list-like, default is (“_x”, “_y”)] A length-2 sequence where each element is optionally a string indicating the suffix to add to overlapping column names in *left* and *right* respectively. Pass a value of *None* instead of a string to indicate that the

column name from *left* or *right* should be left as-is, with no suffix. At least one of the values must not be None.

copy [bool, default True] If False, avoid copy if possible.

indicator [bool or str, default False] If True, adds a column to the output DataFrame called “_merge” with information on the source of each row. The column can be given a different name by providing a string argument. The column will have a Categorical type with the value of “left_only” for observations whose merge key only appears in the left DataFrame, “right_only” for observations whose merge key only appears in the right DataFrame, and “both” if the observation’s merge key is found in both DataFrames.

validate [str, optional] If specified, checks if merge is of specified type.

- “one_to_one” or “1:1”: check if merge keys are unique in both left and right datasets.
- “one_to_many” or “1:m”: check if merge keys are unique in left dataset.
- “many_to_one” or “m:1”: check if merge keys are unique in right dataset.
- “many_to_many” or “m:m”: allowed, but does not result in checks.

Returns

DataFrame A DataFrame of the two merged objects.

See also:

[*merge_ordered*](#) Merge with optional filling/interpolation.

[*merge_asof*](#) Merge on nearest keys.

[*DataFrame.join*](#) Similar method using indices.

Notes

Support for specifying index levels as the *on*, *left_on*, and *right_on* parameters was added in version 0.23.0
Support for merging named Series objects was added in version 0.24.0

Examples

```
>>> df1 = pd.DataFrame({'lkey': ['foo', 'bar', 'baz', 'foo'],
...                    'value': [1, 2, 3, 5]})
>>> df2 = pd.DataFrame({'rkey': ['foo', 'bar', 'baz', 'foo'],
...                    'value': [5, 6, 7, 8]})
>>> df1
   lkey  value
0   foo     1
1   bar     2
2   baz     3
3   foo     5
>>> df2
   rkey  value
0   foo     5
1   bar     6
```

(continues on next page)

(continued from previous page)

| | | |
|---|-----|---|
| 2 | baz | 7 |
| 3 | foo | 8 |

Merge df1 and df2 on the lkey and rkey columns. The value columns have the default suffixes, _x and _y, appended.

```
>>> df1.merge(df2, left_on='lkey', right_on='rkey')
   lkey  value_x rkey  value_y
0  foo         1  foo         5
1  foo         1  foo         8
2  foo         5  foo         5
3  foo         5  foo         8
4  bar         2  bar         6
5  baz         3  baz         7
```

Merge DataFrames df1 and df2 with specified left and right suffixes appended to any overlapping columns.

```
>>> df1.merge(df2, left_on='lkey', right_on='rkey',
...           suffixes=('_left', '_right'))
   lkey  value_left rkey  value_right
0  foo           1  foo           5
1  foo           1  foo           8
2  foo           5  foo           5
3  foo           5  foo           8
4  bar           2  bar           6
5  baz           3  baz           7
```

Merge DataFrames df1 and df2, but raise an exception if the DataFrames have any overlapping columns.

```
>>> df1.merge(df2, left_on='lkey', right_on='rkey', suffixes=(False, False))
Traceback (most recent call last):
...
ValueError: columns overlap but no suffix specified:
   Index(['value'], dtype='object')
```

```
>>> df1 = pd.DataFrame({'a': ['foo', 'bar'], 'b': [1, 2]})
>>> df2 = pd.DataFrame({'a': ['foo', 'baz'], 'c': [3, 4]})
>>> df1
   a  b
0  foo  1
1  bar  2
>>> df2
   a  c
0  foo  3
1  baz  4
```

```
>>> df1.merge(df2, how='inner', on='a')
   a  b  c
0  foo  1  3
```

```
>>> df1.merge(df2, how='left', on='a')
   a  b  c
```

(continues on next page)

(continued from previous page)

```
0  foo  1  3.0
1  bar  2  NaN
```

```
>>> df1 = pd.DataFrame({'left': ['foo', 'bar']})
>>> df2 = pd.DataFrame({'right': [7, 8]})
>>> df1
   left
0  foo
1  bar
>>> df2
   right
0     7
1     8
```

```
>>> df1.merge(df2, how='cross')
   left  right
0  foo     7
1  foo     8
2  bar     7
3  bar     8
```

pandas.DataFrame.min

`DataFrame.min(axis=None, skipna=None, level=None, numeric_only=None, **kwargs)`

Return the minimum of the values over the requested axis.

If you want the *index* of the minimum, use `idxmin`. This is the equivalent of the `numpy.ndarray` method `argmin`.

Parameters

axis [{index (0), columns (1)}] Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a `MultiIndex` (hierarchical), count along a particular level, collapsing into a `Series`.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for `Series`.

****kwargs** Additional keyword arguments to be passed to the function.

Returns

Series or DataFrame (if level specified)

See also:

[`Series.sum`](#) Return the sum.

[`Series.min`](#) Return the minimum.

[`Series.max`](#) Return the maximum.

[`Series.idxmin`](#) Return the index of the minimum.

Series.idxmax Return the index of the maximum.

DataFrame.sum Return the sum over the requested axis.

DataFrame.min Return the minimum over the requested axis.

DataFrame.max Return the maximum over the requested axis.

DataFrame.idxmin Return the index of the minimum over the requested axis.

DataFrame.idxmax Return the index of the maximum over the requested axis.

Examples

```
>>> idx = pd.MultiIndex.from_arrays([
...     ['warm', 'warm', 'cold', 'cold'],
...     ['dog', 'falcon', 'fish', 'spider']],
...     names=['blooded', 'animal'])
>>> s = pd.Series([4, 2, 0, 8], name='legs', index=idx)
>>> s
blooded  animal
warm     dog      4
         falcon   2
cold     fish     0
         spider   8
Name: legs, dtype: int64
```

```
>>> s.min()
0
```

pandas.DataFrame.mod

DataFrame.mod(*other*, *axis*='columns', *level*=None, *fill_value*=None)

Get Modulo of dataframe and other, element-wise (binary operator *mod*).

Equivalent to `dataframe % other`, but with support to substitute a `fill_value` for missing data in one of the inputs. With reverse version, *rmod*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

See also:

DataFrame.add Add DataFrames.

DataFrame.sub Subtract DataFrames.

DataFrame.mul Multiply DataFrames.

DataFrame.div Divide DataFrames (float division).

DataFrame.truediv Divide DataFrames (float division).

DataFrame.floordiv Divide DataFrames (integer division).

DataFrame.mod Calculate modulo (remainder after division).

DataFrame.pow Calculate exponential power.

Notes

Mismatched indices will be unioned together.

Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                    index=['circle', 'triangle', 'rectangle'])
>>> df
```

| | angles | degrees |
|-----------|--------|---------|
| circle | 0 | 360 |
| triangle | 3 | 180 |
| rectangle | 4 | 360 |

Add a scalar with operator version which return the same results.

```
>>> df + 1
```

| | angles | degrees |
|-----------|--------|---------|
| circle | 1 | 361 |
| triangle | 4 | 181 |
| rectangle | 5 | 361 |

```
>>> df.add(1)
```

| | angles | degrees |
|-----------|--------|---------|
| circle | 1 | 361 |
| triangle | 4 | 181 |
| rectangle | 5 | 361 |

Divide by constant with reverse version.

```
>>> df.div(10)
```

| | angles | degrees |
|-----------|--------|---------|
| circle | 0.0 | 36.0 |
| triangle | 0.3 | 18.0 |
| rectangle | 0.4 | 36.0 |

```
>>> df.rdiv(10)
      angles  degrees
circle      inf  0.027778
triangle  3.333333  0.055556
rectangle  2.500000  0.027778
```

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
      angles  degrees
circle      -1    358
triangle     2    178
rectangle     3    358
```

```
>>> df.sub([1, 2], axis='columns')
      angles  degrees
circle      -1    358
triangle     2    178
rectangle     3    358
```

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...        axis='index')
      angles  degrees
circle      -1    359
triangle     2    179
rectangle     3    359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                       index=['circle', 'triangle', 'rectangle'])
>>> other
      angles
circle      0
triangle     3
rectangle     4
```

```
>>> df * other
      angles  degrees
circle      0     NaN
triangle     9     NaN
rectangle   16     NaN
```

```
>>> df.mul(other, fill_value=0)
      angles  degrees
circle      0     0.0
triangle     9     0.0
rectangle   16     0.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                               'degrees': [360, 180, 360, 360, 540, 720]},
...                               index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                       ['circle', 'triangle', 'rectangle',
...                                       'square', 'pentagon', 'hexagon']])
```

```
>>> df_multindex
      angles  degrees
A circle      0     360
  triangle      3     180
  rectangle      4     360
B square      4     360
  pentagon      5     540
  hexagon      6     720
```

```
>>> df.div(df_multindex, level=1, fill_value=0)
```

```
      angles  degrees
A circle   NaN     1.0
  triangle   1.0     1.0
  rectangle   1.0     1.0
B square    0.0     0.0
  pentagon   0.0     0.0
  hexagon    0.0     0.0
```

pandas.DataFrame.mode

`DataFrame.mode(axis=0, numeric_only=False, dropna=True)`

Get the mode(s) of each element along the selected axis.

The mode of a set of values is the value that appears most often. It can be multiple values.

Parameters

axis [{0 or 'index', 1 or 'columns'}], default 0] The axis to iterate over while searching for the mode:

- 0 or 'index' : get mode of each column
- 1 or 'columns' : get mode of each row.

numeric_only [bool, default False] If True, only apply to numeric columns.

dropna [bool, default True] Don't consider counts of NaN/NaT.

Returns

DataFrame The modes of each column or row.

See also:

[Series.mode](#) Return the highest frequency value in a Series.

[Series.value_counts](#) Return the counts of values in a Series.

Examples

```
>>> df = pd.DataFrame([('bird', 2, 2),
...                    ('mammal', 4, np.nan),
...                    ('arthropod', 8, 0),
...                    ('bird', 2, np.nan)],
...                    index=('falcon', 'horse', 'spider', 'ostrich'),
...                    columns=('species', 'legs', 'wings'))
>>> df
```

| | species | legs | wings |
|---------|-----------|------|-------|
| falcon | bird | 2 | 2.0 |
| horse | mammal | 4 | NaN |
| spider | arthropod | 8 | 0.0 |
| ostrich | bird | 2 | NaN |

By default, missing values are not considered, and the mode of wings are both 0 and 2. Because the resulting DataFrame has two rows, the second row of `species` and `legs` contains NaN.

```
>>> df.mode()
  species  legs  wings
0  bird    2.0   0.0
1  NaN    NaN   2.0
```

Setting `dropna=False` NaN values are considered and they can be the mode (like for wings).

```
>>> df.mode(dropna=False)
  species  legs  wings
0  bird    2   NaN
1  NaN    NaN   2.0
```

Setting `numeric_only=True`, only the mode of numeric columns is computed, and columns of other types are ignored.

```
>>> df.mode(numeric_only=True)
  legs  wings
0  2.0   0.0
1  NaN   2.0
```

To compute the mode over columns and not rows, use the `axis` parameter:

```
>>> df.mode(axis='columns', numeric_only=True)
           0    1
falcon    2.0 NaN
horse     4.0 NaN
spider    0.0 8.0
ostrich   2.0 NaN
```

pandas.DataFrame.mul

`DataFrame.mul`(*other*, *axis*='columns', *level*=None, *fill_value*=None)

Get Multiplication of dataframe and other, element-wise (binary operator *mul*).

Equivalent to `dataframe * other`, but with support to substitute a *fill_value* for missing data in one of the inputs. With reverse version, *rmul*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: +, -, *, /, //, %, **.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

See also:

[*DataFrame.add*](#) Add DataFrames.

[*DataFrame.sub*](#) Subtract DataFrames.

[*DataFrame.mul*](#) Multiply DataFrames.

[*DataFrame.div*](#) Divide DataFrames (float division).

[*DataFrame.truediv*](#) Divide DataFrames (float division).

[*DataFrame.floordiv*](#) Divide DataFrames (integer division).

[*DataFrame.mod*](#) Calculate modulo (remainder after division).

[*DataFrame.pow*](#) Calculate exponential power.

Notes

Mismatched indices will be unioned together.

Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                    index=['circle', 'triangle', 'rectangle'])
>>> df
```

| | angles | degrees |
|-----------|--------|---------|
| circle | 0 | 360 |
| triangle | 3 | 180 |
| rectangle | 4 | 360 |

Add a scalar with operator version which return the same results.

```
>>> df + 1
```

| | angles | degrees |
|-----------|--------|---------|
| circle | 1 | 361 |
| triangle | 4 | 181 |
| rectangle | 5 | 361 |

```
>>> df.add(1)
```

| | angles | degrees |
|-----------|--------|---------|
| circle | 1 | 361 |
| triangle | 4 | 181 |
| rectangle | 5 | 361 |

Divide by constant with reverse version.

```
>>> df.div(10)
```

| | angles | degrees |
|-----------|--------|---------|
| circle | 0.0 | 36.0 |
| triangle | 0.3 | 18.0 |
| rectangle | 0.4 | 36.0 |

```
>>> df.rdiv(10)
```

| | angles | degrees |
|-----------|----------|----------|
| circle | inf | 0.027778 |
| triangle | 3.333333 | 0.055556 |
| rectangle | 2.500000 | 0.027778 |

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
```

| | angles | degrees |
|-----------|--------|---------|
| circle | -1 | 358 |
| triangle | 2 | 178 |
| rectangle | 3 | 358 |

```
>>> df.sub([1, 2], axis='columns')
```

| | angles | degrees |
|-----------|--------|---------|
| circle | -1 | 358 |
| triangle | 2 | 178 |
| rectangle | 3 | 358 |

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...         axis='index')
      angles  degrees
circle      -1     359
triangle     2     179
rectangle    3     359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                       index=['circle', 'triangle', 'rectangle'])
>>> other
      angles
circle      0
triangle     3
rectangle    4
```

```
>>> df * other
      angles  degrees
circle      0     NaN
triangle     9     NaN
rectangle   16     NaN
```

```
>>> df.mul(other, fill_value=0)
      angles  degrees
circle      0     0.0
triangle     9     0.0
rectangle   16     0.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                               'degrees': [360, 180, 360, 360, 540, 720]},
...                              index=[[ 'A', 'A', 'A', 'B', 'B', 'B'],
...                                     ['circle', 'triangle', 'rectangle',
...                                      'square', 'pentagon', 'hexagon']])
>>> df_multindex
      angles  degrees
A circle      0     360
  triangle     3     180
  rectangle    4     360
B square      4     360
  pentagon     5     540
  hexagon      6     720
```

```
>>> df.div(df_multindex, level=1, fill_value=0)
      angles  degrees
A circle    NaN     1.0
  triangle  1.0     1.0
  rectangle  1.0     1.0
B square    0.0     0.0
  pentagon  0.0     0.0
  hexagon   0.0     0.0
```

pandas.DataFrame.multiply

`DataFrame.multiply(other, axis='columns', level=None, fill_value=None)`

Get Multiplication of dataframe and other, element-wise (binary operator *mul*).

Equivalent to `dataframe * other`, but with support to substitute a `fill_value` for missing data in one of the inputs. With reverse version, *rmul*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

See also:

[*DataFrame.add*](#) Add DataFrames.

[*DataFrame.sub*](#) Subtract DataFrames.

[*DataFrame.mul*](#) Multiply DataFrames.

[*DataFrame.div*](#) Divide DataFrames (float division).

[*DataFrame.truediv*](#) Divide DataFrames (float division).

[*DataFrame.floordiv*](#) Divide DataFrames (integer division).

[*DataFrame.mod*](#) Calculate modulo (remainder after division).

[*DataFrame.pow*](#) Calculate exponential power.

Notes

Mismatched indices will be unioned together.

Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                    index=['circle', 'triangle', 'rectangle'])
>>> df
```

| | angles | degrees |
|-----------|--------|---------|
| circle | 0 | 360 |
| triangle | 3 | 180 |
| rectangle | 4 | 360 |

Add a scalar with operator version which return the same results.

```
>>> df + 1
```

| | angles | degrees |
|-----------|--------|---------|
| circle | 1 | 361 |
| triangle | 4 | 181 |
| rectangle | 5 | 361 |

```
>>> df.add(1)
```

| | angles | degrees |
|-----------|--------|---------|
| circle | 1 | 361 |
| triangle | 4 | 181 |
| rectangle | 5 | 361 |

Divide by constant with reverse version.

```
>>> df.div(10)
```

| | angles | degrees |
|-----------|--------|---------|
| circle | 0.0 | 36.0 |
| triangle | 0.3 | 18.0 |
| rectangle | 0.4 | 36.0 |

```
>>> df.rdiv(10)
```

| | angles | degrees |
|-----------|----------|----------|
| circle | inf | 0.027778 |
| triangle | 3.333333 | 0.055556 |
| rectangle | 2.500000 | 0.027778 |

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
```

| | angles | degrees |
|-----------|--------|---------|
| circle | -1 | 358 |
| triangle | 2 | 178 |
| rectangle | 3 | 358 |

```
>>> df.sub([1, 2], axis='columns')
```

| | angles | degrees |
|-----------|--------|---------|
| circle | -1 | 358 |
| triangle | 2 | 178 |
| rectangle | 3 | 358 |

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...         axis='index')
          angles  degrees
circle      -1     359
triangle     2     179
rectangle    3     359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                       index=['circle', 'triangle', 'rectangle'])
>>> other
          angles
circle         0
triangle       3
rectangle      4
```

```
>>> df * other
          angles  degrees
circle         0     NaN
triangle       9     NaN
rectangle     16     NaN
```

```
>>> df.mul(other, fill_value=0)
          angles  degrees
circle         0     0.0
triangle       9     0.0
rectangle     16     0.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                               'degrees': [360, 180, 360, 360, 540, 720]},
...                              index=[[ 'A', 'A', 'A', 'B', 'B', 'B'],
...                                     ['circle', 'triangle', 'rectangle',
...                                      'square', 'pentagon', 'hexagon']])
>>> df_multindex
          angles  degrees
A circle         0     360
  triangle       3     180
  rectangle      4     360
B square         4     360
  pentagon      5     540
  hexagon       6     720
```

```
>>> df.div(df_multindex, level=1, fill_value=0)
          angles  degrees
A circle      NaN     1.0
  triangle    1.0     1.0
  rectangle    1.0     1.0
B square      0.0     0.0
  pentagon    0.0     0.0
  hexagon     0.0     0.0
```

pandas.DataFrame.ne

`DataFrame.ne`(*other*, *axis*='columns', *level*=None)

Get Not equal to of dataframe and other, element-wise (binary operator *ne*).

Among flexible wrappers (*eq*, *ne*, *le*, *lt*, *ge*, *gt*) to comparison operators.

Equivalent to `==`, `!=`, `<=`, `<`, `>=`, `>` with support to choose axis (rows or columns) and level for comparison.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}, default 'columns'] Whether to compare by the index (0 or 'index') or columns (1 or 'columns').

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

DataFrame of bool Result of the comparison.

See also:

[`DataFrame.eq`](#) Compare DataFrames for equality elementwise.

[`DataFrame.ne`](#) Compare DataFrames for inequality elementwise.

[`DataFrame.le`](#) Compare DataFrames for less than inequality or equality elementwise.

[`DataFrame.lt`](#) Compare DataFrames for strictly less than inequality elementwise.

[`DataFrame.ge`](#) Compare DataFrames for greater than inequality or equality elementwise.

[`DataFrame.gt`](#) Compare DataFrames for strictly greater than inequality elementwise.

Notes

Mismatched indices will be unioned together. *NaN* values are considered different (i.e. *NaN* != *NaN*).

Examples

```
>>> df = pd.DataFrame({'cost': [250, 150, 100],
...                    'revenue': [100, 250, 300]},
...                    index=['A', 'B', 'C'])
>>> df
   cost  revenue
A   250     100
B   150     250
C   100     300
```

Comparison with a scalar, using either the operator or method:

```
>>> df == 100
      cost  revenue
A  False    True
B  False    False
C   True    False
```

```
>>> df.eq(100)
      cost  revenue
A  False    True
B  False    False
C   True    False
```

When *other* is a *Series*, the columns of a DataFrame are aligned with the index of *other* and broadcast:

```
>>> df != pd.Series([100, 250], index=["cost", "revenue"])
      cost  revenue
A   True    True
B   True    False
C  False    True
```

Use the method to control the broadcast axis:

```
>>> df.ne(pd.Series([100, 300], index=["A", "D"]), axis='index')
      cost  revenue
A   True    False
B   True    True
C   True    True
D   True    True
```

When comparing to an arbitrary sequence, the number of columns must match the number elements in *other*:

```
>>> df == [250, 100]
      cost  revenue
A   True    True
B  False    False
C  False    False
```

Use the method to control the axis:

```
>>> df.eq([250, 250, 100], axis='index')
      cost  revenue
A   True    False
B  False    True
C   True    False
```

Compare to a DataFrame of different shape.

```
>>> other = pd.DataFrame({'revenue': [300, 250, 100, 150]},
...                       index=['A', 'B', 'C', 'D'])
>>> other
      revenue
A         300
```

(continues on next page)

(continued from previous page)

| | |
|---|-----|
| B | 250 |
| C | 100 |
| D | 150 |

```
>>> df.gt(other)
      cost  revenue
A  False   False
B  False   False
C  False    True
D  False   False
```

Compare to a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'cost': [250, 150, 100, 150, 300, 220],
...                               'revenue': [100, 250, 300, 200, 175, 225]},
...                               index=[['Q1', 'Q1', 'Q1', 'Q2', 'Q2', 'Q2'],
...                                       ['A', 'B', 'C', 'A', 'B', 'C']])
>>> df_multindex
      cost  revenue
Q1 A   250     100
   B   150     250
   C   100     300
Q2 A   150     200
   B   300     175
   C   220     225
```

```
>>> df.le(df_multindex, level=1)
      cost  revenue
Q1 A   True     True
   B   True     True
   C   True     True
Q2 A  False     True
   B   True     False
   C   True     False
```

pandas.DataFrame.nlargest

`DataFrame.nlargest`(*n*, *columns*, *keep*='first')

Return the first *n* rows ordered by *columns* in descending order.

Return the first *n* rows with the largest values in *columns*, in descending order. The columns that are not specified are returned as well, but not used for ordering.

This method is equivalent to `df.sort_values(columns, ascending=False).head(n)`, but more performant.

Parameters

n [int] Number of rows to return.

columns [label or list of labels] Column label(s) to order by.

keep [{ 'first', 'last', 'all' }, default 'first'] Where there are duplicate values:

- *first* : prioritize the first occurrence(s)
- *last* : prioritize the last occurrence(s)
- **all** [do not drop any duplicates, even it means] selecting more than *n* items.

Returns

DataFrame The first *n* rows ordered by the given columns in descending order.

See also:

DataFrame.nsmallest Return the first *n* rows ordered by *columns* in ascending order.

DataFrame.sort_values Sort DataFrame by the values.

DataFrame.head Return the first *n* rows without re-ordering.

Notes

This function cannot be used with all column types. For example, when specifying columns with *object* or *category* dtypes, `TypeError` is raised.

Examples

```
>>> df = pd.DataFrame({'population': [59000000, 65000000, 434000,
...                                   434000, 434000, 337000, 11300,
...                                   11300, 11300],
...                    'GDP': [1937894, 2583560, 12011, 4520, 12128,
...                              17036, 182, 38, 311],
...                    'alpha-2': ["IT", "FR", "MT", "MV", "BN",
...                                  "IS", "NR", "TV", "AI"]},
...                    index=["Italy", "France", "Malta",
...                              "Maldives", "Brunei", "Iceland",
...                              "Nauru", "Tuvalu", "Anguilla"])
>>> df
```

| | population | GDP | alpha-2 |
|----------|------------|---------|---------|
| Italy | 59000000 | 1937894 | IT |
| France | 65000000 | 2583560 | FR |
| Malta | 434000 | 12011 | MT |
| Maldives | 434000 | 4520 | MV |
| Brunei | 434000 | 12128 | BN |
| Iceland | 337000 | 17036 | IS |
| Nauru | 11300 | 182 | NR |
| Tuvalu | 11300 | 38 | TV |
| Anguilla | 11300 | 311 | AI |

In the following example, we will use `nlargest` to select the three rows having the largest values in column “population”.

```
>>> df.nlargest(3, 'population')
```

| | population | GDP | alpha-2 |
|--------|------------|---------|---------|
| France | 65000000 | 2583560 | FR |
| Italy | 59000000 | 1937894 | IT |
| Malta | 434000 | 12011 | MT |

When using `keep='last'`, ties are resolved in reverse order:

```
>>> df.nlargest(3, 'population', keep='last')
   population  GDP alpha-2
France  65000000  2583560    FR
Italy   59000000  1937894    IT
Brunei   434000   12128     BN
```

When using `keep='all'`, all duplicate items are maintained:

```
>>> df.nlargest(3, 'population', keep='all')
   population  GDP alpha-2
France  65000000  2583560    FR
Italy   59000000  1937894    IT
Malta   434000   12011     MT
Maldives 434000   4520     MV
Brunei  434000   12128     BN
```

To order by the largest values in column “population” and then “GDP”, we can specify multiple columns like in the next example.

```
>>> df.nlargest(3, ['population', 'GDP'])
   population  GDP alpha-2
France  65000000  2583560    FR
Italy   59000000  1937894    IT
Brunei   434000   12128     BN
```

pandas.DataFrame.notna

DataFrame.notna()

Detect existing (non-missing) values.

Return a boolean same-sized object indicating if the values are not NA. Non-missing values get mapped to True. Characters such as empty strings '' or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`). NA values, such as `None` or `numpy.NaN`, get mapped to False values.

Returns

DataFrame Mask of bool values for each element in DataFrame that indicates whether an element is not an NA value.

See also:

DataFrame.notnull Alias of `notna`.

DataFrame.isna Boolean inverse of `notna`.

DataFrame.droptna Omit axes labels with missing values.

notna Top-level `notna`.

Examples

Show which entries in a DataFrame are not NA.

```
>>> df = pd.DataFrame(dict(age=[5, 6, np.NaN],
...                          born=[pd.NaT, pd.Timestamp('1939-05-27'),
...                                pd.Timestamp('1940-04-25')],
...                          name=['Alfred', 'Batman', ''],
...                          toy=[None, 'Batmobile', 'Joker']))
>>> df
   age      born  name      toy
0  5.0      NaT  Alfred  None
1  6.0 1939-05-27  Batman  Batmobile
2  NaN 1940-04-25           Joker
```

```
>>> df.notna()
   age  born  name  toy
0  True False  True False
1  True  True  True  True
2  False  True  True  True
```

Show which entries in a Series are not NA.

```
>>> ser = pd.Series([5, 6, np.NaN])
>>> ser
0    5.0
1    6.0
2    NaN
dtype: float64
```

```
>>> ser.notna()
0     True
1     True
2    False
dtype: bool
```

pandas.DataFrame.notnull

DataFrame.notnull()

Detect existing (non-missing) values.

Return a boolean same-sized object indicating if the values are not NA. Non-missing values get mapped to True. Characters such as empty strings '' or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`). NA values, such as `None` or `numpy.NaN`, get mapped to False values.

Returns

DataFrame Mask of bool values for each element in DataFrame that indicates whether an element is not an NA value.

See also:

[`DataFrame.notnull`](#) Alias of `notna`.

DataFrame.isna Boolean inverse of notna.

DataFrame.dropna Omit axes labels with missing values.

notna Top-level notna.

Examples

Show which entries in a DataFrame are not NA.

```
>>> df = pd.DataFrame(dict(age=[5, 6, np.NaN],
...                          born=[pd.NaT, pd.Timestamp('1939-05-27'),
...                                pd.Timestamp('1940-04-25')],
...                          name=['Alfred', 'Batman', ''],
...                          toy=[None, 'Batmobile', 'Joker']))
>>> df
   age      born  name      toy
0  5.0      NaT  Alfred  None
1  6.0 1939-05-27  Batman  Batmobile
2  NaN 1940-04-25           Joker
```

```
>>> df.notna()
   age  born  name  toy
0  True  False  True  False
1  True   True  True  True
2  False  True  True  True
```

Show which entries in a Series are not NA.

```
>>> ser = pd.Series([5, 6, np.NaN])
>>> ser
0    5.0
1    6.0
2    NaN
dtype: float64
```

```
>>> ser.notna()
0     True
1     True
2    False
dtype: bool
```

pandas.DataFrame.nsmallest

DataFrame.nsmallest(*n*, *columns*, *keep*='first')

Return the first *n* rows ordered by *columns* in ascending order.

Return the first *n* rows with the smallest values in *columns*, in ascending order. The columns that are not specified are returned as well, but not used for ordering.

This method is equivalent to `df.sort_values(columns, ascending=True).head(n)`, but more performant.

Parameters

n [int] Number of items to retrieve.

columns [list or str] Column name or names to order by.

keep [{ 'first', 'last', 'all' }, default 'first'] Where there are duplicate values:

- **first** : take the first occurrence.
- **last** : take the last occurrence.
- **all** : do not drop any duplicates, even it means selecting more than *n* items.

Returns

DataFrame

See also:

DataFrame.nlargest Return the first *n* rows ordered by *columns* in descending order.

DataFrame.sort_values Sort DataFrame by the values.

DataFrame.head Return the first *n* rows without re-ordering.

Examples

```
>>> df = pd.DataFrame({'population': [59000000, 65000000, 434000,
...                                   434000, 434000, 337000, 337000,
...                                   11300, 11300],
...                    'GDP': [1937894, 2583560, 12011, 4520, 12128,
...                              17036, 182, 38, 311],
...                    'alpha-2': ["IT", "FR", "MT", "MV", "BN",
...                                  "IS", "NR", "TV", "AI"]},
...                    index=["Italy", "France", "Malta",
...                              "Maldives", "Brunei", "Iceland",
...                              "Nauru", "Tuvalu", "Anguilla"])
>>> df
```

| | population | GDP | alpha-2 |
|----------|------------|---------|---------|
| Italy | 59000000 | 1937894 | IT |
| France | 65000000 | 2583560 | FR |
| Malta | 434000 | 12011 | MT |
| Maldives | 434000 | 4520 | MV |
| Brunei | 434000 | 12128 | BN |
| Iceland | 337000 | 17036 | IS |
| Nauru | 337000 | 182 | NR |
| Tuvalu | 11300 | 38 | TV |
| Anguilla | 11300 | 311 | AI |

In the following example, we will use `nsmallest` to select the three rows having the smallest values in column “population”.

```
>>> df.nsmallest(3, 'population')
```

| | population | GDP | alpha-2 |
|----------|------------|-------|---------|
| Tuvalu | 11300 | 38 | TV |
| Anguilla | 11300 | 311 | AI |
| Iceland | 337000 | 17036 | IS |

When using `keep='last'`, ties are resolved in reverse order:

```
>>> df.nsmallest(3, 'population', keep='last')
      population  GDP alpha-2
Anguilla      11300    311     AI
Tuvalu        11300     38     TV
Nauru         337000   182     NR
```

When using `keep='all'`, all duplicate items are maintained:

```
>>> df.nsmallest(3, 'population', keep='all')
      population  GDP alpha-2
Tuvalu        11300     38     TV
Anguilla      11300    311     AI
Iceland       337000  17036     IS
Nauru         337000   182     NR
```

To order by the smallest values in column “population” and then “GDP”, we can specify multiple columns like in the next example.

```
>>> df.nsmallest(3, ['population', 'GDP'])
      population  GDP alpha-2
Tuvalu        11300     38     TV
Anguilla      11300    311     AI
Nauru         337000   182     NR
```

pandas.DataFrame.nunique

`DataFrame.nunique` (*axis=0, dropna=True*)

Count number of distinct elements in specified axis.

Return Series with number of distinct elements. Can ignore NaN values.

Parameters

axis [{0 or 'index', 1 or 'columns'}, default 0] The axis to use. 0 or 'index' for row-wise, 1 or 'columns' for column-wise.

dropna [bool, default True] Don't include NaN in the counts.

Returns

Series

See also:

[`Series.nunique`](#) Method `nunique` for Series.

[`DataFrame.count`](#) Count non-NA cells for each column or row.

Examples

```
>>> df = pd.DataFrame({'A': [4, 5, 6], 'B': [4, 1, 1]})
>>> df.nunique()
A    3
B    2
dtype: int64
```

```
>>> df.nunique(axis=1)
0    1
1    2
2    2
dtype: int64
```

pandas.DataFrame.pad

`DataFrame.pad(axis=None, inplace=False, limit=None, downcast=None)`
Synonym for `DataFrame.fillna()` with `method='ffill'`.

Returns

Series/DataFrame or None Object with missing values filled or None if `inplace=True`.

pandas.DataFrame.pct_change

`DataFrame.pct_change(periods=1, fill_method='pad', limit=None, freq=None, **kwargs)`
Percentage change between the current and a prior element.

Computes the percentage change from the immediately previous row by default. This is useful in comparing the percentage of change in a time series of elements.

Parameters

periods [int, default 1] Periods to shift for forming percent change.

fill_method [str, default 'pad'] How to handle NAs before computing percent changes.

limit [int, default None] The number of consecutive NAs to fill before stopping.

freq [DateOffset, timedelta, or str, optional] Increment to use from time series API (e.g. 'M' or BDay()).

****kwargs** Additional keyword arguments are passed into `DataFrame.shift` or `Series.shift`.

Returns

chg [Series or DataFrame] The same type as the calling object.

See also:

[`Series.diff`](#) Compute the difference of two elements in a Series.

[`DataFrame.diff`](#) Compute the difference of two elements in a DataFrame.

[`Series.shift`](#) Shift the index by some number of periods.

[`DataFrame.shift`](#) Shift the index by some number of periods.

Examples

Series

```
>>> s = pd.Series([90, 91, 85])
>>> s
0    90
1    91
2    85
dtype: int64
```

```
>>> s.pct_change()
0         NaN
1    0.011111
2   -0.065934
dtype: float64
```

```
>>> s.pct_change(periods=2)
0         NaN
1         NaN
2   -0.055556
dtype: float64
```

See the percentage change in a Series where filling NAs with last valid observation forward to next valid.

```
>>> s = pd.Series([90, 91, None, 85])
>>> s
0    90.0
1    91.0
2     NaN
3    85.0
dtype: float64
```

```
>>> s.pct_change(fill_method='ffill')
0         NaN
1    0.011111
2    0.000000
3   -0.065934
dtype: float64
```

DataFrame

Percentage change in French franc, Deutsche Mark, and Italian lira from 1980-01-01 to 1980-03-01.

```
>>> df = pd.DataFrame({
...     'FR': [4.0405, 4.0963, 4.3149],
...     'GR': [1.7246, 1.7482, 1.8519],
...     'IT': [804.74, 810.01, 860.13]},
...     index=['1980-01-01', '1980-02-01', '1980-03-01'])
>>> df
              FR      GR      IT
1980-01-01  4.0405  1.7246  804.74
1980-02-01  4.0963  1.7482  810.01
1980-03-01  4.3149  1.8519  860.13
```

```
>>> df.pct_change()
              FR          GR          IT
1980-01-01    NaN          NaN          NaN
1980-02-01  0.013810  0.013684  0.006549
1980-03-01  0.053365  0.059318  0.061876
```

Percentage of change in GOOG and APPL stock volume. Shows computing the percentage change between columns.

```
>>> df = pd.DataFrame({
...     '2016': [1769950, 30586265],
...     '2015': [1500923, 40912316],
...     '2014': [1371819, 41403351]},
...     index=['GOOG', 'APPL'])
>>> df
           2016      2015      2014
GOOG  1769950  1500923  1371819
APPL  30586265  40912316  41403351
```

```
>>> df.pct_change(axis='columns', periods=-1)
           2016      2015  2014
GOOG  0.179241  0.094112  NaN
APPL -0.252395 -0.011860  NaN
```

pandas.DataFrame.pipe

`DataFrame.pipe(func, *args, **kwargs)`
Apply `func(self, *args, **kwargs)`.

Parameters

func [function] Function to apply to the Series/DataFrame. `args`, and `kwargs` are passed into `func`. Alternatively a (callable, `data_keyword`) tuple where `data_keyword` is a string indicating the keyword of callable that expects the Series/DataFrame.

args [iterable, optional] Positional arguments passed into `func`.

kwargs [mapping, optional] A dictionary of keyword arguments passed into `func`.

Returns

object [the return type of `func`.]

See also:

[`DataFrame.apply`](#) Apply a function along input axis of DataFrame.

[`DataFrame.applymap`](#) Apply a function elementwise on a whole DataFrame.

[`Series.map`](#) Apply a mapping correspondence on a [`Series`](#).

Notes

Use `.pipe` when chaining together functions that expect Series, DataFrames or GroupBy objects. Instead of writing

```
>>> func(g(h(df), arg1=a), arg2=b, arg3=c)
```

You can write

```
>>> (df.pipe(h)
...   .pipe(g, arg1=a)
...   .pipe(func, arg2=b, arg3=c)
... )
```

If you have a function that takes the data as (say) the second argument, pass a tuple indicating which keyword expects the data. For example, suppose `f` takes its data as `arg2`:

```
>>> (df.pipe(h)
...   .pipe(g, arg1=a)
...   .pipe((func, 'arg2'), arg1=a, arg3=c)
... )
```

pandas.DataFrame.pivot

`DataFrame.pivot` (*index=None, columns=None, values=None*)

Return reshaped DataFrame organized by given index / column values.

Reshape data (produce a “pivot” table) based on column values. Uses unique values from specified *index* / *columns* to form axes of the resulting DataFrame. This function does not support data aggregation, multiple values will result in a MultiIndex in the columns. See the *User Guide* for more on reshaping.

Parameters

index [str or object or a list of str, optional] Column to use to make new frame’s index. If None, uses existing index.

Changed in version 1.1.0: Also accept list of index names.

columns [str or object or a list of str] Column to use to make new frame’s columns.

Changed in version 1.1.0: Also accept list of columns names.

values [str, object or a list of the previous, optional] Column(s) to use for populating new frame’s values. If not specified, all remaining columns will be used and the result will have hierarchically indexed columns.

Returns

DataFrame Returns reshaped DataFrame.

Raises

ValueError: When there are any *index, columns* combinations with multiple values. *DataFrame.pivot_table* when you need to aggregate.

See also:

[*DataFrame.pivot_table*](#) Generalization of pivot that can handle duplicate values for one index/column pair.

DataFrame.unstack Pivot based on the index values instead of a column.

wide_to_long Wide panel to long format. Less flexible but more user-friendly than melt.

Notes

For finer-tuned control, see hierarchical indexing documentation along with the related stack/unstack methods.

Examples

```
>>> df = pd.DataFrame({'foo': ['one', 'one', 'one', 'two', 'two',
...                             'two'],
...                    'bar': ['A', 'B', 'C', 'A', 'B', 'C'],
...                    'baz': [1, 2, 3, 4, 5, 6],
...                    'zoo': ['x', 'y', 'z', 'q', 'w', 't']})
>>> df
   foo  bar  baz  zoo
0  one   A    1    x
1  one   B    2    y
2  one   C    3    z
3  two   A    4    q
4  two   B    5    w
5  two   C    6    t
```

```
>>> df.pivot(index='foo', columns='bar', values='baz')
bar  A  B  C
foo
one  1  2  3
two  4  5  6
```

```
>>> df.pivot(index='foo', columns='bar')['baz']
bar  A  B  C
foo
one  1  2  3
two  4  5  6
```

```
>>> df.pivot(index='foo', columns='bar', values=['baz', 'zoo'])
      baz      zoo
bar  A B C  A B C
foo
one  1 2 3  x y z
two  4 5 6  q w t
```

You could also assign a list of column names or a list of index names.

```
>>> df = pd.DataFrame({
...     "lev1": [1, 1, 1, 2, 2, 2],
...     "lev2": [1, 1, 2, 1, 1, 2],
...     "lev3": [1, 2, 1, 2, 1, 2],
...     "lev4": [1, 2, 3, 4, 5, 6],
```

(continues on next page)

(continued from previous page)

```
...         "values": [0, 1, 2, 3, 4, 5])
>>> df
   lev1 lev2 lev3 lev4 values
0     1     1     1     1     0
1     1     1     2     2     1
2     1     2     1     3     2
3     2     1     2     4     3
4     2     1     1     5     4
5     2     2     2     6     5
```

```
>>> df.pivot(index="lev1", columns=["lev2", "lev3"], values="values")
lev2     1     2
lev3     1     2     1     2
lev1
1     0.0  1.0  2.0  NaN
2     4.0  3.0  NaN  5.0
```

```
>>> df.pivot(index=["lev1", "lev2"], columns=["lev3"], values="values")
lev3     1     2
lev1 lev2
1     1  0.0  1.0
     2  2.0  NaN
2     1  4.0  3.0
     2  NaN  5.0
```

A `ValueError` is raised if there are any duplicates.

```
>>> df = pd.DataFrame({"foo": ['one', 'one', 'two', 'two'],
...                    "bar": ['A', 'A', 'B', 'C'],
...                    "baz": [1, 2, 3, 4]})
>>> df
   foo bar  baz
0  one  A    1
1  one  A    2
2  two  B    3
3  two  C    4
```

Notice that the first two rows are the same for our *index* and *columns* arguments.

```
>>> df.pivot(index='foo', columns='bar', values='baz')
Traceback (most recent call last):
...
ValueError: Index contains duplicate entries, cannot reshape
```

pandas.DataFrame.pivot_table

`DataFrame.pivot_table(values=None, index=None, columns=None, aggfunc='mean', fill_value=None, margins=False, dropna=True, margins_name='All', observed=False, sort=True)`

Create a spreadsheet-style pivot table as a DataFrame.

The levels in the pivot table will be stored in MultiIndex objects (hierarchical indexes) on the index and columns of the result DataFrame.

Parameters

values [column to aggregate, optional]

index [column, Grouper, array, or list of the previous] If an array is passed, it must be the same length as the data. The list can contain any of the other types (except list). Keys to group by on the pivot table index. If an array is passed, it is being used as the same manner as column values.

columns [column, Grouper, array, or list of the previous] If an array is passed, it must be the same length as the data. The list can contain any of the other types (except list). Keys to group by on the pivot table column. If an array is passed, it is being used as the same manner as column values.

aggfunc [function, list of functions, dict, default numpy.mean] If list of functions passed, the resulting pivot table will have hierarchical columns whose top level are the function names (inferred from the function objects themselves) If dict is passed, the key is column to aggregate and value is function or list of functions.

fill_value [scalar, default None] Value to replace missing values with (in the resulting pivot table, after aggregation).

margins [bool, default False] Add all row / columns (e.g. for subtotal / grand totals).

dropna [bool, default True] Do not include columns whose entries are all NaN.

margins_name [str, default 'All'] Name of the row / column that will contain the totals when margins is True.

observed [bool, default False] This only applies if any of the groupers are Categoricals. If True: only show observed values for categorical groupers. If False: show all values for categorical groupers.

Changed in version 0.25.0.

sort [bool, default True] Specifies if the result should be sorted.

New in version 1.3.0.

Returns

DataFrame An Excel style pivot table.

See also:

[`DataFrame.pivot`](#) Pivot without aggregation that can handle non-numeric data.

[`DataFrame.melt`](#) Unpivot a DataFrame from wide to long format, optionally leaving identifiers set.

[`wide_to_long`](#) Wide panel to long format. Less flexible but more user-friendly than melt.

Examples

```
>>> df = pd.DataFrame({"A": ["foo", "foo", "foo", "foo", "foo",
...                           "bar", "bar", "bar", "bar"],
...                    "B": ["one", "one", "one", "two", "two",
...                           "one", "one", "two", "two"],
...                    "C": ["small", "large", "large", "small",
...                           "small", "large", "small", "small",
...                           "large"],
...                    "D": [1, 2, 2, 3, 3, 4, 5, 6, 7],
...                    "E": [2, 4, 5, 5, 6, 6, 8, 9, 9]})
>>> df
   A  B  C  D  E
0  foo one small 1 2
1  foo one large 2 4
2  foo one large 2 5
3  foo two small 3 5
4  foo two small 3 6
5  bar one large 4 6
6  bar one small 5 8
7  bar two small 6 9
8  bar two large 7 9
```

This first example aggregates values by taking the sum.

```
>>> table = pd.pivot_table(df, values='D', index=['A', 'B'],
...                          columns=['C'], aggfunc=np.sum)
>>> table
C      large  small
A  B
bar one    4.0    5.0
   two    7.0    6.0
foo one    4.0    1.0
   two    NaN    6.0
```

We can also fill missing values using the *fill_value* parameter.

```
>>> table = pd.pivot_table(df, values='D', index=['A', 'B'],
...                          columns=['C'], aggfunc=np.sum, fill_value=0)
>>> table
C      large  small
A  B
bar one     4     5
   two     7     6
foo one     4     1
   two     0     6
```

The next example aggregates by taking the mean across multiple columns.

```
>>> table = pd.pivot_table(df, values=['D', 'E'], index=['A', 'C'],
...                          aggfunc={'D': np.mean,
...                                    'E': np.mean})
>>> table
```

(continues on next page)

(continued from previous page)

| | | D | E |
|-----|-------|----------|----------|
| A | C | | |
| bar | large | 5.500000 | 7.500000 |
| | small | 5.500000 | 8.500000 |
| foo | large | 2.000000 | 4.500000 |
| | small | 2.333333 | 4.333333 |

We can also calculate multiple types of aggregations for any given value column.

```
>>> table = pd.pivot_table(df, values=['D', 'E'], index=['A', 'C'],
...                          aggfunc={'D': np.mean,
...                                    'E': [min, max, np.mean]})
>>> table
```

| | | D | | E | |
|-----|-------|----------|-----|----------|-----|
| | | mean | max | mean | min |
| A | C | | | | |
| bar | large | 5.500000 | 9.0 | 7.500000 | 6.0 |
| | small | 5.500000 | 9.0 | 8.500000 | 8.0 |
| foo | large | 2.000000 | 5.0 | 4.500000 | 4.0 |
| | small | 2.333333 | 6.0 | 4.333333 | 2.0 |

pandas.DataFrame.plot

`DataFrame.plot(*args, **kwargs)`

Make plots of Series or DataFrame.

Uses the backend specified by the option `plotting.backend`. By default, matplotlib is used.

Parameters

data [Series or DataFrame] The object for which the method is called.

x [label or position, default None] Only used if data is a DataFrame.

y [label, position or list of label, positions, default None] Allows plotting of one column versus another. Only used if data is a DataFrame.

kind [str] The kind of plot to produce:

- 'line' : line plot (default)
- 'bar' : vertical bar plot
- 'barh' : horizontal bar plot
- 'hist' : histogram
- 'box' : boxplot
- 'kde' : Kernel Density Estimation plot
- 'density' : same as 'kde'
- 'area' : area plot
- 'pie' : pie plot
- 'scatter' : scatter plot (DataFrame only)
- 'hexbin' : hexbin plot (DataFrame only)

ax [matplotlib axes object, default None] An axes of the current figure.

subplots [bool, default False] Make separate subplots for each column.

sharex [bool, default True if ax is None else False] In case `subplots=True`, share x axis and set some x axis labels to invisible; defaults to True if ax is None otherwise False if an ax is passed in; Be aware, that passing in both an ax and `sharex=True` will alter all x axis labels for all axis in a figure.

sharey [bool, default False] In case `subplots=True`, share y axis and set some y axis labels to invisible.

layout [tuple, optional] (rows, columns) for the layout of subplots.

figsize [a tuple (width, height) in inches] Size of a figure object.

use_index [bool, default True] Use index as ticks for x axis.

title [str or list] Title to use for the plot. If a string is passed, print the string at the top of the figure. If a list is passed and `subplots` is True, print each item in the list above the corresponding subplot.

grid [bool, default None (matlab style default)] Axis grid lines.

legend [bool or {'reverse'}] Place legend on axis subplots.

style [list or dict] The matplotlib line style per column.

logx [bool or 'sym', default False] Use log scaling or symlog scaling on x axis. .. versionchanged:: 0.25.0

logy [bool or 'sym' default False] Use log scaling or symlog scaling on y axis. .. versionchanged:: 0.25.0

loglog [bool or 'sym', default False] Use log scaling or symlog scaling on both x and y axes. .. versionchanged:: 0.25.0

xticks [sequence] Values to use for the xticks.

yticks [sequence] Values to use for the yticks.

xlim [2-tuple/list] Set the x limits of the current axes.

ylim [2-tuple/list] Set the y limits of the current axes.

xlabel [label, optional] Name to use for the xlabel on x-axis. Default uses index name as xlabel, or the x-column name for planar plots.
New in version 1.1.0.
Changed in version 1.2.0: Now applicable to planar plots (*scatter*, *hexbin*).

ylabel [label, optional] Name to use for the ylabel on y-axis. Default will show no ylabel, or the y-column name for planar plots.
New in version 1.1.0.
Changed in version 1.2.0: Now applicable to planar plots (*scatter*, *hexbin*).

rot [int, default None] Rotation for ticks (xticks for vertical, yticks for horizontal plots).

fontsize [int, default None] Font size for xticks and yticks.

colormap [str or matplotlib colormap object, default None] Colormap to select colors from. If string, load colormap with that name from matplotlib.

colorbar [bool, optional] If True, plot colorbar (only relevant for ‘scatter’ and ‘hexbin’ plots).

position [float] Specify relative alignments for bar plot layout. From 0 (left/bottom-end) to 1 (right/top-end). Default is 0.5 (center).

table [bool, Series or DataFrame, default False] If True, draw a table using the data in the DataFrame and the data will be transposed to meet matplotlib’s default layout. If a Series or DataFrame is passed, use passed data to draw a table.

yerr [DataFrame, Series, array-like, dict and str] See *Plotting with Error Bars* for detail.

xerr [DataFrame, Series, array-like, dict and str] Equivalent to yerr.

stacked [bool, default False in line and bar plots, and True in area plot] If True, create stacked plot.

sort_columns [bool, default False] Sort column names to determine plot ordering.

secondary_y [bool or sequence, default False] Whether to plot on the secondary y-axis if a list/tuple, which columns to plot on secondary y-axis.

mark_right [bool, default True] When using a secondary_y axis, automatically mark the column labels with “(right)” in the legend.

include_bool [bool, default is False] If True, boolean values can be plotted.

backend [str, default None] Backend to use instead of the backend specified in the option `plotting.backend`. For instance, ‘matplotlib’. Alternatively, to specify the `plotting.backend` for the whole session, set `pd.options.plotting.backend`.

New in version 1.0.0.

****kwargs** Options to pass to matplotlib plotting method.

Returns

matplotlib.axes.Axes or numpy.ndarray of them If the backend is not the default matplotlib one, the return value will be the object returned by the backend.

Notes

- See matplotlib documentation online for more on this subject
- If *kind* = ‘bar’ or ‘barh’, you can specify relative alignments for bar plot layout by *position* keyword. From 0 (left/bottom-end) to 1 (right/top-end). Default is 0.5 (center)

pandas.DataFrame.pop

DataFrame.**pop**(*item*)

Return item and drop from frame. Raise KeyError if not found.

Parameters

item [label] Label of column to be popped.

Returns

Series

Examples

```
>>> df = pd.DataFrame([('falcon', 'bird', 389.0),
...                   ('parrot', 'bird', 24.0),
...                   ('lion', 'mammal', 80.5),
...                   ('monkey', 'mammal', np.nan)],
...                   columns=('name', 'class', 'max_speed'))
>>> df
   name  class  max_speed
0  falcon   bird    389.0
1  parrot   bird     24.0
2   lion  mammal     80.5
3  monkey  mammal      NaN
```

```
>>> df.pop('class')
0    bird
1    bird
2  mammal
3  mammal
Name: class, dtype: object
```

```
>>> df
   name  max_speed
0  falcon    389.0
1  parrot     24.0
2   lion     80.5
3  monkey      NaN
```

pandas.DataFrame.pow

`DataFrame.pow(other, axis='columns', level=None, fill_value=None)`

Get Exponential power of dataframe and other, element-wise (binary operator *pow*).

Equivalent to `dataframe ** other`, but with support to substitute a `fill_value` for missing data in one of the inputs. With reverse version, *rpow*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

See also:

DataFrame.add Add DataFrames.

DataFrame.sub Subtract DataFrames.

DataFrame.mul Multiply DataFrames.

DataFrame.div Divide DataFrames (float division).

DataFrame.truediv Divide DataFrames (float division).

DataFrame.floordiv Divide DataFrames (integer division).

DataFrame.mod Calculate modulo (remainder after division).

DataFrame.pow Calculate exponential power.

Notes

Mismatched indices will be unioned together.

Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                    index=['circle', 'triangle', 'rectangle'])
>>> df
```

| | angles | degrees |
|-----------|--------|---------|
| circle | 0 | 360 |
| triangle | 3 | 180 |
| rectangle | 4 | 360 |

Add a scalar with operator version which return the same results.

```
>>> df + 1
```

| | angles | degrees |
|-----------|--------|---------|
| circle | 1 | 361 |
| triangle | 4 | 181 |
| rectangle | 5 | 361 |

```
>>> df.add(1)
```

| | angles | degrees |
|-----------|--------|---------|
| circle | 1 | 361 |
| triangle | 4 | 181 |
| rectangle | 5 | 361 |

Divide by constant with reverse version.

```
>>> df.div(10)
```

| | angles | degrees |
|-----------|--------|---------|
| circle | 0.0 | 36.0 |
| triangle | 0.3 | 18.0 |
| rectangle | 0.4 | 36.0 |

```
>>> df.rdiv(10)
      angles  degrees
circle      inf  0.027778
triangle  3.333333  0.055556
rectangle  2.500000  0.027778
```

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
      angles  degrees
circle      -1    358
triangle     2    178
rectangle     3    358
```

```
>>> df.sub([1, 2], axis='columns')
      angles  degrees
circle      -1    358
triangle     2    178
rectangle     3    358
```

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...        axis='index')
      angles  degrees
circle      -1    359
triangle     2    179
rectangle     3    359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                       index=['circle', 'triangle', 'rectangle'])
>>> other
      angles
circle      0
triangle     3
rectangle     4
```

```
>>> df * other
      angles  degrees
circle      0     NaN
triangle     9     NaN
rectangle   16     NaN
```

```
>>> df.mul(other, fill_value=0)
      angles  degrees
circle      0     0.0
triangle     9     0.0
rectangle   16     0.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                               'degrees': [360, 180, 360, 360, 540, 720]},
...                               index=[[ 'A', 'A', 'A', 'B', 'B', 'B'],
...                                      ['circle', 'triangle', 'rectangle',
...                                       'square', 'pentagon', 'hexagon']])
>>> df_multindex
```

| | angles | degrees |
|-----------|--------|---------|
| A circle | 0 | 360 |
| triangle | 3 | 180 |
| rectangle | 4 | 360 |
| B square | 4 | 360 |
| pentagon | 5 | 540 |
| hexagon | 6 | 720 |

```
>>> df.div(df_multindex, level=1, fill_value=0)
```

| | angles | degrees |
|-----------|--------|---------|
| A circle | NaN | 1.0 |
| triangle | 1.0 | 1.0 |
| rectangle | 1.0 | 1.0 |
| B square | 0.0 | 0.0 |
| pentagon | 0.0 | 0.0 |
| hexagon | 0.0 | 0.0 |

pandas.DataFrame.prod

`DataFrame.prod(axis=None, skipna=None, level=None, numeric_only=None, min_count=0, **kwargs)`
Return the product of the values over the requested axis.

Parameters

axis [{index (0), columns (1)}] Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

min_count [int, default 0] The required number of valid values to perform the operation. If fewer than `min_count` non-NA values are present the result will be NA.

****kwargs** Additional keyword arguments to be passed to the function.

Returns

Series or DataFrame (if level specified)

See also:

[`Series.sum`](#) Return the sum.

[`Series.min`](#) Return the minimum.

[`Series.max`](#) Return the maximum.

Series.idxmin Return the index of the minimum.

Series.idxmax Return the index of the maximum.

DataFrame.sum Return the sum over the requested axis.

DataFrame.min Return the minimum over the requested axis.

DataFrame.max Return the maximum over the requested axis.

DataFrame.idxmin Return the index of the minimum over the requested axis.

DataFrame.idxmax Return the index of the maximum over the requested axis.

Examples

By default, the product of an empty or all-NA Series is 1

```
>>> pd.Series([], dtype="float64").prod()
1.0
```

This can be controlled with the `min_count` parameter

```
>>> pd.Series([], dtype="float64").prod(min_count=1)
nan
```

Thanks to the `skipna` parameter, `min_count` handles all-NA and empty series identically.

```
>>> pd.Series([np.nan]).prod()
1.0
```

```
>>> pd.Series([np.nan]).prod(min_count=1)
nan
```

pandas.DataFrame.product

DataFrame.product (*axis=None, skipna=None, level=None, numeric_only=None, min_count=0, **kwargs*)
Return the product of the values over the requested axis.

Parameters

axis [{index (0), columns (1)}] Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

min_count [int, default 0] The required number of valid values to perform the operation. If fewer than `min_count` non-NA values are present the result will be NA.

****kwargs** Additional keyword arguments to be passed to the function.

Returns

Series or DataFrame (if level specified)

See also:

Series.sum Return the sum.

Series.min Return the minimum.

Series.max Return the maximum.

Series.idxmin Return the index of the minimum.

Series.idxmax Return the index of the maximum.

DataFrame.sum Return the sum over the requested axis.

DataFrame.min Return the minimum over the requested axis.

DataFrame.max Return the maximum over the requested axis.

DataFrame.idxmin Return the index of the minimum over the requested axis.

DataFrame.idxmax Return the index of the maximum over the requested axis.

Examples

By default, the product of an empty or all-NA Series is 1

```
>>> pd.Series([], dtype="float64").prod()
1.0
```

This can be controlled with the `min_count` parameter

```
>>> pd.Series([], dtype="float64").prod(min_count=1)
nan
```

Thanks to the `skipna` parameter, `min_count` handles all-NA and empty series identically.

```
>>> pd.Series([np.nan]).prod()
1.0
```

```
>>> pd.Series([np.nan]).prod(min_count=1)
nan
```

pandas.DataFrame.quantile

DataFrame.quantile (*q=0.5, axis=0, numeric_only=True, interpolation='linear'*)

Return values at the given quantile over requested axis.

Parameters

q [float or array-like, default 0.5 (50% quantile)] Value between $0 \leq q \leq 1$, the quantile(s) to compute.

axis [{0, 1, 'index', 'columns'}, default 0] Equals 0 or 'index' for row-wise, 1 or 'columns' for column-wise.

numeric_only [bool, default True] If False, the quantile of datetime and timedelta data will be computed as well.

interpolation [{‘linear’, ‘lower’, ‘higher’, ‘midpoint’, ‘nearest’}] This optional parameter specifies the interpolation method to use, when the desired quantile lies between two data points i and j :

- linear: $i + (j - i) * fraction$, where *fraction* is the fractional part of the index surrounded by i and j .
- lower: i .
- higher: j .
- nearest: i or j whichever is nearest.
- midpoint: $(i + j) / 2$.

Returns

Series or DataFrame

If q is an array, a DataFrame will be returned where the index is q , the columns are the columns of self, and the values are the quantiles.

If q is a float, a Series will be returned where the index is the columns of self and the values are the quantiles.

See also:

`core.window.Rolling.quantile` Rolling quantile.

`numpy.percentile` Numpy function to compute the percentile.

Examples

```
>>> df = pd.DataFrame(np.array([[1, 1], [2, 10], [3, 100], [4, 100]]),
...                   columns=['a', 'b'])
>>> df.quantile(.1)
a    1.3
b    3.7
Name: 0.1, dtype: float64
>>> df.quantile([.1, .5])
      a    b
0.1  1.3  3.7
0.5  2.5 55.0
```

Specifying `numeric_only=False` will also compute the quantile of datetime and timedelta data.

```
>>> df = pd.DataFrame({'A': [1, 2],
...                   'B': [pd.Timestamp('2010'),
...                          pd.Timestamp('2011')],
...                   'C': [pd.Timedelta('1 days'),
...                          pd.Timedelta('2 days')]}])
>>> df.quantile(0.5, numeric_only=False)
A          1.5
B    2010-07-02 12:00:00
C          1 days 12:00:00
Name: 0.5, dtype: object
```

pandas.DataFrame.query

`DataFrame.query`(*expr*, *inplace=False*, ***kwargs*)

Query the columns of a DataFrame with a boolean expression.

Parameters

expr [str] The query string to evaluate.

You can refer to variables in the environment by prefixing them with an '@' character like `@a + b`.

You can refer to column names that are not valid Python variable names by surrounding them in backticks. Thus, column names containing spaces or punctuations (besides underscores) or starting with digits must be surrounded by backticks. (For example, a column named "Area (cm²)" would be referenced as ``Area (cm2)``). Column names which are Python keywords (like "list", "for", "import", etc) cannot be used.

For example, if one of your columns is called `a a` and you want to sum it with `b`, your query should be ``a a` + b`.

New in version 0.25.0: Backtick quoting introduced.

New in version 1.0.0: Expanding functionality of backtick quoting for more than only spaces.

inplace [bool] Whether the query should modify the data in place or return a modified copy.

****kwargs** See the documentation for `eval()` for complete details on the keyword arguments accepted by `DataFrame.query()`.

Returns

DataFrame or None DataFrame resulting from the provided query expression or None if `inplace=True`.

See also:

[`eval`](#) Evaluate a string describing operations on DataFrame columns.

[`DataFrame.eval`](#) Evaluate a string describing operations on DataFrame columns.

Notes

The result of the evaluation of this expression is first passed to `DataFrame.loc` and if that fails because of a multidimensional key (e.g., a DataFrame) then the result will be passed to `DataFrame.__getitem__()`.

This method uses the top-level `eval()` function to evaluate the passed query.

The `query()` method uses a slightly modified Python syntax by default. For example, the `&` and `|` (bitwise) operators have the precedence of their boolean cousins, `and` and `or`. This *is* syntactically valid Python, however the semantics are different.

You can change the semantics of the expression by passing the keyword argument `parser='python'`. This enforces the same semantics as evaluation in Python space. Likewise, you can pass `engine='python'` to evaluate an expression using Python itself as a backend. This is not recommended as it is inefficient compared to using `numexpr` as the engine.

The `DataFrame.index` and `DataFrame.columns` attributes of the `DataFrame` instance are placed in the query namespace by default, which allows you to treat both the index and columns of the frame as a column in the frame. The identifier `index` is used for the frame index; you can also use the name of the index to identify it in a query. Please note that Python keywords may not be used as identifiers.

For further details and examples see the query documentation in [indexing](#).

Backtick quoted variables

Backtick quoted variables are parsed as literal Python code and are converted internally to a Python valid identifier. This can lead to the following problems.

During parsing a number of disallowed characters inside the backtick quoted string are replaced by strings that are allowed as a Python identifier. These characters include all operators in Python, the space character, the question mark, the exclamation mark, the dollar sign, and the euro sign. For other characters that fall outside the ASCII range (U+0001..U+007F) and those that are not further specified in PEP 3131, the query parser will raise an error. This excludes whitespace different than the space character, but also the hashtag (as it is used for comments) and the backtick itself (backtick can also not be escaped).

In a special case, quotes that make a pair around a backtick can confuse the parser. For example, ``it's` > `that's`` will raise an error, as it forms a quoted string (`'s > `that'``) with a backtick inside.

See also the Python documentation about lexical analysis (https://docs.python.org/3/reference/lexical_analysis.html) in combination with the source code in `pandas.core.computation.parsing`.

Examples

```
>>> df = pd.DataFrame({'A': range(1, 6),
...                   'B': range(10, 0, -2),
...                   'C C': range(10, 5, -1)})
>>> df
   A  B  C C
0  1 10  10
1  2  8   9
2  3  6   8
3  4  4   7
4  5  2   6
>>> df.query('A > B')
```

| | A | B | C C |
|---|---|---|-----|
| 4 | 5 | 2 | 6 |

The previous expression is equivalent to

```
>>> df[df.A > df.B]
   A  B  C C
4  5  2   6
```

For columns with spaces in their name, you can use backtick quoting.

```
>>> df.query('B == `C C`')
   A  B  C C
0  1 10  10
```

The previous expression is equivalent to

```
>>> df[df.B == df['C C']]
   A  B  C C
0  1  10 10
```

pandas.DataFrame.radd

`DataFrame.radd`(*other*, *axis*='columns', *level*=None, *fill_value*=None)

Get Addition of dataframe and other, element-wise (binary operator *radd*).

Equivalent to `other + dataframe`, but with support to substitute a `fill_value` for missing data in one of the inputs. With reverse version, *add*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: +, -, *, /, //, %, **.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

See also:

[*DataFrame.add*](#) Add DataFrames.

[*DataFrame.sub*](#) Subtract DataFrames.

[*DataFrame.mul*](#) Multiply DataFrames.

[*DataFrame.div*](#) Divide DataFrames (float division).

[*DataFrame.truediv*](#) Divide DataFrames (float division).

[*DataFrame.floordiv*](#) Divide DataFrames (integer division).

[*DataFrame.mod*](#) Calculate modulo (remainder after division).

[*DataFrame.pow*](#) Calculate exponential power.

Notes

Mismatched indices will be unioned together.

Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                    index=['circle', 'triangle', 'rectangle'])
>>> df
```

| | angles | degrees |
|-----------|--------|---------|
| circle | 0 | 360 |
| triangle | 3 | 180 |
| rectangle | 4 | 360 |

Add a scalar with operator version which return the same results.

```
>>> df + 1
```

| | angles | degrees |
|-----------|--------|---------|
| circle | 1 | 361 |
| triangle | 4 | 181 |
| rectangle | 5 | 361 |

```
>>> df.add(1)
```

| | angles | degrees |
|-----------|--------|---------|
| circle | 1 | 361 |
| triangle | 4 | 181 |
| rectangle | 5 | 361 |

Divide by constant with reverse version.

```
>>> df.div(10)
```

| | angles | degrees |
|-----------|--------|---------|
| circle | 0.0 | 36.0 |
| triangle | 0.3 | 18.0 |
| rectangle | 0.4 | 36.0 |

```
>>> df.rdiv(10)
```

| | angles | degrees |
|-----------|----------|----------|
| circle | inf | 0.027778 |
| triangle | 3.333333 | 0.055556 |
| rectangle | 2.500000 | 0.027778 |

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
```

| | angles | degrees |
|-----------|--------|---------|
| circle | -1 | 358 |
| triangle | 2 | 178 |
| rectangle | 3 | 358 |

```
>>> df.sub([1, 2], axis='columns')
          angles  degrees
circle        -1    358
triangle       2    178
rectangle      3    358
```

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...        axis='index')
          angles  degrees
circle        -1    359
triangle       2    179
rectangle      3    359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                       index=['circle', 'triangle', 'rectangle'])
>>> other
          angles
circle         0
triangle       3
rectangle      4
```

```
>>> df * other
          angles  degrees
circle         0     NaN
triangle       9     NaN
rectangle     16     NaN
```

```
>>> df.mul(other, fill_value=0)
          angles  degrees
circle         0     0.0
triangle       9     0.0
rectangle     16     0.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                              'degrees': [360, 180, 360, 360, 540, 720]},
...                              index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                      ['circle', 'triangle', 'rectangle',
...                                       'square', 'pentagon', 'hexagon']])
>>> df_multindex
          angles  degrees
A circle         0    360
  triangle       3    180
  rectangle      4    360
B square         4    360
  pentagon       5    540
  hexagon        6    720
```

```
>>> df.div(df_multindex, level=1, fill_value=0)
      angles  degrees
A circle   NaN     1.0
  triangle  1.0     1.0
 rectangle  1.0     1.0
B square    0.0     0.0
 pentagon   0.0     0.0
 hexagon    0.0     0.0
```

pandas.DataFrame.rank

`DataFrame.rank`(*axis=0, method='average', numeric_only=None, na_option='keep', ascending=True, pct=False*)

Compute numerical data ranks (1 through n) along axis.

By default, equal values are assigned a rank that is the average of the ranks of those values.

Parameters

axis [{0 or 'index', 1 or 'columns'}, default 0] Index to direct ranking.

method [{'average', 'min', 'max', 'first', 'dense'}, default 'average'] How to rank the group of records that have the same value (i.e. ties):

- average: average rank of the group
- min: lowest rank in the group
- max: highest rank in the group
- first: ranks assigned in order they appear in the array
- dense: like 'min', but rank always increases by 1 between groups.

numeric_only [bool, optional] For DataFrame objects, rank only numeric columns if set to True.

na_option [{'keep', 'top', 'bottom'}, default 'keep'] How to rank NaN values:

- keep: assign NaN rank to NaN values
- top: assign lowest rank to NaN values
- bottom: assign highest rank to NaN values

ascending [bool, default True] Whether or not the elements should be ranked in ascending order.

pct [bool, default False] Whether or not to display the returned rankings in percentile form.

Returns

same type as caller Return a Series or DataFrame with data ranks as values.

See also:

[`core.groupby.GroupBy.rank`](#) Rank of values within each group.

Examples

```
>>> df = pd.DataFrame(data={'Animal': ['cat', 'penguin', 'dog',
...                                   'spider', 'snake'],
...                        'Number_legs': [4, 2, 4, 8, np.nan]})
>>> df
   Animal  Number_legs
0     cat             4.0
1  penguin             2.0
2     dog             4.0
3  spider             8.0
4  snake             NaN
```

The following example shows how the method behaves with the above parameters:

- `default_rank`: this is the default behaviour obtained without using any parameter.
- `max_rank`: setting `method = 'max'` the records that have the same values are ranked using the highest rank (e.g.: since 'cat' and 'dog' are both in the 2nd and 3rd position, rank 3 is assigned.)
- `NA_bottom`: choosing `na_option = 'bottom'`, if there are records with NaN values they are placed at the bottom of the ranking.
- `pct_rank`: when setting `pct = True`, the ranking is expressed as percentile rank.

```
>>> df['default_rank'] = df['Number_legs'].rank()
>>> df['max_rank'] = df['Number_legs'].rank(method='max')
>>> df['NA_bottom'] = df['Number_legs'].rank(na_option='bottom')
>>> df['pct_rank'] = df['Number_legs'].rank(pct=True)
>>> df
   Animal  Number_legs  default_rank  max_rank  NA_bottom  pct_rank
0     cat             4.0           2.5       3.0         2.5     0.625
1  penguin             2.0           1.0       1.0         1.0     0.250
2     dog             4.0           2.5       3.0         2.5     0.625
3  spider             8.0           4.0       4.0         4.0     1.000
4  snake             NaN           NaN       NaN         5.0     NaN
```

pandas.DataFrame.rdiv

`DataFrame.rdiv`(*other*, *axis='columns'*, *level=None*, *fill_value=None*)

Get Floating division of dataframe and other, element-wise (binary operator *rtruediv*).

Equivalent to `other / dataframe`, but with support to substitute a `fill_value` for missing data in one of the inputs. With reverse version, *truediv*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

See also:

DataFrame.add Add DataFrames.

DataFrame.sub Subtract DataFrames.

DataFrame.mul Multiply DataFrames.

DataFrame.div Divide DataFrames (float division).

DataFrame.truediv Divide DataFrames (float division).

DataFrame.floordiv Divide DataFrames (integer division).

DataFrame.mod Calculate modulo (remainder after division).

DataFrame.pow Calculate exponential power.

Notes

Mismatched indices will be unioned together.

Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                    index=['circle', 'triangle', 'rectangle'])
>>> df
```

| | angles | degrees |
|-----------|--------|---------|
| circle | 0 | 360 |
| triangle | 3 | 180 |
| rectangle | 4 | 360 |

Add a scalar with operator version which return the same results.

```
>>> df + 1
```

| | angles | degrees |
|-----------|--------|---------|
| circle | 1 | 361 |
| triangle | 4 | 181 |
| rectangle | 5 | 361 |

```
>>> df.add(1)
```

| | angles | degrees |
|-----------|--------|---------|
| circle | 1 | 361 |
| triangle | 4 | 181 |
| rectangle | 5 | 361 |

Divide by constant with reverse version.

```
>>> df.div(10)
      angles  degrees
circle     0.0    36.0
triangle   0.3    18.0
rectangle  0.4    36.0
```

```
>>> df.rdiv(10)
      angles  degrees
circle      inf  0.027778
triangle  3.333333  0.055556
rectangle  2.500000  0.027778
```

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
      angles  degrees
circle     -1    358
triangle    2    178
rectangle   3    358
```

```
>>> df.sub([1, 2], axis='columns')
      angles  degrees
circle     -1    358
triangle    2    178
rectangle   3    358
```

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...        axis='index')
      angles  degrees
circle     -1    359
triangle    2    179
rectangle   3    359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                       index=['circle', 'triangle', 'rectangle'])
>>> other
      angles
circle      0
triangle    3
rectangle   4
```

```
>>> df * other
      angles  degrees
circle      0     NaN
triangle    9     NaN
rectangle  16     NaN
```

```
>>> df.mul(other, fill_value=0)
      angles  degrees
circle      0     0.0
```

(continues on next page)

(continued from previous page)

| | | |
|-----------|----|-----|
| triangle | 9 | 0.0 |
| rectangle | 16 | 0.0 |

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                               'degrees': [360, 180, 360, 360, 540, 720]},
...                               index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                       ['circle', 'triangle', 'rectangle',
...                                       'square', 'pentagon', 'hexagon']])

| B square | 0.0 | 0.0 |
| pentagon | 0.0 | 0.0 |
| hexagon | 0.0 | 0.0 |

pandas.DataFrame.reindex

`DataFrame.reindex(labels=None, index=None, columns=None, axis=None, method=None, copy=True, level=None, fill_value=nan, limit=None, tolerance=None)`

Conform Series/DataFrame to new index with optional filling logic.

Places NA/NaN in locations having no value in the previous index. A new object is produced unless the new index is equivalent to the current one and `copy=False`.

Parameters

keywords for axes [array-like, optional] New labels / index to conform to, should be specified using keywords. Preferably an Index object to avoid duplicating data.

method [{None, 'backfill'/'bfill', 'pad'/'fill', 'nearest'}] Method to use for filling holes in reindexed DataFrame. Please note: this is only applicable to DataFrames/Series with a monotonically increasing/decreasing index.

- None (default): don't fill gaps
- pad / ffill: Propagate last valid observation forward to next valid.
- backfill / bfill: Use next valid observation to fill gap.
- nearest: Use nearest valid observations to fill gap.

copy [bool, default True] Return a new object, even if the passed indexes are the same.

level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [scalar, default np.NaN] Value to use for missing values. Defaults to NaN, but can be any “compatible” value.

limit [int, default None] Maximum number of consecutive elements to forward or backward fill.

tolerance [optional] Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations must satisfy the equation $\text{abs}(\text{index}[\text{indexer}] - \text{target}) \leq \text{tolerance}$.

Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple, array, Series, and must be the same size as the index and its dtype must exactly match the index’s type.

Returns

Series/DataFrame with changed index.

See also:

[`DataFrame.set_index`](#) Set row labels.

[`DataFrame.reset_index`](#) Remove row labels or move them to new columns.

[`DataFrame.reindex_like`](#) Change to same indices as other DataFrame.

Examples

`DataFrame.reindex` supports two calling conventions

- `(index=index_labels, columns=column_labels, ...)`
- `(labels, axis={'index', 'columns'}, ...)`

We *highly* recommend using keyword arguments to clarify your intent.

Create a dataframe with some fictional data.

```
>>> index = ['Firefox', 'Chrome', 'Safari', 'IE10', 'Konqueror']
>>> df = pd.DataFrame({'http_status': [200, 200, 404, 404, 301],
...                    'response_time': [0.04, 0.02, 0.07, 0.08, 1.0]},
...                    index=index)
>>> df
```

| | http_status | response_time |
|-----------|-------------|---------------|
| Firefox | 200 | 0.04 |
| Chrome | 200 | 0.02 |
| Safari | 404 | 0.07 |
| IE10 | 404 | 0.08 |
| Konqueror | 301 | 1.00 |

Create a new index and reindex the dataframe. By default values in the new index that do not have corresponding records in the dataframe are assigned NaN.

```
>>> new_index = ['Safari', 'Iceweasel', 'Comodo Dragon', 'IE10',
...              'Chrome']
```

(continues on next page)

(continued from previous page)

```
>>> df.reindex(new_index)
           http_status  response_time
Safari             404.0             0.07
Iceweasel           NaN             NaN
Comodo Dragon       NaN             NaN
IE10                404.0             0.08
Chrome              200.0             0.02
```

We can fill in the missing values by passing a value to the keyword `fill_value`. Because the index is not monotonically increasing or decreasing, we cannot use arguments to the keyword method to fill the NaN values.

```
>>> df.reindex(new_index, fill_value=0)
           http_status  response_time
Safari             404             0.07
Iceweasel           0             0.00
Comodo Dragon       0             0.00
IE10                404             0.08
Chrome              200             0.02
```

```
>>> df.reindex(new_index, fill_value='missing')
           http_status  response_time
Safari             404             0.07
Iceweasel          missing          missing
Comodo Dragon      missing          missing
IE10                404             0.08
Chrome              200             0.02
```

We can also reindex the columns.

```
>>> df.reindex(columns=['http_status', 'user_agent'])
           http_status  user_agent
Firefox             200          NaN
Chrome              200          NaN
Safari              404          NaN
IE10                404          NaN
Konqueror           301          NaN
```

Or we can use “axis-style” keyword arguments

```
>>> df.reindex(['http_status', 'user_agent'], axis="columns")
           http_status  user_agent
Firefox             200          NaN
Chrome              200          NaN
Safari              404          NaN
IE10                404          NaN
Konqueror           301          NaN
```

To further illustrate the filling functionality in `reindex`, we will create a dataframe with a monotonically increasing index (for example, a sequence of dates).

```
>>> date_index = pd.date_range('1/1/2010', periods=6, freq='D')
>>> df2 = pd.DataFrame({"prices": [100, 101, np.nan, 100, 89, 88]}),
```

(continues on next page)

(continued from previous page)

```
... index=date_index)
>>> df2
      prices
2010-01-01  100.0
2010-01-02  101.0
2010-01-03   NaN
2010-01-04  100.0
2010-01-05   89.0
2010-01-06   88.0
```

Suppose we decide to expand the dataframe to cover a wider date range.

```
>>> date_index2 = pd.date_range('12/29/2009', periods=10, freq='D')
>>> df2.reindex(date_index2)
      prices
2009-12-29   NaN
2009-12-30   NaN
2009-12-31   NaN
2010-01-01  100.0
2010-01-02  101.0
2010-01-03   NaN
2010-01-04  100.0
2010-01-05   89.0
2010-01-06   88.0
2010-01-07   NaN
```

The index entries that did not have a value in the original data frame (for example, '2009-12-29') are by default filled with NaN. If desired, we can fill in the missing values using one of several options.

For example, to back-propagate the last valid value to fill the NaN values, pass `bfill` as an argument to the `method` keyword.

```
>>> df2.reindex(date_index2, method='bfill')
      prices
2009-12-29  100.0
2009-12-30  100.0
2009-12-31  100.0
2010-01-01  100.0
2010-01-02  101.0
2010-01-03   NaN
2010-01-04  100.0
2010-01-05   89.0
2010-01-06   88.0
2010-01-07   NaN
```

Please note that the NaN value present in the original dataframe (at index value 2010-01-03) will not be filled by any of the value propagation schemes. This is because filling while reindexing does not look at dataframe values, but only compares the original and desired indexes. If you do want to fill in the NaN values present in the original dataframe, use the `fillna()` method.

See the [user guide](#) for more.

pandas.DataFrame.reindex_like

`DataFrame.reindex_like`(*other*, *method=None*, *copy=True*, *limit=None*, *tolerance=None*)

Return an object with matching indices as other object.

Conform the object to the same index on all axes. Optional filling logic, placing NaN in locations having no value in the previous index. A new object is produced unless the new index is equivalent to the current one and `copy=False`.

Parameters

other [Object of the same data type] Its row and column indices are used to define the new indices of this object.

method [{None, 'backfill'/'bfill', 'pad'/'ffill', 'nearest' }] Method to use for filling holes in reindexed DataFrame. Please note: this is only applicable to DataFrames/Series with a monotonically increasing/decreasing index.

- None (default): don't fill gaps
- pad / ffill: propagate last valid observation forward to next valid
- backfill / bfill: use next valid observation to fill gap
- nearest: use nearest valid observations to fill gap.

copy [bool, default True] Return a new object, even if the passed indexes are the same.

limit [int, default None] Maximum number of consecutive labels to fill for inexact matches.

tolerance [optional] Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations must satisfy the equation $\text{abs}(\text{index}[\text{indexer}] - \text{target}) \leq \text{tolerance}$.

Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple, array, Series, and must be the same size as the index and its dtype must exactly match the index's type.

Returns

Series or DataFrame Same type as caller, but with changed indices on each axis.

See also:

[`DataFrame.set_index`](#) Set row labels.

[`DataFrame.reset_index`](#) Remove row labels or move them to new columns.

[`DataFrame.reindex`](#) Change to new indices or expand indices.

Notes

Same as calling `.reindex(index=other.index, columns=other.columns,...)`.

Examples

```
>>> df1 = pd.DataFrame([[24.3, 75.7, 'high'],
...                     [31, 87.8, 'high'],
...                     [22, 71.6, 'medium'],
...                     [35, 95, 'medium']],
...                     columns=['temp_celsius', 'temp_fahrenheit',
...                               'windspeed'],
...                     index=pd.date_range(start='2014-02-12',
...                                         end='2014-02-15', freq='D'))
```

```
>>> df1
           temp_celsius  temp_fahrenheit  windspeed
2014-02-12           24.3             75.7        high
2014-02-13           31.0             87.8         high
2014-02-14           22.0             71.6        medium
2014-02-15           35.0             95.0        medium
```

```
>>> df2 = pd.DataFrame([[28, 'low'],
...                     [30, 'low'],
...                     [35.1, 'medium']],
...                     columns=['temp_celsius', 'windspeed'],
...                     index=pd.DatetimeIndex(['2014-02-12', '2014-02-13',
...                                             '2014-02-15']))
```

```
>>> df2
           temp_celsius  windspeed
2014-02-12           28.0         low
2014-02-13           30.0         low
2014-02-15           35.1        medium
```

```
>>> df2.reindex_like(df1)
           temp_celsius  temp_fahrenheit  windspeed
2014-02-12           28.0             NaN         low
2014-02-13           30.0             NaN         low
2014-02-14           NaN             NaN         NaN
2014-02-15           35.1             NaN        medium
```

pandas.DataFrame.rename

`DataFrame.rename`(*mapper=None, index=None, columns=None, axis=None, copy=True, inplace=False, level=None, errors='ignore'*)

Alter axes labels.

Function / dict values must be unique (1-to-1). Labels not contained in a dict / Series will be left as-is. Extra labels listed don't throw an error.

See the *user guide* for more.

Parameters

mapper [dict-like or function] Dict-like or function transformations to apply to that axis' values. Use either `mapper` and `axis` to specify the axis to target with `mapper`, or `index` and `columns`.

index [dict-like or function] Alternative to specifying axis (`mapper`, `axis=0` is equivalent to `index=mapper`).

columns [dict-like or function] Alternative to specifying axis (`mapper`, `axis=1` is equivalent to `columns=mapper`).

axis [{0 or 'index', 1 or 'columns'}, default 0] Axis to target with `mapper`. Can be either the axis name ('index', 'columns') or number (0, 1). The default is 'index'.

copy [bool, default True] Also copy underlying data.

inplace [bool, default False] Whether to return a new DataFrame. If True then value of `copy` is ignored.

level [int or level name, default None] In case of a MultiIndex, only rename labels in the specified level.

errors [{'ignore', 'raise'}, default 'ignore'] If 'raise', raise a *KeyError* when a dict-like `mapper`, `index`, or `columns` contains labels that are not present in the Index being transformed. If 'ignore', existing keys will be renamed and extra keys will be ignored.

Returns

DataFrame or None DataFrame with the renamed axis labels or None if `inplace=True`.

Raises

KeyError If any of the labels is not found in the selected axis and "errors='raise'".

See also:

`DataFrame.rename_axis` Set the name of the axis.

Examples

DataFrame.rename supports two calling conventions

- (index=index_mapper, columns=columns_mapper, ...)
- (mapper, axis={'index', 'columns'}, ...)

We *highly* recommend using keyword arguments to clarify your intent.

Rename columns using a mapping:

```
>>> df = pd.DataFrame({"A": [1, 2, 3], "B": [4, 5, 6]})
>>> df.rename(columns={"A": "a", "B": "c"})
   a  c
0  1  4
1  2  5
2  3  6
```

Rename index using a mapping:

```
>>> df.rename(index={0: "x", 1: "y", 2: "z"})
   A  B
x  1  4
y  2  5
z  3  6
```

Cast index labels to a different type:

```
>>> df.index
RangeIndex(start=0, stop=3, step=1)
>>> df.rename(index=str).index
Index(['0', '1', '2'], dtype='object')
```

```
>>> df.rename(columns={"A": "a", "B": "b", "C": "c"}, errors="raise")
Traceback (most recent call last):
KeyError: ['C'] not found in axis
```

Using axis-style parameters:

```
>>> df.rename(str.lower, axis='columns')
   a  b
0  1  4
1  2  5
2  3  6
```

```
>>> df.rename({1: 2, 2: 4}, axis='index')
   A  B
0  1  4
2  2  5
4  3  6
```

pandas.DataFrame.rename_axis

`DataFrame.rename_axis`(*mapper=None, index=None, columns=None, axis=None, copy=True, inplace=False*)

Set the name of the axis for the index or columns.

Parameters

mapper [scalar, list-like, optional] Value to set the axis name attribute.

index, columns [scalar, list-like, dict-like or function, optional] A scalar, list-like, dict-like or functions transformations to apply to that axis' values. Note that the `columns` parameter is not allowed if the object is a `Series`. This parameter only apply for `DataFrame` type objects.

Use either `mapper` and `axis` to specify the axis to target with `mapper`, or `index` and/or `columns`.

axis [{0 or 'index', 1 or 'columns'}, default 0] The axis to rename.

copy [bool, default True] Also copy underlying data.

inplace [bool, default False] Modifies the object directly, instead of creating a new `Series` or `DataFrame`.

Returns

Series, DataFrame, or None The same type as the caller or `None` if `inplace=True`.

See also:

[`Series.rename`](#) Alter `Series` index labels or name.

[`DataFrame.rename`](#) Alter `DataFrame` index labels or name.

[`Index.rename`](#) Set new names on index.

Notes

`DataFrame.rename_axis` supports two calling conventions

- (`index=index_mapper, columns=columns_mapper, ...`)
- (`mapper, axis={'index', 'columns'}, ...`)

The first calling convention will only modify the names of the index and/or the names of the `Index` object that is the `columns`. In this case, the parameter `copy` is ignored.

The second calling convention will modify the names of the corresponding index if `mapper` is a list or a scalar. However, if `mapper` is dict-like or a function, it will use the deprecated behavior of modifying the axis *labels*.

We *highly* recommend using keyword arguments to clarify your intent.

Examples

Series

```
>>> s = pd.Series(["dog", "cat", "monkey"])
>>> s
0      dog
1      cat
2    monkey
dtype: object
>>> s.rename_axis("animal")
animal
0      dog
1      cat
2    monkey
dtype: object
```

DataFrame

```
>>> df = pd.DataFrame({"num_legs": [4, 4, 2],
...                    "num_arms": [0, 0, 2]},
...                    ["dog", "cat", "monkey"])
>>> df
   num_legs  num_arms
dog         4         0
cat         4         0
monkey      2         2
>>> df = df.rename_axis("animal")
>>> df
   num_legs  num_arms
animal
dog         4         0
cat         4         0
monkey      2         2
>>> df = df.rename_axis("limbs", axis="columns")
>>> df
limbs  num_legs  num_arms
animal
dog         4         0
cat         4         0
monkey      2         2
```

MultiIndex

```
>>> df.index = pd.MultiIndex.from_product(['mammal'],
...                                       ['dog', 'cat', 'monkey']],
...                                       names=['type', 'name'])
>>> df
limbs  num_legs  num_arms
type  name
mammal dog         4         0
      cat         4         0
      monkey      2         2
```

```
>>> df.rename_axis(index={'type': 'class'})
limbs      num_legs  num_arms
class name
mammal dog         4         0
        cat         4         0
        monkey      2         2
```

```
>>> df.rename_axis(columns=str.upper)
LIMBS      num_legs  num_arms
type name
mammal dog         4         0
        cat         4         0
        monkey      2         2
```

pandas.DataFrame.reorder_levels

`DataFrame.reorder_levels`(*order*, *axis=0*)

Rearrange index levels using input order. May not drop or duplicate levels.

Parameters

order [list of int or list of str] List representing new level order. Reference level by number (position) or by key (label).

axis [{0 or 'index', 1 or 'columns'}], default 0] Where to reorder levels.

Returns

DataFrame

pandas.DataFrame.replace

`DataFrame.replace`(*to_replace=None*, *value=None*, *inplace=False*, *limit=None*, *regex=False*, *method='pad'*)

Replace values given in *to_replace* with *value*.

Values of the DataFrame are replaced with other values dynamically.

This differs from updating with `.loc` or `.iloc`, which require you to specify a location to update with some value.

Parameters

to_replace [str, regex, list, dict, Series, int, float, or None] How to find the values that will be replaced.

- numeric, str or regex:
 - **numeric:** numeric values equal to *to_replace* will be replaced with *value*
 - **str:** string exactly matching *to_replace* will be replaced with *value*
 - **regex:** regexs matching *to_replace* will be replaced with *value*
- list of str, regex, or numeric:
 - **First, if *to_replace* and *value* are both lists, they must** be the same length.

- **Second, if `regex=True` then all of the strings in both** lists will be interpreted as regexs otherwise they will match directly. This doesn't matter much for *value* since there are only a few possible substitution regexes you can use.
- str, regex and numeric rules apply as above.
- dict:
 - **Dicts can be used to specify different replacement values** for different existing values. For example, `{'a': 'b', 'y': 'z'}` replaces the value 'a' with 'b' and 'y' with 'z'. To use a dict in this way the *value* parameter should be *None*.
 - **For a DataFrame a dict can specify that different values** should be replaced in different columns. For example, `{'a': 1, 'b': 'z'}` looks for the value 1 in column 'a' and the value 'z' in column 'b' and replaces these values with whatever is specified in *value*. The *value* parameter should not be *None* in this case. You can treat this as a special case of passing two lists except that you are specifying the column to search in.
 - **For a DataFrame nested dictionaries, e.g.,** `{'a': {'b': np.nan}}`, are read as follows: look in column 'a' for the value 'b' and replace it with NaN. The *value* parameter should be *None* to use a nested dict in this way. You can nest regular expressions as well. Note that column names (the top-level dictionary keys in a nested dictionary) **cannot** be regular expressions.
- None:
 - **This means that the *regex* argument must be a string**, compiled regular expression, or list, dict, ndarray or Series of such elements. If *value* is also *None* then this **must** be a nested dictionary or Series.

See the examples section for examples of each of these.

value [scalar, dict, list, str, regex, default None] Value to replace any values matching *to_replace* with. For a DataFrame a dict of values can be used to specify which value to use for each column (columns not in the dict will not be filled). Regular expressions, strings and lists or dicts of such objects are also allowed.

inplace [bool, default False] If True, performs operation inplace and returns None.

limit [int, default None] Maximum size gap to forward or backward fill.

regex [bool or same types as *to_replace*, default False] Whether to interpret *to_replace* and/or *value* as regular expressions. If this is True then *to_replace* must be a string. Alternatively, this could be a regular expression or a list, dict, or array of regular expressions in which case *to_replace* must be *None*.

method [{ 'pad', 'ffill', 'bfill', None}] The method to use when for replacement, when *to_replace* is a scalar, list or tuple and *value* is *None*.

Changed in version 0.23.0: Added to DataFrame.

Returns

DataFrame Object after replacement.

Raises

AssertionError

- If *regex* is not a bool and *to_replace* is not None.

TypeError

- If *to_replace* is not a scalar, array-like, dict, or None
- If *to_replace* is a dict and *value* is not a list, dict, ndarray, or Series
- If *to_replace* is None and *regex* is not compilable into a regular expression or is a list, dict, ndarray, or Series.
- When replacing multiple bool or datetime64 objects and the arguments to *to_replace* does not match the type of the value being replaced

ValueError

- If a list or an ndarray is passed to *to_replace* and *value* but they are not the same length.

See also:

[*DataFrame.fillna*](#) Fill NA values.

[*DataFrame.where*](#) Replace values based on boolean condition.

[*Series.str.replace*](#) Simple string replacement.

Notes

- **Regex substitution is performed under the hood with `re.sub`.** The rules for substitution for `re.sub` are the same.
- **Regular expressions will only substitute on strings, meaning you** cannot provide, for example, a regular expression matching floating point numbers and expect the columns in your frame that have a numeric dtype to be matched. However, if those floating point numbers *are* strings, then you can do this.
- **This method has a lot of options. You are encouraged to experiment** and play with this method to gain intuition about how it works.
- **When dict is used as the *to_replace* value, it is like** key(s) in the dict are the *to_replace* part and value(s) in the dict are the value parameter.

Examples

Scalar `to_replace` and `value`

```
>>> s = pd.Series([0, 1, 2, 3, 4])
>>> s.replace(0, 5)
0    5
1    1
2    2
3    3
4    4
dtype: int64
```

```

>>> df = pd.DataFrame({'A': [0, 1, 2, 3, 4],
...                    'B': [5, 6, 7, 8, 9],
...                    'C': ['a', 'b', 'c', 'd', 'e']})
>>> df.replace(0, 5)
   A  B  C
0  5  5  a
1  1  6  b
2  2  7  c
3  3  8  d
4  4  9  e

```

List-like `to_replace`

```

>>> df.replace([0, 1, 2, 3], 4)
   A  B  C
0  4  5  a
1  4  6  b
2  4  7  c
3  4  8  d
4  4  9  e

```

```

>>> df.replace([0, 1, 2, 3], [4, 3, 2, 1])
   A  B  C
0  4  5  a
1  3  6  b
2  2  7  c
3  1  8  d
4  4  9  e

```

```

>>> s.replace([1, 2], method='bfill')
0    0
1    3
2    3
3    3
4    4
dtype: int64

```

dict-like `to_replace`

```

>>> df.replace({0: 10, 1: 100})
   A  B  C
0  10  5  a
1 100  6  b
2   2  7  c
3   3  8  d
4   4  9  e

```

```

>>> df.replace({'A': 0, 'B': 5}, 100)
   A  B  C
0 100 100  a
1   1   6  b
2   2   7  c

```

(continues on next page)

(continued from previous page)

```
3    3    8    d
4    4    9    e
```

```
>>> df.replace({'A': {0: 100, 4: 400}})
      A  B  C
0  100  5  a
1     1  6  b
2     2  7  c
3     3  8  d
4  400  9  e
```

Regular expression `to_replace`

```
>>> df = pd.DataFrame({'A': ['bat', 'foo', 'bait'],
...                    'B': ['abc', 'bar', 'xyz']})
>>> df.replace(to_replace=r'^ba.$', value='new', regex=True)
      A  B
0  new  abc
1  foo  new
2  bait xyz
```

```
>>> df.replace({'A': r'^ba.$'}, {'A': 'new'}, regex=True)
      A  B
0  new  abc
1  foo  bar
2  bait xyz
```

```
>>> df.replace(regex=r'^ba.$', value='new')
      A  B
0  new  abc
1  foo  new
2  bait xyz
```

```
>>> df.replace(regex={r'^ba.$': 'new', 'foo': 'xyz'})
      A  B
0  new  abc
1  xyz  new
2  bait xyz
```

```
>>> df.replace(regex=[r'^ba.$', 'foo'], value='new')
      A  B
0  new  abc
1  new  new
2  bait xyz
```

Compare the behavior of `s.replace({'a': None})` and `s.replace('a', None)` to understand the peculiarities of the `to_replace` parameter:

```
>>> s = pd.Series([10, 'a', 'a', 'b', 'a'])
```

When one uses a dict as the `to_replace` value, it is like the value(s) in the dict are equal to the `value` parameter. `s.replace({'a': None})` is equivalent to `s.replace(to_replace={'a': None},`

```
value=None, method=None):
```

```
>>> s.replace({'a': None})
0      10
1     None
2     None
3       b
4     None
dtype: object
```

When `value=None` and `to_replace` is a scalar, list or tuple, `replace` uses the `method` parameter (default 'pad') to do the replacement. So this is why the 'a' values are being replaced by 10 in rows 1 and 2 and 'b' in row 4 in this case. The command `s.replace('a', None)` is actually equivalent to `s.replace(to_replace='a', value=None, method='pad')`:

```
>>> s.replace('a', None)
0      10
1      10
2      10
3       b
4       b
dtype: object
```

pandas.DataFrame.resample

`DataFrame.resample(rule, axis=0, closed=None, label=None, convention='start', kind=None, loffset=None, base=None, on=None, level=None, origin='start_day', offset=None)`

Resample time-series data.

Convenience method for frequency conversion and resampling of time series. The object must have a datetime-like index (*DatetimeIndex*, *PeriodIndex*, or *TimedeltaIndex*), or the caller must pass the label of a datetime-like series/index to the `on/level` keyword parameter.

Parameters

- rule** [DateOffset, Timedelta or str] The offset string or object representing target conversion.
- axis** [{0 or 'index', 1 or 'columns'}, default 0] Which axis to use for up- or down-sampling. For *Series* this will default to 0, i.e. along the rows. Must be *DatetimeIndex*, *TimedeltaIndex* or *PeriodIndex*.
- closed** [{'right', 'left'}, default None] Which side of bin interval is closed. The default is 'left' for all frequency offsets except for 'M', 'A', 'Q', 'BM', 'BA', 'BQ', and 'W' which all have a default of 'right'.
- label** [{'right', 'left'}, default None] Which bin edge label to label bucket with. The default is 'left' for all frequency offsets except for 'M', 'A', 'Q', 'BM', 'BA', 'BQ', and 'W' which all have a default of 'right'.
- convention** [{'start', 'end', 's', 'e'}, default 'start'] For *PeriodIndex* only, controls whether to use the start or end of *rule*.
- kind** [{'timestamp', 'period'}, optional, default None] Pass 'timestamp' to convert the resulting index to a *DatetimeIndex* or 'period' to convert it to a *PeriodIndex*. By default the input representation is retained.

loffset [timedelta, default None] Adjust the resampled time labels.

Deprecated since version 1.1.0: You should add the `loffset` to the `df.index` after the `resample`. See below.

base [int, default 0] For frequencies that evenly subdivide 1 day, the “origin” of the aggregated intervals. For example, for ‘5min’ frequency, base could range from 0 through 4. Defaults to 0.

Deprecated since version 1.1.0: The new arguments that you should use are ‘`offset`’ or ‘`origin`’.

on [str, optional] For a DataFrame, column to use instead of index for resampling. Column must be datetime-like.

level [str or int, optional] For a MultiIndex, level (name or number) to use for resampling. *level* must be datetime-like.

origin [{‘epoch’, ‘start’, ‘start_day’, ‘end’, ‘end_day’}, Timestamp] or str, default ‘start_day’ The timestamp on which to adjust the grouping. The timezone of origin must match the timezone of the index. If a timestamp is not used, these values are also supported:

- ‘epoch’: *origin* is 1970-01-01
- ‘start’: *origin* is the first value of the timeseries
- ‘start_day’: *origin* is the first day at midnight of the timeseries

New in version 1.1.0.

- ‘end’: *origin* is the last value of the timeseries
- ‘end_day’: *origin* is the ceiling midnight of the last day

New in version 1.3.0.

offset [Timedelta or str, default is None] An offset timedelta added to the origin.

New in version 1.1.0.

Returns

pandas.core.Resampler Resampler object.

See also:

[*Series.resample*](#) Resample a Series.

[*DataFrame.resample*](#) Resample a DataFrame.

[*groupby*](#) Group DataFrame by mapping, function, label, or list of labels.

[*asfreq*](#) Reindex a DataFrame with the given frequency without grouping.

Notes

See the [user guide](#) for more.

To learn more about the offset strings, please see [this link](#).

Examples

Start by creating a series with 9 one minute timestamps.

```
>>> index = pd.date_range('1/1/2000', periods=9, freq='T')
>>> series = pd.Series(range(9), index=index)
>>> series
2000-01-01 00:00:00    0
2000-01-01 00:01:00    1
2000-01-01 00:02:00    2
2000-01-01 00:03:00    3
2000-01-01 00:04:00    4
2000-01-01 00:05:00    5
2000-01-01 00:06:00    6
2000-01-01 00:07:00    7
2000-01-01 00:08:00    8
Freq: T, dtype: int64
```

Downsample the series into 3 minute bins and sum the values of the timestamps falling into a bin.

```
>>> series.resample('3T').sum()
2000-01-01 00:00:00    3
2000-01-01 00:03:00   12
2000-01-01 00:06:00   21
Freq: 3T, dtype: int64
```

Downsample the series into 3 minute bins as above, but label each bin using the right edge instead of the left. Please note that the value in the bucket used as the label is not included in the bucket, which it labels. For example, in the original series the bucket `2000-01-01 00:03:00` contains the value 3, but the summed value in the resampled bucket with the label `2000-01-01 00:03:00` does not include 3 (if it did, the summed value would be 6, not 3). To include this value close the right side of the bin interval as illustrated in the example below this one.

```
>>> series.resample('3T', label='right').sum()
2000-01-01 00:03:00    3
2000-01-01 00:06:00   12
2000-01-01 00:09:00   21
Freq: 3T, dtype: int64
```

Downsample the series into 3 minute bins as above, but close the right side of the bin interval.

```
>>> series.resample('3T', label='right', closed='right').sum()
2000-01-01 00:00:00    0
2000-01-01 00:03:00    6
2000-01-01 00:06:00   15
2000-01-01 00:09:00   15
Freq: 3T, dtype: int64
```

Upsample the series into 30 second bins.

```
>>> series.resample('30S').asfreq()[0:5] # Select first 5 rows
2000-01-01 00:00:00    0.0
2000-01-01 00:00:30    NaN
2000-01-01 00:01:00    1.0
2000-01-01 00:01:30    NaN
2000-01-01 00:02:00    2.0
Freq: 30S, dtype: float64
```

Upsample the series into 30 second bins and fill the NaN values using the pad method.

```
>>> series.resample('30S').pad()[0:5]
2000-01-01 00:00:00    0
2000-01-01 00:00:30    0
2000-01-01 00:01:00    1
2000-01-01 00:01:30    1
2000-01-01 00:02:00    2
Freq: 30S, dtype: int64
```

Upsample the series into 30 second bins and fill the NaN values using the bfill method.

```
>>> series.resample('30S').bfill()[0:5]
2000-01-01 00:00:00    0
2000-01-01 00:00:30    1
2000-01-01 00:01:00    1
2000-01-01 00:01:30    2
2000-01-01 00:02:00    2
Freq: 30S, dtype: int64
```

Pass a custom function via apply

```
>>> def custom_resampler(arraylike):
...     return np.sum(arraylike) + 5
...
>>> series.resample('3T').apply(custom_resampler)
2000-01-01 00:00:00    8
2000-01-01 00:03:00   17
2000-01-01 00:06:00   26
Freq: 3T, dtype: int64
```

For a Series with a PeriodIndex, the keyword *convention* can be used to control whether to use the start or end of *rule*.

Resample a year by quarter using 'start' *convention*. Values are assigned to the first quarter of the period.

```
>>> s = pd.Series([1, 2], index=pd.period_range('2012-01-01',
...                                           freq='A',
...                                           periods=2))
>>> s
2012    1
2013    2
Freq: A-DEC, dtype: int64
>>> s.resample('Q', convention='start').asfreq()
2012Q1    1.0
2012Q2    NaN
```

(continues on next page)

(continued from previous page)

```

2012Q3    NaN
2012Q4    NaN
2013Q1    2.0
2013Q2    NaN
2013Q3    NaN
2013Q4    NaN
Freq: Q-DEC, dtype: float64

```

Resample quarters by month using *'end' convention*. Values are assigned to the last month of the period.

```

>>> q = pd.Series([1, 2, 3, 4], index=pd.period_range('2018-01-01',
...
...
...
...
>>> q
2018Q1    1
2018Q2    2
2018Q3    3
2018Q4    4
Freq: Q-DEC, dtype: int64
>>> q.resample('M', convention='end').asfreq()
2018-03    1.0
2018-04    NaN
2018-05    NaN
2018-06    2.0
2018-07    NaN
2018-08    NaN
2018-09    3.0
2018-10    NaN
2018-11    NaN
2018-12    4.0
Freq: M, dtype: float64

```

For DataFrame objects, the keyword *on* can be used to specify the column instead of the index for resampling.

```

>>> d = {'price': [10, 11, 9, 13, 14, 18, 17, 19],
...
...
...
...
>>> df = pd.DataFrame(d)
>>> df['week_starting'] = pd.date_range('01/01/2018',
...
...
...
...
>>> df
   price  volume week_starting
0     10     50  2018-01-07
1     11     60  2018-01-14
2      9     40  2018-01-21
3     13    100  2018-01-28
4     14     50  2018-02-04
5     18    100  2018-02-11
6     17     40  2018-02-18
7     19     50  2018-02-25
>>> df.resample('M', on='week_starting').mean()

```

(continues on next page)

(continued from previous page)

| week_starting | price | volume |
|---------------|-------|--------|
| 2018-01-31 | 10.75 | 62.5 |
| 2018-02-28 | 17.00 | 60.0 |

For a DataFrame with MultiIndex, the keyword *level* can be used to specify on which level the resampling needs to take place.

```
>>> days = pd.date_range('1/1/2000', periods=4, freq='D')
>>> d2 = {'price': [10, 11, 9, 13, 14, 18, 17, 19],
...       'volume': [50, 60, 40, 100, 50, 100, 40, 50]}
>>> df2 = pd.DataFrame(
...     d2,
...     index=pd.MultiIndex.from_product(
...         [days, ['morning', 'afternoon']]
...     )
... )
>>> df2
```

| | | price | volume |
|------------|-----------|-------|--------|
| 2000-01-01 | morning | 10 | 50 |
| | afternoon | 11 | 60 |
| 2000-01-02 | morning | 9 | 40 |
| | afternoon | 13 | 100 |
| 2000-01-03 | morning | 14 | 50 |
| | afternoon | 18 | 100 |
| 2000-01-04 | morning | 17 | 40 |
| | afternoon | 19 | 50 |

```
>>> df2.resample('D', level=0).sum()
      price  volume
2000-01-01    21    110
2000-01-02    22    140
2000-01-03    32    150
2000-01-04    36     90
```

If you want to adjust the start of the bins based on a fixed timestamp:

```
>>> start, end = '2000-10-01 23:30:00', '2000-10-02 00:30:00'
>>> rng = pd.date_range(start, end, freq='7min')
>>> ts = pd.Series(np.arange(len(rng)) * 3, index=rng)
>>> ts
```

| Timestamp | Value |
|---------------------|-------|
| 2000-10-01 23:30:00 | 0 |
| 2000-10-01 23:37:00 | 3 |
| 2000-10-01 23:44:00 | 6 |
| 2000-10-01 23:51:00 | 9 |
| 2000-10-01 23:58:00 | 12 |
| 2000-10-02 00:05:00 | 15 |
| 2000-10-02 00:12:00 | 18 |
| 2000-10-02 00:19:00 | 21 |
| 2000-10-02 00:26:00 | 24 |

```
Freq: 7T, dtype: int64
```

```
>>> ts.resample('17min').sum()
```

(continues on next page)

(continued from previous page)

```

2000-10-01 23:14:00    0
2000-10-01 23:31:00    9
2000-10-01 23:48:00   21
2000-10-02 00:05:00   54
2000-10-02 00:22:00   24
Freq: 17T, dtype: int64

```

```

>>> ts.resample('17min', origin='epoch').sum()
2000-10-01 23:18:00    0
2000-10-01 23:35:00   18
2000-10-01 23:52:00   27
2000-10-02 00:09:00   39
2000-10-02 00:26:00   24
Freq: 17T, dtype: int64

```

```

>>> ts.resample('17min', origin='2000-01-01').sum()
2000-10-01 23:24:00    3
2000-10-01 23:41:00   15
2000-10-01 23:58:00   45
2000-10-02 00:15:00   45
Freq: 17T, dtype: int64

```

If you want to adjust the start of the bins with an *offset* Timedelta, the two following lines are equivalent:

```

>>> ts.resample('17min', origin='start').sum()
2000-10-01 23:30:00    9
2000-10-01 23:47:00   21
2000-10-02 00:04:00   54
2000-10-02 00:21:00   24
Freq: 17T, dtype: int64

```

```

>>> ts.resample('17min', offset='23h30min').sum()
2000-10-01 23:30:00    9
2000-10-01 23:47:00   21
2000-10-02 00:04:00   54
2000-10-02 00:21:00   24
Freq: 17T, dtype: int64

```

If you want to take the largest Timestamp as the end of the bins:

```

>>> ts.resample('17min', origin='end').sum()
2000-10-01 23:35:00    0
2000-10-01 23:52:00   18
2000-10-02 00:09:00   27
2000-10-02 00:26:00   63
Freq: 17T, dtype: int64

```

In contrast with the *start_day*, you can use *end_day* to take the ceiling midnight of the largest Timestamp as the end of the bins and drop the bins not containing data:

```

>>> ts.resample('17min', origin='end_day').sum()
2000-10-01 23:38:00    3

```

(continues on next page)

(continued from previous page)

```

2000-10-01 23:55:00    15
2000-10-02 00:12:00    45
2000-10-02 00:29:00    45
Freq: 17T, dtype: int64

```

To replace the use of the deprecated *base* argument, you can now use *offset*, in this example it is equivalent to have *base=2*:

```

>>> ts.resample('17min', offset='2min').sum()
2000-10-01 23:16:00     0
2000-10-01 23:33:00     9
2000-10-01 23:50:00    36
2000-10-02 00:07:00    39
2000-10-02 00:24:00    24
Freq: 17T, dtype: int64

```

To replace the use of the deprecated *loffset* argument:

```

>>> from pandas.tseries.frequencies import to_offset
>>> loffset = '19min'
>>> ts_out = ts.resample('17min').sum()
>>> ts_out.index = ts_out.index + to_offset(loffset)
>>> ts_out
2000-10-01 23:33:00     0
2000-10-01 23:50:00     9
2000-10-02 00:07:00    21
2000-10-02 00:24:00    54
2000-10-02 00:41:00    24
Freq: 17T, dtype: int64

```

pandas.DataFrame.reset_index

`DataFrame.reset_index(level=None, drop=False, inplace=False, col_level=0, col_fill='')`

Reset the index, or a level of it.

Reset the index of the DataFrame, and use the default one instead. If the DataFrame has a MultiIndex, this method can remove one or more levels.

Parameters

level [int, str, tuple, or list, default None] Only remove the given levels from the index. Removes all levels by default.

drop [bool, default False] Do not try to insert index into dataframe columns. This resets the index to the default integer index.

inplace [bool, default False] Modify the DataFrame in place (do not create a new object).

col_level [int or str, default 0] If the columns have multiple levels, determines which level the labels are inserted into. By default it is inserted into the first level.

col_fill [object, default ''] If the columns have multiple levels, determines how the other levels are named. If None then the index name is repeated.

Returns

DataFrame or None DataFrame with the new index or None if `inplace=True`.

See also:

[`DataFrame.set_index`](#) Opposite of `reset_index`.

[`DataFrame.reindex`](#) Change to new indices or expand indices.

[`DataFrame.reindex_like`](#) Change to same indices as other DataFrame.

Examples

```
>>> df = pd.DataFrame([('bird', 389.0),
...                   ('bird', 24.0),
...                   ('mammal', 80.5),
...                   ('mammal', np.nan)],
...                   index=['falcon', 'parrot', 'lion', 'monkey'],
...                   columns=('class', 'max_speed'))
>>> df
```

| | class | max_speed |
|--------|--------|-----------|
| falcon | bird | 389.0 |
| parrot | bird | 24.0 |
| lion | mammal | 80.5 |
| monkey | mammal | NaN |

When we reset the index, the old index is added as a column, and a new sequential index is used:

```
>>> df.reset_index()
   index  class  max_speed
0  falcon   bird    389.0
1  parrot   bird     24.0
2    lion  mammal    80.5
3  monkey  mammal     NaN
```

We can use the `drop` parameter to avoid the old index being added as a column:

```
>>> df.reset_index(drop=True)
   class  max_speed
0   bird    389.0
1   bird     24.0
2  mammal    80.5
3  mammal     NaN
```

You can also use `reset_index` with *MultiIndex*.

```
>>> index = pd.MultiIndex.from_tuples([('bird', 'falcon'),
...                                  ('bird', 'parrot'),
...                                  ('mammal', 'lion'),
...                                  ('mammal', 'monkey')],
...                                  names=['class', 'name'])
>>> columns = pd.MultiIndex.from_tuples([('speed', 'max'),
...                                     ('species', 'type')])
>>> df = pd.DataFrame([(389.0, 'fly'),
...                   ( 24.0, 'fly')],
```

(continues on next page)

(continued from previous page)

```

...         ( 80.5, 'run'),
...         (np.nan, 'jump')],
...         index=index,
...         columns=columns)
>>> df

```

| | | speed | species |
|--------|--------|-------|---------|
| | | max | type |
| class | name | | |
| bird | falcon | 389.0 | fly |
| | parrot | 24.0 | fly |
| mammal | lion | 80.5 | run |
| | monkey | NaN | jump |

If the index has multiple levels, we can reset a subset of them:

```

>>> df.reset_index(level='class')

```

| | class | speed | species |
|--------|--------|-------|---------|
| | | max | type |
| name | | | |
| falcon | bird | 389.0 | fly |
| parrot | bird | 24.0 | fly |
| lion | mammal | 80.5 | run |
| monkey | mammal | NaN | jump |

If we are not dropping the index, by default, it is placed in the top level. We can place it in another level:

```

>>> df.reset_index(level='class', col_level=1)

```

| | | speed | species |
|--------|--------|-------|---------|
| | class | max | type |
| name | | | |
| falcon | bird | 389.0 | fly |
| parrot | bird | 24.0 | fly |
| lion | mammal | 80.5 | run |
| monkey | mammal | NaN | jump |

When the index is inserted under another level, we can specify under which one with the parameter `col_fill`:

```

>>> df.reset_index(level='class', col_level=1, col_fill='species')

```

| | | species | speed | species |
|--------|--------|---------|-------|---------|
| | class | | max | type |
| name | | | | |
| falcon | bird | bird | 389.0 | fly |
| parrot | bird | bird | 24.0 | fly |
| lion | mammal | mammal | 80.5 | run |
| monkey | mammal | mammal | NaN | jump |

If we specify a nonexistent level for `col_fill`, it is created:

```

>>> df.reset_index(level='class', col_level=1, col_fill='genus')

```

| | | genus | speed | species |
|--------|-------|-------|-------|---------|
| | class | | max | type |
| name | | | | |
| falcon | bird | bird | 389.0 | fly |

(continues on next page)

(continued from previous page)

| | | | |
|--------|--------|------|------|
| parrot | bird | 24.0 | fly |
| lion | mammal | 80.5 | run |
| monkey | mammal | NaN | jump |

pandas.DataFrame.rfloordiv**DataFrame.rfloordiv**(*other*, *axis*='columns', *level*=None, *fill_value*=None)Get Integer division of dataframe and other, element-wise (binary operator *rfloordiv*).Equivalent to `other // dataframe`, but with support to substitute a *fill_value* for missing data in one of the inputs. With reverse version, *floordiv*.Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: +, -, *, /, //, %, **.**Parameters****other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.**axis** [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.**level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.**fill_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.**Returns****DataFrame** Result of the arithmetic operation.**See also:****DataFrame.add** Add DataFrames.**DataFrame.sub** Subtract DataFrames.**DataFrame.mul** Multiply DataFrames.**DataFrame.div** Divide DataFrames (float division).**DataFrame.truediv** Divide DataFrames (float division).**DataFrame.floordiv** Divide DataFrames (integer division).**DataFrame.mod** Calculate modulo (remainder after division).**DataFrame.pow** Calculate exponential power.

Notes

Mismatched indices will be unioned together.

Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                    index=['circle', 'triangle', 'rectangle'])
>>> df
```

| | angles | degrees |
|-----------|--------|---------|
| circle | 0 | 360 |
| triangle | 3 | 180 |
| rectangle | 4 | 360 |

Add a scalar with operator version which return the same results.

```
>>> df + 1
```

| | angles | degrees |
|-----------|--------|---------|
| circle | 1 | 361 |
| triangle | 4 | 181 |
| rectangle | 5 | 361 |

```
>>> df.add(1)
```

| | angles | degrees |
|-----------|--------|---------|
| circle | 1 | 361 |
| triangle | 4 | 181 |
| rectangle | 5 | 361 |

Divide by constant with reverse version.

```
>>> df.div(10)
```

| | angles | degrees |
|-----------|--------|---------|
| circle | 0.0 | 36.0 |
| triangle | 0.3 | 18.0 |
| rectangle | 0.4 | 36.0 |

```
>>> df.rdiv(10)
```

| | angles | degrees |
|-----------|----------|----------|
| circle | inf | 0.027778 |
| triangle | 3.333333 | 0.055556 |
| rectangle | 2.500000 | 0.027778 |

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
```

| | angles | degrees |
|-----------|--------|---------|
| circle | -1 | 358 |
| triangle | 2 | 178 |
| rectangle | 3 | 358 |

```
>>> df.sub([1, 2], axis='columns')
          angles  degrees
circle      -1    358
triangle     2    178
rectangle    3    358
```

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...        axis='index')
          angles  degrees
circle      -1    359
triangle     2    179
rectangle    3    359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                       index=['circle', 'triangle', 'rectangle'])
>>> other
          angles
circle         0
triangle       3
rectangle      4
```

```
>>> df * other
          angles  degrees
circle         0     NaN
triangle        9     NaN
rectangle      16     NaN
```

```
>>> df.mul(other, fill_value=0)
          angles  degrees
circle         0     0.0
triangle        9     0.0
rectangle      16     0.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                              'degrees': [360, 180, 360, 360, 540, 720]},
...                              index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                      ['circle', 'triangle', 'rectangle',
...                                       'square', 'pentagon', 'hexagon']])
>>> df_multindex
          angles  degrees
A circle         0    360
  triangle        3    180
  rectangle        4    360
B square          4    360
  pentagon         5    540
  hexagon          6    720
```

```
>>> df.div(df_multindex, level=1, fill_value=0)
      angles  degrees
A circle   NaN     1.0
  triangle   1.0     1.0
 rectangle   1.0     1.0
B square    0.0     0.0
  pentagon   0.0     0.0
  hexagon    0.0     0.0
```

pandas.DataFrame.rmod

`DataFrame.rmod(other, axis='columns', level=None, fill_value=None)`

Get Modulo of dataframe and other, element-wise (binary operator *rmod*).

Equivalent to `other % dataframe`, but with support to substitute a `fill_value` for missing data in one of the inputs. With reverse version, *mod*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

Notes

Mismatched indices will be unioned together.

Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                    index=['circle', 'triangle', 'rectangle'])
>>> df
```

| | angles | degrees |
|-----------|--------|---------|
| circle | 0 | 360 |
| triangle | 3 | 180 |
| rectangle | 4 | 360 |

Add a scalar with operator version which return the same results.

```
>>> df + 1
```

| | angles | degrees |
|-----------|--------|---------|
| circle | 1 | 361 |
| triangle | 4 | 181 |
| rectangle | 5 | 361 |

```
>>> df.add(1)
```

| | angles | degrees |
|-----------|--------|---------|
| circle | 1 | 361 |
| triangle | 4 | 181 |
| rectangle | 5 | 361 |

Divide by constant with reverse version.

```
>>> df.div(10)
```

| | angles | degrees |
|-----------|--------|---------|
| circle | 0.0 | 36.0 |
| triangle | 0.3 | 18.0 |
| rectangle | 0.4 | 36.0 |

```
>>> df.rdiv(10)
```

| | angles | degrees |
|-----------|----------|----------|
| circle | inf | 0.027778 |
| triangle | 3.333333 | 0.055556 |
| rectangle | 2.500000 | 0.027778 |

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
```

| | angles | degrees |
|-----------|--------|---------|
| circle | -1 | 358 |
| triangle | 2 | 178 |
| rectangle | 3 | 358 |

```
>>> df.sub([1, 2], axis='columns')
      angles  degrees
circle     -1     358
triangle    2     178
rectangle   3     358
```

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...        axis='index')
      angles  degrees
circle     -1     359
triangle    2     179
rectangle   3     359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                       index=['circle', 'triangle', 'rectangle'])
>>> other
      angles
circle      0
triangle    3
rectangle   4
```

```
>>> df * other
      angles  degrees
circle      0      NaN
triangle     9      NaN
rectangle   16      NaN
```

```
>>> df.mul(other, fill_value=0)
      angles  degrees
circle      0      0.0
triangle     9      0.0
rectangle   16      0.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                               'degrees': [360, 180, 360, 360, 540, 720]},
...                              index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                     ['circle', 'triangle', 'rectangle',
...                                      'square', 'pentagon', 'hexagon']])
>>> df_multindex
      angles  degrees
A circle      0     360
  triangle    3     180
  rectangle    4     360
B square      4     360
  pentagon    5     540
  hexagon     6     720
```

```
>>> df.div(df_multindex, level=1, fill_value=0)
      angles  degrees
A circle   NaN     1.0
  triangle   1.0     1.0
 rectangle   1.0     1.0
B square    0.0     0.0
  pentagon   0.0     0.0
  hexagon    0.0     0.0
```

pandas.DataFrame.rmul

`DataFrame.rmul`(*other*, *axis*='columns', *level*=None, *fill_value*=None)

Get Multiplication of dataframe and other, element-wise (binary operator *rmul*).

Equivalent to `other * dataframe`, but with support to substitute a *fill_value* for missing data in one of the inputs. With reverse version, *mul*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: +, -, *, /, //, %, **.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

```
>>> df.div(df_multindex, level=1, fill_value=0)
      angles  degrees
A circle   NaN     1.0
  triangle   1.0     1.0
 rectangle   1.0     1.0
B square    0.0     0.0
 pentagon   0.0     0.0
 hexagon    0.0     0.0
```

pandas.DataFrame.rolling

`DataFrame.rolling`(*window*, *min_periods=None*, *center=False*, *win_type=None*, *on=None*, *axis=0*, *closed=None*, *method='single'*)

Provide rolling window calculations.

Parameters

window [int, offset, or BaseIndexer subclass] Size of the moving window. This is the number of observations used for calculating the statistic. Each window will be a fixed size.

If its an offset then this will be the time period of each window. Each window will be a variable sized based on the observations included in the time-period. This is only valid for datetimelike indexes.

If a BaseIndexer subclass is passed, calculates the window boundaries based on the defined `get_window_bounds` method. Additional rolling keyword arguments, namely *min_periods*, *center*, and *closed* will be passed to `get_window_bounds`.

min_periods [int, default None] Minimum number of observations in window required to have a value (otherwise result is NA). For a window that is specified by an offset, *min_periods* will default to 1. Otherwise, *min_periods* will default to the size of the window.

center [bool, default False] Set the labels at the center of the window.

win_type [str, default None] Provide a window type. If None, all points are evenly weighted. See the notes below for further information.

on [str, optional] For a DataFrame, a datetime-like column or Index level on which to calculate the rolling window, rather than the DataFrame's index. Provided integer column is ignored and excluded from result since an integer index is not used to calculate the rolling window.

axis [int or str, default 0]

closed [str, default None] Make the interval closed on the 'right', 'left', 'both' or 'neither' endpoints. Defaults to 'right'.

Changed in version 1.2.0: The closed parameter with fixed windows is now supported.

method [str {'single', 'table'}, default 'single'] Execute the rolling operation per single column or row ('single') or over the entire object ('table').

This argument is only implemented when specifying `engine='numba'` in the method call.

New in version 1.3.0.

Returns

a **Window or Rolling** sub-classed for the particular operation

See also:

expanding Provides expanding transformations.

ewm Provides exponential weighted functions.

Notes

By default, the result is set to the right edge of the window. This can be changed to the center of the window by setting `center=True`.

To learn more about the offsets & frequency strings, please see [this link](#).

If `win_type=None`, all points are evenly weighted; otherwise, `win_type` can accept a string of any [scipy.signal](#) window function.

Certain Scipy window types require additional parameters to be passed in the aggregation function. The additional parameters must match the keywords specified in the Scipy window type method signature. Please see the third example below on how to add the additional parameters.

Examples

```
>>> df = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]})
>>> df
   B
0  0.0
1  1.0
2  2.0
3  NaN
4  4.0
```

Rolling sum with a window length of 2, using the 'triang' window type.

```
>>> df.rolling(2, win_type='triang').sum()
   B
0  NaN
1  0.5
2  1.5
3  NaN
4  NaN
```

Rolling sum with a window length of 2, using the 'gaussian' window type (note how we need to specify `std`).

```
>>> df.rolling(2, win_type='gaussian').sum(std=3)
   B
0  NaN
1  0.986207
2  2.958621
3  NaN
4  NaN
```

Rolling sum with a window length of 2, `min_periods` defaults to the window length.

```
>>> df.rolling(2).sum()
      B
0  NaN
1  1.0
2  3.0
3  NaN
4  NaN
```

Same as above, but explicitly set the `min_periods`

```
>>> df.rolling(2, min_periods=1).sum()
      B
0  0.0
1  1.0
2  3.0
3  2.0
4  4.0
```

Same as above, but with forward-looking windows

```
>>> indexer = pd.api.indexers.FixedForwardWindowIndexer(window_size=2)
>>> df.rolling(window=indexer, min_periods=1).sum()
      B
0  1.0
1  3.0
2  2.0
3  4.0
4  4.0
```

A ragged (meaning not-a-regular frequency), time-indexed DataFrame

```
>>> df = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]},
...                    index = [pd.Timestamp('20130101 09:00:00'),
...                               pd.Timestamp('20130101 09:00:02'),
...                               pd.Timestamp('20130101 09:00:03'),
...                               pd.Timestamp('20130101 09:00:05'),
...                               pd.Timestamp('20130101 09:00:06')])
```

```
>>> df
                B
2013-01-01 09:00:00  0.0
2013-01-01 09:00:02  1.0
2013-01-01 09:00:03  2.0
2013-01-01 09:00:05  NaN
2013-01-01 09:00:06  4.0
```

Contrasting to an integer rolling window, this will roll a variable length window corresponding to the time period. The default for `min_periods` is 1.

```
>>> df.rolling('2s').sum()
                B
2013-01-01 09:00:00  0.0
```

(continues on next page)

(continued from previous page)

```

2013-01-01 09:00:02  1.0
2013-01-01 09:00:03  3.0
2013-01-01 09:00:05  NaN
2013-01-01 09:00:06  4.0

```

pandas.DataFrame.round

DataFrame.**round**(*decimals=0*, *args, **kwargs)

Round a DataFrame to a variable number of decimal places.

Parameters

decimals [int, dict, Series] Number of decimal places to round each column to. If an int is given, round each column to the same number of places. Otherwise dict and Series round to variable numbers of places. Column names should be in the keys if *decimals* is a dict-like, or in the index if *decimals* is a Series. Any columns not included in *decimals* will be left as is. Elements of *decimals* which are not columns of the input will be ignored.

***args** Additional keywords have no effect but might be accepted for compatibility with numpy.

****kwargs** Additional keywords have no effect but might be accepted for compatibility with numpy.

Returns

DataFrame A DataFrame with the affected columns rounded to the specified number of decimal places.

See also:

[numpy.around](#) Round a numpy array to the given number of decimals.

[Series.round](#) Round a Series to the given number of decimals.

Examples

```

>>> df = pd.DataFrame([(0.21, 0.32), (0.01, 0.67), (0.66, 0.03), (0.21, 0.18)],
...                    columns=['dogs', 'cats'])
>>> df
   dogs  cats
0  0.21  0.32
1  0.01  0.67
2  0.66  0.03
3  0.21  0.18

```

By providing an integer each column is rounded to the same number of decimal places

```

>>> df.round(1)
   dogs  cats
0   0.2  0.3
1   0.0  0.7

```

(continues on next page)

(continued from previous page)

```
2  0.7  0.0
3  0.2  0.2
```

With a dict, the number of places for specific columns can be specified with the column names as key and the number of decimal places as value

```
>>> df.round({'dogs': 1, 'cats': 0})
   dogs  cats
0  0.2  0.0
1  0.0  1.0
2  0.7  0.0
3  0.2  0.0
```

Using a Series, the number of places for specific columns can be specified with the column names as index and the number of decimal places as value

```
>>> decimals = pd.Series([0, 1], index=['cats', 'dogs'])
>>> df.round(decimals)
   dogs  cats
0  0.2  0.0
1  0.0  1.0
2  0.7  0.0
3  0.2  0.0
```

pandas.DataFrame.rpow

DataFrame.rpow(*other*, *axis*='columns', *level*=None, *fill_value*=None)

Get Exponential power of dataframe and other, element-wise (binary operator *rpow*).

Equivalent to `other ** dataframe`, but with support to substitute a *fill_value* for missing data in one of the inputs. With reverse version, *pow*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: +, -, *, /, //, %, **.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

See also:

[DataFrame.add](#) Add DataFrames.

DataFrame.sub Subtract DataFrames.

DataFrame.mul Multiply DataFrames.

DataFrame.div Divide DataFrames (float division).

DataFrame.truediv Divide DataFrames (float division).

DataFrame.floordiv Divide DataFrames (integer division).

DataFrame.mod Calculate modulo (remainder after division).

DataFrame.pow Calculate exponential power.

Notes

Mismatched indices will be unioned together.

Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                    index=['circle', 'triangle', 'rectangle'])
>>> df
```

| | angles | degrees |
|-----------|--------|---------|
| circle | 0 | 360 |
| triangle | 3 | 180 |
| rectangle | 4 | 360 |

Add a scalar with operator version which return the same results.

```
>>> df + 1
```

| | angles | degrees |
|-----------|--------|---------|
| circle | 1 | 361 |
| triangle | 4 | 181 |
| rectangle | 5 | 361 |

```
>>> df.add(1)
```

| | angles | degrees |
|-----------|--------|---------|
| circle | 1 | 361 |
| triangle | 4 | 181 |
| rectangle | 5 | 361 |

Divide by constant with reverse version.

```
>>> df.div(10)
```

| | angles | degrees |
|-----------|--------|---------|
| circle | 0.0 | 36.0 |
| triangle | 0.3 | 18.0 |
| rectangle | 0.4 | 36.0 |

```
>>> df.rdiv(10)
```

| | angles | degrees |
|--------|--------|----------|
| circle | inf | 0.027778 |

(continues on next page)

(continued from previous page)

```
triangle  3.333333  0.055556
rectangle 2.500000  0.027778
```

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
      angles  degrees
circle     -1    358
triangle     2    178
rectangle     3    358
```

```
>>> df.sub([1, 2], axis='columns')
      angles  degrees
circle     -1    358
triangle     2    178
rectangle     3    358
```

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...        axis='index')
      angles  degrees
circle     -1    359
triangle     2    179
rectangle     3    359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                       index=['circle', 'triangle', 'rectangle'])
>>> other
      angles
circle      0
triangle     3
rectangle    4
```

```
>>> df * other
      angles  degrees
circle      0     NaN
triangle     9     NaN
rectangle   16     NaN
```

```
>>> df.mul(other, fill_value=0)
      angles  degrees
circle      0     0.0
triangle     9     0.0
rectangle   16     0.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                               'degrees': [360, 180, 360, 360, 540, 720]},
...                              index=[['A', 'A', 'A', 'B', 'B', 'B'],
```

(continues on next page)

(continued from previous page)

```

...                                     ['circle', 'triangle', 'rectangle',
...                                     'square', 'pentagon', 'hexagon']]
>>> df_multindex
      angles  degrees
A circle      0    360
  triangle      3    180
  rectangle      4    360
B square      4    360
  pentagon      5    540
  hexagon      6    720

```

```

>>> df.div(df_multindex, level=1, fill_value=0)
      angles  degrees
A circle   NaN     1.0
  triangle  1.0     1.0
  rectangle 1.0     1.0
B square   0.0     0.0
  pentagon 0.0     0.0
  hexagon  0.0     0.0

```

pandas.DataFrame.rsub

`DataFrame.rsub`(*other*, *axis*='columns', *level*=None, *fill_value*=None)

Get Subtraction of dataframe and other, element-wise (binary operator *rsub*).

Equivalent to `other - dataframe`, but with support to substitute a *fill_value* for missing data in one of the inputs. With reverse version, *sub*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: +, -, *, /, //, %, **.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

Notes

Mismatched indices will be unioned together.

Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                    index=['circle', 'triangle', 'rectangle'])
>>> df
```

| | angles | degrees |
|-----------|--------|---------|
| circle | 0 | 360 |
| triangle | 3 | 180 |
| rectangle | 4 | 360 |

Add a scalar with operator version which return the same results.

```
>>> df + 1
```

| | angles | degrees |
|-----------|--------|---------|
| circle | 1 | 361 |
| triangle | 4 | 181 |
| rectangle | 5 | 361 |

```
>>> df.add(1)
```

| | angles | degrees |
|-----------|--------|---------|
| circle | 1 | 361 |
| triangle | 4 | 181 |
| rectangle | 5 | 361 |

Divide by constant with reverse version.

```
>>> df.div(10)
```

| | angles | degrees |
|-----------|--------|---------|
| circle | 0.0 | 36.0 |
| triangle | 0.3 | 18.0 |
| rectangle | 0.4 | 36.0 |

```

```

| | angles | degrees |
|-----------|----------|----------|
| circle | inf | 0.027778 |
| triangle | 3.333333 | 0.055556 |
| rectangle | 2.500000 | 0.027778 |

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
      angles  degrees
circle      -1     358
triangle     2     178
rectangle   3     358
```

```
>>> df.sub([1, 2], axis='columns')
      angles  degrees
circle      -1     358
triangle     2     178
rectangle   3     358
```

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...        axis='index')
      angles  degrees
circle      -1     359
triangle     2     179
rectangle   3     359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                       index=['circle', 'triangle', 'rectangle'])
>>> other
      angles
circle      0
triangle     3
rectangle   4
```

```
>>> df * other
      angles  degrees
circle      0     NaN
triangle     9     NaN
rectangle   16     NaN
```

```
>>> df.mul(other, fill_value=0)
      angles  degrees
circle      0     0.0
triangle     9     0.0
rectangle   16     0.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                               'degrees': [360, 180, 360, 360, 540, 720]},
...                               index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                       ['circle', 'triangle', 'rectangle',
...                                        'square', 'pentagon', 'hexagon']])
>>> df_multindex
      angles  degrees
A circle      0     360
  triangle     3     180
```

(continues on next page)

  pentagon    0.0      0.0
  hexagon     0.0      0.0
```

pandas.DataFrame.rtruediv

`DataFrame.rtruediv(other, axis='columns', level=None, fill_value=None)`

Get Floating division of dataframe and other, element-wise (binary operator *rtruediv*).

Equivalent to `other / dataframe`, but with support to substitute a `fill_value` for missing data in one of the inputs. With reverse version, *truediv*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

  pentagon        5    540
  hexagon         6    720
```

```
>>> df.div(df_multindex, level=1, fill_value=0)
      angles  degrees
A circle   NaN     1.0
  triangle   1.0     1.0
 rectangle   1.0     1.0
B square    0.0     0.0
 pentagon   0.0     0.0
 hexagon    0.0     0.0
```

pandas.DataFrame.sample

`DataFrame.sample` (*n=None, frac=None, replace=False, weights=None, random_state=None, axis=None, ignore_index=False*)

Return a random sample of items from an axis of object.

You can use *random_state* for reproducibility.

Parameters

n [int, optional] Number of items from axis to return. Cannot be used with *frac*. Default = 1 if *frac* = None.

frac [float, optional] Fraction of axis items to return. Cannot be used with *n*.

replace [bool, default False] Allow or disallow sampling of the same row more than once.

weights [str or ndarray-like, optional] Default 'None' results in equal probability weighting. If passed a Series, will align with target object on index. Index values in weights not found in sampled object will be ignored and index values in sampled object not in weights will be assigned weights of zero. If called on a DataFrame, will accept the name of a column when *axis* = 0. Unless weights are a Series, weights must be same length as axis being sampled. If weights do not sum to 1, they will be normalized to sum to 1. Missing values in the weights column will be treated as zero. Infinite values not allowed.

random_state [int, array-like, BitGenerator, np.random.RandomState, optional] If int, array-like, or BitGenerator (NumPy>=1.17), seed for random number generator. If np.random.RandomState, use as numpy RandomState object.

Changed in version 1.1.0: array-like and BitGenerator (for NumPy>=1.17) object now passed to np.random.RandomState() as seed

axis [{0 or 'index', 1 or 'columns', None}, default None] Axis to sample. Accepts axis number or name. Default is stat axis for given data type (0 for Series and DataFrames).

ignore_index [bool, default False] If True, the resulting index will be labeled 0, 1, ..., n - 1.

New in version 1.3.0.

Returns

Series or DataFrame A new object of same type as caller containing *n* items randomly sampled from the caller object.

See also:

DataFrameGroupBy.sample Generates random samples from each group of a DataFrame object.

SeriesGroupBy.sample Generates random samples from each group of a Series object.

numpy.random.choice Generates a random sample from a given 1-D numpy array.

Notes

If $frac > 1$, *replacement* should be set to *True*.

Examples

```
>>> df = pd.DataFrame({'num_legs': [2, 4, 8, 0],
...                    'num_wings': [2, 0, 0, 0],
...                    'num_specimen_seen': [10, 2, 1, 8]},
...                    index=['falcon', 'dog', 'spider', 'fish'])
>>> df
```

| | num_legs | num_wings | num_specimen_seen |
|--------|----------|-----------|-------------------|
| falcon | 2 | 2 | 10 |
| dog | 4 | 0 | 2 |
| spider | 8 | 0 | 1 |
| fish | 0 | 0 | 8 |

Extract 3 random elements from the Series `df['num_legs']`: Note that we use *random_state* to ensure the reproducibility of the examples.

```
>>> df['num_legs'].sample(n=3, random_state=1)
fish      0
spider    8
falcon    2
Name: num_legs, dtype: int64
```

A random 50% sample of the DataFrame with replacement:

```
>>> df.sample(frac=0.5, replace=True, random_state=1)
   num_legs  num_wings  num_specimen_seen
dog         4         0                 2
fish        0         0                 8
```

An upsample sample of the DataFrame with replacement: Note that *replace* parameter has to be *True* for *frac* parameter > 1 .

```
>>> df.sample(frac=2, replace=True, random_state=1)
   num_legs  num_wings  num_specimen_seen
dog         4         0                 2
fish        0         0                 8
falcon      2         2                 10
falcon      2         2                 10
fish        0         0                 8
dog         4         0                 2
fish        0         0                 8
dog         4         0                 2
```

Using a DataFrame column as weights. Rows with larger value in the `num_specimen_seen` column are more likely to be sampled.

```
>>> df.sample(n=2, weights='num_specimen_seen', random_state=1)
   num_legs  num_wings  num_specimen_seen
falcon      2         2                 10
fish        0         0                 8
```

pandas.DataFrame.select_dtypes

`DataFrame.select_dtypes(include=None, exclude=None)`

Return a subset of the DataFrame's columns based on the column dtypes.

Parameters

include, exclude [scalar or list-like] A selection of dtypes or strings to be included/excluded. At least one of these parameters must be supplied.

Returns

DataFrame The subset of the frame including the dtypes in `include` and excluding the dtypes in `exclude`.

Raises

ValueError

- If both of `include` and `exclude` are empty
- If `include` and `exclude` have overlapping elements
- If any kind of string dtype is passed in.

See also:

[`DataFrame.dtypes`](#) Return Series with the data type of each column.

Notes

- To select all *numeric* types, use `np.number` or `'number'`
- To select strings you must use the `object` dtype, but note that this will return *all* object dtype columns
- See the [numpy dtype hierarchy](#)
- To select datetimes, use `np.datetime64`, `'datetime'` or `'datetime64'`
- To select timedeltas, use `np.timedelta64`, `'timedelta'` or `'timedelta64'`
- To select Pandas categorical dtypes, use `'category'`
- To select Pandas datetimetz dtypes, use `'datetimez'` (new in 0.20.0) or `'datetime64[ns, tz]'`

Examples

```
>>> df = pd.DataFrame({'a': [1, 2] * 3,
...                    'b': [True, False] * 3,
...                    'c': [1.0, 2.0] * 3})
>>> df
```

| | a | b | c |
|---|---|-------|-----|
| 0 | 1 | True | 1.0 |
| 1 | 2 | False | 2.0 |
| 2 | 1 | True | 1.0 |
| 3 | 2 | False | 2.0 |
| 4 | 1 | True | 1.0 |
| 5 | 2 | False | 2.0 |

```
>>> df.select_dtypes(include='bool')
b
0 True
1 False
2 True
3 False
4 True
5 False
```

```
>>> df.select_dtypes(include=['float64'])
c
0 1.0
1 2.0
2 1.0
3 2.0
4 1.0
5 2.0
```

```
>>> df.select_dtypes(exclude=['int64'])
b c
0 True 1.0
1 False 2.0
2 True 1.0
3 False 2.0
4 True 1.0
5 False 2.0
```

pandas.DataFrame.sem

`DataFrame.sem`(*axis=None, skipna=None, level=None, ddof=1, numeric_only=None, **kwargs*)

Return unbiased standard error of the mean over requested axis.

Normalized by N-1 by default. This can be changed using the `ddof` argument

Parameters

axis [{index (0), columns (1)}]

skipna [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

ddof [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is $N - \text{ddof}$, where N represents the number of elements.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

Returns

Series or DataFrame (if level specified)

Notes

To have the same behaviour as *numpy.std*, use *ddof=0* (instead of the default *ddof=1*)

pandas.DataFrame.set_axis

`DataFrame.set_axis(labels, axis=0, inplace=False)`

Assign desired index to given axis.

Indexes for column or row labels can be changed by assigning a list-like or Index.

Parameters

labels [list-like, Index] The values for the new index.

axis [{0 or 'index', 1 or 'columns'}, default 0] The axis to update. The value 0 identifies the rows, and 1 identifies the columns.

inplace [bool, default False] Whether to return a new DataFrame instance.

Returns

renamed [DataFrame or None] An object of type DataFrame or None if *inplace=True*.

See also:

[`DataFrame.rename_axis`](#) Alter the name of the index or columns.

Examples

```
>>> df = pd.DataFrame({"A": [1, 2, 3], "B": [4, 5, 6]})
```

Change the row labels.

```
>>> df.set_axis(['a', 'b', 'c'], axis='index')
   A  B
a  1  4
b  2  5
c  3  6
```

Change the column labels.

```
>>> df.set_axis(['I', 'II'], axis='columns')
   I  II
0  1   4
1  2   5
2  3   6
```

Now, update the labels inplace.

```
>>> df.set_axis(['i', 'ii'], axis='columns', inplace=True)
>>> df
   i  ii
0  1   4
1  2   5
2  3   6
```

pandas.DataFrame.set_flags

`DataFrame.set_flags(*, copy=False, allows_duplicate_labels=None)`

Return a new object with updated flags.

Parameters

allows_duplicate_labels [bool, optional] Whether the returned object allows duplicate labels.

Returns

Series or DataFrame The same type as the caller.

See also:

[`DataFrame.attrs`](#) Global metadata applying to this dataset.

[`DataFrame.flags`](#) Global flags applying to this object.

Notes

This method returns a new object that's a view on the same data as the input. Mutating the input or the output values will be reflected in the other.

This method is intended to be used in method chains.

“Flags” differ from “metadata”. Flags reflect properties of the pandas object (the Series or DataFrame). Metadata refer to properties of the dataset, and should be stored in [`DataFrame.attrs`](#).

Examples

```
>>> df = pd.DataFrame({"A": [1, 2]})
>>> df.flags.allows_duplicate_labels
True
>>> df2 = df.set_flags(allows_duplicate_labels=False)
>>> df2.flags.allows_duplicate_labels
False
```

pandas.DataFrame.set_index

`DataFrame.set_index(keys, drop=True, append=False, inplace=False, verify_integrity=False)`
Set the DataFrame index using existing columns.

Set the DataFrame index (row labels) using one or more existing columns or arrays (of the correct length). The index can replace the existing index or expand on it.

Parameters

keys [label or array-like or list of labels/arrays] This parameter can be either a single column key, a single array of the same length as the calling DataFrame, or a list containing an arbitrary combination of column keys and arrays. Here, “array” encompasses *Series*, *Index*, `np.ndarray`, and instances of *Iterator*.

drop [bool, default True] Delete columns to be used as the new index.

append [bool, default False] Whether to append columns to existing index.

inplace [bool, default False] If True, modifies the DataFrame in place (do not create a new object).

verify_integrity [bool, default False] Check the new index for duplicates. Otherwise defer the check until necessary. Setting to False will improve the performance of this method.

Returns

DataFrame or None Changed row labels or None if `inplace=True`.

See also:

[*DataFrame.reset_index*](#) Opposite of `set_index`.

[*DataFrame.reindex*](#) Change to new indices or expand indices.

[*DataFrame.reindex_like*](#) Change to same indices as other DataFrame.

Examples

```
>>> df = pd.DataFrame({'month': [1, 4, 7, 10],
...                   'year': [2012, 2014, 2013, 2014],
...                   'sale': [55, 40, 84, 31]})
>>> df
   month  year  sale
0      1  2012    55
1      4  2014    40
```

(continues on next page)

(continued from previous page)

| | | | |
|---|----|------|----|
| 2 | 7 | 2013 | 84 |
| 3 | 10 | 2014 | 31 |

Set the index to become the 'month' column:

```
>>> df.set_index('month')
      year  sale
month
1      2012   55
4      2014   40
7      2013   84
10     2014   31
```

Create a MultiIndex using columns 'year' and 'month':

```
>>> df.set_index(['year', 'month'])
      sale
year month
2012  1    55
2014  4    40
2013  7    84
2014 10    31
```

Create a MultiIndex using an Index and a column:

```
>>> df.set_index([pd.Index([1, 2, 3, 4]), 'year'])
      month  sale
year
1 2012  1    55
2 2014  4    40
3 2013  7    84
4 2014 10    31
```

Create a MultiIndex using two Series:

```
>>> s = pd.Series([1, 2, 3, 4])
>>> df.set_index([s, s**2])
      month year  sale
1 1      1    2012   55
2 4      4    2014   40
3 9      7    2013   84
4 16     10   2014   31
```

pandas.DataFrame.shift

`DataFrame.shift` (*periods=1, freq=None, axis=0, fill_value=NoDefault.no_default*)

Shift index by desired number of periods with an optional time *freq*.

When *freq* is not passed, shift the index without realigning the data. If *freq* is passed (in this case, the index must be date or datetime, or it will raise a *NotImplementedError*), the index will be increased using the periods and the *freq*. *freq* can be inferred when specified as “infer” as long as either *freq* or *inferred_freq* attribute is set in the index.

Parameters

periods [int] Number of periods to shift. Can be positive or negative.

freq [DateOffset, tseries.offsets, timedelta, or str, optional] Offset to use from the tseries module or time rule (e.g. ‘EOM’). If *freq* is specified then the index values are shifted but the data is not realigned. That is, use *freq* if you would like to extend the index when shifting and preserve the original data. If *freq* is specified as “infer” then it will be inferred from the *freq* or *inferred_freq* attributes of the index. If neither of those attributes exist, a *ValueError* is thrown.

axis [{0 or ‘index’, 1 or ‘columns’, None}, default None] Shift direction.

fill_value [object, optional] The scalar value to use for newly introduced missing values. the default depends on the dtype of *self*. For numeric data, `np.nan` is used. For datetime, timedelta, or period data, etc. `NaT` is used. For extension dtypes, `self.dtype.na_value` is used.

Changed in version 1.1.0.

Returns

DataFrame Copy of input object, shifted.

See also:

[*Index.shift*](#) Shift values of Index.

[*DatetimeIndex.shift*](#) Shift values of DatetimeIndex.

[*PeriodIndex.shift*](#) Shift values of PeriodIndex.

[*tshift*](#) Shift the time index, using the index’s frequency if available.

Examples

```
>>> df = pd.DataFrame({"Col1": [10, 20, 15, 30, 45],
...                    "Col2": [13, 23, 18, 33, 48],
...                    "Col3": [17, 27, 22, 37, 52]},
...                    index=pd.date_range("2020-01-01", "2020-01-05"))
>>> df
```

| | Col1 | Col2 | Col3 |
|------------|------|------|------|
| 2020-01-01 | 10 | 13 | 17 |
| 2020-01-02 | 20 | 23 | 27 |
| 2020-01-03 | 15 | 18 | 22 |
| 2020-01-04 | 30 | 33 | 37 |
| 2020-01-05 | 45 | 48 | 52 |

```
>>> df.shift(periods=3)
      Col1  Col2  Col3
2020-01-01  NaN  NaN  NaN
2020-01-02  NaN  NaN  NaN
2020-01-03  NaN  NaN  NaN
2020-01-04  10.0  13.0  17.0
2020-01-05  20.0  23.0  27.0
```

```
>>> df.shift(periods=1, axis="columns")
      Col1  Col2  Col3

2020-01-08   45   48   52
```

```
>>> df.shift(periods=3, freq="infer")
      Col1  Col2  Col3
2020-01-04   10   13   17
2020-01-05   20   23   27
2020-01-06   15   18   22
2020-01-07   30   33   37
2020-01-08   45   48   52
```

pandas.DataFrame.skew

`DataFrame.skew`(*axis=None, skipna=None, level=None, numeric_only=None, **kwargs*)

Return unbiased skew over requested axis.

Normalized by N-1.

Parameters

axis [{index (0), columns (1)}] Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

****kwargs** Additional keyword arguments to be passed to the function.

Returns

Series or DataFrame (if level specified)

pandas.DataFrame.slice_shift

DataFrame.**slice_shift**(*periods=1, axis=0*)

Equivalent to *shift* without copying data. The shifted data will not include the dropped periods and the shifted axis will be smaller than the original.

Deprecated since version 1.2.0: *slice_shift* is deprecated, use DataFrame/Series.*shift* instead.

Parameters

periods [int] Number of periods to move, can be positive or negative.

Returns

shifted [same type as caller]

Notes

While the *slice_shift* is faster than *shift*, you may pay for it later during alignment.

pandas.DataFrame.sort_index

DataFrame.**sort_index**(*axis=0, level=None, ascending=True, inplace=False, kind='quicksort', na_position='last', sort_remaining=True, ignore_index=False, key=None*)

Sort object by labels (along an axis).

Returns a new DataFrame sorted by label if *inplace* argument is False, otherwise updates the original DataFrame and returns None.

Parameters

axis [{0 or 'index', 1 or 'columns'}, default 0] The axis along which to sort. The value 0 identifies the rows, and 1 identifies the columns.

level [int or level name or list of ints or list of level names] If not None, sort on values in specified index level(s).

ascending [bool or list-like of bools, default True] Sort ascending vs. descending. When the index is a MultiIndex the sort direction can be controlled for each level individually.

inplace [bool, default False] If True, perform operation in-place.

kind [{'quicksort', 'mergesort', 'heapsort', 'stable'}, default 'quicksort'] Choice of sorting algorithm. See also [numpy.sort\(\)](#) for more information. *mergesort* and

stable are the only stable algorithms. For DataFrames, this option is only applied when sorting on a single column or label.

na_position [{ 'first', 'last' }, default 'last'] Puts NaNs at the beginning if *first*; *last* puts NaNs at the end. Not implemented for MultiIndex.

sort_remaining [bool, default True] If True and sorting by level and index is multilevel, sort by other levels too (in order) after sorting by specified level.

ignore_index [bool, default False] If True, the resulting axis will be labeled 0, 1, ..., n - 1.

New in version 1.0.0.

key [callable, optional] If not None, apply the key function to the index values before sorting. This is similar to the *key* argument in the builtin `sorted()` function, with the notable difference that this *key* function should be *vectorized*. It should expect an `Index` and return an `Index` of the same shape. For MultiIndex inputs, the key is applied *per level*.

New in version 1.1.0.

Returns

DataFrame or None The original DataFrame sorted by the labels or None if `inplace=True`.

See also:

[`Series.sort_index`](#) Sort Series by the index.

[`DataFrame.sort_values`](#) Sort DataFrame by the value.

[`Series.sort_values`](#) Sort Series by the value.

Examples

```
>>> df = pd.DataFrame([1, 2, 3, 4, 5], index=[100, 29, 234, 1, 150],
...                   columns=['A'])
>>> df.sort_index()
   A
1  4
29 2
100 1
150 5
234 3
```

By default, it sorts in ascending order, to sort in descending order, use `ascending=False`

```
>>> df.sort_index(ascending=False)
   A
234 3
150 5
100 1
29  2
1  4
```

A key function can be specified which is applied to the index before sorting. For a `MultiIndex` this is applied to each level separately.

```

>>> df = pd.DataFrame({"a": [1, 2, 3, 4]}, index=['A', 'b', 'C', 'd'])
>>> df.sort_index(key=lambda x: x.str.lower())
a
A 1
b 2
C 3
d 4

```

pandas.DataFrame.sort_values

`DataFrame.sort_values`(*by*, *axis=0*, *ascending=True*, *inplace=False*, *kind='quicksort'*, *na_position='last'*, *ignore_index=False*, *key=None*)

Sort by the values along either axis.

Parameters

by [str or list of str] Name or list of names to sort by.

- if *axis* is 0 or *'index'* then *by* may contain index levels and/or column labels.
- if *axis* is 1 or *'columns'* then *by* may contain column levels and/or index labels.

axis [{0 or *'index'*, 1 or *'columns'*}, default 0] Axis to be sorted.

ascending [bool or list of bool, default True] Sort ascending vs. descending. Specify list for multiple sort orders. If this is a list of bools, must match the length of the *by*.

inplace [bool, default False] If True, perform operation in-place.

kind [{*'quicksort'*, *'mergesort'*, *'heapsort'*, *'stable'*}, default *'quicksort'*] Choice of sorting algorithm. See also `numpy.sort()` for more information. *mergesort* and *stable* are the only stable algorithms. For DataFrames, this option is only applied when sorting on a single column or label.

na_position [{*'first'*, *'last'*}, default *'last'*] Puts NaNs at the beginning if *first*; *last* puts NaNs at the end.

ignore_index [bool, default False] If True, the resulting axis will be labeled 0, 1, ..., n - 1.

New in version 1.0.0.

key [callable, optional] Apply the key function to the values before sorting. This is similar to the *key* argument in the builtin `sorted()` function, with the notable difference that this *key* function should be *vectorized*. It should expect a `Series` and return a `Series` with the same shape as the input. It will be applied to each column in *by* independently.

New in version 1.1.0.

Returns

DataFrame or None DataFrame with sorted values or None if *inplace=True*.

See also:

[`DataFrame.sort_index`](#) Sort a DataFrame by the index.

[`Series.sort_values`](#) Similar method for a Series.

Examples

```
>>> df = pd.DataFrame({
...     'col1': ['A', 'A', 'B', np.nan, 'D', 'C'],
...     'col2': [2, 1, 9, 8, 7, 4],
...     'col3': [0, 1, 9, 4, 2, 3],
...     'col4': ['a', 'B', 'c', 'D', 'e', 'F']
... })
>>> df
   col1  col2  col3 col4
0    A     2     0    a
1    A     1     1    B
2    B     9     9    c
3  NaN     8     4    D
4    D     7     2    e
5    C     4     3    F
```

Sort by col1

```
>>> df.sort_values(by=['col1'])
   col1  col2  col3 col4
0    A     2     0    a
1    A     1     1    B
2    B     9     9    c
5    C     4     3    F
4    D     7     2    e
3  NaN     8     4    D
```

Sort by multiple columns

```
>>> df.sort_values(by=['col1', 'col2'])
   col1  col2  col3 col4
1    A     1     1    B
0    A     2     0    a
2    B     9     9    c
5    C     4     3    F
4    D     7     2    e
3  NaN     8     4    D
```

Sort Descending

```
>>> df.sort_values(by='col1', ascending=False)
   col1  col2  col3 col4
4    D     7     2    e
5    C     4     3    F
2    B     9     9    c
0    A     2     0    a
1    A     1     1    B
3  NaN     8     4    D
```

Putting NAs first

```
>>> df.sort_values(by='col1', ascending=False, na_position='first')
   col1  col2  col3 col4
```

(continues on next page)

(continued from previous page)

| | | | | |
|---|-----|---|---|---|
| 3 | NaN | 8 | 4 | D |
| 4 | D | 7 | 2 | e |
| 5 | C | 4 | 3 | F |
| 2 | B | 9 | 9 | c |
| 0 | A | 2 | 0 | a |
| 1 | A | 1 | 1 | B |

Sorting with a key function

```
>>> df.sort_values(by='col4', key=lambda col: col.str.lower())
   col1  col2  col3 col4
0     A     2     0    a
1     A     1     1    B
2     B     9     9    c
3  NaN     8     4    D
4     D     7     2    e
5     C     4     3    F
```

Natural sort with the key argument, using the *natsort* <<https://github.com/SethMMorton/natsort>> package.

```
>>> df = pd.DataFrame({
...     "time": ['0hr', '128hr', '72hr', '48hr', '96hr'],
...     "value": [10, 20, 30, 40, 50]
... })
>>> df
   time  value
0   0hr     10
1 128hr     20
2   72hr     30
3   48hr     40
4   96hr     50
>>> from natsort import index_natsorted
>>> df.sort_values(
...     by="time",
...     key=lambda x: np.argsort(index_natsorted(df["time"]))
... )
   time  value
0   0hr     10
3   48hr     40
2   72hr     30
4   96hr     50
1 128hr     20
```

pandas.DataFrame.sparse

`DataFrame.sparse()`

DataFrame accessor for sparse data.

New in version 0.25.0.

pandas.DataFrame.squeeze

`DataFrame.squeeze(axis=None)`

Squeeze 1 dimensional axis objects into scalars.

Series or DataFrames with a single element are squeezed to a scalar. DataFrames with a single column or a single row are squeezed to a Series. Otherwise the object is unchanged.

This method is most useful when you don't know if your object is a Series or DataFrame, but you do know it has just a single column. In that case you can safely call *squeeze* to ensure you have a Series.

Parameters

axis [{0 or 'index', 1 or 'columns', None}, default None] A specific axis to squeeze. By default, all length-1 axes are squeezed.

Returns

DataFrame, Series, or scalar The projection after squeezing *axis* or all the axes.

See also:

[*Series.iloc*](#) Integer-location based indexing for selecting scalars.

[*DataFrame.iloc*](#) Integer-location based indexing for selecting Series.

[*Series.to_frame*](#) Inverse of `DataFrame.squeeze` for a single-column DataFrame.

Examples

```
>>> primes = pd.Series([2, 3, 5, 7])
```

Slicing might produce a Series with a single value:

```
>>> even_primes = primes[primes % 2 == 0]
>>> even_primes
0    2
dtype: int64
```

```
>>> even_primes.squeeze()
2
```

Squeezing objects with more than one value in every axis does nothing:

```
>>> odd_primes = primes[primes % 2 == 1]
>>> odd_primes
1    3
2    5
```

(continues on next page)

(continued from previous page)

```
3    7
dtype: int64
```

```
>>> odd_primes.squeeze()
1    3
2    5
3    7
dtype: int64
```

Squeezing is even more effective when used with DataFrames.

```
>>> df = pd.DataFrame([[1, 2], [3, 4]], columns=['a', 'b'])
>>> df
   a  b
0  1  2
1  3  4
```

Slicing a single column will produce a DataFrame with the columns having only one value:

```
>>> df_a = df[['a']]
>>> df_a
   a
0  1
1  3
```

So the columns can be squeezed down, resulting in a Series:

```
>>> df_a.squeeze('columns')
0    1
1    3
Name: a, dtype: int64
```

Slicing a single row from a single column will produce a single scalar DataFrame:

```
>>> df_0a = df.loc[df.index < 1, ['a']]
>>> df_0a
   a
0  1
```

Squeezing the rows produces a single scalar Series:

```
>>> df_0a.squeeze('rows')
a    1
Name: 0, dtype: int64
```

Squeezing all axes will project directly into a scalar:

```
>>> df_0a.squeeze()
1
```

pandas.DataFrame.stack

`DataFrame.stack(level=-1, dropna=True)`

Stack the prescribed level(s) from columns to index.

Return a reshaped DataFrame or Series having a multi-level index with one or more new inner-most levels compared to the current DataFrame. The new inner-most levels are created by pivoting the columns of the current dataframe:

- if the columns have a single level, the output is a Series;
- if the columns have multiple levels, the new index level(s) is (are) taken from the prescribed level(s) and the output is a DataFrame.

Parameters

level [int, str, list, default -1] Level(s) to stack from the column axis onto the index axis, defined as one index or label, or a list of indices or labels.

dropna [bool, default True] Whether to drop rows in the resulting Frame/Series with missing values. Stacking a column level onto the index axis can create combinations of index and column values that are missing from the original dataframe. See Examples section.

Returns

DataFrame or Series Stacked dataframe or series.

See also:

[`DataFrame.unstack`](#) Unstack prescribed level(s) from index axis onto column axis.

[`DataFrame.pivot`](#) Reshape dataframe from long format to wide format.

[`DataFrame.pivot_table`](#) Create a spreadsheet-style pivot table as a DataFrame.

Notes

The function is named by analogy with a collection of books being reorganized from being side by side on a horizontal position (the columns of the dataframe) to being stacked vertically on top of each other (in the index of the dataframe).

Examples

Single level columns

```
>>> df_single_level_cols = pd.DataFrame([[0, 1], [2, 3]],
...                                     index=['cat', 'dog'],
...                                     columns=['weight', 'height'])
```

Stacking a dataframe with a single level column axis returns a Series:

```
>>> df_single_level_cols
   weight height
cat      0      1
dog      2      3
```

(continues on next page)

(continued from previous page)

```
>>> df_single_level_cols.stack()
cat weight    0
   height    1
dog weight    2
   height    3
dtype: int64
```

Multi level columns: simple case

```
>>> multicol1 = pd.MultiIndex.from_tuples([('weight', 'kg'),
...                                     ('weight', 'pounds')])
>>> df_multi_level_cols1 = pd.DataFrame([[1, 2], [2, 4]],
...                                     index=['cat', 'dog'],
...                                     columns=multicol1)
```

Stacking a dataframe with a multi-level column axis:

```
>>> df_multi_level_cols1
   weight
   kg    pounds
cat    1      2
dog    2      4
>>> df_multi_level_cols1.stack()
   weight
cat kg    1
   pounds 2
dog kg    2
   pounds 4
```

Missing values

```
>>> multicol2 = pd.MultiIndex.from_tuples([('weight', 'kg'),
...                                     ('height', 'm')])
>>> df_multi_level_cols2 = pd.DataFrame([[1.0, 2.0], [3.0, 4.0]],
...                                     index=['cat', 'dog'],
...                                     columns=multicol2)
```

It is common to have missing values when stacking a dataframe with multi-level columns, as the stacked dataframe typically has more values than the original dataframe. Missing values are filled with NaNs:

```
>>> df_multi_level_cols2
   weight height
   kg      m
cat  1.0    2.0
dog  3.0    4.0
>>> df_multi_level_cols2.stack()
   height weight
cat kg    NaN  1.0
   m     2.0  NaN
dog kg    NaN  3.0
   m     4.0  NaN
```

Prescribing the level(s) to be stacked

The first parameter controls which level or levels are stacked:

```
>>> df_multi_level_cols2.stack(0)
      kg      m
cat height NaN  2.0
   weight  1.0 NaN
dog height NaN  4.0
   weight  3.0 NaN
>>> df_multi_level_cols2.stack([0, 1])
cat height m      2.0
   weight kg      1.0
dog height m      4.0
   weight kg      3.0
dtype: float64
```

Dropping missing values

```
>>> df_multi_level_cols3 = pd.DataFrame([[None, 1.0], [2.0, 3.0]],
...                                     index=['cat', 'dog'],
...                                     columns=multicol2)
```

Note that rows where all values are missing are dropped by default but this behaviour can be controlled via the `dropna` keyword parameter:

```
>>> df_multi_level_cols3
   weight height
      kg      m
cat   NaN      1.0
dog   2.0      3.0
>>> df_multi_level_cols3.stack(dropna=False)
      height weight
cat kg   NaN   NaN
   m    1.0   NaN
dog kg   NaN   2.0
   m    3.0   NaN
>>> df_multi_level_cols3.stack(dropna=True)
      height weight
cat m    1.0   NaN
dog kg   NaN   2.0
   m    3.0   NaN
```

pandas.DataFrame.std

`DataFrame.std(axis=None, skipna=None, level=None, ddof=1, numeric_only=None, **kwargs)`

Return sample standard deviation over requested axis.

Normalized by N-1 by default. This can be changed using the `ddof` argument

Parameters

axis [{index (0), columns (1)}]

skipna [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

ddof [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is $N - \text{ddof}$, where N represents the number of elements.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

Returns

Series or DataFrame (if level specified)

Notes

To have the same behaviour as *numpy.std*, use *ddof=0* (instead of the default *ddof=1*)

pandas.DataFrame.sub

`DataFrame.sub(other, axis='columns', level=None, fill_value=None)`

Get Subtraction of dataframe and other, element-wise (binary operator *sub*).

Equivalent to `dataframe - other`, but with support to substitute a `fill_value` for missing data in one of the inputs. With reverse version, *rsub*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

[*DataFrame.add*](#) Add DataFrames.

[*DataFrame.sub*](#) Subtract DataFrames.

[*DataFrame.mul*](#) Multiply DataFrames.

[*DataFrame.div*](#) Divide DataFrames (float division).

[*DataFrame.truediv*](#) Divide DataFrames (float division).

[*DataFrame.floordiv*](#) Divide DataFrames (integer division).

DataFrame.mod Calculate modulo (remainder after division).

DataFrame.pow Calculate exponential power.

Notes

Mismatched indices will be unioned together.

Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                    index=['circle', 'triangle', 'rectangle'])
>>> df
```

| | angles | degrees |
|-----------|--------|---------|
| circle | 0 | 360 |
| triangle | 3 | 180 |
| rectangle | 4 | 360 |

Add a scalar with operator version which return the same results.

```
>>> df + 1
```

| | angles | degrees |
|-----------|--------|---------|
| circle | 1 | 361 |
| triangle | 4 | 181 |
| rectangle | 5 | 361 |

```
>>> df.add(1)
```

| | angles | degrees |
|-----------|--------|---------|
| circle | 1 | 361 |
| triangle | 4 | 181 |
| rectangle | 5 | 361 |

Divide by constant with reverse version.

```
>>> df.div(10)
```

| | angles | degrees |
|-----------|--------|---------|
| circle | 0.0 | 36.0 |
| triangle | 0.3 | 18.0 |
| rectangle | 0.4 | 36.0 |

```
>>> df.rdiv(10)
```

| | angles | degrees |
|-----------|----------|----------|
| circle | inf | 0.027778 |
| triangle | 3.333333 | 0.055556 |
| rectangle | 2.500000 | 0.027778 |

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
```

| | angles | degrees |
|--------|--------|---------|
| circle | -1 | 358 |

(continues on next page)

(continued from previous page)

```
triangle    2    178
rectangle   3    358
```

```
>>> df.sub([1, 2], axis='columns')
          angles  degrees
circle      -1    358
triangle    2    178
rectangle   3    358
```

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...        axis='index')
          angles  degrees
circle      -1    359
triangle     2    179
rectangle    3    359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                       index=['circle', 'triangle', 'rectangle'])
>>> other
          angles
circle         0
triangle        3
rectangle       4
```

```
>>> df * other
          angles  degrees
circle         0     NaN
triangle        9     NaN
rectangle      16     NaN
```

```
>>> df.mul(other, fill_value=0)
          angles  degrees
circle         0     0.0
triangle        9     0.0
rectangle      16     0.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                              'degrees': [360, 180, 360, 360, 540, 720]},
...                              index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                      ['circle', 'triangle', 'rectangle',
...                                       'square', 'pentagon', 'hexagon']])
>>> df_multindex
          angles  degrees
A circle         0    360
  triangle        3    180
  rectangle        4    360
B square         4    360
```

(continues on next page)

(continued from previous page)

| | | |
|----------|---|-----|
| pentagon | 5 | 540 |
| hexagon | 6 | 720 |

```
>>> df.div(df_multindex, level=1, fill_value=0)
      angles  degrees
A circle   NaN     1.0
  triangle   1.0     1.0
 rectangle   1.0     1.0
B square    0.0     0.0
  pentagon   0.0     0.0
  hexagon    0.0     0.0
```

pandas.DataFrame.subtract

`DataFrame.subtract`(*other*, *axis*='columns', *level*=None, *fill_value*=None)

Get Subtraction of dataframe and other, element-wise (binary operator *sub*).

Equivalent to `dataframe - other`, but with support to substitute a `fill_value` for missing data in one of the inputs. With reverse version, *rsub*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: +, -, *, /, //, %, **.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

Notes

Mismatched indices will be unioned together.

Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                    index=['circle', 'triangle', 'rectangle'])
>>> df
```

| | angles | degrees |
|-----------|--------|---------|
| circle | 0 | 360 |
| triangle | 3 | 180 |
| rectangle | 4 | 360 |

Add a scalar with operator version which return the same results.

```
>>> df + 1
```

| | angles | degrees |
|-----------|--------|---------|
| circle | 1 | 361 |
| triangle | 4 | 181 |
| rectangle | 5 | 361 |

```
>>> df.add(1)
```

| | angles | degrees |
|-----------|--------|---------|
| circle | 1 | 361 |
| triangle | 4 | 181 |
| rectangle | 5 | 361 |

Divide by constant with reverse version.

```
>>> df.div(10)
```

| | angles | degrees |
|-----------|--------|---------|
| circle | 0.0 | 36.0 |
| triangle | 0.3 | 18.0 |
| rectangle | 0.4 | 36.0 |

```
>>> df.rdiv(10)
```

| | angles | degrees |
|-----------|----------|----------|
| circle | inf | 0.027778 |
| triangle | 3.333333 | 0.055556 |
| rectangle | 2.500000 | 0.027778 |

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
```

| | angles | degrees |
|-----------|--------|---------|
| circle | -1 | 358 |
| triangle | 2 | 178 |
| rectangle | 3 | 358 |

```
>>> df.sub([1, 2], axis='columns')
           angles  degrees
circle         -1     358
triangle        2     178
rectangle       3     358
```

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...        axis='index')
           angles  degrees
circle         -1     359
triangle        2     179
rectangle       3     359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                       index=['circle', 'triangle', 'rectangle'])
>>> other
           angles
circle          0
triangle         3
rectangle        4
```

```
>>> df * other
           angles  degrees
circle          0      NaN
triangle         9      NaN
rectangle       16      NaN
```

```
>>> df.mul(other, fill_value=0)
           angles  degrees
circle          0      0.0
triangle         9      0.0
rectangle       16      0.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                               'degrees': [360, 180, 360, 360, 540, 720]},
...                              index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                     ['circle', 'triangle', 'rectangle',
...                                      'square', 'pentagon', 'hexagon']])
>>> df_multindex
           angles  degrees
A circle          0     360
  triangle         3     180
  rectangle        4     360
B square          4     360
  pentagon         5     540
  hexagon          6     720
```

```
>>> df.div(df_multindex, level=1, fill_value=0)
      angles  degrees
A circle   NaN     1.0
  triangle   1.0     1.0
 rectangle   1.0     1.0
B square    0.0     0.0
  pentagon   0.0     0.0
  hexagon    0.0     0.0
```

pandas.DataFrame.sum

`DataFrame.sum(axis=None, skipna=None, level=None, numeric_only=None, min_count=0, **kwargs)`

Return the sum of the values over the requested axis.

This is equivalent to the method `numpy.sum`.

Parameters

axis [{index (0), columns (1)}] Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

min_count [int, default 0] The required number of valid values to perform the operation. If fewer than `min_count` non-NA values are present the result will be NA.

****kwargs** Additional keyword arguments to be passed to the function.

Returns

Series or DataFrame (if level specified)

See also:

[`Series.sum`](#) Return the sum.

[`Series.min`](#) Return the minimum.

[`Series.max`](#) Return the maximum.

[`Series.idxmin`](#) Return the index of the minimum.

[`Series.idxmax`](#) Return the index of the maximum.

[`DataFrame.sum`](#) Return the sum over the requested axis.

[`DataFrame.min`](#) Return the minimum over the requested axis.

[`DataFrame.max`](#) Return the maximum over the requested axis.

[`DataFrame.idxmin`](#) Return the index of the minimum over the requested axis.

[`DataFrame.idxmax`](#) Return the index of the maximum over the requested axis.

Examples

```
>>> idx = pd.MultiIndex.from_arrays([
...     ['warm', 'warm', 'cold', 'cold'],
...     ['dog', 'falcon', 'fish', 'spider']],
...     names=['blooded', 'animal'])
>>> s = pd.Series([4, 2, 0, 8], name='legs', index=idx)
>>> s
blooded  animal
warm     dog      4
         falcon   2
cold     fish     0
         spider   8
Name: legs, dtype: int64
```

```
>>> s.sum()
14
```

By default, the sum of an empty or all-NA Series is 0.

```
>>> pd.Series([], dtype="float64").sum() # min_count=0 is the default
0.0
```

This can be controlled with the `min_count` parameter. For example, if you'd like the sum of an empty series to be NaN, pass `min_count=1`.

```
>>> pd.Series([], dtype="float64").sum(min_count=1)
nan
```

Thanks to the `skipna` parameter, `min_count` handles all-NA and empty series identically.

```
>>> pd.Series([np.nan]).sum()
0.0
```

```
>>> pd.Series([np.nan]).sum(min_count=1)
nan
```

pandas.DataFrame.swapaxes

`DataFrame.swapaxes(axis1, axis2, copy=True)`

Interchange axes and swap values axes appropriately.

Returns

y [same as input]

pandas.DataFrame.swaplevel

`DataFrame.swaplevel(i=-2, j=-1, axis=0)`

Swap levels *i* and *j* in a *MultiIndex*.

Default is to swap the two innermost levels of the index.

Parameters

i, j [int or str] Levels of the indices to be swapped. Can pass level name as string.

axis [{0 or 'index', 1 or 'columns'}, default 0] The axis to swap levels on. 0 or 'index' for row-wise, 1 or 'columns' for column-wise.

Returns

DataFrame DataFrame with levels swapped in MultiIndex.

Examples

```
>>> df = pd.DataFrame(
...     {"Grade": ["A", "B", "A", "C"]},
...     index=[
...         ["Final exam", "Final exam", "Coursework", "Coursework"],
...         ["History", "Geography", "History", "Geography"],
...         ["January", "February", "March", "April"],
...     ],
... )
>>> df
```

| | | | Grade |
|------------|-----------|----------|-------|
| Final exam | History | January | A |
| | Geography | February | B |
| Coursework | History | March | A |
| | Geography | April | C |

In the following example, we will swap the levels of the indices. Here, we will swap the levels column-wise, but levels can be swapped row-wise in a similar manner. Note that column-wise is the default behaviour. By not supplying any arguments for *i* and *j*, we swap the last and second to last indices.

```
>>> df.swaplevel()

Final exam  January  History  Grade
            February Geography  B
Coursework  March    History  A
            April   Geography  C
```

By supplying one argument, we can choose which index to swap the last index with. We can for example swap the first index with the last one as follows.

```
>>> df.swaplevel(0)

January  History  Final exam  Grade
February Geography  Final exam  B
March    History  Coursework   A
April    Geography  Coursework   C
```

We can also define explicitly which indices we want to swap by supplying values for both *i* and *j*. Here, we for example swap the first and second indices.

```
>>> df.swaplevel(0, 1)

```

| | | | Grade |
|-----------|------------|----------|-------|
| History | Final exam | January | A |
| Geography | Final exam | February | B |
| History | Coursework | March | A |
| Geography | Coursework | April | C |

pandas.DataFrame.tail

`DataFrame.tail(n=5)`

Return the last *n* rows.

This function returns last *n* rows from the object based on position. It is useful for quickly verifying data, for example, after sorting or appending rows.

For negative values of *n*, this function returns all rows except the first *n* rows, equivalent to `df[n:]`.

Parameters

n [int, default 5] Number of rows to select.

Returns

type of caller The last *n* rows of the caller object.

See also:

[`DataFrame.head`](#) The first *n* rows of the caller object.

Examples

```
>>> df = pd.DataFrame({'animal': ['alligator', 'bee', 'falcon', 'lion',
...                               'monkey', 'parrot', 'shark', 'whale', 'zebra']})
>>> df

```

| | animal |
|---|-----------|
| 0 | alligator |
| 1 | bee |
| 2 | falcon |
| 3 | lion |
| 4 | monkey |
| 5 | parrot |
| 6 | shark |
| 7 | whale |
| 8 | zebra |

Viewing the last 5 lines

```
>>> df.tail()

```

| | animal |
|---|--------|
| 4 | monkey |
| 5 | parrot |
| 6 | shark |

(continues on next page)

(continued from previous page)

```
7  whale
8  zebra
```

Viewing the last n lines (three in this case)

```
>>> df.tail(3)
   animal
6  shark
7  whale
8  zebra
```

For negative values of n

```
>>> df.tail(-3)
   animal
3  lion
4  monkey
5  parrot
6  shark
7  whale
8  zebra
```

pandas.DataFrame.take

`DataFrame.take(indices, axis=0, is_copy=None, **kwargs)`

Return the elements in the given *positional* indices along an axis.

This means that we are not indexing according to actual values in the index attribute of the object. We are indexing according to the actual position of the element in the object.

Parameters

indices [array-like] An array of ints indicating which positions to take.

axis [{0 or 'index', 1 or 'columns', None}, default 0] The axis on which to select elements. 0 means that we are selecting rows, 1 means that we are selecting columns.

is_copy [bool] Before pandas 1.0, `is_copy=False` can be specified to ensure that the return value is an actual copy. Starting with pandas 1.0, `take` always returns a copy, and the keyword is therefore deprecated.

Deprecated since version 1.0.0.

****kwargs** For compatibility with `numpy.take()`. Has no effect on the output.

Returns

taken [same type as caller] An array-like containing the elements taken from the object.

See also:

[`DataFrame.loc`](#) Select a subset of a DataFrame by labels.

[`DataFrame.iloc`](#) Select a subset of a DataFrame by positions.

[`numpy.take`](#) Take elements from an array along an axis.

Examples

```
>>> df = pd.DataFrame([('falcon', 'bird', 389.0),
...                    ('parrot', 'bird', 24.0),
...                    ('lion', 'mammal', 80.5),
...                    ('monkey', 'mammal', np.nan)],
...                    columns=['name', 'class', 'max_speed'],
...                    index=[0, 2, 3, 1])
>>> df
   name  class  max_speed
0  falcon  bird    389.0
2  parrot  bird     24.0
3   lion  mammal    80.5
1  monkey  mammal     NaN
```

Take elements at positions 0 and 3 along the axis 0 (default).

Note how the actual indices selected (0 and 1) do not correspond to our selected indices 0 and 3. That's because we are selecting the 0th and 3rd rows, not rows whose indices equal 0 and 3.

```
>>> df.take([0, 3])
   name  class  max_speed
0  falcon  bird    389.0
1  monkey  mammal     NaN
```

Take elements at indices 1 and 2 along the axis 1 (column selection).

```
>>> df.take([1, 2], axis=1)
   class  max_speed
0   bird    389.0
2   bird     24.0
3  mammal    80.5
1  mammal     NaN
```

We may take elements using negative integers for positive indices, starting from the end of the object, just like with Python lists.

```
>>> df.take([-1, -2])
   name  class  max_speed
1  monkey  mammal     NaN
3   lion  mammal    80.5
```

pandas.DataFrame.to_dict

`DataFrame.to_dict(orient='dict', into=<class 'dict'>)`

Convert the DataFrame to a dictionary.

The type of the key-value pairs can be customized with the parameters (see below).

Parameters

orient [str {'dict', 'list', 'series', 'split', 'records', 'index'}] Determines the type of the values of the dictionary.

- 'dict' (default): dict like {column -> {index -> value}}

- 'list' : dict like {column -> [values]}
- 'series' : dict like {column -> Series(values)}
- 'split' : dict like {'index' -> [index], 'columns' -> [columns], 'data' -> [values]}
- 'records' : list like [{column -> value}, ... , {column -> value}]
- 'index' : dict like {index -> {column -> value}}

Abbreviations are allowed. *s* indicates *series* and *sp* indicates *split*.

into [class, default dict] The collections.abc.Mapping subclass used for all Mappings in the return value. Can be the actual class or an empty instance of the mapping type you want. If you want a collections.defaultdict, you must pass it initialized.

Returns

dict, list or collections.abc.Mapping Return a collections.abc.Mapping object representing the DataFrame. The resulting transformation depends on the *orient* parameter.

See also:

[*DataFrame.from_dict*](#) Create a DataFrame from a dictionary.

[*DataFrame.to_json*](#) Convert a DataFrame to JSON format.

Examples

```
>>> df = pd.DataFrame({'col1': [1, 2],
...                   'col2': [0.5, 0.75]},
...                   index=['row1', 'row2'])
>>> df
   col1  col2
row1    1  0.50
row2    2  0.75
>>> df.to_dict()
{'col1': {'row1': 1, 'row2': 2}, 'col2': {'row1': 0.5, 'row2': 0.75}}
```

You can specify the return orientation.

```
>>> df.to_dict('series')
{'col1': row1    1
         row2    2
Name: col1, dtype: int64,
 'col2': row1    0.50
         row2    0.75
Name: col2, dtype: float64}
```

```
>>> df.to_dict('split')
{'index': ['row1', 'row2'], 'columns': ['col1', 'col2'],
 'data': [[1, 0.5], [2, 0.75]]}
```

```
>>> df.to_dict('records')
[{'col1': 1, 'col2': 0.5}, {'col1': 2, 'col2': 0.75}]
```

```
>>> df.to_dict('index')
{'row1': {'col1': 1, 'col2': 0.5}, 'row2': {'col1': 2, 'col2': 0.75}}
```

You can also specify the mapping type.

```
>>> from collections import OrderedDict, defaultdict
>>> df.to_dict(into=OrderedDict)
OrderedDict([('col1', OrderedDict([('row1', 1), ('row2', 2)])),
            ('col2', OrderedDict([('row1', 0.5), ('row2', 0.75)]))])
```

If you want a *defaultdict*, you need to initialize it:

```
>>> dd = defaultdict(list)
>>> df.to_dict('records', into=dd)
[defaultdict(<class 'list'>, {'col1': 1, 'col2': 0.5}),
 defaultdict(<class 'list'>, {'col1': 2, 'col2': 0.75})]
```

pandas.DataFrame.to_gbq

`DataFrame.to_gbq(destination_table, project_id=None, chunksize=None, reauth=False, if_exists='fail', auth_local_webserver=False, table_schema=None, location=None, progress_bar=True, credentials=None)`

Write a DataFrame to a Google BigQuery table.

This function requires the `pandas-gbq` package.

See the [How to authenticate with Google BigQuery](#) guide for authentication instructions.

Parameters

destination_table [str] Name of table to be written, in the form `dataset.tablename`.

project_id [str, optional] Google BigQuery Account project ID. Optional when available from the environment.

chunksize [int, optional] Number of rows to be inserted in each chunk from the dataframe. Set to `None` to load the whole dataframe at once.

reauth [bool, default `False`] Force Google BigQuery to re-authenticate the user. This is useful if multiple accounts are used.

if_exists [str, default `'fail'`] Behavior when the destination table exists. Value can be one of:

'fail' If table exists raise `pandas_gbq.gbq.TableCreationError`.

'replace' If table exists, drop it, recreate it, and insert data.

'append' If table exists, insert data. Create if does not exist.

auth_local_webserver [bool, default `False`] Use the [local webserver flow](#) instead of the [console flow](#) when getting user credentials.

New in version 0.2.0 of pandas-gbq.

table_schema [list of dicts, optional] List of BigQuery table fields to which according DataFrame columns conform to, e.g. `[{'name': 'col1', 'type': 'STRING'}, ...]`. If schema is not provided, it will be generated according to

dtypes of DataFrame columns. See BigQuery API documentation on available names of a field.

New in version 0.3.1 of pandas-gbq.

location [str, optional] Location where the load job should run. See the [BigQuery locations documentation](#) for a list of available locations. The location must match that of the target dataset.

New in version 0.5.0 of pandas-gbq.

progress_bar [bool, default True] Use the library *tqdm* to show the progress bar for the upload, chunk by chunk.

New in version 0.5.0 of pandas-gbq.

credentials [google.auth.credentials.Credentials, optional] Credentials for accessing Google APIs. Use this parameter to override default credentials, such as to use Compute Engine `google.auth.compute_engine.Credentials` or Service Account `google.oauth2.service_account.Credentials` directly.

New in version 0.8.0 of pandas-gbq.

See also:

[pandas_gbq.to_gbq](#) This function in the pandas-gbq library.

[read_gbq](#) Read a DataFrame from Google BigQuery.

pandas.DataFrame.to_hdf

`DataFrame.to_hdf`(*path_or_buf*, *key*, *mode='a'*, *complevel=None*, *complib=None*, *append=False*, *format=None*, *index=True*, *min_itemsize=None*, *nan_rep=None*, *dropna=None*, *data_columns=None*, *errors='strict'*, *encoding='UTF-8'*)

Write the contained data to an HDF5 file using HDFStore.

Hierarchical Data Format (HDF) is self-describing, allowing an application to interpret the structure and contents of a file with no outside information. One HDF file can hold a mix of related objects which can be accessed as a group or as individual objects.

In order to add another DataFrame or Series to an existing HDF file please use append mode and a different a key.

Warning: One can store a subclass of DataFrame or Series to HDF5, but the type of the subclass is lost upon storing.

For more information see the [user guide](#).

Parameters

path_or_buf [str or pandas.HDFStore] File path or HDFStore object.

key [str] Identifier for the group in the store.

mode [{ 'a', 'w', 'r+' }, default 'a'] Mode to open file:

- 'w': write, a new file is created (an existing file with the same name would be deleted).

- ‘a’: append, an existing file is opened for reading and writing, and if the file does not exist it is created.
- ‘r+’: similar to ‘a’, but the file must already exist.

complevel [{0-9}, optional] Specifies a compression level for data. A value of 0 disables compression.

complib [{‘zlib’, ‘lzo’, ‘bzip2’, ‘blosc’}, default ‘zlib’] Specifies the compression library to be used. As of v0.20.2 these additional compressors for Blosc are supported (default if no compressor specified: ‘blosc:blosclz’): {‘blosc:blosclz’, ‘blosc:lz4’, ‘blosc:lz4hc’, ‘blosc:snappy’, ‘blosc:zlib’, ‘blosc:zstd’}. Specifying a compression library which is not available issues a ValueError.

append [bool, default False] For Table formats, append the input data to the existing.

format [{‘fixed’, ‘table’, None}, default ‘fixed’] Possible values:

- ‘fixed’: Fixed format. Fast writing/reading. Not-appendable, nor searchable.
- ‘table’: Table format. Write as a PyTables Table structure which may perform worse but allow more flexible operations like searching / selecting subsets of the data.
- If None, `pd.get_option(‘io.hdf.default_format’)` is checked, followed by fallback to “fixed”

errors [str, default ‘strict’] Specifies how encoding and decoding errors are to be handled. See the errors argument for `open()` for a full list of options.

encoding [str, default “UTF-8”]

min_itemsize [dict or int, optional] Map column names to minimum string sizes for columns.

nan_rep [Any, optional] How to represent null values as str. Not allowed with `append=True`.

data_columns [list of columns or True, optional] List of columns to create as indexed data columns for on-disk queries, or True to use all columns. By default only the axes of the object are indexed. See [Query via data columns](#). Applicable only to `format=‘table’`.

See also:

[read_hdf](#) Read from HDF file.

[DataFrame.to_parquet](#) Write a DataFrame to the binary parquet format.

[DataFrame.to_sql](#) Write to a SQL table.

[DataFrame.to_feather](#) Write out feather-format for DataFrames.

[DataFrame.to_csv](#) Write out to a csv file.

Examples

```
>>> df = pd.DataFrame({'A': [1, 2, 3], 'B': [4, 5, 6]},
...                    index=['a', 'b', 'c'])
>>> df.to_hdf('data.h5', key='df', mode='w')
```

We can add another object to the same file:

```
>>> s = pd.Series([1, 2, 3, 4])
>>> s.to_hdf('data.h5', key='s')
```

Reading from HDF file:

```
>>> pd.read_hdf('data.h5', 'df')
A  B
a  1  4
b  2  5
c  3  6
>>> pd.read_hdf('data.h5', 's')
0    1
1    2
2    3
3    4
dtype: int64
```

Deleting file with data:

```
>>> import os
>>> os.remove('data.h5')
```

pandas.DataFrame.to_json

`DataFrame.to_json`(*path_or_buf=None, orient=None, date_format=None, double_precision=10, force_ascii=True, date_unit='ms', default_handler=None, lines=False, compression='infer', index=True, indent=None, storage_options=None*)

Convert the object to a JSON string.

Note NaN's and None will be converted to null and datetime objects will be converted to UNIX timestamps.

Parameters

path_or_buf [str or file handle, optional] File path or object. If not specified, the result is returned as a string.

orient [str] Indication of expected JSON string format.

- Series:
 - default is 'index'
 - allowed values are: {'split', 'records', 'index', 'table'}.
- DataFrame:
 - default is 'columns'
 - allowed values are: {'split', 'records', 'index', 'columns', 'values', 'table'}.

- The format of the JSON string:
 - ‘split’ : dict like { ‘index’ -> [index], ‘columns’ -> [columns], ‘data’ -> [values] }
 - ‘records’ : list like [{column -> value}, ... , {column -> value}]
 - ‘index’ : dict like { index -> {column -> value} }
 - ‘columns’ : dict like { column -> {index -> value} }
 - ‘values’ : just the values array
 - ‘table’ : dict like { ‘schema’: {schema}, ‘data’: {data} }

Describing the data, where data component is like `orient='records'`.

date_format [{None, ‘epoch’, ‘iso’}] Type of date conversion. ‘epoch’ = epoch milliseconds, ‘iso’ = ISO8601. The default depends on the *orient*. For `orient='table'`, the default is ‘iso’. For all other orients, the default is ‘epoch’.

double_precision [int, default 10] The number of decimal places to use when encoding floating point values.

force_ascii [bool, default True] Force encoded string to be ASCII.

date_unit [str, default ‘ms’ (milliseconds)] The time unit to encode to, governs timestamp and ISO8601 precision. One of ‘s’, ‘ms’, ‘us’, ‘ns’ for second, millisecond, microsecond, and nanosecond respectively.

default_handler [callable, default None] Handler to call if object cannot otherwise be converted to a suitable format for JSON. Should receive a single argument which is the object to convert and return a serialisable object.

lines [bool, default False] If ‘orient’ is ‘records’ write out line-delimited json format. Will throw ValueError if incorrect ‘orient’ since others are not list-like.

compression [{‘infer’, ‘gzip’, ‘bz2’, ‘zip’, ‘xz’, None}] A string representing the compression to use in the output file, only used when the first argument is a filename. By default, the compression is inferred from the filename.

index [bool, default True] Whether to include the index values in the JSON string. Not including the index (`index=False`) is only supported when orient is ‘split’ or ‘table’.

indent [int, optional] Length of whitespace used to indent each record.

New in version 1.0.0.

storage_options [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to `urllib` as header options. For other URLs (e.g. starting with “s3://”, and “gcs://”) the key-value pairs are forwarded to `fsspec`. Please see `fsspec` and `urllib` for more details.

New in version 1.2.0.

Returns

None or str If `path_or_buf` is None, returns the resulting json format as a string. Otherwise returns None.

See also:

read_json Convert a JSON string to pandas object.

Notes

The behavior of `indent=0` varies from the `stdlib`, which does not indent the output but does insert newlines. Currently, `indent=0` and the default `indent=None` are equivalent in `pandas`, though this may change in a future release.

`orient='table'` contains a `'pandas_version'` field under `'schema'`. This stores the version of `pandas` used in the latest revision of the schema.

Examples

```
>>> import json
>>> df = pd.DataFrame(
...     [ ["a", "b"], ["c", "d"] ],
...     index=["row 1", "row 2"],
...     columns=["col 1", "col 2"],
... )
```

```
>>> result = df.to_json(orient="split")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
{
    "columns": [
        "col 1",
        "col 2"
    ],
    "index": [
        "row 1",
        "row 2"
    ],
    "data": [
        [
            "a",
            "b"
        ],
        [
            "c",
            "d"
        ]
    ]
}
```

Encoding/decoding a Dataframe using `'records'` formatted JSON. Note that index labels are not preserved with this encoding.

```
>>> result = df.to_json(orient="records")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
[
    {
        "col 1": "a",
        "col 2": "b"
    },

```

(continues on next page)

(continued from previous page)

```
{
  "col 1": "c",
  "col 2": "d"
}
```

Encoding/decoding a Dataframe using 'index' formatted JSON:

```
>>> result = df.to_json(orient="index")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
{
  "row 1": {
    "col 1": "a",
    "col 2": "b"
  },
  "row 2": {
    "col 1": "c",
    "col 2": "d"
  }
}
```

Encoding/decoding a Dataframe using 'columns' formatted JSON:

```
>>> result = df.to_json(orient="columns")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
{
  "col 1": {
    "row 1": "a",
    "row 2": "c"
  },
  "col 2": {
    "row 1": "b",
    "row 2": "d"
  }
}
```

Encoding/decoding a Dataframe using 'values' formatted JSON:

```
>>> result = df.to_json(orient="values")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
[
  [
    "a",
    "b"
  ],
  [
    "c",
    "d"
  ]
]
```

Encoding with Table Schema:

```
>>> result = df.to_json(orient="table")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
{
  "schema": {
    "fields": [
      {
        "name": "index",
        "type": "string"
      },
      {
        "name": "col 1",
        "type": "string"
      },
      {
        "name": "col 2",
        "type": "string"
      }
    ],
    "primaryKey": [
      "index"
    ],
    "pandas_version": "0.20.0"
  },
  "data": [
    {
      "index": "row 1",
      "col 1": "a",
      "col 2": "b"
    },
    {
      "index": "row 2",
      "col 1": "c",
      "col 2": "d"
    }
  ]
}
```

pandas.DataFrame.to_markdown

`DataFrame.to_markdown`(*buf=None, mode='wt, index=True, storage_options=None, **kwargs*)
Print DataFrame in Markdown-friendly format.

New in version 1.0.0.

Parameters

buf [str, Path or StringIO-like, optional, default None] Buffer to write to. If None, the output is returned as a string.

mode [str, optional] Mode in which file is opened, “wt” by default.

index [bool, optional, default True] Add index (row) labels.

New in version 1.1.0.

storage_options [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to `urllib` as header options. For other URLs (e.g. starting with `s3://`, and `gcs://`) the key-value pairs are forwarded to `fsspec`. Please see `fsspec` and `urllib` for more details.

New in version 1.2.0.

****kwargs** These parameters will be passed to `tabulate`.

Returns

str DataFrame in Markdown-friendly format.

Notes

Requires the `tabulate` package.

Examples

```
>>> s = pd.Series(["elk", "pig", "dog", "quetzal"], name="animal")
>>> print(s.to_markdown())
|   | animal |
|---:|:-----|
| 0 | elk     |
| 1 | pig     |
| 2 | dog     |
| 3 | quetzal |
```

Output markdown with a tabulate option.

```
>>> print(s.to_markdown(tablefmt="grid"))
+-----+
|   | animal |
+====+=====+
| 0 | elk     |
+-----+
| 1 | pig     |
+-----+
| 2 | dog     |
+-----+
| 3 | quetzal |
+-----+
```

pandas.DataFrame.to_numpy

`DataFrame.to_numpy(dtype=None, copy=False, na_value=NoDefault.no_default)`

Convert the DataFrame to a NumPy array.

By default, the dtype of the returned array will be the common NumPy dtype of all types in the DataFrame. For example, if the dtypes are `float16` and `float32`, the results dtype will be `float32`. This may require copying data and coercing values, which may be expensive.

Parameters

dtype [str or `numpy.dtype`, optional] The dtype to pass to `numpy.asarray()`.

copy [bool, default `False`] Whether to ensure that the returned value is not a view on another array. Note that `copy=False` does not *ensure* that `to_numpy()` is no-copy. Rather, `copy=True` ensure that a copy is made, even if not strictly necessary.

na_value [Any, optional] The value to use for missing values. The default value depends on *dtype* and the dtypes of the DataFrame columns.

New in version 1.1.0.

Returns

`numpy.ndarray`

See also:

[Series.to_numpy](#) Similar method for Series.

Examples

```
>>> pd.DataFrame({"A": [1, 2], "B": [3, 4]}).to_numpy()
array([[1, 3],
       [2, 4]])
```

With heterogeneous data, the lowest common type will have to be used.

```
>>> df = pd.DataFrame({"A": [1, 2], "B": [3.0, 4.5]})
>>> df.to_numpy()
array([[1. , 3. ],
       [2. , 4.5]])
```

For a mix of numeric and non-numeric types, the output array will have object dtype.

```
>>> df['C'] = pd.date_range('2000', periods=2)
>>> df.to_numpy()
array([[1, 3.0, Timestamp('2000-01-01 00:00:00')],
       [2, 4.5, Timestamp('2000-01-02 00:00:00')]], dtype=object)
```

pandas.DataFrame.to_period

`DataFrame.to_period(freq=None, axis=0, copy=True)`

Convert DataFrame from DatetimeIndex to PeriodIndex.

Convert DataFrame from DatetimeIndex to PeriodIndex with desired frequency (inferred from index if not passed).

Parameters

freq [str, default] Frequency of the PeriodIndex.

axis [{0 or 'index', 1 or 'columns'}, default 0] The axis to convert (the index by default).

copy [bool, default True] If False then underlying input data is not copied.

Returns

DataFrame with PeriodIndex

pandas.DataFrame.to_records

`DataFrame.to_records(index=True, column_dtypes=None, index_dtypes=None)`

Convert DataFrame to a NumPy record array.

Index will be included as the first field of the record array if requested.

Parameters

index [bool, default True] Include index in resulting record array, stored in 'index' field or using the index label, if set.

column_dtypes [str, type, dict, default None] If a string or type, the data type to store all columns. If a dictionary, a mapping of column names and indices (zero-indexed) to specific data types.

index_dtypes [str, type, dict, default None] If a string or type, the data type to store all index levels. If a dictionary, a mapping of index level names and indices (zero-indexed) to specific data types.

This mapping is applied only if *index=True*.

Returns

numpy.recarray NumPy ndarray with the DataFrame labels as fields and each row of the DataFrame as entries.

See also:

[*DataFrame.from_records*](#) Convert structured or record ndarray to DataFrame.

[*numpy.recarray*](#) An ndarray that allows field access using attributes, analogous to typed columns in a spreadsheet.

Examples

```
>>> df = pd.DataFrame({'A': [1, 2], 'B': [0.5, 0.75]},
...                    index=['a', 'b'])
>>> df
   A    B
a  1  0.50
b  2  0.75
>>> df.to_records()
rec.array([(('a', 1, 0.5 ), ('b', 2, 0.75))],
          dtype=[('index', 'O'), ('A', '<i8'), ('B', '<f8')])
```

If the DataFrame index has no label then the recarray field name is set to 'index'. If the index has a label then this is used as the field name:

```
>>> df.index = df.index.rename("I")
>>> df.to_records()
rec.array([(('a', 1, 0.5 ), ('b', 2, 0.75))],
          dtype=[('I', 'O'), ('A', '<i8'), ('B', '<f8')])
```

The index can be excluded from the record array:

```
>>> df.to_records(index=False)
rec.array([(1, 0.5 ), (2, 0.75)],
          dtype=[('A', '<i8'), ('B', '<f8')])
```

Data types can be specified for the columns:

```
>>> df.to_records(column_dtypes={"A": "int32"})
rec.array([(('a', 1, 0.5 ), ('b', 2, 0.75))],
          dtype=[('I', 'O'), ('A', '<i4'), ('B', '<f8')])
```

As well as for the index:

```
>>> df.to_records(index_dtypes="<S2")
rec.array([(b'a', 1, 0.5 ), (b'b', 2, 0.75)],
          dtype=[('I', 'S2'), ('A', '<i8'), ('B', '<f8')])
```

```
>>> index_dtypes = f"<S{df.index.str.len().max()}"
>>> df.to_records(index_dtypes=index_dtypes)
rec.array([(b'a', 1, 0.5 ), (b'b', 2, 0.75)],
          dtype=[('I', 'S1'), ('A', '<i8'), ('B', '<f8')])
```

pandas.DataFrame.to_string

`DataFrame.to_string`(*buf=None, columns=None, col_space=None, header=True, index=True, na_rep='NaN', formatters=None, float_format=None, sparsify=None, index_names=True, justify=None, max_rows=None, min_rows=None, max_cols=None, show_dimensions=False, decimal='.', line_width=None, max_colwidth=None, encoding=None*)

Render a DataFrame to a console-friendly tabular output.

Parameters

buf [str, Path or StringIO-like, optional, default None] Buffer to write to. If None, the output is returned as a string.

columns [sequence, optional, default None] The subset of columns to write. Writes all columns by default.

col_space [int, list or dict of int, optional] The minimum width of each column.

header [bool or sequence, optional] Write out the column names. If a list of strings is given, it is assumed to be aliases for the column names.

index [bool, optional, default True] Whether to print index (row) labels.

na_rep [str, optional, default 'NaN'] String representation of NaN to use.

formatters [list, tuple or dict of one-param. functions, optional] Formatter functions to apply to columns' elements by position or name. The result of each function must be a unicode string. List/tuple must be of length equal to the number of columns.

float_format [one-parameter function, optional, default None] Formatter function to apply to columns' elements if they are floats. This function must return a unicode string and will be applied only to the non-NaN elements, with NaN being handled by `na_rep`.

Changed in version 1.2.0.

sparsify [bool, optional, default True] Set to False for a DataFrame with a hierarchical index to print every multiindex key at each row.

index_names [bool, optional, default True] Prints the names of the indexes.

justify [str, default None] How to justify the column labels. If None uses the option from the print configuration (controlled by `set_option`), 'right' out of the box. Valid values are

- left
- right
- center
- justify
- justify-all
- start
- end
- inherit
- match-parent
- initial
- unset.

max_rows [int, optional] Maximum number of rows to display in the console.

min_rows [int, optional] The number of rows to display in the console in a truncated repr (when number of rows is above `max_rows`).

max_cols [int, optional] Maximum number of columns to display in the console.

show_dimensions [bool, default False] Display DataFrame dimensions (number of rows by number of columns).

decimal [str, default '.'] Character recognized as decimal separator, e.g. ',' in Europe.

line_width [int, optional] Width to wrap a line in characters.

max_colwidth [int, optional] Max width to truncate each column in characters. By default, no limit.

New in version 1.0.0.

encoding [str, default "utf-8"] Set character encoding.

New in version 1.0.

Returns

str or None If buf is None, returns the result as a string. Otherwise returns None.

See also:

[`to_html`](#) Convert DataFrame to HTML.

Examples

```
>>> d = {'col1': [1, 2, 3], 'col2': [4, 5, 6]}
>>> df = pd.DataFrame(d)
>>> print(df.to_string())
  col1  col2
0     1     4
1     2     5
2     3     6
```

`pandas.DataFrame.to_timestamp`

`DataFrame.to_timestamp(freq=None, how='start', axis=0, copy=True)`

Cast to DatetimeIndex of timestamps, at *beginning* of period.

Parameters

freq [str, default frequency of PeriodIndex] Desired frequency.

how [{ 's', 'e', 'start', 'end' }] Convention for converting period to timestamp; start of period vs. end.

axis [{0 or 'index', 1 or 'columns'}, default 0] The axis to convert (the index by default).

copy [bool, default True] If False then underlying input data is not copied.

Returns

DataFrame with DatetimeIndex

pandas.DataFrame.to_xarray

DataFrame.to_xarray()

Return an xarray object from the pandas object.

Returns

xarray.DataArray or xarray.Dataset Data in the pandas structure converted to Dataset if the object is a DataFrame, or a DataArray if the object is a Series.

See also:

[*DataFrame.to_hdf*](#) Write DataFrame to an HDF5 file.

[*DataFrame.to_parquet*](#) Write a DataFrame to the binary parquet format.

Notes

See the [xarray docs](#)

Examples

```
>>> df = pd.DataFrame([('falcon', 'bird', 389.0, 2),
...                   ('parrot', 'bird', 24.0, 2),
...                   ('lion', 'mammal', 80.5, 4),
...                   ('monkey', 'mammal', np.nan, 4)],
...                   columns=['name', 'class', 'max_speed',
...                           'num_legs'])
>>> df
```

| | name | class | max_speed | num_legs |
|---|--------|--------|-----------|----------|
| 0 | falcon | bird | 389.0 | 2 |
| 1 | parrot | bird | 24.0 | 2 |
| 2 | lion | mammal | 80.5 | 4 |
| 3 | monkey | mammal | NaN | 4 |

```
>>> df.to_xarray()
<xarray.Dataset>
Dimensions:  (index: 4)
Coordinates:
  * index    (index) int64 0 1 2 3
Data variables:
  name      (index) object 'falcon' 'parrot' 'lion' 'monkey'
  class     (index) object 'bird' 'bird' 'mammal' 'mammal'
  max_speed (index) float64 389.0 24.0 80.5 nan
  num_legs  (index) int64 2 2 4 4
```

```
>>> df['max_speed'].to_xarray()
<xarray.DataArray 'max_speed' (index: 4)>
array([389. , 24. , 80.5,  nan])
Coordinates:
  * index    (index) int64 0 1 2 3
```

```
>>> dates = pd.to_datetime(['2018-01-01', '2018-01-01',
...                          '2018-01-02', '2018-01-02'])
>>> df_multiindex = pd.DataFrame({'date': dates,
...                               'animal': ['falcon', 'parrot',
...                                         'falcon', 'parrot'],
...                               'speed': [350, 18, 361, 15]})
>>> df_multiindex = df_multiindex.set_index(['date', 'animal'])
```

```
>>> df_multiindex
           speed
date  animal
2018-01-01 falcon    350
           parrot     18
2018-01-02 falcon    361
           parrot     15
```

```
>>> df_multiindex.to_xarray()
<xarray.Dataset>
Dimensions: (animal: 2, date: 2)
Coordinates:
  * date      (date) datetime64[ns] 2018-01-01 2018-01-02
  * animal    (animal) object 'falcon' 'parrot'
Data variables:
  speed      (date, animal) int64 350 18 361 15
```

pandas.DataFrame.transform

`DataFrame.transform(func, axis=0, *args, **kwargs)`

Call `func` on self producing a DataFrame with transformed values.

Produced DataFrame will have same axis length as self.

Parameters

func [function, str, list-like or dict-like] Function to use for transforming the data. If a function, must either work when passed a DataFrame or when passed to `DataFrame.apply`. If `func` is both list-like and dict-like, dict-like behavior takes precedence.

Accepted combinations are:

- function
- string function name
- list-like of functions and/or function names, e.g. `[np.exp, 'sqrt']`
- dict-like of axis labels -> functions, function names or list-like of such.

axis [{0 or 'index', 1 or 'columns'}, default 0] If 0 or 'index': apply function to each column. If 1 or 'columns': apply function to each row.

***args** Positional arguments to pass to `func`.

****kwargs** Keyword arguments to pass to `func`.

Returns

DataFrame A DataFrame that must have the same length as self.

Raises

ValueError [If the returned DataFrame has a different length than self.]

See also:

DataFrame.agg Only perform aggregating type operations.

DataFrame.apply Invoke function on a DataFrame.

Notes

Functions that mutate the passed object can produce unexpected behavior or errors and are not supported. See *Mutating with User Defined Function (UDF) methods* for more details.

Examples

```
>>> df = pd.DataFrame({'A': range(3), 'B': range(1, 4)})
>>> df
   A  B
0  0  1
1  1  2
2  2  3
>>> df.transform(lambda x: x + 1)
   A  B
0  1  2
1  2  3
2  3  4
```

Even though the resulting DataFrame must have the same length as the input DataFrame, it is possible to provide several input functions:

```
>>> s = pd.Series(range(3))
>>> s
0    0
1    1
2    2
dtype: int64
>>> s.transform([np.sqrt, np.exp])
      sqrt      exp
0  0.000000  1.000000
1  1.000000  2.718282
2  1.414214  7.389056
```

You can call transform on a GroupBy object:

```
>>> df = pd.DataFrame({
...     "Date": [
...         "2015-05-08", "2015-05-07", "2015-05-06", "2015-05-05",
...         "2015-05-08", "2015-05-07", "2015-05-06", "2015-05-05"],
...     "Data": [5, 8, 6, 1, 50, 100, 60, 120],
... })
```

(continues on next page)

(continued from previous page)

```
>>> df
   Date  Data
0 2015-05-08    5
1 2015-05-07    8
2 2015-05-06    6
3 2015-05-05    1
4 2015-05-08   50
5 2015-05-07  100
6 2015-05-06   60
7 2015-05-05  120
>>> df.groupby('Date')['Data'].transform('sum')
0    55
1   108
2    66
3   121
4    55
5   108
6    66
7   121
Name: Data, dtype: int64
```

```
>>> df = pd.DataFrame({
...     "c": [1, 1, 1, 2, 2, 2, 2],
...     "type": ["m", "n", "o", "m", "m", "n", "n"]
... })
>>> df
   c type
0  1  m
1  1  n
2  1  o
3  2  m
4  2  m
5  2  n
6  2  n
>>> df['size'] = df.groupby('c')['type'].transform(len)
>>> df
   c type size
0  1  m     3
1  1  n     3
2  1  o     3
3  2  m     4
4  2  m     4
5  2  n     4
6  2  n     4
```

pandas.DataFrame.transpose

DataFrame.**transpose**(*args, copy=False)

Transpose index and columns.

Reflect the DataFrame over its main diagonal by writing rows as columns and vice-versa. The property *T* is an accessor to the method `transpose()`.

Parameters

***args** [tuple, optional] Accepted for compatibility with NumPy.

copy [bool, default False] Whether to copy the data after transposing, even for DataFrames with a single dtype.

Note that a copy is always required for mixed dtype DataFrames, or for DataFrames with any extension types.

Returns

DataFrame The transposed DataFrame.

See also:

[numpy.transpose](#) Permute the dimensions of a given array.

Notes

Transposing a DataFrame with mixed dtypes will result in a homogeneous DataFrame with the *object* dtype. In such a case, a copy of the data is always made.

Examples

Square DataFrame with homogeneous dtype

```
>>> d1 = {'col1': [1, 2], 'col2': [3, 4]}
>>> df1 = pd.DataFrame(data=d1)
>>> df1
   col1  col2
0     1     3
1     2     4
```

```
>>> df1_transposed = df1.T # or df1.transpose()
>>> df1_transposed
   0  1
col1 1  2
col2 3  4
```

When the dtype is homogeneous in the original DataFrame, we get a transposed DataFrame with the same dtype:

```
>>> df1.dtypes
col1    int64
col2    int64
dtype: object
```

(continues on next page)

(continued from previous page)

```
>>> df1_transposed.dtypes
0    int64
1    int64
dtype: object
```

Non-square DataFrame with mixed dtypes

```
>>> d2 = {'name': ['Alice', 'Bob'],
...      'score': [9.5, 8],
...      'employed': [False, True],
...      'kids': [0, 0]}
>>> df2 = pd.DataFrame(data=d2)
>>> df2
   name  score  employed  kids
0  Alice   9.5     False    0
1   Bob   8.0      True    0
```

```
>>> df2_transposed = df2.T # or df2.transpose()
>>> df2_transposed
      0    1
name   Alice  Bob
score   9.5  8.0
employed False  True
kids     0    0
```

When the DataFrame has mixed dtypes, we get a transposed DataFrame with the *object* dtype:

```
>>> df2.dtypes
name      object
score    float64
employed   bool
kids      int64
dtype: object
>>> df2_transposed.dtypes
0    object
1    object
dtype: object
```

pandas.DataFrame.truediv

DataFrame.truediv(*other*, *axis='columns'*, *level=None*, *fill_value=None*)

Get Floating division of dataframe and other, element-wise (binary operator *truediv*).

Equivalent to `dataframe / other`, but with support to substitute a *fill_value* for missing data in one of the inputs. With reverse version, *rtruediv*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

See also:

DataFrame.add Add DataFrames.

DataFrame.sub Subtract DataFrames.

DataFrame.mul Multiply DataFrames.

DataFrame.div Divide DataFrames (float division).

DataFrame.truediv Divide DataFrames (float division).

DataFrame.floordiv Divide DataFrames (integer division).

DataFrame.mod Calculate modulo (remainder after division).

DataFrame.pow Calculate exponential power.

Notes

Mismatched indices will be unioned together.

Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                   index=['circle', 'triangle', 'rectangle'])
>>> df
```

| | angles | degrees |
|-----------|--------|---------|
| circle | 0 | 360 |
| triangle | 3 | 180 |
| rectangle | 4 | 360 |

Add a scalar with operator version which return the same results.

```
>>> df + 1
```

| | angles | degrees |
|-----------|--------|---------|
| circle | 1 | 361 |
| triangle | 4 | 181 |
| rectangle | 5 | 361 |

```
>>> df.add(1)
      angles  degrees
circle      1     361
triangle    4     181
rectangle   5     361
```

Divide by constant with reverse version.

```
>>> df.div(10)
      angles  degrees
circle    0.0    36.0
triangle  0.3    18.0
rectangle 0.4    36.0
```

```
>>> df.rdiv(10)
      angles  degrees
circle      inf  0.027778
triangle  3.333333  0.055556
rectangle  2.500000  0.027778
```

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
      angles  degrees
circle     -1     358
triangle    2     178
rectangle   3     358
```

```
>>> df.sub([1, 2], axis='columns')
      angles  degrees
circle     -1     358
triangle    2     178
rectangle   3     358
```

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...        axis='index')
      angles  degrees
circle     -1     359
triangle    2     179
rectangle   3     359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                       index=['circle', 'triangle', 'rectangle'])
>>> other
      angles
circle      0
triangle    3
rectangle   4
```

```
>>> df * other
      angles  degrees
circle      0      NaN
triangle    9      NaN
rectangle  16      NaN
```

```
>>> df.mul(other, fill_value=0)
      angles  degrees
circle      0      0.0
triangle    9      0.0
rectangle  16      0.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                               'degrees': [360, 180, 360, 360, 540, 720]},
...                               index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                       ['circle', 'triangle', 'rectangle',
...                                       'square', 'pentagon', 'hexagon']])
>>> df_multindex
      angles  degrees
A circle      0      360
  triangle    3      180
  rectangle    4      360
B square      4      360
  pentagon    5      540
  hexagon     6      720
```

```
>>> df.div(df_multindex, level=1, fill_value=0)
      angles  degrees
A circle    NaN      1.0
  triangle  1.0      1.0
  rectangle  1.0      1.0
B square    0.0      0.0
  pentagon  0.0      0.0
  hexagon   0.0      0.0
```

pandas.DataFrame.truncate

DataFrame.**truncate**(*before=None, after=None, axis=None, copy=True*)

Truncate a Series or DataFrame before and after some index value.

This is a useful shorthand for boolean indexing based on index values above or below certain thresholds.

Parameters

before [date, str, int] Truncate all rows before this index value.

after [date, str, int] Truncate all rows after this index value.

axis [{0 or 'index', 1 or 'columns'}, optional] Axis to truncate. Truncates the index (rows) by default.

copy [bool, default is True,] Return a copy of the truncated section.

Returns

type of caller The truncated Series or DataFrame.

See also:

[*DataFrame.loc*](#) Select a subset of a DataFrame by label.

[*DataFrame.iloc*](#) Select a subset of a DataFrame by position.

Notes

If the index being truncated contains only datetime values, *before* and *after* may be specified as strings instead of Timestamps.

Examples

```

>>> df = pd.DataFrame({'A': ['a', 'b', 'c', 'd', 'e'],
...                    'B': ['f', 'g', 'h', 'i', 'j'],
...                    'C': ['k', 'l', 'm', 'n', 'o']},
...                    index=[1, 2, 3, 4, 5])
>>> df
   A B C
1  a f k
2  b g l
3  c h m
4  d i n
5  e j o

```

```

>>> df.truncate(before=2, after=4)
   A B C
2  b g l
3  c h m
4  d i n

```

The columns of a DataFrame can be truncated.

```

>>> df.truncate(before="A", after="B", axis="columns")
   A B
1  a f
2  b g
3  c h
4  d i
5  e j

```

For Series, only rows can be truncated.

```

>>> df['A'].truncate(before=2, after=4)
2    b
3    c
4    d
Name: A, dtype: object

```

The index values in `truncate` can be datetimes or string dates.

```
>>> dates = pd.date_range('2016-01-01', '2016-02-01', freq='s')
>>> df = pd.DataFrame(index=dates, data={'A': 1})
>>> df.tail()
                A
2016-01-31 23:59:56  1
2016-01-31 23:59:57  1
2016-01-31 23:59:58  1
2016-01-31 23:59:59  1
2016-02-01 00:00:00  1
```

```
>>> df.truncate(before=pd.Timestamp('2016-01-05'),
...             after=pd.Timestamp('2016-01-10')).tail()
                A
2016-01-09 23:59:56  1
2016-01-09 23:59:57  1
2016-01-09 23:59:58  1
2016-01-09 23:59:59  1
2016-01-10 00:00:00  1
```

Because the index is a `DatetimeIndex` containing only dates, we can specify *before* and *after* as strings. They will be coerced to `Timestamps` before truncation.

```
>>> df.truncate('2016-01-05', '2016-01-10').tail()
                A
2016-01-09 23:59:56  1
2016-01-09 23:59:57  1
2016-01-09 23:59:58  1
2016-01-09 23:59:59  1
2016-01-10 00:00:00  1
```

Note that `truncate` assumes a 0 value for any unspecified time component (midnight). This differs from partial string slicing, which returns any partially matching dates.

```
>>> df.loc['2016-01-05':'2016-01-10', :].tail()
                A
2016-01-10 23:59:55  1
2016-01-10 23:59:56  1
2016-01-10 23:59:57  1
2016-01-10 23:59:58  1
2016-01-10 23:59:59  1
```

pandas.DataFrame.tshift

`DataFrame.tshift` (*periods=1, freq=None, axis=0*)

Shift the time index, using the index's frequency if available.

Deprecated since version 1.1.0: Use *shift* instead.

Parameters

periods [int] Number of periods to move, can be positive or negative.

freq [DateOffset, timedelta, or str, default None] Increment to use from the `tseries` module or time rule expressed as a string (e.g. 'EOM').

axis [{0 or 'index', 1 or 'columns', None}, default 0] Corresponds to the axis that contains the Index.

Returns

shifted [Series/DataFrame]

Notes

If freq is not specified then tries to use the freq or inferred_freq attributes of the index. If neither of those attributes exist, a ValueError is thrown

pandas.DataFrame.tz_convert

`DataFrame.tz_convert(tz, axis=0, level=None, copy=True)`

Convert tz-aware axis to target time zone.

Parameters

tz [str or tzinfo object]

axis [the axis to convert]

level [int, str, default None] If axis is a MultiIndex, convert a specific level. Otherwise must be None.

copy [bool, default True] Also make a copy of the underlying data.

Returns

{klass} Object with time zone converted axis.

Raises

TypeError If the axis is tz-naive.

pandas.DataFrame.tz_localize

`DataFrame.tz_localize(tz, axis=0, level=None, copy=True, ambiguous='raise', nonexistent='raise')`

Localize tz-naive index of a Series or DataFrame to target time zone.

This operation localizes the Index. To localize the values in a timezone-naive Series, use `Series.dt.tz_localize()`.

Parameters

tz [str or tzinfo]

axis [the axis to localize]

level [int, str, default None] If axis is a MultiIndex, localize a specific level. Otherwise must be None.

copy [bool, default True] Also make a copy of the underlying data.

ambiguous ['infer', bool-ndarray, 'NaT', default 'raise'] When clocks moved backward due to DST, ambiguous times may arise. For example in Central European Time (UTC+01), when going from 03:00 DST to 02:00 non-DST, 02:30:00 local time occurs both at 00:30:00 UTC and at 01:30:00 UTC. In such a situation, the *ambiguous* parameter dictates how ambiguous times should be handled.

- ‘infer’ will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- ‘NaT’ will return NaT where there are ambiguous times
- ‘raise’ will raise an `AmbiguousTimeError` if there are ambiguous times.

nonexistent [str, default ‘raise’] A nonexistent time does not exist in a particular time-zone where clocks moved forward due to DST. Valid values are:

- ‘shift_forward’ will shift the nonexistent time forward to the closest existing time
- ‘shift_backward’ will shift the nonexistent time backward to the closest existing time
- ‘NaT’ will return NaT where there are nonexistent times
- `timedelta` objects will shift nonexistent times by the `timedelta`
- ‘raise’ will raise an `NonExistentTimeError` if there are nonexistent times.

Returns

Series or DataFrame Same type as the input.

Raises

TypeError If the `TimeSeries` is tz-aware and `tz` is not `None`.

Examples

Localize local times:

```
>>> s = pd.Series([1],
...                index=pd.DatetimeIndex(['2018-09-15 01:30:00']))
>>> s.tz_localize('CET')
2018-09-15 01:30:00+02:00    1
dtype: int64
```

Be careful with DST changes. When there is sequential data, pandas can infer the DST time:

```
>>> s = pd.Series(range(7),
...                index=pd.DatetimeIndex(['2018-10-28 01:30:00',
...                                         '2018-10-28 02:00:00',
...                                         '2018-10-28 02:30:00',
...                                         '2018-10-28 02:00:00',
...                                         '2018-10-28 02:30:00',
...                                         '2018-10-28 03:00:00',
...                                         '2018-10-28 03:30:00']))
>>> s.tz_localize('CET', ambiguous='infer')
2018-10-28 01:30:00+02:00    0
2018-10-28 02:00:00+02:00    1
2018-10-28 02:30:00+02:00    2
2018-10-28 02:00:00+01:00    3
2018-10-28 02:30:00+01:00    4
2018-10-28 03:00:00+01:00    5
```

(continues on next page)

(continued from previous page)

```
2018-10-28 03:30:00+01:00    6
dtype: int64
```

In some cases, inferring the DST is impossible. In such cases, you can pass an ndarray to the `ambiguous` parameter to set the DST explicitly

```
>>> s = pd.Series(range(3),
...               index=pd.DatetimeIndex(['2018-10-28 01:20:00',
...                                       '2018-10-28 02:36:00',
...                                       '2018-10-28 03:46:00']))
>>> s.tz_localize('CET', ambiguous=np.array([True, True, False]))
2018-10-28 01:20:00+02:00    0
2018-10-28 02:36:00+02:00    1
2018-10-28 03:46:00+01:00    2
dtype: int64
```

If the DST transition causes nonexistent times, you can shift these dates forward or backward with a `timedelta` object or `'shift_forward'` or `'shift_backward'`.

```
>>> s = pd.Series(range(2),
...               index=pd.DatetimeIndex(['2015-03-29 02:30:00',
...                                       '2015-03-29 03:30:00']))
>>> s.tz_localize('Europe/Warsaw', nonexistent='shift_forward')
2015-03-29 03:00:00+02:00    0
2015-03-29 03:30:00+02:00    1
dtype: int64
>>> s.tz_localize('Europe/Warsaw', nonexistent='shift_backward')
2015-03-29 01:59:59.999999999+01:00    0
2015-03-29 03:30:00+02:00            1
dtype: int64
>>> s.tz_localize('Europe/Warsaw', nonexistent=pd.Timedelta('1H'))
2015-03-29 03:30:00+02:00    0
2015-03-29 03:30:00+02:00    1
dtype: int64
```

pandas.DataFrame.unstack

`DataFrame.unstack(level=-1, fill_value=None)`

Pivot a level of the (necessarily hierarchical) index labels.

Returns a `DataFrame` having a new level of column labels whose inner-most level consists of the pivoted index labels.

If the index is not a `MultiIndex`, the output will be a `Series` (the analogue of `stack` when the columns are not a `MultiIndex`).

Parameters

level [int, str, or list of these, default -1 (last level)] Level(s) of index to unstack, can pass level name.

fill_value [int, str or dict] Replace NaN with this value if the unstack produces missing values.

Returns

Series or DataFrame

See also:

[`DataFrame.pivot`](#) Pivot a table based on column values.

[`DataFrame.stack`](#) Pivot a level of the column labels (inverse operation from *unstack*).

Examples

```
>>> index = pd.MultiIndex.from_tuples([('one', 'a'), ('one', 'b'),
...                                  ('two', 'a'), ('two', 'b')])
>>> s = pd.Series(np.arange(1.0, 5.0), index=index)
>>> s
one  a    1.0
     b    2.0
two  a    3.0
     b    4.0
dtype: float64
```

```
>>> s.unstack(level=-1)
     a    b
one  1.0  2.0
two  3.0  4.0
```

```
>>> s.unstack(level=0)
     one  two
a    1.0  3.0
b    2.0  4.0
```

```
>>> df = s.unstack(level=0)
>>> df.unstack()
one  a    1.0
     b    2.0
two  a    3.0
     b    4.0
dtype: float64
```

pandas.DataFrame.update

`DataFrame.update`(*other*, *join*='left', *overwrite*=True, *filter_func*=None, *errors*='ignore')

Modify in place using non-NA values from another DataFrame.

Aligns on indices. There is no return value.

Parameters

other [DataFrame, or object coercible into a DataFrame] Should have at least one matching index/column label with the original DataFrame. If a Series is passed, its name attribute must be set, and that will be used as the column name to align with the original DataFrame.

join [{'left'}, default 'left'] Only left join is implemented, keeping the index and columns of the original object.

overwrite [bool, default True] How to handle non-NA values for overlapping keys:

- True: overwrite original DataFrame's values with values from *other*.
- False: only update values that are NA in the original DataFrame.

filter_func [callable(1d-array) -> bool 1d-array, optional] Can choose to replace values other than NA. Return True for values that should be updated.

errors [{'raise', 'ignore'}, default 'ignore'] If 'raise', will raise a ValueError if the DataFrame and *other* both contain non-NA data in the same place.

Returns

None [method directly changes calling object]

Raises

ValueError

- When *errors*='raise' and there's overlapping non-NA data.
- When *errors* is not either 'ignore' or 'raise'

NotImplementedError

- If *join* != 'left'

See also:

[dict.update](#) Similar method for dictionaries.

[DataFrame.merge](#) For column(s)-on-column(s) operations.

Examples

```
>>> df = pd.DataFrame({'A': [1, 2, 3],
...                    'B': [400, 500, 600]})
>>> new_df = pd.DataFrame({'B': [4, 5, 6],
...                         'C': [7, 8, 9]})
>>> df.update(new_df)
>>> df
   A  B
0  1  4
1  2  5
2  3  6
```

The DataFrame's length does not increase as a result of the update, only values at matching index/column labels are updated.

```
>>> df = pd.DataFrame({'A': ['a', 'b', 'c'],
...                    'B': ['x', 'y', 'z']})
>>> new_df = pd.DataFrame({'B': ['d', 'e', 'f', 'g', 'h', 'i']})
>>> df.update(new_df)
>>> df
   A  B
0  a  d
1  b  e
2  c  f
```

For Series, its name attribute must be set.

```
>>> df = pd.DataFrame({'A': ['a', 'b', 'c'],
...                    'B': ['x', 'y', 'z']})
>>> new_column = pd.Series(['d', 'e'], name='B', index=[0, 2])
>>> df.update(new_column)
>>> df
   A B
0  a d
1  b y
2  c e
>>> df = pd.DataFrame({'A': ['a', 'b', 'c'],
...                    'B': ['x', 'y', 'z']})
>>> new_df = pd.DataFrame({'B': ['d', 'e'], index=[1, 2]})
>>> df.update(new_df)
>>> df
   A B
0  a x
1  b d
2  c e
```

If *other* contains NaNs the corresponding values are not updated in the original dataframe.

```
>>> df = pd.DataFrame({'A': [1, 2, 3],
...                    'B': [400, 500, 600]})
>>> new_df = pd.DataFrame({'B': [4, np.nan, 6]})
>>> df.update(new_df)
>>> df
   A    B
0  1  4.0
1  2  500.0
2  3  6.0
```

pandas.DataFrame.value_counts

`DataFrame.value_counts` (*subset=None, normalize=False, sort=True, ascending=False, dropna=True*)
Return a Series containing counts of unique rows in the DataFrame.

New in version 1.1.0.

Parameters

- subset** [list-like, optional] Columns to use when counting unique combinations.
- normalize** [bool, default False] Return proportions rather than frequencies.
- sort** [bool, default True] Sort by frequencies.
- ascending** [bool, default False] Sort in ascending order.
- dropna** [bool, default True] Don't include counts of rows that contain NA values.

New in version 1.3.0.

Returns

Series

See also:

[`Series.value_counts`](#) Equivalent method on Series.

Notes

The returned Series will have a MultiIndex with one level per input column. By default, rows that contain any NA values are omitted from the result. By default, the resulting Series will be in descending order so that the first element is the most frequently-occurring row.

Examples

```
>>> df = pd.DataFrame({'num_legs': [2, 4, 4, 6],
...                    'num_wings': [2, 0, 0, 0]},
...                    index=['falcon', 'dog', 'cat', 'ant'])
>>> df
```

| | num_legs | num_wings |
|--------|----------|-----------|
| falcon | 2 | 2 |
| dog | 4 | 0 |
| cat | 4 | 0 |
| ant | 6 | 0 |

```
>>> df.value_counts()
num_legs  num_wings
4          0          2
2          2          1
6          0          1
dtype: int64
```

```
>>> df.value_counts(sort=False)
num_legs  num_wings
2          2          1
4          0          2
6          0          1
dtype: int64
```

```
>>> df.value_counts(ascending=True)
num_legs  num_wings
2          2          1
6          0          1
4          0          2
dtype: int64
```

```
>>> df.value_counts(normalize=True)
num_legs  num_wings
4          0          0.50
2          2          0.25
6          0          0.25
dtype: float64
```

With `dropna` set to `False` we can also count rows with NA values.

```
>>> df = pd.DataFrame({'first_name': ['John', 'Anne', 'John', 'Beth'],
...                    'middle_name': ['Smith', pd.NA, pd.NA, 'Louise']})
>>> df
  first_name middle_name
0        John         Smith
1         Anne         <NA>
2         John         <NA>
3         Beth         Louise
```

```
>>> df.value_counts()
first_name middle_name
Beth      Louise         1
John      Smith         1
dtype: int64
```

```
>>> df.value_counts(dropna=False)
first_name middle_name
Anne      NaN         1
Beth      Louise         1
John      Smith         1
          NaN         1
dtype: int64
```

pandas.DataFrame.var

`DataFrame.var` (*axis=None, skipna=None, level=None, ddof=1, numeric_only=None, **kwargs*)

Return unbiased variance over requested axis.

Normalized by N-1 by default. This can be changed using the `ddof` argument

Parameters

axis [{index (0), columns (1)}]

skipna [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

ddof [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is N - ddof, where N represents the number of elements.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

Returns

Series or DataFrame (if level specified)

Notes

To have the same behaviour as *numpy.std*, use *ddof=0* (instead of the default *ddof=1*)

pandas.DataFrame.where

`DataFrame.where(cond, other=nan, inplace=False, axis=None, level=None, errors='raise', try_cast=NoDefault.no_default)`

Replace values where the condition is False.

Parameters

cond [bool Series/DataFrame, array-like, or callable] Where *cond* is True, keep the original value. Where False, replace with corresponding value from *other*. If *cond* is callable, it is computed on the Series/DataFrame and should return boolean Series/DataFrame or array. The callable must not change input Series/DataFrame (though pandas doesn't check it).

other [scalar, Series/DataFrame, or callable] Entries where *cond* is False are replaced with corresponding value from *other*. If *other* is callable, it is computed on the Series/DataFrame and should return scalar or Series/DataFrame. The callable must not change input Series/DataFrame (though pandas doesn't check it).

inplace [bool, default False] Whether to perform the operation in place on the data.

axis [int, default None] Alignment axis if needed.

level [int, default None] Alignment level if needed.

errors [str, {'raise', 'ignore'}, default 'raise'] Note that currently this parameter won't affect the results and will always coerce to a suitable dtype.

- 'raise' : allow exceptions to be raised.
- 'ignore' : suppress exceptions. On error return original object.

try_cast [bool, default None] Try to cast the result back to the input type (if possible).

Deprecated since version 1.3.0: Manually cast back if necessary.

Returns

Same type as caller or None if **inplace=True**.

See also:

[`DataFrame.mask\(\)`](#) Return an object of same shape as self.

Notes

The where method is an application of the if-then idiom. For each element in the calling DataFrame, if *cond* is True the element is used; otherwise the corresponding element from the DataFrame *other* is used.

The signature for `DataFrame.where()` differs from `numpy.where()`. Roughly `df1.where(m, df2)` is equivalent to `np.where(m, df1, df2)`.

For further details and examples see the where documentation in [indexing](#).

Examples

```

>>> s = pd.Series(range(5))
>>> s.where(s > 0)
0    NaN
1    1.0
2    2.0
3    3.0
4    4.0
dtype: float64
>>> s.mask(s > 0)
0    0.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64

```

```

>>> s.where(s > 1, 10)
0    10
1    10
2     2
3     3
4     4
dtype: int64
>>> s.mask(s > 1, 10)
0     0
1     1
2    10
3    10
4    10
dtype: int64

```

```

>>> df = pd.DataFrame(np.arange(10).reshape(-1, 2), columns=['A', 'B'])
>>> df
   A  B
0  0  1
1  2  3
2  4  5
3  6  7
4  8  9
>>> m = df % 3 == 0
>>> df.where(m, -df)
   A  B
0  0 -1
1 -2  3
2 -4 -5
3  6 -7
4 -8  9
>>> df.where(m, -df) == np.where(m, df, -df)
   A  B
0  True  True

```

(continues on next page)

(continued from previous page)

```
1 True True
2 True True
3 True True
4 True True
>>> df.where(m, -df) == df.mask(~m, -df)
      A      B
0 True True
1 True True
2 True True
3 True True
4 True True
```

pandas.DataFrame.xs

`DataFrame.xs(key, axis=0, level=None, drop_level=True)`

Return cross-section from the Series/DataFrame.

This method takes a *key* argument to select data at a particular level of a MultiIndex.

Parameters

key [label or tuple of label] Label contained in the index, or partially in a MultiIndex.

axis [{0 or 'index', 1 or 'columns'}, default 0] Axis to retrieve cross-section on.

level [object, defaults to first n levels (n=1 or len(key))] In case of a key partially contained in a MultiIndex, indicate which levels are used. Levels can be referred by label or position.

drop_level [bool, default True] If False, returns object with same levels as self.

Returns

Series or DataFrame Cross-section from the original Series or DataFrame corresponding to the selected index levels.

See also:

[*DataFrame.loc*](#) Access a group of rows and columns by label(s) or a boolean array.

[*DataFrame.iloc*](#) Purely integer-location based indexing for selection by position.

Notes

xs can not be used to set values.

MultiIndex Slicers is a generic way to get/set values on any level or levels. It is a superset of *xs* functionality, see [*MultiIndex Slicers*](#).

Examples

```
>>> d = {'num_legs': [4, 4, 2, 2],
...       'num_wings': [0, 0, 2, 2],
...       'class': ['mammal', 'mammal', 'mammal', 'bird'],
...       'animal': ['cat', 'dog', 'bat', 'penguin'],
...       'locomotion': ['walks', 'walks', 'flies', 'walks']}
>>> df = pd.DataFrame(data=d)
>>> df = df.set_index(['class', 'animal', 'locomotion'])
>>> df
```

| | | | num_legs | num_wings |
|--------|---------|------------|----------|-----------|
| class | animal | locomotion | | |
| mammal | cat | walks | 4 | 0 |
| | dog | walks | 4 | 0 |
| | bat | flies | 2 | 2 |
| bird | penguin | walks | 2 | 2 |

Get values at specified index

```
>>> df.xs('mammal')
```

| | | num_legs | num_wings |
|--------|------------|----------|-----------|
| animal | locomotion | | |
| cat | walks | 4 | 0 |
| dog | walks | 4 | 0 |
| bat | flies | 2 | 2 |

Get values at several indexes

```
>>> df.xs(('mammal', 'dog'))
```

| | num_legs | num_wings |
|------------|----------|-----------|
| locomotion | | |
| walks | 4 | 0 |

Get values at specified index and level

```
>>> df.xs('cat', level=1)
```

| | | num_legs | num_wings |
|--------|------------|----------|-----------|
| class | locomotion | | |
| mammal | walks | 4 | 0 |

Get values at several indexes and levels

```
>>> df.xs(('bird', 'walks'),
...       level=[0, 'locomotion'])
```

| | num_legs | num_wings |
|---------|----------|-----------|
| animal | | |
| penguin | 2 | 2 |

Get values at specified column and axis

```
>>> df.xs('num_wings', axis=1)
```

| | class | animal | locomotion | |
|--------|-------|--------|------------|---|
| mammal | cat | walks | | 0 |
| | dog | walks | | 0 |

(continues on next page)

(continued from previous page)

```

        bat      flies      2
bird  penguin  walks      2
Name: num_wings, dtype: int64

```

3.4.2 Attributes and underlying data

Axes

| | |
|--|--|
| <code>DataFrame.index</code> | The index (row labels) of the DataFrame. |
| <code>DataFrame.columns</code> | The column labels of the DataFrame. |
| <code>DataFrame.dtypes</code> | Return the dtypes in the DataFrame. |
| <code>DataFrame.info([verbose, buf, max_cols, ...])</code> | Print a concise summary of a DataFrame. |
| <code>DataFrame.select_dtypes([include, exclude])</code> | Return a subset of the DataFrame's columns based on the column dtypes. |
| <code>DataFrame.values</code> | Return a Numpy representation of the DataFrame. |
| <code>DataFrame.axes</code> | Return a list representing the axes of the DataFrame. |
| <code>DataFrame.ndim</code> | Return an int representing the number of axes / array dimensions. |
| <code>DataFrame.size</code> | Return an int representing the number of elements in this object. |
| <code>DataFrame.shape</code> | Return a tuple representing the dimensionality of the DataFrame. |
| <code>DataFrame.memory_usage([index, deep])</code> | Return the memory usage of each column in bytes. |
| <code>DataFrame.empty</code> | Indicator whether DataFrame is empty. |
| <code>DataFrame.set_flags(*[, copy, ...])</code> | Return a new object with updated flags. |

3.4.3 Conversion

| | |
|---|--|
| <code>DataFrame.astype(dtype[, copy, errors])</code> | Cast a pandas object to a specified dtype dtype. |
| <code>DataFrame.convert_dtypes([infer_objects, ...])</code> | Convert columns to best possible dtypes using dtypes supporting <code>pd.NA</code> . |
| <code>DataFrame.infer_objects()</code> | Attempt to infer better dtypes for object columns. |
| <code>DataFrame.copy([deep])</code> | Make a copy of this object's indices and data. |
| <code>DataFrame.bool()</code> | Return the bool of a single element Series or DataFrame. |

3.4.4 Indexing, iteration

| | |
|----------------------------------|--|
| <code>DataFrame.head([n])</code> | Return the first <i>n</i> rows. |
| <code>DataFrame.at</code> | Access a single value for a row/column label pair. |
| <code>DataFrame.iat</code> | Access a single value for a row/column pair by integer position. |
| <code>DataFrame.loc</code> | Access a group of rows and columns by label(s) or a boolean array. |

continues on next page

Table 69 – continued from previous page

| | |
|--|---|
| <code>DataFrame.iloc</code> | Purely integer-location based indexing for selection by position. |
| <code>DataFrame.insert(loc, column, value[, ...])</code> | Insert column into DataFrame at specified location. |
| <code>DataFrame.__iter__()</code> | Iterate over info axis. |
| <code>DataFrame.items()</code> | Iterate over (column name, Series) pairs. |
| <code>DataFrame.iteritems()</code> | Iterate over (column name, Series) pairs. |
| <code>DataFrame.keys()</code> | Get the ‘info axis’ (see Indexing for more). |
| <code>DataFrame.iterrows()</code> | Iterate over DataFrame rows as (index, Series) pairs. |
| <code>DataFrame.itertuples([index, name])</code> | Iterate over DataFrame rows as namedtuples. |
| <code>DataFrame.lookup(row_labels, col_labels)</code> | (DEPRECATED) Label-based “fancy indexing” function for DataFrame. |
| <code>DataFrame.pop(item)</code> | Return item and drop from frame. |
| <code>DataFrame.tail([n])</code> | Return the last <i>n</i> rows. |
| <code>DataFrame.xs(key[, axis, level, drop_level])</code> | Return cross-section from the Series/DataFrame. |
| <code>DataFrame.get(key[, default])</code> | Get item from object for given key (ex: DataFrame column). |
| <code>DataFrame.isin(values)</code> | Whether each element in the DataFrame is contained in values. |
| <code>DataFrame.where(cond[, other, inplace, ...])</code> | Replace values where the condition is False. |
| <code>DataFrame.mask(cond[, other, inplace, axis, ...])</code> | Replace values where the condition is True. |
| <code>DataFrame.query(expr[, inplace])</code> | Query the columns of a DataFrame with a boolean expression. |

pandas.DataFrame.__iter__`DataFrame.__iter__()`

Iterate over info axis.

Returns**iterator** Info axis as iterator.For more information on `.at`, `.iat`, `.loc`, and `.iloc`, see the [indexing documentation](#).**3.4.5 Binary operator functions**

| | |
|--|---|
| <code>DataFrame.add(other[, axis, level, fill_value])</code> | Get Addition of dataframe and other, element-wise (binary operator <i>add</i>). |
| <code>DataFrame.sub(other[, axis, level, fill_value])</code> | Get Subtraction of dataframe and other, element-wise (binary operator <i>sub</i>). |
| <code>DataFrame.mul(other[, axis, level, fill_value])</code> | Get Multiplication of dataframe and other, element-wise (binary operator <i>mul</i>). |
| <code>DataFrame.div(other[, axis, level, fill_value])</code> | Get Floating division of dataframe and other, element-wise (binary operator <i>truediv</i>). |
| <code>DataFrame.truediv(other[, axis, level, ...])</code> | Get Floating division of dataframe and other, element-wise (binary operator <i>truediv</i>). |
| <code>DataFrame.floordiv(other[, axis, level, ...])</code> | Get Integer division of dataframe and other, element-wise (binary operator <i>floordiv</i>). |
| <code>DataFrame.mod(other[, axis, level, fill_value])</code> | Get Modulo of dataframe and other, element-wise (binary operator <i>mod</i>). |

continues on next page

Table 70 – continued from previous page

| | |
|---|---|
| <code>DataFrame.pow</code> (other[, axis, level, fill_value]) | Get Exponential power of dataframe and other, element-wise (binary operator <i>pow</i>). |
| <code>DataFrame.dot</code> (other) | Compute the matrix multiplication between the DataFrame and other. |
| <code>DataFrame.radd</code> (other[, axis, level, fill_value]) | Get Addition of dataframe and other, element-wise (binary operator <i>radd</i>). |
| <code>DataFrame.rsub</code> (other[, axis, level, fill_value]) | Get Subtraction of dataframe and other, element-wise (binary operator <i>rsub</i>). |
| <code>DataFrame.rmul</code> (other[, axis, level, fill_value]) | Get Multiplication of dataframe and other, element-wise (binary operator <i>rmul</i>). |
| <code>DataFrame.rdiv</code> (other[, axis, level, fill_value]) | Get Floating division of dataframe and other, element-wise (binary operator <i>rtruediv</i>). |
| <code>DataFrame.rtruediv</code> (other[, axis, level, ...]) | Get Floating division of dataframe and other, element-wise (binary operator <i>rtruediv</i>). |
| <code>DataFrame.rfloordiv</code> (other[, axis, level, ...]) | Get Integer division of dataframe and other, element-wise (binary operator <i>rfloordiv</i>). |
| <code>DataFrame.rmod</code> (other[, axis, level, fill_value]) | Get Modulo of dataframe and other, element-wise (binary operator <i>rmod</i>). |
| <code>DataFrame.rpow</code> (other[, axis, level, fill_value]) | Get Exponential power of dataframe and other, element-wise (binary operator <i>rpow</i>). |
| <code>DataFrame.lt</code> (other[, axis, level]) | Get Less than of dataframe and other, element-wise (binary operator <i>lt</i>). |
| <code>DataFrame.gt</code> (other[, axis, level]) | Get Greater than of dataframe and other, element-wise (binary operator <i>gt</i>). |
| <code>DataFrame.le</code> (other[, axis, level]) | Get Less than or equal to of dataframe and other, element-wise (binary operator <i>le</i>). |
| <code>DataFrame.ge</code> (other[, axis, level]) | Get Greater than or equal to of dataframe and other, element-wise (binary operator <i>ge</i>). |
| <code>DataFrame.ne</code> (other[, axis, level]) | Get Not equal to of dataframe and other, element-wise (binary operator <i>ne</i>). |
| <code>DataFrame.eq</code> (other[, axis, level]) | Get Equal to of dataframe and other, element-wise (binary operator <i>eq</i>). |
| <code>DataFrame.combine</code> (other, func[, fill_value, ...]) | Perform column-wise combine with another DataFrame. |
| <code>DataFrame.combine_first</code> (other) | Update null elements with value in the same location in <i>other</i> . |

3.4.6 Function application, GroupBy & window

| | |
|---|--|
| <code>DataFrame.apply</code> (func[, axis, raw, ...]) | Apply a function along an axis of the DataFrame. |
| <code>DataFrame.applymap</code> (func[, na_action]) | Apply a function to a Dataframe elementwise. |
| <code>DataFrame.pipe</code> (func, *args, **kwargs) | Apply func(self, *args, **kwargs). |
| <code>DataFrame.agg</code> ([func, axis]) | Aggregate using one or more operations over the specified axis. |
| <code>DataFrame.aggregate</code> ([func, axis]) | Aggregate using one or more operations over the specified axis. |
| <code>DataFrame.transform</code> (func[, axis]) | Call func on self producing a DataFrame with transformed values. |
| <code>DataFrame.groupby</code> ([by, axis, level, ...]) | Group DataFrame using a mapper or by a Series of columns. |

continues on next page

Table 71 – continued from previous page

| | |
|---|--|
| <code>DataFrame.rolling(window[, min_periods, ...])</code> | Provide rolling window calculations. |
| <code>DataFrame.expanding([min_periods, center, ...])</code> | Provide expanding transformations. |
| <code>DataFrame.ewm([com, span, halflife, alpha, ...])</code> | Provide exponential weighted (EW) functions. |

3.4.7 Computations / descriptive stats

| | |
|--|---|
| <code>DataFrame.abs()</code> | Return a Series/DataFrame with absolute numeric value of each element. |
| <code>DataFrame.all([axis, bool_only, skipna, level])</code> | Return whether all elements are True, potentially over an axis. |
| <code>DataFrame.any([axis, bool_only, skipna, level])</code> | Return whether any element is True, potentially over an axis. |
| <code>DataFrame.clip([lower, upper, axis, inplace])</code> | Trim values at input threshold(s). |
| <code>DataFrame.corr([method, min_periods])</code> | Compute pairwise correlation of columns, excluding NA/null values. |
| <code>DataFrame.corrwith(other[, axis, drop, method])</code> | Compute pairwise correlation. |
| <code>DataFrame.count([axis, level, numeric_only])</code> | Count non-NA cells for each column or row. |
| <code>DataFrame.cov([min_periods, ddof])</code> | Compute pairwise covariance of columns, excluding NA/null values. |
| <code>DataFrame.cummax([axis, skipna])</code> | Return cumulative maximum over a DataFrame or Series axis. |
| <code>DataFrame.cummin([axis, skipna])</code> | Return cumulative minimum over a DataFrame or Series axis. |
| <code>DataFrame.cumprod([axis, skipna])</code> | Return cumulative product over a DataFrame or Series axis. |
| <code>DataFrame.cumsum([axis, skipna])</code> | Return cumulative sum over a DataFrame or Series axis. |
| <code>DataFrame.describe([percentiles, include, ...])</code> | Generate descriptive statistics. |
| <code>DataFrame.diff([periods, axis])</code> | First discrete difference of element. |
| <code>DataFrame.eval(expr[, inplace])</code> | Evaluate a string describing operations on DataFrame columns. |
| <code>DataFrame.kurt([axis, skipna, level, ...])</code> | Return unbiased kurtosis over requested axis. |
| <code>DataFrame.kurtosis([axis, skipna, level, ...])</code> | Return unbiased kurtosis over requested axis. |
| <code>DataFrame.mad([axis, skipna, level])</code> | Return the mean absolute deviation of the values over the requested axis. |
| <code>DataFrame.max([axis, skipna, level, ...])</code> | Return the maximum of the values over the requested axis. |
| <code>DataFrame.mean([axis, skipna, level, ...])</code> | Return the mean of the values over the requested axis. |
| <code>DataFrame.median([axis, skipna, level, ...])</code> | Return the median of the values over the requested axis. |
| <code>DataFrame.min([axis, skipna, level, ...])</code> | Return the minimum of the values over the requested axis. |
| <code>DataFrame.mode([axis, numeric_only, dropna])</code> | Get the mode(s) of each element along the selected axis. |
| <code>DataFrame.pct_change([periods, fill_method, ...])</code> | Percentage change between the current and a prior element. |
| <code>DataFrame.prod([axis, skipna, level, ...])</code> | Return the product of the values over the requested axis. |
| <code>DataFrame.product([axis, skipna, level, ...])</code> | Return the product of the values over the requested axis. |
| <code>DataFrame.quantile([q, axis, numeric_only, ...])</code> | Return values at the given quantile over requested axis. |
| <code>DataFrame.rank([axis, method, numeric_only, ...])</code> | Compute numerical data ranks (1 through n) along axis. |
| <code>DataFrame.round([decimals])</code> | Round a DataFrame to a variable number of decimal places. |

continues on next page

Table 72 – continued from previous page

| | |
|--|--|
| <code>DataFrame.sem</code> ([axis, skipna, level, ddof, ...]) | Return unbiased standard error of the mean over requested axis. |
| <code>DataFrame.skew</code> ([axis, skipna, level, ...]) | Return unbiased skew over requested axis. |
| <code>DataFrame.sum</code> ([axis, skipna, level, ...]) | Return the sum of the values over the requested axis. |
| <code>DataFrame.std</code> ([axis, skipna, level, ddof, ...]) | Return sample standard deviation over requested axis. |
| <code>DataFrame.var</code> ([axis, skipna, level, ddof, ...]) | Return unbiased variance over requested axis. |
| <code>DataFrame.nunique</code> ([axis, dropna]) | Count number of distinct elements in specified axis. |
| <code>DataFrame.value_counts</code> ([subset, normalize, ...]) | Return a Series containing counts of unique rows in the DataFrame. |

3.4.8 Reindexing / selection / label manipulation

| | |
|--|---|
| <code>DataFrame.add_prefix</code> (prefix) | Prefix labels with string <i>prefix</i> . |
| <code>DataFrame.add_suffix</code> (suffix) | Suffix labels with string <i>suffix</i> . |
| <code>DataFrame.align</code> (other[, join, axis, level, ...]) | Align two objects on their axes with the specified join method. |
| <code>DataFrame.at_time</code> (time[, asof, axis]) | Select values at particular time of day (e.g., 9:30AM). |
| <code>DataFrame.between_time</code> (start_time, end_time) | Select values between particular times of the day (e.g., 9:00-9:30 AM). |
| <code>DataFrame.drop</code> ([labels, axis, index, ...]) | Drop specified labels from rows or columns. |
| <code>DataFrame.drop_duplicates</code> ([subset, keep, ...]) | Return DataFrame with duplicate rows removed. |
| <code>DataFrame.duplicated</code> ([subset, keep]) | Return boolean Series denoting duplicate rows. |
| <code>DataFrame.equals</code> (other) | Test whether two objects contain the same elements. |
| <code>DataFrame.filter</code> ([items, like, regex, axis]) | Subset the dataframe rows or columns according to the specified index labels. |
| <code>DataFrame.first</code> (offset) | Select initial periods of time series data based on a date offset. |
| <code>DataFrame.head</code> ([n]) | Return the first <i>n</i> rows. |
| <code>DataFrame.idxmax</code> ([axis, skipna]) | Return index of first occurrence of maximum over requested axis. |
| <code>DataFrame.idxmin</code> ([axis, skipna]) | Return index of first occurrence of minimum over requested axis. |
| <code>DataFrame.last</code> (offset) | Select final periods of time series data based on a date offset. |
| <code>DataFrame.reindex</code> ([labels, index, columns, ...]) | Conform Series/DataFrame to new index with optional filling logic. |
| <code>DataFrame.reindex_like</code> (other[, method, ...]) | Return an object with matching indices as other object. |
| <code>DataFrame.rename</code> ([mapper, index, columns, ...]) | Alter axes labels. |
| <code>DataFrame.rename_axis</code> ([mapper, index, ...]) | Set the name of the axis for the index or columns. |
| <code>DataFrame.reset_index</code> ([level, drop, ...]) | Reset the index, or a level of it. |
| <code>DataFrame.sample</code> ([n, frac, replace, ...]) | Return a random sample of items from an axis of object. |
| <code>DataFrame.set_axis</code> (labels[, axis, inplace]) | Assign desired index to given axis. |
| <code>DataFrame.set_index</code> (keys[, drop, append, ...]) | Set the DataFrame index using existing columns. |
| <code>DataFrame.tail</code> ([n]) | Return the last <i>n</i> rows. |
| <code>DataFrame.take</code> (indices[, axis, is_copy]) | Return the elements in the given <i>positional</i> indices along an axis. |
| <code>DataFrame.truncate</code> ([before, after, axis, copy]) | Truncate a Series or DataFrame before and after some index value. |

3.4.9 Missing data handling

| | |
|--|--|
| <code>DataFrame.backfill([axis, inplace, limit, ...])</code> | Synonym for <code>DataFrame.fillna()</code> with <code>method='bfill'</code> . |
| <code>DataFrame.bfill([axis, inplace, limit, downcast])</code> | Synonym for <code>DataFrame.fillna()</code> with <code>method='bfill'</code> . |
| <code>DataFrame.dropna([axis, how, thresh, ...])</code> | Remove missing values. |
| <code>DataFrame.ffill([axis, inplace, limit, downcast])</code> | Synonym for <code>DataFrame.fillna()</code> with <code>method='ffill'</code> . |
| <code>DataFrame.fillna([value, method, axis, ...])</code> | Fill NA/NaN values using the specified method. |
| <code>DataFrame.interpolate([method, axis, limit, ...])</code> | Fill NaN values using an interpolation method. |
| <code>DataFrame.isna()</code> | Detect missing values. |
| <code>DataFrame.isnull()</code> | Detect missing values. |
| <code>DataFrame.notna()</code> | Detect existing (non-missing) values. |
| <code>DataFrame.notnull()</code> | Detect existing (non-missing) values. |
| <code>DataFrame.pad([axis, inplace, limit, downcast])</code> | Synonym for <code>DataFrame.fillna()</code> with <code>method='ffill'</code> . |
| <code>DataFrame.replace([to_replace, value, ...])</code> | Replace values given in <code>to_replace</code> with <code>value</code> . |

3.4.10 Reshaping, sorting, transposing

| | |
|--|---|
| <code>DataFrame.droplevel(level[, axis])</code> | Return Series/DataFrame with requested index / column level(s) removed. |
| <code>DataFrame.pivot([index, columns, values])</code> | Return reshaped DataFrame organized by given index / column values. |
| <code>DataFrame.pivot_table([values, index, ...])</code> | Create a spreadsheet-style pivot table as a DataFrame. |
| <code>DataFrame.reorder_levels(order[, axis])</code> | Rearrange index levels using input order. |
| <code>DataFrame.sort_values(by[, axis, ascending, ...])</code> | Sort by the values along either axis. |
| <code>DataFrame.sort_index([axis, level, ...])</code> | Sort object by labels (along an axis). |
| <code>DataFrame.nlargest(n, columns[, keep])</code> | Return the first <i>n</i> rows ordered by <i>columns</i> in descending order. |
| <code>DataFrame.nsmallest(n, columns[, keep])</code> | Return the first <i>n</i> rows ordered by <i>columns</i> in ascending order. |
| <code>DataFrame.swaplevel([i, j, axis])</code> | Swap levels <i>i</i> and <i>j</i> in a <i>MultiIndex</i> . |
| <code>DataFrame.stack([level, dropna])</code> | Stack the prescribed level(s) from columns to index. |
| <code>DataFrame.unstack([level, fill_value])</code> | Pivot a level of the (necessarily hierarchical) index labels. |
| <code>DataFrame.swapaxes(axis1, axis2[, copy])</code> | Interchange axes and swap values axes appropriately. |
| <code>DataFrame.melt([id_vars, value_vars, ...])</code> | Unpivot a DataFrame from wide to long format, optionally leaving identifiers set. |
| <code>DataFrame.explode(column[, ignore_index])</code> | Transform each element of a list-like to a row, replicating index values. |
| <code>DataFrame.squeeze([axis])</code> | Squeeze 1 dimensional axis objects into scalars. |
| <code>DataFrame.to_xarray()</code> | Return an xarray object from the pandas object. |
| <code>DataFrame.T</code> | |
| <code>DataFrame.transpose(*args[, copy])</code> | Transpose index and columns. |

pandas.DataFrame.T

property DataFrame.T

3.4.11 Combining / comparing / joining / merging

| | |
|--|---|
| <code>DataFrame.append(other[, ignore_index, ...])</code> | Append rows of <i>other</i> to the end of caller, returning a new object. |
| <code>DataFrame.assign(**kwargs)</code> | Assign new columns to a DataFrame. |
| <code>DataFrame.compare(other[, align_axis, ...])</code> | Compare to another DataFrame and show the differences. |
| <code>DataFrame.join(other[, on, how, lsuffix, ...])</code> | Join columns of another DataFrame. |
| <code>DataFrame.merge(right[, how, on, left_on, ...])</code> | Merge DataFrame or named Series objects with a database-style join. |
| <code>DataFrame.update(other[, join, overwrite, ...])</code> | Modify in place using non-NA values from another DataFrame. |

3.4.12 Time Series-related

| | |
|--|--|
| <code>DataFrame.asfreq(freq[, method, how, ...])</code> | Convert time series to specified frequency. |
| <code>DataFrame.asof(when[, subset])</code> | Return the last row(s) without any NaNs before <i>when</i> . |
| <code>DataFrame.shift([periods, freq, axis, ...])</code> | Shift index by desired number of periods with an optional time <i>freq</i> . |
| <code>DataFrame.slice_shift([periods, axis])</code> | (DEPRECATED) Equivalent to <i>shift</i> without copying data. |
| <code>DataFrame.tshift([periods, freq, axis])</code> | (DEPRECATED) Shift the time index, using the index's frequency if available. |
| <code>DataFrame.first_valid_index()</code> | Return index for first non-NA value or None, if no NA value is found. |
| <code>DataFrame.last_valid_index()</code> | Return index for last non-NA value or None, if no NA value is found. |
| <code>DataFrame.resample(rule[, axis, closed, ...])</code> | Resample time-series data. |
| <code>DataFrame.to_period([freq, axis, copy])</code> | Convert DataFrame from DatetimeIndex to PeriodIndex. |
| <code>DataFrame.to_timestamp([freq, how, axis, copy])</code> | Cast to DatetimeIndex of timestamps, at <i>beginning</i> of period. |
| <code>DataFrame.tz_convert(tz[, axis, level, copy])</code> | Convert tz-aware axis to target time zone. |
| <code>DataFrame.tz_localize(tz[, axis, level, ...])</code> | Localize tz-naive index of a Series or DataFrame to target time zone. |

3.4.13 Flags

Flags refer to attributes of the pandas object. Properties of the dataset (like the date it was recorded, the URL it was accessed from, etc.) should be stored in `DataFrame.attrs`.

| | |
|---|-------------------------------------|
| <code>Flags(obj, *, allows_duplicate_labels)</code> | Flags that apply to pandas objects. |
|---|-------------------------------------|

3.4.14 Metadata

`DataFrame.attrs` is a dictionary for storing global metadata for this DataFrame.

| |
|---|
| Warning: <code>DataFrame.attrs</code> is considered experimental and may change without warning. |
|---|

| | |
|------------------------------|--|
| <code>DataFrame.attrs</code> | Dictionary of global attributes of this dataset. |
|------------------------------|--|

3.4.15 Plotting

`DataFrame.plot` is both a callable method and a namespace attribute for specific plotting methods of the form `DataFrame.plot.<kind>`.

| | |
|---|---|
| <code>DataFrame.plot([x, y, kind, ax, ...])</code> | DataFrame plotting accessor and method |
| <code>DataFrame.plot.area(x, y)</code> | Draw a stacked area plot. |
| <code>DataFrame.plot.bar(x, y)</code> | Vertical bar plot. |
| <code>DataFrame.plot.barh(x, y)</code> | Make a horizontal bar plot. |
| <code>DataFrame.plot.box([by])</code> | Make a box plot of the DataFrame columns. |
| <code>DataFrame.plot.density([bw_method, ind])</code> | Generate Kernel Density Estimate plot using Gaussian kernels. |
| <code>DataFrame.plot.hexbin(x, y[, C, ...])</code> | Generate a hexagonal binning plot. |
| <code>DataFrame.plot.hist([by, bins])</code> | Draw one histogram of the DataFrame's columns. |
| <code>DataFrame.plot.kde([bw_method, ind])</code> | Generate Kernel Density Estimate plot using Gaussian kernels. |
| <code>DataFrame.plot.line(x, y)</code> | Plot Series or DataFrame as lines. |
| <code>DataFrame.plot.pie(**kwargs)</code> | Generate a pie plot. |
| <code>DataFrame.plot.scatter(x, y[, s, c])</code> | Create a scatter plot with varying marker point size and color. |

pandas.DataFrame.plot.area

`DataFrame.plot.area(x=None, y=None, **kwargs)`

Draw a stacked area plot.

An area plot displays quantitative data visually. This function wraps the matplotlib area function.

Parameters

x [label or position, optional] Coordinates for the X axis. By default uses the index.

y [label or position, optional] Column to plot. By default uses all columns.

stacked [bool, default True] Area plots are stacked by default. Set to False to create a unstacked plot.

****kwargs** Additional keyword arguments are documented in `DataFrame.plot()`.

Returns

`matplotlib.axes.Axes` or `numpy.ndarray` Area plot, or array of area plots if subplots is True.

See also:

[`DataFrame.plot`](#) Make plots of DataFrame using matplotlib / pylab.

Examples

Draw an area plot based on basic business metrics:

```
>>> df = pd.DataFrame({
...     'sales': [3, 2, 3, 9, 10, 6],
...     'signups': [5, 5, 6, 12, 14, 13],
...     'visits': [20, 42, 28, 62, 81, 50],
... }, index=pd.date_range(start='2018/01/01', end='2018/07/01',
...                          freq='M'))
>>> ax = df.plot.area()
```

Area plots are stacked by default. To produce an unstacked plot, pass `stacked=False`:

```
>>> ax = df.plot.area(stacked=False)
```

Draw an area plot for a single column:

```
>>> ax = df.plot.area(y='sales')
```

Draw with a different x:

```
>>> df = pd.DataFrame({
...     'sales': [3, 2, 3],
...     'visits': [20, 42, 28],
...     'day': [1, 2, 3],
... })
>>> ax = df.plot.area(x='day')
```

pandas.DataFrame.plot.bar

`DataFrame.plot.bar`(*x=None, y=None, **kwargs*)

Vertical bar plot.

A bar plot is a plot that presents categorical data with rectangular bars with lengths proportional to the values that they represent. A bar plot shows comparisons among discrete categories. One axis of the plot shows the specific categories being compared, and the other axis represents a measured value.

Parameters

- x** [label or position, optional] Allows plotting of one column versus another. If not specified, the index of the DataFrame is used.
- y** [label or position, optional] Allows plotting of one column versus another. If not specified, all numerical columns are used.
- color** [str, array-like, or dict, optional] The color for each of the DataFrame's columns. Possible values are:
 - A single color string referred to by name, RGB or RGBA code, for instance 'red' or '#a98d19'.
 - A sequence of color strings referred to by name, RGB or RGBA code, which will be used for each column recursively. For instance ['green','yellow'] each column's bar will be filled in green or yellow, alternatively. If there is only a single column to be plotted, then only the first color from the color list will be used.
 - A dict of the form {column name [color]}, so that each column will be colored accordingly. For example, if your columns are called *a* and *b*, then passing {'a': 'green', 'b': 'red'} will color bars for column *a* in green and bars for column *b* in red.

New in version 1.1.0.

****kwargs** Additional keyword arguments are documented in `DataFrame.plot()`.

Returns

matplotlib.axes.Axes or np.ndarray of them An ndarray is returned with one `matplotlib.axes.Axes` per column when `subplots=True`.

See also:

`DataFrame.plot.barh` Horizontal bar plot.

`DataFrame.plot` Make plots of a DataFrame.

`matplotlib.pyplot.bar` Make a bar plot with matplotlib.

Examples

Basic plot.

```
>>> df = pd.DataFrame({'lab':['A', 'B', 'C'], 'val':[10, 30, 20]})
>>> ax = df.plot.bar(x='lab', y='val', rot=0)
```

Plot a whole dataframe to a bar plot. Each column is assigned a distinct color, and each row is nested in a group along the horizontal axis.

```

>>> speed = [0.1, 17.5, 40, 48, 52, 69, 88]
>>> lifespan = [2, 8, 70, 1.5, 25, 12, 28]
>>> index = ['snail', 'pig', 'elephant',
...         'rabbit', 'giraffe', 'coyote', 'horse']
>>> df = pd.DataFrame({'speed': speed,
...                   'lifespan': lifespan}, index=index)
>>> ax = df.plot.bar(rot=0)

```

Plot stacked bar charts for the DataFrame

```

>>> ax = df.plot.bar(stacked=True)

```

Instead of nesting, the figure can be split by column with `subplots=True`. In this case, a `numpy.ndarray` of `matplotlib.axes.Axes` are returned.

```

>>> axes = df.plot.bar(rot=0, subplots=True)
>>> axes[1].legend(loc=2)

```

If you don't like the default colours, you can specify how you'd like each column to be colored.

```

>>> axes = df.plot.bar(
...     rot=0, subplots=True, color={"speed": "red", "lifespan": "green"}
... )

```

(continues on next page)

(continued from previous page)

```
>>> axes[1].legend(loc=2)
```

Plot a single column.

```
>>> ax = df.plot.bar(y='speed', rot=0)
```

Plot only selected categories for the DataFrame.

```
>>> ax = df.plot.bar(x='lifespan', rot=0)
```

pandas.DataFrame.plot.barh

`DataFrame.plot.barh`(*x=None*, *y=None*, ***kwargs*)

Make a horizontal bar plot.

A horizontal bar plot is a plot that presents quantitative data with rectangular bars with lengths proportional to the values that they represent. A bar plot shows comparisons among discrete categories. One axis of the plot shows the specific categories being compared, and the other axis represents a measured value.

Parameters

- x** [label or position, optional] Allows plotting of one column versus another. If not specified, the index of the DataFrame is used.

y [label or position, optional] Allows plotting of one column versus another. If not specified, all numerical columns are used.

color [str, array-like, or dict, optional] The color for each of the DataFrame's columns. Possible values are:

- **A single color string referred to by name, RGB or RGBA code**, for instance 'red' or '#a98d19'.
- **A sequence of color strings referred to by name, RGB or RGBA code**, which will be used for each column recursively. For instance ['green','yellow'] each column's bar will be filled in green or yellow, alternatively. If there is only a single column to be plotted, then only the first color from the color list will be used.
- **A dict of the form {column name [color]}**, so that each column will be colored accordingly. For example, if your columns are called *a* and *b*, then passing {'a': 'green', 'b': 'red'} will color bars for column *a* in green and bars for column *b* in red.

New in version 1.1.0.

****kwargs** Additional keyword arguments are documented in `DataFrame.plot()`.

Returns

matplotlib.axes.Axes or np.ndarray of them An ndarray is returned with one `matplotlib.axes.Axes` per column when `subplots=True`.

See also:

`DataFrame.plot.bar` Vertical bar plot.

`DataFrame.plot` Make plots of DataFrame using matplotlib.

`matplotlib.axes.Axes.bar` Plot a vertical bar plot using matplotlib.

Examples

Basic example

```
>>> df = pd.DataFrame({'lab': ['A', 'B', 'C'], 'val': [10, 30, 20]})
>>> ax = df.plot.barh(x='lab', y='val')
```

Plot a whole DataFrame to a horizontal bar plot

```
>>> speed = [0.1, 17.5, 40, 48, 52, 69, 88]
>>> lifespan = [2, 8, 70, 1.5, 25, 12, 28]
>>> index = ['snail', 'pig', 'elephant',
...         'rabbit', 'giraffe', 'coyote', 'horse']
>>> df = pd.DataFrame({'speed': speed,
...                   'lifespan': lifespan}, index=index)
>>> ax = df.plot.barh()
```

Plot stacked barh charts for the DataFrame

```
>>> ax = df.plot.barh(stacked=True)
```

We can specify colors for each column

```
>>> ax = df.plot.barh(color={"speed": "red", "lifespan": "green"})
```

Plot a column of the DataFrame to a horizontal bar plot

```
>>> speed = [0.1, 17.5, 40, 48, 52, 69, 88]
>>> lifespan = [2, 8, 70, 1.5, 25, 12, 28]
>>> index = ['snail', 'pig', 'elephant',
...         'rabbit', 'giraffe', 'coyote', 'horse']
>>> df = pd.DataFrame({'speed': speed,
...                   'lifespan': lifespan}, index=index)
>>> ax = df.plot.barh(y='speed')
```

Plot DataFrame versus the desired column

```
>>> speed = [0.1, 17.5, 40, 48, 52, 69, 88]
>>> lifespan = [2, 8, 70, 1.5, 25, 12, 28]
>>> index = ['snail', 'pig', 'elephant',
...         'rabbit', 'giraffe', 'coyote', 'horse']
>>> df = pd.DataFrame({'speed': speed,
...                   'lifespan': lifespan}, index=index)
>>> ax = df.plot.barh(x='lifespan')
```

pandas.DataFrame.plot.box

`DataFrame.plot.box`(*by=None, **kwargs*)

Make a box plot of the DataFrame columns.

A box plot is a method for graphically depicting groups of numerical data through their quartiles. The box extends from the Q1 to Q3 quartile values of the data, with a line at the median (Q2). The whiskers extend from the edges of box to show the range of the data. The position of the whiskers is set by default to $1.5 \times \text{IQR}$ ($\text{IQR} = \text{Q3} - \text{Q1}$) from the edges of the box. Outlier points are those past the end of the whiskers.

For further details see Wikipedia's entry for [boxplot](#).

A consideration when using this chart is that the box and the whiskers can overlap, which is very common when plotting small sets of data.

Parameters

by [str or sequence] Column in the DataFrame to group by.

****kwargs** Additional keywords are documented in `DataFrame.plot()`.

Returns

`matplotlib.axes.Axes` or `numpy.ndarray` of them

See also:

[DataFrame.boxplot](#) Another method to draw a box plot.

[Series.plot.box](#) Draw a box plot from a Series object.

[matplotlib.pyplot.boxplot](#) Draw a box plot in matplotlib.

Examples

Draw a box plot from a DataFrame with four columns of randomly generated data.

```
>>> data = np.random.randn(25, 4)
>>> df = pd.DataFrame(data, columns=list('ABCD'))
>>> ax = df.plot.box()
```

pandas.DataFrame.plot.density

`DataFrame.plot.density`(*bw_method=None, ind=None, **kwargs*)

Generate Kernel Density Estimate plot using Gaussian kernels.

In statistics, [kernel density estimation](#) (KDE) is a non-parametric way to estimate the probability density function (PDF) of a random variable. This function uses Gaussian kernels and includes automatic bandwidth determination.

Parameters

bw_method [str, scalar or callable, optional] The method used to calculate the estimator bandwidth. This can be 'scott', 'silverman', a scalar constant or a callable. If None (default), 'scott' is used. See `scipy.stats.gaussian_kde` for more information.

ind [NumPy array or int, optional] Evaluation points for the estimated PDF. If None (default), 1000 equally spaced points are used. If *ind* is a NumPy array, the KDE is evaluated at the points passed. If *ind* is an integer, *ind* number of equally spaced points are used.

****kwargs** Additional keyword arguments are documented in `pandas.DataFrame.plot()`.

Returns

`matplotlib.axes.Axes` or `numpy.ndarray` of them

See also:

`scipy.stats.gaussian_kde` Representation of a kernel-density estimate using Gaussian kernels. This is the function used internally to estimate the PDF.

Examples

Given a Series of points randomly sampled from an unknown distribution, estimate its PDF using KDE with automatic bandwidth determination and plot the results, evaluating them at 1000 equally spaced points (default):

```
>>> s = pd.Series([1, 2, 2.5, 3, 3.5, 4, 5])
>>> ax = s.plot.kde()
```

A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:

```
>>> ax = s.plot.kde(bw_method=0.3)
```

```
>>> ax = s.plot.kde(bw_method=3)
```

Finally, the *ind* parameter determines the evaluation points for the plot of the estimated PDF:

```
>>> ax = s.plot.kde(ind=[1, 2, 3, 4, 5])
```

For DataFrame, it works in the same way:

```
>>> df = pd.DataFrame({
...     'x': [1, 2, 2.5, 3, 3.5, 4, 5],
...     'y': [4, 4, 4.5, 5, 5.5, 6, 6],
... })
>>> ax = df.plot.kde()
```

A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:

```
>>> ax = df.plot.kde(bw_method=0.3)
```

```
>>> ax = df.plot.kde(bw_method=3)
```

Finally, the *ind* parameter determines the evaluation points for the plot of the estimated PDF:

```
>>> ax = df.plot.kde(ind=[1, 2, 3, 4, 5, 6])
```

pandas.DataFrame.plot.hexbin

`DataFrame.plot.hexbin(x, y, C=None, reduce_C_function=None, gridsize=None, **kwargs)`

Generate a hexagonal binning plot.

Generate a hexagonal binning plot of x versus y . If C is *None* (the default), this is a histogram of the number of occurrences of the observations at $(x[i], y[i])$.

If C is specified, specifies values at given coordinates $(x[i], y[i])$. These values are accumulated for each hexagonal bin and then reduced according to *reduce_C_function*, having as default the NumPy's mean function (`numpy.mean()`). (If C is specified, it must also be a 1-D sequence of the same length as x and y , or a column label.)

Parameters

x [int or str] The column label or position for x points.

y [int or str] The column label or position for y points.

C [int or str, optional] The column label or position for the value of (x, y) point.

reduce_C_function [callable, default `np.mean`] Function of one argument that reduces all the values in a bin to a single number (e.g. `np.mean`, `np.max`, `np.sum`, `np.std`).

gridsize [int or tuple of (int, int), default 100] The number of hexagons in the x-direction. The corresponding number of hexagons in the y-direction is chosen in a way that the hexagons are approximately regular. Alternatively, `gridsize` can be a tuple with two elements specifying the number of hexagons in the x-direction and the y-direction.

****kwargs** Additional keyword arguments are documented in `DataFrame.plot()`.

Returns

matplotlib.AxesSubplot The matplotlib Axes on which the hexbin is plotted.

See also:

[DataFrame.plot](#) Make plots of a DataFrame.

[matplotlib.pyplot.hexbin](#) Hexagonal binning plot using matplotlib, the matplotlib function that is used under the hood.

Examples

The following examples are generated with random data from a normal distribution.

```
>>> n = 10000
>>> df = pd.DataFrame({'x': np.random.randn(n),
...                   'y': np.random.randn(n)})
>>> ax = df.plot.hexbin(x='x', y='y', gridsize=20)
```

The next example uses C and `np.sum` as *reduce_C_function*. Note that `'observations'` values ranges from 1 to 5 but the result plot shows values up to more than 25. This is because of the *reduce_C_function*.

```
>>> n = 500
>>> df = pd.DataFrame({
...     'coord_x': np.random.uniform(-3, 3, size=n),
...     'coord_y': np.random.uniform(30, 50, size=n),
...     'observations': np.random.randint(1,5, size=n)
... })
>>> ax = df.plot.hexbin(x='coord_x',
```

(continues on next page)

(continued from previous page)

```

...     y='coord_y',
...     C='observations',
...     reduce_C_function=np.sum,
...     gridsize=10,
...     cmap="viridis")

```

pandas.DataFrame.plot.hist

`DataFrame.plot.hist`(*by=None, bins=10, **kwargs*)

Draw one histogram of the DataFrame's columns.

A histogram is a representation of the distribution of data. This function groups the values of all given Series in the DataFrame into bins and draws all bins in one `matplotlib.axes.Axes`. This is useful when the DataFrame's Series are in a similar scale.

Parameters

by [str or sequence, optional] Column in the DataFrame to group by.

bins [int, default 10] Number of histogram bins to be used.

****kwargs** Additional keyword arguments are documented in `DataFrame.plot()`.

Returns

`class:matplotlib.AxesSubplot` Return a histogram plot.

See also:

`DataFrame.hist` Draw histograms per DataFrame's Series.

`Series.hist` Draw a histogram with Series' data.

Examples

When we draw a dice 6000 times, we expect to get each value around 1000 times. But when we draw two dices and sum the result, the distribution is going to be quite different. A histogram illustrates those distributions.

```
>>> df = pd.DataFrame(  
...     np.random.randint(1, 7, 6000),  
...     columns = ['one'])  
>>> df['two'] = df['one'] + np.random.randint(1, 7, 6000)  
>>> ax = df.plot.hist(bins=12, alpha=0.5)
```

pandas.DataFrame.plot.kde

`DataFrame.plot.kde(bw_method=None, ind=None, **kwargs)`

Generate Kernel Density Estimate plot using Gaussian kernels.

In statistics, [kernel density estimation](#) (KDE) is a non-parametric way to estimate the probability density function (PDF) of a random variable. This function uses Gaussian kernels and includes automatic bandwidth determination.

Parameters

bw_method [str, scalar or callable, optional] The method used to calculate the estimator bandwidth. This can be 'scott', 'silverman', a scalar constant or a callable. If None (default), 'scott' is used. See [scipy.stats.gaussian_kde](#) for more information.

ind [NumPy array or int, optional] Evaluation points for the estimated PDF. If None (default), 1000 equally spaced points are used. If *ind* is a NumPy array, the KDE is evaluated at the points passed. If *ind* is an integer, *ind* number of equally spaced points are used.

****kwargs** Additional keyword arguments are documented in `pandas.%(this-datatype)s.plot()`.

Returns

`matplotlib.axes.Axes` or `numpy.ndarray` of them

See also:

[scipy.stats.gaussian_kde](#) Representation of a kernel-density estimate using Gaussian kernels. This is the function used internally to estimate the PDF.

Examples

Given a Series of points randomly sampled from an unknown distribution, estimate its PDF using KDE with automatic bandwidth determination and plot the results, evaluating them at 1000 equally spaced points (default):

```
>>> s = pd.Series([1, 2, 2.5, 3, 3.5, 4, 5])
>>> ax = s.plot.kde()
```

A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:

```
>>> ax = s.plot.kde(bw_method=0.3)
```

```
>>> ax = s.plot.kde(bw_method=3)
```

Finally, the *ind* parameter determines the evaluation points for the plot of the estimated PDF:

```
>>> ax = s.plot.kde(ind=[1, 2, 3, 4, 5])
```

For DataFrame, it works in the same way:

```
>>> df = pd.DataFrame({
...     'x': [1, 2, 2.5, 3, 3.5, 4, 5],
...     'y': [4, 4, 4.5, 5, 5.5, 6, 6],
... })
>>> ax = df.plot.kde()
```

A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:

```
>>> ax = df.plot.kde(bw_method=0.3)
```

```
>>> ax = df.plot.kde(bw_method=3)
```

Finally, the *ind* parameter determines the evaluation points for the plot of the estimated PDF:

```
>>> ax = df.plot.kde(ind=[1, 2, 3, 4, 5, 6])
```

pandas.DataFrame.plot.line

`DataFrame.plot.line`(*x=None*, *y=None*, ***kwargs*)

Plot Series or DataFrame as lines.

This function is useful to plot lines using DataFrame's values as coordinates.

Parameters

- x** [label or position, optional] Allows plotting of one column versus another. If not specified, the index of the DataFrame is used.
- y** [label or position, optional] Allows plotting of one column versus another. If not specified, all numerical columns are used.

color [str, array-like, or dict, optional] The color for each of the DataFrame's columns. Possible values are:

- A single color string referred to by name, RGB or RGBA code, for instance 'red' or '#a98d19'.
- A sequence of color strings referred to by name, RGB or RGBA code, which will be used for each column recursively. For instance ['green','yellow'] each column's line will be filled in green or yellow, alternatively. If there is only a single column to be plotted, then only the first color from the color list will be used.
- A dict of the form {column name [color]}, so that each column will be colored accordingly. For example, if your columns are called *a* and *b*, then passing {'a': 'green', 'b': 'red'} will color lines for column *a* in green and lines for column *b* in red.

New in version 1.1.0.

****kwargs** Additional keyword arguments are documented in `DataFrame.plot()`.

Returns

matplotlib.axes.Axes or np.ndarray of them An ndarray is returned with one `matplotlib.axes.Axes` per column when `subplots=True`.

See also:

`matplotlib.pyplot.plot` Plot y versus x as lines and/or markers.

Examples

```
>>> s = pd.Series([1, 3, 2])
>>> s.plot.line()
```

The following example shows the populations for some animals over the years.

```
>>> df = pd.DataFrame({
...     'pig': [20, 18, 489, 675, 1776],
...     'horse': [4, 25, 281, 600, 1900]
...     }, index=[1990, 1997, 2003, 2009, 2014])
>>> lines = df.plot.line()
```

An example with subplots, so an array of axes is returned.

```
>>> axes = df.plot.line(subplots=True)
>>> type(axes)
<class 'numpy.ndarray'>
```

Let's repeat the same example, but specifying colors for each column (in this case, for each animal).

```
>>> axes = df.plot.line(
...     subplots=True, color={"pig": "pink", "horse": "#742802"}
... )
```

The following example shows the relationship between both populations.

```
>>> lines = df.plot.line(x='pig', y='horse')
```

pandas.DataFrame.plot.pie

`DataFrame.plot.pie(**kwargs)`

Generate a pie plot.

A pie plot is a proportional representation of the numerical data in a column. This function wraps `matplotlib.pyplot.pie()` for the specified column. If no column reference is passed and `subplots=True` a pie plot is drawn for each numerical column independently.

Parameters

y [int or label, optional] Label or position of the column to plot. If not provided, `subplots=True` argument must be passed.

****kwargs** Keyword arguments to pass on to `DataFrame.plot()`.

Returns

matplotlib.axes.Axes or np.ndarray of them A NumPy array is returned when `subplots` is `True`.

See also:

[`Series.plot.pie`](#) Generate a pie plot for a Series.

[`DataFrame.plot`](#) Make plots of a DataFrame.

Examples

In the example below we have a DataFrame with the information about planet's mass and radius. We pass the 'mass' column to the pie function to get a pie plot.

```
>>> df = pd.DataFrame({'mass': [0.330, 4.87, 5.97],
...                   'radius': [2439.7, 6051.8, 6378.1]},
...                   index=['Mercury', 'Venus', 'Earth'])
>>> plot = df.plot.pie(y='mass', figsize=(5, 5))
```

```
>>> plot = df.plot.pie(subplots=True, figsize=(11, 6))
```

pandas.DataFrame.plot.scatter

`DataFrame.plot.scatter(x, y, s=None, c=None, **kwargs)`

Create a scatter plot with varying marker point size and color.

The coordinates of each point are defined by two dataframe columns and filled circles are used to represent each point. This kind of plot is useful to see complex correlations between two variables. Points could be for instance natural 2D coordinates like longitude and latitude in a map or, in general, any pair of metrics that can be plotted against each other.

Parameters

x [int or str] The column name or column position to be used as horizontal coordinates for each point.

y [int or str] The column name or column position to be used as vertical coordinates for each point.

s [str, scalar or array-like, optional] The size of each point. Possible values are:

- A string with the name of the column to be used for marker's size.
- A single scalar so all points have the same size.

- A sequence of scalars, which will be used for each point's size recursively. For instance, when passing [2,14] all points size will be either 2 or 14, alternatively.

Changed in version 1.1.0.

c [str, int or array-like, optional] The color of each point. Possible values are:

- A single color string referred to by name, RGB or RGBA code, for instance 'red' or '#a98d19'.
- A sequence of color strings referred to by name, RGB or RGBA code, which will be used for each point's color recursively. For instance ['green','yellow'] all points will be filled in green or yellow, alternatively.
- A column name or position whose values will be used to color the marker points according to a colormap.

****kwargs** Keyword arguments to pass on to `DataFrame.plot()`.

Returns

`matplotlib.axes.Axes` or `numpy.ndarray` of them

See also:

`matplotlib.pyplot.scatter` Scatter plot using multiple input data formats.

Examples

Let's see how to draw a scatter plot using coordinates from the values in a DataFrame's columns.

```
>>> df = pd.DataFrame([[5.1, 3.5, 0], [4.9, 3.0, 0], [7.0, 3.2, 1],
...                    [6.4, 3.2, 1], [5.9, 3.0, 2]],
...                    columns=['length', 'width', 'species'])
>>> ax1 = df.plot.scatter(x='length',
...                        y='width',
...                        c='DarkBlue')
```

And now with the color determined by a column as well.

```
>>> ax2 = df.plot.scatter(x='length',
...                        y='width',
...                        c='species',
...                        colormap='viridis')
```

| | |
|--|--|
| <code>DataFrame.boxplot</code> ([column, by, ax, ...]) | Make a box plot from DataFrame columns. |
| <code>DataFrame.hist</code> ([column, by, grid, ...]) | Make a histogram of the DataFrame's columns. |

3.4.16 Sparse accessor

Sparse-dtype specific methods and attributes are provided under the `DataFrame.sparse` accessor.

| | |
|---------------------------------------|--|
| <code>DataFrame.sparse.density</code> | Ratio of non-sparse points to total (dense) data points. |
|---------------------------------------|--|

`pandas.DataFrame.sparse.density`

`DataFrame.sparse.density`

Ratio of non-sparse points to total (dense) data points.

| | |
|--|--|
| <code>DataFrame.sparse.from_spmatrix(data[, ...])</code> | Create a new DataFrame from a scipy sparse matrix. |
| <code>DataFrame.sparse.to_coo()</code> | Return the contents of the frame as a sparse SciPy COO matrix. |
| <code>DataFrame.sparse.to_dense()</code> | Convert a DataFrame with sparse values to dense. |

`pandas.DataFrame.sparse.from_spmatrix`

classmethod `DataFrame.sparse.from_spmatrix(data, index=None, columns=None)`

Create a new DataFrame from a scipy sparse matrix.

New in version 0.25.0.

Parameters

data [`scipy.sparse.spmatrix`] Must be convertible to csc format.

index, columns [`Index`, optional] Row and column labels to use for the resulting DataFrame. Defaults to a `RangeIndex`.

Returns

DataFrame Each column of the DataFrame is stored as a `arrays.SparseArray`.

Examples

```
>>> import scipy.sparse
>>> mat = scipy.sparse.eye(3)
>>> pd.DataFrame.sparse.from_spmatrix(mat)
   0  1  2
0  1.0 0.0 0.0
1  0.0 1.0 0.0
2  0.0 0.0 1.0
```

pandas.DataFrame.sparse.to_coo

`DataFrame.sparse.to_coo()`

Return the contents of the frame as a sparse SciPy COO matrix.

New in version 0.25.0.

Returns

coo_matrix [`scipy.sparse.spmatrix`] If the caller is heterogeneous and contains booleans or objects, the result will be of `dtype=object`. See Notes.

Notes

The dtype will be the lowest-common-denominator type (implicit upcasting); that is to say if the dtypes (even of numeric types) are mixed, the one that accommodates all will be chosen.

e.g. If the dtypes are `float16` and `float32`, dtype will be upcast to `float32`. By `numpy.find_common_type` convention, mixing `int64` and `uint64` will result in a `float64` dtype.

pandas.DataFrame.sparse.to_dense

`DataFrame.sparse.to_dense()`

Convert a DataFrame with sparse values to dense.

New in version 0.25.0.

Returns

DataFrame A DataFrame with the same values stored as dense arrays.

Examples

```

>>> df = pd.DataFrame({"A": pd.arrays.SparseArray([0, 1, 0])})
>>> df.sparse.to_dense()
   A
0  0
1  1
2  0

```

3.4.17 Serialization / IO / conversion

| | |
|--|--|
| <code>DataFrame.from_dict(data[, orient, dtype, ...])</code> | Construct DataFrame from dict of array-like or dicts. |
| <code>DataFrame.from_records(data[, index, ...])</code> | Convert structured or record ndarray to DataFrame. |
| <code>DataFrame.to_parquet([path, engine, ...])</code> | Write a DataFrame to the binary parquet format. |
| <code>DataFrame.to_pickle(path[, compression, ...])</code> | Pickle (serialize) object to file. |
| <code>DataFrame.to_csv([path_or_buf, sep, na_rep, ...])</code> | Write object to a comma-separated values (csv) file. |
| <code>DataFrame.to_hdf(path_or_buf, key[, mode, ...])</code> | Write the contained data to an HDF5 file using HDFStore. |
| <code>DataFrame.to_sql(name, con[, schema, ...])</code> | Write records stored in a DataFrame to a SQL database. |
| <code>DataFrame.to_dict([orient, into])</code> | Convert the DataFrame to a dictionary. |
| <code>DataFrame.to_excel(excel_writer[, ...])</code> | Write object to an Excel sheet. |
| <code>DataFrame.to_json([path_or_buf, orient, ...])</code> | Convert the object to a JSON string. |

continues on next page

Table 85 – continued from previous page

| | |
|---|---|
| <code>DataFrame.to_html</code> ([buf, columns, col_space, ...]) | Render a DataFrame as an HTML table. |
| <code>DataFrame.to_feather</code> (path, **kwargs) | Write a DataFrame to the binary Feather format. |
| <code>DataFrame.to_latex</code> ([buf, columns, ...]) | Render object to a LaTeX tabular, longtable, or nested table/tabular. |
| <code>DataFrame.to_stata</code> (path[, convert_dates, ...]) | Export DataFrame object to Stata dta format. |
| <code>DataFrame.to_gbq</code> (destination_table[, ...]) | Write a DataFrame to a Google BigQuery table. |
| <code>DataFrame.to_records</code> ([index, column_dtypes, ...]) | Convert DataFrame to a NumPy record array. |
| <code>DataFrame.to_string</code> ([buf, columns, ...]) | Render a DataFrame to a console-friendly tabular output. |
| <code>DataFrame.to_clipboard</code> ([excel, sep]) | Copy object to the system clipboard. |
| <code>DataFrame.to_markdown</code> ([buf, mode, index, ...]) | Print DataFrame in Markdown-friendly format. |
| <code>DataFrame.style</code> | Returns a Styler object. |

3.5 pandas arrays

For most data types, pandas uses NumPy arrays as the concrete objects contained with a *Index*, *Series*, or *DataFrame*.

For some data types, pandas extends NumPy’s type system. String aliases for these types can be found at *dtypes*.

| Kind of Data | pandas Data Type | Scalar | Array |
|---------------------|-------------------------|------------------|---|
| TZ-aware datetime | <i>DatetimeTZDtype</i> | <i>Timestamp</i> | <i>Datetime data</i> |
| Timedeltas | (none) | <i>Timedelta</i> | <i>Timedelta data</i> |
| Period (time spans) | <i>PeriodDtype</i> | <i>Period</i> | <i>Timespan data</i> |
| Intervals | <i>IntervalDtype</i> | <i>Interval</i> | <i>Interval data</i> |
| Nullable Integer | <i>Int64Dtype</i> , ... | (none) | <i>Nullable integer</i> |
| Categorical | <i>CategoricalDtype</i> | (none) | <i>Categorical data</i> |
| Sparse | <i>SparseDtype</i> | (none) | <i>Sparse data</i> |
| Strings | <i>StringDtype</i> | <i>str</i> | <i>Text data</i> |
| Boolean (with NA) | <i>BooleanDtype</i> | <i>bool</i> | <i>Boolean data with missing values</i> |

pandas and third-party libraries can extend NumPy’s type system (see *Extension types*). The top-level `array()` method can be used to create a new array, which may be stored in a *Series*, *Index*, or as a column in a *DataFrame*.

| | |
|--|------------------|
| <code>array</code> (data[, dtype, copy]) | Create an array. |
|--|------------------|

3.5.1 pandas.array

`pandas.array`(data, dtype=None, copy=True)

Create an array.

Parameters

data [Sequence of objects] The scalars inside *data* should be instances of the scalar type for *dtype*. It’s expected that *data* represents a 1-dimensional array of data.

When *data* is an Index or Series, the underlying array will be extracted from *data*.

dtype [str, np.dtype, or ExtensionDtype, optional] The dtype to use for the array. This may be a NumPy dtype or an extension type registered with pandas using `pandas.api.extensions.register_extension_dtype()`.

If not specified, there are two possibilities:

1. When *data* is a *Series*, *Index*, or *ExtensionArray*, the *dtype* will be taken from the data.
2. Otherwise, pandas will attempt to infer the *dtype* from the data.

Note that when *data* is a NumPy array, `data.dtype` is *not* used for inferring the array type. This is because NumPy cannot represent all the types of data that can be held in extension arrays.

Currently, pandas will infer an extension dtype for sequences of

| Scalar Type | Array Type |
|---------------------------------|---|
| <code>pandas.Interval</code> | <code>pandas.arrays.IntervalArray</code> |
| <code>pandas.Period</code> | <code>pandas.arrays.PeriodArray</code> |
| <code>datetime.datetime</code> | <code>pandas.arrays.DatetimeArray</code> |
| <code>datetime.timedelta</code> | <code>pandas.arrays.TimedeltaArray</code> |
| <code>int</code> | <code>pandas.arrays.IntegerArray</code> |
| <code>float</code> | <code>pandas.arrays.FloatingArray</code> |
| <code>str</code> | <code>pandas.arrays.StringArray</code> or <code>pandas.arrays.ArrowStringArray</code> |
| <code>bool</code> | <code>pandas.arrays.BooleanArray</code> |

The *ExtensionArray* created when the scalar type is `str` is determined by `pd.options.mode.string_storage` if the dtype is not explicitly given.

For all other cases, NumPy's usual inference rules will be used.

Changed in version 1.0.0: Pandas infers nullable-integer dtype for integer data, string dtype for string data, and nullable-boolean dtype for boolean data.

Changed in version 1.2.0: Pandas now also infers nullable-floating dtype for float-like input data

copy [bool, default True] Whether to copy the data, even if not necessary. Depending on the type of *data*, creating the new array may require copying data, even if `copy=False`.

Returns

ExtensionArray The newly created array.

Raises

ValueError When *data* is not 1-dimensional.

See also:

numpy.array Construct a NumPy array.

Series Construct a pandas Series.

Index Construct a pandas Index.

arrays.PandasArray *ExtensionArray* wrapping a NumPy array.

Series.array Extract the array stored within a Series.

Notes

Omitting the *dtype* argument means pandas will attempt to infer the best array type from the values in the data. As new array types are added by pandas and 3rd party libraries, the “best” array type may change. We recommend specifying *dtype* to ensure that

1. the correct array type for the data is returned
2. the returned array type doesn't change as new extension types are added by pandas and third-party libraries

Additionally, if the underlying memory representation of the returned array matters, we recommend specifying the *dtype* as a concrete object rather than a string alias or allowing it to be inferred. For example, a future version of pandas or a 3rd-party library may include a dedicated `ExtensionArray` for string data. In this event, the following would no longer return a `arrays.PandasArray` backed by a NumPy array.

```
>>> pd.array(['a', 'b'], dtype=str)
<PandasArray>
['a', 'b']
Length: 2, dtype: str32
```

This would instead return the new `ExtensionArray` dedicated for string data. If you really need the new array to be backed by a NumPy array, specify that in the *dtype*.

```
>>> pd.array(['a', 'b'], dtype=np.dtype("<U1"))
<PandasArray>
['a', 'b']
Length: 2, dtype: str32
```

Finally, Pandas has arrays that mostly overlap with NumPy

- `arrays.DatetimeArray`
- `arrays.TimedeltaArray`

When data with a `datetime64[ns]` or `timedelta64[ns]` dtype is passed, pandas will always return a `DatetimeArray` or `TimedeltaArray` rather than a `PandasArray`. This is for symmetry with the case of timezone-aware data, which NumPy does not natively support.

```
>>> pd.array(['2015', '2016'], dtype='datetime64[ns]')
<DatetimeArray>
['2015-01-01 00:00:00', '2016-01-01 00:00:00']
Length: 2, dtype: datetime64[ns]
```

```
>>> pd.array(["1H", "2H"], dtype='timedelta64[ns]')
<TimedeltaArray>
['0 days 01:00:00', '0 days 02:00:00']
Length: 2, dtype: timedelta64[ns]
```

Examples

If a dtype is not specified, pandas will infer the best dtype from the values. See the description of *dtype* for the types pandas infers for.

```
>>> pd.array([1, 2])
<IntegerArray>
[1, 2]
Length: 2, dtype: Int64
```

```
>>> pd.array([1, 2, np.nan])
<IntegerArray>
[1, 2, <NA>]
Length: 3, dtype: Int64
```

```
>>> pd.array([1.1, 2.2])
<FloatingArray>
[1.1, 2.2]
Length: 2, dtype: Float64
```

```
>>> pd.array(["a", None, "c"])
<StringArray>
['a', <NA>, 'c']
Length: 3, dtype: string
```

```
>>> with pd.option_context("string_storage", "pyarrow"):
...     arr = pd.array(["a", None, "c"])
...
>>> arr
<ArrowStringArray>
['a', <NA>, 'c']
Length: 3, dtype: string
```

```
>>> pd.array([pd.Period('2000', freq="D"), pd.Period("2000", freq="D")])
<PeriodArray>
['2000-01-01', '2000-01-01']
Length: 2, dtype: period[D]
```

You can use the string alias for *dtype*

```
>>> pd.array(['a', 'b', 'a'], dtype='category')
['a', 'b', 'a']
Categories (2, object): ['a', 'b']
```

Or specify the actual dtype

```
>>> pd.array(['a', 'b', 'a'],
...          dtype=pd.CategoricalDtype(['a', 'b', 'c'], ordered=True))
['a', 'b', 'a']
Categories (3, object): ['a' < 'b' < 'c']
```

If pandas does not infer a dedicated extension type a *arrays.PandasArray* is returned.

```
>>> pd.array([1 + 1j, 3 + 2j])
<PandasArray>
[(1+1j), (3+2j)]
Length: 2, dtype: complex128
```

As mentioned in the “Notes” section, new extension types may be added in the future (by pandas or 3rd party libraries), causing the return value to no longer be a *arrays.PandasArray*. Specify the *dtype* as a NumPy dtype if you need to ensure there’s no future change in behavior.

```
>>> pd.array([1, 2], dtype=np.dtype("int32"))
<PandasArray>
[1, 2]
Length: 2, dtype: int32
```

data must be 1-dimensional. A `ValueError` is raised when the input has the wrong dimensionality.

```
>>> pd.array(1)
Traceback (most recent call last):
...
ValueError: Cannot pass scalar '1' to 'pandas.array'.
```

3.5.2 Datetime data

NumPy cannot natively represent timezone-aware datetimes. pandas supports this with the `arrays.DatetimeArray` extension array, which can hold timezone-naive or timezone-aware values.

`Timestamp`, a subclass of `datetime.datetime`, is pandas' scalar type for timezone-naive or timezone-aware datetime data.

| | |
|---|--|
| <code>Timestamp</code> ([<i>ts_input</i> , <i>freq</i> , <i>tz</i> , <i>unit</i> , <i>year</i> , ...]) | Pandas replacement for python <code>datetime.datetime</code> object. |
|---|--|

pandas.Timestamp

```
class pandas.Timestamp(ts_input=<object object>, freq=None, tz=None, unit=None, year=None,
                       month=None, day=None, hour=None, minute=None, second=None,
                       microsecond=None, nanosecond=None, tzinfo=None, *, fold=None)
```

Pandas replacement for python `datetime.datetime` object.

`Timestamp` is the pandas equivalent of python's `Datetime` and is interchangeable with it in most cases. It's the type used for the entries that make up a `DatetimeIndex`, and other timeseries oriented data structures in pandas.

Parameters

ts_input [datetime-like, str, int, float] Value to be converted to `Timestamp`.

freq [str, `DateOffset`] Offset which `Timestamp` will have.

tz [str, `pytz.timezone`, `dateutil.tz.tzfile` or `None`] Time zone for time which `Timestamp` will have.

unit [str] Unit used for conversion if *ts_input* is of type `int` or `float`. The valid values are 'D', 'h', 'm', 's', 'ms', 'us', and 'ns'. For example, 's' means seconds and 'ms' means milliseconds.

year, month, day [int]

hour, minute, second, microsecond [int, optional, default 0]

nanosecond [int, optional, default 0]

tzinfo [`datetime.tzinfo`, optional, default `None`]

fold [{0, 1}, default `None`, keyword-only] Due to daylight saving time, one wall clock time can occur twice when shifting from summer to winter time; `fold` describes whether the

datetime-like corresponds to the first (0) or the second time (1) the wall clock hits the ambiguous time

New in version 1.1.0.

Notes

There are essentially three calling conventions for the constructor. The primary form accepts four parameters. They can be passed by position or keyword.

The other two forms mimic the parameters from `datetime.datetime`. They can be passed by either position or keyword, but not both mixed together.

Examples

Using the primary calling convention:

This converts a datetime-like string

```
>>> pd.Timestamp('2017-01-01T12')
Timestamp('2017-01-01 12:00:00')
```

This converts a float representing a Unix epoch in units of seconds

```
>>> pd.Timestamp(1513393355.5, unit='s')
Timestamp('2017-12-16 03:02:35.500000')
```

This converts an int representing a Unix-epoch in units of seconds and for a particular timezone

```
>>> pd.Timestamp(1513393355, unit='s', tz='US/Pacific')
Timestamp('2017-12-15 19:02:35-0800', tz='US/Pacific')
```

Using the other two forms that mimic the API for `datetime.datetime`:

```
>>> pd.Timestamp(2017, 1, 1, 12)
Timestamp('2017-01-01 12:00:00')
```

```
>>> pd.Timestamp(year=2017, month=1, day=1, hour=12)
Timestamp('2017-01-01 12:00:00')
```

Attributes

| | |
|----------------------|--|
| <i>asm8</i> | Return numpy datetime64 format in nanoseconds. |
| <i>day_of_week</i> | Return day of the week. |
| <i>day_of_year</i> | Return the day of the year. |
| <i>dayofweek</i> | Return day of the week. |
| <i>dayofyear</i> | Return the day of the year. |
| <i>days_in_month</i> | Return the number of days in the month. |
| <i>daysinmonth</i> | Return the number of days in the month. |
| <i>freqstr</i> | Return the total number of days in the month. |
| <i>is_leap_year</i> | Return True if year is a leap year. |

continues on next page

Table 88 – continued from previous page

| | |
|-------------------------|--|
| <i>is_month_end</i> | Return True if date is last day of month. |
| <i>is_month_start</i> | Return True if date is first day of month. |
| <i>is_quarter_end</i> | Return True if date is last day of the quarter. |
| <i>is_quarter_start</i> | Return True if date is first day of the quarter. |
| <i>is_year_end</i> | Return True if date is last day of the year. |
| <i>is_year_start</i> | Return True if date is first day of the year. |
| <i>quarter</i> | Return the quarter of the year. |
| <i>tz</i> | Alias for tzinfo. |
| <i>week</i> | Return the week number of the year. |
| <i>weekofyear</i> | Return the week number of the year. |

pandas.Timestamp.asm8

Timestamp.asm8

Return numpy datetime64 format in nanoseconds.

Examples

```
>>> ts = pd.Timestamp(2020, 3, 14, 15)
>>> ts.asm8
numpy.datetime64('2020-03-14T15:00:00.000000000')
```

pandas.Timestamp.day_of_week

Timestamp.day_of_week

Return day of the week.

Examples

```
>>> ts = pd.Timestamp(2020, 3, 14)
>>> ts.day_of_week
5
```

pandas.Timestamp.day_of_year

Timestamp.day_of_year

Return the day of the year.

Examples

```
>>> ts = pd.Timestamp(2020, 3, 14)
>>> ts.day_of_year
74
```

pandas.Timestamp.dayofweek

Timestamp.dayofweek

Return day of the week.

Examples

```
>>> ts = pd.Timestamp(2020, 3, 14)
>>> ts.day_of_week
5
```

pandas.Timestamp.dayofyear

Timestamp.dayofyear

Return the day of the year.

Examples

```
>>> ts = pd.Timestamp(2020, 3, 14)
>>> ts.day_of_year
74
```

pandas.Timestamp.days_in_month

Timestamp.days_in_month

Return the number of days in the month.

Examples

```
>>> ts = pd.Timestamp(2020, 3, 14)
>>> ts.days_in_month
31
```

pandas.Timestamp.daysinmonth

Timestamp.daysinmonth

Return the number of days in the month.

Examples

```
>>> ts = pd.Timestamp(2020, 3, 14)
>>> ts.days_in_month
31
```

pandas.Timestamp.freqstr

property Timestamp.freqstr

Return the total number of days in the month.

pandas.Timestamp.is_leap_year

Timestamp.is_leap_year

Return True if year is a leap year.

Examples

```
>>> ts = pd.Timestamp(2020, 3, 14)
>>> ts.is_leap_year
True
```

pandas.Timestamp.is_month_end

Timestamp.is_month_end

Return True if date is last day of month.

Examples

```
>>> ts = pd.Timestamp(2020, 3, 14)
>>> ts.is_month_end
False
```

```
>>> ts = pd.Timestamp(2020, 12, 31)
>>> ts.is_month_end
True
```

pandas.Timestamp.is_month_start

Timestamp.is_month_start

Return True if date is first day of month.

Examples

```
>>> ts = pd.Timestamp(2020, 3, 14)
>>> ts.is_month_start
False
```

```
>>> ts = pd.Timestamp(2020, 1, 1)
>>> ts.is_month_start
True
```

pandas.Timestamp.is_quarter_end

Timestamp.is_quarter_end

Return True if date is last day of the quarter.

Examples

```
>>> ts = pd.Timestamp(2020, 3, 14)
>>> ts.is_quarter_end
False
```

```
>>> ts = pd.Timestamp(2020, 3, 31)
>>> ts.is_quarter_end
True
```

pandas.Timestamp.is_quarter_start

Timestamp.is_quarter_start

Return True if date is first day of the quarter.

Examples

```
>>> ts = pd.Timestamp(2020, 3, 14)
>>> ts.is_quarter_start
False
```

```
>>> ts = pd.Timestamp(2020, 4, 1)
>>> ts.is_quarter_start
True
```

`pandas.Timestamp.is_year_end`

`Timestamp.is_year_end`

Return True if date is last day of the year.

Examples

```
>>> ts = pd.Timestamp(2020, 3, 14)
>>> ts.is_year_end
False
```

```
>>> ts = pd.Timestamp(2020, 12, 31)
>>> ts.is_year_end
True
```

`pandas.Timestamp.is_year_start`

`Timestamp.is_year_start`

Return True if date is first day of the year.

Examples

```
>>> ts = pd.Timestamp(2020, 3, 14)
>>> ts.is_year_start
False
```

```
>>> ts = pd.Timestamp(2020, 1, 1)
>>> ts.is_year_start
True
```

`pandas.Timestamp.quarter`

`Timestamp.quarter`

Return the quarter of the year.

Examples

```
>>> ts = pd.Timestamp(2020, 3, 14)
>>> ts.quarter
1
```

pandas.Timestamp.tz

property Timestamp.tz

Alias for tzinfo.

Examples

```
>>> ts = pd.Timestamp(1584226800, unit='s', tz='Europe/Stockholm')
>>> ts.tz
<DstTzInfo 'Europe/Stockholm' CET+1:00:00 STD>
```

pandas.Timestamp.week

Timestamp.week

Return the week number of the year.

Examples

```
>>> ts = pd.Timestamp(2020, 3, 14)
>>> ts.week
11
```

pandas.Timestamp.weekofyear

Timestamp.weekofyear

Return the week number of the year.

Examples

```
>>> ts = pd.Timestamp(2020, 3, 14)
>>> ts.week
11
```

| | |
|--------------------|--|
| day | |
| fold | |
| freq | |
| hour | |
| microsecond | |
| minute | |
| month | |
| nanosecond | |
| second | |
| tzinfo | |
| value | |
| year | |

Methods

| | |
|--|---|
| <i>astimezone</i> (tz) | Convert tz-aware Timestamp to another time zone. |
| <i>ceil</i> (freq[, ambiguous, nonexistent]) | Return a new Timestamp ceiled to this resolution. |
| <i>combine</i> (date, time) | Combine date, time into datetime with same date and time fields. |
| <i>ctime</i> | Return ctime() style string. |
| <i>date</i> | Return date object with same year, month and day. |
| <i>day_name</i> | Return the day name of the Timestamp with specified locale. |
| <i>dst</i> | Return self.tzinfo.dst(self). |
| <i>floor</i> (freq[, ambiguous, nonexistent]) | Return a new Timestamp floored to this resolution. |
| <i>fromisocalendar</i> | int, int, int -> Construct a date from the ISO year, week number and weekday. |
| <i>fromisoformat</i> | string -> datetime from datetime.isoformat() output |
| <i>fromordinal</i> (ordinal[, freq, tz]) | Passed an ordinal, translate and convert to a ts. |
| <i>fromtimestamp</i> (ts) | Transform timestamp[, tz] to tz's local time from POSIX timestamp. |
| <i>isocalendar</i> | Return a 3-tuple containing ISO year, week number, and weekday. |
| <i>isoformat</i> | [sep] -> string in ISO 8601 format, YYYY-MM-DDT[HH[:MM[:SS[.mmm[uuu]]]]][+HH:MM]. |
| <i>isoweekday</i> | Return the day of the week represented by the date. |
| <i>month_name</i> | Return the month name of the Timestamp with specified locale. |
| <i>normalize</i> | Normalize Timestamp to midnight, preserving tz information. |
| <i>now</i> ([tz]) | Return new Timestamp object representing current time local to tz. |
| <i>replace</i> ([year, month, day, hour, minute, ...]) | Implements datetime.replace, handles nanoseconds. |
| <i>round</i> (freq[, ambiguous, nonexistent]) | Round the Timestamp to the specified resolution. |
| <i>strftime</i> (format) | Return a string representing the given POSIX timestamp controlled by an explicit format string. |
| <i>strptime</i> (string, format) | Function is not implemented. |
| <i>time</i> | Return time object with same time but with tzinfo=None. |
| <i>timestamp</i> | Return POSIX timestamp as float. |
| <i>timetuple</i> | Return time tuple, compatible with time.localtime(). |
| <i>timetz</i> | Return time object with same time and tzinfo. |
| <i>to_datetime64</i> | Return a numpy.datetime64 object with 'ns' precision. |
| <i>to_julian_date</i> () | Convert TimeStamp to a Julian Date. |
| <i>to_numpy</i> | Convert the Timestamp to a NumPy datetime64. |
| <i>to_period</i> | Return an period of which this timestamp is an observation. |
| <i>to_pydatetime</i> | Convert a Timestamp object to a native Python datetime object. |
| <i>today</i> (cls[, tz]) | Return the current time in the local timezone. |
| <i>toordinal</i> | Return proleptic Gregorian ordinal. |
| <i>tz_convert</i> (tz) | Convert tz-aware Timestamp to another time zone. |

continues on next page

Table 89 – continued from previous page

| | |
|--|---|
| <code>tz_localize(tz[, ambiguous, nonexistent])</code> | Convert naive Timestamp to local time zone, or remove timezone from tz-aware Timestamp. |
| <code>tzname</code> | Return <code>self.tzinfo.tzname(self)</code> . |
| <code>utcfromtimestamp(ts)</code> | Construct a naive UTC datetime from a POSIX timestamp. |
| <code>utcnow()</code> | Return a new Timestamp representing UTC day and time. |
| <code>utcoffset</code> | Return <code>self.tzinfo.utcoffset(self)</code> . |
| <code>utctimetuple</code> | Return UTC time tuple, compatible with <code>time.localtime()</code> . |
| <code>weekday</code> | Return the day of the week represented by the date. |

pandas.Timestamp.astimezone

`Timestamp.astimezone(tz)`

Convert tz-aware Timestamp to another time zone.

Parameters

tz [str, pytz.timezone, dateutil.tz.tzfile or None] Time zone for time which Timestamp will be converted to. None will remove timezone holding UTC time.

Returns

converted [Timestamp]

Raises

TypeError If Timestamp is tz-naive.

Examples

Create a timestamp object with UTC timezone:

```
>>> ts = pd.Timestamp('2020-03-14T15:32:52.192548651', tz='UTC')
>>> ts
Timestamp('2020-03-14 15:32:52.192548651+0000', tz='UTC')
```

Change to Tokyo timezone:

```
>>> ts.tz_convert(tz='Asia/Tokyo')
Timestamp('2020-03-15 00:32:52.192548651+0900', tz='Asia/Tokyo')
```

Can also use `astimezone`:

```
>>> ts.astimezone(tz='Asia/Tokyo')
Timestamp('2020-03-15 00:32:52.192548651+0900', tz='Asia/Tokyo')
```

Analogous for `pd.NaT`:

```
>>> pd.NaT.tz_convert(tz='Asia/Tokyo')
NaT
```

pandas.Timestamp.ceil

`Timestamp.ceil(freq, ambiguous='raise', nonexistent='raise')`

Return a new Timestamp ceiled to this resolution.

Parameters

freq [str] Frequency string indicating the ceiling resolution.

ambiguous [bool or {'raise', 'NaT'}, default 'raise'] The behavior is as follows:

- bool contains flags to determine if time is dst or not (note that this flag is only applicable for ambiguous fall dst dates).
- 'NaT' will return NaT for an ambiguous time.
- 'raise' will raise an `AmbiguousTimeError` for an ambiguous time.

nonexistent [{'raise', 'shift_forward', 'shift_backward', 'NaT', 'timedelta'}, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- 'shift_forward' will shift the nonexistent time forward to the closest existing time.
- 'shift_backward' will shift the nonexistent time backward to the closest existing time.
- 'NaT' will return NaT where there are nonexistent times.
- `timedelta` objects will shift nonexistent times by the `timedelta`.
- 'raise' will raise an `NonExistentTimeError` if there are nonexistent times.

Raises

ValueError if the `freq` cannot be converted.

Examples

Create a timestamp object:

```
>>> ts = pd.Timestamp('2020-03-14T15:32:52.192548651')
```

A timestamp can be ceiled using multiple frequency units:

```
>>> ts.ceil(freq='H') # hour
Timestamp('2020-03-14 16:00:00')
```

```
>>> ts.ceil(freq='T') # minute
Timestamp('2020-03-14 15:33:00')
```

```
>>> ts.ceil(freq='S') # seconds
Timestamp('2020-03-14 15:32:53')
```

```
>>> ts.ceil(freq='U') # microseconds
Timestamp('2020-03-14 15:32:52.192549')
```

`freq` can also be a multiple of a single unit, like '5T' (i.e. 5 minutes):

```
>>> ts.ceil(freq='5T')
Timestamp('2020-03-14 15:35:00')
```

or a combination of multiple units, like '1H30T' (i.e. 1 hour and 30 minutes):

```
>>> ts.ceil(freq='1H30T')
Timestamp('2020-03-14 16:30:00')
```

Analogous for `pd.NaT`:

```
>>> pd.NaT.ceil()
NaT
```

pandas.Timestamp.combine

classmethod `Timestamp.combine(date, time)`

Combine date, time into datetime with same date and time fields.

Examples

```
>>> from datetime import date, time
>>> pd.Timestamp.combine(date(2020, 3, 14), time(15, 30, 15))
Timestamp('2020-03-14 15:30:15')
```

pandas.Timestamp.ctime

`Timestamp.ctime()`

Return `ctime()` style string.

pandas.Timestamp.date

`Timestamp.date()`

Return date object with same year, month and day.

pandas.Timestamp.day_name

`Timestamp.day_name()`

Return the day name of the Timestamp with specified locale.

Parameters

locale [str, default None (English locale)] Locale determining the language in which to return the day name.

Returns

str

Examples

```
>>> ts = pd.Timestamp('2020-03-14T15:32:52.192548651')
>>> ts.day_name()
'Saturday'
```

Analogous for `pd.NaT`:

```
>>> pd.NaT.day_name()
nan
```

pandas.Timestamp.dst

`Timestamp.dst()`

Return `self.tzinfo.dst(self)`.

pandas.Timestamp.floor

`Timestamp.floor(freq, ambiguous='raise', nonexistent='raise')`

Return a new Timestamp floored to this resolution.

Parameters

freq [str] Frequency string indicating the flooring resolution.

ambiguous [bool or {'raise', 'NaT'}, default 'raise'] The behavior is as follows:

- bool contains flags to determine if time is dst or not (note that this flag is only applicable for ambiguous fall dst dates).
- 'NaT' will return NaT for an ambiguous time.
- 'raise' will raise an `AmbiguousTimeError` for an ambiguous time.

nonexistent [{'raise', 'shift_forward', 'shift_backward', 'NaT', timedelta}, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- 'shift_forward' will shift the nonexistent time forward to the closest existing time.
- 'shift_backward' will shift the nonexistent time backward to the closest existing time.
- 'NaT' will return NaT where there are nonexistent times.
- timedelta objects will shift nonexistent times by the timedelta.
- 'raise' will raise an `NonExistentTimeError` if there are nonexistent times.

Raises

ValueError if the `freq` cannot be converted.

Examples

Create a timestamp object:

```
>>> ts = pd.Timestamp('2020-03-14T15:32:52.192548651')
```

A timestamp can be floored using multiple frequency units:

```
>>> ts.floor(freq='H') # hour
Timestamp('2020-03-14 15:00:00')
```

```
>>> ts.floor(freq='T') # minute
Timestamp('2020-03-14 15:32:00')
```

```
>>> ts.floor(freq='S') # seconds
Timestamp('2020-03-14 15:32:52')
```

```
>>> ts.floor(freq='N') # nanoseconds
Timestamp('2020-03-14 15:32:52.192548651')
```

freq can also be a multiple of a single unit, like '5T' (i.e. 5 minutes):

```
>>> ts.floor(freq='5T')
Timestamp('2020-03-14 15:30:00')
```

or a combination of multiple units, like '1H30T' (i.e. 1 hour and 30 minutes):

```
>>> ts.floor(freq='1H30T')
Timestamp('2020-03-14 15:00:00')
```

Analogous for pd.NaT:

```
>>> pd.NaT.floor()
NaT
```

pandas.Timestamp.fromisocalendar

Timestamp.**fromisocalendar**()

int, int, int -> Construct a date from the ISO year, week number and weekday.

This is the inverse of the date.isocalendar() function

pandas.Timestamp.fromisoformat

Timestamp.**fromisoformat**()

string -> datetime from datetime.isoformat() output

pandas.Timestamp.fromordinal

classmethod Timestamp.**fromordinal**(*ordinal*, *freq=None*, *tz=None*)

Passed an ordinal, translate and convert to a ts. Note: by definition there cannot be any tz info on the ordinal itself.

Parameters

ordinal [int] Date corresponding to a proleptic Gregorian ordinal.

freq [str, DateOffset] Offset to apply to the Timestamp.

tz [str, pytz.timezone, dateutil.tz.tzfile or None] Time zone for the Timestamp.

Examples

```
>>> pd.Timestamp.fromordinal(737425)
Timestamp('2020-01-01 00:00:00')
```

pandas.Timestamp.fromtimestamp

classmethod Timestamp.**fromtimestamp**(*ts*)

Transform timestamp[, tz] to tz's local time from POSIX timestamp.

Examples

```
>>> pd.Timestamp.utctimestamp(1584199972)
Timestamp('2020-03-14 15:32:52')
```

Note that the output may change depending on your local time.

pandas.Timestamp.isocalendar

Timestamp.**isocalendar**()

Return a 3-tuple containing ISO year, week number, and weekday.

pandas.Timestamp.isoformat

Timestamp.**isoformat**()

[sep] -> string in ISO 8601 format, YYYY-MM-DDT[HH[:MM[:SS[.mmm[uuu]]]]][+HH:MM]. sep is used to separate the year from the time, and defaults to 'T'. The optional argument timespec specifies the number of additional terms of the time to include. Valid options are 'auto', 'hours', 'minutes', 'seconds', 'milliseconds' and 'microseconds'.

pandas.Timestamp.isoweekday

Timestamp.**isoweekday**()

Return the day of the week represented by the date. Monday == 1 ... Sunday == 7

pandas.Timestamp.month_name

Timestamp.**month_name**()

Return the month name of the Timestamp with specified locale.

Parameters

locale [str, default None (English locale)] Locale determining the language in which to return the month name.

Returns

str

Examples

```
>>> ts = pd.Timestamp('2020-03-14T15:32:52.192548651')
>>> ts.month_name()
'March'
```

Analogous for pd.NaT:

```
>>> pd.NaT.month_name()
nan
```

pandas.Timestamp.normalize

Timestamp.**normalize**()

Normalize Timestamp to midnight, preserving tz information.

Examples

```
>>> ts = pd.Timestamp(2020, 3, 14, 15, 30)
>>> ts.normalize()
Timestamp('2020-03-14 00:00:00')
```

pandas.Timestamp.now

classmethod `Timestamp.now(tz=None)`

Return new Timestamp object representing current time local to tz.

Parameters

tz [str or timezone object, default None] Timezone to localize to.

Examples

```
>>> pd.Timestamp.now()
Timestamp('2020-11-16 22:06:16.378782')
```

Analogous for `pd.NaT`:

```
>>> pd.NaT.now()
NaT
```

pandas.Timestamp.replace

Timestamp.replace(*year=None, month=None, day=None, hour=None, minute=None, second=None, microsecond=None, nanosecond=None, tzinfo=<class 'object'>, fold=None*)

Implements `datetime.replace`, handles nanoseconds.

Parameters

year [int, optional]

month [int, optional]

day [int, optional]

hour [int, optional]

minute [int, optional]

second [int, optional]

microsecond [int, optional]

nanosecond [int, optional]

tzinfo [tz-convertible, optional]

fold [int, optional]

Returns

Timestamp with fields replaced

Examples

Create a timestamp object:

```
>>> ts = pd.Timestamp('2020-03-14T15:32:52.192548651', tz='UTC')
>>> ts
Timestamp('2020-03-14 15:32:52.192548651+0000', tz='UTC')
```

Replace year and the hour:

```
>>> ts.replace(year=1999, hour=10)
Timestamp('1999-03-14 10:32:52.192548651+0000', tz='UTC')
```

Replace timezone (not a conversion):

```
>>> import pytz
>>> ts.replace(tzinfo=pytz.timezone('US/Pacific'))
Timestamp('2020-03-14 15:32:52.192548651-0700', tz='US/Pacific')
```

Analogous for pd.NaT:

```
>>> pd.NaT.replace(tzinfo=pytz.timezone('US/Pacific'))
NaT
```

pandas.Timestamp.round

`Timestamp.round(freq, ambiguous='raise', nonexistent='raise')`

Round the Timestamp to the specified resolution.

Parameters

freq [str] Frequency string indicating the rounding resolution.

ambiguous [bool or {'raise', 'NaT'}, default 'raise'] The behavior is as follows:

- bool contains flags to determine if time is dst or not (note that this flag is only applicable for ambiguous fall dst dates).
- 'NaT' will return NaT for an ambiguous time.
- 'raise' will raise an AmbiguousTimeError for an ambiguous time.

nonexistent [{'raise', 'shift_forward', 'shift_backward', 'NaT', timedelta}, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- 'shift_forward' will shift the nonexistent time forward to the closest existing time.
- 'shift_backward' will shift the nonexistent time backward to the closest existing time.
- 'NaT' will return NaT where there are nonexistent times.
- timedelta objects will shift nonexistent times by the timedelta.
- 'raise' will raise a NonExistentTimeError if there are nonexistent times.

Returns

a new Timestamp rounded to the given resolution of *freq*
Raises
ValueError if the *freq* cannot be converted

Examples

Create a timestamp object:

```
>>> ts = pd.Timestamp('2020-03-14T15:32:52.192548651')
```

A timestamp can be rounded using multiple frequency units:

```
>>> ts.round(freq='H') # hour
Timestamp('2020-03-14 16:00:00')
```

```
>>> ts.round(freq='T') # minute
Timestamp('2020-03-14 15:33:00')
```

```
>>> ts.round(freq='S') # seconds
Timestamp('2020-03-14 15:32:52')
```

```
>>> ts.round(freq='L') # milliseconds
Timestamp('2020-03-14 15:32:52.193000')
```

freq can also be a multiple of a single unit, like '5T' (i.e. 5 minutes):

```
>>> ts.round(freq='5T')
Timestamp('2020-03-14 15:35:00')
```

or a combination of multiple units, like '1H30T' (i.e. 1 hour and 30 minutes):

```
>>> ts.round(freq='1H30T')
Timestamp('2020-03-14 15:00:00')
```

Analogous for `pd.NaT`:

```
>>> pd.NaT.round()
NaT
```

`pandas.Timestamp.strftime`

`Timestamp.strftime(format)`

Return a string representing the given POSIX timestamp controlled by an explicit format string.

Parameters

format [str] Format string to convert Timestamp to string. See `strftime` documentation for more information on the format string: <https://docs.python.org/3/library/datetime.html#strftime-and-strptime-behavior>.

Examples

```
>>> ts = pd.Timestamp('2020-03-14T15:32:52.192548651')
>>> ts.strftime('%Y-%m-%d %X')
'2020-03-14 15:32:52'
```

pandas.Timestamp.strptime

classmethod `Timestamp.strptime(string, format)`
Function is not implemented. Use `pd.to_datetime()`.

pandas.Timestamp.time

`Timestamp.time()`
Return time object with same time but with `tzinfo=None`.

pandas.Timestamp.timestamp

`Timestamp.timestamp()`
Return POSIX timestamp as float.

Examples

```
>>> ts = pd.Timestamp('2020-03-14T15:32:52.192548')
>>> ts.timestamp()
1584199972.192548
```

pandas.Timestamp.timetuple

`Timestamp.timetuple()`
Return time tuple, compatible with `time.localtime()`.

pandas.Timestamp.timetz

`Timestamp.timetz()`
Return time object with same time and `tzinfo`.

`pandas.Timestamp.to_datetime64`

`Timestamp.to_datetime64()`

Return a `numpy.datetime64` object with 'ns' precision.

`pandas.Timestamp.to_julian_date`

`Timestamp.to_julian_date()`

Convert `TimeStamp` to a Julian Date. 0 Julian date is noon January 1, 4713 BC.

Examples

```
>>> ts = pd.Timestamp('2020-03-14T15:32:52')
>>> ts.to_julian_date()
2458923.147824074
```

`pandas.Timestamp.to_numpy`

`Timestamp.to_numpy()`

Convert the `Timestamp` to a NumPy `datetime64`.

New in version 0.25.0.

This is an alias method for `Timestamp.to_datetime64()`. The `dtype` and `copy` parameters are available here only for compatibility. Their values will not affect the return value.

Returns

`numpy.datetime64`

See also:

`DatetimeIndex.to_numpy` Similar method for `DatetimeIndex`.

Examples

```
>>> ts = pd.Timestamp('2020-03-14T15:32:52.192548651')
>>> ts.to_numpy()
numpy.datetime64('2020-03-14T15:32:52.192548651')
```

Analogous for `pd.NaT`:

```
>>> pd.NaT.to_numpy()
numpy.datetime64('NaT')
```

pandas.Timestamp.to_period

Timestamp.to_period()

Return an period of which this timestamp is an observation.

Examples

```
>>> ts = pd.Timestamp('2020-03-14T15:32:52.192548651')
>>> ts.to_period(freq='Y') # Year end frequency
numpy.datetime64('2020-03-14T15:32:52.192548651')
```

```
>>> ts.to_period(freq='M') # Month end frequency
Period('2020-03', 'M')
```

```
>>> ts.to_period(freq='W') # Weekly frequency
Period('2020-03-09/2020-03-15', 'W-SUN')
```

```
>>> ts.to_period(freq='Q') # Quarter end frequency
Period('2020Q1', 'Q-DEC')
```

pandas.Timestamp.to_pydatetime

Timestamp.to_pydatetime()

Convert a Timestamp object to a native Python datetime object.

If warn=True, issue a warning if nanoseconds is nonzero.

Examples

```
>>> ts = pd.Timestamp('2020-03-14T15:32:52.192548')
>>> ts.to_pydatetime()
datetime.datetime(2020, 3, 14, 15, 32, 52, 192548)
```

Analogous for pd.NaT:

```
>>> pd.NaT.to_pydatetime()
NaT
```

pandas.Timestamp.today

classmethod Timestamp.today(cls, tz=None)

Return the current time in the local timezone. This differs from datetime.today() in that it can be localized to a passed timezone.

Parameters

tz [str or timezone object, default None] Timezone to localize to.

Examples

```
>>> pd.Timestamp.today()
Timestamp('2020-11-16 22:37:39.969883')
```

Analogous for `pd.NaT`:

```
>>> pd.NaT.today()
NaT
```

`pandas.Timestamp.toordinal`

`Timestamp.toordinal()`

Return proleptic Gregorian ordinal. January 1 of year 1 is day 1.

`pandas.Timestamp.tz_convert`

`Timestamp.tz_convert(tz)`

Convert tz-aware Timestamp to another time zone.

Parameters

tz [str, pytz.timezone, dateutil.tz.tzfile or None] Time zone for time which Timestamp will be converted to. None will remove timezone holding UTC time.

Returns

converted [Timestamp]

Raises

TypeError If Timestamp is tz-naive.

Examples

Create a timestamp object with UTC timezone:

```
>>> ts = pd.Timestamp('2020-03-14T15:32:52.192548651', tz='UTC')
>>> ts
Timestamp('2020-03-14 15:32:52.192548651+0000', tz='UTC')
```

Change to Tokyo timezone:

```
>>> ts.tz_convert(tz='Asia/Tokyo')
Timestamp('2020-03-15 00:32:52.192548651+0900', tz='Asia/Tokyo')
```

Can also use `astimezone`:

```
>>> ts.astimezone(tz='Asia/Tokyo')
Timestamp('2020-03-15 00:32:52.192548651+0900', tz='Asia/Tokyo')
```

Analogous for `pd.NaT`:

```
>>> pd.NaT.tz_convert(tz='Asia/Tokyo')
NaT
```

pandas.Timestamp.tz_localize

`Timestamp.tz_localize(tz, ambiguous='raise', nonexistent='raise')`

Convert naive Timestamp to local time zone, or remove timezone from tz-aware Timestamp.

Parameters

tz [str, pytz.timezone, dateutil.tz.tzfile or None] Time zone for time which Timestamp will be converted to. None will remove timezone holding local time.

ambiguous [bool, 'NaT', default 'raise'] When clocks moved backward due to DST, ambiguous times may arise. For example in Central European Time (UTC+01), when going from 03:00 DST to 02:00 non-DST, 02:30:00 local time occurs both at 00:30:00 UTC and at 01:30:00 UTC. In such a situation, the *ambiguous* parameter dictates how ambiguous times should be handled.

The behavior is as follows:

- bool contains flags to determine if time is dst or not (note that this flag is only applicable for ambiguous fall dst dates).
- 'NaT' will return NaT for an ambiguous time.
- 'raise' will raise an AmbiguousTimeError for an ambiguous time.

nonexistent ['shift_forward', 'shift_backward', 'NaT', timedelta, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

The behavior is as follows:

- 'shift_forward' will shift the nonexistent time forward to the closest existing time.
- 'shift_backward' will shift the nonexistent time backward to the closest existing time.
- 'NaT' will return NaT where there are nonexistent times.
- timedelta objects will shift nonexistent times by the timedelta.
- 'raise' will raise a NonExistentTimeError if there are nonexistent times.

Returns

localized [Timestamp]

Raises

TypeError If the Timestamp is tz-aware and tz is not None.

Examples

Create a naive timestamp object:

```
>>> ts = pd.Timestamp('2020-03-14T15:32:52.192548651')
>>> ts
Timestamp('2020-03-14 15:32:52.192548651')
```

Add 'Europe/Stockholm' as timezone:

```
>>> ts.tz_localize(tz='Europe/Stockholm')
Timestamp('2020-03-14 15:32:52.192548651+0100', tz='Europe/Stockholm')
```

Analogous for pd.NaT:

```
>>> pd.NaT.tz_localize()
NaT
```

pandas.Timestamp.tzname

`Timestamp.tzname()`
Return self.tzinfo.tzname(self).

pandas.Timestamp.utctimestamp

classmethod `Timestamp.utctimestamp(ts)`
Construct a naive UTC datetime from a POSIX timestamp.

Examples

```
>>> pd.Timestamp.fromtimestamp(1584199972)
Timestamp('2020-03-14 15:32:52')
```

pandas.Timestamp.utcnow

classmethod `Timestamp.utcnow()`
Return a new Timestamp representing UTC day and time.

Examples

```
>>> pd.Timestamp.utcnow()
Timestamp('2020-11-16 22:50:18.092888+0000', tz='UTC')
```

pandas.Timestamp.utcoffset

`Timestamp.utcoffset()`
Return `self.tzinfo.utcoffset(self)`.

pandas.Timestamp.utctimetuple

`Timestamp.utctimetuple()`
Return UTC time tuple, compatible with `time.localtime()`.

pandas.Timestamp.weekday

`Timestamp.weekday()`
Return the day of the week represented by the date. Monday == 0 ... Sunday == 6

Properties

| | |
|---|--|
| <code>Timestamp.asm8</code> | Return numpy datetime64 format in nanoseconds. |
| <code>Timestamp.day</code> | |
| <code>Timestamp.dayofweek</code> | Return day of the week. |
| <code>Timestamp.day_of_week</code> | Return day of the week. |
| <code>Timestamp.dayofyear</code> | Return the day of the year. |
| <code>Timestamp.day_of_year</code> | Return the day of the year. |
| <code>Timestamp.days_in_month</code> | Return the number of days in the month. |
| <code>Timestamp.daysinmonth</code> | Return the number of days in the month. |
| <code>Timestamp.fold</code> | |
| <code>Timestamp.hour</code> | |
| <code>Timestamp.is_leap_year</code> | Return True if year is a leap year. |
| <code>Timestamp.is_month_end</code> | Return True if date is last day of month. |
| <code>Timestamp.is_month_start</code> | Return True if date is first day of month. |
| <code>Timestamp.is_quarter_end</code> | Return True if date is last day of the quarter. |
| <code>Timestamp.is_quarter_start</code> | Return True if date is first day of the quarter. |
| <code>Timestamp.is_year_end</code> | Return True if date is last day of the year. |
| <code>Timestamp.is_year_start</code> | Return True if date is first day of the year. |
| <code>Timestamp.max</code> | |
| <code>Timestamp.microsecond</code> | |
| <code>Timestamp.min</code> | |
| <code>Timestamp.minute</code> | |
| <code>Timestamp.month</code> | |

continues on next page

Table 90 – continued from previous page

| | |
|-----------------------------|-------------------------------------|
| <i>Timestamp.nanosecond</i> | |
| <i>Timestamp.quarter</i> | Return the quarter of the year. |
| <i>Timestamp.resolution</i> | |
| <i>Timestamp.second</i> | |
| <i>Timestamp.tz</i> | Alias for tzinfo. |
| <i>Timestamp.tzinfo</i> | |
| <i>Timestamp.value</i> | |
| <i>Timestamp.week</i> | Return the week number of the year. |
| <i>Timestamp.weekofyear</i> | Return the week number of the year. |
| <i>Timestamp.year</i> | |

pandas.Timestamp.day

`Timestamp.day`

pandas.Timestamp.fold

`Timestamp.fold`

pandas.Timestamp.hour

`Timestamp.hour`

pandas.Timestamp.max

`Timestamp.max = Timestamp('2262-04-11 23:47:16.854775807')`

pandas.Timestamp.microsecond

`Timestamp.microsecond`

pandas.Timestamp.min

`Timestamp.min = Timestamp('1677-09-21 00:12:43.145224193')`

pandas.Timestamp.minute

`Timestamp.minute`

pandas.Timestamp.month

`Timestamp.month`

pandas.Timestamp.nanosecond

`Timestamp.nanosecond`

pandas.Timestamp.resolution

`Timestamp.resolution = Timedelta('0 days 00:00:00.000000001')`

pandas.Timestamp.second

`Timestamp.second`

pandas.Timestamp.tzinfo

`Timestamp.tzinfo`

pandas.Timestamp.value

`Timestamp.value`

pandas.Timestamp.year

`Timestamp.year`

Methods

| | |
|---|---|
| <i>Timestamp. astimezone</i> (tz) | Convert tz-aware Timestamp to another time zone. |
| <i>Timestamp. ceil</i> (freq[, ambiguous, nonexistent]) | Return a new Timestamp ceiled to this resolution. |
| <i>Timestamp. combine</i> (date, time) | Combine date, time into datetime with same date and time fields. |
| <i>Timestamp. ctime</i> | Return ctime() style string. |
| <i>Timestamp. date</i> | Return date object with same year, month and day. |
| <i>Timestamp. day_name</i> | Return the day name of the Timestamp with specified locale. |
| <i>Timestamp. dst</i> | Return self.tzinfo.dst(self). |
| <i>Timestamp. floor</i> (freq[, ambiguous, nonexistent]) | Return a new Timestamp floored to this resolution. |
| <i>Timestamp. freq</i> | |
| <i>Timestamp. freqstr</i> | Return the total number of days in the month. |
| <i>Timestamp. fromordinal</i> (ordinal[, freq, tz]) | Passed an ordinal, translate and convert to a ts. |
| <i>Timestamp. fromtimestamp</i> (ts) | Transform timestamp[, tz] to tz's local time from POSIX timestamp. |
| <i>Timestamp. isocalendar</i> | Return a 3-tuple containing ISO year, week number, and weekday. |
| <i>Timestamp. isoformat</i> | [sep] -> string in ISO 8601 format, YYYY-MM-DDT[HH[:MM[:SS[.mmm[uuu]]]]][+HH:MM]. |
| <i>Timestamp. isoweekday</i> | Return the day of the week represented by the date. |
| <i>Timestamp. month_name</i> | Return the month name of the Timestamp with specified locale. |
| <i>Timestamp. normalize</i> | Normalize Timestamp to midnight, preserving tz information. |
| <i>Timestamp. now</i> ([tz]) | Return new Timestamp object representing current time local to tz. |
| <i>Timestamp. replace</i> ([year, month, day, hour, ...]) | Implements datetime.replace, handles nanoseconds. |
| <i>Timestamp. round</i> (freq[, ambiguous, nonexistent]) | Round the Timestamp to the specified resolution. |
| <i>Timestamp. strftime</i> (format) | Return a string representing the given POSIX timestamp controlled by an explicit format string. |
| <i>Timestamp. strptime</i> (string, format) | Function is not implemented. |
| <i>Timestamp. time</i> | Return time object with same time but with tzinfo=None. |
| <i>Timestamp. timestamp</i> | Return POSIX timestamp as float. |
| <i>Timestamp. timetuple</i> | Return time tuple, compatible with time.localtime(). |
| <i>Timestamp. timetz</i> | Return time object with same time and tzinfo. |
| <i>Timestamp. to_datetime64</i> | Return a numpy.datetime64 object with 'ns' precision. |
| <i>Timestamp. to_numpy</i> | Convert the Timestamp to a NumPy datetime64. |
| <i>Timestamp. to_julian_date</i> () | Convert TimeStamp to a Julian Date. |
| <i>Timestamp. to_period</i> | Return an period of which this timestamp is an observation. |
| <i>Timestamp. to_pydatetime</i> | Convert a Timestamp object to a native Python datetime object. |
| <i>Timestamp. today</i> (cls[, tz]) | Return the current time in the local timezone. |
| <i>Timestamp. toordinal</i> | Return proleptic Gregorian ordinal. |
| <i>Timestamp. tz_convert</i> (tz) | Convert tz-aware Timestamp to another time zone. |
| <i>Timestamp. tz_localize</i> (tz[, ambiguous, ...]) | Convert naive Timestamp to local time zone, or remove timezone from tz-aware Timestamp. |
| <i>Timestamp. tzname</i> | Return self.tzinfo.tzname(self). |

Table 91 – continued from previous page

| | |
|---|--|
| <code>Timestamp.utctimestamp(ts)</code> | Construct a naive UTC datetime from a POSIX timestamp. |
| <code>Timestamp.utcnow()</code> | Return a new Timestamp representing UTC day and time. |
| <code>Timestamp.utcoffset</code> | Return <code>self.tzinfo.utcoffset(self)</code> . |
| <code>Timestamp.utctimetuple</code> | Return UTC time tuple, compatible with <code>time.localtime()</code> . |
| <code>Timestamp.weekday</code> | Return the day of the week represented by the date. |

pandas.Timestamp.freq

Timestamp.freq

A collection of timestamps may be stored in a `arrays.DatetimeArray`. For timezone-aware data, the `.dtype` of a `DatetimeArray` is a `DatetimeTZDtype`. For timezone-naive data, `np.dtype("datetime64[ns]")` is used.

If the data are tz-aware, then every value in the array must have the same timezone.

| | |
|--|---|
| <code>arrays.DatetimeArray(values[, dtype, freq, copy])</code> | Pandas ExtensionArray for tz-naive or tz-aware datetime data. |
|--|---|

pandas.arrays.DatetimeArray

class `pandas.arrays.DatetimeArray(values, dtype=dtype('<M8[ns]'), freq=None, copy=False)`
Pandas ExtensionArray for tz-naive or tz-aware datetime data.

Warning: `DatetimeArray` is currently experimental, and its API may change without warning. In particular, `DatetimeArray.dtype` is expected to change to always be an instance of an `ExtensionDtype` subclass.

Parameters

values [Series, Index, `DatetimeArray`, ndarray] The datetime data.

For `DatetimeArray` *values* (or a Series or Index boxing one), *dtype* and *freq* will be extracted from *values*.

dtype [numpy.dtype or `DatetimeTZDtype`] Note that the only NumPy dtype allowed is 'datetime64[ns]'.

freq [str or Offset, optional] The frequency.

copy [bool, default False] Whether to copy the underlying array of values.

Attributes

None

Methods

None

DatetimeTZDtype([unit, tz])An ExtensionDtype for timezone-aware datetime data.

pandas.DatetimeTZDtype

class pandas.**DatetimeTZDtype**(*unit='ns', tz=None*)
An ExtensionDtype for timezone-aware datetime data.

This is not an actual numpy dtype, but a duck type.

Parameters

unit [str, default “ns”] The precision of the datetime data. Currently limited to "ns".

tz [str, int, or datetime.tzinfo] The timezone.

Raises

pytz.UnknownTimeZoneError When the requested timezone cannot be found.

Examples

```
>>> pd.DatetimeTZDtype(tz='UTC')
datetime64[ns, UTC]
```

```
>>> pd.DatetimeTZDtype(tz='dateutil/US/Central')
datetime64[ns, tzfile('/usr/share/zoneinfo/US/Central')]
```

Attributes

unit

The precision of the datetime data.

*tz*The timezone.

pandas.DatetimeTZDtype.unit

property `DatetimeTZDtype.unit`
The precision of the datetime data.

pandas.DatetimeTZDtype.tz

property `DatetimeTZDtype.tz`
The timezone.

Methods

| | |
|------|--|
| None | |
|------|--|

3.5.3 Timedelta data

NumPy can natively represent timedeltas. pandas provides *Timedelta* for symmetry with *Timestamp*.

| | |
|----------------------------------|---|
| <i>Timedelta</i> ([value, unit]) | Represents a duration, the difference between two dates or times. |
|----------------------------------|---|

pandas.Timedelta

class `pandas.Timedelta`(*value=<object object>*, *unit=None*, ***kwargs*)
Represents a duration, the difference between two dates or times.

Timedelta is the pandas equivalent of python's `datetime.timedelta` and is interchangeable with it in most cases.

Parameters

value [Timedelta, timedelta, np.timedelta64, str, or int]

unit [str, default 'ns'] Denote the unit of the input, if input is an integer.

Possible values:

- 'W', 'D', 'T', 'S', 'L', 'U', or 'N'
- 'days' or 'day'
- 'hours', 'hour', 'hr', or 'h'
- 'minutes', 'minute', 'min', or 'm'
- 'seconds', 'second', or 'sec'
- 'milliseconds', 'millisecond', 'millis', or 'milli'
- 'microseconds', 'microsecond', 'micros', or 'micro'
- 'nanoseconds', 'nanosecond', 'nanos', 'nano', or 'ns'.

****kwargs** Available kwargs: {days, seconds, microseconds, milliseconds, minutes, hours, weeks}. Values for construction in compat with `datetime.timedelta`. Numpy ints and floats will be coerced to python ints and floats.

Notes

The `.value` attribute is always in ns.

If the precision is higher than nanoseconds, the precision of the duration is truncated to nanoseconds.

Attributes

| | |
|--------------------------------|---|
| <code>asm8</code> | Return a numpy timedelta64 array scalar view. |
| <code>components</code> | Return a components namedtuple-like. |
| <code>days</code> | Number of days. |
| <code>delta</code> | Return the timedelta in nanoseconds (ns), for internal compatibility. |
| <code>microseconds</code> | Number of microseconds (≥ 0 and less than 1 second). |
| <code>nanoseconds</code> | Return the number of nanoseconds (n), where $0 \leq n < 1$ microsecond. |
| <code>resolution_string</code> | Return a string representing the lowest timedelta resolution. |
| <code>seconds</code> | Number of seconds (≥ 0 and less than 1 day). |

pandas.Timedelta.asm8

Timedelta.asm8

Return a numpy timedelta64 array scalar view.

Provides access to the array scalar view (i.e. a combination of the value and the units) associated with the `numpy.timedelta64().view()`, including a 64-bit integer representation of the timedelta in nanoseconds (Python int compatible).

Returns

numpy timedelta64 array scalar view Array scalar view of the timedelta in nanoseconds.

Examples

```
>>> td = pd.Timedelta('1 days 2 min 3 us 42 ns')
>>> td.asm8
numpy.timedelta64(86520000003042, 'ns')
```

```
>>> td = pd.Timedelta('2 min 3 s')
>>> td.asm8
numpy.timedelta64(123000000000, 'ns')
```

```
>>> td = pd.Timedelta('3 ms 5 us')
>>> td.asm8
numpy.timedelta64(3005000, 'ns')
```

```
>>> td = pd.Timedelta(42, unit='ns')
>>> td.asm8
numpy.timedelta64(42, 'ns')
```

pandas.Timedelta.components

Timedelta.components

Return a components namedtuple-like.

pandas.Timedelta.days

Timedelta.days

Number of days.

pandas.Timedelta.delta

Timedelta.delta

Return the timedelta in nanoseconds (ns), for internal compatibility.

Returns

int Timedelta in nanoseconds.

Examples

```
>>> td = pd.Timedelta('1 days 42 ns')
>>> td.delta
86400000000042
```

```
>>> td = pd.Timedelta('3 s')
>>> td.delta
3000000000
```

```
>>> td = pd.Timedelta('3 ms 5 us')
>>> td.delta
3005000
```

```
>>> td = pd.Timedelta(42, unit='ns')
>>> td.delta
42
```

pandas.Timedelta.microseconds

Timedelta.microseconds

Number of microseconds (≥ 0 and less than 1 second).

pandas.Timedelta.nanoseconds

Timedelta.nanoseconds

Return the number of nanoseconds (n), where $0 \leq n < 1$ microsecond.

Returns

int Number of nanoseconds.

See also:

Timedelta.components Return all attributes with assigned values (i.e. days, hours, minutes, seconds, milliseconds, microseconds, nanoseconds).

Examples

Using string input

```
>>> td = pd.Timedelta('1 days 2 min 3 us 42 ns')
```

```
>>> td.nanoseconds
42
```

Using integer input

```
>>> td = pd.Timedelta(42, unit='ns')
>>> td.nanoseconds
42
```

pandas.Timedelta.resolution_string

Timedelta.resolution_string

Return a string representing the lowest timedelta resolution.

Each timedelta has a defined resolution that represents the lowest OR most granular level of precision. Each level of resolution is represented by a short string as defined below:

Resolution: Return value

- Days: 'D'
- Hours: 'H'
- Minutes: 'T'
- Seconds: 'S'
- Milliseconds: 'L'
- Microseconds: 'U'
- Nanoseconds: 'N'

Returns

str Timedelta resolution.

Examples

```
>>> td = pd.Timedelta('1 days 2 min 3 us 42 ns')
>>> td.resolution_string
'N'
```

```
>>> td = pd.Timedelta('1 days 2 min 3 us')
>>> td.resolution_string
'U'
```

```
>>> td = pd.Timedelta('2 min 3 s')
>>> td.resolution_string
'S'
```

```
>>> td = pd.Timedelta(36, unit='us')
>>> td.resolution_string
'U'
```

pandas.Timedelta.seconds

Timedelta.seconds

Number of seconds (≥ 0 and less than 1 day).

| | |
|---------------------|--|
| freq | |
| is_populated | |
| value | |

Methods

| | |
|-----------------------|--|
| <i>ceil</i> (freq) | Return a new Timedelta ceiled to this resolution. |
| <i>floor</i> (freq) | Return a new Timedelta floored to this resolution. |
| <i>isoformat</i> | Format Timedelta as ISO 8601 Duration like P[n]Y[n]M[n]DT[n]H[n]M[n]S, where the [n] s are replaced by the values. |
| <i>round</i> (freq) | Round the Timedelta to the specified resolution. |
| <i>to_numpy</i> | Convert the Timedelta to a NumPy timedelta64. |
| <i>to_pytimedelta</i> | Convert a pandas Timedelta object into a python timedelta object. |
| <i>to_timedelta64</i> | Return a numpy.timedelta64 object with 'ns' precision. |
| <i>total_seconds</i> | Total seconds in the duration. |
| <i>view</i> | Array view compatibility. |

`pandas.Timedelta.ceil`

`Timedelta.ceil(freq)`

Return a new `Timedelta` ceiled to this resolution.

Parameters

freq [str] Frequency string indicating the ceiling resolution.

`pandas.Timedelta.floor`

`Timedelta.floor(freq)`

Return a new `Timedelta` floored to this resolution.

Parameters

freq [str] Frequency string indicating the flooring resolution.

`pandas.Timedelta.isoformat`

`Timedelta.isoformat()`

Format `Timedelta` as ISO 8601 Duration like `P[n]Y[n]M[n]DT[n]H[n]M[n]S`, where the `[n]` s are replaced by the values. See https://en.wikipedia.org/wiki/ISO_8601#Durations.

Returns

`str`

See also:

[`Timestamp.isoformat`](#) Function is used to convert the given `Timestamp` object into the ISO format.

Notes

The longest component is days, whose value may be larger than 365. Every component is always included, even if its value is 0. Pandas uses nanosecond precision, so up to 9 decimal places may be included in the seconds component. Trailing 0's are removed from the seconds component after the decimal. We do not 0 pad components, so it's `...T5H...`, not `...T05H...`

Examples

```
>>> td = pd.Timedelta(days=6, minutes=50, seconds=3,
...                   milliseconds=10, microseconds=10, nanoseconds=12)
```

```
>>> td.isoformat()
'P6DT0H50M3.010010012S'
>>> pd.Timedelta(hours=1, seconds=10).isoformat()
'P0DT1H0M10S'
>>> pd.Timedelta(days=500.5).isoformat()
'P500DT12H0M0S'
```

pandas.Timedelta.round

`Timedelta.round(freq)`

Round the Timedelta to the specified resolution.

Parameters

freq [str] Frequency string indicating the rounding resolution.

Returns

a new Timedelta rounded to the given resolution of *freq*

Raises

ValueError if the freq cannot be converted

pandas.Timedelta.to_numpy

`Timedelta.to_numpy()`

Convert the Timedelta to a NumPy timedelta64.

New in version 0.25.0.

This is an alias method for `Timedelta.to_timedelta64()`. The dtype and copy parameters are available here only for compatibility. Their values will not affect the return value.

Returns

numpy.timedelta64

See also:

[*Series.to_numpy*](#) Similar method for Series.

pandas.Timedelta.to_pytimedelta

`Timedelta.to_pytimedelta()`

Convert a pandas Timedelta object into a python timedelta object.

Timedelta objects are internally saved as numpy datetime64[ns] dtype. Use `to_pytimedelta()` to convert to object dtype.

Returns

datetime.timedelta or numpy.array of datetime.timedelta

See also:

[*to_timedelta*](#) Convert argument to Timedelta type.

Notes

Any nanosecond resolution will be lost.

pandas.Timedelta.to_timedelta64

`Timedelta.to_timedelta64()`

Return a `numpy.timedelta64` object with 'ns' precision.

pandas.Timedelta.total_seconds

`Timedelta.total_seconds()`

Total seconds in the duration.

pandas.Timedelta.view

`Timedelta.view()`

Array view compatibility.

Properties

| | |
|-------------------------------------|--|
| <code>Timedelta.asm8</code> | Return a numpy <code>timedelta64</code> array scalar view. |
| <code>Timedelta.components</code> | Return a components namedtuple-like. |
| <code>Timedelta.days</code> | Number of days. |
| <code>Timedelta.delta</code> | Return the <code>timedelta</code> in nanoseconds (ns), for internal compatibility. |
| <code>Timedelta.freq</code> | |
| <code>Timedelta.is_populated</code> | |
| <code>Timedelta.max</code> | |
| <code>Timedelta.microseconds</code> | Number of microseconds (≥ 0 and less than 1 second). |
| <code>Timedelta.min</code> | |
| <code>Timedelta.nanoseconds</code> | Return the number of nanoseconds (n), where $0 \leq n < 1$ microsecond. |
| <code>Timedelta.resolution</code> | |
| <code>Timedelta.seconds</code> | Number of seconds (≥ 0 and less than 1 day). |
| <code>Timedelta.value</code> | |
| <code>Timedelta.view</code> | Array view compatibility. |

| <i>Timedelta.to_numpy</i> | Convert the Timedelta to a NumPy timedelta64. |
| <i>Timedelta.total_seconds</i> | Total seconds in the duration. |

A collection of timedeltas may be stored in a `TimedeltaArray`.

| | |
|---|---|
| <i>arrays.TimedeltaArray</i> (values[, dtype, freq, ...]) | Pandas ExtensionArray for timedelta data. |
|---|---|

pandas.arrays.TimedeltaArray

```
class pandas.arrays.TimedeltaArray(values, dtype=dtype('<m8[ns]'), freq=NoDefault.no_default,
                                   copy=False)
```

Pandas ExtensionArray for timedelta data.

Warning: TimedeltaArray is currently experimental, and its API may change without warning. In particular, `TimedeltaArray.dtype` is expected to change to be an instance of an `ExtensionDtype` subclass.

Parameters

- values** [array-like] The timedelta data.
- dtype** [numpy.dtype] Currently, only `numpy.dtype("timedelta64[ns]")` is accepted.
- freq** [Offset, optional]
- copy** [bool, default False] Whether to copy the underlying array of data.

|------|--|

Methods

| | |
|------|--|
| None | |
|------|--|

3.5.4 Timespan data

pandas represents spans of times as *Period* objects.

3.5.5 Period

| | |
|--|------------------------------|
| <i>Period</i> ([value, freq, ordinal, year, month, ...]) | Represents a period of time. |
|--|------------------------------|

pandas.Period

```
class pandas.Period(value=None, freq=None, ordinal=None, year=None, month=None, quarter=None,
                    day=None, hour=None, minute=None, second=None)
```

Represents a period of time.

Parameters

- value** [Period or str, default None] The time period represented (e.g., '4Q2005').
- freq** [str, default None] One of pandas period strings or corresponding objects.
- ordinal** [int, default None] The period offset from the proleptic Gregorian epoch.
- year** [int, default None] Year value of the period.

month [int, default 1] Month value of the period.

quarter [int, default None] Quarter value of the period.

day [int, default 1] Day value of the period.

hour [int, default 0] Hour value of the period.

minute [int, default 0] Minute value of the period.

second [int, default 0] Second value of the period.

Attributes

| | |
|----------------------|--|
| <i>day</i> | Get day of the month that a Period falls on. |
| <i>day_of_week</i> | Day of the week the period lies in, with Monday=0 and Sunday=6. |
| <i>day_of_year</i> | Return the day of the year. |
| <i>dayofweek</i> | Day of the week the period lies in, with Monday=0 and Sunday=6. |
| <i>dayofyear</i> | Return the day of the year. |
| <i>days_in_month</i> | Get the total number of days in the month that this period falls on. |
| <i>daysinmonth</i> | Get the total number of days of the month that the Period falls in. |
| <i>hour</i> | Get the hour of the day component of the Period. |
| <i>minute</i> | Get minute of the hour component of the Period. |
| <i>qyear</i> | Fiscal year the Period lies in according to its starting-quarter. |
| <i>second</i> | Get the second component of the Period. |
| <i>start_time</i> | Get the Timestamp for the start of the period. |
| <i>week</i> | Get the week of the year on the given Period. |
| <i>weekday</i> | Day of the week the period lies in, with Monday=0 and Sunday=6. |

pandas.Period.day

Period.day

Get day of the month that a Period falls on.

Returns

int

See also:

Period.dayofweek Get the day of the week.

Period.dayofyear Get the day of the year.

Examples

```
>>> p = pd.Period("2018-03-11", freq='H')
>>> p.day
11
```

pandas.Period.day_of_week

Period.day_of_week

Day of the week the period lies in, with Monday=0 and Sunday=6.

If the period frequency is lower than daily (e.g. hourly), and the period spans over multiple days, the day at the start of the period is used.

If the frequency is higher than daily (e.g. monthly), the last day of the period is used.

Returns

int Day of the week.

See also:

Period.day_of_week Day of the week the period lies in.

Period.weekday Alias of Period.day_of_week.

Period.day Day of the month.

Period.dayofyear Day of the year.

Examples

```
>>> per = pd.Period('2017-12-31 22:00', 'H')
>>> per.day_of_week
6
```

For periods that span over multiple days, the day at the beginning of the period is returned.

```
>>> per = pd.Period('2017-12-31 22:00', '4H')
>>> per.day_of_week
6
>>> per.start_time.day_of_week
6
```

For periods with a frequency higher than days, the last day of the period is returned.

```
>>> per = pd.Period('2018-01', 'M')
>>> per.day_of_week
2
>>> per.end_time.day_of_week
2
```

pandas.Period.day_of_year

Period.day_of_year

Return the day of the year.

This attribute returns the day of the year on which the particular date occurs. The return value ranges between 1 to 365 for regular years and 1 to 366 for leap years.

Returns

int The day of year.

See also:

Period.day Return the day of the month.

Period.day_of_week Return the day of week.

PeriodIndex.day_of_year Return the day of year of all indexes.

Examples

```

>>> period = pd.Period("2015-10-23", freq='H')
>>> period.day_of_year
296
>>> period = pd.Period("2012-12-31", freq='D')
>>> period.day_of_year
366
>>> period = pd.Period("2013-01-01", freq='D')
>>> period.day_of_year
1

```

pandas.Period.dayofweek

Period.dayofweek

Day of the week the period lies in, with Monday=0 and Sunday=6.

If the period frequency is lower than daily (e.g. hourly), and the period spans over multiple days, the day at the start of the period is used.

If the frequency is higher than daily (e.g. monthly), the last day of the period is used.

Returns

int Day of the week.

See also:

Period.day_of_week Day of the week the period lies in.

Period.weekday Alias of Period.day_of_week.

Period.day Day of the month.

Period.dayofyear Day of the year.

Examples

```
>>> per = pd.Period('2017-12-31 22:00', 'H')
>>> per.day_of_week
6
```

For periods that span over multiple days, the day at the beginning of the period is returned.

```
>>> per = pd.Period('2017-12-31 22:00', '4H')
>>> per.day_of_week
6
>>> per.start_time.day_of_week
6
```

For periods with a frequency higher than days, the last day of the period is returned.

```
>>> per = pd.Period('2018-01', 'M')
>>> per.day_of_week
2
>>> per.end_time.day_of_week
2
```

pandas.Period.dayofyear

Period.dayofyear

Return the day of the year.

This attribute returns the day of the year on which the particular date occurs. The return value ranges between 1 to 365 for regular years and 1 to 366 for leap years.

Returns

int The day of year.

See also:

Period.day Return the day of the month.

Period.day_of_week Return the day of week.

PeriodIndex.day_of_year Return the day of year of all indexes.

Examples

```
>>> period = pd.Period("2015-10-23", freq='H')
>>> period.day_of_year
296
>>> period = pd.Period("2012-12-31", freq='D')
>>> period.day_of_year
366
>>> period = pd.Period("2013-01-01", freq='D')
>>> period.day_of_year
1
```

pandas.Period.days_in_month

Period.days_in_month

Get the total number of days in the month that this period falls on.

Returns

int

See also:

Period.daysinmonth Gets the number of days in the month.

DatetimeIndex.daysinmonth Gets the number of days in the month.

calendar.monthrange Returns a tuple containing weekday (0-6 ~ Mon-Sun) and number of days (28-31).

Examples

```
>>> p = pd.Period('2018-2-17')
>>> p.days_in_month
28
```

```
>>> pd.Period('2018-03-01').days_in_month
31
```

Handles the leap year case as well:

```
>>> p = pd.Period('2016-2-17')
>>> p.days_in_month
29
```

pandas.Period.daysinmonth

Period.daysinmonth

Get the total number of days of the month that the Period falls in.

Returns

int

See also:

Period.days_in_month Return the days of the month.

Period.dayofyear Return the day of the year.

Examples

```
>>> p = pd.Period("2018-03-11", freq='H')
>>> p.daysinmonth
31
```

pandas.Period.hour

Period.hour

Get the hour of the day component of the Period.

Returns

int The hour as an integer, between 0 and 23.

See also:

Period.second Get the second component of the Period.

Period.minute Get the minute component of the Period.

Examples

```
>>> p = pd.Period("2018-03-11 13:03:12.050000")
>>> p.hour
13
```

Period longer than a day

```
>>> p = pd.Period("2018-03-11", freq="M")
>>> p.hour
0
```

pandas.Period.minute

Period.minute

Get minute of the hour component of the Period.

Returns

int The minute as an integer, between 0 and 59.

See also:

Period.hour Get the hour component of the Period.

Period.second Get the second component of the Period.

Examples

```
>>> p = pd.Period("2018-03-11 13:03:12.050000")
>>> p.minute
3
```

pandas.Period.qyear

Period.qyear

Fiscal year the Period lies in according to its starting-quarter.

The *year* and the *qyear* of the period will be the same if the fiscal and calendar years are the same. When they are not, the fiscal year can be different from the calendar year of the period.

Returns

int The fiscal year of the period.

See also:

Period.year Return the calendar year of the period.

Examples

If the natural and fiscal year are the same, *qyear* and *year* will be the same.

```
>>> per = pd.Period('2018Q1', freq='Q')
>>> per.qyear
2018
>>> per.year
2018
```

If the fiscal year starts in April (*Q-MAR*), the first quarter of 2018 will start in April 2017. *year* will then be 2018, but *qyear* will be the fiscal year, 2018.

```
>>> per = pd.Period('2018Q1', freq='Q-MAR')
>>> per.start_time
Timestamp('2017-04-01 00:00:00')
>>> per.qyear
2018
>>> per.year
2017
```

pandas.Period.second

Period.second

Get the second component of the Period.

Returns

int The second of the Period (ranges from 0 to 59).

See also:

Period.hour Get the hour component of the Period.

Period.minute Get the minute component of the Period.

Examples

```
>>> p = pd.Period("2018-03-11 13:03:12.050000")
>>> p.second
12
```

pandas.Period.start_time

Period.start_time

Get the Timestamp for the start of the period.

Returns

Timestamp

See also:

Period.end_time Return the end Timestamp.

Period.dayofyear Return the day of year.

Period.daysinmonth Return the days in that month.

Period.dayofweek Return the day of the week.

Examples

```
>>> period = pd.Period('2012-1-1', freq='D')
>>> period
Period('2012-01-01', 'D')
```

```
>>> period.start_time
Timestamp('2012-01-01 00:00:00')
```

```
>>> period.end_time
Timestamp('2012-01-01 23:59:59.999999999')
```

pandas.Period.week

Period.week

Get the week of the year on the given Period.

Returns

int

See also:

Period.dayofweek Get the day component of the Period.

Period.weekday Get the day component of the Period.

Examples

```
>>> p = pd.Period("2018-03-11", "H")
>>> p.week
10
```

```
>>> p = pd.Period("2018-02-01", "D")
>>> p.week
5
```

```
>>> p = pd.Period("2018-01-06", "D")
>>> p.week
1
```

pandas.Period.weekday

Period.weekday

Day of the week the period lies in, with Monday=0 and Sunday=6.

If the period frequency is lower than daily (e.g. hourly), and the period spans over multiple days, the day at the start of the period is used.

If the frequency is higher than daily (e.g. monthly), the last day of the period is used.

Returns

int Day of the week.

See also:

Period.dayofweek Day of the week the period lies in.

Period.weekday Alias of Period.dayofweek.

Period.day Day of the month.

Period.dayofyear Day of the year.

Examples

```
>>> per = pd.Period('2017-12-31 22:00', 'H')
>>> per.dayofweek
6
```

For periods that span over multiple days, the day at the beginning of the period is returned.

```
>>> per = pd.Period('2017-12-31 22:00', '4H')
>>> per.dayofweek
6
>>> per.start_time.dayofweek
6
```

For periods with a frequency higher than days, the last day of the period is returned.

```
>>> per = pd.Period('2018-01', 'M')
>>> per.dayofweek
2
>>> per.end_time.dayofweek
2
```

| | |
|--------------|--|
| end_time | |
| freq | |
| freqstr | |
| is_leap_year | |
| month | |
| ordinal | |
| quarter | |
| weekofyear | |
| year | |

Methods

| | |
|---------------------|---|
| <i>asfreq</i> | Convert Period to desired frequency, at the start or end of the interval. |
| <i>strftime</i> | Returns the string representation of the <i>Period</i> , depending on the selected <i>fmt</i> . |
| <i>to_timestamp</i> | Return the Timestamp representation of the Period. |

pandas.Period.asfreq

Period.asfreq()

Convert Period to desired frequency, at the start or end of the interval.

Parameters

freq [str] The desired frequency.

how [{ 'E', 'S', 'end', 'start' }, default 'end'] Start or end of the timespan.

Returns

resampled [Period]

pandas.Period.strftime

Period.strftime()

Returns the string representation of the *Period*, depending on the selected *fmt*. *fmt* must be a string containing one or several directives. The method recognizes the same directives as the `time.strftime()` function of the standard Python distribution, as well as the specific additional directives %f, %F, %q. (formatting & docs originally from scikits.timeries).

| Directive | Meaning | Notes |
|-----------|--|-------|
| %a | Locale's abbreviated weekday name. | |
| %A | Locale's full weekday name. | |
| %b | Locale's abbreviated month name. | |
| %B | Locale's full month name. | |
| %c | Locale's appropriate date and time representation. | |
| %d | Day of the month as a decimal number [01,31]. | |
| %f | 'Fiscal' year without a century as a decimal number [00,99] | (1) |
| %F | 'Fiscal' year with a century as a decimal number | (2) |
| %H | Hour (24-hour clock) as a decimal number [00,23]. | |
| %I | Hour (12-hour clock) as a decimal number [01,12]. | |
| %j | Day of the year as a decimal number [001,366]. | |
| %m | Month as a decimal number [01,12]. | |
| %M | Minute as a decimal number [00,59]. | |
| %p | Locale's equivalent of either AM or PM. | (3) |
| %q | Quarter as a decimal number [01,04] | |
| %S | Second as a decimal number [00,61]. | (4) |
| %U | Week number of the year (Sunday as the first day of the week) as a decimal number [00,53]. All days in a new year preceding the first Sunday are considered to be in week 0. | (5) |
| %w | Weekday as a decimal number [0(Sunday),6]. | |
| %W | Week number of the year (Monday as the first day of the week) as a decimal number [00,53]. All days in a new year preceding the first Monday are considered to be in week 0. | (5) |
| %x | Locale's appropriate date representation. | |
| %X | Locale's appropriate time representation. | |
| %y | Year without century as a decimal number [00,99]. | |
| %Y | Year with century as a decimal number. | |
| %Z | Time zone name (no characters if no time zone exists). | |
| %% | A literal '%' character. | |

Notes

- (1) The %f directive is the same as %y if the frequency is not quarterly. Otherwise, it corresponds to the 'fiscal' year, as defined by the [qyear](#) attribute.
- (2) The %F directive is the same as %Y if the frequency is not quarterly. Otherwise, it corresponds to the 'fiscal' year, as defined by the [qyear](#) attribute.
- (3) The %p directive only affects the output hour field if the %I directive is used to parse the hour.
- (4) The range really is 0 to 61; this accounts for leap seconds and the (very rare) double leap seconds.
- (5) The %U and %W directives are only used in calculations when the day of the week and the year are specified.

Examples

```
>>> a = Period(freq='Q-JUL', year=2006, quarter=1)
>>> a.strftime('%F-Q%q')
'2006-Q1'
>>> # Output the last month in the quarter of this date
>>> a.strftime('%b-%Y')
'Oct-2005'
>>>
>>> a = Period(freq='D', year=2001, month=1, day=1)
>>> a.strftime('%d-%b-%Y')
'01-Jan-2006'
>>> a.strftime('%b. %d, %Y was a %A')
'Jan. 01, 2001 was a Monday'
```

pandas.Period.to_timestamp

Period.to_timestamp()

Return the Timestamp representation of the Period.

Uses the target frequency specified at the part of the period specified by *how*, which is either *Start* or *Finish*.

Parameters

freq [str or DateOffset] Target frequency. Default is 'D' if self.freq is week or longer and 'S' otherwise.

how [str, default 'S' (start)] One of 'S', 'E'. Can be aliased as case insensitive 'Start', 'Finish', 'Begin', 'End'.

Returns

Timestamp

| | |
|-----|--|
| now | |
|-----|--|

Properties

| | |
|-----------------------------------|--|
| <code>Period.day</code> | Get day of the month that a Period falls on. |
| <code>Period.dayofweek</code> | Day of the week the period lies in, with Monday=0 and Sunday=6. |
| <code>Period.day_of_week</code> | Day of the week the period lies in, with Monday=0 and Sunday=6. |
| <code>Period.dayofyear</code> | Return the day of the year. |
| <code>Period.day_of_year</code> | Return the day of the year. |
| <code>Period.days_in_month</code> | Get the total number of days in the month that this period falls on. |
| <code>Period.daysinmonth</code> | Get the total number of days of the month that the Period falls in. |
| <code>Period.end_time</code> | |

Methods

| | |
|----------------------------|---|
| <i>Period.asfreq</i> | Convert Period to desired frequency, at the start or end of the interval. |
| <i>Period.now</i> | |
| <i>Period.strftime</i> | Returns the string representation of the <i>Period</i> , depending on the selected <i>fmt</i> . |
| <i>Period.to_timestamp</i> | Return the Timestamp representation of the Period. |

pandas.Period.now

Period.**now()**

A collection of timedeltas may be stored in a *arrays.PeriodArray*. Every period in a *PeriodArray* must have the same *freq*.

| | |
|---|--|
| <i>arrays.PeriodArray</i> (values[, dtype, freq, copy]) | Pandas ExtensionArray for storing Period data. |
|---|--|

pandas.arrays.PeriodArray

class pandas.arrays.**PeriodArray**(*values*, *dtype=None*, *freq=None*, *copy=False*)

Pandas ExtensionArray for storing Period data.

Users should use `period_array()` to create new instances. Alternatively, `array()` can be used to create new instances from a sequence of Period scalars.

Parameters

values [Union[PeriodArray, Series[period], ndarray[int], PeriodIndex]] The data to store. These should be arrays that can be directly converted to ordinals without inference or copy (PeriodArray, ndarray[int64]), or a box around such an array (Series[period], PeriodIndex).

dtype [PeriodDtype, optional] A PeriodDtype instance from which to extract a *freq*. If both *freq* and *dtype* are specified, then the frequencies must match.

freq [str or DateOffset] The *freq* to use for the array. Mostly applicable when *values* is an ndarray of integers, when *freq* is required. When *values* is a PeriodArray (or box around), it's checked that `values.freq` matches *freq*.

copy [bool, default False] Whether to copy the ordinals before storing.

See also:

Period Represents a period of time.

PeriodIndex Immutable Index for period data.

period_range Create a fixed-frequency PeriodArray.

array Construct a pandas array.

Notes

There are two components to a PeriodArray

- ordinals : integer ndarray
- freq : pd.tseries.offsets.Offset

The values are physically stored as a 1-D ndarray of integers. These are called “ordinals” and represent some kind of offset from a base.

The *freq* indicates the span covered by each element of the array. All elements in the PeriodArray have the same *freq*.

Attributes

| | |
|------|--|
| None | |
|------|--|

Methods

| | |
|------|--|
| None | |
|------|--|

PeriodDtype([freq])

An ExtensionDtype for Period data.

pandas.PeriodDtype

class pandas.PeriodDtype(*freq=None*)

An ExtensionDtype for Period data.

This is not an actual numpy dtype, but a duck type.

Parameters

freq [str or DateOffset] The frequency of this PeriodDtype.

Examples

```
>>> pd.PeriodDtype(freq='D')
period[D]
```

```
>>> pd.PeriodDtype(freq=pd.offsets.MonthEnd())
period[M]
```

Attributes

| | |
|-------------|---|
| <i>freq</i> | The frequency object of this PeriodDtype. |
|-------------|---|

pandas.PeriodDtype.freq

property PeriodDtype.**freq**

The frequency object of this PeriodDtype.

Methods

| None | |
|------|--|

3.5.6 Interval data

Arbitrary intervals can be represented as *Interval* objects.

| | |
|-----------------|---|
| <i>Interval</i> | Immutable object implementing an Interval, a bounded slice-like interval. |
|-----------------|---|

pandas.Interval

class pandas.Interval

Immutable object implementing an Interval, a bounded slice-like interval.

Parameters

left [orderable scalar] Left bound for the interval.

right [orderable scalar] Right bound for the interval.

closed [{ 'right', 'left', 'both', 'neither' }, default 'right'] Whether the interval is closed on the left-side, right-side, both or neither. See the Notes for more detailed explanation.

See also:

IntervalIndex An Index of Interval objects that are all closed on the same side.

cut Convert continuous data into discrete bins (Categorical of Interval objects).

qcut Convert continuous data into bins (Categorical of Interval objects) based on quantiles.

Period Represents a period of time.

Notes

The parameters *left* and *right* must be from the same type, you must be able to compare them and they must satisfy $left \leq right$.

A closed interval (in mathematics denoted by square brackets) contains its endpoints, i.e. the closed interval $[0, 5]$ is characterized by the conditions $0 \leq x \leq 5$. This is what `closed='both'` stands for. An open interval (in mathematics denoted by parentheses) does not contain its endpoints, i.e. the open interval $(0, 5)$ is characterized by the conditions $0 < x < 5$. This is what `closed='neither'` stands for. Intervals can also be half-open or half-closed, i.e. $[0, 5)$ is described by $0 \leq x < 5$ (`closed='left'`) and $(0, 5]$ is described by $0 < x \leq 5$ (`closed='right'`).

Examples

It is possible to build Intervals of different types, like numeric ones:

```
>>> iv = pd.Interval(left=0, right=5)
>>> iv
Interval(0, 5, closed='right')
```

You can check if an element belongs to it

```
>>> 2.5 in iv
True
```

You can test the bounds (`closed='right'`, so $0 < x \leq 5$):

```
>>> 0 in iv
False
>>> 5 in iv
True
>>> 0.0001 in iv
True
```

Calculate its length

```
>>> iv.length
5
```

You can operate with `+` and `*` over an Interval and the operation is applied to each of its bounds, so the result depends on the type of the bound elements

```
>>> shifted_iv = iv + 3
>>> shifted_iv
Interval(3, 8, closed='right')
>>> extended_iv = iv * 10.0
>>> extended_iv
Interval(0.0, 50.0, closed='right')
```

To create a time interval you can use Timestamps as the bounds

```
>>> year_2017 = pd.Interval(pd.Timestamp('2017-01-01 00:00:00'),
...                        pd.Timestamp('2018-01-01 00:00:00'),
...                        closed='left')
>>> pd.Timestamp('2017-01-01 00:00:00') in year_2017
True
>>> year_2017.length
Timedelta('365 days 00:00:00')
```

Attributes

| | |
|---------------------|---|
| <i>closed</i> | Whether the interval is closed on the left-side, right-side, both or neither. |
| <i>closed_left</i> | Check if the interval is closed on the left side. |
| <i>closed_right</i> | Check if the interval is closed on the right side. |
| <i>is_empty</i> | Indicates if an interval is empty, meaning it contains no points. |
| <i>left</i> | Left bound for the interval. |
| <i>length</i> | Return the length of the Interval. |
| <i>mid</i> | Return the midpoint of the Interval. |
| <i>open_left</i> | Check if the interval is open on the left side. |
| <i>open_right</i> | Check if the interval is open on the right side. |
| <i>right</i> | Right bound for the interval. |

pandas.Interval.closed

Interval.closed

Whether the interval is closed on the left-side, right-side, both or neither.

pandas.Interval.closed_left

Interval.closed_left

Check if the interval is closed on the left side.

For the meaning of *closed* and *open* see [Interval](#).

Returns

bool True if the Interval is closed on the left-side.

pandas.Interval.closed_right

Interval.closed_right

Check if the interval is closed on the right side.

For the meaning of *closed* and *open* see [Interval](#).

Returns

bool True if the Interval is closed on the left-side.

pandas.Interval.is_empty

Interval.is_empty

Indicates if an interval is empty, meaning it contains no points.

New in version 0.25.0.

Returns

bool or ndarray A boolean indicating if a scalar [Interval](#) is empty, or a boolean ndarray positionally indicating if an Interval in an [IntervalArray](#) or [IntervalIndex](#) is empty.

Examples

An [Interval](#) that contains points is not empty:

```
>>> pd.Interval(0, 1, closed='right').is_empty
False
```

An Interval that does not contain any points is empty:

```
>>> pd.Interval(0, 0, closed='right').is_empty
True
>>> pd.Interval(0, 0, closed='left').is_empty
True
>>> pd.Interval(0, 0, closed='neither').is_empty
True
```

An Interval that contains a single point is not empty:

```
>>> pd.Interval(0, 0, closed='both').is_empty
False
```

An `IntervalArray` or `IntervalIndex` returns a boolean ndarray positionally indicating if an `Interval` is empty:

```
>>> ivs = [pd.Interval(0, 0, closed='neither'),
...        pd.Interval(1, 2, closed='neither')]
>>> pd.arrays.IntervalArray(ivs).is_empty
array([ True, False])
```

Missing values are not considered empty:

```
>>> ivs = [pd.Interval(0, 0, closed='neither'), np.nan]
>>> pd.IntervalIndex(ivs).is_empty
array([ True, False])
```

`pandas.Interval.left`

`Interval.left`

Left bound for the interval.

`pandas.Interval.length`

`Interval.length`

Return the length of the `Interval`.

`pandas.Interval.mid`

`Interval.mid`

Return the midpoint of the `Interval`.

`pandas.Interval.open_left`

`Interval.open_left`

Check if the interval is open on the left side.

For the meaning of *closed* and *open* see [Interval](#).

Returns

bool True if the `Interval` is closed on the left-side.

`pandas.Interval.open_right`

`Interval.open_right`

Check if the interval is open on the right side.

For the meaning of *closed* and *open* see [Interval](#).

Returns

bool True if the `Interval` is closed on the left-side.

pandas.Interval.right

Interval.right

Right bound for the interval.

Methods

overlaps

Check whether two Interval objects overlap.

pandas.Interval.overlaps

Interval.overlaps()

Check whether two Interval objects overlap.

Two intervals overlap if they share a common point, including closed endpoints. Intervals that only have an open endpoint in common do not overlap.

Parameters

other [Interval] Interval to check against for an overlap.

Returns

bool True if the two intervals overlap.

See also:

IntervalArray.overlaps The corresponding method for IntervalArray.

IntervalIndex.overlaps The corresponding method for IntervalIndex.

Examples

```
>>> i1 = pd.Interval(0, 2)
>>> i2 = pd.Interval(1, 3)
>>> i1.overlaps(i2)
True
>>> i3 = pd.Interval(4, 5)
>>> i1.overlaps(i3)
False
```

Intervals that share closed endpoints overlap:

```
>>> i4 = pd.Interval(0, 1, closed='both')
>>> i5 = pd.Interval(1, 2, closed='both')
>>> i4.overlaps(i5)
True
```

Intervals that only have an open endpoint in common do not overlap:

```
>>> i6 = pd.Interval(1, 2, closed='neither')
>>> i4.overlaps(i6)
False
```

Properties

| | |
|------------------------------------|---|
| <code>Interval.closed</code> | Whether the interval is closed on the left-side, right-side, both or neither. |
| <code>Interval.closed_left</code> | Check if the interval is closed on the left side. |
| <code>Interval.closed_right</code> | Check if the interval is closed on the right side. |
| <code>Interval.is_empty</code> | Indicates if an interval is empty, meaning it contains no points. |
| <code>Interval.left</code> | Left bound for the interval. |
| <code>Interval.length</code> | Return the length of the Interval. |
| <code>Interval.mid</code> | Return the midpoint of the Interval. |
| <code>Interval.open_left</code> | Check if the interval is open on the left side. |
| <code>Interval.open_right</code> | Check if the interval is open on the right side. |
| <code>Interval.overlaps</code> | Check whether two Interval objects overlap. |
| <code>Interval.right</code> | Right bound for the interval. |

A collection of intervals may be stored in an `arrays.IntervalArray`.

| | |
|---|--|
| <code>arrays.IntervalArray(data[, closed, dtype, ...])</code> | Pandas array for interval data that are closed on the same side. |
|---|--|

pandas.arrays.IntervalArray

class `pandas.arrays.IntervalArray`(*data*, *closed=None*, *dtype=None*, *copy=False*, *verify_integrity=True*)
Pandas array for interval data that are closed on the same side.

New in version 0.24.0.

Parameters

- data** [array-like (1-dimensional)] Array-like containing Interval objects from which to build the IntervalArray.
- closed** [{‘left’, ‘right’, ‘both’, ‘neither’}, default ‘right’] Whether the intervals are closed on the left-side, right-side, both or neither.
- dtype** [dtype or None, default None] If None, dtype will be inferred.
- copy** [bool, default False] Copy the input data.
- verify_integrity** [bool, default True] Verify that the IntervalArray is valid.

See also:

- Index** The base pandas Index type.
- Interval** A bounded slice-like interval; the elements of an IntervalArray.
- interval_range** Function to create a fixed frequency IntervalIndex.
- cut** Bin values into discrete Intervals.
- qcut** Bin values into equal-sized Intervals based on rank or sample quantiles.

Notes

See the [user guide](#) for more.

Examples

A new `IntervalArray` can be constructed directly from an array-like of `Interval` objects:

```
>>> pd.arrays.IntervalArray([pd.Interval(0, 1), pd.Interval(1, 5)])
<IntervalArray>
[[0, 1], (1, 5]]
Length: 2, dtype: interval[int64, right]
```

It may also be constructed using one of the constructor methods: `IntervalArray.from_arrays()`, `IntervalArray.from_breaks()`, and `IntervalArray.from_tuples()`.

Attributes

| | |
|---|--|
| <code>left</code> | Return the left endpoints of each <code>Interval</code> in the <code>IntervalArray</code> as an <code>Index</code> . |
| <code>right</code> | Return the right endpoints of each <code>Interval</code> in the <code>IntervalArray</code> as an <code>Index</code> . |
| <code>closed</code> | Whether the intervals are closed on the left-side, right-side, both or neither. |
| <code>mid</code> | Return the midpoint of each <code>Interval</code> in the <code>IntervalArray</code> as an <code>Index</code> . |
| <code>length</code> | Return an <code>Index</code> with entries denoting the length of each <code>Interval</code> in the <code>IntervalArray</code> . |
| <code>is_empty</code> | Indicates if an interval is empty, meaning it contains no points. |
| <code>is_non_overlapping_monotonic</code> | Return <code>True</code> if the <code>IntervalArray</code> is non-overlapping (no <code>Intervals</code> share points) and is either monotonic increasing or monotonic decreasing, else <code>False</code> . |

`pandas.arrays.IntervalArray.left`

property `IntervalArray.left`

Return the left endpoints of each `Interval` in the `IntervalArray` as an `Index`.

`pandas.arrays.IntervalArray.right`

property `IntervalArray.right`

Return the right endpoints of each Interval in the IntervalArray as an Index.

`pandas.arrays.IntervalArray.closed`

property `IntervalArray.closed`

Whether the intervals are closed on the left-side, right-side, both or neither.

`pandas.arrays.IntervalArray.mid`

property `IntervalArray.mid`

Return the midpoint of each Interval in the IntervalArray as an Index.

`pandas.arrays.IntervalArray.length`

property `IntervalArray.length`

Return an Index with entries denoting the length of each Interval in the IntervalArray.

`pandas.arrays.IntervalArray.is_empty`

`IntervalArray.is_empty`

Indicates if an interval is empty, meaning it contains no points.

New in version 0.25.0.

Returns

bool or ndarray A boolean indicating if a scalar Interval is empty, or a boolean ndarray positionally indicating if an Interval in an IntervalArray or IntervalIndex is empty.

Examples

An Interval that contains points is not empty:

```
>>> pd.Interval(0, 1, closed='right').is_empty
False
```

An Interval that does not contain any points is empty:

```
>>> pd.Interval(0, 0, closed='right').is_empty
True
>>> pd.Interval(0, 0, closed='left').is_empty
True
>>> pd.Interval(0, 0, closed='neither').is_empty
True
```

An Interval that contains a single point is not empty:

```
>>> pd.Interval(0, 0, closed='both').is_empty
False
```

An `IntervalArray` or `IntervalIndex` returns a boolean ndarray positionally indicating if an `Interval` is empty:

```
>>> ivs = [pd.Interval(0, 0, closed='neither'),
...        pd.Interval(1, 2, closed='neither')]
>>> pd.arrays.IntervalArray(ivs).is_empty
array([ True, False])
```

Missing values are not considered empty:

```
>>> ivs = [pd.Interval(0, 0, closed='neither'), np.nan]
>>> pd.IntervalIndex(ivs).is_empty
array([ True, False])
```

pandas.arrays.IntervalArray.is_non_overlapping_monotonic

property IntervalArray.is_non_overlapping_monotonic

Return True if the `IntervalArray` is non-overlapping (no `Intervals` share points) and is either monotonic increasing or monotonic decreasing, else False.

Methods

| | |
|--|---|
| <code>from_arrays(left, right[, closed, copy, dtype])</code> | Construct from two arrays defining the left and right bounds. |
| <code>from_tuples(data[, closed, copy, dtype])</code> | Construct an <code>IntervalArray</code> from an array-like of tuples. |
| <code>from_breaks(breaks[, closed, copy, dtype])</code> | Construct an <code>IntervalArray</code> from an array of splits. |
| <code>contains(other)</code> | Check elementwise if the <code>Intervals</code> contain the value. |
| <code>overlaps(other)</code> | Check elementwise if an <code>Interval</code> overlaps the values in the <code>IntervalArray</code> . |
| <code>set_closed(closed)</code> | Return an <code>IntervalArray</code> identical to the current one, but closed on the specified side. |
| <code>to_tuples([na_tuple])</code> | Return an ndarray of tuples of the form (left, right). |

pandas.arrays.IntervalArray.from_arrays

classmethod IntervalArray.from_arrays(left, right, closed='right', copy=False, dtype=None)

Construct from two arrays defining the left and right bounds.

Parameters

left [array-like (1-dimensional)] Left bounds for each interval.

right [array-like (1-dimensional)] Right bounds for each interval.

closed [{‘left’, ‘right’, ‘both’, ‘neither’}, default ‘right’] Whether the intervals are closed on the left-side, right-side, both or neither.

copy [bool, default False] Copy the data.

dtype [dtype, optional] If None, dtype will be inferred.

Returns

IntervalArray

Raises

ValueError When a value is missing in only one of *left* or *right*. When a value in *left* is greater than the corresponding value in *right*.

See also:

interval_range Function to create a fixed frequency IntervalIndex.

[*IntervalArray.from_breaks*](#) Construct an IntervalArray from an array of splits.

[*IntervalArray.from_tuples*](#) Construct an IntervalArray from an array-like of tuples.

Notes

Each element of *left* must be less than or equal to the *right* element at the same position. If an element is missing, it must be missing in both *left* and *right*. A `TypeError` is raised when using an unsupported type for *left* or *right*. At the moment, ‘category’, ‘object’, and ‘string’ subtypes are not supported.

```
>>> pd.arrays.IntervalArray.from_arrays([0, 1, 2], [1, 2, 3])
<IntervalArray>
[[0, 1], (1, 2], (2, 3]]
Length: 3, dtype: interval[int64, right]
```

pandas.arrays.IntervalArray.from_tuples

classmethod `IntervalArray.from_tuples(data, closed='right', copy=False, dtype=None)`
Construct an IntervalArray from an array-like of tuples.

Parameters

data [array-like (1-dimensional)] Array of tuples.

closed [{'left', 'right', 'both', 'neither'}, default 'right'] Whether the intervals are closed on the left-side, right-side, both or neither.

copy [bool, default False] By-default copy the data, this is compat only and ignored.

dtype [dtype or None, default None] If None, dtype will be inferred.

Returns

IntervalArray

See also:

interval_range Function to create a fixed frequency IntervalIndex.

[*IntervalArray.from_arrays*](#) Construct an IntervalArray from a left and right array.

[*IntervalArray.from_breaks*](#) Construct an IntervalArray from an array of splits.

Examples

```
>>> pd.arrays.IntervalArray.from_tuples([(0, 1), (1, 2)])
<IntervalArray>
[[0, 1], (1, 2]]
Length: 2, dtype: interval[int64, right]
```

pandas.arrays.IntervalArray.from_breaks

classmethod `IntervalArray.from_breaks`(*breaks*, *closed='right'*, *copy=False*, *dtype=None*)

Construct an IntervalArray from an array of splits.

Parameters

breaks [array-like (1-dimensional)] Left and right bounds for each interval.

closed [{'left', 'right', 'both', 'neither'}, default 'right'] Whether the intervals are closed on the left-side, right-side, both or neither.

copy [bool, default False] Copy the data.

dtype [dtype or None, default None] If None, dtype will be inferred.

Returns

IntervalArray

See also:

interval_range Function to create a fixed frequency IntervalIndex.

IntervalArray.from_arrays Construct from a left and right array.

IntervalArray.from_tuples Construct from a sequence of tuples.

Examples

```
>>> pd.arrays.IntervalArray.from_breaks([0, 1, 2, 3])
<IntervalArray>
[[0, 1], (1, 2], (2, 3]]
Length: 3, dtype: interval[int64, right]
```

pandas.arrays.IntervalArray.contains

`IntervalArray.contains`(*other*)

Check elementwise if the Intervals contain the value.

Return a boolean mask whether the value is contained in the Intervals of the IntervalArray.

New in version 0.25.0.

Parameters

other [scalar] The value to check whether it is contained in the Intervals.

Returns

boolean array

See also:

Interval.contains Check whether Interval object contains value.

IntervalArray.overlaps Check if an Interval overlaps the values in the IntervalArray.

Examples

```
>>> intervals = pd.arrays.IntervalArray.from_tuples([(0, 1), (1, 3), (2, 4)])
>>> intervals
<IntervalArray>
[(0, 1], (1, 3], (2, 4]]
Length: 3, dtype: interval[int64, right]
```

```
>>> intervals.contains(0.5)
array([ True, False, False])
```

pandas.arrays.IntervalArray.overlaps

IntervalArray.overlaps(*other*)

Check elementwise if an Interval overlaps the values in the IntervalArray.

Two intervals overlap if they share a common point, including closed endpoints. Intervals that only have an open endpoint in common do not overlap.

Parameters

other [IntervalArray] Interval to check against for an overlap.

Returns

ndarray Boolean array positionally indicating where an overlap occurs.

See also:

Interval.overlaps Check whether two Interval objects overlap.

Examples

```
>>> data = [(0, 1), (1, 3), (2, 4)]
>>> intervals = pd.arrays.IntervalArray.from_tuples(data)
>>> intervals
<IntervalArray>
[(0, 1], (1, 3], (2, 4]]
Length: 3, dtype: interval[int64, right]
```

```
>>> intervals.overlaps(pd.Interval(0.5, 1.5))
array([ True,  True, False])
```

Intervals that share closed endpoints overlap:

```
>>> intervals.overlaps(pd.Interval(1, 3, closed='left'))
array([ True,  True,  True])
```

Intervals that only have an open endpoint in common do not overlap:

```
>>> intervals.overlaps(pd.Interval(1, 2, closed='right'))
array([False,  True, False])
```

pandas.arrays.IntervalArray.set_closed

IntervalArray.**set_closed**(*closed*)

Return an IntervalArray identical to the current one, but closed on the specified side.

Parameters

closed [({'left', 'right', 'both', 'neither'})] Whether the intervals are closed on the left-side, right-side, both or neither.

Returns

new_index [IntervalArray]

Examples

```
>>> index = pd.arrays.IntervalArray.from_breaks(range(4))
>>> index
<IntervalArray>
[[0, 1], (1, 2], (2, 3]]
Length: 3, dtype: interval[int64, right]
>>> index.set_closed('both')
<IntervalArray>
[[0, 1], [1, 2], [2, 3]]
Length: 3, dtype: interval[int64, both]
```

pandas.arrays.IntervalArray.to_tuples

IntervalArray.**to_tuples**(*na_tuple=True*)

Return an ndarray of tuples of the form (left, right).

Parameters

na_tuple [bool, default True] Returns NA as a tuple if True, (nan, nan), or just as the NA value itself if False, nan.

Returns

tuples: ndarray

IntervalDtype([subtype, closed])

An ExtensionDtype for Interval data.

pandas.IntervalDtype

class pandas.IntervalDtype(*subtype=None, closed=None*)
An ExtensionDtype for Interval data.

This is not an actual numpy dtype, but a duck type.

Parameters

subtype [str, np.dtype] The dtype of the Interval bounds.

Examples

```
>>> pd.IntervalDtype(subtype='int64', closed='both')
interval[int64, both]
```

Attributes

| | |
|----------------|-----------------------------------|
| <i>subtype</i> | The dtype of the Interval bounds. |
|----------------|-----------------------------------|

pandas.IntervalDtype.subtype

property pandas.IntervalDtype.subtype
The dtype of the Interval bounds.

Methods

| |
|------|
| None |
|------|

3.5.7 Nullable integer

numpy.ndarray cannot natively represent integer-data with missing values. pandas provides this through *arrays.IntegerArray*.

| | |
|---|---|
| <i>arrays.IntegerArray</i> (values, mask[, copy]) | Array of integer (optional missing) values. |
|---|---|

pandas.arrays.IntegerArray

class pandas.arrays.IntegerArray(*values, mask, copy=False*)
Array of integer (optional missing) values.

Changed in version 1.0.0: Now uses pandas.NA as the missing value rather than numpy.nan.

| |
|--|
| Warning: IntegerArray is currently experimental, and its API or internal implementation may change without warning. |
|--|

We represent an IntegerArray with 2 numpy arrays:

- data: contains a numpy integer array of the appropriate dtype
- mask: a boolean array holding a mask on the data, True is missing

To construct an IntegerArray from generic array-like input, use `pandas.array()` with one of the integer dtypes (see examples).

See *Nullable integer data type* for more.

Parameters

values [numpy.ndarray] A 1-d integer-dtype array.

mask [numpy.ndarray] A 1-d boolean-dtype array indicating missing values.

copy [bool, default False] Whether to copy the *values* and *mask*.

Returns

IntegerArray

Examples

Create an IntegerArray with `pandas.array()`.

```
>>> int_array = pd.array([1, None, 3], dtype=pd.Int32Dtype())
>>> int_array
<IntegerArray>
[1, <NA>, 3]
Length: 3, dtype: Int32
```

String aliases for the dtypes are also available. They are capitalized.

```
>>> pd.array([1, None, 3], dtype='Int32')
<IntegerArray>
[1, <NA>, 3]
Length: 3, dtype: Int32
```

```
>>> pd.array([1, None, 3], dtype='UInt16')
<IntegerArray>
[1, <NA>, 3]
Length: 3, dtype: UInt16
```

3.5.8 Categorical data

pandas defines a custom data type for representing data that can take only a limited, fixed set of values. The dtype of a Categorical can be described by a pandas.api.types.CategoricalDtype.

| | |
|---|--|
| <i>CategoricalDtype</i> ([categories, ordered]) | Type for categorical data with the categories and orderedness. |
|---|--|

pandas.CategoricalDtype

class pandas.CategoricalDtype(*categories=None, ordered=False*)

Type for categorical data with the categories and orderedness.

Parameters

categories [sequence, optional] Must be unique, and must not contain any nulls. The categories are stored in an Index, and if an index is provided the dtype of that index will be used.

ordered [bool or None, default False] Whether or not this categorical is treated as an ordered categorical. None can be used to maintain the ordered value of existing categoricals when used in operations that combine categoricals, e.g. astype, and will resolve to False if there is no existing ordered to maintain.

See also:

Categorical Represent a categorical variable in classic R / S-plus fashion.

Notes

This class is useful for specifying the type of a `Categorical` independent of the values. See *CategoricalDtype* for more.

Examples

```
>>> t = pd.CategoricalDtype(categories=['b', 'a'], ordered=True)
>>> pd.Series(['a', 'b', 'a', 'c'], dtype=t)
0      a
1      b
2      a
3     NaN
dtype: category
Categories (2, object): ['b' < 'a']
```

An empty `CategoricalDtype` with a specific dtype can be created by providing an empty index. As follows,

```
>>> pd.CategoricalDtype(pd.DatetimeIndex([])).categories.dtype
dtype('<M8[ns]')
```

Attributes

| | |
|-------------------|--|
| <i>categories</i> | An Index containing the unique categories allowed. |
| <i>ordered</i> | Whether the categories have an ordered relationship. |

`pandas.CategoricalDtype.categories`

property `CategoricalDtype.categories`
An Index containing the unique categories allowed.

`pandas.CategoricalDtype.ordered`

property `CategoricalDtype.ordered`
Whether the categories have an ordered relationship.

Methods

| | |
|------|--|
| None | |
|------|--|

| | |
|------------------------------------|--|
| <i>CategoricalDtype.categories</i> | An Index containing the unique categories allowed. |
| <i>CategoricalDtype.ordered</i> | Whether the categories have an ordered relationship. |

Categorical data can be stored in a *pandas.Categorical*

| | |
|--|---|
| <code>Categorical(values[, categories, ordered, ...])</code> | Represent a categorical variable in classic R / S-plus fashion. |
|--|---|

pandas.Categorical

class `pandas.Categorical`(*values*, *categories=None*, *ordered=None*, *dtype=None*, *fastpath=False*, *copy=True*)
 Represent a categorical variable in classic R / S-plus fashion.

Categoricals can only take on only a limited, and usually fixed, number of possible values (*categories*). In contrast to statistical categorical variables, a *Categorical* might have an order, but numerical operations (additions, divisions, ...) are not possible.

All values of the *Categorical* are either in *categories* or *np.nan*. Assigning values outside of *categories* will raise a *ValueError*. Order is defined by the order of the *categories*, not lexical order of the values.

Parameters

values [list-like] The values of the categorical. If categories are given, values not in categories will be replaced with NaN.

categories [Index-like (unique), optional] The unique categories for this categorical. If not given, the categories are assumed to be the unique values of *values* (sorted, if possible, otherwise in the order in which they appear).

ordered [bool, default False] Whether or not this categorical is treated as a ordered categorical. If True, the resulting categorical will be ordered. An ordered categorical respects, when sorted, the order of its *categories* attribute (which in turn is the *categories* argument, if provided).

dtype [CategoricalDtype] An instance of `CategoricalDtype` to use for this categorical.

Raises

ValueError If the categories do not validate.

TypeError If an explicit `ordered=True` is given but no *categories* and the *values* are not sortable.

See also:

[*CategoricalDtype*](#) Type for categorical data.

[*CategoricalIndex*](#) An Index with an underlying `Categorical`.

Notes

See the [user guide](#) for more.

Examples

```
>>> pd.Categorical([1, 2, 3, 1, 2, 3])
[1, 2, 3, 1, 2, 3]
Categories (3, int64): [1, 2, 3]
```

```
>>> pd.Categorical(['a', 'b', 'c', 'a', 'b', 'c'])
['a', 'b', 'c', 'a', 'b', 'c']
Categories (3, object): ['a', 'b', 'c']
```

Missing values are not included as a category.

```
>>> c = pd.Categorical([1, 2, 3, 1, 2, 3, np.nan])
>>> c
[1, 2, 3, 1, 2, 3, NaN]
Categories (3, int64): [1, 2, 3]
```

However, their presence is indicated in the *codes* attribute by code *-1*.

```
>>> c.codes
array([ 0,  1,  2,  0,  1,  2, -1], dtype=int8)
```

Ordered *Categoricals* can be sorted according to the custom order of the categories and can have a min and max value.

```
>>> c = pd.Categorical(['a', 'b', 'c', 'a', 'b', 'c'], ordered=True,
...                   categories=['c', 'b', 'a'])
>>> c
['a', 'b', 'c', 'a', 'b', 'c']
Categories (3, object): ['c' < 'b' < 'a']
>>> c.min()
'c'
```

Attributes

| | |
|-------------------|--|
| <i>categories</i> | The categories of this categorical. |
| <i>codes</i> | The category codes of this categorical. |
| <i>ordered</i> | Whether the categories have an ordered relationship. |
| <i>dtype</i> | The <code>CategoricalDtype</code> for this instance. |

`pandas.Categorical.categories`

property `Categorical.categories`

The categories of this categorical.

`Setting` assigns new values to each category (effectively a rename of each individual category).

The assigned value has to be a list-like object. All items must be unique and the number of items in the new categories must be the same as the number of items in the old categories.

Assigning to *categories* is an inplace operation!

Raises

ValueError If the new categories do not validate as categories or if the number of new categories is unequal the number of old categories

See also:

rename_categories Rename categories.

reorder_categories Reorder categories.

add_categories Add new categories.

remove_categories Remove the specified categories.

remove_unused_categories Remove categories which are not used.

set_categories Set the categories to the specified ones.

pandas.Categorical.codes

property Categorical.codes

The category codes of this categorical.

Codes are an array of integers which are the positions of the actual values in the categories array.

There is no setter, use the other categorical methods and the normal item setter to change values in the categorical.

Returns

ndarray[int] A non-writable view of the *codes* array.

pandas.Categorical.ordered

property Categorical.ordered

Whether the categories have an ordered relationship.

pandas.Categorical.dtype

property Categorical.dtype

The CategoricalDtype for this instance.

Methods

| | |
|---|---|
| <i>from_codes</i> (codes[, categories, ordered, dtype]) | Make a Categorical type from codes and categories or dtype. |
| <i>__array__</i> ([dtype]) | The numpy array interface. |

pandas.Categorical.from_codes

classmethod Categorical.from_codes(codes, categories=None, ordered=None, dtype=None)

Make a Categorical type from codes and categories or dtype.

This constructor is useful if you already have codes and categories/dtype and so do not need the (computation intensive) factorization step, which is usually done on the constructor.

If your data does not follow this convention, please use the normal constructor.

Parameters

codes [array-like of int] An integer array, where each integer points to a category in categories or dtype.categories, or else is -1 for NaN.

categories [index-like, optional] The categories for the categorical. Items need to be unique. If the categories are not given here, then they must be provided in *dtype*.

ordered [bool, optional] Whether or not this categorical is treated as an ordered categorical. If not given here or in *dtype*, the resulting categorical will be unordered.

dtype [CategoricalDtype or “category”, optional] If *CategoricalDtype*, cannot be used together with *categories* or *ordered*.

Returns

Categorical

Examples

```
>>> dtype = pd.CategoricalDtype(['a', 'b'], ordered=True)
>>> pd.Categorical.from_codes(codes=[0, 1, 0, 1], dtype=dtype)
['a', 'b', 'a', 'b']
Categories (2, object): ['a' < 'b']
```

pandas.Categorical.__array__

Categorical.__array__(*dtype=None*)
The numpy array interface.

Returns

numpy.array A numpy array of either the specified dtype or, if dtype==None (default), the same dtype as *categorical.categories.dtype*.

The alternative *Categorical.from_codes()* constructor can be used when you have the categories and integer codes already:

| | |
|--|---|
| <i>Categorical.from_codes</i> (codes[, categories, ...]) | Make a Categorical type from codes and categories or dtype. |
|--|---|

The dtype information is available on the Categorical

| | |
|-------------------------------|--|
| <i>Categorical.dtype</i> | The CategoricalDtype for this instance. |
| <i>Categorical.categories</i> | The categories of this categorical. |
| <i>Categorical.ordered</i> | Whether the categories have an ordered relationship. |
| <i>Categorical.codes</i> | The category codes of this categorical. |

np.asarray(categorical) works by implementing the array interface. Be aware, that this converts the Categorical back to a NumPy array, so categories and order information is not preserved!

| | |
|--|----------------------------|
| <i>Categorical.__array__</i> ([dtype]) | The numpy array interface. |
|--|----------------------------|

A Categorical can be stored in a Series or DataFrame. To create a Series of dtype category, use *cat = s.astype(dtype)* or *Series(..., dtype=dtype)* where dtype is either

- the string 'category'
- an instance of CategoricalDtype.

If the Series is of dtype CategoricalDtype, *Series.cat* can be used to change the categorical data. See *Categorical accessor* for more.

3.5.9 Sparse data

Data where a single value is repeated many times (e.g. 0 or NaN) may be stored efficiently as a `arrays.SparseArray`.

`arrays.SparseArray`(data[, sparse_index, ...]) An ExtensionArray for storing sparse data.

`pandas.arrays.SparseArray`

class `pandas.arrays.SparseArray`(data, sparse_index=None, index=None, fill_value=None, kind='integer', dtype=None, copy=False)

An ExtensionArray for storing sparse data.

Parameters

data [array-like] A dense array of values to store in the SparseArray. This may contain *fill_value*.

sparse_index [SparseIndex, optional]

index [Index]

fill_value [scalar, optional] Elements in *data* that are *fill_value* are not stored in the SparseArray. For memory savings, this should be the most common value in *data*. By default, *fill_value* depends on the dtype of *data*:

| data.dtype | na_value |
|-------------|----------|
| float | np.nan |
| int | 0 |
| bool | False |
| datetime64 | pd.NaT |
| timedelta64 | pd.NaT |

The fill value is potentially specified in three ways. In order of precedence, these are

1. The *fill_value* argument
2. `dtype.fill_value` if *fill_value* is None and *dtype* is a `SparseDtype`
3. `data.dtype.fill_value` if *fill_value* is None and *dtype* is not a `SparseDtype` and *data* is a `SparseArray`.

kind [{ 'integer', 'block' }, default 'integer'] The type of storage for sparse locations.

- 'block': Stores a *block* and *block_length* for each contiguous *span* of sparse values. This is best when sparse data tends to be clumped together, with large regions of fill-value values between sparse values.
- 'integer': uses an integer to store the location of each sparse value.

dtype [np.dtype or SparseDtype, optional] The dtype to use for the SparseArray. For numpy dtypes, this determines the dtype of `self.sp_values`. For SparseDtype, this determines `self.sp_values` and `self.fill_value`.

copy [bool, default False] Whether to explicitly copy the incoming *data* array.

Examples

```
>>> from pandas.arrays import SparseArray
>>> arr = SparseArray([0, 0, 1, 2])
>>> arr
[0, 0, 1, 2]
Fill: 0
IntIndex
Indices: array([2, 3], dtype=int32)
```

Attributes

| | |
|------|--|
| None | |
|------|--|

Methods

| | |
|------|--|
| None | |
|------|--|

SparseDtype(dtype, fill_value)

Dtype for data stored in SparseArray.

pandas.SparseDtype

class pandas.SparseDtype(dtype=<class 'numpy.float64'>, fill_value=None)

Dtype for data stored in SparseArray.

This dtype implements the pandas ExtensionDtype interface.

Parameters

dtype [str, ExtensionDtype, numpy.dtype, type, default numpy.float64] The dtype of the underlying array storing the non-fill value values.

fill_value [scalar, optional] The scalar value not stored in the SparseArray. By default, this depends on *dtype*.

| dtype | na_value |
|-------------|----------|
| float | np.nan |
| int | 0 |
| bool | False |
| datetime64 | pd.NaT |
| timedelta64 | pd.NaT |

The default value may be overridden by specifying a *fill_value*.

Attributes

None

Methods

None

The `Series.sparse` accessor may be used to access sparse-specific attributes and methods if the *Series* contains sparse values. See *Sparse accessor* for more.

3.5.10 Text data

When working with text data, where each valid element is a string or missing, we recommend using *StringDtype* (with the alias "string").

| | |
|---|--|
| <code>arrays.StringArray(values[, copy])</code> | Extension array for string data. |
| <code>arrays.ArrowStringArray(values)</code> | Extension array for string data in a pyarrow. ChunkedArray. |

pandas.arrays.StringArray

class `pandas.arrays.StringArray(values, copy=False)`

Extension array for string data.

New in version 1.0.0.

Warning: `StringArray` is considered experimental. The implementation and parts of the API may change without warning.

Parameters

values [array-like] The array of data.

Warning: Currently, this expects an object-dtype ndarray where the elements are Python strings or `pandas.NA`. This may change without warning in the future. Use `pandas.array()` with `dtype="string"` for a stable way of creating a *StringArray* from any sequence.

copy [bool, default False] Whether to copy the array of data.

See also:

array The recommended function for creating a *StringArray*.

Series.str The string methods are available on Series backed by a *StringArray*.

Notes

StringArray returns a BooleanArray for comparison methods.

Examples

```
>>> pd.array(['This is', 'some text', None, 'data.'], dtype="string")
<StringArray>
['This is', 'some text', <NA>, 'data.']
Length: 4, dtype: string
```

Unlike arrays instantiated with `dtype="object"`, `StringArray` will convert the values to strings.

```
>>> pd.array(['1', 1], dtype="object")
<PandasArray>
['1', 1]
Length: 2, dtype: object
>>> pd.array(['1', 1], dtype="string")
<StringArray>
['1', '1']
Length: 2, dtype: string
```

However, instantiating `StringArrays` directly with non-strings will raise an error.

For comparison methods, `StringArray` returns a `pandas.BooleanArray`:

```
>>> pd.array(["a", None, "c"], dtype="string") == "a"
<BooleanArray>
[True, <NA>, False]
Length: 3, dtype: boolean
```

Attributes

| | |
|------|--|
| None | |
|------|--|

Methods

| | |
|------|--|
| None | |
|------|--|

pandas.arrays.ArrowStringArray

class `pandas.arrays.ArrowStringArray`(*values*)

Extension array for string data in a `pyarrow.ChunkedArray`.

New in version 1.2.0.

| |
|---|
| Warning: <code>ArrowStringArray</code> is considered experimental. The implementation and parts of the API may change without warning. |
|---|

Parameters

values [pyarrow.Array or pyarrow.ChunkedArray] The array of data.

See also:

array The recommended function for creating a ArrowStringArray.

Series.str The string methods are available on Series backed by a ArrowStringArray.

Notes

ArrowStringArray returns a BooleanArray for comparison methods.

Examples

```
>>> pd.array(['This is', 'some text', None, 'data.'], dtype="string[pyarrow]")
<ArrowStringArray>
['This is', 'some text', <NA>, 'data.']
Length: 4, dtype: string
```

Attributes

| | |
|------|--|
| None | |
|------|--|

Methods

| | |
|------|--|
| None | |
|------|--|

StringDtype([storage])

Extension dtype for string data.

pandas.StringDtype

class pandas.**StringDtype**(*storage=None*)

Extension dtype for string data.

New in version 1.0.0.

Warning: StringDtype is considered experimental. The implementation and parts of the API may change without warning.

In particular, StringDtype.na_value may change to no longer be `numpy.nan`.

Parameters

storage [{"python", "pyarrow"}, optional] If not given, the value of `pd.options.mode.string_storage`.

Examples

```
>>> pd.StringDtype()
string[python]
```

```
>>> pd.StringDtype(storage="pyarrow")
string[pyarrow]
```

Attributes

| | |
|------|--|
| None | |
|------|--|

Methods

| | |
|------|--|
| None | |
|------|--|

The `Series.str` accessor is available for `Series` backed by a `arrays.StringArray`. See *String handling* for more.

3.5.11 Boolean data with missing values

The boolean dtype (with the alias "boolean") provides support for storing boolean data (True, False values) with missing values, which is not possible with a bool `numpy.ndarray`.

| | |
|--|---|
| <code>arrays.BooleanArray(values, mask[, copy])</code> | Array of boolean (True/False) data with missing values. |
|--|---|

pandas.arrays.BooleanArray

class `pandas.arrays.BooleanArray(values, mask, copy=False)`

Array of boolean (True/False) data with missing values.

This is a pandas Extension array for boolean data, under the hood represented by 2 numpy arrays: a boolean array with the data and a boolean array with the mask (True indicating missing).

`BooleanArray` implements Kleene logic (sometimes called three-value logic) for logical operations. See *Kleene logical operations* for more.

To construct an `BooleanArray` from generic array-like input, use `pandas.array()` specifying `dtype="boolean"` (see examples below).

New in version 1.0.0.

| |
|---|
| Warning: <code>BooleanArray</code> is considered experimental. The implementation and parts of the API may change without warning. |
|---|

Parameters

values [`numpy.ndarray`] A 1-d boolean-dtype array with the data.

mask [numpy.ndarray] A 1-d boolean-dtype array indicating missing values (True indicates missing).

copy [bool, default False] Whether to copy the *values* and *mask* arrays.

Returns

BooleanArray

Examples

Create an BooleanArray with `pandas.array()`:

```
>>> pd.array([True, False, None], dtype="boolean")
<BooleanArray>
[True, False, <NA>]
Length: 3, dtype: boolean
```

Attributes

None

Methods

None

`BooleanDtype()`

Extension dtype for boolean data.

pandas.BooleanDtype

class pandas.**BooleanDtype**

Extension dtype for boolean data.

New in version 1.0.0.

Warning: BooleanDtype is considered experimental. The implementation and parts of the API may change without warning.

Examples

```
>>> pd.BooleanDtype()
BooleanDtype
```

Attributes

| | |
|------|--|
| None | |
|------|--|

Methods

| | |
|------|--|
| None | |
|------|--|

3.6 Index objects

3.6.1 Index

Many of these methods or variants thereof are available on the objects that contain an index (Series/DataFrame) and those should most likely be used before calling these methods directly.

| | |
|---|---|
| <i>Index</i> ([data, dtype, copy, name, tupleize_cols]) | Immutable sequence used for indexing and alignment. |
|---|---|

pandas.Index

class pandas.**Index**(*data=None, dtype=None, copy=False, name=None, tupleize_cols=True, **kwargs*)
 Immutable sequence used for indexing and alignment. The basic object storing axis labels for all pandas objects.

Parameters

data [array-like (1-dimensional)]

dtype [NumPy dtype (default: object)] If dtype is None, we find the dtype that best fits the data. If an actual dtype is provided, we coerce to that dtype if it's safe. Otherwise, an error will be raised.

copy [bool] Make a copy of input ndarray.

name [object] Name to be stored in the index.

tupleize_cols [bool (default: True)] When True, attempt to create a MultiIndex if possible.

See also:

RangeIndex Index implementing a monotonic integer range.

CategoricalIndex Index of *Categorical* s.

MultiIndex A multi-level, or hierarchical Index.

IntervalIndex An Index of *Interval* s.

DatetimeIndex Index of datetime64 data.

TimedeltaIndex Index of timedelta64 data.

PeriodIndex Index of Period data.

Int64Index A special case of *Index* with purely integer labels.

UInt64Index A special case of *Index* with purely unsigned integer labels.

Float64Index A special case of *Index* with purely float labels.

Notes

An Index instance can **only** contain hashable objects

Examples

```
>>> pd.Index([1, 2, 3])
Int64Index([1, 2, 3], dtype='int64')
```

```
>>> pd.Index(list('abc'))
Index(['a', 'b', 'c'], dtype='object')
```

Attributes

| | |
|--------------------------------|--|
| <i>T</i> | Return the transpose, which is by definition self. |
| <i>array</i> | The ExtensionArray of the data backing this Series or Index. |
| <i>asi8</i> | Integer representation of the values. |
| <i>dtype</i> | Return the dtype object of the underlying data. |
| <i>has_duplicates</i> | Check if the Index has duplicate values. |
| <i>hasnans</i> | Return if I have any nans; enables various perf speedups. |
| <i>inferred_type</i> | Return a string of the type inferred from the values. |
| <i>is_all_dates</i> | Whether or not the index values only consist of dates. |
| <i>is_monotonic</i> | Alias for <i>is_monotonic_increasing</i> . |
| <i>is_monotonic_decreasing</i> | Return if the index is monotonic decreasing (only equal or decreasing) values. |
| <i>is_monotonic_increasing</i> | Return if the index is monotonic increasing (only equal or increasing) values. |
| <i>is_unique</i> | Return if the index has unique values. |
| <i>name</i> | Return Index or MultiIndex name. |
| <i>nbytes</i> | Return the number of bytes in the underlying data. |
| <i>ndim</i> | Number of dimensions of the underlying data, by definition 1. |
| <i>nlevels</i> | Number of levels. |
| <i>shape</i> | Return a tuple of the shape of the underlying data. |
| <i>size</i> | Return the number of elements in the underlying data. |
| <i>values</i> | Return an array representing the data in the Index. |

pandas.Index.T

property Index.T

Return the transpose, which is by definition self.

pandas.Index.array

Index.array

The ExtensionArray of the data backing this Series or Index.

Returns

ExtensionArray An ExtensionArray of the values stored within. For extension types, this is the actual array. For NumPy native types, this is a thin (no copy) wrapper around `numpy.ndarray`.

`.array` differs `.values` which may require converting the data to a different form.

See also:

[*Index.to_numpy*](#) Similar method that always returns a NumPy array.

[*Series.to_numpy*](#) Similar method that always returns a NumPy array.

Notes

This table lays out the different array types for each extension dtype within pandas.

| dtype | array type |
|--------------------|---------------|
| category | Categorical |
| period | PeriodArray |
| interval | IntervalArray |
| IntegerNA | IntegerArray |
| string | StringArray |
| boolean | BooleanArray |
| datetime64[ns, tz] | DatetimeArray |

For any 3rd-party extension types, the array type will be an ExtensionArray.

For all remaining dtypes `.array` will be a `arrays.NumpyExtensionArray` wrapping the actual ndarray stored within. If you absolutely need a NumPy array (possibly with copying / coercing data), then use `Series.to_numpy()` instead.

Examples

For regular NumPy types like int, and float, a PandasArray is returned.

```
>>> pd.Series([1, 2, 3]).array
<PandasArray>
[1, 2, 3]
Length: 3, dtype: int64
```

For extension types, like Categorical, the actual ExtensionArray is returned

```
>>> ser = pd.Series(pd.Categorical(['a', 'b', 'a']))
>>> ser.array
['a', 'b', 'a']
Categories (2, object): ['a', 'b']
```

pandas.Index.asi8

property Index.asi8

Integer representation of the values.

Returns

ndarray An ndarray with int64 dtype.

pandas.Index.dtype

Index.dtype

Return the dtype object of the underlying data.

pandas.Index.has_duplicates

property Index.has_duplicates

Check if the Index has duplicate values.

Returns

bool Whether or not the Index has duplicate values.

Examples

```
>>> idx = pd.Index([1, 5, 7, 7])
>>> idx.has_duplicates
True
```

```
>>> idx = pd.Index([1, 5, 7])
>>> idx.has_duplicates
False
```

```
>>> idx = pd.Index(["Watermelon", "Orange", "Apple",
...                 "Watermelon"]).astype("category")
>>> idx.has_duplicates
True
```

```
>>> idx = pd.Index(["Orange", "Apple",
...                 "Watermelon"]).astype("category")
>>> idx.has_duplicates
False
```

pandas.Index.hasnans

Index.hasnans

Return if I have any nans; enables various perf speedups.

pandas.Index.inferred_type

Index.inferred_type

Return a string of the type inferred from the values.

pandas.Index.is_all_dates

Index.is_all_dates

Whether or not the index values only consist of dates.

pandas.Index.is_monotonic

property Index.is_monotonic

Alias for `is_monotonic_increasing`.

pandas.Index.is_monotonic_decreasing

property Index.is_monotonic_decreasing

Return if the index is monotonic decreasing (only equal or decreasing) values.

Examples

```
>>> Index([3, 2, 1]).is_monotonic_decreasing
True
>>> Index([3, 2, 2]).is_monotonic_decreasing
True
>>> Index([3, 1, 2]).is_monotonic_decreasing
False
```

pandas.Index.is_monotonic_increasing

property Index.is_monotonic_increasing

Return if the index is monotonic increasing (only equal or increasing) values.

Examples

```
>>> Index([1, 2, 3]).is_monotonic_increasing
True
>>> Index([1, 2, 2]).is_monotonic_increasing
True
>>> Index([1, 3, 2]).is_monotonic_increasing
False
```

pandas.Index.is_unique

Index.is_unique

Return if the index has unique values.

pandas.Index.name

property Index.name

Return Index or MultiIndex name.

pandas.Index.nbytes

property Index.nbytes

Return the number of bytes in the underlying data.

pandas.Index.ndim

property Index.ndim

Number of dimensions of the underlying data, by definition 1.

pandas.Index.nlevels

property Index.nlevels

Number of levels.

pandas.Index.shape

property Index.shape

Return a tuple of the shape of the underlying data.

pandas.Index.size**property** `Index.size`

Return the number of elements in the underlying data.

pandas.Index.values**property** `Index.values`

Return an array representing the data in the Index.

Warning: We recommend using `Index.array` or `Index.to_numpy()`, depending on whether you need a reference to the underlying data or a NumPy array.

Returns

array: `numpy.ndarray` or `ExtensionArray`

See also:

`Index.array` Reference to the underlying data.

`Index.to_numpy` A NumPy array representing the underlying data.

| | |
|--------------|--|
| empty | |
| names | |

Methods

| | |
|---|--|
| <code>all(*args, **kwargs)</code> | Return whether all elements are Truthy. |
| <code>any(*args, **kwargs)</code> | Return whether any element is Truthy. |
| <code>append(other)</code> | Append a collection of Index options together. |
| <code>argmax([axis, skipna])</code> | Return int position of the largest value in the Series. |
| <code>argmin([axis, skipna])</code> | Return int position of the smallest value in the Series. |
| <code>argsort(*args, **kwargs)</code> | Return the integer indices that would sort the index. |
| <code>asof(label)</code> | Return the label from the index, or, if not present, the previous one. |
| <code>asof_locs(where, mask)</code> | Return the locations (indices) of labels in the index. |
| <code>astype(dtype[, copy])</code> | Create an Index with values cast to dtypes. |
| <code>copy([name, deep, dtype, names])</code> | Make a copy of this object. |
| <code>delete(loc)</code> | Make new Index with passed location(-s) deleted. |
| <code>difference(other[, sort])</code> | Return a new Index with elements of index not in <i>other</i> . |
| <code>drop(labels[, errors])</code> | Make new Index with passed list of labels deleted. |
| <code>drop_duplicates([keep])</code> | Return Index with duplicate values removed. |
| <code>droplevel([level])</code> | Return index with requested level(s) removed. |
| <code>dropna([how])</code> | Return Index without NA/NaN values. |
| <code>duplicated([keep])</code> | Indicate duplicate index values. |
| <code>equals(other)</code> | Determine if two Index object are equal. |

continues on next page

Table 137 – continued from previous page

| | |
|--|---|
| <i>factorize</i> ([sort, na_sentinel]) | Encode the object as an enumerated type or categorical variable. |
| <i>fillna</i> ([value, downcast]) | Fill NA/NaN values with the specified value. |
| <i>format</i> ([name, formatter, na_rep]) | Render a string representation of the Index. |
| <i>get_indexer</i> (target[, method, limit, tolerance]) | Compute indexer and mask for new index given the current index. |
| <i>get_indexer_for</i> (target, **kwargs) | Guaranteed return of an indexer even when non-unique. |
| <i>get_indexer_non_unique</i> (target) | Compute indexer and mask for new index given the current index. |
| <i>get_level_values</i> (level) | Return an Index of values for requested level. |
| <i>get_loc</i> (key[, method, tolerance]) | Get integer location, slice or boolean mask for requested label. |
| <i>get_slice_bound</i> (label, side[, kind]) | Calculate slice bound that corresponds to given label. |
| <i>get_value</i> (series, key) | Fast lookup of value from 1-dimensional ndarray. |
| <i>groupby</i> (values) | Group the index labels by a given array of values. |
| <i>holds_integer</i> () | Whether the type is an integer type. |
| <i>identical</i> (other) | Similar to equals, but checks that object attributes and types are also equal. |
| <i>insert</i> (loc, item) | Make new Index inserting new item at location. |
| <i>intersection</i> (other[, sort]) | Form the intersection of two Index objects. |
| <i>is</i> (other) | More flexible, faster check like <code>is</code> but that works through views. |
| <i>is_boolean</i> () | Check if the Index only consists of booleans. |
| <i>is_categorical</i> () | Check if the Index holds categorical data. |
| <i>is_floating</i> () | Check if the Index is a floating type. |
| <i>is_integer</i> () | Check if the Index only consists of integers. |
| <i>is_interval</i> () | Check if the Index holds Interval objects. |
| <i>is_mixed</i> () | Check if the Index holds data with mixed data types. |
| <i>is_numeric</i> () | Check if the Index only consists of numeric data. |
| <i>is_object</i> () | Check if the Index is of the object dtype. |
| <i>is_type_compatible</i> (kind) | Whether the index type is compatible with the provided type. |
| <i>isin</i> (values[, level]) | Return a boolean array where the index values are in <i>values</i> . |
| <i>isna</i> () | Detect missing values. |
| <i>isnull</i> () | Detect missing values. |
| <i>item</i> () | Return the first element of the underlying data as a Python scalar. |
| <i>join</i> (other[, how, level, return_indexers, sort]) | Compute <code>join_index</code> and indexers to conform data structures to the new index. |
| <i>map</i> (mapper[, na_action]) | Map values using input correspondence (a dict, Series, or function). |
| <i>max</i> ([axis, skipna]) | Return the maximum value of the Index. |
| <i>memory_usage</i> ([deep]) | Memory usage of the values. |
| <i>min</i> ([axis, skipna]) | Return the minimum value of the Index. |
| <i>notna</i> () | Detect existing (non-missing) values. |
| <i>notnull</i> () | Detect existing (non-missing) values. |
| <i>nunique</i> ([dropna]) | Return number of unique elements in the object. |
| <i>putmask</i> (mask, value) | Return a new Index of the values set with the mask. |

continues on next page

Table 137 – continued from previous page

| | |
|---|--|
| <code>ravel([order])</code> | Return an ndarray of the flattened values of the underlying data. |
| <code>reindex(target[, method, level, limit, ...])</code> | Create index with target's values. |
| <code>rename(name[, inplace])</code> | Alter Index or MultiIndex name. |
| <code>repeat(repeats[, axis])</code> | Repeat elements of a Index. |
| <code>searchsorted(value[, side, sorter])</code> | Find indices where elements should be inserted to maintain order. |
| <code>set_names(names[, level, inplace])</code> | Set Index or MultiIndex name. |
| <code>set_value(arr, key, value)</code> | (DEPRECATED) Fast lookup of value from 1-dimensional ndarray. |
| <code>shift([periods, freq])</code> | Shift index by desired number of time frequency increments. |
| <code>slice_indexer([start, end, step, kind])</code> | Compute the slice indexer for input labels and step. |
| <code>slice_locs([start, end, step, kind])</code> | Compute slice locations for input labels. |
| <code>sort(*args, **kwargs)</code> | Use <code>sort_values</code> instead. |
| <code>sort_values([return_indexer, ascending, ...])</code> | Return a sorted copy of the index. |
| <code>sortlevel([level, ascending, sort_remaining])</code> | For internal compatibility with the Index API. |
| <code>str</code> | alias of <code>pandas.core.strings.accessor.StringMethods</code> |
| <code>symmetric_difference(other[, result_name, sort])</code> | Compute the symmetric difference of two Index objects. |
| <code>take(indices[, axis, allow_fill, fill_value])</code> | Return a new Index of the values selected by the indices. |
| <code>to_flat_index()</code> | Identity method. |
| <code>to_frame([index, name])</code> | Create a DataFrame with a column containing the Index. |
| <code>to_list()</code> | Return a list of the values. |
| <code>to_native_types([slicer])</code> | (DEPRECATED) Format specified values of <i>self</i> and return them. |
| <code>to_numpy([dtype, copy, na_value])</code> | A NumPy ndarray representing the values in this Series or Index. |
| <code>to_series([index, name])</code> | Create a Series with both index and values equal to the index keys. |
| <code>tolist()</code> | Return a list of the values. |
| <code>transpose(*args, **kwargs)</code> | Return the transpose, which is by definition self. |
| <code>union(other[, sort])</code> | Form the union of two Index objects. |
| <code>unique([level])</code> | Return unique values in the index. |
| <code>value_counts([normalize, sort, ascending, ...])</code> | Return a Series containing counts of unique values. |
| <code>where(cond[, other])</code> | Replace values where the condition is False. |

pandas.Index.all**Index.all**(*args, **kwargs)

Return whether all elements are Truthy.

Parameters***args** Required for compatibility with numpy.****kwargs** Required for compatibility with numpy.**Returns**

all [bool or array-like (if axis is specified)] A single element array-like may be converted to bool.

See also:

Index.any Return whether any element in an Index is True.

Series.any Return whether any element in a Series is True.

Series.all Return whether all elements in a Series are True.

Notes

Not a Number (NaN), positive infinity and negative infinity evaluate to True because these are not equal to zero.

Examples

all

True, because nonzero integers are considered True.

```
>>> pd.Index([1, 2, 3]).all()
True
```

False, because 0 is considered False.

```
>>> pd.Index([0, 1, 2]).all()
False
```

any

True, because 1 is considered True.

```
>>> pd.Index([0, 0, 1]).any()
True
```

False, because 0 is considered False.

```
>>> pd.Index([0, 0, 0]).any()
False
```

pandas.Index.any

Index.any(*args, **kwargs)

Return whether any element is Truthy.

Parameters

***args** Required for compatibility with numpy.

****kwargs** Required for compatibility with numpy.

Returns

any [bool or array-like (if axis is specified)] A single element array-like may be converted to bool.

See also:

[*Index.all*](#) Return whether all elements are True.

[*Series.all*](#) Return whether all elements are True.

Notes

Not a Number (NaN), positive infinity and negative infinity evaluate to True because these are not equal to zero.

Examples

```
>>> index = pd.Index([0, 1, 2])
>>> index.any()
True
```

```
>>> index = pd.Index([0, 0, 0])
>>> index.any()
False
```

pandas.Index.append

`Index.append(other)`

Append a collection of Index options together.

Parameters

other [Index or list/tuple of indices]

Returns

Index

pandas.Index.argmax

`Index.argmax(axis=None, skipna=True, *args, **kwargs)`

Return int position of the largest value in the Series.

If the maximum is achieved in multiple locations, the first row position is returned.

Parameters

axis [{None}] Dummy argument for consistency with Series.

skipna [bool, default True] Exclude NA/null values when showing the result.

***args, **kwargs** Additional arguments and keywords for compatibility with NumPy.

Returns

int Row position of the maximum value.

See also:

[*Series.argmax*](#) Return position of the maximum value.

Series.argmax Return position of the minimum value.

numpy.ndarray.argmax Equivalent method for numpy arrays.

Series.idxmax Return index label of the maximum values.

Series.idxmin Return index label of the minimum values.

Examples

Consider dataset containing cereal calories

```
>>> s = pd.Series({'Corn Flakes': 100.0, 'Almond Delight': 110.0,
...               'Cinnamon Toast Crunch': 120.0, 'Cocoa Puff': 110.0})
>>> s
Corn Flakes          100.0
Almond Delight      110.0
Cinnamon Toast Crunch 120.0
Cocoa Puff          110.0
dtype: float64
```

```
>>> s.argmax()
2
>>> s.argmin()
0
```

The maximum cereal calories is the third element and the minimum cereal calories is the first element, since series is zero-indexed.

pandas.Index.argmax

Index.argmax(*axis=None, skipna=True, *args, **kwargs*)

Return int position of the smallest value in the Series.

If the minimum is achieved in multiple locations, the first row position is returned.

Parameters

axis [{None}] Dummy argument for consistency with Series.

skipna [bool, default True] Exclude NA/null values when showing the result.

***args, **kwargs** Additional arguments and keywords for compatibility with NumPy.

Returns

int Row position of the minimum value.

See also:

Series.argmax Return position of the minimum value.

Series.argmax Return position of the maximum value.

numpy.ndarray.argmax Equivalent method for numpy arrays.

Series.idxmax Return index label of the maximum values.

Series.idxmin Return index label of the minimum values.

Examples

Consider dataset containing cereal calories

```
>>> s = pd.Series({'Corn Flakes': 100.0, 'Almond Delight': 110.0,
...               'Cinnamon Toast Crunch': 120.0, 'Cocoa Puff': 110.0})
>>> s
Corn Flakes          100.0
Almond Delight       110.0
Cinnamon Toast Crunch 120.0
Cocoa Puff           110.0
dtype: float64
```

```
>>> s.argmax()
2
>>> s.argmin()
0
```

The maximum cereal calories is the third element and the minimum cereal calories is the first element, since series is zero-indexed.

pandas.Index.argsort

`Index.argsort(*args, **kwargs)`

Return the integer indices that would sort the index.

Parameters

***args** Passed to `numpy.ndarray.argsort`.

****kwargs** Passed to `numpy.ndarray.argsort`.

Returns

`np.ndarray[np.intp]` Integer indices that would sort the index if used as an indexer.

See also:

[numpy.argsort](#) Similar method for NumPy arrays.

[Index.sort_values](#) Return sorted copy of Index.

Examples

```
>>> idx = pd.Index(['b', 'a', 'd', 'c'])
>>> idx
Index(['b', 'a', 'd', 'c'], dtype='object')
```

```
>>> order = idx.argsort()
>>> order
array([1, 0, 3, 2])
```

```
>>> idx[order]
Index(['a', 'b', 'c', 'd'], dtype='object')
```

pandas.Index.asof

Index.asof(*label*)

Return the label from the index, or, if not present, the previous one.

Assuming that the index is sorted, return the passed index label if it is in the index, or return the previous index label if the passed one is not in the index.

Parameters

label [object] The label up to which the method returns the latest index label.

Returns

object The passed label if it is in the index. The previous label if the passed label is not in the sorted index or *NaN* if there is no such label.

See also:

Series.asof Return the latest value in a Series up to the passed index.

merge_asof Perform an asof merge (similar to left join but it matches on nearest key rather than equal key).

Index.get_loc An *asof* is a thin wrapper around *get_loc* with *method='pad'*.

Examples

Index.asof returns the latest index label up to the passed label.

```
>>> idx = pd.Index(['2013-12-31', '2014-01-02', '2014-01-03'])
>>> idx.asof('2014-01-01')
'2013-12-31'
```

If the label is in the index, the method returns the passed label.

```
>>> idx.asof('2014-01-02')
'2014-01-02'
```

If all of the labels in the index are later than the passed label, NaN is returned.

```
>>> idx.asof('1999-01-02')
nan
```

If the index is not sorted, an error is raised.

```
>>> idx_not_sorted = pd.Index(['2013-12-31', '2015-01-02',
...                             '2014-01-03'])
>>> idx_not_sorted.asof('2013-12-31')
Traceback (most recent call last):
ValueError: index must be monotonic increasing or decreasing
```

pandas.Index.asof_locs

`Index.asof_locs` (*where, mask*)

Return the locations (indices) of labels in the index.

As in the *asof* function, if the label (a particular entry in *where*) is not in the index, the latest index label up to the passed label is chosen and its index returned.

If all of the labels in the index are later than a label in *where*, -1 is returned.

mask is used to ignore NA values in the index during calculation.

Parameters

where [Index] An Index consisting of an array of timestamps.

mask [np.ndarray[bool]] Array of booleans denoting where values in the original data are not NA.

Returns

np.ndarray[np.intp] An array of locations (indices) of the labels from the Index which correspond to the return values of the *asof* function for every element in *where*.

pandas.Index.astype

`Index.astype` (*dtype, copy=True*)

Create an Index with values cast to dtypes.

The class of a new Index is determined by *dtype*. When conversion is impossible, a `TypeError` exception is raised.

Parameters

dtype [numpy dtype or pandas type] Note that any signed integer *dtype* is treated as `'int64'`, and any unsigned integer *dtype* is treated as `'uint64'`, regardless of the size.

copy [bool, default True] By default, *astype* always returns a newly allocated object. If *copy* is set to False and internal requirements on *dtype* are satisfied, the original data is used to create a new Index or the original Index is returned.

Returns

Index Index with values cast to specified dtype.

pandas.Index.copy

`Index.copy` (*name=None, deep=False, dtype=None, names=None*)

Make a copy of this object.

Name and dtype sets those attributes on the new object.

Parameters

name [Label, optional] Set name for new object.

deep [bool, default False]

dtype [numpy dtype or pandas type, optional] Set dtype for new object.

Deprecated since version 1.2.0: use *astype* method instead.

names [list-like, optional] Kept for compatibility with MultiIndex. Should not be used.

Returns

Index Index refer to new object which is a copy of this object.

Notes

In most cases, there should be no functional difference from using `deep`, but if `deep` is passed it will attempt to deepcopy.

pandas.Index.delete

Index.delete(*loc*)

Make new Index with passed location(-s) deleted.

Parameters

loc [int or list of int] Location of item(-s) which will be deleted. Use a list of locations to delete more than one value at the same time.

Returns

Index Will be same type as self, except for RangeIndex.

See also:

numpy.delete Delete any rows and column from NumPy array (ndarray).

Examples

```
>>> idx = pd.Index(['a', 'b', 'c'])
>>> idx.delete(1)
Index(['a', 'c'], dtype='object')
```

```
>>> idx = pd.Index(['a', 'b', 'c'])
>>> idx.delete([0, 2])
Index(['b'], dtype='object')
```

pandas.Index.difference

Index.difference(*other*, *sort=None*)

Return a new Index with elements of index not in *other*.

This is the set difference of two Index objects.

Parameters

other [Index or array-like]

sort [False or None, default None] Whether to sort the resulting index. By default, the values are attempted to be sorted, but any `TypeError` from incomparable elements is caught by pandas.

- None : Attempt to sort the result, but catch any `TypeError`s from comparing incomparable elements.

- False : Do not sort the result.

Returns

difference [Index]

Examples

```
>>> idx1 = pd.Index([2, 1, 3, 4])
>>> idx2 = pd.Index([3, 4, 5, 6])
>>> idx1.difference(idx2)
Int64Index([1, 2], dtype='int64')
>>> idx1.difference(idx2, sort=False)
Int64Index([2, 1], dtype='int64')
```

pandas.Index.drop

Index.**drop**(*labels, errors='raise'*)

Make new Index with passed list of labels deleted.

Parameters

labels [array-like]

errors [{ 'ignore', 'raise' }, default 'raise'] If 'ignore', suppress error and existing labels are dropped.

Returns

dropped [Index] Will be same type as self, except for RangeIndex.

Raises

KeyError If not all of the labels are found in the selected axis

pandas.Index.drop_duplicates

Index.**drop_duplicates**(*keep='first'*)

Return Index with duplicate values removed.

Parameters

keep [{ 'first', 'last', False }, default 'first']

- 'first' : Drop duplicates except for the first occurrence.
- 'last' : Drop duplicates except for the last occurrence.
- False : Drop all duplicates.

Returns

deduplicated [Index]

See also:

[Series.drop_duplicates](#) Equivalent method on Series.

[DataFrame.drop_duplicates](#) Equivalent method on DataFrame.

Index.duplicated Related method on Index, indicating duplicate Index values.

Examples

Generate an pandas.Index with duplicate values.

```
>>> idx = pd.Index(['lama', 'cow', 'lama', 'beetle', 'lama', 'hippo'])
```

The *keep* parameter controls which duplicate values are removed. The value 'first' keeps the first occurrence for each set of duplicated entries. The default value of keep is 'first'.

```
>>> idx.drop_duplicates(keep='first')
Index(['lama', 'cow', 'beetle', 'hippo'], dtype='object')
```

The value 'last' keeps the last occurrence for each set of duplicated entries.

```
>>> idx.drop_duplicates(keep='last')
Index(['cow', 'beetle', 'lama', 'hippo'], dtype='object')
```

The value False discards all sets of duplicated entries.

```
>>> idx.drop_duplicates(keep=False)
Index(['cow', 'beetle', 'hippo'], dtype='object')
```

pandas.Index.droplevel

Index.**droplevel** (*level=0*)

Return index with requested level(s) removed.

If resulting index has only 1 level left, the result will be of Index type, not MultiIndex.

Parameters

level [int, str, or list-like, default 0] If a string is given, must be the name of a level. If list-like, elements must be names or indexes of levels.

Returns

Index or MultiIndex

Examples

```
>>> mi = pd.MultiIndex.from_arrays(
... [[1, 2], [3, 4], [5, 6]], names=['x', 'y', 'z'])
>>> mi
MultiIndex([(1, 3, 5),
            (2, 4, 6)],
            names=['x', 'y', 'z'])
```

```
>>> mi.droplevel()
MultiIndex([(3, 5),
            (4, 6)],
            names=['y', 'z'])
```

```
>>> mi.droplevel(2)
MultiIndex([(1, 3),
            (2, 4)],
            names=['x', 'y'])
```

```
>>> mi.droplevel('z')
MultiIndex([(1, 3),
            (2, 4)],
            names=['x', 'y'])
```

```
>>> mi.droplevel(['x', 'y'])
Int64Index([5, 6], dtype='int64', name='z')
```

pandas.Index.dropna

`Index.dropna` (*how='any'*)

Return Index without NA/NaN values.

Parameters

how [{'any', 'all'}, default 'any'] If the Index is a MultiIndex, drop the value when any or all levels are NaN.

Returns

Index

pandas.Index.duplicated

`Index.duplicated` (*keep='first'*)

Indicate duplicate index values.

Duplicated values are indicated as `True` values in the resulting array. Either all duplicates, all except the first, or all except the last occurrence of duplicates can be indicated.

Parameters

keep [{'first', 'last', False}, default 'first'] The value or values in a set of duplicates to mark as missing.

- 'first' : Mark duplicates as `True` except for the first occurrence.
- 'last' : Mark duplicates as `True` except for the last occurrence.
- False : Mark all duplicates as `True`.

Returns

`np.ndarray[bool]`

See also:

[*Series.duplicated*](#) Equivalent method on `pandas.Series`.

[*DataFrame.duplicated*](#) Equivalent method on `pandas.DataFrame`.

[*Index.drop_duplicates*](#) Remove duplicate values from Index.

Examples

By default, for each set of duplicated values, the first occurrence is set to False and all others to True:

```
>>> idx = pd.Index(['lama', 'cow', 'lama', 'beetle', 'lama'])
>>> idx.duplicated()
array([False, False,  True, False,  True])
```

which is equivalent to

```
>>> idx.duplicated(keep='first')
array([False, False,  True, False,  True])
```

By using 'last', the last occurrence of each set of duplicated values is set on False and all others on True:

```
>>> idx.duplicated(keep='last')
array([ True, False,  True, False, False])
```

By setting keep on False, all duplicates are True:

```
>>> idx.duplicated(keep=False)
array([ True, False,  True, False,  True])
```

pandas.Index.equals

`Index.equals` (*other*)

Determine if two Index object are equal.

The things that are being compared are:

- The elements inside the Index object.
- The order of the elements inside the Index object.

Parameters

other [Any] The other object to compare against.

Returns

bool True if “other” is an Index and it has the same elements and order as the calling index; False otherwise.

Examples

```
>>> idx1 = pd.Index([1, 2, 3])
>>> idx1
Int64Index([1, 2, 3], dtype='int64')
>>> idx1.equals(pd.Index([1, 2, 3]))
True
```

The elements inside are compared

```
>>> idx2 = pd.Index(["1", "2", "3"])
>>> idx2
Index(['1', '2', '3'], dtype='object')
```

```
>>> idx1.equals(idx2)
False
```

The order is compared

```
>>> ascending_idx = pd.Index([1, 2, 3])
>>> ascending_idx
Int64Index([1, 2, 3], dtype='int64')
>>> descending_idx = pd.Index([3, 2, 1])
>>> descending_idx
Int64Index([3, 2, 1], dtype='int64')
>>> ascending_idx.equals(descending_idx)
False
```

The dtype is *not* compared

```
>>> int64_idx = pd.Int64Index([1, 2, 3])
>>> int64_idx
Int64Index([1, 2, 3], dtype='int64')
>>> uint64_idx = pd.UInt64Index([1, 2, 3])
>>> uint64_idx
UInt64Index([1, 2, 3], dtype='uint64')
>>> int64_idx.equals(uint64_idx)
True
```

pandas.Index.factorize

Index.factorize(*sort=False, na_sentinel=-1*)

Encode the object as an enumerated type or categorical variable.

This method is useful for obtaining a numeric representation of an array when all that matters is identifying distinct values. *factorize* is available as both a top-level function [pandas.factorize\(\)](#), and as a method [Series.factorize\(\)](#) and [Index.factorize\(\)](#).

Parameters

sort [bool, default False] Sort *uniques* and shuffle *codes* to maintain the relationship.

na_sentinel [int or None, default -1] Value to mark “not found”. If None, will not drop the NaN from the uniques of the values.

Changed in version 1.1.2.

Returns

codes [ndarray] An integer ndarray that’s an indexer into *uniques*. *uniques.take(codes)* will have the same values as *values*.

uniques [ndarray, Index, or Categorical] The unique valid values. When *values* is Categorical, *uniques* is a Categorical. When *values* is some other pandas object, an *Index* is returned. Otherwise, a 1-D ndarray is returned.

Note: Even if there's a missing value in *values*, *uniques* will *not* contain an entry for it.

See also:

cut Discretize continuous-valued array.

unique Find the unique value in an array.

Examples

These examples all show `factorize` as a top-level method like `pd.factorize(values)`. The results are identical for methods like `Series.factorize()`.

```
>>> codes, uniques = pd.factorize(['b', 'b', 'a', 'c', 'b'])
>>> codes
array([0, 0, 1, 2, 0]...)
>>> uniques
array(['b', 'a', 'c'], dtype=object)
```

With `sort=True`, the *uniques* will be sorted, and *codes* will be shuffled so that the relationship is the maintained.

```
>>> codes, uniques = pd.factorize(['b', 'b', 'a', 'c', 'b'], sort=True)
>>> codes
array([1, 1, 0, 2, 1]...)
>>> uniques
array(['a', 'b', 'c'], dtype=object)
```

Missing values are indicated in *codes* with *na_sentinel* (-1 by default). Note that missing values are never included in *uniques*.

```
>>> codes, uniques = pd.factorize(['b', None, 'a', 'c', 'b'])
>>> codes
array([ 0, -1,  1,  2,  0]...)
>>> uniques
array(['b', 'a', 'c'], dtype=object)
```

Thus far, we've only factorized lists (which are internally coerced to NumPy arrays). When factorizing pandas objects, the type of *uniques* will differ. For Categoricals, a *Categorical* is returned.

```
>>> cat = pd.Categorical(['a', 'a', 'c'], categories=['a', 'b', 'c'])
>>> codes, uniques = pd.factorize(cat)
>>> codes
array([0, 0, 1]...)
>>> uniques
['a', 'c']
Categories (3, object): ['a', 'b', 'c']
```

Notice that 'b' is in `uniques.categories`, despite not being present in `cat.values`.

For all other pandas objects, an Index of the appropriate type is returned.

```
>>> cat = pd.Series(['a', 'a', 'c'])
>>> codes, uniques = pd.factorize(cat)
>>> codes
array([0, 0, 1]...)
>>> uniques
Index(['a', 'c'], dtype='object')
```

If NaN is in the values, and we want to include NaN in the uniques of the values, it can be achieved by setting `na_sentinel=None`.

```
>>> values = np.array([1, 2, 1, np.nan])
>>> codes, uniques = pd.factorize(values) # default: na_sentinel=-1
>>> codes
array([ 0,  1,  0, -1])
>>> uniques
array([1., 2.]
```

```
>>> codes, uniques = pd.factorize(values, na_sentinel=None)
>>> codes
array([0, 1, 0, 2])
>>> uniques
array([ 1.,  2., nan])
```

pandas.Index.fillna

`Index.fillna`(*value=None, downcast=None*)

Fill NA/NaN values with the specified value.

Parameters

value [scalar] Scalar value to use to fill holes (e.g. 0). This value cannot be a list-likes.

downcast [dict, default is None] A dict of item->dtype of what to downcast if possible, or the string 'infer' which will try to downcast to an appropriate equal type (e.g. float64 to int64 if possible).

Returns

Index

See also:

[*DataFrame.fillna*](#) Fill NaN values of a DataFrame.

[*Series.fillna*](#) Fill NaN Values of a Series.

pandas.Index.format

`Index.format`(*name=False, formatter=None, na_rep='NaN'*)

Render a string representation of the Index.

pandas.Index.get_indexer

`Index.get_indexer`(*target, method=None, limit=None, tolerance=None*)

Compute indexer and mask for new index given the current index. The indexer should be then used as an input to `ndarray.take` to align the current data to the new index.

Parameters

target [Index]

method [{None, 'pad'/'ffill', 'backfill'/'bfill', 'nearest'}, optional]

- default: exact matches only.
- pad / ffill: find the PREVIOUS index value if no exact match.
- backfill / bfill: use NEXT index value if no exact match
- nearest: use the NEAREST index value if no exact match. Tied distances are broken by preferring the larger index value.

limit [int, optional] Maximum number of consecutive labels in `target` to match for inexact matches.

tolerance [optional] Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations must satisfy the equation $\text{abs}(\text{index}[\text{indexer}] - \text{target}) \leq \text{tolerance}$.

Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple, array, Series, and must be the same size as the index and its dtype must exactly match the index's type.

Returns

indexer [np.ndarray[np.intp]] Integers from 0 to `n - 1` indicating that the index at these positions matches the corresponding target values. Missing values in the target are marked by -1.

Examples

```
>>> index = pd.Index(['c', 'a', 'b'])
>>> index.get_indexer(['a', 'b', 'x'])
array([ 1,  2, -1])
```

Notice that the return value is an array of locations in `index` and `x` is marked by -1, as it is not in `index`.

`pandas.Index.get_indexer_for`

`Index.get_indexer_for(target, **kwargs)`

Guaranteed return of an indexer even when non-unique.

This dispatches to `get_indexer` or `get_indexer_non_unique` as appropriate.

Returns

`np.ndarray[np.intp]` List of indices.

`pandas.Index.get_indexer_non_unique`

`Index.get_indexer_non_unique(target)`

Compute indexer and mask for new index given the current index. The indexer should be then used as an input to `ndarray.take` to align the current data to the new index.

Parameters

target [Index]

Returns

indexer [np.ndarray[np.intp]] Integers from 0 to n - 1 indicating that the index at these positions matches the corresponding target values. Missing values in the target are marked by -1.

missing [np.ndarray[np.intp]] An indexer into the target of the values not found. These correspond to the -1 in the indexer array.

`pandas.Index.get_level_values`

`Index.get_level_values(level)`

Return an Index of values for requested level.

This is primarily useful to get an individual level of values from a MultiIndex, but is provided on Index as well for compatibility.

Parameters

level [int or str] It is either the integer position or the name of the level.

Returns

Index Calling object, as there is only one level in the Index.

See also:

[`MultiIndex.get_level_values`](#) Get values for a level of a MultiIndex.

Notes

For Index, level should be 0, since there are no multiple levels.

Examples

```
>>> idx = pd.Index(list('abc'))
>>> idx
Index(['a', 'b', 'c'], dtype='object')
```

Get level values by supplying *level* as integer:

```
>>> idx.get_level_values(0)
Index(['a', 'b', 'c'], dtype='object')
```

pandas.Index.get_loc

`Index.get_loc(key, method=None, tolerance=None)`

Get integer location, slice or boolean mask for requested label.

Parameters

key [label]

method [{None, 'pad'/'ffill', 'backfill'/'bfill', 'nearest'}, optional]

- default: exact matches only.
- pad / ffill: find the PREVIOUS index value if no exact match.
- backfill / bfill: use NEXT index value if no exact match
- nearest: use the NEAREST index value if no exact match. Tied distances are broken by preferring the larger index value.

tolerance [int or float, optional] Maximum distance from index value for inexact matches. The value of the index at the matching location must satisfy the equation $\text{abs}(\text{index}[\text{loc}] - \text{key}) \leq \text{tolerance}$.

Returns

loc [int if unique index, slice if monotonic index, else mask]

Examples

```
>>> unique_index = pd.Index(list('abc'))
>>> unique_index.get_loc('b')
1
```

```
>>> monotonic_index = pd.Index(list('abbc'))
>>> monotonic_index.get_loc('b')
slice(1, 3, None)
```

```
>>> non_monotonic_index = pd.Index(list('abcb'))
>>> non_monotonic_index.get_loc('b')
array([False,  True, False,  True])
```

pandas.Index.get_slice_bound

`Index.get_slice_bound`(*label*, *side*, *kind=None*)

Calculate slice bound that corresponds to given label.

Returns leftmost (one-past-the-rightmost if `side=='right'`) position of given label.

Parameters

label [object]

side [{ 'left', 'right' }]

kind [{ 'loc', 'getitem' } or None]

Returns

int Index of label.

pandas.Index.get_value

`Index.get_value`(*series*, *key*)

Fast lookup of value from 1-dimensional ndarray.

Only use this if you know what you're doing.

Returns

scalar or Series

pandas.Index.groupby

`Index.groupby`(*values*)

Group the index labels by a given array of values.

Parameters

values [array] Values used to determine the groups.

Returns

dict {group name -> group labels}

pandas.Index.holds_integer

`Index.holds_integer()`

Whether the type is an integer type.

pandas.Index.identical

`Index.identical(other)`

Similar to equals, but checks that object attributes and types are also equal.

Returns

bool If two Index objects have equal elements and same type True, otherwise False.

pandas.Index.insert

`Index.insert(loc, item)`

Make new Index inserting new item at location.

Follows Python list.append semantics for negative values.

Parameters

loc [int]

item [object]

Returns

new_index [Index]

pandas.Index.intersection

`Index.intersection(other, sort=False)`

Form the intersection of two Index objects.

This returns a new Index with elements common to the index and *other*.

Parameters

other [Index or array-like]

sort [False or None, default False] Whether to sort the resulting index.

- False : do not sort the result.
- None : sort the result, except when *self* and *other* are equal or when the values cannot be compared.

Returns

intersection [Index]

Examples

```
>>> idx1 = pd.Index([1, 2, 3, 4])
>>> idx2 = pd.Index([3, 4, 5, 6])
>>> idx1.intersection(idx2)
Int64Index([3, 4], dtype='int64')
```

pandas.Index.is_

Index.is_(other)

More flexible, faster check like `is` but that works through views.

Note: this is *not* the same as `Index.identical()`, which checks that metadata is also the same.

Parameters

other [object] Other object to compare against.

Returns

bool True if both have same underlying data, False otherwise.

See also:

[*Index.identical*](#) Works like `Index.is_` but also checks metadata.

pandas.Index.is_boolean

Index.is_boolean()

Check if the Index only consists of booleans.

Returns

bool Whether or not the Index only consists of booleans.

See also:

[*is_integer*](#) Check if the Index only consists of integers.

[*is_floating*](#) Check if the Index is a floating type.

[*is_numeric*](#) Check if the Index only consists of numeric data.

[*is_object*](#) Check if the Index is of the object dtype.

[*is_categorical*](#) Check if the Index holds categorical data.

[*is_interval*](#) Check if the Index holds Interval objects.

[*is_mixed*](#) Check if the Index holds data with mixed data types.

Examples

```
>>> idx = pd.Index([True, False, True])
>>> idx.is_boolean()
True
```

```
>>> idx = pd.Index(["True", "False", "True"])
>>> idx.is_boolean()
False
```

```
>>> idx = pd.Index([True, False, "True"])
>>> idx.is_boolean()
False
```

pandas.Index.is_categorical

Index.is_categorical()

Check if the Index holds categorical data.

Returns

bool True if the Index is categorical.

See also:

CategoricalIndex Index for categorical data.

is_boolean Check if the Index only consists of booleans.

is_integer Check if the Index only consists of integers.

is_floating Check if the Index is a floating type.

is_numeric Check if the Index only consists of numeric data.

is_object Check if the Index is of the object dtype.

is_interval Check if the Index holds Interval objects.

is_mixed Check if the Index holds data with mixed data types.

Examples

```
>>> idx = pd.Index(["Watermelon", "Orange", "Apple",
...                "Watermelon"]).astype("category")
>>> idx.is_categorical()
True
```

```
>>> idx = pd.Index([1, 3, 5, 7])
>>> idx.is_categorical()
False
```

```
>>> s = pd.Series(["Peter", "Victor", "Elisabeth", "Mar"])
>>> s
0      Peter
1      Victor
2  Elisabeth
3         Mar
dtype: object
>>> s.index.is_categorical()
False
```

pandas.Index.is_floating

Index.is_floating()

Check if the Index is a floating type.

The Index may consist of only floats, NaNs, or a mix of floats, integers, or NaNs.

Returns

bool Whether or not the Index only consists of only consists of floats, NaNs, or a mix of floats, integers, or NaNs.

See also:

is_boolean Check if the Index only consists of booleans.

is_integer Check if the Index only consists of integers.

is_numeric Check if the Index only consists of numeric data.

is_object Check if the Index is of the object dtype.

is_categorical Check if the Index holds categorical data.

is_interval Check if the Index holds Interval objects.

is_mixed Check if the Index holds data with mixed data types.

Examples

```
>>> idx = pd.Index([1.0, 2.0, 3.0, 4.0])
>>> idx.is_floating()
True
```

```
>>> idx = pd.Index([1.0, 2.0, np.nan, 4.0])
>>> idx.is_floating()
True
```

```
>>> idx = pd.Index([1, 2, 3, 4, np.nan])
>>> idx.is_floating()
True
```

```
>>> idx = pd.Index([1, 2, 3, 4])
>>> idx.is_floating()
False
```

pandas.Index.is_integer

Index.**is_integer**()

Check if the Index only consists of integers.

Returns

bool Whether or not the Index only consists of integers.

See also:

is_boolean Check if the Index only consists of booleans.

is_floating Check if the Index is a floating type.

is_numeric Check if the Index only consists of numeric data.

is_object Check if the Index is of the object dtype.

is_categorical Check if the Index holds categorical data.

is_interval Check if the Index holds Interval objects.

is_mixed Check if the Index holds data with mixed data types.

Examples

```
>>> idx = pd.Index([1, 2, 3, 4])
>>> idx.is_integer()
True
```

```
>>> idx = pd.Index([1.0, 2.0, 3.0, 4.0])
>>> idx.is_integer()
False
```

```
>>> idx = pd.Index(["Apple", "Mango", "Watermelon"])
>>> idx.is_integer()
False
```

pandas.Index.is_interval

Index.**is_interval**()

Check if the Index holds Interval objects.

Returns

bool Whether or not the Index holds Interval objects.

See also:

IntervalIndex Index for Interval objects.

is_boolean Check if the Index only consists of booleans.

is_integer Check if the Index only consists of integers.

is_floating Check if the Index is a floating type.

is_numeric Check if the Index only consists of numeric data.

is_object Check if the Index is of the object dtype.

is_categorical Check if the Index holds categorical data.

is_mixed Check if the Index holds data with mixed data types.

Examples

```
>>> idx = pd.Index([pd.Interval(left=0, right=5),
...                 pd.Interval(left=5, right=10)])
>>> idx.is_interval()
True
```

```
>>> idx = pd.Index([1, 3, 5, 7])
>>> idx.is_interval()
False
```

pandas.Index.is_mixed

Index.*is_mixed*()

Check if the Index holds data with mixed data types.

Returns

bool Whether or not the Index holds data with mixed data types.

See also:

is_boolean Check if the Index only consists of booleans.

is_integer Check if the Index only consists of integers.

is_floating Check if the Index is a floating type.

is_numeric Check if the Index only consists of numeric data.

is_object Check if the Index is of the object dtype.

is_categorical Check if the Index holds categorical data.

is_interval Check if the Index holds Interval objects.

Examples

```
>>> idx = pd.Index(['a', np.nan, 'b'])
>>> idx.is_mixed()
True
```

```
>>> idx = pd.Index([1.0, 2.0, 3.0, 5.0])
>>> idx.is_mixed()
False
```

pandas.Index.is_numeric

Index.is_numeric()

Check if the Index only consists of numeric data.

Returns

bool Whether or not the Index only consists of numeric data.

See also:

is_boolean Check if the Index only consists of booleans.

is_integer Check if the Index only consists of integers.

is_floating Check if the Index is a floating type.

is_object Check if the Index is of the object dtype.

is_categorical Check if the Index holds categorical data.

is_interval Check if the Index holds Interval objects.

is_mixed Check if the Index holds data with mixed data types.

Examples

```
>>> idx = pd.Index([1.0, 2.0, 3.0, 4.0])
>>> idx.is_numeric()
True
```

```
>>> idx = pd.Index([1, 2, 3, 4.0])
>>> idx.is_numeric()
True
```

```
>>> idx = pd.Index([1, 2, 3, 4])
>>> idx.is_numeric()
True
```

```
>>> idx = pd.Index([1, 2, 3, 4.0, np.nan])
>>> idx.is_numeric()
True
```

```
>>> idx = pd.Index([1, 2, 3, 4.0, np.nan, "Apple"])
>>> idx.is_numeric()
False
```

pandas.Index.is_object

Index.is_object()

Check if the Index is of the object dtype.

Returns

bool Whether or not the Index is of the object dtype.

See also:

is_boolean Check if the Index only consists of booleans.

is_integer Check if the Index only consists of integers.

is_floating Check if the Index is a floating type.

is_numeric Check if the Index only consists of numeric data.

is_categorical Check if the Index holds categorical data.

is_interval Check if the Index holds Interval objects.

is_mixed Check if the Index holds data with mixed data types.

Examples

```
>>> idx = pd.Index(["Apple", "Mango", "Watermelon"])
>>> idx.is_object()
True
```

```
>>> idx = pd.Index(["Apple", "Mango", 2.0])
>>> idx.is_object()
True
```

```
>>> idx = pd.Index(["Watermelon", "Orange", "Apple",
...                 "Watermelon"]).astype("category")
>>> idx.is_object()
False
```

```
>>> idx = pd.Index([1.0, 2.0, 3.0, 4.0])
>>> idx.is_object()
False
```

pandas.Index.is_type_compatible

Index.is_type_compatible(*kind*)

Whether the index type is compatible with the provided type.

pandas.Index.isin

`Index.isin(values, level=None)`

Return a boolean array where the index values are in *values*.

Compute boolean array of whether each index value is found in the passed set of values. The length of the returned boolean array matches the length of the index.

Parameters

values [set or list-like] Sought values.

level [str or int, optional] Name or position of the index level to use (if the index is a *MultiIndex*).

Returns

np.ndarray[bool] NumPy array of boolean values.

See also:

[*Series.isin*](#) Same for Series.

[*DataFrame.isin*](#) Same method for DataFrames.

Notes

In the case of *MultiIndex* you must either specify *values* as a list-like object containing tuples that are the same length as the number of levels, or specify *level*. Otherwise it will raise a `ValueError`.

If *level* is specified:

- if it is the name of one *and only one* index level, use that level;
- otherwise it should be a number indicating level position.

Examples

```
>>> idx = pd.Index([1,2,3])
>>> idx
Int64Index([1, 2, 3], dtype='int64')
```

Check whether each index value in a list of values.

```
>>> idx.isin([1, 4])
array([ True, False, False])
```

```
>>> midx = pd.MultiIndex.from_arrays([[1,2,3],
...                                  ['red', 'blue', 'green']],
...                                  names=('number', 'color'))
>>> midx
MultiIndex([(1, 'red'),
            (2, 'blue'),
            (3, 'green')],
            names=['number', 'color'])
```

Check whether the strings in the 'color' level of the `MultiIndex` are in a list of colors.

```
>>> midx.isin(['red', 'orange', 'yellow'], level='color')
array([ True, False, False])
```

To check across the levels of a MultiIndex, pass a list of tuples:

```
>>> midx.isin([(1, 'red'), (3, 'red')])
array([ True, False, False])
```

For a DatetimeIndex, string values in *values* are converted to Timestamps.

```
>>> dates = ['2000-03-11', '2000-03-12', '2000-03-13']
>>> dti = pd.to_datetime(dates)
>>> dti
DatetimeIndex(['2000-03-11', '2000-03-12', '2000-03-13'],
              dtype='datetime64[ns]', freq=None)
```

```
>>> dti.isin(['2000-03-11'])
array([ True, False, False])
```

pandas.Index.isna

Index.isna()

Detect missing values.

Return a boolean same-sized object indicating if the values are NA. NA values, such as `None`, `numpy.NaN` or `pd.NaT`, get mapped to `True` values. Everything else get mapped to `False` values. Characters such as empty strings `' '` or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`).

Returns

`numpy.ndarray[bool]` A boolean array of whether my values are NA.

See also:

[*Index.notna*](#) Boolean inverse of `isna`.

[*Index.dropna*](#) Omit entries with missing values.

[*isna*](#) Top-level `isna`.

[*Series.isna*](#) Detect missing values in Series object.

Examples

Show which entries in a `pandas.Index` are NA. The result is an array.

```
>>> idx = pd.Index([5.2, 6.0, np.NaN])
>>> idx
Float64Index([5.2, 6.0, nan], dtype='float64')
>>> idx.isna()
array([False, False,  True])
```

Empty strings are not considered NA values. `None` is considered an NA value.

```
>>> idx = pd.Index(['black', '', 'red', None])
>>> idx
Index(['black', '', 'red', None], dtype='object')
>>> idx.isna()
array([False, False, False,  True])
```

For datetimes, *NaT* (Not a Time) is considered as an NA value.

```
>>> idx = pd.DatetimeIndex([pd.Timestamp('1940-04-25'),
...                          pd.Timestamp(''), None, pd.NaT])
>>> idx
DatetimeIndex(['1940-04-25', 'NaT', 'NaT', 'NaT'],
              dtype='datetime64[ns]', freq=None)
>>> idx.isna()
array([False,  True,  True,  True])
```

pandas.Index.isnull

Index.isnull()

Detect missing values.

Return a boolean same-sized object indicating if the values are NA. NA values, such as `None`, `numpy.NaN` or `pd.NaT`, get mapped to `True` values. Everything else get mapped to `False` values. Characters such as empty strings `''` or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`).

Returns

numpy.ndarray[bool] A boolean array of whether my values are NA.

See also:

Index.notna Boolean inverse of `isna`.

Index.dropna Omit entries with missing values.

isna Top-level `isna`.

Series.isna Detect missing values in Series object.

Examples

Show which entries in a `pandas.Index` are NA. The result is an array.

```
>>> idx = pd.Index([5.2, 6.0, np.NaN])
>>> idx
Float64Index([5.2, 6.0, nan], dtype='float64')
>>> idx.isna()
array([False, False,  True])
```

Empty strings are not considered NA values. `None` is considered an NA value.

```
>>> idx = pd.Index(['black', '', 'red', None])
>>> idx
```

(continues on next page)

(continued from previous page)

```
Index(['black', '', 'red', None], dtype='object')
>>> idx.isna()
array([False, False, False,  True])
```

For datetimes, *NaT* (Not a Time) is considered as an NA value.

```
>>> idx = pd.DatetimeIndex([pd.Timestamp('1940-04-25'),
...                         pd.Timestamp(''), None, pd.NaT])
>>> idx
DatetimeIndex(['1940-04-25', 'NaT', 'NaT', 'NaT'],
              dtype='datetime64[ns]', freq=None)
>>> idx.isna()
array([False,  True,  True,  True])
```

pandas.Index.item

Index.item()

Return the first element of the underlying data as a Python scalar.

Returns

scalar The first element of *%(klass)s*.

Raises

ValueError If the data is not length-1.

pandas.Index.join

Index.join(*other, how='left', level=None, return_indexers=False, sort=False*)

Compute *join_index* and *indexers* to conform data structures to the new index.

Parameters

other [Index]

how [{'left', 'right', 'inner', 'outer'}]

level [int or level name, default None]

return_indexers [bool, default False]

sort [bool, default False] Sort the join keys lexicographically in the result Index. If False, the order of the join keys depends on the join type (how keyword).

Returns

join_index, (left_indexer, right_indexer)

pandas.Index.map

`Index.map`(*mapper*, *na_action=None*)

Map values using input correspondence (a dict, Series, or function).

Parameters

mapper [function, dict, or Series] Mapping correspondence.

na_action [{None, 'ignore'}] If 'ignore', propagate NA values, without passing them to the mapping correspondence.

Returns

applied [Union[Index, MultiIndex], inferred] The output of the mapping function applied to the index. If the function returns a tuple with more than one element a MultiIndex will be returned.

pandas.Index.max

`Index.max`(*axis=None*, *skipna=True*, **args*, ***kwargs*)

Return the maximum value of the Index.

Parameters

axis [int, optional] For compatibility with NumPy. Only 0 or None are allowed.

skipna [bool, default True] Exclude NA/null values when showing the result.

***args, **kwargs** Additional arguments and keywords for compatibility with NumPy.

Returns

scalar Maximum value.

See also:

[`Index.min`](#) Return the minimum value in an Index.

[`Series.max`](#) Return the maximum value in a Series.

[`DataFrame.max`](#) Return the maximum values in a DataFrame.

Examples

```
>>> idx = pd.Index([3, 2, 1])
>>> idx.max()
3
```

```
>>> idx = pd.Index(['c', 'b', 'a'])
>>> idx.max()
'c'
```

For a MultiIndex, the maximum is determined lexicographically.

```
>>> idx = pd.MultiIndex.from_product(['a', 'b'], (2, 1))
>>> idx.max()
('b', 2)
```

pandas.Index.memory_usage

Index.**memory_usage**(*deep=False*)

Memory usage of the values.

Parameters

deep [bool, default False] Introspect the data deeply, interrogate *object* dtypes for system-level memory consumption.

Returns

bytes used

See also:

[numpy.ndarray.nbytes](#) Total bytes consumed by the elements of the array.

Notes

Memory usage does not include memory consumed by elements that are not components of the array if *deep=False* or if used on PyPy

pandas.Index.min

Index.**min**(*axis=None, skipna=True, *args, **kwargs*)

Return the minimum value of the Index.

Parameters

axis [{None}] Dummy argument for consistency with Series.

skipna [bool, default True] Exclude NA/null values when showing the result.

***args, **kwargs** Additional arguments and keywords for compatibility with NumPy.

Returns

scalar Minimum value.

See also:

[Index.max](#) Return the maximum value of the object.

[Series.min](#) Return the minimum value in a Series.

[DataFrame.min](#) Return the minimum values in a DataFrame.

Examples

```
>>> idx = pd.Index([3, 2, 1])
>>> idx.min()
1
```

```
>>> idx = pd.Index(['c', 'b', 'a'])
>>> idx.min()
'a'
```

For a MultiIndex, the minimum is determined lexicographically.

```
>>> idx = pd.MultiIndex.from_product([('a', 'b'), (2, 1)])
>>> idx.min()
('a', 1)
```

pandas.Index.notna

Index.notna()

Detect existing (non-missing) values.

Return a boolean same-sized object indicating if the values are not NA. Non-missing values get mapped to True. Characters such as empty strings '' or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`). NA values, such as `None` or `numpy.NaN`, get mapped to False values.

Returns

numpy.ndarray[bool] Boolean array to indicate which entries are not NA.

See also:

[*Index.notnull*](#) Alias of `notna`.

[*Index.isna*](#) Inverse of `notna`.

[*notna*](#) Top-level `notna`.

Examples

Show which entries in an Index are not NA. The result is an array.

```
>>> idx = pd.Index([5.2, 6.0, np.NaN])
>>> idx
Float64Index([5.2, 6.0, nan], dtype='float64')
>>> idx.notna()
array([ True,  True, False])
```

Empty strings are not considered NA values. `None` is considered a NA value.

```
>>> idx = pd.Index(['black', '', 'red', None])
>>> idx
Index(['black', '', 'red', None], dtype='object')
>>> idx.notna()
array([ True,  True,  True, False])
```

pandas.Index.notnull

Index.notnull()

Detect existing (non-missing) values.

Return a boolean same-sized object indicating if the values are not NA. Non-missing values get mapped to True. Characters such as empty strings '' or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`). NA values, such as `None` or `numpy.NaN`, get mapped to False values.

Returns

numpy.ndarray[bool] Boolean array to indicate which entries are not NA.

See also:

[*Index.notnull*](#) Alias of `notna`.

[*Index.isna*](#) Inverse of `notna`.

[*notna*](#) Top-level `notna`.

Examples

Show which entries in an Index are not NA. The result is an array.

```
>>> idx = pd.Index([5.2, 6.0, np.NaN])
>>> idx
Float64Index([5.2, 6.0, nan], dtype='float64')
>>> idx.notna()
array([ True,  True, False])
```

Empty strings are not considered NA values. `None` is considered a NA value.

```
>>> idx = pd.Index(['black', '', 'red', None])
>>> idx
Index(['black', '', 'red', None], dtype='object')
>>> idx.notna()
array([ True,  True,  True, False])
```

pandas.Index.nunique

Index.nunique(dropna=True)

Return number of unique elements in the object.

Excludes NA values by default.

Parameters

dropna [bool, default True] Don't include NaN in the count.

Returns

int

See also:

[*DataFrame.nunique*](#) Method `nunique` for `DataFrame`.

Series.count Count non-NA/null observations in the Series.

Examples

```
>>> s = pd.Series([1, 3, 5, 7, 7])
>>> s
0    1
1    3
2    5
3    7
4    7
dtype: int64
```

```
>>> s.nunique()
4
```

pandas.Index.putmask

Index.putmask(*mask, value*)

Return a new Index of the values set with the mask.

Returns

Index

See also:

numpy.ndarray.putmask Changes elements of an array based on conditional and input values.

pandas.Index.ravel

Index.ravel(*order='C'*)

Return an ndarray of the flattened values of the underlying data.

Returns

numpy.ndarray Flattened array.

See also:

numpy.ndarray.ravel Return a flattened array.

pandas.Index.reindex

Index.reindex(*target, method=None, level=None, limit=None, tolerance=None*)

Create index with target's values.

Parameters

target [an iterable]

Returns

new_index [pd.Index] Resulting index.

indexer [np.ndarray[np.intp] or None] Indices of output values in original index.

pandas.Index.rename

`Index.rename(name, inplace=False)`

Alter Index or MultiIndex name.

Able to set new names without level. Defaults to returning new index. Length of names must match number of levels in MultiIndex.

Parameters

name [label or list of labels] Name(s) to set.

inplace [bool, default False] Modifies the object directly, instead of creating a new Index or MultiIndex.

Returns

Index or None The same type as the caller or None if `inplace=True`.

See also:

[`Index.set_names`](#) Able to set new names partially and by level.

Examples

```
>>> idx = pd.Index(['A', 'C', 'A', 'B'], name='score')
>>> idx.rename('grade')
Index(['A', 'C', 'A', 'B'], dtype='object', name='grade')
```

```
>>> idx = pd.MultiIndex.from_product([['python', 'cobra'],
...                                  [2018, 2019]],
...                                  names=['kind', 'year'])
>>> idx
MultiIndex([( 'python', 2018),
            ( 'python', 2019),
            ( 'cobra', 2018),
            ( 'cobra', 2019)],
            names=['kind', 'year'])
>>> idx.rename(['species', 'year'])
MultiIndex([( 'python', 2018),
            ( 'python', 2019),
            ( 'cobra', 2018),
            ( 'cobra', 2019)],
            names=['species', 'year'])
>>> idx.rename('species')
Traceback (most recent call last):
TypeError: Must pass list-like as `names`.
```

pandas.Index.repeat

`Index.repeat(repeats, axis=None)`

Repeat elements of a Index.

Returns a new Index where each element of the current Index is repeated consecutively a given number of times.

Parameters

repeats [int or array of ints] The number of repetitions for each element. This should be a non-negative integer. Repeating 0 times will return an empty Index.

axis [None] Must be None. Has no effect but is accepted for compatibility with numpy.

Returns

repeated_index [Index] Newly created Index with repeated elements.

See also:

[`Series.repeat`](#) Equivalent function for Series.

[`numpy.repeat`](#) Similar method for `numpy.ndarray`.

Examples

```

>>> idx = pd.Index(['a', 'b', 'c'])
>>> idx
Index(['a', 'b', 'c'], dtype='object')
>>> idx.repeat(2)
Index(['a', 'a', 'b', 'b', 'c', 'c'], dtype='object')
>>> idx.repeat([1, 2, 3])
Index(['a', 'b', 'b', 'c', 'c', 'c'], dtype='object')

```

pandas.Index.searchsorted

`Index.searchsorted(value, side='left', sorter=None)`

Find indices where elements should be inserted to maintain order.

Find the indices into a sorted Index *self* such that, if the corresponding elements in *value* were inserted before the indices, the order of *self* would be preserved.

Note: The Index *must* be monotonically sorted, otherwise wrong locations will likely be returned. Pandas does *not* check this for you.

Parameters

value [array-like] Values to insert into *self*.

side [{'left', 'right'}, optional] If 'left', the index of the first suitable location found is given. If 'right', return the last such index. If there is no suitable index, return either 0 or N (where N is the length of *self*).

sorter [1-D array-like, optional] Optional array of integer indices that sort *self* into ascending order. They are typically the result of `np.argsort`.

Returns

int or array of int A scalar or array of insertion points with the same shape as *value*.

See also:

[`sort_values`](#) Sort by the values along either axis.

[`numpy.searchsorted`](#) Similar method from NumPy.

Notes

Binary search is used to find the required insertion points.

Examples

```
>>> ser = pd.Series([1, 2, 3])
>>> ser
0    1
1    2
2    3
dtype: int64
```

```
>>> ser.searchsorted(4)
3
```

```
>>> ser.searchsorted([0, 4])
array([0, 3])
```

```
>>> ser.searchsorted([1, 3], side='left')
array([0, 2])
```

```
>>> ser.searchsorted([1, 3], side='right')
array([1, 3])
```

```
>>> ser = pd.Series(pd.to_datetime(['3/11/2000', '3/12/2000', '3/13/2000']))
>>> ser
0    2000-03-11
1    2000-03-12
2    2000-03-13
dtype: datetime64[ns]
```

```
>>> ser.searchsorted('3/14/2000')
3
```

```
>>> ser = pd.Categorical(
...     ['apple', 'bread', 'bread', 'cheese', 'milk'], ordered=True
... )
>>> ser
['apple', 'bread', 'bread', 'cheese', 'milk']
Categories (4, object): ['apple' < 'bread' < 'cheese' < 'milk']
```

```
>>> ser.searchsorted('bread')
1
```

```
>>> ser.searchsorted(['bread'], side='right')
array([3])
```

If the values are not monotonically sorted, wrong locations may be returned:

```
>>> ser = pd.Series([2, 1, 3])
>>> ser
0    2
1    1
2    3
dtype: int64
```

```
>>> ser.searchsorted(1)
0 # wrong result, correct would be 1
```

pandas.Index.set_names

`Index.set_names(names, level=None, inplace=False)`

Set Index or MultiIndex name.

Able to set new names partially and by level.

Parameters

names [label or list of label or dict-like for MultiIndex] Name(s) to set.

Changed in version 1.3.0.

level [int, label or list of int or label, optional] If the index is a MultiIndex and names is not dict-like, level(s) to set (None for all levels). Otherwise level must be None.

Changed in version 1.3.0.

inplace [bool, default False] Modifies the object directly, instead of creating a new Index or MultiIndex.

Returns

Index or None The same type as the caller or None if `inplace=True`.

See also:

[*Index.rename*](#) Able to set new names without level.

Examples

```
>>> idx = pd.Index([1, 2, 3, 4])
>>> idx
Int64Index([1, 2, 3, 4], dtype='int64')
>>> idx.set_names('quarter')
Int64Index([1, 2, 3, 4], dtype='int64', name='quarter')
```

```
>>> idx = pd.MultiIndex.from_product([[ 'python', 'cobra'],
...                                  [2018, 2019]])
>>> idx
MultiIndex([( 'python', 2018),
            ( 'python', 2019),
            ( 'cobra', 2018),
            ( 'cobra', 2019)],
           )
>>> idx.set_names(['kind', 'year'], inplace=True)
>>> idx
MultiIndex([( 'python', 2018),
            ( 'python', 2019),
            ( 'cobra', 2018),
            ( 'cobra', 2019)],
           names=['kind', 'year'])
>>> idx.set_names('species', level=0)
MultiIndex([( 'python', 2018),
            ( 'python', 2019),
            ( 'cobra', 2018),
            ( 'cobra', 2019)],
           names=['species', 'year'])
```

When renaming levels with a dict, levels can not be passed.

```
>>> idx.set_names({'kind': 'snake'})
MultiIndex([( 'python', 2018),
            ( 'python', 2019),
            ( 'cobra', 2018),
            ( 'cobra', 2019)],
           names=['snake', 'year'])
```

pandas.Index.set_value

`Index.set_value(arr, key, value)`

Fast lookup of value from 1-dimensional ndarray.

Deprecated since version 1.0.

Notes

Only use this if you know what you're doing.

pandas.Index.shift

`Index.shift(periods=1, freq=None)`

Shift index by desired number of time frequency increments.

This method is for shifting the values of datetime-like indexes by a specified time increment a given number of times.

Parameters

periods [int, default 1] Number of periods (or increments) to shift by, can be positive or negative.

freq [pandas.DateOffset, pandas.Timedelta or str, optional] Frequency increment to shift by. If None, the index is shifted by its own *freq* attribute. Offset aliases are valid strings, e.g., 'D', 'W', 'M' etc.

Returns

pandas.Index Shifted index.

See also:

[Series.shift](#) Shift values of Series.

Notes

This method is only implemented for datetime-like index classes, i.e., DatetimeIndex, PeriodIndex and TimedeltaIndex.

Examples

Put the first 5 month starts of 2011 into an index.

```

>>> month_starts = pd.date_range('1/1/2011', periods=5, freq='MS')
>>> month_starts
DatetimeIndex(['2011-01-01', '2011-02-01', '2011-03-01', '2011-04-01',
              '2011-05-01'],
              dtype='datetime64[ns]', freq='MS')

```

Shift the index by 10 days.

```
>>> month_starts.shift(10, freq='D')
DatetimeIndex(['2011-01-11', '2011-02-11', '2011-03-11', '2011-04-11',
              '2011-05-11'],
              dtype='datetime64[ns]', freq=None)
```

The default value of *freq* is the *freq* attribute of the index, which is 'MS' (month start) in this example.

```
>>> month_starts.shift(10)
DatetimeIndex(['2011-11-01', '2011-12-01', '2012-01-01', '2012-02-01',
              '2012-03-01'],
              dtype='datetime64[ns]', freq='MS')
```

pandas.Index.slice_indexer

Index.**slice_indexer** (*start=None, end=None, step=None, kind=None*)

Compute the slice indexer for input labels and step.

Index needs to be ordered and unique.

Parameters

start [label, default None] If None, defaults to the beginning.

end [label, default None] If None, defaults to the end.

step [int, default None]

kind [str, default None]

Returns

indexer [slice]

Raises

KeyError [If key does not exist, or key is not unique and index is] not ordered.

Notes

This function assumes that the data is sorted, so use at your own peril

Examples

This is a method on all index types. For example you can do:

```
>>> idx = pd.Index(list('abcd'))
>>> idx.slice_indexer(start='b', end='c')
slice(1, 3, None)
```

```
>>> idx = pd.MultiIndex.from_arrays([list('abcd'), list('efgh')])
>>> idx.slice_indexer(start='b', end=('c', 'g'))
slice(1, 3, None)
```

pandas.Index.slice_locs

`Index.slice_locs`(*start=None, end=None, step=None, kind=None*)
 Compute slice locations for input labels.

Parameters

start [label, default None] If None, defaults to the beginning.

end [label, default None] If None, defaults to the end.

step [int, defaults None] If None, defaults to 1.

kind [{ 'loc', 'getitem' } or None]

Returns

start, end [int]

See also:

[`Index.get_loc`](#) Get location for a single label.

Notes

This method only works if the index is monotonic or unique.

Examples

```
>>> idx = pd.Index(list('abcd'))
>>> idx.slice_locs(start='b', end='c')
(1, 3)
```

pandas.Index.sort

`Index.sort`(*args, **kwargs)
 Use `sort_values` instead.

pandas.Index.sort_values

`Index.sort_values`(*return_indexer=False, ascending=True, na_position='last', key=None*)
 Return a sorted copy of the index.

Return a sorted copy of the index, and optionally return the indices that sorted the index itself.

Parameters

return_indexer [bool, default False] Should the indices that would sort the index be returned.

ascending [bool, default True] Should the index values be sorted in an ascending order.

na_position [{ 'first' or 'last' }, default 'last'] Argument 'first' puts NaNs at the beginning, 'last' puts NaNs at the end.

New in version 1.2.0.

key [callable, optional] If not None, apply the key function to the index values before sorting. This is similar to the *key* argument in the builtin `sorted()` function, with the notable difference that this *key* function should be *vectorized*. It should expect an `Index` and return an `Index` of the same shape.

New in version 1.1.0.

Returns

sorted_index [pandas.Index] Sorted copy of the index.

indexer [numpy.ndarray, optional] The indices that the index itself was sorted by.

See also:

[*Series.sort_values*](#) Sort values of a Series.

[*DataFrame.sort_values*](#) Sort values in a DataFrame.

Examples

```
>>> idx = pd.Index([10, 100, 1, 1000])
>>> idx
Int64Index([10, 100, 1, 1000], dtype='int64')
```

Sort values in ascending order (default behavior).

```
>>> idx.sort_values()
Int64Index([1, 10, 100, 1000], dtype='int64')
```

Sort values in descending order, and also get the indices *idx* was sorted by.

```
>>> idx.sort_values(ascending=False, return_indexer=True)
(Int64Index([1000, 100, 10, 1], dtype='int64'), array([3, 1, 0, 2]))
```

pandas.Index.sortlevel

`Index.sortlevel` (*level=None, ascending=True, sort_remaining=None*)

For internal compatibility with the Index API.

Sort the Index. This is for compat with MultiIndex

Parameters

ascending [bool, default True] False to sort in descending order

level, sort_remaining are compat parameters

Returns

Index

pandas.Index.str

Index.str()

Vectorized string functions for Series and Index.

NAs stay NA unless handled otherwise by a particular method. Patterned after Python's string methods, with some inspiration from R's stringr package.

Examples

```
>>> s = pd.Series(["A_Str_Series"])
>>> s
0    A_Str_Series
dtype: object
```

```
>>> s.str.split("_")
0    [A, Str, Series]
dtype: object
```

```
>>> s.str.replace("_", "")
0    AStrSeries
dtype: object
```

pandas.Index.symmetric_difference

Index.**symmetric_difference**(*other*, *result_name=None*, *sort=None*)

Compute the symmetric difference of two Index objects.

Parameters

other [Index or array-like]

result_name [str]

sort [False or None, default None] Whether to sort the resulting index. By default, the values are attempted to be sorted, but any TypeError from incomparable elements is caught by pandas.

- None : Attempt to sort the result, but catch any TypeErrors from comparing incomparable elements.
- False : Do not sort the result.

Returns

symmetric_difference [Index]

Notes

`symmetric_difference` contains elements that appear in either `idx1` or `idx2` but not both. Equivalent to the Index created by `idx1.difference(idx2) | idx2.difference(idx1)` with duplicates dropped.

Examples

```
>>> idx1 = pd.Index([1, 2, 3, 4])
>>> idx2 = pd.Index([2, 3, 4, 5])
>>> idx1.symmetric_difference(idx2)
Int64Index([1, 5], dtype='int64')
```

pandas.Index.take

`Index.take(indices, axis=0, allow_fill=True, fill_value=None, **kwargs)`

Return a new Index of the values selected by the indices.

For internal compatibility with numpy arrays.

Parameters

indices [array-like] Indices to be taken.

axis [int, optional] The axis over which to select values, always 0.

allow_fill [bool, default True]

fill_value [scalar, default None] If `allow_fill=True` and `fill_value` is not None, indices specified by -1 are regarded as NA. If Index doesn't hold NA, raise `ValueError`.

Returns

Index An index formed of elements at the given indices. Will be the same type as self, except for `RangeIndex`.

See also:

[numpy.ndarray.take](#) Return an array formed from the elements of a at the given indices.

pandas.Index.to_flat_index

`Index.to_flat_index()`

Identity method.

This is implemented for compatibility with subclass implementations when chaining.

Returns

pd.Index Caller.

See also:

[MultiIndex.to_flat_index](#) Subclass implementation.

pandas.Index.to_frame

`Index.to_frame(index=True, name=None)`

Create a DataFrame with a column containing the Index.

Parameters

index [bool, default True] Set the index of the returned DataFrame as the original Index.

name [object, default None] The passed name should substitute for the index name (if it has one).

Returns

DataFrame DataFrame containing the original Index data.

See also:

[*Index.to_series*](#) Convert an Index to a Series.

[*Series.to_frame*](#) Convert Series to DataFrame.

Examples

```
>>> idx = pd.Index(['Ant', 'Bear', 'Cow'], name='animal')
>>> idx.to_frame()
      animal
animal
Ant      Ant
Bear    Bear
Cow      Cow
```

By default, the original Index is reused. To enforce a new Index:

```
>>> idx.to_frame(index=False)
      animal
0      Ant
1     Bear
2      Cow
```

To override the name of the resulting column, specify *name*:

```
>>> idx.to_frame(index=False, name='zoo')
      zoo
0      Ant
1     Bear
2      Cow
```

`pandas.Index.to_list`

`Index.to_list()`

Return a list of the values.

These are each a scalar type, which is a Python scalar (for str, int, float) or a pandas scalar (for Timestamp/Timedelta/Interval/Period)

Returns

list

See also:

`numpy.ndarray.tolist` Return the array as an a.ndim-levels deep nested list of Python scalars.

`pandas.Index.to_native_types`

`Index.to_native_types(slicer=None, **kwargs)`

Format specified values of *self* and return them.

Deprecated since version 1.2.0.

Parameters

slicer [int, array-like] An indexer into *self* that specifies which values are used in the formatting process.

kwargs [dict] Options for specifying how the values should be formatted. These options include the following:

- 1) **na_rep** [str] The value that serves as a placeholder for NULL values
- 2) **quoting** [bool or None] Whether or not there are quoted values in *self*
- 3) **date_format** [str] The format used to represent date-like values.

Returns

`numpy.ndarray` Formatted values.

`pandas.Index.to_numpy`

`Index.to_numpy(dtype=None, copy=False, na_value=NoDefault.no_default, **kwargs)`

A NumPy ndarray representing the values in this Series or Index.

Parameters

dtype [str or numpy.dtype, optional] The dtype to pass to `numpy.asarray()`.

copy [bool, default False] Whether to ensure that the returned value is not a view on another array. Note that `copy=False` does not *ensure* that `to_numpy()` is no-copy. Rather, `copy=True` ensure that a copy is made, even if not strictly necessary.

na_value [Any, optional] The value to use for missing values. The default value depends on *dtype* and the type of the array.

New in version 1.0.0.

****kwargs** Additional keywords passed through to the `to_numpy` method of the underlying array (for extension arrays).

New in version 1.0.0.

Returns

`numpy.ndarray`

See also:

[*Series.array*](#) Get the actual data stored within.

[*Index.array*](#) Get the actual data stored within.

[*DataFrame.to_numpy*](#) Similar method for DataFrame.

Notes

The returned array will be the same up to equality (values equal in *self* will be equal in the returned array; likewise for values that are not equal). When *self* contains an `ExtensionArray`, the dtype may be different. For example, for a category-dtype Series, `to_numpy()` will return a NumPy array and the categorical dtype will be lost.

For NumPy dtypes, this will be a reference to the actual data stored in this Series or Index (assuming `copy=False`). Modifying the result in place will modify the data stored in the Series or Index (not that we recommend doing that).

For extension types, `to_numpy()` may require copying data and coercing the result to a NumPy type (possibly object), which may be expensive. When you need a no-copy reference to the underlying data, [*Series.array*](#) should be used instead.

This table lays out the different dtypes and default return types of `to_numpy()` for various dtypes within pandas.

| dtype | array type |
|--------------------|----------------------------------|
| category[T] | ndarray[T] (same dtype as input) |
| period | ndarray[object] (Periods) |
| interval | ndarray[object] (Intervals) |
| IntegerNA | ndarray[object] |
| datetime64[ns] | datetime64[ns] |
| datetime64[ns, tz] | ndarray[object] (Timestamps) |

Examples

```
>>> ser = pd.Series(pd.Categorical(['a', 'b', 'a']))
>>> ser.to_numpy()
array(['a', 'b', 'a'], dtype=object)
```

Specify the *dtype* to control how datetime-aware data is represented. Use `dtype=object` to return an ndarray of pandas [*Timestamp*](#) objects, each with the correct `tz`.

```
>>> ser = pd.Series(pd.date_range('2000', periods=2, tz="CET"))
>>> ser.to_numpy(dtype=object)
array([Timestamp('2000-01-01 00:00:00+0100', tz='CET'),
```

(continues on next page)

(continued from previous page)

```
Timestamp('2000-01-02 00:00:00+0100', tz='CET')],
dtype=object)
```

Or `dtype='datetime64[ns]'` to return an ndarray of native `datetime64` values. The values are converted to UTC and the timezone info is dropped.

```
>>> ser.to_numpy(dtype="datetime64[ns]")
...
array(['1999-12-31T23:00:00.000000000', '2000-01-01T23:00:00...'],
      dtype='datetime64[ns]')
```

pandas.Index.to_series

`Index.to_series(index=None, name=None)`

Create a Series with both index and values equal to the index keys.

Useful with `map` for returning an indexer based on an index.

Parameters

index [Index, optional] Index of resulting Series. If None, defaults to original index.

name [str, optional] Name of resulting Series. If None, defaults to name of original index.

Returns

Series The dtype will be based on the type of the Index values.

See also:

[`Index.to_frame`](#) Convert an Index to a DataFrame.

[`Series.to_frame`](#) Convert Series to DataFrame.

Examples

```
>>> idx = pd.Index(['Ant', 'Bear', 'Cow'], name='animal')
```

By default, the original Index and original name is reused.

```
>>> idx.to_series()
animal
Ant    Ant
Bear   Bear
Cow    Cow
Name: animal, dtype: object
```

To enforce a new Index, specify new labels to index:

```
>>> idx.to_series(index=[0, 1, 2])
0    Ant
1    Bear
2    Cow
Name: animal, dtype: object
```

To override the name of the resulting column, specify *name*:

```
>>> idx.to_series(name='zoo')
animal
Ant      Ant
Bear     Bear
Cow      Cow
Name: zoo, dtype: object
```

pandas.Index.tolist

Index.tolist()

Return a list of the values.

These are each a scalar type, which is a Python scalar (for str, int, float) or a pandas scalar (for Timestamp/Timedelta/Interval/Period)

Returns

list

See also:

[numpy.ndarray.tolist](#) Return the array as an a.ndim-levels deep nested list of Python scalars.

pandas.Index.transpose

Index.transpose(*args, **kwargs)

Return the transpose, which is by definition self.

Returns

%(klass)s

pandas.Index.union

Index.union(other, sort=None)

Form the union of two Index objects.

If the Index objects are incompatible, both Index objects will be cast to dtype('object') first.

Changed in version 0.25.0.

Parameters

other [Index or array-like]

sort [bool or None, default None] Whether to sort the resulting Index.

- None : Sort the result, except when
 1. *self* and *other* are equal.
 2. *self* or *other* has length 0.
 3. Some values in *self* or *other* cannot be compared. A RuntimeWarning is issued in this case.

- False : do not sort the result.

Returns

union [Index]

Examples

Union matching dtypes

```
>>> idx1 = pd.Index([1, 2, 3, 4])
>>> idx2 = pd.Index([3, 4, 5, 6])
>>> idx1.union(idx2)
Int64Index([1, 2, 3, 4, 5, 6], dtype='int64')
```

Union mismatched dtypes

```
>>> idx1 = pd.Index(['a', 'b', 'c', 'd'])
>>> idx2 = pd.Index([1, 2, 3, 4])
>>> idx1.union(idx2)
Index(['a', 'b', 'c', 'd', 1, 2, 3, 4], dtype='object')
```

MultiIndex case

```
>>> idx1 = pd.MultiIndex.from_arrays(
...     [[1, 1, 2, 2], ["Red", "Blue", "Red", "Blue"]]
... )
>>> idx1
MultiIndex([(1, 'Red'),
            (1, 'Blue'),
            (2, 'Red'),
            (2, 'Blue')],
           )
>>> idx2 = pd.MultiIndex.from_arrays(
...     [[3, 3, 2, 2], ["Red", "Green", "Red", "Green"]]
... )
>>> idx2
MultiIndex([(3, 'Red'),
            (3, 'Green'),
            (2, 'Red'),
            (2, 'Green')],
           )
>>> idx1.union(idx2)
MultiIndex([(1, 'Blue'),
            (1, 'Red'),
            (2, 'Blue'),
            (2, 'Green'),
            (2, 'Red'),
            (3, 'Green'),
            (3, 'Red')],
           )
>>> idx1.union(idx2, sort=False)
MultiIndex([(1, 'Red'),
            (1, 'Blue'),
```

(continues on next page)

(continued from previous page)

```
(2, 'Red'),
(2, 'Blue'),
(3, 'Red'),
(3, 'Green'),
(2, 'Green')],
)
```

pandas.Index.unique

`Index.unique(level=None)`

Return unique values in the index.

Unique values are returned in order of appearance, this does NOT sort.

Parameters

level [int or hashable, optional] Only return values from specified level (for MultiIndex).
If int, gets the level by integer position, else by level name.

Returns

Index

See also:

[`unique`](#) Numpy array of unique values in that column.

[`Series.unique`](#) Return unique values of Series object.

pandas.Index.value_counts

`Index.value_counts(normalize=False, sort=True, ascending=False, bins=None, dropna=True)`

Return a Series containing counts of unique values.

The resulting object will be in descending order so that the first element is the most frequently-occurring element. Excludes NA values by default.

Parameters

normalize [bool, default False] If True then the object returned will contain the relative frequencies of the unique values.

sort [bool, default True] Sort by frequencies.

ascending [bool, default False] Sort in ascending order.

bins [int, optional] Rather than count values, group them into half-open bins, a convenience for `pd.cut`, only works with numeric data.

dropna [bool, default True] Don't include counts of NaN.

Returns

Series

See also:

[`Series.count`](#) Number of non-NA elements in a Series.

DataFrame.count Number of non-NA elements in a DataFrame.

DataFrame.value_counts Equivalent method on DataFrames.

Examples

```
>>> index = pd.Index([3, 1, 2, 3, 4, np.nan])
>>> index.value_counts()
3.0    2
1.0    1
2.0    1
4.0    1
dtype: int64
```

With *normalize* set to *True*, returns the relative frequency by dividing all values by the sum of values.

```
>>> s = pd.Series([3, 1, 2, 3, 4, np.nan])
>>> s.value_counts(normalize=True)
3.0    0.4
1.0    0.2
2.0    0.2
4.0    0.2
dtype: float64
```

bins

Bins can be useful for going from a continuous variable to a categorical variable; instead of counting unique apparitions of values, divide the index in the specified number of half-open bins.

```
>>> s.value_counts(bins=3)
(0.996, 2.0]    2
(2.0, 3.0]     2
(3.0, 4.0]     1
dtype: int64
```

dropna

With *dropna* set to *False* we can also see NaN index values.

```
>>> s.value_counts(dropna=False)
3.0    2
1.0    1
2.0    1
4.0    1
NaN    1
dtype: int64
```

pandas.Index.where

`Index.where(cond, other=None)`

Replace values where the condition is False.

The replacement is taken from other.

Parameters

cond [bool array-like with the same length as self] Condition to select the values on.

other [scalar, or array-like, default None] Replacement if the condition is False.

Returns

pandas.Index A copy of self with values replaced from other where the condition is False.

See also:

[Series.where](#) Same method for Series.

[DataFrame.where](#) Same method for DataFrame.

Examples

```
>>> idx = pd.Index(['car', 'bike', 'train', 'tractor'])
>>> idx
Index(['car', 'bike', 'train', 'tractor'], dtype='object')
>>> idx.where(idx.isin(['car', 'train']), 'other')
Index(['car', 'other', 'train', 'other'], dtype='object')
```

[view](#)

Properties

| | |
|--|--|
| <i>Index.values</i> | Return an array representing the data in the Index. |
| <i>Index.is_monotonic</i> | Alias for <code>is_monotonic_increasing</code> . |
| <i>Index.is_monotonic_increasing</i> | Return if the index is monotonic increasing (only equal or increasing) values. |
| <i>Index.is_monotonic_decreasing</i> | Return if the index is monotonic decreasing (only equal or decreasing) values. |
| <i>Index.is_unique</i> | Return if the index has unique values. |
| <i>Index.has_duplicates</i> | Check if the Index has duplicate values. |
| <i>Index.hasnans</i> | Return if I have any nans; enables various perf speedups. |
| <i>Index.dtype</i> | Return the dtype object of the underlying data. |
| <i>Index.inferred_type</i> | Return a string of the type inferred from the values. |
| <i>Index.is_all_dates</i> | Whether or not the index values only consist of dates. |
| <i>Index.shape</i> | Return a tuple of the shape of the underlying data. |
| <i>Index.name</i> | Return Index or MultiIndex name. |
| <i>Index.names</i> | |
| <i>Index.nbytes</i> | Return the number of bytes in the underlying data. |

continues on next page

Table 138 – continued from previous page

| | |
|------------------------------------|---|
| <i>Index.ndim</i> | Number of dimensions of the underlying data, by definition 1. |
| <i>Index.size</i> | Return the number of elements in the underlying data. |
| <i>Index.empty</i> | |
| <i>Index.T</i> | Return the transpose, which is by definition self. |
| <i>Index.memory_usage</i> ([deep]) | Memory usage of the values. |

pandas.Index.names**property** `Index.names`**pandas.Index.empty****property** `Index.empty`**Modifying and computations**

| | |
|---|--|
| <i>Index.all</i> (*args, **kwargs) | Return whether all elements are Truthy. |
| <i>Index.any</i> (*args, **kwargs) | Return whether any element is Truthy. |
| <i>Index.argmax</i> ([axis, skipna]) | Return int position of the smallest value in the Series. |
| <i>Index.argmin</i> ([axis, skipna]) | Return int position of the largest value in the Series. |
| <i>Index.copy</i> ([name, deep, dtype, names]) | Make a copy of this object. |
| <i>Index.delete</i> (loc) | Make new Index with passed location(-s) deleted. |
| <i>Index.drop</i> (labels[, errors]) | Make new Index with passed list of labels deleted. |
| <i>Index.drop_duplicates</i> ([keep]) | Return Index with duplicate values removed. |
| <i>Index.duplicated</i> ([keep]) | Indicate duplicate index values. |
| <i>Index.equals</i> (other) | Determine if two Index object are equal. |
| <i>Index.factorize</i> ([sort, na_sentinel]) | Encode the object as an enumerated type or categorical variable. |
| <i>Index.identical</i> (other) | Similar to equals, but checks that object attributes and types are also equal. |
| <i>Index.insert</i> (loc, item) | Make new Index inserting new item at location. |
| <i>Index.is_</i> (other) | More flexible, faster check like <code>is</code> but that works through views. |
| <i>Index.is_boolean</i> () | Check if the Index only consists of booleans. |
| <i>Index.is_categorical</i> () | Check if the Index holds categorical data. |
| <i>Index.is_floating</i> () | Check if the Index is a floating type. |
| <i>Index.is_integer</i> () | Check if the Index only consists of integers. |
| <i>Index.is_interval</i> () | Check if the Index holds Interval objects. |
| <i>Index.is_mixed</i> () | Check if the Index holds data with mixed data types. |
| <i>Index.is_numeric</i> () | Check if the Index only consists of numeric data. |
| <i>Index.is_object</i> () | Check if the Index is of the object dtype. |
| <i>Index.min</i> ([axis, skipna]) | Return the minimum value of the Index. |
| <i>Index.max</i> ([axis, skipna]) | Return the maximum value of the Index. |
| <i>Index.reindex</i> (target[, method, level, ...]) | Create index with target's values. |
| <i>Index.rename</i> (name[, inplace]) | Alter Index or MultiIndex name. |

continues on next page

Table 139 – continued from previous page

| | |
|---|---|
| <code>Index.repeat(repeats[, axis])</code> | Repeat elements of a Index. |
| <code>Index.where(cond[, other])</code> | Replace values where the condition is False. |
| <code>Index.take(indices[, axis, allow_fill, ...])</code> | Return a new Index of the values selected by the indices. |
| <code>Index.putmask(mask, value)</code> | Return a new Index of the values set with the mask. |
| <code>Index.unique([level])</code> | Return unique values in the index. |
| <code>Index.nunique([dropna])</code> | Return number of unique elements in the object. |
| <code>Index.value_counts([normalize, sort, ...])</code> | Return a Series containing counts of unique values. |

Compatibility with MultiIndex

| | |
|---|---|
| <code>Index.set_names(names[, level, inplace])</code> | Set Index or MultiIndex name. |
| <code>Index.droplevel([level])</code> | Return index with requested level(s) removed. |

Missing values

| | |
|--|--|
| <code>Index.fillna([value, downcast])</code> | Fill NA/NaN values with the specified value. |
| <code>Index.dropna([how])</code> | Return Index without NA/NaN values. |
| <code>Index.isna()</code> | Detect missing values. |
| <code>Index.notna()</code> | Detect existing (non-missing) values. |

Conversion

| | |
|--|--|
| <code>Index.astype(dtype[, copy])</code> | Create an Index with values cast to dtypes. |
| <code>Index.item()</code> | Return the first element of the underlying data as a Python scalar. |
| <code>Index.map(mapper[, na_action])</code> | Map values using input correspondence (a dict, Series, or function). |
| <code>Index.ravel([order])</code> | Return an ndarray of the flattened values of the underlying data. |
| <code>Index.to_list()</code> | Return a list of the values. |
| <code>Index.to_native_types([slicer])</code> | (DEPRECATED) Format specified values of <i>self</i> and return them. |
| <code>Index.to_series([index, name])</code> | Create a Series with both index and values equal to the index keys. |
| <code>Index.to_frame([index, name])</code> | Create a DataFrame with a column containing the Index. |
| <code>Index.view([cls])</code> | |

pandas.Index.view`Index.view(cls=None)`**Sorting**

| | |
|--|---|
| <code>Index.argsort(*args, **kwargs)</code> | Return the integer indices that would sort the index. |
| <code>Index.searchsorted(value[, side, sorter])</code> | Find indices where elements should be inserted to maintain order. |
| <code>Index.sort_values([return_indexer, ...])</code> | Return a sorted copy of the index. |

Time-specific operations

| | |
|---|---|
| <code>Index.shift([periods, freq])</code> | Shift index by desired number of time frequency increments. |
|---|---|

Combining / joining / set operations

| | |
|---|--|
| <code>Index.append(other)</code> | Append a collection of Index options together. |
| <code>Index.join(other[, how, level, ...])</code> | Compute join_index and indexers to conform data structures to the new index. |
| <code>Index.intersection(other[, sort])</code> | Form the intersection of two Index objects. |
| <code>Index.union(other[, sort])</code> | Form the union of two Index objects. |
| <code>Index.difference(other[, sort])</code> | Return a new Index with elements of index not in <i>other</i> . |
| <code>Index.symmetric_difference(other[, ...])</code> | Compute the symmetric difference of two Index objects. |

Selecting

| | |
|--|--|
| <code>Index.asof(label)</code> | Return the label from the index, or, if not present, the previous one. |
| <code>Index.asof_locs(where, mask)</code> | Return the locations (indices) of labels in the index. |
| <code>Index.get_indexer(target[, method, limit, ...])</code> | Compute indexer and mask for new index given the current index. |
| <code>Index.get_indexer_for(target, **kwargs)</code> | Guaranteed return of an indexer even when non-unique. |
| <code>Index.get_indexer_non_unique(target)</code> | Compute indexer and mask for new index given the current index. |
| <code>Index.get_level_values(level)</code> | Return an Index of values for requested level. |
| <code>Index.get_loc(key[, method, tolerance])</code> | Get integer location, slice or boolean mask for requested label. |
| <code>Index.get_slice_bound(label, side[, kind])</code> | Calculate slice bound that corresponds to given label. |
| <code>Index.get_value(series, key)</code> | Fast lookup of value from 1-dimensional ndarray. |
| <code>Index.isin(values[, level])</code> | Return a boolean array where the index values are in <i>values</i> . |
| <code>Index.slice_indexer([start, end, step, kind])</code> | Compute the slice indexer for input labels and step. |

continues on next page

Table 146 – continued from previous page

| | |
|---|---|
| <code>Index.slice_locs([start, end, step, kind])</code> | Compute slice locations for input labels. |
|---|---|

3.6.2 Numeric Index

| | |
|--|---|
| <code>RangeIndex([start, stop, step, dtype, copy, ...])</code> | Immutable Index implementing a monotonic integer range. |
| <code>Int64Index([data, dtype, copy, name])</code> | Immutable sequence used for indexing and alignment. |
| <code>UInt64Index([data, dtype, copy, name])</code> | Immutable sequence used for indexing and alignment. |
| <code>Float64Index([data, dtype, copy, name])</code> | Immutable sequence used for indexing and alignment. |

pandas.RangeIndex

class pandas.**RangeIndex** (*start=None, stop=None, step=None, dtype=None, copy=False, name=None*)

Immutable Index implementing a monotonic integer range.

RangeIndex is a memory-saving special case of Int64Index limited to representing monotonic ranges. Using RangeIndex may in some instances improve computing speed.

This is the default index type used by DataFrame and Series when no explicit index is provided by the user.

Parameters

start [int (default: 0), range, or other RangeIndex instance] If int and “stop” is not given, interpreted as “stop” instead.

stop [int (default: 0)]

step [int (default: 1)]

dtype [np.int64] Unused, accepted for homogeneity with other index types.

copy [bool, default False] Unused, accepted for homogeneity with other index types.

name [object, optional] Name to be stored in the index.

See also:

[Index](#) The base pandas Index type.

[Int64Index](#) Index of int64 data.

Attributes

| | |
|--------------------|---|
| <code>start</code> | The value of the <code>start</code> parameter (0 if this was not supplied). |
| <code>stop</code> | The value of the <code>stop</code> parameter. |
| <code>step</code> | The value of the <code>step</code> parameter (1 if this was not supplied). |

`pandas.RangeIndex.start`

property `RangeIndex.start`

The value of the *start* parameter (0 if this was not supplied).

`pandas.RangeIndex.stop`

property `RangeIndex.stop`

The value of the *stop* parameter.

`pandas.RangeIndex.step`

property `RangeIndex.step`

The value of the *step* parameter (1 if this was not supplied).

Methods

| | |
|--|---|
| <code>from_range(data[, name, dtype])</code> | Create <code>RangeIndex</code> from a range object. |
|--|---|

`pandas.RangeIndex.from_range`

classmethod `RangeIndex.from_range(data, name=None, dtype=None)`

Create `RangeIndex` from a range object.

Returns

`RangeIndex`

`pandas.Int64Index`

class `pandas.Int64Index(data=None, dtype=None, copy=False, name=None)`

Immutable sequence used for indexing and alignment. The basic object storing axis labels for all pandas objects. `Int64Index` is a special case of `Index` with purely integer labels. .

Parameters

data [array-like (1-dimensional)]

dtype [NumPy dtype (default: int64)]

copy [bool] Make a copy of input ndarray.

name [object] Name to be stored in the index.

See also:

[*Index*](#) The base pandas Index type.

Notes

An Index instance can **only** contain hashable objects.

Attributes

| | |
|------|--|
| None | |
|------|--|

Methods

| | |
|------|--|
| None | |
|------|--|

pandas.UInt64Index

class pandas.**UInt64Index**(*data=None, dtype=None, copy=False, name=None*)

Immutable sequence used for indexing and alignment. The basic object storing axis labels for all pandas objects. UInt64Index is a special case of *Index* with purely unsigned integer labels. .

Parameters

data [array-like (1-dimensional)]

dtype [NumPy dtype (default: uint64)]

copy [bool] Make a copy of input ndarray.

name [object] Name to be stored in the index.

See also:

[*Index*](#) The base pandas Index type.

Notes

An Index instance can **only** contain hashable objects.

Attributes

| | |
|------|--|
| None | |
|------|--|

Methods

| | |
|------|--|
| None | |
|------|--|

pandas.Float64Index

class pandas.**Float64Index**(*data=None, dtype=None, copy=False, name=None*)

Immutable sequence used for indexing and alignment. The basic object storing axis labels for all pandas objects. Float64Index is a special case of *Index* with purely float labels. .

Parameters

- data** [array-like (1-dimensional)]
- dtype** [NumPy dtype (default: float64)]
- copy** [bool] Make a copy of input ndarray.
- name** [object] Name to be stored in the index.

See also:

[Index](#) The base pandas Index type.

Notes

An Index instance can **only** contain hashable objects.

Attributes

| | |
|------|--|
| None | |
|------|--|

Methods

| | |
|------|--|
| None | |
|------|--|

| | |
|--|---|
| <i>RangeIndex.start</i> | The value of the <i>start</i> parameter (0 if this was not supplied). |
| <i>RangeIndex.stop</i> | The value of the <i>stop</i> parameter. |
| <i>RangeIndex.step</i> | The value of the <i>step</i> parameter (1 if this was not supplied). |
| <i>RangeIndex.from_range</i> (data[, name, dtype]) | Create RangeIndex from a range object. |

3.6.3 CategoricalIndex

| | |
|---|---|
| <i>CategoricalIndex</i> ([data, categories, ...]) | Index based on an underlying <i>Categorical</i> . |
|---|---|

pandas.CategoricalIndex

class pandas.CategoricalIndex(*data=None, categories=None, ordered=None, dtype=None, copy=False, name=None*)

Index based on an underlying [Categorical](#).

CategoricalIndex, like Categorical, can only take on a limited, and usually fixed, number of possible values (*categories*). Also, like Categorical, it might have an order, but numerical operations (additions, divisions, ...) are not possible.

Parameters

data [array-like (1-dimensional)] The values of the categorical. If *categories* are given, values not in *categories* will be replaced with NaN.

categories [index-like, optional] The categories for the categorical. Items need to be unique. If the categories are not given here (and also not in *dtype*), they will be inferred from the *data*.

ordered [bool, optional] Whether or not this categorical is treated as an ordered categorical. If not given here or in *dtype*, the resulting categorical will be unordered.

dtype [CategoricalDtype or “category”, optional] If [CategoricalDtype](#), cannot be used together with *categories* or *ordered*.

copy [bool, default False] Make a copy of input ndarray.

name [object, optional] Name to be stored in the index.

Raises

ValueError If the categories do not validate.

TypeError If an explicit *ordered=True* is given but no *categories* and the *values* are not sortable.

See also:

[Index](#) The base pandas Index type.

[Categorical](#) A categorical array.

[CategoricalDtype](#) Type for categorical data.

Notes

See the [user guide](#) for more.

Examples

```
>>> pd.CategoricalIndex(["a", "b", "c", "a", "b", "c"])
CategoricalIndex(['a', 'b', 'c', 'a', 'b', 'c'],
                  categories=['a', 'b', 'c'], ordered=False, dtype='category')
```

CategoricalIndex can also be instantiated from a Categorical:

```
>>> c = pd.Categorical(["a", "b", "c", "a", "b", "c"])
>>> pd.CategoricalIndex(c)
CategoricalIndex(['a', 'b', 'c', 'a', 'b', 'c'],
                  categories=['a', 'b', 'c'], ordered=False, dtype='category')
```

Ordered CategoricalIndex can have a min and max value.

```

>>> ci = pd.CategoricalIndex(
...     ["a", "b", "c", "a", "b", "c"], ordered=True, categories=["c", "b", "a"]
... )
>>> ci
CategoricalIndex(['a', 'b', 'c', 'a', 'b', 'c'],
                  categories=['c', 'b', 'a'], ordered=True, dtype='category')
>>> ci.min()
'c'

```

Attributes

| | |
|-------------------|--|
| <i>codes</i> | The category codes of this categorical. |
| <i>categories</i> | The categories of this categorical. |
| <i>ordered</i> | Whether the categories have an ordered relationship. |

pandas.CategoricalIndex.codes

property CategoricalIndex.codes

The category codes of this categorical.

Codes are an array of integers which are the positions of the actual values in the categories array.

There is no setter, use the other categorical methods and the normal item setter to change values in the categorical.

Returns

ndarray[int] A non-writable view of the *codes* array.

pandas.CategoricalIndex.categories

property CategoricalIndex.categories

The categories of this categorical.

Setting assigns new values to each category (effectively a rename of each individual category).

The assigned value has to be a list-like object. All items must be unique and the number of items in the new categories must be the same as the number of items in the old categories.

Assigning to *categories* is an inplace operation!

Raises

ValueError If the new categories do not validate as categories or if the number of new categories is unequal the number of old categories

See also:

[*rename_categories*](#) Rename categories.

[*reorder_categories*](#) Reorder categories.

[*add_categories*](#) Add new categories.

[*remove_categories*](#) Remove the specified categories.

remove_unused_categories Remove categories which are not used.

set_categories Set the categories to the specified ones.

pandas.CategoricalIndex.ordered

property CategoricalIndex.ordered

Whether the categories have an ordered relationship.

Methods

| | |
|---|--|
| <i>rename_categories</i> (*args, **kwargs) | Rename categories. |
| <i>reorder_categories</i> (*args, **kwargs) | Reorder categories as specified in new_categories. |
| <i>add_categories</i> (*args, **kwargs) | Add new categories. |
| <i>remove_categories</i> (*args, **kwargs) | Remove the specified categories. |
| <i>remove_unused_categories</i> (*args, **kwargs) | Remove categories which are not used. |
| <i>set_categories</i> (*args, **kwargs) | Set the categories to the specified new_categories. |
| <i>as_ordered</i> (*args, **kwargs) | Set the Categorical to be ordered. |
| <i>as_unordered</i> (*args, **kwargs) | Set the Categorical to be unordered. |
| <i>map</i> (mapper) | Map values using input correspondence (a dict, Series, or function). |

pandas.CategoricalIndex.rename_categories

CategoricalIndex.**rename_categories**(*args, **kwargs)

Rename categories.

Parameters

new_categories [list-like, dict-like or callable] New categories which will replace old categories.

- list-like: all items must be unique and the number of items in the new categories must match the existing number of categories.
- dict-like: specifies a mapping from old categories to new. Categories not contained in the mapping are passed through and extra categories in the mapping are ignored.
- callable : a callable that is called on all items in the old categories and whose return values comprise the new categories.

inplace [bool, default False] Whether or not to rename the categories inplace or return a copy of this categorical with renamed categories.

Deprecated since version 1.3.0.

Returns

cat [Categorical or None] Categorical with removed categories or None if inplace=True.

Raises

ValueError If new categories are list-like and do not have the same number of items than the current categories or do not validate as categories

See also:

reorder_categories Reorder categories.

add_categories Add new categories.

remove_categories Remove the specified categories.

remove_unused_categories Remove categories which are not used.

set_categories Set the categories to the specified ones.

Examples

```
>>> c = pd.Categorical(['a', 'a', 'b'])
>>> c.rename_categories([0, 1])
[0, 0, 1]
Categories (2, int64): [0, 1]
```

For dict-like `new_categories`, extra keys are ignored and categories not in the dictionary are passed through

```
>>> c.rename_categories({'a': 'A', 'c': 'C'})
['A', 'A', 'b']
Categories (2, object): ['A', 'b']
```

You may also provide a callable to create the new categories

```
>>> c.rename_categories(lambda x: x.upper())
['A', 'A', 'B']
Categories (2, object): ['A', 'B']
```

pandas.CategoricalIndex.reorder_categories

`CategoricalIndex.reorder_categories(*args, **kwargs)`

Reorder categories as specified in `new_categories`.

`new_categories` need to include all old categories and no new category items.

Parameters

new_categories [Index-like] The categories in new order.

ordered [bool, optional] Whether or not the categorical is treated as a ordered categorical. If not given, do not change the ordered information.

inplace [bool, default False] Whether or not to reorder the categories inplace or return a copy of this categorical with reordered categories.

Deprecated since version 1.3.0.

Returns

cat [Categorical or None] Categorical with removed categories or None if `inplace=True`.

Raises

ValueError If the new categories do not contain all old category items or any new ones

See also:

rename_categories Rename categories.

add_categories Add new categories.

remove_categories Remove the specified categories.

remove_unused_categories Remove categories which are not used.

set_categories Set the categories to the specified ones.

pandas.CategoricalIndex.add_categories

`CategoricalIndex.add_categories(*args, **kwargs)`

Add new categories.

new_categories will be included at the last/highest place in the categories and will be unused directly after this call.

Parameters

new_categories [category or list-like of category] The new categories to be included.

inplace [bool, default False] Whether or not to add the categories inplace or return a copy of this categorical with added categories.

Deprecated since version 1.3.0.

Returns

cat [Categorical or None] Categorical with new categories added or None if `inplace=True`.

Raises

ValueError If the new categories include old categories or do not validate as categories

See also:

rename_categories Rename categories.

reorder_categories Reorder categories.

remove_categories Remove the specified categories.

remove_unused_categories Remove categories which are not used.

set_categories Set the categories to the specified ones.

pandas.CategoricalIndex.remove_categories

`CategoricalIndex.remove_categories(*args, **kwargs)`

Remove the specified categories.

removals must be included in the old categories. Values which were in the removed categories will be set to NaN

Parameters

removals [category or list of categories] The categories which should be removed.

inplace [bool, default False] Whether or not to remove the categories inplace or return a copy of this categorical with removed categories.

Deprecated since version 1.3.0.

Returns

cat [Categorical or None] Categorical with removed categories or None if `inplace=True`.

Raises

ValueError If the removals are not contained in the categories

See also:

rename_categories Rename categories.

reorder_categories Reorder categories.

add_categories Add new categories.

remove_unused_categories Remove categories which are not used.

set_categories Set the categories to the specified ones.

pandas.CategoricalIndex.remove_unused_categories

`CategoricalIndex.remove_unused_categories(*args, **kwargs)`

Remove categories which are not used.

Parameters

inplace [bool, default False] Whether or not to drop unused categories inplace or return a copy of this categorical with unused categories dropped.

Deprecated since version 1.2.0.

Returns

cat [Categorical or None] Categorical with unused categories dropped or None if `inplace=True`.

See also:

rename_categories Rename categories.

reorder_categories Reorder categories.

add_categories Add new categories.

remove_categories Remove the specified categories.

set_categories Set the categories to the specified ones.

pandas.CategoricalIndex.set_categories

`CategoricalIndex.set_categories(*args, **kwargs)`

Set the categories to the specified `new_categories`.

`new_categories` can include new categories (which will result in unused categories) or remove old categories (which results in values set to NaN). If `rename==True`, the categories will simply be renamed (less or more items than in old categories will result in values set to NaN or in unused categories respectively).

This method can be used to perform more than one action of adding, removing, and reordering simultaneously and is therefore faster than performing the individual steps via the more specialised methods.

On the other hand this methods does not do checks (e.g., whether the old categories are included in the new categories on a reorder), which can result in surprising changes, for example when using special string dtypes, which does not considers a S1 string equal to a single char python string.

Parameters

new_categories [Index-like] The categories in new order.

ordered [bool, default False] Whether or not the categorical is treated as a ordered categorical. If not given, do not change the ordered information.

rename [bool, default False] Whether or not the `new_categories` should be considered as a rename of the old categories or as reordered categories.

inplace [bool, default False] Whether or not to reorder the categories in-place or return a copy of this categorical with reordered categories.

Deprecated since version 1.3.0.

Returns

Categorical with reordered categories or None if inplace.

Raises

ValueError If `new_categories` does not validate as categories

See also:

[`rename_categories`](#) Rename categories.

[`reorder_categories`](#) Reorder categories.

[`add_categories`](#) Add new categories.

[`remove_categories`](#) Remove the specified categories.

[`remove_unused_categories`](#) Remove categories which are not used.

pandas.CategoricalIndex.as_ordered

`CategoricalIndex.as_ordered(*args, **kwargs)`

Set the Categorical to be ordered.

Parameters

inplace [bool, default False] Whether or not to set the ordered attribute in-place or return a copy of this categorical with ordered set to True.

Returns

Categorical or None Ordered Categorical or None if `inplace=True`.

pandas.CategoricalIndex.as_unordered

`CategoricalIndex.as_unordered(*args, **kwargs)`

Set the Categorical to be unordered.

Parameters

inplace [bool, default False] Whether or not to set the ordered attribute in-place or return a copy of this categorical with ordered set to False.

Returns

Categorical or None Unordered Categorical or None if `inplace=True`.

pandas.CategoricalIndex.map

`CategoricalIndex.map(mapper)`

Map values using input correspondence (a dict, Series, or function).

Maps the values (their categories, not the codes) of the index to new categories. If the mapping correspondence is one-to-one the result is a *CategoricalIndex* which has the same order property as the original, otherwise an *Index* is returned.

If a *dict* or *Series* is used any unmapped category is mapped to *NaN*. Note that if this happens an *Index* will be returned.

Parameters

mapper [function, dict, or Series] Mapping correspondence.

Returns

pandas.CategoricalIndex or pandas.Index Mapped index.

See also:

Index.map Apply a mapping correspondence on an *Index*.

Series.map Apply a mapping correspondence on a *Series*.

Series.apply Apply more complex functions on a *Series*.

Examples

```
>>> idx = pd.CategoricalIndex(['a', 'b', 'c'])
>>> idx
CategoricalIndex(['a', 'b', 'c'], categories=['a', 'b', 'c'],
                  ordered=False, dtype='category')
>>> idx.map(lambda x: x.upper())
CategoricalIndex(['A', 'B', 'C'], categories=['A', 'B', 'C'],
                  ordered=False, dtype='category')
>>> idx.map({'a': 'first', 'b': 'second', 'c': 'third'})
CategoricalIndex(['first', 'second', 'third'], categories=['first',
                  'second', 'third'], ordered=False, dtype='category')
```

If the mapping is one-to-one the ordering of the categories is preserved:

```
>>> idx = pd.CategoricalIndex(['a', 'b', 'c'], ordered=True)
>>> idx
CategoricalIndex(['a', 'b', 'c'], categories=['a', 'b', 'c'],
                 ordered=True, dtype='category')
>>> idx.map({'a': 3, 'b': 2, 'c': 1})
CategoricalIndex([3, 2, 1], categories=[3, 2, 1], ordered=True,
                 dtype='category')
```

If the mapping is not one-to-one an *Index* is returned:

```
>>> idx.map({'a': 'first', 'b': 'second', 'c': 'first'})
Index(['first', 'second', 'first'], dtype='object')
```

If a *dict* is used, all unmapped categories are mapped to *NaN* and the result is an *Index*:

```
>>> idx.map({'a': 'first', 'b': 'second'})
Index(['first', 'second', nan], dtype='object')
```

Categorical components

| | |
|---|---|
| <code>CategoricalIndex.codes</code> | The category codes of this categorical. |
| <code>CategoricalIndex.categories</code> | The categories of this categorical. |
| <code>CategoricalIndex.ordered</code> | Whether the categories have an ordered relationship. |
| <code>CategoricalIndex.rename_categories(*args, ...)</code> | Rename categories. |
| <code>CategoricalIndex.reorder_categories(*args, ...)</code> | Reorder categories as specified in <code>new_categories</code> . |
| <code>CategoricalIndex.add_categories(*args, **kwargs)</code> | Add new categories. |
| <code>CategoricalIndex.remove_categories(*args, ...)</code> | Remove the specified categories. |
| <code>CategoricalIndex.remove_unused_categories(...)</code> | Remove categories which are not used. |
| <code>CategoricalIndex.set_categories(*args, **kwargs)</code> | Set the categories to the specified <code>new_categories</code> . |
| <code>CategoricalIndex.as_ordered(*args, **kwargs)</code> | Set the Categorical to be ordered. |
| <code>CategoricalIndex.as_unordered(*args, **kwargs)</code> | Set the Categorical to be unordered. |

Modifying and computations

| | |
|---|--|
| <code>CategoricalIndex.map(mapper)</code> | Map values using input correspondence (a dict, Series, or function). |
| <code>CategoricalIndex.equals(other)</code> | Determine if two CategoricalIndex objects contain the same elements. |

pandas.CategoricalIndex.equals

CategoricalIndex.equals(*other*)

Determine if two CategoricalIndex objects contain the same elements.

Returns

bool If two CategoricalIndex objects have equal elements True, otherwise False.

3.6.4 IntervalIndex

| | |
|---|--|
| <i>IntervalIndex</i> (data[, closed, dtype, copy, ...]) | Immutable index of intervals that are closed on the same side. |
|---|--|

pandas.IntervalIndex

class pandas.IntervalIndex(*data*, *closed=None*, *dtype=None*, *copy=False*, *name=None*, *verify_integrity=True*)

Immutable index of intervals that are closed on the same side.

New in version 0.20.0.

Parameters

data [array-like (1-dimensional)] Array-like containing Interval objects from which to build the IntervalIndex.

closed [{ 'left', 'right', 'both', 'neither' }, default 'right'] Whether the intervals are closed on the left-side, right-side, both or neither.

dtype [dtype or None, default None] If None, dtype will be inferred.

copy [bool, default False] Copy the input data.

name [object, optional] Name to be stored in the index.

verify_integrity [bool, default True] Verify that the IntervalIndex is valid.

See also:

Index The base pandas Index type.

Interval A bounded slice-like interval; the elements of an IntervalIndex.

interval_range Function to create a fixed frequency IntervalIndex.

cut Bin values into discrete Intervals.

qcut Bin values into equal-sized Intervals based on rank or sample quantiles.

Notes

See the [user guide](#) for more.

Examples

A new `IntervalIndex` is typically constructed using `interval_range()`:

```
>>> pd.interval_range(start=0, end=5)
IntervalIndex([(0, 1], (1, 2], (2, 3], (3, 4], (4, 5]],
              dtype='interval[int64, right]')
```

It may also be constructed using one of the constructor methods: `IntervalIndex.from_arrays()`, `IntervalIndex.from_breaks()`, and `IntervalIndex.from_tuples()`.

See further examples in the doc strings of `interval_range` and the mentioned constructor methods.

Attributes

| | |
|---|---|
| <code>closed</code> | Whether the intervals are closed on the left-side, right-side, both or neither. |
| <code>is_empty</code> | Indicates if an interval is empty, meaning it contains no points. |
| <code>is_non_overlapping_monotonic</code> | Return True if the <code>IntervalArray</code> is non-overlapping (no <code>Intervals</code> share points) and is either monotonic increasing or monotonic decreasing, else False. |
| <code>is_overlapping</code> | Return True if the <code>IntervalIndex</code> has overlapping intervals, else False. |
| <code>values</code> | Return an array representing the data in the Index. |

`pandas.IntervalIndex.closed`

`IntervalIndex.closed`

Whether the intervals are closed on the left-side, right-side, both or neither.

`pandas.IntervalIndex.is_empty`

property `IntervalIndex.is_empty`

Indicates if an interval is empty, meaning it contains no points.

New in version 0.25.0.

Returns

bool or ndarray A boolean indicating if a scalar `Interval` is empty, or a boolean ndarray positionally indicating if an `Interval` in an `IntervalArray` or `IntervalIndex` is empty.

Examples

An *Interval* that contains points is not empty:

```
>>> pd.Interval(0, 1, closed='right').is_empty
False
```

An Interval that does not contain any points is empty:

```
>>> pd.Interval(0, 0, closed='right').is_empty
True
>>> pd.Interval(0, 0, closed='left').is_empty
True
>>> pd.Interval(0, 0, closed='neither').is_empty
True
```

An Interval that contains a single point is not empty:

```
>>> pd.Interval(0, 0, closed='both').is_empty
False
```

An *IntervalArray* or *IntervalIndex* returns a boolean ndarray positionally indicating if an Interval is empty:

```
>>> ivs = [pd.Interval(0, 0, closed='neither'),
...        pd.Interval(1, 2, closed='neither')]
>>> pd.arrays.IntervalArray(ivs).is_empty
array([ True, False])
```

Missing values are not considered empty:

```
>>> ivs = [pd.Interval(0, 0, closed='neither'), np.nan]
>>> pd.IntervalIndex(ivs).is_empty
array([ True, False])
```

pandas.IntervalIndex.is_non_overlapping_monotonic

IntervalIndex.is_non_overlapping_monotonic

Return True if the IntervalArray is non-overlapping (no Intervals share points) and is either monotonic increasing or monotonic decreasing, else False.

pandas.IntervalIndex.is_overlapping

property IntervalIndex.is_overlapping

Return True if the IntervalIndex has overlapping intervals, else False.

Two intervals overlap if they share a common point, including closed endpoints. Intervals that only have an open endpoint in common do not overlap.

Returns

bool Boolean indicating if the IntervalIndex has overlapping intervals.

See also:

Interval.overlaps Check whether two Interval objects overlap.

IntervalIndex.overlaps Check an IntervalIndex elementwise for overlaps.

Examples

```
>>> index = pd.IntervalIndex.from_tuples([(0, 2), (1, 3), (4, 5)])
>>> index
IntervalIndex([(0, 2], (1, 3], (4, 5]],
              dtype='interval[int64, right]')
>>> index.is_overlapping
True
```

Intervals that share closed endpoints overlap:

```
>>> index = pd.interval_range(0, 3, closed='both')
>>> index
IntervalIndex([(0, 1], [1, 2], [2, 3]],
              dtype='interval[int64, both]')
>>> index.is_overlapping
True
```

Intervals that only have an open endpoint in common do not overlap:

```
>>> index = pd.interval_range(0, 3, closed='left')
>>> index
IntervalIndex([(0, 1), [1, 2), [2, 3)],
              dtype='interval[int64, left]')
>>> index.is_overlapping
False
```

pandas.IntervalIndex.values

property IntervalIndex.values

Return an array representing the data in the Index.

Warning: We recommend using *Index.array* or *Index.to_numpy()*, depending on whether you need a reference to the underlying data or a NumPy array.

Returns

array: `numpy.ndarray` or `ExtensionArray`

See also:

Index.array Reference to the underlying data.

Index.to_numpy A NumPy array representing the underlying data.

| | |
|---------------|--|
| left | |
| right | |
| mid | |
| length | |

Methods

| | |
|--|---|
| <i>from_arrays</i> (left, right[, closed, name, ...]) | Construct from two arrays defining the left and right bounds. |
| <i>from_tuples</i> (data[, closed, name, copy, dtype]) | Construct an IntervalIndex from an array-like of tuples. |
| <i>from_breaks</i> (breaks[, closed, name, copy, dtype]) | Construct an IntervalIndex from an array of splits. |
| <i>contains</i> (*args, **kwargs) | Check elementwise if the Intervals contain the value. |
| <i>overlaps</i> (*args, **kwargs) | Check elementwise if an Interval overlaps the values in the IntervalArray. |
| <i>set_closed</i> (*args, **kwargs) | Return an IntervalArray identical to the current one, but closed on the specified side. |
| <i>to_tuples</i> (*args, **kwargs) | Return an ndarray of tuples of the form (left, right). |

pandas.IntervalIndex.from_arrays

classmethod IntervalIndex.**from_arrays**(*left, right, closed='right', name=None, copy=False, dtype=None*)

Construct from two arrays defining the left and right bounds.

Parameters

left [array-like (1-dimensional)] Left bounds for each interval.

right [array-like (1-dimensional)] Right bounds for each interval.

closed [{'left', 'right', 'both', 'neither'}, default 'right'] Whether the intervals are closed on the left-side, right-side, both or neither.

copy [bool, default False] Copy the data.

dtype [dtype, optional] If None, dtype will be inferred.

Returns

IntervalIndex

Raises

ValueError When a value is missing in only one of *left* or *right*. When a value in *left* is greater than the corresponding value in *right*.

See also:

[*interval_range*](#) Function to create a fixed frequency IntervalIndex.

[*IntervalIndex.from_breaks*](#) Construct an IntervalIndex from an array of splits.

[*IntervalIndex.from_tuples*](#) Construct an IntervalIndex from an array-like of tuples.

Notes

Each element of *left* must be less than or equal to the *right* element at the same position. If an element is missing, it must be missing in both *left* and *right*. A `TypeError` is raised when using an unsupported type for *left* or *right*. At the moment, 'category', 'object', and 'string' subtypes are not supported.

Examples

```
>>> pd.IntervalIndex.from_arrays([0, 1, 2], [1, 2, 3])
IntervalIndex([(0, 1], (1, 2], (2, 3]],
              dtype='interval[int64, right]')
```

pandas.IntervalIndex.from_tuples

classmethod `IntervalIndex.from_tuples`(*data*, *closed*='right', *name*=None, *copy*=False, *dtype*=None)
Construct an `IntervalIndex` from an array-like of tuples.

Parameters

- data** [array-like (1-dimensional)] Array of tuples.
- closed** [{'left', 'right', 'both', 'neither'}, default 'right'] Whether the intervals are closed on the left-side, right-side, both or neither.
- copy** [bool, default False] By-default copy the data, this is compat only and ignored.
- dtype** [dtype or None, default None] If None, dtype will be inferred.

Returns

`IntervalIndex`

See also:

- [`interval_range`](#) Function to create a fixed frequency `IntervalIndex`.
- [`IntervalIndex.from_arrays`](#) Construct an `IntervalIndex` from a left and right array.
- [`IntervalIndex.from_breaks`](#) Construct an `IntervalIndex` from an array of splits.

Examples

```
>>> pd.IntervalIndex.from_tuples([(0, 1), (1, 2)])
IntervalIndex([(0, 1], (1, 2]],
              dtype='interval[int64, right]')
```

pandas.IntervalIndex.from_breaks

classmethod IntervalIndex.**from_breaks**(*breaks*, *closed*='right', *name*=None, *copy*=False, *dtype*=None)

Construct an IntervalIndex from an array of splits.

Parameters

breaks [array-like (1-dimensional)] Left and right bounds for each interval.

closed [{'left', 'right', 'both', 'neither'}, default 'right'] Whether the intervals are closed on the left-side, right-side, both or neither.

copy [bool, default False] Copy the data.

dtype [dtype or None, default None] If None, dtype will be inferred.

Returns

IntervalIndex

See also:

[*interval_range*](#) Function to create a fixed frequency IntervalIndex.

[*IntervalIndex.from_arrays*](#) Construct from a left and right array.

[*IntervalIndex.from_tuples*](#) Construct from a sequence of tuples.

Examples

```
>>> pd.IntervalIndex.from_breaks([0, 1, 2, 3])
IntervalIndex([(0, 1], (1, 2], (2, 3]],
              dtype='interval[int64, right]')
```

pandas.IntervalIndex.contains

IntervalIndex.**contains**(*args, **kwargs)

Check elementwise if the Intervals contain the value.

Return a boolean mask whether the value is contained in the Intervals of the IntervalArray.

New in version 0.25.0.

Parameters

other [scalar] The value to check whether it is contained in the Intervals.

Returns

boolean array

See also:

[*Interval.contains*](#) Check whether Interval object contains value.

[*IntervalArray.overlaps*](#) Check if an Interval overlaps the values in the IntervalArray.

Examples

```
>>> intervals = pd.arrays.IntervalArray.from_tuples([(0, 1), (1, 3), (2, 4)])
>>> intervals
<IntervalArray>
[[0, 1], (1, 3], (2, 4]]
Length: 3, dtype: interval[int64, right]
```

```
>>> intervals.contains(0.5)
array([ True, False, False])
```

pandas.IntervalIndex.overlaps

`IntervalIndex.overlaps(*args, **kwargs)`

Check elementwise if an Interval overlaps the values in the IntervalArray.

Two intervals overlap if they share a common point, including closed endpoints. Intervals that only have an open endpoint in common do not overlap.

Parameters

other [IntervalArray] Interval to check against for an overlap.

Returns

ndarray Boolean array positionally indicating where an overlap occurs.

See also:

[Interval.overlaps](#) Check whether two Interval objects overlap.

Examples

```
>>> data = [(0, 1), (1, 3), (2, 4)]
>>> intervals = pd.arrays.IntervalArray.from_tuples(data)
>>> intervals
<IntervalArray>
[[0, 1], (1, 3], (2, 4]]
Length: 3, dtype: interval[int64, right]
```

```
>>> intervals.overlaps(pd.Interval(0.5, 1.5))
array([ True,  True, False])
```

Intervals that share closed endpoints overlap:

```
>>> intervals.overlaps(pd.Interval(1, 3, closed='left'))
array([ True,  True,  True])
```

Intervals that only have an open endpoint in common do not overlap:

```
>>> intervals.overlaps(pd.Interval(1, 2, closed='right'))
array([False,  True, False])
```

pandas.IntervalIndex.set_closed**IntervalIndex.set_closed**(*args, **kwargs)

Return an IntervalArray identical to the current one, but closed on the specified side.

Parameters**closed** [{'left', 'right', 'both', 'neither'}] Whether the intervals are closed on the left-side, right-side, both or neither.**Returns****new_index** [IntervalArray]**Examples**

```

>>> index = pd.arrays.IntervalArray.from_breaks(range(4))
>>> index
<IntervalArray>
[[0, 1], (1, 2], (2, 3]]
Length: 3, dtype: interval[int64, right]
>>> index.set_closed('both')
<IntervalArray>
[[0, 1], [1, 2], [2, 3]]
Length: 3, dtype: interval[int64, both]

```

pandas.IntervalIndex.to_tuples**IntervalIndex.to_tuples**(*args, **kwargs)

Return an ndarray of tuples of the form (left, right).

Parameters**na_tuple** [bool, default True] Returns NA as a tuple if True, (nan, nan), or just as the NA value itself if False, nan.**Returns****tuples: ndarray****IntervalIndex components**

pandas.IntervalIndex.left

IntervalIndex.left

pandas.IntervalIndex.right

IntervalIndex.right

pandas.IntervalIndex.mid

IntervalIndex.mid

pandas.IntervalIndex.length**property** IntervalIndex.length

pandas.IntervalIndex.get_loc

`IntervalIndex.get_loc`(*key*, *method=None*, *tolerance=None*)
Get integer location, slice or boolean mask for requested label.

Parameters

key [label]

method [{None}, optional]

- default: matches where the label is within an interval only.

Returns

int if unique index, slice if monotonic index, else mask

Examples

```
>>> i1, i2 = pd.Interval(0, 1), pd.Interval(1, 2)
>>> index = pd.IntervalIndex([i1, i2])
>>> index.get_loc(1)
0
```

You can also supply a point inside an interval.

```
>>> index.get_loc(1.5)
1
```

If a label is in several intervals, you get the locations of all the relevant intervals.

```
>>> i3 = pd.Interval(0, 2)
>>> overlapping_index = pd.IntervalIndex([i1, i2, i3])
>>> overlapping_index.get_loc(0.5)
array([ True, False,  True])
```

Only exact matches will be returned if an interval is provided.

```
>>> index.get_loc(pd.Interval(0, 1))
0
```

pandas.IntervalIndex.get_indexer

`IntervalIndex.get_indexer`(*target*, *method=None*, *limit=None*, *tolerance=None*)

Compute indexer and mask for new index given the current index. The indexer should be then used as an input to `ndarray.take` to align the current data to the new index.

Parameters

target [Index]

method [{None, 'pad'/'ffill', 'backfill'/'bfill', 'nearest'}], optional]

- default: exact matches only.
- pad / ffill: find the PREVIOUS index value if no exact match.
- backfill / bfill: use NEXT index value if no exact match

- nearest: use the NEAREST index value if no exact match. Tied distances are broken by preferring the larger index value.

limit [int, optional] Maximum number of consecutive labels in `target` to match for inexact matches.

tolerance [optional] Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations must satisfy the equation $\text{abs}(\text{index}[\text{indexer}] - \text{target}) \leq \text{tolerance}$.

Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple, array, Series, and must be the same size as the index and its dtype must exactly match the index's type.

Returns

indexer [np.ndarray[np.intp]] Integers from 0 to `n - 1` indicating that the index at these positions matches the corresponding target values. Missing values in the target are marked by -1.

Examples

```
>>> index = pd.Index(['c', 'a', 'b'])
>>> index.get_indexer(['a', 'b', 'x'])
array([ 1,  2, -1])
```

Notice that the return value is an array of locations in `index` and `x` is marked by -1, as it is not in `index`.

3.6.5 MultiIndex

| | |
|---|--|
| <i>MultiIndex</i> ([levels, codes, sortorder, ...]) | A multi-level, or hierarchical, index object for pandas objects. |
|---|--|

pandas.MultiIndex

class pandas.**MultiIndex**(*levels=None, codes=None, sortorder=None, names=None, dtype=None, copy=False, name=None, verify_integrity=True*)

A multi-level, or hierarchical, index object for pandas objects.

Parameters

levels [sequence of arrays] The unique labels for each level.

codes [sequence of arrays] Integers for each level designating which label at each location.

sortorder [optional int] Level of sortedness (must be lexicographically sorted by that level).

names [optional sequence of objects] Names for each of the index levels. (name is accepted for compat).

copy [bool, default False] Copy the meta-data.

verify_integrity [bool, default True] Check that the levels/codes are consistent and valid.

See also:

[*MultiIndex.from_arrays*](#) Convert list of arrays to MultiIndex.

MultiIndex.from_product Create a MultiIndex from the cartesian product of iterables.
MultiIndex.from_tuples Convert list of tuples to a MultiIndex.
MultiIndex.from_frame Make a MultiIndex from a DataFrame.
Index The base pandas Index type.

Notes

See the [user guide](#) for more.

Examples

A new MultiIndex is typically constructed using one of the helper methods *MultiIndex.from_arrays()*, *MultiIndex.from_product()* and *MultiIndex.from_tuples()*. For example (using `.from_arrays()`):

```
>>> arrays = [[1, 1, 2, 2], ['red', 'blue', 'red', 'blue']]
>>> pd.MultiIndex.from_arrays(arrays, names=('number', 'color'))
MultiIndex([(1, 'red'),
            (1, 'blue'),
            (2, 'red'),
            (2, 'blue')],
            names=['number', 'color'])
```

See further examples for how to construct a MultiIndex in the doc strings of the mentioned helper methods.

Attributes

| | |
|-----------------|--|
| <i>names</i> | Names of levels in MultiIndex. |
| <i>nlevels</i> | Integer number of levels in this MultiIndex. |
| <i>levshape</i> | A tuple with the length of each level. |

pandas.MultiIndex.names

property `MultiIndex.names`
Names of levels in MultiIndex.

Examples

```
>>> mi = pd.MultiIndex.from_arrays(
... [[1, 2], [3, 4], [5, 6]], names=['x', 'y', 'z'])
>>> mi
MultiIndex([(1, 3, 5),
            (2, 4, 6)],
            names=['x', 'y', 'z'])
>>> mi.names
FrozenList(['x', 'y', 'z'])
```

pandas.MultiIndex.nlevels**property** MultiIndex.nlevels

Integer number of levels in this MultiIndex.

Examples

```
>>> mi = pd.MultiIndex.from_arrays([[ 'a' ], [ 'b' ], [ 'c' ]])
>>> mi
MultiIndex([( 'a', 'b', 'c' )],
            )
>>> mi.nlevels
3
```

pandas.MultiIndex.levshape**property** MultiIndex.levshape

A tuple with the length of each level.

Examples

```
>>> mi = pd.MultiIndex.from_arrays([[ 'a' ], [ 'b' ], [ 'c' ]])
>>> mi
MultiIndex([( 'a', 'b', 'c' )],
            )
>>> mi.levshape
(1, 1, 1)
```

| | |
|--------|--|
| levels | |
| codes | |

Methods

| | |
|---|---|
| <i>from_arrays</i> (arrays[, sortorder, names]) | Convert arrays to MultiIndex. |
| <i>from_tuples</i> (tuples[, sortorder, names]) | Convert list of tuples to MultiIndex. |
| <i>from_product</i> (iterables[, sortorder, names]) | Make a MultiIndex from the cartesian product of multiple iterables. |
| <i>from_frame</i> (df[, sortorder, names]) | Make a MultiIndex from a DataFrame. |
| <i>set_levels</i> (levels[, level, inplace, ...]) | Set new levels on MultiIndex. |
| <i>set_codes</i> (codes[, level, inplace, ...]) | Set new codes on MultiIndex. |
| <i>to_frame</i> ([index, name]) | Create a DataFrame with the levels of the MultiIndex as columns. |
| <i>to_flat_index</i> () | Convert a MultiIndex to an Index of Tuples containing the level values. |
| <i>sortlevel</i> ([level, ascending, sort_remaining]) | Sort MultiIndex at the requested level. |
| <i>droplevel</i> ([level]) | Return index with requested level(s) removed. |

continues on next page

Table 162 – continued from previous page

| | |
|-------------------------------------|--|
| <code>swaplevel(i, j)</code> | Swap level <i>i</i> with level <i>j</i> . |
| <code>reorder_levels(order)</code> | Rearrange levels using input order. |
| <code>remove_unused_levels()</code> | Create new MultiIndex from current that removes unused levels. |
| <code>get_locs(seq)</code> | Get location for a sequence of labels. |

pandas.MultiIndex.from_arrays

classmethod `MultiIndex.from_arrays(arrays, sortorder=None, names=NoDefault.no_default)`

Convert arrays to MultiIndex.

Parameters

arrays [list / sequence of array-likes] Each array-like gives one level's value for each data point. `len(arrays)` is the number of levels.

sortorder [int or None] Level of sortedness (must be lexicographically sorted by that level).

names [list / sequence of str, optional] Names for the levels in the index.

Returns

MultiIndex

See also:

[*MultiIndex.from_tuples*](#) Convert list of tuples to MultiIndex.

[*MultiIndex.from_product*](#) Make a MultiIndex from cartesian product of iterables.

[*MultiIndex.from_frame*](#) Make a MultiIndex from a DataFrame.

Examples

```
>>> arrays = [[1, 1, 2, 2], ['red', 'blue', 'red', 'blue']]
>>> pd.MultiIndex.from_arrays(arrays, names=('number', 'color'))
MultiIndex([(1, 'red'),
            (1, 'blue'),
            (2, 'red'),
            (2, 'blue')],
            names=['number', 'color'])
```

pandas.MultiIndex.from_tuples

classmethod `MultiIndex.from_tuples(tuples, sortorder=None, names=None)`

Convert list of tuples to MultiIndex.

Parameters

tuples [list / sequence of tuple-likes] Each tuple is the index of one row/column.

sortorder [int or None] Level of sortedness (must be lexicographically sorted by that level).

names [list / sequence of str, optional] Names for the levels in the index.

Returns**MultiIndex****See also:***MultiIndex.from_arrays* Convert list of arrays to MultiIndex.*MultiIndex.from_product* Make a MultiIndex from cartesian product of iterables.*MultiIndex.from_frame* Make a MultiIndex from a DataFrame.**Examples**

```

>>> tuples = [(1, 'red'), (1, 'blue'),
...           (2, 'red'), (2, 'blue')]
>>> pd.MultiIndex.from_tuples(tuples, names=('number', 'color'))
MultiIndex([(1, 'red'),
            (1, 'blue'),
            (2, 'red'),
            (2, 'blue')],
            names=['number', 'color'])

```

pandas.MultiIndex.from_product**classmethod** `MultiIndex.from_product(iterables, sortorder=None, names=NoDefault.no_default)`

Make a MultiIndex from the cartesian product of multiple iterables.

Parameters**iterables** [list / sequence of iterables] Each iterable has unique labels for each level of the index.**sortorder** [int or None] Level of sortedness (must be lexicographically sorted by that level).**names** [list / sequence of str, optional] Names for the levels in the index.

Changed in version 1.0.0: If not explicitly provided, names will be inferred from the elements of iterables if an element has a name attribute

Returns**MultiIndex****See also:***MultiIndex.from_arrays* Convert list of arrays to MultiIndex.*MultiIndex.from_tuples* Convert list of tuples to MultiIndex.*MultiIndex.from_frame* Make a MultiIndex from a DataFrame.

Examples

```
>>> numbers = [0, 1, 2]
>>> colors = ['green', 'purple']
>>> pd.MultiIndex.from_product([numbers, colors],
...                             names=['number', 'color'])
MultiIndex([(0, 'green'),
            (0, 'purple'),
            (1, 'green'),
            (1, 'purple'),
            (2, 'green'),
            (2, 'purple')],
            names=['number', 'color'])
```

pandas.MultiIndex.from_frame

classmethod `MultiIndex.from_frame`(*df*, *sortorder=None*, *names=None*)

Make a MultiIndex from a DataFrame.

Parameters

df [DataFrame] DataFrame to be converted to MultiIndex.

sortorder [int, optional] Level of sortedness (must be lexicographically sorted by that level).

names [list-like, optional] If no names are provided, use the column names, or tuple of column names if the columns is a MultiIndex. If a sequence, overwrite names with the given sequence.

Returns

MultiIndex The MultiIndex representation of the given DataFrame.

See also:

[*MultiIndex.from_arrays*](#) Convert list of arrays to MultiIndex.

[*MultiIndex.from_tuples*](#) Convert list of tuples to MultiIndex.

[*MultiIndex.from_product*](#) Make a MultiIndex from cartesian product of iterables.

Examples

```
>>> df = pd.DataFrame([[['HI', 'Temp'], ['HI', 'Precip']],
...                    [['NJ', 'Temp'], ['NJ', 'Precip']],
...                    columns=['a', 'b'])
>>> df
   a      b
0  HI  Temp
1  HI  Precip
2  NJ  Temp
3  NJ  Precip
```

```
>>> pd.MultiIndex.from_frame(df)
MultiIndex([(HI', 'Temp'),
            (HI', 'Precip'),
            (NJ', 'Temp'),
            (NJ', 'Precip')],
           names=['a', 'b'])
```

Using explicit names, instead of the column names

```
>>> pd.MultiIndex.from_frame(df, names=['state', 'observation'])
MultiIndex([(HI', 'Temp'),
            (HI', 'Precip'),
            (NJ', 'Temp'),
            (NJ', 'Precip')],
           names=['state', 'observation'])
```

pandas.MultiIndex.set_levels

`MultiIndex.set_levels(levels, level=None, inplace=None, verify_integrity=True)`

Set new levels on MultiIndex. Defaults to returning new index.

Parameters

levels [sequence or list of sequence] New level(s) to apply.

level [int, level name, or sequence of int/level names (default None)] Level(s) to set (None for all levels).

inplace [bool] If True, mutates in place.

Deprecated since version 1.2.0.

verify_integrity [bool, default True] If True, checks that levels and codes are compatible.

Returns

new index (of same type and class...etc) or None The same type as the caller or None if `inplace=True`.

Examples

```
>>> idx = pd.MultiIndex.from_tuples(
...     [
...         (1, "one"),
...         (1, "two"),
...         (2, "one"),
...         (2, "two"),
...         (3, "one"),
...         (3, "two")
...     ],
...     names=["foo", "bar"]
... )
>>> idx
```

(continues on next page)

(continued from previous page)

```
MultiIndex([(1, 'one'),
            (1, 'two'),
            (2, 'one'),
            (2, 'two'),
            (3, 'one'),
            (3, 'two')],
           names=['foo', 'bar'])
```

```
>>> idx.set_levels(['a', 'b', 'c'], [1, 2])
MultiIndex([('a', 1),
            ('a', 2),
            ('b', 1),
            ('b', 2),
            ('c', 1),
            ('c', 2)],
           names=['foo', 'bar'])
>>> idx.set_levels(['a', 'b', 'c'], level=0)
MultiIndex([('a', 'one'),
            ('a', 'two'),
            ('b', 'one'),
            ('b', 'two'),
            ('c', 'one'),
            ('c', 'two')],
           names=['foo', 'bar'])
>>> idx.set_levels(['a', 'b'], level='bar')
MultiIndex([(1, 'a'),
            (1, 'b'),
            (2, 'a'),
            (2, 'b'),
            (3, 'a'),
            (3, 'b')],
           names=['foo', 'bar'])
```

If any of the levels passed to `set_levels()` exceeds the existing length, all of the values from that argument will be stored in the `MultiIndex` levels, though the values will be truncated in the `MultiIndex` output.

```
>>> idx.set_levels(['a', 'b', 'c'], [1, 2, 3, 4], level=[0, 1])
MultiIndex([('a', 1),
            ('a', 2),
            ('b', 1),
            ('b', 2),
            ('c', 1),
            ('c', 2)],
           names=['foo', 'bar'])
>>> idx.set_levels(['a', 'b', 'c'], [1, 2, 3, 4], level=[0, 1]).levels
FrozenList(['a', 'b', 'c'], [1, 2, 3, 4])
```

pandas.MultiIndex.set_codes

`MultiIndex.set_codes(codes, level=None, inplace=None, verify_integrity=True)`

Set new codes on MultiIndex. Defaults to returning new index.

Parameters

codes [sequence or list of sequence] New codes to apply.

level [int, level name, or sequence of int/level names (default None)] Level(s) to set (None for all levels).

inplace [bool] If True, mutates in place.

Deprecated since version 1.2.0.

verify_integrity [bool, default True] If True, checks that levels and codes are compatible.

Returns

new index (of same type and class...etc) or None The same type as the caller or None if `inplace=True`.

Examples

```
>>> idx = pd.MultiIndex.from_tuples(
...     [(1, "one"), (1, "two"), (2, "one"), (2, "two")], names=["foo", "bar"]
... )
>>> idx
MultiIndex([(1, 'one'),
            (1, 'two'),
            (2, 'one'),
            (2, 'two')],
           names=['foo', 'bar'])
```

```
>>> idx.set_codes([[1, 0, 1, 0], [0, 0, 1, 1]])
MultiIndex([(2, 'one'),
            (1, 'one'),
            (2, 'two'),
            (1, 'two')],
           names=['foo', 'bar'])
>>> idx.set_codes([1, 0, 1, 0], level=0)
MultiIndex([(2, 'one'),
            (1, 'two'),
            (2, 'one'),
            (1, 'two')],
           names=['foo', 'bar'])
>>> idx.set_codes([0, 0, 1, 1], level='bar')
MultiIndex([(1, 'one'),
            (1, 'one'),
            (2, 'two'),
            (2, 'two')],
           names=['foo', 'bar'])
>>> idx.set_codes([[1, 0, 1, 0], [0, 0, 1, 1]], level=[0, 1])
```

(continues on next page)

(continued from previous page)

```
MultiIndex([(2, 'one'),
            (1, 'one'),
            (2, 'two'),
            (1, 'two')],
           names=['foo', 'bar'])
```

pandas.MultiIndex.to_frame

`MultiIndex.to_frame(index=True, name=None)`

Create a DataFrame with the levels of the MultiIndex as columns.

Column ordering is determined by the DataFrame constructor with data as a dict.

Parameters

index [bool, default True] Set the index of the returned DataFrame as the original MultiIndex.

name [list / sequence of str, optional] The passed names should substitute index level names.

Returns

DataFrame [a DataFrame containing the original MultiIndex data.]

See also:

DataFrame Two-dimensional, size-mutable, potentially heterogeneous tabular data.

Examples

```
>>> mi = pd.MultiIndex.from_arrays(['a', 'b'], ['c', 'd'])
>>> mi
MultiIndex([('a', 'c'),
            ('b', 'd')],
           )
```

```
>>> df = mi.to_frame()
>>> df
   0 1
a c a c
b d b d
```

```
>>> df = mi.to_frame(index=False)
>>> df
   0 1
0 a c
1 b d
```

```
>>> df = mi.to_frame(name=['x', 'y'])
>>> df
   x y
```

(continues on next page)

(continued from previous page)

```
a c a c
b d b d
```

pandas.MultiIndex.to_flat_index**MultiIndex.to_flat_index()**

Convert a MultiIndex to an Index of Tuples containing the level values.

Returns

pd.Index Index with the MultiIndex data represented in Tuples.

See also:

MultiIndex.from_tuples Convert flat index back to MultiIndex.

Notes

This method will simply return the caller if called by anything other than a MultiIndex.

Examples

```
>>> index = pd.MultiIndex.from_product(
...     [['foo', 'bar'], ['baz', 'qux']],
...     names=['a', 'b'])
>>> index.to_flat_index()
Index([( 'foo', 'baz'), ('foo', 'qux'),
      ('bar', 'baz'), ('bar', 'qux')],
      dtype='object')
```

pandas.MultiIndex.sortlevel**MultiIndex.sortlevel**(*level=0, ascending=True, sort_remaining=True*)

Sort MultiIndex at the requested level.

The result will respect the original ordering of the associated factor at that level.

Parameters

level [list-like, int or str, default 0] If a string is given, must be a name of the level. If list-like must be names or ints of levels.

ascending [bool, default True] False to sort in descending order. Can also be a list to specify a directed ordering.

sort_remaining [sort by the remaining levels after level]

Returns

sorted_index [pd.MultiIndex] Resulting index.

indexer [np.ndarray] Indices of output values in original index.

Examples

```
>>> mi = pd.MultiIndex.from_arrays([[0, 0], [2, 1]])
>>> mi
MultiIndex([(0, 2),
            (0, 1)],
            )
```

```
>>> mi.sortlevel()
(MultiIndex([(0, 1),
            (0, 2)],
            ), array([1, 0]))
```

```
>>> mi.sortlevel(sort_remaining=False)
(MultiIndex([(0, 2),
            (0, 1)],
            ), array([0, 1]))
```

```
>>> mi.sortlevel(1)
(MultiIndex([(0, 1),
            (0, 2)],
            ), array([1, 0]))
```

```
>>> mi.sortlevel(1, ascending=False)
(MultiIndex([(0, 2),
            (0, 1)],
            ), array([0, 1]))
```

pandas.MultiIndex.droplevel

MultiIndex.droplevel (*level=0*)

Return index with requested level(s) removed.

If resulting index has only 1 level left, the result will be of Index type, not MultiIndex.

Parameters

level [int, str, or list-like, default 0] If a string is given, must be the name of a level. If list-like, elements must be names or indexes of levels.

Returns

Index or MultiIndex

Examples

```
>>> mi = pd.MultiIndex.from_arrays(
... [[1, 2], [3, 4], [5, 6]], names=['x', 'y', 'z'])
>>> mi
MultiIndex([(1, 3, 5),
            (2, 4, 6)],
            names=['x', 'y', 'z'])
```

```
>>> mi.droplevel()
MultiIndex([(3, 5),
            (4, 6)],
            names=['y', 'z'])
```

```
>>> mi.droplevel(2)
MultiIndex([(1, 3),
            (2, 4)],
            names=['x', 'y'])
```

```
>>> mi.droplevel('z')
MultiIndex([(1, 3),
            (2, 4)],
            names=['x', 'y'])
```

```
>>> mi.droplevel(['x', 'y'])
Int64Index([5, 6], dtype='int64', name='z')
```

pandas.MultiIndex.swaplevel

MultiIndex.swaplevel(*i=-2, j=-1*)

Swap level *i* with level *j*.

Calling this method does not change the ordering of the values.

Parameters

i [int, str, default -2] First level of index to be swapped. Can pass level name as string. Type of parameters can be mixed.

j [int, str, default -1] Second level of index to be swapped. Can pass level name as string. Type of parameters can be mixed.

Returns

MultiIndex A new MultiIndex.

See also:

[*Series.swaplevel*](#) Swap levels *i* and *j* in a MultiIndex.

[*Dataframe.swaplevel*](#) Swap levels *i* and *j* in a MultiIndex on a particular axis.

Examples

```

>>> mi = pd.MultiIndex(levels=[['a', 'b'], ['bb', 'aa']],
...                     codes=[[0, 0, 1, 1], [0, 1, 0, 1]])
>>> mi
MultiIndex([(a, 'bb'),
            (a, 'aa'),
            (b, 'bb'),
            (b, 'aa')],
           )
>>> mi.swaplevel(0, 1)
MultiIndex([(bb, 'a'),
            (aa, 'a'),
            (bb, 'b'),
            (aa, 'b')],
           )

```

pandas.MultiIndex.reorder_levels

`MultiIndex.reorder_levels`(*order*)

Rearrange levels using input order. May not drop or duplicate levels.

Parameters

order [list of int or list of str] List representing new level order. Reference level by number (position) or by key (label).

Returns

MultiIndex

Examples

```

>>> mi = pd.MultiIndex.from_arrays([[1, 2], [3, 4]], names=['x', 'y'])
>>> mi
MultiIndex([(1, 3),
            (2, 4)],
           names=['x', 'y'])

```

```

>>> mi.reorder_levels(order=[1, 0])
MultiIndex([(3, 1),
            (4, 2)],
           names=['y', 'x'])

```

```

>>> mi.reorder_levels(order=['y', 'x'])
MultiIndex([(3, 1),
            (4, 2)],
           names=['y', 'x'])

```

pandas.MultiIndex.remove_unused_levels

MultiIndex.remove_unused_levels()

Create new MultiIndex from current that removes unused levels.

Unused level(s) means levels that are not expressed in the labels. The resulting MultiIndex will have the same outward appearance, meaning the same .values and ordering. It will also be .equals() to the original.

Returns

MultiIndex

Examples

```
>>> mi = pd.MultiIndex.from_product([range(2), list('ab')])
>>> mi
MultiIndex([(0, 'a'),
            (0, 'b'),
            (1, 'a'),
            (1, 'b')],
           )
```

```
>>> mi[2:]
MultiIndex([(1, 'a'),
            (1, 'b')],
           )
```

The 0 from the first level is not represented and can be removed

```
>>> mi2 = mi[2:].remove_unused_levels()
>>> mi2.levels
FrozenList([[1], ['a', 'b']])
```

pandas.MultiIndex.get_locs

MultiIndex.get_locs(seq)

Get location for a sequence of labels.

Parameters

seq [label, slice, list, mask or a sequence of such] You should use one of the above for each level. If a level should not be used, set it to slice(None).

Returns

numpy.ndarray NumPy array of integers suitable for passing to iloc.

See also:

MultiIndex.get_loc Get location for a label or a tuple of labels.

MultiIndex.slice_locs Get slice location given start label(s) and end label(s).

Examples

```
>>> mi = pd.MultiIndex.from_arrays([list('abb'), list('def')])
```

```
>>> mi.get_locs('b')
array([1, 2], dtype=int64)
```

```
>>> mi.get_locs([slice(None), ['e', 'f']])
array([1, 2], dtype=int64)
```

```
>>> mi.get_locs([[True, False, True], slice('e', 'f')])
array([2], dtype=int64)
```

IndexSlice

Create an object to more easily perform multi-index slicing.

pandas.IndexSlice

pandas.IndexSlice = <pandas.core.indexing._IndexSlice object>

Create an object to more easily perform multi-index slicing.

See also:

[*MultiIndex.remove_unused_levels*](#) New MultiIndex with no unused levels.

Notes

See [*Defined Levels*](#) for further info on slicing a MultiIndex.

Examples

```
>>> midx = pd.MultiIndex.from_product([['A0', 'A1'], ['B0', 'B1', 'B2', 'B3']])
>>> columns = ['foo', 'bar']
>>> dfmi = pd.DataFrame(np.arange(16).reshape((len(midx), len(columns))),
...                    index=midx, columns=columns)
```

Using the default slice command:

```
>>> dfmi.loc[(slice(None), slice('B0', 'B1')), :]
      foo  bar
A0 B0    0    1
   B1    2    3
A1 B0    8    9
   B1   10   11
```

Using the IndexSlice class for a more intuitive command:

```
>>> idx = pd.IndexSlice
>>> dfmi.loc[idx[:, 'B0':'B1'], :]
      foo  bar
```

Multindex constructors

| | |
|--|---|
| <i>MultiIndex.from_arrays</i> (arrays[, sortorder, ...]) | Convert arrays to MultiIndex. |
| <i>MultiIndex.from_tuples</i> (tuples[, sortorder, ...]) | Convert list of tuples to MultiIndex. |
| <i>MultiIndex.from_product</i> (iterables[, ...]) | Make a MultiIndex from the cartesian product of multiple iterables. |
| <i>MultiIndex.from_frame</i> (df[, sortorder, names]) | Make a MultiIndex from a DataFrame. |

Multindex properties

| | |
|----------------------------|---|
| <i>MultiIndex.names</i> | Names of levels in MultiIndex. |
| <i>MultiIndex.levels</i> | |
| <i>MultiIndex.codes</i> | |
| <i>MultiIndex.nlevels</i> | Integer number of levels in this MultiIndex. |
| <i>MultiIndex.levshape</i> | A tuple with the length of each level. |
| <i>MultiIndex.dtypes</i> | Return the dtypes as a Series for the underlying MultiIndex |

pandas.MultiIndex.levels`MultiIndex.levels`**pandas.MultiIndex.codes**`property MultiIndex.codes`**pandas.MultiIndex.dtypes**`MultiIndex.dtypes`

Return the dtypes as a Series for the underlying MultiIndex

MultiIndex components

| | |
|--|---|
| <code>MultiIndex.set_levels(levels[, level, ...])</code> | Set new levels on MultiIndex. |
| <code>MultiIndex.set_codes(codes[, level, ...])</code> | Set new codes on MultiIndex. |
| <code>MultiIndex.to_flat_index()</code> | Convert a MultiIndex to an Index of Tuples containing the level values. |
| <code>MultiIndex.to_frame([index, name])</code> | Create a DataFrame with the levels of the MultiIndex as columns. |
| <code>MultiIndex.sortlevel([level, ascending, ...])</code> | Sort MultiIndex at the requested level. |
| <code>MultiIndex.droplevel([level])</code> | Return index with requested level(s) removed. |
| <code>MultiIndex.swaplevel([i, j])</code> | Swap level i with level j. |
| <code>MultiIndex.reorder_levels(order)</code> | Rearrange levels using input order. |
| <code>MultiIndex.remove_unused_levels()</code> | Create new MultiIndex from current that removes unused levels. |

MultiIndex selecting

| | |
|--|---|
| <code>MultiIndex.get_loc(key[, method])</code> | Get location for a label or a tuple of labels. |
| <code>MultiIndex.get_locs(seq)</code> | Get location for a sequence of labels. |
| <code>MultiIndex.get_loc_level(key[, level, ...])</code> | Get location and sliced index for requested label(s)/level(s). |
| <code>MultiIndex.get_indexer(target[, method, ...])</code> | Compute indexer and mask for new index given the current index. |
| <code>MultiIndex.get_level_values(level)</code> | Return vector of label values for requested level. |

pandas.MultiIndex.get_loc

`MultiIndex.get_loc(key, method=None)`

Get location for a label or a tuple of labels.

The location is returned as an integer/slice or boolean mask.

Parameters

key [label or tuple of labels (one for each level)]

method [None]

Returns

loc [int, slice object or boolean mask] If the key is past the lexsort depth, the return may be a boolean mask array, otherwise it is always a slice or int.

See also:

[`Index.get_loc`](#) The `get_loc` method for (single-level) index.

[`MultiIndex.slice_locs`](#) Get slice location given start label(s) and end label(s).

[`MultiIndex.get_locs`](#) Get location for a label/slice/list/mask or a sequence of such.

Notes

The key cannot be a slice, list of same-level labels, a boolean mask, or a sequence of such. If you want to use those, use `MultiIndex.get_locs()` instead.

Examples

```
>>> mi = pd.MultiIndex.from_arrays([list('abb'), list('def')])
```

```
>>> mi.get_loc('b')
slice(1, 3, None)
```

```
>>> mi.get_loc(('b', 'e'))
1
```

pandas.MultiIndex.get_loc_level

`MultiIndex.get_loc_level(key, level=0, drop_level=True)`

Get location and sliced index for requested label(s)/level(s).

Parameters

key [label or sequence of labels]

level [int/level name or list thereof, optional]

drop_level [bool, default True] If False, the resulting index will not drop any level.

Returns

loc [A 2-tuple where the elements are:] Element 0: int, slice object or boolean array Element 1: The resulting sliced multiindex/index. If the key contains all levels, this will be None.

See also:

[`MultiIndex.get_loc`](#) Get location for a label or a tuple of labels.

[`MultiIndex.get_locs`](#) Get location for a label/slice/list/mask or a sequence of such.

Examples

```
>>> mi = pd.MultiIndex.from_arrays([list('abb'), list('def')],
...                               names=['A', 'B'])
```

```
>>> mi.get_loc_level('b')
(slice(1, 3, None), Index(['e', 'f'], dtype='object', name='B'))
```

```
>>> mi.get_loc_level('e', level='B')
(array([False, True, False]), Index(['b'], dtype='object', name='A'))
```

```
>>> mi.get_loc_level(['b', 'e'])
(1, None)
```

pandas.MultiIndex.get_indexer

`MultiIndex.get_indexer(target, method=None, limit=None, tolerance=None)`

Compute indexer and mask for new index given the current index. The indexer should be then used as an input to `ndarray.take` to align the current data to the new index.

Parameters

target [Index]

method [{None, 'pad'/'ffill', 'backfill'/'bfill', 'nearest'}], optional

- default: exact matches only.
- pad / ffill: find the PREVIOUS index value if no exact match.
- backfill / bfill: use NEXT index value if no exact match
- nearest: use the NEAREST index value if no exact match. Tied distances are broken by preferring the larger index value.

limit [int, optional] Maximum number of consecutive labels in `target` to match for inexact matches.

tolerance [optional] Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations must satisfy the equation $\text{abs}(\text{index}[\text{indexer}] - \text{target}) \leq \text{tolerance}$.

Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple, array, Series, and must be the same size as the index and its dtype must exactly match the index's type.

Returns

indexer [np.ndarray[np.intp]] Integers from 0 to `n - 1` indicating that the index at these positions matches the corresponding target values. Missing values in the target are marked by `-1`.

Examples

```
>>> index = pd.Index(['c', 'a', 'b'])
>>> index.get_indexer(['a', 'b', 'x'])
array([ 1,  2, -1])
```

Notice that the return value is an array of locations in `index` and `x` is marked by `-1`, as it is not in `index`.

pandas.MultiIndex.get_level_values

`MultiIndex.get_level_values(level)`

Return vector of label values for requested level.

Length of returned vector is equal to the length of the index.

Parameters

level [int or str] `level` is either the integer position of the level in the `MultiIndex`, or the name of the level.

Returns

values [Index] Values is a level of this MultiIndex converted to a single *Index* (or subclass thereof).

Examples

Create a MultiIndex:

```
>>> mi = pd.MultiIndex.from_arrays((list('abc'), list('def')))
>>> mi.names = ['level_1', 'level_2']
```

Get level values by supplying level as either integer or name:

```
>>> mi.get_level_values(0)
Index(['a', 'b', 'c'], dtype='object', name='level_1')
>>> mi.get_level_values('level_2')
Index(['d', 'e', 'f'], dtype='object', name='level_2')
```

3.6.6 DatetimeIndex

DatetimeIndex([data, freq, tz, normalize, ...]) Immutable ndarray-like of datetime64 data.

pandas.DatetimeIndex

class pandas.**DatetimeIndex**(*data=None, freq=None, tz=None, normalize=False, closed=None, ambiguous='raise', dayfirst=False, yearfirst=False, dtype=None, copy=False, name=None*)

Immutable ndarray-like of datetime64 data.

Represented internally as int64, and which can be boxed to Timestamp objects that are subclasses of datetime and carry metadata.

Parameters

- data** [array-like (1-dimensional), optional] Optional datetime-like data to construct index with.
- freq** [str or pandas offset object, optional] One of pandas date offset strings or corresponding objects. The string 'infer' can be passed in order to set the frequency of the index as the inferred frequency upon creation.
- tz** [pytz.timezone or dateutil.tz.tzfile or datetime.tzinfo or str] Set the Timezone of the data.
- normalize** [bool, default False] Normalize start/end dates to midnight before generating date range.
- closed** [{ 'left', 'right' }, optional] Set whether to include *start* and *end* that are on the boundary. The default includes boundary points on either end.
- ambiguous** ['infer', bool-ndarray, 'NaT', default 'raise'] When clocks moved backward due to DST, ambiguous times may arise. For example in Central European Time (UTC+01), when going from 03:00 DST to 02:00 non-DST, 02:30:00 local time occurs both at 00:30:00 UTC and at 01:30:00 UTC. In such a situation, the *ambiguous* parameter dictates how ambiguous times should be handled.

- 'infer' will attempt to infer fall dst-transition hours based on order

- bool-ndarray where True signifies a DST time, False signifies a non-DST time (note that this flag is only applicable for ambiguous times)
- 'NaT' will return NaT where there are ambiguous times
- 'raise' will raise an AmbiguousTimeError if there are ambiguous times.

dayfirst [bool, default False] If True, parse dates in *data* with the day first order.

yearfirst [bool, default False] If True parse dates in *data* with the year first order.

dtype [numpy.dtype or DatetimeTZDtype or str, default None] Note that the only NumPy dtype allowed is 'datetime64[ns]'.

copy [bool, default False] Make a copy of input ndarray.

name [label, default None] Name to be stored in the index.

See also:

- Index** The base pandas Index type.
- TimedeltaIndex** Index of timedelta64 data.
- PeriodIndex** Index of Period data.
- to_datetime** Convert argument to datetime.
- date_range** Create a fixed-frequency DatetimeIndex.

Notes

To learn more about the frequency strings, please see [this link](#).

Attributes

| | |
|--------------------|--|
| <i>year</i> | The year of the datetime. |
| <i>month</i> | The month as January=1, December=12. |
| <i>day</i> | The day of the datetime. |
| <i>hour</i> | The hours of the datetime. |
| <i>minute</i> | The minutes of the datetime. |
| <i>second</i> | The seconds of the datetime. |
| <i>microsecond</i> | The microseconds of the datetime. |
| <i>nanosecond</i> | The nanoseconds of the datetime. |
| <i>date</i> | Returns numpy array of python datetime.date objects (namely, the date part of Timestamps without time-zone information). |
| <i>time</i> | Returns numpy array of datetime.time. |
| <i>timetz</i> | Returns numpy array of datetime.time also containing timezone information. |
| <i>dayofyear</i> | The ordinal day of the year. |
| <i>day_of_year</i> | The ordinal day of the year. |
| <i>weekofyear</i> | (DEPRECATED) The week ordinal of the year. |
| <i>week</i> | (DEPRECATED) The week ordinal of the year. |
| <i>dayofweek</i> | The day of the week with Monday=0, Sunday=6. |
| <i>day_of_week</i> | The day of the week with Monday=0, Sunday=6. |
| <i>weekday</i> | The day of the week with Monday=0, Sunday=6. |
| <i>quarter</i> | The quarter of the date. |
| <i>tz</i> | Return timezone, if any. |

continues on next page

Table 169 – continued from previous page

| | |
|-------------------------|---|
| <i>freq</i> | Return the frequency object if it is set, otherwise None. |
| <i>freqstr</i> | Return the frequency object as a string if its set, otherwise None. |
| <i>is_month_start</i> | Indicates whether the date is the first day of the month. |
| <i>is_month_end</i> | Indicates whether the date is the last day of the month. |
| <i>is_quarter_start</i> | Indicator for whether the date is the first day of a quarter. |
| <i>is_quarter_end</i> | Indicator for whether the date is the last day of a quarter. |
| <i>is_year_start</i> | Indicate whether the date is the first day of a year. |
| <i>is_year_end</i> | Indicate whether the date is the last day of the year. |
| <i>is_leap_year</i> | Boolean indicator if the date belongs to a leap year. |
| <i>inferred_freq</i> | Tries to return a string representing a frequency guess, generated by <code>infer_freq</code> . |

pandas.DatetimeIndex.year**property** `DatetimeIndex.year`

The year of the datetime.

Examples

```
>>> datetime_series = pd.Series(
...     pd.date_range("2000-01-01", periods=3, freq="Y")
... )
>>> datetime_series
0    2000-12-31
1    2001-12-31
2    2002-12-31
dtype: datetime64[ns]
>>> datetime_series.dt.year
0    2000
1    2001
2    2002
dtype: int64
```

pandas.DatetimeIndex.month**property** `DatetimeIndex.month`

The month as January=1, December=12.

Examples

```
>>> datetime_series = pd.Series(
...     pd.date_range("2000-01-01", periods=3, freq="M")
... )
>>> datetime_series
0    2000-01-31
1    2000-02-29
2    2000-03-31
dtype: datetime64[ns]
>>> datetime_series.dt.month
0     1
1     2
2     3
dtype: int64
```

pandas.DatetimeIndex.day

property DatetimeIndex.day

The day of the datetime.

Examples

```
>>> datetime_series = pd.Series(
...     pd.date_range("2000-01-01", periods=3, freq="D")
... )
>>> datetime_series
0    2000-01-01
1    2000-01-02
2    2000-01-03
dtype: datetime64[ns]
>>> datetime_series.dt.day
0     1
1     2
2     3
dtype: int64
```

pandas.DatetimeIndex.hour

property DatetimeIndex.hour

The hours of the datetime.

Examples

```
>>> datetime_series = pd.Series(
...     pd.date_range("2000-01-01", periods=3, freq="h")
... )
>>> datetime_series
0    2000-01-01 00:00:00
1    2000-01-01 01:00:00
2    2000-01-01 02:00:00
dtype: datetime64[ns]
>>> datetime_series.dt.hour
0     0
1     1
2     2
dtype: int64
```

pandas.DatetimeIndex.minute

property `DatetimeIndex.minute`

The minutes of the datetime.

Examples

```
>>> datetime_series = pd.Series(
...     pd.date_range("2000-01-01", periods=3, freq="T")
... )
>>> datetime_series
0    2000-01-01 00:00:00
1    2000-01-01 00:01:00
2    2000-01-01 00:02:00
dtype: datetime64[ns]
>>> datetime_series.dt.minute
0     0
1     1
2     2
dtype: int64
```

pandas.DatetimeIndex.second

property `DatetimeIndex.second`

The seconds of the datetime.

Examples

```
>>> datetime_series = pd.Series(
...     pd.date_range("2000-01-01", periods=3, freq="s")
... )
>>> datetime_series
0    2000-01-01 00:00:00
1    2000-01-01 00:00:01
2    2000-01-01 00:00:02
dtype: datetime64[ns]
>>> datetime_series.dt.second
0    0
1    1
2    2
dtype: int64
```

`pandas.DatetimeIndex.microsecond`

property `DatetimeIndex.microsecond`

The microseconds of the datetime.

Examples

```
>>> datetime_series = pd.Series(
...     pd.date_range("2000-01-01", periods=3, freq="us")
... )
>>> datetime_series
0    2000-01-01 00:00:00.000000
1    2000-01-01 00:00:00.000001
2    2000-01-01 00:00:00.000002
dtype: datetime64[ns]
>>> datetime_series.dt.microsecond
0    0
1    1
2    2
dtype: int64
```

`pandas.DatetimeIndex.nanosecond`

property `DatetimeIndex.nanosecond`

The nanoseconds of the datetime.

Examples

```

>>> datetime_series = pd.Series(
...     pd.date_range("2000-01-01", periods=3, freq="ns")
... )
>>> datetime_series
0    2000-01-01 00:00:00.000000000
1    2000-01-01 00:00:00.000000001
2    2000-01-01 00:00:00.000000002
dtype: datetime64[ns]
>>> datetime_series.dt.nanosecond
0      0
1      1
2      2
dtype: int64

```

pandas.DatetimeIndex.date

property `DatetimeIndex.date`

Returns numpy array of python `datetime.date` objects (namely, the date part of Timestamps without time-zone information).

pandas.DatetimeIndex.time

property `DatetimeIndex.time`

Returns numpy array of `datetime.time`. The time part of the Timestamps.

pandas.DatetimeIndex.timetz

property `DatetimeIndex.timetz`

Returns numpy array of `datetime.time` also containing timezone information. The time part of the Timestamps.

pandas.DatetimeIndex.dayofyear

property `DatetimeIndex.dayofyear`

The ordinal day of the year.

pandas.DatetimeIndex.day_of_year

property `DatetimeIndex.day_of_year`

The ordinal day of the year.

pandas.DatetimeIndex.weekofyear

property `DatetimeIndex.weekofyear`

The week ordinal of the year.

Deprecated since version 1.1.0.

`weekofyear` and `week` have been deprecated. Please use `DatetimeIndex.isocalendar().week` instead.

pandas.DatetimeIndex.week

property `DatetimeIndex.week`

The week ordinal of the year.

Deprecated since version 1.1.0.

`weekofyear` and `week` have been deprecated. Please use `DatetimeIndex.isocalendar().week` instead.

pandas.DatetimeIndex.dayofweek

property `DatetimeIndex.dayofweek`

The day of the week with Monday=0, Sunday=6.

Return the day of the week. It is assumed the week starts on Monday, which is denoted by 0 and ends on Sunday which is denoted by 6. This method is available on both Series with datetime values (using the `dt` accessor) or `DatetimeIndex`.

Returns

Series or Index Containing integers indicating the day number.

See also:

[*Series.dt.dayofweek*](#) Alias.

[*Series.dt.weekday*](#) Alias.

[*Series.dt.day_name*](#) Returns the name of the day of the week.

Examples

```
>>> s = pd.date_range('2016-12-31', '2017-01-08', freq='D').to_series()
>>> s.dt.dayofweek
2016-12-31    5
2017-01-01    6
2017-01-02    0
2017-01-03    1
2017-01-04    2
2017-01-05    3
2017-01-06    4
2017-01-07    5
2017-01-08    6
Freq: D, dtype: int64
```

pandas.DatetimeIndex.day_of_week

property DatetimeIndex.day_of_week

The day of the week with Monday=0, Sunday=6.

Return the day of the week. It is assumed the week starts on Monday, which is denoted by 0 and ends on Sunday which is denoted by 6. This method is available on both Series with datetime values (using the *dt* accessor) or DatetimeIndex.

Returns

Series or Index Containing integers indicating the day number.

See also:

[*Series.dt.dayofweek*](#) Alias.

[*Series.dt.weekday*](#) Alias.

[*Series.dt.day_name*](#) Returns the name of the day of the week.

Examples

```

>>> s = pd.date_range('2016-12-31', '2017-01-08', freq='D').to_series()
>>> s.dt.dayofweek
2016-12-31    5
2017-01-01    6
2017-01-02    0
2017-01-03    1
2017-01-04    2
2017-01-05    3
2017-01-06    4
2017-01-07    5
2017-01-08    6
Freq: D, dtype: int64

```

pandas.DatetimeIndex.weekday

property DatetimeIndex.weekday

The day of the week with Monday=0, Sunday=6.

Return the day of the week. It is assumed the week starts on Monday, which is denoted by 0 and ends on Sunday which is denoted by 6. This method is available on both Series with datetime values (using the *dt* accessor) or DatetimeIndex.

Returns

Series or Index Containing integers indicating the day number.

See also:

[*Series.dt.dayofweek*](#) Alias.

[*Series.dt.weekday*](#) Alias.

[*Series.dt.day_name*](#) Returns the name of the day of the week.

Examples

```
>>> s = pd.date_range('2016-12-31', '2017-01-08', freq='D').to_series()
>>> s.dt.dayofweek
2016-12-31    5
2017-01-01    6
2017-01-02    0
2017-01-03    1
2017-01-04    2
2017-01-05    3
2017-01-06    4
2017-01-07    5
2017-01-08    6
Freq: D, dtype: int64
```

pandas.DatetimeIndex.quarter

property `DatetimeIndex.quarter`

The quarter of the date.

pandas.DatetimeIndex.tz

property `DatetimeIndex.tz`

Return timezone, if any.

Returns

datetime.tzinfo, pytz.tzinfo.BaseTZInfo, dateutil.tz.tzfile, or None Returns None when the array is tz-naive.

pandas.DatetimeIndex.freq

property `DatetimeIndex.freq`

Return the frequency object if it is set, otherwise None.

pandas.DatetimeIndex.freqstr

property `DatetimeIndex.freqstr`

Return the frequency object as a string if its set, otherwise None.

pandas.DatetimeIndex.is_month_start

property DatetimeIndex.is_month_start

Indicates whether the date is the first day of the month.

Returns

Series or array For Series, returns a Series with boolean values. For DatetimeIndex, returns a boolean array.

See also:

[*is_month_start*](#) Return a boolean indicating whether the date is the first day of the month.

[*is_month_end*](#) Return a boolean indicating whether the date is the last day of the month.

Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on `DatetimeIndex`.

```

>>> s = pd.Series(pd.date_range("2018-02-27", periods=3))
>>> s
0    2018-02-27
1    2018-02-28
2    2018-03-01
dtype: datetime64[ns]
>>> s.dt.is_month_start
0    False
1    False
2     True
dtype: bool
>>> s.dt.is_month_end
0    False
1     True
2    False
dtype: bool

```

```

>>> idx = pd.date_range("2018-02-27", periods=3)
>>> idx.is_month_start
array([False, False,  True])
>>> idx.is_month_end
array([False,  True, False])

```

pandas.DatetimeIndex.is_month_end

property DatetimeIndex.is_month_end

Indicates whether the date is the last day of the month.

Returns

Series or array For Series, returns a Series with boolean values. For `DatetimeIndex`, returns a boolean array.

See also:

is_month_start Return a boolean indicating whether the date is the first day of the month.

is_month_end Return a boolean indicating whether the date is the last day of the month.

Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on `DatetimeIndex`.

```
>>> s = pd.Series(pd.date_range("2018-02-27", periods=3))
>>> s
0    2018-02-27
1    2018-02-28
2    2018-03-01
dtype: datetime64[ns]
>>> s.dt.is_month_start
0    False
1    False
2     True
dtype: bool
>>> s.dt.is_month_end
0    False
1     True
2    False
dtype: bool
```

```
>>> idx = pd.date_range("2018-02-27", periods=3)
>>> idx.is_month_start
array([False, False,  True])
>>> idx.is_month_end
array([False,  True,  False])
```

`pandas.DatetimeIndex.is_quarter_start`

property `DatetimeIndex.is_quarter_start`

Indicator for whether the date is the first day of a quarter.

Returns

is_quarter_start [Series or `DatetimeIndex`] The same type as the original data with boolean values. Series will have the same name and index. `DatetimeIndex` will have the same name.

See also:

quarter Return the quarter of the date.

is_quarter_end Similar property for indicating the quarter start.

Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on `DatetimeIndex`.

```
>>> df = pd.DataFrame({'dates': pd.date_range("2017-03-30",
...                                           periods=4)})
>>> df.assign(quarter=df.dates.dt.quarter,
...           is_quarter_start=df.dates.dt.is_quarter_start)
   dates  quarter  is_quarter_start
0 2017-03-30      1             False
1 2017-03-31      1             False
2 2017-04-01      2              True
3 2017-04-02      2             False
```

```
>>> idx = pd.date_range('2017-03-30', periods=4)
>>> idx
DatetimeIndex(['2017-03-30', '2017-03-31', '2017-04-01', '2017-04-02'],
              dtype='datetime64[ns]', freq='D')
```

```
>>> idx.is_quarter_start
array([False, False,  True, False])
```

pandas.DatetimeIndex.is_quarter_end

property `DatetimeIndex.is_quarter_end`

Indicator for whether the date is the last day of a quarter.

Returns

is_quarter_end [Series or `DatetimeIndex`] The same type as the original data with boolean values. Series will have the same name and index. `DatetimeIndex` will have the same name.

See also:

quarter Return the quarter of the date.

is_quarter_start Similar property indicating the quarter start.

Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on `DatetimeIndex`.

```
>>> df = pd.DataFrame({'dates': pd.date_range("2017-03-30",
...                                           periods=4)})
>>> df.assign(quarter=df.dates.dt.quarter,
...           is_quarter_end=df.dates.dt.is_quarter_end)
   dates  quarter  is_quarter_end
0 2017-03-30      1             False
1 2017-03-31      1              True
```

(continues on next page)

(continued from previous page)

```
2 2017-04-01      2      False
3 2017-04-02      2      False
```

```
>>> idx = pd.date_range('2017-03-30', periods=4)
>>> idx
DatetimeIndex(['2017-03-30', '2017-03-31', '2017-04-01', '2017-04-02'],
              dtype='datetime64[ns]', freq='D')
```

```
>>> idx.is_quarter_end
array([False,  True,  False,  False])
```

pandas.DatetimeIndex.is_year_start

property DatetimeIndex.is_year_start

Indicate whether the date is the first day of a year.

Returns

Series or DatetimeIndex The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

See also:

[*is_year_end*](#) Similar property indicating the last day of the year.

Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on `DatetimeIndex`.

```
>>> dates = pd.Series(pd.date_range("2017-12-30", periods=3))
>>> dates
0    2017-12-30
1    2017-12-31
2    2018-01-01
dtype: datetime64[ns]
```

```
>>> dates.dt.is_year_start
0    False
1    False
2     True
dtype: bool
```

```
>>> idx = pd.date_range("2017-12-30", periods=3)
>>> idx
DatetimeIndex(['2017-12-30', '2017-12-31', '2018-01-01'],
              dtype='datetime64[ns]', freq='D')
```

```
>>> idx.is_year_start
array([False,  False,  True])
```

pandas.DatetimeIndex.is_year_end

property DatetimeIndex.is_year_end

Indicate whether the date is the last day of the year.

Returns

Series or DatetimeIndex The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

See also:

[*is_year_start*](#) Similar property indicating the start of the year.

Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on DatetimeIndex.

```
>>> dates = pd.Series(pd.date_range("2017-12-30", periods=3))
>>> dates
0    2017-12-30
1    2017-12-31
2    2018-01-01
dtype: datetime64[ns]
```

```
>>> dates.dt.is_year_end
0    False
1     True
2    False
dtype: bool
```

```
>>> idx = pd.date_range("2017-12-30", periods=3)
>>> idx
DatetimeIndex(['2017-12-30', '2017-12-31', '2018-01-01'],
              dtype='datetime64[ns]', freq='D')
```

```
>>> idx.is_year_end
array([False,  True, False])
```

pandas.DatetimeIndex.is_leap_year

property DatetimeIndex.is_leap_year

Boolean indicator if the date belongs to a leap year.

A leap year is a year, which has 366 days (instead of 365) including 29th of February as an intercalary day. Leap years are years which are multiples of four with the exception of years divisible by 100 but not by 400.

Returns

Series or ndarray Booleans indicating if dates belong to a leap year.

Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on `DatetimeIndex`.

```
>>> idx = pd.date_range("2012-01-01", "2015-01-01", freq="Y")
>>> idx
DatetimeIndex(['2012-12-31', '2013-12-31', '2014-12-31'],
              dtype='datetime64[ns]', freq='A-DEC')
>>> idx.is_leap_year
array([ True, False, False])
```

```
>>> dates_series = pd.Series(idx)
>>> dates_series
0    2012-12-31
1    2013-12-31
2    2014-12-31
dtype: datetime64[ns]
>>> dates_series.dt.is_leap_year
0     True
1    False
2    False
dtype: bool
```

pandas.DatetimeIndex.inferred_freq

DatetimeIndex.inferred_freq

Tries to return a string representing a frequency guess, generated by `infer_freq`. Returns `None` if it can't autodetect the frequency.

Methods

| | |
|--|---|
| <code>normalize(*args, **kwargs)</code> | Convert times to midnight. |
| <code>strftime(*args, **kwargs)</code> | Convert to Index using specified <code>date_format</code> . |
| <code>snap([freq])</code> | Snap time stamps to nearest occurring frequency. |
| <code>tz_convert(tz)</code> | Convert tz-aware Datetime Array/Index from one time zone to another. |
| <code>tz_localize(tz[, ambiguous, nonexistent])</code> | Localize tz-naive Datetime Array/Index to tz-aware Datetime Array/Index. |
| <code>round(*args, **kwargs)</code> | Perform round operation on the data to the specified <i>freq</i> . |
| <code>floor(*args, **kwargs)</code> | Perform floor operation on the data to the specified <i>freq</i> . |
| <code>ceil(*args, **kwargs)</code> | Perform ceil operation on the data to the specified <i>freq</i> . |
| <code>to_period(*args, **kwargs)</code> | Cast to PeriodArray/Index at a particular frequency. |
| <code>to_perioddelta(freq)</code> | Calculate TimedeltaArray of difference between index values and index converted to PeriodArray at specified <i>freq</i> . |

continues on next page

Table 170 – continued from previous page

| | |
|--|--|
| <code>to_pydatetime(*args, **kwargs)</code> | Return Datetime Array/Index as object ndarray of datetime.datetime objects. |
| <code>to_series([keep_tz, index, name])</code> | Create a Series with both index and values equal to the index keys useful with map for returning an indexer based on an index. |
| <code>to_frame([index, name])</code> | Create a DataFrame with a column containing the Index. |
| <code>month_name(*args, **kwargs)</code> | Return the month names of the DateTimeIndex with specified locale. |
| <code>day_name(*args, **kwargs)</code> | Return the day names of the DateTimeIndex with specified locale. |
| <code>mean(*args, **kwargs)</code> | Return the mean value of the Array. |

pandas.DatetimeIndex.normalize

`DatetimeIndex.normalize(*args, **kwargs)`

Convert times to midnight.

The time component of the date-time is converted to midnight i.e. 00:00:00. This is useful in cases, when the time does not matter. Length is unaltered. The timezones are unaffected.

This method is available on Series with datetime values under the `.dt` accessor, and directly on Datetime Array/Index.

Returns

DatetimeArray, DatetimeIndex or Series The same type as the original data. Series will have the same name and index. DatetimeIndex will have the same name.

See also:

floor Floor the datetimes to the specified freq.

ceil Ceil the datetimes to the specified freq.

round Round the datetimes to the specified freq.

Examples

```
>>> idx = pd.date_range(start='2014-08-01 10:00', freq='H',
...                       periods=3, tz='Asia/Calcutta')
>>> idx
DatetimeIndex(['2014-08-01 10:00:00+05:30',
               '2014-08-01 11:00:00+05:30',
               '2014-08-01 12:00:00+05:30'],
              dtype='datetime64[ns, Asia/Calcutta]', freq='H')
>>> idx.normalize()
DatetimeIndex(['2014-08-01 00:00:00+05:30',
               '2014-08-01 00:00:00+05:30',
               '2014-08-01 00:00:00+05:30'],
              dtype='datetime64[ns, Asia/Calcutta]', freq=None)
```

pandas.DatetimeIndex.strftime

DatetimeIndex.**strftime**(*args, **kwargs)

Convert to Index using specified date_format.

Return an Index of formatted strings specified by date_format, which supports the same string format as the python standard library. Details of the string format can be found in [python string format doc](#).

Parameters

date_format [str] Date format string (e.g. “%Y-%m-%d”).

Returns

ndarray NumPy ndarray of formatted strings.

See also:

[to_datetime](#) Convert the given argument to datetime.

[DatetimeIndex.normalize](#) Return DatetimeIndex with times to midnight.

[DatetimeIndex.round](#) Round the DatetimeIndex to the specified freq.

[DatetimeIndex.floor](#) Floor the DatetimeIndex to the specified freq.

Examples

```
>>> rng = pd.date_range(pd.Timestamp("2018-03-10 09:00"),
...                      periods=3, freq='s')
>>> rng.strftime('%B %d, %Y, %r')
Index(['March 10, 2018, 09:00:00 AM', 'March 10, 2018, 09:00:01 AM',
       'March 10, 2018, 09:00:02 AM'],
      dtype='object')
```

pandas.DatetimeIndex.snap

DatetimeIndex.**snap**(freq='S')

Snap time stamps to nearest occurring frequency.

Returns

DatetimeIndex

pandas.DatetimeIndex.tz_convert

DatetimeIndex.**tz_convert**(tz)

Convert tz-aware Datetime Array/Index from one time zone to another.

Parameters

tz [str, pytz.timezone, dateutil.tz.tzfile or None] Time zone for time. Corresponding timestamps would be converted to this time zone of the Datetime Array/Index. A tz of None will convert to UTC and remove the timezone information.

Returns

Array or Index

Raises

TypeError If Datetime Array/Index is tz-naive.

See also:

DatetimeIndex.tz A timezone that has a variable offset from UTC.

DatetimeIndex.tz_localize Localize tz-naive DatetimeIndex to a given time zone, or remove time-zone from a tz-aware DatetimeIndex.

Examples

With the `tz` parameter, we can change the DatetimeIndex to other time zones:

```
>>> dti = pd.date_range(start='2014-08-01 09:00',
...                       freq='H', periods=3, tz='Europe/Berlin')
```

```
>>> dti
DatetimeIndex(['2014-08-01 09:00:00+02:00',
               '2014-08-01 10:00:00+02:00',
               '2014-08-01 11:00:00+02:00'],
              dtype='datetime64[ns, Europe/Berlin]', freq='H')
```

```
>>> dti.tz_convert('US/Central')
DatetimeIndex(['2014-08-01 02:00:00-05:00',
               '2014-08-01 03:00:00-05:00',
               '2014-08-01 04:00:00-05:00'],
              dtype='datetime64[ns, US/Central]', freq='H')
```

With the `tz=None`, we can remove the timezone (after converting to UTC if necessary):

```
>>> dti = pd.date_range(start='2014-08-01 09:00', freq='H',
...                       periods=3, tz='Europe/Berlin')
```

```
>>> dti
DatetimeIndex(['2014-08-01 09:00:00+02:00',
               '2014-08-01 10:00:00+02:00',
               '2014-08-01 11:00:00+02:00'],
              dtype='datetime64[ns, Europe/Berlin]', freq='H')
```

```
>>> dti.tz_convert(None)
DatetimeIndex(['2014-08-01 07:00:00',
               '2014-08-01 08:00:00',
               '2014-08-01 09:00:00'],
              dtype='datetime64[ns]', freq='H')
```

pandas.DatetimeIndex.tz_localize

DatetimeIndex.tz_localize(*tz*, *ambiguous='raise'*, *nonexistent='raise'*)

Localize tz-naive Datetime Array/Index to tz-aware Datetime Array/Index.

This method takes a time zone (*tz*) naive Datetime Array/Index object and makes this time zone aware. It does not move the time to another time zone.

This method can also be used to do the inverse – to create a time zone unaware object from an aware object. To that end, pass *tz=None*.

Parameters

tz [str, pytz.timezone, dateutil.tz.tzfile or None] Time zone to convert timestamps to. Passing None will remove the time zone information preserving local time.

ambiguous ['infer', 'NaT', bool array, default 'raise'] When clocks moved backward due to DST, ambiguous times may arise. For example in Central European Time (UTC+01), when going from 03:00 DST to 02:00 non-DST, 02:30:00 local time occurs both at 00:30:00 UTC and at 01:30:00 UTC. In such a situation, the *ambiguous* parameter dictates how ambiguous times should be handled.

- 'infer' will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False signifies a non-DST time (note that this flag is only applicable for ambiguous times)
- 'NaT' will return NaT where there are ambiguous times
- 'raise' will raise an AmbiguousTimeError if there are ambiguous times.

nonexistent ['shift_forward', 'shift_backward', 'NaT', timedelta, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- 'shift_forward' will shift the nonexistent time forward to the closest existing time
- 'shift_backward' will shift the nonexistent time backward to the closest existing time
- 'NaT' will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- 'raise' will raise a NonExistentTimeError if there are nonexistent times.

Returns

Same type as self Array/Index converted to the specified time zone.

Raises

TypeError If the Datetime Array/Index is tz-aware and *tz* is not None.

See also:

[*DatetimeIndex.tz_convert*](#) Convert tz-aware DatetimeIndex from one time zone to another.

Examples

```
>>> tz_naive = pd.date_range('2018-03-01 09:00', periods=3)
>>> tz_naive
DatetimeIndex(['2018-03-01 09:00:00', '2018-03-02 09:00:00',
              '2018-03-03 09:00:00'],
              dtype='datetime64[ns]', freq='D')
```

Localize DatetimeIndex in US/Eastern time zone:

```
>>> tz_aware = tz_naive.tz_localize(tz='US/Eastern')
>>> tz_aware
DatetimeIndex(['2018-03-01 09:00:00-05:00',
              '2018-03-02 09:00:00-05:00',
              '2018-03-03 09:00:00-05:00'],
              dtype='datetime64[ns, US/Eastern]', freq=None)
```

With the tz=None, we can remove the time zone information while keeping the local time (not converted to UTC):

```
>>> tz_aware.tz_localize(None)
DatetimeIndex(['2018-03-01 09:00:00', '2018-03-02 09:00:00',
              '2018-03-03 09:00:00'],
              dtype='datetime64[ns]', freq=None)
```

Be careful with DST changes. When there is sequential data, pandas can infer the DST time:

```
>>> s = pd.to_datetime(pd.Series(['2018-10-28 01:30:00',
...                               '2018-10-28 02:00:00',
...                               '2018-10-28 02:30:00',
...                               '2018-10-28 02:00:00',
...                               '2018-10-28 02:30:00',
...                               '2018-10-28 03:00:00',
...                               '2018-10-28 03:30:00']))
>>> s.dt.tz_localize('CET', ambiguous='infer')
0    2018-10-28 01:30:00+02:00
1    2018-10-28 02:00:00+02:00
2    2018-10-28 02:30:00+02:00
3    2018-10-28 02:00:00+01:00
4    2018-10-28 02:30:00+01:00
5    2018-10-28 03:00:00+01:00
6    2018-10-28 03:30:00+01:00
dtype: datetime64[ns, CET]
```

In some cases, inferring the DST is impossible. In such cases, you can pass an ndarray to the ambiguous parameter to set the DST explicitly

```
>>> s = pd.to_datetime(pd.Series(['2018-10-28 01:20:00',
...                               '2018-10-28 02:36:00',
...                               '2018-10-28 03:46:00']))
>>> s.dt.tz_localize('CET', ambiguous=np.array([True, True, False]))
0    2018-10-28 01:20:00+02:00
1    2018-10-28 02:36:00+02:00
```

(continues on next page)

(continued from previous page)

```
2 2018-10-28 03:46:00+01:00
dtype: datetime64[ns, CET]
```

If the DST transition causes nonexistent times, you can shift these dates forward or backwards with a `timedelta` object or `'shift_forward'` or `'shift_backwards'`.

```
>>> s = pd.to_datetime(pd.Series(['2015-03-29 02:30:00',
...                               '2015-03-29 03:30:00']))
>>> s.dt.tz_localize('Europe/Warsaw', nonexistent='shift_forward')
0 2015-03-29 03:00:00+02:00
1 2015-03-29 03:30:00+02:00
dtype: datetime64[ns, Europe/Warsaw]
```

```
>>> s.dt.tz_localize('Europe/Warsaw', nonexistent='shift_backward')
0 2015-03-29 01:59:59.999999999+01:00
1 2015-03-29 03:30:00+02:00
dtype: datetime64[ns, Europe/Warsaw]
```

```
>>> s.dt.tz_localize('Europe/Warsaw', nonexistent=pd.Timedelta('1H'))
0 2015-03-29 03:30:00+02:00
1 2015-03-29 03:30:00+02:00
dtype: datetime64[ns, Europe/Warsaw]
```

pandas.DatetimeIndex.round

`DatetimeIndex.round(*args, **kwargs)`

Perform round operation on the data to the specified *freq*.

Parameters

freq [str or Offset] The frequency level to round the index to. Must be a fixed frequency like 'S' (second) not 'ME' (month end). See *frequency aliases* for a list of possible *freq* values.

ambiguous ['infer', bool-ndarray, 'NaT', default 'raise'] Only relevant for `DatetimeIndex`:

- 'infer' will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- 'NaT' will return NaT where there are ambiguous times
- 'raise' will raise an `AmbiguousTimeError` if there are ambiguous times.

nonexistent ['shift_forward', 'shift_backward', 'NaT', `timedelta`, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- 'shift_forward' will shift the nonexistent time forward to the closest existing time
- 'shift_backward' will shift the nonexistent time backward to the closest existing time

- ‘NaT’ will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- ‘raise’ will raise an NonExistentTimeError if there are nonexistent times.

Returns

DatetimeIndex, TimedeltaIndex, or Series Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

Raises

ValueError if the *freq* cannot be converted.

Examples

DatetimeIndex

```
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
              '2018-01-01 12:01:00'],
              dtype='datetime64[ns]', freq='T')
>>> rng.round('H')
DatetimeIndex(['2018-01-01 12:00:00', '2018-01-01 12:00:00',
              '2018-01-01 12:00:00'],
              dtype='datetime64[ns]', freq=None)
```

Series

```
>>> pd.Series(rng).dt.round("H")
0    2018-01-01 12:00:00
1    2018-01-01 12:00:00
2    2018-01-01 12:00:00
dtype: datetime64[ns]
```

pandas.DatetimeIndex.floor

`DatetimeIndex.floor(*args, **kwargs)`

Perform floor operation on the data to the specified *freq*.

Parameters

freq [str or Offset] The frequency level to floor the index to. Must be a fixed frequency like ‘S’ (second) not ‘ME’ (month end). See [frequency aliases](#) for a list of possible *freq* values.

ambiguous [‘infer’, bool-ndarray, ‘NaT’, default ‘raise’] Only relevant for DatetimeIndex:

- ‘infer’ will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- ‘NaT’ will return NaT where there are ambiguous times
- ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times.

nonexistent ['shift_forward', 'shift_backward', 'NaT', timedelta, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- 'shift_forward' will shift the nonexistent time forward to the closest existing time
- 'shift_backward' will shift the nonexistent time backward to the closest existing time
- 'NaT' will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- 'raise' will raise a NonExistentTimeError if there are nonexistent times.

Returns

DatetimeIndex, TimedeltaIndex, or Series Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

Raises

ValueError if the *freq* cannot be converted.

Examples

DatetimeIndex

```
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
              '2018-01-01 12:01:00'],
              dtype='datetime64[ns]', freq='T')
>>> rng.floor('H')
DatetimeIndex(['2018-01-01 11:00:00', '2018-01-01 12:00:00',
              '2018-01-01 12:00:00'],
              dtype='datetime64[ns]', freq=None)
```

Series

```
>>> pd.Series(rng).dt.floor("H")
0    2018-01-01 11:00:00
1    2018-01-01 12:00:00
2    2018-01-01 12:00:00
dtype: datetime64[ns]
```

pandas.DatetimeIndex.ceil

`DatetimeIndex.ceil(*args, **kwargs)`

Perform ceil operation on the data to the specified *freq*.

Parameters

freq [str or Offset] The frequency level to ceil the index to. Must be a fixed frequency like 'S' (second) not 'ME' (month end). See *frequency aliases* for a list of possible *freq* values.

ambiguous [`'infer'`, bool-ndarray, `'NaT'`, default `'raise'`] Only relevant for DatetimeIndex:

- `'infer'` will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- `'NaT'` will return NaT where there are ambiguous times
- `'raise'` will raise an `AmbiguousTimeError` if there are ambiguous times.

nonexistent [`'shift_forward'`, `'shift_backward'`, `'NaT'`, timedelta, default `'raise'`] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- `'shift_forward'` will shift the nonexistent time forward to the closest existing time
- `'shift_backward'` will shift the nonexistent time backward to the closest existing time
- `'NaT'` will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- `'raise'` will raise a `NonExistentTimeError` if there are nonexistent times.

Returns

DatetimeIndex, TimedeltaIndex, or Series Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

Raises

ValueError if the *freq* cannot be converted.

Examples

DatetimeIndex

```
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
              '2018-01-01 12:01:00'],
              dtype='datetime64[ns]', freq='T')
>>> rng.ceil('H')
DatetimeIndex(['2018-01-01 12:00:00', '2018-01-01 12:00:00',
              '2018-01-01 13:00:00'],
              dtype='datetime64[ns]', freq=None)
```

Series

```
>>> pd.Series(rng).dt.ceil("H")
0    2018-01-01 12:00:00
1    2018-01-01 12:00:00
2    2018-01-01 13:00:00
dtype: datetime64[ns]
```

pandas.DatetimeIndex.to_period

DatetimeIndex.**to_period**(*args, **kwargs)

Cast to PeriodArray/Index at a particular frequency.

Converts DatetimeArray/Index to PeriodArray/Index.

Parameters

freq [str or Offset, optional] One of pandas' *offset strings* or an Offset object. Will be inferred by default.

Returns

PeriodArray/Index

Raises

ValueError When converting a DatetimeArray/Index with non-regular values, so that a frequency cannot be inferred.

See also:

[*PeriodIndex*](#) Immutable ndarray holding ordinal values.

[*DatetimeIndex.to_pydatetime*](#) Return DatetimeIndex as object.

Examples

```
>>> df = pd.DataFrame({"y": [1, 2, 3]},
...                    index=pd.to_datetime(["2000-03-31 00:00:00",
...                    "2000-05-31 00:00:00",
...                    "2000-08-31 00:00:00"]))
>>> df.index.to_period("M")
PeriodIndex(['2000-03', '2000-05', '2000-08'],
            dtype='period[M]')
```

Infer the daily frequency

```
>>> idx = pd.date_range("2017-01-01", periods=2)
>>> idx.to_period()
PeriodIndex(['2017-01-01', '2017-01-02'],
            dtype='period[D]')
```

pandas.DatetimeIndex.to_perioddelta

DatetimeIndex.**to_perioddelta**(freq)

Calculate TimedeltaArray of difference between index values and index converted to PeriodArray at specified freq. Used for vectorized offsets.

Parameters

freq [Period frequency]

Returns

TimedeltaArray/Index

pandas.DatetimeIndex.to_pydatetime**DatetimeIndex.to_pydatetime**(*args, **kwargs)

Return Datetime Array/Index as object ndarray of datetime.datetime objects.

Returns**datetimes** [ndarray[object]]**pandas.DatetimeIndex.to_series****DatetimeIndex.to_series**(keep_tz=NoDefault.no_default, index=None, name=None)

Create a Series with both index and values equal to the index keys useful with map for returning an indexer based on an index.

Parameters**keep_tz** [optional, defaults True] Return the data keeping the timezone.

If keep_tz is True:

If the timezone is not set, the resulting Series will have a datetime64[ns] dtype.

Otherwise the Series will have an datetime64[ns, tz] dtype; the tz will be preserved.

If keep_tz is False:

Series will have a datetime64[ns] dtype. TZ aware objects will have the tz removed.

Changed in version 1.0.0: The default value is now True. In a future version, this keyword will be removed entirely. Stop passing the argument to obtain the future behavior and silence the warning.

index [Index, optional] Index of resulting Series. If None, defaults to original index.**name** [str, optional] Name of resulting Series. If None, defaults to name of original index.**Returns****Series****pandas.DatetimeIndex.to_frame****DatetimeIndex.to_frame**(index=True, name=None)

Create a DataFrame with a column containing the Index.

Parameters**index** [bool, default True] Set the index of the returned DataFrame as the original Index.**name** [object, default None] The passed name should substitute for the index name (if it has one).**Returns****DataFrame** DataFrame containing the original Index data.

See also:

Index.to_series Convert an Index to a Series.

Series.to_frame Convert Series to DataFrame.

Examples

```
>>> idx = pd.Index(['Ant', 'Bear', 'Cow'], name='animal')
>>> idx.to_frame()
      animal
animal
Ant      Ant
Bear    Bear
Cow     Cow
```

By default, the original Index is reused. To enforce a new Index:

```
>>> idx.to_frame(index=False)
      animal
0     Ant
1    Bear
2     Cow
```

To override the name of the resulting column, specify *name*:

```
>>> idx.to_frame(index=False, name='zoo')
      zoo
0     Ant
1    Bear
2     Cow
```

pandas.DatetimeIndex.month_name

`DatetimeIndex.month_name(*args, **kwargs)`

Return the month names of the `DatetimeIndex` with specified locale.

Parameters

locale [str, optional] Locale determining the language in which to return the month name. Default is English locale.

Returns

Index Index of month names.

Examples

```
>>> idx = pd.date_range(start='2018-01', freq='M', periods=3)
>>> idx
DatetimeIndex(['2018-01-31', '2018-02-28', '2018-03-31'],
              dtype='datetime64[ns]', freq='M')
>>> idx.month_name()
Index(['January', 'February', 'March'], dtype='object')
```

pandas.DatetimeIndex.day_name

DatetimeIndex.**day_name**(*args, **kwargs)

Return the day names of the DateTimeIndex with specified locale.

Parameters

locale [str, optional] Locale determining the language in which to return the day name.
Default is English locale.

Returns

Index Index of day names.

Examples

```
>>> idx = pd.date_range(start='2018-01-01', freq='D', periods=3)
>>> idx
DatetimeIndex(['2018-01-01', '2018-01-02', '2018-01-03'],
              dtype='datetime64[ns]', freq='D')
>>> idx.day_name()
Index(['Monday', 'Tuesday', 'Wednesday'], dtype='object')
```

pandas.DatetimeIndex.mean

DatetimeIndex.**mean**(*args, **kwargs)

Return the mean value of the Array.

New in version 0.25.0.

Parameters

skipna [bool, default True] Whether to ignore any NaT elements.

axis [int, optional, default 0]

Returns

scalar Timestamp or Timedelta.

See also:

[numpy.ndarray.mean](#) Returns the average of array elements along a given axis.

[Series.mean](#) Return the mean value in a Series.

Notes

mean is only defined for Datetime and Timedelta dtypes, not for Period.

|-----|--|
| std | |
|-----|--|

Time/date components

| | |
|---|---|
| <code>DatetimeIndex.year</code> | The year of the datetime. |
| <code>DatetimeIndex.month</code> | The month as January=1, December=12. |
| <code>DatetimeIndex.day</code> | The day of the datetime. |
| <code>DatetimeIndex.hour</code> | The hours of the datetime. |
| <code>DatetimeIndex.minute</code> | The minutes of the datetime. |
| <code>DatetimeIndex.second</code> | The seconds of the datetime. |
| <code>DatetimeIndex.microsecond</code> | The microseconds of the datetime. |
| <code>DatetimeIndex.nanosecond</code> | The nanoseconds of the datetime. |
| <code>DatetimeIndex.date</code> | Returns numpy array of python datetime.date objects (namely, the date part of Timestamps without timezone information). |
| <code>DatetimeIndex.time</code> | Returns numpy array of datetime.time. |
| <code>DatetimeIndex.timetz</code> | Returns numpy array of datetime.time also containing timezone information. |
| <code>DatetimeIndex.dayofyear</code> | The ordinal day of the year. |
| <code>DatetimeIndex.day_of_year</code> | The ordinal day of the year. |
| <code>DatetimeIndex.weekofyear</code> | (DEPRECATED) The week ordinal of the year. |
| <code>DatetimeIndex.week</code> | (DEPRECATED) The week ordinal of the year. |
| <code>DatetimeIndex.dayofweek</code> | The day of the week with Monday=0, Sunday=6. |
| <code>DatetimeIndex.day_of_week</code> | The day of the week with Monday=0, Sunday=6. |
| <code>DatetimeIndex.weekday</code> | The day of the week with Monday=0, Sunday=6. |
| <code>DatetimeIndex.quarter</code> | The quarter of the date. |
| <code>DatetimeIndex.tz</code> | Return timezone, if any. |
| <code>DatetimeIndex.freq</code> | Return the frequency object if it is set, otherwise None. |
| <code>DatetimeIndex.freqstr</code> | Return the frequency object as a string if its set, otherwise None. |
| <code>DatetimeIndex.is_month_start</code> | Indicates whether the date is the first day of the month. |
| <code>DatetimeIndex.is_month_end</code> | Indicates whether the date is the last day of the month. |
| <code>DatetimeIndex.is_quarter_start</code> | Indicator for whether the date is the first day of a quarter. |
| <code>DatetimeIndex.is_quarter_end</code> | Indicator for whether the date is the last day of a quarter. |
| <code>DatetimeIndex.is_year_start</code> | Indicate whether the date is the first day of a year. |
| <code>DatetimeIndex.is_year_end</code> | Indicate whether the date is the last day of the year. |
| <code>DatetimeIndex.is_leap_year</code> | Boolean indicator if the date belongs to a leap year. |
| <code>DatetimeIndex.inferred_freq</code> | Tries to return a string representing a frequency guess, generated by infer_freq. |

Selecting

| | |
|---|---|
| <code>DatetimeIndex.indexer_at_time(time[, asof])</code> | Return index locations of values at particular time of day (e.g. |
| <code>DatetimeIndex.indexer_between_time(...[, ...])</code> | Return index locations of values between particular times of day (e.g., 9:00-9:30AM). |

pandas.DatetimeIndex.indexer_at_time

DatetimeIndex.**indexer_at_time**(time, asof=False)

Return index locations of values at particular time of day (e.g. 9:30AM).

Parameters

time [datetime.time or str] Time passed in either as object (datetime.time) or as string in appropriate format (“%H:%M”, “%H%M”, “%I:%M%p”, “%I%M%p”, “%H:%M:%S”, “%H%M%S”, “%I:%M:%S%p”, “%I%M%S%p”).

Returns

np.ndarray[np.intp]

See also:

[indexer_between_time](#) Get index locations of values between particular times of day.

[DataFrame.at_time](#) Select values at particular time of day.

pandas.DatetimeIndex.indexer_between_time

DatetimeIndex.**indexer_between_time**(start_time, end_time, include_start=True, include_end=True)

Return index locations of values between particular times of day (e.g., 9:00-9:30AM).

Parameters

start_time, end_time [datetime.time, str] Time passed either as object (datetime.time) or as string in appropriate format (“%H:%M”, “%H%M”, “%I:%M%p”, “%I%M%p”, “%H:%M:%S”, “%H%M%S”, “%I:%M:%S%p”, “%I%M%S%p”).

include_start [bool, default True]

include_end [bool, default True]

Returns

np.ndarray[np.intp]

See also:

[indexer_at_time](#) Get index locations of values at particular time of day.

[DataFrame.between_time](#) Select values between particular times of day.

Time-specific operations

| | |
|--|--|
| DatetimeIndex.normalize (*args, **kwargs) | Convert times to midnight. |
| DatetimeIndex.strftime (*args, **kwargs) | Convert to Index using specified date_format. |
| DatetimeIndex.snap ([freq]) | Snap time stamps to nearest occurring frequency. |
| DatetimeIndex.tz_convert (tz) | Convert tz-aware Datetime Array/Index from one time zone to another. |
| DatetimeIndex.tz_localize (tz[, ambiguous, ...]) | Localize tz-naive Datetime Array/Index to tz-aware Datetime Array/Index. |
| DatetimeIndex.round (*args, **kwargs) | Perform round operation on the data to the specified freq. |
| DatetimeIndex.floor (*args, **kwargs) | Perform floor operation on the data to the specified freq. |
| DatetimeIndex.ceil (*args, **kwargs) | Perform ceil operation on the data to the specified freq. |
| DatetimeIndex.month_name (*args, **kwargs) | Return the month names of the DateTimeIndex with specified locale. |

3.6.7 TimedeltaIndex

| | |
|--|--|
| <code>TimedeltaIndex([data, unit, freq, closed, ...])</code> | Immutable ndarray of <code>timedelta64</code> data, represented internally as <code>int64</code> , and which can be boxed to <code>timedelta</code> objects. |
|--|--|

pandas.TimedeltaIndex

```
class pandas.TimedeltaIndex(data=None, unit=None, freq=NoDefault.no_default, closed=None,
                             dtype=dtype('<m8[ns]'), copy=False, name=None)
```

Immutable ndarray of `timedelta64` data, represented internally as `int64`, and which can be boxed to `timedelta` objects.

Parameters

- data** [array-like (1-dimensional), optional] Optional `timedelta`-like data to construct index with.
- unit** [unit of the arg (D,h,m,s,ms,us,ns) denote the unit, optional] Which is an integer/float number.
- freq** [str or pandas offset object, optional] One of pandas date offset strings or corresponding objects. The string 'infer' can be passed in order to set the frequency of the index as the inferred frequency upon creation.
- copy** [bool] Make a copy of input ndarray.
- name** [object] Name to be stored in the index.

See also:

Index The base pandas Index type.
Timedelta Represents a duration between two dates or times.
DatetimeIndex Index of datetime64 data.
PeriodIndex Index of Period data.
timedelta_range Create a fixed-frequency TimedeltaIndex.

Notes

To learn more about the frequency strings, please see [this link](#).

Attributes

| | |
|----------------------|--|
| <i>days</i> | Number of days for each element. |
| <i>seconds</i> | Number of seconds (≥ 0 and less than 1 day) for each element. |
| <i>microseconds</i> | Number of microseconds (≥ 0 and less than 1 second) for each element. |
| <i>nanoseconds</i> | Number of nanoseconds (≥ 0 and less than 1 microsecond) for each element. |
| <i>components</i> | Return a dataframe of the components (days, hours, minutes, seconds, milliseconds, microseconds, nanoseconds) of the Timedeltas. |
| <i>inferred_freq</i> | Tries to return a string representing a frequency guess, generated by <code>infer_freq</code> . |

pandas.TimedeltaIndex.days

property `TimedeltaIndex.days`
 Number of days for each element.

pandas.TimedeltaIndex.seconds

property `TimedeltaIndex.seconds`
 Number of seconds (≥ 0 and less than 1 day) for each element.

pandas.TimedeltaIndex.microseconds

property `TimedeltaIndex.microseconds`

Number of microseconds (≥ 0 and less than 1 second) for each element.

pandas.TimedeltaIndex.nanoseconds

property `TimedeltaIndex.nanoseconds`

Number of nanoseconds (≥ 0 and less than 1 microsecond) for each element.

pandas.TimedeltaIndex.components

property `TimedeltaIndex.components`

Return a dataframe of the components (days, hours, minutes, seconds, milliseconds, microseconds, nanoseconds) of the Timedeltas.

Returns

DataFrame

pandas.TimedeltaIndex.inferred_freq

`TimedeltaIndex.inferred_freq`

Tries to return a string representing a frequency guess, generated by `infer_freq`. Returns None if it can't autodetect the frequency.

Methods

| | |
|--|--|
| <code>to_pytimedelta(*args, **kwargs)</code> | Return Timedelta Array/Index as object ndarray of <code>datetime.timedelta</code> objects. |
| <code>to_series([index, name])</code> | Create a Series with both index and values equal to the index keys. |
| <code>round(*args, **kwargs)</code> | Perform round operation on the data to the specified <i>freq</i> . |
| <code>floor(*args, **kwargs)</code> | Perform floor operation on the data to the specified <i>freq</i> . |
| <code>ceil(*args, **kwargs)</code> | Perform ceil operation on the data to the specified <i>freq</i> . |
| <code>to_frame([index, name])</code> | Create a DataFrame with a column containing the Index. |
| <code>mean(*args, **kwargs)</code> | Return the mean value of the Array. |

pandas.TimedeltaIndex.to_pytimedelta

`TimedeltaIndex.to_pytimedelta(*args, **kwargs)`

Return Timedelta Array/Index as object ndarray of datetime.timedelta objects.

Returns

timedeltas [ndarray[object]]

pandas.TimedeltaIndex.to_series

`TimedeltaIndex.to_series(index=None, name=None)`

Create a Series with both index and values equal to the index keys.

Useful with map for returning an indexer based on an index.

Parameters

index [Index, optional] Index of resulting Series. If None, defaults to original index.

name [str, optional] Name of resulting Series. If None, defaults to name of original index.

Returns

Series The dtype will be based on the type of the Index values.

See also:

[*Index.to_frame*](#) Convert an Index to a DataFrame.

[*Series.to_frame*](#) Convert Series to DataFrame.

Examples

```
>>> idx = pd.Index(['Ant', 'Bear', 'Cow'], name='animal')
```

By default, the original Index and original name is reused.

```
>>> idx.to_series()
animal
Ant    Ant
Bear   Bear
Cow    Cow
Name: animal, dtype: object
```

To enforce a new Index, specify new labels to `index`:

```
>>> idx.to_series(index=[0, 1, 2])
0    Ant
1    Bear
2    Cow
Name: animal, dtype: object
```

To override the name of the resulting column, specify `name`:

```
>>> idx.to_series(name='zoo')
animal
Ant      Ant
Bear     Bear
Cow      Cow
Name: zoo, dtype: object
```

pandas.TimedeltaIndex.round

`TimedeltaIndex.round(*args, **kwargs)`

Perform round operation on the data to the specified *freq*.

Parameters

freq [str or Offset] The frequency level to round the index to. Must be a fixed frequency like 'S' (second) not 'ME' (month end). See [frequency aliases](#) for a list of possible *freq* values.

ambiguous ['infer', bool-ndarray, 'NaT', default 'raise'] Only relevant for DatetimeIndex:

- 'infer' will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- 'NaT' will return NaT where there are ambiguous times
- 'raise' will raise an AmbiguousTimeError if there are ambiguous times.

nonexistent ['shift_forward', 'shift_backward', 'NaT', timedelta, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- 'shift_forward' will shift the nonexistent time forward to the closest existing time
- 'shift_backward' will shift the nonexistent time backward to the closest existing time
- 'NaT' will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- 'raise' will raise a NonExistentTimeError if there are nonexistent times.

Returns

DatetimeIndex, TimedeltaIndex, or Series Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

Raises

ValueError if the *freq* cannot be converted.

Examples

DatetimeIndex

```
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
              '2018-01-01 12:01:00'],
              dtype='datetime64[ns]', freq='T')
>>> rng.round('H')
DatetimeIndex(['2018-01-01 12:00:00', '2018-01-01 12:00:00',
              '2018-01-01 12:00:00'],
              dtype='datetime64[ns]', freq=None)
```

Series

```
>>> pd.Series(rng).dt.round("H")
0    2018-01-01 12:00:00
1    2018-01-01 12:00:00
2    2018-01-01 12:00:00
dtype: datetime64[ns]
```

pandas.TimedeltaIndex.floor

`TimedeltaIndex.floor(*args, **kwargs)`

Perform floor operation on the data to the specified *freq*.

Parameters

freq [str or Offset] The frequency level to floor the index to. Must be a fixed frequency like 'S' (second) not 'ME' (month end). See *frequency aliases* for a list of possible *freq* values.

ambiguous ['infer', bool-ndarray, 'NaT', default 'raise'] Only relevant for DatetimeIndex:

- 'infer' will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- 'NaT' will return NaT where there are ambiguous times
- 'raise' will raise an AmbiguousTimeError if there are ambiguous times.

nonexistent ['shift_forward', 'shift_backward', 'NaT', timedelta, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- 'shift_forward' will shift the nonexistent time forward to the closest existing time
- 'shift_backward' will shift the nonexistent time backward to the closest existing time
- 'NaT' will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta

- ‘raise’ will raise an `NonExistentTimeError` if there are nonexistent times.

Returns

DatetimeIndex, TimedeltaIndex, or Series Index of the same type for a `DatetimeIndex` or `TimedeltaIndex`, or a `Series` with the same index for a `Series`.

Raises

ValueError if the *freq* cannot be converted.

Examples**DatetimeIndex**

```
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
              '2018-01-01 12:01:00'],
              dtype='datetime64[ns]', freq='T')
>>> rng.floor('H')
DatetimeIndex(['2018-01-01 11:00:00', '2018-01-01 12:00:00',
              '2018-01-01 12:00:00'],
              dtype='datetime64[ns]', freq=None)
```

Series

```
>>> pd.Series(rng).dt.floor("H")
0    2018-01-01 11:00:00
1    2018-01-01 12:00:00
2    2018-01-01 12:00:00
dtype: datetime64[ns]
```

pandas.TimedeltaIndex.ceil

`TimedeltaIndex.ceil(*args, **kwargs)`

Perform ceil operation on the data to the specified *freq*.

Parameters

freq [str or Offset] The frequency level to ceil the index to. Must be a fixed frequency like ‘S’ (second) not ‘ME’ (month end). See *frequency aliases* for a list of possible *freq* values.

ambiguous [‘infer’, bool-ndarray, ‘NaT’, default ‘raise’] Only relevant for `DatetimeIndex`:

- ‘infer’ will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- ‘NaT’ will return NaT where there are ambiguous times
- ‘raise’ will raise an `AmbiguousTimeError` if there are ambiguous times.

nonexistent ['shift_forward', 'shift_backward', 'NaT', timedelta, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- 'shift_forward' will shift the nonexistent time forward to the closest existing time
- 'shift_backward' will shift the nonexistent time backward to the closest existing time
- 'NaT' will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- 'raise' will raise a NonExistentTimeError if there are nonexistent times.

Returns

DatetimeIndex, TimedeltaIndex, or Series Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

Raises

ValueError if the *freq* cannot be converted.

Examples

DatetimeIndex

```
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
              '2018-01-01 12:01:00'],
              dtype='datetime64[ns]', freq='T')
>>> rng.ceil('H')
DatetimeIndex(['2018-01-01 12:00:00', '2018-01-01 12:00:00',
              '2018-01-01 13:00:00'],
              dtype='datetime64[ns]', freq=None)
```

Series

```
>>> pd.Series(rng).dt.ceil("H")
0    2018-01-01 12:00:00
1    2018-01-01 12:00:00
2    2018-01-01 13:00:00
dtype: datetime64[ns]
```

pandas.TimedeltaIndex.to_frame

TimedeltaIndex.to_frame(*index=True, name=None*)

Create a DataFrame with a column containing the Index.

Parameters

index [bool, default True] Set the index of the returned DataFrame as the original Index.

name [object, default None] The passed name should substitute for the index name (if it has one).

Returns

DataFrame DataFrame containing the original Index data.

See also:

[Index.to_series](#) Convert an Index to a Series.

[Series.to_frame](#) Convert Series to DataFrame.

Examples

```
>>> idx = pd.Index(['Ant', 'Bear', 'Cow'], name='animal')
>>> idx.to_frame()
      animal
animal
Ant      Ant
Bear    Bear
Cow     Cow
```

By default, the original Index is reused. To enforce a new Index:

```
>>> idx.to_frame(index=False)
      animal
0     Ant
1    Bear
2     Cow
```

To override the name of the resulting column, specify *name*:

```
>>> idx.to_frame(index=False, name='zoo')
      zoo
0     Ant
1    Bear
2     Cow
```

pandas.TimedeltaIndex.mean

`TimedeltaIndex.mean(*args, **kwargs)`

Return the mean value of the Array.

New in version 0.25.0.

Parameters

skipna [bool, default True] Whether to ignore any NaT elements.

axis [int, optional, default 0]

Returns

scalar Timestamp or Timedelta.

See also:

[numpy.ndarray.mean](#) Returns the average of array elements along a given axis.

[Series.mean](#) Return the mean value in a Series.

Notes

mean is only defined for Datetime and Timedelta dtypes, not for Period.

Components

| | |
|---|--|
| <code>TimedeltaIndex.days</code> | Number of days for each element. |
| <code>TimedeltaIndex.seconds</code> | Number of seconds (≥ 0 and less than 1 day) for each element. |
| <code>TimedeltaIndex.microseconds</code> | Number of microseconds (≥ 0 and less than 1 second) for each element. |
| <code>TimedeltaIndex.nanoseconds</code> | Number of nanoseconds (≥ 0 and less than 1 microsecond) for each element. |
| <code>TimedeltaIndex.components</code> | Return a dataframe of the components (days, hours, minutes, seconds, milliseconds, microseconds, nanoseconds) of the Timedeltas. |
| <code>TimedeltaIndex.inferred_freq</code> | Tries to return a string representing a frequency guess, generated by <code>infer_freq</code> . |

Conversion

| | |
|---|--|
| <code>TimedeltaIndex.to_pytimedelta(*args, **kwargs)</code> | Return Timedelta Array/Index as object ndarray of date-time.timedelta objects. |
| <code>TimedeltaIndex.to_series([index, name])</code> | Create a Series with both index and values equal to the index keys. |
| <code>TimedeltaIndex.round(*args, **kwargs)</code> | Perform round operation on the data to the specified <code>freq</code> . |
| <code>TimedeltaIndex.floor(*args, **kwargs)</code> | Perform floor operation on the data to the specified <code>freq</code> . |
| <code>TimedeltaIndex.ceil(*args, **kwargs)</code> | Perform ceil operation on the data to the specified <code>freq</code> . |
| <code>TimedeltaIndex.to_frame([index, name])</code> | Create a DataFrame with a column containing the Index. |

Methods

| | |
|---|-------------------------------------|
| <code>TimedeltaIndex.mean(*args, **kwargs)</code> | Return the mean value of the Array. |
|---|-------------------------------------|

3.6.8 PeriodIndex

| | |
|---|--|
| <code>PeriodIndex([data, ordinal, freq, dtype, ...])</code> | Immutable ndarray holding ordinal values indicating regular periods in time. |
|---|--|

pandas.PeriodIndex

class pandas.**PeriodIndex**(*data=None, ordinal=None, freq=None, dtype=None, copy=False, name=None, **fields*)

Immutable ndarray holding ordinal values indicating regular periods in time.

Index keys are boxed to Period objects which carries the metadata (eg, frequency information).

Parameters

data [array-like (1d int np.ndarray or PeriodArray), optional] Optional period-like data to construct index with.

copy [bool] Make a copy of input ndarray.

freq [str or period object, optional] One of pandas period strings or corresponding objects.

year [int, array, or Series, default None]

month [int, array, or Series, default None]

quarter [int, array, or Series, default None]

day [int, array, or Series, default None]

hour [int, array, or Series, default None]

minute [int, array, or Series, default None]

second [int, array, or Series, default None]

dtype [str or PeriodDtype, default None]

See also:

Index The base pandas Index type.

Period Represents a period of time.

DatetimeIndex Index with datetime64 data.

TimedeltaIndex Index of timedelta64 data.

period_range Create a fixed-frequency PeriodIndex.

Examples

```
>>> idx = pd.PeriodIndex(year=[2000, 2002], quarter=[1, 3])
>>> idx
PeriodIndex(['2000Q1', '2002Q3'], dtype='period[Q-DEC]')
```

Attributes

| | |
|----------------------|---|
| <i>day</i> | The days of the period. |
| <i>dayofweek</i> | The day of the week with Monday=0, Sunday=6. |
| <i>day_of_week</i> | The day of the week with Monday=0, Sunday=6. |
| <i>dayofyear</i> | The ordinal day of the year. |
| <i>day_of_year</i> | The ordinal day of the year. |
| <i>days_in_month</i> | The number of days in the month. |
| <i>daysinmonth</i> | The number of days in the month. |
| <i>freq</i> | Return the frequency object if it is set, otherwise None. |

continues on next page

Table 183 – continued from previous page

| | |
|---------------------|---|
| <i>freqstr</i> | Return the frequency object as a string if its set, otherwise None. |
| <i>hour</i> | The hour of the period. |
| <i>is_leap_year</i> | Logical indicating if the date belongs to a leap year. |
| <i>minute</i> | The minute of the period. |
| <i>month</i> | The month as January=1, December=12. |
| <i>quarter</i> | The quarter of the date. |
| <i>second</i> | The second of the period. |
| <i>week</i> | The week ordinal of the year. |
| <i>weekday</i> | The day of the week with Monday=0, Sunday=6. |
| <i>weekofyear</i> | The week ordinal of the year. |
| <i>year</i> | The year of the period. |

pandas.PeriodIndex.day**property** `PeriodIndex.day`

The days of the period.

pandas.PeriodIndex.dayofweek**property** `PeriodIndex.dayofweek`

The day of the week with Monday=0, Sunday=6.

pandas.PeriodIndex.day_of_week**property** `PeriodIndex.day_of_week`

The day of the week with Monday=0, Sunday=6.

pandas.PeriodIndex.dayofyear**property** `PeriodIndex.dayofyear`

The ordinal day of the year.

pandas.PeriodIndex.day_of_year**property** `PeriodIndex.day_of_year`

The ordinal day of the year.

pandas.PeriodIndex.days_in_month

property `PeriodIndex.days_in_month`
The number of days in the month.

pandas.PeriodIndex.daysinmonth

property `PeriodIndex.daysinmonth`
The number of days in the month.

pandas.PeriodIndex.freq

property `PeriodIndex.freq`
Return the frequency object if it is set, otherwise None.

pandas.PeriodIndex.freqstr

property `PeriodIndex.freqstr`
Return the frequency object as a string if its set, otherwise None.

pandas.PeriodIndex.hour

property `PeriodIndex.hour`
The hour of the period.

pandas.PeriodIndex.is_leap_year

property `PeriodIndex.is_leap_year`
Logical indicating if the date belongs to a leap year.

pandas.PeriodIndex.minute

property `PeriodIndex.minute`
The minute of the period.

pandas.PeriodIndex.month

property `PeriodIndex.month`
The month as January=1, December=12.

pandas.PeriodIndex.quarter

property `PeriodIndex.quarter`
The quarter of the date.

pandas.PeriodIndex.second

property `PeriodIndex.second`
The second of the period.

pandas.PeriodIndex.week

property `PeriodIndex.week`
The week ordinal of the year.

pandas.PeriodIndex.weekday

property `PeriodIndex.weekday`
The day of the week with Monday=0, Sunday=6.

pandas.PeriodIndex.weekofyear

property `PeriodIndex.weekofyear`
The week ordinal of the year.

pandas.PeriodIndex.year

property `PeriodIndex.year`
The year of the period.

| | |
|-------------------|--|
| end_time | |
| qyear | |
| start_time | |

Methods

| | |
|--|--|
| <code>asfreq([freq, how])</code> | Convert the PeriodArray to the specified frequency <i>freq</i> . |
| <code>strftime(*args, **kwargs)</code> | Convert to Index using specified <code>date_format</code> . |
| <code>to_timestamp([freq, how])</code> | Cast to DatetimeArray/Index. |

pandas.PeriodIndex.asfreq

PeriodIndex.**asfreq**(*freq=None, how='E'*)

Convert the PeriodArray to the specified frequency *freq*.

Equivalent to applying `pandas.Period.asfreq()` with the given arguments to each *Period* in this PeriodArray.

Parameters

freq [str] A frequency.

how [str {'E', 'S'}, default 'E'] Whether the elements should be aligned to the end or start within a period.

- 'E', 'END', or 'FINISH' for end,
- 'S', 'START', or 'BEGIN' for start.

January 31st ('END') vs. January 1st ('START') for example.

Returns

PeriodArray The transformed PeriodArray with the new frequency.

See also:

pandas.arrays.PeriodArray.asfreq Convert each Period in a PeriodArray to the given frequency.

Period.asfreq Convert a *Period* object to the given frequency.

Examples

```
>>> pidx = pd.period_range('2010-01-01', '2015-01-01', freq='A')
>>> pidx
PeriodIndex(['2010', '2011', '2012', '2013', '2014', '2015'],
            dtype='period[A-DEC]')
```

```
>>> pidx.asfreq('M')
PeriodIndex(['2010-12', '2011-12', '2012-12', '2013-12', '2014-12',
            '2015-12'], dtype='period[M]')
```

```
>>> pidx.asfreq('M', how='S')
PeriodIndex(['2010-01', '2011-01', '2012-01', '2013-01', '2014-01',
            '2015-01'], dtype='period[M]')
```

pandas.PeriodIndex.strptime

PeriodIndex.**strptime**(*args, **kwargs)

Convert to Index using specified *date_format*.

Return an Index of formatted strings specified by *date_format*, which supports the same string format as the python standard library. Details of the string format can be found in [python string format doc](#).

Parameters

date_format [str] Date format string (e.g. "%Y-%m-%d").

Returns

ndarray NumPy ndarray of formatted strings.

See also:

to_datetime Convert the given argument to datetime.

DatetimeIndex.normalize Return DatetimeIndex with times to midnight.

DatetimeIndex.round Round the DatetimeIndex to the specified freq.

DatetimeIndex.floor Floor the DatetimeIndex to the specified freq.

Examples

```
>>> rng = pd.date_range(pd.Timestamp("2018-03-10 09:00"),
...                      periods=3, freq='s')
>>> rng.strftime('%B %d, %Y, %r')
Index(['March 10, 2018, 09:00:00 AM', 'March 10, 2018, 09:00:01 AM',
       'March 10, 2018, 09:00:02 AM'],
      dtype='object')
```

pandas.PeriodIndex.to_timestamp

PeriodIndex.to_timestamp(*freq=None, how='start'*)

Cast to DatetimeArray/Index.

Parameters

freq [str or DateOffset, optional] Target frequency. The default is 'D' for week or longer, 'S' otherwise.

how [{'s', 'e', 'start', 'end'}] Whether to use the start or end of the time period being converted.

Returns

DatetimeArray/Index

Properties

| | |
|----------------------------------|---|
| <i>PeriodIndex.day</i> | The days of the period. |
| <i>PeriodIndex.dayofweek</i> | The day of the week with Monday=0, Sunday=6. |
| <i>PeriodIndex.day_of_week</i> | The day of the week with Monday=0, Sunday=6. |
| <i>PeriodIndex.dayofyear</i> | The ordinal day of the year. |
| <i>PeriodIndex.day_of_year</i> | The ordinal day of the year. |
| <i>PeriodIndex.days_in_month</i> | The number of days in the month. |
| <i>PeriodIndex.daysinmonth</i> | The number of days in the month. |
| <i>PeriodIndex.end_time</i> | |
| <i>PeriodIndex.freq</i> | Return the frequency object if it is set, otherwise None. |
| <i>PeriodIndex.freqstr</i> | Return the frequency object as a string if its set, otherwise None. |

| | |
|---------------------------------|--|
| <i>PeriodIndex.hour</i> | The hour of the period. |
| <i>PeriodIndex.is_leap_year</i> | Logical indicating if the date belongs to a leap year. |
| <i>PeriodIndex.minute</i> | The minute of the period. |
| <i>PeriodIndex.month</i> | The month as January=1, December=12. |
| <i>PeriodIndex.quarter</i> | The quarter of the date. |
| <i>PeriodIndex.qyear</i> | |
| <i>PeriodIndex.second</i> | The second of the period. |
| <i>PeriodIndex.start_time</i> | |
| <i>PeriodIndex.week</i> | The week ordinal of the year. |
| <i>PeriodIndex.weekday</i> | The day of the week with Monday=0, Sunday=6. |
| <i>PeriodIndex.weekofyear</i> | The week ordinal of the year. |
| <i>PeriodIndex.year</i> | The year of the period. |

| <i>PeriodIndex.strftime</i> (*args, **kwargs) | Convert to Index using specified <i>date_format</i> . |
| <i>PeriodIndex.to_timestamp</i> ([freq, how]) | Cast to DatetimeArray/Index. |

3.7 Date offsets

3.7.1 DateOffset

| | |
|-------------------|--|
| <i>DateOffset</i> | Standard kind of date increment used for a date range. |
|-------------------|--|

pandas.tseries.offsets.DateOffset

class pandas.tseries.offsets.DateOffset

Standard kind of date increment used for a date range.

Works exactly like `relativedelta` in terms of the keyword args you pass in, use of the keyword `n` is discouraged—you would be better off specifying `n` in the keywords you use, but regardless it is there for you. `n` is needed for `DateOffset` subclasses.

`DateOffset` work as follows. Each offset specify a set of dates that conform to the `DateOffset`. For example, `Bday` defines this set to be the set of dates that are weekdays (M-F). To test if a date is in the set of a `DateOffset` `dateOffset` we can use the `is_on_offset` method: `dateOffset.is_on_offset(date)`.

If a date is not on a valid date, the `rollback` and `rollforward` methods can be used to roll the date to the nearest valid date before/after the date.

`DateOffsets` can be created to move dates forward a given number of valid dates. For example, `Bday(2)` can be added to a date to move it two business days forward. If the date does not start on a valid date, first it is moved to a valid date. Thus pseudo code is:

```
def __add__(date): date = rollback(date) # does nothing if date is valid return date + <n number of periods>
```

When a date offset is created for a negative number of periods, the date is first rolled forward. The pseudo code is:

```
def __add__(date): date = rollforward(date) # does nothing is date is valid return date + <n number of periods>
```

Zero presents a problem. Should it roll forward or back? We arbitrarily have it rollforward:

```
date + BDay(0) == BDay.rollforward(date)
```

Since 0 is a bit weird, we suggest avoiding its use.

Parameters

n [int, default 1] The number of time periods the offset represents.

normalize [bool, default False] Whether to round the result of a `DateOffset` addition down to the previous midnight.

****kwds** Temporal parameter that add to or replace the offset value.

Parameters that **add** to the offset (like `Timedelta`):

- years
- months
- weeks
- days
- hours
- minutes
- seconds
- microseconds
- nanoseconds

Parameters that **replace** the offset value:

- year
- month
- day
- weekday

- hour
- minute
- second
- microsecond
- nanosecond.

See also:

`dateutil.relativedelta.relativedelta` The `relativedelta` type is designed to be applied to an existing datetime and can replace specific components of that datetime, or represents an interval of time.

Examples

```
>>> from pandas.tseries.offsets import DateOffset
>>> ts = pd.Timestamp('2017-01-01 09:10:11')
>>> ts + DateOffset(months=3)
Timestamp('2017-04-01 09:10:11')
```

```
>>> ts = pd.Timestamp('2017-01-01 09:10:11')
>>> ts + DateOffset(months=2)
Timestamp('2017-03-01 09:10:11')
```

Attributes

| | |
|-------------|---|
| <i>base</i> | Returns a copy of the calling offset object with <code>n=1</code> and all other attributes equal. |
|-------------|---|

`pandas.tseries.offsets.DateOffset.base`

`DateOffset.base`

Returns a copy of the calling offset object with `n=1` and all other attributes equal.

Methods

| | |
|--|---|
| <code>__call__(*args, **kwargs)</code> | Call self as a function. |
| <code>rollback</code> | Roll provided date backward to next offset only if not on offset. |
| <code>rollforward</code> | Roll provided date forward to next offset only if not on offset. |

pandas.tseries.offsets.DateOffset.__call__

`DateOffset.__call__(*args, **kwargs)`
Call self as a function.

pandas.tseries.offsets.DateOffset.rollback

`DateOffset.rollback()`
Roll provided date backward to next offset only if not on offset.

Returns

TimeStamp Rolled timestamp if not on offset, otherwise unchanged timestamp.

pandas.tseries.offsets.DateOffset.rollforward

`DateOffset.rollforward()`
Roll provided date forward to next offset only if not on offset.

Returns

TimeStamp Rolled timestamp if not on offset, otherwise unchanged timestamp.

`BusinessDay.is_year_end()`

3.7.3 BusinessHour

BusinessHour

DateOffset subclass representing possibly n business hours.

`pandas.tseries.offsets.BusinessHour`

class `pandas.tseries.offsets.BusinessHour`

DateOffset subclass representing possibly n business hours.

Parameters

n [int, default 1] The number of months represented.

normalize [bool, default False] Normalize start/end dates to midnight before generating date range.

weekmask [str, Default 'Mon Tue Wed Thu Fri'] Weekmask of valid business days, passed to `numpy.busdaycalendar`.

start [str, default "09:00"] Start time of your custom business hour in 24h format.

end [str, default: "17:00"] End time of your custom business hour in 24h format.

Attributes

| | |
|------------------|--|
| <i>base</i> | Returns a copy of the calling offset object with n=1 and all other attributes equal. |
| <i>next_bday</i> | Used for moving to next business day. |
| <i>offset</i> | Alias for self._offset. |

pandas.tseries.offsets.BusinessHour.base

BusinessHour.base

Returns a copy of the calling offset object with n=1 and all other attributes equal.

pandas.tseries.offsets.BusinessHour.next_bday

BusinessHour.next_bday

Used for moving to next business day.

pandas.tseries.offsets.BusinessHour.offset

BusinessHour.offset

Alias for self._offset.

3.7.4 CustomBusinessDay

CustomBusinessDay

DateOffset subclass representing custom business days excluding holidays.

pandas.tseries.offsets.CustomBusinessDay

class pandas.tseries.offsets.**CustomBusinessDay**

DateOffset subclass representing custom business days excluding holidays.

Parameters

n [int, default 1]

normalize [bool, default False] Normalize start/end dates to midnight before generating date range.

weekmask [str, Default 'Mon Tue Wed Thu Fri'] Weekmask of valid business days, passed

to `numpy.busdaycalendar`.

holidays [list] List/array of dates to exclude from the set of valid business days, passed to `numpy.busdaycalendar`.

calendar [pd.HolidayCalendar or np.busdaycalendar]

offset [timedelta, default timedelta(0)]

Attributes

| | |
|---------------|--|
| <i>base</i> | Returns a copy of the calling offset object with n=1 and all other attributes equal. |
| <i>offset</i> | Alias for self._offset. |

pandas.tseries.offsets.CustomBusinessDay.base

`CustomBusinessDay.base`

Returns a copy of the calling offset object with n=1 and all other attributes equal.

pandas.tseries.offsets.CustomBusinessDay.offset

`CustomBusinessDay.offset`

Alias for self._offset.

Methods

| | |
|--|---|
| <code>__call__(*args, **kwargs)</code> | Call self as a function. |
| <code>rollback</code> | Roll provided date backward to next offset only if not on offset. |
| <code>rollforward</code> | Roll provided date forward to next offset only if not on offset. |

`pandas.tseries.offsets.CustomBusinessDay.__call__`

`CustomBusinessDay.__call__(*args, **kwargs)`
Call self as a function.

`pandas.tseries.offsets.CustomBusinessDay.rollback`

`CustomBusinessDay.rollback()`
Roll provided date backward to next offset only if not on offset.

Returns

TimeStamp Rolled timestamp if not on offset, otherwise unchanged timestamp.

`pandas.tseries.offsets.CustomBusinessDay.rollforward`

`CustomBusinessDay.rollforward()`
Roll provided date forward to next offset only if not on offset.

Returns

TimeStamp Rolled timestamp if not on offset, otherwise unchanged timestamp.

3.7.5 CustomBusinessHour

| | |
|---------------------------|---|
| <i>CustomBusinessHour</i> | DateOffset subclass representing possibly n custom business days. |
|---------------------------|---|

pandas.tseries.offsets.CustomBusinessHour

class pandas.tseries.offsets.**CustomBusinessHour**

DateOffset subclass representing possibly n custom business days.

Parameters

- n** [int, default 1] The number of months represented.
- normalize** [bool, default False] Normalize start/end dates to midnight before generating date range.
- weekmask** [str, Default 'Mon Tue Wed Thu Fri'] Weekmask of valid business days, passed to `numpy.busdaycalendar`.
- start** [str, default "09:00"] Start time of your custom business hour in 24h format.
- end** [str, default: "17:00"] End time of your custom business hour in 24h format.

Attributes

| | |
|------------------|--|
| <i>base</i> | Returns a copy of the calling offset object with n=1 and all other attributes equal. |
| <i>next_bday</i> | Used for moving to next business day. |
| <i>offset</i> | Alias for self._offset. |

pandas.tseries.offsets.CustomBusinessHour.base

CustomBusinessHour.**base**

Returns a copy of the calling offset object with n=1 and all other attributes equal.

pandas.tseries.offsets.CustomBusinessHour.next_bday

CustomBusinessHour.**next_bday**

Used for moving to next business day.

pandas.tseries.offsets.CustomBusinessHour.offset

CustomBusinessHour.**offset**

Alias for self._offset.

3.7.9 BusinessMonthBegin

BusinessMonthBegin

DateOffset of one month at the first business day.

pandas.tseries.offsets.BusinessMonthBegin

class pandas.tseries.offsets.**BusinessMonthBegin**
DateOffset of one month at the first business day.

Examples

```
>>> from pandas.tseries.offset import BMonthBegin
>>> ts=pd.Timestamp('2020-05-24 05:01:15')
>>> ts + BMonthBegin()
Timestamp('2020-06-01 05:01:15')
>>> ts + BMonthBegin(2)
Timestamp('2020-07-01 05:01:15')
>>> ts + BMonthBegin(-3)
Timestamp('2020-03-02 05:01:15')
```

Attributes

| | |
|-------------|--|
| <i>base</i> | Returns a copy of the calling offset object with n=1 and all other attributes equal. |

Methods

| | |
|-----------------------------------|---|
| <i>__call__</i> (*args, **kwargs) | Call self as a function. |
| <i>rollback</i> | Roll provided date backward to next offset only if not on offset. |
| <i>rollforward</i> | Roll provided date forward to next offset only if not on offset. |

pandas.tseries.offsets.BusinessMonthBegin.__call__

BusinessMonthBegin.__call__(*args, **kwargs)

Call self as a function.

pandas.tseries.offsets.BusinessMonthBegin.rollback

BusinessMonthBegin.rollback()

Roll provided date backward to next offset only if not on offset.

Returns

TimeStamp Rolled timestamp if not on offset, otherwise unchanged timestamp.

pandas.tseries.offsets.BusinessMonthBegin.rollforward

BusinessMonthBegin.rollforward()

Roll provided date forward to next offset only if not on offset.

Returns

TimeStamp Rolled timestamp if not on offset, otherwise unchanged timestamp.

3.7.14 Week

| | |
|-------------|----------------|
| <i>Week</i> | Weekly offset. |
|-------------|----------------|

pandas.tseries.offsets.Week

class pandas.tseries.offsets.**Week**

Weekly offset.

Parameters

weekday [int or None, default None] Always generate specific day of week. 0 for Monday.

Attributes

| | |
|-------------|--|
| <i>base</i> | Returns a copy of the calling offset object with n=1 and all other attributes equal. |
|-------------|--|

pandas.tseries.offsets.Week.base

Week.base

Returns a copy of the calling offset object with n=1 and all other attributes equal.

Methods

| | |
|--|---|
| <code>__call__(*args, **kwargs)</code> | Call self as a function. |
| <i>rollback</i> | Roll provided date backward to next offset only if not on offset. |
| <i>rollforward</i> | Roll provided date forward to next offset only if not on offset. |

pandas.tseries.offsets.Week.__call__

Week.**__call__**(*args, **kwargs)
Call self as a function.

pandas.tseries.offsets.Week.rollback

Week.**rollback**()
Roll provided date backward to next offset only if not on offset.

Returns

TimeStamp Rolled timestamp if not on offset, otherwise unchanged timestamp.

pandas.tseries.offsets.Week.rollforward**Week.rollforward()**

Roll provided date forward to next offset only if not on offset.

Returns

TimeStamp Rolled timestamp if not on offset, otherwise unchanged timestamp.

3.7.15 WeekOfMonth

WeekOfMonth

Describes monthly dates like “the Tuesday of the 2nd week of each month”.

pandas.tseries.offsets.WeekOfMonth

class pandas.tseries.offsets.**WeekOfMonth**

Describes monthly dates like “the Tuesday of the 2nd week of each month”.

Parameters

n [int]

week [int {0, 1, 2, 3, ...}, default 0] A specific integer for the week of the month. e.g. 0 is 1st week of month, 1 is the 2nd week, etc.

weekday [int {0, 1, ..., 6}, default 0] A specific integer for the day of the week.

- 0 is Monday
- 1 is Tuesday
- 2 is Wednesday
- 3 is Thursday
- 4 is Friday
- 5 is Saturday
- 6 is Sunday.

Attributes

base

Returns a copy of the calling offset object with n=1 and all other attributes equal.

pandas.tseries.offsets.WeekOfMonth.base

WeekOfMonth.base

Returns a copy of the calling offset object with n=1 and all other attributes equal.

| <code>rollforward</code> | Roll provided date forward to next offset only if not on offset. |

`pandas.tseries.offsets.WeekOfMonth.__call__`

`WeekOfMonth.__call__(*args, **kwargs)`
 Call self as a function.

`pandas.tseries.offsets.WeekOfMonth.rollback`

`WeekOfMonth.rollback()`
 Roll provided date backward to next offset only if not on offset.

Returns

TimeStamp Rolled timestamp if not on offset, otherwise unchanged timestamp.

`pandas.tseries.offsets.WeekOfMonth.rollforward`

`WeekOfMonth.rollforward()`
 Roll provided date forward to next offset only if not on offset.

Returns

TimeStamp Rolled timestamp if not on offset, otherwise unchanged timestamp.

3.7.16 LastWeekOfMonth

LastWeekOfMonth

Describes monthly dates in last week of month like “the last Tuesday of each month”.

pandas.tseries.offsets.LastWeekOfMonth

class `pandas.tseries.offsets.LastWeekOfMonth`

Describes monthly dates in last week of month like “the last Tuesday of each month”.

Parameters

n [int, default 1]

weekday [int {0, 1, ..., 6}, default 0] A specific integer for the day of the week.

- 0 is Monday
- 1 is Tuesday

- 2 is Wednesday
- 3 is Thursday
- 4 is Friday
- 5 is Saturday
- 6 is Sunday.

Attributes

| | |
|-------------|--|
| <i>base</i> | Returns a copy of the calling offset object with n=1 and all other attributes equal. |
|-------------|--|

pandas.tseries.offsets.LastWeekOfMonth.base

3.7.17 BQuarterEnd

BQuarterEnd

DateOffset increments between the last business day of each Quarter.

`pandas.tseries.offsets.BQuarterEnd`

class `pandas.tseries.offsets.BQuarterEnd`

DateOffset increments between the last business day of each Quarter.

startingMonth = 1 corresponds to dates like 1/31/2007, 4/30/2007, ... startingMonth = 2 corresponds to dates like 2/28/2007, 5/31/2007, ... startingMonth = 3 corresponds to dates like 3/30/2007, 6/29/2007, ...

Examples

```
>>> from pandas.tseries.offset import BQuarterEnd
>>> ts = pd.Timestamp('2020-05-24 05:01:15')
>>> ts + BQuarterEnd()
Timestamp('2020-06-30 05:01:15')
>>> ts + BQuarterEnd(2)
Timestamp('2020-09-30 05:01:15')
>>> ts + BQuarterEnd(1, startingMonth=2)
Timestamp('2020-05-29 05:01:15')
>>> ts + BQuarterEnd(startingMonth=2)
Timestamp('2020-05-29 05:01:15')
```

3.7.25 FY5253

FY5253

Describes 52-53 week fiscal year.

pandas.tseries.offsets.FY5253

class pandas.tseries.offsets.FY5253

Describes 52-53 week fiscal year. This is also known as a 4-4-5 calendar.

It is used by companies that desire that their fiscal year always end on the same day of the week.

It is a method of managing accounting periods. It is a common calendar structure for some industries, such as retail, manufacturing and parking industry.

For more information see: https://en.wikipedia.org/wiki/4-4-5_calendar

The year may either:

- end on the last X day of the Y month.
- end on the last X day closest to the last day of the Y month.

X is a specific day of the week. Y is a certain month of the year

Parameters

n [int]

weekday [int {0, 1, ..., 6}, default 0] A specific integer for the day of the week.

- 0 is Monday
- 1 is Tuesday
- 2 is Wednesday
- 3 is Thursday
- 4 is Friday
- 5 is Saturday
- 6 is Sunday.

startingMonth [int {1, 2, ... 12}, default 1] The month in which the fiscal year ends.

variation [str, default “nearest”] Method of employing 4-4-5 calendar.

There are two options:

- “nearest” means year end is **weekday** closest to last day of month in year.
- “last” means year end is final **weekday** of the final month in fiscal year.

Attributes

| | |
|-------------|--|

3.7.26 FY5253Quarter

FY5253Quarter

DateOffset increments between business quarter dates for 52-53 week fiscal year (also known as a 4-4-5 calendar).

pandas.tseries.offsets.FY5253Quarter

class pandas.tseries.offsets.FY5253Quarter

DateOffset increments between business quarter dates for 52-53 week fiscal year (also known as a 4-4-5 calendar).

It is used by companies that desire that their fiscal year always end on the same day of the week.

It is a method of managing accounting periods. It is a common calendar structure for some industries, such as retail, manufacturing and parking industry.

For more information see: https://en.wikipedia.org/wiki/4-4-5_calendar

The year may either:

- end on the last X day of the Y month.
- end on the last X day closest to the last day of the Y month.

X is a specific day of the week. Y is a certain month of the year

startingMonth = 1 corresponds to dates like 1/31/2007, 4/30/2007, ... startingMonth = 2 corresponds to dates like 2/28/2007, 5/31/2007, ... startingMonth = 3 corresponds to dates like 3/30/2007, 6/29/2007, ...

Parameters

n [int]

weekday [int {0, 1, ..., 6}, default 0] A specific integer for the day of the week.

- 0 is Monday
- 1 is Tuesday
- 2 is Wednesday
- 3 is Thursday
- 4 is Friday
- 5 is Saturday
- 6 is Sunday.

startingMonth [int {1, 2, ..., 12}, default 1] The month in which fiscal years end.

qtr_with_extra_week [int {1, 2, 3, 4}, default 1] The quarter number that has the leap or 14 week when needed.

variation [str, default “nearest”] Method of employing 4-4-5 calendar.

There are two options:

- “nearest” means year end is **weekday** closest to last day of month in year.
- “last” means year end is final **weekday** of the final month in fiscal year.

Attributes

3.8 Frequencies

to_offset

Return DateOffset object from string or tuple representation or datetime.timedelta object.

3.8.1 `pandas.tseries.frequencies.to_offset`

`pandas.tseries.frequencies.to_offset()`

Return DateOffset object from string or tuple representation or datetime.timedelta object.

Parameters

freq [str, tuple, datetime.timedelta, DateOffset or None]

Returns

DateOffset or None

Raises

ValueError If freq is an invalid frequency

See also:

DateOffset Standard kind of date increment used for a date range.

Examples

```
>>> to_offset("5min")
<5 * Minutes>
```

```
>>> to_offset("1D1H")
<25 * Hours>
```

```
>>> to_offset("2W")
<2 * Weeks: weekday=6>
```

```
>>> to_offset("2B")
<2 * BusinessDays>
```

```
>>> to_offset(pd.Timedelta(days=1))
<Day>
```

```
>>> to_offset(Hour())
<Hour>
```

3.9 Window

Rolling objects are returned by `.rolling` calls: `pandas.DataFrame.rolling()`, `pandas.Series.rolling()`, etc. Expanding objects are returned by `.expanding` calls: `pandas.DataFrame.expanding()`, `pandas.Series.expanding()`, etc. ExponentialMovingWindow objects are returned by `.ewm` calls: `pandas.DataFrame.ewm()`, `pandas.Series.ewm()`, etc.

3.9.1 Rolling window functions

| | |
|---|---|
| <code>Rolling.count()</code> | Calculate the rolling count of non NaN observations. |
| <code>Rolling.sum(*args[, engine, engine_kwargs])</code> | Calculate the rolling sum. |
| <code>Rolling.mean(*args[, engine, engine_kwargs])</code> | Calculate the rolling mean. |
| <code>Rolling.median([engine, engine_kwargs])</code> | Calculate the rolling median. |
| <code>Rolling.var([ddof])</code> | Calculate the rolling variance. |
| <code>Rolling.std([ddof])</code> | Calculate the rolling standard deviation. |
| <code>Rolling.min(*args[, engine, engine_kwargs])</code> | Calculate the rolling minimum. |
| <code>Rolling.max(*args[, engine, engine_kwargs])</code> | Calculate the rolling maximum. |
| <code>Rolling.corr([other, pairwise, ddof])</code> | Calculate the rolling correlation. |
| <code>Rolling.cov([other, pairwise, ddof])</code> | Calculate the rolling sample covariance. |
| <code>Rolling.skew(**kwargs)</code> | Calculate the rolling unbiased skewness. |
| <code>Rolling.kurt(**kwargs)</code> | Calculate the rolling Fisher's definition of kurtosis without bias. |
| <code>Rolling.apply(func[, raw, engine, ...])</code> | Calculate the rolling custom aggregation function. |
| <code>Rolling.aggregate(func, *args, **kwargs)</code> | Aggregate using one or more operations over the specified axis. |
| <code>Rolling.quantile(quantile[, interpolation])</code> | Calculate the rolling quantile. |
| <code>Rolling.sem([ddof])</code> | Calculate the rolling standard error of mean. |

pandas.core.window.rolling.Rolling.count

Rolling.count()

Calculate the rolling count of non NaN observations.

Returns

Series or DataFrame Return type is the same as the original object.

See also:

[*pandas.Series.rolling*](#) Calling rolling with Series data.

[*pandas.DataFrame.rolling*](#) Calling rolling with DataFrames.

[*pandas.Series.count*](#) Aggregating count for Series.

[*pandas.DataFrame.count*](#) Aggregating count for DataFrame.

Examples

```

>>> s = pd.Series([2, 3, np.nan, 10])
>>> s.rolling(2).count()
0    1.0
1    2.0
2    1.0
3    1.0
dtype: float64
>>> s.rolling(3).count()
0    1.0
1    2.0
2    2.0
3    2.0
dtype: float64
>>> s.rolling(4).count()
0    1.0
1    2.0
2    2.0
3    3.0
dtype: float64

```

pandas.core.window.rolling.Rolling.sum

Rolling.sum(*args, engine=None, engine_kwargs=None, **kwargs)

Calculate the rolling sum.

Parameters

***args** For NumPy compatibility and will not have an effect on the result.

engine [str, default None]

- 'cython' : Runs the operation through C-extensions from cython.
- 'numba' : Runs the operation through JIT compiled code from numba.
- None : Defaults to 'cython' or globally setting `compute.use_numba`

New in version 1.3.0.

engine_kwargs [dict, default None]

- For 'cython' engine, there are no accepted engine_kwargs

- For 'numba' engine, the engine can accept `nopython`, `nogil` and `parallel` dictionary keys. The values must either be `True` or `False`. The default `engine_kwargs` for the 'numba' engine is `{'nopython': True, 'nogil': False, 'parallel': False}`

New in version 1.3.0.

****kwargs** For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame Return type is the same as the original object.

See also:

[*pandas.Series.rolling*](#) Calling rolling with Series data.

[*pandas.DataFrame.rolling*](#) Calling rolling with DataFrames.

[*pandas.Series.sum*](#) Aggregating sum for Series.

[*pandas.DataFrame.sum*](#) Aggregating sum for DataFrame.

Notes

See [Numba engine](#) and [Numba \(JIT compilation\)](#) for extended documentation and performance considerations for the Numba engine.

Examples

```
>>> s = pd.Series([1, 2, 3, 4, 5])
>>> s
0    1
1    2
2    3
3    4
4    5
dtype: int64
```

```
>>> s.rolling(3).sum()
0    NaN
1    NaN
2    6.0
3    9.0
4   12.0
dtype: float64
```

```
>>> s.rolling(3, center=True).sum()
0    NaN
1    6.0
2    9.0
3   12.0
4    NaN
dtype: float64
```

For DataFrame, each sum is computed column-wise.

```
>>> df = pd.DataFrame({"A": s, "B": s ** 2})
>>> df
   A  B
0  1  1
1  2  4
2  3  9
3  4 16
4  5 25
```

```
>>> df.rolling(3).sum()
   A    B
0 NaN NaN
1 NaN NaN
2 6.0 14.0
3 9.0 29.0
4 12.0 50.0
```

pandas.core.window.rolling.Rolling.mean

`Rolling.mean(*args, engine=None, engine_kwargs=None, **kwargs)`

Calculate the rolling mean.

Parameters

***args** For NumPy compatibility and will not have an effect on the result.

engine [str, default None]

- 'cython' : Runs the operation through C-extensions from cython.
- 'numba' : Runs the operation through JIT compiled code from numba.
- None : Defaults to 'cython' or globally setting `compute.use_numba`

New in version 1.3.0.

engine_kwargs [dict, default None]

- For 'cython' engine, there are no accepted `engine_kwargs`
- For 'numba' engine, the engine can accept `nopython`, `nogil` and `parallel` dictionary keys. The values must either be True or False. The default `engine_kwargs` for the 'numba' engine is `{'nopython': True, 'nogil': False, 'parallel': False}`

New in version 1.3.0.

****kwargs** For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame Return type is the same as the original object.

See also:

[`pandas.Series.rolling`](#) Calling rolling with Series data.

[`pandas.DataFrame.rolling`](#) Calling rolling with DataFrames.

[`pandas.Series.mean`](#) Aggregating mean for Series.

[`pandas.DataFrame.mean`](#) Aggregating mean for DataFrame.

Notes

See *Numba engine* and *Numba (JIT compilation)* for extended documentation and performance considerations for the Numba engine.

Examples

The below examples will show rolling mean calculations with window sizes of two and three, respectively.

```
>>> s = pd.Series([1, 2, 3, 4])
>>> s.rolling(2).mean()
0    NaN
1    1.5
2    2.5
3    3.5
dtype: float64
```

```
>>> s.rolling(3).mean()
0    NaN
1    NaN
2    2.0
3    3.0
dtype: float64
```

pandas.core.window.rolling.Rolling.median

Rolling.**median**(*engine=None, engine_kwargs=None, **kwargs*)

Calculate the rolling median.

Parameters

engine [str, default None]

- 'cython' : Runs the operation through C-extensions from cython.
- 'numba' : Runs the operation through JIT compiled code from numba.
- None : Defaults to 'cython' or globally setting `compute.use_numba`

New in version 1.3.0.

engine_kwargs [dict, default None]

- For 'cython' engine, there are no accepted `engine_kwargs`
- For 'numba' engine, the engine can accept `nopython`, `nogil` and `parallel` dictionary keys. The values must either be `True` or `False`. The default `engine_kwargs` for the 'numba' engine is `{'nopython': True, 'nogil': False, 'parallel': False}`

New in version 1.3.0.

****kwargs** For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame Return type is the same as the original object.

See also:

`pandas.Series.rolling` Calling rolling with Series data.
`pandas.DataFrame.rolling` Calling rolling with DataFrames.
`pandas.Series.median` Aggregating median for Series.
`pandas.DataFrame.median` Aggregating median for DataFrame.

Notes

See *Numba engine* and *Numba (JIT compilation)* for extended documentation and performance considerations for the Numba engine.

Examples

Compute the rolling median of a series with a window size of 3.

```
>>> s = pd.Series([0, 1, 2, 3, 4])
>>> s.rolling(3).median()
0    NaN
1    NaN
2    1.0
3    2.0
4    3.0
dtype: float64
```

`pandas.core.window.rolling.Rolling.var`

`Rolling.var(ddof=1, *args, **kwargs)`

Calculate the rolling variance.

Parameters

ddof [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is $N - \text{ddof}$, where N represents the number of elements.

***args** For NumPy compatibility and will not have an effect on the result.

****kwargs** For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame Return type is the same as the original object.

See also:

`numpy.var` Equivalent method for NumPy array.

`pandas.Series.rolling` Calling rolling with Series data.

`pandas.DataFrame.rolling` Calling rolling with DataFrames.

`pandas.Series.var` Aggregating var for Series.

`pandas.DataFrame.var` Aggregating var for DataFrame.

Notes

The default `ddof` of 1 used in `Series.var()` is different than the default `ddof` of 0 in `numpy.var()`.

A minimum of one period is required for the rolling calculation.

The implementation is susceptible to floating point imprecision as shown in the example below.

Examples

```
>>> s = pd.Series([5, 5, 6, 7, 5, 5, 5])
>>> s.rolling(3).var()
0          NaN
1          NaN
2    3.333333e-01
3    1.000000e+00
4    1.000000e+00
5    1.333333e+00
6    6.661338e-16
dtype: float64
```

`pandas.core.window.rolling.Rolling.std`

`Rolling.std(ddof=1, *args, **kwargs)`

Calculate the rolling standard deviation.

Parameters

ddof [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is $N - \text{ddof}$, where N represents the number of elements.

***args** For NumPy compatibility and will not have an effect on the result.

****kwargs** For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame Return type is the same as the original object.

See also:

[`numpy.std`](#) Equivalent method for NumPy array.

[`pandas.Series.rolling`](#) Calling rolling with Series data.

[`pandas.DataFrame.rolling`](#) Calling rolling with DataFrames.

[`pandas.Series.std`](#) Aggregating std for Series.

[`pandas.DataFrame.std`](#) Aggregating std for DataFrame.

Notes

The default `ddof` of 1 used in `Series.std()` is different than the default `ddof` of 0 in `numpy.std()`.

A minimum of one period is required for the rolling calculation.

The implementation is susceptible to floating point imprecision as shown in the example below.

Examples

```
>>> s = pd.Series([5, 5, 6, 7, 5, 5, 5])
>>> s.rolling(3).std()
0          NaN
1          NaN
2    5.773503e-01
3    1.000000e+00
4    1.000000e+00
5    1.154701e+00
6    2.580957e-08
dtype: float64
```

pandas.core.window.rolling.Rolling.min

`Rolling.min(*args, engine=None, engine_kwargs=None, **kwargs)`

Calculate the rolling minimum.

Parameters

***args** For NumPy compatibility and will not have an effect on the result.

engine [str, default None]

- 'cython' : Runs the operation through C-extensions from cython.
- 'numba' : Runs the operation through JIT compiled code from numba.
- None : Defaults to 'cython' or globally setting `compute.use_numba`

New in version 1.3.0.

engine_kwargs [dict, default None]

- For 'cython' engine, there are no accepted `engine_kwargs`
- For 'numba' engine, the engine can accept `nopython`, `nogil` and `parallel` dictionary keys. The values must either be `True` or `False`. The default `engine_kwargs` for the 'numba' engine is `{'nopython': True, 'nogil': False, 'parallel': False}`

New in version 1.3.0.

****kwargs** For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame Return type is the same as the original object.

See also:

[`pandas.Series.rolling`](#) Calling rolling with Series data.

[`pandas.DataFrame.rolling`](#) Calling rolling with DataFrames.

[`pandas.Series.min`](#) Aggregating min for Series.

[`pandas.DataFrame.min`](#) Aggregating min for DataFrame.

Notes

See *Numba engine* and *Numba (JIT compilation)* for extended documentation and performance considerations for the Numba engine.

Examples

Performing a rolling minimum with a window size of 3.

```
>>> s = pd.Series([4, 3, 5, 2, 6])
>>> s.rolling(3).min()
0    NaN
1    NaN
2    3.0
3    2.0
4    2.0
dtype: float64
```

pandas.core.window.rolling.Rolling.max

`Rolling.max(*args, engine=None, engine_kwargs=None, **kwargs)`

Calculate the rolling maximum.

Parameters

***args** For NumPy compatibility and will not have an effect on the result.

engine [str, default None]

- 'cython' : Runs the operation through C-extensions from cython.
- 'numba' : Runs the operation through JIT compiled code from numba.
- None : Defaults to 'cython' or globally setting `compute.use_numba`

New in version 1.3.0.

engine_kwargs [dict, default None]

- For 'cython' engine, there are no accepted `engine_kwargs`
- For 'numba' engine, the engine can accept `nopython`, `nogil` and `parallel` dictionary keys. The values must either be `True` or `False`. The default `engine_kwargs` for the 'numba' engine is `{'nopython': True, 'nogil': False, 'parallel': False}`

New in version 1.3.0.

****kwargs** For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame Return type is the same as the original object.

See also:

[*pandas.Series.rolling*](#) Calling rolling with Series data.

[*pandas.DataFrame.rolling*](#) Calling rolling with DataFrames.

[*pandas.Series.max*](#) Aggregating max for Series.

[*pandas.DataFrame.max*](#) Aggregating max for DataFrame.

Notes

See *Numba engine* and *Numba (JIT compilation)* for extended documentation and performance considerations for the Numba engine.

pandas.core.window.rolling.Rolling.corr

`Rolling.corr` (*other=None, pairwise=None, ddof=1, **kwargs*)

Calculate the rolling correlation.

Parameters

other [Series or DataFrame, optional] If not supplied then will default to self and produce pairwise output.

pairwise [bool, default None] If False then only matching columns between self and other will be used and the output will be a DataFrame. If True then all pairwise combinations will be calculated and the output will be a MultiIndexed DataFrame in the case of DataFrame inputs. In the case of missing elements, only complete pairwise observations will be used.

ddof [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is $N - \text{ddof}$, where N represents the number of elements.

****kwargs** For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame Return type is the same as the original object.

See also:

`cov` Similar method to calculate covariance.

`numpy.corrcoef` NumPy Pearson's correlation calculation.

`pandas.Series.rolling` Calling rolling with Series data.

`pandas.DataFrame.rolling` Calling rolling with DataFrames.

`pandas.Series.corr` Aggregating corr for Series.

`pandas.DataFrame.corr` Aggregating corr for DataFrame.

Notes

This function uses Pearson's definition of correlation (https://en.wikipedia.org/wiki/Pearson_correlation_coefficient).

When *other* is not specified, the output will be self correlation (e.g. all 1's), except for *DataFrame* inputs with *pairwise* set to *True*.

Function will return NaN for correlations of equal valued sequences; this is the result of a 0/0 division error.

When *pairwise* is set to *False*, only matching columns between *self* and *other* will be used.

When *pairwise* is set to *True*, the output will be a MultiIndex DataFrame with the original index on the first level, and the *other* DataFrame columns on the second level.

In the case of missing elements, only complete pairwise observations will be used.

Examples

The below example shows a rolling calculation with a window size of four matching the equivalent function call using `numpy.corrcoef()`.

```
>>> v1 = [3, 3, 3, 5, 8]
>>> v2 = [3, 4, 4, 4, 8]
>>> # numpy returns a 2X2 array, the correlation coefficient
>>> # is the number at entry [0][1]
>>> print(f"{np.corrcoef(v1[:-1], v2[:-1])[0][1]:.6f}")
0.333333
>>> print(f"{np.corrcoef(v1[1:], v2[1:])[0][1]:.6f}")
0.916949
>>> s1 = pd.Series(v1)
>>> s2 = pd.Series(v2)
>>> s1.rolling(4).corr(s2)
0      NaN
1      NaN
2      NaN
3    0.333333
4    0.916949
dtype: float64
```

The below example shows a similar rolling calculation on a DataFrame using the pairwise option.

```
>>> matrix = np.array([[51., 35.], [49., 30.], [47., 32.], [46., 31.], [50., 36.]])
>>> print(np.corrcoef(matrix[:-1,0], matrix[:-1,1]).round(7))
[[1.         0.6263001]
 [0.6263001  1.         ]]
>>> print(np.corrcoef(matrix[1:,0], matrix[1:,1]).round(7))
[[1.         0.5553681]
 [0.5553681  1.         ]]
>>> df = pd.DataFrame(matrix, columns=['X', 'Y'])
>>> df
   X    Y
0 51.0 35.0
1 49.0 30.0
2 47.0 32.0
3 46.0 31.0
4 50.0 36.0
>>> df.rolling(4).corr(pairwise=True)
   X      X      Y
0 X      NaN      NaN
  Y      NaN      NaN
1 X      NaN      NaN
  Y      NaN      NaN
2 X      NaN      NaN
  Y      NaN      NaN
3 X  1.000000  0.626300
  Y  0.626300  1.000000
4 X  1.000000  0.555368
  Y  0.555368  1.000000
```

pandas.core.window.rolling.Rolling.cov

`Rolling.cov`(*other=None, pairwise=None, ddof=1, **kwargs*)

Calculate the rolling sample covariance.

Parameters

other [Series or DataFrame, optional] If not supplied then will default to self and produce pairwise output.

pairwise [bool, default None] If False then only matching columns between self and other will be used and the output will be a DataFrame. If True then all pairwise combinations will be calculated and the output will be a MultiIndexed DataFrame in the case of DataFrame inputs. In the case of missing elements, only complete pairwise observations will be used.

ddof [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is $N - \text{ddof}$, where N represents the number of elements.

****kwargs** For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame Return type is the same as the original object.

See also:

[`pandas.Series.rolling`](#) Calling rolling with Series data.

[`pandas.DataFrame.rolling`](#) Calling rolling with DataFrames.

[`pandas.Series.cov`](#) Aggregating cov for Series.

[`pandas.DataFrame.cov`](#) Aggregating cov for DataFrame.

pandas.core.window.rolling.Rolling.skew

`Rolling.skew`(***kwargs*)

Calculate the rolling unbiased skewness.

Parameters

****kwargs** For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame Return type is the same as the original object.

See also:

[`scipy.stats.skew`](#) Third moment of a probability density.

[`pandas.Series.rolling`](#) Calling rolling with Series data.

[`pandas.DataFrame.rolling`](#) Calling rolling with DataFrames.

[`pandas.Series.skew`](#) Aggregating skew for Series.

[`pandas.DataFrame.skew`](#) Aggregating skew for DataFrame.

Notes

A minimum of three periods is required for the rolling calculation.

pandas.core.window.rolling.Rolling.kurt

Rolling.**kurt**(**kwargs)

Calculate the rolling Fisher's definition of kurtosis without bias.

Parameters

****kwargs** For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame Return type is the same as the original object.

See also:

[scipy.stats.kurtosis](#) Reference SciPy method.

[pandas.Series.rolling](#) Calling rolling with Series data.

[pandas.DataFrame.rolling](#) Calling rolling with DataFrames.

[pandas.Series.kurt](#) Aggregating kurt for Series.

[pandas.DataFrame.kurt](#) Aggregating kurt for DataFrame.

Notes

A minimum of four periods is required for the calculation.

Examples

The example below will show a rolling calculation with a window size of four matching the equivalent function call using *scipy.stats*.

```
>>> arr = [1, 2, 3, 4, 999]
>>> import scipy.stats
>>> print(f"{scipy.stats.kurtosis(arr[:-1], bias=False):.6f}")
-1.200000
>>> print(f"{scipy.stats.kurtosis(arr[1:], bias=False):.6f}")
3.999946
>>> s = pd.Series(arr)
>>> s.rolling(4).kurt()
0      NaN
1      NaN
2      NaN
3    -1.200000
4     3.999946
dtype: float64
```

pandas.core.window.rolling.Rolling.apply

Rolling.apply(*func*, *raw=False*, *engine=None*, *engine_kwargs=None*, *args=None*, *kwargs=None*)

Calculate the rolling custom aggregation function.

Parameters

func [function] Must produce a single value from an ndarray input if *raw=True* or a single value from a Series if *raw=False*. Can also accept a Numba JIT function with *engine='numba'* specified.

Changed in version 1.0.0.

raw [bool, default None]

- *False* : passes each row or column as a Series to the function.
- *True* : the passed function will receive ndarray objects instead. If you are just applying a NumPy reduction function this will achieve much better performance.

engine [str, default None]

- *'cython'* : Runs rolling apply through C-extensions from cython.
- *'numba'* : Runs rolling apply through JIT compiled code from numba. Only available when *raw* is set to *True*.
- *None* : Defaults to *'cython'* or globally setting `compute.use_numba`

New in version 1.0.0.

engine_kwargs [dict, default None]

- For *'cython'* engine, there are no accepted *engine_kwargs*
- For *'numba'* engine, the engine can accept *nopython*, *nogil* and *parallel* dictionary keys. The values must either be *True* or *False*. The default *engine_kwargs* for the *'numba'* engine is `{'nopython': True, 'nogil': False, 'parallel': False}` and will be applied to both the *func* and the *apply* rolling aggregation.

New in version 1.0.0.

args [tuple, default None] Positional arguments to be passed into *func*.

kwargs [dict, default None] Keyword arguments to be passed into *func*.

Returns

Series or DataFrame Return type is the same as the original object.

See also:

[*pandas.Series.rolling*](#) Calling rolling with Series data.

[*pandas.DataFrame.rolling*](#) Calling rolling with DataFrames.

[*pandas.Series.apply*](#) Aggregating apply for Series.

[*pandas.DataFrame.apply*](#) Aggregating apply for DataFrame.

pandas.core.window.rolling.Rolling.aggregate

Rolling.**aggregate**(*func*, **args*, ***kwargs*)

Aggregate using one or more operations over the specified axis.

Parameters

func [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a Series/Dataframe or when passed to Series/Dataframe.apply.

Accepted combinations are:

- function
- string function name
- list of functions and/or function names, e.g. [`np.sum`, 'mean']
- dict of axis labels -> functions, function names or list of such.

***args** Positional arguments to pass to *func*.

****kwargs** Keyword arguments to pass to *func*.

Returns

scalar, Series or DataFrame The return can be:

- scalar : when Series.agg is called with single function
- Series : when DataFrame.agg is called with a single function
- DataFrame : when DataFrame.agg is called with several functions

Return scalar, Series or DataFrame.

See also:

[*pandas.Series.rolling*](#) Calling object with Series data.

[*pandas.DataFrame.rolling*](#) Calling object with DataFrame data.

Notes

agg is an alias for *aggregate*. Use the alias.

Functions that mutate the passed object can produce unexpected behavior or errors and are not supported. See [*Mutating with User Defined Function \(UDF\) methods*](#) for more details.

A passed user-defined-function will be passed a Series for evaluation.

Examples

```
>>> df = pd.DataFrame({"A": [1, 2, 3], "B": [4, 5, 6], "C": [7, 8, 9]})
>>> df
   A  B  C
0  1  4  7
1  2  5  8
2  3  6  9
```

```
>>> df.rolling(2).sum()
      A      B      C
0  NaN  NaN  NaN
1  3.0  9.0  15.0
2  5.0  11.0  17.0
```

```
>>> df.rolling(2).agg({"A": "sum", "B": "min"})
      A      B
0  NaN  NaN
1  3.0  4.0
2  5.0  5.0
```

pandas.core.window.rolling.Rolling.quantile

Rolling.**quantile**(*quantile*, *interpolation='linear'*, ***kwargs*)

Calculate the rolling quantile.

Parameters

quantile [float] Quantile to compute. $0 \leq \text{quantile} \leq 1$.

interpolation [{"linear", "lower", "higher", "midpoint", "nearest"}] This optional parameter specifies the interpolation method to use, when the desired quantile lies between two data points *i* and *j*:

- linear: $i + (j - i) * \text{fraction}$, where *fraction* is the fractional part of the index surrounded by *i* and *j*.
- lower: *i*.
- higher: *j*.
- nearest: *i* or *j* whichever is nearest.
- midpoint: $(i + j) / 2$.

****kwargs** For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame Return type is the same as the original object.

See also:

[*pandas.Series.rolling*](#) Calling rolling with Series data.

[*pandas.DataFrame.rolling*](#) Calling rolling with DataFrames.

[*pandas.Series.quantile*](#) Aggregating quantile for Series.

[*pandas.DataFrame.quantile*](#) Aggregating quantile for DataFrame.

Examples

```
>>> s = pd.Series([1, 2, 3, 4])
>>> s.rolling(2).quantile(.4, interpolation='lower')
0    NaN
1    1.0
2    2.0
3    3.0
dtype: float64
```

```
>>> s.rolling(2).quantile(.4, interpolation='midpoint')
0    NaN
1    1.5
2    2.5
3    3.5
dtype: float64
```

pandas.core.window.rolling.Rolling.sem

Rolling.**sem**(*ddof=1, *args, **kwargs*)

Calculate the rolling standard error of mean.

Parameters

ddof [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is $N - \text{ddof}$, where N represents the number of elements.

***args** For NumPy compatibility and will not have an effect on the result.

****kwargs** For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame Return type is the same as the original object.

See also:

[*pandas.Series.rolling*](#) Calling rolling with Series data.

[*pandas.DataFrame.rolling*](#) Calling rolling with DataFrames.

[*pandas.Series.sem*](#) Aggregating sem for Series.

[*pandas.DataFrame.sem*](#) Aggregating sem for DataFrame.

Notes

A minimum of one period is required for the calculation.

Examples

```
>>> s = pd.Series([0, 1, 2, 3])
>>> s.rolling(2, min_periods=1).sem()
0          NaN
1    0.707107
2    0.707107
3    0.707107
dtype: float64
```

3.9.2 Weighted window functions

| | |
|---|---|
| <code>Window.mean(*args, **kwargs)</code> | Calculate the rolling weighted window mean. |
| <code>Window.sum(*args, **kwargs)</code> | Calculate the rolling weighted window sum. |
| <code>Window.var([ddof])</code> | Calculate the rolling weighted window variance. |
| <code>Window.std([ddof])</code> | Calculate the rolling weighted window standard deviation. |

pandas.core.window.rolling.Window.mean

`Window.mean(*args, **kwargs)`

Calculate the rolling weighted window mean.

Parameters

****kwargs** Keyword arguments to configure the SciPy weighted window type.

Returns

Series or DataFrame Return type is the same as the original object.

See also:

[`pandas.Series.rolling`](#) Calling rolling with Series data.

[`pandas.DataFrame.rolling`](#) Calling rolling with DataFrames.

[`pandas.Series.mean`](#) Aggregating mean for Series.

[`pandas.DataFrame.mean`](#) Aggregating mean for DataFrame.

pandas.core.window.rolling.Window.sum

`Window.sum(*args, **kwargs)`

Calculate the rolling weighted window sum.

Parameters

****kwargs** Keyword arguments to configure the SciPy weighted window type.

Returns

Series or DataFrame Return type is the same as the original object.

See also:

[`pandas.Series.rolling`](#) Calling rolling with Series data.

[`pandas.DataFrame.rolling`](#) Calling rolling with DataFrames.

[`pandas.Series.sum`](#) Aggregating sum for Series.

[`pandas.DataFrame.sum`](#) Aggregating sum for DataFrame.

pandas.core.window.rolling.Window.var

`Window.var(ddof=1, *args, **kwargs)`

Calculate the rolling weighted window variance.

New in version 1.0.0.

Parameters

****kwargs** Keyword arguments to configure the SciPy weighted window type.

Returns

Series or DataFrame Return type is the same as the original object.

See also:

[*pandas.Series.rolling*](#) Calling rolling with Series data.

[*pandas.DataFrame.rolling*](#) Calling rolling with DataFrames.

[*pandas.Series.var*](#) Aggregating var for Series.

[*pandas.DataFrame.var*](#) Aggregating var for DataFrame.

pandas.core.window.rolling.Window.std

`Window.std(ddof=1, *args, **kwargs)`

Calculate the rolling weighted window standard deviation.

New in version 1.0.0.

Parameters

****kwargs** Keyword arguments to configure the SciPy weighted window type.

Returns

Series or DataFrame Return type is the same as the original object.

See also:

[*pandas.Series.rolling*](#) Calling rolling with Series data.

[*pandas.DataFrame.rolling*](#) Calling rolling with DataFrames.

[*pandas.Series.std*](#) Aggregating std for Series.

[*pandas.DataFrame.std*](#) Aggregating std for DataFrame.

3.9.3 Expanding window functions

| | |
|---|---|
| <code>Expanding.count()</code> | Calculate the expanding count of non NaN observations. |
| <code>Expanding.sum(*args[, engine, engine_kwargs])</code> | Calculate the expanding sum. |
| <code>Expanding.mean(*args[, engine, engine_kwargs])</code> | Calculate the expanding mean. |
| <code>Expanding.median([engine, engine_kwargs])</code> | Calculate the expanding median. |
| <code>Expanding.var([ddof])</code> | Calculate the expanding variance. |
| <code>Expanding.std([ddof])</code> | Calculate the expanding standard deviation. |
| <code>Expanding.min(*args[, engine, engine_kwargs])</code> | Calculate the expanding minimum. |
| <code>Expanding.max(*args[, engine, engine_kwargs])</code> | Calculate the expanding maximum. |
| <code>Expanding.corr([other, pairwise, ddof])</code> | Calculate the expanding correlation. |
| <code>Expanding.cov([other, pairwise, ddof])</code> | Calculate the expanding sample covariance. |
| <code>Expanding.skew(**kwargs)</code> | Calculate the expanding unbiased skewness. |
| <code>Expanding.kurt(**kwargs)</code> | Calculate the expanding Fisher's definition of kurtosis without bias. |

continues on next page

Table 371 – continued from previous page

| | |
|--|---|
| <code>Expanding.apply(func[, raw, engine, ...])</code> | Calculate the expanding custom aggregation function. |
| <code>Expanding.aggregate(func, *args, **kwargs)</code> | Aggregate using one or more operations over the specified axis. |
| <code>Expanding.quantile(quantile[, interpolation])</code> | Calculate the expanding quantile. |
| <code>Expanding.sem([ddof])</code> | Calculate the expanding standard error of mean. |

pandas.core.window.expanding.Expanding.count

`Expanding.count()`

Calculate the expanding count of non NaN observations.

Returns

Series or DataFrame Return type is the same as the original object.

See also:

`pandas.Series.expanding` Calling expanding with Series data.

`pandas.DataFrame.expanding` Calling expanding with DataFrames.

`pandas.Series.count` Aggregating count for Series.

`pandas.DataFrame.count` Aggregating count for DataFrame.

pandas.core.window.expanding.Expanding.sum

`Expanding.sum(*args, engine=None, engine_kwargs=None, **kwargs)`

Calculate the expanding sum.

Parameters

***args** For NumPy compatibility and will not have an effect on the result.

engine [str, default None]

- 'cython' : Runs the operation through C-extensions from cython.
 - 'numba' : Runs the operation through JIT compiled code from numba.
 - None : Defaults to 'cython' or globally setting `compute.use_numba`
- New in version 1.3.0.

engine_kwargs [dict, default None]

- For 'cython' engine, there are no accepted `engine_kwargs`
 - For 'numba' engine, the engine can accept `nopython`, `nogil` and `parallel` dictionary keys. The values must either be `True` or `False`. The default `engine_kwargs` for the 'numba' engine is `{'nopython': True, 'nogil': False, 'parallel': False}`
- New in version 1.3.0.

****kwargs** For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame Return type is the same as the original object.

See also:

`pandas.Series.expanding` Calling expanding with Series data.

`pandas.DataFrame.expanding` Calling expanding with DataFrames.

`pandas.Series.sum` Aggregating sum for Series.

`pandas.DataFrame.sum` Aggregating sum for DataFrame.

Notes

See *Numba engine* and *Numba (JIT compilation)* for extended documentation and performance considerations for the Numba engine.

pandas.core.window.expanding.Expanding.mean

`Expanding.mean(*args, engine=None, engine_kwargs=None, **kwargs)`

Calculate the expanding mean.

Parameters

***args** For NumPy compatibility and will not have an effect on the result.

engine [str, default None]

- 'cython' : Runs the operation through C-extensions from cython.
- 'numba' : Runs the operation through JIT compiled code from numba.
- None : Defaults to 'cython' or globally setting `compute.use_numba`

New in version 1.3.0.

engine_kwargs [dict, default None]

- For 'cython' engine, there are no accepted `engine_kwargs`
- For 'numba' engine, the engine can accept `nopython`, `nogil` and `parallel` dictionary keys. The values must either be True or False. The default `engine_kwargs` for the 'numba' engine is `{'nopython': True, 'nogil': False, 'parallel': False}`

New in version 1.3.0.

****kwargs** For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame Return type is the same as the original object.

See also:

`pandas.Series.expanding` Calling expanding with Series data.

`pandas.DataFrame.expanding` Calling expanding with DataFrames.

`pandas.Series.mean` Aggregating mean for Series.

`pandas.DataFrame.mean` Aggregating mean for DataFrame.

Notes

See *Numba engine* and *Numba (JIT compilation)* for extended documentation and performance considerations for the Numba engine.

pandas.core.window.expanding.Expanding.median

Expanding.**median**(*engine=None, engine_kwargs=None, **kwargs*)

Calculate the expanding median.

Parameters

engine [str, default None]

- 'cython' : Runs the operation through C-extensions from cython.
 - 'numba' : Runs the operation through JIT compiled code from numba.
 - None : Defaults to 'cython' or globally setting `compute.use_numba`
- New in version 1.3.0.

engine_kwargs [dict, default None]

- For 'cython' engine, there are no accepted `engine_kwargs`
 - For 'numba' engine, the engine can accept `nopython`, `nogil` and `parallel` dictionary keys. The values must either be `True` or `False`. The default `engine_kwargs` for the 'numba' engine is `{'nopython': True, 'nogil': False, 'parallel': False}`
- New in version 1.3.0.

****kwargs** For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame Return type is the same as the original object.

See also:

[*pandas.Series.expanding*](#) Calling expanding with Series data.

[*pandas.DataFrame.expanding*](#) Calling expanding with DataFrames.

[*pandas.Series.median*](#) Aggregating median for Series.

[*pandas.DataFrame.median*](#) Aggregating median for DataFrame.

Notes

See *Numba engine* and *Numba (JIT compilation)* for extended documentation and performance considerations for the Numba engine.

pandas.core.window.expanding.Expanding.var

Expanding.**var**(*ddof=1, *args, **kwargs*)

Calculate the expanding variance.

Parameters

ddof [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is $N - \text{ddof}$, where N represents the number of elements.

***args** For NumPy compatibility and will not have an effect on the result.

****kwargs** For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame Return type is the same as the original object.

See also:

`numpy.var` Equivalent method for NumPy array.
`pandas.Series.expanding` Calling expanding with Series data.
`pandas.DataFrame.expanding` Calling expanding with DataFrames.
`pandas.Series.var` Aggregating var for Series.
`pandas.DataFrame.var` Aggregating var for DataFrame.

Notes

The default `ddof` of 1 used in `Series.var()` is different than the default `ddof` of 0 in `numpy.var()`.
A minimum of one period is required for the rolling calculation.

Examples

```
>>> s = pd.Series([5, 5, 6, 7, 5, 5, 5])
```

```
>>> s.expanding(3).var()
0      NaN
1      NaN
2    0.333333
3    0.916667
4    0.800000
5    0.700000
6    0.619048
dtype: float64
```

`pandas.core.window.expanding.Expanding.std`

`Expanding.std(ddof=1, *args, **kwargs)`

Calculate the expanding standard deviation.

Parameters

ddof [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is $N - \text{ddof}$, where N represents the number of elements.

***args** For NumPy compatibility and will not have an effect on the result.

****kwargs** For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame Return type is the same as the original object.

See also:

`numpy.std` Equivalent method for NumPy array.
`pandas.Series.expanding` Calling expanding with Series data.
`pandas.DataFrame.expanding` Calling expanding with DataFrames.
`pandas.Series.std` Aggregating std for Series.
`pandas.DataFrame.std` Aggregating std for DataFrame.

Notes

The default ddof of 1 used in `Series.std()` is different than the default ddof of 0 in `numpy.std()`.

A minimum of one period is required for the rolling calculation.

Examples

```
>>> s = pd.Series([5, 5, 6, 7, 5, 5, 5])
```

```
>>> s.expanding(3).std()
0      NaN
1      NaN
2    0.577350
3    0.957427
4    0.894427
5    0.836660
6    0.786796
dtype: float64
```

pandas.core.window.expanding.Expanding.min

`Expanding.min(*args, engine=None, engine_kwargs=None, **kwargs)`

Calculate the expanding minimum.

Parameters

***args** For NumPy compatibility and will not have an effect on the result.

engine [str, default None]

- 'cython' : Runs the operation through C-extensions from cython.
- 'numba' : Runs the operation through JIT compiled code from numba.
- None : Defaults to 'cython' or globally setting `compute.use_numba`

New in version 1.3.0.

engine_kwargs [dict, default None]

- For 'cython' engine, there are no accepted `engine_kwargs`
- For 'numba' engine, the engine can accept `nopython`, `nogil` and `parallel` dictionary keys. The values must either be True or False. The default `engine_kwargs` for the 'numba' engine is `{'nopython': True, 'nogil': False, 'parallel': False}`

New in version 1.3.0.

****kwargs** For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame Return type is the same as the original object.

See also:

[*pandas.Series.expanding*](#) Calling expanding with Series data.

[*pandas.DataFrame.expanding*](#) Calling expanding with DataFrames.

[*pandas.Series.min*](#) Aggregating min for Series.

`pandas.DataFrame.min` Aggregating min for DataFrame.

Notes

See *Numba engine* and *Numba (JIT compilation)* for extended documentation and performance considerations for the Numba engine.

pandas.core.window.expanding.Expanding.max

`Expanding.max(*args, engine=None, engine_kwargs=None, **kwargs)`

Calculate the expanding maximum.

Parameters

***args** For NumPy compatibility and will not have an effect on the result.

engine [str, default None]

- 'cython' : Runs the operation through C-extensions from cython.
- 'numba' : Runs the operation through JIT compiled code from numba.
- None : Defaults to 'cython' or globally setting `compute.use_numba`

New in version 1.3.0.

engine_kwargs [dict, default None]

- For 'cython' engine, there are no accepted `engine_kwargs`
- For 'numba' engine, the engine can accept `nopython`, `nogil` and `parallel` dictionary keys. The values must either be True or False. The default `engine_kwargs` for the 'numba' engine is `{'nopython': True, 'nogil': False, 'parallel': False}`

New in version 1.3.0.

****kwargs** For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame Return type is the same as the original object.

See also:

`pandas.Series.expanding` Calling expanding with Series data.

`pandas.DataFrame.expanding` Calling expanding with DataFrames.

`pandas.Series.max` Aggregating max for Series.

`pandas.DataFrame.max` Aggregating max for DataFrame.

Notes

See *Numba engine* and *Numba (JIT compilation)* for extended documentation and performance considerations for the Numba engine.

pandas.core.window.expanding.Expanding.corr

`Expanding.corr` (*other=None, pairwise=None, ddof=1, **kwargs*)

Calculate the expanding correlation.

Parameters

other [Series or DataFrame, optional] If not supplied then will default to self and produce pairwise output.

pairwise [bool, default None] If False then only matching columns between self and other will be used and the output will be a DataFrame. If True then all pairwise combinations will be calculated and the output will be a MultiIndexed DataFrame in the case of DataFrame inputs. In the case of missing elements, only complete pairwise observations will be used.

****kwargs** For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame Return type is the same as the original object.

See also:

`cov` Similar method to calculate covariance.

`numpy.corrcoef` NumPy Pearson's correlation calculation.

`pandas.Series.expanding` Calling expanding with Series data.

`pandas.DataFrame.expanding` Calling expanding with DataFrames.

`pandas.Series.corr` Aggregating corr for Series.

`pandas.DataFrame.corr` Aggregating corr for DataFrame.

Notes

This function uses Pearson's definition of correlation (https://en.wikipedia.org/wiki/Pearson_correlation_coefficient).

When *other* is not specified, the output will be self correlation (e.g. all 1's), except for *DataFrame* inputs with *pairwise* set to *True*.

Function will return NaN for correlations of equal valued sequences; this is the result of a 0/0 division error.

When *pairwise* is set to *False*, only matching columns between *self* and *other* will be used.

When *pairwise* is set to *True*, the output will be a MultiIndex DataFrame with the original index on the first level, and the *other* DataFrame columns on the second level.

In the case of missing elements, only complete pairwise observations will be used.

pandas.core.window.expanding.Expanding.cov

`Expanding.cov` (*other=None, pairwise=None, ddof=1, **kwargs*)

Calculate the expanding sample covariance.

Parameters

other [Series or DataFrame, optional] If not supplied then will default to self and produce pairwise output.

pairwise [bool, default None] If False then only matching columns between self and other will be used and the output will be a DataFrame. If True then all pairwise combinations will be calculated and the output will be a MultiIndexed DataFrame in the case of

DataFrame inputs. In the case of missing elements, only complete pairwise observations will be used.

ddof [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is $N - \text{ddof}$, where N represents the number of elements.

****kwargs** For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame Return type is the same as the original object.

See also:

[*pandas.Series.expanding*](#) Calling expanding with Series data.

[*pandas.DataFrame.expanding*](#) Calling expanding with DataFrames.

[*pandas.Series.cov*](#) Aggregating cov for Series.

[*pandas.DataFrame.cov*](#) Aggregating cov for DataFrame.

pandas.core.window.expanding.Expanding.skew

Expanding.**skew**(**kwargs)

Calculate the expanding unbiased skewness.

Parameters

****kwargs** For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame Return type is the same as the original object.

See also:

[*scipy.stats.skew*](#) Third moment of a probability density.

[*pandas.Series.expanding*](#) Calling expanding with Series data.

[*pandas.DataFrame.expanding*](#) Calling expanding with DataFrames.

[*pandas.Series.skew*](#) Aggregating skew for Series.

[*pandas.DataFrame.skew*](#) Aggregating skew for DataFrame.

Notes

A minimum of three periods is required for the rolling calculation.

pandas.core.window.expanding.Expanding.kurt

Expanding.**kurt**(**kwargs)

Calculate the expanding Fisher's definition of kurtosis without bias.

Parameters

****kwargs** For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame Return type is the same as the original object.

See also:

[*scipy.stats.kurtosis*](#) Reference SciPy method.

[*pandas.Series.expanding*](#) Calling expanding with Series data.

[*pandas.DataFrame.expanding*](#) Calling expanding with DataFrames.

[*pandas.Series.kurt*](#) Aggregating kurt for Series.

`pandas.DataFrame.kurt` Aggregating kurt for DataFrame.

Notes

A minimum of four periods is required for the calculation.

Examples

The example below will show a rolling calculation with a window size of four matching the equivalent function call using `scipy.stats`.

```
>>> arr = [1, 2, 3, 4, 999]
>>> import scipy.stats
>>> print(f"{scipy.stats.kurtosis(arr[:-1], bias=False):.6f}")
-1.200000
>>> print(f"{scipy.stats.kurtosis(arr, bias=False):.6f}")
4.999874
>>> s = pd.Series(arr)
>>> s.expanding(4).kurt()
0      NaN
1      NaN
2      NaN
3    -1.200000
4     4.999874
dtype: float64
```

`pandas.core.window.expanding.Expanding.apply`

`Expanding.apply(func, raw=False, engine=None, engine_kwargs=None, args=None, kwargs=None)`

Calculate the expanding custom aggregation function.

Parameters

func [function] Must produce a single value from an ndarray input if `raw=True` or a single value from a Series if `raw=False`. Can also accept a Numba JIT function with `engine='numba'` specified.

Changed in version 1.0.0.

raw [bool, default None]

- `False` : passes each row or column as a Series to the function.
- `True` : the passed function will receive ndarray objects instead. If you are just applying a NumPy reduction function this will achieve much better performance.

engine [str, default None]

- `'cython'` : Runs rolling apply through C-extensions from cython.
- `'numba'` : Runs rolling apply through JIT compiled code from numba. Only available when `raw` is set to `True`.
- `None` : Defaults to `'cython'` or globally setting `compute.use_numba`

New in version 1.0.0.

engine_kwargs [dict, default None]

- For 'cython' engine, there are no accepted `engine_kwargs`
- For 'numba' engine, the engine can accept `nopython`, `nogil` and `parallel` dictionary keys. The values must either be `True` or `False`. The default `engine_kwargs` for the 'numba' engine is `{'nopython': True, 'nogil': False, 'parallel': False}` and will be applied to both the `func` and the `apply` rolling aggregation.

New in version 1.0.0.

args [tuple, default None] Positional arguments to be passed into `func`.

kwargs [dict, default None] Keyword arguments to be passed into `func`.

Returns

Series or DataFrame Return type is the same as the original object.

See also:

[`pandas.Series.expanding`](#) Calling `expanding` with Series data.

[`pandas.DataFrame.expanding`](#) Calling `expanding` with DataFrames.

[`pandas.Series.apply`](#) Aggregating `apply` for Series.

[`pandas.DataFrame.apply`](#) Aggregating `apply` for DataFrame.

pandas.core.window.expanding.Expanding.aggregate

`Expanding.aggregate(func, *args, **kwargs)`

Aggregate using one or more operations over the specified axis.

Parameters

func [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a Series/Dataframe or when passed to Series/Dataframe.`apply`.

Accepted combinations are:

- function
- string function name
- list of functions and/or function names, e.g. `[np.sum, 'mean']`
- dict of axis labels -> functions, function names or list of such.

***args** Positional arguments to pass to `func`.

****kwargs** Keyword arguments to pass to `func`.

Returns

scalar, Series or DataFrame The return can be:

- scalar : when `Series.agg` is called with single function
- Series : when `DataFrame.agg` is called with a single function
- DataFrame : when `DataFrame.agg` is called with several functions

Return scalar, Series or DataFrame.

See also:

[`pandas.DataFrame.aggregate`](#) Similar DataFrame method.

[`pandas.Series.aggregate`](#) Similar Series method.

Notes

`agg` is an alias for `aggregate`. Use the alias.

Functions that mutate the passed object can produce unexpected behavior or errors and are not supported. See [Mutating with User Defined Function \(UDF\) methods](#) for more details.

A passed user-defined-function will be passed a Series for evaluation.

Examples

```
>>> df = pd.DataFrame({"A": [1, 2, 3], "B": [4, 5, 6], "C": [7, 8, 9]})
>>> df
   A  B  C
0  1  4  7
1  2  5  8
2  3  6  9
```

```
>>> df.ewm(alpha=0.5).mean()
   A          B          C
0  1.000000  4.000000  7.000000
1  1.666667  4.666667  7.666667
2  2.428571  5.428571  8.428571
```

pandas.core.window.expanding.Expanding.quantile

`Expanding.quantile(quantile, interpolation='linear', **kwargs)`

Calculate the expanding quantile.

Parameters

quantile [float] Quantile to compute. $0 \leq \text{quantile} \leq 1$.

interpolation [{"linear", "lower", "higher", "midpoint", "nearest"}] This optional parameter specifies the interpolation method to use, when the desired quantile lies between two data points i and j :

- linear: $i + (j - i) * \text{fraction}$, where *fraction* is the fractional part of the index surrounded by i and j .
- lower: i .
- higher: j .
- nearest: i or j whichever is nearest.
- midpoint: $(i + j) / 2$.

****kwargs** For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame Return type is the same as the original object.

See also:

[pandas.Series.expanding](#) Calling expanding with Series data.

[pandas.DataFrame.expanding](#) Calling expanding with DataFrames.

[pandas.Series.quantile](#) Aggregating quantile for Series.

[pandas.DataFrame.quantile](#) Aggregating quantile for DataFrame.

pandas.core.window.expanding.Expanding.sem**Expanding.sem**(*ddof=1, *args, **kwargs*)

Calculate the expanding standard error of mean.

Parameters**ddof** [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is $N - \text{ddof}$, where N represents the number of elements.***args** For NumPy compatibility and will not have an effect on the result.****kwargs** For NumPy compatibility and will not have an effect on the result.**Returns****Series or DataFrame** Return type is the same as the original object.**See also:****pandas.Series.expanding** Calling expanding with Series data.**pandas.DataFrame.expanding** Calling expanding with DataFrames.**pandas.Series.sem** Aggregating sem for Series.**pandas.DataFrame.sem** Aggregating sem for DataFrame.**Notes**

A minimum of one period is required for the calculation.

Examples

```
>>> s = pd.Series([0, 1, 2, 3])
```

```
>>> s.expanding().sem()
0      NaN
1    0.707107
2    0.707107
3    0.745356
dtype: float64
```

3.9.4 Exponentially-weighted window functions

| | |
|---|---|
| <i>ExponentialMovingWindow.mean</i> (*args[,...]) | Calculate the ewm (exponential weighted moment) mean. |
| <i>ExponentialMovingWindow.std</i> ([bias]) | Calculate the ewm (exponential weighted moment) standard deviation. |
| <i>ExponentialMovingWindow.var</i> ([bias]) | Calculate the ewm (exponential weighted moment) variance. |
| <i>ExponentialMovingWindow.corr</i> ([other, pairwise]) | Calculate the ewm (exponential weighted moment) sample correlation. |
| <i>ExponentialMovingWindow.cov</i> ([other, ...]) | Calculate the ewm (exponential weighted moment) sample covariance. |

pandas.core.window.ewm.ExponentialMovingWindow.mean

ExponentialMovingWindow.**mean**(*args, engine=None, engine_kwargs=None, **kwargs)

Calculate the ewm (exponential weighted moment) mean.

Parameters

***args** For NumPy compatibility and will not have an effect on the result.

engine [str, default None]

- 'cython' : Runs the operation through C-extensions from cython.
- 'numba' : Runs the operation through JIT compiled code from numba.
- None : Defaults to 'cython' or globally setting `compute.use_numba`

New in version 1.3.0.

engine_kwargs [dict, default None]

- For 'cython' engine, there are no accepted `engine_kwargs`
- For 'numba' engine, the engine can accept `nopython`, `nogil` and `parallel` dictionary keys. The values must either be True or False. The default `engine_kwargs` for the 'numba' engine is `{'nopython': True, 'nogil': False, 'parallel': False}`

New in version 1.3.0.

****kwargs** For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame Return type is the same as the original object.

See also:

[*pandas.Series.ewm*](#) Calling ewm with Series data.

[*pandas.DataFrame.ewm*](#) Calling ewm with DataFrames.

[*pandas.Series.mean*](#) Aggregating mean for Series.

[*pandas.DataFrame.mean*](#) Aggregating mean for DataFrame.

Notes

See [Numba engine](#) and [Numba \(JIT compilation\)](#) for extended documentation and performance considerations for the Numba engine.

pandas.core.window.ewm.ExponentialMovingWindow.std

ExponentialMovingWindow.**std**(bias=False, *args, **kwargs)

Calculate the ewm (exponential weighted moment) standard deviation.

Parameters

bias [bool, default False] Use a standard estimation bias correction.

***args** For NumPy compatibility and will not have an effect on the result.

****kwargs** For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame Return type is the same as the original object.

See also:

`pandas.Series.ewm` Calling ewm with Series data.
`pandas.DataFrame.ewm` Calling ewm with DataFrames.
`pandas.Series.std` Aggregating std for Series.
`pandas.DataFrame.std` Aggregating std for DataFrame.

`pandas.core.window.ewm.ExponentialMovingWindow.var`

`ExponentialMovingWindow.var`(*bias=False, *args, **kwargs*)

Calculate the ewm (exponential weighted moment) variance.

Parameters

- bias** [bool, default False] Use a standard estimation bias correction.
- *args** For NumPy compatibility and will not have an effect on the result.
- **kwargs** For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame Return type is the same as the original object.

See also:

`pandas.Series.ewm` Calling ewm with Series data.
`pandas.DataFrame.ewm` Calling ewm with DataFrames.
`pandas.Series.var` Aggregating var for Series.
`pandas.DataFrame.var` Aggregating var for DataFrame.

`pandas.core.window.ewm.ExponentialMovingWindow.corr`

`ExponentialMovingWindow.corr`(*other=None, pairwise=None, **kwargs*)

Calculate the ewm (exponential weighted moment) sample correlation.

Parameters

- other** [Series or DataFrame, optional] If not supplied then will default to self and produce pairwise output.
- pairwise** [bool, default None] If False then only matching columns between self and other will be used and the output will be a DataFrame. If True then all pairwise combinations will be calculated and the output will be a MultiIndex DataFrame in the case of DataFrame inputs. In the case of missing elements, only complete pairwise observations will be used.
- **kwargs** For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame Return type is the same as the original object.

See also:

`pandas.Series.ewm` Calling ewm with Series data.
`pandas.DataFrame.ewm` Calling ewm with DataFrames.
`pandas.Series.corr` Aggregating corr for Series.
`pandas.DataFrame.corr` Aggregating corr for DataFrame.

pandas.core.window.ewm.ExponentialMovingWindow.cov

`ExponentialMovingWindow.cov`(*other=None, pairwise=None, bias=False, **kwargs*)

Calculate the ewm (exponential weighted moment) sample covariance.

Parameters

other [Series or DataFrame, optional] If not supplied then will default to self and produce pairwise output.

pairwise [bool, default None] If False then only matching columns between self and other will be used and the output will be a DataFrame. If True then all pairwise combinations will be calculated and the output will be a MultiIndex DataFrame in the case of DataFrame inputs. In the case of missing elements, only complete pairwise observations will be used.

bias [bool, default False] Use a standard estimation bias correction.

****kwargs** For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame Return type is the same as the original object.

3.9.5 Window indexer

Base class for defining custom window boundaries.

| | |
|--|--|
| <code>api.indexers.BaseIndexer</code> (<i>[index_array, ...]</i>) | Base class for window bounds calculations. |
| <code>api.indexers.FixedForwardWindowIndexer</code> (<i>[...]</i>) | Creates window boundaries for fixed-length windows that include the current row. |
| <code>api.indexers.VariableOffsetWindowIndexer</code> (<i>[...]</i>) | Calculate window boundaries based on a non-fixed offset such as a <code>BusinessDay</code> |

pandas.api.indexers.BaseIndexer

class `pandas.api.indexers.BaseIndexer`(*index_array=None, window_size=0, **kwargs*)

Base class for window bounds calculations.

Methods

| | |
|--|----------------------------------|
| <code>get_window_bounds</code> (<i>[num_values, min_periods, ...]</i>) | Computes the bounds of a window. |
|--|----------------------------------|

pandas.api.indexers.BaseIndexer.get_window_bounds

`BaseIndexer.get_window_bounds`(*num_values=0, min_periods=None, center=None, closed=None*)
Computes the bounds of a window.

Parameters

num_values [int, default 0] number of values that will be aggregated over
window_size [int, default 0] the number of rows in a window
min_periods [int, default None] min_periods passed from the top level rolling API
center [bool, default None] center passed from the top level rolling API
closed [str, default None] closed passed from the top level rolling API
win_type [str, default None] win_type passed from the top level rolling API

Returns

A tuple of `ndarray[int64]s`, indicating the boundaries of each window

pandas.api.indexers.FixedForwardWindowIndexer

`class pandas.api.indexers.FixedForwardWindowIndexer`(*index_array=None, window_size=0, **kwargs*)
Creates window boundaries for fixed-length windows that include the current row.

Examples

```
>>> df = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]})
>>> df
   B
0  0.0
1  1.0
2  2.0
3  NaN
4  4.0
```

```
>>> indexer = pd.api.indexers.FixedForwardWindowIndexer(window_size=2)
>>> df.rolling(window=indexer, min_periods=1).sum()
   B
0  1.0
1  3.0
2  2.0
3  4.0
4  4.0
```

Methods

`get_window_bounds`(`num_values`, `min_periods`, `center`, `closed`, ...) Computes the bounds of a window.

`pandas.api.indexers.FixedForwardWindowIndexer.get_window_bounds`

`FixedForwardWindowIndexer.get_window_bounds`(`num_values=0`, `min_periods=None`, `center=None`, `closed=None`)

Computes the bounds of a window.

Parameters

num_values [int, default 0] number of values that will be aggregated over

window_size [int, default 0] the number of rows in a window

min_periods [int, default None] min_periods passed from the top level rolling API

center [bool, default None] center passed from the top level rolling API

closed [str, default None] closed passed from the top level rolling API

win_type [str, default None] win_type passed from the top level rolling API

Returns

A tuple of `ndarray[int64]s`, indicating the boundaries of each window

`pandas.api.indexers.VariableOffsetWindowIndexer`

`class pandas.api.indexers.VariableOffsetWindowIndexer`(`index_array=None`, `window_size=0`, `index=None`, `offset=None`, `**kwargs`)

Calculate window boundaries based on a non-fixed offset such as a `BusinessDay`

Methods

`get_window_bounds`(`num_values`, `min_periods`, `center`, `closed`, ...) Computes the bounds of a window.

`pandas.api.indexers.VariableOffsetWindowIndexer.get_window_bounds`

`VariableOffsetWindowIndexer.get_window_bounds`(`num_values=0`, `min_periods=None`, `center=None`, `closed=None`)

Computes the bounds of a window.

Parameters

num_values [int, default 0] number of values that will be aggregated over

window_size [int, default 0] the number of rows in a window

min_periods [int, default None] min_periods passed from the top level rolling API

center [bool, default None] center passed from the top level rolling API
closed [str, default None] closed passed from the top level rolling API
win_type [str, default None] win_type passed from the top level rolling API

Returns

A tuple of ndarray[int64]s, indicating the boundaries of each window

3.10 GroupBy

GroupBy objects are returned by groupby calls: `pandas.DataFrame.groupby()`, `pandas.Series.groupby()`, etc.

3.10.1 Indexing, iteration

| | |
|---|--|
| <code>GroupBy.__iter__()</code> | Groupby iterator. |
| <code>GroupBy.groups</code> | Dict {group name -> group labels}. |
| <code>GroupBy.indices</code> | Dict {group name -> group indices}. |
| <code>GroupBy.get_group(name[, obj])</code> | Construct DataFrame from group with provided name. |

`pandas.core.groupby.GroupBy.__iter__`

`GroupBy.__iter__()`

Groupby iterator.

Returns

Generator yielding sequence of (name, subsetting object)
for each group

`pandas.core.groupby.GroupBy.groups`

property `GroupBy.groups`

Dict {group name -> group labels}.

`pandas.core.groupby.GroupBy.indices`

property `GroupBy.indices`

Dict {group name -> group indices}.

pandas.core.groupby.GroupBy.get_group

GroupBy.**get_group**(*name*, *obj=None*)

Construct DataFrame from group with provided name.

Parameters

name [object] The name of the group to get as a DataFrame.

obj [DataFrame, default None] The DataFrame to take the DataFrame out of. If it is None, the object groupby was called on will be used.

Returns

group [same type as obj]

Grouper(*args, **kwargs)

A Grouper allows the user to specify a groupby instruction for an object.

pandas.Grouper

class pandas.**Grouper**(*args, **kwargs)

A Grouper allows the user to specify a groupby instruction for an object.

This specification will select a column via the key parameter, or if the level and/or axis parameters are given, a level of the index of the target object.

If *axis* and/or *level* are passed as keywords to both *Grouper* and *groupby*, the values passed to *Grouper* take precedence.

Parameters

key [str, defaults to None] Groupby key, which selects the grouping column of the target.

level [name/number, defaults to None] The level for the target index.

freq [str / frequency object, defaults to None] This will groupby the specified frequency if the target selection (via key or level) is a datetime-like object. For full specification of available frequencies, please see [here](#).

axis [str, int, defaults to 0] Number/name of the axis.

sort [bool, default to False] Whether to sort the resulting labels.

closed [{‘left’ or ‘right’}] Closed end of interval. Only when *freq* parameter is passed.

label [{‘left’ or ‘right’}] Interval boundary to use for labeling. Only when *freq* parameter is passed.

convention [{‘start’, ‘end’, ‘e’, ‘s’}] If grouper is PeriodIndex and *freq* parameter is passed.

base [int, default 0] Only when *freq* parameter is passed. For frequencies that evenly subdivide 1 day, the “origin” of the aggregated intervals. For example, for ‘5min’ frequency, base could range from 0 through 4. Defaults to 0.

Deprecated since version 1.1.0: The new arguments that you should use are ‘offset’ or ‘origin’.

loffset [str, DateOffset, timedelta object] Only when *freq* parameter is passed.

Deprecated since version 1.1.0: loffset is only working for `.resample(...)` and not for `Grouper` ([GH28302](#)). However, loffset is also deprecated for `.resample(...)` See: [DataFrame.resample](#)

origin [{{'epoch', 'start', 'start_day', 'end', 'end_day'}}, Timestamp] or str, default 'start_day' The timestamp on which to adjust the grouping. The timezone of origin must match the timezone of the index. If a timestamp is not used, these values are also supported:

- 'epoch': *origin* is 1970-01-01
- 'start': *origin* is the first value of the timeseries
- 'start_day': *origin* is the first day at midnight of the timeseries

New in version 1.1.0.

- 'end': *origin* is the last value of the timeseries
- 'end_day': *origin* is the ceiling midnight of the last day

New in version 1.3.0.

offset [Timedelta or str, default is None] An offset timedelta added to the origin.

New in version 1.1.0.

dropna [bool, default True] If True, and if group keys contain NA values, NA values together with row/column will be dropped. If False, NA values will also be treated as the key in groups.

New in version 1.2.0.

Returns

A specification for a groupby instruction

Examples

Syntactic sugar for `df.groupby('A')`

```
>>> df = pd.DataFrame(
...     {
...         "Animal": ["Falcon", "Parrot", "Falcon", "Falcon", "Parrot"],
...         "Speed": [100, 5, 200, 300, 15],
...     }
... )
>>> df
   Animal  Speed
0  Falcon   100
1  Parrot    5
2  Falcon   200
3  Falcon   300
4  Parrot    15
>>> df.groupby(pd.Grouper(key="Animal")).mean()
   Speed
Animal
Falcon  200.0
Parrot   10.0
```

Specify a resample operation on the column 'Publish date'

```

>>> df = pd.DataFrame(
...     {
...         "Publish date": [
...             pd.Timestamp("2000-01-02"),
...             pd.Timestamp("2000-01-02"),
...             pd.Timestamp("2000-01-09"),
...             pd.Timestamp("2000-01-16")
...         ],
...         "ID": [0, 1, 2, 3],
...         "Price": [10, 20, 30, 40]
...     }
... )
>>> df
   Publish date  ID  Price
0 2000-01-02    0    10
1 2000-01-02    1    20
2 2000-01-09    2    30
3 2000-01-16    3    40
>>> df.groupby(pd.Grouper(key="Publish date", freq="1W")).mean()
   Publish date  ID  Price
2000-01-02    0.5  15.0
2000-01-09    2.0  30.0
2000-01-16    3.0  40.0

```

If you want to adjust the start of the bins based on a fixed timestamp:

```

>>> start, end = '2000-10-01 23:30:00', '2000-10-02 00:30:00'
>>> rng = pd.date_range(start, end, freq='7min')
>>> ts = pd.Series(np.arange(len(rng)) * 3, index=rng)
>>> ts
2000-10-01 23:30:00    0
2000-10-01 23:37:00    3
2000-10-01 23:44:00    6
2000-10-01 23:51:00    9
2000-10-01 23:58:00   12
2000-10-02 00:05:00   15
2000-10-02 00:12:00   18
2000-10-02 00:19:00   21
2000-10-02 00:26:00   24
Freq: 7T, dtype: int64

```

```

>>> ts.groupby(pd.Grouper(freq='17min')).sum()
2000-10-01 23:14:00    0
2000-10-01 23:31:00    9
2000-10-01 23:48:00   21
2000-10-02 00:05:00   54
2000-10-02 00:22:00   24
Freq: 17T, dtype: int64

```

```

>>> ts.groupby(pd.Grouper(freq='17min', origin='epoch')).sum()
2000-10-01 23:18:00    0

```

(continues on next page)

(continued from previous page)

```
2000-10-01 23:35:00    18
2000-10-01 23:52:00    27
2000-10-02 00:09:00    39
2000-10-02 00:26:00    24
Freq: 17T, dtype: int64
```

```
>>> ts.groupby(pd.Grouper(freq='17min', origin='2000-01-01')).sum()
2000-10-01 23:24:00     3
2000-10-01 23:41:00    15
2000-10-01 23:58:00    45
2000-10-02 00:15:00    45
Freq: 17T, dtype: int64
```

If you want to adjust the start of the bins with an *offset* Timedelta, the two following lines are equivalent:

```
>>> ts.groupby(pd.Grouper(freq='17min', origin='start')).sum()
2000-10-01 23:30:00     9
2000-10-01 23:47:00    21
2000-10-02 00:04:00    54
2000-10-02 00:21:00    24
Freq: 17T, dtype: int64
```

```
>>> ts.groupby(pd.Grouper(freq='17min', offset='23h30min')).sum()
2000-10-01 23:30:00     9
2000-10-01 23:47:00    21
2000-10-02 00:04:00    54
2000-10-02 00:21:00    24
Freq: 17T, dtype: int64
```

To replace the use of the deprecated *base* argument, you can now use *offset*, in this example it is equivalent to have *base=2*:

```
>>> ts.groupby(pd.Grouper(freq='17min', offset='2min')).sum()
2000-10-01 23:16:00     0
2000-10-01 23:33:00     9
2000-10-01 23:50:00    36
2000-10-02 00:07:00    39
2000-10-02 00:24:00    24
Freq: 17T, dtype: int64
```

Attributes

| | |
|---------------|--|
| ax | |
| groups | |

3.10.2 Function application

| | |
|--|---|
| <code>GroupBy.apply(func, *args, **kwargs)</code> | Apply function <code>func</code> group-wise and combine the results together. |
| <code>GroupBy.agg(func, *args, **kwargs)</code> | |
| <code>SeriesGroupBy.aggregate([func, engine, ...])</code> | Aggregate using one or more operations over the specified axis. |
| <code>DataFrameGroupBy.aggregate([func, engine, ...])</code> | Aggregate using one or more operations over the specified axis. |
| <code>SeriesGroupBy.transform(func, *args[, ...])</code> | Call function producing a like-indexed Series on each group and return a Series having the same indexes as the original object filled with the transformed values |
| <code>DataFrameGroupBy.transform(func, *args[, ...])</code> | Call function producing a like-indexed DataFrame on each group and return a DataFrame having the same indexes as the original object filled with the transformed values |
| <code>GroupBy.pipe(func, *args, **kwargs)</code> | Apply a function <code>func</code> with arguments to this GroupBy object and return the function's result. |

pandas.core.groupby.GroupBy.apply

`GroupBy.apply(func, *args, **kwargs)`

Apply function `func` group-wise and combine the results together.

The function passed to `apply` must take a dataframe as its first argument and return a DataFrame, Series or scalar. `apply` will then take care of combining the results back together into a single dataframe or series. `apply` is therefore a highly flexible grouping method.

While `apply` is a very flexible method, its downside is that using it can be quite a bit slower than using more specific methods like `agg` or `transform`. Pandas offers a wide range of method that will be much faster than using `apply` for their specific purposes, so try to use them before reaching for `apply`.

Parameters

func [callable] A callable that takes a dataframe as its first argument, and returns a dataframe, a series or a scalar. In addition the callable may take positional and keyword arguments.

args, kwargs [tuple and dict] Optional positional and keyword arguments to pass to `func`.

Returns

applied [Series or DataFrame]

See also:

pipe Apply function to the full GroupBy object instead of to each group.

aggregate Apply aggregate function to the GroupBy object.

transform Apply function column-by-column to the GroupBy object.

Series.apply Apply a function to a Series.

DataFrame.apply Apply a function to each row or column of a DataFrame.

Notes

In the current implementation `apply` calls `func` twice on the first group to decide whether it can take a fast or slow code path. This can lead to unexpected behavior if `func` has side-effects, as they will take effect twice for the first group.

Changed in version 1.3.0: The resulting dtype will reflect the return value of the passed `func`, see the examples below.

Examples

```
>>> df = pd.DataFrame({'A': 'a a b'.split(),
...                   'B': [1,2,3],
...                   'C': [4,6,5]})
>>> g = df.groupby('A')
```

Notice that `g` has two groups, `a` and `b`. Calling *apply* in various ways, we can get different grouping results:

Example 1: below the function passed to *apply* takes a DataFrame as its argument and returns a DataFrame. *apply* combines the result for each group together into a new DataFrame:

```
>>> g[['B', 'C']].apply(lambda x: x / x.sum())
      B      C
0  0.333333  0.4
1  0.666667  0.6
2  1.000000  1.0
```

Example 2: The function passed to *apply* takes a DataFrame as its argument and returns a Series. *apply* combines the result for each group together into a new DataFrame.

Changed in version 1.3.0: The resulting dtype will reflect the return value of the passed `func`.

```
>>> g[['B', 'C']].apply(lambda x: x.astype(float).max() - x.min())
      B      C
A
a  1.0  2.0
b  0.0  0.0
```

Example 3: The function passed to *apply* takes a DataFrame as its argument and returns a scalar. *apply* combines the result for each group together into a Series, including setting the index as appropriate:

```
>>> g.apply(lambda x: x.C.max() - x.B.min())
A
a    5
b    2
dtype: int64
```

pandas.core.groupby.GroupBy.agg

GroupBy.agg(*func*, **args*, ***kwargs*)

pandas.core.groupby.SeriesGroupBy.aggregate

SeriesGroupBy.aggregate(*func=None*, **args*, *engine=None*, *engine_kwargs=None*, ***kwargs*)

Aggregate using one or more operations over the specified axis.

Parameters

func [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a Series or when passed to Series.apply.

Accepted combinations are:

- function
- string function name
- list of functions and/or function names, e.g. [np.sum, 'mean']
- dict of axis labels -> functions, function names or list of such.

Can also accept a Numba JIT function with `engine='numba'` specified. Only passing a single function is supported with this engine.

If the 'numba' engine is chosen, the function must be a user defined function with `values` and `index` as the first and second arguments respectively in the function signature. Each group's index will be passed to the user defined function and optionally available for use.

Changed in version 1.1.0.

***args** Positional arguments to pass to func.

engine [str, default None]

- 'cython' : Runs the function through C-extensions from cython.
- 'numba' : Runs the function through JIT compiled code from numba.
- None : Defaults to 'cython' or globally setting `compute.use_numba`

New in version 1.1.0.

engine_kwargs [dict, default None]

- For 'cython' engine, there are no accepted `engine_kwargs`
- For 'numba' engine, the engine can accept `nopython`, `nogil` and `parallel` dictionary keys. The values must either be True or False. The default `engine_kwargs` for the 'numba' engine is `{'nopython': True, 'nogil': False, 'parallel': False}` and will be applied to the function

New in version 1.1.0.

****kwargs** Keyword arguments to be passed into func.

Returns

Series

See also:

Series.groupby.apply Apply function func group-wise and combine the results together.

Series.groupby.transform Aggregate using one or more operations over the specified axis.

Series.aggregate Transforms the Series on each group based on the given function.

Notes

When using `engine='numba'`, there will be no “fall back” behavior internally. The group data and group index will be passed as numpy arrays to the JITed user defined function, and no alternative execution attempts will be tried.

Functions that mutate the passed object can produce unexpected behavior or errors and are not supported. See *Mutating with User Defined Function (UDF) methods* for more details.

Changed in version 1.3.0: The resulting dtype will reflect the return value of the passed `func`, see the examples below.

Examples

```
>>> s = pd.Series([1, 2, 3, 4])
```

```
>>> s
0    1
1    2
2    3
3    4
dtype: int64
```

```
>>> s.groupby([1, 1, 2, 2]).min()
1    1
2    3
dtype: int64
```

```
>>> s.groupby([1, 1, 2, 2]).agg('min')
1    1
2    3
dtype: int64
```

```
>>> s.groupby([1, 1, 2, 2]).agg(['min', 'max'])
   min  max
1    1    2
2    3    4
```

The output column names can be controlled by passing the desired column names and aggregations as keyword arguments.

```
>>> s.groupby([1, 1, 2, 2]).agg(
...     minimum='min',
...     maximum='max',
... )
   minimum  maximum
1         1         2
2         3         4
```

Changed in version 1.3.0: The resulting dtype will reflect the return value of the aggregating function.

```
>>> s.groupby([1, 1, 2, 2]).agg(lambda x: x.astype(float).min())
1    1.0
2    3.0
dtype: float64
```

pandas.core.groupby.DataFrameGroupBy.aggregate

`DataFrameGroupBy.aggregate(func=None, *args, engine=None, engine_kwargs=None, **kwargs)`

Aggregate using one or more operations over the specified axis.

Parameters

func [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a DataFrame or when passed to DataFrame.apply.

Accepted combinations are:

- function
- string function name
- list of functions and/or function names, e.g. `[np.sum, 'mean']`
- dict of axis labels -> functions, function names or list of such.

Can also accept a Numba JIT function with `engine='numba'` specified. Only passing a single function is supported with this engine.

If the 'numba' engine is chosen, the function must be a user defined function with `values` and `index` as the first and second arguments respectively in the function signature. Each group's index will be passed to the user defined function and optionally available for use.

Changed in version 1.1.0.

***args** Positional arguments to pass to func.

engine [str, default None]

- 'cython' : Runs the function through C-extensions from cython.
- 'numba' : Runs the function through JIT compiled code from numba.
- None : Defaults to 'cython' or globally setting `compute.use_numba`

New in version 1.1.0.

engine_kwargs [dict, default None]

- For 'cython' engine, there are no accepted `engine_kwargs`
- For 'numba' engine, the engine can accept `nopython`, `nogil` and `parallel` dictionary keys. The values must either be True or False. The default `engine_kwargs` for the 'numba' engine is `{'nopython': True, 'nogil': False, 'parallel': False}` and will be applied to the function

New in version 1.1.0.

****kwargs** Keyword arguments to be passed into func.

Returns

DataFrame

See also:

DataFrame.groupby.apply Apply function func group-wise and combine the results together.

DataFrame.groupby.transform Aggregate using one or more operations over the specified axis.

DataFrame.aggregate Transforms the Series on each group based on the given function.

Notes

When using `engine='numba'`, there will be no “fall back” behavior internally. The group data and group index will be passed as numpy arrays to the JITed user defined function, and no alternative execution attempts will be tried.

Functions that mutate the passed object can produce unexpected behavior or errors and are not supported. See *Mutating with User Defined Function (UDF) methods* for more details.

Changed in version 1.3.0: The resulting dtype will reflect the return value of the passed `func`, see the examples below.

Examples

```
>>> df = pd.DataFrame(
...     {
...         "A": [1, 1, 2, 2],
...         "B": [1, 2, 3, 4],
...         "C": [0.362838, 0.227877, 1.267767, -0.562860],
...     }
... )
```

```
>>> df
   A  B      C
0  1  1  0.362838
1  1  2  0.227877
2  2  3  1.267767
3  2  4 -0.562860
```

The aggregation is for each column.

```
>>> df.groupby('A').agg('min')
   B      C
A
1  1  0.227877
2  3 -0.562860
```

Multiple aggregations

```
>>> df.groupby('A').agg(['min', 'max'])
   B      C
   min max   min   max
A
1  1  2  0.227877  0.362838
2  3  4 -0.562860  1.267767
```

Select a column for aggregation

```
>>> df.groupby('A').B.agg(['min', 'max'])
      min  max
A
1      1    2
2      3    4
```

Different aggregations per column

```
>>> df.groupby('A').agg({'B': ['min', 'max'], 'C': 'sum'})
      B      C
      min max  sum
A
1      1    2  0.590715
2      3    4  0.704907
```

To control the output names with different aggregations per column, pandas supports “named aggregation”

```
>>> df.groupby("A").agg(
...     b_min=pd.NamedAgg(column="B", aggfunc="min"),
...     c_sum=pd.NamedAgg(column="C", aggfunc="sum"))
      b_min  c_sum
A
1         1  0.590715
2         3  0.704907
```

- The keywords are the *output* column names
- The values are tuples whose first element is the column to select and the second element is the aggregation to apply to that column. Pandas provides the `pandas.NamedAgg` namedtuple with the fields `['column', 'aggfunc']` to make it clearer what the arguments are. As usual, the aggregation can be a callable or a string alias.

See [Named aggregation](#) for more.

Changed in version 1.3.0: The resulting dtype will reflect the return value of the aggregating function.

```
>>> df.groupby("A")[["B"]].agg(lambda x: x.astype(float).min())
      B
A
1     1.0
2     3.0
```

pandas.core.groupby.SeriesGroupBy.transform

`SeriesGroupBy.transform(func, *args, engine=None, engine_kwargs=None, **kwargs)`

Call function producing a like-indexed Series on each group and return a Series having the same indexes as the original object filled with the transformed values

Parameters

f [function] Function to apply to each group.

Can also accept a Numba JIT function with `engine='numba'` specified.

If the 'numba' engine is chosen, the function must be a user defined function with `values` and `index` as the first and second arguments respectively in the function sig-

nature. Each group's index will be passed to the user defined function and optionally available for use.

Changed in version 1.1.0.

***args** Positional arguments to pass to func.

engine [str, default None]

- 'cython' : Runs the function through C-extensions from cython.
- 'numba' : Runs the function through JIT compiled code from numba.
- None : Defaults to 'cython' or the global setting `compute.use_numba`

New in version 1.1.0.

engine_kwargs [dict, default None]

- For 'cython' engine, there are no accepted `engine_kwargs`
- For 'numba' engine, the engine can accept `nopython`, `nogil` and `parallel` dictionary keys. The values must either be `True` or `False`. The default `engine_kwargs` for the 'numba' engine is `{'nopython': True, 'nogil': False, 'parallel': False}` and will be applied to the function

New in version 1.1.0.

****kwargs** Keyword arguments to be passed into func.

Returns

Series

See also:

Series.groupby.apply Apply function `func` group-wise and combine the results together.

Series.groupby.aggregate Aggregate using one or more operations over the specified axis.

Series.transform Call `func` on self producing a Series with transformed values.

Notes

Each group is endowed the attribute 'name' in case you need to know which group you are working on.

The current implementation imposes three requirements on `f`:

- `f` must return a value that either has the same shape as the input subframe or can be broadcast to the shape of the input subframe. For example, if `f` returns a scalar it will be broadcast to have the same shape as the input subframe.
- if this is a DataFrame, `f` must support application column-by-column in the subframe. If `f` also supports application to the entire subframe, then a fast path is used starting from the second chunk.
- `f` must not mutate groups. Mutation is not supported and may produce unexpected results. See [Mutating with User Defined Function \(UDF\) methods](#) for more details.

When using `engine='numba'`, there will be no "fall back" behavior internally. The group data and group index will be passed as numpy arrays to the JITed user defined function, and no alternative execution attempts will be tried.

Changed in version 1.3.0: The resulting dtype will reflect the return value of the passed `func`, see the examples below.

Examples

```
>>> df = pd.DataFrame({'A' : ['foo', 'bar', 'foo', 'bar',
...                           'foo', 'bar'],
...                   'B' : ['one', 'one', 'two', 'three',
...                           'two', 'two'],
...                   'C' : [1, 5, 5, 2, 5, 5],
...                   'D' : [2.0, 5., 8., 1., 2., 9.]})
>>> grouped = df.groupby('A')
>>> grouped.transform(lambda x: (x - x.mean()) / x.std())
   C      D
0 -1.154701 -0.577350
1  0.577350  0.000000
2  0.577350  1.154701
3 -1.154701 -1.000000
4  0.577350 -0.577350
5  0.577350  1.000000
```

Broadcast result of the transformation

```
>>> grouped.transform(lambda x: x.max() - x.min())
   C      D
0  4  6.0
1  3  8.0
2  4  6.0
3  3  8.0
4  4  6.0
5  3  8.0
```

Changed in version 1.3.0: The resulting dtype will reflect the return value of the passed func, for example:

```
>>> grouped[['C', 'D']].transform(lambda x: x.astype(int).max())
   C      D
0  5  8
1  5  9
2  5  8
3  5  9
4  5  8
5  5  9
```

pandas.core.groupby.DataFrameGroupBy.transform

`DataFrameGroupBy.transform(func, *args, engine=None, engine_kwargs=None, **kwargs)`

Call function producing a like-indexed DataFrame on each group and return a DataFrame having the same indexes as the original object filled with the transformed values

Parameters

f [function] Function to apply to each group.

Can also accept a Numba JIT function with `engine='numba'` specified.

If the 'numba' engine is chosen, the function must be a user defined function with `values` and `index` as the first and second arguments respectively in the function signature. Each group's index will be passed to the user defined function and optionally

available for use.

Changed in version 1.1.0.

***args** Positional arguments to pass to func.

engine [str, default None]

- 'cython' : Runs the function through C-extensions from cython.
- 'numba' : Runs the function through JIT compiled code from numba.
- None : Defaults to 'cython' or the global setting `compute.use_numba`

New in version 1.1.0.

engine_kwargs [dict, default None]

- For 'cython' engine, there are no accepted `engine_kwargs`
- For 'numba' engine, the engine can accept `nopython`, `nogil` and `parallel` dictionary keys. The values must either be `True` or `False`. The default `engine_kwargs` for the 'numba' engine is `{'nopython': True, 'nogil': False, 'parallel': False}` and will be applied to the function

New in version 1.1.0.

****kwargs** Keyword arguments to be passed into func.

Returns

DataFrame

See also:

DataFrame.groupby.apply Apply function `func` group-wise and combine the results together.

DataFrame.groupby.aggregate Aggregate using one or more operations over the specified axis.

DataFrame.transform Call `func` on self producing a DataFrame with transformed values.

Notes

Each group is endowed the attribute `'name'` in case you need to know which group you are working on.

The current implementation imposes three requirements on `f`:

- `f` must return a value that either has the same shape as the input subframe or can be broadcast to the shape of the input subframe. For example, if `f` returns a scalar it will be broadcast to have the same shape as the input subframe.
- if this is a DataFrame, `f` must support application column-by-column in the subframe. If `f` also supports application to the entire subframe, then a fast path is used starting from the second chunk.
- `f` must not mutate groups. Mutation is not supported and may produce unexpected results. See [Mutating with User Defined Function \(UDF\) methods](#) for more details.

When using `engine='numba'`, there will be no “fall back” behavior internally. The group data and group index will be passed as numpy arrays to the JITed user defined function, and no alternative execution attempts will be tried.

Changed in version 1.3.0: The resulting dtype will reflect the return value of the passed `func`, see the examples below.

Examples

```
>>> df = pd.DataFrame({'A' : ['foo', 'bar', 'foo', 'bar',
...                           'foo', 'bar'],
...                   'B' : ['one', 'one', 'two', 'three',
...                           'two', 'two'],
...                   'C' : [1, 5, 5, 2, 5, 5],
...                   'D' : [2.0, 5., 8., 1., 2., 9.]})
>>> grouped = df.groupby('A')
>>> grouped.transform(lambda x: (x - x.mean()) / x.std())
   C      D
0 -1.154701 -0.577350
1  0.577350  0.000000
2  0.577350  1.154701
3 -1.154701 -1.000000
4  0.577350 -0.577350
5  0.577350  1.000000
```

Broadcast result of the transformation

```
>>> grouped.transform(lambda x: x.max() - x.min())
   C      D
0  4  6.0
1  3  8.0
2  4  6.0
3  3  8.0
4  4  6.0
5  3  8.0
```

Changed in version 1.3.0: The resulting dtype will reflect the return value of the passed func, for example:

```
>>> grouped[['C', 'D']].transform(lambda x: x.astype(int).max())
   C      D
0  5  8
1  5  9
2  5  8
3  5  9
4  5  8
5  5  9
```

pandas.core.groupby.GroupBy.pipe

GroupBy.pipe(*func*, **args*, ***kwargs*)

Apply a function *func* with arguments to this GroupBy object and return the function's result.

Use *.pipe* when you want to improve readability by chaining together functions that expect Series, DataFrames, GroupBy or Resampler objects. Instead of writing

```
>>> h(g(f(df.groupby('group')), arg1=a), arg2=b, arg3=c)
```

You can write

```
>>> (df.groupby('group')
...   .pipe(f)
...   .pipe(g, arg1=a)
...   .pipe(h, arg2=b, arg3=c))
```

which is much more readable.

Parameters

func [callable or tuple of (callable, str)] Function to apply to this GroupBy object or, alternatively, a (callable, data_keyword) tuple where *data_keyword* is a string indicating the keyword of *callable* that expects the GroupBy object.

args [iterable, optional] Positional arguments passed into *func*.

kwargs [dict, optional] A dictionary of keyword arguments passed into *func*.

Returns

object [the return type of *func*.]

See also:

Series.pipe Apply a function with arguments to a series.

DataFrame.pipe Apply a function with arguments to a dataframe.

apply Apply function to each group instead of to the full GroupBy object.

Notes

See more [here](#)

Examples

```
>>> df = pd.DataFrame({'A': 'a b a b'.split(), 'B': [1, 2, 3, 4]})
>>> df
   A  B
0  a  1
1  b  2
2  a  3
3  b  4
```

To get the difference between each groups maximum and minimum value in one pass, you can do

```
>>> df.groupby('A').pipe(lambda x: x.max() - x.min())
   B
A
a  2
b  2
```

3.10.3 Computations / descriptive stats

| | |
|--|--|
| <code>GroupBy.all([skipna])</code> | Return True if all values in the group are truthful, else False. |
| <code>GroupBy.any([skipna])</code> | Return True if any value in the group is truthful, else False. |
| <code>GroupBy.bfill([limit])</code> | Backward fill the values. |
| <code>GroupBy.backfill([limit])</code> | Backward fill the values. |
| <code>GroupBy.count()</code> | Compute count of group, excluding missing values. |
| <code>GroupBy.cumcount([ascending])</code> | Number each item in each group from 0 to the length of that group - 1. |
| <code>GroupBy.cummax([axis])</code> | Cumulative max for each group. |
| <code>GroupBy.cummin([axis])</code> | Cumulative min for each group. |
| <code>GroupBy.cumprod([axis])</code> | Cumulative product for each group. |
| <code>GroupBy.cumsum([axis])</code> | Cumulative sum for each group. |
| <code>GroupBy.ffill([limit])</code> | Forward fill the values. |
| <code>GroupBy.first([numeric_only, min_count])</code> | Compute first of group values. |
| <code>GroupBy.head([n])</code> | Return first n rows of each group. |
| <code>GroupBy.last([numeric_only, min_count])</code> | Compute last of group values. |
| <code>GroupBy.max([numeric_only, min_count])</code> | Compute max of group values. |
| <code>GroupBy.mean([numeric_only])</code> | Compute mean of groups, excluding missing values. |
| <code>GroupBy.median([numeric_only])</code> | Compute median of groups, excluding missing values. |
| <code>GroupBy.min([numeric_only, min_count])</code> | Compute min of group values. |
| <code>GroupBy.ngroup([ascending])</code> | Number each group from 0 to the number of groups - 1. |
| <code>GroupBy.nth([n, dropna])</code> | Take the nth row from each group if n is an int, or a subset of rows if n is a list of ints. |
| <code>GroupBy.ohlc()</code> | Compute open, high, low and close values of a group, excluding missing values. |
| <code>GroupBy.pad([limit])</code> | Forward fill the values. |
| <code>GroupBy.prod([numeric_only, min_count])</code> | Compute prod of group values. |
| <code>GroupBy.rank([method, ascending, na_option, ...])</code> | Provide the rank of values within each group. |
| <code>GroupBy.pct_change([periods, fill_method, ...])</code> | Calculate pct_change of each value to previous entry in group. |
| <code>GroupBy.size()</code> | Compute group sizes. |
| <code>GroupBy.sem([ddof])</code> | Compute standard error of the mean of groups, excluding missing values. |
| <code>GroupBy.std([ddof])</code> | Compute standard deviation of groups, excluding missing values. |
| <code>GroupBy.sum([numeric_only, min_count])</code> | Compute sum of group values. |
| <code>GroupBy.var([ddof])</code> | Compute variance of groups, excluding missing values. |
| <code>GroupBy.tail([n])</code> | Return last n rows of each group. |

pandas.core.groupby.GroupBy.all

GroupBy.**all**(*skipna=True*)

Return True if all values in the group are truthful, else False.

Parameters

skipna [bool, default True] Flag to ignore nan values during truth testing.

Returns

Series or DataFrame DataFrame or Series of boolean values, where a value is True if all elements are True within its respective group, False otherwise.

See also:

Series.groupby Apply a function groupby to a Series.

DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

pandas.core.groupby.GroupBy.any

GroupBy.**any**(*skipna=True*)

Return True if any value in the group is truthful, else False.

Parameters

skipna [bool, default True] Flag to ignore nan values during truth testing.

Returns

Series or DataFrame DataFrame or Series of boolean values, where a value is True if any element is True within its respective group, False otherwise.

See also:

Series.groupby Apply a function groupby to a Series.

DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

pandas.core.groupby.GroupBy.bfill

GroupBy.**bfill**(*limit=None*)

Backward fill the values.

Parameters

limit [int, optional] Limit of how many values to fill.

Returns

Series or DataFrame Object with missing values filled.

See also:

Series.backfill Backward fill the missing values in the dataset.

DataFrame.backfill Backward fill the missing values in the dataset.

Series.fillna Fill NaN values of a Series.

DataFrame.fillna Fill NaN values of a DataFrame.

pandas.core.groupby.GroupBy.backfill**GroupBy.backfill** (*limit=None*)

Backward fill the values.

Parameters**limit** [int, optional] Limit of how many values to fill.**Returns****Series or DataFrame** Object with missing values filled.**See also:****Series.backfill** Backward fill the missing values in the dataset.**DataFrame.backfill** Backward fill the missing values in the dataset.**Series.fillna** Fill NaN values of a Series.**DataFrame.fillna** Fill NaN values of a DataFrame.**pandas.core.groupby.GroupBy.count****GroupBy.count** ()

Compute count of group, excluding missing values.

Returns**Series or DataFrame** Count of values within each group.**See also:****Series.groupby** Apply a function groupby to a Series.**DataFrame.groupby** Apply a function groupby to each row or column of a DataFrame.**pandas.core.groupby.GroupBy.cumcount****GroupBy.cumcount** (*ascending=True*)

Number each item in each group from 0 to the length of that group - 1.

Essentially this is equivalent to

```
self.apply(lambda x: pd.Series(np.arange(len(x)), x.index))
```

Parameters**ascending** [bool, default True] If False, number in reverse, from length of group - 1 to 0.**Returns****Series** Sequence number of each element within each group.**See also:****ngroup** Number the groups themselves.

Examples

```

>>> df = pd.DataFrame([[ 'a'], [ 'a'], [ 'a'], [ 'b'], [ 'b'], [ 'a']],
...                    columns=[ 'A'])
>>> df
   A
0  a
1  a
2  a
3  b
4  b
5  a
>>> df.groupby('A').cumcount()
0    0
1    1
2    2
3    0
4    1
5    3
dtype: int64
>>> df.groupby('A').cumcount(ascending=False)
0    3
1    2
2    1
3    1
4    0
5    0
dtype: int64

```

pandas.core.groupby.GroupBy.cummax

GroupBy.**cummax**(*axis=0*, ***kwargs*)
Cumulative max for each group.

Returns

Series or DataFrame

See also:

Series.groupby Apply a function groupby to a Series.

DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

pandas.core.groupby.GroupBy.cummin

GroupBy.**cummin**(*axis=0*, ***kwargs*)
Cumulative min for each group.

Returns

Series or DataFrame

See also:

Series.groupby Apply a function groupby to a Series.

DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

pandas.core.groupby.GroupBy.cumprod

GroupBy.**cumprod**(*axis=0, *args, **kwargs*)

Cumulative product for each group.

Returns

Series or DataFrame

See also:

Series.groupby Apply a function groupby to a Series.

DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

pandas.core.groupby.GroupBy.cumsum

GroupBy.**cumsum**(*axis=0, *args, **kwargs*)

Cumulative sum for each group.

Returns

Series or DataFrame

See also:

Series.groupby Apply a function groupby to a Series.

DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

pandas.core.groupby.GroupBy.ffill

GroupBy.**ffill**(*limit=None*)

Forward fill the values.

Parameters

limit [int, optional] Limit of how many values to fill.

Returns

Series or DataFrame Object with missing values filled.

See also:

Series.pad Returns Series with minimum number of char in object.

DataFrame.pad Object with missing values filled or None if inplace=True.

Series.fillna Fill NaN values of a Series.

DataFrame.fillna Fill NaN values of a DataFrame.

pandas.core.groupby.GroupBy.first

GroupBy.**first**(*numeric_only=False, min_count=-1*)

Compute first of group values.

Parameters

numeric_only [bool, default False] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

min_count [int, default -1] The required number of valid values to perform the operation. If fewer than min_count non-NA values are present the result will be NA.

Returns

Series or DataFrame Computed first of values within each group.

pandas.core.groupby.GroupBy.head

GroupBy.**head**(*n*=5)

Return first *n* rows of each group.

Similar to `.apply(lambda x: x.head(n))`, but it returns a subset of rows from the original DataFrame with original index and order preserved (`as_index` flag is ignored).

Does not work for negative values of *n*.

Returns

Series or DataFrame

See also:

Series.groupby Apply a function groupby to a Series.

DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

Examples

```
>>> df = pd.DataFrame([[1, 2], [1, 4], [5, 6]],
...                   columns=['A', 'B'])
>>> df.groupby('A').head(1)
   A  B
0  1  2
2  5  6
>>> df.groupby('A').head(-1)
Empty DataFrame
Columns: [A, B]
Index: []
```

pandas.core.groupby.GroupBy.last

GroupBy.**last**(*numeric_only*=False, *min_count*=-1)

Compute last of group values.

Parameters

numeric_only [bool, default False] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

min_count [int, default -1] The required number of valid values to perform the operation. If fewer than `min_count` non-NA values are present the result will be NA.

Returns

Series or DataFrame Computed last of values within each group.

pandas.core.groupby.GroupBy.max

GroupBy.**max**(*numeric_only=False, min_count=-1*)

Compute max of group values.

Parameters

numeric_only [bool, default False] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

min_count [int, default -1] The required number of valid values to perform the operation. If fewer than `min_count` non-NA values are present the result will be NA.

Returns

Series or DataFrame Computed max of values within each group.

pandas.core.groupby.GroupBy.mean

GroupBy.**mean**(*numeric_only=NoDefault.no_default*)

Compute mean of groups, excluding missing values.

Parameters

numeric_only [bool, default True] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

Returns

pandas.Series or pandas.DataFrame

See also:

Series.groupby Apply a function groupby to a Series.

DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

Examples

```
>>> df = pd.DataFrame({'A': [1, 1, 2, 1, 2],
...                    'B': [np.nan, 2, 3, 4, 5],
...                    'C': [1, 2, 1, 1, 2]}, columns=['A', 'B', 'C'])
```

Groupby one column and return the mean of the remaining columns in each group.

```
>>> df.groupby('A').mean()
   B      C
A
1  3.0  1.333333
2  4.0  1.500000
```

Groupby two columns and return the mean of the remaining column.

```
>>> df.groupby(['A', 'B']).mean()
   C
A B
1  2.0  2.0
   4.0  1.0
2  3.0  1.0
   5.0  2.0
```

Groupby one column and return the mean of only particular column in the group.

```
>>> df.groupby('A')['B'].mean()
A
1    3.0
2    4.0
Name: B, dtype: float64
```

pandas.core.groupby.GroupBy.median

GroupBy.**median**(*numeric_only=NoDefault.no_default*)

Compute median of groups, excluding missing values.

For multiple groupings, the result index will be a MultiIndex

Parameters

numeric_only [bool, default True] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

Returns

Series or DataFrame Median of values within each group.

See also:

Series.groupby Apply a function groupby to a Series.

DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

pandas.core.groupby.GroupBy.min

GroupBy.**min**(*numeric_only=False, min_count=-1*)

Compute min of group values.

Parameters

numeric_only [bool, default False] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

min_count [int, default -1] The required number of valid values to perform the operation. If fewer than `min_count` non-NA values are present the result will be NA.

Returns

Series or DataFrame Computed min of values within each group.

pandas.core.groupby.GroupBy.ngroup

GroupBy.**ngroup**(*ascending=True*)

Number each group from 0 to the number of groups - 1.

This is the enumerative complement of `cumcount`. Note that the numbers given to the groups match the order in which the groups would be seen when iterating over the groupby object, not the order they are first observed.

Parameters

ascending [bool, default True] If False, number in reverse, from number of group - 1 to 0.

Returns

Series Unique numbers for each group.

See also:

cumcount Number the rows in each group.

Examples

```
>>> df = pd.DataFrame({"A": list("aaabba")})
>>> df
   A
0  a
1  a
2  a
3  b
4  b
5  a
>>> df.groupby('A').ngroup()
0    0
1    0
2    0
3    1
4    1
5    0
dtype: int64
>>> df.groupby('A').ngroup(ascending=False)
0    1
1    1
2    1
3    0
4    0
5    1
dtype: int64
>>> df.groupby(["A", [1,1,2,3,2,1]]).ngroup()
0    0
1    0
2    1
3    3
4    2
5    0
dtype: int64
```

pandas.core.groupby.GroupBy.nth

GroupBy.nth(*n*, *dropna=None*)

Take the *n*th row from each group if *n* is an int, or a subset of rows if *n* is a list of ints.

If *dropna*, will take the *n*th non-null row, *dropna* is either 'all' or 'any'; this is equivalent to calling `dropna(how=dropna)` before the groupby.

Parameters

n [int or list of ints] A single *n*th value for the row or a list of *n*th values.

dropna [{'any', 'all', None}, default None] Apply the specified *dropna* operation before counting which row is the *n*th row.

Returns

Series or DataFrame N-th value within each group.

See also:

Series.groupby Apply a function groupby to a Series.

DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

Examples

```
>>> df = pd.DataFrame({'A': [1, 1, 2, 1, 2],
...                    'B': [np.nan, 2, 3, 4, 5]}, columns=['A', 'B'])
>>> g = df.groupby('A')
>>> g.nth(0)
   B
A
1 NaN
2 3.0
>>> g.nth(1)
   B
A
1 2.0
2 5.0
>>> g.nth(-1)
   B
A
1 4.0
2 5.0
>>> g.nth([0, 1])
   B
A
1 NaN
1 2.0
2 3.0
2 5.0
```

Specifying *dropna* allows count ignoring NaN

```
>>> g.nth(0, dropna='any')
   B
A
1 2.0
2 3.0
```

NaNs denote group exhausted when using *dropna*

```
>>> g.nth(3, dropna='any')
   B
A
1 NaN
2 NaN
```

Specifying *as_index=False* in *groupby* keeps the original index.

```
>>> df.groupby('A', as_index=False).nth(1)
   A  B
1  1  2.0
4  2  5.0
```

pandas.core.groupby.GroupBy.ohlc

GroupBy.ohlc()

Compute open, high, low and close values of a group, excluding missing values.

For multiple groupings, the result index will be a MultiIndex

Returns

DataFrame Open, high, low and close values within each group.

See also:

Series.groupby Apply a function groupby to a Series.

DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

pandas.core.groupby.GroupBy.pad

GroupBy.pad(*limit=None*)

Forward fill the values.

Parameters

limit [int, optional] Limit of how many values to fill.

Returns

Series or DataFrame Object with missing values filled.

See also:

Series.pad Returns Series with minimum number of char in object.

DataFrame.pad Object with missing values filled or None if inplace=True.

Series.fillna Fill NaN values of a Series.

DataFrame.fillna Fill NaN values of a DataFrame.

pandas.core.groupby.GroupBy.prod

GroupBy.prod(*numeric_only=NoDefault.no_default, min_count=0*)

Compute prod of group values.

Parameters

numeric_only [bool, default True] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

min_count [int, default 0] The required number of valid values to perform the operation. If fewer than min_count non-NA values are present the result will be NA.

Returns

Series or DataFrame Computed prod of values within each group.

pandas.core.groupby.GroupBy.rank

GroupBy.**rank**(*method='average', ascending=True, na_option='keep', pct=False, axis=0*)

Provide the rank of values within each group.

Parameters

method [{ 'average', 'min', 'max', 'first', 'dense' }, default 'average']

- average: average rank of group.
- min: lowest rank in group.
- max: highest rank in group.
- first: ranks assigned in order they appear in the array.
- dense: like 'min', but rank always increases by 1 between groups.

ascending [bool, default True] False for ranks by high (1) to low (N).

na_option [{ 'keep', 'top', 'bottom' }, default 'keep']

- keep: leave NA values where they are.
- top: smallest rank if ascending.
- bottom: smallest rank if descending.

pct [bool, default False] Compute percentage rank of data within each group.

axis [int, default 0] The axis of the object over which to compute the rank.

Returns

DataFrame with ranking of values within each group

See also:

Series.groupby Apply a function groupby to a Series.

DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

pandas.core.groupby.GroupBy.pct_change

GroupBy.**pct_change**(*periods=1, fill_method='pad', limit=None, freq=None, axis=0*)

Calculate pct_change of each value to previous entry in group.

Returns

Series or DataFrame Percentage changes within each group.

See also:

Series.groupby Apply a function groupby to a Series.

DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

pandas.core.groupby.GroupBy.size

GroupBy.size()

Compute group sizes.

Returns

DataFrame or Series Number of rows in each group as a Series if as_index is True or a DataFrame if as_index is False.

See also:

Series.groupby Apply a function groupby to a Series.

DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

pandas.core.groupby.GroupBy.sem

GroupBy.sem(ddof=1)

Compute standard error of the mean of groups, excluding missing values.

For multiple groupings, the result index will be a MultiIndex.

Parameters

ddof [int, default 1] Degrees of freedom.

Returns

Series or DataFrame Standard error of the mean of values within each group.

See also:

Series.groupby Apply a function groupby to a Series.

DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

pandas.core.groupby.GroupBy.std

GroupBy.std(ddof=1)

Compute standard deviation of groups, excluding missing values.

For multiple groupings, the result index will be a MultiIndex.

Parameters

ddof [int, default 1] Degrees of freedom.

Returns

Series or DataFrame Standard deviation of values within each group.

See also:

Series.groupby Apply a function groupby to a Series.

DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

pandas.core.groupby.GroupBy.sum

GroupBy.**sum**(*numeric_only=NoDefault.no_default, min_count=0*)

Compute sum of group values.

Parameters

numeric_only [bool, default True] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

min_count [int, default 0] The required number of valid values to perform the operation. If fewer than **min_count** non-NA values are present the result will be NA.

Returns

Series or DataFrame Computed sum of values within each group.

pandas.core.groupby.GroupBy.var

GroupBy.**var**(*ddof=1*)

Compute variance of groups, excluding missing values.

For multiple groupings, the result index will be a MultiIndex.

Parameters

ddof [int, default 1] Degrees of freedom.

Returns

Series or DataFrame Variance of values within each group.

See also:

Series.groupby Apply a function groupby to a Series.

DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

pandas.core.groupby.GroupBy.tail

GroupBy.**tail**(*n=5*)

Return last *n* rows of each group.

Similar to `.apply(lambda x: x.tail(n))`, but it returns a subset of rows from the original DataFrame with original index and order preserved (`as_index` flag is ignored).

Does not work for negative values of *n*.

Returns

Series or DataFrame

See also:

Series.groupby Apply a function groupby to a Series.

DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

Examples

```
>>> df = pd.DataFrame([[ 'a', 1], [ 'a', 2], [ 'b', 1], [ 'b', 2]],
...                    columns=[ 'A', 'B'])
>>> df.groupby('A').tail(1)
   A  B
1  a  2
3  b  2
>>> df.groupby('A').tail(-1)
Empty DataFrame
Columns: [A, B]
Index: []
```

The following methods are available in both `SeriesGroupBy` and `DataFrameGroupBy` objects, but may differ slightly, usually in that the `DataFrameGroupBy` version usually permits the specification of an axis argument, and often an argument indicating whether to restrict application to columns of a specific data type.

| | |
|--|---|
| <code>DataFrameGroupBy.all([skipna])</code> | Return True if all values in the group are truthful, else False. |
| <code>DataFrameGroupBy.any([skipna])</code> | Return True if any value in the group is truthful, else False. |
| <code>DataFrameGroupBy.backfill([limit])</code> | Backward fill the values. |
| <code>DataFrameGroupBy.bfill([limit])</code> | Backward fill the values. |
| <code>DataFrameGroupBy.corr</code> | Compute pairwise correlation of columns, excluding NA/null values. |
| <code>DataFrameGroupBy.count()</code> | Compute count of group, excluding missing values. |
| <code>DataFrameGroupBy.cov</code> | Compute pairwise covariance of columns, excluding NA/null values. |
| <code>DataFrameGroupBy.cumcount([ascending])</code> | Number each item in each group from 0 to the length of that group - 1. |
| <code>DataFrameGroupBy.cummax([axis])</code> | Cumulative max for each group. |
| <code>DataFrameGroupBy.cummin([axis])</code> | Cumulative min for each group. |
| <code>DataFrameGroupBy.cumprod([axis])</code> | Cumulative product for each group. |
| <code>DataFrameGroupBy.cumsum([axis])</code> | Cumulative sum for each group. |
| <code>DataFrameGroupBy.describe(**kwargs)</code> | Generate descriptive statistics. |
| <code>DataFrameGroupBy.diff</code> | First discrete difference of element. |
| <code>DataFrameGroupBy.ffill([limit])</code> | Forward fill the values. |
| <code>DataFrameGroupBy.fillna</code> | Fill NA/NaN values using the specified method. |
| <code>DataFrameGroupBy.filter(func[, dropna])</code> | Return a copy of a DataFrame excluding filtered elements. |
| <code>DataFrameGroupBy.hist</code> | Make a histogram of the DataFrame's columns. |
| <code>DataFrameGroupBy.idxmax([axis, skipna])</code> | Return index of first occurrence of maximum over requested axis. |
| <code>DataFrameGroupBy.idxmin([axis, skipna])</code> | Return index of first occurrence of minimum over requested axis. |
| <code>DataFrameGroupBy.mad</code> | Return the mean absolute deviation of the values over the requested axis. |
| <code>DataFrameGroupBy.nunique([dropna])</code> | Return DataFrame with counts of unique elements in each position. |
| <code>DataFrameGroupBy.pad([limit])</code> | Forward fill the values. |
| <code>DataFrameGroupBy.pct_change([periods, ...])</code> | Calculate pct_change of each value to previous entry in group. |

continues on next page

Table 381 – continued from previous page

| | |
|--|---|
| <code>DataFrameGroupBy.plot</code> | Class implementing the <code>.plot</code> attribute for groupby objects. |
| <code>DataFrameGroupBy.quantile</code> ([q, interpolation]) | Return group values at the given quantile, a la <code>numpy.percentile</code> . |
| <code>DataFrameGroupBy.rank</code> ([method, ascending, ...]) | Provide the rank of values within each group. |
| <code>DataFrameGroupBy.resample</code> (rule, *args, **kwargs) | Provide resampling when using a <code>TimeGrouper</code> . |
| <code>DataFrameGroupBy.sample</code> ([n, frac, replace, ...]) | Return a random sample of items from each group. |
| <code>DataFrameGroupBy.shift</code> ([periods, freq, ...]) | Shift each group by periods observations. |
| <code>DataFrameGroupBy.size</code> () | Compute group sizes. |
| <code>DataFrameGroupBy.skew</code> | Return unbiased skew over requested axis. |
| <code>DataFrameGroupBy.take</code> | Return the elements in the given <i>positional</i> indices along an axis. |
| <code>DataFrameGroupBy.tshift</code> | (DEPRECATED) Shift the time index, using the index's frequency if available. |

pandas.core.groupby.DataFrameGroupBy.all

`DataFrameGroupBy.all`(*skipna=True*)

Return True if all values in the group are truthful, else False.

Parameters

skipna [bool, default True] Flag to ignore nan values during truth testing.

Returns

Series or DataFrame DataFrame or Series of boolean values, where a value is True if all elements are True within its respective group, False otherwise.

See also:

Series.groupby Apply a function groupby to a Series.

DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

pandas.core.groupby.DataFrameGroupBy.any

`DataFrameGroupBy.any`(*skipna=True*)

Return True if any value in the group is truthful, else False.

Parameters

skipna [bool, default True] Flag to ignore nan values during truth testing.

Returns

Series or DataFrame DataFrame or Series of boolean values, where a value is True if any element is True within its respective group, False otherwise.

See also:

Series.groupby Apply a function groupby to a Series.

DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

pandas.core.groupby.DataFrameGroupBy.backfill

`DataFrameGroupBy.backfill` (*limit=None*)

Backward fill the values.

Parameters

limit [int, optional] Limit of how many values to fill.

Returns

Series or DataFrame Object with missing values filled.

See also:

Series.backfill Backward fill the missing values in the dataset.

DataFrame.backfill Backward fill the missing values in the dataset.

Series.fillna Fill NaN values of a Series.

DataFrame.fillna Fill NaN values of a DataFrame.

pandas.core.groupby.DataFrameGroupBy.bfill

`DataFrameGroupBy.bfill` (*limit=None*)

Backward fill the values.

Parameters

limit [int, optional] Limit of how many values to fill.

Returns

Series or DataFrame Object with missing values filled.

See also:

Series.backfill Backward fill the missing values in the dataset.

DataFrame.backfill Backward fill the missing values in the dataset.

Series.fillna Fill NaN values of a Series.

DataFrame.fillna Fill NaN values of a DataFrame.

pandas.core.groupby.DataFrameGroupBy.corr

property `DataFrameGroupBy.corr`

Compute pairwise correlation of columns, excluding NA/null values.

Parameters

method [{‘pearson’, ‘kendall’, ‘spearman’} or callable] Method of correlation:

- **pearson** : standard correlation coefficient
- **kendall** : Kendall Tau correlation coefficient
- **spearman** : Spearman rank correlation
- **callable**: **callable with input two 1d ndarrays** and returning a float. Note that the returned matrix from `corr` will have 1 along the diagonals and will be symmetric regardless of the callable’s behavior.

min_periods [int, optional] Minimum number of observations required per pair of columns to have a valid result. Currently only available for Pearson and Spearman correlation.

Returns

DataFrame Correlation matrix.

See also:

DataFrame.corrwith Compute pairwise correlation with another DataFrame or Series.

Series.corr Compute the correlation between two Series.

Examples

```
>>> def histogram_intersection(a, b):
...     v = np.minimum(a, b).sum().round(decimals=1)
...     return v
>>> df = pd.DataFrame([(0.2, 0.3), (0.0, 0.6), (0.6, 0.0), (0.2, 0.1)],
...                   columns=['dogs', 'cats'])
>>> df.corr(method=histogram_intersection)
      dogs  cats
dogs  1.0   0.3
cats  0.3   1.0
```

pandas.core.groupby.DataFrameGroupBy.count

DataFrameGroupBy.**count**()

Compute count of group, excluding missing values.

Returns

DataFrame Count of values within each group.

pandas.core.groupby.DataFrameGroupBy.cov

property DataFrameGroupBy.cov

Compute pairwise covariance of columns, excluding NA/null values.

Compute the pairwise covariance among the series of a DataFrame. The returned data frame is the **covariance matrix** of the columns of the DataFrame.

Both NA and null values are automatically excluded from the calculation. (See the note below about bias from missing values.) A threshold can be set for the minimum number of observations for each value created. Comparisons with observations below this threshold will be returned as NaN.

This method is generally used for the analysis of time series data to understand the relationship between different measures across time.

Parameters

min_periods [int, optional] Minimum number of observations required per pair of columns to have a valid result.

ddof [int, default 1] Delta degrees of freedom. The divisor used in calculations is $N - \text{ddof}$, where N represents the number of elements.

New in version 1.1.0.

Returns

DataFrame The covariance matrix of the series of the DataFrame.

See also:

Series.cov Compute covariance with another Series.

core.window.ExponentialMovingWindow.cov Exponential weighted sample covariance.

core.window.Expanding.cov Expanding sample covariance.

core.window.Rolling.cov Rolling sample covariance.

Notes

Returns the covariance matrix of the DataFrame's time series. The covariance is normalized by N-ddof.

For DataFrames that have Series that are missing data (assuming that data is [missing at random](#)) the returned covariance matrix will be an unbiased estimate of the variance and covariance between the member Series.

However, for many applications this estimate may not be acceptable because the estimate covariance matrix is not guaranteed to be positive semi-definite. This could lead to estimate correlations having absolute values which are greater than one, and/or a non-invertible covariance matrix. See [Estimation of covariance matrices](#) for more details.

Examples

```
>>> df = pd.DataFrame([(1, 2), (0, 3), (2, 0), (1, 1)],
...                    columns=['dogs', 'cats'])
>>> df.cov()
           dogs      cats
dogs  0.666667 -1.000000
cats -1.000000  1.666667
```

```
>>> np.random.seed(42)
>>> df = pd.DataFrame(np.random.randn(1000, 5),
...                    columns=['a', 'b', 'c', 'd', 'e'])
>>> df.cov()
           a          b          c          d          e
a  0.998438 -0.020161  0.059277 -0.008943  0.014144
b -0.020161  1.059352 -0.008543 -0.024738  0.009826
c  0.059277 -0.008543  1.010670 -0.001486 -0.000271
d -0.008943 -0.024738 -0.001486  0.921297 -0.013692
e  0.014144  0.009826 -0.000271 -0.013692  0.977795
```

Minimum number of periods

This method also supports an optional `min_periods` keyword that specifies the required minimum number of non-NA observations for each column pair in order to have a valid result:

```
>>> np.random.seed(42)
>>> df = pd.DataFrame(np.random.randn(20, 3),
...                    columns=['a', 'b', 'c'])
>>> df.loc[df.index[:5], 'a'] = np.nan
>>> df.loc[df.index[5:10], 'b'] = np.nan
>>> df.cov(min_periods=12)
           a          b          c
a  0.316741      NaN -0.150812
b      NaN  1.248003  0.191417
c -0.150812  0.191417  0.895202
```

pandas.core.groupby.DataFrameGroupBy.cumcount

DataFrameGroupBy.**cumcount** (*ascending=True*)

Number each item in each group from 0 to the length of that group - 1.

Essentially this is equivalent to

```
self.apply(lambda x: pd.Series(np.arange(len(x)), x.index))
```

Parameters

ascending [bool, default True] If False, number in reverse, from length of group - 1 to 0.

Returns

Series Sequence number of each element within each group.

See also:

ngroup Number the groups themselves.

Examples

```
>>> df = pd.DataFrame([[ 'a'], [ 'a'], [ 'a'], [ 'b'], [ 'b'], [ 'a']],
...                    columns=[ 'A'])
>>> df
   A
0  a
1  a
2  a
3  b
4  b
5  a
>>> df.groupby('A').cumcount()
0    0
1    1
2    2
3    0
4    1
5    3
dtype: int64
>>> df.groupby('A').cumcount(ascending=False)
0    3
1    2
2    1
3    1
4    0
5    0
dtype: int64
```

pandas.core.groupby.DataFrameGroupBy.cummax

DataFrameGroupBy.**cummax**(axis=0, **kwargs)
Cumulative max for each group.

Returns

Series or DataFrame

See also:

Series.groupby Apply a function groupby to a Series.

DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

pandas.core.groupby.DataFrameGroupBy.cummin

DataFrameGroupBy.**cummin**(axis=0, **kwargs)
Cumulative min for each group.

Returns

Series or DataFrame

See also:

Series.groupby Apply a function groupby to a Series.

DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

pandas.core.groupby.DataFrameGroupBy.cumprod

DataFrameGroupBy.**cumprod**(axis=0, *args, **kwargs)
Cumulative product for each group.

Returns

Series or DataFrame

See also:

Series.groupby Apply a function groupby to a Series.

DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

pandas.core.groupby.DataFrameGroupBy.cumsum

DataFrameGroupBy.**cumsum**(axis=0, *args, **kwargs)
Cumulative sum for each group.

Returns

Series or DataFrame

See also:

Series.groupby Apply a function groupby to a Series.

DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

pandas.core.groupby.DataFrameGroupBy.describe

DataFrameGroupBy.**describe**(**kwargs)

Generate descriptive statistics.

Descriptive statistics include those that summarize the central tendency, dispersion and shape of a dataset's distribution, excluding NaN values.

Analyzes both numeric and object series, as well as DataFrame column sets of mixed data types. The output will vary depending on what is provided. Refer to the notes below for more detail.

Parameters

percentiles [list-like of numbers, optional] The percentiles to include in the output. All should fall between 0 and 1. The default is [.25, .5, .75], which returns the 25th, 50th, and 75th percentiles.

include ['all', list-like of dtypes or None (default), optional] A white list of data types to include in the result. Ignored for Series. Here are the options:

- 'all': All columns of the input will be included in the output.
- A list-like of dtypes: Limits the results to the provided data types. To limit the result to numeric types submit `numpy.number`. To limit it instead to object columns submit the `numpy.object` data type. Strings can also be used in the style of `select_dtypes` (e.g. `df.describe(include=['O'])`). To select pandas categorical columns, use 'category'
- None (default): The result will include all numeric columns.

exclude [list-like of dtypes or None (default), optional,] A black list of data types to omit from the result. Ignored for Series. Here are the options:

- A list-like of dtypes: Excludes the provided data types from the result. To exclude numeric types submit `numpy.number`. To exclude object columns submit the data type `numpy.object`. Strings can also be used in the style of `select_dtypes` (e.g. `df.describe(exclude=['O'])`). To exclude pandas categorical columns, use 'category'
- None (default): The result will exclude nothing.

datetime_is_numeric [bool, default False] Whether to treat datetime dtypes as numeric. This affects statistics calculated for the column. For DataFrame input, this also controls whether datetime columns are included by default.

New in version 1.1.0.

Returns

Series or DataFrame Summary statistics of the Series or Dataframe provided.

See also:

DataFrame.count Count number of non-NA/null observations.

DataFrame.max Maximum of the values in the object.

DataFrame.min Minimum of the values in the object.

DataFrame.mean Mean of the values.

DataFrame.std Standard deviation of the observations.

DataFrame.select_dtypes Subset of a DataFrame including/excluding columns based on their dtype.

Notes

For numeric data, the result's index will include `count`, `mean`, `std`, `min`, `max` as well as `lower`, `50` and upper percentiles. By default the lower percentile is 25 and the upper percentile is 75. The `50` percentile is the same as the median.

For object data (e.g. strings or timestamps), the result's index will include `count`, `unique`, `top`, and `freq`. The `top` is the most common value. The `freq` is the most common value's frequency. Timestamps also include the `first` and `last` items.

If multiple object values have the highest count, then the `count` and `top` results will be arbitrarily chosen from among those with the highest count.

For mixed data types provided via a `DataFrame`, the default is to return only an analysis of numeric columns. If the dataframe consists only of object and categorical data without any numeric columns, the default is to return an analysis of both the object and categorical columns. If `include='all'` is provided as an option, the result will include a union of attributes of each type.

The `include` and `exclude` parameters can be used to limit which columns in a `DataFrame` are analyzed for the output. The parameters are ignored when analyzing a `Series`.

Examples

Describing a numeric Series.

```
>>> s = pd.Series([1, 2, 3])
>>> s.describe()
count      3.0
mean       2.0
std        1.0
min        1.0
25%        1.5
50%        2.0
75%        2.5
max        3.0
dtype: float64
```

Describing a categorical Series.

```
>>> s = pd.Series(['a', 'a', 'b', 'c'])
>>> s.describe()
count      4
unique     3
top        a
freq       2
dtype: object
```

Describing a timestamp Series.

```
>>> s = pd.Series([
...     np.datetime64("2000-01-01"),
...     np.datetime64("2010-01-01"),
...     np.datetime64("2010-01-01")
... ])
>>> s.describe(datetime_is_numeric=True)
```

(continues on next page)

(continued from previous page)

```

count          3
mean    2006-09-01 08:00:00
min      2000-01-01 00:00:00
25%      2004-12-31 12:00:00
50%      2010-01-01 00:00:00
75%      2010-01-01 00:00:00
max       2010-01-01 00:00:00
dtype: object

```

Describing a DataFrame. By default only numeric fields are returned.

```

>>> df = pd.DataFrame({'categorical': pd.Categorical(['d', 'e', 'f']),
...                    'numeric': [1, 2, 3],
...                    'object': ['a', 'b', 'c']
...                    })
>>> df.describe()
      numeric
count      3.0
mean       2.0
std        1.0
min        1.0
25%        1.5
50%        2.0
75%        2.5
max        3.0

```

Describing all columns of a DataFrame regardless of data type.

```

>>> df.describe(include='all')
      categorical  numeric  object
count           3        3.0      3
unique          3         NaN      3
top            f         NaN      a
freq           1         NaN      1
mean           NaN        2.0     NaN
std            NaN        1.0     NaN
min            NaN        1.0     NaN
25%            NaN        1.5     NaN
50%            NaN        2.0     NaN
75%            NaN        2.5     NaN
max            NaN        3.0     NaN

```

Describing a column from a DataFrame by accessing it as an attribute.

```

>>> df.numeric.describe()
count      3.0
mean       2.0
std        1.0
min        1.0
25%        1.5
50%        2.0
75%        2.5

```

(continues on next page)

(continued from previous page)

```
max      3.0
Name: numeric, dtype: float64
```

Including only numeric columns in a DataFrame description.

```
>>> df.describe(include=[np.number])
      numeric
count      3.0
mean       2.0
std        1.0
min        1.0
25%        1.5
50%        2.0
75%        2.5
max        3.0
```

Including only string columns in a DataFrame description.

```
>>> df.describe(include=[object])
      object
count      3
unique      3
top        a
freq       1
```

Including only categorical columns from a DataFrame description.

```
>>> df.describe(include=['category'])
      categorical
count          3
unique         3
top           d
freq          1
```

Excluding numeric columns from a DataFrame description.

```
>>> df.describe(exclude=[np.number])
      categorical  object
count           3      3
unique          3      3
top            f      a
freq           1      1
```

Excluding object columns from a DataFrame description.

```
>>> df.describe(exclude=[object])
      categorical  numeric
count           3      3.0
unique          3      NaN
top            f      NaN
freq           1      NaN
mean           NaN      2.0
std            NaN      1.0
```

(continues on next page)

(continued from previous page)

| | | |
|-----|-----|-----|
| min | NaN | 1.0 |
| 25% | NaN | 1.5 |
| 50% | NaN | 2.0 |
| 75% | NaN | 2.5 |
| max | NaN | 3.0 |

pandas.core.groupby.DataFrameGroupBy.diff**property** DataFrameGroupBy.**diff**

First discrete difference of element.

Calculates the difference of a Dataframe element compared with another element in the Dataframe (default is element in previous row).

Parameters

periods [int, default 1] Periods to shift for calculating difference, accepts negative values.

axis [{0 or 'index', 1 or 'columns'}, default 0] Take difference over rows (0) or columns (1).

Returns

Dataframe First differences of the Series.

See also:

Dataframe.pct_change Percent change over given number of periods.

Dataframe.shift Shift index by desired number of periods with an optional time freq.

Series.diff First discrete difference of object.

Notes

For boolean dtypes, this uses `operator.xor()` rather than `operator.sub()`. The result is calculated according to current dtype in Dataframe, however dtype of the result is always float64.

Examples

Difference with previous row

```
>>> df = pd.DataFrame({'a': [1, 2, 3, 4, 5, 6],
...                    'b': [1, 1, 2, 3, 5, 8],
...                    'c': [1, 4, 9, 16, 25, 36]})
>>> df
   a  b  c
0  1  1  1
1  2  1  4
2  3  2  9
3  4  3 16
4  5  5 25
5  6  8 36
```

```
>>> df.diff()
   a  b  c
0 NaN NaN NaN
```

(continues on next page)

(continued from previous page)

```

1  1.0  0.0  3.0
2  1.0  1.0  5.0
3  1.0  1.0  7.0
4  1.0  2.0  9.0
5  1.0  3.0 11.0

```

Difference with previous column

```

>>> df.diff(axis=1)
   a  b  c
0 NaN 0  0
1 NaN -1 3
2 NaN -1 7
3 NaN -1 13
4 NaN  0 20
5 NaN  2 28

```

Difference with 3rd previous row

```

>>> df.diff( periods=3)
   a  b  c
0 NaN NaN NaN
1 NaN NaN NaN
2 NaN NaN NaN
3 3.0 2.0 15.0
4 3.0 4.0 21.0
5 3.0 6.0 27.0

```

Difference with following row

```

>>> df.diff( periods=-1)
   a  b  c
0 -1.0 0.0 -3.0
1 -1.0 -1.0 -5.0
2 -1.0 -1.0 -7.0
3 -1.0 -2.0 -9.0
4 -1.0 -3.0 -11.0
5 NaN NaN NaN

```

Overflow in input dtype

```

>>> df = pd.DataFrame({'a': [1, 0]}, dtype=np.uint8)
>>> df.diff()
   a
0 NaN
1 255.0

```

pandas.core.groupby.DataFrameGroupBy. ffill

DataFrameGroupBy. **ffill** (*limit=None*)

Forward fill the values.

Parameters

limit [int, optional] Limit of how many values to fill.

Returns

Series or DataFrame Object with missing values filled.

See also:

Series.pad Returns Series with minimum number of char in object.

DataFrame.pad Object with missing values filled or None if inplace=True.

Series.fillna Fill NaN values of a Series.

DataFrame.fillna Fill NaN values of a DataFrame.

pandas.core.groupby.DataFrameGroupBy.fillna

property DataFrameGroupBy. **fillna**

Fill NA/NaN values using the specified method.

Parameters

value [scalar, dict, Series, or DataFrame] Value to use to fill holes (e.g. 0), alternately a dict/Series/DataFrame of values specifying which value to use for each index (for a Series) or column (for a DataFrame). Values not in the dict/Series/DataFrame will not be filled. This value cannot be a list.

method [{‘backfill’, ‘bfill’, ‘pad’, ‘ffill’, None}, default None] Method to use for filling holes in reindexed Series pad / ffill: propagate last valid observation forward to next valid backfill / bfill: use next valid observation to fill gap.

axis [{0 or ‘index’, 1 or ‘columns’}] Axis along which to fill missing values.

inplace [bool, default False] If True, fill in-place. Note: this will modify any other views on this object (e.g., a no-copy slice for a column in a DataFrame).

limit [int, default None] If method is specified, this is the maximum number of consecutive NaN values to forward/backward fill. In other words, if there is a gap with more than this number of consecutive NaNs, it will only be partially filled. If method is not specified, this is the maximum number of entries along the entire axis where NaNs will be filled. Must be greater than 0 if not None.

downcast [dict, default is None] A dict of item->dtype of what to downcast if possible, or the string ‘infer’ which will try to downcast to an appropriate equal type (e.g. float64 to int64 if possible).

Returns

DataFrame or None Object with missing values filled or None if inplace=True.

See also:

interpolate Fill NaN values using interpolation.

reindex Conform object to new index.

asfreq Convert TimeSeries to specified frequency.

Examples

```
>>> df = pd.DataFrame([[np.nan, 2, np.nan, 0],
...                    [3, 4, np.nan, 1],
...                    [np.nan, np.nan, np.nan, 5],
...                    [np.nan, 3, np.nan, 4]],
...                    columns=list("ABCD"))
>>> df
   A    B    C  D
0 NaN  2.0 NaN  0
1  3.0  4.0 NaN  1
2 NaN  NaN NaN  5
3 NaN  3.0 NaN  4
```

Replace all NaN elements with 0s.

```
>>> df.fillna(0)
   A    B    C  D
0  0.0  2.0  0.0  0
1  3.0  4.0  0.0  1
2  0.0  0.0  0.0  5
3  0.0  3.0  0.0  4
```

We can also propagate non-null values forward or backward.

```
>>> df.fillna(method="ffill")
   A    B    C  D
0 NaN  2.0 NaN  0
1  3.0  4.0 NaN  1
2  3.0  4.0 NaN  5
3  3.0  3.0 NaN  4
```

Replace all NaN elements in column 'A', 'B', 'C', and 'D', with 0, 1, 2, and 3 respectively.

```
>>> values = {"A": 0, "B": 1, "C": 2, "D": 3}
>>> df.fillna(value=values)
   A    B    C  D
0  0.0  2.0  2.0  0
1  3.0  4.0  2.0  1
2  0.0  1.0  2.0  5
3  0.0  3.0  2.0  4
```

Only replace the first NaN element.

```
>>> df.fillna(value=values, limit=1)
   A    B    C  D
0  0.0  2.0  2.0  0
1  3.0  4.0 NaN  1
2  NaN  1.0 NaN  5
3  NaN  3.0 NaN  4
```

When filling using a DataFrame, replacement happens along the same column names and same indices

```
>>> df2 = pd.DataFrame(np.zeros((4, 4)), columns=list("ABCE"))
>>> df.fillna(df2)
   A    B    C    D
0  0.0  2.0  0.0  0
1  3.0  4.0  0.0  1
2  0.0  0.0  0.0  5
3  0.0  3.0  0.0  4
```

pandas.core.groupby.DataFrameGroupBy.filter

DataFrameGroupBy.**filter**(*func*, *dropna=True*, *args, **kwargs)

Return a copy of a DataFrame excluding filtered elements.

Elements from groups are filtered if they do not satisfy the boolean criterion specified by *func*.

Parameters

func [function] Function to apply to each subframe. Should return True or False.

dropna [Drop groups that do not pass the filter. True by default;] If False, groups that evaluate False are filled with NaNs.

Returns

filtered [DataFrame]

Notes

Each subframe is endowed the attribute 'name' in case you need to know which group you are working on.

Functions that mutate the passed object can produce unexpected behavior or errors and are not supported. See *Mutating with User Defined Function (UDF) methods* for more details.

Examples

```
>>> df = pd.DataFrame({'A' : ['foo', 'bar', 'foo', 'bar',
...                          'foo', 'bar'],
...                   'B' : [1, 2, 3, 4, 5, 6],
...                   'C' : [2.0, 5., 8., 1., 2., 9.]})
>>> grouped = df.groupby('A')
>>> grouped.filter(lambda x: x['B'].mean() > 3.)
   A  B    C
1  bar  2  5.0
3  bar  4  1.0
5  bar  6  9.0
```

pandas.core.groupby.DataFrameGroupBy.hist**property** DataFrameGroupBy.**hist**

Make a histogram of the DataFrame's columns.

A [histogram](#) is a representation of the distribution of data. This function calls `matplotlib.pyplot.hist()`, on each series in the DataFrame, resulting in one histogram per column.

Parameters

- data** [DataFrame] The pandas object holding the data.
- column** [str or sequence, optional] If passed, will be used to limit data to a subset of columns.
- by** [object, optional] If passed, then used to form histograms for separate groups.
- grid** [bool, default True] Whether to show axis grid lines.
- xlabelsize** [int, default None] If specified changes the x-axis label size.
- xrot** [float, default None] Rotation of x axis labels. For example, a value of 90 displays the x labels rotated 90 degrees clockwise.
- ylabelsize** [int, default None] If specified changes the y-axis label size.
- yrot** [float, default None] Rotation of y axis labels. For example, a value of 90 displays the y labels rotated 90 degrees clockwise.
- ax** [Matplotlib axes object, default None] The axes to plot the histogram on.
- sharex** [bool, default True if ax is None else False] In case subplots=True, share x axis and set some x axis labels to invisible; defaults to True if ax is None otherwise False if an ax is passed in. Note that passing in both an ax and sharex=True will alter all x axis labels for all subplots in a figure.
- sharey** [bool, default False] In case subplots=True, share y axis and set some y axis labels to invisible.
- figsize** [tuple, optional] The size in inches of the figure to create. Uses the value in `matplotlib.rcParams` by default.
- layout** [tuple, optional] Tuple of (rows, columns) for the layout of the histograms.
- bins** [int or sequence, default 10] Number of histogram bins to be used. If an integer is given, bins + 1 bin edges are calculated and returned. If bins is a sequence, gives bin edges, including left edge of first bin and right edge of last bin. In this case, bins is returned unmodified.
- backend** [str, default None] Backend to use instead of the backend specified in the option `plotting.backend`. For instance, 'matplotlib'. Alternatively, to specify the `plotting.backend` for the whole session, set `pd.options.plotting.backend`.
New in version 1.0.0.
- legend** [bool, default False] Whether to show the legend.
New in version 1.1.0.
- **kwargs** All other plotting keyword arguments to be passed to `matplotlib.pyplot.hist()`.

Returns

matplotlib.AxesSubplot or numpy.ndarray of them

See also:

`matplotlib.pyplot.hist` Plot a histogram using matplotlib.

Examples

This example draws a histogram based on the length and width of some animals, displayed in three bins

```
>>> df = pd.DataFrame({
...     'length': [1.5, 0.5, 1.2, 0.9, 3],
...     'width': [0.7, 0.2, 0.15, 0.2, 1.1]
...     }, index=['pig', 'rabbit', 'duck', 'chicken', 'horse'])
>>> hist = df.hist(bins=3)
```

`pandas.core.groupby.DataFrameGroupBy.idxmax`

`DataFrameGroupBy.idxmax`(*axis=0*, *skipna=True*)

Return index of first occurrence of maximum over requested axis.

NA/null values are excluded.

Parameters

axis [{0 or 'index', 1 or 'columns'}, default 0] The axis to use. 0 or 'index' for row-wise, 1 or 'columns' for column-wise.

skipna [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

Returns

Series Indexes of maxima along the specified axis.

Raises

ValueError

- If the row/column is empty

See also:

Series.idxmax Return index of the maximum element.

Notes

This method is the DataFrame version of `ndarray.argmax`.

Examples

Consider a dataset containing food consumption in Argentina.

```
>>> df = pd.DataFrame({'consumption': [10.51, 103.11, 55.48],
...                    'co2_emissions': [37.2, 19.66, 1712]},
...                    index=['Pork', 'Wheat Products', 'Beef'])
```

```
>>> df
      consumption  co2_emissions
Pork           10.51           37.20
Wheat Products  103.11           19.66
Beef           55.48          1712.00
```

By default, it returns the index for the maximum value in each column.

```
>>> df.idxmax()
consumption    Wheat Products
co2_emissions           Beef
dtype: object
```

To return the index for the maximum value in each row, use `axis="columns"`.

```
>>> df.idxmax(axis="columns")
Pork           co2_emissions
Wheat Products    consumption
Beef           co2_emissions
dtype: object
```

pandas.core.groupby.DataFrameGroupBy.idxmin

DataFrameGroupBy.**idxmin**(axis=0, skipna=True)

Return index of first occurrence of minimum over requested axis.

NA/null values are excluded.

Parameters

axis [{0 or 'index', 1 or 'columns'}, default 0] The axis to use. 0 or 'index' for row-wise, 1 or 'columns' for column-wise.

skipna [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

Returns

Series Indexes of minima along the specified axis.

Raises**ValueError**

- If the row/column is empty

See also:

Series.idxmin Return index of the minimum element.

Notes

This method is the DataFrame version of `ndarray.argmax`.

Examples

Consider a dataset containing food consumption in Argentina.

```
>>> df = pd.DataFrame({'consumption': [10.51, 103.11, 55.48],
...                    'co2_emissions': [37.2, 19.66, 1712]},
...                    index=['Pork', 'Wheat Products', 'Beef'])
```

```
>>> df
      consumption  co2_emissions
Pork             10.51           37.20
Wheat Products   103.11           19.66
Beef              55.48          1712.00
```

By default, it returns the index for the minimum value in each column.

```
>>> df.idxmin()
consumption           Pork
co2_emissions  Wheat Products
dtype: object
```

To return the index for the minimum value in each row, use `axis="columns"`.

```
>>> df.idxmin(axis="columns")
Pork                consumption
Wheat Products     co2_emissions
Beef                consumption
dtype: object
```

pandas.core.groupby.DataFrameGroupBy.mad

property DataFrameGroupBy.mad

Return the mean absolute deviation of the values over the requested axis.

Parameters

axis [{index (0), columns (1)}] Axis for the function to be applied on.

skipna [bool, default None] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

Returns

Series or DataFrame (if level specified)

pandas.core.groupby.DataFrameGroupBy.nunique

DataFrameGroupBy.nunique(dropna=True)

Return DataFrame with counts of unique elements in each position.

Parameters

dropna [bool, default True] Don't include NaN in the counts.

Returns

nunique: DataFrame

Examples

```
>>> df = pd.DataFrame({'id': ['spam', 'egg', 'egg', 'spam',
...                          'ham', 'ham'],
...                   'value1': [1, 5, 5, 2, 5, 5],
...                   'value2': list('abbaxy')})
>>> df
   id  value1 value2
0  spam     1     a
1  egg     5     b
2  egg     5     b
3  spam     2     a
4  ham     5     x
5  ham     5     y
```

```
>>> df.groupby('id').nunique()
   value1 value2
id
```

(continues on next page)

(continued from previous page)

| | | |
|------|---|---|
| egg | 1 | 1 |
| ham | 1 | 2 |
| spam | 2 | 1 |

Check for rows with the same id but conflicting values:

```
>>> df.groupby('id').filter(lambda g: (g.nunique() > 1).any())
   id  value1 value2
0  spam      1      a
3  spam      2      a
4   ham      5      x
5   ham      5      y
```

pandas.core.groupby.DataFrameGroupBy.pad

DataFrameGroupBy.**pad**(*limit=None*)

Forward fill the values.

Parameters

limit [int, optional] Limit of how many values to fill.

Returns

Series or DataFrame Object with missing values filled.

See also:

Series.pad Returns Series with minimum number of char in object.

DataFrame.pad Object with missing values filled or None if inplace=True.

Series.fillna Fill NaN values of a Series.

DataFrame.fillna Fill NaN values of a DataFrame.

pandas.core.groupby.DataFrameGroupBy.pct_change

DataFrameGroupBy.**pct_change**(*periods=1, fill_method='pad', limit=None, freq=None, axis=0*)

Calculate pct_change of each value to previous entry in group.

Returns

Series or DataFrame Percentage changes within each group.

See also:

Series.groupby Apply a function groupby to a Series.

DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

pandas.core.groupby.DataFrameGroupBy.plot

property DataFrameGroupBy.**plot**

Class implementing the .plot attribute for groupby objects.

pandas.core.groupby.DataFrameGroupBy.quantile

DataFrameGroupBy.**quantile**(*q=0.5, interpolation='linear'*)

Return group values at the given quantile, a la numpy.percentile.

Parameters

q [float or array-like, default 0.5 (50% quantile)] Value(s) between 0 and 1 providing the quantile(s) to compute.

interpolation [{‘linear’, ‘lower’, ‘higher’, ‘midpoint’, ‘nearest’}] Method to use when the desired quantile falls between two points.

Returns

Series or DataFrame Return type determined by caller of GroupBy object.

See also:

Series.quantile Similar method for Series.

DataFrame.quantile Similar method for DataFrame.

numpy.percentile NumPy method to compute qth percentile.

Examples

```
>>> df = pd.DataFrame([
...     ['a', 1], ['a', 2], ['a', 3],
...     ['b', 1], ['b', 3], ['b', 5]
... ], columns=['key', 'val'])
>>> df.groupby('key').quantile()
val
key
a    2.0
b    3.0
```

pandas.core.groupby.DataFrameGroupBy.rank

DataFrameGroupBy.**rank**(*method='average', ascending=True, na_option='keep', pct=False, axis=0*)

Provide the rank of values within each group.

Parameters

method [{‘average’, ‘min’, ‘max’, ‘first’, ‘dense’}, default ‘average’]

- average: average rank of group.
- min: lowest rank in group.
- max: highest rank in group.
- first: ranks assigned in order they appear in the array.
- dense: like ‘min’, but rank always increases by 1 between groups.

ascending [bool, default True] False for ranks by high (1) to low (N).

na_option [{‘keep’, ‘top’, ‘bottom’}, default ‘keep’]

- keep: leave NA values where they are.
- top: smallest rank if ascending.
- bottom: smallest rank if descending.

pct [bool, default False] Compute percentage rank of data within each group.

axis [int, default 0] The axis of the object over which to compute the rank.

Returns

DataFrame with ranking of values within each group

See also:

Series.groupby Apply a function groupby to a Series.

DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

pandas.core.groupby.DataFrameGroupBy.resample

DataFrameGroupBy.**resample**(rule, *args, **kwargs)

Provide resampling when using a TimeGrouper.

Given a grouper, the function resamples it according to a string “string” -> “frequency”.

See the [frequency aliases](#) documentation for more details.

Parameters

rule [str or DateOffset] The offset string or object representing target grouper conversion.

***args, **kwargs** Possible arguments are *how*, *fill_method*, *limit*, *kind* and *on*, and other arguments of *TimeGrouper*.

Returns

Grouper Return a new grouper with our resampler appended.

See also:

Grouper Specify a frequency to resample with when grouping by a key.

DatetimeIndex.resample Frequency conversion and resampling of time series.

Examples

```
>>> idx = pd.date_range('1/1/2000', periods=4, freq='T')
>>> df = pd.DataFrame(data=4 * [range(2)],
...                   index=idx,
...                   columns=['a', 'b'])
>>> df.iloc[2, 0] = 5
>>> df
```

| | a | b |
|---------------------|---|---|
| 2000-01-01 00:00:00 | 0 | 1 |
| 2000-01-01 00:01:00 | 0 | 1 |
| 2000-01-01 00:02:00 | 5 | 1 |
| 2000-01-01 00:03:00 | 0 | 1 |

Downsample the DataFrame into 3 minute bins and sum the values of the timestamps falling into a bin.

```
>>> df.groupby('a').resample('3T').sum()
```

| | a | b |
|---|---------------------|-----|
| a | | |
| 0 | 2000-01-01 00:00:00 | 0 2 |
| | 2000-01-01 00:03:00 | 0 1 |
| 5 | 2000-01-01 00:00:00 | 5 1 |

Upsample the series into 30 second bins.

```
>>> df.groupby('a').resample('30S').sum()
      a  b
a
0  2000-01-01 00:00:00  0  1
   2000-01-01 00:00:30  0  0
   2000-01-01 00:01:00  0  1
   2000-01-01 00:01:30  0  0
   2000-01-01 00:02:00  0  0
   2000-01-01 00:02:30  0  0
   2000-01-01 00:03:00  0  1
5  2000-01-01 00:02:00  5  1
```

Resample by month. Values are assigned to the month of the period.

```
>>> df.groupby('a').resample('M').sum()
      a  b
a
0  2000-01-31  0  3
5  2000-01-31  5  1
```

Downsample the series into 3 minute bins as above, but close the right side of the bin interval.

```
>>> df.groupby('a').resample('3T', closed='right').sum()
      a  b
a
0  1999-12-31 23:57:00  0  1
   2000-01-01 00:00:00  0  2
5  2000-01-01 00:00:00  5  1
```

Downsample the series into 3 minute bins and close the right side of the bin interval, but label each bin using the right edge instead of the left.

```
>>> df.groupby('a').resample('3T', closed='right', label='right').sum()
      a  b
a
0  2000-01-01 00:00:00  0  1
   2000-01-01 00:03:00  0  2
5  2000-01-01 00:03:00  5  1
```

pandas.core.groupby.DataFrameGroupBy.sample

`DataFrameGroupBy.sample`(*n=None, frac=None, replace=False, weights=None, random_state=None*)

Return a random sample of items from each group.

You can use `random_state` for reproducibility.

New in version 1.1.0.

Parameters

n [int, optional] Number of items to return for each group. Cannot be used with `frac` and must be no larger than the smallest group unless `replace` is True. Default is one if `frac` is None.

frac [float, optional] Fraction of items to return. Cannot be used with `n`.

replace [bool, default False] Allow or disallow sampling of the same row more than once.

weights [list-like, optional] Default None results in equal probability weighting. If passed a list-like then values must have the same length as the underlying DataFrame or Series object and will be used as sampling probabilities after normalization within each group. Values must be non-negative with at least one positive element within each group.

random_state [int, array-like, BitGenerator, np.random.RandomState, optional] If int, array-like, or BitGenerator (NumPy>=1.17), seed for random number generator. If np.random.RandomState, use as numpy RandomState object.

Returns

Series or DataFrame A new object of same type as caller containing items randomly sampled within each group from the caller object.

See also:

DataFrame.sample Generate random samples from a DataFrame object.

numpy.random.choice Generate a random sample from a given 1-D numpy array.

Examples

```
>>> df = pd.DataFrame(
...     {"a": ["red"] * 2 + ["blue"] * 2 + ["black"] * 2, "b": range(6)}
... )
>>> df
   a  b
0  red 0
1  red 1
2  blue 2
3  blue 3
4  black 4
5  black 5
```

Select one row at random for each distinct value in column a. The *random_state* argument can be used to guarantee reproducibility:

```
>>> df.groupby("a").sample(n=1, random_state=1)
   a  b
4  black 4
2  blue 2
1  red 1
```

Set *frac* to sample fixed proportions rather than counts:

```
>>> df.groupby("a")["b"].sample(frac=0.5, random_state=2)
5    5
2    2
0    0
Name: b, dtype: int64
```

Control sample probabilities within groups by setting weights:

```
>>> df.groupby("a").sample(
...     n=1,
```

(continues on next page)

(continued from previous page)

```

...     weights=[1, 1, 1, 0, 0, 1],
...     random_state=1,
... )
   a  b
5  black  5
2   blue  2
0    red  0

```

pandas.core.groupby.DataFrameGroupBy.shift

DataFrameGroupBy.**shift** (*periods=1, freq=None, axis=0, fill_value=None*)

Shift each group by periods observations.

If freq is passed, the index will be increased using the periods and the freq.

Parameters

periods [int, default 1] Number of periods to shift.

freq [str, optional] Frequency string.

axis [axis to shift, default 0] Shift direction.

fill_value [optional] The scalar value to use for newly introduced missing values.

Returns

Series or DataFrame Object shifted within each group.

See also:

Index.shift Shift values of Index.

tshift Shift the time index, using the index's frequency if available.

pandas.core.groupby.DataFrameGroupBy.size

DataFrameGroupBy.**size**()

Compute group sizes.

Returns

DataFrame or Series Number of rows in each group as a Series if `as_index` is True or a DataFrame if `as_index` is False.

See also:

Series.groupby Apply a function groupby to a Series.

DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

pandas.core.groupby.DataFrameGroupBy.skew

property DataFrameGroupBy.**skew**

Return unbiased skew over requested axis.

Normalized by N-1.

Parameters

axis [{index (0), columns (1)}] Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

****kwargs** Additional keyword arguments to be passed to the function.

Returns

Series or DataFrame (if level specified)

pandas.core.groupby.DataFrameGroupBy.take

property DataFrameGroupBy.take

Return the elements in the given *positional* indices along an axis.

This means that we are not indexing according to actual values in the index attribute of the object. We are indexing according to the actual position of the element in the object.

Parameters

indices [array-like] An array of ints indicating which positions to take.

axis [{0 or 'index', 1 or 'columns', None}, default 0] The axis on which to select elements. 0 means that we are selecting rows, 1 means that we are selecting columns.

is_copy [bool] Before pandas 1.0, `is_copy=False` can be specified to ensure that the return value is an actual copy. Starting with pandas 1.0, `take` always returns a copy, and the keyword is therefore deprecated.

Deprecated since version 1.0.0.

****kwargs** For compatibility with `numpy.take()`. Has no effect on the output.

Returns

taken [same type as caller] An array-like containing the elements taken from the object.

See also:

DataFrame.loc Select a subset of a DataFrame by labels.

DataFrame.iloc Select a subset of a DataFrame by positions.

numpy.take Take elements from an array along an axis.

Examples

```
>>> df = pd.DataFrame([('falcon', 'bird', 389.0),
...                   ('parrot', 'bird', 24.0),
...                   ('lion', 'mammal', 80.5),
...                   ('monkey', 'mammal', np.nan)],
...                   columns=['name', 'class', 'max_speed'],
...                   index=[0, 2, 3, 1])
>>> df
   name  class  max_speed
0  falcon  bird    389.0
2  parrot  bird     24.0
3   lion  mammal    80.5
1  monkey  mammal     NaN
```

Take elements at positions 0 and 3 along the axis 0 (default).

Note how the actual indices selected (0 and 1) do not correspond to our selected indices 0 and 3. That's because we are selecting the 0th and 3rd rows, not rows whose indices equal 0 and 3.

```
>>> df.take([0, 3])
   name  class  max_speed
0  falcon  bird    389.0
1  monkey  mammal     NaN
```

Take elements at indices 1 and 2 along the axis 1 (column selection).

```
>>> df.take([1, 2], axis=1)
   class  max_speed
0   bird    389.0
2   bird    24.0
3  mammal    80.5
1  mammal     NaN
```

We may take elements using negative integers for positive indices, starting from the end of the object, just like with Python lists.

```
>>> df.take([-1, -2])
   name  class  max_speed
1  monkey  mammal     NaN
3   lion  mammal    80.5
```

pandas.core.groupby.DataFrameGroupBy.tshift

property DataFrameGroupBy.tshift

Shift the time index, using the index's frequency if available.

Deprecated since version 1.1.0: Use *shift* instead.

Parameters

periods [int] Number of periods to move, can be positive or negative.

freq [DateOffset, timedelta, or str, default None] Increment to use from the tseries module or time rule expressed as a string (e.g. 'EOM').

axis [{0 or 'index', 1 or 'columns', None}, default 0] Corresponds to the axis that contains the Index.

Returns

shifted [Series/DataFrame]

Notes

If `freq` is not specified then tries to use the `freq` or `inferred_freq` attributes of the index. If neither of those attributes exist, a `ValueError` is thrown

The following methods are available only for `SeriesGroupBy` objects.

| | |
|---|--|
| <code>SeriesGroupBy.hist</code> | Draw histogram of the input series using matplotlib. |
| <code>SeriesGroupBy.nlargest</code> | Return the largest n elements. |
| <code>SeriesGroupBy.nsmallest</code> | Return the smallest n elements. |
| <code>SeriesGroupBy.nunique([dropna])</code> | Return number of unique elements in the group. |
| <code>SeriesGroupBy.unique</code> | Return unique values of Series object. |
| <code>SeriesGroupBy.value_counts([normalize, ...])</code> | |
| <code>SeriesGroupBy.is_monotonic_increasing</code> | Alias for <code>is_monotonic</code> . |
| <code>SeriesGroupBy.is_monotonic_decreasing</code> | Return boolean if values in the object are monotonic_decreasing. |

pandas.core.groupby.SeriesGroupBy.hist

property `SeriesGroupBy.hist`

Draw histogram of the input series using matplotlib.

Parameters

by [object, optional] If passed, then used to form histograms for separate groups.

ax [matplotlib axis object] If not passed, uses `gca()`.

grid [bool, default True] Whether to show axis grid lines.

xlabelsize [int, default None] If specified changes the x-axis label size.

xrot [float, default None] Rotation of x axis labels.

ylabelsize [int, default None] If specified changes the y-axis label size.

yrot [float, default None] Rotation of y axis labels.

figsize [tuple, default None] Figure size in inches by default.

bins [int or sequence, default 10] Number of histogram bins to be used. If an integer is given, `bins + 1` bin edges are calculated and returned. If `bins` is a sequence, gives bin edges, including left edge of first bin and right edge of last bin. In this case, `bins` is returned unmodified.

backend [str, default None] Backend to use instead of the backend specified in the option `plotting.backend`. For instance, `'matplotlib'`. Alternatively, to specify the `plotting.backend` for the whole session, set `pd.options.plotting.backend`.

New in version 1.0.0.

legend [bool, default False] Whether to show the legend.

New in version 1.1.0.

****kwargs** To be passed to the actual plotting function.

Returns

`matplotlib.AxesSubplot` A histogram plot.

See also:

`matplotlib.axes.Axes.hist` Plot a histogram using matplotlib.

pandas.core.groupby.SeriesGroupBy.nlargest

property SeriesGroupBy.nlargest

Return the largest n elements.

Parameters

n [int, default 5] Return this many descending sorted values.

keep [{'first', 'last', 'all'}, default 'first'] When there are duplicate values that cannot all fit in a Series of n elements:

- **first** [return the first n occurrences in order] of appearance.
- **last** [return the last n occurrences in reverse] order of appearance.
- **all** [keep all occurrences. This can result in a Series of] size larger than n .

Returns

Series The n largest values in the Series, sorted in decreasing order.

See also:

Series.nsmallest Get the n smallest elements.

Series.sort_values Sort Series by values.

Series.head Return the first n rows.

Notes

Faster than `.sort_values(ascending=False).head(n)` for small n relative to the size of the Series object.

Examples

```
>>> countries_population = {"Italy": 59000000, "France": 65000000,
...                          "Malta": 434000, "Maldives": 434000,
...                          "Brunei": 434000, "Iceland": 337000,
...                          "Nauru": 11300, "Tuvalu": 11300,
...                          "Anguilla": 11300, "Montserrat": 5200}
>>> s = pd.Series(countries_population)
>>> s
Italy          59000000
France         65000000
Malta           434000
Maldives       434000
Brunei         434000
Iceland        337000
Nauru           11300
Tuvalu         11300
Anguilla       11300
Montserrat     5200
dtype: int64
```

The n largest elements where $n=5$ by default.

```
>>> s.nlargest()
France      65000000
Italy       59000000
Malta       434000
Maldives    434000
Brunei      434000
dtype: int64
```

The n largest elements where $n=3$. Default *keep* value is 'first' so Malta will be kept.

```
>>> s.nlargest(3)
France      65000000
Italy       59000000
Malta       434000
dtype: int64
```

The n largest elements where $n=3$ and keeping the last duplicates. Brunei will be kept since it is the last with value 434000 based on the index order.

```
>>> s.nlargest(3, keep='last')
France      65000000
Italy       59000000
Brunei      434000
dtype: int64
```

The n largest elements where $n=3$ with all duplicates kept. Note that the returned Series has five elements due to the three duplicates.

```
>>> s.nlargest(3, keep='all')
France      65000000
Italy       59000000
Malta       434000
Maldives    434000
Brunei      434000
dtype: int64
```

pandas.core.groupby.SeriesGroupBy.nsmallest

property SeriesGroupBy.nsmallest

Return the smallest n elements.

Parameters

n [int, default 5] Return this many ascending sorted values.

keep [{ 'first', 'last', 'all' }, default 'first'] When there are duplicate values that cannot all fit in a Series of n elements:

- **first** [return the first n occurrences in order] of appearance.
- **last** [return the last n occurrences in reverse] order of appearance.
- **all** [keep all occurrences. This can result in a Series of] size larger than n .

Returns

Series The n smallest values in the Series, sorted in increasing order.

See also:

Series.nlargest Get the n largest elements.

Series.sort_values Sort Series by values.

Series.head Return the first n rows.

Notes

Faster than `.sort_values().head(n)` for small n relative to the size of the Series object.

Examples

```
>>> countries_population = {"Italy": 59000000, "France": 65000000,
...                          "Brunei": 434000, "Malta": 434000,
...                          "Maldives": 434000, "Iceland": 337000,
...                          "Nauru": 11300, "Tuvalu": 11300,
...                          "Anguilla": 11300, "Montserrat": 5200}
>>> s = pd.Series(countries_population)
>>> s
Italy          59000000
France         65000000
Brunei          434000
Malta           434000
Maldives        434000
Iceland         337000
Nauru           11300
Tuvalu          11300
Anguilla        11300
Montserrat       5200
dtype: int64
```

The n smallest elements where $n=5$ by default.

```
>>> s.nsmallest()
Montserrat     5200
Nauru          11300
Tuvalu         11300
Anguilla       11300
Iceland        337000
dtype: int64
```

The n smallest elements where $n=3$. Default *keep* value is 'first' so Nauru and Tuvalu will be kept.

```
>>> s.nsmallest(3)
Montserrat     5200
Nauru          11300
Tuvalu         11300
dtype: int64
```

The n smallest elements where $n=3$ and keeping the last duplicates. Anguilla and Tuvalu will be kept since they are the last with value 11300 based on the index order.

```
>>> s.nsmallest(3, keep='last')
Montserrat    5200
Anguilla      11300
Tuvalu        11300
dtype: int64
```

The n smallest elements where $n=3$ with all duplicates kept. Note that the returned Series has four elements due to the three duplicates.

```
>>> s.nsmallest(3, keep='all')
Montserrat    5200
Nauru         11300
Tuvalu        11300
Anguilla      11300
dtype: int64
```

pandas.core.groupby.SeriesGroupBy.nunique

SeriesGroupBy.**nunique**(*dropna=True*)

Return number of unique elements in the group.

Returns

Series Number of unique values within each group.

pandas.core.groupby.SeriesGroupBy.unique

property SeriesGroupBy.**unique**

Return unique values of Series object.

Uniques are returned in order of appearance. Hash table-based unique, therefore does NOT sort.

Returns

ndarray or ExtensionArray The unique values returned as a NumPy array. See Notes.

See also:

unique Top-level unique method for any 1-d array-like object.

Index.unique Return Index with unique values from an Index object.

Notes

Returns the unique values as a NumPy array. In case of an extension-array backed Series, a new ExtensionArray of that type with just the unique values is returned. This includes

- Categorical
- Period
- Datetime with Timezone
- Interval
- Sparse
- IntegerNA

See Examples section.

Examples

```
>>> pd.Series([2, 1, 3, 3], name='A').unique()
array([2, 1, 3])
```

```
>>> pd.Series([pd.Timestamp('2016-01-01') for _ in range(3)]).unique()
array(['2016-01-01T00:00:00.000000000'], dtype='datetime64[ns]')
```

```
>>> pd.Series([pd.Timestamp('2016-01-01', tz='US/Eastern')
...           for _ in range(3)]).unique()
<DatetimeArray>
['2016-01-01 00:00:00-05:00']
Length: 1, dtype: datetime64[ns, US/Eastern]
```

An Categorical will return categories in the order of appearance and with the same dtype.

```
>>> pd.Series(pd.Categorical(list('baabc'))).unique()
['b', 'a', 'c']
Categories (3, object): ['a', 'b', 'c']
>>> pd.Series(pd.Categorical(list('baabc'), categories=list('abc'),
...                       ordered=True)).unique()
['b', 'a', 'c']
Categories (3, object): ['a' < 'b' < 'c']
```

pandas.core.groupby.SeriesGroupBy.value_counts

SeriesGroupBy.**value_counts**(*normalize=False, sort=True, ascending=False, bins=None, dropna=True*)

pandas.core.groupby.SeriesGroupBy.is_monotonic_increasing

property SeriesGroupBy.**is_monotonic_increasing**

Alias for `is_monotonic`.

pandas.core.groupby.SeriesGroupBy.is_monotonic_decreasing

property SeriesGroupBy.**is_monotonic_decreasing**

Return boolean if values in the object are `monotonic_decreasing`.

Returns

bool

The following methods are available only for `DataFrameGroupBy` objects.

| | |
|---|---|
| <code>DataFrameGroupBy.corrwith</code> | Compute pairwise correlation. |
| <code>DataFrameGroupBy.boxplot</code> ([subplots, column, ...]) | Make box plots from <code>DataFrameGroupBy</code> data. |

pandas.core.groupby.DataFrameGroupBy.corrwith

property DataFrameGroupBy.corrwith

Compute pairwise correlation.

Pairwise correlation is computed between rows or columns of DataFrame with rows or columns of Series or DataFrame. DataFrames are first aligned along both axes before computing the correlations.

Parameters

other [DataFrame, Series] Object with which to compute correlations.

axis [{0 or 'index', 1 or 'columns'}, default 0] The axis to use. 0 or 'index' to compute column-wise, 1 or 'columns' for row-wise.

drop [bool, default False] Drop missing indices from result.

method [{'pearson', 'kendall', 'spearman'} or callable] Method of correlation:

- pearson : standard correlation coefficient
- kendall : Kendall Tau correlation coefficient
- spearman : Spearman rank correlation
- **callable: callable with input two 1d ndarrays** and returning a float.

Returns

Series Pairwise correlations.

See also:

DataFrame.corr Compute pairwise correlation of columns.

pandas.core.groupby.DataFrameGroupBy.boxplot

DataFrameGroupBy.**boxplot**(*subplots=True, column=None, fontsize=None, rot=0, grid=True, ax=None, figsize=None, layout=None, sharex=False, sharey=True, backend=None, **kwargs*)

Make box plots from DataFrameGroupBy data.

Parameters

grouped [Grouped DataFrame]

subplots [bool]

- False - no subplots will be used
- True - create a subplot for each group.

column [column name or list of names, or vector] Can be any valid input to groupby.

fontsize [int or str]

rot [label rotation angle]

grid [Setting this to True will show the grid]

ax [Matplotlib axis object, default None]

figsize [A tuple (width, height) in inches]

layout [tuple (optional)] The layout of the plot: (rows, columns).

sharex [bool, default False] Whether x-axes will be shared among subplots.

sharey [bool, default True] Whether y-axes will be shared among subplots.

backend [str, default None] Backend to use instead of the backend specified in the option `plotting.backend`. For instance, 'matplotlib'. Alternatively, to specify the `plotting.backend` for the whole session, set `pd.options.plotting.backend`.

New in version 1.0.0.

****kwargs** All other plotting keyword arguments to be passed to matplotlib's boxplot function.

Returns

dict of key/value = group key/DataFrame.boxplot return value

or DataFrame.boxplot return value in case subplots=figures=False

Examples

You can create boxplots for grouped data and show them as separate subplots:

```
>>> import itertools
>>> tuples = [t for t in itertools.product(range(1000), range(4))]
>>> index = pd.MultiIndex.from_tuples(tuples, names=['lvl0', 'lvl1'])
>>> data = np.random.randn(len(index), 4)
>>> df = pd.DataFrame(data, columns=list('ABCD'), index=index)
>>> grouped = df.groupby(level='lvl1')
>>> grouped.boxplot(rot=45, fontsize=12, figsize=(8,10))
```

The `subplots=False` option shows the boxplots in a single figure.

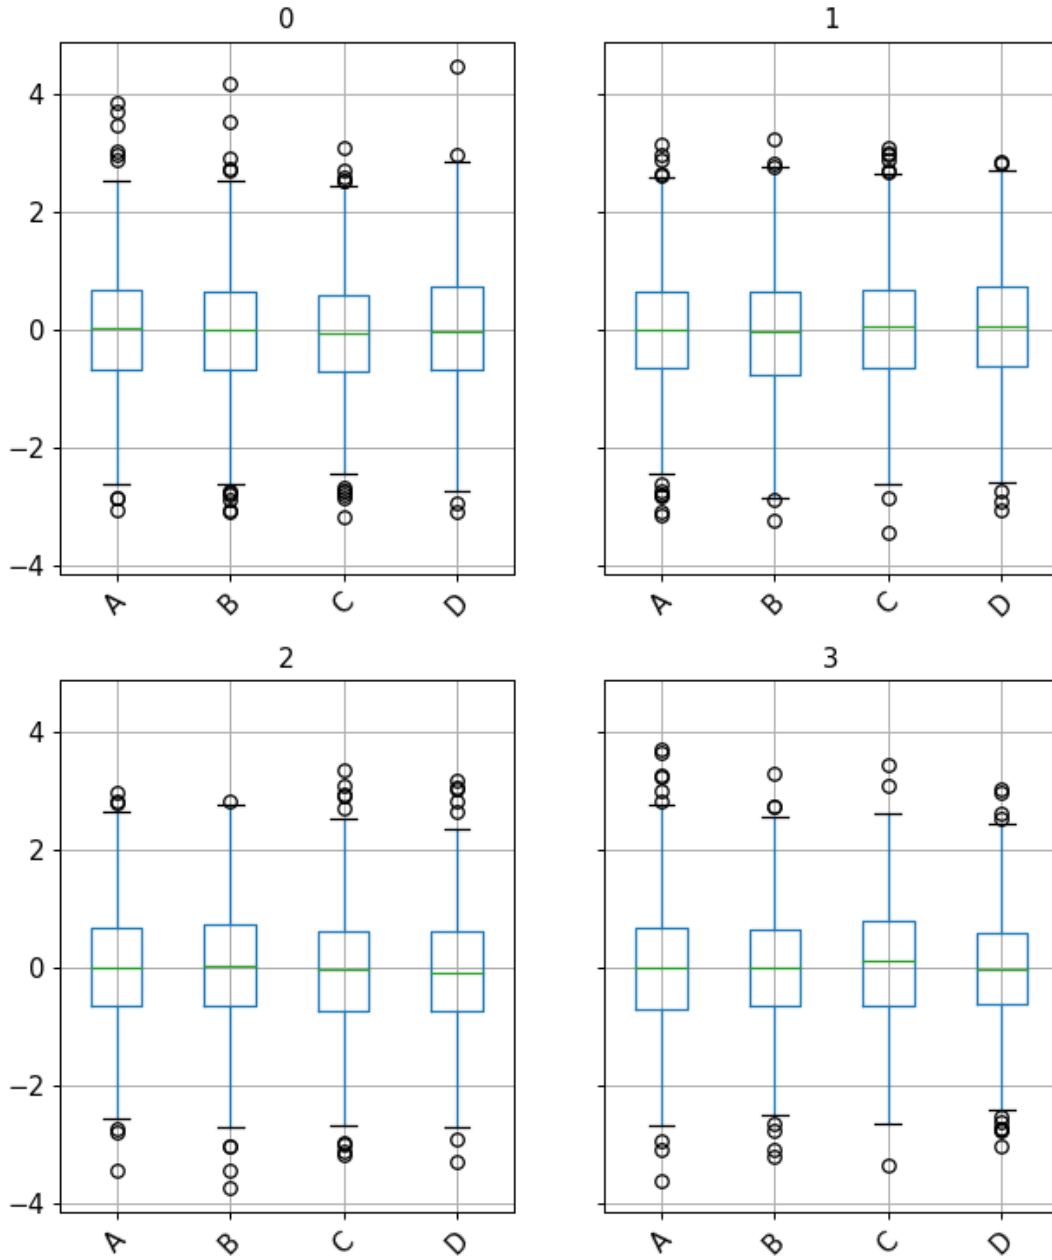

```
>>> grouped.boxplot(subplots=False, rot=45, fontsize=12)
```

3.11 Resampling

Resampler objects are returned by `resample` calls: `pandas.DataFrame.resample()`, `pandas.Series.resample()`.

3.11.1 Indexing, iteration

| | |
|---|--|
| <code>Resampler.__iter__()</code> | Groupby iterator. |
| <code>Resampler.groups</code> | Dict {group name -> group labels}. |
| <code>Resampler.indices</code> | Dict {group name -> group indices}. |
| <code>Resampler.get_group(name[, obj])</code> | Construct DataFrame from group with provided name. |

pandas.core.resample.Resampler.__iter__

Resampler.__iter__()

Groupby iterator.

Returns

Generator yielding sequence of (name, subsetted object)
for each group

pandas.core.resample.Resampler.groups

property Resampler.groups

Dict {group name -> group labels}.

pandas.core.resample.Resampler.indices

property Resampler.indices

Dict {group name -> group indices}.

pandas.core.resample.Resampler.get_group

Resampler.get_group(name, obj=None)

Construct DataFrame from group with provided name.

Parameters

name [object] The name of the group to get as a DataFrame.

obj [DataFrame, default None] The DataFrame to take the DataFrame out of. If it is None, the object groupby was called on will be used.

Returns

group [same type as obj]

3.11.2 Function application

| | |
|--|--|
| <i>Resampler.apply</i> (func, *args, **kwargs) | Aggregate using one or more operations over the specified axis. |
| <i>Resampler.aggregate</i> (func, *args, **kwargs) | Aggregate using one or more operations over the specified axis. |
| <i>Resampler.transform</i> (arg, *args, **kwargs) | Call function producing a like-indexed Series on each group and return a Series with the transformed values. |
| <i>Resampler.pipe</i> (func, *args, **kwargs) | Apply a function <i>func</i> with arguments to this Resampler object and return the function's result. |

pandas.core.resample.Resampler.apply**Resampler.apply**(*func*, **args*, ***kwargs*)

Aggregate using one or more operations over the specified axis.

Parameters**func** [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a DataFrame or when passed to DataFrame.apply.

Accepted combinations are:

- function
- string function name
- list of functions and/or function names, e.g. [`np.sum`, 'mean']
- dict of axis labels -> functions, function names or list of such.

args** Positional arguments to pass to *func*.*kwargs** Keyword arguments to pass to *func*.**Returns****scalar, Series or DataFrame** The return can be:

- scalar : when Series.agg is called with single function
- Series : when DataFrame.agg is called with a single function
- DataFrame : when DataFrame.agg is called with several functions

Return scalar, Series or DataFrame.

See also:**DataFrame.groupby.aggregate** Aggregate using callable, string, dict, or list of string/callables.**DataFrame.resample.transform** Transforms the Series on each group based on the given function.**DataFrame.aggregate** Aggregate using one or more operations over the specified axis.**Notes***agg* is an alias for *aggregate*. Use the alias.Functions that mutate the passed object can produce unexpected behavior or errors and are not supported. See [Mutating with User Defined Function \(UDF\) methods](#) for more details.

A passed user-defined-function will be passed a Series for evaluation.

Examples

```
>>> s = pd.Series([1,2,3,4,5],
                  index=pd.date_range('20130101', periods=5, freq='s'))
2013-01-01 00:00:00    1
2013-01-01 00:00:01    2
2013-01-01 00:00:02    3
2013-01-01 00:00:03    4
2013-01-01 00:00:04    5
Freq: S, dtype: int64
```

```
>>> r = s.resample('2s')
DatetimeIndexResampler [freq=<2 * Seconds>, axis=0, closed=left,
                        label=left, convention=start]
```

```
>>> r.agg(np.sum)
2013-01-01 00:00:00    3
2013-01-01 00:00:02    7
2013-01-01 00:00:04    5
Freq: 2S, dtype: int64
```

```
>>> r.agg(['sum', 'mean', 'max'])
                sum  mean  max
2013-01-01 00:00:00    3   1.5   2
2013-01-01 00:00:02    7   3.5   4
2013-01-01 00:00:04    5   5.0   5
```

```
>>> r.agg({'result' : lambda x: x.mean() / x.std(),
          'total' : np.sum})
                total  result
2013-01-01 00:00:00    3  2.121320
2013-01-01 00:00:02    7  4.949747
2013-01-01 00:00:04    5         NaN
```

pandas.core.resample.Resampler.aggregate

Resampler.**aggregate**(*func*, **args*, ***kwargs*)

Aggregate using one or more operations over the specified axis.

Parameters

func [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a DataFrame or when passed to DataFrame.apply.

Accepted combinations are:

- function
- string function name
- list of functions and/or function names, e.g. [np.sum, 'mean']
- dict of axis labels -> functions, function names or list of such.

***args** Positional arguments to pass to *func*.

****kwargs** Keyword arguments to pass to *func*.

Returns

scalar, Series or DataFrame The return can be:

- scalar : when Series.agg is called with single function
- Series : when DataFrame.agg is called with a single function
- DataFrame : when DataFrame.agg is called with several functions

Return scalar, Series or DataFrame.

See also:

DataFrame.groupby.aggregate Aggregate using callable, string, dict, or list of string/callables.
DataFrame.resample.transform Transforms the Series on each group based on the given function.
DataFrame.aggregate Aggregate using one or more operations over the specified axis.

Notes

agg is an alias for *aggregate*. Use the alias.

Functions that mutate the passed object can produce unexpected behavior or errors and are not supported. See *Mutating with User Defined Function (UDF) methods* for more details.

A passed user-defined-function will be passed a Series for evaluation.

Examples

```
>>> s = pd.Series([1,2,3,4,5],
                  index=pd.date_range('20130101', periods=5,freq='s'))
2013-01-01 00:00:00    1
2013-01-01 00:00:01    2
2013-01-01 00:00:02    3
2013-01-01 00:00:03    4
2013-01-01 00:00:04    5
Freq: S, dtype: int64
```

```
>>> r = s.resample('2s')
DatetimeIndexResampler [freq=<2 * Seconds>, axis=0, closed=left,
                        label=left, convention=start]
```

```
>>> r.agg(np.sum)
2013-01-01 00:00:00    3
2013-01-01 00:00:02    7
2013-01-01 00:00:04    5
Freq: 2S, dtype: int64
```

```
>>> r.agg(['sum', 'mean', 'max'])
                sum  mean  max
2013-01-01 00:00:00    3   1.5   2
2013-01-01 00:00:02    7   3.5   4
2013-01-01 00:00:04    5   5.0   5
```

```
>>> r.agg({'result' : lambda x: x.mean() / x.std(),
          'total' : np.sum})
                total  result
2013-01-01 00:00:00    3  2.121320
2013-01-01 00:00:02    7  4.949747
2013-01-01 00:00:04    5         NaN
```

pandas.core.resample.Resampler.transform

`Resampler.transform(arg, *args, **kwargs)`

Call function producing a like-indexed Series on each group and return a Series with the transformed values.

Parameters

arg [function] To apply to each group. Should return a Series with the same index.

Returns

transformed [Series]

Examples

```
>>> resampled.transform(lambda x: (x - x.mean()) / x.std())
```

pandas.core.resample.Resampler.pipe

`Resampler.pipe(func, *args, **kwargs)`

Apply a function *func* with arguments to this Resampler object and return the function's result.

Use *.pipe* when you want to improve readability by chaining together functions that expect Series, DataFrames, GroupBy or Resampler objects. Instead of writing

```
>>> h(g(f(df.groupby('group')), arg1=a), arg2=b, arg3=c)
```

You can write

```
>>> (df.groupby('group')
...   .pipe(f)
...   .pipe(g, arg1=a)
...   .pipe(h, arg2=b, arg3=c))
```

which is much more readable.

Parameters

func [callable or tuple of (callable, str)] Function to apply to this Resampler object or, alternatively, a (*callable*, *data_keyword*) tuple where *data_keyword* is a string indicating the keyword of *callable* that expects the Resampler object.

args [iterable, optional] Positional arguments passed into *func*.

kwargs [dict, optional] A dictionary of keyword arguments passed into *func*.

Returns

object [the return type of *func*.]

See also:

Series.pipe Apply a function with arguments to a series.

DataFrame.pipe Apply a function with arguments to a dataframe.

apply Apply function to each group instead of to the full Resampler object.

Notes

See more [here](#)

Examples

```
>>> df = pd.DataFrame({'A': [1, 2, 3, 4]},
...                    index=pd.date_range('2012-08-02', periods=4))
>>> df
           A
2012-08-02  1
2012-08-03  2
2012-08-04  3
2012-08-05  4
```

To get the difference between each 2-day period's maximum and minimum value in one pass, you can do

```
>>> df.resample('2D').pipe(lambda x: x.max() - x.min())
           A
2012-08-02  1
2012-08-04  1
```

3.11.3 Upsampling

| | |
|---|---|
| <i>Resampler.ffill</i> ([limit]) | Forward fill the values. |
| <i>Resampler.backfill</i> ([limit]) | Backward fill the new missing values in the resampled data. |
| <i>Resampler.bfill</i> ([limit]) | Backward fill the new missing values in the resampled data. |
| <i>Resampler.pad</i> ([limit]) | Forward fill the values. |
| <i>Resampler.nearest</i> ([limit]) | Resample by using the nearest value. |
| <i>Resampler.fillna</i> (method[, limit]) | Fill missing values introduced by upsampling. |
| <i>Resampler.asfreq</i> ([fill_value]) | Return the values at the new freq, essentially a reindex. |
| <i>Resampler.interpolate</i> ([method, axis, limit, ...]) | Interpolate values according to different methods. |

pandas.core.resample.Resampler.fffll

`Resampler.fffll`(*limit=None*)

Forward fill the values.

Parameters

limit [int, optional] Limit of how many values to fill.

Returns

An upsampled Series.

See also:

Series.fillna Fill NA/NaN values using the specified method.

DataFrame.fillna Fill NA/NaN values using the specified method.

pandas.core.resample.Resampler.backfill**Resampler.backfill**(*limit=None*)

Backward fill the new missing values in the resampled data.

In statistics, imputation is the process of replacing missing data with substituted values [1]. When resampling data, missing values may appear (e.g., when the resampling frequency is higher than the original frequency). The backward fill will replace NaN values that appeared in the resampled data with the next value in the original sequence. Missing values that existed in the original data will not be modified.

Parameters**limit** [int, optional] Limit of how many values to fill.**Returns****Series, DataFrame** An upsampled Series or DataFrame with backward filled NaN values.**See also:****bfill** Alias of backfill.**fillna** Fill NaN values using the specified method, which can be 'backfill'.**nearest** Fill NaN values with nearest neighbor starting from center.**pad** Forward fill NaN values.**Series.fillna** Fill NaN values in the Series using the specified method, which can be 'backfill'.**DataFrame.fillna** Fill NaN values in the DataFrame using the specified method, which can be 'backfill'.**References**

[1]

Examples

Resampling a Series:

```
>>> s = pd.Series([1, 2, 3],
...               index=pd.date_range('20180101', periods=3, freq='h'))
>>> s
2018-01-01 00:00:00    1
2018-01-01 01:00:00    2
2018-01-01 02:00:00    3
Freq: H, dtype: int64
```

```
>>> s.resample('30min').backfill()
2018-01-01 00:00:00    1
2018-01-01 00:30:00    2
2018-01-01 01:00:00    2
2018-01-01 01:30:00    3
2018-01-01 02:00:00    3
Freq: 30T, dtype: int64
```

```
>>> s.resample('15min').backfill(limit=2)
2018-01-01 00:00:00    1.0
2018-01-01 00:15:00    NaN
2018-01-01 00:30:00    2.0
2018-01-01 00:45:00    2.0
```

(continues on next page)

(continued from previous page)

```

2018-01-01 01:00:00    2.0
2018-01-01 01:15:00    NaN

| 2018-01-01 02:00:00 | 6.0 | 5.0 |

pandas.core.resample.Resampler.bfill

Resampler.**bfill**(*limit=None*)

Backward fill the new missing values in the resampled data.

In statistics, imputation is the process of replacing missing data with substituted values [1]. When resampling data, missing values may appear (e.g., when the resampling frequency is higher than the original frequency). The backward fill will replace NaN values that appeared in the resampled data with the next value in the original sequence. Missing values that existed in the original data will not be modified.

Parameters

limit [int, optional] Limit of how many values to fill.

Returns

Series, DataFrame An upsampled Series or DataFrame with backward filled NaN values.

See also:

bfill Alias of backfill.

fillna Fill NaN values using the specified method, which can be 'backfill'.

nearest Fill NaN values with nearest neighbor starting from center.

pad Forward fill NaN values.

Series.fillna Fill NaN values in the Series using the specified method, which can be 'backfill'.

DataFrame.fillna Fill NaN values in the DataFrame using the specified method, which can be 'backfill'.

```

pandas.core.resample.Resampler.pad

`Resampler.pad(limit=None)`

Forward fill the values.

Parameters

limit [int, optional] Limit of how many values to fill.

Returns

An upsampled Series.

See also:

Series.fillna Fill NA/NaN values using the specified method.

DataFrame.fillna Fill NA/NaN values using the specified method.

pandas.core.resample.Resampler.nearest

`Resampler.nearest(limit=None)`

Resample by using the nearest value.

When resampling data, missing values may appear (e.g., when the resampling frequency is higher than the original frequency). The *nearest* method will replace NaN values that appeared in the resampled data with the value from the nearest member of the sequence, based on the index value. Missing values that existed in the original data will not be modified. If *limit* is given, fill only this many values in each direction for each of the original values.

Parameters

limit [int, optional] Limit of how many values to fill.

Returns

Series or DataFrame An upsampled Series or DataFrame with NaN values filled with their nearest value.

See also:

backfill Backward fill the new missing values in the resampled data.

pad Forward fill NaN values.

Examples

```
>>> s = pd.Series([1, 2],
...               index=pd.date_range('20180101',
...                                   periods=2,
...                                   freq='1h'))
>>> s
2018-01-01 00:00:00    1
2018-01-01 01:00:00    2
Freq: H, dtype: int64
```

```
>>> s.resample('15min').nearest()
2018-01-01 00:00:00    1
2018-01-01 00:15:00    1
2018-01-01 00:30:00    2
2018-01-01 00:45:00    2
2018-01-01 01:00:00    2
Freq: 15T, dtype: int64
```

Limit the number of upsampled values imputed by the nearest:

```
>>> s.resample('15min').nearest(limit=1)
2018-01-01 00:00:00    1.0
2018-01-01 00:15:00    1.0
2018-01-01 00:30:00    NaN
2018-01-01 00:45:00    2.0
2018-01-01 01:00:00    2.0
Freq: 15T, dtype: float64
```

pandas.core.resample.Resampler.fillna

Resampler.fillna(*method*, *limit=None*)

Fill missing values introduced by upsampling.

In statistics, imputation is the process of replacing missing data with substituted values [1]. When resampling data, missing values may appear (e.g., when the resampling frequency is higher than the original frequency).

Missing values that existed in the original data will not be modified.

Parameters

method [{‘pad’, ‘backfill’, ‘fill’, ‘bfill’, ‘nearest’}] Method to use for filling holes in resampled data

- ‘pad’ or ‘fill’: use previous valid observation to fill gap (forward fill).

- ‘backfill’ or ‘bfill’: use next valid observation to fill gap.
- ‘nearest’: use nearest valid observation to fill gap.

limit [int, optional] Limit of how many consecutive missing values to fill.

Returns

Series or DataFrame An upsampled Series or DataFrame with missing values filled.

See also:

backfill Backward fill NaN values in the resampled data.

pad Forward fill NaN values in the resampled data.

nearest Fill NaN values in the resampled data with nearest neighbor starting from center.

interpolate Fill NaN values using interpolation.

Series.fillna Fill NaN values in the Series using the specified method, which can be ‘bfill’ and ‘ffill’.

DataFrame.fillna Fill NaN values in the DataFrame using the specified method, which can be ‘bfill’ and ‘ffill’.

References

[1]

Examples

Resampling a Series:

```
>>> s = pd.Series([1, 2, 3],
...               index=pd.date_range('20180101', periods=3, freq='h'))
>>> s
2018-01-01 00:00:00    1
2018-01-01 01:00:00    2
2018-01-01 02:00:00    3
Freq: H, dtype: int64
```

Without filling the missing values you get:

```
>>> s.resample("30min").asfreq()
2018-01-01 00:00:00    1.0
2018-01-01 00:30:00    NaN
2018-01-01 01:00:00    2.0
2018-01-01 01:30:00    NaN
2018-01-01 02:00:00    3.0
Freq: 30T, dtype: float64
```

```
>>> s.resample('30min').fillna("backfill")
2018-01-01 00:00:00    1
2018-01-01 00:30:00    2
2018-01-01 01:00:00    2
2018-01-01 01:30:00    3
2018-01-01 02:00:00    3
Freq: 30T, dtype: int64
```

```
>>> s.resample('15min').fillna("backfill", limit=2)
2018-01-01 00:00:00    1.0
2018-01-01 00:15:00    NaN
2018-01-01 00:30:00    2.0
2018-01-01 00:45:00    2.0
2018-01-01 01:00:00    2.0
2018-01-01 01:15:00    NaN
2018-01-01 01:30:00    3.0
2018-01-01 01:45:00    3.0
2018-01-01 02:00:00    3.0
Freq: 15T, dtype: float64
```

```
>>> s.resample('30min').fillna("pad")
2018-01-01 00:00:00    1
2018-01-01 00:30:00    1
2018-01-01 01:00:00    2
2018-01-01 01:30:00    2
2018-01-01 02:00:00    3
Freq: 30T, dtype: int64
```

```
>>> s.resample('30min').fillna("nearest")
2018-01-01 00:00:00    1
2018-01-01 00:30:00    2
2018-01-01 01:00:00    2
2018-01-01 01:30:00    3
2018-01-01 02:00:00    3
Freq: 30T, dtype: int64
```

Missing values present before the upsampling are not affected.

```
>>> sm = pd.Series([1, None, 3],
...                index=pd.date_range('20180101', periods=3, freq='h'))
>>> sm
2018-01-01 00:00:00    1.0
2018-01-01 01:00:00    NaN
2018-01-01 02:00:00    3.0
Freq: H, dtype: float64
```

```
>>> sm.resample('30min').fillna('backfill')
2018-01-01 00:00:00    1.0
2018-01-01 00:30:00    NaN
2018-01-01 01:00:00    NaN
2018-01-01 01:30:00    3.0
2018-01-01 02:00:00    3.0
Freq: 30T, dtype: float64
```

```
>>> sm.resample('30min').fillna('pad')
2018-01-01 00:00:00    1.0
2018-01-01 00:30:00    1.0
2018-01-01 01:00:00    NaN
2018-01-01 01:30:00    NaN
2018-01-01 02:00:00    3.0
```

(continues on next page)

(continued from previous page)

```
Freq: 30T, dtype: float64
```

```
>>> sm.resample('30min').fillna('nearest')
2018-01-01 00:00:00    1.0
2018-01-01 00:30:00    NaN
2018-01-01 01:00:00    NaN
2018-01-01 01:30:00    3.0
2018-01-01 02:00:00    3.0
Freq: 30T, dtype: float64
```

DataFrame resampling is done column-wise. All the same options are available.

```
>>> df = pd.DataFrame({'a': [2, np.nan, 6], 'b': [1, 3, 5]},
...                   index=pd.date_range('20180101', periods=3,
...                                       freq='h'))
>>> df
              a  b
2018-01-01 00:00:00  2.0  1
2018-01-01 01:00:00  NaN  3
2018-01-01 02:00:00  6.0  5
```

```
>>> df.resample('30min').fillna("bfill")
              a  b
2018-01-01 00:00:00  2.0  1
2018-01-01 00:30:00  NaN  3
2018-01-01 01:00:00  NaN  3
2018-01-01 01:30:00  6.0  5
2018-01-01 02:00:00  6.0  5
```

pandas.core.resample.Resampler.asfreq

Resampler.**asfreq**(*fill_value=None*)

Return the values at the new freq, essentially a reindex.

Parameters

fill_value [scalar, optional] Value to use for missing values, applied during upsampling (note this does not fill NaNs that already were present).

Returns

DataFrame or Series Values at the specified freq.

See also:

Series.asfreq Convert TimeSeries to specified frequency.

DataFrame.asfreq Convert TimeSeries to specified frequency.

pandas.core.resample.Resampler.interpolate

`Resampler.interpolate`(*method='linear', axis=0, limit=None, inplace=False, limit_direction='forward', limit_area=None, downcast=None, **kwargs*)

Interpolate values according to different methods.

Fill NaN values using an interpolation method.

Please note that only `method='linear'` is supported for DataFrame/Series with a MultiIndex.

Parameters

method [str, default 'linear'] Interpolation technique to use. One of:

- 'linear': Ignore the index and treat the values as equally spaced. This is the only method supported on MultiIndexes.
- 'time': Works on daily and higher resolution data to interpolate given length of interval.
- 'index', 'values': use the actual numerical values of the index.
- 'pad': Fill in NaNs using existing values.
- 'nearest', 'zero', 'slinear', 'quadratic', 'cubic', 'spline', 'barycentric', 'polynomial': Passed to `scipy.interpolate.interp1d`. These methods use the numerical values of the index. Both 'polynomial' and 'spline' require that you also specify an *order* (int), e.g. `df.interpolate(method='polynomial', order=5)`.
- 'krogh', 'piecewise_polynomial', 'spline', 'pchip', 'akima', 'cubicspline': Wrappers around the SciPy interpolation methods of similar names. See *Notes*.
- 'from_derivatives': Refers to `scipy.interpolate.BPoly.from_derivatives` which replaces 'piecewise_polynomial' interpolation method in scipy 0.18.

axis [{0 or 'index', 1 or 'columns', None}], default None] Axis to interpolate along.

limit [int, optional] Maximum number of consecutive NaNs to fill. Must be greater than 0.

inplace [bool, default False] Update the data in place if possible.

limit_direction [{ 'forward', 'backward', 'both' }, Optional] Consecutive NaNs will be filled in this direction.

If limit is specified:

- If 'method' is 'pad' or 'ffill', 'limit_direction' must be 'forward'.
- If 'method' is 'backfill' or 'bfill', 'limit_direction' must be 'backwards'.

If 'limit' is not specified:

- If 'method' is 'backfill' or 'bfill', the default is 'backward'
- else the default is 'forward'

Changed in version 1.1.0: raises `ValueError` if *limit_direction* is 'forward' or 'both' and method is 'backfill' or 'bfill'. raises `ValueError` if *limit_direction* is 'backward' or 'both' and method is 'pad' or 'ffill'.

limit_area [{None, 'inside', 'outside'}], default None] If limit is specified, consecutive NaNs will be filled with this restriction.

- None: No fill restriction.
- 'inside': Only fill NaNs surrounded by valid values (interpolate).

- ‘outside’: Only fill NaNs outside valid values (extrapolate).

downcast [optional, ‘infer’ or None, defaults to None] Downcast dtypes if possible.

kwargs [optional] Keyword arguments to pass on to the interpolating function.

Returns

Series or DataFrame or None Returns the same object type as the caller, interpolated at some or all NaN values or None if `inplace=True`.

See also:

[`fillna`](#) Fill missing values using different methods.

[`scipy.interpolate.Akima1DInterpolator`](#) Piecewise cubic polynomials (Akima interpolator).

[`scipy.interpolate.BPoly.from_derivatives`](#) Piecewise polynomial in the Bernstein basis.

[`scipy.interpolate.interp1d`](#) Interpolate a 1-D function.

[`scipy.interpolate.KroghInterpolator`](#) Interpolate polynomial (Krogh interpolator).

[`scipy.interpolate.PchipInterpolator`](#) PCHIP 1-d monotonic cubic interpolation.

[`scipy.interpolate.CubicSpline`](#) Cubic spline data interpolator.

Notes

The ‘krogh’, ‘piecewise_polynomial’, ‘spline’, ‘pchip’ and ‘akima’ methods are wrappers around the respective SciPy implementations of similar names. These use the actual numerical values of the index. For more information on their behavior, see the [SciPy documentation](#) and [SciPy tutorial](#).

Examples

Filling in NaN in a *Series* via linear interpolation.

```
>>> s = pd.Series([0, 1, np.nan, 3])
>>> s
0    0.0
1    1.0
2    NaN
3    3.0
dtype: float64
>>> s.interpolate()
0    0.0
1    1.0
2    2.0
3    3.0
dtype: float64
```

Filling in NaN in a Series by padding, but filling at most two consecutive NaN at a time.

```
>>> s = pd.Series([np.nan, "single_one", np.nan,
...               "fill_two_more", np.nan, np.nan, np.nan,
...               4.71, np.nan])
>>> s
0         NaN
1    single_one
2         NaN
3    fill_two_more
4         NaN
```

(continues on next page)

(continued from previous page)

```

5          NaN
6          NaN
7          4.71
8          NaN
dtype: object
>>> s.interpolate(method='pad', limit=2)
0          NaN
1    single_one
2    single_one
3  fill_two_more
4  fill_two_more
5  fill_two_more
6          NaN
7          4.71
8          4.71
dtype: object

```

Filling in NaN in a Series via polynomial interpolation or splines: Both ‘polynomial’ and ‘spline’ methods require that you also specify an `order` (int).

```

>>> s = pd.Series([0, 2, np.nan, 8])
>>> s.interpolate(method='polynomial', order=2)
0    0.000000
1    2.000000
2    4.666667
3    8.000000
dtype: float64

```

Fill the DataFrame forward (that is, going down) along each column using linear interpolation.

Note how the last entry in column ‘a’ is interpolated differently, because there is no entry after it to use for interpolation. Note how the first entry in column ‘b’ remains NaN, because there is no entry before it to use for interpolation.

```

>>> df = pd.DataFrame([(0.0, np.nan, -1.0, 1.0),
...                    (np.nan, 2.0, np.nan, np.nan),
...                    (2.0, 3.0, np.nan, 9.0),
...                    (np.nan, 4.0, -4.0, 16.0)],
...                    columns=list('abcd'))
>>> df
   a    b    c    d
0  0.0 NaN -1.0  1.0
1 NaN  2.0 NaN  NaN
2  2.0  3.0 NaN  9.0
3 NaN  4.0 -4.0 16.0
>>> df.interpolate(method='linear', limit_direction='forward', axis=0)
   a    b    c    d
0  0.0 NaN -1.0  1.0
1  1.0  2.0 -2.0  5.0
2  2.0  3.0 -3.0  9.0
3  2.0  4.0 -4.0 16.0

```

Using polynomial interpolation.

```
>>> df['d'].interpolate(method='polynomial', order=2)
0    1.0
1    4.0
2    9.0
3   16.0
Name: d, dtype: float64
```

3.11.4 Computations / descriptive stats

| | |
|---|--|
| <i>Resampler.count()</i> | Compute count of group, excluding missing values. |
| <i>Resampler.nunique</i> ([_method]) | Return number of unique elements in the group. |

| <i>Resampler.var</i> ([ddof]) | Compute variance of groups, excluding missing values. |
| <i>Resampler.quantile</i> ([q]) | Return value at the given quantile. |

pandas.core.resample.Resampler.count

Resampler.count()

Compute count of group, excluding missing values.

Returns

Series or DataFrame Count of values within each group.

See also:

Series.groupby Apply a function groupby to a Series.

DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

pandas.core.resample.Resampler.nunique

`Resampler.nunique(_method='nunique')`

Return number of unique elements in the group.

Returns

Series Number of unique values within each group.

pandas.core.resample.Resampler.first

`Resampler.first(_method='first', min_count=0, *args, **kwargs)`

Compute first of group values.

Parameters

numeric_only [bool, default False] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

min_count [int, default -1] The required number of valid values to perform the operation. If fewer than `min_count` non-NA values are present the result will be NA.

Returns

Series or DataFrame Computed first of values within each group.

pandas.core.resample.Resampler.last

`Resampler.last(_method='last', min_count=0, *args, **kwargs)`

Compute last of group values.

Parameters

numeric_only [bool, default False] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

min_count [int, default -1] The required number of valid values to perform the operation. If fewer than `min_count` non-NA values are present the result will be NA.

Returns

Series or DataFrame Computed last of values within each group.

pandas.core.resample.Resampler.max

`Resampler.max(_method='max', min_count=0, *args, **kwargs)`

Compute max of group values.

Parameters

numeric_only [bool, default False] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

min_count [int, default -1] The required number of valid values to perform the operation. If fewer than `min_count` non-NA values are present the result will be NA.

Returns

Series or DataFrame Computed max of values within each group.

pandas.core.resample.Resampler.mean

`Resampler.mean(_method='mean', *args, **kwargs)`

Compute mean of groups, excluding missing values.

Parameters

numeric_only [bool, default True] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

Returns

pandas.Series or pandas.DataFrame

See also:

Series.groupby Apply a function groupby to a Series.

DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

Examples

```
>>> df = pd.DataFrame({'A': [1, 1, 2, 1, 2],
...                   'B': [np.nan, 2, 3, 4, 5],
...                   'C': [1, 2, 1, 1, 2]}, columns=['A', 'B', 'C'])
```

Groupby one column and return the mean of the remaining columns in each group.

```
>>> df.groupby('A').mean()
   B      C
A
1  3.0  1.333333
2  4.0  1.500000
```

Groupby two columns and return the mean of the remaining column.

```
>>> df.groupby(['A', 'B']).mean()
   C
A B
1  2.0  2.0
   4.0  1.0
2  3.0  1.0
   5.0  2.0
```

Groupby one column and return the mean of only particular column in the group.

```
>>> df.groupby('A')['B'].mean()
A
1      3.0
2      4.0
Name: B, dtype: float64
```

pandas.core.resample.Resampler.median

Resampler.**median**(*_method='median', *args, **kwargs*)

Compute median of groups, excluding missing values.

For multiple groupings, the result index will be a MultiIndex

Parameters

numeric_only [bool, default True] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

Returns

Series or DataFrame Median of values within each group.

See also:

Series.groupby Apply a function groupby to a Series.

DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

pandas.core.resample.Resampler.min

Resampler.**min**(*_method='min', min_count=0, *args, **kwargs*)

Compute min of group values.

Parameters

numeric_only [bool, default False] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

min_count [int, default -1] The required number of valid values to perform the operation. If fewer than `min_count` non-NA values are present the result will be NA.

Returns

Series or DataFrame Computed min of values within each group.

pandas.core.resample.Resampler.ohlc

Resampler.**ohlc**(*_method='ohlc', *args, **kwargs*)

Compute open, high, low and close values of a group, excluding missing values.

For multiple groupings, the result index will be a MultiIndex

Returns

DataFrame Open, high, low and close values within each group.

See also:

Series.groupby Apply a function groupby to a Series.

DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

pandas.core.resample.Resampler.prod

`Resampler.prod(_method='prod', min_count=0, *args, **kwargs)`

Compute prod of group values.

Parameters

numeric_only [bool, default True] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

min_count [int, default 0] The required number of valid values to perform the operation. If fewer than `min_count` non-NA values are present the result will be NA.

Returns

Series or DataFrame Computed prod of values within each group.

pandas.core.resample.Resampler.size

`Resampler.size()`

Compute group sizes.

Returns

DataFrame or Series Number of rows in each group as a Series if `as_index` is True or a DataFrame if `as_index` is False.

See also:

Series.groupby Apply a function groupby to a Series.

DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

pandas.core.resample.Resampler.sem

`Resampler.sem(_method='sem', *args, **kwargs)`

Compute standard error of the mean of groups, excluding missing values.

For multiple groupings, the result index will be a MultiIndex.

Parameters

ddof [int, default 1] Degrees of freedom.

Returns

Series or DataFrame Standard error of the mean of values within each group.

See also:

Series.groupby Apply a function groupby to a Series.

DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

pandas.core.resample.Resampler.std

`Resampler.std(ddof=1, *args, **kwargs)`

Compute standard deviation of groups, excluding missing values.

Parameters

ddof [int, default 1] Degrees of freedom.

Returns

DataFrame or Series Standard deviation of values within each group.

pandas.core.resample.Resampler.sum

`Resampler.sum(_method='sum', min_count=0, *args, **kwargs)`

Compute sum of group values.

Parameters

numeric_only [bool, default True] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

min_count [int, default 0] The required number of valid values to perform the operation. If fewer than `min_count` non-NA values are present the result will be NA.

Returns

Series or DataFrame Computed sum of values within each group.

pandas.core.resample.Resampler.var

`Resampler.var(ddof=1, *args, **kwargs)`

Compute variance of groups, excluding missing values.

Parameters

ddof [int, default 1] Degrees of freedom.

Returns

DataFrame or Series Variance of values within each group.

pandas.core.resample.Resampler.quantile

`Resampler.quantile(q=0.5, **kwargs)`

Return value at the given quantile.

Parameters

q [float or array-like, default 0.5 (50% quantile)]

Returns

DataFrame or Series Quantile of values within each group.

See also:

Series.quantile Return a series, where the index is `q` and the values are the quantiles.

DataFrame.quantile Return a DataFrame, where the columns are the columns of self, and the values are the quantiles.

DataFrameGroupBy.quantile Return a DataFrame, where the columns are groupby columns, and the values are its quantiles.

3.12 Style

Styler objects are returned by `pandas.DataFrame.style`.

3.12.1 Styler constructor

| | |
|---|--|
| <code>Styler(data[, precision, table_styles, ...])</code> | Helps style a DataFrame or Series according to the data with HTML and CSS. |
| <code>Styler.from_custom_template(searchpath[, ...])</code> | Factory function for creating a subclass of <code>Styler</code> . |

pandas.io.formats.style.Styler

```
class pandas.io.formats.style.Styler(data, precision=None, table_styles=None, uuid=None,
                                     caption=None, table_attributes=None, cell_ids=True,
                                     na_rep=None, uuid_len=5, decimal=',', thousands=None,
                                     escape=None)
```

Helps style a DataFrame or Series according to the data with HTML and CSS.

Parameters

- data** [Series or DataFrame] Data to be styled - either a Series or DataFrame.
- precision** [int] Precision to round floats to, defaults to `pd.options.display.precision`.
- table_styles** [list-like, default None] List of {selector: (attr, value)} dicts; see Notes.
- uuid** [str, default None] A unique identifier to avoid CSS collisions; generated automatically.
- caption** [str, tuple, default None] String caption to attach to the table. Tuple only used for LaTeX dual captions.
- table_attributes** [str, default None] Items that show up in the opening `<table>` tag in addition to automatic (by default) id.
- cell_ids** [bool, default True] If True, each cell will have an id attribute in their HTML tag. The id takes the form `T_<uuid>_row<num_row>_col<num_col>` where `<uuid>` is the unique identifier, `<num_row>` is the row number and `<num_col>` is the column number.
- na_rep** [str, optional] Representation for missing values. If `na_rep` is None, no special formatting is applied.
New in version 1.0.0.
- uuid_len** [int, default 5] If `uuid` is not specified, the length of the `uuid` to randomly generate expressed in hex characters, in range `[0, 32]`.
New in version 1.2.0.
- decimal** [str, default “.”] Character used as decimal separator for floats, complex and integers
New in version 1.3.0.
- thousands** [str, optional, default None] Character used as thousands separator for floats, complex and integers
New in version 1.3.0.
- escape** [str, optional] Use ‘html’ to replace the characters `&`, `<`, `>`, `'`, and `"` in cell display string with HTML-safe sequences. Use ‘latex’ to replace the characters `&`, `%`, `$`, `#`, `_`, `{`, `}`, `~`, `^`, and `\` in the cell display string with LaTeX-safe sequences.
New in version 1.3.0.

See also:

DataFrame.style Return a `Styler` object containing methods for building a styled HTML representation for the DataFrame.

Notes

Most styling will be done by passing style functions into `Styler.apply` or `Styler.applymap`. Style functions should return values with strings containing CSS `'attr: value'` that will be applied to the indicated cells.

If using in the Jupyter notebook, `Styler` has defined a `_repr_html_` to automatically render itself. Otherwise call `Styler.render` to get the generated HTML.

CSS classes are attached to the generated HTML

- Index and Column names include `index_name` and `level<k>` where k is its level in a `MultiIndex`
- Index label cells include
 - `row_heading`
 - `row<n>` where n is the numeric position of the row
 - `level<k>` where k is the level in a `MultiIndex`
- Column label cells include `* col_heading * col<n>` where n is the numeric position of the column `* level<k>` where k is the level in a `MultiIndex`
- Blank cells include `blank`
- Data cells include `data`

Attributes

| | |
|-----------------|---|
| env | (Jinja2 <code>jinja2.Environment</code>) |
| template | (Jinja2 <code>Template</code>) |
| loader | (Jinja2 <code>Loader</code>) |

Methods

| | |
|--|---|
| <code>apply(func[, axis, subset])</code> | Apply a CSS-styling function column-wise, row-wise, or table-wise. |
| <code>applymap(func[, subset])</code> | Apply a CSS-styling function elementwise. |
| <code>background_gradient([cmap, low, high, axis, ...])</code> | Color the background in a gradient style. |
| <code>bar([subset, axis, color, width, align, ...])</code> | Draw bar chart in the cell backgrounds. |
| <code>clear()</code> | Reset the <code>Styler</code> , removing any previously applied styles. |
| <code>export()</code> | Export the styles applied to the current <code>Styler</code> . |
| <code>format([formatter, subset, na_rep, ...])</code> | Format the text display value of cells. |
| <code>from_custom_template(searchpath[, ...])</code> | Factory function for creating a subclass of <code>Styler</code> . |
| <code>hide_columns([subset])</code> | Hide the column headers or specific keys in the columns from rendering. |
| <code>hide_index([subset])</code> | Hide the entire index, or specific keys in the index from rendering. |
| <code>highlight_between([subset, color, axis, ...])</code> | Highlight a defined range with a style. |
| <code>highlight_max([subset, color, axis, props])</code> | Highlight the maximum with a style. |
| <code>highlight_min([subset, color, axis, props])</code> | Highlight the minimum with a style. |
| <code>highlight_null([null_color, subset, props])</code> | Highlight missing values with a style. |
| <code>highlight_quantile([subset, color, axis, ...])</code> | Highlight values defined by a quantile with a style. |
| <code>pipe(func, *args, **kwargs)</code> | Apply <code>func(self, *args, **kwargs)</code> , and return the result. |

continues on next page

Table 389 – continued from previous page

| | |
|--|--|
| <code>render([sparse_index, sparse_columns])</code> | Render the Styler including all applied styles to HTML. |
| <code>set_caption(caption)</code> | Set the text added to a <code><caption></code> HTML element. |
| <code>set_na_rep(na_rep)</code> | (DEPRECATED) Set the missing data representation on a Styler. |
| <code>set_precision(precision)</code> | (DEPRECATED) Set the precision used to display values. |
| <code>set_properties([subset])</code> | Set defined CSS-properties to each <code><td></code> HTML element within the given subset. |
| <code>set_sticky([axis, pixel_size, levels])</code> | Add CSS to permanently display the index or column headers in a scrolling frame. |
| <code>set_table_attributes(attributes)</code> | Set the table attributes added to the <code><table></code> HTML element. |
| <code>set_table_styles(table_styles[, axis, overwrite])</code> | Set the table styles included within the <code><style></code> HTML element. |
| <code>set_td_classes(classes)</code> | Set the DataFrame of strings added to the <code>class</code> attribute of <code><td></code> HTML elements. |
| <code>set_tooltips(ttips[, props, css_class])</code> | Set the DataFrame of strings on Styler generating <code>:hover</code> tooltips. |
| <code>set_uuid(uuid)</code> | Set the uuid applied to <code>id</code> attributes of HTML elements. |
| <code>text_gradient([cmap, low, high, axis, ...])</code> | Color the text in a gradient style. |
| <code>to_excel(excel_writer[, sheet_name, na_rep, ...])</code> | Write Styler to an Excel sheet. |
| <code>to_html([buf, table_uuid, table_attributes, ...])</code> | Write Styler to a file, buffer or string in HTML-CSS format. |
| <code>to_latex([buf, column_format, position, ...])</code> | Write Styler to a file, buffer or string in LaTeX format. |
| <code>use(styles)</code> | Set the styles on the current Styler. |
| <code>where(cond, value[, other, subset])</code> | (DEPRECATED) Apply CSS-styles based on a conditional function elementwise. |

pandas.io.formats.style.Styler.apply

`Styler.apply(func, axis=0, subset=None, **kwargs)`

Apply a CSS-styling function column-wise, row-wise, or table-wise.

Updates the HTML representation with the result.

Parameters

func [function] `func` should take a Series if `axis` in `[0,1]` and return an object of same length, also with identical index if the object is a Series. `func` should take a DataFrame if `axis` is `None` and return either an ndarray with the same shape or a DataFrame with identical columns and index.

Changed in version 1.3.0.

axis [{0 or 'index', 1 or 'columns', None}, default 0] Apply to each column (`axis=0` or `'index'`), to each row (`axis=1` or `'columns'`), or to the entire DataFrame at once with `axis=None`.

subset [label, array-like, IndexSlice, optional] A valid 2d input to `DataFrame.loc[<subset>]`, or, in the case of a 1d input or single key, to `DataFrame.loc[:, <subset>]` where the columns are prioritised, to limit data to before applying the function.

****kwargs** [dict] Pass along to func.

Returns

self [Styler]

See also:

[*Styler.applymap*](#) Apply a CSS-styling function elementwise.

Notes

The elements of the output of `func` should be CSS styles as strings, in the format ‘attribute: value; attribute2: value2; ...’ or, if nothing is to be applied to that element, an empty string or `None`.

This is similar to `DataFrame.apply`, except that `axis=None` applies the function to the entire `DataFrame` at once, rather than column-wise or row-wise.

Examples

```
>>> def highlight_max(x, color):
...     return np.where(x == np.nanmax(x.to_numpy()), f"color: {color};", None)
>>> df = pd.DataFrame(np.random.randn(5, 2), columns=["A", "B"])
>>> df.style.apply(highlight_max, color='red')
>>> df.style.apply(highlight_max, color='blue', axis=1)
>>> df.style.apply(highlight_max, color='green', axis=None)
```

Using `subset` to restrict application to a single column or multiple columns

```
>>> df.style.apply(highlight_max, color='red', subset="A")
>>> df.style.apply(highlight_max, color='red', subset=["A", "B"])
```

Using a 2d input to `subset` to select rows in addition to columns

```
>>> df.style.apply(highlight_max, color='red', subset=([0,1,2], slice(None)))
>>> df.style.apply(highlight_max, color='red', subset=(slice(0,5,2), "A"))
```

pandas.io.formats.style.Styler.applymap

`Styler.applymap(func, subset=None, **kwargs)`

Apply a CSS-styling function elementwise.

Updates the HTML representation with the result.

Parameters

func [function] `func` should take a scalar and return a scalar.

subset [label, array-like, IndexSlice, optional] A valid 2d input to `DataFrame.loc[<subset>]`, or, in the case of a 1d input or single key, to `DataFrame.loc[:, <subset>]` where the columns are prioritised, to limit data to *before* applying the function.

****kwargs** [dict] Pass along to `func`.

Returns

`self` [Styler]

See also:

`Styler.apply` Apply a CSS-styling function column-wise, row-wise, or table-wise.

Notes

The elements of the output of `func` should be CSS styles as strings, in the format ‘attribute: value; attribute2: value2; ...’ or, if nothing is to be applied to that element, an empty string or `None`.

Examples

```
>>> def color_negative(v, color):
...     return f"color: {color};" if v < 0 else None
>>> df = pd.DataFrame(np.random.randn(5, 2), columns=["A", "B"])
>>> df.style.applymap(color_negative, color='red')
```

Using `subset` to restrict application to a single column or multiple columns

```
>>> df.style.applymap(color_negative, color='red', subset="A")
>>> df.style.applymap(color_negative, color='red', subset=["A", "B"])
```

Using a 2d input to `subset` to select rows in addition to columns

```
>>> df.style.applymap(color_negative, color='red', subset=(slice(0,1,2), slice(None)))
>>> df.style.applymap(color_negative, color='red', subset=(slice(0,5,2), "A"))
```

pandas.io.formats.style.Styler.background_gradient

`Styler.background_gradient` (*cmap='PuBu', low=0, high=0, axis=0, subset=None, text_color_threshold=0.408, vmin=None, vmax=None, gmap=None*)

Color the background in a gradient style.

The background color is determined according to the data in each column, row or frame, or by a given gradient map. Requires `matplotlib`.

Parameters

cmap [str or colormap] Matplotlib colormap.

low [float] Compress the color range at the low end. This is a multiple of the data range to extend below the minimum; good values usually in [0, 1], defaults to 0.

high [float] Compress the color range at the high end. This is a multiple of the data range to extend above the maximum; good values usually in [0, 1], defaults to 0.

axis [{0 or 'index', 1 or 'columns', None}, default 0] Apply to each column (`axis=0` or `'index'`), to each row (`axis=1` or `'columns'`), or to the entire DataFrame at once with `axis=None`.

subset [label, array-like, IndexSlice, optional] A valid 2d input to `DataFrame.loc[<subset>]`, or, in the case of a 1d input or single key, to

`DataFrame.loc[:, <subset>]` where the columns are prioritised, to limit data to before applying the function.

text_color_threshold [float or int] Luminance threshold for determining text color in [0, 1]. Facilitates text visibility across varying background colors. All text is dark if 0, and light if 1, defaults to 0.408.

vmin [float, optional] Minimum data value that corresponds to colormap minimum value. If not specified the minimum value of the data (or gmap) will be used.

New in version 1.0.0.

vmax [float, optional] Maximum data value that corresponds to colormap maximum value. If not specified the maximum value of the data (or gmap) will be used.

New in version 1.0.0.

gmap [array-like, optional] Gradient map for determining the background colors. If not supplied will use the underlying data from rows, columns or frame. If given as an ndarray or list-like must be an identical shape to the underlying data considering axis and subset. If given as DataFrame or Series must have same index and column labels considering axis and subset. If supplied, vmin and vmax should be given relative to this gradient map.

New in version 1.3.0.

Returns

self [Styler]

See also:

[`Styler.text_gradient`](#) Color the text in a gradient style.

Notes

When using `low` and `high` the range of the gradient, given by the data if `gmap` is not given or by `gmap`, is extended at the low end effectively by $map.min - low * map.range$ and at the high end by $map.max + high * map.range$ before the colors are normalized and determined.

If combining with `vmin` and `vmax` the `map.min`, `map.max` and `map.range` are replaced by values according to the values derived from `vmin` and `vmax`.

This method will preselect numeric columns and ignore non-numeric columns unless a `gmap` is supplied in which case no preselection occurs.

Examples

```
>>> df = pd.DataFrame(columns=["City", "Temp (c)", "Rain (mm)", "Wind (m/s)"],
...                       data=[["Stockholm", 21.6, 5.0, 3.2],
...                               ["Oslo", 22.4, 13.3, 3.1],
...                               ["Copenhagen", 24.5, 0.0, 6.7]])
```

Shading the values column-wise, with `axis=0`, preselecting numeric columns

```
>>> df.style.background_gradient(axis=0)
```

Shading all values collectively using `axis=None`

| | City | Temp (c) | Rain (mm) | Wind (m/s) |
|---|------------|-----------|-----------|------------|
| 0 | Stockholm | 21.600000 | 5.000000 | 3.200000 |
| 1 | Oslo | 22.400000 | 13.300000 | 3.100000 |
| 2 | Copenhagen | 24.500000 | 0.000000 | 6.700000 |

```
>>> df.style.background_gradient(axis=None)
```

| | City | Temp (c) | Rain (mm) | Wind (m/s) |
|---|------------|-----------|-----------|------------|
| 0 | Stockholm | 21.600000 | 5.000000 | 3.200000 |
| 1 | Oslo | 22.400000 | 13.300000 | 3.100000 |
| 2 | Copenhagen | 24.500000 | 0.000000 | 6.700000 |

Compress the color map from the both low and high ends

```
>>> df.style.background_gradient(axis=None, low=0.75, high=1.0)
```

| | City | Temp (c) | Rain (mm) | Wind (m/s) |
|---|------------|-----------|-----------|------------|
| 0 | Stockholm | 21.600000 | 5.000000 | 3.200000 |
| 1 | Oslo | 22.400000 | 13.300000 | 3.100000 |
| 2 | Copenhagen | 24.500000 | 0.000000 | 6.700000 |

Manually setting vmin and vmax gradient thresholds

```
>>> df.style.background_gradient(axis=None, vmin=6.7, vmax=21.6)
```

Setting a gmap and applying to all columns with another cmap

```
>>> df.style.background_gradient(axis=0, gmap=df['Temp (c)'], cmap='YlOrRd')
```

Setting the gradient map for a dataframe (i.e. axis=None), we need to explicitly state subset to match the gmap shape

```
>>> gmap = np.array([[1,2,3], [2,3,4], [3,4,5]])
>>> df.style.background_gradient(axis=None, gmap=gmap,
...     cmap='YlOrRd', subset=['Temp (c)', 'Rain (mm)', 'Wind (m/s)']
... )
```

| | City | Temp (c) | Rain (mm) | Wind (m/s) |
|---|------------|-----------|-----------|------------|
| 0 | Stockholm | 21.600000 | 5.000000 | 3.200000 |
| 1 | Oslo | 22.400000 | 13.300000 | 3.100000 |
| 2 | Copenhagen | 24.500000 | 0.000000 | 6.700000 |

| | City | Temp (c) | Rain (mm) | Wind (m/s) |
|---|------------|-----------|-----------|------------|
| 0 | Stockholm | 21.600000 | 5.000000 | 3.200000 |
| 1 | Oslo | 22.400000 | 13.300000 | 3.100000 |
| 2 | Copenhagen | 24.500000 | 0.000000 | 6.700000 |

pandas.io.formats.style.Styler.bar

`Styler.bar`(*subset=None*, *axis=0*, *color='#d65f5f'*, *width=100*, *align='left'*, *vmin=None*, *vmax=None*)
Draw bar chart in the cell backgrounds.

Parameters

subset [label, array-like, IndexSlice, optional] A valid 2d input to `DataFrame.loc[<subset>]`, or, in the case of a 1d input or single key, to `DataFrame.loc[:, <subset>]` where the columns are prioritised, to limit data to *before* applying the function.

axis [{0 or 'index', 1 or 'columns', None}, default 0] Apply to each column (`axis=0` or 'index'), to each row (`axis=1` or 'columns'), or to the entire DataFrame at once with `axis=None`.

color [str or 2-tuple/list] If a str is passed, the color is the same for both negative and positive numbers. If 2-tuple/list is used, the first element is the `color_negative` and the second is the `color_positive` (eg: ['#d65f5f', '#5fba7d']).

width [float, default 100] A number between 0 or 100. The largest value will cover *width* percent of the cell's width.

align [{ 'left', 'zero', 'mid' }, default 'left'] How to align the bars with the cells.

- 'left' : the min value starts at the left of the cell.
- 'zero' : a value of zero is located at the center of the cell.
- 'mid' : the center of the cell is at $(\max - \min)/2$, or if values are all negative (positive) the zero is aligned at the right (left) of the cell.

vmin [float, optional] Minimum bar value, defining the left hand limit of the bar drawing range, lower values are clipped to *vmin*. When None (default): the minimum value of the data will be used.

| | City | Temp (c) | Rain (mm) | Wind (m/s) |
|---|------------|-----------|-----------|------------|
| 0 | Stockholm | 21.600000 | 5.000000 | 3.200000 |
| 1 | Oslo | 22.400000 | 13.300000 | 3.100000 |
| 2 | Copenhagen | 24.500000 | 0.000000 | 6.700000 |

vmax [float, optional] Maximum bar value, defining the right hand limit of the bar drawing range, higher values are clipped to *vmax*. When None (default): the maximum value of the data will be used.

Returns

self [Styler]

pandas.io.formats.style.Styler.clear

Styler.clear()

Reset the Styler, removing any previously applied styles.

Returns None.

pandas.io.formats.style.Styler.export

Styler.export()

Export the styles applied to the current Styler.

Can be applied to a second Styler with `Styler.use`.

Returns

styles [list]

See also:

[Styler.use](#) Set the styles on the current Styler.

pandas.io.formats.style.Styler.format

Styler.format(*formatter=None, subset=None, na_rep=None, precision=None, decimal='.', thousands=None, escape=None*)

Format the text display value of cells.

Parameters

formatter [str, callable, dict or None] Object to define how values are displayed. See notes.

subset [label, array-like, IndexSlice, optional] A valid 2d input to `DataFrame.loc[<subset>]`, or, in the case of a 1d input or single key, to `DataFrame.loc[:, <subset>]` where the columns are prioritised, to limit data to *before* applying the function.

na_rep [str, optional] Representation for missing values. If `na_rep` is None, no special formatting is applied.

New in version 1.0.0.

precision [int, optional] Floating point precision to use for display purposes, if not determined by the specified `formatter`.

New in version 1.3.0.

decimal [str, default “.”] Character used as decimal separator for floats, complex and integers

New in version 1.3.0.

thousands [str, optional, default None] Character used as thousands separator for floats, complex and integers

New in version 1.3.0.

escape [str, optional] Use ‘html’ to replace the characters &, <, >, ' , and " in cell display string with HTML-safe sequences. Use ‘latex’ to replace the characters &, %, \$, #, _, {, }, ~, ^, and \ in the cell display string with LaTeX-safe sequences. Escaping is done before `formatter`.

New in version 1.3.0.

Returns

self [Styler]

Notes

This method assigns a formatting function, `formatter`, to each cell in the DataFrame. If `formatter` is None, then the default formatter is used. If a callable then that function should take a data value as input and return a displayable representation, such as a string. If `formatter` is given as a string this is assumed to be a valid Python format specification and is wrapped to a callable as `string.format(x)`. If a dict is given, keys should correspond to column names, and values should be string or callable, as above.

The default formatter currently expresses floats and complex numbers with the pandas display precision unless using the `precision` argument here. The default formatter does not adjust the representation of missing values unless the `na_rep` argument is used.

The `subset` argument defines which region to apply the formatting function to. If the `formatter` argument is given in dict form but does not include all columns within the subset then these columns will have the default formatter applied. Any columns in the `formatter` dict excluded from the subset will be ignored.

When using a `formatter` string the dtypes must be compatible, otherwise a `ValueError` will be raised.

Examples

Using `na_rep` and `precision` with the default formatter

```
>>> df = pd.DataFrame([[np.nan, 1.0, 'A'], [2.0, np.nan, 3.0]])
>>> df.style.format(na_rep='MISS', precision=3)
   0      1      2
0  MISS  1.000  A
1  2.000  MISS  3.000
```

Using a `formatter` specification on consistent column dtypes

```
>>> df.style.format('{:.2f}', na_rep='MISS', subset=[0,1])
   0      1      2
0  MISS  1.00  A
1  2.00  MISS  3.000000
```

Using the default `formatter` for unspecified columns

```
>>> df.style.format({0: '{:.2f}', 1: '£ {:.1f}'}, na_rep='MISS', precision=1)
      0      1      2
0  MISS  £ 1.0  A
1  2.00  MISS  3.0
```

Multiple na_rep or precision specifications under the default formatter.

```
>>> df.style.format(na_rep='MISS', precision=1, subset=[0])
...     .format(na_rep='PASS', precision=2, subset=[1, 2])
      0      1      2
0  MISS  1.00  A
1  2.0  PASS  3.00
```

Using a callable formatter function.

```
>>> func = lambda s: 'STRING' if isinstance(s, str) else 'FLOAT'
>>> df.style.format({0: '{:.1f}', 2: func}, precision=4, na_rep='MISS')
      0      1      2
0  MISS  1.0000  STRING
1  2.0    MISS  FLOAT
```

Using a formatter with HTML escape and na_rep.

```
>>> df = pd.DataFrame([[ '<div></div>', "A&B", None]])
>>> s = df.style.format(
...     '<a href="a.com/{0}">{0}</a>', escape="html", na_rep="NA"
...     )
>>> s.render()
...
<td .. ><a href="a.com/&lt;div&gt;&lt;/div&gt;">&lt;div&gt;&lt;/div&gt;</a></
→td>
<td .. ><a href="a.com/&#34;A&amp;B&#34;">&#34;A&amp;B&#34;</a></td>
<td .. >NA</td>
...

```

Using a formatter with LaTeX escape.

```
>>> df = pd.DataFrame([["123"], ["~ ^"], ["$%#"]])
>>> s = df.style.format("\\textbf{{{}}}", escape="latex").to_latex()
\begin{tabular}{ll}
{} & {0} \\
0 & \textbf{123} \\
1 & \textbf{\textasciitilde \space \textasciicircum } \\
2 & \textbf{\$\%\#} \\
\end{tabular}
```

`pandas.io.formats.style.Styler.from_custom_template`

classmethod `Styler.from_custom_template`(*searchpath*, *html_table=None*, *html_style=None*)

Factory function for creating a subclass of `Styler`.

Uses custom templates and Jinja environment.

Changed in version 1.3.0.

Parameters

searchpath [str or list] Path or paths of directories containing the templates.

html_table [str] Name of your custom template to replace the `html_table` template.

New in version 1.3.0.

html_style [str] Name of your custom template to replace the `html_style` template.

New in version 1.3.0.

Returns

MyStyler [subclass of `Styler`] Has the correct `env`, `template_html``, `template_html_table` and `template_html_style` class attributes set.

`pandas.io.formats.style.Styler.hide_columns`

`Styler.hide_columns`(*subset=None*)

Hide the column headers or specific keys in the columns from rendering.

This method has dual functionality:

- if `subset` is `None` then the entire column headers row will be hidden whilst the data-values remain visible.
- if a `subset` is given then those specific columns, including the data-values will be hidden, whilst the column headers row remains visible.

Changed in version 1.3.0.

Parameters

subset [label, array-like, `IndexSlice`, optional] A valid 1d input or single key along the columns axis within `DataFrame.loc[:, <subset>]`, to limit data to *before* applying the function.

Returns

self [`Styler`]

See also:

[`Styler.hide_index`](#) Hide the entire index, or specific keys in the index.

Examples

Simple application hiding specific columns:

```
>>> df = pd.DataFrame([[1, 2, 3], [4, 5, 6]], columns=["a", "b", "c"])
>>> df.style.hide_columns(["a", "b"])
   c
0  3
1  6
```

Hide column headers and retain the data values:

```
>>> midx = pd.MultiIndex.from_product([["x", "y"], ["a", "b", "c"]])
>>> df = pd.DataFrame(np.random.randn(6,6), index=midx, columns=midx)
>>> df.style.format("{:.1f}").hide_columns()
x  d    0.1    0.0    0.4    1.3    0.6   -1.4
   e    0.7    1.0    1.3    1.5   -0.0   -0.2
   f    1.4   -0.8    1.6   -0.2   -0.4   -0.3
y  d    0.4    1.0   -0.2   -0.8   -1.2    1.1
   e   -0.6    1.2    1.8    1.9    0.3    0.3
   f    0.8    0.5   -0.3    1.2    2.2   -0.8
```

Hide specific columns but retain the column headers:

```
>>> df.style.format("{:.1f}").hide_columns(subset=(slice(None), ["a", "c"]))
      x      y
x  a    0.0    0.6
   b    1.0   -0.0
   c   -0.8   -0.4
y  a    1.0   -1.2
   b    1.2    0.3
   c    0.5    2.2
```

Hide specific columns and the column headers:

```
>>> df.style.format("{:.1f}").hide_columns(subset=(slice(None), ["a", "c"]))
...     .hide_columns()
x  a    0.0    0.6
   b    1.0   -0.0
   c   -0.8   -0.4
y  a    1.0   -1.2
   b    1.2    0.3
   c    0.5    2.2
```

pandas.io.formats.style.Styler.hide_index**Styler.hide_index**(subset=None)

Hide the entire index, or specific keys in the index from rendering.

This method has dual functionality:

- if subset is None then the entire index will be hidden whilst displaying all data-rows.
- if a subset is given then those specific rows will be hidden whilst the index itself remains visible.

Changed in version 1.3.0.

Parameters

subset [label, array-like, IndexSlice, optional] A valid 1d input or single key along the index axis within `DataFrame.loc[<subset>, :]`, to limit data to *before* applying the function.

Returns**self** [Styler]**See also:****Styler.hide_columns** Hide the entire column headers row, or specific columns.**Examples**

Simple application hiding specific rows:

```
>>> df = pd.DataFrame([[1,2], [3,4], [5,6]], index=["a", "b", "c"])
>>> df.style.hide_index(["a", "b"])
   0  1
c  5  6
```

Hide the index and retain the data values:

```
>>> midx = pd.MultiIndex.from_product([["x", "y"], ["a", "b", "c"]])
>>> df = pd.DataFrame(np.random.randn(6,6), index=midx, columns=midx)
>>> df.style.format("{:.1f}").hide_index()
      x      y
a  b  c  a  b  c
0.1  0.0  0.4  1.3  0.6 -1.4
0.7  1.0  1.3  1.5 -0.0 -0.2
1.4 -0.8  1.6 -0.2 -0.4 -0.3
0.4  1.0 -0.2 -0.8 -1.2  1.1
-0.6  1.2  1.8  1.9  0.3  0.3
0.8  0.5 -0.3  1.2  2.2 -0.8
```

Hide specific rows but retain the index:

```
>>> df.style.format("{:.1f}").hide_index(subset=(slice(None), ["a", "c"]))
      x      y
x  b  a  b  c  a  b  c
y  b -0.6  1.2  1.8  1.9  0.3  0.3
```

Hide specific rows and the index:

```
>>> df.style.format("{:.1f}").hide_index(subset=(slice(None), ["a", "c"]))
...     .hide_index()
      x      y
a     b     c     a     b     c
0.7   1.0   1.3   1.5  -0.0  -0.2
-0.6  1.2   1.8   1.9   0.3   0.3
```

pandas.io.formats.style.Styler.highlight_between

`Styler.highlight_between`(subset=None, color='yellow', axis=0, left=None, right=None, inclusive='both', props=None)

Highlight a defined range with a style.

New in version 1.3.0.

Parameters

subset [label, array-like, IndexSlice, optional] A valid 2d input to `DataFrame.loc[<subset>]`, or, in the case of a 1d input or single key, to `DataFrame.loc[:, <subset>]` where the columns are prioritised, to limit data to *before* applying the function.

color [str, default 'yellow'] Background color to use for highlighting.

axis [{0 or 'index', 1 or 'columns', None}, default 0] If `left` or `right` given as sequence, axis along which to apply those boundaries. See examples.

left [scalar or datetime-like, or sequence or array-like, default None] Left bound for defining the range.

right [scalar or datetime-like, or sequence or array-like, default None] Right bound for defining the range.

inclusive [{ 'both', 'neither', 'left', 'right' }] Identify whether bounds are closed or open.

props [str, default None] CSS properties to use for highlighting. If `props` is given, `color` is not used.

Returns

`self` [Styler]

See also:

[`Styler.highlight_null`](#) Highlight missing values with a style.

[`Styler.highlight_max`](#) Highlight the maximum with a style.

[`Styler.highlight_min`](#) Highlight the minimum with a style.

[`Styler.highlight_quantile`](#) Highlight values defined by a quantile with a style.

Notes

If `left` is `None` only the right bound is applied. If `right` is `None` only the left bound is applied. If both are `None` all values are highlighted.

`axis` is only needed if `left` or `right` are provided as a sequence or an array-like object for aligning the shapes. If `left` and `right` are both scalars then all `axis` inputs will give the same result.

This function only works with compatible dtypes. For example a datetime-like region can only use equivalent datetime-like `left` and `right` arguments. Use `subset` to control regions which have multiple dtypes.

Examples

Basic usage

```
>>> df = pd.DataFrame({
...     'One': [1.2, 1.6, 1.5],
...     'Two': [2.9, 2.1, 2.5],
...     'Three': [3.1, 3.2, 3.8],
... })
>>> df.style.highlight_between(left=2.1, right=2.9)
```

| | One | Two | Three |
|---|-----|-----|-------|
| 0 | 1.2 | 2.9 | 3.1 |
| 1 | 1.6 | 2.1 | 3.2 |
| 2 | 1.5 | 2.5 | 3.8 |

Using a range input sequence along an axis, in this case setting a `left` and `right` for each column individually

```
>>> df.style.highlight_between(left=[1.4, 2.4, 3.4], right=[1.6, 2.6, 3.6],
...     axis=1, color="#fffd75")
```

| | One | Two | Three |
|---|-----|-----|-------|
| 0 | 1.2 | 2.9 | 3.1 |
| 1 | 1.6 | 2.1 | 3.2 |
| 2 | 1.5 | 2.5 | 3.8 |

Using `axis=None` and providing the `left` argument as an array that matches the input `DataFrame`, with a constant `right`

```
>>> df.style.highlight_between(left=[[2,2,3],[2,2,3],[3,3,3]], right=3.5,
...     axis=None, color="#fffd75")
```

Using props instead of default background coloring

```
>>> df.style.highlight_between(left=1.5, right=3.5,
...     props='font-weight:bold;color:#e83e8c')
```

| | One | Two | Three |
|---|-----|-----|-------|
| 0 | 1.2 | 2.9 | 3.1 |
| 1 | 1.6 | 2.1 | 3.2 |
| 2 | 1.5 | 2.5 | 3.8 |

| | One | Two | Three |
|---|-----|-----|-------|
| 0 | 1.2 | 2.9 | 3.1 |
| 1 | 1.6 | 2.1 | 3.2 |
| 2 | 1.5 | 2.5 | 3.8 |

pandas.io.formats.style.Styler.highlight_max

`Styler.highlight_max(subset=None, color='yellow', axis=0, props=None)`

Highlight the maximum with a style.

Parameters

subset [label, array-like, IndexSlice, optional] A valid 2d input to `DataFrame.loc[<subset>]`, or, in the case of a 1d input or single key, to `DataFrame.loc[:, <subset>]` where the columns are prioritised, to limit data to before applying the function.

color [str, default 'yellow'] Background color to use for highlighting.

axis [{0 or 'index', 1 or 'columns', None}, default 0] Apply to each column (`axis=0` or 'index'), to each row (`axis=1` or 'columns'), or to the entire DataFrame at once with `axis=None`.

props [str, default None] CSS properties to use for highlighting. If `props` is given, `color` is not used.

New in version 1.3.0.

Returns

`self` [Styler]

See also:

[`Styler.highlight_null`](#) Highlight missing values with a style.

[`Styler.highlight_min`](#) Highlight the minimum with a style.

[`Styler.highlight_between`](#) Highlight a defined range with a style.

[`Styler.highlight_quantile`](#) Highlight values defined by a quantile with a style.

pandas.io.formats.style.Styler.highlight_min

`Styler.highlight_min(subset=None, color='yellow', axis=0, props=None)`

Highlight the minimum with a style.

Parameters

subset [label, array-like, IndexSlice, optional] A valid 2d input to `DataFrame.loc[<subset>]`, or, in the case of a 1d input or single key, to `DataFrame.loc[:, <subset>]` where the columns are prioritised, to limit data to *before* applying the function.

color [str, default 'yellow'] Background color to use for highlighting.

axis [{0 or 'index', 1 or 'columns', None}, default 0] Apply to each column (`axis=0` or 'index'), to each row (`axis=1` or 'columns'), or to the entire DataFrame at once with `axis=None`.

props [str, default None] CSS properties to use for highlighting. If `props` is given, `color` is not used.

New in version 1.3.0.

Returns

`self` [Styler]

See also:

[`Styler.highlight_null`](#) Highlight missing values with a style.

[`Styler.highlight_max`](#) Highlight the maximum with a style.

[`Styler.highlight_between`](#) Highlight a defined range with a style.

[`Styler.highlight_quantile`](#) Highlight values defined by a quantile with a style.

pandas.io.formats.style.Styler.highlight_null

`Styler.highlight_null(null_color='red', subset=None, props=None)`

Highlight missing values with a style.

Parameters

null_color [str, default 'red']

subset [label, array-like, IndexSlice, optional] A valid 2d input to `DataFrame.loc[<subset>]`, or, in the case of a 1d input or single key, to `DataFrame.loc[:, <subset>]` where the columns are prioritised, to limit data to *before* applying the function.

New in version 1.1.0.

props [str, default None] CSS properties to use for highlighting. If `props` is given, `color` is not used.

New in version 1.3.0.

Returns

`self` [Styler]

See also:

`Styler.highlight_max` Highlight the maximum with a style.

`Styler.highlight_min` Highlight the minimum with a style.

`Styler.highlight_between` Highlight a defined range with a style.

`Styler.highlight_quantile` Highlight values defined by a quantile with a style.

pandas.io.formats.style.Styler.highlight_quantile

`Styler.highlight_quantile`(*subset=None, color='yellow', axis=0, q_left=0.0, q_right=1.0, interpolation='linear', inclusive='both', props=None*)

Highlight values defined by a quantile with a style.

New in version 1.3.0.

Parameters

subset [label, array-like, IndexSlice, optional] A valid 2d input to `DataFrame.loc[<subset>]`, or, in the case of a 1d input or single key, to `DataFrame.loc[:, <subset>]` where the columns are prioritised, to limit data to before applying the function.

color [str, default 'yellow'] Background color to use for highlighting

axis [{0 or 'index', 1 or 'columns', None}, default 0] Axis along which to determine and highlight quantiles. If None quantiles are measured over the entire DataFrame. See examples.

q_left [float, default 0] Left bound, in [0, q_right), for the target quantile range.

q_right [float, default 1] Right bound, in (q_left, 1], for the target quantile range.

interpolation [{ 'linear', 'lower', 'higher', 'midpoint', 'nearest' }] Argument passed to `Series.quantile` or `DataFrame.quantile` for quantile estimation.

inclusive [{ 'both', 'neither', 'left', 'right' }] Identify whether quantile bounds are closed or open.

props [str, default None] CSS properties to use for highlighting. If props is given, color is not used.

Returns

self [Styler]

See also:

`Styler.highlight_null` Highlight missing values with a style.

`Styler.highlight_max` Highlight the maximum with a style.

`Styler.highlight_min` Highlight the minimum with a style.

`Styler.highlight_between` Highlight a defined range with a style.

Notes

This function does not work with `str` dtypes.

Examples

Using `axis=None` and apply a quantile to all collective data

```
>>> df = pd.DataFrame(np.arange(10).reshape(2,5) + 1)
>>> df.style.highlight_quantile(axis=None, q_left=0.8, color="#fffd75")
```

| | 0 | 1 | 2 | 3 | 4 |
|---|---|---|---|---|----|
| 0 | 1 | 2 | 3 | 4 | 5 |
| 1 | 6 | 7 | 8 | 9 | 10 |

Or highlight quantiles row-wise or column-wise, in this case by row-wise

```
>>> df.style.highlight_quantile(axis=1, q_left=0.8, color="#fffd75")
```

| | 0 | 1 | 2 | 3 | 4 |
|---|---|---|---|---|----|
| 0 | 1 | 2 | 3 | 4 | 5 |
| 1 | 6 | 7 | 8 | 9 | 10 |

Use props instead of default background coloring

```
>>> df.style.highlight_quantile(axis=None, q_left=0.2, q_right=0.8,
...     props='font-weight:bold;color:#e83e8c')
```

| | 0 | 1 | 2 | 3 | 4 |
|---|---|---|---|---|----|
| 0 | 1 | 2 | 3 | 4 | 5 |
| 1 | 6 | 7 | 8 | 9 | 10 |

pandas.io.formats.style.Styler.pipe

`Styler.pipe(func, *args, **kwargs)`

Apply `func(self, *args, **kwargs)`, and return the result.

Parameters

func [function] Function to apply to the Styler. Alternatively, a (callable, keyword) tuple where keyword is a string indicating the keyword of callable that expects the Styler.

***args** [optional] Arguments passed to `func`.

****kwargs** [optional] A dictionary of keyword arguments passed into `func`.

Returns

object : The value returned by `func`.

See also:

DataFrame.pipe Analogous method for DataFrame.

Styler.apply Apply a CSS-styling function column-wise, row-wise, or table-wise.

Notes

Like `DataFrame.pipe()`, this method can simplify the application of several user-defined functions to a styler. Instead of writing:

```
f(g(df.style.set_precision(3), arg1=a), arg2=b, arg3=c)
```

users can write:

```
(df.style.set_precision(3)
 .pipe(g, arg1=a)
 .pipe(f, arg2=b, arg3=c))
```

In particular, this allows users to define functions that take a styler object, along with other parameters, and return the styler after making styling changes (such as calling `Styler.apply()` or `Styler.set_properties()`). Using `.pipe`, these user-defined style “transformations” can be interleaved with calls to the built-in Styler interface.

Examples

```
>>> def format_conversion(styler):
...     return (styler.set_properties(**{'text-align': 'right'})
...             .format({'conversion': '{:.1%}'))
```

The user-defined `format_conversion` function above can be called within a sequence of other style modifications:

```
>>> df = pd.DataFrame({'trial': list(range(5)),
...                    'conversion': [0.75, 0.85, np.nan, 0.7, 0.72]})
>>> (df.style
...   .highlight_min(subset=['conversion'], color='yellow')
...   .pipe(format_conversion)
...   .set_caption("Results with minimum conversion highlighted."))
```

pandas.io.formats.style.Styler.render

`Styler.render`(*sparse_index=None*, *sparse_columns=None*, ***kwargs*)

Render the Styler including all applied styles to HTML.

Parameters

sparse_index [bool, optional] Whether to sparsify the display of a hierarchical index. Setting to False will display each explicit level element in a hierarchical key for each row. Defaults to `pandas.options.styler.sparse.index` value.

sparse_columns [bool, optional] Whether to sparsify the display of a hierarchical index. Setting to False will display each explicit level element in a hierarchical key for each row. Defaults to `pandas.options.styler.sparse.columns` value.

****kwargs** Any additional keyword arguments are passed through to `self.template.render`. This is useful when you need to provide additional variables for a custom template.

Returns

rendered [str] The rendered HTML.

Notes

Styler objects have defined the `_repr_html_` method which automatically calls `self.render()` when it's the last item in a Notebook cell. When calling `Styler.render()` directly, wrap the result in `IPython.display.HTML` to view the rendered HTML in the notebook.

Pandas uses the following keys in `render`. Arguments passed in `**kwargs` take precedence, so think carefully if you want to override them:

- `head`
- `cellstyle`
- `body`
- `uuid`
- `table_styles`
- `caption`
- `table_attributes`

pandas.io.formats.style.Styler.set_caption

`Styler.set_caption(caption)`

Set the text added to a `<caption>` HTML element.

Parameters

caption [str, tuple] For HTML output either the string input is used or the first element of the tuple. For LaTeX the string input provides a caption and the additional tuple input allows for full captions and short captions, in that order.

Returns

self [Styler]

pandas.io.formats.style.Styler.set_na_rep

`Styler.set_na_rep(na_rep)`

Set the missing data representation on a `Styler`.

New in version 1.0.0.

Deprecated since version 1.3.0.

Parameters

na_rep [str]

Returns

self [Styler]

Notes

This method is deprecated. See *Styler.format()*

pandas.io.formats.style.Styler.set_precision

`Styler.set_precision(precision)`

Set the precision used to display values.

Deprecated since version 1.3.0.

Parameters

precision [int]

Returns

self [Styler]

Notes

This method is deprecated see *Styler.format*.

pandas.io.formats.style.Styler.set_properties

`Styler.set_properties(subset=None, **kwargs)`

Set defined CSS-properties to each <td> HTML element within the given subset.

Parameters

subset [label, array-like, IndexSlice, optional] A valid 2d input to *DataFrame.loc[<subset>]*, or, in the case of a 1d input or single key, to *DataFrame.loc[:, <subset>]* where the columns are prioritised, to limit data to *before* applying the function.

****kwargs** [dict] A dictionary of property, value pairs to be set for each cell.

Returns

self [Styler]

Notes

This is a convenience methods which wraps the *Styler.applymap()* calling a function returning the CSS-properties independently of the data.

Examples

```
>>> df = pd.DataFrame(np.random.randn(10, 4))
>>> df.style.set_properties(color="white", align="right")
>>> df.style.set_properties(**{'background-color': 'yellow'})
```

pandas.io.formats.style.Styler.set_sticky

`Styler.set_sticky`(*axis=0, pixel_size=None, levels=None*)

Add CSS to permanently display the index or column headers in a scrolling frame.

Parameters

axis [{0 or 'index', 1 or 'columns'}, default 0] Whether to make the index or column headers sticky.

pixel_size [int, optional] Required to configure the width of index cells or the height of column header cells when sticking a MultiIndex (or with a named Index). Defaults to 75 and 25 respectively.

levels [list of int] If *axis* is a MultiIndex the specific levels to stick. If *None* will stick all levels.

Returns

self [Styler]

Notes

This method uses the CSS 'position: sticky;' property to display. It is designed to work with visible axes, therefore both:

- `styler.set_sticky(axis="index").hide_index()`
- `styler.set_sticky(axis="columns").hide_columns()`

may produce strange behaviour due to CSS controls with missing elements.

pandas.io.formats.style.Styler.set_table_attributes

`Styler.set_table_attributes`(*attributes*)

Set the table attributes added to the <table> HTML element.

These are items in addition to automatic (by default) id attribute.

Parameters

attributes [str]

Returns

self [Styler]

See also:

[`Styler.set_table_styles`](#) Set the table styles included within the <style> HTML element.

[`Styler.set_td_classes`](#) Set the DataFrame of strings added to the class attribute of <td> HTML elements.

Examples

```
>>> df = pd.DataFrame(np.random.randn(10, 4))
>>> df.style.set_table_attributes('class="pure-table"')
# ... <table class="pure-table"> ...
```

pandas.io.formats.style.Styler.set_table_styles

`Styler.set_table_styles`(*table_styles*, *axis=0*, *overwrite=True*)

Set the table styles included within the `<style>` HTML element.

This function can be used to style the entire table, columns, rows or specific HTML selectors.

Parameters

table_styles [list or dict] If supplying a list, each individual *table_style* should be a dictionary with *selector* and *props* keys. *selector* should be a CSS selector that the style will be applied to (automatically prefixed by the table's UUID) and *props* should be a list of tuples with (*attribute*, *value*). If supplying a dict, the dict keys should correspond to column names or index values, depending upon the specified *axis* argument. These will be mapped to row or col CSS selectors. MultiIndex values as dict keys should be in their respective tuple form. The dict values should be a list as specified in the form with CSS selectors and props that will be applied to the specified row or column.

Changed in version 1.2.0.

axis [{0 or 'index', 1 or 'columns', None}, default 0] Apply to each column (*axis=0* or 'index'), to each row (*axis=1* or 'columns'). Only used if *table_styles* is dict.

New in version 1.2.0.

overwrite [bool, default True] Styles are replaced if *True*, or extended if *False*. CSS rules are preserved so most recent styles set will dominate if selectors intersect.

New in version 1.2.0.

Returns

self [Styler]

See also:

[`Styler.set_td_classes`](#) Set the DataFrame of strings added to the `class` attribute of `<td>` HTML elements.

[`Styler.set_table_attributes`](#) Set the table attributes added to the `<table>` HTML element.

Examples

```
>>> df = pd.DataFrame(np.random.randn(10, 4),
...                    columns=['A', 'B', 'C', 'D'])
>>> df.style.set_table_styles(
...     [{ 'selector': 'tr:hover',
...        'props': [('background-color', 'yellow')]}]
... )
```

Or with CSS strings

```
>>> df.style.set_table_styles(
...     [{ 'selector': 'tr:hover',
...        'props': 'background-color: yellow; font-size: 1em;'}]
... )
```

Adding column styling by name

```
>>> df.style.set_table_styles({
...     'A': [{ 'selector': '',
...             'props': [('color', 'red')]}],
...     'B': [{ 'selector': 'td',
...             'props': 'color: blue;'}]
... }, overwrite=False)
```

Adding row styling

```
>>> df.style.set_table_styles({
...     0: [{ 'selector': 'td:hover',
...          'props': [('font-size', '25px')]}]
... }, axis=1, overwrite=False)
```

pandas.io.formats.style.Styler.set_td_classes

`Styler.set_td_classes(classes)`

Set the DataFrame of strings added to the `class` attribute of `<td>` HTML elements.

Parameters

classes [DataFrame] DataFrame containing strings that will be translated to CSS classes, mapped by identical column and index key values that must exist on the underlying Styler data. None, NaN values, and empty strings will be ignored and not affect the rendered HTML.

Returns

self [Styler]

See also:

[`Styler.set_table_styles`](#) Set the table styles included within the `<style>` HTML element.

[`Styler.set_table_attributes`](#) Set the table attributes added to the `<table>` HTML element.

Notes

Can be used in combination with `Styler.set_table_styles` to define an internal CSS solution without reference to external CSS files.

Examples

```
>>> df = pd.DataFrame(data=[[1, 2, 3], [4, 5, 6]], columns=["A", "B", "C"])
>>> classes = pd.DataFrame([
...     ["min-val red", "", "blue"],
...     ["red", None, "blue max-val"]
... ], index=df.index, columns=df.columns)
>>> df.style.set_td_classes(classes)
```

Using *MultiIndex* columns and a *classes DataFrame* as a subset of the underlying,

```
>>> df = pd.DataFrame([[1,2],[3,4]], index=["a", "b"],
...     columns=["level0", "level0"], ["level1a", "level1b"])
>>> classes = pd.DataFrame(["min-val"], index=["a"],
...     columns=["level0"], ["level1a"])
>>> df.style.set_td_classes(classes)
```

Form of the output with new additional css classes,

```
>>> df = pd.DataFrame([[1]])
>>> css = pd.DataFrame([[ "other-class" ]])
>>> s = Styler(df, uuid="_", cell_ids=False).set_td_classes(css)
>>> s.hide_index().render()
'<style type="text/css"></style>'
'<table id="T_">'
'  <thead>'
'    <tr><th class="col_heading level0 col0" >0</th></tr>'
'  </thead>'
'  <tbody>'
'    <tr><td class="data row0 col0 other-class" >1</td></tr>'
'  </tbody>'
'</table>'
```

pandas.io.formats.style.Styler.set_tooltips

`Styler.set_tooltips(ttips, props=None, css_class=None)`

Set the DataFrame of strings on Styler generating `:hover` tooltips.

These string based tooltips are only applicable to `<td>` HTML elements, and cannot be used for column or index headers.

New in version 1.3.0.

Parameters

ttips [DataFrame] DataFrame containing strings that will be translated to tooltips, mapped by identical column and index values that must exist on the underlying Styler data. None, NaN values, and empty strings will be ignored and not affect the rendered HTML.

props [list-like or str, optional] List of (attr, value) tuples or a valid CSS string. If `None` adopts the internal default values described in notes.

css_class [str, optional] Name of the tooltip class used in CSS, should conform to HTML standards. Only useful if integrating tooltips with external CSS. If `None` uses the internal default value 'pd-t'.

Returns

self [Styler]

Notes

Tooltips are created by adding `` to each data cell and then manipulating the table level CSS to attach pseudo hover and pseudo after selectors to produce the required results.

The default properties for the tooltip CSS class are:

- visibility: hidden
- position: absolute
- z-index: 1
- background-color: black
- color: white
- transform: translate(-20px, -20px)

The property 'visibility: hidden;' is a key prerequisite to the hover functionality, and should always be included in any manual properties specification, using the `props` argument.

Tooltips are not designed to be efficient, and can add large amounts of additional HTML for larger tables, since they also require that `cell_ids` is forced to `True`.

Examples

Basic application

```
>>> df = pd.DataFrame(data=[[0, 1], [2, 3]])
>>> ttips = pd.DataFrame(
...     data=[["Min", ""], [np.nan, "Max"]], columns=df.columns, index=df.index
... )
>>> s = df.style.set_tooltips(ttips).render()
```

Optionally controlling the tooltip visual display

```
>>> df.style.set_tooltips(ttips, css_class='tt-add', props=[
...     ('visibility', 'hidden'),
...     ('position', 'absolute'),
...     ('z-index', 1)])
>>> df.style.set_tooltips(ttips, css_class='tt-add',
...     props='visibility:hidden; position:absolute; z-index:1;')
```

pandas.io.formats.style.Styler.set_uuid**Styler.set_uuid**(*uuid*)

Set the uuid applied to id attributes of HTML elements.

Parameters**uuid** [str]**Returns****self** [Styler]**Notes**

Almost all HTML elements within the table, and including the <table> element are assigned id attributes. The format is T_uuid_<extra> where <extra> is typically a more specific identifier, such as row1_col2.

pandas.io.formats.style.Styler.text_gradient**Styler.text_gradient**(*cmap='PuBu', low=0, high=0, axis=0, subset=None, vmin=None, vmax=None, gmap=None*)

Color the text in a gradient style.

The text color is determined according to the data in each column, row or frame, or by a given gradient map. Requires matplotlib.

Parameters**cmap** [str or colormap] Matplotlib colormap.**low** [float] Compress the color range at the low end. This is a multiple of the data range to extend below the minimum; good values usually in [0, 1], defaults to 0.**high** [float] Compress the color range at the high end. This is a multiple of the data range to extend above the maximum; good values usually in [0, 1], defaults to 0.**axis** [{0 or 'index', 1 or 'columns', None}, default 0] Apply to each column (**axis=0** or 'index'), to each row (**axis=1** or 'columns'), or to the entire DataFrame at once with **axis=None**.**subset** [label, array-like, IndexSlice, optional] A valid 2d input to *DataFrame.loc[<subset>]*, or, in the case of a 1d input or single key, to *DataFrame.loc[:, <subset>]* where the columns are prioritised, to limit data to before applying the function.**text_color_threshold** [float or int] This argument is ignored (only used in *background_gradient*). Luminance threshold for determining text color in [0, 1]. Facilitates text visibility across varying background colors. All text is dark if 0, and light if 1, defaults to 0.408.**vmin** [float, optional] Minimum data value that corresponds to colormap minimum value. If not specified the minimum value of the data (or gmap) will be used.

New in version 1.0.0.

vmax [float, optional] Maximum data value that corresponds to colormap maximum value. If not specified the maximum value of the data (or gmap) will be used.

New in version 1.0.0.

gmap [array-like, optional] Gradient map for determining the text colors. If not supplied will use the underlying data from rows, columns or frame. If given as an ndarray or list-like must be an identical shape to the underlying data considering axis and subset. If given as DataFrame or Series must have same index and column labels considering axis and subset. If supplied, `vmin` and `vmax` should be given relative to this gradient map.

New in version 1.3.0.

Returns

`self` [Styler]

See also:

[`Styler.background_gradient`](#) Color the background in a gradient style.

Notes

When using `low` and `high` the range of the gradient, given by the data if `gmap` is not given or by `gmap`, is extended at the low end effectively by `map.min - low * map.range` and at the high end by `map.max + high * map.range` before the colors are normalized and determined.

If combining with `vmin` and `vmax` the `map.min`, `map.max` and `map.range` are replaced by values according to the values derived from `vmin` and `vmax`.

This method will preselect numeric columns and ignore non-numeric columns unless a `gmap` is supplied in which case no preselection occurs.

Examples

```
>>> df = pd.DataFrame(columns=["City", "Temp (c)", "Rain (mm)", "Wind (m/s)"],
...                       data=[["Stockholm", 21.6, 5.0, 3.2],
...                              ["Oslo", 22.4, 13.3, 3.1],
...                              ["Copenhagen", 24.5, 0.0, 6.7]])
```

Shading the values column-wise, with `axis=0`, preselecting numeric columns

```
>>> df.style.text_gradient(axis=0)
```

| | City | Temp (c) | Rain (mm) | Wind (m/s) |
|---|------------|-----------|-----------|------------|
| 0 | Stockholm | 21.600000 | 5.000000 | 3.200000 |
| 1 | Oslo | 22.400000 | 13.300000 | 3.100000 |
| 2 | Copenhagen | 24.500000 | 0.000000 | 6.700000 |

Shading all values collectively using `axis=None`

```
>>> df.style.text_gradient(axis=None)
```

Compress the color map from the both low and high ends

```
>>> df.style.text_gradient(axis=None, low=0.75, high=1.0)
```

| | City | Temp (c) | Rain (mm) | Wind (m/s) |
|---|------------|-----------|-----------|------------|
| 0 | Stockholm | 21.600000 | 5.000000 | 3.200000 |
| 1 | Oslo | 22.400000 | 13.300000 | 3.100000 |
| 2 | Copenhagen | 24.500000 | 0.000000 | 6.700000 |

| | City | Temp (c) | Rain (mm) | Wind (m/s) |
|---|------------|-----------|-----------|------------|
| 0 | Stockholm | 21.600000 | 5.000000 | 3.200000 |
| 1 | Oslo | 22.400000 | 13.300000 | 3.100000 |
| 2 | Copenhagen | 24.500000 | 0.000000 | 6.700000 |

Manually setting vmin and vmax gradient thresholds

```
>>> df.style.text_gradient(axis=None, vmin=6.7, vmax=21.6)
```

| | City | Temp (c) | Rain (mm) | Wind (m/s) |
|---|------------|-----------|-----------|------------|
| 0 | Stockholm | 21.600000 | 5.000000 | 3.200000 |
| 1 | Oslo | 22.400000 | 13.300000 | 3.100000 |
| 2 | Copenhagen | 24.500000 | 0.000000 | 6.700000 |

Setting a gmap and applying to all columns with another cmap

```
>>> df.style.text_gradient(axis=0, gmap=df['Temp (c)'], cmap='YlOrRd')
```

Setting the gradient map for a dataframe (i.e. axis=None), we need to explicitly state subset to match the gmap shape

```
>>> gmap = np.array([[1,2,3], [2,3,4], [3,4,5]])
>>> df.style.text_gradient(axis=None, gmap=gmap,
...     cmap='YlOrRd', subset=['Temp (c)', 'Rain (mm)', 'Wind (m/s)']
... )
```

pandas.io.formats.style.Styler.use

`Styler.use(styles)`

Set the styles on the current Styler.

Possibly uses styles from `Styler.export`.

Parameters

styles [list] List of style functions.

Returns

self [Styler]

See also:

[`Styler.export`](#) Export the styles to applied to the current Styler.

| | City | Temp (c) | Rain (mm) | Wind (m/s) |
|---|------------|-----------|-----------|------------|
| 0 | Stockholm | 21.800000 | 5.000000 | 3.200000 |
| 1 | Oslo | 22.400000 | 13.300000 | 3.100000 |
| 2 | Copenhagen | 24.500000 | 0.000000 | 6.700000 |

| | City | Temp (c) | Rain (mm) | Wind (m/s) |
|---|------------|-----------|-----------|------------|
| 0 | Stockholm | 21.800000 | 5.000000 | 3.200000 |
| 1 | Oslo | 22.400000 | 13.300000 | 3.100000 |
| 2 | Copenhagen | 24.500000 | 0.000000 | 6.700000 |

`pandas.io.formats.style.Styler.where`

`Styler.where`(*cond*, *value*, *other=None*, *subset=None*, ***kwargs*)

Apply CSS-styles based on a conditional function elementwise.

Deprecated since version 1.3.0.

Updates the HTML representation with a style which is selected in accordance with the return value of a function.

Parameters

cond [callable] *cond* should take a scalar, and optional keyword arguments, and return a boolean.

value [str] Applied when *cond* returns true.

other [str] Applied when *cond* returns false.

subset [label, array-like, IndexSlice, optional] A valid 2d input to `DataFrame.loc[<subset>]`, or, in the case of a 1d input or single key, to `DataFrame.loc[:, <subset>]` where the columns are prioritised, to limit data to *before* applying the function.

****kwargs** [dict] Pass along to *cond*.

Returns

self [Styler]

See also:

`Styler.applymap` Apply a CSS-styling function elementwise.

`Styler.apply` Apply a CSS-styling function column-wise, row-wise, or table-wise.

Notes

This method is deprecated.

This method is a convenience wrapper for `Styler.applymap()`, which we recommend using instead.

The example:

```
>>> df = pd.DataFrame([[1, 2], [3, 4]])
>>> def cond(v, limit=4):
...     return v > 1 and v != limit
>>> df.style.where(cond, value='color:green;', other='color:red;')
```

should be refactored to:

```
>>> def style_func(v, value, other, limit=4):
...     cond = v > 1 and v != limit
...     return value if cond else other
>>> df.style.applymap(style_func, value='color:green;', other='color:red;')
```

3.12.2 Styler properties

`Styler.env`

`Styler.template_html`

`Styler.template_html_style`

`Styler.template_html_table`

`Styler.template_latex`

`Styler.loader`

`pandas.io.formats.style.Styler.env`

`Styler.env = <jinja2.environment.Environment object>`

pandas.io.formats.style.Styler.template_html

`Styler.template_html = <Template 'html.tpl'>`

pandas.io.formats.style.Styler.template_html_style

`Styler.template_html_style = <Template 'html_style.tpl'>`

pandas.io.formats.style.Styler.template_html_table

`Styler.template_html_table = <Template 'html_table.tpl'>`

pandas.io.formats.style.Styler.template_latex

`Styler.template_latex = <Template 'latex.tpl'>`

pandas.io.formats.style.Styler.loader

`Styler.loader = <jinja2.loaders.PackageLoader object>`

3.12.3 Style application

| | |
|--|--|
| <code>Styler.apply(func[, axis, subset])</code> | Apply a CSS-styling function column-wise, row-wise, or table-wise. |
| <code>Styler.applymap(func[, subset])</code> | Apply a CSS-styling function elementwise. |
| <code>Styler.format([formatter, subset, na_rep, ...])</code> | Format the text display value of cells. |
| <code>Styler.hide_index([subset])</code> | Hide the entire index, or specific keys in the index from rendering. |
| <code>Styler.hide_columns([subset])</code> | Hide the column headers or specific keys in the columns from rendering. |
| <code>Styler.set_td_classes(classes)</code> | Set the DataFrame of strings added to the class attribute of <td> HTML elements. |
| <code>Styler.set_table_styles(table_styles[, ...])</code> | Set the table styles included within the <style> HTML element. |
| <code>Styler.set_table_attributes(attributes)</code> | Set the table attributes added to the <table> HTML element. |
| <code>Styler.set_tooltips(ttips[, props, css_class])</code> | Set the DataFrame of strings on Styler generating : hover tooltips. |
| <code>Styler.set_caption(caption)</code> | Set the text added to a <caption> HTML element. |
| <code>Styler.set_sticky([axis, pixel_size, levels])</code> | Add CSS to permanently display the index or column headers in a scrolling frame. |
| <code>Styler.set_properties([subset])</code> | Set defined CSS-properties to each <td> HTML element within the given subset. |
| <code>Styler.set_uuid(uuid)</code> | Set the uuid applied to id attributes of HTML elements. |
| <code>Styler.clear()</code> | Reset the Styler, removing any previously applied styles. |
| <code>Styler.pipe(func, *args, **kwargs)</code> | Apply <code>func(self, *args, **kwargs)</code> , and return the result. |

3.12.4 Builtin styles

| | |
|---|--|
| <code>Styler.highlight_null([null_color, subset, ...])</code> | Highlight missing values with a style. |
| <code>Styler.highlight_max([subset, color, axis, ...])</code> | Highlight the maximum with a style. |
| <code>Styler.highlight_min([subset, color, axis, ...])</code> | Highlight the minimum with a style. |
| <code>Styler.highlight_between([subset, color, ...])</code> | Highlight a defined range with a style. |
| <code>Styler.highlight_quantile([subset, color, ...])</code> | Highlight values defined by a quantile with a style. |
| <code>Styler.background_gradient([cmap, low, ...])</code> | Color the background in a gradient style. |
| <code>Styler.text_gradient([cmap, low, high, ...])</code> | Color the text in a gradient style. |
| <code>Styler.bar([subset, axis, color, width, ...])</code> | Draw bar chart in the cell backgrounds. |

3.12.5 Style export and import

| | |
|---|--|
| <code>Styler.render([sparse_index, sparse_columns])</code> | Render the Styler including all applied styles to HTML. |
| <code>Styler.export()</code> | Export the styles applied to the current Styler. |
| <code>Styler.use(styles)</code> | Set the styles on the current Styler. |
| <code>Styler.to_html([buf, table_uuid, ...])</code> | Write Styler to a file, buffer or string in HTML-CSS format. |
| <code>Styler.to_excel(excel_writer[, sheet_name, ...])</code> | Write Styler to an Excel sheet. |
| <code>Styler.to_latex([buf, column_format, ...])</code> | Write Styler to a file, buffer or string in LaTeX format. |

3.13 Plotting

The following functions are contained in the `pandas.plotting` module.

| | |
|---|--|
| <code>andrews_curves(frame, class_column[, ax, ...])</code> | Generate a matplotlib plot of Andrews curves, for visualising clusters of multivariate data. |
| <code>autocorrelation_plot(series[, ax])</code> | Autocorrelation plot for time series. |
| <code>bootstrap_plot(series[, fig, size, samples])</code> | Bootstrap plot on mean, median and mid-range statistics. |
| <code>boxplot(data[, column, by, ax, fontsize, ...])</code> | Make a box plot from DataFrame columns. |
| <code>deregister_matplotlib_converters()</code> | Remove pandas formatters and converters. |
| <code>lag_plot(series[, lag, ax])</code> | Lag plot for time series. |
| <code>parallel_coordinates(frame, class_column[, ...])</code> | Parallel coordinates plotting. |
| <code>plot_params</code> | Stores pandas plotting options. |
| <code>radviz(frame, class_column[, ax, color, ...])</code> | Plot a multidimensional dataset in 2D. |
| <code>register_matplotlib_converters()</code> | Register pandas formatters and converters with matplotlib. |
| <code>scatter_matrix(frame[, alpha, figsize, ax, ...])</code> | Draw a matrix of scatter plots. |
| <code>table(ax, data[, rowLabels, colLabels])</code> | Helper function to convert DataFrame and Series to matplotlib.table. |

3.13.1 pandas.plotting.andrews_curves

`pandas.plotting.andrews_curves`(*frame*, *class_column*, *ax=None*, *samples=200*, *color=None*, *colormap=None*, ***kwargs*)

Generate a matplotlib plot of Andrews curves, for visualising clusters of multivariate data.

Andrews curves have the functional form:

$$f(t) = x_1/\sqrt{2} + x_2 \sin(t) + x_3 \cos(t) + x_4 \sin(2t) + x_5 \cos(2t) + \dots$$

Where *x* coefficients correspond to the values of each dimension and *t* is linearly spaced between $-\pi$ and $+\pi$.

Each row of *frame* then corresponds to a single curve.

Parameters

frame [DataFrame] Data to be plotted, preferably normalized to (0.0, 1.0).

class_column [Name of the column containing class names]

ax [matplotlib axes object, default None]

samples [Number of points to plot in each curve]

color [list or tuple, optional] Colors to use for the different classes.

colormap [str or matplotlib colormap object, default None] Colormap to select colors from. If string, load colormap with that name from matplotlib.

****kwargs** Options to pass to matplotlib plotting method.

Returns

class:*matplotlib.axis.Axes*

Examples

```
>>> df = pd.read_csv(  
...     'https://raw.githubusercontent.com/pandas-dev/  
...     'pandas/master/pandas/tests/io/data/csv/iris.csv'  
... )  
>>> pd.plotting.andrews_curves(df, 'Name')
```

3.13.2 pandas.plotting.autocorrelation_plot

`pandas.plotting.autocorrelation_plot`(*series*, *ax=None*, ***kwargs*)

Autocorrelation plot for time series.

Parameters

series [Time series]

ax [Matplotlib axis object, optional]

****kwargs** Options to pass to matplotlib plotting method.

Returns

class:*matplotlib.axis.Axes*

Examples

The horizontal lines in the plot correspond to 95% and 99% confidence bands.

The dashed line is 99% confidence band.

```
>>> spacing = np.linspace(-9 * np.pi, 9 * np.pi, num=1000)
>>> s = pd.Series(0.7 * np.random.rand(1000) + 0.3 * np.sin(spacing))
>>> pd.plotting.autocorrelation_plot(s)
```

3.13.3 pandas.plotting.bootstrap_plot

`pandas.plotting.bootstrap_plot(series, fig=None, size=50, samples=500, **kws)`

Bootstrap plot on mean, median and mid-range statistics.

The bootstrap plot is used to estimate the uncertainty of a statistic by relying on random sampling with replacement [1]. This function will generate bootstrapping plots for mean, median and mid-range statistics for the given number of samples of the given size.

Parameters

series [pandas.Series] Series from where to get the samplings for the bootstrapping.

fig [matplotlib.figure.Figure, default None] If given, it will use the *fig* reference for plotting instead of creating a new one with default parameters.

size [int, default 50] Number of data points to consider during each sampling. It must be less than or equal to the length of the *series*.

samples [int, default 500] Number of times the bootstrap procedure is performed.

****kwargs** Options to pass to matplotlib plotting method.

Returns

matplotlib.figure.Figure Matplotlib figure.

See also:

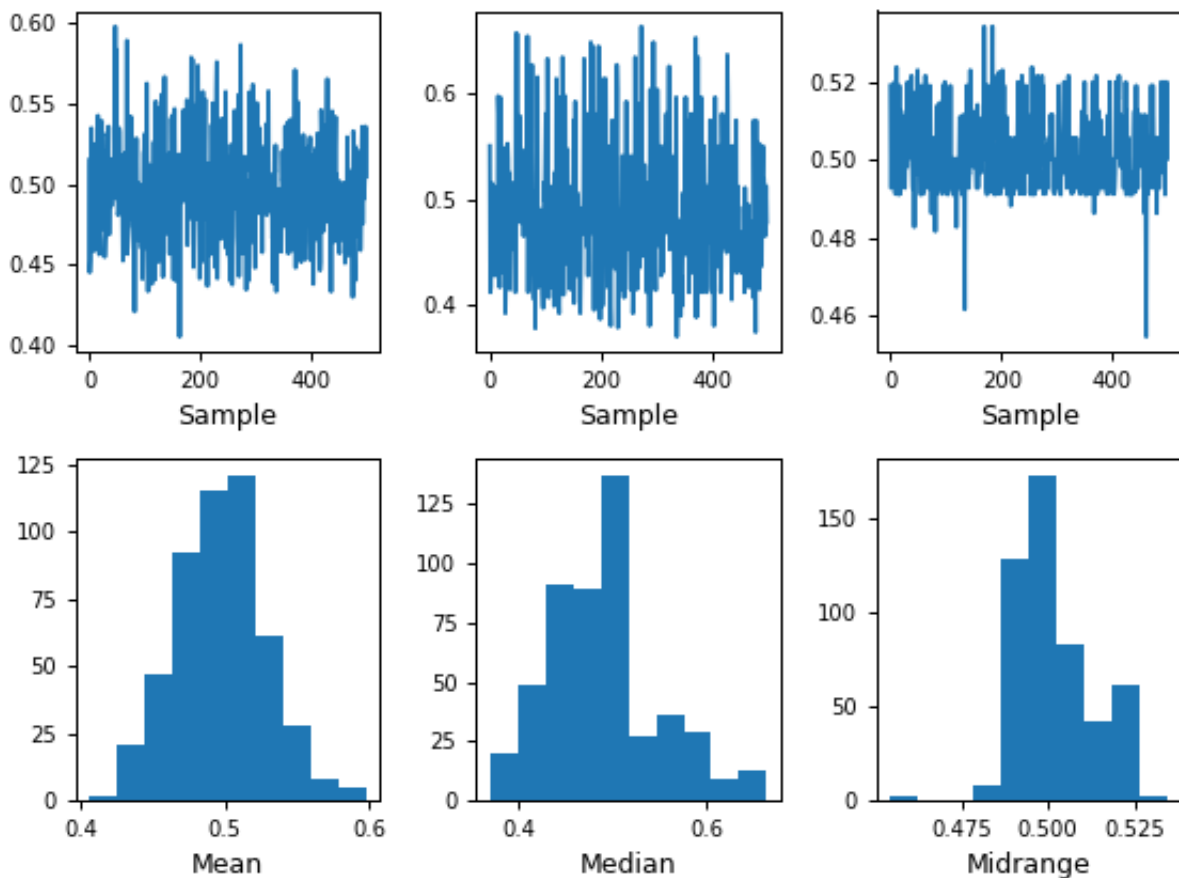

DataFrame.plot Basic plotting for DataFrame objects.

Series.plot Basic plotting for Series objects.

Examples

This example draws a basic bootstrap plot for a Series.

```
>>> s = pd.Series(np.random.uniform(size=100))
>>> pd.plotting.bootstrap_plot(s)
```

3.13.4 pandas.plotting.boxplot

`pandas.plotting.boxplot`(*data*, *column=None*, *by=None*, *ax=None*, *fontsize=None*, *rot=0*, *grid=True*, *figsize=None*, *layout=None*, *return_type=None*, ***kwargs*)

Make a box plot from DataFrame columns.

Make a box-and-whisker plot from DataFrame columns, optionally grouped by some other columns. A box plot is a method for graphically depicting groups of numerical data through their quartiles. The box extends from the Q1 to Q3 quartile values of the data, with a line at the median (Q2). The whiskers extend from the edges of box to show the range of the data. By default, they extend no more than $1.5 * IQR$ ($IQR = Q3 - Q1$) from the edges of the box, ending at the farthest data point within that interval. Outliers are plotted as separate dots.

For further details see Wikipedia's entry for [boxplot](#).

Parameters

column [str or list of str, optional] Column name or list of names, or vector. Can be any valid input to `pandas.DataFrame.groupby()`.

by [str or array-like, optional] Column in the DataFrame to `pandas.DataFrame.groupby()`. One box-plot will be done per value of columns in *by*.

ax [object of class `matplotlib.axes.Axes`, optional] The matplotlib axes to be used by boxplot.

fontsize [float or str] Tick label font size in points or as a string (e.g., *large*).

rot [int or float, default 0] The rotation angle of labels (in degrees) with respect to the screen coordinate system.

grid [bool, default True] Setting this to True will show the grid.

figsize [A tuple (width, height) in inches] The size of the figure to create in matplotlib.

layout [tuple (rows, columns), optional] For example, (3, 5) will display the subplots using 3 columns and 5 rows, starting from the top-left.

return_type [{ 'axes', 'dict', 'both' } or None, default 'axes'] The kind of object to return. The default is `axes`.

- 'axes' returns the matplotlib axes the boxplot is drawn on.
- 'dict' returns a dictionary whose values are the matplotlib Lines of the boxplot.
- 'both' returns a namedtuple with the axes and dict.
- when grouping with *by*, a Series mapping columns to `return_type` is returned.

If `return_type` is `None`, a NumPy array of axes with the same shape as `layout` is returned.

****kwargs** All other plotting keyword arguments to be passed to `matplotlib.pyplot.boxplot()`.

Returns

result See Notes.

See also:

Series.plot.hist Make a histogram.

matplotlib.pyplot.boxplot Matplotlib equivalent plot.

Notes

The return type depends on the *return_type* parameter:

- 'axes' : object of class matplotlib.axes.Axes
- 'dict' : dict of matplotlib.lines.Line2D objects
- 'both' : a namedtuple with structure (ax, lines)

For data grouped with by, return a Series of the above or a numpy array:

- *Series*
- array (for return_type = None)

Use return_type='dict' when you want to tweak the appearance of the lines after plotting. In this case a dict containing the Lines making up the boxes, caps, fliers, medians, and whiskers is returned.

Examples

Boxplots can be created for every column in the dataframe by `df.boxplot()` or indicating the columns to be used:

```
>>> np.random.seed(1234)
>>> df = pd.DataFrame(np.random.randn(10, 4),
...                   columns=['Col1', 'Col2', 'Col3', 'Col4'])
>>> boxplot = df.boxplot(column=['Col1', 'Col2', 'Col3'])
```

Boxplots of variables distributions grouped by the values of a third variable can be created using the option `by`.

For instance:

```
>>> df = pd.DataFrame(np.random.randn(10, 2),
...                    columns=['Col1', 'Col2'])
>>> df['X'] = pd.Series(['A', 'A', 'A', 'A', 'A',
...                     'B', 'B', 'B', 'B', 'B'])
>>> boxplot = df.boxplot(by='X')
```

A list of strings (i.e. ['X', 'Y']) can be passed to boxplot in order to group the data by combination of the variables in the x-axis:

```
>>> df = pd.DataFrame(np.random.randn(10, 3),
...                    columns=['Col1', 'Col2', 'Col3'])
>>> df['X'] = pd.Series(['A', 'A', 'A', 'A', 'A',
...                     'B', 'B', 'B', 'B', 'B'])
>>> df['Y'] = pd.Series(['A', 'B', 'A', 'B', 'A',
...                     'B', 'A', 'B', 'A', 'B'])
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], by=['X', 'Y'])
```

The layout of boxplot can be adjusted giving a tuple to layout:

```
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], by='X',
...                       layout=(2, 1))
```

Additional formatting can be done to the boxplot, like suppressing the grid (`grid=False`), rotating the labels in the x-axis (i.e. `rot=45`) or changing the fontsize (i.e. `fontsize=15`):

```
>>> boxplot = df.boxplot(grid=False, rot=45, fontsize=15)
```

The parameter `return_type` can be used to select the type of element returned by `boxplot`. When `return_type='axes'` is selected, the matplotlib axes on which the boxplot is drawn are returned:

```
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], return_type='axes')
>>> type(boxplot)
<class 'matplotlib.axes._subplots.AxesSubplot'>
```

When grouping with `by`, a Series mapping columns to `return_type` is returned:

```
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], by='X',
...                       return_type='axes')
>>> type(boxplot)
<class 'pandas.core.series.Series'>
```

If `return_type` is `None`, a NumPy array of axes with the same shape as `layout` is returned:

```
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], by='X',
...                       return_type=None)
```

(continues on next page)

(continued from previous page)

```
>>> type(boxplot)
<class 'numpy.ndarray'>
```

3.13.5 pandas.plotting.deregister_matplotlib_converters

`pandas.plotting.deregister_matplotlib_converters()`

Remove pandas formatters and converters.

Removes the custom converters added by `register()`. This attempts to set the state of the registry back to the state before pandas registered its own defaults. Converters for pandas' own types like `Timestamp` and `Period` are removed completely. Converters for types pandas overwrites, like `datetime.datetime`, are restored to their original value.

See also:

[`register_matplotlib_converters`](#) Register pandas formatters and converters with matplotlib.

3.13.6 pandas.plotting.lag_plot

`pandas.plotting.lag_plot(series, lag=1, ax=None, **kwargs)`

Lag plot for time series.

Parameters

series [Time series]

lag [lag of the scatter plot, default 1]

ax [Matplotlib axis object, optional]

****kwargs** Matplotlib scatter method keyword arguments.

Returns

class: `matplotlib.axis.Axes`

Examples

Lag plots are most commonly used to look for patterns in time series data.

Given the following time series

```
>>> np.random.seed(5)
>>> x = np.cumsum(np.random.normal(loc=1, scale=5, size=50))
>>> s = pd.Series(x)
>>> s.plot()
```

A lag plot with `lag=1` returns

```
>>> pd.plotting.lag_plot(s, lag=1)
```

3.13.7 pandas.plotting.parallel_coordinates

`pandas.plotting.parallel_coordinates`(*frame*, *class_column*, *cols=None*, *ax=None*, *color=None*, *use_columns=False*, *xticks=None*, *colormap=None*, *axvlines=True*, *axvlines_kwds=None*, *sort_labels=False*, ***kwargs*)

Parallel coordinates plotting.

Parameters

- frame** [DataFrame] DataFrame to plot.
- class_column** [str] Column name containing class names.
- cols** [list, optional] A list of column names to use.
- ax** [matplotlib.axis, optional] Matplotlib axis object.
- color** [list or tuple, optional] Colors to use for the different classes.
- use_columns** [bool, optional] If true, columns will be used as xticks.
- xticks** [list or tuple, optional] A list of values to use for xticks.
- colormap** [str or matplotlib colormap, default None] Colormap to use for line colors.
- axvlines** [bool, optional] If true, vertical lines will be added at each xtick.
- axvlines_kwds** [keywords, optional] Options to be passed to axvline method for vertical lines.
- sort_labels** [bool, default False] Sort class_column labels, useful when assigning colors.
- **kwargs** Options to pass to matplotlib plotting method.

Returns

class: *matplotlib.axis.Axes*

Examples

```
>>> df = pd.read_csv(
...     'https://raw.githubusercontent.com/pandas-dev/
...     pandas/master/pandas/tests/io/data/csv/iris.csv'
... )
>>> pd.plotting.parallel_coordinates(
...     df, 'Name', color=('556270', '4E CDC4', 'C7F464')
... )
```

3.13.8 pandas.plotting.plot_params

`pandas.plotting.plot_params = {'xaxis.compat': False}`

Stores pandas plotting options.

Allows for parameter aliasing so you can just use parameter names that are the same as the plot function parameters, but is stored in a canonical format that makes it easy to breakdown into groups later.

3.13.9 pandas.plotting.radviz

`pandas.plotting.radviz(frame, class_column, ax=None, color=None, colormap=None, **kws)`

Plot a multidimensional dataset in 2D.

Each Series in the DataFrame is represented as a evenly distributed slice on a circle. Each data point is rendered in the circle according to the value on each Series. Highly correlated *Series* in the *DataFrame* are placed closer on the unit circle.

RadViz allow to project a N-dimensional data set into a 2D space where the influence of each dimension can be interpreted as a balance between the influence of all dimensions.

More info available at the [original article](#) describing RadViz.

Parameters

frame [*DataFrame*] Object holding the data.

class_column [str] Column name containing the name of the data point category.

ax [`matplotlib.axes.Axes`, optional] A plot instance to which to add the information.

color [list[str] or tuple[str], optional] Assign a color to each category. Example: ['blue', 'green'].

colormap [str or `matplotlib.colors.Colormap`, default None] Colormap to select colors from. If string, load colormap with that name from matplotlib.

****kws** Options to pass to matplotlib scatter plotting method.

Returns

class:`matplotlib.axes.Axes`

See also:

`plotting.andrews_curves` Plot clustering visualization.

Examples

```
>>> df = pd.DataFrame(
...     {
...         'SepalLength': [6.5, 7.7, 5.1, 5.8, 7.6, 5.0, 5.4, 4.6, 6.7, 4.6],
...         'SepalWidth': [3.0, 3.8, 3.8, 2.7, 3.0, 2.3, 3.0, 3.2, 3.3, 3.6],
...         'PetalLength': [5.5, 6.7, 1.9, 5.1, 6.6, 3.3, 4.5, 1.4, 5.7, 1.0],
...         'PetalWidth': [1.8, 2.2, 0.4, 1.9, 2.1, 1.0, 1.5, 0.2, 2.1, 0.2],
...         'Category': [
...             'virginica',
...             'virginica',
...             'setosa',
...             'virginica',
...             'virginica',
...             'versicolor',
...             'versicolor',
...             'setosa',
...             'virginica',
...             'setosa'
...         ]
...     }
... )
```

(continues on next page)

(continued from previous page)

```
... )  
>>> pd.plotting.radviz(df, 'Category')
```

3.13.10 pandas.plotting.register_matplotlib_converters

`pandas.plotting.register_matplotlib_converters()`

Register pandas formatters and converters with matplotlib.

This function modifies the global `matplotlib.units.registry` dictionary. pandas adds custom converters for

- `pd.Timestamp`
- `pd.Period`
- `np.datetime64`
- `datetime.datetime`
- `datetime.date`
- `datetime.time`

See also:

[`deregister_matplotlib_converters`](#) Remove pandas formatters and converters.

3.13.11 pandas.plotting.scatter_matrix

`pandas.plotting.scatter_matrix`(*frame*, *alpha*=0.5, *figsize*=None, *ax*=None, *grid*=False, *diagonal*='hist', *marker*='.', *density_kwds*=None, *hist_kwds*=None, *range_padding*=0.05, ***kwargs*)

Draw a matrix of scatter plots.

Parameters

- frame** [DataFrame]
- alpha** [float, optional] Amount of transparency applied.
- figsize** [(float,float), optional] A tuple (width, height) in inches.
- ax** [Matplotlib axis object, optional]
- grid** [bool, optional] Setting this to True will show the grid.
- diagonal** [{'hist', 'kde'}] Pick between 'kde' and 'hist' for either Kernel Density Estimation or Histogram plot in the diagonal.
- marker** [str, optional] Matplotlib marker type, default '.'.
- density_kwds** [keywords] Keyword arguments to be passed to kernel density estimate plot.
- hist_kwds** [keywords] Keyword arguments to be passed to hist function.
- range_padding** [float, default 0.05] Relative extension of axis range in x and y with respect to (x_max - x_min) or (y_max - y_min).
- **kwargs** Keyword arguments to be passed to scatter function.

Returns

numpy.ndarray A matrix of scatter plots.

Examples

```
>>> df = pd.DataFrame(np.random.randn(1000, 4), columns=['A', 'B', 'C', 'D'])
>>> pd.plotting.scatter_matrix(df, alpha=0.2)
```

3.13.12 pandas.plotting.table

`pandas.plotting.table`(*ax*, *data*, *rowLabels*=None, *colLabels*=None, ***kwargs*)

Helper function to convert DataFrame and Series to matplotlib.table.

Parameters

- ax** [Matplotlib axes object]
- data** [DataFrame or Series] Data for table contents.
- **kwargs** Keyword arguments to be passed to matplotlib.table.table. If *rowLabels* or *colLabels* is not specified, data index or column name will be used.

Returns

matplotlib table object

3.14 General utility functions

3.14.1 Working with options

| | |
|--|--|
| <code>describe_option(pat[, _print_desc])</code> | Prints the description for one or more registered options. |
| <code>reset_option(pat)</code> | Reset one or more options to their default value. |
| <code>get_option(pat)</code> | Retrieves the value of the specified option. |
| <code>set_option(pat, value)</code> | Sets the value of the specified option. |
| <code>option_context(*args)</code> | Context manager to temporarily set options in the <i>with</i> statement context. |

pandas.describe_option

`pandas.describe_option(pat, _print_desc=False)` = `<pandas._config.config.CallableDynamicDoc object>`

Prints the description for one or more registered options.

Call with not arguments to get a listing for all registered options.

Available options:

- `compute`.`[use_bottleneck, use_numba, use_numexpr]`
- `display`.`[chop_threshold, colheader_justify, column_space, date_dayfirst, date_yearfirst, encoding, expand_frame_repr, float_format]`
- `display.html`.`[border, table_schema, use_mathjax]`
- `display`.`[large_repr]`
- `display.latex`.`[escape, longtable, multicolumn, multicolumn_format, multirow, repr]`
- `display`.`[max_categories, max_columns, max_colwidth, max_info_columns, max_info_rows, max_rows, max_seq_items, memory_usage, min_rows, multi_sparse, notebook_repr_html, pprint_nest_depth, precision, show_dimensions]`
- `display.unicode`.`[ambiguous_as_wide, east_asian_width]`
- `display`.`[width]`
- `io.excel.ods`.`[reader, writer]`
- `io.excel.xls`.`[reader, writer]`
- `io.excel.xlsb`.`[reader]`
- `io.excel.xlsm`.`[reader, writer]`
- `io.excel.xlsx`.`[reader, writer]`
- `io.hdf`.`[default_format, dropna_table]`
- `io.parquet`.`[engine]`
- `io.sql`.`[engine]`
- `mode`.`[chained_assignment, data_manager, sim_interactive, string_storage, use_inf_as_na, use_inf_as_null]`
- `plotting`.`[backend]`
- `plotting.matplotlib`.`[register_converters]`
- `styler.render`.`[max_elements]`
- `styler.sparse`.`[columns, index]`

Parameters

pat [str] Regexp pattern. All matching keys will have their description displayed.

_print_desc [bool, default True] If True (default) the description(s) will be printed to stdout. Otherwise, the description(s) will be returned as a unicode string (for testing).

Returns

None by default, the description(s) as a unicode string if `_print_desc` is False

Notes

The available options with its descriptions:

- compute.use_bottleneck** [bool] Use the bottleneck library to accelerate if it is installed, the default is True Valid values: False,True [default: True] [currently: True]
- compute.use_numba** [bool] Use the numba engine option for select operations if it is installed, the default is False Valid values: False,True [default: False] [currently: False]
- compute.use_numexpr** [bool] Use the numexpr library to accelerate computation if it is installed, the default is True Valid values: False,True [default: True] [currently: True]
- display.chop_threshold** [float or None] if set to a float value, all float values smaller then the given threshold will be displayed as exactly 0 by repr and friends. [default: None] [currently: None]
- display.colheader_justify** ['left'/'right'] Controls the justification of column headers. used by DataFrameFormatter. [default: right] [currently: right]
- display.column_space** **No description available.** [default: 12] [currently: 12]
- display.date_dayfirst** [boolean] When True, prints and parses dates with the day first, eg 20/01/2005 [default: False] [currently: False]
- display.date_yearfirst** [boolean] When True, prints and parses dates with the year first, eg 2005/01/20 [default: False] [currently: False]
- display.encoding** [str/unicode] Defaults to the detected encoding of the console. Specifies the encoding to be used for strings returned by `to_string`, these are generally strings meant to be displayed on the console. [default: utf-8] [currently: utf-8]
- display.expand_frame_repr** [boolean] Whether to print out the full DataFrame repr for wide DataFrames across multiple lines, `max_columns` is still respected, but the output will wrap-around across multiple “pages” if its width exceeds `display.width`. [default: True] [currently: True]
- display.float_format** [callable] The callable should accept a floating point number and return a string with the desired format of the number. This is used in some places like SeriesFormatter. See `formats.format.EngFormatter` for an example. [default: None] [currently: None]
- display.html.border** [int] A `border=value` attribute is inserted in the `<table>` tag for the DataFrame HTML repr. [default: 1] [currently: 1]
- display.html.table_schema** [boolean] Whether to publish a Table Schema representation for frontends that support it. (default: False) [default: False] [currently: False]
- display.html.use_mathjax** [boolean] When True, Jupyter notebook will process table contents using MathJax, rendering mathematical expressions enclosed by the dollar symbol. (default: True) [default: True] [currently: True]
- display.large_repr** ['truncate'/'info'] For DataFrames exceeding `max_rows/max_cols`, the repr (and HTML repr) can show a truncated table (the default from 0.13), or switch to the view from `df.info()` (the behaviour in earlier versions of pandas). [default: truncate] [currently: truncate]
- display.latex.escape** [bool] This specifies if the `to_latex` method of a Dataframe uses escapes special characters. Valid values: False,True [default: True] [currently: True]
- display.latex.longtable** :bool This specifies if the `to_latex` method of a Dataframe uses the longtable format. Valid values: False,True [default: False] [currently: False]
- display.latex.multicolumn** [bool] This specifies if the `to_latex` method of a Dataframe uses multicolumns to pretty-print MultiIndex columns. Valid values: False,True [default: True] [currently: True]
- display.latex.multicolumn_format** [bool] This specifies if the `to_latex` method of a Dataframe uses multicolumns to pretty-print MultiIndex columns. Valid values: False,True [default: 1] [currently: 1]
- display.latex.multiprow** [bool] This specifies if the `to_latex` method of a Dataframe uses multirows to pretty-print MultiIndex rows. Valid values: False,True [default: False] [currently: False]
- display.latex.repr** [boolean] Whether to produce a latex DataFrame representation for jupyter environments that support it. (default: False) [default: False] [currently: False]

display.max_categories [int] This sets the maximum number of categories pandas should output when printing out a *Categorical* or a Series of dtype “category”. [default: 8] [currently: 8]

display.max_columns [int] If max_cols is exceeded, switch to truncate view. Depending on *large_repr*, objects are either centrally truncated or printed as a summary view. ‘None’ value means unlimited.

In case python/IPython is running in a terminal and *large_repr* equals ‘truncate’ this can be set to 0 and pandas will auto-detect the width of the terminal and print a truncated object which fits the screen width. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: 0] [currently: 0]

display.max_colwidth [int or None] The maximum width in characters of a column in the repr of a pandas data structure. When the column overflows, a “...” placeholder is embedded in the output. A ‘None’ value means unlimited. [default: 50] [currently: 50]

display.max_info_columns [int] max_info_columns is used in DataFrame.info method to decide if per column information will be printed. [default: 100] [currently: 100]

display.max_info_rows [int or None] df.info() will usually show null-counts for each column. For large frames this can be quite slow. max_info_rows and max_info_cols limit this null check only to frames with smaller dimensions than specified. [default: 1690785] [currently: 1690785]

display.max_rows [int] If max_rows is exceeded, switch to truncate view. Depending on *large_repr*, objects are either centrally truncated or printed as a summary view. ‘None’ value means unlimited.

In case python/IPython is running in a terminal and *large_repr* equals ‘truncate’ this can be set to 0 and pandas will auto-detect the height of the terminal and print a truncated object which fits the screen height. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: 60] [currently: 60]

display.max_seq_items [int or None] When pretty-printing a long sequence, no more than *max_seq_items* will be printed. If items are omitted, they will be denoted by the addition of “...” to the resulting string.

If set to None, the number of items to be printed is unlimited. [default: 100] [currently: 100]

display.memory_usage [bool, string or None] This specifies if the memory usage of a DataFrame should be displayed when df.info() is called. Valid values True,False,’deep’ [default: True] [currently: True]

display.min_rows [int] The numbers of rows to show in a truncated view (when *max_rows* is exceeded). Ignored when *max_rows* is set to None or 0. When set to None, follows the value of *max_rows*. [default: 10] [currently: 10]

display.multi_sparse [boolean] “sparsify” MultiIndex display (don’t display repeated elements in outer levels within groups) [default: True] [currently: True]

display.notebook_repr_html [boolean] When True, IPython notebook will use html representation for pandas objects (if it is available). [default: True] [currently: True]

display.pprint_nest_depth [int] Controls the number of nested levels to process when pretty-printing [default: 3] [currently: 3]

display.precision [int] Floating point output precision in terms of number of places after the decimal, for regular formatting as well as scientific notation. Similar to *precision* in *numpy.set_printoptions()*. [default: 6] [currently: 6]

display.show_dimensions [boolean or ‘truncate’] Whether to print out dimensions at the end of DataFrame repr. If ‘truncate’ is specified, only print out the dimensions if the frame is truncated (e.g. not display all rows and/or columns) [default: truncate] [currently: truncate]

display.unicode.ambiguous_as_wide [boolean] Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance (default: False) [default: False] [currently: False]

display.unicode.east_asian_width [boolean] Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance (default: False) [default: False] [currently: False]

display.width [int] Width of the display in characters. In case python/IPython is running in a terminal this can be set to None and pandas will correctly auto-detect the width. Note that the IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to correctly detect the width. [default: 80] [currently: 80]

- io.excel.ods.reader** [string] The default Excel reader engine for ‘ods’ files. Available options: auto, odf. [default: auto] [currently: auto]
- io.excel.ods.writer** [string] The default Excel writer engine for ‘ods’ files. Available options: auto, odf. [default: auto] [currently: auto]
- io.excel.xls.reader** [string] The default Excel reader engine for ‘xls’ files. Available options: auto, xlrd. [default: auto] [currently: auto]
- io.excel.xls.writer** [string] The default Excel writer engine for ‘xls’ files. Available options: auto, xlwt. [default: auto] [currently: auto] (Deprecated, use `` instead.)
- io.excel.xlsb.reader** [string] The default Excel reader engine for ‘xlsb’ files. Available options: auto, pyxlsb. [default: auto] [currently: auto]
- io.excel.xlsm.reader** [string] The default Excel reader engine for ‘xlsm’ files. Available options: auto, xlrd, openpyxl. [default: auto] [currently: auto]
- io.excel.xlsm.writer** [string] The default Excel writer engine for ‘xlsm’ files. Available options: auto, openpyxl. [default: auto] [currently: auto]
- io.excel.xlsx.reader** [string] The default Excel reader engine for ‘xlsx’ files. Available options: auto, xlrd, openpyxl. [default: auto] [currently: auto]
- io.excel.xlsx.writer** [string] The default Excel writer engine for ‘xlsx’ files. Available options: auto, openpyxl, xlsxwriter. [default: auto] [currently: auto]
- io.hdf.default_format** [format] default format writing format, if None, then put will default to ‘fixed’ and append will default to ‘table’ [default: None] [currently: None]
- io.hdf.dropna_table** [boolean] drop ALL nan rows when appending to a table [default: False] [currently: False]
- io.parquet.engine** [string] The default parquet reader/writer engine. Available options: ‘auto’, ‘pyarrow’, ‘fastparquet’, the default is ‘auto’ [default: auto] [currently: auto]
- io.sql.engine** [string] The default sql reader/writer engine. Available options: ‘auto’, ‘sqlalchemy’, the default is ‘auto’ [default: auto] [currently: auto]
- mode.chained_assignment** [string] Raise an exception, warn, or no action if trying to use chained assignment, The default is warn [default: warn] [currently: warn]
- mode.data_manager** [string] Internal data manager type; can be “block” or “array”. Defaults to “block”, unless overridden by the ‘PANDAS_DATA_MANAGER’ environment variable (needs to be set before pandas is imported). [default: block] [currently: block]
- mode.sim_interactive** [boolean] Whether to simulate interactive mode for purposes of testing [default: False] [currently: False]
- mode.string_storage** [string] The default storage for StringDtype. [default: python] [currently: python]
- mode.use_inf_as_na** [boolean] True means treat None, NaN, INF, -INF as NA (old way), False means None and NaN are null, but INF, -INF are not NA (new way). [default: False] [currently: False]
- mode.use_inf_as_null** [boolean] use_inf_as_null had been deprecated and will be removed in a future version. Use *use_inf_as_na* instead. [default: False] [currently: False] (Deprecated, use *mode.use_inf_as_na* instead.)
- plotting.backend** [str] The plotting backend to use. The default value is “matplotlib”, the backend provided with pandas. Other backends can be specified by providing the name of the module that implements the backend. [default: matplotlib] [currently: matplotlib]
- plotting.matplotlib.register_converters** [bool or ‘auto’.] Whether to register converters with matplotlib’s units registry for dates, times, datetimes, and Periods. Toggling to False will remove the converters, restoring any converters that pandas overwrote. [default: auto] [currently: auto]
- styler.render.max_elements** [int] The maximum number of data-cell (<td>) elements that will be rendered before trimming will occur over columns, rows or both if needed. [default: 262144] [currently: 262144]
- styler.sparse.columns** [bool] Whether to sparsify the display of hierarchical columns. Setting to False will display each explicit level element in a hierarchical key for each column. [default: True] [currently: True]
- styler.sparse.index** [bool] Whether to sparsify the display of a hierarchical index. Setting to False will display each explicit level element in a hierarchical key for each row. [default: True] [currently: True]

pandas.reset_option

`pandas.reset_option(pat) = <pandas._config.config.CallableDynamicDoc object>`

Reset one or more options to their default value.

Pass “all” as argument to reset all options.

Available options:

- `compute.[use_bottleneck, use_numba, use_numexpr]`
- `display.[chop_threshold, colheader_justify, column_space, date_dayfirst, date_yearfirst, encoding, expand_frame_repr, float_format]`
- `display.html.[border, table_schema, use_mathjax]`
- `display.[large_repr]`
- `display.latex.[escape, longtable, multicolumn, multicolumn_format, multirow, repr]`
- `display.[max_categories, max_columns, max_colwidth, max_info_columns, max_info_rows, max_rows, max_seq_items, memory_usage, min_rows, multi_sparse, notebook_repr_html, pprint_nest_depth, precision, show_dimensions]`
- `display.unicode.[ambiguous_as_wide, east_asian_width]`
- `display.[width]`
- `io.excel.ods.[reader, writer]`
- `io.excel.xls.[reader, writer]`
- `io.excel.xlsb.[reader]`
- `io.excel.xlsm.[reader, writer]`
- `io.excel.xlsx.[reader, writer]`
- `io.hdf.[default_format, dropna_table]`
- `io.parquet.[engine]`
- `io.sql.[engine]`
- `mode.[chained_assignment, data_manager, sim_interactive, string_storage, use_inf_as_na, use_inf_as_null]`
- `plotting.[backend]`
- `plotting.matplotlib.[register_converters]`
- `styler.render.[max_elements]`
- `styler.sparse.[columns, index]`

Parameters

pat [str/regex] If specified only options matching *prefix** will be reset. Note: partial matches are supported for convenience, but unless you use the full option name (e.g. `x.y.z.option_name`), your code may break in future versions if new options with similar names are introduced.

Returns

None

Notes

The available options with its descriptions:

compute.use_bottleneck [bool] Use the bottleneck library to accelerate if it is installed, the default is True Valid values: False,True [default: True] [currently: True]

compute.use_numba [bool] Use the numba engine option for select operations if it is installed, the default is False Valid values: False,True [default: False] [currently: False]

compute.use_numexpr [bool] Use the numexpr library to accelerate computation if it is installed, the default is True Valid values: False,True [default: True] [currently: True]

display.chop_threshold [float or None] if set to a float value, all float values smaller than the given threshold will be displayed as exactly 0 by repr and friends. [default: None] [currently: None]

- display.colheader_justify** ['left'/'right'] Controls the justification of column headers. used by DataFrameFormatter. [default: right] [currently: right]
- display.column_space** **No description available.** [default: 12] [currently: 12]
- display.date_dayfirst** [boolean] When True, prints and parses dates with the day first, eg 20/01/2005 [default: False] [currently: False]
- display.date_yearfirst** [boolean] When True, prints and parses dates with the year first, eg 2005/01/20 [default: False] [currently: False]
- display.encoding** [str/unicode] Defaults to the detected encoding of the console. Specifies the encoding to be used for strings returned by to_string, these are generally strings meant to be displayed on the console. [default: utf-8] [currently: utf-8]
- display.expand_frame_repr** [boolean] Whether to print out the full DataFrame repr for wide DataFrames across multiple lines, *max_columns* is still respected, but the output will wrap-around across multiple “pages” if its width exceeds *display.width*. [default: True] [currently: True]
- display.float_format** [callable] The callable should accept a floating point number and return a string with the desired format of the number. This is used in some places like SeriesFormatter. See formats.format.EngFormatter for an example. [default: None] [currently: None]
- display.html.border** [int] A border=value attribute is inserted in the <table> tag for the DataFrame HTML repr. [default: 1] [currently: 1]
- display.html.table_schema** [boolean] Whether to publish a Table Schema representation for frontends that support it. (default: False) [default: False] [currently: False]
- display.html.use_mathjax** [boolean] When True, Jupyter notebook will process table contents using MathJax, rendering mathematical expressions enclosed by the dollar symbol. (default: True) [default: True] [currently: True]
- display.large_repr** ['truncate'/'info'] For DataFrames exceeding max_rows/max_cols, the repr (and HTML repr) can show a truncated table (the default from 0.13), or switch to the view from df.info() (the behaviour in earlier versions of pandas). [default: truncate] [currently: truncate]
- display.latex.escape** [bool] This specifies if the to_latex method of a Dataframe uses escapes special characters. Valid values: False,True [default: True] [currently: True]
- display.latex.longtable** :bool This specifies if the to_latex method of a Dataframe uses the longtable format. Valid values: False,True [default: False] [currently: False]
- display.latex.multicolumn** [bool] This specifies if the to_latex method of a Dataframe uses multicolumns to pretty-print MultiIndex columns. Valid values: False,True [default: True] [currently: True]
- display.latex.multicolumn_format** [bool] This specifies if the to_latex method of a Dataframe uses multicolumns to pretty-print MultiIndex columns. Valid values: False,True [default: 1] [currently: 1]
- display.latex.multiprow** [bool] This specifies if the to_latex method of a Dataframe uses multirows to pretty-print MultiIndex rows. Valid values: False,True [default: False] [currently: False]
- display.latex.repr** [boolean] Whether to produce a latex DataFrame representation for jupyter environments that support it. (default: False) [default: False] [currently: False]
- display.max_categories** [int] This sets the maximum number of categories pandas should output when printing out a *Categorical* or a Series of dtype “category”. [default: 8] [currently: 8]
- display.max_columns** [int] If max_cols is exceeded, switch to truncate view. Depending on *large_repr*, objects are either centrally truncated or printed as a summary view. ‘None’ value means unlimited.
- In case python/IPython is running in a terminal and *large_repr* equals ‘truncate’ this can be set to 0 and pandas will auto-detect the width of the terminal and print a truncated object which fits the screen width. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: 0] [currently: 0]
- display.max_colwidth** [int or None] The maximum width in characters of a column in the repr of a pandas data structure. When the column overflows, a “...” placeholder is embedded in the output. A ‘None’ value means unlimited. [default: 50] [currently: 50]
- display.max_info_columns** [int] max_info_columns is used in DataFrame.info method to decide if per column information will be printed. [default: 100] [currently: 100]
- display.max_info_rows** [int or None] df.info() will usually show null-counts for each column. For large frames this can be quite slow. max_info_rows and max_info_cols limit this null check only to frames with smaller

dimensions than specified. [default: 1690785] [currently: 1690785]

display.max_rows [int] If `max_rows` is exceeded, switch to truncate view. Depending on `large_repr`, objects are either centrally truncated or printed as a summary view. ‘None’ value means unlimited.

In case python/IPython is running in a terminal and `large_repr` equals ‘truncate’ this can be set to 0 and pandas will auto-detect the height of the terminal and print a truncated object which fits the screen height. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: 60] [currently: 60]

display.max_seq_items [int or None] When pretty-printing a long sequence, no more than `max_seq_items` will be printed. If items are omitted, they will be denoted by the addition of “...” to the resulting string.

If set to None, the number of items to be printed is unlimited. [default: 100] [currently: 100]

display.memory_usage [bool, string or None] This specifies if the memory usage of a DataFrame should be displayed when `df.info()` is called. Valid values True,False,‘deep’ [default: True] [currently: True]

display.min_rows [int] The numbers of rows to show in a truncated view (when `max_rows` is exceeded). Ignored when `max_rows` is set to None or 0. When set to None, follows the value of `max_rows`. [default: 10] [currently: 10]

display.multi_sparse [boolean] “sparsify” MultiIndex display (don’t display repeated elements in outer levels within groups) [default: True] [currently: True]

display.notebook_repr_html [boolean] When True, IPython notebook will use html representation for pandas objects (if it is available). [default: True] [currently: True]

display.pprint_nest_depth [int] Controls the number of nested levels to process when pretty-printing [default: 3] [currently: 3]

display.precision [int] Floating point output precision in terms of number of places after the decimal, for regular formatting as well as scientific notation. Similar to `precision` in `numpy.set_printoptions()`. [default: 6] [currently: 6]

display.show_dimensions [boolean or ‘truncate’] Whether to print out dimensions at the end of DataFrame repr. If ‘truncate’ is specified, only print out the dimensions if the frame is truncated (e.g. not display all rows and/or columns) [default: truncate] [currently: truncate]

display.unicode.ambiguous_as_wide [boolean] Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance (default: False) [default: False] [currently: False]

display.unicode.east_asian_width [boolean] Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance (default: False) [default: False] [currently: False]

display.width [int] Width of the display in characters. In case python/IPython is running in a terminal this can be set to None and pandas will correctly auto-detect the width. Note that the IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to correctly detect the width. [default: 80] [currently: 80]

io.excel.ods.reader [string] The default Excel reader engine for ‘ods’ files. Available options: auto, odf. [default: auto] [currently: auto]

io.excel.ods.writer [string] The default Excel writer engine for ‘ods’ files. Available options: auto, odf. [default: auto] [currently: auto]

io.excel.xls.reader [string] The default Excel reader engine for ‘xls’ files. Available options: auto, xlrd. [default: auto] [currently: auto]

io.excel.xls.writer [string] The default Excel writer engine for ‘xls’ files. Available options: auto, xlwt. [default: auto] [currently: auto] (Deprecated, use `` instead.)

io.excel.xlsb.reader [string] The default Excel reader engine for ‘xlsb’ files. Available options: auto, pyxlsb. [default: auto] [currently: auto]

io.excel.xlsm.reader [string] The default Excel reader engine for ‘xlsm’ files. Available options: auto, xlrd, openpyxl. [default: auto] [currently: auto]

io.excel.xlsm.writer [string] The default Excel writer engine for ‘xlsm’ files. Available options: auto, openpyxl. [default: auto] [currently: auto]

io.excel.xlsx.reader [string] The default Excel reader engine for ‘xlsx’ files. Available options: auto, xlrd, openpyxl. [default: auto] [currently: auto]

- io.excel.xlsx.writer** [string] The default Excel writer engine for ‘xlsx’ files. Available options: auto, openpyxl, xlsxwriter. [default: auto] [currently: auto]
- io.hdf.default_format** [format] default format writing format, if None, then put will default to ‘fixed’ and append will default to ‘table’ [default: None] [currently: None]
- io.hdf.dropna_table** [boolean] drop ALL nan rows when appending to a table [default: False] [currently: False]
- io.parquet.engine** [string] The default parquet reader/writer engine. Available options: ‘auto’, ‘pyarrow’, ‘fastparquet’, the default is ‘auto’ [default: auto] [currently: auto]
- io.sql.engine** [string] The default sql reader/writer engine. Available options: ‘auto’, ‘sqlalchemy’, the default is ‘auto’ [default: auto] [currently: auto]
- mode.chained_assignment** [string] Raise an exception, warn, or no action if trying to use chained assignment, The default is warn [default: warn] [currently: warn]
- mode.data_manager** [string] Internal data manager type; can be “block” or “array”. Defaults to “block”, unless overridden by the ‘PANDAS_DATA_MANAGER’ environment variable (needs to be set before pandas is imported). [default: block] [currently: block]
- mode.sim_interactive** [boolean] Whether to simulate interactive mode for purposes of testing [default: False] [currently: False]
- mode.string_storage** [string] The default storage for StringDtype. [default: python] [currently: python]
- mode.use_inf_as_na** [boolean] True means treat None, NaN, INF, -INF as NA (old way), False means None and NaN are null, but INF, -INF are not NA (new way). [default: False] [currently: False]
- mode.use_inf_as_null** [boolean] use_inf_as_null had been deprecated and will be removed in a future version. Use *use_inf_as_na* instead. [default: False] [currently: False] (Deprecated, use *mode.use_inf_as_na* instead.)
- plotting.backend** [str] The plotting backend to use. The default value is “matplotlib”, the backend provided with pandas. Other backends can be specified by providing the name of the module that implements the backend. [default: matplotlib] [currently: matplotlib]
- plotting.matplotlib.register_converters** [bool or ‘auto’.] Whether to register converters with matplotlib’s units registry for dates, times, datetimes, and Periods. Toggling to False will remove the converters, restoring any converters that pandas overwrote. [default: auto] [currently: auto]
- styler.render.max_elements** [int] The maximum number of data-cell (<td>) elements that will be rendered before trimming will occur over columns, rows or both if needed. [default: 262144] [currently: 262144]
- styler.sparse.columns** [bool] Whether to sparsify the display of hierarchical columns. Setting to False will display each explicit level element in a hierarchical key for each column. [default: True] [currently: True]
- styler.sparse.index** [bool] Whether to sparsify the display of a hierarchical index. Setting to False will display each explicit level element in a hierarchical key for each row. [default: True] [currently: True]

pandas.get_option

`pandas.get_option(pat) = <pandas._config.config.CallableDynamicDoc object>`

Retrieves the value of the specified option.

Available options:

- compute.[use_bottleneck, use_numba, use_numexpr]
- display.[chop_threshold, colheader_justify, column_space, date_dayfirst, date_yearfirst, encoding, expand_frame_repr, float_format]
- display.html.[border, table_schema, use_mathjax]
- display.[large_repr]
- display.latex.[escape, longtable, multicolumn, multicolumn_format, multirow, repr]
- display.[max_categories, max_columns, max_colwidth, max_info_columns, max_info_rows, max_rows, max_seq_items, memory_usage, min_rows, multi_sparse, notebook_repr_html, pprint_nest_depth, precision, show_dimensions]
- display.unicode.[ambiguous_as_wide, east_asian_width]
- display.[width]
- io.excel.ods.[reader, writer]
- io.excel.xls.[reader, writer]

- `io.excel.xlsb.[reader]`
- `io.excel.xlsm.[reader, writer]`
- `io.excel.xlsx.[reader, writer]`
- `io.hdf.[default_format, dropna_table]`
- `io.parquet.[engine]`
- `io.sql.[engine]`
- `mode.[chained_assignment, data_manager, sim_interactive, string_storage, use_inf_as_na, use_inf_as_null]`
- `plotting.[backend]`
- `plotting.matplotlib.[register_converters]`
- `styler.render.[max_elements]`
- `styler.sparse.[columns, index]`

Parameters

pat [str] Regexp which should match a single option. Note: partial matches are supported for convenience, but unless you use the full option name (e.g. `x.y.z.option_name`), your code may break in future versions if new options with similar names are introduced.

Returns

result [the value of the option]

Raises

OptionError [if no such option exists]

Notes

The available options with its descriptions:

compute.use_bottleneck [bool] Use the bottleneck library to accelerate if it is installed, the default is True Valid values: False, True [default: True] [currently: True]

compute.use_numba [bool] Use the numba engine option for select operations if it is installed, the default is False Valid values: False, True [default: False] [currently: False]

compute.use_numexpr [bool] Use the numexpr library to accelerate computation if it is installed, the default is True Valid values: False, True [default: True] [currently: True]

display.chop_threshold [float or None] if set to a float value, all float values smaller then the given threshold will be displayed as exactly 0 by repr and friends. [default: None] [currently: None]

display.colheader_justify ['left'/'right'] Controls the justification of column headers. used by DataFrameFormatter. [default: right] [currently: right]

display.column_space **No description available.** [default: 12] [currently: 12]

display.date_dayfirst [boolean] When True, prints and parses dates with the day first, eg 20/01/2005 [default: False] [currently: False]

display.date_yearfirst [boolean] When True, prints and parses dates with the year first, eg 2005/01/20 [default: False] [currently: False]

display.encoding [str/unicode] Defaults to the detected encoding of the console. Specifies the encoding to be used for strings returned by `to_string`, these are generally strings meant to be displayed on the console. [default: utf-8] [currently: utf-8]

display.expand_frame_repr [boolean] Whether to print out the full DataFrame repr for wide DataFrames across multiple lines, `max_columns` is still respected, but the output will wrap-around across multiple “pages” if its width exceeds `display.width`. [default: True] [currently: True]

display.float_format [callable] The callable should accept a floating point number and return a string with the desired format of the number. This is used in some places like SeriesFormatter. See `formats.format.EngFormatter` for an example. [default: None] [currently: None]

display.html.border [int] A `border=value` attribute is inserted in the `<table>` tag for the DataFrame HTML repr. [default: 1] [currently: 1]

- display.html.table_schema** [boolean] Whether to publish a Table Schema representation for frontends that support it. (default: False) [default: False] [currently: False]
- display.html.use_mathjax** [boolean] When True, Jupyter notebook will process table contents using MathJax, rendering mathematical expressions enclosed by the dollar symbol. (default: True) [default: True] [currently: True]
- display.large_repr** ['truncate'/'info'] For DataFrames exceeding `max_rows/max_cols`, the repr (and HTML repr) can show a truncated table (the default from 0.13), or switch to the view from `df.info()` (the behaviour in earlier versions of pandas). [default: truncate] [currently: truncate]
- display.latex.escape** [bool] This specifies if the `to_latex` method of a Dataframe uses escapes special characters. Valid values: False,True [default: True] [currently: True]
- display.latex.longtable** :bool This specifies if the `to_latex` method of a Dataframe uses the longtable format. Valid values: False,True [default: False] [currently: False]
- display.latex.multicolumn** [bool] This specifies if the `to_latex` method of a Dataframe uses multicolumns to pretty-print MultiIndex columns. Valid values: False,True [default: True] [currently: True]
- display.latex.multicolumn_format** [bool] This specifies if the `to_latex` method of a Dataframe uses multicolumns to pretty-print MultiIndex columns. Valid values: False,True [default: 1] [currently: 1]
- display.latex.multiprow** [bool] This specifies if the `to_latex` method of a Dataframe uses multirows to pretty-print MultiIndex rows. Valid values: False,True [default: False] [currently: False]
- display.latex.repr** [boolean] Whether to produce a latex DataFrame representation for jupyter environments that support it. (default: False) [default: False] [currently: False]
- display.max_categories** [int] This sets the maximum number of categories pandas should output when printing out a *Categorical* or a Series of dtype "category". [default: 8] [currently: 8]
- display.max_columns** [int] If `max_cols` is exceeded, switch to truncate view. Depending on `large_repr`, objects are either centrally truncated or printed as a summary view. 'None' value means unlimited.
- In case python/IPython is running in a terminal and `large_repr` equals 'truncate' this can be set to 0 and pandas will auto-detect the width of the terminal and print a truncated object which fits the screen width. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: 0] [currently: 0]
- display.max_colwidth** [int or None] The maximum width in characters of a column in the repr of a pandas data structure. When the column overflows, a "..." placeholder is embedded in the output. A 'None' value means unlimited. [default: 50] [currently: 50]
- display.max_info_columns** [int] `max_info_columns` is used in `DataFrame.info` method to decide if per column information will be printed. [default: 100] [currently: 100]
- display.max_info_rows** [int or None] `df.info()` will usually show null-counts for each column. For large frames this can be quite slow. `max_info_rows` and `max_info_cols` limit this null check only to frames with smaller dimensions than specified. [default: 1690785] [currently: 1690785]
- display.max_rows** [int] If `max_rows` is exceeded, switch to truncate view. Depending on `large_repr`, objects are either centrally truncated or printed as a summary view. 'None' value means unlimited.
- In case python/IPython is running in a terminal and `large_repr` equals 'truncate' this can be set to 0 and pandas will auto-detect the height of the terminal and print a truncated object which fits the screen height. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: 60] [currently: 60]
- display.max_seq_items** [int or None] When pretty-printing a long sequence, no more than `max_seq_items` will be printed. If items are omitted, they will be denoted by the addition of "..." to the resulting string.
- If set to None, the number of items to be printed is unlimited. [default: 100] [currently: 100]
- display.memory_usage** [bool, string or None] This specifies if the memory usage of a DataFrame should be displayed when `df.info()` is called. Valid values True,False,'deep' [default: True] [currently: True]
- display.min_rows** [int] The numbers of rows to show in a truncated view (when `max_rows` is exceeded). Ignored when `max_rows` is set to None or 0. When set to None, follows the value of `max_rows`. [default: 10] [currently: 10]
- display.multi_sparse** [boolean] "sparsify" MultiIndex display (don't display repeated elements in outer levels within groups) [default: True] [currently: True]

- display.notebook_repr_html** [boolean] When True, IPython notebook will use html representation for pandas objects (if it is available). [default: True] [currently: True]
- display.pprint_nest_depth** [int] Controls the number of nested levels to process when pretty-printing [default: 3] [currently: 3]
- display.precision** [int] Floating point output precision in terms of number of places after the decimal, for regular formatting as well as scientific notation. Similar to `precision` in `numpy.set_printoptions()`. [default: 6] [currently: 6]
- display.show_dimensions** [boolean or 'truncate'] Whether to print out dimensions at the end of DataFrame repr. If 'truncate' is specified, only print out the dimensions if the frame is truncated (e.g. not display all rows and/or columns) [default: truncate] [currently: truncate]
- display.unicode.ambiguous_as_wide** [boolean] Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance (default: False) [default: False] [currently: False]
- display.unicode.east_asian_width** [boolean] Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance (default: False) [default: False] [currently: False]
- display.width** [int] Width of the display in characters. In case python/IPython is running in a terminal this can be set to None and pandas will correctly auto-detect the width. Note that the IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to correctly detect the width. [default: 80] [currently: 80]
- io.excel.ods.reader** [string] The default Excel reader engine for 'ods' files. Available options: auto, odf. [default: auto] [currently: auto]
- io.excel.ods.writer** [string] The default Excel writer engine for 'ods' files. Available options: auto, odf. [default: auto] [currently: auto]
- io.excel.xls.reader** [string] The default Excel reader engine for 'xls' files. Available options: auto, xlrd. [default: auto] [currently: auto]
- io.excel.xls.writer** [string] The default Excel writer engine for 'xls' files. Available options: auto, xlwt. [default: auto] [currently: auto] (Deprecated, use `` instead.)
- io.excel.xlsb.reader** [string] The default Excel reader engine for 'xlsb' files. Available options: auto, pyxlsb. [default: auto] [currently: auto]
- io.excel.xlsm.reader** [string] The default Excel reader engine for 'xlsm' files. Available options: auto, xlrd, openpyxl. [default: auto] [currently: auto]
- io.excel.xlsm.writer** [string] The default Excel writer engine for 'xlsm' files. Available options: auto, openpyxl. [default: auto] [currently: auto]
- io.excel.xlsx.reader** [string] The default Excel reader engine for 'xlsx' files. Available options: auto, xlrd, openpyxl. [default: auto] [currently: auto]
- io.excel.xlsx.writer** [string] The default Excel writer engine for 'xlsx' files. Available options: auto, openpyxl, xlsxwriter. [default: auto] [currently: auto]
- io.hdf.default_format** [format] default format writing format, if None, then put will default to 'fixed' and append will default to 'table' [default: None] [currently: None]
- io.hdf.dropna_table** [boolean] drop ALL nan rows when appending to a table [default: False] [currently: False]
- io.parquet.engine** [string] The default parquet reader/writer engine. Available options: 'auto', 'pyarrow', 'fastparquet', the default is 'auto' [default: auto] [currently: auto]
- io.sql.engine** [string] The default sql reader/writer engine. Available options: 'auto', 'sqlalchemy', the default is 'auto' [default: auto] [currently: auto]
- mode.chained_assignment** [string] Raise an exception, warn, or no action if trying to use chained assignment, The default is warn [default: warn] [currently: warn]
- mode.data_manager** [string] Internal data manager type; can be "block" or "array". Defaults to "block", unless overridden by the 'PANDAS_DATA_MANAGER' environment variable (needs to be set before pandas is imported). [default: block] [currently: block]
- mode.sim_interactive** [boolean] Whether to simulate interactive mode for purposes of testing [default: False] [currently: False]
- mode.string_storage** [string] The default storage for StringDtype. [default: python] [currently: python]
- mode.use_inf_as_na** [boolean] True means treat None, NaN, INF, -INF as NA (old way), False means None

- and NaN are null, but INF, -INF are not NA (new way). [default: False] [currently: False]
- mode.use_inf_as_null** [boolean] `use_inf_as_null` had been deprecated and will be removed in a future version. Use `use_inf_as_na` instead. [default: False] [currently: False] (Deprecated, use `mode.use_inf_as_na` instead.)
- plotting.backend** [str] The plotting backend to use. The default value is “matplotlib”, the backend provided with pandas. Other backends can be specified by providing the name of the module that implements the backend. [default: matplotlib] [currently: matplotlib]
- plotting.matplotlib.register_converters** [bool or ‘auto’.] Whether to register converters with matplotlib’s units registry for dates, times, datetimes, and Periods. Toggling to False will remove the converters, restoring any converters that pandas overwrote. [default: auto] [currently: auto]
- styler.render.max_elements** [int] The maximum number of data-cell (<td>) elements that will be rendered before trimming will occur over columns, rows or both if needed. [default: 262144] [currently: 262144]
- styler.sparse.columns** [bool] Whether to sparsify the display of hierarchical columns. Setting to False will display each explicit level element in a hierarchical key for each column. [default: True] [currently: True]
- styler.sparse.index** [bool] Whether to sparsify the display of a hierarchical index. Setting to False will display each explicit level element in a hierarchical key for each row. [default: True] [currently: True]

pandas.set_option

`pandas.set_option(pat, value) = <pandas._config.config.CallableDynamicDoc object>`

Sets the value of the specified option.

Available options:

- `compute`.`[use_bottleneck, use_numba, use_numexpr]`
- `display`.`[chop_threshold, colheader_justify, column_space, date_dayfirst, date_yearfirst, encoding, expand_frame_repr, float_format]`
- `display.html`.`[border, table_schema, use_mathjax]`
- `display`.`[large_repr]`
- `display.latex`.`[escape, longtable, multicolumn, multicolumn_format, multirow, repr]`
- `display`.`[max_categories, max_columns, max_colwidth, max_info_columns, max_info_rows, max_rows, max_seq_items, memory_usage, min_rows, multi_sparse, notebook_repr_html, pprint_nest_depth, precision, show_dimensions]`
- `display.unicode`.`[ambiguous_as_wide, east_asian_width]`
- `display`.`[width]`

- `plotting`.`[backend]`
- `plotting.matplotlib`.`[register_converters]`
- `styler.render`.`[max_elements]`
- `styler.sparse`.`[columns, index]`

Parameters

- pat** [str] Regexp which should match a single option. Note: partial matches are supported for convenience, but unless you use the full option name (e.g. `x.y.z.option_name`), your code may break in future versions if new options with similar names are introduced.

value [object] New value of option.

Returns

None

Raises

OptionError if no such option exists

Notes

The available options with its descriptions:

- compute.use_bottleneck** [bool] Use the bottleneck library to accelerate if it is installed, the default is True Valid values: False,True [default: True] [currently: True]
- compute.use_numba** [bool] Use the numba engine option for select operations if it is installed, the default is False Valid values: False,True [default: False] [currently: False]
- compute.use_numexpr** [bool] Use the numexpr library to accelerate computation if it is installed, the default is True Valid values: False,True [default: True] [currently: True]
- display.chop_threshold** [float or None] if set to a float value, all float values smaller then the given threshold will be displayed as exactly 0 by repr and friends. [default: None] [currently: None]
- display.colheader_justify** ['left'/'right'] Controls the justification of column headers. used by DataFrameFormatter. [default: right] [currently: right]
- display.column_space** **No description available.** [default: 12] [currently: 12]
- display.date_dayfirst** [boolean] When True, prints and parses dates with the day first, eg 20/01/2005 [default: False] [currently: False]
- display.date_yearfirst** [boolean] When True, prints and parses dates with the year first, eg 2005/01/20 [default: False] [currently: False]
- display.encoding** [str/unicode] Defaults to the detected encoding of the console. Specifies the encoding to be used for strings returned by to_string, these are generally strings meant to be displayed on the console. [default: utf-8] [currently: utf-8]
- display.expand_frame_repr** [boolean] Whether to print out the full DataFrame repr for wide DataFrames across multiple lines, *max_columns* is still respected, but the output will wrap-around across multiple “pages” if its width exceeds *display.width*. [default: True] [currently: True]
- display.float_format** [callable] The callable should accept a floating point number and return a string with the desired format of the number. This is used in some places like SeriesFormatter. See formats.format.EngFormatter for an example. [default: None] [currently: None]
- display.html.border** [int] A border=value attribute is inserted in the <table> tag for the DataFrame HTML repr. [default: 1] [currently: 1]
- display.html.table_schema** [boolean] Whether to publish a Table Schema representation for frontends that support it. (default: False) [default: False] [currently: False]
- display.html.use_mathjax** [boolean] When True, Jupyter notebook will process table contents using MathJax, rendering mathematical expressions enclosed by the dollar symbol. (default: True) [default: True] [currently: True]
- display.large_repr** ['truncate'/'info'] For DataFrames exceeding max_rows/max_cols, the repr (and HTML repr) can show a truncated table (the default from 0.13), or switch to the view from df.info() (the behaviour in earlier versions of pandas). [default: truncate] [currently: truncate]
- display.latex.escape** [bool] This specifies if the to_latex method of a Dataframe uses escapes special characters. Valid values: False,True [default: True] [currently: True]
- display.latex.longtable** :bool This specifies if the to_latex method of a Dataframe uses the longtable format. Valid values: False,True [default: False] [currently: False]
- display.latex.multicolumn** [bool] This specifies if the to_latex method of a Dataframe uses multicolumns to pretty-print MultiIndex columns. Valid values: False,True [default: True] [currently: True]
- display.latex.multicolumn_format** [bool] This specifies if the to_latex method of a Dataframe uses multicolumns to pretty-print MultiIndex columns. Valid values: False,True [default: 1] [currently: 1]

display.latex.multiprow [bool] This specifies if the `to_latex` method of a DataFrame uses multirows to pretty-print MultiIndex rows. Valid values: `False`, `True` [default: `False`] [currently: `False`]

display.latex.repr [boolean] Whether to produce a latex DataFrame representation for jupyter environments that support it. (default: `False`) [default: `False`] [currently: `False`]

display.max_categories [int] This sets the maximum number of categories pandas should output when printing out a *Categorical* or a Series of dtype “category”. [default: 8] [currently: 8]

display.max_columns [int] If `max_cols` is exceeded, switch to truncate view. Depending on *large_repr*, objects are either centrally truncated or printed as a summary view. ‘None’ value means unlimited.

In case python/IPython is running in a terminal and *large_repr* equals ‘truncate’ this can be set to 0 and pandas will auto-detect the width of the terminal and print a truncated object which fits the screen width. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: 0] [currently: 0]

display.max_colwidth [int or None] The maximum width in characters of a column in the repr of a pandas data structure. When the column overflows, a “...” placeholder is embedded in the output. A ‘None’ value means unlimited. [default: 50] [currently: 50]

display.max_info_columns [int] `max_info_columns` is used in `DataFrame.info` method to decide if per column information will be printed. [default: 100] [currently: 100]

display.max_info_rows [int or None] `df.info()` will usually show null-counts for each column. For large frames this can be quite slow. `max_info_rows` and `max_info_cols` limit this null check only to frames with smaller dimensions than specified. [default: 1690785] [currently: 1690785]

display.max_rows [int] If `max_rows` is exceeded, switch to truncate view. Depending on *large_repr*, objects are either centrally truncated or printed as a summary view. ‘None’ value means unlimited.

In case python/IPython is running in a terminal and *large_repr* equals ‘truncate’ this can be set to 0 and pandas will auto-detect the height of the terminal and print a truncated object which fits the screen height. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: 60] [currently: 60]

display.max_seq_items [int or None] When pretty-printing a long sequence, no more than *max_seq_items* will be printed. If items are omitted, they will be denoted by the addition of “...” to the resulting string.

If set to None, the number of items to be printed is unlimited. [default: 100] [currently: 100]

display.memory_usage [bool, string or None] This specifies if the memory usage of a DataFrame should be displayed when `df.info()` is called. Valid values `True`, `False`, ‘deep’ [default: `True`] [currently: `True`]

display.min_rows [int] The numbers of rows to show in a truncated view (when *max_rows* is exceeded). Ignored when *max_rows* is set to None or 0. When set to None, follows the value of *max_rows*. [default: 10] [currently: 10]

display.multi_sparse [boolean] “sparsify” MultiIndex display (don’t display repeated elements in outer levels within groups) [default: `True`] [currently: `True`]

display.notebook_repr_html [boolean] When `True`, IPython notebook will use html representation for pandas objects (if it is available). [default: `True`] [currently: `True`]

display.pprint_nest_depth [int] Controls the number of nested levels to process when pretty-printing [default: 3] [currently: 3]

display.precision [int] Floating point output precision in terms of number of places after the decimal, for regular formatting as well as scientific notation. Similar to `precision` in `numpy.set_printoptions()`. [default: 6] [currently: 6]

display.show_dimensions [boolean or ‘truncate’] Whether to print out dimensions at the end of DataFrame repr. If ‘truncate’ is specified, only print out the dimensions if the frame is truncated (e.g. not display all rows and/or columns) [default: `truncate`] [currently: `truncate`]

display.unicode.ambiguous_as_wide [boolean] Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance (default: `False`) [default: `False`] [currently: `False`]

display.unicode.east_asian_width [boolean] Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance (default: `False`) [default: `False`] [currently: `False`]

- display.width** [int] Width of the display in characters. In case python/IPython is running in a terminal this can be set to None and pandas will correctly auto-detect the width. Note that the IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to correctly detect the width. [default: 80] [currently: 80]
- io.excel.ods.reader** [string] The default Excel reader engine for ‘ods’ files. Available options: auto, odf. [default: auto] [currently: auto]
- io.excel.ods.writer** [string] The default Excel writer engine for ‘ods’ files. Available options: auto, odf. [default: auto] [currently: auto]
- io.excel.xls.reader** [string] The default Excel reader engine for ‘xls’ files. Available options: auto, xlrd. [default: auto] [currently: auto]
- io.excel.xls.writer** [string] The default Excel writer engine for ‘xls’ files. Available options: auto, xlwt. [default: auto] [currently: auto] (Deprecated, use `` instead.)
- io.excel.xlsb.reader** [string] The default Excel reader engine for ‘xlsb’ files. Available options: auto, pyxlsb. [default: auto] [currently: auto]
- io.excel.xlsm.reader** [string] The default Excel reader engine for ‘xlsm’ files. Available options: auto, xlrd, openpyxl. [default: auto] [currently: auto]
- io.excel.xlsm.writer** [string] The default Excel writer engine for ‘xlsm’ files. Available options: auto, openpyxl. [default: auto] [currently: auto]
- io.excel.xlsx.reader** [string] The default Excel reader engine for ‘xlsx’ files. Available options: auto, xlrd, openpyxl. [default: auto] [currently: auto]
- io.excel.xlsx.writer** [string] The default Excel writer engine for ‘xlsx’ files. Available options: auto, openpyxl, xlsxwriter. [default: auto] [currently: auto]
- io.hdf.default_format** [format] default format writing format, if None, then put will default to ‘fixed’ and append will default to ‘table’ [default: None] [currently: None]
- io.hdf.dropna_table** [boolean] drop ALL nan rows when appending to a table [default: False] [currently: False]
- io.parquet.engine** [string] The default parquet reader/writer engine. Available options: ‘auto’, ‘pyarrow’, ‘fastparquet’, the default is ‘auto’ [default: auto] [currently: auto]
- io.sql.engine** [string] The default sql reader/writer engine. Available options: ‘auto’, ‘sqlalchemy’, the default is ‘auto’ [default: auto] [currently: auto]
- mode.chained_assignment** [string] Raise an exception, warn, or no action if trying to use chained assignment, The default is warn [default: warn] [currently: warn]
- mode.data_manager** [string] Internal data manager type; can be “block” or “array”. Defaults to “block”, unless overridden by the ‘PANDAS_DATA_MANAGER’ environment variable (needs to be set before pandas is imported). [default: block] [currently: block]
- mode.sim_interactive** [boolean] Whether to simulate interactive mode for purposes of testing [default: False] [currently: False]
- mode.string_storage** [string] The default storage for StringDtype. [default: python] [currently: python]
- mode.use_inf_as_na** [boolean] True means treat None, NaN, INF, -INF as NA (old way), False means None and NaN are null, but INF, -INF are not NA (new way). [default: False] [currently: False]
- mode.use_inf_as_null** [boolean] use_inf_as_null had been deprecated and will be removed in a future version. Use *use_inf_as_na* instead. [default: False] [currently: False] (Deprecated, use *mode.use_inf_as_na* instead.)
- plotting.backend** [str] The plotting backend to use. The default value is “matplotlib”, the backend provided with pandas. Other backends can be specified by providing the name of the module that implements the backend. [default: matplotlib] [currently: matplotlib]
- plotting.matplotlib.register_converters** [bool or ‘auto’.] Whether to register converters with matplotlib’s units registry for dates, times, datetimes, and Periods. Toggling to False will remove the converters, restoring any converters that pandas overwrote. [default: auto] [currently: auto]
- styler.render.max_elements** [int] The maximum number of data-cell (<td>) elements that will be rendered before trimming will occur over columns, rows or both if needed. [default: 262144] [currently: 262144]
- styler.sparse.columns** [bool] Whether to sparsify the display of hierarchical columns. Setting to False will display each explicit level element in a hierarchical key for each column. [default: True] [currently: True]
