- styler.sparse.index** [bool] Whether to sparsify the display of a hierarchical index. Setting to False will display each explicit level element in a hierarchical key for each row. [default: True] [currently: True]

pandas.option_context

class pandas.option_context(*args)

Context manager to temporarily set options in the *with* statement context.

You need to invoke as `option_context(pat, val, [(pat, val), ...])`.

Examples

```
>>> with option_context('display.max_rows', 10, 'display.max_columns', 5):
...     ...
```

Methods

| | |
|-----------------------------|--------------------------|
| <code>__call__(func)</code> | Call self as a function. |
|-----------------------------|--------------------------|

pandas.option_context.__call__

`option_context.__call__(func)`

Call self as a function.

3.14.2 Testing functions

| | |
|--|--|
| <code>testing.assert_frame_equal(left, right[, ...])</code> | Check that left and right DataFrame are equal. |
| <code>testing.assert_series_equal(left, right[, ...])</code> | Check that left and right Series are equal. |
| <code>testing.assert_index_equal(left, right[, ...])</code> | Check that left and right Index are equal. |
| <code>testing.assert_extension_array_equal(left, right)</code> | Check that left and right ExtensionArrays are equal. |

pandas.testing.assert_frame_equal

`pandas.testing.assert_frame_equal(left, right, check_dtype=True, check_index_type='equiv', check_column_type='equiv', check_frame_type=True, check_less_precise=NoDefault.no_default, check_names=True, by_blocks=False, check_exact=False, check_datetimelike_compat=False, check_categorical=True, check_like=False, check_freq=True, check_flags=True, rtol=1e-05, atol=1e-08, obj='DataFrame')`

Check that left and right DataFrame are equal.

This function is intended to compare two DataFrames and output any differences. Is mostly intended for use in unit tests. Additional parameters allow varying the strictness of the equality checks performed.

Parameters

left [DataFrame] First DataFrame to compare.

right [DataFrame] Second DataFrame to compare.

check_dtype [bool, default True] Whether to check the DataFrame dtype is identical.

check_index_type [bool or {'equiv'}, default 'equiv'] Whether to check the Index class, dtype and inferred_type are identical.

check_column_type [bool or {'equiv'}, default 'equiv'] Whether to check the columns class, dtype and inferred_type are identical. Is passed as the exact argument of `assert_index_equal()`.

check_frame_type [bool, default True] Whether to check the DataFrame class is identical.

check_less_precise [bool or int, default False] Specify comparison precision. Only used when check_exact is False. 5 digits (False) or 3 digits (True) after decimal points are compared. If int, then specify the digits to compare.

When comparing two numbers, if the first number has magnitude less than $1e-5$, we compare the two numbers directly and check whether they are equivalent within the specified precision. Otherwise, we compare the **ratio** of the second number to the first number and check whether it is equivalent to 1 within the specified precision.

Deprecated since version 1.1.0: Use `rtol` and `atol` instead to define relative/absolute tolerance, respectively. Similar to `math.isclose()`.

check_names [bool, default True] Whether to check that the `names` attribute for both the `index` and `column` attributes of the DataFrame is identical.

by_blocks [bool, default False] Specify how to compare internal data. If False, compare by columns. If True, compare by blocks.

check_exact [bool, default False] Whether to compare number exactly.

check_datetimelike_compat [bool, default False] Compare datetime-like which is comparable ignoring dtype.

check_categorical [bool, default True] Whether to compare internal Categorical exactly.

check_like [bool, default False] If True, ignore the order of index & columns. Note: index labels must match their respective rows (same as in columns) - same labels must be with the same data.

check_freq [bool, default True] Whether to check the `freq` attribute on a DatetimeIndex or TimedeltaIndex.

New in version 1.1.0.

check_flags [bool, default True] Whether to check the `flags` attribute.

rtol [float, default 1e-5] Relative tolerance. Only used when check_exact is False.

New in version 1.1.0.

atol [float, default 1e-8] Absolute tolerance. Only used when check_exact is False.

New in version 1.1.0.

obj [str, default 'DataFrame'] Specify object name being compared, internally used to show appropriate assertion message.

See also:

`assert_series_equal` Equivalent method for asserting Series equality.

`DataFrame.equals` Check DataFrame equality.

Examples

This example shows comparing two DataFrames that are equal but with columns of differing dtypes.

```
>>> from pandas._testing import assert_frame_equal
>>> df1 = pd.DataFrame({'a': [1, 2], 'b': [3, 4]})
>>> df2 = pd.DataFrame({'a': [1, 2], 'b': [3.0, 4.0]})
```

df1 equals itself.

```
>>> assert_frame_equal(df1, df1)
```

df1 differs from df2 as column 'b' is of a different type.

```
>>> assert_frame_equal(df1, df2)
Traceback (most recent call last):
...
AssertionError: Attributes of DataFrame.iloc[:, 1] (column name="b") are different
```

Attribute "dtype" are different [left]: int64 [right]: float64

Ignore differing dtypes in columns with check_dtype.

```
>>> assert_frame_equal(df1, df2, check_dtype=False)
```

pandas.testing.assert_series_equal

```
pandas.testing.assert_series_equal(left, right, check_dtype=True, check_index_type='equiv',
                                   check_series_type=True, check_less_precise=NoDefault.no_default,
                                   check_names=True, check_exact=False,
                                   check_datetimelike_compat=False, check_categorical=True,
                                   check_category_order=True, check_freq=True, check_flags=True,
                                   rtol=1e-05, atol=1e-08, obj='Series', *, check_index=True)
```

Check that left and right Series are equal.

Parameters

left [Series]

right [Series]

check_dtype [bool, default True] Whether to check the Series dtype is identical.

check_index_type [bool or {'equiv'}, default 'equiv'] Whether to check the Index class, dtype and inferred_type are identical.

check_series_type [bool, default True] Whether to check the Series class is identical.

check_less_precise [bool or int, default False] Specify comparison precision. Only used when check_exact is False. 5 digits (False) or 3 digits (True) after decimal points are compared. If int, then specify the digits to compare.

When comparing two numbers, if the first number has magnitude less than 1e-5, we compare the two numbers directly and check whether they are equivalent within the specified precision. Otherwise, we compare the **ratio** of the second number to the first number and check whether it is equivalent to 1 within the specified precision.

Deprecated since version 1.1.0: Use *rtol* and *atol* instead to define relative/absolute tolerance, respectively. Similar to `math.isclose()`.

- check_names** [bool, default True] Whether to check the Series and Index names attribute.
- check_exact** [bool, default False] Whether to compare number exactly.
- check_datetimelike_compat** [bool, default False] Compare datetime-like which is comparable ignoring dtype.
- check_categorical** [bool, default True] Whether to compare internal Categorical exactly.
- check_category_order** [bool, default True] Whether to compare category order of internal Categoricals.
New in version 1.0.2.
- check_freq** [bool, default True] Whether to check the *freq* attribute on a DatetimeIndex or TimedeltaIndex.
New in version 1.1.0.
- check_flags** [bool, default True] Whether to check the *flags* attribute.
New in version 1.2.0.
- rtol** [float, default 1e-5] Relative tolerance. Only used when *check_exact* is False.
New in version 1.1.0.
- atol** [float, default 1e-8] Absolute tolerance. Only used when *check_exact* is False.
New in version 1.1.0.
- obj** [str, default 'Series'] Specify object name being compared, internally used to show appropriate assertion message.
- check_index** [bool, default True] Whether to check index equivalence. If False, then compare only values.
New in version 1.3.0.

Examples

```
>>> from pandas.testing import assert_series_equal
>>> a = pd.Series([1, 2, 3, 4])
>>> b = pd.Series([1, 2, 3, 4])
>>> assert_series_equal(a, b)
```

pandas.testing.assert_index_equal

```
pandas.testing.assert_index_equal(left, right, exact='equiv', check_names=True,
                                  check_less_precise=NoDefault.no_default, check_exact=True,
                                  check_categorical=True, check_order=True, rtol=1e-05, atol=1e-08,
                                  obj='Index')
```

Check that left and right Index are equal.

Parameters

- left** [Index]
- right** [Index]

exact [bool or {'equiv'}, default 'equiv'] Whether to check the Index class, dtype and inferred_type are identical. If 'equiv', then RangeIndex can be substituted for Int64Index as well.

check_names [bool, default True] Whether to check the names attribute.

check_less_precise [bool or int, default False] Specify comparison precision. Only used when check_exact is False. 5 digits (False) or 3 digits (True) after decimal points are compared. If int, then specify the digits to compare.

Deprecated since version 1.1.0: Use *rtol* and *atol* instead to define relative/absolute tolerance, respectively. Similar to `math.isclose()`.

check_exact [bool, default True] Whether to compare number exactly.

check_categorical [bool, default True] Whether to compare internal Categorical exactly.

check_order [bool, default True] Whether to compare the order of index entries as well as their values. If True, both indexes must contain the same elements, in the same order. If False, both indexes must contain the same elements, but in any order.

New in version 1.2.0.

rtol [float, default 1e-5] Relative tolerance. Only used when check_exact is False.

New in version 1.1.0.

atol [float, default 1e-8] Absolute tolerance. Only used when check_exact is False.

New in version 1.1.0.

obj [str, default 'Index'] Specify object name being compared, internally used to show appropriate assertion message.

Examples

```
>>> from pandas.testing import assert_index_equal
>>> a = pd.Index([1, 2, 3])
>>> b = pd.Index([1, 2, 3])
>>> assert_index_equal(a, b)
```

pandas.testing.assert_extension_array_equal

`pandas.testing.assert_extension_array_equal`(*left*, *right*, *check_dtype=True*, *index_values=None*, *check_less_precise=NoDefault.no_default*, *check_exact=False*, *rtol=1e-05*, *atol=1e-08*)

Check that left and right ExtensionArrays are equal.

Parameters

left, right [ExtensionArray] The two arrays to compare.

check_dtype [bool, default True] Whether to check if the ExtensionArray dtypes are identical.

index_values [numpy.ndarray, default None] Optional index (shared by both left and right), used in output.

check_less_precise [bool or int, default False] Specify comparison precision. Only used when check_exact is False. 5 digits (False) or 3 digits (True) after decimal points are compared. If int, then specify the digits to compare.

Deprecated since version 1.1.0: Use *rtol* and *atol* instead to define relative/absolute tolerance, respectively. Similar to `math.isclose()`.

check_exact [bool, default False] Whether to compare number exactly.

rtol [float, default 1e-5] Relative tolerance. Only used when `check_exact` is False.

New in version 1.1.0.

atol [float, default 1e-8] Absolute tolerance. Only used when `check_exact` is False.

New in version 1.1.0.

Notes

Missing values are checked separately from valid values. A mask of missing values is computed for each and checked to match. The remaining all-valid values are cast to object dtype and checked.

Examples

```
>>> from pandas.testing import assert_extension_array_equal
>>> a = pd.Series([1, 2, 3, 4])
>>> b, c = a.array, a.array
>>> assert_extension_array_equal(b, c)
```

3.14.3 Exceptions and warnings

| | |
|---|--|
| <code>errors.AccessorRegistrationWarning</code> | Warning for attribute conflicts in accessor registration. |
| <code>errors.DtypeWarning</code> | Warning raised when reading different dtypes in a column from a file. |
| <code>errors.DuplicateLabelError</code> | Error raised when an operation would introduce duplicate labels. |
| <code>errors.EmptyDataError</code> | Exception that is thrown in <code>pd.read_csv</code> (by both the C and Python engines) when empty data or header is encountered. |
| <code>errors.InvalidIndexError</code> | Exception raised when attempting to use an invalid index key. |
| <code>errors.MergeError</code> | Error raised when problems arise during merging due to problems with input data. |
| <code>errors.NullFrequencyError</code> | Error raised when a null <i>freq</i> attribute is used in an operation that needs a non-null frequency, particularly <code>DatetimeIndex.shift</code> , <code>TimedeltaIndex.shift</code> , <code>PeriodIndex.shift</code> . |
| <code>errors.NumbaUtilError</code> | Error raised for unsupported Numba engine routines. |
| <code>errors.OutOfBoundsDatetime</code> | |
| <code>errors.OutOfBoundsTimedelta</code> | Raised when encountering a timedelta value that cannot be represented as a <code>timedelta64[ns]</code> . |
| <code>errors.ParserError</code> | Exception that is raised by an error encountered in parsing file contents. |
| <code>errors.ParserWarning</code> | Warning raised when reading a file that doesn't use the default 'c' parser. |

| | |
|---|---|
| <code>errors.PerformanceWarning</code> | Warning raised when there is a possible performance impact. |
| <code>errors.UnsortedIndexError</code> | Error raised when attempting to get a slice of a MultiIndex, and the index has not been lexsorted. |
| <code>errors.UnsupportedFunctionCall</code> | Exception raised when attempting to call a numpy function on a pandas object, but that function is not supported by the object e.g. |

pandas.errors.AccessorRegistrationWarning

exception pandas.errors.AccessorRegistrationWarning

Warning for attribute conflicts in accessor registration.

pandas.errors.DtypeWarning

exception pandas.errors.DtypeWarning

Warning raised when reading different dtypes in a column from a file.

Raised for a dtype incompatibility. This can happen whenever `read_csv` or `read_table` encounter non-uniform dtypes in a column(s) of a given CSV file.

See also:

read_csv Read CSV (comma-separated) file into a DataFrame.

read_table Read general delimited file into a DataFrame.

Notes

This warning is issued when dealing with larger files because the dtype checking happens per chunk read.

Despite the warning, the CSV file is read with mixed types in a single column which will be an object type. See the examples below to better understand this issue.

Examples

This example creates and reads a large CSV file with a column that contains *int* and *str*.

```
>>> df = pd.DataFrame({'a': (['1'] * 100000 + ['X'] * 100000 +
...                          ['1'] * 100000),
...                   'b': ['b'] * 300000})
>>> df.to_csv('test.csv', index=False)
>>> df2 = pd.read_csv('test.csv')
... # DtypeWarning: Columns (0) have mixed types
```

Important to notice that `df2` will contain both *str* and *int* for the same input, '1'.

```
>>> df2.iloc[262140, 0]
'1'
>>> type(df2.iloc[262140, 0])
<class 'str'>
>>> df2.iloc[262150, 0]
```

(continues on next page)

(continued from previous page)

```
1
>>> type(df2.iloc[262150, 0])
<class 'int'>
```

One way to solve this issue is using the *dtype* parameter in the *read_csv* and *read_table* functions to explicit the conversion:

```
>>> df2 = pd.read_csv('test.csv', sep=',', dtype={'a': str})
```

No warning was issued.

```
>>> import os
>>> os.remove('test.csv')
```

pandas.errors.DuplicateLabelError

exception pandas.errors.DuplicateLabelError

Error raised when an operation would introduce duplicate labels.

New in version 1.2.0.

Examples

```
>>> s = pd.Series([0, 1, 2], index=['a', 'b', 'c']).set_flags(
...     allows_duplicate_labels=False
... )
>>> s.reindex(['a', 'a', 'b'])
Traceback (most recent call last):
...
DuplicateLabelError: Index has duplicates.
      positions
label
a          [0, 1]
```

pandas.errors.EmptyDataError

exception pandas.errors.EmptyDataError

Exception that is thrown in *pd.read_csv* (by both the C and Python engines) when empty data or header is encountered.

pandas.errors.InvalidIndexError

exception pandas.errors.InvalidIndexError

Exception raised when attempting to use an invalid index key.

New in version 1.1.0.

pandas.errors.MergeError

exception `pandas.errors.MergeError`

Error raised when problems arise during merging due to problems with input data. Subclass of *ValueError*.

pandas.errors.NullFrequencyError

exception `pandas.errors.NullFrequencyError`

Error raised when a null *freq* attribute is used in an operation that needs a non-null frequency, particularly *Date-timeIndex.shift*, *TimedeltaIndex.shift*, *PeriodIndex.shift*.

pandas.errors.NumbaUtilError

exception `pandas.errors.NumbaUtilError`

Error raised for unsupported Numba engine routines.

pandas.errors.OutOfBoundsDatetime

exception `pandas.errors.OutOfBoundsDatetime`

pandas.errors.OutOfBoundsTimedelta

exception `pandas.errors.OutOfBoundsTimedelta`

Raised when encountering a timedelta value that cannot be represented as a `timedelta64[ns]`.

pandas.errors.ParserError

exception `pandas.errors.ParserError`

Exception that is raised by an error encountered in parsing file contents.

This is a generic error raised for errors encountered when functions like *read_csv* or *read_html* are parsing contents of a file.

See also:

read_csv Read CSV (comma-separated) file into a DataFrame.

read_html Read HTML table into a DataFrame.

pandas.errors.ParserWarning

exception `pandas.errors.ParserWarning`

Warning raised when reading a file that doesn't use the default 'c' parser.

Raised by *pd.read_csv* and *pd.read_table* when it is necessary to change parsers, generally from the default 'c' parser to 'python'.

It happens due to a lack of support or functionality for parsing a particular attribute of a CSV file with the requested engine.

Currently, 'c' unsupported options include the following parameters:

1. *sep* other than a single character (e.g. regex separators)
2. *skipfooter* higher than 0
3. *sep=None* with *delim_whitespace=False*

The warning can be avoided by adding `engine='python'` as a parameter in `pd.read_csv` and `pd.read_table` methods.

See also:

pd.read_csv Read CSV (comma-separated) file into DataFrame.

pd.read_table Read general delimited file into DataFrame.

Examples

Using a `sep` in `pd.read_csv` other than a single character:

```
>>> import io
>>> csv = '''a;b;c
...      1;1,8
...      1;2,1'''
>>> df = pd.read_csv(io.StringIO(csv), sep='[;,]')
... # ParserWarning: Falling back to the 'python' engine...
```

Adding `engine='python'` to `pd.read_csv` removes the Warning:

```
>>> df = pd.read_csv(io.StringIO(csv), sep='[;,]', engine='python')
```

pandas.errors.PerformanceWarning

exception pandas.errors.PerformanceWarning

Warning raised when there is a possible performance impact.

pandas.errors.UnsortedIndexError

exception pandas.errors.UnsortedIndexError

Error raised when attempting to get a slice of a MultiIndex, and the index has not been lexsorted. Subclass of `KeyError`.

pandas.errors.UnsupportedFunctionCall

exception pandas.errors.UnsupportedFunctionCall

Exception raised when attempting to call a numpy function on a pandas object, but that function is not supported by the object e.g. `np.cumsum(groupby_object)`.

3.14.4 Data types related functionality

| | |
|--|---|
| <code>api.types.union_categoricals(to_union[, ...])</code> | Combine list-like of Categorical-like, unioning categories. |
| <code>api.types.infer_dtype</code> | Efficiently infer the type of a passed val, or list-like array of values. |
| <code>api.types.pandas_dtype(dtype)</code> | Convert input into a pandas only dtype object or a numpy dtype object. |

pandas.api.types.union_categoricals

`pandas.api.types.union_categoricals(to_union, sort_categories=False, ignore_order=False)`
Combine list-like of Categorical-like, unioning categories.

All categories must have the same dtype.

Parameters

to_union [list-like] Categorical, CategoricalIndex, or Series with dtype='category'.

sort_categories [bool, default False] If true, resulting categories will be lexsorted, otherwise they will be ordered as they appear in the data.

ignore_order [bool, default False] If true, the ordered attribute of the Categoricals will be ignored. Results in an unordered categorical.

Returns

Categorical

Raises

TypeError

- all inputs do not have the same dtype
- all inputs do not have the same ordered property
- all inputs are ordered and their categories are not identical
- sort_categories=True and Categoricals are ordered

ValueError Empty list of categoricals passed

Notes

To learn more about categories, see [link](#)

Examples

```
>>> from pandas.api.types import union_categoricals
```

If you want to combine categoricals that do not necessarily have the same categories, `union_categoricals` will combine a list-like of categoricals. The new categories will be the union of the categories being combined.

```
>>> a = pd.Categorical(["b", "c"])
>>> b = pd.Categorical(["a", "b"])
>>> union_categoricals([a, b])
['b', 'c', 'a', 'b']
Categories (3, object): ['b', 'c', 'a']
```

By default, the resulting categories will be ordered as they appear in the `categories` of the data. If you want the categories to be lexsorted, use `sort_categories=True` argument.

```
>>> union_categoricals([a, b], sort_categories=True)
['b', 'c', 'a', 'b']
Categories (3, object): ['a', 'b', 'c']
```

`union_categoricals` also works with the case of combining two categoricals of the same categories and order information (e.g. what you could also *append* for).

```
>>> a = pd.Categorical(["a", "b"], ordered=True)
>>> b = pd.Categorical(["a", "b", "a"], ordered=True)
>>> union_categoricals([a, b])
['a', 'b', 'a', 'b', 'a']
Categories (2, object): ['a' < 'b']
```

Raises `TypeError` because the categories are ordered and not identical.

```
>>> a = pd.Categorical(["a", "b"], ordered=True)
>>> b = pd.Categorical(["a", "b", "c"], ordered=True)
>>> union_categoricals([a, b])
Traceback (most recent call last):
...
TypeError: to union ordered Categoricals, all categories must be the same
```

New in version 0.20.0

Ordered categoricals with different categories or orderings can be combined by using the `ignore_ordered=True` argument.

```
>>> a = pd.Categorical(["a", "b", "c"], ordered=True)
>>> b = pd.Categorical(["c", "b", "a"], ordered=True)
>>> union_categoricals([a, b], ignore_order=True)
['a', 'b', 'c', 'c', 'b', 'a']
Categories (3, object): ['a', 'b', 'c']
```

`union_categoricals` also works with a `CategoricalIndex`, or `Series` containing categorical data, but note that the resulting array will always be a plain `Categorical`

```
>>> a = pd.Series(["b", "c"], dtype='category')
>>> b = pd.Series(["a", "b"], dtype='category')
>>> union_categoricals([a, b])
['b', 'c', 'a', 'b']
Categories (3, object): ['b', 'c', 'a']
```

pandas.api.types.infer_dtype

`pandas.api.types.infer_dtype()`

Efficiently infer the type of a passed val, or list-like array of values. Return a string describing the type.

Parameters

value [scalar, list, ndarray, or pandas type]

skipna [bool, default True] Ignore NaN values when inferring the type.

Returns

str Describing the common type of the input data.

Results can include:

- `string`
- `bytes`

- **floating**
- **integer**
- **mixed-integer**
- **mixed-integer-float**
- **decimal**
- **complex**
- **categorical**
- **boolean**
- **datetime64**
- **datetime**
- **date**
- **timedelta64**
- **timedelta**
- **time**
- **period**
- **mixed**
- **unknown-array**

Raises

TypeError If ndarray-like but cannot infer the dtype

Notes

- ‘mixed’ is the catchall for anything that is not otherwise specialized
- ‘mixed-integer-float’ are floats and integers
- ‘mixed-integer’ are integers mixed with non-integers
- ‘unknown-array’ is the catchall for something that *is* an array (has a dtype attribute), but has a dtype unknown to pandas (e.g. external extension array)

Examples

```
>>> infer_dtype(['foo', 'bar'])
'string'
```

```
>>> infer_dtype(['a', np.nan, 'b'], skipna=True)
'string'
```

```
>>> infer_dtype(['a', np.nan, 'b'], skipna=False)
'mixed'
```

```
>>> infer_dtype([b'foo', b'bar'])
'bytes'
```

```
>>> infer_dtype([1, 2, 3])
'integer'
```

```
>>> infer_dtype([1, 2, 3.5])
'mixed-integer-float'
```

```
>>> infer_dtype([1.0, 2.0, 3.5])
'floating'
```

```
>>> infer_dtype(['a', 1])
'mixed-integer'
```

```
>>> infer_dtype([Decimal(1), Decimal(2.0)])
'decimal'
```

```
>>> infer_dtype([True, False])
'boolean'
```

```
>>> infer_dtype([True, False, np.nan])
'boolean'
```

```
>>> infer_dtype([pd.Timestamp('20130101')])
'datetime'
```

```
>>> infer_dtype([datetime.date(2013, 1, 1)])
'date'
```

```
>>> infer_dtype([np.datetime64('2013-01-01')])
'datetime64'
```

```
>>> infer_dtype([datetime.timedelta(0, 1, 1)])
'timedelta'
```

```
>>> infer_dtype(pd.Series(list('abc')).astype('category'))
'categorical'
```

pandas.api.types.pandas_dtype

pandas.api.types.pandas_dtype(dtype)

Convert input into a pandas only dtype object or a numpy dtype object.

Parameters

dtype [object to be converted]

Returns

np.dtype or a pandas dtype

Raises

TypeError if not a dtype

Dtype introspection

| | |
|--|---|
| <code>api.types.is_bool_dtype(arr_or_dtype)</code> | Check whether the provided array or dtype is of a boolean dtype. |
| <code>api.types.is_categorical_dtype(arr_or_dtype)</code> | Check whether an array-like or dtype is of the Categorical dtype. |
| <code>api.types.is_complex_dtype(arr_or_dtype)</code> | Check whether the provided array or dtype is of a complex dtype. |
| <code>api.types.is_datetime64_any_dtype(arr_or_dtype)</code> | Check whether the provided array or dtype is of the datetime64 dtype. |
| <code>api.types.is_datetime64_dtype(arr_or_dtype)</code> | Check whether an array-like or dtype is of the datetime64 dtype. |

pandas.api.types.is_bool_dtype

`pandas.api.types.is_bool_dtype(arr_or_dtype)`

Check whether the provided array or dtype is of a boolean dtype.

Parameters

arr_or_dtype [array-like] The array or dtype to check.

Returns

boolean Whether or not the array or dtype is of a boolean dtype.

Notes

An ExtensionArray is considered boolean when the `_is_boolean` attribute is set to True.

Examples

```

>>> is_bool_dtype(str)
False
>>> is_bool_dtype(int)
False
>>> is_bool_dtype(bool)
True
>>> is_bool_dtype(np.bool_)
True
>>> is_bool_dtype(np.array(['a', 'b']))
False
>>> is_bool_dtype(pd.Series([1, 2]))
False
>>> is_bool_dtype(np.array([True, False]))
True
>>> is_bool_dtype(pd.Categorical([True, False]))
True
>>> is_bool_dtype(pd.arrays.SparseArray([True, False]))
True

```

pandas.api.types.is_categorical_dtype

`pandas.api.types.is_categorical_dtype(arr_or_dtype)`

Check whether an array-like or dtype is of the Categorical dtype.

Parameters

arr_or_dtype [array-like] The array-like or dtype to check.

Returns

boolean Whether or not the array-like or dtype is of the Categorical dtype.

Examples

```
>>> is_categorical_dtype(object)
False
>>> is_categorical_dtype(CategoricalDtype())
True
>>> is_categorical_dtype([1, 2, 3])
False
>>> is_categorical_dtype(pd.Categorical([1, 2, 3]))
True
>>> is_categorical_dtype(pd.CategoricalIndex([1, 2, 3]))
True
```

pandas.api.types.is_complex_dtype

pandas.api.types.is_complex_dtype(arr_or_dtype)

Check whether the provided array or dtype is of a complex dtype.

Parameters

arr_or_dtype [array-like] The array or dtype to check.

Returns

boolean Whether or not the array or dtype is of a complex dtype.

Examples

```
>>> is_complex_dtype(str)
False
>>> is_complex_dtype(int)
False
>>> is_complex_dtype(np.complex_)
True
>>> is_complex_dtype(np.array(['a', 'b']))
False
>>> is_complex_dtype(pd.Series([1, 2]))
False
>>> is_complex_dtype(np.array([1 + 1j, 5]))
True
```

pandas.api.types.is_datetime64_any_dtype

pandas.api.types.is_datetime64_any_dtype(arr_or_dtype)

Check whether the provided array or dtype is of the datetime64 dtype.

Parameters

arr_or_dtype [array-like] The array or dtype to check.

Returns

bool Whether or not the array or dtype is of the datetime64 dtype.

Examples

```

>>> is_datetime64_any_dtype(str)
False
>>> is_datetime64_any_dtype(int)
False
>>> is_datetime64_any_dtype(np.datetime64) # can be tz-naive
True
>>> is_datetime64_any_dtype(DatetimeTZDtype("ns", "US/Eastern"))
True
>>> is_datetime64_any_dtype(np.array(['a', 'b']))
False
>>> is_datetime64_any_dtype(np.array([1, 2]))
False
>>> is_datetime64_any_dtype(np.array([], dtype="datetime64[ns]"))
True
>>> is_datetime64_any_dtype(pd.DatetimeIndex([1, 2, 3], dtype="datetime64[ns]"))
True

```

pandas.api.types.is_datetime64_dtype

`pandas.api.types.is_datetime64_dtype(arr_or_dtype)`

Check whether an array-like or dtype is of the datetime64 dtype.

Parameters

arr_or_dtype [array-like] The array-like or dtype to check.

Returns

boolean Whether or not the array-like or dtype is of the datetime64 dtype.

Examples

```

>>> is_datetime64_dtype(object)
False
>>> is_datetime64_dtype(np.datetime64)
True
>>> is_datetime64_dtype(np.array([], dtype=int))
False
>>> is_datetime64_dtype(np.array([], dtype=np.datetime64))
True
>>> is_datetime64_dtype([1, 2, 3])
False

```

pandas.api.types.is_datetime64_ns_dtype

`pandas.api.types.is_datetime64_ns_dtype(arr_or_dtype)`

Check whether the provided array or dtype is of the datetime64[ns] dtype.

Parameters

arr_or_dtype [array-like] The array or dtype to check.

Returns

bool Whether or not the array or dtype is of the datetime64[ns] dtype.

Examples

```
>>> is_datetime64_ns_dtype(str)
False
>>> is_datetime64_ns_dtype(int)
False
>>> is_datetime64_ns_dtype(np.datetime64) # no unit
False
>>> is_datetime64_ns_dtype(DatetimeTZDtype("ns", "US/Eastern"))
True
>>> is_datetime64_ns_dtype(np.array(['a', 'b']))
False
>>> is_datetime64_ns_dtype(np.array([1, 2]))
False
>>> is_datetime64_ns_dtype(np.array([], dtype="datetime64")) # no unit
False
>>> is_datetime64_ns_dtype(np.array([], dtype="datetime64[ps]")) # wrong unit
False
>>> is_datetime64_ns_dtype(pd.DatetimeIndex([1, 2, 3], dtype="datetime64[ns]"))
True
```

pandas.api.types.is_datetime64tz_dtype

`pandas.api.types.is_datetime64tz_dtype(arr_or_dtype)`

Check whether an array-like or dtype is of a DatetimeTZDtype dtype.

Parameters

arr_or_dtype [array-like] The array-like or dtype to check.

Returns

boolean Whether or not the array-like or dtype is of a DatetimeTZDtype dtype.

Examples

```

>>> is_datetime64tz_dtype(object)
False
>>> is_datetime64tz_dtype([1, 2, 3])
False
>>> is_datetime64tz_dtype(pd.DatetimeIndex([1, 2, 3])) # tz-naive
False
>>> is_datetime64tz_dtype(pd.DatetimeIndex([1, 2, 3], tz="US/Eastern"))
True

```

```

>>> dtype = DatetimeTZDtype("ns", tz="US/Eastern")
>>> s = pd.Series([], dtype=dtype)
>>> is_datetime64tz_dtype(dtype)
True
>>> is_datetime64tz_dtype(s)
True

```

pandas.api.types.is_extension_type

`pandas.api.types.is_extension_type(arr)`

Check whether an array-like is of a pandas extension class instance.

Deprecated since version 1.0.0: Use `is_extension_array_dtype` instead.

Extension classes include categoricals, pandas sparse objects (i.e. classes represented within the pandas library and not ones external to it like scipy sparse matrices), and datetime-like arrays.

Parameters

arr [array-like] The array-like to check.

Returns

boolean Whether or not the array-like is of a pandas extension class instance.

Examples

```

>>> is_extension_type([1, 2, 3])
False
>>> is_extension_type(np.array([1, 2, 3]))
False
>>>
>>> cat = pd.Categorical([1, 2, 3])
>>>
>>> is_extension_type(cat)
True
>>> is_extension_type(pd.Series(cat))
True
>>> is_extension_type(pd.arrays.SparseArray([1, 2, 3]))
True
>>> from scipy.sparse import bsr_matrix
>>> is_extension_type(bsr_matrix([1, 2, 3]))
False

```

(continues on next page)

(continued from previous page)

```
>>> is_extension_type(pd.DatetimeIndex([1, 2, 3]))
False
>>> is_extension_type(pd.DatetimeIndex([1, 2, 3], tz="US/Eastern"))
True
>>>
>>> dtype = DatetimeTZDtype("ns", tz="US/Eastern")
>>> s = pd.Series([], dtype=dtype)
>>> is_extension_type(s)
True
```

pandas.api.types.is_extension_array_dtype

pandas.api.types.is_extension_array_dtype(arr_or_dtype)

Check if an object is a pandas extension array type.

See the *Use Guide* for more.

Parameters

arr_or_dtype [object] For array-like input, the `.dtype` attribute will be extracted.

Returns

bool Whether the `arr_or_dtype` is an extension array type.

Notes

This checks whether an object implements the pandas extension array interface. In pandas, this includes:

- Categorical
- Sparse
- Interval
- Period
- DatetimeArray
- TimedeltaArray

Third-party libraries may implement arrays or types satisfying this interface as well.

Examples

```
>>> from pandas.api.types import is_extension_array_dtype
>>> arr = pd.Categorical(['a', 'b'])
>>> is_extension_array_dtype(arr)
True
>>> is_extension_array_dtype(arr.dtype)
True
```

```
>>> arr = np.array(['a', 'b'])
>>> is_extension_array_dtype(arr.dtype)
False
```

pandas.api.types.is_float_dtype

`pandas.api.types.is_float_dtype(arr_or_dtype)`

Check whether the provided array or dtype is of a float dtype.

This function is internal and should not be exposed in the public API.

Parameters

arr_or_dtype [array-like] The array or dtype to check.

Returns

boolean Whether or not the array or dtype is of a float dtype.

Examples

```

>>> is_float_dtype(str)
False
>>> is_float_dtype(int)
False
>>> is_float_dtype(float)
True
>>> is_float_dtype(np.array(['a', 'b']))
False
>>> is_float_dtype(pd.Series([1, 2]))
False
>>> is_float_dtype(pd.Index([1, 2.]))
True

```

pandas.api.types.is_int64_dtype

`pandas.api.types.is_int64_dtype(arr_or_dtype)`

Check whether the provided array or dtype is of the int64 dtype.

Parameters

arr_or_dtype [array-like] The array or dtype to check.

Returns

boolean Whether or not the array or dtype is of the int64 dtype.

Notes

Depending on system architecture, the return value of `is_int64_dtype(int)` will be True if the OS uses 64-bit integers and False if the OS uses 32-bit integers.

Examples

```

>>> is_int64_dtype(str)
False
>>> is_int64_dtype(np.int32)
False
>>> is_int64_dtype(np.int64)
True
>>> is_int64_dtype('int8')
False
>>> is_int64_dtype('Int8')
False
>>> is_int64_dtype(pd.Int64Dtype)
True
>>> is_int64_dtype(float)
False
>>> is_int64_dtype(np.uint64) # unsigned
False
>>> is_int64_dtype(np.array(['a', 'b']))
False
>>> is_int64_dtype(np.array([1, 2], dtype=np.int64))
True
>>> is_int64_dtype(pd.Index([1, 2.])) # float
False
>>> is_int64_dtype(np.array([1, 2], dtype=np.uint32)) # unsigned
False

```

pandas.api.types.is_integer_dtype

`pandas.api.types.is_integer_dtype(arr_or_dtype)`

Check whether the provided array or dtype is of an integer dtype.

Unlike in `in_any_int_dtype`, `timedelta64` instances will return `False`.

The nullable Integer dtypes (e.g. `pandas.Int64Dtype`) are also considered as integer by this function.

Parameters

arr_or_dtype [array-like] The array or dtype to check.

Returns

boolean Whether or not the array or dtype is of an integer dtype and not an instance of `timedelta64`.

Examples

```

>>> is_integer_dtype(str)
False
>>> is_integer_dtype(int)
True
>>> is_integer_dtype(float)
False
>>> is_integer_dtype(np.uint64)

```

(continues on next page)

(continued from previous page)

```

True
>>> is_integer_dtype('int8')
True
>>> is_integer_dtype('Int8')
True
>>> is_integer_dtype(pd.Int8Dtype)
True
>>> is_integer_dtype(np.datetime64)
False
>>> is_integer_dtype(np.timedelta64)
False
>>> is_integer_dtype(np.array(['a', 'b']))
False
>>> is_integer_dtype(pd.Series([1, 2]))
True
>>> is_integer_dtype(np.array([], dtype=np.timedelta64))
False
>>> is_integer_dtype(pd.Index([1, 2.])) # float
False

```

pandas.api.types.is_interval_dtype

pandas.api.types.is_interval_dtype(arr_or_dtype)

Check whether an array-like or dtype is of the Interval dtype.

Parameters

arr_or_dtype [array-like] The array-like or dtype to check.

Returns

boolean Whether or not the array-like or dtype is of the Interval dtype.

Examples

```

>>> is_interval_dtype(object)
False
>>> is_interval_dtype(IntervalDtype())
True
>>> is_interval_dtype([1, 2, 3])
False
>>>
>>> interval = pd.Interval(1, 2, closed="right")
>>> is_interval_dtype(interval)
False
>>> is_interval_dtype(pd.IntervalIndex([interval]))
True

```

pandas.api.types.is_numeric_dtype

pandas.api.types.is_numeric_dtype(*arr_or_dtype*)

Check whether the provided array or dtype is of a numeric dtype.

Parameters

arr_or_dtype [array-like] The array or dtype to check.

Returns

boolean Whether or not the array or dtype is of a numeric dtype.

Examples

```
>>> is_numeric_dtype(str)
False
>>> is_numeric_dtype(int)
True
>>> is_numeric_dtype(float)
True
>>> is_numeric_dtype(np.uint64)
True
>>> is_numeric_dtype(np.datetime64)
False
>>> is_numeric_dtype(np.timedelta64)
False
>>> is_numeric_dtype(np.array(['a', 'b']))
False
>>> is_numeric_dtype(pd.Series([1, 2]))
True
>>> is_numeric_dtype(pd.Index([1, 2.]))
True
>>> is_numeric_dtype(np.array([], dtype=np.timedelta64))
False
```

pandas.api.types.is_object_dtype

pandas.api.types.is_object_dtype(*arr_or_dtype*)

Check whether an array-like or dtype is of the object dtype.

Parameters

arr_or_dtype [array-like] The array-like or dtype to check.

Returns

boolean Whether or not the array-like or dtype is of the object dtype.

Examples

```

>>> is_object_dtype(object)
True
>>> is_object_dtype(int)
False
>>> is_object_dtype(np.array([], dtype=object))
True
>>> is_object_dtype(np.array([], dtype=int))
False
>>> is_object_dtype([1, 2, 3])
False

```

pandas.api.types.is_period_dtype

`pandas.api.types.is_period_dtype(arr_or_dtype)`

Check whether an array-like or dtype is of the Period dtype.

Parameters

arr_or_dtype [array-like] The array-like or dtype to check.

Returns

boolean Whether or not the array-like or dtype is of the Period dtype.

Examples

```

>>> is_period_dtype(object)
False
>>> is_period_dtype(PeriodDtype(freq="D"))
True
>>> is_period_dtype([1, 2, 3])
False
>>> is_period_dtype(pd.Period("2017-01-01"))
False
>>> is_period_dtype(pd.PeriodIndex([], freq="A"))
True

```

pandas.api.types.is_signed_integer_dtype

`pandas.api.types.is_signed_integer_dtype(arr_or_dtype)`

Check whether the provided array or dtype is of a signed integer dtype.

Unlike in `in_any_int_dtype`, `timedelta64` instances will return `False`.

The nullable Integer dtypes (e.g. `pandas.Int64Dtype`) are also considered as integer by this function.

Parameters

arr_or_dtype [array-like] The array or dtype to check.

Returns

boolean Whether or not the array or dtype is of a signed integer dtype and not an instance of `timedelta64`.

Examples

```

>>> is_signed_integer_dtype(str)
False
>>> is_signed_integer_dtype(int)
True
>>> is_signed_integer_dtype(float)
False
>>> is_signed_integer_dtype(np.uint64) # unsigned
False
>>> is_signed_integer_dtype('int8')
True
>>> is_signed_integer_dtype('Int8')
True
>>> is_signed_integer_dtype(pd.Int8Dtype)
True
>>> is_signed_integer_dtype(np.datetime64)
False
>>> is_signed_integer_dtype(np.timedelta64)
False
>>> is_signed_integer_dtype(np.array(['a', 'b']))
False
>>> is_signed_integer_dtype(pd.Series([1, 2]))
True
>>> is_signed_integer_dtype(np.array([], dtype=np.timedelta64))
False
>>> is_signed_integer_dtype(pd.Index([1, 2.])) # float
False
>>> is_signed_integer_dtype(np.array([1, 2], dtype=np.uint32)) # unsigned
False

```

pandas.api.types.is_string_dtype

`pandas.api.types.is_string_dtype(arr_or_dtype)`

Check whether the provided array or dtype is of the string dtype.

Parameters

arr_or_dtype [array-like] The array or dtype to check.

Returns

boolean Whether or not the array or dtype is of the string dtype.

Examples

```

>>> is_string_dtype(str)
True
>>> is_string_dtype(object)
True
>>> is_string_dtype(int)
False
>>>

```

(continues on next page)

(continued from previous page)

```
>>> is_string_dtype(np.array(['a', 'b']))
True
>>> is_string_dtype(pd.Series([1, 2]))
False
```

pandas.api.types.is_timedelta64_dtype

`pandas.api.types.is_timedelta64_dtype(arr_or_dtype)`

Check whether an array-like or dtype is of the timedelta64 dtype.

Parameters

arr_or_dtype [array-like] The array-like or dtype to check.

Returns

boolean Whether or not the array-like or dtype is of the timedelta64 dtype.

Examples

```
>>> is_timedelta64_dtype(object)
False
>>> is_timedelta64_dtype(np.timedelta64)
True
>>> is_timedelta64_dtype([1, 2, 3])
False
>>> is_timedelta64_dtype(pd.Series([], dtype="timedelta64[ns]"))
True
>>> is_timedelta64_dtype('0 days')
False
```

pandas.api.types.is_timedelta64_ns_dtype

`pandas.api.types.is_timedelta64_ns_dtype(arr_or_dtype)`

Check whether the provided array or dtype is of the timedelta64[ns] dtype.

This is a very specific dtype, so generic ones like `np.timedelta64` will return False if passed into this function.

Parameters

arr_or_dtype [array-like] The array or dtype to check.

Returns

boolean Whether or not the array or dtype is of the timedelta64[ns] dtype.

Examples

```

>>> is_timedelta64_ns_dtype(np.dtype('m8[ns]'))
True
>>> is_timedelta64_ns_dtype(np.dtype('m8[ps]')) # Wrong frequency
False
>>> is_timedelta64_ns_dtype(np.array([1, 2], dtype='m8[ns]'))
True
>>> is_timedelta64_ns_dtype(np.array([1, 2], dtype=np.timedelta64))
False

```

pandas.api.types.is_unsigned_integer_dtype

`pandas.api.types.is_unsigned_integer_dtype(arr_or_dtype)`

Check whether the provided array or dtype is of an unsigned integer dtype.

The nullable Integer dtypes (e.g. `pandas.UInt64Dtype`) are also considered as integer by this function.

Parameters

arr_or_dtype [array-like] The array or dtype to check.

Returns

boolean Whether or not the array or dtype is of an unsigned integer dtype.

Examples

```

>>> is_unsigned_integer_dtype(str)
False
>>> is_unsigned_integer_dtype(int) # signed
False
>>> is_unsigned_integer_dtype(float)
False
>>> is_unsigned_integer_dtype(np.uint64)
True
>>> is_unsigned_integer_dtype('uint8')
True
>>> is_unsigned_integer_dtype('UInt8')
True
>>> is_unsigned_integer_dtype(pd.UInt8Dtype)
True
>>> is_unsigned_integer_dtype(np.array(['a', 'b']))
False
>>> is_unsigned_integer_dtype(pd.Series([1, 2])) # signed
False
>>> is_unsigned_integer_dtype(pd.Index([1, 2.])) # float
False
>>> is_unsigned_integer_dtype(np.array([1, 2], dtype=np.uint32))
True

```

pandas.api.types.is_sparse

`pandas.api.types.is_sparse(arr)`

Check whether an array-like is a 1-D pandas sparse array.

Check that the one-dimensional array-like is a pandas sparse array. Returns True if it is a pandas sparse array, not another type of sparse array.

Parameters

arr [array-like] Array-like to check.

Returns

bool Whether or not the array-like is a pandas sparse array.

Examples

Returns *True* if the parameter is a 1-D pandas sparse array.

```
>>> is_sparse(pd.arrays.SparseArray([0, 0, 1, 0]))
True
>>> is_sparse(pd.Series(pd.arrays.SparseArray([0, 0, 1, 0])))
True
```

Returns *False* if the parameter is not sparse.

```
>>> is_sparse(np.array([0, 0, 1, 0]))
False
>>> is_sparse(pd.Series([0, 1, 0, 0]))
False
```

Returns *False* if the parameter is not a pandas sparse array.

```
>>> from scipy.sparse import bsr_matrix
>>> is_sparse(bsr_matrix([0, 1, 0, 0]))
False
```

Returns *False* if the parameter has more than one dimension.

Iterable introspection

| | |
|--|--|
| <code>api.types.is_dict_like(obj)</code> | Check if the object is dict-like. |
| <code>api.types.is_file_like(obj)</code> | Check if the object is a file-like object. |
| <code>api.types.is_list_like</code> | Check if the object is list-like. |
| <code>api.types.is_named_tuple(obj)</code> | Check if the object is a named tuple. |
| <code>api.types.is_iterator</code> | Check if the object is an iterator. |

pandas.api.types.is_dict_like

pandas.api.types.is_dict_like(*obj*)

Check if the object is dict-like.

Parameters

obj [The object to check]

Returns

is_dict_like [bool] Whether *obj* has dict-like properties.

Examples

```
>>> is_dict_like({1: 2})
True
>>> is_dict_like([1, 2, 3])
False
>>> is_dict_like(dict)
False
>>> is_dict_like(dict())
True
```

pandas.api.types.is_file_like

pandas.api.types.is_file_like(*obj*)

Check if the object is a file-like object.

For objects to be considered file-like, they must be an iterator AND have either a *read* and/or *write* method as an attribute.

Note: file-like objects must be iterable, but iterable objects need not be file-like.

Parameters

obj [The object to check]

Returns

is_file_like [bool] Whether *obj* has file-like properties.

Examples

```
>>> import io
>>> buffer = io.StringIO("data")
>>> is_file_like(buffer)
True
>>> is_file_like([1, 2, 3])
False
```

pandas.api.types.is_list_like

pandas.api.types.is_list_like()

Check if the object is list-like.

Objects that are considered list-like are for example Python lists, tuples, sets, NumPy arrays, and Pandas Series.

Strings and datetime objects, however, are not considered list-like.

Parameters

obj [object] Object to check.

allow_sets [bool, default True] If this parameter is False, sets will not be considered list-like.

Returns

bool Whether *obj* has list-like properties.

Examples

```
>>> is_list_like([1, 2, 3])
True
>>> is_list_like({1, 2, 3})
True
>>> is_list_like(datetime(2017, 1, 1))
False
>>> is_list_like("foo")
False
>>> is_list_like(1)
False
>>> is_list_like(np.array([2]))
True
>>> is_list_like(np.array(2))
False
```

pandas.api.types.is_named_tuple

pandas.api.types.is_named_tuple(*obj*)

Check if the object is a named tuple.

Parameters

obj [The object to check]

Returns

is_named_tuple [bool] Whether *obj* is a named tuple.

Examples

```

>>> from collections import namedtuple
>>> Point = namedtuple("Point", ["x", "y"])
>>> p = Point(1, 2)
>>>
>>> is_named_tuple(p)
True
>>> is_named_tuple((1, 2))
False

```

pandas.api.types.is_iterator

pandas.api.types.is_iterator()

Check if the object is an iterator.

This is intended for generators, not list-like objects.

Parameters

obj [The object to check]

Returns

is_iter [bool] Whether *obj* is an iterator.

Examples

```

>>> is_iterator((x for x in []))
True
>>> is_iterator([1, 2, 3])
False
>>> is_iterator(datetime(2017, 1, 1))
False
>>> is_iterator("foo")
False
>>> is_iterator(1)
False

```

Scalar introspection

| | |
|--|---|
| <code>api.types.is_bool</code> | Return True if given object is boolean. |
| <code>api.types.is_categorical(arr)</code> | Check whether an array-like is a Categorical instance. |
| <code>api.types.is_complex</code> | Return True if given object is complex. |
| <code>api.types.is_float</code> | Return True if given object is float. |
| <code>api.types.is_hashable(obj)</code> | Return True if hash(obj) will succeed, False otherwise. |
| <code>api.types.is_integer</code> | Return True if given object is integer. |
| <code>api.types.is_interval</code> | |
| <code>api.types.is_number(obj)</code> | Check if the object is a number. |
| <code>api.types.is_re(obj)</code> | Check if the object is a regex pattern instance. |

continues on next page

Table 402 – continued from previous page

| | |
|--|--|
| <code>api.types.is_re_compilable(obj)</code> | Check if the object can be compiled into a regex pattern instance. |
| <code>api.types.is_scalar</code> | Return True if given object is scalar. |

pandas.api.types.is_bool`pandas.api.types.is_bool()`

Return True if given object is boolean.

Returns**bool****pandas.api.types.is_categorical**`pandas.api.types.is_categorical(arr)`

Check whether an array-like is a Categorical instance.

Parameters**arr** [array-like] The array-like to check.**Returns****boolean** Whether or not the array-like is of a Categorical instance.**Examples**

```
>>> is_categorical([1, 2, 3])
False
```

Categoricals, Series Categoricals, and CategoricalIndex will return True.

```
>>> cat = pd.Categorical([1, 2, 3])
>>> is_categorical(cat)
True
>>> is_categorical(pd.Series(cat))
True
>>> is_categorical(pd.CategoricalIndex([1, 2, 3]))
True
```

pandas.api.types.is_complex`pandas.api.types.is_complex()`

Return True if given object is complex.

Returns**bool**

pandas.api.types.is_float

`pandas.api.types.is_float()`
Return True if given object is float.

Returns

bool

pandas.api.types.is_hashable

`pandas.api.types.is_hashable(obj)`
Return True if `hash(obj)` will succeed, False otherwise.

Some types will pass a test against `collections.abc.Hashable` but fail when they are actually hashed with `hash()`.

Distinguish between these and other types by trying the call to `hash()` and seeing if they raise `TypeError`.

Returns

bool

Examples

```
>>> import collections
>>> a = ([],)
>>> isinstance(a, collections.abc.Hashable)
True
>>> is_hashable(a)
False
```

pandas.api.types.is_integer

`pandas.api.types.is_integer()`
Return True if given object is integer.

Returns

bool

pandas.api.types.is_interval

`pandas.api.types.is_interval()`

pandas.api.types.is_number

`pandas.api.types.is_number(obj)`

Check if the object is a number.

Returns True when the object is a number, and False if is not.

Parameters

obj [any type] The object to check if is a number.

Returns

is_number [bool] Whether *obj* is a number or not.

See also:

api.types.is_integer Checks a subgroup of numbers.

Examples

```
>>> from pandas.api.types import is_number
>>> is_number(1)
True
>>> is_number(7.15)
True
```

Booleans are valid because they are int subclass.

```
>>> is_number(False)
True
```

```
>>> is_number("foo")
False
>>> is_number("5")
False
```

pandas.api.types.is_re

`pandas.api.types.is_re(obj)`

Check if the object is a regex pattern instance.

Parameters

obj [The object to check]

Returns

is_regex [bool] Whether *obj* is a regex pattern.

Examples

```
>>> is_re(re.compile(".*"))
True
>>> is_re("foo")
False
```

pandas.api.types.is_re_compilable

pandas.api.types.is_re_compilable(*obj*)

Check if the object can be compiled into a regex pattern instance.

Parameters

obj [The object to check]

Returns

is_regex_compilable [bool] Whether *obj* can be compiled as a regex pattern.

Examples

```
>>> is_re_compilable(".*")
True
>>> is_re_compilable(1)
False
```

pandas.api.types.is_scalar

pandas.api.types.is_scalar()

Return True if given object is scalar.

Parameters

val [object] This includes:

- numpy array scalar (e.g. np.int64)
- Python builtin numerics
- Python builtin byte arrays and strings
- None
- datetime.datetime
- datetime.timedelta
- Period
- decimal.Decimal
- Interval
- DateOffset
- Fraction
- Number.

Returns

bool Return True if given object is scalar.

Examples

```
>>> dt = datetime.datetime(2018, 10, 3)
>>> pd.api.types.is_scalar(dt)
True
```

```
>>> pd.api.types.is_scalar([2, 3])
False
```

```
>>> pd.api.types.is_scalar({0: 1, 2: 3})
False
```

```
>>> pd.api.types.is_scalar((0, 2))
False
```

pandas supports PEP 3141 numbers:

```
>>> from fractions import Fraction
>>> pd.api.types.is_scalar(Fraction(3, 5))
True
```

3.14.5 Bug report function

`show_versions(as_json)`

Provide useful information, important for bug reports.

pandas.show_versions

`pandas.show_versions(as_json=False)`

Provide useful information, important for bug reports.

It comprises info about hosting operation system, pandas version, and versions of other installed relative packages.

Parameters

as_json [str or bool, default False]

- If False, outputs info in a human readable form to the console.
- If str, it will be considered as a path to a file. Info will be written to that file in JSON format.
- If True, outputs info in JSON format to the console.

3.15 Extensions

These are primarily intended for library authors looking to extend pandas objects.

| | |
|---|---|
| <code>api.extensions.register_extension_dtype(cls)</code> | Register an ExtensionType with pandas as class decorator. |
| <code>api.extensions.register_dataframe_accessor(name)</code> | Register a custom accessor on DataFrame objects. |
| <code>api.extensions.register_series_accessor(name)</code> | Register a custom accessor on Series objects. |
| <code>api.extensions.register_index_accessor(name)</code> | Register a custom accessor on Index objects. |
| <code>api.extensions.ExtensionDtype()</code> | A custom data type, to be paired with an ExtensionArray. |

3.15.1 pandas.api.extensions.register_extension_dtype

`pandas.api.extensions.register_extension_dtype(cls)`

Register an ExtensionType with pandas as class decorator.

This enables operations like `.astype(name)` for the name of the ExtensionDtype.

Returns

callable A class decorator.

Examples

```
>>> from pandas.api.extensions import register_extension_dtype
>>> from pandas.api.extensions import ExtensionDtype
>>> @register_extension_dtype
... class MyExtensionDtype(ExtensionDtype):
...     name = "myextension"
```

3.15.2 pandas.api.extensions.register_dataframe_accessor

`pandas.api.extensions.register_dataframe_accessor(name)`

Register a custom accessor on DataFrame objects.

Parameters

name [str] Name under which the accessor should be registered. A warning is issued if this name conflicts with a preexisting attribute.

Returns

callable A class decorator.

See also:

[`register_dataframe_accessor`](#) Register a custom accessor on DataFrame objects.

[`register_series_accessor`](#) Register a custom accessor on Series objects.

[`register_index_accessor`](#) Register a custom accessor on Index objects.

Notes

When accessed, your accessor will be initialized with the pandas object the user is interacting with. So the signature must be

```
def __init__(self, pandas_object): # noqa: E999
    ...
```

For consistency with pandas methods, you should raise an `AttributeError` if the data passed to your accessor has an incorrect dtype.

```
>>> pd.Series(['a', 'b']).dt
Traceback (most recent call last):
...
AttributeError: Can only use .dt accessor with datetimelike values
```

Examples

In your library code:

```
import pandas as pd

@pd.api.extensions.register_dataframe_accessor("geo")
class GeoAccessor:
    def __init__(self, pandas_obj):
        self._obj = pandas_obj

    @property
    def center(self):
        # return the geographic center point of this DataFrame
        lat = self._obj.latitude
        lon = self._obj.longitude
        return (float(lon.mean()), float(lat.mean()))

    def plot(self):
        # plot this array's data on a map, e.g., using Cartopy
        pass
```

Back in an interactive IPython session:

```
In [1]: ds = pd.DataFrame({"longitude": np.linspace(0, 10),
...:                      "latitude": np.linspace(0, 20)})
In [2]: ds.geo.center
Out[2]: (5.0, 10.0)
In [3]: ds.geo.plot() # plots data on a map
```

3.15.3 pandas.api.extensions.register_series_accessor

pandas.api.extensions.register_series_accessor(*name*)

Register a custom accessor on Series objects.

Parameters

name [str] Name under which the accessor should be registered. A warning is issued if this name conflicts with a preexisting attribute.

Returns

callable A class decorator.

See also:

[*register_dataframe_accessor*](#) Register a custom accessor on DataFrame objects.

[*register_series_accessor*](#) Register a custom accessor on Series objects.

[*register_index_accessor*](#) Register a custom accessor on Index objects.

Notes

When accessed, your accessor will be initialized with the pandas object the user is interacting with. So the signature must be

```
def __init__(self, pandas_object): # noqa: E999
    ...
```

For consistency with pandas methods, you should raise an `AttributeError` if the data passed to your accessor has an incorrect dtype.

```
>>> pd.Series(['a', 'b']).dt
Traceback (most recent call last):
...
AttributeError: Can only use .dt accessor with datetimelike values
```

Examples

In your library code:

```
import pandas as pd

@pd.api.extensions.register_dataframe_accessor("geo")
class GeoAccessor:
    def __init__(self, pandas_obj):
        self._obj = pandas_obj

    @property
    def center(self):
        # return the geographic center point of this DataFrame
        lat = self._obj.latitude
        lon = self._obj.longitude
        return (float(lon.mean()), float(lat.mean()))

    def plot(self):
```

(continues on next page)

(continued from previous page)

```
# plot this array's data on a map, e.g., using Cartopy
pass
```

Back in an interactive IPython session:

```
In [1]: ds = pd.DataFrame({"longitude": np.linspace(0, 10),
...:                      "latitude": np.linspace(0, 20)})
In [2]: ds.geo.center
Out[2]: (5.0, 10.0)
In [3]: ds.geo.plot() # plots data on a map
```

3.15.4 pandas.api.extensions.register_index_accessor

pandas.api.extensions.register_index_accessor(*name*)

Register a custom accessor on Index objects.

Parameters

name [str] Name under which the accessor should be registered. A warning is issued if this name conflicts with a preexisting attribute.

Returns

callable A class decorator.

See also:

[*register_dataframe_accessor*](#) Register a custom accessor on DataFrame objects.

[*register_series_accessor*](#) Register a custom accessor on Series objects.

[*register_index_accessor*](#) Register a custom accessor on Index objects.

Notes

When accessed, your accessor will be initialized with the pandas object the user is interacting with. So the signature must be

```
def __init__(self, pandas_object): # noqa: E999
    ...
```

For consistency with pandas methods, you should raise an `AttributeError` if the data passed to your accessor has an incorrect dtype.

```
>>> pd.Series(['a', 'b']).dt
Traceback (most recent call last):
...
AttributeError: Can only use .dt accessor with datetimelike values
```

Examples

In your library code:

```
import pandas as pd

@pd.api.extensions.register_dataframe_accessor("geo")
class GeoAccessor:
    def __init__(self, pandas_obj):
        self._obj = pandas_obj

    @property
    def center(self):
        # return the geographic center point of this DataFrame
        lat = self._obj.latitude
        lon = self._obj.longitude
        return (float(lon.mean()), float(lat.mean()))

    def plot(self):
        # plot this array's data on a map, e.g., using Cartopy
        pass
```

Back in an interactive IPython session:

```
In [1]: ds = pd.DataFrame({"longitude": np.linspace(0, 10),
...:                      "latitude": np.linspace(0, 20)})
In [2]: ds.geo.center
Out[2]: (5.0, 10.0)
In [3]: ds.geo.plot() # plots data on a map
```

3.15.5 pandas.api.extensions.ExtensionDtype

class pandas.api.extensions.**ExtensionDtype**

A custom data type, to be paired with an ExtensionArray.

See also:

extensions.register_extension_dtype Register an ExtensionType with pandas as class decorator.

extensions.ExtensionArray Abstract base class for custom 1-D array types.

Notes

The interface includes the following abstract methods that must be implemented by subclasses:

- type
- name
- construct_array_type

The following attributes and methods influence the behavior of the dtype in pandas operations

- `_is_numeric`
- `_is_boolean`
- `_get_common_dtype`

The `na_value` class attribute can be used to set the default NA value for this type. `numpy.nan` is used by default.

ExtensionDtypes are required to be hashable. The base class provides a default implementation, which relies on the `_metadata` class attribute. `_metadata` should be a tuple containing the strings that define your data type. For example, with `PeriodDtype` that's the `freq` attribute.

If you have a parametrized dtype you should set the `__metadata__` class property.

Ideally, the attributes in `_metadata` will match the parameters to your `ExtensionDtype`. `__init__` (if any). If any of the attributes in `_metadata` don't implement the standard `__eq__` or `__hash__`, the default implementations here will not work.

For interaction with Apache Arrow (`pyarrow`), a `__from_arrow__` method can be implemented: this method receives a `pyarrow` `Array` or `ChunkedArray` as only argument and is expected to return the appropriate pandas `ExtensionArray` for this dtype and the passed values:

```
class ExtensionDtype:

    def __from_arrow__(
        self, array: Union[pyarrow.Array, pyarrow.ChunkedArray]
    ) -> ExtensionArray:
        ...
```

This class does not inherit from `'abc.ABCMeta'` for performance reasons. Methods and properties required by the interface raise `pandas.errors.AbstractMethodError` and no `register` method is provided for registering virtual subclasses.

Attributes

| | |
|-----------------|--|
| <i>kind</i> | A character code (one of 'biufcmMOSUV'), default 'O' |
| <i>na_value</i> | Default NA value to use for this type. |
| <i>name</i> | A string identifying the data type. |
| <i>names</i> | Ordered list of field names, or None if there are no fields. |
| <i>type</i> | The scalar type for the array, e.g. |

`pandas.api.extensions.ExtensionDtype.kind`

property `ExtensionDtype.kind`

A character code (one of 'biufcmMOSUV'), default 'O'

This should match the NumPy dtype used when the array is converted to an ndarray, which is probably 'O' for object if the extension type cannot be represented as a built-in NumPy type.

See also:

[numpy.dtype.kind](#)

pandas.api.extensions.ExtensionDtype.na_value

property `ExtensionDtype.na_value`

Default NA value to use for this type.

This is used in e.g. `ExtensionArray.take`. This should be the user-facing “boxed” version of the NA value, not the physical NA value for storage. e.g. for `JSONArray`, this is an empty dictionary.

pandas.api.extensions.ExtensionDtype.name

property `ExtensionDtype.name`

A string identifying the data type.

Will be used for display in, e.g. `Series.dtype`

pandas.api.extensions.ExtensionDtype.names

property `ExtensionDtype.names`

Ordered list of field names, or `None` if there are no fields.

This is for compatibility with NumPy arrays, and may be removed in the future.

pandas.api.extensions.ExtensionDtype.type

property `ExtensionDtype.type`

The scalar type for the array, e.g. `int`

It's expected `ExtensionArray[item]` returns an instance of `ExtensionDtype.type` for scalar `item`, assuming that value is valid (not NA). NA values do not need to be instances of `type`.

Methods

| | |
|--|---|
| <code>construct_array_type()</code> | Return the array type associated with this dtype. |
| <code>construct_from_string(string)</code> | Construct this type from a string. |
| <code>is_dtype(dtype)</code> | Check if we match 'dtype'. |

pandas.api.extensions.ExtensionDtype.construct_array_type

classmethod `ExtensionDtype.construct_array_type()`

Return the array type associated with this dtype.

Returns

`type`

pandas.api.extensions.ExtensionDtype.construct_from_string**classmethod** `ExtensionDtype.construct_from_string(string)`

Construct this type from a string.

This is useful mainly for data types that accept parameters. For example, a period dtype accepts a frequency parameter that can be set as `period[H]` (where H means hourly frequency).

By default, in the abstract class, just the name of the type is expected. But subclasses can overwrite this method to accept parameters.

Parameters

string [str] The name of the type, for example category.

Returns

ExtensionDtype Instance of the dtype.

Raises

TypeError If a class cannot be constructed from this 'string'.

Examples

For extension dtypes with arguments the following may be an adequate implementation.

```
>>> @classmethod
... def construct_from_string(cls, string):
...     pattern = re.compile(r"^my_type\[ (?P<arg_name>.+)\]$")
...     match = pattern.match(string)
...     if match:
...         return cls(**match.groupdict())
...     else:
...         raise TypeError(
...             f"Cannot construct a '{cls.__name__}' from '{string}'"
...         )
```

pandas.api.extensions.ExtensionDtype.is_dtype**classmethod** `ExtensionDtype.is_dtype(dtype)`

Check if we match 'dtype'.

Parameters

dtype [object] The object to check.

Returns

bool

Notes

The default implementation is True if

1. `cls.construct_from_string(dtype)` is an instance of `cls`.
2. `dtype` is an object and is an instance of `cls`
3. `dtype` has a `dtype` attribute, and any of the above conditions is true for `dtype.dtype`.

| | |
|---|---|
| <code>api.extensions.ExtensionArray()</code> | Abstract base class for custom 1-D array types. |
| <code>arrays.PandasArray(values[, copy])</code> | A pandas ExtensionArray for NumPy data. |

3.15.6 pandas.api.extensions.ExtensionArray

class `pandas.api.extensions.ExtensionArray`

Abstract base class for custom 1-D array types.

pandas will recognize instances of this class as proper arrays with a custom type and will not attempt to coerce them to objects. They may be stored directly inside a `DataFrame` or `Series`.

Notes

The interface includes the following abstract methods that must be implemented by subclasses:

- `__from_sequence`
- `__from_factorized`
- `__getitem__`
- `__len__`
- `__eq__`
- `dtype`
- `nbytes`
- `isna`
- `take`
- `copy`
- `__concat_same_type`

A default repr displaying the type, (truncated) data, length, and dtype is provided. It can be customized or replaced by overriding:

- `__repr__` : A default repr for the `ExtensionArray`.
- `__formatter` : Print scalars inside a `Series` or `DataFrame`.

Some methods require casting the `ExtensionArray` to an `ndarray` of Python objects with `self.astype(object)`, which may be expensive. When performance is a concern, we highly recommend overriding the following methods:

- `fillna`
- `dropna`
- `unique`
- `factorize / _values_for_factorize`
- `argsort / _values_for_argsort`
- `searchsorted`

The remaining methods implemented on this class should be performant, as they only compose abstract methods. Still, a more efficient implementation may be available, and these methods can be overridden.

One can implement methods to handle array reductions.

- `__reduce`

One can implement methods to handle parsing from strings that will be used in methods such as `pandas.io.parsers.read_csv`.

- `_from_sequence_of_strings`

This class does not inherit from `'abc.ABCMeta'` for performance reasons. Methods and properties required by the interface raise `pandas.errors.AbstractMethodError` and no `register` method is provided for registering virtual subclasses.

ExtensionArrays are limited to 1 dimension.

They may be backed by none, one, or many NumPy arrays. For example, `pandas.Categorical` is an extension array backed by two arrays, one for codes and one for categories. An array of IPv6 address may be backed by a NumPy structured array with two fields, one for the lower 64 bits and one for the upper 64 bits. Or they may be backed by some other storage type, like Python lists. Pandas makes no assumptions on how the data are stored, just that it can be converted to a NumPy array. The `ExtensionArray` interface does not impose any rules on how this data is stored. However, currently, the backing data cannot be stored in attributes called `.values` or `._values` to ensure full compatibility with pandas internals. But other names as `.data`, `._data`, `._items`, ... can be freely used.

If implementing NumPy's `__array_ufunc__` interface, pandas expects that

1. You defer by returning `NotImplemented` when any Series are present in *inputs*. Pandas will extract the arrays and call the ufunc again.
2. You define a `_HANDLED_TYPES` tuple as an attribute on the class. Pandas inspect this to determine whether the ufunc is valid for the types present.

See *NumPy universal functions* for more.

By default, ExtensionArrays are not hashable. Immutable subclasses may override this behavior.

Attributes

| | |
|---------------------|--|
| <code>dtype</code> | An instance of 'ExtensionDtype'. |
| <code>nbytes</code> | The number of bytes needed to store this object in memory. |
| <code>ndim</code> | Extension Arrays are only allowed to be 1-dimensional. |
| <code>shape</code> | Return a tuple of the array dimensions. |

`pandas.api.extensions.ExtensionArray.dtype`

property `ExtensionArray.dtype`
An instance of 'ExtensionDtype'.

pandas.api.extensions.ExtensionArray.nbytes**property** ExtensionArray.nbytes

The number of bytes needed to store this object in memory.

pandas.api.extensions.ExtensionArray.ndim**property** ExtensionArray.ndim

Extension Arrays are only allowed to be 1-dimensional.

pandas.api.extensions.ExtensionArray.shape**property** ExtensionArray.shape

Return a tuple of the array dimensions.

Methods

| | |
|--|---|
| <i>argsort</i> ([ascending, kind, na_position]) | Return the indices that would sort this array. |
| <i>astype</i> (dtype[, copy]) | Cast to a NumPy array with 'dtype'. |
| <i>copy</i> () | Return a copy of the array. |
| <i>dropna</i> () | Return ExtensionArray without NA values. |
| <i>factorize</i> ([na_sentinel]) | Encode the extension array as an enumerated type. |
| <i>fillna</i> ([value, method, limit]) | Fill NA/NaN values using the specified method. |
| <i>equals</i> (other) | Return if another array is equivalent to this array. |
| <i>isin</i> (values) | Pointwise comparison for set containment in the given values. |
| <i>isna</i> () | A 1-D array indicating if each value is missing. |
| <i>ravel</i> ([order]) | Return a flattened view on this array. |
| <i>repeat</i> (repeats[, axis]) | Repeat elements of a ExtensionArray. |
| <i>searchsorted</i> (value[, side, sorter]) | Find indices where elements should be inserted to maintain order. |
| <i>shift</i> ([periods, fill_value]) | Shift values by desired number. |
| <i>take</i> (indices, *[, allow_fill, fill_value]) | Take elements from an array. |
| <i>unique</i> () | Compute the ExtensionArray of unique values. |
| <i>view</i> ([dtype]) | Return a view on the array. |
| <i>_concat_same_type</i> (to_concat) | Concatenate multiple array of this dtype. |
| <i>_formatter</i> ([boxed]) | Formatting function for scalar values. |
| <i>_from_factorized</i> (values, original) | Reconstruct an ExtensionArray after factorization. |
| <i>_from_sequence</i> (scalars, *[, dtype, copy]) | Construct a new ExtensionArray from a sequence of scalars. |
| <i>_from_sequence_of_strings</i> (strings, *[, ...]) | Construct a new ExtensionArray from a sequence of strings. |
| <i>_reduce</i> (name, *[, skipna]) | Return a scalar result of performing the reduction operation. |
| <i>_values_for_argsort</i> () | Return values for sorting. |
| <i>_values_for_factorize</i> () | Return an array and missing value suitable for factorization. |

pandas.api.extensions.ExtensionArray.argsort

`ExtensionArray.argsort`(*ascending=True*, *kind='quicksort'*, *na_position='last'*, *args, **kwargs)
Return the indices that would sort this array.

Parameters

ascending [bool, default True] Whether the indices should result in an ascending or descending sort.

kind [{ 'quicksort', 'mergesort', 'heapsort', 'stable' }, optional] Sorting algorithm.

***args, **kwargs**: Passed through to `numpy.argsort()`.

Returns

np.ndarray[np.intp] Array of indices that sort `self`. If NaN values are contained, NaN values are placed at the end.

See also:

`numpy.argsort` Sorting implementation used internally.

pandas.api.extensions.ExtensionArray.astype

`ExtensionArray.astype`(*dtype*, *copy=True*)
Cast to a NumPy array with 'dtype'.

Parameters

dtype [str or dtype] Typecode or data-type to which the array is cast.

copy [bool, default True] Whether to copy the data, even if not necessary. If False, a copy is made only if the old dtype does not match the new dtype.

Returns

array [ndarray] NumPy ndarray with 'dtype' for its dtype.

pandas.api.extensions.ExtensionArray.copy

`ExtensionArray.copy`()
Return a copy of the array.

Returns

ExtensionArray

pandas.api.extensions.ExtensionArray.dropna

`ExtensionArray.dropna`()
Return ExtensionArray without NA values.

Returns

valid [ExtensionArray]

pandas.api.extensions.ExtensionArray.factorize

ExtensionArray.**factorize**(*na_sentinel=-1*)

Encode the extension array as an enumerated type.

Parameters

na_sentinel [int, default -1] Value to use in the *codes* array to indicate missing values.

Returns

codes [ndarray] An integer NumPy array that's an indexer into the original Extension-Array.

uniques [ExtensionArray] An ExtensionArray containing the unique values of *self*.

Note: *uniques* will *not* contain an entry for the NA value of the ExtensionArray if there are any missing values present in *self*.

See also:

factorize Top-level factorize method that dispatches here.

Notes

pandas.factorize() offers a *sort* keyword as well.

pandas.api.extensions.ExtensionArray.fillna

ExtensionArray.**fillna**(*value=None, method=None, limit=None*)

Fill NA/NaN values using the specified method.

Parameters

value [scalar, array-like] If a scalar value is passed it is used to fill all missing values. Alternatively, an array-like 'value' can be given. It's expected that the array-like have the same length as 'self'.

method [{ 'backfill', 'bfill', 'pad', 'ffill', None }, default None] Method to use for filling holes in reindexed Series *pad* / *ffill*: propagate last valid observation forward to next valid *backfill* / *bfill*: use NEXT valid observation to fill gap.

limit [int, default None] If method is specified, this is the maximum number of consecutive NaN values to forward/backward fill. In other words, if there is a gap with more than this number of consecutive NaNs, it will only be partially filled. If method is not specified, this is the maximum number of entries along the entire axis where NaNs will be filled.

Returns

ExtensionArray With NA/NaN filled.

pandas.api.extensions.ExtensionArray.equals**ExtensionArray.equals**(*other*)

Return if another array is equivalent to this array.

Equivalent means that both arrays have the same shape and dtype, and all values compare equal. Missing values in the same location are considered equal (in contrast with normal equality).

Parameters**other** [ExtensionArray] Array to compare to this Array.**Returns****boolean** Whether the arrays are equivalent.**pandas.api.extensions.ExtensionArray.isin****ExtensionArray.isin**(*values*)

Pointwise comparison for set containment in the given values.

Roughly equivalent to `np.array([x in values for x in self])`**Parameters****values** [Sequence]**Returns****np.ndarray[bool]****pandas.api.extensions.ExtensionArray.isna****ExtensionArray.isna**()

A 1-D array indicating if each value is missing.

Returns**na_values** [Union[np.ndarray, ExtensionArray]] In most cases, this should return a NumPy ndarray. For exceptional cases like `SparseArray`, where returning an ndarray would be expensive, an `ExtensionArray` may be returned.**Notes**If returning an `ExtensionArray`, then

- `na_values._is_boolean` should be `True`
- `na_values` should implement `ExtensionArray._reduce()`
- `na_values.any` and `na_values.all` should be implemented

pandas.api.extensions.ExtensionArray.ravel

`ExtensionArray.ravel`(*order='C'*)

Return a flattened view on this array.

Parameters

order [{None, 'C', 'F', 'A', 'K'}, default 'C']

Returns

ExtensionArray

Notes

- Because ExtensionArrays are 1D-only, this is a no-op.
- The “order” argument is ignored, is for compatibility with NumPy.

pandas.api.extensions.ExtensionArray.repeat

`ExtensionArray.repeat`(*repeats, axis=None*)

Repeat elements of a ExtensionArray.

Returns a new ExtensionArray where each element of the current ExtensionArray is repeated consecutively a given number of times.

Parameters

repeats [int or array of ints] The number of repetitions for each element. This should be a non-negative integer. Repeating 0 times will return an empty ExtensionArray.

axis [None] Must be None. Has no effect but is accepted for compatibility with numpy.

Returns

repeated_array [ExtensionArray] Newly created ExtensionArray with repeated elements.

See also:

Series.repeat Equivalent function for Series.

Index.repeat Equivalent function for Index.

numpy.repeat Similar method for `numpy.ndarray`.

ExtensionArray.take Take arbitrary positions.

Examples

```
>>> cat = pd.Categorical(['a', 'b', 'c'])
>>> cat
['a', 'b', 'c']
Categories (3, object): ['a', 'b', 'c']
>>> cat.repeat(2)
['a', 'a', 'b', 'b', 'c', 'c']
Categories (3, object): ['a', 'b', 'c']
```

(continues on next page)

(continued from previous page)

```
>>> cat.repeat([1, 2, 3])
['a', 'b', 'b', 'c', 'c', 'c']
Categories (3, object): ['a', 'b', 'c']
```

pandas.api.extensions.ExtensionArray.searchsorted

`ExtensionArray.searchsorted(value, side='left', sorter=None)`

Find indices where elements should be inserted to maintain order.

Find the indices into a sorted array *self* (*a*) such that, if the corresponding elements in *value* were inserted before the indices, the order of *self* would be preserved.

Assuming that *self* is sorted:

| <i>side</i> | returned index <i>i</i> satisfies |
|-------------|---|
| left | <code>self[i-1] < value <= self[i]</code> |
| right | <code>self[i-1] <= value < self[i]</code> |

Parameters

value [array-like] Values to insert into *self*.

side [{ 'left', 'right' }, optional] If 'left', the index of the first suitable location found is given. If 'right', return the last such index. If there is no suitable index, return either 0 or N (where N is the length of *self*).

sorter [1-D array-like, optional] Optional array of integer indices that sort array *a* into ascending order. They are typically the result of `argsort`.

Returns

array of ints Array of insertion points with the same shape as *value*.

See also:

[numpy.searchsorted](#) Similar method from NumPy.

pandas.api.extensions.ExtensionArray.shift

`ExtensionArray.shift(periods=1, fill_value=None)`

Shift values by desired number.

Newly introduced missing values are filled with `self.dtype.na_value`.

Parameters

periods [int, default 1] The number of periods to shift. Negative values are allowed for shifting backwards.

fill_value [object, optional] The scalar value to use for newly introduced missing values. The default is `self.dtype.na_value`.

Returns

ExtensionArray Shifted.

Notes

If `self` is empty or `periods` is 0, a copy of `self` is returned.

If `periods > len(self)`, then an array of size `len(self)` is returned, with all values filled with `self.dtype.na_value`.

pandas.api.extensions.ExtensionArray.take

`ExtensionArray.take(indices, *, allow_fill=False, fill_value=None)`

Take elements from an array.

Parameters

indices [sequence of int] Indices to be taken.

allow_fill [bool, default False] How to handle negative values in *indices*.

- False: negative values in *indices* indicate positional indices from the right (the default). This is similar to `numpy.take()`.
- True: negative values in *indices* indicate missing values. These values are set to *fill_value*. Any other other negative values raise a `ValueError`.

fill_value [any, optional] Fill value to use for NA-indices when *allow_fill* is True. This may be `None`, in which case the default NA value for the type, `self.dtype.na_value`, is used.

For many `ExtensionArrays`, there will be two representations of *fill_value*: a user-facing “boxed” scalar, and a low-level physical NA value. *fill_value* should be the user-facing version, and the implementation should handle translating that to the physical version for processing the take if necessary.

Returns

`ExtensionArray`

Raises

IndexError When the indices are out of bounds for the array.

ValueError When *indices* contains negative values other than `-1` and *allow_fill* is True.

See also:

`numpy.take` Take elements from an array along an axis.

`api.extensions.take` Take elements from an array.

Notes

`ExtensionArray.take` is called by `Series.__getitem__`, `.loc`, `iloc`, when *indices* is a sequence of values. Additionally, it's called by `Series.reindex()`, or any other method that causes realignment, with a *fill_value*.

Examples

Here's an example implementation, which relies on casting the extension array to object dtype. This uses the helper method `pandas.api.extensions.take()`.

```
def take(self, indices, allow_fill=False, fill_value=None):
    from pandas.core.algorithms import take

    # If the ExtensionArray is backed by an ndarray, then
    # just pass that here instead of coercing to object.
    data = self.astype(object)

    if allow_fill and fill_value is None:
        fill_value = self.dtype.na_value

    # fill value should always be translated from the scalar
    # type for the array, to the physical storage type for
    # the data, before passing to take.

    result = take(data, indices, fill_value=fill_value,
                  allow_fill=allow_fill)
    return self._from_sequence(result, dtype=self.dtype)
```

`pandas.api.extensions.ExtensionArray.unique`

`ExtensionArray.unique()`

Compute the `ExtensionArray` of unique values.

Returns

uniques [`ExtensionArray`]

`pandas.api.extensions.ExtensionArray.view`

`ExtensionArray.view(dtype=None)`

Return a view on the array.

Parameters

dtype [str, np.dtype, or `ExtensionDtype`, optional] Default None.

Returns

`ExtensionArray` or `np.ndarray` A view on the `ExtensionArray`'s data.

`pandas.api.extensions.ExtensionArray._concat_same_type`

classmethod `ExtensionArray._concat_same_type(to_concat)`
Concatenate multiple array of this dtype.

Parameters

to_concat [sequence of this type]

Returns

`ExtensionArray`

`pandas.api.extensions.ExtensionArray._formatter`

`ExtensionArray._formatter(boxed=False)`
Formatting function for scalar values.

This is used in the default `'__repr__'`. The returned formatting function receives instances of your scalar type.

Parameters

boxed [bool, default False] An indicated for whether or not your array is being printed within a Series, DataFrame, or Index (True), or just by itself (False). This may be useful if you want scalar values to appear differently within a Series versus on its own (e.g. quoted or not).

Returns

Callable[[Any], str] A callable that gets instances of the scalar type and returns a string. By default, `repr()` is used when `boxed=False` and `str()` is used when `boxed=True`.

`pandas.api.extensions.ExtensionArray._from_factorized`

classmethod `ExtensionArray._from_factorized(values, original)`
Reconstruct an `ExtensionArray` after factorization.

Parameters

values [ndarray] An integer ndarray with the factorized values.

original [`ExtensionArray`] The original `ExtensionArray` that factorize was called on.

See also:

[*factorize*](#) Top-level factorize method that dispatches here.

[*ExtensionArray.factorize*](#) Encode the extension array as an enumerated type.

pandas.api.extensions.ExtensionArray._from_sequence**classmethod** `ExtensionArray._from_sequence(scalars, *, dtype=None, copy=False)`Construct a new `ExtensionArray` from a sequence of scalars.**Parameters****scalars** [Sequence] Each element will be an instance of the scalar type for this array, `cls.dtype.type` or be converted into this type in this method.**dtype** [dtype, optional] Construct for this particular dtype. This should be a `Dtype` compatible with the `ExtensionArray`.**copy** [bool, default False] If True, copy the underlying data.**Returns****ExtensionArray****pandas.api.extensions.ExtensionArray._from_sequence_of_strings****classmethod** `ExtensionArray._from_sequence_of_strings(strings, *, dtype=None, copy=False)`Construct a new `ExtensionArray` from a sequence of strings.**Parameters****strings** [Sequence] Each element will be an instance of the scalar type for this array, `cls.dtype.type`.**dtype** [dtype, optional] Construct for this particular dtype. This should be a `Dtype` compatible with the `ExtensionArray`.**copy** [bool, default False] If True, copy the underlying data.**Returns****ExtensionArray****pandas.api.extensions.ExtensionArray._reduce**`ExtensionArray._reduce(name, *, skipna=True, **kwargs)`

Return a scalar result of performing the reduction operation.

Parameters**name** [str] Name of the function, supported values are: { any, all, min, max, sum, mean, median, prod, std, var, sem, kurt, skew }.**skipna** [bool, default True] If True, skip NaN values.****kwargs** Additional keyword arguments passed to the reduction function. Currently, `ddof` is the only supported kwarg.**Returns****scalar****Raises****TypeError** [subclass does not define reductions]

pandas.api.extensions.ExtensionArray._values_for_argsort

`ExtensionArray._values_for_argsort()`

Return values for sorting.

Returns

ndarray The transformed values should maintain the ordering between values within the array.

See also:

[*ExtensionArray.argsort*](#) Return the indices that would sort this array.

pandas.api.extensions.ExtensionArray._values_for_factorize

`ExtensionArray._values_for_factorize()`

Return an array and missing value suitable for factorization.

Returns

values [ndarray] An array suitable for factorization. This should maintain order and be a supported dtype (Float64, Int64, UInt64, String, Object). By default, the extension array is cast to object dtype.

na_value [object] The value in *values* to consider missing. This will be treated as NA in the factorization routines, so it will be coded as *na_sentinel* and not included in *uniques*. By default, `np.nan` is used.

Notes

The values returned by this method are also used in `pandas.util.hash_pandas_object()`.

3.15.7 pandas.arrays.PandasArray

class `pandas.arrays.PandasArray(values, copy=False)`

A pandas ExtensionArray for NumPy data.

This is mostly for internal compatibility, and is not especially useful on its own.

Parameters

values [ndarray] The NumPy ndarray to wrap. Must be 1-dimensional.

copy [bool, default False] Whether to copy *values*.

Attributes

| | |
|------|--|
| None | |
|------|--|

Methods

| | |
|------|--|
| None | |
|------|--|

Additionally, we have some utility methods for ensuring your object behaves correctly.

`api.indexers.check_array_indexer(array, indexer)` Check if *indexer* is a valid array indexer for *array*.

3.15.8 pandas.api.indexers.check_array_indexer

`pandas.api.indexers.check_array_indexer(array, indexer)`

Check if *indexer* is a valid array indexer for *array*.

For a boolean mask, *array* and *indexer* are checked to have the same length. The dtype is validated, and if it is an integer or boolean ExtensionArray, it is checked if there are missing values present, and it is converted to the appropriate numpy array. Other dtypes will raise an error.

Non-array indexers (integer, slice, Ellipsis, tuples, ..) are passed through as is.

New in version 1.0.0.

Parameters

array [array-like] The array that is being indexed (only used for the length).

indexer [array-like or list-like] The array-like that's used to index. List-like input that is not yet a numpy array or an ExtensionArray is converted to one. Other input types are passed through as is.

Returns

numpy.ndarray The validated indexer as a numpy array that can be used to index.

Raises

IndexError When the lengths don't match.

ValueError When *indexer* cannot be converted to a numpy ndarray to index (e.g. presence of missing values).

See also:

api.types.is_bool_dtype Check if *key* is of boolean dtype.

Examples

When checking a boolean mask, a boolean ndarray is returned when the arguments are all valid.

```
>>> mask = pd.array([True, False])
>>> arr = pd.array([1, 2])
>>> pd.api.indexers.check_array_indexer(arr, mask)
array([ True, False])
```

An `IndexError` is raised when the lengths don't match.

```
>>> mask = pd.array([True, False, True])
>>> pd.api.indexers.check_array_indexer(arr, mask)
Traceback (most recent call last):
...
IndexError: Boolean index has wrong length: 3 instead of 2.
```

NA values in a boolean array are treated as False.

```
>>> mask = pd.array([True, pd.NA])
>>> pd.api.indexers.check_array_indexer(arr, mask)
array([ True, False])
```

A numpy boolean mask will get passed through (if the length is correct):

```
>>> mask = np.array([True, False])
>>> pd.api.indexers.check_array_indexer(arr, mask)
array([ True, False])
```

Similarly for integer indexers, an integer ndarray is returned when it is a valid indexer, otherwise an error is (for integer indexers, a matching length is not required):

```
>>> indexer = pd.array([0, 2], dtype="Int64")
>>> arr = pd.array([1, 2, 3])
>>> pd.api.indexers.check_array_indexer(arr, indexer)
array([0, 2])
```

```
>>> indexer = pd.array([0, pd.NA], dtype="Int64")
>>> pd.api.indexers.check_array_indexer(arr, indexer)
Traceback (most recent call last):
...
ValueError: Cannot index with an integer indexer containing NA values
```

For non-integer/boolean dtypes, an appropriate error is raised:

```
>>> indexer = np.array([0., 2.], dtype="float64")
>>> pd.api.indexers.check_array_indexer(arr, indexer)
Traceback (most recent call last):
...
IndexError: arrays used as indices must be of integer or boolean type
```

The sentinel `pandas.api.extensions.no_default` is used as the default value in some methods. Use an `is` comparison to check if the user provides a non-default value.

4.1 Contributing to pandas

Table of contents:

- *Where to start?*
- *Bug reports and enhancement requests*
- *Working with the code*
 - *Version control, Git, and GitHub*
 - *Getting started with Git*
 - *Forking*
 - *Creating a branch*
- *Contributing your changes to pandas*
 - *Committing your code*
 - *Pushing your changes*
 - *Review your code*
 - *Finally, make the pull request*
 - *Updating your pull request*
 - *Autofixing formatting errors*
 - *Delete your merged branch (optional)*
- *Tips for a successful pull request*

4.1.1 Where to start?

All contributions, bug reports, bug fixes, documentation improvements, enhancements, and ideas are welcome.

If you are brand new to pandas or open-source development, we recommend going through the [GitHub “issues” tab](#) to find issues that interest you. There are a number of issues listed under [Docs](#) and [good first issue](#) where you could start out. Once you’ve found an interesting issue, you can return here to get your development environment setup.

When you start working on an issue, it’s a good idea to assign the issue to yourself, so nobody else duplicates the work on it. GitHub restricts assigning issues to maintainers of the project only. In most projects, and until recently in pandas, contributors added a comment letting others know they are working on an issue. While this is ok, you need to check each issue individually, and it’s not possible to find the unassigned ones.

For this reason, we implemented a workaround consisting of adding a comment with the exact text `take`. When you do it, a GitHub action will automatically assign you the issue (this will take seconds, and may require refreshing the page to see it). By doing this, it’s possible to filter the list of issues and find only the unassigned ones.

So, a good way to find an issue to start contributing to pandas is to check the list of [unassigned good first issues](#) and assign yourself one you like by writing a comment with the exact text `take`.

If for whatever reason you are not able to continue working with the issue, please try to unassign it, so other people know it’s available again. You can check the list of assigned issues, since people may not be working in them anymore. If you want to work on one that is assigned, feel free to kindly ask the current assignee if you can take it (please allow at least a week of inactivity before considering work in the issue discontinued).

Feel free to ask questions on the [mailing list](#) or on [Gitter](#).

4.1.2 Bug reports and enhancement requests

Bug reports are an important part of making pandas more stable. Having a complete bug report will allow others to reproduce the bug and provide insight into fixing. See [this stackoverflow article](#) and [this blogpost](#) for tips on writing a good bug report.

Trying the bug-producing code out on the *master* branch is often a worthwhile exercise to confirm the bug still exists. It is also worth searching existing bug reports and pull requests to see if the issue has already been reported and/or fixed.

Bug reports must:

1. Include a short, self-contained Python snippet reproducing the problem. You can format the code nicely by using [GitHub Flavored Markdown](#):

```
```python
>>> from pandas import DataFrame
>>> df = DataFrame(...)
...
...`
```

2. Include the full version string of pandas and its dependencies. You can use the built-in function:

```
>>> import pandas as pd
>>> pd.show_versions()
```

3. Explain why the current behavior is wrong/not desired and what you expect instead.

The issue will then show up to the pandas community and be open to comments/ideas from others.

### 4.1.3 Working with the code

Now that you have an issue you want to fix, enhancement to add, or documentation to improve, you need to learn how to work with GitHub and the pandas code base.

#### Version control, Git, and GitHub

To the new user, working with Git is one of the more daunting aspects of contributing to pandas. It can very quickly become overwhelming, but sticking to the guidelines below will help keep the process straightforward and mostly trouble free. As always, if you are having difficulties please feel free to ask for help.

The code is hosted on [GitHub](#). To contribute you will need to sign up for a [free GitHub account](#). We use [Git](#) for version control to allow many people to work together on the project.

Some great resources for learning Git:

- the [GitHub help pages](#).
- the [NumPy documentation](#).
- [Matthew Brett's Pydagogue](#).

#### Getting started with Git

[GitHub has instructions](#) for installing git, setting up your SSH key, and configuring git. All these steps need to be completed before you can work seamlessly between your local repository and GitHub.

#### Forking

You will need your own fork to work on the code. Go to the [pandas project page](#) and hit the Fork button. You will want to clone your fork to your machine:

```
git clone https://github.com/your-user-name/pandas.git pandas-yourname
cd pandas-yourname
git remote add upstream https://github.com/pandas-dev/pandas.git
```

This creates the directory `pandas-yourname` and connects your repository to the upstream (main project) *pandas* repository.

Note that performing a shallow clone (with `--depth==N`, for some `N` greater or equal to 1) might break some tests and features as `pd.show_versions()` as the version number cannot be computed anymore.

#### Creating a branch

You want your master branch to reflect only production-ready code, so create a feature branch for making your changes. For example:

```
git branch shiny-new-feature
git checkout shiny-new-feature
```

The above can be simplified to:

```
git checkout -b shiny-new-feature
```

This changes your working directory to the shiny-new-feature branch. Keep any changes in this branch specific to one bug or feature so it is clear what the branch brings to pandas. You can have many shiny-new-features and switch in between them using the git checkout command.

When creating this branch, make sure your master branch is up to date with the latest upstream master version. To update your local master branch, you can do:

```
git checkout master
git pull upstream master --ff-only
```

When you want to update the feature branch with changes in master after you created the branch, check the section on *updating a PR*.

### 4.1.4 Contributing your changes to pandas

#### Committing your code

Keep style fixes to a separate commit to make your pull request more readable.

Once you've made changes, you can see them by typing:

```
git status
```

If you have created a new file, it is not being tracked by git. Add it by typing:

```
git add path/to/file-to-be-added.py
```

Doing 'git status' again should give something like:

```
On branch shiny-new-feature
#
modified: /relative/path/to/file-you-added.py
#
```

Finally, commit your changes to your local repository with an explanatory message. pandas uses a convention for commit message prefixes and layout. Here are some common prefixes along with general guidelines for when to use them:

- ENH: Enhancement, new functionality
- BUG: Bug fix
- DOC: Additions/updates to documentation
- TST: Additions/updates to tests
- BLD: Updates to the build process/scripts
- PERF: Performance improvement
- TYP: Type annotations
- CLN: Code cleanup

The following defines how a commit message should be structured. Please reference the relevant GitHub issues in your commit message using GH1234 or #1234. Either style is fine, but the former is generally preferred:

- a subject line with < 80 chars.
- One blank line.

- Optionally, a commit message body.

Now you can commit your changes in your local repository:

```
git commit -m
```

## Pushing your changes

When you want your changes to appear publicly on your GitHub page, push your forked feature branch's commits:

```
git push origin shiny-new-feature
```

Here `origin` is the default name given to your remote repository on GitHub. You can see the remote repositories:

```
git remote -v
```

If you added the upstream repository as described above you will see something like:

```
origin git@github.com:yourname/pandas.git (fetch)
origin git@github.com:yourname/pandas.git (push)
upstream git://github.com/pandas-dev/pandas.git (fetch)
upstream git://github.com/pandas-dev/pandas.git (push)
```

Now your code is on GitHub, but it is not yet a part of the pandas project. For that to happen, a pull request needs to be submitted on GitHub.

## Review your code

When you're ready to ask for a code review, file a pull request. Before you do, once again make sure that you have followed all the guidelines outlined in this document regarding code style, tests, performance tests, and documentation. You should also double check your branch changes against the branch it was based on:

1. Navigate to your repository on GitHub – <https://github.com/your-user-name/pandas>
2. Click on Branches
3. Click on the Compare button for your feature branch
4. Select the base and compare branches, if necessary. This will be `master` and `shiny-new-feature`, respectively.

## Finally, make the pull request

If everything looks good, you are ready to make a pull request. A pull request is how code from a local repository becomes available to the GitHub community and can be looked at and eventually merged into the master version. This pull request and its associated changes will eventually be committed to the master branch and available in the next release. To submit a pull request:

1. Navigate to your repository on GitHub
2. Click on the Pull Request button
3. You can then click on Commits and Files Changed to make sure everything looks okay one last time
4. Write a description of your changes in the Preview Discussion tab
5. Click Send Pull Request.

This request then goes to the repository maintainers, and they will review the code.

### Updating your pull request

Based on the review you get on your pull request, you will probably need to make some changes to the code. In that case, you can make them in your branch, add a new commit to that branch, push it to GitHub, and the pull request will be automatically updated. Pushing them to GitHub again is done by:

```
git push origin shiny-new-feature
```

This will automatically update your pull request with the latest code and restart the *Continuous Integration* tests.

Another reason you might need to update your pull request is to solve conflicts with changes that have been merged into the master branch since you opened your pull request.

To do this, you need to “merge upstream master” in your branch:

```
git checkout shiny-new-feature
git fetch upstream
git merge upstream/master
```

If there are no conflicts (or they could be fixed automatically), a file with a default commit message will open, and you can simply save and quit this file.

If there are merge conflicts, you need to solve those conflicts. See for example at <https://help.github.com/articles/resolving-a-merge-conflict-using-the-command-line/> for an explanation on how to do this. Once the conflicts are merged and the files where the conflicts were solved are added, you can run `git commit` to save those fixes.

If you have uncommitted changes at the moment you want to update the branch with master, you will need to `stash` them prior to updating (see the [stash docs](#)). This will effectively store your changes and they can be reapplied after updating.

After the feature branch has been update locally, you can now update your pull request by pushing to the branch on GitHub:

```
git push origin shiny-new-feature
```

### Autofixing formatting errors

We use several styling checks (e.g. `black`, `flake8`, `isort`) which are run after you make a pull request. If there is a scenario where any of these checks fail then you can comment:

```
@github-actions pre-commit
```

on that pull request. This will trigger a workflow which will autofix formatting errors.

### Delete your merged branch (optional)

Once your feature branch is accepted into upstream, you'll probably want to get rid of the branch. First, merge upstream master into your branch so git knows it is safe to delete your branch:

```
git fetch upstream
git checkout master
git merge upstream/master
```

Then you can do:

```
git branch -d shiny-new-feature
```

Make sure you use a lower-case `-d`, or else git won't warn you if your feature branch has not actually been merged.

The branch will still exist on GitHub, so to delete it there do:

```
git push origin --delete shiny-new-feature
```

### 4.1.5 Tips for a successful pull request

If you have made it to the *Review your code* phase, one of the core contributors may take a look. Please note however that a handful of people are responsible for reviewing all of the contributions, which can often lead to bottlenecks.

To improve the chances of your pull request being reviewed, you should:

- **Reference an open issue** for non-trivial changes to clarify the PR's purpose
- **Ensure you have appropriate tests.** These should be the first part of any PR
- **Keep your pull requests as simple as possible.** Larger PRs take longer to review
- **Ensure that CI is in a green state.** Reviewers may not even look otherwise
- **Keep *Updating your pull request*,** either by request or every few days

## 4.2 Creating a development environment

To test out code changes, you'll need to build pandas from source, which requires a C/C++ compiler and Python environment. If you're making documentation changes, you can skip to *contributing to the documentation* but if you skip creating the development environment you won't be able to build the documentation locally before pushing your changes.

#### Table of contents:

- *Creating an environment using Docker*
- *Creating an environment without Docker*
  - *Installing a C compiler*
  - *Creating a Python environment*
  - *Creating a Python environment (pip)*

## 4.2.1 Creating an environment using Docker

Instead of manually setting up a development environment, you can use [Docker](#) to automatically create the environment with just several commands. pandas provides a DockerFile in the root directory to build a Docker image with a full pandas development environment.

### Docker Commands

Pass your GitHub username in the DockerFile to use your own fork:

```
Build the image pandas-yourname-env
docker build --tag pandas-yourname-env .
Run a container and bind your local forked repo, pandas-yourname, to the container
docker run -it --rm -v path-to-pandas-yourname:/home/pandas-yourname pandas-yourname-env
```

Even easier, you can integrate Docker with the following IDEs:

### Visual Studio Code

You can use the DockerFile to launch a remote session with Visual Studio Code, a popular free IDE, using the `.devcontainer.json` file. See <https://code.visualstudio.com/docs/remote/containers> for details.

### PyCharm (Professional)

Enable Docker support and use the Services tool window to build and manage images as well as run and interact with containers. See <https://www.jetbrains.com/help/pycharm/docker.html> for details.

Note that you might need to rebuild the C extensions if/when you merge with upstream/master using:

```
python setup.py build_ext -j 4
```

## 4.2.2 Creating an environment without Docker

### Installing a C compiler

pandas uses C extensions (mostly written using Cython) to speed up certain operations. To install pandas from source, you need to compile these C extensions, which means you need a C compiler. This process depends on which platform you're using.

If you have setup your environment using conda, the packages `c-compiler` and `cxx-compiler` will install a fitting compiler for your platform that is compatible with the remaining conda packages. On Windows and macOS, you will also need to install the SDKs as they have to be distributed separately. These packages will automatically be installed by using the pandas `environment.yml` file.

### Windows

You will need [Build Tools for Visual Studio 2017](#).

**Warning:** You DO NOT need to install Visual Studio 2019. You only need “Build Tools for Visual Studio 2019” found by scrolling down to “All downloads” -> “Tools for Visual Studio 2019”. In the installer, select the “C++ build tools” workload.

You can install the necessary components on the commandline using `vs_buildtools.exe`:

```
vs_buildtools.exe --quiet --wait --norestart --nocache ^
 --installPath C:\BuildTools ^
 --add "Microsoft.VisualStudio.Workload.VCTools;includeRecommended" ^
 --add Microsoft.VisualStudio.Component.VC.v141 ^
 --add Microsoft.VisualStudio.Component.VC.v141.x86.x64 ^
 --add Microsoft.VisualStudio.Component.Windows10SDK.17763
```

To setup the right paths on the commandline, call "C:\BuildTools\VC\Auxiliary\Build\vcvars64.bat" -vcvars\_ver=14.16 10.0.17763.0.

## macOS

To use the conda-based compilers, you will need to install the Developer Tools using `xcode-select --install`. Otherwise information about compiler installation can be found here: <https://devguide.python.org/setup/#macos>

## Linux

For Linux-based conda installations, you won't have to install any additional components outside of the conda environment. The instructions below are only needed if your setup isn't based on conda environments.

Some Linux distributions will come with a pre-installed C compiler. To find out which compilers (and versions) are installed on your system:

```
for Debian/Ubuntu:
dpkg --get-selections | grep compiler
for Red Hat/RHEL/CentOS/Fedora:
yum list installed | grep -i --color compiler
```

**GCC (GNU Compiler Collection)**, is a widely used compiler, which supports C and a number of other languages. If GCC is listed as an installed compiler nothing more is required. If no C compiler is installed (or you wish to install a newer version) you can install a compiler (GCC in the example code below) with:

```
for recent Debian/Ubuntu:
sudo apt install build-essential
for Red Hat/RHEL/CentOS/Fedora
yum groupinstall "Development Tools"
```

For other Linux distributions, consult your favorite search engine for compiler installation instructions.

Let us know if you have any difficulties by opening an issue or reaching out on [Gitter](#).

## Creating a Python environment

Now create an isolated pandas development environment:

- Install either [Anaconda](#), [miniconda](#), or [miniforge](#)
- Make sure your conda is up to date (`conda update conda`)
- Make sure that you have *cloned the repository*
- `cd` to the pandas source directory

We'll now kick off a three-step process:

1. Install the build dependencies
2. Build and install pandas
3. Install the optional dependencies

```
Create and activate the build environment
conda env create -f environment.yml
conda activate pandas-dev

or with older versions of Anaconda:
source activate pandas-dev

Build and install pandas
python setup.py build_ext -j 4
python -m pip install -e . --no-build-isolation --no-use-pep517
```

At this point you should be able to import pandas from your locally built version:

```
$ python # start an interpreter
>>> import pandas
>>> print(pandas.__version__)
0.22.0.dev0+29.g4ad6d4d74
```

This will create the new environment, and not touch any of your existing environments, nor any existing Python installation.

To view your environments:

```
conda info -e
```

To return to your root environment:

```
conda deactivate
```

See the full conda docs [here](#).

### Creating a Python environment (pip)

If you aren't using conda for your development environment, follow these instructions. You'll need to have at least the *minimum Python version* that pandas supports. You also need to have `setuptools` 51.0.0 or later to build pandas.

#### Unix/macOS with virtualenv

```
Create a virtual environment
Use an ENV_DIR of your choice. We'll use ~/virtualenvs/pandas-dev
Any parent directories should already exist
python3 -m venv ~/virtualenvs/pandas-dev

Activate the virtualenv
. ~/virtualenvs/pandas-dev/bin/activate

Install the build dependencies
python -m pip install -r requirements-dev.txt

Build and install pandas
python setup.py build_ext -j 4
python -m pip install -e . --no-build-isolation --no-use-pep517
```

#### Unix/macOS with pyenv

Consult the docs for setting up pyenv [here](#).

```
Create a virtual environment
Use an ENV_DIR of your choice. We'll use ~/Users/<yourname>/.pyenv/versions/pandas-dev

pyenv virtualenv <version> <name-to-give-it>

For instance:
pyenv virtualenv 3.7.6 pandas-dev

Activate the virtualenv
pyenv activate pandas-dev

Now install the build dependencies in the cloned pandas repo
python -m pip install -r requirements-dev.txt

Build and install pandas
python setup.py build_ext -j 4
python -m pip install -e . --no-build-isolation --no-use-pep517
```

## Windows

Below is a brief overview on how to set-up a virtual environment with Powershell under Windows. For details please refer to the [official virtualenv user guide](#)

Use an ENV\_DIR of your choice. We'll use ~\virtualenvs\pandas-dev where '~' is the folder pointed to by either \$env:USERPROFILE (Powershell) or %USERPROFILE% (cmd.exe) environment variable. Any parent directories should already exist.

```
Create a virtual environment
python -m venv $env:USERPROFILE\virtualenvs\pandas-dev

Activate the virtualenv. Use activate.bat for cmd.exe
~\virtualenvs\pandas-dev\Scripts\Activate.ps1

Install the build dependencies
python -m pip install -r requirements-dev.txt

Build and install pandas
python setup.py build_ext -j 4
python -m pip install -e . --no-build-isolation --no-use-pep517
```

## 4.3 Contributing to the documentation

Contributing to the documentation benefits everyone who uses pandas. We encourage you to help us improve the documentation, and you don't have to be an expert on pandas to do so! In fact, there are sections of the docs that are worse off after being written by experts. If something in the docs doesn't make sense to you, updating the relevant section after you figure it out is a great way to ensure it will help the next person.

### Documentation:

- [About the pandas documentation](#)

- *Updating a pandas docstring*
- *How to build the pandas documentation*
  - *Requirements*
  - *Building the documentation*
  - *Building master branch documentation*
- *Previewing changes*

### 4.3.1 About the pandas documentation

The documentation is written in **reStructuredText**, which is almost like writing in plain English, and built using [Sphinx](#). The Sphinx Documentation has an excellent [introduction to reST](#). Review the Sphinx docs to perform more complex changes to the documentation as well.

Some other important things to know about the docs:

- The pandas documentation consists of two parts: the docstrings in the code itself and the docs in this folder `doc/`. The docstrings provide a clear explanation of the usage of the individual functions, while the documentation in this folder consists of tutorial-like overviews per topic together with some other information (what's new, installation, etc).
- The docstrings follow a pandas convention, based on the **Numpy Docstring Standard**. Follow the [pandas docstring guide](#) for detailed instructions on how to write a correct docstring.

#### pandas docstring guide

##### About docstrings and standards

A Python docstring is a string used to document a Python module, class, function or method, so programmers can understand what it does without having to read the details of the implementation.

Also, it is a common practice to generate online (html) documentation automatically from docstrings. [Sphinx](#) serves this purpose.

The next example gives an idea of what a docstring looks like:

```
def add(num1, num2):
 """
 Add up two integer numbers.

 This function simply wraps the ``+`` operator, and does not
 do anything interesting, except for illustrating what
 the docstring of a very simple function looks like.

 Parameters

 num1 : int
 First number to add.
 num2 : int
 Second number to add.
```

(continues on next page)

(continued from previous page)

```

Returns

int
 The sum of ``num1`` and ``num2``.

See Also

subtract : Subtract one integer from another.

Examples

>>> add(2, 2)
4
>>> add(25, 0)
25
>>> add(10, -10)
0
"""
return num1 + num2

```

Some standards regarding docstrings exist, which make them easier to read, and allow them to be easily exported to other formats such as html or pdf.

The first conventions every Python docstring should follow are defined in [PEP-257](#).

As PEP-257 is quite broad, other more specific standards also exist. In the case of pandas, the NumPy docstring convention is followed. These conventions are explained in this document:

- [numpydoc docstring guide](#) (which is based in the original [Guide to NumPy/SciPy documentation](#))

numpydoc is a Sphinx extension to support the NumPy docstring convention.

The standard uses reStructuredText (reST). reStructuredText is a markup language that allows encoding styles in plain text files. Documentation about reStructuredText can be found in:

- [Sphinx reStructuredText primer](#)
- [Quick reStructuredText reference](#)
- [Full reStructuredText specification](#)

pandas has some helpers for sharing docstrings between related classes, see [Sharing docstrings](#).

The rest of this document will summarize all the above guidelines, and will provide additional conventions specific to the pandas project.

## Writing a docstring

### General rules

Docstrings must be defined with three double-quotes. No blank lines should be left before or after the docstring. The text starts in the next line after the opening quotes. The closing quotes have their own line (meaning that they are not at the end of the last sentence).

On rare occasions reST styles like bold text or italics will be used in docstrings, but it is common to have inline code, which is presented between backticks. The following are considered inline code:

- The name of a parameter
- Python code, a module, function, built-in, type, literal... (e.g. `os`, `list`, `numpy.abs`, `datetime.date`, `True`)
- A pandas class (in the form `:class:`pandas.Series``)
- A pandas method (in the form `:meth:`pandas.Series.sum``)
- A pandas function (in the form `:func:`pandas.to_datetime``)

---

**Note:** To display only the last component of the linked class, method or function, prefix it with `~`. For example, `:class:`~pandas.Series`` will link to `pandas.Series` but only display the last part, `Series` as the link text. See [Sphinx cross-referencing syntax](#) for details.

---

**Good:**

```
def add_values(arr):
 """
 Add the values in ``arr``.

 This is equivalent to Python ``sum`` of :meth:`pandas.Series.sum`.

 Some sections are omitted here for simplicity.
 """
 return sum(arr)
```

**Bad:**

```
def func():

 """Some function.

 With several mistakes in the docstring.

 It has a blank line after the signature ``def func():``.

 The text 'Some function' should go in the line after the
 opening quotes of the docstring, not in the same line.

 There is a blank line between the docstring and the first line
 of code ``foo = 1``.

 The closing quotes should be in the next line, not in this one."""

 foo = 1
 bar = 2
 return foo + bar
```

## Section 1: short summary

The short summary is a single sentence that expresses what the function does in a concise way.

The short summary must start with a capital letter, end with a dot, and fit in a single line. It needs to express what the object does without providing details. For functions and methods, the short summary must start with an infinitive verb.

### Good:

```
def astype(dtype):
 """
 Cast Series type.

 This section will provide further details.
 """
 pass
```

### Bad:

```
def astype(dtype):
 """
 Casts Series type.

 Verb in third-person of the present simple, should be infinitive.
 """
 pass
```

```
def astype(dtype):
 """
 Method to cast Series type.

 Does not start with verb.
 """
 pass
```

```
def astype(dtype):
 """
 Cast Series type
 Missing dot at the end.
 """
 pass
```

```
def astype(dtype):
 """
 Cast Series type from its current type to the new type defined in
 the parameter dtype.

 Summary is too verbose and doesn't fit in a single line.
 """
 pass
```

## Section 2: extended summary

The extended summary provides details on what the function does. It should not go into the details of the parameters, or discuss implementation notes, which go in other sections.

A blank line is left between the short summary and the extended summary. Every paragraph in the extended summary ends with a dot.

The extended summary should provide details on why the function is useful and their use cases, if it is not too generic.

```
def unstack():
 """
 Pivot a row index to columns.

 When using a MultiIndex, a level can be pivoted so each value in
 the index becomes a column. This is especially useful when a subindex
 is repeated for the main index, and data is easier to visualize as a
 pivot table.

 The index level will be automatically removed from the index when added
 as columns.
 """
 pass
```

## Section 3: parameters

The details of the parameters will be added in this section. This section has the title “Parameters”, followed by a line with a hyphen under each letter of the word “Parameters”. A blank line is left before the section title, but not after, and not between the line with the word “Parameters” and the one with the hyphens.

After the title, each parameter in the signature must be documented, including \*args and \*\*kwargs, but not self.

The parameters are defined by their name, followed by a space, a colon, another space, and the type (or types). Note that the space between the name and the colon is important. Types are not defined for \*args and \*\*kwargs, but must be defined for all other parameters. After the parameter definition, it is required to have a line with the parameter description, which is indented, and can have multiple lines. The description must start with a capital letter, and finish with a dot.

For keyword arguments with a default value, the default will be listed after a comma at the end of the type. The exact form of the type in this case will be “int, default 0”. In some cases it may be useful to explain what the default argument means, which can be added after a comma “int, default -1, meaning all cpus”.

In cases where the default value is None, meaning that the value will not be used. Instead of “str, default None”, it is preferred to write “str, optional”. When None is a value being used, we will keep the form “str, default None”. For example, in `df.to_csv(compression=None)`, None is not a value being used, but means that compression is optional, and no compression is being used if not provided. In this case we will use “str, optional”. Only in cases like `func(value=None)` and None is being used in the same way as 0 or foo would be used, then we will specify “str, int or None, default None”.

**Good:**

```
class Series:
 def plot(self, kind, color='blue', **kwargs):
```

(continues on next page)

(continued from previous page)

```

"""
Generate a plot.

Render the data in the Series as a matplotlib plot of the
specified kind.

Parameters

kind : str
 Kind of matplotlib plot.
color : str, default 'blue'
 Color name or rgb code.
**kwargs
 These parameters will be passed to the matplotlib plotting
 function.
"""
pass

```

**Bad:**

```

class Series:
 def plot(self, kind, **kwargs):
 """
 Generate a plot.

 Render the data in the Series as a matplotlib plot of the
 specified kind.

 Note the blank line between the parameters title and the first
 parameter. Also, note that after the name of the parameter ``kind``
 and before the colon, a space is missing.

 Also, note that the parameter descriptions do not start with a
 capital letter, and do not finish with a dot.

 Finally, the ``**kwargs`` parameter is missing.

 Parameters

 kind: str
 kind of matplotlib plot
 """
 pass

```

## Parameter types

When specifying the parameter types, Python built-in data types can be used directly (the Python type is preferred to the more verbose string, integer, boolean, etc):

- int
- float
- str
- bool

For complex types, define the subtypes. For `dict` and `tuple`, as more than one type is present, we use the brackets to help read the type (curly brackets for `dict` and normal brackets for `tuple`):

- list of int
- dict of {str : int}
- tuple of (str, int, int)
- tuple of (str,)
- set of str

In case where there are just a set of values allowed, list them in curly brackets and separated by commas (followed by a space). If the values are ordinal and they have an order, list them in this order. Otherwise, list the default value first, if there is one:

- {0, 10, 25}
- {'simple', 'advanced'}
- {'low', 'medium', 'high'}
- {'cat', 'dog', 'bird'}

If the type is defined in a Python module, the module must be specified:

- `datetime.date`
- `datetime.datetime`
- `decimal.Decimal`

If the type is in a package, the module must be also specified:

- `numpy.ndarray`
- `scipy.sparse.coo_matrix`

If the type is a pandas type, also specify pandas except for `Series` and `DataFrame`:

- `Series`
- `DataFrame`
- `pandas.Index`
- `pandas.Categorical`
- `pandas.arrays.SparseArray`

If the exact type is not relevant, but must be compatible with a NumPy array, array-like can be specified. If Any type that can be iterated is accepted, iterable can be used:

- array-like

- iterable

If more than one type is accepted, separate them by commas, except the last two types, that need to be separated by the word ‘or’:

- int or float
- float, decimal.Decimal or None
- str or list of str

If `None` is one of the accepted values, it always needs to be the last in the list.

For axis, the convention is to use something like:

- axis : {0 or ‘index’, 1 or ‘columns’, None}, default None

#### Section 4: returns or yields

If the method returns a value, it will be documented in this section. Also if the method yields its output.

The title of the section will be defined in the same way as the “Parameters”. With the names “Returns” or “Yields” followed by a line with as many hyphens as the letters in the preceding word.

The documentation of the return is also similar to the parameters. But in this case, no name will be provided, unless the method returns or yields more than one value (a tuple of values).

The types for “Returns” and “Yields” are the same as the ones for the “Parameters”. Also, the description must finish with a dot.

For example, with a single value:

```
def sample():
 """
 Generate and return a random number.

 The value is sampled from a continuous uniform distribution between
 0 and 1.

 Returns

 float
 Random number generated.
 """
 return np.random.random()
```

With more than one value:

```
import string

def random_letters():
 """
 Generate and return a sequence of random letters.

 The length of the returned string is also random, and is also
 returned.

 Returns
```

(continues on next page)

(continued from previous page)

```

length : int
 Length of the returned string.
letters : str
 String of random letters.
"""
length = np.random.randint(1, 10)
letters = ''.join(np.random.choice(string.ascii_lowercase)
 for i in range(length))
return length, letters

```

If the method yields its value:

```

def sample_values():
 """
 Generate an infinite sequence of random numbers.

 The values are sampled from a continuous uniform distribution between
 0 and 1.

 Yields

 float
 Random number generated.
 """
 while True:
 yield np.random.random()

```

### Section 5: see also

This section is used to let users know about pandas functionality related to the one being documented. In rare cases, if no related methods or functions can be found at all, this section can be skipped.

An obvious example would be the `head()` and `tail()` methods. As `tail()` does the equivalent as `head()` but at the end of the `Series` or `DataFrame` instead of at the beginning, it is good to let the users know about it.

To give an intuition on what can be considered related, here there are some examples:

- `loc` and `iloc`, as they do the same, but in one case providing indices and in the other positions
- `max` and `min`, as they do the opposite
- `iterrows`, `itertuples` and `items`, as it is easy that a user looking for the method to iterate over columns ends up in the method to iterate over rows, and vice-versa
- `fillna` and `dropna`, as both methods are used to handle missing values
- `read_csv` and `to_csv`, as they are complementary
- `merge` and `join`, as one is a generalization of the other
- `astype` and `pandas.to_datetime`, as users may be reading the documentation of `astype` to know how to cast as a date, and the way to do it is with `pandas.to_datetime`
- `where` is related to `numpy.where`, as its functionality is based on it

When deciding what is related, you should mainly use your common sense and think about what can be useful for the users reading the documentation, especially the less experienced ones.

When relating to other libraries (mainly `numpy`), use the name of the module first (not an alias like `np`). If the function is in a module which is not the main one, like `scipy.sparse`, list the full module (e.g. `scipy.sparse.coo_matrix`).

This section has a header, “See Also” (note the capital S and A), followed by the line with hyphens and preceded by a blank line.

After the header, we will add a line for each related method or function, followed by a space, a colon, another space, and a short description that illustrates what this method or function does, why is it relevant in this context, and what the key differences are between the documented function and the one being referenced. The description must also end with a dot.

Note that in “Returns” and “Yields”, the description is located on the line after the type. In this section, however, it is located on the same line, with a colon in between. If the description does not fit on the same line, it can continue onto other lines which must be further indented.

For example:

```
class Series:
 def head(self):
 """
 Return the first 5 elements of the Series.

 This function is mainly useful to preview the values of the
 Series without displaying the whole of it.

 Returns

 Series
 Subset of the original series with the 5 first values.

 See Also

 Series.tail : Return the last 5 elements of the Series.
 Series.iloc : Return a slice of the elements in the Series,
 which can also be used to return the first or last n.
 """
 return self.iloc[:5]
```

## Section 6: notes

This is an optional section used for notes about the implementation of the algorithm, or to document technical aspects of the function behavior.

Feel free to skip it, unless you are familiar with the implementation of the algorithm, or you discover some counter-intuitive behavior while writing the examples for the function.

This section follows the same format as the extended summary section.

## Section 7: examples

This is one of the most important sections of a docstring, despite being placed in the last position, as often people understand concepts better by example than through accurate explanations.

Examples in docstrings, besides illustrating the usage of the function or method, must be valid Python code, that returns the given output in a deterministic way, and that can be copied and run by users.

Examples are presented as a session in the Python terminal. `>>>` is used to present code. `...` is used for code continuing from the previous line. Output is presented immediately after the last line of code generating the output (no blank lines in between). Comments describing the examples can be added with blank lines before and after them.

The way to present examples is as follows:

1. Import required libraries (except numpy and pandas)
2. Create the data required for the example
3. Show a very basic example that gives an idea of the most common use case
4. Add examples with explanations that illustrate how the parameters can be used for extended functionality

A simple example could be:

```
class Series:

 def head(self, n=5):
 """
 Return the first elements of the Series.

 This function is mainly useful to preview the values of the
 Series without displaying all of it.

 Parameters

 n : int
 Number of values to return.

 Return

 pandas.Series
 Subset of the original series with the n first values.

 See Also

 tail : Return the last n elements of the Series.

 Examples

 >>> s = pd.Series(['Ant', 'Bear', 'Cow', 'Dog', 'Falcon',
 ... 'Lion', 'Monkey', 'Rabbit', 'Zebra'])
 >>> s.head()
 0 Ant
 1 Bear
 2 Cow
 3 Dog
```

(continues on next page)

(continued from previous page)

```
4 Falcon
dtype: object
```

*With the ``n`` parameter, we can change the number of returned rows:*

```
>>> s.head(n=3)
0 Ant
1 Bear
2 Cow
dtype: object
"""
return self.iloc[:n]
```

The examples should be as concise as possible. In cases where the complexity of the function requires long examples, is recommended to use blocks with headers in bold. Use double star `**` to make a text bold, like in `**this example**`.

### Conventions for the examples

Code in examples is assumed to always start with these two lines which are not shown:

```
import numpy as np
import pandas as pd
```

Any other module used in the examples must be explicitly imported, one per line (as recommended in [PEP 8#imports](#)) and avoiding aliases. Avoid excessive imports, but if needed, imports from the standard library go first, followed by third-party libraries (like matplotlib).

When illustrating examples with a single `Series` use the name `s`, and if illustrating with a single `DataFrame` use the name `df`. For indices, `idx` is the preferred name. If a set of homogeneous `Series` or `DataFrame` is used, name them `s1`, `s2`, `s3...` or `df1`, `df2`, `df3...` If the data is not homogeneous, and more than one structure is needed, name them with something meaningful, for example `df_main` and `df_to_join`.

Data used in the example should be as compact as possible. The number of rows is recommended to be around 4, but make it a number that makes sense for the specific example. For example in the `head` method, it requires to be higher than 5, to show the example with the default values. If doing the `mean`, we could use something like `[1, 2, 3]`, so it is easy to see that the value returned is the mean.

For more complex examples (grouping for example), avoid using data without interpretation, like a matrix of random numbers with columns A, B, C, D... And instead use a meaningful example, which makes it easier to understand the concept. Unless required by the example, use names of animals, to keep examples consistent. And numerical properties of them.

When calling the method, keywords arguments `head(n=3)` are preferred to positional arguments `head(3)`.

#### Good:

```
class Series:

 def mean(self):
 """
 Compute the mean of the input.

 Examples
```

(continues on next page)

(continued from previous page)

```

>>> s = pd.Series([1, 2, 3])
>>> s.mean()
2
"""
pass

def fillna(self, value):
 """
 Replace missing values by ``value``.

 Examples

 >>> s = pd.Series([1, np.nan, 3])
 >>> s.fillna(0)
 [1, 0, 3]
 """
 pass

def groupby_mean(self):
 """
 Group by index and return mean.

 Examples

 >>> s = pd.Series([380., 370., 24., 26],
 ... name='max_speed',
 ... index=['falcon', 'falcon', 'parrot', 'parrot'])
 >>> s.groupby_mean()
 index
 falcon 375.0
 parrot 25.0
 Name: max_speed, dtype: float64
 """
 pass

def contains(self, pattern, case_sensitive=True, na=numpy.nan):
 """
 Return whether each value contains ``pattern``.

 In this case, we are illustrating how to use sections, even
 if the example is simple enough and does not require them.

 Examples

 >>> s = pd.Series('Antelope', 'Lion', 'Zebra', np.nan)
 >>> s.contains(pattern='a')
 0 False
 1 False
 2 True
 3 NaN
 """
```

(continues on next page)

(continued from previous page)

```

dtype: bool

Case sensitivity

With case_sensitive set to False we can match a with both
a and A:

>>> s.contains(pattern='a', case_sensitive=False)
0 True
1 False
2 True
3 NaN
dtype: bool

Missing values

We can fill missing values in the output using the na parameter:

>>> s.contains(pattern='a', na=False)
0 False
1 False
2 True
3 False
dtype: bool
"""
pass

```

**Bad:**

```

def method(foo=None, bar=None):
 """
 A sample DataFrame method.

 Do not import NumPy and pandas.

 Try to use meaningful data, when it makes the example easier
 to understand.

 Try to avoid positional arguments like in df.method(1). They
 can be all right if previously defined with a meaningful name,
 like in present_value(interest_rate), but avoid them otherwise.

 When presenting the behavior with different parameters, do not place
 all the calls one next to the other. Instead, add a short sentence
 explaining what the example shows.

 Examples

 >>> import numpy as np
 >>> import pandas as pd
 >>> df = pd.DataFrame(np.random.randn(3, 3),
 ... columns=('a', 'b', 'c'))

```

(continues on next page)

(continued from previous page)

```
>>> df.method(1)
21
>>> df.method(bar=14)
123
"""
pass
```

## Tips for getting your examples pass the doctests

Getting the examples pass the doctests in the validation script can sometimes be tricky. Here are some attention points:

- Import all needed libraries (except for pandas and NumPy, those are already imported as `import pandas as pd` and `import numpy as np`) and define all variables you use in the example.
- Try to avoid using random data. However random data might be OK in some cases, like if the function you are documenting deals with probability distributions, or if the amount of data needed to make the function result meaningful is too much, such that creating it manually is very cumbersome. In those cases, always use a fixed random seed to make the generated examples predictable. Example:

```
>>> np.random.seed(42)
>>> df = pd.DataFrame({'normal': np.random.normal(100, 5, 20)})
```

- If you have a code snippet that wraps multiple lines, you need to use `'...'` on the continued lines:

```
>>> df = pd.DataFrame([[1, 2, 3], [4, 5, 6]], index=['a', 'b', 'c'],
... columns=['A', 'B'])
```

- If you want to show a case where an exception is raised, you can do:

```
>>> pd.to_datetime(["712-01-01"])
Traceback (most recent call last):
OutOfBoundsDatetime: Out of bounds nanosecond timestamp: 712-01-01 00:00:00
```

It is essential to include the “Traceback (most recent call last):”, but for the actual error only the error name is sufficient.

- If there is a small part of the result that can vary (e.g. a hash in an object representation), you can use `...` to represent this part.

If you want to show that `s.plot()` returns a matplotlib `AxesSubplot` object, this will fail the doctest

```
>>> s.plot()
<matplotlib.axes._subplots.AxesSubplot at 0x7efd0c0b0690>
```

However, you can do (notice the comment that needs to be added)

```
>>> s.plot()
<matplotlib.axes._subplots.AxesSubplot at ...>
```

## Plots in examples

There are some methods in pandas returning plots. To render the plots generated by the examples in the documentation, the `.. plot::` directive exists.

To use it, place the next code after the “Examples” header as shown below. The plot will be generated automatically when building the documentation.

```
class Series:
 def plot(self):
 """
 Generate a plot with the ``Series`` data.

 Examples

 .. plot::
 :context: close-figs

 >>> s = pd.Series([1, 2, 3])
 >>> s.plot()
 """
 pass
```

## Sharing docstrings

pandas has a system for sharing docstrings, with slight variations, between classes. This helps us keep docstrings consistent, while keeping things clear for the user reading. It comes at the cost of some complexity when writing.

Each shared docstring will have a base template with variables, like `{klass}`. The variables filled in later on using the doc decorator. Finally, docstrings can also be appended to with the doc decorator.

In this example, we’ll create a parent docstring normally (this is like `pandas.core.generic.NDFrame`). Then we’ll have two children (like `pandas.core.series.Series` and `pandas.core.frame.DataFrame`). We’ll substitute the class names in this docstring.

```
class Parent:
 @doc(klass="Parent")
 def my_function(self):
 """Apply my function to {klass}."""
 ...

class ChildA(Parent):
 @doc(Parent.my_function, klass="ChildA")
 def my_function(self):
 ...

class ChildB(Parent):
 @doc(Parent.my_function, klass="ChildB")
 def my_function(self):
 ...
```

The resulting docstrings are

```
>>> print(Parent.my_function.__doc__)
Apply my function to Parent.
>>> print(ChildA.my_function.__doc__)
Apply my function to ChildA.
>>> print(ChildB.my_function.__doc__)
Apply my function to ChildB.
```

Notice:

1. We “append” the parent docstring to the children docstrings, which are initially empty.

Our files will often contain a module-level `_shared_doc_kwargs` with some common substitution values (things like `klass`, `axes`, etc).

You can substitute and append in one shot with something like

```
@doc(template, **_shared_doc_kwargs)
def my_function(self):
 ...
```

where `template` may come from a module-level `_shared_docs` dictionary mapping function names to docstrings. Wherever possible, we prefer using `doc`, since the docstring-writing processes is slightly closer to normal.

See `pandas.core.generic.NDFrame.fillna` for an example template, and `pandas.core.series.Series.fillna` and `pandas.core.generic.frame.fillna` for the filled versions.

- The tutorials make heavy use of the `IPython directive` sphinx extension. This directive lets you put code in the documentation which will be run during the doc build. For example:

```
.. ipython:: python

 x = 2
 x**3
```

will be rendered as:

```
In [1]: x = 2

In [2]: x**3
Out[2]: 8
```

Almost all code examples in the docs are run (and the output saved) during the doc build. This approach means that code examples will always be up to date, but it does make the doc building a bit more complex.

- Our API documentation files in `doc/source/reference` house the auto-generated documentation from the docstrings. For classes, there are a few subtleties around controlling which methods and attributes have pages auto-generated.

We have two autosummary templates for classes.

1. `_templates/autosummary/class.rst`. Use this when you want to automatically generate a page for every public method and attribute on the class. The `Attributes` and `Methods` sections will be automatically added to the class’ rendered documentation by `numpydoc`. See `DataFrame` for an example.
2. `_templates/autosummary/class_without_autosummary`. Use this when you want to pick a subset of methods / attributes to auto-generate pages for. When using this template, you should include an

Attributes and Methods section in the class docstring. See `CategoricalIndex` for an example.

Every method should be included in a `toctree` in one of the documentation files in `doc/source/reference`, else Sphinx will emit a warning.

---

**Note:** The `.rst` files are used to automatically generate Markdown and HTML versions of the docs. For this reason, please do not edit `CONTRIBUTING.md` directly, but instead make any changes to `doc/source/development/contributing.rst`. Then, to generate `CONTRIBUTING.md`, use `pandoc` with the following command:

```
pandoc doc/source/development/contributing.rst -t markdown_github > CONTRIBUTING.md
```

---

The utility script `scripts/validate_docstrings.py` can be used to get a csv summary of the API documentation. And also validate common errors in the docstring of a specific class, function or method. The summary also compares the list of methods documented in the files in `doc/source/reference` (which is used to generate the [API Reference](#) page) and the actual public methods. This will identify methods documented in `doc/source/reference` that are not actually class methods, and existing methods that are not documented in `doc/source/reference`.

### 4.3.2 Updating a pandas docstring

When improving a single function or method's docstring, it is not necessarily needed to build the full documentation (see next section). However, there is a script that checks a docstring (for example for the `DataFrame.mean` method):

```
python scripts/validate_docstrings.py pandas.DataFrame.mean
```

This script will indicate some formatting errors if present, and will also run and test the examples included in the docstring. Check the [pandas docstring guide](#) for a detailed guide on how to format the docstring.

The examples in the docstring ('doctests') must be valid Python code, that in a deterministic way returns the presented output, and that can be copied and run by users. This can be checked with the script above, and is also tested on Travis. A failing doctest will be a blocker for merging a PR. Check the [examples](#) section in the docstring guide for some tips and tricks to get the doctests passing.

When doing a PR with a docstring update, it is good to post the output of the validation script in a comment on github.

### 4.3.3 How to build the pandas documentation

#### Requirements

First, you need to have a development environment to be able to build pandas (see the docs on [creating a development environment](#)).

#### Building the documentation

So how do you build the docs? Navigate to your local `doc/` directory in the console and run:

```
python make.py html
```

Then you can find the HTML output in the folder `doc/build/html/`.

The first time you build the docs, it will take quite a while because it has to run all the code examples and build all the generated docstring pages. In subsequent evocations, sphinx will try to only build the pages that have been modified.

If you want to do a full clean build, do:

```
python make.py clean
python make.py html
```

You can tell `make.py` to compile only a single section of the docs, greatly reducing the turn-around time for checking your changes.

```
omit autosummary and API section
python make.py clean
python make.py --no-api

compile the docs with only a single section, relative to the "source" folder.
For example, compiling only this guide (doc/source/development/contributing.rst)
python make.py clean
python make.py --single development/contributing.rst

compile the reference docs for a single function
python make.py clean
python make.py --single pandas.DataFrame.join

compile whatsnew and API section (to resolve links in the whatsnew)
python make.py clean
python make.py --whatsnew
```

For comparison, a full documentation build may take 15 minutes, but a single section may take 15 seconds. Subsequent builds, which only process portions you have changed, will be faster.

The build will automatically use the number of cores available on your machine to speed up the documentation build. You can override this:

```
python make.py html --num-jobs 4
```

Open the following file in a web browser to see the full documentation you just built:

```
doc/build/html/index.html
```

And you'll have the satisfaction of seeing your new and improved documentation!

## Building master branch documentation

When pull requests are merged into the pandas master branch, the main parts of the documentation are also built by Travis-CI. These docs are then hosted [here](#), see also the *Continuous Integration* section.

### 4.3.4 Previewing changes

Once, the pull request is submitted, GitHub Actions will automatically build the documentation. To view the built site:

1. Wait for the CI / Web and docs check to complete.
2. Click `Details` next to it.
3. From the `Artifacts` drop-down, click `docs` or `website` to download the site as a ZIP file.

## 4.4 Contributing to the code base

### Table of Contents:

- *Code standards*
- *Pre-commit*
- *Optional dependencies*
  - *C (cpplint)*
  - *Python (PEP8 / black)*
  - *Import formatting*
  - *Backwards compatibility*
- *Type hints*
  - *Style guidelines*
  - *pandas-specific types*
  - *Validating type hints*
- *Testing with continuous integration*
- *Test-driven development/code writing*
  - *Writing tests*
  - *Transitioning to pytest*
  - *Using pytest*
  - *Using hypothesis*
  - *Testing warnings*
- *Running the test suite*
- *Running the performance test suite*
- *Documenting your code*

### 4.4.1 Code standards

Writing good code is not just about what you write. It is also about *how* you write it. During *Continuous Integration* testing, several tools will be run to check your code for stylistic errors. Generating any warnings will cause the test to fail. Thus, good style is a requirement for submitting code to pandas.

There is a tool in pandas to help contributors verify their changes before contributing them to the project:

```
./ci/code_checks.sh
```

The script verifies the linting of code files, it looks for common mistake patterns (like missing spaces around sphinx directives that make the documentation not being rendered properly) and it also validates the doctests. It is possible to run the checks independently by using the parameters `lint`, `patterns` and `doctests` (e.g. `./ci/code_checks.sh lint`).

In addition, because a lot of people use our library, it is important that we do not make sudden changes to the code

that could have the potential to break a lot of user code as a result, that is, we need it to be as *backwards compatible* as possible to avoid mass breakages.

In addition to `./ci/code_checks.sh`, some extra checks are run by `pre-commit` - see [here](#) for how to run them.

Additional standards are outlined on the [pandas code style guide](#).

### 4.4.2 Pre-commit

You can run many of these styling checks manually as we have described above. However, we encourage you to use `pre-commit` hooks instead to automatically run `black`, `flake8`, `isort` when you make a git commit. This can be done by installing `pre-commit`:

```
pip install pre-commit
```

and then running:

```
pre-commit install
```

from the root of the pandas repository. Now all of the styling checks will be run each time you commit changes without your needing to run each one manually. In addition, using `pre-commit` will also allow you to more easily remain up-to-date with our code checks as they change.

Note that if needed, you can skip these checks with `git commit --no-verify`.

If you don't want to use `pre-commit` as part of your workflow, you can still use it to run its checks with:

```
pre-commit run --files <files you have modified>
```

without needing to have done `pre-commit install` beforehand.

If you want to run checks on all recently committed files on upstream/master you can use:

```
pre-commit run --from-ref=upstream/master --to-ref=HEAD --all-files
```

without needing to have done `pre-commit install` beforehand.

---

**Note:** If you have conflicting installations of `virtualenv`, then you may get an error - see [here](#).

Also, due to a [bug in virtualenv](#), you may run into issues if you're using `conda`. To solve this, you can downgrade `virtualenv` to version `20.0.33`.

---

### 4.4.3 Optional dependencies

Optional dependencies (e.g. `matplotlib`) should be imported with the private helper `pandas.compat._optional.import_optional_dependency`. This ensures a consistent error message when the dependency is not met.

All methods using an optional dependency should include a test asserting that an `ImportError` is raised when the optional dependency is not found. This test should be skipped if the library is present.

All optional dependencies should be documented in [Optional dependencies](#) and the minimum required version should be set in the `pandas.compat._optional.VERSIONS` dict.

## C (cpplint)

pandas uses the [Google](#) standard. Google provides an open source style checker called `cpplint`, but we use a fork of it that can be found [here](#). Here are *some* of the more common `cpplint` issues:

- we restrict line-length to 80 characters to promote readability
- every header file must include a header guard to avoid name collisions if re-included

*Continuous Integration* will run the `cpplint` tool and report any stylistic errors in your code. Therefore, it is helpful before submitting code to run the check yourself:

```
cpplint --extensions=c,h --headers=h --filter=--readability/casting,-runtime/int,-build/
↪include_subdir modified-c-file
```

You can also run this command on an entire directory if necessary:

```
cpplint --extensions=c,h --headers=h --filter=--readability/casting,-runtime/int,-build/
↪include_subdir --recursive modified-c-directory
```

To make your commits compliant with this standard, you can install the [ClangFormat](#) tool, which can be downloaded [here](#). To configure, in your home directory, run the following command:

```
clang-format style=google -dump-config > .clang-format
```

Then modify the file to ensure that any indentation width parameters are at least four. Once configured, you can run the tool as follows:

```
clang-format modified-c-file
```

This will output what your file will look like if the changes are made, and to apply them, run the following command:

```
clang-format -i modified-c-file
```

To run the tool on an entire directory, you can run the following analogous commands:

```
clang-format modified-c-directory/*.c modified-c-directory/*.h
clang-format -i modified-c-directory/*.c modified-c-directory/*.h
```

Do note that this tool is best-effort, meaning that it will try to correct as many errors as possible, but it may not correct *all* of them. Thus, it is recommended that you run `cpplint` to double check and make any other style fixes manually.

## Python (PEP8 / black)

pandas follows the [PEP8](#) standard and uses [Black](#) and [Flake8](#) to ensure a consistent code format throughout the project. We encourage you to use *pre-commit*.

*Continuous Integration* will run those tools and report any stylistic errors in your code. Therefore, it is helpful before submitting code to run the check yourself:

```
black pandas
git diff upstream/master -u -- "*.py" | flake8 --diff
```

to auto-format your code. Additionally, many editors have plugins that will apply `black` as you edit files.

You should use a `black` version 21.5b2 as previous versions are not compatible with the pandas codebase.

One caveat about `git diff upstream/master -u -- "*.py" | flake8 --diff`: this command will catch any stylistic errors in your changes specifically, but be beware it may not catch all of them. For example, if you delete the only usage of an imported function, it is stylistically incorrect to import an unused function. However, style-checking the diff will not catch this because the actual import is not part of the diff. Thus, for completeness, you should run this command, though it may take longer:

```
git diff upstream/master --name-only -- "*.py" | xargs -r flake8
```

Note that on OSX, the `-r` flag is not available, so you have to omit it and run this slightly modified command:

```
git diff upstream/master --name-only -- "*.py" | xargs flake8
```

Windows does not support the `xargs` command (unless installed for example via the [MinGW](#) toolchain), but one can imitate the behaviour as follows:

```
for /f %i in ('git diff upstream/master --name-only -- "*.py"') do flake8 %i
```

This will get all the files being changed by the PR (and ending with `.py`), and run `flake8` on them, one after the other.

Note that these commands can be run analogously with `black`.

### Import formatting

pandas uses `isort` to standardise import formatting across the codebase.

A guide to import layout as per pep8 can be found [here](#).

A summary of our current import sections ( in order ):

- Future
- Python Standard Library
- Third Party
- `pandas._libs`, `pandas.compat`, `pandas.util._*`, `pandas.errors` (largely not dependent on `pandas.core`)
- `pandas.core.dtypes` (largely not dependent on the rest of `pandas.core`)
- Rest of `pandas.core.*`
- Non-core `pandas.io`, `pandas.plotting`, `pandas.tseries`
- Local application/library specific imports

Imports are alphabetically sorted within these sections.

As part of *Continuous Integration* checks we run:

```
isort --check-only pandas
```

to check that imports are correctly formatted as per the `setup.cfg`.

If you see output like the below in *Continuous Integration* checks:

```
Check import format using isort
ERROR: /home/travis/build/pandas-dev/pandas/pandas/io/pytables.py Imports are
↳incorrectly sorted
Check import format using isort DONE
The command "ci/code_checks.sh" exited with 1
```

You should run:

```
isort pandas/io/pytables.py
```

to automatically format imports correctly. This will modify your local copy of the files.

Alternatively, you can run a command similar to what was suggested for `black` and `flake8` *right above*:

```
git diff upstream/master --name-only -- "*.py" | xargs -r isort
```

Where similar caveats apply if you are on OSX or Windows.

You can then verify the changes look ok, then git *commit* and *push*.

## Backwards compatibility

Please try to maintain backward compatibility. pandas has lots of users with lots of existing code, so don't break it if at all possible. If you think breakage is required, clearly state why as part of the pull request. Also, be careful when changing method signatures and add deprecation warnings where needed. Also, add the deprecated sphinx directive to the deprecated functions or methods.

If a function with the same arguments as the one being deprecated exist, you can use the `pandas.util._decorators.deprecate`:

```
from pandas.util._decorators import deprecate

deprecate('old_func', 'new_func', '1.1.0')
```

Otherwise, you need to do it manually:

```
import warnings

def old_func():
 """Summary of the function.

 .. deprecated:: 1.1.0
 Use new_func instead.
 """
 warnings.warn('Use new_func instead.', FutureWarning, stacklevel=2)
 new_func()

def new_func():
 pass
```

You'll also need to

1. Write a new test that asserts a warning is issued when calling with the deprecated argument
2. Update all of pandas existing tests and code to use the new argument

See *Testing warnings* for more.

## 4.4.4 Type hints

pandas strongly encourages the use of [PEP 484](#) style type hints. New development should contain type hints and pull requests to annotate existing code are accepted as well!

### Style guidelines

Types imports should follow the `from typing import ...` convention. So rather than

```
import typing

primes: typing.List[int] = []
```

You should write

```
from typing import List, Optional, Union

primes: List[int] = []
```

`Optional` should be used where applicable, so instead of

```
maybe_primes: List[Union[int, None]] = []
```

You should write

```
maybe_primes: List[Optional[int]] = []
```

In some cases in the code base classes may define class variables that shadow builtins. This causes an issue as described in [MyPy 1775](#). The defensive solution here is to create an unambiguous alias of the builtin and use that without your annotation. For example, if you come across a definition like

```
class SomeClass1:
 str = None
```

The appropriate way to annotate this would be as follows

```
str_type = str

class SomeClass2:
 str: str_type = None
```

In some cases you may be tempted to use `cast` from the typing module when you know better than the analyzer. This occurs particularly when using custom inference functions. For example

```
from typing import cast

from pandas.core.dtypes.common import is_number

def cannot_infer_bad(obj: Union[str, int, float]):
 if is_number(obj):
 ...
 else: # Reasonably only str objects would reach this but...
```

(continues on next page)

(continued from previous page)

```
obj = cast(str, obj) # Mypy complains without this!
return obj.upper()
```

The limitation here is that while a human can reasonably understand that `is_number` would catch the `int` and `float` types mypy cannot make that same inference just yet (see [mypy #5206](#)). While the above works, the use of `cast` is **strongly discouraged**. Where applicable a refactor of the code to appease static analysis is preferable

```
def cannot_infer_good(obj: Union[str, int, float]):

 if isinstance(obj, str):
 return obj.upper()
 else:
 ...
```

With custom types and inference this is not always possible so exceptions are made, but every effort should be exhausted to avoid `cast` before going down such paths.

### pandas-specific types

Commonly used types specific to pandas will appear in `pandas._typing` and you should use these where applicable. This module is private for now but ultimately this should be exposed to third party libraries who want to implement type checking against pandas.

For example, quite a few functions in pandas accept a `dtype` argument. This can be expressed as a string like "object", a `numpy.dtype` like `np.int64` or even a pandas `ExtensionDtype` like `pd.CategoricalDtype`. Rather than burden the user with having to constantly annotate all of those options, this can simply be imported and reused from the `pandas._typing` module

```
from pandas._typing import Dtype

def as_type(dtype: Dtype) -> ...:
 ...
```

This module will ultimately house types for repeatedly used concepts like “path-like”, “array-like”, “numeric”, etc... and can also hold aliases for commonly appearing parameters like `axis`. Development of this module is active so be sure to refer to the source for the most up to date list of available types.

### Validating type hints

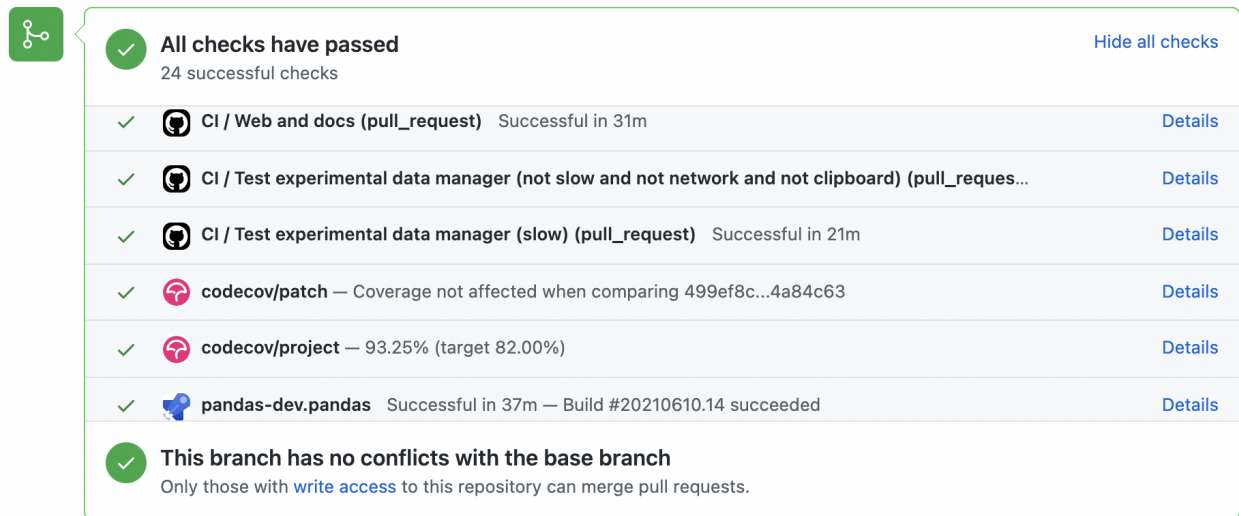

pandas uses `mypy` to statically analyze the code base and type hints. After making any change you can ensure your type hints are correct by running

```
mypy pandas
```

### 4.4.5 Testing with continuous integration

The pandas test suite will run automatically on [GitHub Actions](#) and [Azure Pipelines](#) continuous integration services, once your pull request is submitted. However, if you wish to run the test suite on a branch prior to submitting the pull request, then the continuous integration services need to be hooked to your GitHub repository. Instructions are here for [GitHub Actions](#) and [Azure Pipelines](#).

A pull-request will be considered for merging when you have an all ‘green’ build. If any tests are failing, then you will get a red ‘X’, where you can click through to see the individual failed tests. This is an example of a green build.

### 4.4.6 Test-driven development/code writing

pandas is serious about testing and strongly encourages contributors to embrace [test-driven development \(TDD\)](#). This development process “relies on the repetition of a very short development cycle: first the developer writes an (initially failing) automated test case that defines a desired improvement or new function, then produces the minimum amount of code to pass that test.” So, before actually writing any code, you should write your tests. Often the test can be taken from the original GitHub issue. However, it is always worth considering additional use cases and writing corresponding tests.

Adding tests is one of the most common requests after code is pushed to pandas. Therefore, it is worth getting in the habit of writing tests ahead of time so this is never an issue.

Like many packages, pandas uses [pytest](#) and the convenient extensions in [numpy.testing](#).

---

**Note:** The earliest supported pytest version is 5.0.1.

---

## Writing tests

All tests should go into the `tests` subdirectory of the specific package. This folder contains many current examples of tests, and we suggest looking to these for inspiration. If your test requires working with files or network connectivity, there is more information on the [testing page](#) of the wiki.

The `pandas._testing` module has many special `assert` functions that make it easier to make statements about whether `Series` or `DataFrame` objects are equivalent. The easiest way to verify that your code is correct is to explicitly construct the result you expect, then compare the actual result to the expected correct result:

```
def test_pivot(self):
 data = {
 'index' : ['A', 'B', 'C', 'C', 'B', 'A'],
 'columns' : ['One', 'One', 'One', 'Two', 'Two', 'Two'],
 'values' : [1., 2., 3., 3., 2., 1.]
 }

 frame = DataFrame(data)
 pivoted = frame.pivot(index='index', columns='columns', values='values')

 expected = DataFrame({
 'One' : {'A' : 1., 'B' : 2., 'C' : 3.},
 'Two' : {'A' : 1., 'B' : 2., 'C' : 3.}
 })

 assert_frame_equal(pivoted, expected)
```

Please remember to add the Github Issue Number as a comment to a new test. E.g. “# brief comment, see GH#28907”

## Transitioning to pytest

pandas existing test structure is *mostly* class-based, meaning that you will typically find tests wrapped in a class.

```
class TestReallyCoolFeature:
 pass
```

Going forward, we are moving to a more *functional* style using the `pytest` framework, which offers a richer testing framework that will facilitate testing and developing. Thus, instead of writing test classes, we will write test functions like this:

```
def test_really_cool_feature():
 pass
```

## Using pytest

Here is an example of a self-contained set of tests that illustrate multiple features that we like to use.

- functional style: tests are like `test_*` and *only* take arguments that are either fixtures or parameters
- `pytest.mark` can be used to set metadata on test functions, e.g. `skip` or `xfail`.
- using `parametrize`: allow testing of multiple cases
- to set a mark on a parameter, `pytest.param(..., marks=...)` syntax should be used
- `fixture`, code for object construction, on a per-test basis

- using bare assert for scalars and truth-testing
- `tm.assert_series_equal` (and its counter part `tm.assert_frame_equal`), for pandas object comparisons.
- the typical pattern of constructing an expected and comparing versus the result

We would name this file `test_cool_feature.py` and put in an appropriate place in the `pandas/tests/` structure.

```
import pytest
import numpy as np
import pandas as pd

@pytest.mark.parametrize('dtype', ['int8', 'int16', 'int32', 'int64'])
def test_dtypes(dtype):
 assert str(np.dtype(dtype)) == dtype

@pytest.mark.parametrize(
 'dtype', ['float32', pytest.param('int16', marks=pytest.mark.skip),
 pytest.param('int32', marks=pytest.mark.xfail(
 reason='to show how it works'))])
def test_mark(dtype):
 assert str(np.dtype(dtype)) == 'float32'

@pytest.fixture
def series():
 return pd.Series([1, 2, 3])

@pytest.fixture(params=['int8', 'int16', 'int32', 'int64'])
def dtype(request):
 return request.param

def test_series(series, dtype):
 result = series.astype(dtype)
 assert result.dtype == dtype

 expected = pd.Series([1, 2, 3], dtype=dtype)
 tm.assert_series_equal(result, expected)
```

A test run of this yields

```
((pandas) bash-3.2$ pytest test_cool_feature.py -v
===== test session starts =====
platform darwin -- Python 3.6.2, pytest-3.6.0, py-1.4.31, pluggy-0.4.0
collected 11 items

tester.py::test_dtypes[int8] PASSED
tester.py::test_dtypes[int16] PASSED
tester.py::test_dtypes[int32] PASSED
tester.py::test_dtypes[int64] PASSED
tester.py::test_mark[float32] PASSED
```

(continues on next page)

(continued from previous page)

```

tester.py::test_mark[int16] SKIPPED
tester.py::test_mark[int32] xfail
tester.py::test_series[int8] PASSED
tester.py::test_series[int16] PASSED
tester.py::test_series[int32] PASSED
tester.py::test_series[int64] PASSED

```

Tests that we have parametrized are now accessible via the test name, for example we could run these with `-k int8` to sub-select *only* those tests which match `int8`.

```

((pandas) bash-3.2$ pytest test_cool_feature.py -v -k int8
===== test session starts =====
platform darwin -- Python 3.6.2, pytest-3.6.0, py-1.4.31, pluggy-0.4.0
collected 11 items

test_cool_feature.py::test_dtypes[int8] PASSED
test_cool_feature.py::test_series[int8] PASSED

```

## Using hypothesis

Hypothesis is a library for property-based testing. Instead of explicitly parametrizing a test, you can describe *all* valid inputs and let Hypothesis try to find a failing input. Even better, no matter how many random examples it tries, Hypothesis always reports a single minimal counterexample to your assertions - often an example that you would never have thought to test.

See [Getting Started with Hypothesis](#) for more of an introduction, then refer to the [Hypothesis documentation](#) for details.

```

import json
from hypothesis import given, strategies as st

any_json_value = st.deferred(lambda: st.one_of(
 st.none(), st.booleans(), st.floats(allow_nan=False), st.text(),
 st.lists(any_json_value), st.dictionaries(st.text(), any_json_value)
))

@given(value=any_json_value)
def test_json_roundtrip(value):
 result = json.loads(json.dumps(value))
 assert value == result

```

This test shows off several useful features of Hypothesis, as well as demonstrating a good use-case: checking properties that should hold over a large or complicated domain of inputs.

To keep the pandas test suite running quickly, parametrized tests are preferred if the inputs or logic are simple, with Hypothesis tests reserved for cases with complex logic or where there are too many combinations of options or subtle interactions to test (or think of!) all of them.

## Testing warnings

By default, one of pandas CI workers will fail if any unhandled warnings are emitted.

If your change involves checking that a warning is actually emitted, use `tm.assert_produces_warning(ExpectedWarning)`.

```
import pandas._testing as tm

df = pd.DataFrame()
with tm.assert_produces_warning(FutureWarning):
 df.some_operation()
```

We prefer this to the `pytest.warns` context manager because ours checks that the warning's `stacklevel` is set correctly. The `stacklevel` is what ensure the *user's* file name and line number is printed in the warning, rather than something internal to pandas. It represents the number of function calls from user code (e.g. `df.some_operation()`) to the function that actually emits the warning. Our linter will fail the build if you use `pytest.warns` in a test.

If you have a test that would emit a warning, but you aren't actually testing the warning itself (say because it's going to be removed in the future, or because we're matching a 3rd-party library's behavior), then use `pytest.mark.filterwarnings` to ignore the error.

```
@pytest.mark.filterwarnings("ignore:msg:category")
def test_thing(self):
 ...
```

If the test generates a warning of class `category` whose message starts with `msg`, the warning will be ignored and the test will pass.

If you need finer-grained control, you can use Python's usual `warnings` module to control whether a warning is ignored / raised at different places within a single test.

```
with warnings.catch_warnings():
 warnings.simplefilter("ignore", FutureWarning)
 # Or use warnings.filterwarnings(...)
```

Alternatively, consider breaking up the unit test.

## 4.4.7 Running the test suite

The tests can then be run directly inside your Git clone (without having to install pandas) by typing:

```
pytest pandas
```

The tests suite is exhaustive and takes around 20 minutes to run. Often it is worth running only a subset of tests first around your changes before running the entire suite.

The easiest way to do this is with:

```
pytest pandas/path/to/test.py -k regex_matching_test_name
```

Or with one of the following constructs:

```
pytest pandas/tests/[test-module].py
pytest pandas/tests/[test-module].py::[TestClass]
pytest pandas/tests/[test-module].py::[TestClass]:[test_method]
```

Using `pytest-xdist`, one can speed up local testing on multicore machines. To use this feature, you will need to install `pytest-xdist` via:

```
pip install pytest-xdist
```

Two scripts are provided to assist with this. These scripts distribute testing across 4 threads.

On Unix variants, one can type:

```
test_fast.sh
```

On Windows, one can type:

```
test_fast.bat
```

This can significantly reduce the time it takes to locally run tests before submitting a pull request.

For more, see the [pytest](#) documentation.

Furthermore one can run

```
pd.test()
```

with an imported pandas to run tests similarly.

#### 4.4.8 Running the performance test suite

Performance matters and it is worth considering whether your code has introduced performance regressions. pandas is in the process of migrating to [asv benchmarks](#) to enable easy monitoring of the performance of critical pandas operations. These benchmarks are all found in the `pandas/asv_bench` directory, and the test results can be found [here](#).

To use all features of asv, you will need either `conda` or `virtualenv`. For more details please check the [asv installation webpage](#).

To install asv:

```
pip install git+https://github.com/spacetelescope/asv
```

If you need to run a benchmark, change your directory to `asv_bench/` and run:

```
asv continuous -f 1.1 upstream/master HEAD
```

You can replace `HEAD` with the name of the branch you are working on, and report benchmarks that changed by more than 10%. The command uses `conda` by default for creating the benchmark environments. If you want to use `virtualenv` instead, write:

```
asv continuous -f 1.1 -E virtualenv upstream/master HEAD
```

The `-E virtualenv` option should be added to all `asv` commands that run benchmarks. The default value is defined in `asv.conf.json`.

Running the full benchmark suite can be an all-day process, depending on your hardware and its resource utilization. However, usually it is sufficient to paste only a subset of the results into the pull request to show that the committed changes do not cause unexpected performance regressions. You can run specific benchmarks using the `-b` flag, which takes a regular expression. For example, this will only run benchmarks from a `pandas/asv_bench/benchmarks/groupby.py` file:

```
asv continuous -f 1.1 upstream/master HEAD -b ^groupby
```

If you want to only run a specific group of benchmarks from a file, you can do it using `.` as a separator. For example:

```
asv continuous -f 1.1 upstream/master HEAD -b groupby.GroupByMethods
```

will only run the `GroupByMethods` benchmark defined in `groupby.py`.

You can also run the benchmark suite using the version of `pandas` already installed in your current Python environment. This can be useful if you do not have `virtualenv` or `conda`, or are using the `setup.py develop` approach discussed above; for the in-place build you need to set `PYTHONPATH`, e.g. `PYTHONPATH="$PWD/.." asv [remaining arguments]`. You can run benchmarks using an existing Python environment by:

```
asv run -e -E existing
```

or, to use a specific Python interpreter,:

```
asv run -e -E existing:python3.6
```

This will display `stderr` from the benchmarks, and use your local `python` that comes from your `$PATH`.

Information on how to write a benchmark and how to use `asv` can be found in the [asv documentation](#).

### 4.4.9 Documenting your code

Changes should be reflected in the release notes located in `doc/source/whatsnew/vx.y.z.rst`. This file contains an ongoing change log for each release. Add an entry to this file to document your fix, enhancement or (unavoidable) breaking change. Make sure to include the GitHub issue number when adding your entry (using `:issue:`1234`` where 1234 is the issue/pull request number).

If your code is an enhancement, it is most likely necessary to add usage examples to the existing documentation. This can be done following the section regarding [documentation](#). Further, to let users know when this feature was added, the `versionadded` directive is used. The sphinx syntax for that is:

```
.. versionadded:: 1.1.0
```

This will put the text *New in version 1.1.0* wherever you put the sphinx directive. This should also be put in the docstring when adding a new function or method ([example](#)) or a new keyword argument ([example](#)).

## 4.5 pandas code style guide

### Table of contents:

- [Patterns](#)
- [Testing](#)

- *Failing tests*
- *Do not use `pytest.xfail`*
- *Using `pytest.mark.xfail`*
- *Miscellaneous*
  - *Reading from a url*

pandas follows the [PEP8](#) standard and uses [Black](#) and [Flake8](#) to ensure a consistent code format throughout the project. We encourage you to use *pre-commit* to automatically run `black`, `flake8`, `isort`, and related code checks when you make a git commit.

## 4.5.1 Patterns

We use a `flake8` plugin, `pandas-dev-flaker`, to check our codebase for unwanted patterns. See its [README](#) for the up-to-date list of rules we enforce.

## 4.5.2 Testing

### Failing tests

See <https://docs.pytest.org/en/latest/skipping.html> for background.

### Do not use `pytest.xfail`

Do not use this method. It has the same behavior as `pytest.skip`, namely it immediately stops the test and does not check if the test will fail. If this is the behavior you desire, use `pytest.skip` instead.

### Using `pytest.mark.xfail`

Use this method if a test is known to fail but the manner in which it fails is not meant to be captured. It is common to use this method for a test that exhibits buggy behavior or a non-implemented feature. If the failing test has flaky behavior, use the argument `strict=False`. This will make it so `pytest` does not fail if the test happens to pass.

Prefer the decorator `@pytest.mark.xfail` and the argument `pytest.param` over usage within a test so that the test is appropriately marked during the collection phase of `pytest`. For xfailing a test that involves multiple parameters, a fixture, or a combination of these, it is only possible to `xfail` during the testing phase. To do so, use the request fixture:

```
import pytest

def test_xfail(request):
 mark = pytest.mark.xfail(raises=TypeError, reason="Indicate why here")
 request.node.add_marker(mark)
```

`xfail` is not to be used for tests involving failure due to invalid user arguments. For these tests, we need to verify the correct exception type and error message is being raised, using `pytest.raises` instead.

### 4.5.3 Miscellaneous

#### Reading from a url

Good:

```
from pandas.io.common import urlopen

with urlopen("http://www.google.com") as url:
 raw_text = url.read()
```

## 4.6 pandas maintenance

This guide is for pandas' maintainers. It may also be interesting to contributors looking to understand the pandas development process and what steps are necessary to become a maintainer.

The main contributing guide is available at *Contributing to pandas*.

### 4.6.1 Roles

pandas uses two levels of permissions: **triage** and **core** team members.

Triage members can label and close issues and pull requests.

Core team members can label and close issues and pull request, and can merge pull requests.

GitHub publishes the full [list of permissions](#).

### 4.6.2 Tasks

pandas is largely a volunteer project, so these tasks shouldn't be read as "expectations" of triage and maintainers. Rather, they're general descriptions of what it means to be a maintainer.

- Triage newly filed issues (see *Issue triage*)
- Review newly opened pull requests
- Respond to updates on existing issues and pull requests
- Drive discussion and decisions on stalled issues and pull requests
- Provide experience / wisdom on API design questions to ensure consistency and maintainability
- Project organization (run / attend developer meetings, represent pandas)

<https://matthewrocklin.com/blog/2019/05/18/maintainer> may be interesting background reading.

### 4.6.3 Issue triage

Here's a typical workflow for triaging a newly opened issue.

1. **Thank the reporter for opening an issue**

The issue tracker is many people's first interaction with the pandas project itself, beyond just using the library. As such, we want it to be a welcoming, pleasant experience.

2. **Is the necessary information provided?**

Ideally reporters would fill out the issue template, but many don't. If crucial information (like the version of pandas they used), is missing feel free to ask for that and label the issue with "Needs info". The report should follow the guidelines in *Bug reports and enhancement requests*. You may want to link to that if they didn't follow the template.

Make sure that the title accurately reflects the issue. Edit it yourself if it's not clear.

3. **Is this a duplicate issue?**

We have many open issues. If a new issue is clearly a duplicate, label the new issue as "Duplicate" assign the milestone "No Action", and close the issue with a link to the original issue. Make sure to still thank the reporter, and encourage them to chime in on the original issue, and perhaps try to fix it.

If the new issue provides relevant information, such as a better or slightly different example, add it to the original issue as a comment or an edit to the original post.

4. **Is the issue minimal and reproducible?**

For bug reports, we ask that the reporter provide a minimal reproducible example. See <https://matthewrocklin.com/blog/work/2018/02/28/minimal-bug-reports> for a good explanation. If the example is not reproducible, or if it's *clearly* not minimal, feel free to ask the reporter if they can provide an example or simplify the provided one. Do acknowledge that writing minimal reproducible examples is hard work. If the reporter is struggling, you can try to write one yourself and we'll edit the original post to include it.

If a reproducible example can't be provided, add the "Needs info" label.

If a reproducible example is provided, but you see a simplification, edit the original post with your simpler reproducible example.

5. **Is this a clearly defined feature request?**

Generally, pandas prefers to discuss and design new features in issues, before a pull request is made. Encourage the submitter to include a proposed API for the new feature. Having them write a full docstring is a good way to pin down specifics.

We'll need a discussion from several pandas maintainers before deciding whether the proposal is in scope for pandas.

6. **Is this a usage question?**

We prefer that usage questions are asked on StackOverflow with the pandas tag. <https://stackoverflow.com/questions/tagged/pandas>

If it's easy to answer, feel free to link to the relevant documentation section, let them know that in the future this kind of question should be on StackOverflow, and close the issue.

7. **What labels and milestones should I add?**

Apply the relevant labels. This is a bit of an art, and comes with experience. Look at similar issues to get a feel for how things are labeled.

If the issue is clearly defined and the fix seems relatively straightforward, label the issue as "Good first issue".

Typically, new issues will be assigned the “Contributions welcome” milestone, unless it’s known that this issue should be addressed in a specific release (say because it’s a large regression).

#### 4.6.4 Closing issues

Be delicate here: many people interpret closing an issue as us saying that the conversation is over. It’s typically best to give the reporter some time to respond or self-close their issue if it’s determined that the behavior is not a bug, or the feature is out of scope. Sometimes reporters just go away though, and we’ll close the issue after the conversation has died.

#### 4.6.5 Reviewing pull requests

Anybody can review a pull request: regular contributors, triagers, or core-team members. But only core-team members can merge pull requests when they’re ready.

Here are some things to check when reviewing a pull request.

- Tests should be in a sensible location: in the same file as closely related tests.
- New public APIs should be included somewhere in `doc/source/reference/`.
- New / changed API should use the `versionadded` or `versionchanged` directives in the docstring.
- User-facing changes should have a whatsnew in the appropriate file.
- Regression tests should reference the original GitHub issue number like `# GH-1234`.
- The pull request should be labeled and assigned the appropriate milestone (the next patch release for regression fixes and small bug fixes, the next minor milestone otherwise)
- Changes should comply with our *Version policy*.

#### 4.6.6 Backporting

In the case you want to apply changes to a stable branch from a newer branch then you can comment:

```
@meeseeksdev backport version-branch
```

This will trigger a workflow which will backport a given change to a branch (e.g. `@meeseeksdev backport 1.2.x`)

#### 4.6.7 Cleaning up old issues

Every open issue in pandas has a cost. Open issues make finding duplicates harder, and can make it harder to know what needs to be done in pandas. That said, closing issues isn’t a goal on its own. Our goal is to make pandas the best it can be, and that’s best done by ensuring that the quality of our open issues is high.

Occasionally, bugs are fixed but the issue isn’t linked to in the Pull Request. In these cases, comment that “This has been fixed, but could use a test.” and label the issue as “Good First Issue” and “Needs Test”.

If an older issue doesn’t follow our issue template, edit the original post to include a minimal example, the actual output, and the expected output. Uniformity in issue reports is valuable.

If an older issue lacks a reproducible example, label it as “Needs Info” and ask them to provide one (or write one yourself if possible). If one isn’t provide reasonably soon, close it according to the policies in *Closing issues*.

### 4.6.8 Cleaning up old pull requests

Occasionally, contributors are unable to finish off a pull request. If some time has passed (two weeks, say) since the last review requesting changes, gently ask if they're still interested in working on this. If another two weeks or so passes with no response, thank them for their work and close the pull request. Comment on the original issue that "There's a stalled PR at #1234 that may be helpful.", and perhaps label the issue as "Good first issue" if the PR was relatively close to being accepted.

Additionally, core-team members can push to contributors branches. This can be helpful for pushing an important PR across the line, or for fixing a small merge conflict.

### 4.6.9 Becoming a pandas maintainer

The full process is outlined in our [governance documents](#). In summary, we're happy to give triage permissions to anyone who shows interest by being helpful on the issue tracker.

The current list of core-team members is at <https://github.com/pandas-dev/pandas-governance/blob/master/people.md>

### 4.6.10 Merging pull requests

Only core team members can merge pull requests. We have a few guidelines.

1. You should typically not self-merge your own pull requests. Exceptions include things like small changes to fix CI (e.g. pinning a package version).
2. You should not merge pull requests that have an active discussion, or pull requests that has any -1 votes from a core maintainer. pandas operates by consensus.
3. For larger changes, it's good to have a +1 from at least two core team members.

In addition to the items listed in *Closing issues*, you should verify that the pull request is assigned the correct milestone.

Pull requests merged with a patch-release milestone will typically be backported by our bot. Verify that the bot noticed the merge (it will leave a comment within a minute typically). If a manual backport is needed please do that, and remove the "Needs backport" label once you've done it manually. If you forget to assign a milestone before tagging, you can request the bot to backport it with:

```
@Meeseeksdev backport <branch>
```

## 4.7 Internals

This section will provide a look into some of pandas internals. It's primarily intended for developers of pandas itself.

### 4.7.1 Indexing

In pandas there are a few objects implemented which can serve as valid containers for the axis labels:

- **Index**: the generic "ordered set" object, an ndarray of object dtype assuming nothing about its contents. The labels must be hashable (and likely immutable) and unique. Populates a dict of label to location in Cython to do O(1) lookups.
- **Int64Index**: a version of Index highly optimized for 64-bit integer data, such as time stamps
- **Float64Index**: a version of Index highly optimized for 64-bit float data

- `MultiIndex`: the standard hierarchical index object
- `DatetimeIndex`: An Index object with `Timestamp` boxed elements (impl are the `int64` values)
- `TimedeltaIndex`: An Index object with `Timedelta` boxed elements (impl are the `in64` values)
- `PeriodIndex`: An Index object with `Period` elements

There are functions that make the creation of a regular index easy:

- `date_range`: fixed frequency date range generated from a time rule or `DateOffset`. An ndarray of Python date-time objects
- `period_range`: fixed frequency date range generated from a time rule or `DateOffset`. An ndarray of `Period` objects, representing timespans

The motivation for having an `Index` class in the first place was to enable different implementations of indexing. This means that it's possible for you, the user, to implement a custom `Index` subclass that may be better suited to a particular application than the ones provided in pandas.

From an internal implementation point of view, the relevant methods that an `Index` must define are one or more of the following (depending on how incompatible the new object internals are with the `Index` functions):

- `get_loc`: returns an “indexer” (an integer, or in some cases a slice object) for a label
- `slice_locs`: returns the “range” to slice between two labels
- `get_indexer`: Computes the indexing vector for reindexing / data alignment purposes. See the source / docstrings for more on this
- `get_indexer_non_unique`: Computes the indexing vector for reindexing / data alignment purposes when the index is non-unique. See the source / docstrings for more on this
- `reindex`: Does any pre-conversion of the input index then calls `get_indexer`
- `union, intersection`: computes the union or intersection of two `Index` objects
- `insert`: Inserts a new label into an `Index`, yielding a new object
- `delete`: Delete a label, yielding a new object
- `drop`: Deletes a set of labels
- `take`: Analogous to `ndarray.take`

## MultiIndex

Internally, the `MultiIndex` consists of a few things: the **levels**, the integer **codes** (until version 0.24 named *labels*), and the level **names**:

```
In [1]: index = pd.MultiIndex.from_product(
...: [range(3), ["one", "two"]], names=["first", "second"]
...:)
...:

In [2]: index
Out[2]:
MultiIndex([(0, 'one'),
 (0, 'two'),
 (1, 'one'),
 (1, 'two'),
 (2, 'one'),
```

(continues on next page)

(continued from previous page)

```
(2, 'two']],
names=['first', 'second'])
```

```
In [3]: index.levels
```

```
Out[3]: FrozenList([[0, 1, 2], ['one', 'two']])
```

```
In [4]: index.codes
```

```
Out[4]: FrozenList([[0, 0, 1, 1, 2, 2], [0, 1, 0, 1, 0, 1]])
```

```
In [5]: index.names
```

```
Out[5]: FrozenList(['first', 'second'])
```

You can probably guess that the codes determine which unique element is identified with that location at each layer of the index. It's important to note that sortedness is determined **solely** from the integer codes and does not check (or care) whether the levels themselves are sorted. Fortunately, the constructors `from_tuples` and `from_arrays` ensure that this is true, but if you compute the levels and codes yourself, please be careful.

## Values

pandas extends NumPy's type system with custom types, like `Categorical` or datetimes with a timezone, so we have multiple notions of "values". For 1-D containers (`Index` classes and `Series`) we have the following convention:

- `cls._values` refers to the "best possible" array. This could be an `ndarray` or `ExtensionArray`.

So, for example, `Series[category]._values` is a `Categorical`.

## 4.7.2 Subclassing pandas data structures

This section has been moved to *Subclassing pandas data structures*.

## 4.8 Test organization

Ideally, there should be one, and only one, obvious place for a test to reside. Until we reach that ideal, these are some rules of thumb for where a test should be located.

1. Does your test depend only on code in `pd._libs.tslibs`? This test likely belongs in one of:

- `tests.tslibs`

---

**Note:** No file in `tests.tslibs` should import from any pandas modules outside of `pd._libs.tslibs`

---

- `tests.scalar`
- `tests.tseries.offsets`

2. Does your test depend only on code in `pd._libs`? This test likely belongs in one of:

- `tests.libs`
- `tests.groupby.test_libgroupby`

3. Is your test for an arithmetic or comparison method? This test likely belongs in one of:

- tests.arithmetic

---

**Note:** These are intended for tests that can be shared to test the behavior of DataFrame/Series/Index/ExtensionArray using the `box_with_array` fixture.

---

- tests.frame.test\_arithmetic
- tests.series.test\_arithmetic

4. Is your test for a reduction method (min, max, sum, prod, ...)? This test likely belongs in one of:

- tests.reductions

---

**Note:** These are intended for tests that can be shared to test the behavior of DataFrame/Series/Index/ExtensionArray.

---

- tests.frame.test\_reductions
- tests.series.test\_reductions
- tests.test\_nanops

5. Is your test for an indexing method? This is the most difficult case for deciding where a test belongs, because there are many of these tests, and many of them test more than one method (e.g. both `Series.__getitem__` and `Series.loc.__getitem__`)

A) Is the test specifically testing an Index method (e.g. `Index.get_loc`, `Index.get_indexer`)? This test likely belongs in one of:

- tests.indexes.test\_indexing
- tests.indexes.foindex.test\_indexing

Within that files there should be a method-specific test class e.g. `TestGetLoc`.

In most cases, neither `Series` nor `DataFrame` objects should be needed in these tests.

B) Is the test for a Series or DataFrame indexing method *other* than `__getitem__` or `__setitem__`, e.g. `xs`, `where`, `take`, `mask`, `lookup`, or `insert`? This test likely belongs in one of:

- tests.frame.indexing.test\_methodname
- tests.series.indexing.test\_methodname

C) Is the test for any of `loc`, `iloc`, `at`, or `iat`? This test likely belongs in one of:

- tests.indexing.test\_loc
- tests.indexing.test\_iloc
- tests.indexing.test\_at
- tests.indexing.test\_iat

Within the appropriate file, test classes correspond to either types of indexers (e.g. `TestLocBooleanMask`) or major use cases (e.g. `TestLocSetitemWithExpansion`).

See the note in section D) about tests that test multiple indexing methods.

D) Is the test for `Series.__getitem__`, `Series.__setitem__`, `DataFrame.__getitem__`, or `DataFrame.__setitem__`? This test likely belongs in one of:

- tests.series.test\_getitem

- tests.series.test\_setitem
- tests.frame.test\_getitem
- tests.frame.test\_setitem

If many cases such a test may test multiple similar methods, e.g.

```
import pandas as pd
import pandas._testing as tm

def test_getitem_listlike_of_ints():
 ser = pd.Series(range(5))

 result = ser[[3, 4]]
 expected = pd.Series([2, 3])
 tm.assert_series_equal(result, expected)

 result = ser.loc[[3, 4]]
 tm.assert_series_equal(result, expected)
```

In cases like this, the test location should be based on the *underlying* method being tested. Or in the case of a test for a bugfix, the location of the actual bug. So in this example, we know that `Series.__getitem__` calls `Series.loc.__getitem__`, so this is *really* a test for `loc.__getitem__`. So this test belongs in `tests.indexing.test_loc`.

6. Is your test for a DataFrame or Series method?

A) Is the method a plotting method? This test likely belongs in one of:

- tests.plotting

B) Is the method an IO method? This test likely belongs in one of:

- tests.io

C) Otherwise This test likely belongs in one of:

- tests.series.methods.test\_mymethod
- tests.frame.methods.test\_mymethod

---

**Note:** If a test can be shared between DataFrame/Series using the `frame_or_series` fixture, by convention it goes in the `tests.frame` file.

---

7. Is your test for an Index method, not depending on Series/DataFrame? This test likely belongs in one of:

- tests.indexes

8) Is your test for one of the pandas-provided ExtensionArrays (Categorical, DatetimeArray, TimedeltaArray, PeriodArray, IntervalArray, PandasArray, FloatArray, BoolArray, StringArray)? This test likely belongs in one of:

- tests.arrays

9) Is your test for *all* ExtensionArray subclasses (the “EA Interface”)? This test likely belongs in one of:

- tests.extension

## 4.9 Debugging C extensions

Pandas uses select C extensions for high performance IO operations. In case you need to debug segfaults or general issues with those extensions, the following steps may be helpful.

First, be sure to compile the extensions with the appropriate flags to generate debug symbols and remove optimizations. This can be achieved as follows:

```
python setup.py build_ext --inplace -j4 --with-debugging-symbols
```

### 4.9.1 Using a debugger

Assuming you are on a Unix-like operating system, you can use either lldb or gdb to debug. The choice between either is largely dependent on your compilation toolchain - typically you would use lldb if using clang and gdb if using gcc. For macOS users, please note that gcc is on modern systems an alias for clang, so if using Xcode you usually opt for lldb. Regardless of which debugger you choose, please refer to your operating systems instructions on how to install.

After installing a debugger you can create a script that hits the extension module you are looking to debug. For demonstration purposes, let's assume you have a script called `debug_testing.py` with the following contents:

```
import pandas as pd

pd.DataFrame([[1, 2]]).to_json()
```

Place the `debug_testing.py` script in the project root and launch a Python process under your debugger. If using lldb:

```
lldb python
```

If using gdb:

```
gdb python
```

Before executing our script, let's set a breakpoint in our JSON serializer in its entry function called `objToJSON`. The lldb syntax would look as follows:

```
breakpoint set --name objToJSON
```

Similarly for gdb:

```
break objToJSON
```

---

**Note:** You may get a warning that this breakpoint cannot be resolved in lldb. gdb may give a similar warning and prompt you to make the breakpoint on a future library load, which you should say yes to. This should only happen on the very first invocation as the module you wish to debug has not yet been loaded into memory.

---

Now go ahead and execute your script:

```
run <the_script>.py
```

Code execution will halt at the breakpoint defined or at the occurrence of any segfault. LLDB's [GDB to LLDB command map](#) provides a listing of debugger command that you can execute using either debugger.

Another option to execute the entire test suite under lldb would be to run the following:

```
lldb -- python -m pytest
```

Or for gdb

```
gdb --args python -m pytest
```

Once the process launches, simply type run and the test suite will begin, stopping at any segmentation fault that may occur.

## 4.9.2 Checking memory leaks with valgrind

You can use `Valgrind` to check for and log memory leaks in extensions. For instance, to check for a memory leak in a test from the suite you can run:

```
PYTHONMALLOC=malloc valgrind --leak-check=yes --track-origins=yes --log-file=valgrind-
↪log.txt python -m pytest <path_to_a_test>
```

Note that code execution under valgrind will take much longer than usual. While you can run valgrind against extensions compiled with any optimization level, it is suggested to have optimizations turned off from compiled extensions to reduce the amount of false positives. The `--with-debugging-symbols` flag passed during package setup will do this for you automatically.

---

**Note:** For best results, you should run use a Python installation configured with Valgrind support (`--with-valgrind`)

---

## 4.10 Extending pandas

While pandas provides a rich set of methods, containers, and data types, your needs may not be fully satisfied. pandas offers a few options for extending pandas.

### 4.10.1 Registering custom accessors

Libraries can use the decorators `pandas.api.extensions.register_dataframe_accessor()`, `pandas.api.extensions.register_series_accessor()`, and `pandas.api.extensions.register_index_accessor()`, to add additional “namespaces” to pandas objects. All of these follow a similar convention: you decorate a class, providing the name of attribute to add. The class’s `__init__` method gets the object being decorated. For example:

```
@pd.api.extensions.register_dataframe_accessor("geo")
class GeoAccessor:
 def __init__(self, pandas_obj):
 self._validate(pandas_obj)
 self._obj = pandas_obj

 @staticmethod
 def _validate(obj):
 # verify there is a column latitude and a column longitude
 if "latitude" not in obj.columns or "longitude" not in obj.columns:
 raise AttributeError("Must have 'latitude' and 'longitude'.")
```

(continues on next page)

(continued from previous page)

```
@property
def center(self):
 # return the geographic center point of this DataFrame
 lat = self._obj.latitude
 lon = self._obj.longitude
 return (float(lon.mean()), float(lat.mean()))

def plot(self):
 # plot this array's data on a map, e.g., using Cartopy
 pass
```

Now users can access your methods using the `geo` namespace:

```
>>> ds = pd.DataFrame(
... {"longitude": np.linspace(0, 10), "latitude": np.linspace(0, 20)}
...)
>>> ds.geo.center
(5.0, 10.0)
>>> ds.geo.plot()
plots data on a map
```

This can be a convenient way to extend pandas objects without subclassing them. If you write a custom accessor, make a pull request adding it to our ecosystem page.

We highly recommend validating the data in your accessor's `__init__`. In our `GeoAccessor`, we validate that the data contains the expected columns, raising an `AttributeError` when the validation fails. For a `Series` accessor, you should validate the `dtype` if the accessor applies only to certain dtypes.

## 4.10.2 Extension types

**Warning:** The `pandas.api.extensions.ExtensionDtype` and `pandas.api.extensions.ExtensionArray` APIs are new and experimental. They may change between versions without warning.

pandas defines an interface for implementing data types and arrays that *extend* NumPy's type system. pandas itself uses the extension system for some types that aren't built into NumPy (categorical, period, interval, datetime with timezone).

Libraries can define a custom array and data type. When pandas encounters these objects, they will be handled properly (i.e. not converted to an ndarray of objects). Many methods like `pandas.isna()` will dispatch to the extension type's implementation.

If you're building a library that implements the interface, please publicize it on [ecosystem.extensions](https://ecosystem.extensions.org).

The interface consists of two classes.

## ExtensionDtype

A `pandas.api.extensions.ExtensionDtype` is similar to a `numpy.dtype` object. It describes the data type. Implementors are responsible for a few unique items like the name.

One particularly important item is the `type` property. This should be the class that is the scalar type for your data. For example, if you were writing an extension array for IP Address data, this might be `ipaddress.IPv4Address`.

See the [extension dtype source](#) for interface definition.

`pandas.api.extensions.ExtensionDtype` can be registered to pandas to allow creation via a string dtype name. This allows one to instantiate `Series` and `.astype()` with a registered string name, for example `'category'` is a registered string accessor for the `CategoricalDtype`.

See the [extension dtype dtypes](#) for more on how to register dtypes.

## ExtensionArray

This class provides all the array-like functionality. `ExtensionArrays` are limited to 1 dimension. An `ExtensionArray` is linked to an `ExtensionDtype` via the `dtype` attribute.

pandas makes no restrictions on how an extension array is created via its `__new__` or `__init__`, and puts no restrictions on how you store your data. We do require that your array be convertible to a NumPy array, even if this is relatively expensive (as it is for `Categorical`).

They may be backed by none, one, or many NumPy arrays. For example, `pandas.Categorical` is an extension array backed by two arrays, one for codes and one for categories. An array of IPv6 addresses may be backed by a NumPy structured array with two fields, one for the lower 64 bits and one for the upper 64 bits. Or they may be backed by some other storage type, like Python lists.

See the [extension array source](#) for the interface definition. The docstrings and comments contain guidance for properly implementing the interface.

## ExtensionArray operator support

By default, there are no operators defined for the class `ExtensionArray`. There are two approaches for providing operator support for your `ExtensionArray`:

1. Define each of the operators on your `ExtensionArray` subclass.
2. Use an operator implementation from pandas that depends on operators that are already defined on the underlying elements (scalars) of the `ExtensionArray`.

---

**Note:** Regardless of the approach, you may want to set `__array_priority__` if you want your implementation to be called when involved in binary operations with NumPy arrays.

---

For the first approach, you define selected operators, e.g., `__add__`, `__le__`, etc. that you want your `ExtensionArray` subclass to support.

The second approach assumes that the underlying elements (i.e., scalar type) of the `ExtensionArray` have the individual operators already defined. In other words, if your `ExtensionArray` named `MyExtensionArray` is implemented so that each element is an instance of the class `MyExtensionElement`, then if the operators are defined for `MyExtensionElement`, the second approach will automatically define the operators for `MyExtensionArray`.

A mixin class, `ExtensionScalarOpsMixin` supports this second approach. If developing an `ExtensionArray` subclass, for example `MyExtensionArray`, can simply include `ExtensionScalarOpsMixin` as a parent class of

`MyExtensionArray`, and then call the methods `_add_arithmetic_ops()` and/or `_add_comparison_ops()` to hook the operators into your `MyExtensionArray` class, as follows:

```
from pandas.api.extensions import ExtensionArray, ExtensionScalarOpsMixin

class MyExtensionArray(ExtensionArray, ExtensionScalarOpsMixin):
 pass

MyExtensionArray._add_arithmetic_ops()
MyExtensionArray._add_comparison_ops()
```

---

**Note:** Since pandas automatically calls the underlying operator on each element one-by-one, this might not be as performant as implementing your own version of the associated operators directly on the `ExtensionArray`.

---

For arithmetic operations, this implementation will try to reconstruct a new `ExtensionArray` with the result of the element-wise operation. Whether or not that succeeds depends on whether the operation returns a result that's valid for the `ExtensionArray`. If an `ExtensionArray` cannot be reconstructed, an `ndarray` containing the scalars returned instead.

For ease of implementation and consistency with operations between pandas and NumPy `ndarrays`, we recommend *not* handling `Series` and `Indexes` in your binary ops. Instead, you should detect these cases and return `NotImplemented`. When pandas encounters an operation like `op(Series, ExtensionArray)`, pandas will

1. unbox the array from the `Series` (`Series.array`)
2. call `result = op(values, ExtensionArray)`
3. re-box the result in a `Series`

### NumPy universal functions

`Series` implements `__array_ufunc__`. As part of the implementation, pandas unboxes the `ExtensionArray` from the `Series`, applies the `ufunc`, and re-boxes it if necessary.

If applicable, we highly recommend that you implement `__array_ufunc__` in your extension array to avoid coercion to an `ndarray`. See [the NumPy documentation](#) for an example.

As part of your implementation, we require that you defer to pandas when a pandas container (`Series`, `DataFrame`, `Index`) is detected in `inputs`. If any of those is present, you should return `NotImplemented`. pandas will take care of unboxing the array from the container and re-calling the `ufunc` with the unwrapped input.

### Testing extension arrays

We provide a test suite for ensuring that your extension arrays satisfy the expected behavior. To use the test suite, you must provide several `pytest` fixtures and inherit from the base test class. The required fixtures are found in <https://github.com/pandas-dev/pandas/blob/master/pandas/tests/extension/conftest.py>.

To use a test, subclass it:

```
from pandas.tests.extension import base
```

(continues on next page)

(continued from previous page)

```
class TestConstructors(base.BaseConstructorsTests):
 pass
```

See [https://github.com/pandas-dev/pandas/blob/master/pandas/tests/extension/base/\\_\\_init\\_\\_.py](https://github.com/pandas-dev/pandas/blob/master/pandas/tests/extension/base/__init__.py) for a list of all the tests available.

### Compatibility with Apache Arrow

An `ExtensionArray` can support conversion to / from `pyarrow` arrays (and thus support for example serialization to the Parquet file format) by implementing two methods: `ExtensionArray.__arrow_array__` and `ExtensionDtype.__from_arrow__`.

The `ExtensionArray.__arrow_array__` ensures that `pyarrow` knows how to convert the specific extension array into a `pyarrow.Array` (also when included as a column in a pandas `DataFrame`):

```
class MyExtensionArray(ExtensionArray):
 ...

 def __arrow_array__(self, type=None):
 # convert the underlying array values to a pyarrow Array
 import pyarrow

 return pyarrow.array(..., type=type)
```

The `ExtensionDtype.__from_arrow__` method then controls the conversion back from `pyarrow` to a pandas `ExtensionArray`. This method receives a `pyarrow Array` or `ChunkedArray` as only argument and is expected to return the appropriate pandas `ExtensionArray` for this dtype and the passed values:

```
class ExtensionDtype:
 ...

 def __from_arrow__(self, array: pyarrow.Array/ChunkedArray) -> ExtensionArray:
 ...
```

See more in the [Arrow documentation](#).

Those methods have been implemented for the nullable integer and string extension dtypes included in pandas, and ensure roundtrip to `pyarrow` and the Parquet file format.

### 4.10.3 Subclassing pandas data structures

**Warning:** There are some easier alternatives before considering subclassing pandas data structures.

1. Extensible method chains with *pipe*
2. Use *composition*. See [here](#).
3. Extending by *registering an accessor*
4. Extending by *extension type*

This section describes how to subclass pandas data structures to meet more specific needs. There are two points that need attention:

1. Override constructor properties.
2. Define original properties

---

**Note:** You can find a nice example in [geopandas](#) project.

---

### Override constructor properties

Each data structure has several *constructor properties* for returning a new data structure as the result of an operation. By overriding these properties, you can retain subclasses through pandas data manipulations.

There are 3 possible constructor properties to be defined on a subclass:

- `DataFrame/Series._constructor`: Used when a manipulation result has the same dimension as the original.
- `DataFrame._constructor_sliced`: Used when a `DataFrame` (sub-)class manipulation result should be a `Series` (sub-)class.
- `Series._constructor_expanddim`: Used when a `Series` (sub-)class manipulation result should be a `DataFrame` (sub-)class, e.g. `Series.to_frame()`.

Below example shows how to define `SubclassedSeries` and `SubclassedDataFrame` overriding constructor properties.

```
class SubclassedSeries(pd.Series):
 @property
 def _constructor(self):
 return SubclassedSeries

 @property
 def _constructor_expanddim(self):
 return SubclassedDataFrame

class SubclassedDataFrame(pd.DataFrame):
 @property
 def _constructor(self):
 return SubclassedDataFrame

 @property
 def _constructor_sliced(self):
 return SubclassedSeries
```

```
>>> s = SubclassedSeries([1, 2, 3])
>>> type(s)
<class '__main__.SubclassedSeries'>

>>> to_framed = s.to_frame()
>>> type(to_framed)
<class '__main__.SubclassedDataFrame'>

>>> df = SubclassedDataFrame({"A": [1, 2, 3], "B": [4, 5, 6], "C": [7, 8, 9]})
>>> df
 A B C
```

(continues on next page)

(continued from previous page)

```

0 1 4 7
1 2 5 8
2 3 6 9

>>> type(df)
<class '__main__.SubclassedDataFrame'>

>>> sliced1 = df[["A", "B"]]
>>> sliced1
 A B
0 1 4
1 2 5
2 3 6

>>> type(sliced1)
<class '__main__.SubclassedDataFrame'>

>>> sliced2 = df["A"]
>>> sliced2
0 1
1 2
2 3
Name: A, dtype: int64

>>> type(sliced2)
<class '__main__.SubclassedSeries'>

```

### Define original properties

To let original data structures have additional properties, you should let pandas know what properties are added. pandas maps unknown properties to data names overriding `__getattr__`. Defining original properties can be done in one of 2 ways:

1. Define `_internal_names` and `_internal_names_set` for temporary properties which WILL NOT be passed to manipulation results.
2. Define `_metadata` for normal properties which will be passed to manipulation results.

Below is an example to define two original properties, “`internal_cache`” as a temporary property and “`added_property`” as a normal property

```

class SubclassedDataFrame2(pd.DataFrame):

 # temporary properties
 _internal_names = pd.DataFrame._internal_names + ["internal_cache"]
 _internal_names_set = set(_internal_names)

 # normal properties
 _metadata = ["added_property"]

 @property
 def _constructor(self):
 return SubclassedDataFrame2

```

```

>>> df = SubclassedDataFrame2({"A": [1, 2, 3], "B": [4, 5, 6], "C": [7, 8, 9]})
>>> df
 A B C
0 1 4 7
1 2 5 8
2 3 6 9

>>> df.internal_cache = "cached"
>>> df.added_property = "property"

>>> df.internal_cache
cached
>>> df.added_property
property

properties defined in _internal_names is reset after manipulation
>>> df[["A", "B"]].internal_cache
AttributeError: 'SubclassedDataFrame2' object has no attribute 'internal_cache'

properties defined in _metadata are retained
>>> df[["A", "B"]].added_property
property

```

#### 4.10.4 Plotting backends

Starting in 0.25 pandas can be extended with third-party plotting backends. The main idea is letting users select a plotting backend different than the provided one based on Matplotlib. For example:

```

>>> pd.set_option("plotting.backend", "backend.module")
>>> pd.Series([1, 2, 3]).plot()

```

This would be more or less equivalent to:

```

>>> import backend.module
>>> backend.module.plot(pd.Series([1, 2, 3]))

```

The backend module can then use other visualization tools (Bokeh, Altair, ...) to generate the plots.

Libraries implementing the plotting backend should use `entry points` to make their backend discoverable to pandas. The key is `"pandas_plotting_backends"`. For example, pandas registers the default “matplotlib” backend as follows.

```

in setup.py
setup(# noqa: F821
 ...,
 entry_points={
 "pandas_plotting_backends": [
 "matplotlib = pandas:plotting._matplotlib",
],
 },
)

```

More information on how to implement a third-party plotting backend can be found at [https://github.com/pandas-dev/pandas/blob/master/pandas/plotting/\\_\\_init\\_\\_.py#L1](https://github.com/pandas-dev/pandas/blob/master/pandas/plotting/__init__.py#L1).

## 4.11 Developer

This section will focus on downstream applications of pandas.

### 4.11.1 Storing pandas DataFrame objects in Apache Parquet format

The [Apache Parquet](#) format provides key-value metadata at the file and column level, stored in the footer of the Parquet file:

```
5: optional list<KeyValue> key_value_metadata
```

where KeyValue is

```
struct KeyValue {
 1: required string key
 2: optional string value
}
```

So that a `pandas.DataFrame` can be faithfully reconstructed, we store a pandas metadata key in the `FileMetaData` with the value stored as :

```
{'index_columns': [<descr0>, <descr1>, ...],
 'column_indexes': [<ci0>, <ci1>, ..., <ciN>],
 'columns': [<c0>, <c1>, ...],
 'pandas_version': $VERSION,
 'creator': {
 'library': $LIBRARY,
 'version': $LIBRARY_VERSION
 }}
```

The “descriptor” values `<descr0>` in the `'index_columns'` field are strings (referring to a column) or dictionaries with values as described below.

The `<c0>/<ci0>` and so forth are dictionaries containing the metadata for each column, *including the index columns*. This has JSON form:

```
{'name': column_name,
 'field_name': parquet_column_name,
 'pandas_type': pandas_type,
 'numpy_type': numpy_type,
 'metadata': metadata}
```

See below for the detailed specification for these.

## Index metadata descriptors

RangeIndex can be stored as metadata only, not requiring serialization. The descriptor format for these as is follows:

```
index = pd.RangeIndex(0, 10, 2)
{
 "kind": "range",
 "name": index.name,
 "start": index.start,
 "stop": index.stop,
 "step": index.step,
}
```

Other index types must be serialized as data columns along with the other DataFrame columns. The metadata for these is a string indicating the name of the field in the data columns, for example `'__index_level_0__'`.

If an index has a non-None name attribute, and there is no other column with a name matching that value, then the `index.name` value can be used as the descriptor. Otherwise (for unnamed indexes and ones with names colliding with other column names) a disambiguating name with pattern matching `__index_level_\d+__` should be used. In cases of named indexes as data columns, `name` attribute is always stored in the column descriptors as above.

## Column metadata

`pandas_type` is the logical type of the column, and is one of:

- Boolean: `'bool'`
- Integers: `'int8'`, `'int16'`, `'int32'`, `'int64'`, `'uint8'`, `'uint16'`, `'uint32'`, `'uint64'`
- Floats: `'float16'`, `'float32'`, `'float64'`
- Date and Time Types: `'datetime'`, `'datetimez'`, `'timedelta'`
- String: `'unicode'`, `'bytes'`
- Categorical: `'categorical'`
- Other Python objects: `'object'`

The `numpy_type` is the physical storage type of the column, which is the result of `str(dtype)` for the underlying NumPy array that holds the data. So for `datetimez` this is `datetime64[ns]` and for `categorical`, it may be any of the supported integer categorical types.

The `metadata` field is `None` except for:

- `datetimez`: `{'timezone': zone, 'unit': 'ns'}`, e.g. `{'timezone': 'America/New_York', 'unit': 'ns'}`. The `'unit'` is optional, and if omitted it is assumed to be nanoseconds.
- `categorical`: `{'num_categories': K, 'ordered': is_ordered, 'type': $TYPE}`
  - Here `'type'` is optional, and can be a nested pandas type specification here (but not categorical)
- `unicode`: `{'encoding': encoding}`
  - The encoding is optional, and if not present is UTF-8
- `object`: `{'encoding': encoding}`. Objects can be serialized and stored in `BYTE_ARRAY` Parquet columns. The encoding can be one of:
  - `'pickle'`
  - `'bson'`

- 'json'

- `timedelta`: {'unit': 'ns'}. The 'unit' is optional, and if omitted it is assumed to be nanoseconds. This metadata is optional altogether

For types other than these, the 'metadata' key can be omitted. Implementations can assume None if the key is not present.

As an example of fully-formed metadata:

```
{'index_columns': ['__index_level_0__'],
 'column_indexes': [
 {'name': None,
 'field_name': 'None',
 'pandas_type': 'unicode',
 'numpy_type': 'object',
 'metadata': {'encoding': 'UTF-8'}}
],
 'columns': [
 {'name': 'c0',
 'field_name': 'c0',
 'pandas_type': 'int8',
 'numpy_type': 'int8',
 'metadata': None},
 {'name': 'c1',
 'field_name': 'c1',
 'pandas_type': 'bytes',
 'numpy_type': 'object',
 'metadata': None},
 {'name': 'c2',
 'field_name': 'c2',
 'pandas_type': 'categorical',
 'numpy_type': 'int16',
 'metadata': {'num_categories': 1000, 'ordered': False}},
 {'name': 'c3',
 'field_name': 'c3',
 'pandas_type': 'datetimez',
 'numpy_type': 'datetime64[ns]',
 'metadata': {'timezone': 'America/Los_Angeles'}},
 {'name': 'c4',
 'field_name': 'c4',
 'pandas_type': 'object',
 'numpy_type': 'object',
 'metadata': {'encoding': 'pickle'}},
 {'name': None,
 'field_name': '__index_level_0__',
 'pandas_type': 'int64',
 'numpy_type': 'int64',
 'metadata': None}
],
 'pandas_version': '0.20.0',
 'creator': {
 'library': 'pyarrow',
 'version': '0.13.0'
 }}
```

## 4.12 Policies

### 4.12.1 Version policy

Changed in version 1.0.0.

pandas uses a loose variant of semantic versioning ([SemVer](#)) to govern deprecations, API compatibility, and version numbering.

A pandas release number is made up of MAJOR.MINOR.PATCH.

API breaking changes should only occur in **major** releases. These changes will be documented, with clear guidance on what is changing, why it's changing, and how to migrate existing code to the new behavior.

Whenever possible, a deprecation path will be provided rather than an outright breaking change.

pandas will introduce deprecations in **minor** releases. These deprecations will preserve the existing behavior while emitting a warning that provide guidance on:

- How to achieve similar behavior if an alternative is available
- The pandas version in which the deprecation will be enforced.

We will not introduce new deprecations in patch releases.

Deprecations will only be enforced in **major** releases. For example, if a behavior is deprecated in pandas 1.2.0, it will continue to work, with a warning, for all releases in the 1.x series. The behavior will change and the deprecation removed in the next major release (2.0.0).

---

**Note:** pandas will sometimes make *behavior changing* bug fixes, as part of minor or patch releases. Whether or not a change is a bug fix or an API-breaking change is a judgement call. We'll do our best, and we invite you to participate in development discussion on the issue tracker or mailing list.

---

These policies do not apply to features marked as **experimental** in the documentation. pandas may change the behavior of experimental features at any time.

### 4.12.2 Python support

pandas will only drop support for specific Python versions (e.g. 3.6.x, 3.7.x) in pandas **major** or **minor** releases.

## 4.13 Roadmap

This page provides an overview of the major themes in pandas' development. Each of these items requires a relatively large amount of effort to implement. These may be achieved more quickly with dedicated funding or interest from contributors.

An item being on the roadmap does not mean that it will *necessarily* happen, even with unlimited funding. During the implementation period we may discover issues preventing the adoption of the feature.

Additionally, an item *not* being on the roadmap does not exclude it from inclusion in pandas. The roadmap is intended for larger, fundamental changes to the project that are likely to take months or years of developer time. Smaller-scoped items will continue to be tracked on our [issue tracker](#).

See [Roadmap evolution](#) for proposing changes to this document.

### 4.13.1 Extensibility

pandas *Extension types* allow for extending NumPy types with custom data types and array storage. pandas uses extension types internally, and provides an interface for 3rd-party libraries to define their own custom data types.

Many parts of pandas still unintentionally convert data to a NumPy array. These problems are especially pronounced for nested data.

We'd like to improve the handling of extension arrays throughout the library, making their behavior more consistent with the handling of NumPy arrays. We'll do this by cleaning up pandas' internals and adding new methods to the extension array interface.

### 4.13.2 String data type

Currently, pandas stores text data in an `object`-dtype NumPy array. The current implementation has two primary drawbacks: First, `object`-dtype is not specific to strings: any Python object can be stored in an `object`-dtype array, not just strings. Second: this is not efficient. The NumPy memory model isn't especially well-suited to variable width text data.

To solve the first issue, we propose a new extension type for string data. This will initially be opt-in, with users explicitly requesting `dtype="string"`. The array backing this string dtype may initially be the current implementation: an `object`-dtype NumPy array of Python strings.

To solve the second issue (performance), we'll explore alternative in-memory array libraries (for example, Apache Arrow). As part of the work, we may need to implement certain operations expected by pandas users (for example the algorithm used in `Series.str.upper`). That work may be done outside of pandas.

### 4.13.3 Consistent missing value handling

Currently, pandas handles missing data differently for different data types. We use different types to indicate that a value is missing (`np.nan` for floating-point data, `np.nan` or `None` for object-dtype data – typically strings or booleans – with missing values, and `pd.NaT` for datetimelike data). Integer data cannot store missing data or are cast to float. In addition, pandas 1.0 introduced a new missing value sentinel, `pd.NA`, which is being used for the experimental nullable integer, boolean, and string data types.

These different missing values have different behaviors in user-facing operations. Specifically, we introduced different semantics for the nullable data types for certain operations (e.g. propagating in comparison operations instead of comparing as `False`).

Long term, we want to introduce consistent missing data handling for all data types. This includes consistent behavior in all operations (indexing, arithmetic operations, comparisons, etc.). There has been discussion of eventually making the new semantics the default.

This has been discussed at [github #28095](#) (and linked issues), and described in more detail in this [design doc](#).

### 4.13.4 Apache Arrow interoperability

[Apache Arrow](#) is a cross-language development platform for in-memory data. The Arrow logical types are closely aligned with typical pandas use cases.

We'd like to provide better-integrated support for Arrow memory and data types within pandas. This will let us take advantage of its I/O capabilities and provide for better interoperability with other languages and libraries using Arrow.

### 4.13.5 Block manager rewrite

We'd like to replace pandas current internal data structures (a collection of 1 or 2-D arrays) with a simpler collection of 1-D arrays.

pandas internal data model is quite complex. A DataFrame is made up of one or more 2-dimensional "blocks", with one or more blocks per dtype. This collection of 2-D arrays is managed by the BlockManager.

The primary benefit of the BlockManager is improved performance on certain operations (construction from a 2D array, binary operations, reductions across the columns), especially for wide DataFrames. However, the BlockManager substantially increases the complexity and maintenance burden of pandas.

By replacing the BlockManager we hope to achieve

- Substantially simpler code
- Easier extensibility with new logical types
- Better user control over memory use and layout
- Improved micro-performance
- Option to provide a C / Cython API to pandas' internals

See [these design documents](#) for more.

### 4.13.6 Decoupling of indexing and internals

The code for getting and setting values in pandas' data structures needs refactoring. In particular, we must clearly separate code that converts keys (e.g., the argument to `DataFrame.loc`) to positions from code that uses these positions to get or set values. This is related to the proposed BlockManager rewrite. Currently, the BlockManager sometimes uses label-based, rather than position-based, indexing. We propose that it should only work with positional indexing, and the translation of keys to positions should be entirely done at a higher level.

Indexing is a complicated API with many subtleties. This refactor will require care and attention. More details are discussed at [https://github.com/pandas-dev/pandas/wiki/\(Tentative\)-rules-for-restructuring-indexing-code](https://github.com/pandas-dev/pandas/wiki/(Tentative)-rules-for-restructuring-indexing-code)

### 4.13.7 Numba-accelerated operations

[Numba](#) is a JIT compiler for Python code. We'd like to provide ways for users to apply their own Numba-jitted functions where pandas accepts user-defined functions (for example, `Series.apply()`, `DataFrame.apply()`, `DataFrame.applymap()`, and in groupby and window contexts). This will improve the performance of user-defined-functions in these operations by staying within compiled code.

### 4.13.8 Performance monitoring

pandas uses [airspeed velocity](#) to monitor for performance regressions. ASV itself is a fabulous tool, but requires some additional work to be integrated into an open source project's workflow.

The [asv-runner](#) organization, currently made up of pandas maintainers, provides tools built on top of ASV. We have a physical machine for running a number of project's benchmarks, and tools managing the benchmark runs and reporting on results.

We'd like to fund improvements and maintenance of these tools to

- Be more stable. Currently, they're maintained on the nights and weekends when a maintainer has free time.

- Tune the system for benchmarks to improve stability, following <https://pyperf.readthedocs.io/en/latest/system.html>
- Build a GitHub bot to request ASV runs *before* a PR is merged. Currently, the benchmarks are only run nightly.

### 4.13.9 Roadmap evolution

pandas continues to evolve. The direction is primarily determined by community interest. Everyone is welcome to review existing items on the roadmap and to propose a new item.

Each item on the roadmap should be a short summary of a larger design proposal. The proposal should include

1. Short summary of the changes, which would be appropriate for inclusion in the roadmap if accepted.
2. Motivation for the changes.
3. An explanation of why the change is in scope for pandas.
4. Detailed design: Preferably with example-usage (even if not implemented yet) and API documentation
5. API Change: Any API changes that may result from the proposal.

That proposal may then be submitted as a GitHub issue, where the pandas maintainers can review and comment on the design. The [pandas mailing list](#) should be notified of the proposal.

When there's agreement that an implementation would be welcome, the roadmap should be updated to include the summary and a link to the discussion issue.

### 4.13.10 Completed items

This section records now completed items from the pandas roadmap.

#### Documentation improvements

We improved the pandas documentation

- The pandas community worked with others to build the [pydata-sphinx-theme](#), which is now used for <https://pandas.pydata.org/docs/> (GH15556).
- *Getting started* contains a number of resources intended for new pandas users coming from a variety of backgrounds (GH26831).

## 4.14 Developer meetings

We hold regular developer meetings on the second Wednesday of each month at 18:00 UTC. These meetings and their minutes are open to the public. All are welcome to join.

### **4.14.1 Minutes**

The minutes of past meetings are available in [this Google Document](#).

### **4.14.2 Calendar**

This calendar shows all the developer meetings.

You can subscribe to this calendar with the following links:

- [iCal](#)
- [Google calendar](#)

Additionally, we'll sometimes have one-off meetings on specific topics. These will be published on the same calendar.

## RELEASE NOTES

This is the list of changes to pandas between each release. For full details, see the [commit logs](#). For install and upgrade instructions, see *Installation*.

### 5.1 Version 1.3

#### 5.1.1 What's new in 1.3.3 (September 12, 2021)

These are the changes in pandas 1.3.3. See *Release notes* for a full changelog including other versions of pandas.

##### Fixed regressions

- Fixed regression in `DataFrame` constructor failing to broadcast for defined `Index` and len one list of `Timestamp` (GH42810)
- Fixed regression in `GroupBy.agg()` incorrectly raising in some cases (GH42390)
- Fixed regression in `GroupBy.apply()` where nan values were dropped even with `dropna=False` (GH43205)
- Fixed regression in `GroupBy.quantile()` which was failing with `pandas.NA` (GH42849)
- Fixed regression in `merge()` where on columns with `ExtensionDtype` or `bool` data types were cast to object in right and outer merge (GH40073)
- Fixed regression in `RangeIndex.where()` and `RangeIndex.putmask()` raising `AssertionError` when result did not represent a `RangeIndex` (GH43240)
- Fixed regression in `read_parquet()` where the `fastparquet` engine would not work properly with `fastparquet 0.7.0` (GH43075)
- Fixed regression in `DataFrame.loc.__setitem__()` raising `ValueError` when setting array as cell value (GH43422)
- Fixed regression in `is_list_like()` where objects with `__iter__` set to `None` would be identified as iterable (GH43373)
- Fixed regression in `DataFrame.__getitem__()` raising error for slice of `DatetimeIndex` when index is non monotonic (GH43223)
- Fixed regression in `Resampler.aggregate()` when used after column selection would raise if `func` is a list of aggregation functions (GH42905)
- Fixed regression in `DataFrame.corr()` where Kendall correlation would produce incorrect results for columns with repeated values (GH43401)

- Fixed regression in `DataFrame.groupby()` where aggregation on columns with object types dropped results on those columns (GH42395, GH43108)
- Fixed regression in `Series.fillna()` raising `TypeError` when filling float Series with list-like fill value having a dtype which couldn't cast lostlessly (like float32 filled with float64) (GH43424)
- Fixed regression in `read_csv()` raising `AttributeError` when the file handle is an `tempfile.SpooledTemporaryFile` object (GH43439)
- Fixed performance regression in `core.window.ewm.ExponentialMovingWindow.mean()` (GH42333)

### Performance improvements

- Performance improvement for `DataFrame.__setitem__()` when the key or value is not a `DataFrame`, or key is not list-like (GH43274)

### Bug fixes

- Fixed bug in `DataFrameGroupBy.agg()` and `DataFrameGroupBy.transform()` with `engine="numba"` where index data was not being correctly passed into `func` (GH43133)

### Contributors

A total of 18 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

## 5.1.2 What's new in 1.3.2 (August 15, 2021)

These are the changes in pandas 1.3.2. See *Release notes* for a full changelog including other versions of pandas.

### Fixed regressions

- Performance regression in `DataFrame.isin()` and `Series.isin()` for nullable data types (GH42714)
- Regression in updating values of `Series` using boolean index, created by using `DataFrame.pop()` (GH42530)
- Regression in `DataFrame.from_records()` with empty records (GH42456)
- Fixed regression in `DataFrame.shift()` where `TypeError` occurred when shifting `DataFrame` created by concatenation of slices and fills with values (GH42719)
- Regression in `DataFrame.agg()` when the `func` argument returned lists and `axis=1` (GH42727)
- Regression in `DataFrame.drop()` does nothing if `MultiIndex` has duplicates and `indexer` is a tuple or list of tuples (GH42771)
- Fixed regression where `read_csv()` raised a `ValueError` when parameters `names` and `prefix` were both set to `None` (GH42387)
- Fixed regression in comparisons between `Timestamp` object and `datetime64` objects outside the implementation bounds for nanosecond `datetime64` (GH42794)
- Fixed regression in `Styler.highlight_min()` and `Styler.highlight_max()` where `pandas.NA` was not successfully ignored (GH42650)
- Fixed regression in `concat()` where `copy=False` was not honored in `axis=1` `Series` concatenation (GH42501)
- Regression in `Series.nlargest()` and `Series.nsmallest()` with nullable integer or float dtype (GH42816)
- Fixed regression in `Series.quantile()` with `Int64Dtype` (GH42626)
- Fixed regression in `Series.groupby()` and `DataFrame.groupby()` where supplying the `by` argument with a `Series` named with a tuple would incorrectly raise (GH42731)

### Bug fixes

- Bug in `read_excel()` modifies the dtypes dictionary when reading a file with duplicate columns (GH42462)
- 1D slices over extension types turn into N-dimensional slices over `ExtensionArrays` (GH42430)
- Fixed bug in `Series.rolling()` and `DataFrame.rolling()` not calculating window bounds correctly for the first row when `center=True` and `window` is an offset that covers all the rows (GH42753)
- `Styler.hide_columns()` now hides the index name header row as well as column headers (GH42101)
- `Styler.set_sticky()` has amended CSS to control the column/index names and ensure the correct sticky positions (GH42537)
- Bug in de-serializing `datetime` indexes in `PYTHONOPTIMIZED` mode (GH42866)

## Contributors

### 5.1.3 What’s new in 1.3.1 (July 25, 2021)

These are the changes in pandas 1.3.1. See *Release notes* for a full changelog including other versions of pandas.

#### Fixed regressions

- Pandas could not be built on PyPy (GH42355)
- *DataFrame* constructed with an older version of pandas could not be unpickled (GH42345)
- Performance regression in constructing a *DataFrame* from a dictionary of dictionaries (GH42248)
- Fixed regression in *DataFrame.agg()* dropping values when the DataFrame had an Extension Array dtype, a duplicate index, and *axis=1* (GH42380)
- Fixed regression in *DataFrame.astype()* changing the order of noncontiguous data (GH42396)
- Performance regression in *DataFrame* in reduction operations requiring casting such as *DataFrame.mean()* on integer data (GH38592)
- Performance regression in *DataFrame.to\_dict()* and *Series.to\_dict()* when *orient* argument one of “records”, “dict”, or “split” (GH42352)
- Fixed regression in indexing with a *list* subclass incorrectly raising *TypeError* (GH42433, GH42461)
- Fixed regression in *DataFrame.isin()* and *Series.isin()* raising *TypeError* with nullable data containing at least one missing value (GH42405)

- Regression in `concat()` between objects with bool dtype and integer dtype casting to object instead of to integer (GH42092)
- Bug in `Series` constructor not accepting a `dask.Array` (GH38645)
- Fixed regression for `SettingWithCopyWarning` displaying incorrect stacklevel (GH42570)
- Fixed regression for `merge_asof()` raising `KeyError` when one of the by columns is in the index (GH34488)
- Fixed regression in `to_datetime()` returning `pd.NaT` for inputs that produce duplicated values, when `cache=True` (GH42259)
- Fixed regression in `SeriesGroupBy.value_counts()` that resulted in an `IndexError` when called on a `Series` with one row (GH42618)

## Bug fixes

- Fixed bug in `DataFrame.transpose()` dropping values when the `DataFrame` had an `Extension Array` dtype and a duplicate index (GH42380)
- Fixed bug in `DataFrame.to_xml()` raising `KeyError` when called with `index=False` and an offset index (GH42458)
- Fixed bug in `Styler.set_sticky()` not handling index names correctly for single index columns case (GH42537)
- Fixed bug in `DataFrame.copy()` failing to consolidate blocks in the result (GH42579)

## Contributors

A total of 17 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

## 5.1.4 What's new in 1.3.0 (July 2, 2021)

These are the changes in pandas 1.3.0. See [Release notes](#) for a full changelog including other versions of pandas.

**Warning:** When reading new Excel 2007+ (.xlsx) files, the default argument `engine=None` to `read_excel()` will now result in using the `openpyxl` engine in all cases when the option `io.excel.xlsx.reader` is set to "auto". Previously, some cases would use the `xlrd` engine instead. See [What's new 1.2.0](#) for background on this change.

### Enhancements

#### Custom HTTP(s) headers when reading csv or json files

When reading from a remote URL that is not handled by fsspec (e.g. HTTP and HTTPS) the dictionary passed to `storage_options` will be used to create the headers included in the request. This can be used to control the User-Agent header or send other custom headers (GH36688). For example:

```
In [1]: headers = {"User-Agent": "pandas"}

In [2]: df = pd.read_csv(
...: "https://download.bls.gov/pub/time.series/cu/cu.item",
...: sep="\t",
...: storage_options=headers
...:)
...:
```

#### Read and write XML documents

We added I/O support to read and render shallow versions of XML documents with `read_xml()` and `DataFrame.to_xml()`. Using `lxml` as parser, both XPath 1.0 and XSLT 1.0 are available. (GH27554)

```
In [1]: xml = """<?xml version='1.0' encoding='utf-8'?>
...: <data>
...: <row>
...: <shape>square</shape>
...: <degrees>360</degrees>
...: <sides>4.0</sides>
...: </row>
...: <row>
...: <shape>circle</shape>
...: <degrees>360</degrees>
...: <sides/>
...: </row>
...: <row>
...: <shape>triangle</shape>
...: <degrees>180</degrees>
...: <sides>3.0</sides>
...: </row>
...: """
```

(continues on next page)

(continued from previous page)

```
...: </data>"""
In [2]: df = pd.read_xml(xml)
In [3]: df
Out[3]:
 shape degrees sides
0 square 360 4.0
1 circle 360 NaN
2 triangle 180 3.0

In [4]: df.to_xml()
Out[4]:
<?xml version='1.0' encoding='utf-8'?>
<data>
 <row>
 <index>0</index>
 <shape>square</shape>
 <degrees>360</degrees>
 <sides>4.0</sides>
 </row>
 <row>
 <index>1</index>
 <shape>circle</shape>
 <degrees>360</degrees>
 <sides/>
 </row>
 <row>
 <index>2</index>
 <shape>triangle</shape>
 <degrees>180</degrees>
 <sides>3.0</sides>
 </row>
</data>
```

For more, see [Writing XML](#) in the user guide on IO tools.

## Styler enhancements

We provided some focused development on *Styler*. See also the *Styler documentation* which has been revised and improved (GH39720, GH39317, GH40493).

- The method *Styler.set\_table\_styles()* can now accept more natural CSS language for arguments, such as `'color:red;'` instead of `[('color', 'red')]` (GH39563)
- The methods *Styler.highlight\_null()*, *Styler.highlight\_min()*, and *Styler.highlight\_max()* now allow custom CSS highlighting instead of the default background coloring (GH40242)
- *Styler.apply()* now accepts functions that return an ndarray when `axis=None`, making it now consistent with the `axis=0` and `axis=1` behavior (GH39359)
- When incorrectly formatted CSS is given via *Styler.apply()* or *Styler.applymap()*, an error is now raised upon rendering (GH39660)

- `Styler.format()` now accepts the keyword argument `escape` for optional HTML and LaTeX escaping (GH40388, GH41619)
- `Styler.background_gradient()` has gained the argument `gmap` to supply a specific gradient map for shading (GH22727)
- `Styler.clear()` now clears `Styler.hidden_index` and `Styler.hidden_columns` as well (GH40484)
- Added the method `Styler.highlight_between()` (GH39821)
- Added the method `Styler.highlight_quantile()` (GH40926)
- Added the method `Styler.text_gradient()` (GH41098)
- Added the method `Styler.set_tooltips()` to allow hover tooltips; this can be used enhance interactive displays (GH21266, GH40284)
- Added the parameter `precision` to the method `Styler.format()` to control the display of floating point numbers (GH40134)
- `Styler` rendered HTML output now follows the [w3 HTML Style Guide](#) (GH39626)
- Many features of the `Styler` class are now either partially or fully usable on a `DataFrame` with a non-unique indexes or columns (GH41143)
- One has greater control of the display through separate sparsification of the index or columns using the *new styler options*, which are also usable via `option_context()` (GH41142)
- Added the option `styler.render.max_elements` to avoid browser overload when styling large `DataFrames` (GH40712)
- Added the method `Styler.to_latex()` (GH21673, GH42320), which also allows some limited CSS conversion (GH40731)
- Added the method `Styler.to_html()` (GH13379)
- Added the method `Styler.set_sticky()` to make index and column headers permanently visible in scrolling HTML frames (GH29072)

### DataFrame constructor honors `copy=False` with dict

When passing a dictionary to `DataFrame` with `copy=False`, a copy will no longer be made (GH32960).

```
In [3]: arr = np.array([1, 2, 3])
In [4]: df = pd.DataFrame({"A": arr, "B": arr.copy()}, copy=False)
In [5]: df
Out[5]:
 A B
0 1 1
1 2 2
2 3 3
```

`df["A"]` remains a view on `arr`:

```
In [6]: arr[0] = 0
In [7]: assert df.iloc[0, 0] == 0
```

The default behavior when not passing copy will remain unchanged, i.e. a copy will be made.

## PyArrow backed string data type

We've enhanced the *StringDtype*, an extension type dedicated to string data. (GH39908)

It is now possible to specify a storage keyword option to *StringDtype*. Use pandas options or specify the dtype using `dtype='string[pyarrow]'` to allow the *StringArray* to be backed by a PyArrow array instead of a NumPy array of Python objects.

The PyArrow backed *StringArray* requires pyarrow 1.0.0 or greater to be installed.

**Warning:** `string[pyarrow]` is currently considered experimental. The implementation and parts of the API may change without warning.

```
In [8]: pd.Series(['abc', None, 'def'], dtype=pd.StringDtype(storage="pyarrow"))
Out[8]:
0 abc
1 <NA>
2 def
dtype: string
```

You can use the alias `"string[pyarrow]"` as well.

```
In [9]: s = pd.Series(['abc', None, 'def'], dtype="string[pyarrow]")

In [10]: s
Out[10]:
0 abc
1 <NA>
2 def
dtype: string
```

You can also create a PyArrow backed string array using pandas options.

```
In [11]: with pd.option_context("string_storage", "pyarrow"):
.....: s = pd.Series(['abc', None, 'def'], dtype="string")
.....:

In [12]: s
Out[12]:
0 abc
1 <NA>
2 def
dtype: string
```

The usual string accessor methods work. Where appropriate, the return type of the Series or columns of a DataFrame will also have string dtype.

```
In [13]: s.str.upper()
Out[13]:
0 ABC
```

(continues on next page)

(continued from previous page)

```
1 <NA>
2 DEF
dtype: string

In [14]: s.str.split('b', expand=True).dtypes
Out[14]:
0 string
1 string
dtype: object
```

String accessor methods returning integers will return a value with *Int64Dtype*

```
In [15]: s.str.count("a")
Out[15]:
0 1
1 <NA>
2 0
dtype: Int64
```

### Centered datetime-like rolling windows

When performing rolling calculations on DataFrame and Series objects with a datetime-like index, a centered datetime-like window can now be used ([GH38780](#)). For example:

```
In [16]: df = pd.DataFrame(
.....: {"A": [0, 1, 2, 3, 4]}, index=pd.date_range("2020", periods=5, freq="1D")
.....:)
.....:

In [17]: df
Out[17]:
 A
2020-01-01 0
2020-01-02 1
2020-01-03 2
2020-01-04 3
2020-01-05 4

In [18]: df.rolling("2D", center=True).mean()
Out[18]:
 A
2020-01-01 0.5
2020-01-02 1.5
2020-01-03 2.5
2020-01-04 3.5
2020-01-05 4.0
```

## Other enhancements

- `DataFrame.rolling()`, `Series.rolling()`, `DataFrame.expanding()`, and `Series.expanding()` now support a `method` argument with a `'table'` option that performs the windowing operation over an entire `DataFrame`. See [Window Overview](#) for performance and functional benefits (GH15095, GH38995)
- `ExponentialMovingWindow` now support a `online` method that can perform mean calculations in an online fashion. See [Window Overview](#) (GH41673)
- Added `MultiIndex.dtypes()` (GH37062)
- Added `end` and `end_day` options for the `origin` argument in `DataFrame.resample()` (GH37804)
- Improved error message when `usecols` and `names` do not match for `read_csv()` and `engine="c"` (GH29042)
- Improved consistency of error messages when passing an invalid `win_type` argument in [Window methods](#) (GH15969)
- `read_sql_query()` now accepts a `dtype` argument to cast the columnar data from the SQL database based on user input (GH10285)
- `read_csv()` now raising `ParserWarning` if length of header or given names does not match length of data when `usecols` is not specified (GH21768)
- Improved integer type mapping from pandas to SQLAlchemy when using `DataFrame.to_sql()` (GH35076)
- `to_numeric()` now supports downcasting of nullable `ExtensionDtype` objects (GH33013)
- Added support for dict-like names in `MultiIndex.set_names` and `MultiIndex.rename` (GH20421)
- `read_excel()` can now auto-detect `.xlsb` files and older `.xls` files (GH35416, GH41225)
- `ExcelWriter` now accepts an `if_sheet_exists` parameter to control the behavior of `append` mode when writing to existing sheets (GH40230)
- `Rolling.sum()`, `Expanding.sum()`, `Rolling.mean()`, `Expanding.mean()`, `ExponentialMovingWindow.mean()`, `Rolling.median()`, `Expanding.median()`, `Rolling.max()`, `Expanding.max()`, `Rolling.min()`, and `Expanding.min()` now support Numba execution with the `engine` keyword (GH38895, GH41267)
- `DataFrame.apply()` can now accept NumPy unary operators as strings, e.g. `df.apply("sqrt")`, which was already the case for `Series.apply()` (GH39116)
- `DataFrame.apply()` can now accept non-callable `DataFrame` properties as strings, e.g. `df.apply("size")`, which was already the case for `Series.apply()` (GH39116)
- `DataFrame.applymap()` can now accept `kwargs` to pass on to the user-provided `func` (GH39987)
- Passing a `DataFrame` indexer to `iloc` is now disallowed for `Series.__getitem__()` and `DataFrame.__getitem__()` (GH39004)
- `Series.apply()` can now accept list-like or dictionary-like arguments that aren't lists or dictionaries, e.g. `ser.apply(np.array(["sum", "mean"]))`, which was already the case for `DataFrame.apply()` (GH39140)
- `DataFrame.plot.scatter()` can now accept a categorical column for the argument `c` (GH12380, GH31357)
- `Series.loc()` now raises a helpful error message when the `Series` has a `MultiIndex` and the indexer has too many dimensions (GH35349)
- `read_stata()` now supports reading data from compressed files (GH26599)
- Added support for parsing ISO 8601-like timestamps with negative signs to `Timedelta` (GH37172)
- Added support for unary operators in `FloatingArray` (GH38749)

- `RangeIndex` can now be constructed by passing a range object directly e.g. `pd.RangeIndex(range(3))` (GH12067)
- `Series.round()` and `DataFrame.round()` now work with nullable integer and floating dtypes (GH38844)
- `read_csv()` and `read_json()` expose the argument `encoding_errors` to control how encoding errors are handled (GH39450)
- `GroupBy.any()` and `GroupBy.all()` use Kleene logic with nullable data types (GH37506)
- `GroupBy.any()` and `GroupBy.all()` return a `BooleanDtype` for columns with nullable data types (GH33449)
- `GroupBy.any()` and `GroupBy.all()` raising with object data containing `pd.NA` even when `skipna=True` (GH37501)
- `GroupBy.rank()` now supports object-dtype data (GH38278)
- Constructing a `DataFrame` or `Series` with the data argument being a Python iterable that is *not* a NumPy ndarray consisting of NumPy scalars will now result in a dtype with a precision the maximum of the NumPy scalars; this was already the case when data is a NumPy ndarray (GH40908)
- Add keyword `sort` to `pivot_table()` to allow non-sorting of the result (GH39143)
- Add keyword `dropna` to `DataFrame.value_counts()` to allow counting rows that include NA values (GH41325)
- `Series.replace()` will now cast results to `PeriodDtype` where possible instead of object dtype (GH41526)
- Improved error message in `corr` and `cov` methods on `Rolling`, `Expanding`, and `ExponentialMovingWindow` when other is not a `DataFrame` or `Series` (GH41741)
- `Series.between()` can now accept `left` or `right` as arguments to `inclusive` to include only the left or right boundary (GH40245)
- `DataFrame.explode()` now supports exploding multiple columns. Its `column` argument now also accepts a list of str or tuples for exploding on multiple columns at the same time (GH39240)
- `DataFrame.sample()` now accepts the `ignore_index` argument to reset the index after sampling, similar to `DataFrame.drop_duplicates()` and `DataFrame.sort_values()` (GH38581)

## Notable bug fixes

These are bug fixes that might have notable behavior changes.

### Categorical.unique now always maintains same dtype as original

Previously, when calling `Categorical.unique()` with categorical data, unused categories in the new array would be removed, making the dtype of the new array different than the original (GH18291)

As an example of this, given:

```
In [19]: dtype = pd.CategoricalDtype(['bad', 'neutral', 'good'], ordered=True)
In [20]: cat = pd.Categorical(['good', 'good', 'bad', 'bad'], dtype=dtype)
In [21]: original = pd.Series(cat)
In [22]: unique = original.unique()
```

*Previous behavior:*

```
In [1]: unique
['good', 'bad']
Categories (2, object): ['bad' < 'good']
In [2]: original.dtype == unique.dtype
False
```

*New behavior:*

```
In [23]: unique
Out[23]:
['good', 'bad']
Categories (3, object): ['bad' < 'neutral' < 'good']

In [24]: original.dtype == unique.dtype
Out[24]: True
```

### Preserve dtypes in DataFrame.combine\_first()

*DataFrame.combine\_first()* will now preserve dtypes (GH7509)

```
In [25]: df1 = pd.DataFrame({"A": [1, 2, 3], "B": [1, 2, 3]}, index=[0, 1, 2])

In [26]: df1
Out[26]:
 A B
0 1 1
1 2 2
2 3 3

In [27]: df2 = pd.DataFrame({"B": [4, 5, 6], "C": [1, 2, 3]}, index=[2, 3, 4])

In [28]: df2
Out[28]:
 B C
2 4 1
3 5 2
4 6 3

In [29]: combined = df1.combine_first(df2)
```

*Previous behavior:*

```
In [1]: combined.dtypes
Out[2]:
A float64
B float64
C float64
dtype: object
```

*New behavior:*

```
In [30]: combined.dtypes
```

```
Out[30]:
```

```
A float64
B int64
C float64
dtype: object
```

### Groupby methods agg and transform no longer changes return dtype for callables

Previously the methods `DataFrameGroupBy.aggregate()`, `SeriesGroupBy.aggregate()`, `DataFrameGroupBy.transform()`, and `SeriesGroupBy.transform()` might cast the result dtype when the argument `func` is callable, possibly leading to undesirable results (GH21240). The cast would occur if the result is numeric and casting back to the input dtype does not change any values as measured by `np.allclose`. Now no such casting occurs.

```
In [31]: df = pd.DataFrame({'key': [1, 1], 'a': [True, False], 'b': [True, True]})
```

```
In [32]: df
```

```
Out[32]:
```

```
 key a b
0 1 True True
1 1 False True
```

*Previous behavior:*

```
In [5]: df.groupby('key').agg(lambda x: x.sum())
```

```
Out[5]:
```

```
 a b
key
1 True 2
```

*New behavior:*

```
In [33]: df.groupby('key').agg(lambda x: x.sum())
```

```
Out[33]:
```

```
 a b
key
1 1 2
```

### float result for GroupBy.mean(), GroupBy.median(), and GroupBy.var()

Previously, these methods could result in different dtypes depending on the input values. Now, these methods will always return a float dtype. (GH41137)

```
In [34]: df = pd.DataFrame({'a': [True], 'b': [1], 'c': [1.0]})
```

*Previous behavior:*

```
In [5]: df.groupby(df.index).mean()
```

```
Out[5]:
```

```
 a b c
0 True 1 1.0
```

*New behavior:*

```
In [35]: df.groupby(df.index).mean()
Out[35]:
 a b c
0 1.0 1.0 1.0
```

### Try operating inplace when setting values with loc and iloc

When setting an entire column using `loc` or `iloc`, pandas will try to insert the values into the existing data rather than create an entirely new array.

```
In [36]: df = pd.DataFrame(range(3), columns=["A"], dtype="float64")
In [37]: values = df.values
In [38]: new = np.array([5, 6, 7], dtype="int64")
In [39]: df.loc[[0, 1, 2], "A"] = new
```

In both the new and old behavior, the data in `values` is overwritten, but in the old behavior the dtype of `df["A"]` changed to `int64`.

*Previous behavior:*

```
In [1]: df.dtypes
Out[1]:
A int64
dtype: object
In [2]: np.shares_memory(df["A"].values, new)
Out[2]: False
In [3]: np.shares_memory(df["A"].values, values)
Out[3]: False
```

In pandas 1.3.0, `df` continues to share data with `values`

*New behavior:*

```
In [40]: df.dtypes
Out[40]:
A float64
dtype: object

In [41]: np.shares_memory(df["A"], new)
Out[41]: False

In [42]: np.shares_memory(df["A"], values)
Out[42]: True
```

### Never operate inplace when setting `frame[keys] = values`

When setting multiple columns using `frame[keys] = values` new arrays will replace pre-existing arrays for these keys, which will *not* be over-written (GH39510). As a result, the columns will retain the dtype(s) of values, never casting to the dtypes of the existing arrays.

```
In [43]: df = pd.DataFrame(range(3), columns=["A"], dtype="float64")
In [44]: df[["A"]] = 5
```

In the old behavior, 5 was cast to float64 and inserted into the existing array backing df:

*Previous behavior:*

```
In [1]: df.dtypes
Out[1]:
A float64
```

In the new behavior, we get a new array, and retain an integer-dtyped 5:

*New behavior:*

```
In [45]: df.dtypes
Out[45]:
A int64
dtype: object
```

### Consistent casting with setting into Boolean Series

Setting non-boolean values into a *Series* with `dtype=bool` now consistently casts to `dtype=object` (GH38709)

```
In [46]: orig = pd.Series([True, False])
In [47]: ser = orig.copy()
In [48]: ser.iloc[1] = np.nan
In [49]: ser2 = orig.copy()
In [50]: ser2.iloc[1] = 2.0
```

*Previous behavior:*

```
In [1]: ser
Out [1]:
0 1.0
1 NaN
dtype: float64

In [2]: ser2
Out [2]:
0 True
1 2.0
dtype: object
```

*New behavior:*

```
In [51]: ser
Out[51]:
0 True
1 NaN
dtype: object

In [52]: ser2
Out[52]:
0 True
1 2.0
dtype: object
```

### GroupBy.rolling no longer returns grouped-by column in values

The group-by column will now be dropped from the result of a `groupby.rolling` operation ([GH32262](#))

```
In [53]: df = pd.DataFrame({"A": [1, 1, 2, 3], "B": [0, 1, 2, 3]})

In [54]: df
Out[54]:
 A B
0 1 0
1 1 1
2 2 2
3 3 3
```

*Previous behavior:*

```
In [1]: df.groupby("A").rolling(2).sum()
Out[1]:
 A B
A
1 0 NaN NaN
1 2.0 1.0
2 2 NaN NaN
3 3 NaN NaN
```

*New behavior:*

```
In [55]: df.groupby("A").rolling(2).sum()
Out[55]:
 B
A
1 0 NaN
 1 1.0
2 2 NaN
3 3 NaN
```

### Removed artificial truncation in rolling variance and standard deviation

`Rolling.std()` and `Rolling.var()` will no longer artificially truncate results that are less than  $\sim 1e-8$  and  $\sim 1e-15$  respectively to zero (GH37051, GH40448, GH39872).

However, floating point artifacts may now exist in the results when rolling over larger values.

```
In [56]: s = pd.Series([7, 5, 5, 5])
```

```
In [57]: s.rolling(3).var()
```

```
Out[57]:
```

```
0 NaN
1 NaN
2 1.333333e+00
3 4.440892e-16
dtype: float64
```

### GroupBy.rolling with MultiIndex no longer drops levels in the result

`GroupBy.rolling()` will no longer drop levels of a `DataFrame` with a `MultiIndex` in the result. This can lead to a perceived duplication of levels in the resulting `MultiIndex`, but this change restores the behavior that was present in version 1.1.3 (GH38787, GH38523).

```
In [58]: index = pd.MultiIndex.from_tuples([('idx1', 'idx2')], names=['label1', 'label2
→'])
```

```
In [59]: df = pd.DataFrame({'a': [1], 'b': [2]}, index=index)
```

```
In [60]: df
```

```
Out[60]:
```

```
 a b
label1 label2
idx1 idx2 1 2
```

*Previous behavior:*

```
In [1]: df.groupby('label1').rolling(1).sum()
```

```
Out[1]:
```

```
 a b
label1
idx1 1.0 2.0
```

*New behavior:*

```
In [61]: df.groupby('label1').rolling(1).sum()
```

```
Out[61]:
```

```
 a b
label1 label1 label2
idx1 idx1 idx2 1.0 2.0
```

## Backwards incompatible API changes

### Increased minimum versions for dependencies

Some minimum supported versions of dependencies were updated. If installed, we now require:

| Package         | Minimum Version | Required | Changed |
|-----------------|-----------------|----------|---------|
| numpy           | 1.17.3          | X        | X       |
| pytz            | 2017.3          | X        |         |
| python-dateutil | 2.7.3           | X        |         |
| bottleneck      | 1.2.1           |          |         |
| numexpr         | 2.7.0           |          | X       |
| pytest (dev)    | 6.0             |          | X       |
| mypy (dev)      | 0.812           |          | X       |
| setuptools      | 38.6.0          |          | X       |

For [optional libraries](#) the general recommendation is to use the latest version. The following table lists the lowest version per library that is currently being tested throughout the development of pandas. Optional libraries below the lowest tested version may still work, but are not considered supported.

| Package        | Minimum Version | Changed |
|----------------|-----------------|---------|
| beautifulsoup4 | 4.6.0           |         |
| fastparquet    | 0.4.0           | X       |
| fsspec         | 0.7.4           |         |
| gcsfs          | 0.6.0           |         |
| lxml           | 4.3.0           |         |
| matplotlib     | 2.2.3           |         |
| numba          | 0.46.0          |         |
| openpyxl       | 3.0.0           | X       |
| pyarrow        | 0.17.0          | X       |
| pymysql        | 0.8.1           | X       |
| pytables       | 3.5.1           |         |
| s3fs           | 0.4.0           |         |
| scipy          | 1.2.0           |         |
| sqlalchemy     | 1.3.0           | X       |
| tabulate       | 0.8.7           | X       |
| xarray         | 0.12.0          |         |
| xlrd           | 1.2.0           |         |
| xlsxwriter     | 1.0.2           |         |
| xlwt           | 1.3.0           |         |
| pandas-gbq     | 0.12.0          |         |

See [Dependencies](#) and [Optional dependencies](#) for more.

## Other API changes

- Partially initialized `CategoricalDtype` objects (i.e. those with `categories=None`) will no longer compare as equal to fully initialized dtype objects (GH38516)
- Accessing `_constructor_expanddim` on a `DataFrame` and `_constructor_sliced` on a `Series` now raise an `AttributeError`. Previously a `NotImplementedError` was raised (GH38782)
- Added new engine and `**engine_kwargs` parameters to `DataFrame.to_sql()` to support other future “SQL engines”. Currently we still only use SQLAlchemy under the hood, but more engines are planned to be supported such as `turbodbc` (GH36893)
- Removed redundant `freq` from `PeriodIndex` string representation (GH41653)
- `ExtensionDtype.construct_array_type()` is now a required method instead of an optional one for `ExtensionDtype` subclasses (GH24860)
- Calling `hash` on non-hashable pandas objects will now raise `TypeError` with the built-in error message (e.g. `unhashable type: 'Series'`). Previously it would raise a custom message such as `'Series' objects are mutable, thus they cannot be hashed`. Furthermore, `isinstance(<Series>, abc.collections.Hashable)` will now return `False` (GH40013)
- `Styler.from_custom_template()` now has two new arguments for template names, and removed the old name, due to template inheritance having been introducing for better parsing (GH42053). Subclassing modifications to `Styler` attributes are also needed.

## Build

- Documentation in `.pptx` and `.pdf` formats are no longer included in wheels or source distributions. (GH30741)

## Deprecations

### Deprecated dropping nuisance columns in `DataFrame` reductions and `DataFrameGroupBy` operations

Calling a reduction (e.g. `.min`, `.max`, `.sum`) on a `DataFrame` with `numeric_only=None` (the default), columns where the reduction raises a `TypeError` are silently ignored and dropped from the result.

This behavior is deprecated. In a future version, the `TypeError` will be raised, and users will need to select only valid columns before calling the function.

For example:

```
In [62]: df = pd.DataFrame({"A": [1, 2, 3, 4], "B": pd.date_range("2016-01-01",
↳ periods=4)})
```

```
In [63]: df
```

```
Out[63]:
 A B
0 1 2016-01-01
1 2 2016-01-02
2 3 2016-01-03
3 4 2016-01-04
```

*Old behavior:*

```
In [3]: df.prod()
Out[3]:
Out[3]:
A 24
dtype: int64
```

*Future behavior:*

```
In [4]: df.prod()
...
TypeError: 'DatetimeArray' does not implement reduction 'prod'

In [5]: df[["A"]].prod()
Out[5]:
A 24
dtype: int64
```

Similarly, when applying a function to `DataFrameGroupBy`, columns on which the function raises `TypeError` are currently silently ignored and dropped from the result.

This behavior is deprecated. In a future version, the `TypeError` will be raised, and users will need to select only valid columns before calling the function.

For example:

```
In [64]: df = pd.DataFrame({"A": [1, 2, 3, 4], "B": pd.date_range("2016-01-01",
↳ periods=4)})

In [65]: gb = df.groupby([1, 1, 2, 2])
```

*Old behavior:*

```
In [4]: gb.prod(numeric_only=False)
Out[4]:
A
1 2
2 12
```

*Future behavior:*

```
In [5]: gb.prod(numeric_only=False)
...
TypeError: datetime64 type does not support prod operations

In [6]: gb[["A"]].prod(numeric_only=False)
Out[6]:
A
1 2
2 12
```

## Other Deprecations

- Deprecated allowing scalars to be passed to the *Categorical* constructor (GH38433)
- Deprecated constructing *CategoricalIndex* without passing list-like data (GH38944)
- Deprecated allowing subclass-specific keyword arguments in the *Index* constructor, use the specific subclass directly instead (GH14093, GH21311, GH22315, GH26974)
- Deprecated the *astype()* method of datetimelike (*timedelta64[ns]*, *datetime64[ns]*, *Datetime64TZDtype*, *PeriodDtype*) to convert to integer dtypes, use *values.view(...)* instead (GH38544)
- Deprecated *MultiIndex.is\_lexsorted()* and *MultiIndex.lexsort\_depth()*, use *MultiIndex.is\_monotonic\_increasing()* instead (GH32259)
- Deprecated keyword *try\_cast* in *Series.where()*, *Series.mask()*, *DataFrame.where()*, *DataFrame.mask()*; cast results manually if desired (GH38836)
- Deprecated comparison of *Timestamp* objects with *datetime.date* objects. Instead of e.g. *ts <= mydate* use *ts <= pd.Timestamp(mydate)* or *ts.date() <= mydate* (GH36131)
- Deprecated *Rolling.win\_type* returning "freq" (GH38963)
- Deprecated *Rolling.is\_datetimelike* (GH38963)
- Deprecated *DataFrame* indexer for *Series.\_\_setitem\_\_()* and *DataFrame.\_\_setitem\_\_()* (GH39004)
- Deprecated *ExponentialMovingWindow.vol()* (GH39220)
- Using *.astype* to convert between *datetime64[ns]* dtype and *DatetimeTZDtype* is deprecated and will raise in a future version, use *obj.tz\_localize* or *obj.dt.tz\_localize* instead (GH38622)
- Deprecated casting *datetime.date* objects to *datetime64* when used as *fill\_value* in *DataFrame.unstack()*, *DataFrame.shift()*, *Series.shift()*, and *DataFrame.reindex()*, pass *pd.Timestamp(dateobj)* instead (GH39767)
- Deprecated *Styler.set\_na\_rep()* and *Styler.set\_precision()* in favor of *Styler.format()* with *na\_rep* and *precision* as existing and new input arguments respectively (GH40134, GH40425)
- Deprecated *Styler.where()* in favor of using an alternative formulation with *Styler.applymap()* (GH40821)
- Deprecated allowing partial failure in *Series.transform()* and *DataFrame.transform()* when *func* is list-like or dict-like and raises anything but *TypeError*; *func* raising anything but a *TypeError* will raise in a future version (GH40211)
- Deprecated arguments *error\_bad\_lines* and *warn\_bad\_lines* in *read\_csv()* and *read\_table()* in favor of argument *on\_bad\_lines* (GH15122)
- Deprecated support for *np.ma.mrecords.MaskedRecords* in the *DataFrame* constructor, pass *{name: data[name] for name in data.dtypes.names}* instead (GH40363)
- Deprecated using *merge()*, *DataFrame.merge()*, and *DataFrame.join()* on a different number of levels (GH34862)
- Deprecated the use of *\*\*kwargs* in *ExcelWriter*; use the keyword argument *engine\_kwargs* instead (GH40430)
- Deprecated the *level* keyword for *DataFrame* and *Series* aggregations; use *groupby* instead (GH39983)
- Deprecated the *inplace* parameter of *Categorical.remove\_categories()*, *Categorical.add\_categories()*, *Categorical.reorder\_categories()*, *Categorical.rename\_categories()*, *Categorical.set\_categories()* and will be removed in a future version (GH37643)

- Deprecated `merge()` producing duplicated columns through the `suffixes` keyword and already existing columns (GH22818)
- Deprecated setting `Categorical._codes`, create a new `Categorical` with the desired codes instead (GH40606)
- Deprecated the `convert_float` optional argument in `read_excel()` and `ExcelFile.parse()` (GH41127)
- Deprecated behavior of `DatetimeIndex.union()` with mixed timezones; in a future version both will be cast to UTC instead of object dtype (GH39328)
- Deprecated using `usecols` with out of bounds indices for `read_csv()` with `engine="c"` (GH25623)
- Deprecated special treatment of lists with first element a `Categorical` in the `DataFrame` constructor; pass as `pd.DataFrame({col: categorical, ...})` instead (GH38845)
- Deprecated behavior of `DataFrame` constructor when a `dtype` is passed and the data cannot be cast to that dtype. In a future version, this will raise instead of being silently ignored (GH24435)
- Deprecated the `Timestamp.freq` attribute. For the properties that use it (`is_month_start`, `is_month_end`, `is_quarter_start`, `is_quarter_end`, `is_year_start`, `is_year_end`), when you have a `freq`, use e.g. `freq.is_month_start(ts)` (GH15146)
- Deprecated construction of `Series` or `DataFrame` with `DatetimeTZDtype` data and `datetime64[ns]` dtype. Use `Series(data).dt.tz_localize(None)` instead (GH41555, GH33401)
- Deprecated behavior of `Series` construction with large-integer values and small-integer dtype silently overflowing; use `Series(data).astype(dtype)` instead (GH41734)
- Deprecated behavior of `DataFrame` construction with floating data and integer dtype casting even when lossy; in a future version this will remain floating, matching `Series` behavior (GH41770)
- Deprecated inference of `timedelta64[ns]`, `datetime64[ns]`, or `DatetimeTZDtype` dtypes in `Series` construction when data containing strings is passed and no `dtype` is passed (GH33558)
- In a future version, constructing `Series` or `DataFrame` with `datetime64[ns]` data and `DatetimeTZDtype` will treat the data as wall-times instead of as UTC times (matching `DatetimeIndex` behavior). To treat the data as UTC times, use `pd.Series(data).dt.tz_localize("UTC").dt.tz_convert(dtype.tz)` or `pd.Series(data.view("int64"), dtype=dtype)` (GH33401)
- Deprecated passing lists as key to `DataFrame.xs()` and `Series.xs()` (GH41760)
- Deprecated boolean arguments of `inclusive` in `Series.between()` to have {"left", "right", "neither", "both"} as standard argument values (GH40628)
- Deprecated passing arguments as positional for all of the following, with exceptions noted (GH41485):
  - `concat()` (other than objs)
  - `read_csv()` (other than `filepath_or_buffer`)
  - `read_table()` (other than `filepath_or_buffer`)
  - `DataFrame.clip()` and `Series.clip()` (other than upper and lower)
  - `DataFrame.drop_duplicates()` (except for `subset`), `Series.drop_duplicates()`, `Index.drop_duplicates()` and `MultiIndex.drop_duplicates()`
  - `DataFrame.drop()` (other than labels) and `Series.drop()`
  - `DataFrame.dropna()` and `Series.dropna()`
  - `DataFrame.ffill()`, `Series.ffill()`, `DataFrame.bfill()`, and `Series.bfill()`
  - `DataFrame.fillna()` and `Series.fillna()` (apart from value)

- `DataFrame.interpolate()` and `Series.interpolate()` (other than method)
- `DataFrame.mask()` and `Series.mask()` (other than cond and other)
- `DataFrame.reset_index()` (other than level) and `Series.reset_index()`
- `DataFrame.set_axis()` and `Series.set_axis()` (other than labels)
- `DataFrame.set_index()` (other than keys)
- `DataFrame.sort_index()` and `Series.sort_index()`
- `DataFrame.sort_values()` (other than by) and `Series.sort_values()`
- `DataFrame.where()` and `Series.where()` (other than cond and other)
- `Index.set_names()` and `MultiIndex.set_names()` (except for names)
- `MultiIndex.codes()` (except for codes)
- `MultiIndex.set_levels()` (except for levels)
- `Resampler.interpolate()` (other than method)

## Performance improvements

- Performance improvement in `IntervalIndex.isin()` (GH38353)
- Performance improvement in `Series.mean()` for nullable data types (GH34814)
- Performance improvement in `Series.isin()` for nullable data types (GH38340)
- Performance improvement in `DataFrame.fillna()` with `method="pad"` or `method="backfill"` for nullable floating and nullable integer dtypes (GH39953)
- Performance improvement in `DataFrame.corr()` for `method=kendall` (GH28329)
- Performance improvement in `DataFrame.corr()` for `method=spearman` (GH40956, GH41885)
- Performance improvement in `Rolling.corr()` and `Rolling.cov()` (GH39388)
- Performance improvement in `RollingGroupby.corr()`, `ExpandingGroupby.corr()`, `ExpandingGroupby.corr()` and `ExpandingGroupby.cov()` (GH39591)
- Performance improvement in `unique()` for object data type (GH37615)
- Performance improvement in `json_normalize()` for basic cases (including separators) (GH40035 GH15621)
- Performance improvement in `ExpandingGroupby` aggregation methods (GH39664)
- Performance improvement in `Styler` where render times are more than 50% reduced and now matches `DataFrame.to_html()` (GH39972 GH39952, GH40425)
- The method `Styler.set_td_classes()` is now as performant as `Styler.apply()` and `Styler.applymap()`, and even more so in some cases (GH40453)
- Performance improvement in `ExponentialMovingWindow.mean()` with `times` (GH39784)
- Performance improvement in `GroupBy.apply()` when requiring the Python fallback implementation (GH40176)
- Performance improvement in the conversion of a PyArrow Boolean array to a pandas nullable Boolean array (GH41051)
- Performance improvement for concatenation of data with type `CategoricalDtype` (GH40193)
- Performance improvement in `GroupBy.cummin()` and `GroupBy.cummax()` with nullable data types (GH37493)

- Performance improvement in `Series.nunique()` with nan values (GH40865)
- Performance improvement in `DataFrame.transpose()`, `Series.unstack()` with `DatetimeTZDtype` (GH40149)
- Performance improvement in `Series.plot()` and `DataFrame.plot()` with entry point lazy loading (GH41492)

## Bug fixes

### Categorical

- Bug in `CategoricalIndex` incorrectly failing to raise `TypeError` when scalar data is passed (GH38614)
- Bug in `CategoricalIndex.reindex` failed when the `Index` passed was not categorical but whose values were all labels in the category (GH28690)
- Bug where constructing a `Categorical` from an object-dtype array of date objects did not round-trip correctly with `astype` (GH38552)
- Bug in constructing a `DataFrame` from an `ndarray` and a `CategoricalDtype` (GH38857)
- Bug in setting categorical values into an object-dtype column in a `DataFrame` (GH39136)
- Bug in `DataFrame.reindex()` was raising an `IndexError` when the new index contained duplicates and the old index was a `CategoricalIndex` (GH38906)
- Bug in `Categorical.fillna()` with a tuple-like category raising `NotImplementedError` instead of `ValueError` when filling with a non-category tuple (GH41914)

### Datetimelike

- Bug in `DataFrame` and `Series` constructors sometimes dropping nanoseconds from `Timestamp` (resp. `Timedelta`) data, with `dtype=datetime64[ns]` (resp. `timedelta64[ns]`) (GH38032)
- Bug in `DataFrame.first()` and `Series.first()` with an offset of one month returning an incorrect result when the first day is the last day of a month (GH29623)
- Bug in constructing a `DataFrame` or `Series` with mismatched `datetime64` data and `timedelta64` dtype, or vice-versa, failing to raise a `TypeError` (GH38575, GH38764, GH38792)
- Bug in constructing a `Series` or `DataFrame` with a `datetime` object out of bounds for `datetime64[ns]` dtype or a `timedelta` object out of bounds for `timedelta64[ns]` dtype (GH38792, GH38965)
- Bug in `DatetimeIndex.intersection()`, `DatetimeIndex.symmetric_difference()`, `PeriodIndex.intersection()`, `PeriodIndex.symmetric_difference()` always returning object-dtype when operating with `CategoricalIndex` (GH38741)
- Bug in `DatetimeIndex.intersection()` giving incorrect results with non-Tick frequencies with `n != 1` (GH42104)
- Bug in `Series.where()` incorrectly casting `datetime64` values to `int64` (GH37682)
- Bug in `Categorical` incorrectly typecasting `datetime` object to `Timestamp` (GH38878)
- Bug in comparisons between `Timestamp` object and `datetime64` objects just outside the implementation bounds for nanosecond `datetime64` (GH39221)
- Bug in `Timestamp.round()`, `Timestamp.floor()`, `Timestamp.ceil()` for values near the implementation bounds of `Timestamp` (GH39244)

- Bug in `Timedelta.round()`, `Timedelta.floor()`, `Timedelta.ceil()` for values near the implementation bounds of `Timedelta` (GH38964)
- Bug in `date_range()` incorrectly creating `DatetimeIndex` containing NaT instead of raising `OutOfBoundsDatetime` in corner cases (GH24124)
- Bug in `infer_freq()` incorrectly fails to infer 'H' frequency of `DatetimeIndex` if the latter has a timezone and crosses DST boundaries (GH39556)
- Bug in `Series` backed by `DatetimeArray` or `TimedeltaArray` sometimes failing to set the array's `freq` to `None` (GH41425)

## Timedelta

- Bug in constructing `Timedelta` from `np.timedelta64` objects with non-nanosecond units that are out of bounds for `timedelta64[ns]` (GH38965)
- Bug in constructing a `TimedeltaIndex` incorrectly accepting `np.datetime64("NaT")` objects (GH39462)
- Bug in constructing `Timedelta` from an input string with only symbols and no digits failed to raise an error (GH39710)
- Bug in `TimedeltaIndex` and `to_timedelta()` failing to raise when passed non-nanosecond `timedelta64` arrays that overflow when converting to `timedelta64[ns]` (GH40008)

## Timezones

- Bug in different `tzinfo` objects representing UTC not being treated as equivalent (GH39216)
- Bug in `dateutil.tz.gettz("UTC")` not being recognized as equivalent to other UTC-representing `tzinfos` (GH39276)

## Numeric

- Bug in `DataFrame.quantile()`, `DataFrame.sort_values()` causing incorrect subsequent indexing behavior (GH38351)
- Bug in `DataFrame.sort_values()` raising an `IndexError` for empty by (GH40258)
- Bug in `DataFrame.select_dtypes()` with `include=np.number` would drop numeric `ExtensionDtype` columns (GH35340)
- Bug in `DataFrame.mode()` and `Series.mode()` not keeping consistent integer `Index` for empty input (GH33321)
- Bug in `DataFrame.rank()` when the `DataFrame` contained `np.inf` (GH32593)
- Bug in `DataFrame.rank()` with `axis=0` and columns holding incomparable types raising an `IndexError` (GH38932)
- Bug in `Series.rank()`, `DataFrame.rank()`, and `GroupBy.rank()` treating the most negative `int64` value as missing (GH32859)
- Bug in `DataFrame.select_dtypes()` different behavior between Windows and Linux with `include="int"` (GH36596)
- Bug in `DataFrame.apply()` and `DataFrame.agg()` when passed the argument `func="size"` would operate on the entire `DataFrame` instead of rows or columns (GH39934)

- Bug in `DataFrame.transform()` would raise a `SpecificationError` when passed a dictionary and columns were missing; will now raise a `KeyError` instead (GH40004)
- Bug in `GroupBy.rank()` giving incorrect results with `pct=True` and equal values between consecutive groups (GH40518)
- Bug in `Series.count()` would result in an `int32` result on 32-bit platforms when argument `level=None` (GH40908)
- Bug in `Series` and `DataFrame` reductions with methods `any` and `all` not returning Boolean results for object data (GH12863, GH35450, GH27709)
- Bug in `Series.clip()` would fail if the Series contains NA values and has nullable int or float as a data type (GH40851)
- Bug in `UInt64Index.where()` and `UInt64Index.putmask()` with an `np.int64` dtype other incorrectly raising `TypeError` (GH41974)
- Bug in `DataFrame.agg()` not sorting the aggregated axis in the order of the provided aggregation functions when one or more aggregation function fails to produce results (GH33634)
- Bug in `DataFrame.clip()` not interpreting missing values as no threshold (GH40420)

## Conversion

- Bug in `Series.to_dict()` with `orient='records'` now returns Python native types (GH25969)
- Bug in `Series.view()` and `Index.view()` when converting between datetime-like (`datetime64[ns]`, `datetime64[ns, tz]`, `timedelta64`, `period`) dtypes (GH39788)
- Bug in creating a `DataFrame` from an empty `np.recarray` not retaining the original dtypes (GH40121)
- Bug in `DataFrame` failing to raise a `TypeError` when constructing from a `frozenset` (GH40163)
- Bug in `Index` construction silently ignoring a passed dtype when the data cannot be cast to that dtype (GH21311)
- Bug in `StringArray.astype()` falling back to NumPy and raising when converting to `dtype='categorical'` (GH40450)
- Bug in `factorize()` where, when given an array with a numeric NumPy dtype lower than `int64`, `uint64` and `float64`, the unique values did not keep their original dtype (GH41132)
- Bug in `DataFrame` construction with a dictionary containing an array-like with `ExtensionDtype` and `copy=True` failing to make a copy (GH38939)
- Bug in `qcut()` raising error when taking `Float64Dtype` as input (GH40730)
- Bug in `DataFrame` and `Series` construction with `datetime64[ns]` data and `dtype=object` resulting in datetime objects instead of `Timestamp` objects (GH41599)
- Bug in `DataFrame` and `Series` construction with `timedelta64[ns]` data and `dtype=object` resulting in `np.timedelta64` objects instead of `Timedelta` objects (GH41599)
- Bug in `DataFrame` construction when given a two-dimensional object-dtype `np.ndarray` of `Period` or `Interval` objects failing to cast to `PeriodDtype` or `IntervalDtype`, respectively (GH41812)
- Bug in constructing a `Series` from a list and a `PandasDtype` (GH39357)
- Bug in creating a `Series` from a `range` object that does not fit in the bounds of `int64` dtype (GH30173)
- Bug in creating a `Series` from a `dict` with all-tuple keys and an `Index` that requires reindexing (GH41707)
- Bug in `infer_dtype()` not recognizing `Series`, `Index`, or array with a `Period` dtype (GH23553)

- Bug in `infer_dtype()` raising an error for general `ExtensionArray` objects. It will now return "unknown-array" instead of raising (GH37367)
- Bug in `DataFrame.convert_dtypes()` incorrectly raised a `ValueError` when called on an empty `DataFrame` (GH40393)

## Strings

- Bug in the conversion from `pyarrow.ChunkedArray` to `StringArray` when the original had zero chunks (GH41040)
- Bug in `Series.replace()` and `DataFrame.replace()` ignoring replacements with `regex=True` for `StringDType` data (GH41333, GH35977)
- Bug in `Series.str.extract()` with `StringArray` returning object dtype for an empty `DataFrame` (GH41441)
- Bug in `Series.str.replace()` where the case argument was ignored when `regex=False` (GH41602)

## Interval

- Bug in `IntervalIndex.intersection()` and `IntervalIndex.symmetric_difference()` always returning object-dtype when operating with `CategoricalIndex` (GH38653, GH38741)
- Bug in `IntervalIndex.intersection()` returning duplicates when at least one of the `Index` objects have duplicates which are present in the other (GH38743)
- `IntervalIndex.union()`, `IntervalIndex.intersection()`, `IntervalIndex.difference()`, and `IntervalIndex.symmetric_difference()` now cast to the appropriate dtype instead of raising a `TypeError` when operating with another `IntervalIndex` with incompatible dtype (GH39267)
- `PeriodIndex.union()`, `PeriodIndex.intersection()`, `PeriodIndex.symmetric_difference()`, `PeriodIndex.difference()` now cast to object dtype instead of raising `IncompatibleFrequency` when operating with another `PeriodIndex` with incompatible dtype (GH39306)
- Bug in `IntervalIndex.is_monotonic()`, `IntervalIndex.get_loc()`, `IntervalIndex.get_indexer_for()`, and `IntervalIndex.__contains__()` when NA values are present (GH41831)

## Indexing

- Bug in `Index.union()` and `MultiIndex.union()` dropping duplicate Index values when Index was not monotonic or sort was set to `False` (GH36289, GH31326, GH40862)
- Bug in `CategoricalIndex.get_indexer()` failing to raise `InvalidIndexError` when non-unique (GH38372)
- Bug in `IntervalIndex.get_indexer()` when target has `CategoricalDtype` and both the index and the target contain NA values (GH41934)
- Bug in `Series.loc()` raising a `ValueError` when input was filtered with a Boolean list and values to set were a list with lower dimension (GH20438)
- Bug in inserting many new columns into a `DataFrame` causing incorrect subsequent indexing behavior (GH38380)
- Bug in `DataFrame.__setitem__()` raising a `ValueError` when setting multiple values to duplicate columns (GH15695)

- Bug in `DataFrame.loc()`, `Series.loc()`, `DataFrame.__getitem__()` and `Series.__getitem__()` returning incorrect elements for non-monotonic `DatetimeIndex` for string slices (GH33146)
- Bug in `DataFrame.reindex()` and `Series.reindex()` with timezone aware indexes raising a `TypeError` for `method="ffill"` and `method="bfill"` and specified tolerance (GH38566)
- Bug in `DataFrame.reindex()` with `datetime64[ns]` or `timedelta64[ns]` incorrectly casting to integers when the `fill_value` requires casting to object dtype (GH39755)
- Bug in `DataFrame.__setitem__()` raising a `ValueError` when setting on an empty `DataFrame` using specified columns and a nonempty `DataFrame` value (GH38831)
- Bug in `DataFrame.loc.__setitem__()` raising a `ValueError` when operating on a unique column when the `DataFrame` has duplicate columns (GH38521)
- Bug in `DataFrame.iloc.__setitem__()` and `DataFrame.loc.__setitem__()` with mixed dtypes when setting with a dictionary value (GH38335)
- Bug in `Series.loc.__setitem__()` and `DataFrame.loc.__setitem__()` raising `KeyError` when provided a Boolean generator (GH39614)
- Bug in `Series.iloc()` and `DataFrame.iloc()` raising a `KeyError` when provided a generator (GH39614)
- Bug in `DataFrame.__setitem__()` not raising a `ValueError` when the right hand side is a `DataFrame` with wrong number of columns (GH38604)
- Bug in `Series.__setitem__()` raising a `ValueError` when setting a `Series` with a scalar indexer (GH38303)
- Bug in `DataFrame.loc()` dropping levels of a `MultiIndex` when the `DataFrame` used as input has only one row (GH10521)
- Bug in `DataFrame.__getitem__()` and `Series.__getitem__()` always raising `KeyError` when slicing with existing strings where the `Index` has milliseconds (GH33589)
- Bug in setting `timedelta64` or `datetime64` values into numeric `Series` failing to cast to object dtype (GH39086, GH39619)
- Bug in setting `Interval` values into a `Series` or `DataFrame` with mismatched `IntervalDtype` incorrectly casting the new values to the existing dtype (GH39120)
- Bug in setting `datetime64` values into a `Series` with integer-dtype incorrectly casting the `datetime64` values to integers (GH39266)
- Bug in setting `np.datetime64("NaT")` into a `Series` with `Datetime64TZDtype` incorrectly treating the timezone-naive value as timezone-aware (GH39769)
- Bug in `Index.get_loc()` not raising `KeyError` when `key=NaN` and `method` is specified but `NaN` is not in the `Index` (GH39382)
- Bug in `DatetimeIndex.insert()` when inserting `np.datetime64("NaT")` into a timezone-aware index incorrectly treating the timezone-naive value as timezone-aware (GH39769)
- Bug in incorrectly raising in `Index.insert()`, when setting a new column that cannot be held in the existing `frame.columns`, or in `Series.reset_index()` or `DataFrame.reset_index()` instead of casting to a compatible dtype (GH39068)
- Bug in `RangeIndex.append()` where a single object of length 1 was concatenated incorrectly (GH39401)
- Bug in `RangeIndex.astype()` where when converting to `CategoricalIndex`, the categories became a `Int64Index` instead of a `RangeIndex` (GH41263)
- Bug in setting `numpy.timedelta64` values into an object-dtype `Series` using a Boolean indexer (GH39488)
- Bug in setting numeric values into a into a boolean-dtypes `Series` using `at` or `iat` failing to cast to object-dtype (GH39582)

- Bug in `DataFrame.__setitem__()` and `DataFrame.iloc.__setitem__()` raising `ValueError` when trying to index with a row-slice and setting a list as values (GH40440)
- Bug in `DataFrame.loc()` not raising `KeyError` when the key was not found in `MultiIndex` and the levels were not fully specified (GH41170)
- Bug in `DataFrame.loc.__setitem__()` when setting-with-expansion incorrectly raising when the index in the expanding axis contained duplicates (GH40096)
- Bug in `DataFrame.loc.__getitem__()` with `MultiIndex` casting to float when at least one index column has float dtype and we retrieve a scalar (GH41369)
- Bug in `DataFrame.loc()` incorrectly matching non-Boolean index elements (GH20432)
- Bug in indexing with `np.nan` on a `Series` or `DataFrame` with a `CategoricalIndex` incorrectly raising `KeyError` when `np.nan` keys are present (GH41933)
- Bug in `Series.__delitem__()` with `ExtensionDtype` incorrectly casting to `ndarray` (GH40386)
- Bug in `DataFrame.at()` with a `CategoricalIndex` returning incorrect results when passed integer keys (GH41846)
- Bug in `DataFrame.loc()` returning a `MultiIndex` in the wrong order if an indexer has duplicates (GH40978)
- Bug in `DataFrame.__setitem__()` raising a `TypeError` when using a `str` subclass as the column name with a `DatetimeIndex` (GH37366)
- Bug in `PeriodIndex.get_loc()` failing to raise a `KeyError` when given a `Period` with a mismatched `freq` (GH41670)
- Bug `.loc.__getitem__` with a `UInt64Index` and negative-integer keys raising `OverflowError` instead of `KeyError` in some cases, wrapping around to positive integers in others (GH41777)
- Bug in `Index.get_indexer()` failing to raise `ValueError` in some cases with invalid `method`, `limit`, or `tolerance` arguments (GH41918)
- Bug when slicing a `Series` or `DataFrame` with a `TimedeltaIndex` when passing an invalid string raising `ValueError` instead of a `TypeError` (GH41821)
- Bug in `Index` constructor sometimes silently ignoring a specified `dtype` (GH38879)
- `Index.where()` behavior now mirrors `Index.putmask()` behavior, i.e. `index.where(mask, other)` matches `index.putmask(~mask, other)` (GH39412)

## Missing

- Bug in `Grouper` did not correctly propagate the `dropna` argument; `DataFrameGroupBy.transform()` now correctly handles missing values for `dropna=True` (GH35612)
- Bug in `isna()`, `Series.isna()`, `Index.isna()`, `DataFrame.isna()`, and the corresponding `notna` functions not recognizing `Decimal("NaN")` objects (GH39409)
- Bug in `DataFrame.fillna()` not accepting a dictionary for the `downcast` keyword (GH40809)
- Bug in `isna()` not returning a copy of the mask for nullable types, causing any subsequent mask modification to change the original array (GH40935)
- Bug in `DataFrame` construction with float data containing `NaN` and an integer `dtype` casting instead of retaining the `NaN` (GH26919)
- Bug in `Series.isin()` and `MultiIndex.isin()` didn't treat all nans as equivalent if they were in tuples (GH41836)

## Multindex

- Bug in `DataFrame.drop()` raising a `TypeError` when the `MultiIndex` is non-unique and `level` is not provided (GH36293)
- Bug in `MultiIndex.intersection()` duplicating `NaN` in the result (GH38623)
- Bug in `MultiIndex.equals()` incorrectly returning `True` when the `MultiIndex` contained `NaN` even when they are differently ordered (GH38439)
- Bug in `MultiIndex.intersection()` always returning an empty result when intersecting with `CategoricalIndex` (GH38653)
- Bug in `MultiIndex.difference()` incorrectly raising `TypeError` when indexes contain non-sortable entries (GH41915)
- Bug in `MultiIndex.reindex()` raising a `ValueError` when used on an empty `MultiIndex` and indexing only a specific level (GH41170)
- Bug in `MultiIndex.reindex()` raising `TypeError` when reindexing against a flat `Index` (GH41707)

## I/O

- Bug in `Index.__repr__()` when `display.max_seq_items=1` (GH38415)
- Bug in `read_csv()` not recognizing scientific notation if the argument `decimal` is set and `engine="python"` (GH31920)
- Bug in `read_csv()` interpreting `NA` value as comment, when `NA` does contain the comment string fixed for `engine="python"` (GH34002)
- Bug in `read_csv()` raising an `IndexError` with multiple header columns and `index_col` is specified when the file has no data rows (GH38292)
- Bug in `read_csv()` not accepting `usecols` with a different length than names for `engine="python"` (GH16469)
- Bug in `read_csv()` returning object dtype when `delimiter=","` with `usecols` and `parse_dates` specified for `engine="python"` (GH35873)
- Bug in `read_csv()` raising a `TypeError` when `names` and `parse_dates` is specified for `engine="c"` (GH33699)
- Bug in `read_clipboard()` and `DataFrame.to_clipboard()` not working in WSL (GH38527)
- Allow custom error values for the `parse_dates` argument of `read_sql()`, `read_sql_query()` and `read_sql_table()` (GH35185)
- Bug in `DataFrame.to_hdf()` and `Series.to_hdf()` raising a `KeyError` when trying to apply for subclasses of `DataFrame` or `Series` (GH33748)
- Bug in `HDFStore.put()` raising a wrong `TypeError` when saving a `DataFrame` with non-string dtype (GH34274)
- Bug in `json_normalize()` resulting in the first element of a generator object not being included in the returned `DataFrame` (GH35923)
- Bug in `read_csv()` applying the thousands separator to date columns when the column should be parsed for dates and `usecols` is specified for `engine="python"` (GH39365)
- Bug in `read_excel()` forward filling `MultiIndex` names when multiple header and index columns are specified (GH34673)

- Bug in `read_excel()` not respecting `set_option()` (GH34252)
- Bug in `read_csv()` not switching `true_values` and `false_values` for nullable Boolean dtype (GH34655)
- Bug in `read_json()` when `orient="split"` not maintaining a numeric string index (GH28556)
- `read_sql()` returned an empty generator if `chunksize` was non-zero and the query returned no results. Now returns a generator with a single empty DataFrame (GH34411)
- Bug in `read_hdf()` returning unexpected records when filtering on categorical string columns using the `where` parameter (GH39189)
- Bug in `read_sas()` raising a `ValueError` when datetimes were null (GH39725)
- Bug in `read_excel()` dropping empty values from single-column spreadsheets (GH39808)
- Bug in `read_excel()` loading trailing empty rows/columns for some filetypes (GH41167)
- Bug in `read_excel()` raising an `AttributeError` when the excel file had a `MultiIndex` header followed by two empty rows and no index (GH40442)
- Bug in `read_excel()`, `read_csv()`, `read_table()`, `read_fwf()`, and `read_clipboard()` where one blank row after a `MultiIndex` header with no index would be dropped (GH40442)
- Bug in `DataFrame.to_string()` misplacing the truncation column when `index=False` (GH40904)
- Bug in `DataFrame.to_string()` adding an extra dot and misaligning the truncation row when `index=False` (GH40904)
- Bug in `read_orc()` always raising an `AttributeError` (GH40918)
- Bug in `read_csv()` and `read_table()` silently ignoring `prefix` if `names` and `prefix` are defined, now raising a `ValueError` (GH39123)
- Bug in `read_csv()` and `read_excel()` not respecting the dtype for a duplicated column name when `mangle_dupe_cols` is set to `True` (GH35211)
- Bug in `read_csv()` silently ignoring `sep` if `delimiter` and `sep` are defined, now raising a `ValueError` (GH39823)
- Bug in `read_csv()` and `read_table()` misinterpreting arguments when `sys.setprofile` had been previously called (GH41069)
- Bug in the conversion from PyArrow to pandas (e.g. for reading Parquet) with nullable dtypes and a PyArrow array whose data buffer size is not a multiple of the dtype size (GH40896)
- Bug in `read_excel()` would raise an error when pandas could not determine the file type even though the user specified the `engine` argument (GH41225)
- Bug in `read_clipboard()` copying from an excel file shifts values into the wrong column if there are null values in first column (GH41108)
- Bug in `DataFrame.to_hdf()` and `Series.to_hdf()` raising a `TypeError` when trying to append a string column to an incompatible column (GH41897)

## Period

- Comparisons of *Period* objects or *Index*, *Series*, or *DataFrame* with mismatched *PeriodDtype* now behave like other mismatched-type comparisons, returning `False` for equals, `True` for not-equal, and raising `TypeError` for inequality checks (GH39274)

## Plotting

- Bug in `plotting.scatter_matrix()` raising when 2d `ax` argument passed (GH16253)
- Prevent warnings when Matplotlib's `constrained_layout` is enabled (GH25261)
- Bug in `DataFrame.plot()` was showing the wrong colors in the legend if the function was called repeatedly and some calls used `yerr` while others didn't (GH39522)
- Bug in `DataFrame.plot()` was showing the wrong colors in the legend if the function was called repeatedly and some calls used `secondary_y` and others use `legend=False` (GH40044)
- Bug in `DataFrame.plot.box()` when `dark_background` theme was selected, caps or min/max markers for the plot were not visible (GH40769)

## Groupby/resample/rolling

- Bug in `GroupBy.agg()` with *PeriodDtype* columns incorrectly casting results too aggressively (GH38254)
- Bug in `SeriesGroupBy.value_counts()` where unobserved categories in a grouped categorical *Series* were not tallied (GH38672)
- Bug in `SeriesGroupBy.value_counts()` where an error was raised on an empty *Series* (GH39172)
- Bug in `GroupBy.indices()` would contain non-existent indices when null values were present in the groupby keys (GH9304)
- Fixed bug in `GroupBy.sum()` causing a loss of precision by now using Kahan summation (GH38778)
- Fixed bug in `GroupBy.cumsum()` and `GroupBy.mean()` causing loss of precision through using Kahan summation (GH38934)
- Bug in `Resampler.aggregate()` and `DataFrame.transform()` raising a `TypeError` instead of `SpecificationError` when missing keys had mixed dtypes (GH39025)
- Bug in `DataFrameGroupBy.idxmin()` and `DataFrameGroupBy.idxmax()` with *ExtensionDtype* columns (GH38733)
- Bug in `Series.resample()` would raise when the index was a *PeriodIndex* consisting of `NaT` (GH39227)
- Bug in `RollingGroupby.corr()` and `ExpandingGroupby.corr()` where the groupby column would return `0` instead of `np.nan` when providing `other` that was longer than each group (GH39591)
- Bug in `ExpandingGroupby.corr()` and `ExpandingGroupby.cov()` where `1` would be returned instead of `np.nan` when providing `other` that was longer than each group (GH39591)
- Bug in `GroupBy.mean()`, `GroupBy.median()` and `DataFrame.pivot_table()` not propagating metadata (GH28283)
- Bug in `Series.rolling()` and `DataFrame.rolling()` not calculating window bounds correctly when window is an offset and dates are in descending order (GH40002)

- Bug in `Series.groupby()` and `DataFrame.groupby()` on an empty Series or DataFrame would lose index, columns, and/or data types when directly using the methods `idxmax`, `idxmin`, `mad`, `min`, `max`, `sum`, `prod`, and `skew` or using them through `apply`, `aggregate`, or `resample` (GH26411)
- Bug in `GroupBy.apply()` where a `MultiIndex` would be created instead of an `Index` when used on a `RollingGroupby` object (GH39732)
- Bug in `DataFrameGroupBy.sample()` where an error was raised when `weights` was specified and the index was an `Int64Index` (GH39927)
- Bug in `DataFrameGroupBy.aggregate()` and `Resampler.aggregate()` would sometimes raise a `SpecificationError` when passed a dictionary and columns were missing; will now always raise a `KeyError` instead (GH40004)
- Bug in `DataFrameGroupBy.sample()` where column selection was not applied before computing the result (GH39928)
- Bug in `ExponentialMovingWindow` when calling `__getitem__` would incorrectly raise a `ValueError` when providing `times` (GH40164)
- Bug in `ExponentialMovingWindow` when calling `__getitem__` would not retain `com`, `span`, `alpha` or `half-life` attributes (GH40164)
- `ExponentialMovingWindow` now raises a `NotImplementedError` when specifying `times` with `adjust=False` due to an incorrect calculation (GH40098)
- Bug in `ExponentialMovingWindowGroupby.mean()` where the `times` argument was ignored when `engine='numba'` (GH40951)
- Bug in `ExponentialMovingWindowGroupby.mean()` where the wrong `times` were used in the case of multiple groups (GH40951)
- Bug in `ExponentialMovingWindowGroupby` where the `times` vector and values became out of sync for non-trivial groups (GH40951)
- Bug in `Series.asfreq()` and `DataFrame.asfreq()` dropping rows when the index was not sorted (GH39805)
- Bug in aggregation functions for `DataFrame` not respecting `numeric_only` argument when `level` keyword was given (GH40660)
- Bug in `SeriesGroupBy.aggregate()` where using a user-defined function to aggregate a Series with an object-typed `Index` causes an incorrect `Index` shape (GH40014)
- Bug in `RollingGroupby` where `as_index=False` argument in `groupby` was ignored (GH39433)
- Bug in `GroupBy.any()` and `GroupBy.all()` raising a `ValueError` when using with nullable type columns holding NA even with `skipna=True` (GH40585)
- Bug in `GroupBy.cummin()` and `GroupBy.cummax()` incorrectly rounding integer values near the `int64` implementations bounds (GH40767)
- Bug in `GroupBy.rank()` with nullable dtypes incorrectly raising a `TypeError` (GH41010)
- Bug in `GroupBy.cummin()` and `GroupBy.cummax()` computing wrong result with nullable data types too large to roundtrip when casting to float (GH37493)
- Bug in `DataFrame.rolling()` returning mean zero for all NaN window with `min_periods=0` if calculation is not numerical stable (GH41053)
- Bug in `DataFrame.rolling()` returning sum not zero for all NaN window with `min_periods=0` if calculation is not numerical stable (GH41053)
- Bug in `SeriesGroupBy.agg()` failing to retain ordered `CategoricalDtype` on order-preserving aggregations (GH41147)

- Bug in `GroupBy.min()` and `GroupBy.max()` with multiple object-dtype columns and `numeric_only=False` incorrectly raising a `ValueError` (GH41111)
- Bug in `DataFrameGroupBy.rank()` with the `GroupBy` object's `axis=0` and the `rank` method's keyword `axis=1` (GH41320)
- Bug in `DataFrameGroupBy.__getitem__()` with non-unique columns incorrectly returning a malformed `SeriesGroupBy` instead of `DataFrameGroupBy` (GH41427)
- Bug in `DataFrameGroupBy.transform()` with non-unique columns incorrectly raising an `AttributeError` (GH41427)
- Bug in `Resampler.apply()` with non-unique columns incorrectly dropping duplicated columns (GH41445)
- Bug in `Series.groupby()` aggregations incorrectly returning empty `Series` instead of raising `TypeError` on aggregations that are invalid for its dtype, e.g. `.prod` with `datetime64[ns]` dtype (GH41342)
- Bug in `DataFrameGroupBy` aggregations incorrectly failing to drop columns with invalid dtypes for that aggregation when there are no valid columns (GH41291)
- Bug in `DataFrame.rolling.__iter__()` where `on` was not assigned to the index of the resulting objects (GH40373)
- Bug in `DataFrameGroupBy.transform()` and `DataFrameGroupBy.agg()` with `engine="numba"` where `*args` were being cached with the user passed function (GH41647)
- Bug in `DataFrameGroupBy` methods `agg`, `transform`, `sum`, `bfill`, `ffill`, `pad`, `pct_change`, `shift`, `ohlc` dropping `.columns.names` (GH41497)

## Reshaping

- Bug in `merge()` raising error when performing an inner join with partial index and `right_index=True` when there was no overlap between indices (GH33814)
- Bug in `DataFrame.unstack()` with missing levels led to incorrect index names (GH37510)
- Bug in `merge_asof()` propagating the right Index with `left_index=True` and `right_on` specification instead of left Index (GH33463)
- Bug in `DataFrame.join()` on a `DataFrame` with a `MultiIndex` returned the wrong result when one of both indexes had only one level (GH36909)
- `merge_asof()` now raises a `ValueError` instead of a cryptic `TypeError` in case of non-numerical merge columns (GH29130)
- Bug in `DataFrame.join()` not assigning values correctly when the `DataFrame` had a `MultiIndex` where at least one dimension had dtype `Categorical` with non-alphabetically sorted categories (GH38502)
- `Series.value_counts()` and `Series.mode()` now return consistent keys in original order (GH12679, GH11227 and GH39007)
- Bug in `DataFrame.stack()` not handling `NaN` in `MultiIndex` columns correctly (GH39481)
- Bug in `DataFrame.apply()` would give incorrect results when the argument `func` was a string, `axis=1`, and the `axis` argument was not supported; now raises a `ValueError` instead (GH39211)
- Bug in `DataFrame.sort_values()` not reshaping the index correctly after sorting on columns when `ignore_index=True` (GH39464)
- Bug in `DataFrame.append()` returning incorrect dtypes with combinations of `ExtensionDtype` dtypes (GH39454)

- Bug in `DataFrame.append()` returning incorrect dtypes when used with combinations of `datetime64` and `timedelta64` dtypes (GH39574)
- Bug in `DataFrame.append()` with a `DataFrame` with a `MultiIndex` and appending a `Series` whose `Index` is not a `MultiIndex` (GH41707)
- Bug in `DataFrame.pivot_table()` returning a `MultiIndex` for a single value when operating on an empty `DataFrame` (GH13483)
- `Index` can now be passed to the `numpy.all()` function (GH40180)
- Bug in `DataFrame.stack()` not preserving `CategoricalDtype` in a `MultiIndex` (GH36991)
- Bug in `to_datetime()` raising an error when the input sequence contained unhashable items (GH39756)
- Bug in `Series.explode()` preserving the index when `ignore_index` was `True` and values were scalars (GH40487)
- Bug in `to_datetime()` raising a `ValueError` when `Series` contains `None` and `NaT` and has more than 50 elements (GH39882)
- Bug in `Series.unstack()` and `DataFrame.unstack()` with object-dtype values containing timezone-aware datetime objects incorrectly raising `TypeError` (GH41875)
- Bug in `DataFrame.melt()` raising `InvalidIndexError` when `DataFrame` has duplicate columns used as `value_vars` (GH41951)

### Sparse

- Bug in `DataFrame.sparse.to_coo()` raising a `KeyError` with columns that are a numeric `Index` without a `0` (GH18414)
- Bug in `SparseArray.astype()` with `copy=False` producing incorrect results when going from integer dtype to floating dtype (GH34456)
- Bug in `SparseArray.max()` and `SparseArray.min()` would always return an empty result (GH40921)

### ExtensionArray

- Bug in `DataFrame.where()` when `other` is a `Series` with an `ExtensionDtype` (GH38729)
- Fixed bug where `Series.idxmax()`, `Series.idxmin()`, `Series.argmax()`, and `Series.argmin()` would fail when the underlying data is an `ExtensionArray` (GH32749, GH33719, GH36566)
- Fixed bug where some properties of subclasses of `PandasExtensionDtype` were improperly cached (GH40329)
- Bug in `DataFrame.mask()` where masking a `DataFrame` with an `ExtensionDtype` raises a `ValueError` (GH40941)

## Styler

- Bug in *Styler* where the subset argument in methods raised an error for some valid MultiIndex slices (GH33562)
- *Styler* rendered HTML output has seen minor alterations to support w3 good code standards (GH39626)
- Bug in *Styler* where rendered HTML was missing a column class identifier for certain header cells (GH39716)
- Bug in *Styler.background\_gradient()* where text-color was not determined correctly (GH39888)
- Bug in *Styler.set\_table\_styles()* where multiple elements in CSS-selectors of the `table_styles` argument were not correctly added (GH34061)
- Bug in *Styler* where copying from Jupyter dropped the top left cell and misaligned headers (GH12147)
- Bug in *Styler.where* where `kwargs` were not passed to the applicable callable (GH40845)
- Bug in *Styler* causing CSS to duplicate on multiple renders (GH39395, GH40334)

## Other

- `inspect.getmembers(Series)` no longer raises an `AbstractMethodError` (GH38782)
- Bug in *Series.where()* with numeric dtype and `other=None` not casting to nan (GH39761)
- Bug in `assert_series_equal()`, `assert_frame_equal()`, `assert_index_equal()` and `assert_extension_array_equal()` incorrectly raising when an attribute has an unrecognized NA type (GH39461)
- Bug in `assert_index_equal()` with `exact=True` not raising when comparing *CategoricalIndex* instances with *Int64Index* and *RangeIndex* categories (GH41263)
- Bug in *DataFrame.equals()*, *Series.equals()*, and *Index.equals()* with object-dtype containing `np.datetime64("NaT")` or `np.timedelta64("NaT")` (GH39650)
- Bug in `show_versions()` where console JSON output was not proper JSON (GH39701)
- pandas can now compile on z/OS when using `xlcv` (GH35826)
- Bug in `pandas.util.hash_pandas_object()` not recognizing `hash_key`, `encoding` and `categorize` when the input object type is a *DataFrame* (GH41404)

## **5.2 Version 1.2**

### **5.2.1 What's new in 1.2.5 (June 22, 2021)**

These are the changes in pandas 1.2.5. See *Release notes* for a full changelog including other versions of pandas.

## Fixed regressions

- Fixed regression in `concat()` between two `DataFrame` where one has an `Index` that is all-None and the other is `DatetimeIndex` incorrectly raising (GH40841)
- Fixed regression in `DataFrame.sum()` and `DataFrame.prod()` when `min_count` and `numeric_only` are both given (GH41074)
- Fixed regression in `read_csv()` when using `memory_map=True` with a non-UTF8 encoding (GH40986)
- Fixed regression in `DataFrame.replace()` and `Series.replace()` when the values to replace is a NumPy float array (GH40371)
- Fixed regression in `ExcelFile()` when a corrupt file is opened but not closed (GH41778)
- Fixed regression in `DataFrame.astype()` with `dtype=str` failing to convert NaN in categorical columns (GH41797)

## Contributors

A total of 12 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

### 5.2.2 What’s new in 1.2.4 (April 12, 2021)

These are the changes in pandas 1.2.4. See [Release notes](#) for a full changelog including other versions of pandas.

## Fixed regressions

- Fixed regression in `DataFrame.sum()` when `min_count` greater than the `DataFrame` shape was passed resulted in a `ValueError` (GH39738)
- Fixed regression in `DataFrame.to_json()` raising `AttributeError` when run on PyPy (GH39837)
- Fixed regression in (in)equality comparison of `pd.NaT` with a non-datetime-like numpy array returning a scalar instead of an array (GH40722)
- Fixed regression in `DataFrame.where()` not returning a copy in the case of an all True condition (GH39595)
- Fixed regression in `DataFrame.replace()` raising `IndexError` when `regex` was a multi-key dictionary (GH39338)
- Fixed regression in repr of floats in an object column not respecting `float_format` when printed in the console or outputted through `DataFrame.to_string()`, `DataFrame.to_html()`, and `DataFrame.to_latex()` (GH40024)
- Fixed regression in NumPy ufuncs such as `np.add` not passing through all arguments for `DataFrame` (GH40662)

## Contributors

A total of 9 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

## 5.2.3 What’s new in 1.2.3 (March 02, 2021)

These are the changes in pandas 1.2.3. See *Release notes* for a full changelog including other versions of pandas.

## Fixed regressions

- Fixed regression in `to_excel()` raising `KeyError` when giving duplicate columns with `columns` attribute (GH39695)
- Fixed regression in nullable integer unary ops propagating mask on assignment (GH39943)
- Fixed regression in `DataFrame.__setitem__()` not aligning `DataFrame` on right-hand side for boolean indexer (GH39931)
- Fixed regression in `to_json()` failing to use `compression` with URL-like paths that are internally opened in binary mode or with user-provided file objects that are opened in binary mode (GH39985)

- Fixed regression in `Series.sort_index()` and `DataFrame.sort_index()`, which exited with an ungraceful error when having kwarg `ascending=None` passed. Passing `ascending=None` is still considered invalid, and the improved error message suggests a proper usage (`ascending` must be a boolean or a list-like of boolean) (GH39434)
- Fixed regression in `DataFrame.transform()` and `Series.transform()` giving incorrect column labels when passed a dictionary with a mix of list and non-list values (GH40018)

## Contributors

A total of 14 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

## 5.2.4 What’s new in 1.2.2 (February 09, 2021)

These are the changes in pandas 1.2.2. See [Release notes](#) for a full changelog including other versions of pandas.

### Fixed regressions

- Fixed regression in `read_excel()` that caused it to raise `AttributeError` when checking version of older xlrld versions (GH38955)
- Fixed regression in `DataFrame` constructor reordering element when construction from datetime ndarray with dtype not `"datetime64[ns]"` (GH39422)
- Fixed regression in `DataFrame.astype()` and `Series.astype()` not casting to bytes dtype (GH39474)
- Fixed regression in `to_pickle()` failing to create bz2/xz compressed pickle files with `protocol=5` (GH39002)
- Fixed regression in `pandas.testing.assert_series_equal()` and `pandas.testing.assert_frame_equal()` always raising `AssertionError` when comparing extension dtypes (GH39410)
- Fixed regression in `to_csv()` opening `codecs.StreamWriter` in binary mode instead of in text mode and ignoring user-provided mode (GH39247)

- Fixed regression in `Categorical.astype()` casting to incorrect dtype when `np.int32` is passed to dtype argument (GH39402)
- Fixed regression in `to_excel()` creating corrupt files when appending (`mode="a"`) to an existing file (GH39576)
- Fixed regression in `DataFrame.transform()` failing in case of an empty DataFrame or Series (GH39636)
- Fixed regression in `groupby()` or `resample()` when aggregating an all-NaN or numeric object dtype column (GH39329)
- Fixed regression in `Rolling.count()` where the `min_periods` argument would be set to 0 after the operation (GH39554)
- Fixed regression in `read_excel()` that incorrectly raised when the argument `io` was a non-path and non-buffer and the `engine` argument was specified (GH39528)

### Bug fixes

- `pandas.read_excel()` error message when a specified sheetname does not exist is now uniform across engines (GH39250)
- Fixed bug in `pandas.read_excel()` producing incorrect results when the engine `openpyxl` is used and the excel file is missing or has incorrect dimension information; the fix requires `openpyxl >= 3.0.0`, prior versions may still fail (GH38956, GH39001)
- Fixed bug in `pandas.read_excel()` sometimes producing a DataFrame with trailing rows of `np.nan` when the engine `openpyxl` is used (GH39181)

### Contributors

## 5.2.5 What's new in 1.2.1 (January 20, 2021)

These are the changes in pandas 1.2.1. See *Release notes* for a full changelog including other versions of pandas.

### Fixed regressions

- Fixed regression in `to_csv()` that created corrupted zip files when there were more rows than `chunksize` (GH38714)
- Fixed regression in `to_csv()` opening codecs. `StreamReaderWriter` in binary mode instead of in text mode (GH39247)
- Fixed regression in `read_csv()` and other read functions where the encoding error policy (`errors`) did not default to "replace" when no encoding was specified (GH38989)
- Fixed regression in `read_excel()` with non-rawbyte file handles (GH38788)
- Fixed regression in `DataFrame.to_stata()` not removing the created file when an error occurred (GH39202)
- Fixed regression in `DataFrame.__setitem__` raising `ValueError` when expanding `DataFrame` and new column is from type "`0 - name`" (GH39010)
- Fixed regression in setting with `DataFrame.loc()` raising `ValueError` when `DataFrame` has unsorted `MultiIndex` columns and indexer is a scalar (GH38601)
- Fixed regression in setting with `DataFrame.loc()` raising `KeyError` with `MultiIndex` and list-like columns indexer enlarging `DataFrame` (GH39147)
- Fixed regression in `groupby()` with `Categorical` grouping column not showing unused categories for `grouped.indices` (GH38642)
- Fixed regression in `GroupBy.sem()` where the presence of non-numeric columns would cause an error instead of being dropped (GH38774)
- Fixed regression in `DataFrameGroupBy.diff()` raising for `int8` and `int16` columns (GH39050)
- Fixed regression in `DataFrame.groupby()` when aggregating an `ExtensionDType` that could fail for non-numeric values (GH38980)
- Fixed regression in `Rolling.skew()` and `Rolling.kurt()` modifying the object inplace (GH38908)
- Fixed regression in `DataFrame.any()` and `DataFrame.all()` not returning a result for tz-aware `datetime64` columns (GH38723)
- Fixed regression in `DataFrame.apply()` with `axis=1` using str accessor in apply function (GH38979)
- Fixed regression in `DataFrame.replace()` raising `ValueError` when `DataFrame` has dtype bytes (GH38900)
- Fixed regression in `Series.fillna()` that raised `RecursionError` with `datetime64[ns, UTC]` dtype (GH38851)
- Fixed regression in comparisons between `NaT` and `datetime.date` objects incorrectly returning `True` (GH39151)
- Fixed regression in calling NumPy `accumulate()` ufuncs on DataFrames, e.g. `np.maximum.accumulate(df)` (GH39259)
- Fixed regression in repr of float-like strings of an object dtype having trailing 0's truncated after the decimal (GH38708)
- Fixed regression that raised `AttributeError` with PyArrow versions [0.16.0, 1.0.0) (GH38801)

- Fixed regression in `pandas.testing.assert_frame_equal()` raising `TypeError` with `check_like=True` when `Index` or columns have mixed dtype (GH39168)

We have reverted a commit that resulted in several plotting related regressions in pandas 1.2.0 (GH38969, GH38736, GH38865, GH38947 and GH39126). As a result, bugs reported as fixed in pandas 1.2.0 related to inconsistent tick labeling in bar plots are again present (GH26186 and GH11465)

### Calling NumPy ufuncs on non-aligned DataFrames

Before pandas 1.2.0, calling a NumPy ufunc on non-aligned DataFrames (or DataFrame / Series combination) would ignore the indices, only match the inputs by shape, and use the index/columns of the first DataFrame for the result:

```
In [1]: df1 = pd.DataFrame({"a": [1, 2], "b": [3, 4]}, index=[0, 1])
In [2]: df2 = pd.DataFrame({"a": [1, 2], "b": [3, 4]}, index=[1, 2])
In [3]: df1
Out[3]:
 a b
0 1 3
1 2 4
In [4]: df2
Out[4]:
 a b
1 1 3
2 2 4

In [5]: np.add(df1, df2)
Out[5]:
 a b
0 2 6
1 4 8
```

This contrasts with how other pandas operations work, which first align the inputs:

```
In [6]: df1 + df2
Out[6]:
 a b
0 NaN NaN
1 3.0 7.0
2 NaN NaN
```

In pandas 1.2.0, we refactored how NumPy ufuncs are called on DataFrames, and this started to align the inputs first (GH39184), as happens in other pandas operations and as it happens for ufuncs called on Series objects.

For pandas 1.2.1, we restored the previous behaviour to avoid a breaking change, but the above example of `np.add(df1, df2)` with non-aligned inputs will now to raise a warning, and a future pandas 2.0 release will start aligning the inputs first (GH39184). Calling a NumPy ufunc on Series objects (eg `np.add(s1, s2)`) already aligns and continues to do so.

To avoid the warning and keep the current behaviour of ignoring the indices, convert one of the arguments to a NumPy array:

```
In [7]: np.add(df1, np.asarray(df2))
Out[7]:
 a b
```

(continues on next page)

(continued from previous page)

```
0 2 6
1 4 8
```

To obtain the future behaviour and silence the warning, you can align manually before passing the arguments to the `ufunc`:

```
In [8]: df1, df2 = df1.align(df2)
```

```
In [9]: np.add(df1, df2)
```

```
Out[9]:
```

```
 a b
0 NaN NaN
1 3.0 7.0
2 NaN NaN
```

## Bug fixes

- Bug in `read_csv()` with `float_precision="high"` caused segfault or wrong parsing of long exponent strings. This resulted in a regression in some cases as the default for `float_precision` was changed in pandas 1.2.0 (GH38753)
- Bug in `read_csv()` not closing an opened file handle when a `csv.Error` or `UnicodeDecodeError` occurred while initializing (GH39024)
- Bug in `pandas.testing.assert_index_equal()` raising `TypeError` with `check_order=False` when `Index` has mixed dtype (GH39168)

## Other

- The deprecated attributes `_AXIS_NAMES` and `_AXIS_NUMBERS` of `DataFrame` and `Series` will no longer show up in `dir` or `inspect.getmembers` calls (GH38740)
- Bumped minimum fastparquet version to 0.4.0 to avoid `AttributeError` from numba (GH38344)
- Bumped minimum pymysql version to 0.8.1 to avoid test failures (GH38344)
- Fixed build failure on MacOS 11 in Python 3.9.1 (GH38766)
- Added reference to backwards incompatible `check_freq` arg of `testing.assert_frame_equal()` and `testing.assert_series_equal()` in *pandas 1.1.0 what's new* (GH34050)

## Contributors

A total of 20 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

## 5.2.6 What's new in 1.2.0 (December 26, 2020)

These are the changes in pandas 1.2.0. See *Release notes* for a full changelog including other versions of pandas.

**Warning:** The `xlwt` package for writing old-style `.xls` excel files is no longer maintained. The `xlrd` package is now only for reading old-style `.xls` files.

Previously, the default argument `engine=None` to `read_excel()` would result in using the `xlrd` engine in many cases, including new Excel 2007+ (`.xlsx`) files. If `openpyxl` is installed, many of these cases will now default to using the `openpyxl` engine. See the `read_excel()` documentation for more details.

Thus, it is strongly encouraged to install `openpyxl` to read Excel 2007+ (`.xlsx`) files. **Please do not report issues when using `xlrd` to read `.xlsx` files.** This is no longer supported, switch to using `openpyxl` instead.

Attempting to use the `xlwt` engine will raise a `FutureWarning` unless the option `io.excel.xls.writer` is set to `"xlwt"`. While this option is now deprecated and will also raise a `FutureWarning`, it can be globally set and the warning suppressed. Users are recommended to write `.xlsx` files using the `openpyxl` engine instead.

## Enhancements

### Optionally disallow duplicate labels

`Series` and `DataFrame` can now be created with `allows_duplicate_labels=False` flag to control whether the index or columns can contain duplicate labels (GH28394). This can be used to prevent accidental introduction of duplicate labels, which can affect downstream operations.

By default, duplicates continue to be allowed.

```

In [1]: pd.Series([1, 2], index=['a', 'a'])
Out[1]:
a 1
a 2
Length: 2, dtype: int64

In [2]: pd.Series([1, 2], index=['a', 'a']).set_flags(allows_duplicate_labels=False)
...
DuplicateLabelError: Index has duplicates.
 positions
label
a [0, 1]

```

pandas will propagate the `allows_duplicate_labels` property through many operations.

```

In [3]: a = (
...: pd.Series([1, 2], index=['a', 'b'])
...: .set_flags(allows_duplicate_labels=False)
...:)

In [4]: a
Out[4]:
a 1
b 2
Length: 2, dtype: int64

An operation introducing duplicates
In [5]: a.reindex(['a', 'b', 'a'])
...
DuplicateLabelError: Index has duplicates.
 positions
label
a [0, 2]

[1 rows x 1 columns]

```

**Warning:** This is an experimental feature. Currently, many methods fail to propagate the `allows_duplicate_labels` value. In future versions it is expected that every method taking or returning one or more DataFrame or Series objects will propagate `allows_duplicate_labels`.

See *Duplicate Labels* for more.

The `allows_duplicate_labels` flag is stored in the new `DataFrame.flags` attribute. This stores global attributes that apply to the *pandas object*. This differs from `DataFrame.attrs`, which stores information that applies to the dataset.

## Passing arguments to fsspec backends

Many read/write functions have acquired the `storage_options` optional argument, to pass a dictionary of parameters to the storage backend. This allows, for example, for passing credentials to S3 and GCS storage. The details of what parameters can be passed to which backends can be found in the documentation of the individual storage backends (detailed from the fsspec docs for [builtin implementations](#) and linked to [external ones](#)). See Section *Reading/writing remote files*.

[GH35655](#) added fsspec support (including `storage_options`) for reading excel files.

## Support for binary file handles in `to_csv`

`to_csv()` supports file handles in binary mode ([GH19827](#) and [GH35058](#)) with `encoding` ([GH13068](#) and [GH23854](#)) and `compression` ([GH22555](#)). If pandas does not automatically detect whether the file handle is opened in binary or text mode, it is necessary to provide `mode="wb"`.

For example:

```
In [1]: import io
In [2]: data = pd.DataFrame([0, 1, 2])
In [3]: buffer = io.BytesIO()
In [4]: data.to_csv(buffer, encoding="utf-8", compression="gzip")
```

## Support for short caption and table position in `to_latex`

`DataFrame.to_latex()` now allows one to specify a floating table position ([GH35281](#)) and a short caption ([GH36267](#)).

The keyword `position` has been added to set the position.

```
In [5]: data = pd.DataFrame({'a': [1, 2], 'b': [3, 4]})
In [6]: table = data.to_latex(position='ht')
In [7]: print(table)
\begin{table}[ht]
\centering
\begin{tabular}{lrr}
\toprule
{} & a & b \\
\midrule
0 & 1 & 3 \\
1 & 2 & 4 \\
\bottomrule
\end{tabular}
\end{table}
```

Usage of the keyword `caption` has been extended. Besides taking a single string as an argument, one can optionally provide a tuple (`full_caption`, `short_caption`) to add a short caption macro.

```

In [8]: data = pd.DataFrame({'a': [1, 2], 'b': [3, 4]})

In [9]: table = data.to_latex(caption=('the full long caption', 'short caption'))

In [10]: print(table)
\begin{table}
\centering
\caption[short caption]{the full long caption}
\begin{tabular}{lrr}
\toprule
{} & a & b \\
\midrule
0 & 1 & 3 \\
1 & 2 & 4 \\
\bottomrule
\end{tabular}
\end{table}

```

### Change in default floating precision for `read_csv` and `read_table`

For the C parsing engine, the methods `read_csv()` and `read_table()` previously defaulted to a parser that could read floating point numbers slightly incorrectly with respect to the last bit in precision. The option `floating_precision="high"` has always been available to avoid this issue. Beginning with this version, the default is now to use the more accurate parser by making `floating_precision=None` correspond to the high precision parser, and the new option `floating_precision="legacy"` to use the legacy parser. The change to using the higher precision parser by default should have no impact on performance. ([GH17154](#))

### Experimental nullable data types for float data

We've added `Float32Dtype` / `Float64Dtype` and `FloatingArray`. These are extension data types dedicated to floating point data that can hold the `pd.NA` missing value indicator ([GH32265](#), [GH34307](#)).

While the default float data type already supports missing values using `np.nan`, these new data types use `pd.NA` (and its corresponding behavior) as the missing value indicator, in line with the already existing nullable *integer* and *boolean* data types.

One example where the behavior of `np.nan` and `pd.NA` is different is comparison operations:

```

the default NumPy float64 dtype
In [11]: s1 = pd.Series([1.5, None])

In [12]: s1
Out[12]:
0 1.5
1 NaN
dtype: float64

In [13]: s1 > 1
Out[13]:
0 True
1 False
dtype: bool

```

```
the new nullable float64 dtype
In [14]: s2 = pd.Series([1.5, None], dtype="Float64")

In [15]: s2
Out[15]:
0 1.5
1 <NA>
dtype: Float64

In [16]: s2 > 1
Out[16]:
0 True
1 <NA>
dtype: boolean
```

See the *Experimental NA scalar to denote missing values* doc section for more details on the behavior when using the `pd.NA` missing value indicator.

As shown above, the dtype can be specified using the “Float64” or “Float32” string (capitalized to distinguish it from the default “float64” data type). Alternatively, you can also use the dtype object:

```
In [17]: pd.Series([1.5, None], dtype=pd.Float32Dtype())
Out[17]:
0 1.5
1 <NA>
dtype: Float32
```

Operations with the existing integer or boolean nullable data types that give float results will now also use the nullable floating data types (GH38178).

**Warning:** Experimental: the new floating data types are currently experimental, and their behavior or API may still change without warning. Especially the behavior regarding NaN (distinct from NA missing values) is subject to change.

## Index/column name preservation when aggregating

When aggregating using `concat()` or the `DataFrame` constructor, pandas will now attempt to preserve index and column names whenever possible (GH35847). In the case where all inputs share a common name, this name will be assigned to the result. When the input names do not all agree, the result will be unnamed. Here is an example where the index name is preserved:

```
In [18]: idx = pd.Index(range(5), name='abc')

In [19]: ser = pd.Series(range(5, 10), index=idx)

In [20]: pd.concat({'x': ser[1:], 'y': ser[:-1]}, axis=1)
Out[20]:
 x y
abc
0 NaN 5.0
1 6.0 6.0
```

(continues on next page)

(continued from previous page)

```

2 7.0 7.0
3 8.0 8.0
4 9.0 NaN

```

The same is true for *MultiIndex*, but the logic is applied separately on a level-by-level basis.

## GroupBy supports EWM operations directly

DataFrameGroupBy now supports exponentially weighted window operations directly (GH16037).

```
In [21]: df = pd.DataFrame({'A': ['a', 'b', 'a', 'b'], 'B': range(4)})
```

```
In [22]: df
```

```
Out[22]:
```

```

 A B
0 a 0
1 b 1
2 a 2
3 b 3

```

```
In [23]: df.groupby('A').ewm(com=1.0).mean()
```

```
Out[23]:
```

```

 B
A
a 0 0.000000
 2 1.333333
b 1 1.000000
 3 2.333333

```

Additionally mean supports execution via *Numba* with the `engine` and `engine_kwargs` arguments. *Numba* must be installed as an optional dependency to use this feature.

## Other enhancements

- Added `day_of_week` (compatibility alias `dayofweek`) property to *Timestamp*, *DatetimeIndex*, *Period*, *PeriodIndex* (GH9605)
- Added `day_of_year` (compatibility alias `dayofyear`) property to *Timestamp*, *DatetimeIndex*, *Period*, *PeriodIndex* (GH9605)
- Added `set_flags()` for setting table-wide flags on a Series or DataFrame (GH28394)
- *DataFrame.applymap()* now supports `na_action` (GH23803)
- *Index* with object dtype supports division and multiplication (GH34160)
- `io.sql.get_schema()` now supports a `schema` keyword argument that will add a schema into the create table statement (GH28486)
- *DataFrame.explode()* and *Series.explode()* now support exploding of sets (GH35614)
- *DataFrame.hist()* now supports time series (datetime) data (GH32590)
- *Styler.set\_table\_styles()* now allows the direct styling of rows and columns and can be chained (GH35607)

- *Styler* now allows direct CSS class name addition to individual data cells (GH36159)
- *Rolling.mean()* and *Rolling.sum()* use Kahan summation to calculate the mean to avoid numerical problems (GH10319, GH11645, GH13254, GH32761, GH36031)
- *DatetimeIndex.searchsorted()*, *TimedeltaIndex.searchsorted()*, *PeriodIndex.searchsorted()*, and *Series.searchsorted()* with datetime-like dtypes will now try to cast string arguments (list-like and scalar) to the matching datetime-like type (GH36346)
- Added methods *IntegerArray.prod()*, *IntegerArray.min()*, and *IntegerArray.max()* (GH33790)
- Calling a NumPy ufunc on a *DataFrame* with extension types now preserves the extension types when possible (GH23743)
- Calling a binary-input NumPy ufunc on multiple *DataFrame* objects now aligns, matching the behavior of binary operations and ufuncs on *Series* (GH23743). This change has been reverted in pandas 1.2.1, and the behaviour to not align *DataFrames* is deprecated instead, see the *the 1.2.1 release notes*.
- Where possible *RangeIndex.difference()* and *RangeIndex.symmetric\_difference()* will return *RangeIndex* instead of *Int64Index* (GH36564)
- *DataFrame.to\_parquet()* now supports *MultiIndex* for columns in parquet format (GH34777)
- *read\_parquet()* gained a *use\_nullable\_dtypes=True* option to use nullable dtypes that use *pd.NA* as missing value indicator where possible for the resulting *DataFrame* (default is *False*, and only applicable for *engine="pyarrow"*) (GH31242)
- Added *Rolling.sem()* and *Expanding.sem()* to compute the standard error of the mean (GH26476)
- *Rolling.var()* and *Rolling.std()* use Kahan summation and Welford's Method to avoid numerical issues (GH37051)
- *DataFrame.corr()* and *DataFrame.cov()* use Welford's Method to avoid numerical issues (GH37448)
- *DataFrame.plot()* now recognizes *xlabel* and *ylabel* arguments for plots of type *scatter* and *hexbin* (GH37001)
- *DataFrame* now supports the *divmod* operation (GH37165)
- *DataFrame.to\_parquet()* now returns a bytes object when no path argument is passed (GH37105)
- *Rolling* now supports the *closed* argument for fixed windows (GH34315)
- *DatetimeIndex* and *Series* with *datetime64* or *datetime64tz* dtypes now support *std* (GH37436)
- *Window* now supports all Scipy window types in *win\_type* with flexible keyword argument support (GH34556)
- *testing.assert\_index\_equal()* now has a *check\_order* parameter that allows indexes to be checked in an order-insensitive manner (GH37478)
- *read\_csv()* supports memory-mapping for compressed files (GH37621)
- Add support for *min\_count* keyword for *DataFrame.groupby()* and *DataFrame.resample()* for functions *min*, *max*, *first* and *last* (GH37821, GH37768)
- Improve error reporting for *DataFrame.merge()* when invalid merge column definitions were given (GH16228)
- Improve numerical stability for *Rolling.skew()*, *Rolling.kurt()*, *Expanding.skew()* and *Expanding.kurt()* through implementation of Kahan summation (GH6929)
- Improved error reporting for subsetting columns of a *DataFrameGroupBy* with *axis=1* (GH37725)
- Implement method *cross* for *DataFrame.merge()* and *DataFrame.join()* (GH5401)
- When *read\_csv()*, *read\_sas()* and *read\_json()* are called with *chunksize/iterator* they can be used in a *with* statement as they return context-managers (GH38225)

- Augmented the list of named colors available for styling Excel exports, enabling all of CSS4 colors ([GH38247](#))

## Notable bug fixes

These are bug fixes that might have notable behavior changes.

## Consistency of DataFrame Reductions

`DataFrame.any()` and `DataFrame.all()` with `bool_only=True` now determines whether to exclude object-dtype columns on a column-by-column basis, instead of checking if *all* object-dtype columns can be considered boolean.

This prevents pathological behavior where applying the reduction on a subset of columns could result in a larger Series result. See ([GH37799](#)).

```
In [24]: df = pd.DataFrame({"A": ["foo", "bar"], "B": [True, False]}, dtype=object)
```

```
In [25]: df["C"] = pd.Series([True, True])
```

*Previous behavior:*

```
In [5]: df.all(bool_only=True)
```

```
Out[5]:
```

```
C True
dtype: bool
```

```
In [6]: df[["B", "C"]].all(bool_only=True)
```

```
Out[6]:
```

```
B False
C True
dtype: bool
```

*New behavior:*

```
In [26]: In [5]: df.all(bool_only=True)
```

```
Out[26]:
```

```
B False
C True
dtype: bool
```

```
In [27]: In [6]: df[["B", "C"]].all(bool_only=True)
```

```
Out[27]:
```

```
B False
C True
dtype: bool
```

Other DataFrame reductions with `numeric_only=None` will also avoid this pathological behavior ([GH37827](#)):

```
In [28]: df = pd.DataFrame({"A": [0, 1, 2], "B": ["a", "b", "c"]}, dtype=object)
```

*Previous behavior:*

```
In [3]: df.mean()
```

```
Out[3]: Series([], dtype: float64)
```

(continues on next page)

(continued from previous page)

```
In [4]: df[["A"]].mean()
Out[4]:
A 1.0
dtype: float64
```

*New behavior:*

```
In [29]: df.mean()
Out[29]:
A 1.0
dtype: float64

In [30]: df[["A"]].mean()
Out[30]:
A 1.0
dtype: float64
```

Moreover, DataFrame reductions with `numeric_only=None` will now be consistent with their Series counterparts. In particular, for reductions where the Series method raises `TypeError`, the DataFrame reduction will now consider that column non-numeric instead of casting to a NumPy array which may have different semantics ([GH36076](#), [GH28949](#), [GH21020](#)).

```
In [31]: ser = pd.Series([0, 1], dtype="category", name="A")
In [32]: df = ser.to_frame()
```

*Previous behavior:*

```
In [5]: df.any()
Out[5]:
A True
dtype: bool
```

*New behavior:*

```
In [33]: df.any()
Out[33]: Series([], dtype: bool)
```

## Increased minimum version for Python

pandas 1.2.0 supports Python 3.7.1 and higher ([GH35214](#)).

## Increased minimum versions for dependencies

Some minimum supported versions of dependencies were updated ([GH35214](#)). If installed, we now require:

| Package         | Minimum Version | Required | Changed |
|-----------------|-----------------|----------|---------|
| numpy           | 1.16.5          | X        | X       |
| pytz            | 2017.3          | X        | X       |
| python-dateutil | 2.7.3           | X        |         |
| bottleneck      | 1.2.1           |          |         |
| numexpr         | 2.6.8           |          | X       |
| pytest (dev)    | 5.0.1           |          | X       |
| mypy (dev)      | 0.782           |          | X       |

For [optional libraries](#) the general recommendation is to use the latest version. The following table lists the lowest version per library that is currently being tested throughout the development of pandas. Optional libraries below the lowest tested version may still work, but are not considered supported.

| Package        | Minimum Version | Changed |
|----------------|-----------------|---------|
| beautifulsoup4 | 4.6.0           |         |
| fastparquet    | 0.3.2           |         |
| fsspec         | 0.7.4           |         |
| gcsfs          | 0.6.0           |         |
| lxml           | 4.3.0           | X       |
| matplotlib     | 2.2.3           | X       |
| numba          | 0.46.0          |         |
| openpyxl       | 2.6.0           | X       |
| pyarrow        | 0.15.0          | X       |
| pymysql        | 0.7.11          | X       |
| pytables       | 3.5.1           | X       |
| s3fs           | 0.4.0           |         |
| scipy          | 1.2.0           |         |
| sqlalchemy     | 1.2.8           | X       |
| xarray         | 0.12.3          | X       |
| xlrd           | 1.2.0           | X       |
| xlswriter      | 1.0.2           | X       |
| xlwt           | 1.3.0           | X       |
| pandas-gbq     | 0.12.0          |         |

See [Dependencies](#) and [Optional dependencies](#) for more.

## Other API changes

- Sorting in descending order is now stable for `Series.sort_values()` and `Index.sort_values()` for Datetime-like `Index` subclasses. This will affect sort order when sorting a `DataFrame` on multiple columns, sorting with a key function that produces duplicates, or requesting the sorting index when using `Index.sort_values()`. When using `Series.value_counts()`, the count of missing values is no longer necessarily last in the list of duplicate counts. Instead, its position corresponds to the position in the original `Series`. When using `Index.sort_values()` for Datetime-like `Index` subclasses, `NaTs` ignored the `na_position` argument and were sorted to the beginning. Now they respect `na_position`, the default being last, same as other `Index` subclasses (GH35992)
- Passing an invalid `fill_value` to `Categorical.take()`, `DatetimeArray.take()`, `TimedeltaArray.take()`, or `PeriodArray.take()` now raises a `TypeError` instead of a `ValueError` (GH37733)
- Passing an invalid `fill_value` to `Series.shift()` with a `CategoricalDtype` now raises a `TypeError` instead of a `ValueError` (GH37733)
- Passing an invalid value to `IntervalIndex.insert()` or `CategoricalIndex.insert()` now raises a `TypeError` instead of a `ValueError` (GH37733)
- Attempting to reindex a `Series` with a `CategoricalIndex` with an invalid `fill_value` now raises a `TypeError` instead of a `ValueError` (GH37733)
- `CategoricalIndex.append()` with an index that contains non-category values will now cast instead of raising `TypeError` (GH38098)

## Deprecations

- Deprecated parameter `inplace` in `MultiIndex.set_codes()` and `MultiIndex.set_levels()` (GH35626)
- Deprecated parameter `dtype` of method `copy()` for all `Index` subclasses. Use the `astype()` method instead for changing dtype (GH35853)
- Deprecated parameters `levels` and `codes` in `MultiIndex.copy()`. Use the `set_levels()` and `set_codes()` methods instead (GH36685)
- Date parser functions `parse_date_time()`, `parse_date_fields()`, `parse_all_fields()` and `generic_parser()` from `pandas.io.date_converters` are deprecated and will be removed in a future version; use `to_datetime()` instead (GH35741)
- `DataFrame.lookup()` is deprecated and will be removed in a future version, use `DataFrame.melt()` and `DataFrame.loc()` instead (GH35224)
- The method `Index.to_native_types()` is deprecated. Use `.astype(str)` instead (GH28867)
- Deprecated indexing `DataFrame` rows with a single datetime-like string as `df[string]` (given the ambiguity whether it is indexing the rows or selecting a column), use `df.loc[string]` instead (GH36179)
- Deprecated `Index.is_all_dates()` (GH27744)
- The default value of `regex` for `Series.str.replace()` will change from `True` to `False` in a future release. In addition, single character regular expressions will *not* be treated as literal strings when `regex=True` is set (GH24804)
- Deprecated automatic alignment on comparison operations between `DataFrame` and `Series`, do `frame, ser = frame.align(ser, axis=1, copy=False)` before e.g. `frame == ser` (GH28759)
- `Rolling.count()` with `min_periods=None` will default to the size of the window in a future version (GH31302)

- Using “outer” ufuncs on DataFrames to return 4d ndarray is now deprecated. Convert to an ndarray first (GH23743)
- Deprecated slice-indexing on tz-aware *DatetimeIndex* with naive datetime objects, to match scalar indexing behavior (GH36148)
- *Index.ravel()* returning a `np.ndarray` is deprecated, in the future this will return a view on the same index (GH19956)
- Deprecate use of strings denoting units with ‘M’, ‘Y’ or ‘y’ in *to\_timedelta()* (GH36666)
- *Index* methods `&`, `|`, and `^` behaving as the set operations *Index.intersection()*, *Index.union()*, and *Index.symmetric\_difference()*, respectively, are deprecated and in the future will behave as pointwise boolean operations matching *Series* behavior. Use the named set methods instead (GH36758)
- *Categorical.is\_dtype\_equal()* and *CategoricalIndex.is\_dtype\_equal()* are deprecated, will be removed in a future version (GH37545)
- *Series.slice\_shift()* and *DataFrame.slice\_shift()* are deprecated, use *Series.shift()* or *DataFrame.shift()* instead (GH37601)
- Partial slicing on unordered *DatetimeIndex* objects with keys that are not in the index is deprecated and will be removed in a future version (GH18531)
- The `how` keyword in *PeriodIndex.astype()* is deprecated and will be removed in a future version, use `index.to_timestamp(how=how)` instead (GH37982)
- Deprecated *Index.asi8()* for *Index* subclasses other than *DatetimeIndex*, *TimedeltaIndex*, and *PeriodIndex* (GH37877)
- The `inplace` parameter of *Categorical.remove\_unused\_categories()* is deprecated and will be removed in a future version (GH37643)
- The `null_counts` parameter of *DataFrame.info()* is deprecated and replaced by `show_counts`. It will be removed in a future version (GH37999)

### Calling NumPy ufuncs on non-aligned DataFrames

Calling NumPy ufuncs on non-aligned DataFrames changed behaviour in pandas 1.2.0 (to align the inputs before calling the ufunc), but this change is reverted in pandas 1.2.1. The behaviour to not align is now deprecated instead, see the [1.2.1 release notes](#) for more details.

### Performance improvements

- Performance improvements when creating DataFrame or Series with dtype `str` or *StringDtype* from array with many string elements (GH36304, GH36317, GH36325, GH36432, GH37371)
- Performance improvement in *GroupBy.agg()* with the numba engine (GH35759)
- Performance improvements when creating *Series.map()* from a huge dictionary (GH34717)
- Performance improvement in *GroupBy.transform()* with the numba engine (GH36240)
- *Styler* `uid` method altered to compress data transmission over web whilst maintaining reasonably low table collision probability (GH36345)
- Performance improvement in *to\_datetime()* with non-ns time unit for `float` dtype columns (GH20445)
- Performance improvement in setting values on an *IntervalArray* (GH36310)
- The internal index method `_shallow_copy()` now makes the new index and original index share cached attributes, avoiding creating these again, if created on either. This can speed up operations that depend on creating copies of existing indexes (GH36840)

- Performance improvement in `RollingGroupby.count()` (GH35625)
- Small performance decrease to `Rolling.min()` and `Rolling.max()` for fixed windows (GH36567)
- Reduced peak memory usage in `DataFrame.to_pickle()` when using `protocol=5` in python 3.8+ (GH34244)
- Faster `dir` calls when the object has many index labels, e.g. `dir(ser)` (GH37450)
- Performance improvement in `ExpandingGroupby` (GH37064)
- Performance improvement in `Series.astype()` and `DataFrame.astype()` for `Categorical` (GH8628)
- Performance improvement in `DataFrame.groupby()` for float dtype (GH28303), changes of the underlying hash-function can lead to changes in float based indexes sort ordering for ties (e.g. `Index.value_counts()`)
- Performance improvement in `pd.isin()` for inputs with more than 1e6 elements (GH36611)
- Performance improvement for `DataFrame.__setitem__()` with list-like indexers (GH37954)
- `read_json()` now avoids reading entire file into memory when `chunksize` is specified (GH34548)

## Bug fixes

### Categorical

- `Categorical.fillna()` will always return a copy, validate a passed fill value regardless of whether there are any NAs to fill, and disallow an `NaT` as a fill value for numeric categories (GH36530)
- Bug in `Categorical.__setitem__()` that incorrectly raised when trying to set a tuple value (GH20439)
- Bug in `CategoricalIndex.equals()` incorrectly casting non-category entries to `np.nan` (GH37667)
- Bug in `CategoricalIndex.where()` incorrectly setting non-category entries to `np.nan` instead of raising `TypeError` (GH37977)
- Bug in `Categorical.to_numpy()` and `np.array(categorical)` with tz-aware `datetime64` categories incorrectly dropping the time zone information instead of casting to object dtype (GH38136)

### Datetime-like

- Bug in `DataFrame.combine_first()` that would convert datetime-like column on other `DataFrame` to integer when the column is not present in original `DataFrame` (GH28481)
- Bug in `DatetimeArray.date` where a `ValueError` would be raised with a read-only backing array (GH33530)
- Bug in `NaT` comparisons failing to raise `TypeError` on invalid inequality comparisons (GH35046)
- Bug in `DateOffset` where attributes reconstructed from pickle files differ from original objects when input values exceed normal ranges (e.g. `months=12`) (GH34511)
- Bug in `DatetimeIndex.get_slice_bound()` where `datetime.date` objects were not accepted or naive `Timestamp` with a tz-aware `DatetimeIndex` (GH35690)
- Bug in `DatetimeIndex.slice_locs()` where `datetime.date` objects were not accepted (GH34077)
- Bug in `DatetimeIndex.searchsorted()`, `TimedeltaIndex.searchsorted()`, `PeriodIndex.searchsorted()`, and `Series.searchsorted()` with `datetime64`, `timedelta64` or `Period` dtype placement of `NaT` values being inconsistent with NumPy (GH36176, GH36254)
- Inconsistency in `DatetimeArray`, `TimedeltaArray`, and `PeriodArray` method `__setitem__` casting arrays of strings to datetime-like scalars but not scalar strings (GH36261)

- Bug in `DatetimeArray.take()` incorrectly allowing `fill_value` with a mismatched time zone (GH37356)
- Bug in `DatetimeIndex.shift` incorrectly raising when shifting empty indexes (GH14811)
- `Timestamp` and `DatetimeIndex` comparisons between tz-aware and tz-naive objects now follow the standard library datetime behavior, returning True/False for `!/=` and raising for inequality comparisons (GH28507)
- Bug in `DatetimeIndex.equals()` and `TimedeltaIndex.equals()` incorrectly considering `int64` indexes as equal (GH36744)
- `Series.to_json()`, `DataFrame.to_json()`, and `read_json()` now implement time zone parsing when orient structure is `table` (GH35973)
- `astype()` now attempts to convert to `datetime64[ns, tz]` directly from object with inferred time zone from string (GH35973)
- Bug in `TimedeltaIndex.sum()` and `Series.sum()` with `timedelta64` dtype on an empty index or series returning `NaT` instead of `Timedelta(0)` (GH31751)
- Bug in `DatetimeArray.shift()` incorrectly allowing `fill_value` with a mismatched time zone (GH37299)
- Bug in adding a `BusinessDay` with nonzero offset to a non-scalar other (GH37457)
- Bug in `to_datetime()` with a read-only array incorrectly raising (GH34857)
- Bug in `Series.isin()` with `datetime64[ns]` dtype and `DatetimeIndex.isin()` incorrectly casting integers to datetimes (GH36621)
- Bug in `Series.isin()` with `datetime64[ns]` dtype and `DatetimeIndex.isin()` failing to consider tz-aware and tz-naive datetimes as always different (GH35728)
- Bug in `Series.isin()` with `PeriodDtype` dtype and `PeriodIndex.isin()` failing to consider arguments with different `PeriodDtype` as always different (GH37528)
- Bug in `Period` constructor now correctly handles nanoseconds in the value argument (GH34621 and GH17053)

## Timedelta

- Bug in `TimedeltaIndex`, `Series`, and `DataFrame` floor-division with `timedelta64` dtypes and `NaT` in the denominator (GH35529)
- Bug in parsing of ISO 8601 durations in `Timedelta` and `to_datetime()` (GH29773, GH36204)
- Bug in `to_timedelta()` with a read-only array incorrectly raising (GH34857)
- Bug in `Timedelta` incorrectly truncating to sub-second portion of a string input when it has precision higher than nanoseconds (GH36738)

## Timezones

- Bug in `date_range()` was raising `AmbiguousTimeError` for valid input with `ambiguous=False` (GH35297)
- Bug in `Timestamp.replace()` was losing fold information (GH37610)

## Numeric

- Bug in `to_numeric()` where float precision was incorrect (GH31364)
- Bug in `DataFrame.any()` with `axis=1` and `bool_only=True` ignoring the `bool_only` keyword (GH32432)
- Bug in `Series.equals()` where a `ValueError` was raised when NumPy arrays were compared to scalars (GH35267)
- Bug in `Series` where two Series each have a `DatetimeIndex` with different time zones having those indexes incorrectly changed when performing arithmetic operations (GH33671)
- Bug in `pandas.testing` module functions when used with `check_exact=False` on complex numeric types (GH28235)
- Bug in `DataFrame.__rmatmul__()` error handling reporting transposed shapes (GH21581)
- Bug in `Series` flex arithmetic methods where the result when operating with a list, tuple or `np.ndarray` would have an incorrect name (GH36760)
- Bug in `IntegerArray` multiplication with `timedelta` and `np.timedelta64` objects (GH36870)
- Bug in `MultiIndex` comparison with tuple incorrectly treating tuple as array-like (GH21517)
- Bug in `DataFrame.diff()` with `datetime64` dtypes including `NaT` values failing to fill `NaT` results correctly (GH32441)
- Bug in `DataFrame` arithmetic ops incorrectly accepting keyword arguments (GH36843)
- Bug in `IntervalArray` comparisons with `Series` not returning `Series` (GH36908)
- Bug in `DataFrame` allowing arithmetic operations with list of array-likes with undefined results. Behavior changed to raising `ValueError` (GH36702)
- Bug in `DataFrame.std()` with `timedelta64` dtype and `skipna=False` (GH37392)
- Bug in `DataFrame.min()` and `DataFrame.max()` with `datetime64` dtype and `skipna=False` (GH36907)
- Bug in `DataFrame.idxmax()` and `DataFrame.idxmin()` with mixed dtypes incorrectly raising `TypeError` (GH38195)

## Conversion

- Bug in `DataFrame.to_dict()` with `orient='records'` now returns python native datetime objects for datetime-like columns (GH21256)
- Bug in `Series.astype()` conversion from `string` to `float` raised in presence of `pd.NA` values (GH37626)

## Strings

- Bug in `Series.to_string()`, `DataFrame.to_string()`, and `DataFrame.to_latex()` adding a leading space when `index=False` (GH24980)
- Bug in `to_numeric()` raising a `TypeError` when attempting to convert a string dtype Series containing only numeric strings and `NA` (GH37262)

## Interval

- Bug in `DataFrame.replace()` and `Series.replace()` where `Interval` dtypes would be converted to object dtypes (GH34871)
- Bug in `IntervalIndex.take()` with negative indices and `fill_value=None` (GH37330)
- Bug in `IntervalIndex.putmask()` with datetime-like dtype incorrectly casting to object dtype (GH37968)
- Bug in `IntervalArray.astype()` incorrectly dropping dtype information with a `CategoricalDtype` object (GH37984)

## Indexing

- Bug in `PeriodIndex.get_loc()` incorrectly raising `ValueError` on non-datelike strings instead of `KeyError`, causing similar errors in `Series.__getitem__()`, `Series.__contains__()`, and `Series.loc.__getitem__()` (GH34240)
- Bug in `Index.sort_values()` where, when empty values were passed, the method would break by trying to compare missing values instead of pushing them to the end of the sort order (GH35584)
- Bug in `Index.get_indexer()` and `Index.get_indexer_non_unique()` where `int64` arrays are returned instead of `intp` (GH36359)
- Bug in `DataFrame.sort_index()` where parameter `ascending` passed as a list on a single level index gives wrong result (GH32334)
- Bug in `DataFrame.reset_index()` was incorrectly raising a `ValueError` for input with a `MultiIndex` with missing values in a level with `Categorical` dtype (GH24206)
- Bug in indexing with boolean masks on datetime-like values sometimes returning a view instead of a copy (GH36210)
- Bug in `DataFrame.__getitem__()` and `DataFrame.loc.__getitem__()` with `IntervalIndex` columns and a numeric indexer (GH26490)
- Bug in `Series.loc.__getitem__()` with a non-unique `MultiIndex` and an empty-list indexer (GH13691)
- Bug in indexing on a `Series` or `DataFrame` with a `MultiIndex` and a level named `"0"` (GH37194)
- Bug in `Series.__getitem__()` when using an unsigned integer array as an indexer giving incorrect results or segfaulting instead of raising `KeyError` (GH37218)
- Bug in `Index.where()` incorrectly casting numeric values to strings (GH37591)
- Bug in `DataFrame.loc()` returning empty result when indexer is a slice with negative step size (GH38071)
- Bug in `Series.loc()` and `DataFrame.loc()` raises when the index was of object dtype and the given numeric label was in the index (GH26491)
- Bug in `DataFrame.loc()` returned requested key plus missing values when `loc` was applied to single level from a `MultiIndex` (GH27104)
- Bug in indexing on a `Series` or `DataFrame` with a `CategoricalIndex` using a list-like indexer containing NA values (GH37722)
- Bug in `DataFrame.loc.__setitem__()` expanding an empty `DataFrame` with mixed dtypes (GH37932)
- Bug in `DataFrame.xs()` ignored `droplevel=False` for columns (GH19056)
- Bug in `DataFrame.reindex()` raising `IndexingError` wrongly for empty `DataFrame` with `tolerance` not `None` or `method="nearest"` (GH27315)

- Bug in indexing on a *Series* or *DataFrame* with a *CategoricalIndex* using list-like indexer that contains elements that are in the index's categories but not in the index itself failing to raise *KeyError* (GH37901)
- Bug on inserting a boolean label into a *DataFrame* with a numeric *Index* columns incorrectly casting to integer (GH36319)
- Bug in *DataFrame.iloc()* and *Series.iloc()* aligning objects in `__setitem__` (GH22046)
- Bug in *MultiIndex.drop()* does not raise if labels are partially found (GH37820)
- Bug in *DataFrame.loc()* did not raise *KeyError* when missing combination was given with `slice(None)` for remaining levels (GH19556)
- Bug in *DataFrame.loc()* raising *TypeError* when non-integer slice was given to select values from *MultiIndex* (GH25165, GH24263)
- Bug in *Series.at()* returning *Series* with one element instead of scalar when index is a *MultiIndex* with one level (GH38053)
- Bug in *DataFrame.loc()* returning and assigning elements in wrong order when indexer is differently ordered than the *MultiIndex* to filter (GH31330, GH34603)
- Bug in *DataFrame.loc()* and *DataFrame.\_\_getitem\_\_()* raising *KeyError* when columns were *MultiIndex* with only one level (GH29749)
- Bug in *Series.\_\_getitem\_\_()* and *DataFrame.\_\_getitem\_\_()* raising blank *KeyError* without missing keys for *IntervalIndex* (GH27365)
- Bug in setting a new label on a *DataFrame* or *Series* with a *CategoricalIndex* incorrectly raising *TypeError* when the new label is not among the index's categories (GH38098)
- Bug in *Series.loc()* and *Series.iloc()* raising *ValueError* when inserting a list-like `np.array`, `list` or `tuple` in an object *Series* of equal length (GH37748, GH37486)
- Bug in *Series.loc()* and *Series.iloc()* setting all the values of an object *Series* with those of a list-like *ExtensionArray* instead of inserting it (GH38271)

## Missing

- Bug in *SeriesGroupBy.transform()* now correctly handles missing values for `dropna=False` (GH35014)
- Bug in *Series.nunique()* with `dropna=True` was returning incorrect results when both `NA` and `None` missing values were present (GH37566)
- Bug in *Series.interpolate()* where kwarg `limit_area` and `limit_direction` had no effect when using methods `pad` and `backfill` (GH31048)

## MultiIndex

- Bug in *DataFrame.xs()* when used with *IndexSlice* raises *TypeError* with message "Expected label or tuple of labels" (GH35301)
- Bug in *DataFrame.reset\_index()* with `NaT` values in index raises *ValueError* with message "cannot convert float NaN to integer" (GH36541)
- Bug in *DataFrame.combine\_first()* when used with *MultiIndex* containing string and `NaN` values raises *TypeError* (GH36562)
- Bug in *MultiIndex.drop()* dropped `NaN` values when non existing key was given as input (GH18853)

- Bug in `MultiIndex.drop()` dropping more values than expected when index has duplicates and is not sorted (GH33494)

## I/O

- `read_sas()` no longer leaks resources on failure (GH35566)
- Bug in `DataFrame.to_csv()` and `Series.to_csv()` caused a `ValueError` when it was called with a filename in combination with mode containing a b (GH35058)
- Bug in `read_csv()` with `float_precision='round_trip'` did not handle decimal and thousands parameters (GH35365)
- `to_pickle()` and `read_pickle()` were closing user-provided file objects (GH35679)
- `to_csv()` passes compression arguments for 'gzip' always to `gzip.GzipFile` (GH28103)
- `to_csv()` did not support zip compression for binary file object not having a filename (GH35058)
- `to_csv()` and `read_csv()` did not honor `compression` and `encoding` for path-like objects that are internally converted to file-like objects (GH35677, GH26124, GH32392)
- `DataFrame.to_pickle()`, `Series.to_pickle()`, and `read_pickle()` did not support compression for file-objects (GH26237, GH29054, GH29570)
- Bug in `LongTableBuilder.middle_separator()` was duplicating LaTeX longtable entries in the List of Tables of a LaTeX document (GH34360)
- Bug in `read_csv()` with `engine='python'` truncating data if multiple items present in first row and first element started with BOM (GH36343)
- Removed `private_key` and `verbose` from `read_gbq()` as they are no longer supported in `pandas-gbq` (GH34654, GH30200)
- Bumped minimum `pytables` version to 3.5.1 to avoid a `ValueError` in `read_hdf()` (GH24839)
- Bug in `read_table()` and `read_csv()` when `delim_whitespace=True` and `sep=default` (GH36583)
- Bug in `DataFrame.to_json()` and `Series.to_json()` when used with `lines=True` and `orient='records'` the last line of the record is not appended with 'new line character' (GH36888)
- Bug in `read_parquet()` with fixed offset time zones. String representation of time zones was not recognized (GH35997, GH36004)
- Bug in `DataFrame.to_html()`, `DataFrame.to_string()`, and `DataFrame.to_latex()` ignoring the `na_rep` argument when `float_format` was also specified (GH9046, GH13828)
- Bug in output rendering of complex numbers showing too many trailing zeros (GH36799)
- Bug in `HDFStore` threw a `TypeError` when exporting an empty `DataFrame` with `datetime64[ns, tz]` dtypes with a fixed HDF5 store (GH20594)
- Bug in `HDFStore` was dropping time zone information when exporting a `Series` with `datetime64[ns, tz]` dtypes with a fixed HDF5 store (GH20594)
- `read_csv()` was closing user-provided binary file handles when `engine="c"` and an encoding was requested (GH36980)
- Bug in `DataFrame.to_hdf()` was not dropping missing rows with `dropna=True` (GH35719)
- Bug in `read_html()` was raising a `TypeError` when supplying a `pathlib.Path` argument to the `io` parameter (GH37705)

- `DataFrame.to_excel()`, `Series.to_excel()`, `DataFrame.to_markdown()`, and `Series.to_markdown()` now support writing to fsspec URLs such as S3 and Google Cloud Storage (GH33987)
- Bug in `read_fwf()` with `skip_blank_lines=True` was not skipping blank lines (GH37758)
- Parse missing values using `read_json()` with `dtype=False` to NaN instead of None (GH28501)
- `read_fwf()` was inferring compression with `compression=None` which was not consistent with the other `read_*` functions (GH37909)
- `DataFrame.to_html()` was ignoring `formatters` argument for `ExtensionDtype` columns (GH36525)
- Bumped minimum xarray version to 0.12.3 to avoid reference to the removed `Panel` class (GH27101, GH37983)
- `DataFrame.to_csv()` was re-opening file-like handles that also implement `os.PathLike` (GH38125)
- Bug in the conversion of a sliced `pyarrow.Table` with missing values to a `DataFrame` (GH38525)
- Bug in `read_sql_table()` raising a `sqlalchemy.exc.OperationalError` when column names contained a percentage sign (GH37517)

## Period

- Bug in `DataFrame.replace()` and `Series.replace()` where `Period` dtypes would be converted to object dtypes (GH34871)

## Plotting

- Bug in `DataFrame.plot()` was rotating `xticklabels` when `subplots=True`, even if the x-axis wasn't an irregular time series (GH29460)
- Bug in `DataFrame.plot()` where a marker letter in the `style` keyword sometimes caused a `ValueError` (GH21003)
- Bug in `DataFrame.plot.bar()` and `Series.plot.bar()` where ticks positions were assigned by value order instead of using the actual value for numeric or a smart ordering for string (GH26186, GH11465). This fix has been reverted in pandas 1.2.1, see *What's new in 1.2.1 (January 20, 2021)*
- Twinned axes were losing their tick labels which should only happen to all but the last row or column of 'externally' shared axes (GH33819)
- Bug in `Series.plot()` and `DataFrame.plot()` was throwing a `ValueError` when the Series or DataFrame was indexed by a `TimedeltaIndex` with a fixed frequency and the x-axis lower limit was greater than the upper limit (GH37454)
- Bug in `DataFrameGroupBy.boxplot()` when `subplots=False` would raise a `KeyError` (GH16748)
- Bug in `DataFrame.plot()` and `Series.plot()` was overwriting matplotlib's shared y axes behavior when no `sharey` parameter was passed (GH37942)
- Bug in `DataFrame.plot()` was raising a `TypeError` with `ExtensionDtype` columns (GH32073)

## Styler

- Bug in `Styler.render()` HTML was generated incorrectly because of formatting error in `rowspan` attribute, it now matches with w3 syntax ([GH38234](#))

## Groupby/resample/rolling

- Bug in `DataFrameGroupBy.count()` and `SeriesGroupBy.sum()` returning NaN for missing categories when grouped on multiple Categoricals. Now returning 0 ([GH35028](#))
- Bug in `DataFrameGroupBy.apply()` that would sometimes throw an erroneous `ValueError` if the grouping axis had duplicate entries ([GH16646](#))
- Bug in `DataFrame.resample()` that would throw a `ValueError` when resampling from "D" to "24H" over a transition into daylight savings time (DST) ([GH35219](#))
- Bug when combining methods `DataFrame.groupby()` with `DataFrame.resample()` and `DataFrame.interpolate()` raising a `TypeError` ([GH35325](#))
- Bug in `DataFrameGroupBy.apply()` where a non- nuisance grouping column would be dropped from the output columns if another groupby method was called before `.apply()` ([GH34656](#))
- Bug when subsetting columns on a `DataFrameGroupBy` (e.g. `df.groupby('a')[['b']]`) would reset the attributes `axis`, `dropna`, `group_keys`, `level`, `mutated`, `sort`, and `squeeze` to their default values ([GH9959](#))
- Bug in `DataFrameGroupBy.tshift()` failing to raise `ValueError` when a frequency cannot be inferred for the index of a group ([GH35937](#))
- Bug in `DataFrame.groupby()` does not always maintain column index name for `any`, `all`, `bfill`, `ffill`, `shift` ([GH29764](#))
- Bug in `DataFrameGroupBy.apply()` raising error with `np.nan` group(s) when `dropna=False` ([GH35889](#))
- Bug in `Rolling.sum()` returned wrong values when dtypes were mixed between float and integer and `axis=1` ([GH20649](#), [GH35596](#))
- Bug in `Rolling.count()` returned `np.nan` with `FixedForwardWindowIndexer` as window, `min_periods=0` and only missing values in the window ([GH35579](#))
- Bug where `pandas.core.window.Rolling` produces incorrect window sizes when using a `PeriodIndex` ([GH34225](#))
- Bug in `DataFrameGroupBy.ffill()` and `DataFrameGroupBy.bfill()` where a NaN group would return filled values instead of NaN when `dropna=True` ([GH34725](#))
- Bug in `RollingGroupBy.count()` where a `ValueError` was raised when specifying the `closed` parameter ([GH35869](#))
- Bug in `DataFrameGroupBy.rolling()` returning wrong values with partial centered window ([GH36040](#))
- Bug in `DataFrameGroupBy.rolling()` returned wrong values with time aware window containing NaN. Raises `ValueError` because windows are not monotonic now ([GH34617](#))
- Bug in `Rolling.__iter__()` where a `ValueError` was not raised when `min_periods` was larger than window ([GH37156](#))
- Using `Rolling.var()` instead of `Rolling.std()` avoids numerical issues for `Rolling.corr()` when `Rolling.var()` is still within floating point precision while `Rolling.std()` is not ([GH31286](#))
- Bug in `DataFrameGroupBy.quantile()` and `Resampler.quantile()` raised `TypeError` when values were of type `Timedelta` ([GH29485](#))

- Bug in `Rolling.median()` and `Rolling.quantile()` returned wrong values for `BaseIndexer` subclasses with non-monotonic starting or ending points for windows (GH37153)
- Bug in `DataFrame.groupby()` dropped nan groups from result with `dropna=False` when grouping over a single column (GH35646, GH35542)
- Bug in `DataFrameGroupBy.head()`, `DataFrameGroupBy.tail()`, `SeriesGroupBy.head()`, and `SeriesGroupBy.tail()` would raise when used with `axis=1` (GH9772)
- Bug in `DataFrameGroupBy.transform()` would raise when used with `axis=1` and a transformation kernel (e.g. “shift”) (GH36308)
- Bug in `DataFrameGroupBy.resample()` using `.agg` with `sum` produced different result than just calling `.sum` (GH33548)
- Bug in `DataFrameGroupBy.apply()` dropped values on nan group when returning the same axes with the original frame (GH38227)
- Bug in `DataFrameGroupBy.quantile()` couldn't handle with arraylike `q` when grouping by columns (GH33795)
- Bug in `DataFrameGroupBy.rank()` with `datetime64tz` or `period` dtype incorrectly casting results to those dtypes instead of returning `float64` dtype (GH38187)

## Reshaping

- Bug in `DataFrame.crosstab()` was returning incorrect results on inputs with duplicate row names, duplicate column names or duplicate names between row and column labels (GH22529)
- Bug in `DataFrame.pivot_table()` with `aggfunc='count'` or `aggfunc='sum'` returning NaN for missing categories when pivoted on a `Categorical`. Now returning 0 (GH31422)
- Bug in `concat()` and `DataFrame` constructor where input index names are not preserved in some cases (GH13475)
- Bug in func `crosstab()` when using multiple columns with `margins=True` and `normalize=True` (GH35144)
- Bug in `DataFrame.stack()` where an empty `DataFrame.stack` would raise an error (GH36113). Now returning an empty `Series` with empty `MultiIndex`.
- Bug in `Series.unstack()`. Now a `Series` with single level of `Index` trying to unstack would raise a `ValueError` (GH36113)
- Bug in `DataFrame.agg()` with `func={'name': <FUNC>}` incorrectly raising `TypeError` when `DataFrame.columns=['Name']` (GH36212)
- Bug in `Series.transform()` would give incorrect results or raise when the argument `func` was a dictionary (GH35811)
- Bug in `DataFrame.pivot()` did not preserve `MultiIndex` level names for columns when rows and columns are both multiindexed (GH36360)
- Bug in `DataFrame.pivot()` modified index argument when columns was passed but values was not (GH37635)
- Bug in `DataFrame.join()` returned a non deterministic level-order for the resulting `MultiIndex` (GH36910)
- Bug in `DataFrame.combine_first()` caused wrong alignment with dtype string and one level of `MultiIndex` containing only NA (GH37591)
- Fixed regression in `merge()` on merging `DatetimeIndex` with empty `DataFrame` (GH36895)
- Bug in `DataFrame.apply()` not setting index of return value when `func` return type is dict (GH37544)

- Bug in `DataFrame.merge()` and `pandas.merge()` returning inconsistent ordering in result for `how=right` and `how=left` (GH35382)
- Bug in `merge_ordered()` couldn't handle list-like `left_by` or `right_by` (GH35269)
- Bug in `merge_ordered()` returned wrong join result when length of `left_by` or `right_by` equals to the rows of left or right (GH38166)
- Bug in `merge_ordered()` didn't raise when elements in `left_by` or `right_by` not exist in left columns or right columns (GH38167)
- Bug in `DataFrame.drop_duplicates()` not validating bool dtype for `ignore_index` keyword (GH38274)

## ExtensionArray

- Fixed bug where `DataFrame` column set to scalar extension type via a dict instantiation was considered an object type rather than the extension type (GH35965)
- Fixed bug where `astype()` with equal dtype and `copy=False` would return a new object (GH28488)
- Fixed bug when applying a NumPy ufunc with multiple outputs to an `IntegerArray` returning None (GH36913)
- Fixed an inconsistency in `PeriodArray`'s `__init__` signature to those of `DatetimeArray` and `TimedeltaArray` (GH37289)
- Reductions for `BooleanArray`, `Categorical`, `DatetimeArray`, `FloatingArray`, `IntegerArray`, `PeriodArray`, `TimedeltaArray`, and `PandasArray` are now keyword-only methods (GH37541)
- Fixed a bug where a `TypeError` was wrongly raised if a membership check was made on an `ExtensionArray` containing nan-like values (GH37867)

## Other

- Bug in `DataFrame.replace()` and `Series.replace()` incorrectly raising an `AssertionError` instead of a `ValueError` when invalid parameter combinations are passed (GH36045)
- Bug in `DataFrame.replace()` and `Series.replace()` with numeric values and string `to_replace` (GH34789)
- Fixed metadata propagation in `Series.abs()` and ufuncs called on Series and DataFrames (GH28283)
- Bug in `DataFrame.replace()` and `Series.replace()` incorrectly casting from `PeriodDtype` to object dtype (GH34871)
- Fixed bug in metadata propagation incorrectly copying DataFrame columns as metadata when the column name overlaps with the metadata name (GH37037)
- Fixed metadata propagation in the `Series.dt`, `Series.str` accessors, `DataFrame.duplicated`, `DataFrame.stack`, `DataFrame.unstack`, `DataFrame.pivot`, `DataFrame.append`, `DataFrame.diff`, `DataFrame.applymap` and `DataFrame.update` methods (GH28283, GH37381)
- Fixed metadata propagation when selecting columns with `DataFrame.__getitem__` (GH28283)
- Bug in `Index.intersection()` with non-`Index` failing to set the correct name on the returned `Index` (GH38111)
- Bug in `RangeIndex.intersection()` failing to set the correct name on the returned `Index` in some corner cases (GH38197)
- Bug in `Index.difference()` failing to set the correct name on the returned `Index` in some corner cases (GH38268)

- Bug in `Index.union()` behaving differently depending on whether operand is an `Index` or other list-like (GH36384)
- Bug in `Index.intersection()` with non-matching numeric dtypes casting to object dtype instead of minimal common dtype (GH38122)
- Bug in `IntervalIndex.union()` returning an incorrectly-typed `Index` when empty (GH38282)
- Passing an array with 2 or more dimensions to the `Series` constructor now raises the more specific `ValueError` rather than a bare `Exception` (GH35744)
- Bug in `dir` where `dir(obj)` wouldn't show attributes defined on the instance for pandas objects (GH37173)
- Bug in `Index.drop()` raising `InvalidIndexError` when index has duplicates (GH38051)
- Bug in `RangeIndex.difference()` returning `Int64Index` in some cases where it should return `RangeIndex` (GH38028)
- Fixed bug in `assert_series_equal()` when comparing a datetime-like array with an equivalent non extension dtype array (GH37609)
- Bug in `is_bool_dtype()` would raise when passed a valid string such as "boolean" (GH38386)
- Fixed regression in logical operators raising `ValueError` when columns of `DataFrame` are a `CategoricalIndex` with unused categories (GH38367)

## 5.3 Version 1.1

### 5.3.1 What's new in 1.1.5 (December 07, 2020)

These are the changes in pandas 1.1.5. See [Release notes](#) for a full changelog including other versions of pandas.

#### Fixed regressions

- Fixed regression in addition of a timedelta-like scalar to a *DatetimeIndex* raising incorrectly ([GH37295](#))
- Fixed regression in *Series.groupby()* raising when the *Index* of the *Series* had a tuple as its name ([GH37755](#))
- Fixed regression in *DataFrame.loc()* and *Series.loc()* for `__setitem__` when one-dimensional tuple was given to select from *MultiIndex* ([GH37711](#))
- Fixed regression in inplace operations on *Series* with *ExtensionDtype* with NumPy dtyped operand ([GH37910](#))

- Fixed regression in metadata propagation for `groupby` iterator (GH37343)
- Fixed regression in `MultiIndex` constructed from a `DatetimeIndex` not retaining frequency (GH35563)
- Fixed regression in `Index` constructor raising a `AttributeError` when passed a `SparseArray` with `datetime64` values (GH35843)
- Fixed regression in `DataFrame.unstack()` with columns with integer dtype (GH37115)
- Fixed regression in indexing on a `Series` with `CategoricalDtype` after unpickling (GH37631)
- Fixed regression in `DataFrame.groupby()` aggregation with out-of-bounds datetime objects in an object-dtype column (GH36003)
- Fixed regression in `df.groupby(...).rolling(...)` with the resulting `MultiIndex` when grouping by a label that is in the index (GH37641)
- Fixed regression in `DataFrame.fillna()` not filling NaN after other operations such as `DataFrame.pivot()` (GH36495).
- Fixed performance regression in `df.groupby(...).rolling(...)` (GH38038)
- Fixed regression in `MultiIndex.intersection()` returning duplicates when at least one of the indexes had duplicates (GH36915)
- Fixed regression in `GroupBy.first()` and `GroupBy.last()` where `None` was considered a non-NA value (GH38286)

### Bug fixes

- Bug in `pytables` methods in python 3.9 (GH38041)

### Other

- Only set `-Werror` as a compiler flag in the CI jobs (GH33315, GH33314)

### Contributors

A total of 12 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

- Andrew Wieteska
- Fangchen Li
- Janus
- Joris Van den Bossche
- Matthew Roeschke
- MeeseeksMachine

## 5.3.2 What's new in 1.1.4 (October 30, 2020)

These are the changes in pandas 1.1.4. See *Release notes* for a full changelog including other versions of pandas.

### Fixed regressions

- Fixed regression in `read_csv()` raising a `ValueError` when `names` was of type `dict_keys` (GH36928)
- Fixed regression in `read_csv()` with more than 1M rows and specifying a `index_col` argument (GH37094)
- Fixed regression where attempting to mutate a `DateOffset` object would no longer raise an `AttributeError` (GH36940)
- Fixed regression where `DataFrame.agg()` would fail with `TypeError` when passed positional arguments to be passed on to the aggregation function (GH36948).
- Fixed regression in `RollingGroupby` with `sort=False` not being respected (GH36889)
- Fixed regression in `Series.astype()` converting `None` to "nan" when casting to string (GH36904)
- Fixed regression in `Series.rank()` method failing for read-only data (GH37290)
- Fixed regression in `RollingGroupby` causing a segmentation fault with `Index` of `dtype` object (GH36727)
- Fixed regression in `DataFrame.resample(...).apply(...)` raised `AttributeError` when input was a `DataFrame` and only a `Series` was evaluated (GH36951)
- Fixed regression in `DataFrame.groupby(...).std()` with nullable integer dtype (GH37415)
- Fixed regression in `PeriodDtype` comparing both equal and unequal to its string representation (GH37265)
- Fixed regression where slicing `DatetimeIndex` raised `AssertionError` on irregular time series with `pd.NaT` or on unsorted indices (GH36953 and GH35509)
- Fixed regression in certain offsets (`pd.offsets.Day()` and below) no longer being hashable (GH37267)
- Fixed regression in `StataReader` which required `chunksizes` to be manually set when using an iterator to read a dataset (GH37280)
- Fixed regression in `setitem` with `DataFrame.iloc()` which raised error when trying to set a value while filtering with a boolean list (GH36741)
- Fixed regression in `setitem` with a `Series` getting aligned before setting the values (GH37427)
- Fixed regression in `MultiIndex.is_monotonic_increasing` returning wrong results with `NaN` in at least one of the levels (GH37220)
- Fixed regression in inplace arithmetic operation on a `Series` not updating the parent `DataFrame` (GH36373)

## Bug fixes

- Bug causing `groupby(...).sum()` and similar to not preserve metadata ([GH29442](#))
- Bug in `Series.isin()` and `DataFrame.isin()` raising a `ValueError` when the target was read-only ([GH37174](#))
- Bug in `GroupBy.fillna()` that introduced a performance regression after 1.0.5 ([GH36757](#))
- Bug in `DataFrame.info()` was raising a `KeyError` when the `DataFrame` has integer column names ([GH37245](#))
- Bug in `DataFrameGroupby.apply()` would drop a `CategoricalIndex` when grouped on ([GH35792](#))

### 5.3.3 What's new in 1.1.3 (October 5, 2020)

These are the changes in pandas 1.1.3. See *Release notes* for a full changelog including other versions of pandas.

#### Enhancements

##### Added support for new Python version

pandas 1.1.3 now supports Python 3.9 (GH36296).

#### Development Changes

- The minimum version of Cython is now the most recent bug-fix version (0.29.21) (GH36296).

#### Fixed regressions

- Fixed regression in *DataFrame.agg()*, *DataFrame.apply()*, *Series.agg()*, and *Series.apply()* where internal suffix is exposed to the users when no relabelling is applied (GH36189)
- Fixed regression in IntegerArray unary plus and minus operations raising a TypeError (GH36063)
- Fixed regression when adding a *timedelta\_range()* to a *Timestamp* raised a ValueError (GH35897)
- Fixed regression in *Series.\_\_getitem\_\_()* incorrectly raising when the input was a tuple (GH35534)
- Fixed regression in *Series.\_\_getitem\_\_()* incorrectly raising when the input was a frozenset (GH35747)
- Fixed regression in modulo of *Index*, *Series* and *DataFrame* using *numexpr* using C not Python semantics (GH36047, GH36526)
- Fixed regression in *read\_excel()* with *engine="odf"* caused *UnboundLocalError* in some cases where cells had nested child nodes (GH36122, GH35802)
- Fixed regression in *DataFrame.replace()* inconsistent replace when using a float in the replace method (GH35376)
- Fixed regression in *Series.loc()* on a *Series* with a *MultiIndex* containing *Timestamp* raising *InvalidIndexError* (GH35858)
- Fixed regression in *DataFrame* and *Series* comparisons between numeric arrays and strings (GH35700, GH36377)
- Fixed regression in *DataFrame.apply()* with *raw=True* and user-function returning string (GH35940)
- Fixed regression when setting empty *DataFrame* column to a *Series* in preserving name of index in frame (GH36527)
- Fixed regression in *Period* incorrect value for ordinal over the maximum timestamp (GH36430)
- Fixed regression in *read\_table()* raised *ValueError* when *delim\_whitespace* was set to *True* (GH35958)
- Fixed regression in *Series.dt.normalize()* when normalizing pre-epoch dates the result was shifted one day (GH36294)

## Bug fixes

- Bug in `read_spss()` where passing a `pathlib.Path` as `path` would raise a `TypeError` (GH33666)
- Bug in `Series.str.startswith()` and `Series.str.endswith()` with category dtype not propagating `na` parameter (GH36241)
- Bug in `Series` constructor where integer overflow would occur for sufficiently large scalar inputs when an index was provided (GH36291)
- Bug in `DataFrame.sort_values()` raising an `AttributeError` when sorting on a key that casts column to categorical dtype (GH36383)
- Bug in `DataFrame.stack()` raising a `ValueError` when stacking `MultiIndex` columns based on position when the levels had duplicate names (GH36353)
- Bug in `Series.astype()` showing too much precision when casting from `np.float32` to string dtype (GH36451)
- Bug in `Series.isin()` and `DataFrame.isin()` when using `NaN` and a row length above 1,000,000 (GH22205)
- Bug in `cut()` raising a `ValueError` when passed a `Series` of labels with `ordered=False` (GH36603)

## Other

- Reverted enhancement added in pandas-1.1.0 where `timedelta_range()` infers a frequency when passed `start`, `stop`, and `periods` (GH32377)

## Contributors

A total of 16 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

- Asish Mahapatra
- Dan Moore +
- Daniel Saxton
- Fangchen Li
- Hans
- Irv Lustig
- Joris Van den Bossche

- patrick

### 5.3.4 What's new in 1.1.2 (September 8, 2020)

These are the changes in pandas 1.1.2. See *Release notes* for a full changelog including other versions of pandas.

#### Fixed regressions

- Regression in `DatetimeIndex.intersection()` incorrectly raising `AssertionError` when intersecting against a list (GH35876)
- Fix regression in updating a column inplace (e.g. using `df['col'].fillna(..., inplace=True)`) (GH35731)
- Fix regression in `DataFrame.append()` mixing tz-aware and tz-naive datetime columns (GH35460)
- Performance regression for `RangeIndex.format()` (GH35712)
- Regression where `MultiIndex.get_loc()` would return a slice spanning the full index when passed an empty list (GH35878)
- Fix regression in invalid cache after an indexing operation; this can manifest when setting which does not update the data (GH35521)
- Regression in `DataFrame.replace()` where a `TypeError` would be raised when attempting to replace elements of type `Interval` (GH35931)
- Fix regression in pickle roundtrip of the closed attribute of `IntervalIndex` (GH35658)
- Fixed regression in `DataFrameGroupBy.agg()` where a `ValueError: buffer source array is read-only` would be raised when the underlying array is read-only (GH36014)
- Fixed regression in `Series.groupby.rolling()` number of levels of `MultiIndex` in input was compressed to one (GH36018)
- Fixed regression in `DataFrameGroupBy` on an empty `DataFrame` (GH36197)

#### Bug fixes

- Bug in `DataFrame.eval()` with object dtype column binary operations (GH35794)
- Bug in `Series` constructor raising a `TypeError` when constructing sparse datetime64 dtypes (GH35762)
- Bug in `DataFrame.apply()` with `result_type="reduce"` returning with incorrect index (GH35683)
- Bug in `Series.astype()` and `DataFrame.astype()` not respecting the `errors` argument when set to "ignore" for extension dtypes (GH35471)
- Bug in `DateTimeIndex.format()` and `PeriodIndex.format()` with `name=True` setting the first item to "None" where it should be "" (GH35712)
- Bug in `Float64Index.__contains__()` incorrectly raising `TypeError` instead of returning `False` (GH35788)
- Bug in `Series` constructor incorrectly raising a `TypeError` when passed an ordered set (GH36044)
- Bug in `Series.dt.isocalendar()` and `DatetimeIndex.isocalendar()` that returned incorrect year for certain dates (GH36032)
- Bug in `DataFrame` indexing returning an incorrect `Series` in some cases when the series has been altered and a cache not invalidated (GH33675)
- Bug in `DataFrame.corr()` causing subsequent indexing lookups to be incorrect (GH35882)

- Bug in `import_optional_dependency()` returning incorrect package names in cases where package name is different from import name (GH35948)
- Bug when setting empty `DataFrame` column to a `Series` in preserving name of index in frame (GH31368)

### Other

- `factorize()` now supports `na_sentinel=None` to include NaN in the uniques of the values and remove `dropna` keyword which was unintentionally exposed to public facing API in 1.1 version from `factorize()` (GH35667)
- `DataFrame.plot()` and `Series.plot()` raise `UserWarning` about usage of `FixedFormatter` and `FixedLocator` (GH35684 and GH35945)

### Contributors

A total of 16 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

### 5.3.5 What's new in 1.1.1 (August 20, 2020)

These are the changes in pandas 1.1.1. See *Release notes* for a full changelog including other versions of pandas.

#### Fixed regressions

- Fixed regression in `CategoricalIndex.format()` where, when stringified scalars had different lengths, the shorter string would be right-filled with spaces, so it had the same length as the longest string (GH35439)
- Fixed regression in `Series.truncate()` when trying to truncate a single-element series (GH35544)
- Fixed regression where `DataFrame.to_numpy()` would raise a `RuntimeError` for mixed dtypes when converting to `str` (GH35455)
- Fixed regression where `read_csv()` would raise a `ValueError` when `pandas.options.mode.use_inf_as_na` was set to `True` (GH35493)
- Fixed regression where `pandas.testing.assert_series_equal()` would raise an error when non-numeric dtypes were passed with `check_exact=True` (GH35446)
- Fixed regression in `.groupby(...).rolling(...)` where column selection was ignored (GH35486)
- Fixed regression where `DataFrame.interpolate()` would raise a `TypeError` when the `DataFrame` was empty (GH35598)
- Fixed regression in `DataFrame.shift()` with `axis=1` and heterogeneous dtypes (GH35488)
- Fixed regression in `DataFrame.diff()` with read-only data (GH35559)
- Fixed regression in `.groupby(...).rolling(...)` where a segfault would occur with `center=True` and an odd number of values (GH35552)
- Fixed regression in `DataFrame.apply()` where functions that altered the input in-place only operated on a single row (GH35462)
- Fixed regression in `DataFrame.reset_index()` would raise a `ValueError` on empty `DataFrame` with a `MultiIndex` with a `datetime64` dtype level (GH35606, GH35657)
- Fixed regression where `pandas.merge_asof()` would raise a `UnboundLocalError` when `left_index`, `right_index` and `tolerance` were set (GH35558)
- Fixed regression in `.groupby(...).rolling(...)` where a custom `BaseIndexer` would be ignored (GH35557)
- Fixed regression in `DataFrame.replace()` and `Series.replace()` where compiled regular expressions would be ignored during replacement (GH35680)
- Fixed regression in `aggregate()` where a list of functions would produce the wrong results if at least one of the functions did not aggregate (GH35490)
- Fixed memory usage issue when instantiating large `pandas.arrays.StringArray` (GH35499)

## Bug fixes

- Bug in *Styler* whereby `cell_ids` argument had no effect due to other recent changes (GH35588) (GH35663)
- Bug in `pandas.testing.assert_series_equal()` and `pandas.testing.assert_frame_equal()` where extension dtypes were not ignored when `check_dtypes` was set to `False` (GH35715)
- Bug in `to_timedelta()` fails when `arg` is a *Series* with `Int64` dtype containing null values (GH35574)
- Bug in `.groupby(...).rolling(...)` where passing `closed` with column selection would raise a `ValueError` (GH35549)
- Bug in *DataFrame* constructor failing to raise `ValueError` in some cases when `data` and `index` have mismatched lengths (GH33437)

## Contributors

### 5.3.6 What's new in 1.1.0 (July 28, 2020)

These are the changes in pandas 1.1.0. See *Release notes* for a full changelog including other versions of pandas.

#### Enhancements

##### KeyErrors raised by loc specify missing labels

Previously, if labels were missing for a `.loc` call, a `KeyError` was raised stating that this was no longer supported.

Now the error message also includes a list of the missing labels (max 10 items, display width 80 characters). See [GH34272](#).

##### All dtypes can now be converted to StringDtype

Previously, declaring or converting to `StringDtype` was in general only possible if the data was already only `str` or nan-like ([GH31204](#)). `StringDtype` now works in all situations where `astype(str)` or `dtype=str` work:

For example, the below now works:

```
In [1]: ser = pd.Series([1, "abc", np.nan], dtype="string")

In [2]: ser
Out[2]:
0 1
1 abc
2 <NA>
dtype: string

In [3]: ser[0]
Out[3]: '1'

In [4]: pd.Series([1, 2, np.nan], dtype="Int64").astype("string")
Out[4]:
0 1
1 2
2 <NA>
dtype: string
```

##### Non-monotonic PeriodIndex partial string slicing

`PeriodIndex` now supports partial string slicing for non-monotonic indexes, mirroring `DatetimeIndex` behavior ([GH31096](#))

For example:

```
In [5]: dti = pd.date_range("2014-01-01", periods=30, freq="30D")

In [6]: pi = dti.to_period("D")

In [7]: ser_monotonic = pd.Series(np.arange(30), index=pi)
```

(continues on next page)

(continued from previous page)

```
In [8]: shuffler = list(range(0, 30, 2)) + list(range(1, 31, 2))
```

```
In [9]: ser = ser_monotonic[shuffler]
```

```
In [10]: ser
```

```
Out[10]:
```

```
2014-01-01 0
2014-03-02 2
2014-05-01 4
2014-06-30 6
2014-08-29 8
```

```
..
2015-09-23 21
2015-11-22 23
2016-01-21 25
2016-03-21 27
2016-05-20 29
```

```
Freq: D, Length: 30, dtype: int64
```

```
In [11]: ser["2014"]
```

```
Out[11]:
```

```
2014-01-01 0
2014-03-02 2
2014-05-01 4
2014-06-30 6
2014-08-29 8
2014-10-28 10
2014-12-27 12
2014-01-31 1
2014-04-01 3
2014-05-31 5
2014-07-30 7
2014-09-28 9
2014-11-27 11
```

```
Freq: D, dtype: int64
```

```
In [12]: ser.loc["May 2015"]
```

```
Out[12]:
```

```
2015-05-26 17
```

```
Freq: D, dtype: int64
```

## Comparing two DataFrame or two Series and summarizing the differences

We've added `DataFrame.compare()` and `Series.compare()` for comparing two DataFrame or two Series (GH30429)

```
In [13]: df = pd.DataFrame(
...: {
...: "col1": ["a", "a", "b", "b", "a"],
...: "col2": [1.0, 2.0, 3.0, np.nan, 5.0],
...: "col3": [1.0, 2.0, 3.0, 4.0, 5.0]
...: },
...: columns=["col1", "col2", "col3"],
...:)
...:
```

```
In [14]: df
```

```
Out[14]:
 col1 col2 col3
0 a 1.0 1.0
1 a 2.0 2.0
2 b 3.0 3.0
3 b NaN 4.0
4 a 5.0 5.0
```

```
In [15]: df2 = df.copy()
```

```
In [16]: df2.loc[0, 'col1'] = 'c'
```

```
In [17]: df2.loc[2, 'col3'] = 4.0
```

```
In [18]: df2
```

```
Out[18]:
 col1 col2 col3
0 c 1.0 1.0
1 a 2.0 2.0
2 b 3.0 4.0
3 b NaN 4.0
4 a 5.0 5.0
```

```
In [19]: df.compare(df2)
```

```
Out[19]:
 col1 col3
self other self other
0 a c NaN NaN
2 NaN NaN 3.0 4.0
```

See [User Guide](#) for more details.

## Allow NA in groupby key

With *groupby*, we've added a *dropna* keyword to *DataFrame.groupby()* and *Series.groupby()* in order to allow NA values in group keys. Users can define *dropna* to *False* if they want to include NA values in groupby keys. The default is set to *True* for *dropna* to keep backwards compatibility (GH3729)

```
In [20]: df_list = [[1, 2, 3], [1, None, 4], [2, 1, 3], [1, 2, 2]]
```

```
In [21]: df_dropna = pd.DataFrame(df_list, columns=["a", "b", "c"])
```

```
In [22]: df_dropna
```

```
Out[22]:
```

```
 a b c
0 1 2.0 3
1 1 NaN 4
2 2 1.0 3
3 1 2.0 2
```

```
Default ``dropna`` is set to True, which will exclude NaNs in keys
```

```
In [23]: df_dropna.groupby(by=["b"], dropna=True).sum()
```

```
Out[23]:
```

```
 a c
b
1.0 2 3
2.0 2 5
```

```
In order to allow NaN in keys, set ``dropna`` to False
```

```
In [24]: df_dropna.groupby(by=["b"], dropna=False).sum()
```

```
Out[24]:
```

```
 a c
b
1.0 2 3
2.0 2 5
NaN 1 4
```

The default setting of *dropna* argument is *True* which means NA are not included in group keys.

## Sorting with keys

We've added a *key* argument to the *DataFrame* and *Series* sorting methods, including *DataFrame.sort\_values()*, *DataFrame.sort\_index()*, *Series.sort\_values()*, and *Series.sort\_index()*. The *key* can be any callable function which is applied column-by-column to each column used for sorting, before sorting is performed (GH27237). See *sort\_values with keys* and *sort\_index with keys* for more information.

```
In [25]: s = pd.Series(['C', 'a', 'B'])
```

```
In [26]: s
```

```
Out[26]:
```

```
0 C
1 a
2 B
dtype: object
```

```
In [27]: s.sort_values()
Out[27]:
2 B
0 C
1 a
dtype: object
```

Note how this is sorted with capital letters first. If we apply the `Series.str.lower()` method, we get

```
In [28]: s.sort_values(key=lambda x: x.str.lower())
Out[28]:
1 a
2 B
0 C
dtype: object
```

When applied to a DataFrame, the key is applied per-column to all columns or a subset if `by` is specified, e.g.

```
In [29]: df = pd.DataFrame({'a': ['C', 'C', 'a', 'a', 'B', 'B'],
.....: 'b': [1, 2, 3, 4, 5, 6]})
.....:

In [30]: df
Out[30]:
 a b
0 C 1
1 C 2
2 a 3
3 a 4
4 B 5
5 B 6
```

```
In [31]: df.sort_values(by=['a'], key=lambda col: col.str.lower())
Out[31]:
 a b
2 a 3
3 a 4
4 B 5
5 B 6
0 C 1
1 C 2
```

For more details, see examples and documentation in `DataFrame.sort_values()`, `Series.sort_values()`, and `sort_index()`.

### Fold argument support in Timestamp constructor

Timestamp: now supports the keyword-only fold argument according to [PEP 495](#) similar to parent datetime.datetime class. It supports both accepting fold as an initialization argument and inferring fold from other constructor arguments ([GH25057](#), [GH31338](#)). Support is limited to dateutil timezones as pytz doesn't support fold.

For example:

```
In [32]: ts = pd.Timestamp("2019-10-27 01:30:00+00:00")
```

```
In [33]: ts.fold
```

```
Out[33]: 0
```

```
In [34]: ts = pd.Timestamp(year=2019, month=10, day=27, hour=1, minute=30,
.....: tz="dateutil/Europe/London", fold=1)
.....:
```

```
In [35]: ts
```

```
Out[35]: Timestamp('2019-10-27 01:30:00+0000', tz='dateutil//usr/share/zoneinfo/Europe/
↳London')
```

For more on working with fold, see *Fold subsection* in the user guide.

### Parsing timezone-aware format with different timezones in to\_datetime

`to_datetime()` now supports parsing formats containing timezone names (%Z) and UTC offsets (%z) from different timezones then converting them to UTC by setting `utc=True`. This would return a *DatetimeIndex* with timezone at UTC as opposed to an *Index* with object dtype if `utc=True` is not set ([GH32792](#)).

For example:

```
In [36]: tz_strs = ["2010-01-01 12:00:00 +0100", "2010-01-01 12:00:00 -0100",
.....: "2010-01-01 12:00:00 +0300", "2010-01-01 12:00:00 +0400"]
.....:
```

```
In [37]: pd.to_datetime(tz_strs, format='%Y-%m-%d %H:%M:%S %z', utc=True)
```

```
Out[37]:
```

```
DatetimeIndex(['2010-01-01 11:00:00+00:00', '2010-01-01 13:00:00+00:00',
 '2010-01-01 09:00:00+00:00', '2010-01-01 08:00:00+00:00'],
 dtype='datetime64[ns, UTC]', freq=None)
```

```
In [38]: pd.to_datetime(tz_strs, format='%Y-%m-%d %H:%M:%S %z')
```

```
Out[38]:
```

```
Index([2010-01-01 12:00:00+01:00, 2010-01-01 12:00:00-01:00,
 2010-01-01 12:00:00+03:00, 2010-01-01 12:00:00+04:00],
 dtype='object')
```

## Groupby and resample now supports the arguments origin and offset

`Groupby` and `DataFrame.resample()` now supports the arguments `origin` and `offset`. It let the user control the timestamp on which to adjust the grouping. (GH31809)

The bins of the grouping are adjusted based on the beginning of the day of the time series starting point. This works well with frequencies that are multiples of a day (like `30D`) or that divides a day (like `90s` or `1min`). But it can create inconsistencies with some frequencies that do not meet this criteria. To change this behavior you can now specify a fixed timestamp with the argument `origin`.

Two arguments are now deprecated (more information in the documentation of `DataFrame.resample()`):

- `base` should be replaced by `offset`.
- `loffset` should be replaced by directly adding an offset to the index `DataFrame` after being resampled.

Small example of the use of `origin`:

```
In [39]: start, end = '2000-10-01 23:30:00', '2000-10-02 00:30:00'

In [40]: middle = '2000-10-02 00:00:00'

In [41]: rng = pd.date_range(start, end, freq='7min')

In [42]: ts = pd.Series(np.arange(len(rng)) * 3, index=rng)

In [43]: ts
Out[43]:
2000-10-01 23:30:00 0
2000-10-01 23:37:00 3
2000-10-01 23:44:00 6
2000-10-01 23:51:00 9
2000-10-01 23:58:00 12
2000-10-02 00:05:00 15
2000-10-02 00:12:00 18
2000-10-02 00:19:00 21
2000-10-02 00:26:00 24
Freq: 7T, dtype: int64
```

Resample with the default behavior `'start_day'` (origin is `2000-10-01 00:00:00`):

```
In [44]: ts.resample('17min').sum()
Out[44]:
2000-10-01 23:14:00 0
2000-10-01 23:31:00 9
2000-10-01 23:48:00 21
2000-10-02 00:05:00 54
2000-10-02 00:22:00 24
Freq: 17T, dtype: int64

In [45]: ts.resample('17min', origin='start_day').sum()
Out[45]:
2000-10-01 23:14:00 0
2000-10-01 23:31:00 9
2000-10-01 23:48:00 21
2000-10-02 00:05:00 54
```

(continues on next page)

(continued from previous page)

```
2000-10-02 00:22:00 24
Freq: 17T, dtype: int64
```

Resample using a fixed origin:

```
In [46]: ts.resample('17min', origin='epoch').sum()
Out[46]:
2000-10-01 23:18:00 0
2000-10-01 23:35:00 18
2000-10-01 23:52:00 27
2000-10-02 00:09:00 39
2000-10-02 00:26:00 24
Freq: 17T, dtype: int64

In [47]: ts.resample('17min', origin='2000-01-01').sum()
Out[47]:
2000-10-01 23:24:00 3
2000-10-01 23:41:00 15
2000-10-01 23:58:00 45
2000-10-02 00:15:00 45
Freq: 17T, dtype: int64
```

If needed you can adjust the bins with the argument `offset` (a *Timedelta*) that would be added to the default origin.

For a full example, see: *Use origin or offset to adjust the start of the bins*.

### fsspec now used for filesystem handling

For reading and writing to filesystems other than local and reading from HTTP(S), the optional dependency `fsspec` will be used to dispatch operations (GH33452). This will give unchanged functionality for S3 and GCS storage, which were already supported, but also add support for several other storage implementations such as [Azure Datalake and Blob](#), SSH, FTP, dropbox and github. For docs and capabilities, see the [fsspec docs](#).

The existing capability to interface with S3 and GCS will be unaffected by this change, as `fsspec` will still bring in the same packages as before.

### Other enhancements

- Compatibility with matplotlib 3.3.0 (GH34850)
- `IntegerArray.astype()` now supports `datetime64` dtype (GH32538)
- `IntegerArray` now implements the `sum` operation (GH33172)
- Added `pandas.errors.InvalidIndexError` (GH34570).
- Added `DataFrame.value_counts()` (GH5377)
- Added a `pandas.api.indexers.FixedForwardWindowIndexer()` class to support forward-looking windows during rolling operations.
- Added a `pandas.api.indexers.VariableOffsetWindowIndexer()` class to support rolling operations with non-fixed offsets (GH34994)

- `describe()` now includes a `datetime_is_numeric` keyword to control how datetime columns are summarized (GH30164, GH34798)
- `Styler` may now render CSS more efficiently where multiple cells have the same styling (GH30876)
- `highlight_null()` now accepts subset argument (GH31345)
- When writing directly to a sqlite connection `DataFrame.to_sql()` now supports the `multi` method (GH29921)
- `pandas.errors.OptionError` is now exposed in `pandas.errors` (GH27553)
- Added `api.extensions.ExtensionArray.argmax()` and `api.extensions.ExtensionArray.argmin()` (GH24382)
- `timedelta_range()` will now infer a frequency when passed `start`, `stop`, and `periods` (GH32377)
- Positional slicing on a `IntervalIndex` now supports slices with `step > 1` (GH31658)
- `Series.str` now has a `fullmatch` method that matches a regular expression against the entire string in each row of the `Series`, similar to `re.fullmatch` (GH32806).
- `DataFrame.sample()` will now also allow array-like and BitGenerator objects to be passed to `random_state` as seeds (GH32503)
- `Index.union()` will now raise `RuntimeWarning` for `MultiIndex` objects if the object inside are unsortable. Pass `sort=False` to suppress this warning (GH33015)
- Added `Series.dt.isocalendar()` and `DatetimeIndex.isocalendar()` that returns a `DataFrame` with year, week, and day calculated according to the ISO 8601 calendar (GH33206, GH34392).
- The `DataFrame.to_feather()` method now supports additional keyword arguments (e.g. to set the compression) that are added in `pyarrow 0.17` (GH33422).
- The `cut()` will now accept parameter `ordered` with default `ordered=True`. If `ordered=False` and no labels are provided, an error will be raised (GH33141)
- `DataFrame.to_csv()`, `DataFrame.to_pickle()`, and `DataFrame.to_json()` now support passing a dict of compression arguments when using the `gzip` and `bz2` protocols. This can be used to set a custom compression level, e.g., `df.to_csv(path, compression={'method': 'gzip', 'compresslevel': 1})` (GH33196)
- `melt()` has gained an `ignore_index` (default `True`) argument that, if set to `False`, prevents the method from dropping the index (GH17440).
- `Series.update()` now accepts objects that can be coerced to a `Series`, such as `dict` and `list`, mirroring the behavior of `DataFrame.update()` (GH33215)
- `transform()` and `aggregate()` have gained `engine` and `engine_kwags` arguments that support executing functions with `Numba` (GH32854, GH33388)
- `interpolate()` now supports SciPy interpolation method `scipy.interpolate.CubicSpline` as method `cubic spline` (GH33670)
- `DataFrameGroupBy` and `SeriesGroupBy` now implement the `sample` method for doing random sampling within groups (GH31775)
- `DataFrame.to_numpy()` now supports the `na_value` keyword to control the NA sentinel in the output array (GH33820)
- Added `api.extension.ExtensionArray.equals` to the extension array interface, similar to `Series.equals()` (GH27081)
- The minimum supported dta version has increased to 105 in `read_stata()` and `StataReader` (GH26667).

- `to_stata()` supports compression using the `compression` keyword argument. Compression can either be inferred or explicitly set using a string or a dictionary containing both the method and any additional arguments that are passed to the compression library. Compression was also added to the low-level Stata-file writers `StataWriter`, `StataWriter117`, and `StataWriterUTF8` (GH26599).
- `HDFStore.put()` now accepts a `track_times` parameter. This parameter is passed to the `create_table` method of `PyTables` (GH32682).
- `Series.plot()` and `DataFrame.plot()` now accepts `xlabel` and `ylabel` parameters to present labels on x and y axis (GH9093).
- Made `pandas.core.window.rolling.Rolling` and `pandas.core.window.expanding.Expanding` iterable (GH11704)
- Made `option_context` a `contextlib.ContextDecorator`, which allows it to be used as a decorator over an entire function (GH34253).
- `DataFrame.to_csv()` and `Series.to_csv()` now accept an `errors` argument (GH22610)
- `transform()` now allows `func` to be `pad`, `backfill` and `cumcount` (GH31269).
- `read_json()` now accepts an `nrows` parameter. (GH33916).
- `DataFrame.hist()`, `Series.hist()`, `core.groupby.DataFrameGroupBy.hist()`, and `core.groupby.SeriesGroupBy.hist()` have gained the `legend` argument. Set to `True` to show a legend in the histogram. (GH6279)
- `concat()` and `append()` now preserve extension dtypes, for example combining a nullable integer column with a numpy integer column will no longer result in object dtype but preserve the integer dtype (GH33607, GH34339, GH34095).
- `read_gbq()` now allows to disable progress bar (GH33360).
- `read_gbq()` now supports the `max_results` kwarg from `pandas-gbq` (GH34639).
- `DataFrame.cov()` and `Series.cov()` now support a new parameter `ddof` to support delta degrees of freedom as in the corresponding numpy methods (GH34611).
- `DataFrame.to_html()` and `DataFrame.to_string()`'s `col_space` parameter now accepts a list or dict to change only some specific columns' width (GH28917).
- `DataFrame.to_excel()` can now also write OpenOffice spreadsheet (.ods) files (GH27222)
- `explode()` now accepts `ignore_index` to reset the index, similar to `pd.concat()` or `DataFrame.sort_values()` (GH34932).
- `DataFrame.to_markdown()` and `Series.to_markdown()` now accept `index` argument as an alias for `tabulate`'s `showindex` (GH32667)
- `read_csv()` now accepts string values like "0", "0.0", "1", "1.0" as convertible to the nullable Boolean dtype (GH34859)
- `pandas.core.window.ExponentialMovingWindow` now supports a `times` argument that allows mean to be calculated with observations spaced by the timestamps in `times` (GH34839)
- `DataFrame.agg()` and `Series.agg()` now accept named aggregation for renaming the output columns/indexes. (GH26513)
- `compute.use_numba` now exists as a configuration option that utilizes the numba engine when available (GH33966, GH35374)
- `Series.plot()` now supports asymmetric error bars. Previously, if `Series.plot()` received a "2xN" array with error values for `yerr` and/or `xerr`, the left/lower values (first row) were mirrored, while the right/upper

values (second row) were ignored. Now, the first row represents the left/lower error values and the second row the right/upper error values. (GH9536)

## Notable bug fixes

These are bug fixes that might have notable behavior changes.

### MultiIndex.get\_indexer interprets method argument correctly

This restores the behavior of `MultiIndex.get_indexer()` with `method='backfill'` or `method='pad'` to the behavior before pandas 0.23.0. In particular, MultiIndexes are treated as a list of tuples and padding or backfilling is done with respect to the ordering of these lists of tuples (GH29896).

As an example of this, given:

```
In [48]: df = pd.DataFrame({
.....: 'a': [0, 0, 0, 0],
.....: 'b': [0, 2, 3, 4],
.....: 'c': ['A', 'B', 'C', 'D'],
.....: }).set_index(['a', 'b'])
.....:

In [49]: mi_2 = pd.MultiIndex.from_product([[0], [-1, 0, 1, 3, 4, 5]])
```

The differences in reindexing `df` with `mi_2` and using `method='backfill'` can be seen here:

*pandas >= 0.23, < 1.1.0:*

```
In [1]: df.reindex(mi_2, method='backfill')
Out[1]:
 c
0 -1 A
 0 A
 1 D
 3 A
 4 A
 5 C
```

*pandas < 0.23, >= 1.1.0*

```
In [50]: df.reindex(mi_2, method='backfill')
Out[50]:
 c
0 -1 A
 0 A
 1 B
 3 C
 4 D
 5 NaN
```

And the differences in reindexing `df` with `mi_2` and using `method='pad'` can be seen here:

*pandas >= 0.23, < 1.1.0*

```
In [1]: df.reindex(mi_2, method='pad')
```

```
Out[1]:
```

```
 c
0 -1 NaN
 0 NaN
 1 D
 3 NaN
 4 A
 5 C
```

*pandas < 0.23, >= 1.1.0*

```
In [51]: df.reindex(mi_2, method='pad')
```

```
Out[51]:
```

```
 c
0 -1 NaN
 0 A
 1 A
 3 C
 4 D
 5 D
```

### Failed label-based lookups always raise KeyError

Label lookups `series[key]`, `series.loc[key]` and `frame.loc[key]` used to raise either `KeyError` or `TypeError` depending on the type of key and type of *Index*. These now consistently raise `KeyError` (GH31867)

```
In [52]: ser1 = pd.Series(range(3), index=[0, 1, 2])
```

```
In [53]: ser2 = pd.Series(range(3), index=pd.date_range("2020-02-01", periods=3))
```

*Previous behavior:*

```
In [3]: ser1[1.5]
```

```
...
```

```
TypeError: cannot do label indexing on Int64Index with these indexers [1.5] of type float
```

```
In [4]: ser1["foo"]
```

```
...
```

```
KeyError: 'foo'
```

```
In [5]: ser1.loc[1.5]
```

```
...
```

```
TypeError: cannot do label indexing on Int64Index with these indexers [1.5] of type float
```

```
In [6]: ser1.loc["foo"]
```

```
...
```

```
KeyError: 'foo'
```

```
In [7]: ser2.loc[1]
```

```
...
```

```
TypeError: cannot do label indexing on DatetimeIndex with these indexers [1] of type int
```

(continues on next page)

(continued from previous page)

```
In [8]: ser2.loc[pd.Timestamp(0)]
...
KeyError: Timestamp('1970-01-01 00:00:00')
```

*New behavior:*

```
In [3]: ser1[1.5]
...
KeyError: 1.5

In [4] ser1["foo"]
...
KeyError: 'foo'

In [5]: ser1.loc[1.5]
...
KeyError: 1.5

In [6]: ser1.loc["foo"]
...
KeyError: 'foo'

In [7]: ser2.loc[1]
...
KeyError: 1

In [8]: ser2.loc[pd.Timestamp(0)]
...
KeyError: Timestamp('1970-01-01 00:00:00')
```

Similarly, `DataFrame.at()` and `Series.at()` will raise a `TypeError` instead of a `ValueError` if an incompatible key is passed, and `KeyError` if a missing key is passed, matching the behavior of `.loc[]` ([GH31722](#))

### Failed Integer Lookups on MultiIndex Raise KeyError

Indexing with integers with a `MultiIndex` that has an integer-dtype first level incorrectly failed to raise `KeyError` when one or more of those integer keys is not present in the first level of the index ([GH33539](#))

```
In [54]: idx = pd.Index(range(4))

In [55]: dti = pd.date_range("2000-01-03", periods=3)

In [56]: mi = pd.MultiIndex.from_product([idx, dti])

In [57]: ser = pd.Series(range(len(mi)), index=mi)
```

*Previous behavior:*

```
In [5]: ser[[5]]
Out[5]: Series([], dtype: int64)
```

*New behavior:*

```
In [5]: ser[[5]]
...
KeyError: '[5] not in index'
```

### DataFrame.merge() preserves right frame's row order

`DataFrame.merge()` now preserves the right frame's row order when executing a right merge ([GH27453](#))

```
In [58]: left_df = pd.DataFrame({'animal': ['dog', 'pig'],
...: 'max_speed': [40, 11]})
...:
In [59]: right_df = pd.DataFrame({'animal': ['quetzal', 'pig'],
...: 'max_speed': [80, 11]})
...:
In [60]: left_df
Out[60]:
 animal max_speed
0 dog 40
1 pig 11
In [61]: right_df
Out[61]:
 animal max_speed
0 quetzal 80
1 pig 11
```

*Previous behavior:*

```
>>> left_df.merge(right_df, on=['animal', 'max_speed'], how="right")
 animal max_speed
0 pig 11
1 quetzal 80
```

*New behavior:*

```
In [62]: left_df.merge(right_df, on=['animal', 'max_speed'], how="right")
Out[62]:
 animal max_speed
0 quetzal 80
1 pig 11
```

### Assignment to multiple columns of a DataFrame when some columns do not exist

Assignment to multiple columns of a *DataFrame* when some of the columns do not exist would previously assign the values to the last column. Now, new columns will be constructed with the right values. (GH13658)

```
In [63]: df = pd.DataFrame({'a': [0, 1, 2], 'b': [3, 4, 5]})
```

```
In [64]: df
```

```
Out[64]:
 a b
0 0 3
1 1 4
2 2 5
```

*Previous behavior:*

```
In [3]: df[['a', 'c']] = 1
```

```
In [4]: df
```

```
Out[4]:
 a b
0 1 1
1 1 1
2 1 1
```

*New behavior:*

```
In [65]: df[['a', 'c']] = 1
```

```
In [66]: df
```

```
Out[66]:
 a b c
0 1 3 1
1 1 4 1
2 1 5 1
```

### Consistency across groupby reductions

Using *DataFrame.groupby()* with `as_index=True` and the aggregation `nunique` would include the grouping column(s) in the columns of the result. Now the grouping column(s) only appear in the index, consistent with other reductions. (GH32579)

```
In [67]: df = pd.DataFrame({'a': ["x", "x", "y", "y"], "b": [1, 1, 2, 3]})
```

```
In [68]: df
```

```
Out[68]:
 a b
0 x 1
1 x 1
2 y 2
3 y 3
```

*Previous behavior:*

```
In [3]: df.groupby("a", as_index=True).nunique()
Out[4]:
 a b
a
x 1 1
y 1 2
```

*New behavior:*

```
In [69]: df.groupby("a", as_index=True).nunique()
Out[69]:
 b
a
x 1
y 2
```

Using `DataFrame.groupby()` with `as_index=False` and the function `idxmax`, `idxmin`, `mad`, `nunique`, `sem`, `skew`, or `std` would modify the grouping column. Now the grouping column remains unchanged, consistent with other reductions. (GH21090, GH10355)

*Previous behavior:*

```
In [3]: df.groupby("a", as_index=False).nunique()
Out[4]:
 a b
0 1 1
1 1 2
```

*New behavior:*

```
In [70]: df.groupby("a", as_index=False).nunique()
Out[70]:
 a b
0 x 1
1 y 2
```

The method `size()` would previously ignore `as_index=False`. Now the grouping columns are returned as columns, making the result a `DataFrame` instead of a `Series`. (GH32599)

*Previous behavior:*

```
In [3]: df.groupby("a", as_index=False).size()
Out[4]:
a
x 2
y 2
dtype: int64
```

*New behavior:*

```
In [71]: df.groupby("a", as_index=False).size()
Out[71]:
 a size
0 x 2
1 y 2
```

**agg() lost results with as\_index=False when relabeling columns**

Previously `agg()` lost the result columns, when the `as_index` option was set to `False` and the result columns were relabeled. In this case the result values were replaced with the previous index ([GH32240](#)).

```
In [72]: df = pd.DataFrame({"key": ["x", "y", "z", "x", "y", "z"],
.....: "val": [1.0, 0.8, 2.0, 3.0, 3.6, 0.75]})
.....:
```

```
In [73]: df
```

```
Out[73]:
```

```
 key val
0 x 1.00
1 y 0.80
2 z 2.00
3 x 3.00
4 y 3.60
5 z 0.75
```

*Previous behavior:*

```
In [2]: grouped = df.groupby("key", as_index=False)
```

```
In [3]: result = grouped.agg(min_val=pd.NamedAgg(column="val", aggfunc="min"))
```

```
In [4]: result
```

```
Out[4]:
```

```
 min_val
0 x
1 y
2 z
```

*New behavior:*

```
In [74]: grouped = df.groupby("key", as_index=False)
```

```
In [75]: result = grouped.agg(min_val=pd.NamedAgg(column="val", aggfunc="min"))
```

```
In [76]: result
```

```
Out[76]:
```

```
 key min_val
0 x 1.00
1 y 0.80
2 z 0.75
```

**apply and applymap on DataFrame evaluates first row/column only once**

```
In [77]: df = pd.DataFrame({'a': [1, 2], 'b': [3, 6]})
```

```
In [78]: def func(row):
```

```
.....: print(row)
```

```
.....: return row
```

```
.....:
```

*Previous behavior:*

```
In [4]: df.apply(func, axis=1)
a 1
b 3
Name: 0, dtype: int64
a 1
b 3
Name: 0, dtype: int64
a 2
b 6
Name: 1, dtype: int64
Out[4]:
 a b
0 1 3
1 2 6
```

*New behavior:*

```
In [79]: df.apply(func, axis=1)
a 1
b 3
Name: 0, dtype: int64
a 2
b 6
Name: 1, dtype: int64
Out[79]:
 a b
0 1 3
1 2 6
```

## Backwards incompatible API changes

### Added `check_freq` argument to `testing.assert_frame_equal` and `testing.assert_series_equal`

The `check_freq` argument was added to `testing.assert_frame_equal()` and `testing.assert_series_equal()` in pandas 1.1.0 and defaults to `True`. `testing.assert_frame_equal()` and `testing.assert_series_equal()` now raise `AssertionError` if the indexes do not have the same frequency. Before pandas 1.1.0, the index frequency was not checked.

### Increased minimum versions for dependencies

Some minimum supported versions of dependencies were updated (GH33718, GH29766, GH29723, pytables >= 3.4.3). If installed, we now require:

| Package         | Minimum Version | Required | Changed |
|-----------------|-----------------|----------|---------|
| numpy           | 1.15.4          | X        | X       |
| pytz            | 2015.4          | X        |         |
| python-dateutil | 2.7.3           | X        | X       |
| bottleneck      | 1.2.1           |          |         |
| numexpr         | 2.6.2           |          |         |
| pytest (dev)    | 4.0.2           |          |         |

For [optional libraries](#) the general recommendation is to use the latest version. The following table lists the lowest version per library that is currently being tested throughout the development of pandas. Optional libraries below the lowest tested version may still work, but are not considered supported.

| Package        | Minimum Version | Changed |
|----------------|-----------------|---------|
| beautifulsoup4 | 4.6.0           |         |
| fastparquet    | 0.3.2           |         |
| fsspec         | 0.7.4           |         |
| gcsfs          | 0.6.0           | X       |
| lxml           | 3.8.0           |         |
| matplotlib     | 2.2.2           |         |
| numba          | 0.46.0          |         |
| openpyxl       | 2.5.7           |         |
| pyarrow        | 0.13.0          |         |
| pymysql        | 0.7.1           |         |
| pytables       | 3.4.3           | X       |
| s3fs           | 0.4.0           | X       |
| scipy          | 1.2.0           | X       |
| sqlalchemy     | 1.1.4           |         |
| xarray         | 0.8.2           |         |
| xlrd           | 1.1.0           |         |
| xlswriter      | 0.9.8           |         |
| xlwt           | 1.2.0           |         |
| pandas-gbq     | 1.2.0           | X       |

See [Dependencies](#) and [Optional dependencies](#) for more.

## Development changes

- The minimum version of Cython is now the most recent bug-fix version (0.29.16) ([GH33334](#)).

## Deprecations

- Lookups on a [Series](#) with a single-item list containing a slice (e.g. `ser[[slice(0, 4)]]`) are deprecated and will raise in a future version. Either convert the list to a tuple, or pass the slice directly instead ([GH31333](#))
- [DataFrame.mean\(\)](#) and [DataFrame.median\(\)](#) with `numeric_only=None` will include `datetime64` and `datetime64tz` columns in a future version ([GH29941](#))
- Setting values with `.loc` using a positional slice is deprecated and will raise in a future version. Use `.loc` with labels or `.iloc` with positions instead ([GH31840](#))
- [DataFrame.to\\_dict\(\)](#) has deprecated accepting short names for `orient` and will raise in a future version ([GH32515](#))
- [Categorical.to\\_dense\(\)](#) is deprecated and will be removed in a future version, use `np.asarray(cat)` instead ([GH32639](#))
- The `fastpath` keyword in the `SingleBlockManager` constructor is deprecated and will be removed in a future version ([GH33092](#))
- Providing suffixes as a set in [pandas.merge\(\)](#) is deprecated. Provide a tuple instead ([GH33740](#), [GH34741](#)).
- Indexing a [Series](#) with a multi-dimensional indexer like `[:, None]` to return an `ndarray` now raises a `FutureWarning`. Convert to a NumPy array before indexing instead ([GH27837](#))

- `Index.is_mixed()` is deprecated and will be removed in a future version, check `index.inferred_type` directly instead (GH32922)
- Passing any arguments but the first one to `read_html()` as positional arguments is deprecated. All other arguments should be given as keyword arguments (GH27573).
- Passing any arguments but `path_or_buf` (the first one) to `read_json()` as positional arguments is deprecated. All other arguments should be given as keyword arguments (GH27573).
- Passing any arguments but the first two to `read_excel()` as positional arguments is deprecated. All other arguments should be given as keyword arguments (GH27573).
- `pandas.api.types.is_categorical()` is deprecated and will be removed in a future version; use `pandas.api.types.is_categorical_dtype()` instead (GH33385)
- `Index.get_value()` is deprecated and will be removed in a future version (GH19728)
- `Series.dt.week()` and `Series.dt.weekofyear()` are deprecated and will be removed in a future version, use `Series.dt.isocalendar().week()` instead (GH33595)
- `DatetimeIndex.week()` and `DatetimeIndex.weekofyear` are deprecated and will be removed in a future version, use `DatetimeIndex.isocalendar().week` instead (GH33595)
- `DatetimeArray.week()` and `DatetimeArray.weekofyear` are deprecated and will be removed in a future version, use `DatetimeArray.isocalendar().week` instead (GH33595)
- `DateOffset.__call__()` is deprecated and will be removed in a future version, use `offset + other` instead (GH34171)
- `apply_index()` is deprecated and will be removed in a future version. Use `offset + other` instead (GH34580)
- `DataFrame.tshift()` and `Series.tshift()` are deprecated and will be removed in a future version, use `DataFrame.shift()` and `Series.shift()` instead (GH11631)
- Indexing an `Index` object with a float key is deprecated, and will raise an `IndexError` in the future. You can manually convert to an integer key instead (GH34191).
- The `squeeze` keyword in `groupby()` is deprecated and will be removed in a future version (GH32380)
- The `tz` keyword in `Period.to_timestamp()` is deprecated and will be removed in a future version; use `per.to_timestamp(...).tz_localize(tz)` instead (GH34522)
- `DatetimeIndex.to_perioddelta()` is deprecated and will be removed in a future version. Use `index - index.to_period(freq).to_timestamp()` instead (GH34853)
- `DataFrame.melt()` accepting a `value_name` that already exists is deprecated, and will be removed in a future version (GH34731)
- The `center` keyword in the `DataFrame.expanding()` function is deprecated and will be removed in a future version (GH20647)

## Performance improvements

- Performance improvement in *Timedelta* constructor (GH30543)
- Performance improvement in *Timestamp* constructor (GH30543)
- Performance improvement in flex arithmetic ops between *DataFrame* and *Series* with `axis=0` (GH31296)
- Performance improvement in arithmetic ops between *DataFrame* and *Series* with `axis=1` (GH33600)
- The internal index method `_shallow_copy()` now copies cached attributes over to the new index, avoiding creating these again on the new index. This can speed up many operations that depend on creating copies of existing indexes (GH28584, GH32640, GH32669)
- Significant performance improvement when creating a *DataFrame* with sparse values from `scipy.sparse` matrices using the `DataFrame.sparse.from_spmatrix()` constructor (GH32821, GH32825, GH32826, GH32856, GH32858).
- Performance improvement for groupby methods `first()` and `last()` (GH34178)
- Performance improvement in `factorize()` for nullable (integer and Boolean) dtypes (GH33064).
- Performance improvement when constructing *Categorical* objects (GH33921)
- Fixed performance regression in `pandas.qcut()` and `pandas.cut()` (GH33921)
- Performance improvement in reductions (sum, prod, min, max) for nullable (integer and Boolean) dtypes (GH30982, GH33261, GH33442).
- Performance improvement in arithmetic operations between two *DataFrame* objects (GH32779)
- Performance improvement in `pandas.core.groupby.RollingGroupby` (GH34052)
- Performance improvement in arithmetic operations (sub, add, mul, div) for *MultiIndex* (GH34297)
- Performance improvement in `DataFrame[bool_indexer]` when `bool_indexer` is a list (GH33924)
- Significant performance improvement of `io.formats.style.Styler.render()` with styles added with various ways such as `io.formats.style.Styler.apply()`, `io.formats.style.Styler.applymap()` or `io.formats.style.Styler.bar()` (GH19917)

## Bug fixes

### Categorical

- Passing an invalid `fill_value` to `Categorical.take()` raises a `ValueError` instead of `TypeError` (GH33660)
- Combining a *Categorical* with integer categories and which contains missing values with a float dtype column in operations such as `concat()` or `append()` will now result in a float column instead of an object dtype column (GH33607)
- Bug where `merge()` was unable to join on non-unique categorical indices (GH28189)
- Bug when passing categorical data to *Index* constructor along with `dtype=object` incorrectly returning a *CategoricalIndex* instead of object-dtype *Index* (GH32167)
- Bug where *Categorical* comparison operator `__ne__` would incorrectly evaluate to `False` when either element was missing (GH32276)
- `Categorical.fillna()` now accepts *Categorical* `other` argument (GH32420)
- Repr of *Categorical* was not distinguishing between `int` and `str` (GH33676)

## Datetimelike

- Passing an integer dtype other than `int64` to `np.array(period_index, dtype=...)` will now raise `TypeError` instead of incorrectly using `int64` (GH32255)
- `Series.to_timestamp()` now raises a `TypeError` if the axis is not a `PeriodIndex`. Previously an `AttributeError` was raised (GH33327)
- `Series.to_period()` now raises a `TypeError` if the axis is not a `DatetimeIndex`. Previously an `AttributeError` was raised (GH33327)
- `Period` no longer accepts tuples for the `freq` argument (GH34658)
- Bug in `Timestamp` where constructing a `Timestamp` from ambiguous epoch time and calling constructor again changed the `Timestamp.value()` property (GH24329)
- `DatetimeArray.searchsorted()`, `TimedeltaArray.searchsorted()`, `PeriodArray.searchsorted()` not recognizing non-pandas scalars and incorrectly raising `ValueError` instead of `TypeError` (GH30950)
- Bug in `Timestamp` where constructing `Timestamp` with dateutil timezone less than 128 nanoseconds before daylight saving time switch from winter to summer would result in nonexistent time (GH31043)
- Bug in `Period.to_timestamp()`, `Period.start_time()` with microsecond frequency returning a timestamp one nanosecond earlier than the correct time (GH31475)
- `Timestamp` raised a confusing error message when year, month or day is missing (GH31200)
- Bug in `DatetimeIndex` constructor incorrectly accepting `bool`-dtype inputs (GH32668)
- Bug in `DatetimeIndex.searchsorted()` not accepting a `list` or `Series` as its argument (GH32762)
- Bug where `PeriodIndex()` raised when passed a `Series` of strings (GH26109)
- Bug in `Timestamp` arithmetic when adding or subtracting an `np.ndarray` with `timedelta64` dtype (GH33296)
- Bug in `DatetimeIndex.to_period()` not inferring the frequency when called with no arguments (GH33358)
- Bug in `DatetimeIndex.tz_localize()` incorrectly retaining `freq` in some cases where the original `freq` is no longer valid (GH30511)
- Bug in `DatetimeIndex.intersection()` losing `freq` and `timezone` in some cases (GH33604)
- Bug in `DatetimeIndex.get_indexer()` where incorrect output would be returned for mixed datetime-like targets (GH33741)
- Bug in `DatetimeIndex` addition and subtraction with some types of `DateOffset` objects incorrectly retaining an invalid `freq` attribute (GH33779)
- Bug in `DatetimeIndex` where setting the `freq` attribute on an index could silently change the `freq` attribute on another index viewing the same data (GH33552)
- `DataFrame.min()` and `DataFrame.max()` were not returning consistent results with `Series.min()` and `Series.max()` when called on objects initialized with empty `pd.to_datetime()`
- Bug in `DatetimeIndex.intersection()` and `TimedeltaIndex.intersection()` with results not having the correct name attribute (GH33904)
- Bug in `DatetimeArray.__setitem__()`, `TimedeltaArray.__setitem__()`, `PeriodArray.__setitem__()` incorrectly allowing values with `int64` dtype to be silently cast (GH33717)
- Bug in subtracting `TimedeltaIndex` from `Period` incorrectly raising `TypeError` in some cases where it should succeed and `IncompatibleFrequency` in some cases where it should raise `TypeError` (GH33883)
- Bug in constructing a `Series` or `Index` from a read-only NumPy array with non-ns resolution which converted to object dtype instead of coercing to `datetime64[ns]` dtype when within the timestamp bounds (GH34843).

- The `freq` keyword in `Period`, `date_range()`, `period_range()`, `pd.tseries.frequencies.to_offset()` no longer allows tuples, pass as string instead (GH34703)
- Bug in `DataFrame.append()` when appending a `Series` containing a scalar tz-aware `Timestamp` to an empty `DataFrame` resulted in an object column instead of `datetime64[ns, tz]` dtype (GH35038)
- `OutOfBoundsDatetime` issues an improved error message when timestamp is out of implementation bounds. (GH32967)
- Bug in `AbstractHolidayCalendar.holidays()` when no rules were defined (GH31415)
- Bug in Tick comparisons raising `TypeError` when comparing against `timedelta`-like objects (GH34088)
- Bug in Tick multiplication raising `TypeError` when multiplying by a float (GH34486)

### Timedelta

- Bug in constructing a `Timedelta` with a high precision integer that would round the `Timedelta` components (GH31354)
- Bug in dividing `np.nan` or `None` by `Timedelta` incorrectly returning `NaT` (GH31869)
- `Timedelta` now understands `µs` as an identifier for microsecond (GH32899)
- `Timedelta` string representation now includes nanoseconds, when nanoseconds are non-zero (GH9309)
- Bug in comparing a `Timedelta` object against an `np.ndarray` with `timedelta64` dtype incorrectly viewing all entries as unequal (GH33441)
- Bug in `timedelta_range()` that produced an extra point on a edge case (GH30353, GH33498)
- Bug in `DataFrame.resample()` that produced an extra point on a edge case (GH30353, GH13022, GH33498)
- Bug in `DataFrame.resample()` that ignored the `loffset` argument when dealing with `timedelta` (GH7687, GH33498)
- Bug in `Timedelta` and `pandas.to_timedelta()` that ignored the `unit` argument for string input (GH12136)

### Timezones

- Bug in `to_datetime()` with `infer_datetime_format=True` where timezone names (e.g. UTC) would not be parsed correctly (GH33133)

### Numeric

- Bug in `DataFrame.floordiv()` with `axis=0` not treating division-by-zero like `Series.floordiv()` (GH31271)
- Bug in `to_numeric()` with string argument `"uint64"` and `errors="coerce"` silently fails (GH32394)
- Bug in `to_numeric()` with `downcast="unsigned"` fails for empty data (GH32493)
- Bug in `DataFrame.mean()` with `numeric_only=False` and either `datetime64` dtype or `PeriodDtype` column incorrectly raising `TypeError` (GH32426)
- Bug in `DataFrame.count()` with `level="foo"` and index level `"foo"` containing NaNs causes segmentation fault (GH21824)
- Bug in `DataFrame.diff()` with `axis=1` returning incorrect results with mixed dtypes (GH32995)

- Bug in `DataFrame.corr()` and `DataFrame.cov()` raising when handling nullable integer columns with `pandas.NA` (GH33803)
- Bug in arithmetic operations between `DataFrame` objects with non-overlapping columns with duplicate labels causing an infinite loop (GH35194)
- Bug in `DataFrame` and `Series` addition and subtraction between object-dtype objects and `datetime64` dtype objects (GH33824)
- Bug in `Index.difference()` giving incorrect results when comparing a `Float64Index` and object `Index` (GH35217)
- Bug in `DataFrame` reductions (e.g. `df.min()`, `df.max()`) with `ExtensionArray` dtypes (GH34520, GH32651)
- `Series.interpolate()` and `DataFrame.interpolate()` now raise a `ValueError` if `limit_direction` is 'forward' or 'both' and method is 'backfill' or 'bfill' or `limit_direction` is 'backward' or 'both' and method is 'pad' or 'ffill' (GH34746)

## Conversion

- Bug in `Series` construction from NumPy array with big-endian `datetime64` dtype (GH29684)
- Bug in `Timedelta` construction with large nanoseconds keyword value (GH32402)
- Bug in `DataFrame` construction where sets would be duplicated rather than raising (GH32582)
- The `DataFrame` constructor no longer accepts a list of `DataFrame` objects. Because of changes to NumPy, `DataFrame` objects are now consistently treated as 2D objects, so a list of `DataFrame` objects is considered 3D, and no longer acceptable for the `DataFrame` constructor (GH32289).
- Bug in `DataFrame` when initiating a frame with lists and assign columns with nested list for `MultiIndex` (GH32173)
- Improved error message for invalid construction of list when creating a new index (GH35190)

## Strings

- Bug in the `astype()` method when converting “string” dtype data to nullable integer dtype (GH32450).
- Fixed issue where taking min or max of a `StringArray` or `Series` with `StringDtype` type would raise. (GH31746)
- Bug in `Series.str.cat()` returning NaN output when other had `Index` type (GH33425)
- `pandas.api.dtypes.is_string_dtype()` no longer incorrectly identifies categorical series as string.

## Interval

- Bug in `IntervalArray` incorrectly allowing the underlying data to be changed when setting values (GH32782)

## Indexing

- `DataFrame.xs()` now raises a `TypeError` if a level keyword is supplied and the axis is not a `MultiIndex`. Previously an `AttributeError` was raised (GH33610)
- Bug in slicing on a `DatetimeIndex` with a partial-timestamp dropping high-resolution indices near the end of a year, quarter, or month (GH31064)
- Bug in `PeriodIndex.get_loc()` treating higher-resolution strings differently from `PeriodIndex.get_value()` (GH31172)
- Bug in `Series.at()` and `DataFrame.at()` not matching `.loc` behavior when looking up an integer in a `Float64Index` (GH31329)
- Bug in `PeriodIndex.is_monotonic()` incorrectly returning `True` when containing leading `NaT` entries (GH31437)
- Bug in `DatetimeIndex.get_loc()` raising `KeyError` with converted-integer key instead of the user-passed key (GH31425)
- Bug in `Series.xs()` incorrectly returning `Timestamp` instead of `datetime64` in some object-dtype cases (GH31630)
- Bug in `DataFrame.iat()` incorrectly returning `Timestamp` instead of `datetime` in some object-dtype cases (GH32809)
- Bug in `DataFrame.at()` when either columns or index is non-unique (GH33041)
- Bug in `Series.loc()` and `DataFrame.loc()` when indexing with an integer key on a object-dtype `Index` that is not all-integers (GH31905)
- Bug in `DataFrame.iloc.__setitem__()` on a `DataFrame` with duplicate columns incorrectly setting values for all matching columns (GH15686, GH22036)
- Bug in `DataFrame.loc()` and `Series.loc()` with a `DatetimeIndex`, `TimedeltaIndex`, or `PeriodIndex` incorrectly allowing lookups of non-matching datetime-like dtypes (GH32650)
- Bug in `Series.__getitem__()` indexing with non-standard scalars, e.g. `np.dtype` (GH32684)
- Bug in `Index` constructor where an unhelpful error message was raised for NumPy scalars (GH33017)
- Bug in `DataFrame.lookup()` incorrectly raising an `AttributeError` when `frame.index` or `frame.columns` is not unique; this will now raise a `ValueError` with a helpful error message (GH33041)
- Bug in `Interval` where a `Timedelta` could not be added or subtracted from a `Timestamp` interval (GH32023)
- Bug in `DataFrame.copy()` not invalidating `_item_cache` after copy caused post-copy value updates to not be reflected (GH31784)
- Fixed regression in `DataFrame.loc()` and `Series.loc()` throwing an error when a `datetime64[ns, tz]` value is provided (GH32395)
- Bug in `Series.__getitem__()` with an integer key and a `MultiIndex` with leading integer level failing to raise `KeyError` if the key is not present in the first level (GH33355)
- Bug in `DataFrame.iloc()` when slicing a single column `DataFrame` with `ExtensionDtype` (e.g. `df.iloc[:, :1]`) returning an invalid result (GH32957)
- Bug in `DatetimeIndex.insert()` and `TimedeltaIndex.insert()` causing index `freq` to be lost when setting an element into an empty `Series` (GH33573)
- Bug in `Series.__setitem__()` with an `IntervalIndex` and a list-like key of integers (GH33473)
- Bug in `Series.__getitem__()` allowing missing labels with `np.ndarray`, `Index`, `Series` indexers but not `list`, these now all raise `KeyError` (GH33646)

- Bug in `DataFrame.truncate()` and `Series.truncate()` where index was assumed to be monotone increasing (GH33756)
- Indexing with a list of strings representing datetimes failed on `DatetimeIndex` or `PeriodIndex` (GH11278)
- Bug in `Series.at()` when used with a `MultiIndex` would raise an exception on valid inputs (GH26989)
- Bug in `DataFrame.loc()` with dictionary of values changes columns with dtype of int to float (GH34573)
- Bug in `Series.loc()` when used with a `MultiIndex` would raise an `IndexingError` when accessing a `None` value (GH34318)
- Bug in `DataFrame.reset_index()` and `Series.reset_index()` would not preserve data types on an empty `DataFrame` or `Series` with a `MultiIndex` (GH19602)
- Bug in `Series` and `DataFrame` indexing with a time key on a `DatetimeIndex` with `NaT` entries (GH35114)

## Missing

- Calling `fillna()` on an empty `Series` now correctly returns a shallow copied object. The behaviour is now consistent with `Index`, `DataFrame` and a non-empty `Series` (GH32543).
- Bug in `Series.replace()` when argument `to_replace` is of type dict/list and is used on a `Series` containing `<NA>` was raising a `TypeError`. The method now handles this by ignoring `<NA>` values when doing the comparison for the replacement (GH32621)
- Bug in `any()` and `all()` incorrectly returning `<NA>` for all `False` or all `True` values using the nullable Boolean dtype and with `skipna=False` (GH33253)
- Clarified documentation on `interpolate` with `method=akima`. The `der` parameter must be scalar or `None` (GH33426)
- `DataFrame.interpolate()` uses the correct axis convention now. Previously interpolating along columns lead to interpolation along indices and vice versa. Furthermore interpolating with methods `pad`, `ffill`, `bfill` and `backfill` are identical to using these methods with `DataFrame.fillna()` (GH12918, GH29146)
- Bug in `DataFrame.interpolate()` when called on a `DataFrame` with column names of string type was throwing a `ValueError`. The method is now independent of the type of the column names (GH33956)
- Passing `NA` into a format string using format specs will now work. For example `"{: .1f}".format(pd.NA)` would previously raise a `ValueError`, but will now return the string `"<NA>"` (GH34740)
- Bug in `Series.map()` not raising on invalid `na_action` (GH32815)

## MultiIndex

- `DataFrame.swaplevels()` now raises a `TypeError` if the axis is not a `MultiIndex`. Previously an `AttributeError` was raised (GH31126)
- Bug in `DataFrame.loc()` when used with a `MultiIndex`. The returned values were not in the same order as the given inputs (GH22797)

```
In [80]: df = pd.DataFrame(np.arange(4),
.....: index=[["a", "a", "b", "b"], [1, 2, 1, 2]])
.....:

Rows are now ordered as the requested keys
In [81]: df.loc([['b', 'a'], [2, 1]], :)
```

(continues on next page)

(continued from previous page)

**Out[81]:**

```

 0
b 2 3
 1 2
a 2 1
 1 0

```

- Bug in `MultiIndex.intersection()` was not guaranteed to preserve order when `sort=False`. (GH31325)
- Bug in `DataFrame.truncate()` was dropping `MultiIndex` names. (GH34564)

```
In [82]: left = pd.MultiIndex.from_arrays([["b", "a"], [2, 1]])
```

```
In [83]: right = pd.MultiIndex.from_arrays([["a", "b", "c"], [1, 2, 3]])
```

```
Common elements are now guaranteed to be ordered by the left side
```

```
In [84]: left.intersection(right, sort=False)
```

**Out[84]:**

```
MultiIndex([('b', 2),
 ('a', 1)],
)
```

- Bug when joining two `MultiIndex` without specifying level with different columns. Return-indexers parameter was ignored. (GH34074)

## IO

- Passing a set as names argument to `pandas.read_csv()`, `pandas.read_table()`, or `pandas.read_fwf()` will raise `ValueError: Names should be an ordered collection`. (GH34946)
- Bug in print-out when `display.precision` is zero. (GH20359)
- Bug in `read_json()` where integer overflow was occurring when json contains big number strings. (GH30320)
- `read_csv()` will now raise a `ValueError` when the arguments `header` and `prefix` both are not `None`. (GH27394)
- Bug in `DataFrame.to_json()` was raising `NotFoundError` when `path_or_buf` was an S3 URI (GH28375)
- Bug in `DataFrame.to_parquet()` overwriting pyarrow's default for `coerce_timestamps`; following pyarrow's default allows writing nanosecond timestamps with `version="2.0"` (GH31652).
- Bug in `read_csv()` was raising `TypeError` when `sep=None` was used in combination with `comment` keyword (GH31396)
- Bug in `HDFStore` that caused it to set to `int64` the dtype of a `datetime64` column when reading a `DataFrame` in Python 3 from fixed format written in Python 2 (GH31750)
- `read_sas()` now handles dates and datetimes larger than `Timestamp.max` returning them as `datetime.datetime` objects (GH20927)
- Bug in `DataFrame.to_json()` where `Timedelta` objects would not be serialized correctly with `date_format="iso"` (GH28256)
- `read_csv()` will raise a `ValueError` when the column names passed in `parse_dates` are missing in the `Dataframe` (GH31251)

- Bug in `read_excel()` where a UTF-8 string with a high surrogate would cause a segmentation violation (GH23809)
- Bug in `read_csv()` was causing a file descriptor leak on an empty file (GH31488)
- Bug in `read_csv()` was causing a segfault when there were blank lines between the header and data rows (GH28071)
- Bug in `read_csv()` was raising a misleading exception on a permissions issue (GH23784)
- Bug in `read_csv()` was raising an `IndexError` when `header=None` and two extra data columns
- Bug in `read_sas()` was raising an `AttributeError` when reading files from Google Cloud Storage (GH33069)
- Bug in `DataFrame.to_sql()` where an `AttributeError` was raised when saving an out of bounds date (GH26761)
- Bug in `read_excel()` did not correctly handle multiple embedded spaces in OpenDocument text cells. (GH32207)
- Bug in `read_json()` was raising `TypeError` when reading a list of Booleans into a `Series`. (GH31464)
- Bug in `pandas.io.json.json_normalize()` where location specified by `record_path` doesn't point to an array. (GH26284)
- `pandas.read_hdf()` has a more explicit error message when loading an unsupported HDF file (GH9539)
- Bug in `read_feather()` was raising an `ArrowIOError` when reading an s3 or http file path (GH29055)
- Bug in `to_excel()` could not handle the column name `render` and was raising an `KeyError` (GH34331)
- Bug in `execute()` was raising a `ProgrammingError` for some DB-API drivers when the SQL statement contained the `%` character and no parameters were present (GH34211)
- Bug in `StataReader()` which resulted in categorical variables with different dtypes when reading data using an iterator. (GH31544)
- `HDFStore.keys()` has now an optional `include` parameter that allows the retrieval of all native HDF5 table names (GH29916)
- `TypeError` exceptions raised by `read_csv()` and `read_table()` were showing as `parser_f` when an unexpected keyword argument was passed (GH25648)
- Bug in `read_excel()` for ODS files removes 0.0 values (GH27222)
- Bug in `ujson.encode()` was raising an `OverflowError` with numbers larger than `sys.maxsize` (GH34395)
- Bug in `HDFStore.append_to_multiple()` was raising a `ValueError` when the `min_itemsize` parameter is set (GH11238)
- Bug in `create_table()` now raises an error when `column` argument was not specified in `data_columns` on input (GH28156)
- `read_json()` now could read line-delimited json file from a file url while `lines` and `chunksize` are set.
- Bug in `DataFrame.to_sql()` when reading DataFrames with `-np.inf` entries with MySQL now has a more explicit `ValueError` (GH34431)
- Bug where capitalised files extensions were not decompressed by `read_*` functions (GH35164)
- Bug in `read_excel()` that was raising a `TypeError` when `header=None` and `index_col` is given as a list (GH31783)
- Bug in `read_excel()` where datetime values are used in the header in a `MultiIndex` (GH34748)

- `read_excel()` no longer takes `**kwargs` arguments. This means that passing in the keyword argument `chunksize` now raises a `TypeError` (previously raised a `NotImplementedError`), while passing in the keyword argument `encoding` now raises a `TypeError` (GH34464)
- Bug in `DataFrame.to_records()` was incorrectly losing timezone information in timezone-aware `datetime64` columns (GH32535)

## Plotting

- `DataFrame.plot()` for line/bar now accepts color by dictionary (GH8193).
- Bug in `DataFrame.plot.hist()` where weights are not working for multiple columns (GH33173)
- Bug in `DataFrame.boxplot()` and `DataFrame.plot.boxplot()` lost color attributes of `medianprops`, `whiskerprops`, `capprops` and `boxprops` (GH30346)
- Bug in `DataFrame.hist()` where the order of `column` argument was ignored (GH29235)
- Bug in `DataFrame.plot.scatter()` that when adding multiple plots with different `cmap`, colorbars always use the first `cmap` (GH33389)
- Bug in `DataFrame.plot.scatter()` was adding a colorbar to the plot even if the argument `c` was assigned to a column containing color names (GH34316)
- Bug in `pandas.plotting.bootstrap_plot()` was causing cluttered axes and overlapping labels (GH34905)
- Bug in `DataFrame.plot.scatter()` caused an error when plotting variable marker sizes (GH32904)

## GroupBy/resample/rolling

- Using a `pandas.api.indexers.BaseIndexer` with `count`, `min`, `max`, `median`, `skew`, `cov`, `corr` will now return correct results for any monotonic `pandas.api.indexers.BaseIndexer` descendant (GH32865)
- `DataFrameGroupby.mean()` and `SeriesGroupby.mean()` (and similarly for `median()`, `std()` and `var()`) now raise a `TypeError` if a non-accepted keyword argument is passed into it. Previously an `UnsupportedFunctionCall` was raised (`AssertionError` if `min_count` passed into `median()`) (GH31485)
- Bug in `GroupBy.apply()` raises `ValueError` when the `by` axis is not sorted, has duplicates, and the applied `func` does not mutate passed in objects (GH30667)
- Bug in `DataFrameGroupBy.transform()` produces an incorrect result with transformation functions (GH30918)
- Bug in `Groupby.transform()` was returning the wrong result when grouping by multiple keys of which some were categorical and others not (GH32494)
- Bug in `GroupBy.count()` causes segmentation fault when grouped-by columns contain NaNs (GH32841)
- Bug in `DataFrame.groupby()` and `Series.groupby()` produces inconsistent type when aggregating Boolean `Series` (GH32894)
- Bug in `DataFrameGroupBy.sum()` and `SeriesGroupBy.sum()` where a large negative number would be returned when the number of non-null values was below `min_count` for nullable integer dtypes (GH32861)
- Bug in `SeriesGroupBy.quantile()` was raising on nullable integers (GH33136)
- Bug in `DataFrame.resample()` where an `AmbiguousTimeError` would be raised when the resulting timezone aware `DatetimeIndex` had a DST transition at midnight (GH25758)
- Bug in `DataFrame.groupby()` where a `ValueError` would be raised when grouping by a categorical column with read-only categories and `sort=False` (GH33410)

- Bug in `GroupBy.agg()`, `GroupBy.transform()`, and `GroupBy.resample()` where subclasses are not preserved (GH28330)
- Bug in `SeriesGroupBy.agg()` where any column name was accepted in the named aggregation of `SeriesGroupBy` previously. The behaviour now allows only `str` and callables else would raise `TypeError`. (GH34422)
- Bug in `DataFrame.groupby()` lost the name of the `Index` when one of the `agg` keys referenced an empty list (GH32580)
- Bug in `Rolling.apply()` where `center=True` was ignored when `engine='numba'` was specified (GH34784)
- Bug in `DataFrame.ewm.cov()` was throwing `AssertionError` for `MultiIndex` inputs (GH34440)
- Bug in `core.groupby.DataFrameGroupBy.quantile()` raised `TypeError` for non-numeric types rather than dropping the columns (GH27892)
- Bug in `core.groupby.DataFrameGroupBy.transform()` when `func='nunique'` and columns are of type `datetime64`, the result would also be of type `datetime64` instead of `int64` (GH35109)
- Bug in `DataFrame.groupby()` raising an `AttributeError` when selecting a column and aggregating with `as_index=False` (GH35246).
- Bug in `DataFrameGroupBy.first()` and `DataFrameGroupBy.last()` that would raise an unnecessary `ValueError` when grouping on multiple `Categoricals` (GH34951)

## Reshaping

- Bug effecting all numeric and Boolean reduction methods not returning subclassed data type. (GH25596)
- Bug in `DataFrame.pivot_table()` when only `MultiIndexed` columns is set (GH17038)
- Bug in `DataFrame.unstack()` and `Series.unstack()` can take tuple names in `MultiIndexed` data (GH19966)
- Bug in `DataFrame.pivot_table()` when `margin` is `True` and only `column` is defined (GH31016)
- Fixed incorrect error message in `DataFrame.pivot()` when `columns` is set to `None`. (GH30924)
- Bug in `crosstab()` when inputs are two `Series` and have tuple names, the output will keep a dummy `MultiIndex` as columns. (GH18321)
- `DataFrame.pivot()` can now take lists for `index` and `columns` arguments (GH21425)
- Bug in `concat()` where the resulting indices are not copied when `copy=True` (GH29879)
- Bug in `SeriesGroupBy.aggregate()` was resulting in aggregations being overwritten when they shared the same name (GH30880)
- Bug where `Index.astype()` would lose the name attribute when converting from `Float64Index` to `Int64Index`, or when casting to an `ExtensionArray` dtype (GH32013)
- `Series.append()` will now raise a `TypeError` when passed a `DataFrame` or a sequence containing `DataFrame` (GH31413)
- `DataFrame.replace()` and `Series.replace()` will raise a `TypeError` if `to_replace` is not an expected type. Previously the `replace` would fail silently (GH18634)
- Bug on inplace operation of a `Series` that was adding a column to the `DataFrame` from where it was originally dropped from (using `inplace=True`) (GH30484)
- Bug in `DataFrame.apply()` where `callback` was called with `Series` parameter even though `raw=True` requested. (GH32423)

- Bug in `DataFrame.pivot_table()` losing timezone information when creating a `MultiIndex` level from a column with timezone-aware dtype (GH32558)
- Bug in `concat()` where when passing a non-dict mapping as objs would raise a `TypeError` (GH32863)
- `DataFrame.agg()` now provides more descriptive `SpecificationError` message when attempting to aggregate a non-existent column (GH32755)
- Bug in `DataFrame.unstack()` when `MultiIndex` columns and `MultiIndex` rows were used (GH32624, GH24729 and GH28306)
- Appending a dictionary to a `DataFrame` without passing `ignore_index=True` will raise `TypeError: Can only append a dict if ignore_index=True` instead of `TypeError: Can only append a :class: `Series` if ignore_index=True or if the :class: `Series` has a name` (GH30871)
- Bug in `DataFrame.corrwith()`, `DataFrame.memory_usage()`, `DataFrame.dot()`, `DataFrame.idxmin()`, `DataFrame.idxmax()`, `DataFrame.duplicated()`, `DataFrame.isin()`, `DataFrame.count()`, `Series.explode()`, `Series.asof()` and `DataFrame.asof()` not returning subclassed types. (GH31331)
- Bug in `concat()` was not allowing for concatenation of `DataFrame` and `Series` with duplicate keys (GH33654)
- Bug in `cut()` raised an error when the argument `labels` contains duplicates (GH33141)
- Ensure only named functions can be used in `eval()` (GH32460)
- Bug in `DataFrame.aggregate()` and `Series.aggregate()` was causing a recursive loop in some cases (GH34224)
- Fixed bug in `melt()` where melting `MultiIndex` columns with `col_level > 0` would raise a `KeyError` on `id_vars` (GH34129)
- Bug in `Series.where()` with an empty `Series` and empty `cond` having non-bool dtype (GH34592)
- Fixed regression where `DataFrame.apply()` would raise `ValueError` for elements with `S` dtype (GH34529)

## Sparse

- Creating a `SparseArray` from timezone-aware dtype will issue a warning before dropping timezone information, instead of doing so silently (GH32501)
- Bug in `arrays.SparseArray.from_spmatrix()` wrongly read scipy sparse matrix (GH31991)
- Bug in `Series.sum()` with `SparseArray` raised a `TypeError` (GH25777)
- Bug where `DataFrame` containing an all-sparse `SparseArray` filled with `NaN` when indexed by a list-like (GH27781, GH29563)
- The repr of `SparseDtype` now includes the repr of its `fill_value` attribute. Previously it used `fill_value`'s string representation (GH34352)
- Bug where empty `DataFrame` could not be cast to `SparseDtype` (GH33113)
- Bug in `arrays.SparseArray()` was returning the incorrect type when indexing a sparse dataframe with an iterable (GH34526, GH34540)

## ExtensionArray

- Fixed bug where `Series.value_counts()` would raise on empty input of Int64 dtype (GH33317)
- Fixed bug in `concat()` when concatenating `DataFrame` objects with non-overlapping columns resulting in object-dtype columns rather than preserving the extension dtype (GH27692, GH33027)
- Fixed bug where `StringArray.isna()` would return False for NA values when `pandas.options.mode.use_inf_as_na` was set to True (GH33655)
- Fixed bug in `Series` construction with EA dtype and index but no data or scalar data fails (GH26469)
- Fixed bug that caused `Series.__repr__()` to crash for extension types whose elements are multidimensional arrays (GH33770).
- Fixed bug where `Series.update()` would raise a `ValueError` for `ExtensionArray` dtypes with missing values (GH33980)
- Fixed bug where `StringArray.memory_usage()` was not implemented (GH33963)
- Fixed bug where `DataFrame.groupby()` would ignore the `min_count` argument for aggregations on nullable Boolean dtypes (GH34051)
- Fixed bug where the constructor of `DataFrame` with `dtype='string'` would fail (GH27953, GH33623)
- Bug where `DataFrame` column set to scalar extension type was considered an object type rather than the extension type (GH34832)
- Fixed bug in `IntegerArray.astype()` to correctly copy the mask as well (GH34931).

## Other

- Set operations on an object-dtype `Index` now always return object-dtype results (GH31401)
- Fixed `pandas.testing.assert_series_equal()` to correctly raise if the `left` argument is a different subclass with `check_series_type=True` (GH32670).
- Getting a missing attribute in a `DataFrame.query()` or `DataFrame.eval()` string raises the correct `AttributeError` (GH32408)
- Fixed bug in `pandas.testing.assert_series_equal()` where dtypes were checked for `Interval` and `ExtensionArray` operands when `check_dtype` was False (GH32747)
- Bug in `DataFrame.__dir__()` caused a segfault when using unicode surrogates in a column name (GH25509)
- Bug in `DataFrame.equals()` and `Series.equals()` in allowing subclasses to be equal (GH34402).

## Contributors

A total of 368 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

## 5.4 Version 1.0

### 5.4.1 What's new in 1.0.5 (June 17, 2020)

These are the changes in pandas 1.0.5. See [Release notes](#) for a full changelog including other versions of pandas.

#### Fixed regressions

- Fix regression in `read_parquet()` when reading from file-like objects (GH34467).
- Fix regression in reading from public S3 buckets (GH34626).

Note this disables the ability to read Parquet files from directories on S3 again (GH26388, GH34632), which was added in the 1.0.4 release, but is now targeted for pandas 1.1.0.

- Fixed regression in `replace()` raising an `AssertionError` when replacing values in an extension dtype with values of a different dtype (GH34530)

#### Bug fixes

- Fixed building from source with Python 3.8 fetching the wrong version of NumPy (GH34666)

#### Contributors

A total of 8 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

- Joris Van den Bossche
- MeeseeksMachine
- Natalie Jann +
- Pandas Development Team

## 5.4.2 What's new in 1.0.4 (May 28, 2020)

These are the changes in pandas 1.0.4. See *Release notes* for a full changelog including other versions of pandas.

### Fixed regressions

- Fix regression where `Series.isna()` and `DataFrame.isna()` would raise for categorical dtype when `pandas.options.mode.use_inf_as_na` was set to `True` (GH33594)
- Fix regression in `GroupBy.first()` and `GroupBy.last()` where `None` is not preserved in object dtype (GH32800)
- Fix regression in `DataFrame` reductions using `numeric_only=True` and `ExtensionArrays` (GH33256).
- Fix performance regression in `memory_usage(deep=True)` for object dtype (GH33012)
- Fix regression where `Categorical.replace()` would replace with `NaN` whenever the new value and replacement value were equal (GH33288)
- Fix regression where an ordered `Categorical` containing only `NaN` values would raise rather than returning `NaN` when taking the minimum or maximum (GH33450)
- Fix regression in `DataFrameGroupBy.agg()` with dictionary input losing `ExtensionArray` dtypes (GH32194)
- Fix to preserve the ability to index with the “nearest” method with `xarray`'s `CFTIMEIndex`, an `Index` subclass (pydata/xarray#3751, GH32905).
- Fix regression in `DataFrame.describe()` raising `TypeError: unhashable type: 'dict'` (GH32409)
- Fix regression in `DataFrame.replace()` casts columns to object dtype if items in `to_replace` not in values (GH32988)
- Fix regression in `Series.groupby()` would raise `ValueError` when grouping by `PeriodIndex` level (GH34010)
- Fix regression in `GroupBy.rolling.apply()` ignores args and kwargs parameters (GH33433)
- Fix regression in error message with `np.min` or `np.max` on unordered `Categorical` (GH33115)
- Fix regression in `DataFrame.loc()` and `Series.loc()` throwing an error when a `datetime64[ns, tz]` value is provided (GH32395)

### Bug fixes

- Bug in `SeriesGroupBy.first()`, `SeriesGroupBy.last()`, `SeriesGroupBy.min()`, and `SeriesGroupBy.max()` returning floats when applied to nullable Booleans (GH33071)
- Bug in `Rolling.min()` and `Rolling.max()`: Growing memory usage after multiple calls when using a fixed window (GH30726)
- Bug in `to_parquet()` was not raising `PermissionError` when writing to a private s3 bucket with invalid creds. (GH27679)
- Bug in `to_csv()` was silently failing when writing to an invalid s3 bucket. (GH32486)
- Bug in `read_parquet()` was raising a `FileNotFoundError` when passed an s3 directory path. (GH26388)
- Bug in `to_parquet()` was throwing an `AttributeError` when writing a partitioned parquet file to s3 (GH27596)
- Bug in `GroupBy.quantile()` causes the quantiles to be shifted when the by axis contains `NaN` (GH33200, GH33569)

### 5.4.3 What’s new in 1.0.3 (March 17, 2020)

These are the changes in pandas 1.0.3. See *Release notes* for a full changelog including other versions of pandas.

#### Fixed regressions

- Fixed regression in `resample.agg` when the underlying data is non-writeable ([GH31710](#))
- Fixed regression in `DataFrame` exponentiation with reindexing ([GH32685](#))

#### Bug fixes

#### Contributors

A total of 5 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

- MeeseeksMachine

## 5.4.4 What's new in 1.0.2 (March 12, 2020)

These are the changes in pandas 1.0.2. See *Release notes* for a full changelog including other versions of pandas.

### Fixed regressions

#### Groupby

- Fixed regression in `groupby(...).agg()` which was failing on frames with *MultiIndex* columns and a custom function (GH31777)
- Fixed regression in `groupby(...).rolling(...).apply()` (`RollingGroupby`) where the `raw` parameter was ignored (GH31754)
- Fixed regression in `rolling(...).corr()` when using a time offset (GH31789)
- Fixed regression in `groupby(...).nunique()` which was modifying the original values if NaN values were present (GH31950)
- Fixed regression in `DataFrame.groupby` raising a `ValueError` from an internal operation (GH31802)
- Fixed regression in `groupby(...).agg()` calling a user-provided function an extra time on an empty input (GH31760)

#### I/O

- Fixed regression in `read_csv()` in which the encoding option was not recognized with certain file-like objects (GH31819)
- Fixed regression in `DataFrame.to_excel()` when the `columns` keyword argument is passed (GH31677)
- Fixed regression in `ExcelFile` where the stream passed into the function was closed by the destructor. (GH31467)
- Fixed regression where `read_pickle()` raised a `UnicodeDecodeError` when reading a py27 pickle with *MultiIndex* column (GH31988).

#### Reindexing/alignment

- Fixed regression in `Series.align()` when `other` is a *DataFrame* and `method` is not `None` (GH31785)
- Fixed regression in `DataFrame.reindex()` and `Series.reindex()` when reindexing with (tz-aware) index and `method=nearest` (GH26683)
- Fixed regression in `DataFrame.reindex_like()` on a *DataFrame* subclass raised an `AssertionError` (GH31925)
- Fixed regression in *DataFrame* arithmetic operations with mis-matched columns (GH31623)

#### Other

- Fixed regression in joining on *DatetimeIndex* or *TimedeltaIndex* to preserve `freq` in simple cases (GH32166)
- Fixed regression in `Series.shift()` with `datetime64` dtype when passing an integer `fill_value` (GH32591)
- Fixed regression in the repr of an object-dtype *Index* with booleans and missing values (GH32146)

## Indexing with nullable boolean arrays

Previously indexing with a nullable Boolean array containing NA would raise a `ValueError`, however this is now permitted with NA being treated as `False`. (GH31503)

```
In [1]: s = pd.Series([1, 2, 3, 4])

In [2]: mask = pd.array([True, True, False, None], dtype="boolean")

In [3]: s
Out[3]:
0 1
1 2
2 3
3 4
dtype: int64

In [4]: mask
Out[4]:
<BooleanArray>
[True, True, False, <NA>]
Length: 4, dtype: boolean
```

*pandas 1.0.0-1.0.1*

```
>>> s[mask]
Traceback (most recent call last):
...
ValueError: cannot mask with array containing NA / NaN values
```

*pandas 1.0.2*

```
In [5]: s[mask]
Out[5]:
0 1
1 2
dtype: int64
```

## Bug fixes

### Datetimelike

- Bug in `Series.astype()` not copying for tz-naive and tz-aware `datetime64` dtype (GH32490)
- Bug where `to_datetime()` would raise when passed `pd.NA` (GH32213)
- Improved error message when subtracting two `Timestamp` that result in an out-of-bounds `Timedelta` (GH31774)

### Categorical

- Fixed bug where `Categorical.from_codes()` improperly raised a `ValueError` when passed nullable integer codes. (GH31779)
- Fixed bug where `Categorical()` constructor would raise a `TypeError` when given a numpy array containing `pd.NA`. (GH31927)

- Bug in *Categorical* that would ignore or crash when calling *Series.replace()* with a list-like *to\_replace* (GH31720)

### I/O

- Using *pd.NA* with *DataFrame.to\_json()* now correctly outputs a null value instead of an empty object (GH31615)
- Bug in *pandas.json\_normalize()* when value in meta path is not iterable (GH31507)
- Fixed pickling of *pandas.NA*. Previously a new object was returned, which broke computations relying on *NA* being a singleton (GH31847)
- Fixed bug in parquet roundtrip with nullable unsigned integer dtypes (GH31896).

### Experimental dtypes

- Fixed bug in *DataFrame.convert\_dtypes()* for columns that were already using the "string" dtype (GH31731).
- Fixed bug in *DataFrame.convert\_dtypes()* for series with mix of integers and strings (GH32117)
- Fixed bug in *DataFrame.convert\_dtypes()* where *BooleanDtype* columns were converted to *Int64* (GH32287)
- Fixed bug in setting values using a slice indexer with string dtype (GH31772)
- Fixed bug where *pandas.core.groupby.GroupBy.first()* and *pandas.core.groupby.GroupBy.last()* would raise a *TypeError* when groups contained *pd.NA* in a column of object dtype (GH32123)
- Fixed bug where *DataFrameGroupBy.mean()*, *DataFrameGroupBy.median()*, *DataFrameGroupBy.var()*, and *DataFrameGroupBy.std()* would raise a *TypeError* on *Int64* dtype columns (GH32219)

### Strings

- Using *pd.NA* with *Series.str.repeat()* now correctly outputs a null value instead of raising error for vector inputs (GH31632)

### Rolling

- Fixed rolling operations with variable window (defined by time duration) on decreasing time index (GH32385).

### Contributors

A total of 25 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

### 5.4.5 What's new in 1.0.1 (February 5, 2020)

These are the changes in pandas 1.0.1. See *Release notes* for a full changelog including other versions of pandas.

#### Fixed regressions

- Fixed regression in *DataFrame* setting values with a slice (e.g. `df[-4:] = 1`) indexing by label instead of position (GH31469)
- Fixed regression when indexing a *Series* or *DataFrame* indexed by *DatetimeIndex* with a slice containing a `datetime.date` (GH31501)
- Fixed regression in *DataFrame*.`__setitem__` raising an *AttributeError* with a *MultiIndex* and a non-monotonic indexer (GH31449)
- Fixed regression in *Series* multiplication when multiplying a numeric *Series* with >10000 elements with a `timedelta`-like scalar (GH31457)
- Fixed regression in `.groupby().agg()` raising an *AssertionError* for some reductions like `min` on object-dtype columns (GH31522)
- Fixed regression in `.groupby()` aggregations with categorical dtype using Cythonized reduction functions (e.g. `first`) (GH31450)
- Fixed regression in *GroupBy*.`apply()` if called with a function which returned a non-pandas non-scalar object (e.g. a list or numpy array) (GH31441)
- Fixed regression in *DataFrame*.`groupby()` whereby taking the minimum or maximum of a column with period dtype would raise a *TypeError*. (GH31471)
- Fixed regression in *DataFrame*.`groupby()` with an empty *DataFrame* grouping by a level of a *MultiIndex* (GH31670).
- Fixed regression in *DataFrame*.`apply()` with object dtype and non-reducing function (GH31505)

- Fixed regression in `to_datetime()` when parsing non-nanosecond resolution datetimes (GH31491)
- Fixed regression in `to_csv()` where specifying an `na_rep` might truncate the values written (GH31447)
- Fixed regression in `Categorical` construction with `numpy.str_` categories (GH31499)
- Fixed regression in `DataFrame.loc()` and `DataFrame.iloc()` when selecting a row containing a single `datetime64` or `timedelta64` column (GH31649)
- Fixed regression where setting `pd.options.display.max_colwidth` was not accepting negative integer. In addition, this behavior has been deprecated in favor of using `None` (GH31532)
- Fixed regression in `objTOJSON.c` fix return-type warning (GH31463)
- Fixed regression in `qcut()` when passed a nullable integer. (GH31389)
- Fixed regression in assigning to a `Series` using a nullable integer dtype (GH31446)
- Fixed performance regression when indexing a `DataFrame` or `Series` with a `MultiIndex` for the index using a list of labels (GH31648)
- Fixed regression in `read_csv()` used in file like object `RawIOBase` is not recognize encoding option (GH31575)

### Deprecations

- Support for negative integer for `pd.options.display.max_colwidth` is deprecated in favor of using `None` (GH31532)

### Bug fixes

#### Datetimelike

- Fixed bug in `to_datetime()` raising when `cache=True` and out-of-bound values are present (GH31491)

#### Numeric

- Bug in dtypes being lost in `DataFrame.__invert__` (~ operator) with mixed dtypes (GH31183) and for extension-array backed `Series` and `DataFrame` (GH23087)

#### Plotting

- Plotting tz-aware timeseries no longer gives `UserWarning` (GH31205)

#### Interval

- Bug in `Series.shift()` with `interval` dtype raising a `TypeError` when shifting an interval array of integers or datetimes (GH34195)

## 5.4.6 What's new in 1.0.0 (January 29, 2020)

These are the changes in pandas 1.0.0. See *Release notes* for a full changelog including other versions of pandas.

---

**Note:** The pandas 1.0 release removed a lot of functionality that was deprecated in previous releases (see *below* for an overview). It is recommended to first upgrade to pandas 0.25 and to ensure your code is working without warnings, before upgrading to pandas 1.0.

---

### New deprecation policy

Starting with pandas 1.0.0, pandas will adopt a variant of [SemVer](#) to version releases. Briefly,

- Deprecations will be introduced in minor releases (e.g. 1.1.0, 1.2.0, 2.1.0, ...)
- Deprecations will be enforced in major releases (e.g. 1.0.0, 2.0.0, 3.0.0, ...)
- API-breaking changes will be made only in major releases (except for experimental features)

See *Version policy* for more.

### Enhancements

#### Using Numba in `rolling.apply` and `expanding.apply`

We've added an `engine` keyword to `apply()` and `apply()` that allows the user to execute the routine using [Numba](#) instead of Cython. Using the Numba engine can yield significant performance gains if the `apply` function can operate on numpy arrays and the data set is larger (1 million rows or greater). For more details, see *rolling apply documentation* ([GH28987](#), [GH30936](#))

## Defining custom windows for rolling operations

We've added a `pandas.api.indexers.BaseIndexer()` class that allows users to define how window bounds are created during rolling operations. Users can define their own `get_window_bounds` method on a `pandas.api.indexers.BaseIndexer()` subclass that will generate the start and end indices used for each window during the rolling aggregation. For more details and example usage, see the [custom window rolling documentation](#)

## Converting to markdown

We've added `to_markdown()` for creating a markdown table (GH11052)

```
In [1]: df = pd.DataFrame({"A": [1, 2, 3], "B": [1, 2, 3]}, index=['a', 'a', 'b'])
In [2]: print(df.to_markdown())
| | A | B |
|:--|----:|----:|
| a | 1 | 1 |
| a | 2 | 2 |
| b | 3 | 3 |
```

## Experimental new features

### Experimental NA scalar to denote missing values

A new `pd.NA` value (singleton) is introduced to represent scalar missing values. Up to now, pandas used several values to represent missing data: `np.nan` is used for this for float data, `np.nan` or `None` for object-dtype data and `pd.NaT` for datetime-like data. The goal of `pd.NA` is to provide a “missing” indicator that can be used consistently across data types. `pd.NA` is currently used by the nullable integer and boolean data types and the new string data type (GH28095).

**Warning:** Experimental: the behaviour of `pd.NA` can still change without warning.

For example, creating a Series using the nullable integer dtype:

```
In [3]: s = pd.Series([1, 2, None], dtype="Int64")
In [4]: s
Out[4]:
0 1
1 2
2 <NA>
dtype: Int64
In [5]: s[2]
Out[5]: <NA>
```

Compared to `np.nan`, `pd.NA` behaves differently in certain operations. In addition to arithmetic operations, `pd.NA` also propagates as “missing” or “unknown” in comparison operations:

```
In [6]: np.nan > 1
Out[6]: False

In [7]: pd.NA > 1
Out[7]: <NA>
```

For logical operations, `pd.NA` follows the rules of the [three-valued logic](#) (or *Kleene logic*). For example:

```
In [8]: pd.NA | True
Out[8]: True
```

For more, see [NA section](#) in the user guide on missing data.

### Dedicated string data type

We've added `StringDtype`, an extension type dedicated to string data. Previously, strings were typically stored in object-dtype NumPy arrays. ([GH29975](#))

**Warning:** `StringDtype` is currently considered experimental. The implementation and parts of the API may change without warning.

The `'string'` extension type solves several issues with object-dtype NumPy arrays:

1. You can accidentally store a *mixture* of strings and non-strings in an object dtype array. A `StringArray` can only store strings.
2. object dtype breaks dtype-specific operations like `DataFrame.select_dtypes()`. There isn't a clear way to select *just* text while excluding non-text, but still object-dtype columns.
3. When reading code, the contents of an object dtype array is less clear than `string`.

```
In [9]: pd.Series(['abc', None, 'def'], dtype=pd.StringDtype())
Out[9]:
0 abc
1 <NA>
2 def
dtype: string
```

You can use the alias `"string"` as well.

```
In [10]: s = pd.Series(['abc', None, 'def'], dtype="string")

In [11]: s
Out[11]:
0 abc
1 <NA>
2 def
dtype: string
```

The usual string accessor methods work. Where appropriate, the return type of the Series or columns of a DataFrame will also have string dtype.

```
In [12]: s.str.upper()
Out[12]:
0 ABC
1 <NA>
2 DEF
dtype: string

In [13]: s.str.split('b', expand=True).dtypes
Out[13]:
0 string
1 string
dtype: object
```

String accessor methods returning integers will return a value with *Int64Dtype*

```
In [14]: s.str.count("a")
Out[14]:
0 1
1 <NA>
2 0
dtype: Int64
```

We recommend explicitly using the `string` data type when working with strings. See *Text data types* for more.

### Boolean data type with missing values support

We've added *BooleanDtype* / *BooleanArray*, an extension type dedicated to boolean data that can hold missing values. The default `bool` data type based on a `bool`-dtype NumPy array, the column can only hold `True` or `False`, and not missing values. This new *BooleanArray* can store missing values as well by keeping track of this in a separate mask. (GH29555, GH30095, GH31131)

```
In [15]: pd.Series([True, False, None], dtype=pd.BooleanDtype())
Out[15]:
0 True
1 False
2 <NA>
dtype: boolean
```

You can use the alias `"boolean"` as well.

```
In [16]: s = pd.Series([True, False, None], dtype="boolean")

In [17]: s
Out[17]:
0 True
1 False
2 <NA>
dtype: boolean
```

## Method `convert_dtypes` to ease use of supported extension dtypes

In order to encourage use of the extension dtypes `StringDtype`, `BooleanDtype`, `Int64Dtype`, `Int32Dtype`, etc., that support `pd.NA`, the methods `DataFrame.convert_dtypes()` and `Series.convert_dtypes()` have been introduced. (GH29752) (GH30929)

Example:

```
In [18]: df = pd.DataFrame({'x': ['abc', None, 'def'],
.....: 'y': [1, 2, np.nan],
.....: 'z': [True, False, True]})
.....:
```

```
In [19]: df
Out[19]:
 x y z
0 abc 1.0 True
1 None 2.0 False
2 def NaN True
```

```
In [20]: df.dtypes
Out[20]:
x object
y float64
z bool
dtype: object
```

```
In [21]: converted = df.convert_dtypes()
```

```
In [22]: converted
Out[22]:
 x y z
0 abc 1 True
1 <NA> 2 False
2 def <NA> True
```

```
In [23]: converted.dtypes
Out[23]:
x string
y Int64
z boolean
dtype: object
```

This is especially useful after reading in data using readers such as `read_csv()` and `read_excel()`. See [here](#) for a description.

## Other enhancements

- `DataFrame.to_string()` added the `max_colwidth` parameter to control when wide columns are truncated (GH9784)
- Added the `na_value` argument to `Series.to_numpy()`, `Index.to_numpy()` and `DataFrame.to_numpy()` to control the value used for missing data (GH30322)
- `MultiIndex.from_product()` infers level names from inputs if not explicitly provided (GH27292)
- `DataFrame.to_latex()` now accepts `caption` and `label` arguments (GH25436)
- DataFrames with `nullable integer`, the `new string dtype` and period data type can now be converted to `pyarrow` (`>=0.15.0`), which means that it is supported in writing to the Parquet file format when using the `pyarrow` engine (GH28368). Full roundtrip to parquet (writing and reading back in with `to_parquet()` / `read_parquet()`) is supported starting with `pyarrow >= 0.16` (GH20612).
- `to_parquet()` now appropriately handles the `schema` argument for user defined schemas in the `pyarrow` engine. (GH30270)
- `DataFrame.to_json()` now accepts an `indent` integer argument to enable pretty printing of JSON output (GH12004)
- `read_stata()` can read Stata 119 dta files. (GH28250)
- Implemented `pandas.core.window.Window.var()` and `pandas.core.window.Window.std()` functions (GH26597)
- Added encoding argument to `DataFrame.to_string()` for non-ascii text (GH28766)
- Added encoding argument to `DataFrame.to_html()` for non-ascii text (GH28663)
- `Styler.background_gradient()` now accepts `vmin` and `vmax` arguments (GH12145)
- `Styler.format()` added the `na_rep` parameter to help format the missing values (GH21527, GH28358)
- `read_excel()` now can read binary Excel (`.xlsb`) files by passing `engine='pyxlsb'`. For more details and example usage, see the *Binary Excel files documentation*. Closes GH8540.
- The `partition_cols` argument in `DataFrame.to_parquet()` now accepts a string (GH27117)
- `pandas.read_json()` now parses NaN, Infinity and -Infinity (GH12213)
- `DataFrame` constructor preserve `ExtensionArray` dtype with `ExtensionArray` (GH11363)
- `DataFrame.sort_values()` and `Series.sort_values()` have gained `ignore_index` keyword to be able to reset index after sorting (GH30114)
- `DataFrame.sort_index()` and `Series.sort_index()` have gained `ignore_index` keyword to reset index (GH30114)
- `DataFrame.drop_duplicates()` has gained `ignore_index` keyword to reset index (GH30114)
- Added new writer for exporting Stata dta files in versions 118 and 119, `StataWriterUTF8`. These files formats support exporting strings containing Unicode characters. Format 119 supports data sets with more than 32,767 variables (GH23573, GH30959)
- `Series.map()` now accepts `collections.abc.Mapping` subclasses as a mapper (GH29733)
- Added an experimental `attrs` for storing global metadata about a dataset (GH29062)
- `Timestamp.fromisocalendar()` is now compatible with python 3.8 and above (GH28115)
- `DataFrame.to_pickle()` and `read_pickle()` now accept URL (GH30163)

## Backwards incompatible API changes

### Avoid using names from `MultiIndex.levels`

As part of a larger refactor to *MultiIndex* the level names are now stored separately from the levels (GH27242). We recommend using *MultiIndex.names* to access the names, and *Index.set\_names()* to update the names.

For backwards compatibility, you can still *access* the names via the levels.

```
In [24]: mi = pd.MultiIndex.from_product([[1, 2], ['a', 'b']], names=['x', 'y'])
```

```
In [25]: mi.levels[0].name
```

```
Out[25]: 'x'
```

However, it is no longer possible to *update* the names of the `MultiIndex` via the level.

```
In [26]: mi.levels[0].name = "new name"
```

```

RuntimeError Traceback (most recent call last)
<ipython-input-26-65f4400a0c97> in <module>
----> 1 mi.levels[0].name = "new name"

/pandas/pandas/core/indexes/base.py in name(self, value)
 1458 if self._no_setting_name:
 1459 # Used in MultiIndex.levels to avoid silently ignoring name updates.
-> 1460 raise RuntimeError(
 1461 "Cannot set name on a level of a MultiIndex. Use "
 1462 "'MultiIndex.set_names' instead."
```

```
RuntimeError: Cannot set name on a level of a MultiIndex. Use 'MultiIndex.set_names'
↳ instead.
```

```
In [27]: mi.names
```

```
Out[27]: FrozenList(['x', 'y'])
```

To update, use `MultiIndex.set_names`, which returns a new `MultiIndex`.

```
In [28]: mi2 = mi.set_names("new name", level=0)
```

```
In [29]: mi2.names
```

```
Out[29]: FrozenList(['new name', 'y'])
```

### New repr for `IntervalArray`

`pandas.arrays.IntervalArray` adopts a new `__repr__` in accordance with other array classes (GH25022)

*pandas 0.25.x*

```
In [1]: pd.arrays.IntervalArray.from_tuples([(0, 1), (2, 3)])
```

```
Out[2]:
```

```
IntervalArray([(0, 1], (2, 3]],
 closed='right',
 dtype='interval[int64]')
```

*pandas 1.0.0*

```
In [30]: pd.arrays.IntervalArray.from_tuples([(0, 1), (2, 3)])
Out[30]:
<IntervalArray>
[[0, 1], (2, 3]]
Length: 2, dtype: interval[int64, right]
```

### DataFrame.rename now only accepts one positional argument

`DataFrame.rename()` would previously accept positional arguments that would lead to ambiguous or undefined behavior. From pandas 1.0, only the very first argument, which maps labels to their new names along the default axis, is allowed to be passed by position (GH29136).

*pandas 0.25.x*

```
In [1]: df = pd.DataFrame([[1]])
In [2]: df.rename({0: 1}, {0: 2})
Out[2]:
FutureWarning: ...Use named arguments to resolve ambiguity...
 2
1 1
```

*pandas 1.0.0*

```
In [3]: df.rename({0: 1}, {0: 2})
Traceback (most recent call last):
...
TypeError: rename() takes from 1 to 2 positional arguments but 3 were given
```

Note that errors will now be raised when conflicting or potentially ambiguous arguments are provided.

*pandas 0.25.x*

```
In [4]: df.rename({0: 1}, index={0: 2})
Out[4]:
 0
1 1

In [5]: df.rename(mapper={0: 1}, index={0: 2})
Out[5]:
 0
2 1
```

*pandas 1.0.0*

```
In [6]: df.rename({0: 1}, index={0: 2})
Traceback (most recent call last):
...
TypeError: Cannot specify both 'mapper' and any of 'index' or 'columns'

In [7]: df.rename(mapper={0: 1}, index={0: 2})
Traceback (most recent call last):
```

(continues on next page)

(continued from previous page)

```
...
TypeError: Cannot specify both 'mapper' and any of 'index' or 'columns'
```

You can still change the axis along which the first positional argument is applied by supplying the `axis` keyword argument.

```
In [31]: df.rename({0: 1})
Out[31]:
 0
1 1

In [32]: df.rename({0: 1}, axis=1)
Out[32]:
 1
0 1
```

If you would like to update both the index and column labels, be sure to use the respective keywords.

```
In [33]: df.rename(index={0: 1}, columns={0: 2})
Out[33]:
 2
1 1
```

### Extended verbose info output for DataFrame

`DataFrame.info()` now shows line numbers for the columns summary (GH17304)

*pandas 0.25.x*

```
In [1]: df = pd.DataFrame({"int_col": [1, 2, 3],
... "text_col": ["a", "b", "c"],
... "float_col": [0.0, 0.1, 0.2]})
In [2]: df.info(verbose=True)
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 3 entries, 0 to 2
Data columns (total 3 columns):
int_col 3 non-null int64
text_col 3 non-null object
float_col 3 non-null float64
dtypes: float64(1), int64(1), object(1)
memory usage: 152.0+ bytes
```

*pandas 1.0.0*

```
In [34]: df = pd.DataFrame({"int_col": [1, 2, 3],
... "text_col": ["a", "b", "c"],
... "float_col": [0.0, 0.1, 0.2]})
In [35]: df.info(verbose=True)
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 3 entries, 0 to 2
```

(continues on next page)

(continued from previous page)

```
Data columns (total 3 columns):
Column Non-Null Count Dtype
--- -
0 int_col 3 non-null int64
1 text_col 3 non-null object
2 float_col 3 non-null float64
dtypes: float64(1), int64(1), object(1)
memory usage: 200.0+ bytes
```

### pandas.array() inference changes

`pandas.array()` now infers pandas' new extension types in several cases (GH29791):

1. String data (including missing values) now returns a `arrays.StringArray`.
2. Integer data (including missing values) now returns a `arrays.IntegerArray`.
3. Boolean data (including missing values) now returns the new `arrays.BooleanArray`

*pandas 0.25.x*

```
In [1]: pd.array(["a", None])
```

```
Out[1]:
```

```
<PandasArray>
```

```
['a', None]
```

```
Length: 2, dtype: object
```

```
In [2]: pd.array([1, None])
```

```
Out[2]:
```

```
<PandasArray>
```

```
[1, None]
```

```
Length: 2, dtype: object
```

*pandas 1.0.0*

```
In [36]: pd.array(["a", None])
```

```
Out[36]:
```

```
<StringArray>
```

```
['a', <NA>]
```

```
Length: 2, dtype: string
```

```
In [37]: pd.array([1, None])
```

```
Out[37]:
```

```
<IntegerArray>
```

```
[1, <NA>]
```

```
Length: 2, dtype: Int64
```

As a reminder, you can specify the dtype to disable all inference.

**arrays.IntegerArray now uses pandas.NA**

`arrays.IntegerArray` now uses `pandas.NA` rather than `numpy.nan` as its missing value marker (GH29964).

*pandas 0.25.x*

```
In [1]: a = pd.array([1, 2, None], dtype="Int64")
In [2]: a
Out[2]:
<IntegerArray>
[1, 2, NaN]
Length: 3, dtype: Int64

In [3]: a[2]
Out[3]:
nan
```

*pandas 1.0.0*

```
In [38]: a = pd.array([1, 2, None], dtype="Int64")

In [39]: a
Out[39]:
<IntegerArray>
[1, 2, <NA>]
Length: 3, dtype: Int64

In [40]: a[2]
Out[40]: <NA>
```

This has a few API-breaking consequences.

**Converting to a NumPy ndarray**

When converting to a NumPy array missing values will be `pd.NA`, which cannot be converted to a float. So calling `np.asarray(integer_array, dtype="float")` will now raise.

*pandas 0.25.x*

```
In [1]: np.asarray(a, dtype="float")
Out[1]:
array([1., 2., nan])
```

*pandas 1.0.0*

```
In [41]: np.asarray(a, dtype="float")

ValueError Traceback (most recent call last)
<ipython-input-41-4578f04da2b3> in <module>
----> 1 np.asarray(a, dtype="float")

/pandas/pandas/core/arrays/masked.py in __array__(self, dtype)
 333 We return an object array here to preserve our scalar values
 334 """
--> 335 return self.to_numpy(dtype=dtype)
 336
```

(continues on next page)

(continued from previous page)

```

337 def __arrow_array__(self, type=None):
/pandas/pandas/core/arrays/masked.py in to_numpy(self, dtype, copy, na_value)
290 and na_value is libmissing.NA
291):
--> 292 raise ValueError(
293 f"cannot convert to '{dtype}'-dtype NumPy array "
294 "with missing values. Specify an appropriate 'na_value' "
ValueError: cannot convert to 'float64'-dtype NumPy array with missing values. Specify_
↪ an appropriate 'na_value' for this dtype.

```

Use `arrays.IntegerArray.to_numpy()` with an explicit `na_value` instead.

```

In [42]: a.to_numpy(dtype="float", na_value=np.nan)
Out[42]: array([1., 2., nan])

```

### Reductions can return `pd.NA`

When performing a reduction such as a sum with `skipna=False`, the result will now be `pd.NA` instead of `np.nan` in presence of missing values (GH30958).

*pandas 0.25.x*

```

In [1]: pd.Series(a).sum(skipna=False)
Out[1]:
nan

```

*pandas 1.0.0*

```

In [43]: pd.Series(a).sum(skipna=False)
Out[43]: <NA>

```

### `value_counts` returns a nullable integer dtype

`Series.value_counts()` with a nullable integer dtype now returns a nullable integer dtype for the values.

*pandas 0.25.x*

```

In [1]: pd.Series([2, 1, 1, None], dtype="Int64").value_counts().dtype
Out[1]:
dtype('int64')

```

*pandas 1.0.0*

```

In [44]: pd.Series([2, 1, 1, None], dtype="Int64").value_counts().dtype
Out[44]: Int64Dtype()

```

See *Experimental NA scalar to denote missing values* for more on the differences between `pandas.NA` and `numpy.nan`.

**arrays.IntegerArray comparisons return arrays.BooleanArray**

Comparison operations on a `arrays.IntegerArray` now returns a `arrays.BooleanArray` rather than a NumPy array (GH29964).

*pandas 0.25.x*

```
In [1]: a = pd.array([1, 2, None], dtype="Int64")
In [2]: a
Out[2]:
<IntegerArray>
[1, 2, NaN]
Length: 3, dtype: Int64

In [3]: a > 1
Out[3]:
array([False, True, False])
```

*pandas 1.0.0*

```
In [45]: a = pd.array([1, 2, None], dtype="Int64")
In [46]: a > 1
Out[46]:
<BooleanArray>
[False, True, <NA>]
Length: 3, dtype: boolean
```

Note that missing values now propagate, rather than always comparing unequal like `numpy.nan`. See *Experimental NA scalar to denote missing values* for more.

**By default Categorical.min() now returns the minimum instead of np.nan**

When `Categorical` contains `np.nan`, `Categorical.min()` no longer return `np.nan` by default (`skipna=True`) (GH25303)

*pandas 0.25.x*

```
In [1]: pd.Categorical([1, 2, np.nan], ordered=True).min()
Out[1]: nan
```

*pandas 1.0.0*

```
In [47]: pd.Categorical([1, 2, np.nan], ordered=True).min()
Out[47]: 1
```

## Default dtype of empty pandas.Series

Initialising an empty `pandas.Series` without specifying a dtype will raise a `DeprecationWarning` now (GH17261). The default dtype will change from `float64` to `object` in future releases so that it is consistent with the behaviour of `DataFrame` and `Index`.

*pandas 1.0.0*

```
In [1]: pd.Series()
Out[2]:
DeprecationWarning: The default dtype for empty Series will be 'object' instead of
↳ 'float64' in a future version. Specify a dtype explicitly to silence this warning.
Series([], dtype: float64)
```

## Result dtype inference changes for resample operations

The rules for the result dtype in `DataFrame.resample()` aggregations have changed for extension types (GH31359). Previously, pandas would attempt to convert the result back to the original dtype, falling back to the usual inference rules if that was not possible. Now, pandas will only return a result of the original dtype if the scalar values in the result are instances of the extension dtype's scalar type.

```
In [48]: df = pd.DataFrame({"A": ['a', 'b']}, dtype='category',
.....: index=pd.date_range('2000', periods=2))
.....:
```

```
In [49]: df
Out[49]:
 A
2000-01-01 a
2000-01-02 b
```

*pandas 0.25.x*

```
In [1]: df.resample("2D").agg(lambda x: 'a').A.dtype
Out[1]:
CategoricalDtype(categories=['a', 'b'], ordered=False)
```

*pandas 1.0.0*

```
In [50]: df.resample("2D").agg(lambda x: 'a').A.dtype
Out[50]: dtype('O')
```

This fixes an inconsistency between `resample` and `groupby`. This also fixes a potential bug, where the **values** of the result might change depending on how the results are cast back to the original dtype.

*pandas 0.25.x*

```
In [1]: df.resample("2D").agg(lambda x: 'c')
Out[1]:
 A
0 NaN
```

*pandas 1.0.0*

```
In [51]: df.resample("2D").agg(lambda x: 'c')
```

```
Out[51]:
```

```
 A
2000-01-01 c
```

### Increased minimum version for Python

pandas 1.0.0 supports Python 3.6.1 and higher ([GH29212](#)).

### Increased minimum versions for dependencies

Some minimum supported versions of dependencies were updated ([GH29766](#), [GH29723](#)). If installed, we now require:

| Package         | Minimum Version | Required | Changed |
|-----------------|-----------------|----------|---------|
| numpy           | 1.13.3          | X        |         |
| pytz            | 2015.4          | X        |         |
| python-dateutil | 2.6.1           | X        |         |
| bottleneck      | 1.2.1           |          |         |
| numexpr         | 2.6.2           |          |         |
| pytest (dev)    | 4.0.2           |          |         |

For [optional libraries](#) the general recommendation is to use the latest version. The following table lists the lowest version per library that is currently being tested throughout the development of pandas. Optional libraries below the lowest tested version may still work, but are not considered supported.

| Package        | Minimum Version | Changed |
|----------------|-----------------|---------|
| beautifulsoup4 | 4.6.0           |         |
| fastparquet    | 0.3.2           | X       |
| gcsfs          | 0.2.2           |         |
| lxml           | 3.8.0           |         |
| matplotlib     | 2.2.2           |         |
| numba          | 0.46.0          | X       |
| openpyxl       | 2.5.7           | X       |
| pyarrow        | 0.13.0          | X       |
| pymysql        | 0.7.1           |         |
| pytables       | 3.4.2           |         |
| s3fs           | 0.3.0           | X       |
| scipy          | 0.19.0          |         |
| sqlalchemy     | 1.1.4           |         |
| xarray         | 0.8.2           |         |
| xlrd           | 1.1.0           |         |
| xlswriter      | 0.9.8           |         |
| xlwt           | 1.2.0           |         |

See [Dependencies](#) and [Optional dependencies](#) for more.

## Build changes

pandas has added a `pyproject.toml` file and will no longer include cythonized files in the source distribution uploaded to PyPI (GH28341, GH20775). If you're installing a built distribution (wheel) or via conda, this shouldn't have any effect on you. If you're building pandas from source, you should no longer need to install Cython into your build environment before calling `pip install pandas`.

## Other API changes

- `core.groupby.GroupBy.transform` now raises on invalid operation names (GH27489)
- `pandas.api.types.infer_dtype()` will now return "integer-na" for integer and `np.nan` mix (GH27283)
- `MultiIndex.from_arrays()` will no longer infer names from arrays if `names=None` is explicitly provided (GH27292)
- In order to improve tab-completion, pandas does not include most deprecated attributes when introspecting a pandas object using `dir` (e.g. `dir(df)`). To see which attributes are excluded, see an object's `_deprecations` attribute, for example `pd.DataFrame._deprecations` (GH28805).
- The returned dtype of `unique()` now matches the input dtype. (GH27874)
- Changed the default configuration value for `options.matplotlib.register_converters` from `True` to `"auto"` (GH18720). Now, pandas custom formatters will only be applied to plots created by pandas, through `plot()`. Previously, pandas' formatters would be applied to all plots created *after* a `plot()`. See *units registration* for more.
- `Series.dropna()` has dropped its `**kwargs` argument in favor of a single `how` parameter. Supplying anything else than `how` to `**kwargs` raised a `TypeError` previously (GH29388)
- When testing pandas, the new minimum required version of `pytest` is 5.0.1 (GH29664)
- `Series.str.__iter__()` was deprecated and will be removed in future releases (GH28277).
- Added `<NA>` to the list of default NA values for `read_csv()` (GH30821)

## Documentation improvements

- Added new section on *Scaling to large datasets* (GH28315).
- Added sub-section on *Query MultiIndex* for HDF5 datasets (GH28791).

## Deprecations

- `Series.item()` and `Index.item()` have been `_undeprecated_` (GH29250)
- `Index.set_value` has been deprecated. For a given index `idx`, array `arr`, value in `idx` of `idx_val` and a new value of `val`, `idx.set_value(arr, idx_val, val)` is equivalent to `arr[idx.get_loc(idx_val)] = val`, which should be used instead (GH28621).
- `is_extension_type()` is deprecated, `is_extension_array_dtype()` should be used instead (GH29457)
- `eval()` keyword argument "truediv" is deprecated and will be removed in a future version (GH29812)
- `DateOffset.isAnchored()` and `DatetimeOffset.onOffset()` are deprecated and will be removed in a future version, use `DateOffset.is_anchored()` and `DateOffset.is_on_offset()` instead (GH30340)

- `pandas.tseries.frequencies.get_offset` is deprecated and will be removed in a future version, use `pandas.tseries.frequencies.to_offset` instead (GH4205)
- `Categorical.take_nd()` and `CategoricalIndex.take_nd()` are deprecated, use `Categorical.take()` and `CategoricalIndex.take()` instead (GH27745)
- The parameter `numeric_only` of `Categorical.min()` and `Categorical.max()` is deprecated and replaced with `skipna` (GH25303)
- The parameter `label` in `lreshape()` has been deprecated and will be removed in a future version (GH29742)
- `pandas.core.index` has been deprecated and will be removed in a future version, the public classes are available in the top-level namespace (GH19711)
- `pandas.json_normalize()` is now exposed in the top-level namespace. Usage of `json_normalize` as `pandas.io.json.json_normalize` is now deprecated and it is recommended to use `json_normalize` as `pandas.json_normalize()` instead (GH27586).
- The `numpy` argument of `pandas.read_json()` is deprecated (GH28512).
- `DataFrame.to_stata()`, `DataFrame.to_feather()`, and `DataFrame.to_parquet()` argument “fname” is deprecated, use “path” instead (GH23574)
- The deprecated internal attributes `_start`, `_stop` and `_step` of `RangeIndex` now raise a `FutureWarning` instead of a `DeprecationWarning` (GH26581)
- The `pandas.util.testing` module has been deprecated. Use the public API in `pandas.testing` documented at *Testing functions* (GH16232).
- `pandas.SparseArray` has been deprecated. Use `pandas.arrays.SparseArray` (`arrays.SparseArray`) instead. (GH30642)
- The parameter `is_copy` of `Series.take()` and `DataFrame.take()` has been deprecated and will be removed in a future version. (GH27357)
- Support for multi-dimensional indexing (e.g. `index[:, None]`) on a `Index` is deprecated and will be removed in a future version, convert to a `numpy` array before indexing instead (GH30588)
- The `pandas.np` submodule is now deprecated. Import `numpy` directly instead (GH30296)
- The `pandas.datetime` class is now deprecated. Import from `datetime` instead (GH30610)
- `diff` will raise a `TypeError` rather than implicitly losing the `dtype` of extension types in the future. Convert to the correct `dtype` before calling `diff` instead (GH31025)

### Selecting Columns from a Grouped DataFrame

When selecting columns from a `DataFrameGroupBy` object, passing individual keys (or a tuple of keys) inside single brackets is deprecated, a list of items should be used instead. (GH23566) For example:

```
df = pd.DataFrame({
 "A": ["foo", "bar", "foo", "bar", "foo", "bar", "foo", "foo"],
 "B": np.random.randn(8),
 "C": np.random.randn(8),
})
g = df.groupby('A')

single key, returns SeriesGroupBy
g['B']

tuple of single key, returns SeriesGroupBy
g[('B',)]
```

(continues on next page)

(continued from previous page)

```
tuple of multiple keys, returns DataFrameGroupBy, raises FutureWarning
g[('B', 'C')]

multiple keys passed directly, returns DataFrameGroupBy, raises FutureWarning
(implicitly converts the passed strings into a single tuple)
g['B', 'C']

proper way, returns DataFrameGroupBy
g[['B', 'C']]
```

## Removal of prior version deprecations/changes

### Removed SparseSeries and SparseDataFrame

SparseSeries, SparseDataFrame and the DataFrame.to\_sparse method have been removed (GH28425). We recommend using a Series or DataFrame with sparse values instead. See *Migrating* for help with migrating existing code.

### Matplotlib unit registration

Previously, pandas would register converters with matplotlib as a side effect of importing pandas (GH18720). This changed the output of plots made via matplotlib plots after pandas was imported, even if you were using matplotlib directly rather than `plot()`.

To use pandas formatters with a matplotlib plot, specify

```
In [1]: import pandas as pd
In [2]: pd.options.plotting.matplotlib.register_converters = True
```

Note that plots created by `DataFrame.plot()` and `Series.plot()` do register the converters automatically. The only behavior change is when plotting a date-like object via `matplotlib.pyplot.plot` or `matplotlib.Axes.plot`. See *Custom formatters for timeseries plots* for more.

### Other removals

- Removed the previously deprecated keyword “index” from `read_stata()`, `StataReader`, and `StataReader.read()`, use “index\_col” instead (GH17328)
- Removed `StataReader.data` method, use `StataReader.read()` instead (GH9493)
- Removed `pandas.plotting._matplotlib.tsplot`, use `Series.plot()` instead (GH19980)
- `pandas.tseries.converter.register` has been moved to `pandas.plotting.register_matplotlib_converters()` (GH18307)
- `Series.plot()` no longer accepts positional arguments, pass keyword arguments instead (GH30003)
- `DataFrame.hist()` and `Series.hist()` no longer allows `figsize="default"`, specify figure size by passing a tuple instead (GH30003)
- Floordiv of integer-dtyped array by `Timedelta` now raises `TypeError` (GH21036)
- `TimedeltaIndex` and `DatetimeIndex` no longer accept non-nanosecond dtype strings like “timedelta64” or “datetime64”, use “timedelta64[ns]” and “datetime64[ns]” instead (GH24806)
- Changed the default “skipna” argument in `pandas.api.types.infer_dtype()` from `False` to `True` (GH24050)

- Removed `Series.ix` and `DataFrame.ix` (GH26438)
- Removed `Index.summary` (GH18217)
- Removed the previously deprecated keyword “fastpath” from the `Index` constructor (GH23110)
- Removed `Series.get_value`, `Series.set_value`, `DataFrame.get_value`, `DataFrame.set_value` (GH17739)
- Removed `Series.compound` and `DataFrame.compound` (GH26405)
- Changed the default “inplace” argument in `DataFrame.set_index()` and `Series.set_axis()` from `None` to `False` (GH27600)
- Removed `Series.cat.categorical`, `Series.cat.index`, `Series.cat.name` (GH24751)
- Removed the previously deprecated keyword “box” from `to_datetime()` and `to_timedelta()`; in addition these now always returns `DatetimeIndex`, `TimedeltaIndex`, `Index`, `Series`, or `DataFrame` (GH24486)
- `to_timedelta()`, `Timedelta`, and `TimedeltaIndex` no longer allow “M”, “y”, or “Y” for the “unit” argument (GH23264)
- Removed the previously deprecated keyword “time\_rule” from (non-public) `offsets.generate_range`, which has been moved to `core.arrays._ranges.generate_range()` (GH24157)
- `DataFrame.loc()` or `Series.loc()` with listlike indexers and missing labels will no longer reindex (GH17295)
- `DataFrame.to_excel()` and `Series.to_excel()` with non-existent columns will no longer reindex (GH17295)
- Removed the previously deprecated keyword “join\_axes” from `concat()`; use `reindex_like` on the result instead (GH22318)
- Removed the previously deprecated keyword “by” from `DataFrame.sort_index()`, use `DataFrame.sort_values()` instead (GH10726)
- Removed support for nested renaming in `DataFrame.aggregate()`, `Series.aggregate()`, `core.groupby.DataFrameGroupBy.aggregate()`, `core.groupby.SeriesGroupBy.aggregate()`, `core.window.Rolling.Rolling.aggregate()` (GH18529)
- Passing `datetime64` data to `TimedeltaIndex` or `timedelta64` data to `DatetimeIndex` now raises `TypeError` (GH23539, GH23937)
- Passing `int64` values to `DatetimeIndex` and a `timezone` now interprets the values as nanosecond timestamps in UTC, not wall times in the given `timezone` (GH24559)
- A tuple passed to `DataFrame.groupby()` is now exclusively treated as a single key (GH18314)
- Removed `Index.contains`, use `key in index` instead (GH30103)
- Addition and subtraction of `int` or integer-arrays is no longer allowed in `Timestamp`, `DatetimeIndex`, `TimedeltaIndex`, use `obj + n * obj.freq` instead of `obj + n` (GH22535)
- Removed `Series.ptp` (GH21614)
- Removed `Series.from_array` (GH18258)
- Removed `DataFrame.from_items` (GH18458)
- Removed `DataFrame.as_matrix`, `Series.as_matrix` (GH18458)
- Removed `Series.asobject` (GH18477)
- Removed `DataFrame.as_blocks`, `Series.as_blocks`, `DataFrame.blocks`, `Series.blocks` (GH17656)
- `pandas.Series.str.cat()` now defaults to aligning others, using `join='left'` (GH27611)

- `pandas.Series.str.cat()` does not accept list-likes *within* list-likes anymore (GH27611)
- `Series.where()` with Categorical dtype (or `DataFrame.where()` with Categorical column) no longer allows setting new categories (GH24114)
- Removed the previously deprecated keywords “start”, “end”, and “periods” from the `DatetimeIndex`, `TimedeltaIndex`, and `PeriodIndex` constructors; use `date_range()`, `timedelta_range()`, and `period_range()` instead (GH23919)
- Removed the previously deprecated keyword “verify\_integrity” from the `DatetimeIndex` and `TimedeltaIndex` constructors (GH23919)
- Removed the previously deprecated keyword “fastpath” from `pandas.core.internals.blocks.make_block` (GH19265)
- Removed the previously deprecated keyword “dtype” from `Block.make_block_same_class()` (GH19434)
- Removed `ExtensionArray._formatting_values`. Use `ExtensionArray._formatter` instead. (GH23601)
- Removed `MultiIndex.to_hierarchical` (GH21613)
- Removed `MultiIndex.labels`, use `MultiIndex.codes` instead (GH23752)
- Removed the previously deprecated keyword “labels” from the `MultiIndex` constructor, use “codes” instead (GH23752)
- Removed `MultiIndex.set_labels`, use `MultiIndex.set_codes()` instead (GH23752)
- Removed the previously deprecated keyword “labels” from `MultiIndex.set_codes()`, `MultiIndex.copy()`, `MultiIndex.drop()`, use “codes” instead (GH23752)
- Removed support for legacy HDF5 formats (GH29787)
- Passing a dtype alias (e.g. ‘datetime64[ns, UTC]’) to `DatetimeTZDtype` is no longer allowed, use `DatetimeTZDtype.construct_from_string()` instead (GH23990)
- Removed the previously deprecated keyword “skip\_footer” from `read_excel()`; use “skipfooter” instead (GH18836)
- `read_excel()` no longer allows an integer value for the parameter `usecols`, instead pass a list of integers from 0 to `usecols` inclusive (GH23635)
- Removed the previously deprecated keyword “convert\_datetime64” from `DataFrame.to_records()` (GH18902)
- Removed `IntervalIndex.from_intervals` in favor of the `IntervalIndex` constructor (GH19263)
- Changed the default “keep\_tz” argument in `DatetimeIndex.to_series()` from None to True (GH23739)
- Removed `api.types.is_period` and `api.types.is_datetimetz` (GH23917)
- Ability to read pickles containing `Categorical` instances created with pre-0.16 version of pandas has been removed (GH27538)
- Removed `pandas.tseries.plotting.tsplot` (GH18627)
- Removed the previously deprecated keywords “reduce” and “broadcast” from `DataFrame.apply()` (GH18577)
- Removed the previously deprecated `assert_raises_regex` function in `pandas._testing` (GH29174)
- Removed the previously deprecated `FrozenNDArray` class in `pandas.core.indexes.frozen` (GH29335)
- Removed the previously deprecated keyword “nthreads” from `read_feather()`, use “use\_threads” instead (GH23053)
- Removed `Index.is_lexsorted_for_tuple` (GH29305)

- Removed support for nested renaming in `DataFrame.aggregate()`, `Series.aggregate()`, `core.groupby.DataFrameGroupBy.aggregate()`, `core.groupby.SeriesGroupBy.aggregate()`, `core.window.rolling.Rolling.aggregate()` (GH29608)
- Removed `Series.valid`; use `Series.dropna()` instead (GH18800)
- Removed `DataFrame.is_copy`, `Series.is_copy` (GH18812)
- Removed `DataFrame.get_ftype_counts`, `Series.get_ftype_counts` (GH18243)
- Removed `DataFrame.ftypes`, `Series.ftypes`, `Series.ftype` (GH26744)
- Removed `Index.get_duplicates`, use `idx[idx.duplicated()].unique()` instead (GH20239)
- Removed `Series.clip_upper`, `Series.clip_lower`, `DataFrame.clip_upper`, `DataFrame.clip_lower` (GH24203)
- Removed the ability to alter `DatetimeIndex.freq`, `TimedeltaIndex.freq`, or `PeriodIndex.freq` (GH20772)
- Removed `DatetimeIndex.offset` (GH20730)
- Removed `DatetimeIndex.asobject`, `TimedeltaIndex.asobject`, `PeriodIndex.asobject`, use `astype(object)` instead (GH29801)
- Removed the previously deprecated keyword “order” from `factorize()` (GH19751)
- Removed the previously deprecated keyword “encoding” from `read_stata()` and `DataFrame.to_stata()` (GH21400)
- Changed the default “sort” argument in `concat()` from `None` to `False` (GH20613)
- Removed the previously deprecated keyword “raise\_conflict” from `DataFrame.update()`, use “errors” instead (GH23585)
- Removed the previously deprecated keyword “n” from `DatetimeIndex.shift()`, `TimedeltaIndex.shift()`, `PeriodIndex.shift()`, use “periods” instead (GH22458)
- Removed the previously deprecated keywords “how”, “fill\_method”, and “limit” from `DataFrame.resample()` (GH30139)
- Passing an integer to `Series.fillna()` or `DataFrame.fillna()` with `timedelta64[ns]` dtype now raises `TypeError` (GH24694)
- Passing multiple axes to `DataFrame.dropna()` is no longer supported (GH20995)
- Removed `Series.nonzero`, use `to_numpy().nonzero()` instead (GH24048)
- Passing floating dtype codes to `Categorical.from_codes()` is no longer supported, pass `codes.astype(np.int64)` instead (GH21775)
- Removed the previously deprecated keyword “pat” from `Series.str.partition()` and `Series.str.rpartition()`, use “sep” instead (GH23767)
- Removed `Series.put` (GH27106)
- Removed `Series.real`, `Series.imag` (GH27106)
- Removed `Series.to_dense`, `DataFrame.to_dense` (GH26684)
- Removed `Index.dtype_str`, use `str(index.dtype)` instead (GH27106)
- `Categorical.ravel()` returns a `Categorical` instead of a `ndarray` (GH27199)
- The ‘outer’ method on Numpy ufuncs, e.g. `np.subtract.outer` operating on `Series` objects is no longer supported, and will raise `NotImplementedError` (GH27198)

- Removed `Series.get_dtype_counts` and `DataFrame.get_dtype_counts` (GH27145)
- Changed the default “fill\_value” argument in `Categorical.take()` from `True` to `False` (GH20841)
- Changed the default value for the `raw` argument in `Series.rolling().apply()`, `DataFrame.rolling().apply()`, `Series.expanding().apply()`, and `DataFrame.expanding().apply()` from `None` to `False` (GH20584)
- Removed deprecated behavior of `Series.argmax()` and `Series.argmax()`, use `Series.idxmin()` and `Series.idxmax()` for the old behavior (GH16955)
- Passing a tz-aware `datetime.datetime` or `Timestamp` into the `Timestamp` constructor with the `tz` argument now raises a `ValueError` (GH23621)
- Removed `Series.base`, `Index.base`, `Categorical.base`, `Series.flags`, `Index.flags`, `PeriodArray.flags`, `Series.strides`, `Index.strides`, `Series.itemsize`, `Index.itemsize`, `Series.data`, `Index.data` (GH20721)
- Changed `Timedelta.resolution()` to match the behavior of the standard library `datetime.timedelta.resolution`, for the old behavior, use `Timedelta.resolution_string()` (GH26839)
- Removed `Timestamp.weekday_name`, `DatetimeIndex.weekday_name`, and `Series.dt.weekday_name` (GH18164)
- Removed the previously deprecated keyword “errors” in `Timestamp.tz_localize()`, `DatetimeIndex.tz_localize()`, and `Series.tz_localize()` (GH22644)
- Changed the default “ordered” argument in `CategoricalDtype` from `None` to `False` (GH26336)
- `Series.set_axis()` and `DataFrame.set_axis()` now require “labels” as the first argument and “axis” as an optional named parameter (GH30089)
- Removed `to_msgpack`, `read_msgpack`, `DataFrame.to_msgpack`, `Series.to_msgpack` (GH27103)
- Removed `Series.compress` (GH21930)
- Removed the previously deprecated keyword “fill\_value” from `Categorical.fillna()`, use “value” instead (GH19269)
- Removed the previously deprecated keyword “data” from `andrews_curves()`, use “frame” instead (GH6956)
- Removed the previously deprecated keyword “data” from `parallel_coordinates()`, use “frame” instead (GH6956)
- Removed the previously deprecated keyword “colors” from `parallel_coordinates()`, use “color” instead (GH6956)
- Removed the previously deprecated keywords “verbose” and “private\_key” from `read_gbq()` (GH30200)
- Calling `np.array` and `np.asarray` on tz-aware `Series` and `DatetimeIndex` will now return an object array of tz-aware `Timestamp` (GH24596)
-

## Performance improvements

- Performance improvement in `DataFrame` arithmetic and comparison operations with scalars (GH24990, GH29853)
- Performance improvement in indexing with a non-unique `IntervalIndex` (GH27489)
- Performance improvement in `MultiIndex.is_monotonic` (GH27495)
- Performance improvement in `cut()` when bins is an `IntervalIndex` (GH27668)
- Performance improvement when initializing a `DataFrame` using a range (GH30171)
- Performance improvement in `DataFrame.corr()` when method is "spearman" (GH28139)
- Performance improvement in `DataFrame.replace()` when provided a list of values to replace (GH28099)
- Performance improvement in `DataFrame.select_dtypes()` by using vectorization instead of iterating over a loop (GH28317)
- Performance improvement in `Categorical.searchsorted()` and `CategoricalIndex.searchsorted()` (GH28795)
- Performance improvement when comparing a `Categorical` with a scalar and the scalar is not found in the categories (GH29750)
- Performance improvement when checking if values in a `Categorical` are equal, equal or larger or larger than a given scalar. The improvement is not present if checking if the `Categorical` is less than or less than or equal than the scalar (GH29820)
- Performance improvement in `Index.equals()` and `MultiIndex.equals()` (GH29134)
- Performance improvement in `infer_dtype()` when skipna is True (GH28814)

## Bug fixes

### Categorical

- Added test to assert the `fillna()` raises the correct `ValueError` message when the value isn't a value from categories (GH13628)
- Bug in `Categorical.astype()` where NaN values were handled incorrectly when casting to int (GH28406)
- `DataFrame.reindex()` with a `CategoricalIndex` would fail when the targets contained duplicates, and wouldn't fail if the source contained duplicates (GH28107)
- Bug in `Categorical.astype()` not allowing for casting to extension dtypes (GH28668)
- Bug where `merge()` was unable to join on categorical and extension dtype columns (GH28668)
- `Categorical.searchsorted()` and `CategoricalIndex.searchsorted()` now work on unordered categoricals also (GH21667)
- Added test to assert roundtripping to parquet with `DataFrame.to_parquet()` or `read_parquet()` will preserve Categorical dtypes for string types (GH27955)
- Changed the error message in `Categorical.remove_categories()` to always show the invalid removals as a set (GH28669)
- Using date accessors on a categorical dtyped `Series` of datetimes was not returning an object of the same type as if one used the `str.()` / `dt.()` on a `Series` of that type. E.g. when accessing `Series.dt.tz_localize()` on a `Categorical` with duplicate entries, the accessor was skipping duplicates (GH27952)

- Bug in `DataFrame.replace()` and `Series.replace()` that would give incorrect results on categorical data (GH26988)
- Bug where calling `Categorical.min()` or `Categorical.max()` on an empty `Categorical` would raise a numpy exception (GH30227)
- The following methods now also correctly output values for unobserved categories when called through `groupby(..., observed=False)` (GH17605) \* `core.groupby.SeriesGroupBy.count()` \* `core.groupby.SeriesGroupBy.size()` \* `core.groupby.SeriesGroupBy.nunique()` \* `core.groupby.SeriesGroupBy.nth()`

## Datetimelike

- Bug in `Series.__setitem__()` incorrectly casting `np.timedelta64("NaT")` to `np.datetime64("NaT")` when inserting into a `Series` with `datetime64` dtype (GH27311)
- Bug in `Series.dt()` property lookups when the underlying data is read-only (GH27529)
- Bug in `HDFStore.__getitem__` incorrectly reading `tz` attribute created in Python 2 (GH26443)
- Bug in `to_datetime()` where passing arrays of malformed `str` with `errors="coerce"` could incorrectly lead to raising `ValueError` (GH28299)
- Bug in `core.groupby.SeriesGroupBy.nunique()` where `NaT` values were interfering with the count of unique values (GH27951)
- Bug in `Timestamp` subtraction when subtracting a `Timestamp` from a `np.datetime64` object incorrectly raising `TypeError` (GH28286)
- Addition and subtraction of integer or integer-dtype arrays with `Timestamp` will now raise `NullFrequencyError` instead of `ValueError` (GH28268)
- Bug in `Series` and `DataFrame` with integer dtype failing to raise `TypeError` when adding or subtracting a `np.datetime64` object (GH28080)
- Bug in `Series.astype()`, `Index.astype()`, and `DataFrame.astype()` failing to handle `NaT` when casting to an integer dtype (GH28492)
- Bug in `Week` with `weekday` incorrectly raising `AttributeError` instead of `TypeError` when adding or subtracting an invalid type (GH28530)
- Bug in `DataFrame` arithmetic operations when operating with a `Series` with dtype `'timedelta64[ns]'` (GH28049)
- Bug in `core.groupby.generic.SeriesGroupBy.apply()` raising `ValueError` when a column in the original `DataFrame` is a `datetime` and the column labels are not standard integers (GH28247)
- Bug in `pandas._config.localization.get_locales()` where the `locales -a` encodes the locales list as `windows-1252` (GH23638, GH24760, GH27368)
- Bug in `Series.var()` failing to raise `TypeError` when called with `timedelta64[ns]` dtype (GH28289)
- Bug in `DatetimeIndex.strftime()` and `Series.dt.strftime()` where `NaT` was converted to the string `'NaT'` instead of `np.nan` (GH29578)
- Bug in masking `datetime`-like arrays with a boolean mask of an incorrect length not raising an `IndexError` (GH30308)
- Bug in `Timestamp.resolution` being a property instead of a class attribute (GH29910)
- Bug in `pandas.to_datetime()` when called with `None` raising `TypeError` instead of returning `NaT` (GH30011)

- Bug in `pandas.to_datetime()` failing for dequeues when using `cache=True` (the default) (GH29403)
- Bug in `Series.item()` with `datetime64` or `timedelta64` dtype, `DatetimeIndex.item()`, and `TimedeltaIndex.item()` returning an integer instead of a `Timestamp` or `Timedelta` (GH30175)
- Bug in `DatetimeIndex` addition when adding a non-optimized `DateOffset` incorrectly dropping timezone information (GH30336)
- Bug in `DataFrame.drop()` where attempting to drop non-existent values from a `DatetimeIndex` would yield a confusing error message (GH30399)
- Bug in `DataFrame.append()` would remove the timezone-awareness of new data (GH30238)
- Bug in `Series.cummin()` and `Series.cummax()` with timezone-aware dtype incorrectly dropping its timezone (GH15553)
- Bug in `DatetimeArray`, `TimedeltaArray`, and `PeriodArray` where inplace addition and subtraction did not actually operate inplace (GH24115)
- Bug in `pandas.to_datetime()` when called with `Series` storing `IntegerArray` raising `TypeError` instead of returning `Series` (GH30050)
- Bug in `date_range()` with custom business hours as `freq` and given number of periods (GH30593)
- Bug in `PeriodIndex` comparisons with incorrectly casting integers to `Period` objects, inconsistent with the `Period` comparison behavior (GH30722)
- Bug in `DatetimeIndex.insert()` raising a `ValueError` instead of a `TypeError` when trying to insert a timezone-aware `Timestamp` into a timezone-naive `DatetimeIndex`, or vice-versa (GH30806)

## Timedelta

- Bug in subtracting a `TimedeltaIndex` or `TimedeltaArray` from a `np.datetime64` object (GH29558)
- 

## Timezones

- 

## Numeric

- Bug in `DataFrame.quantile()` with zero-column `DataFrame` incorrectly raising (GH23925)
- `DataFrame` flex inequality comparisons methods (`DataFrame.lt()`, `DataFrame.le()`, `DataFrame.gt()`, `DataFrame.ge()`) with object-dtype and complex entries failing to raise `TypeError` like their `Series` counterparts (GH28079)
- Bug in `DataFrame` logical operations (`&`, `|`, `^`) not matching `Series` behavior by filling NA values (GH28741)
- Bug in `DataFrame.interpolate()` where specifying axis by name references variable before it is assigned (GH29142)
- Bug in `Series.var()` not computing the right value with a nullable integer dtype series not passing through `ddof` argument (GH29128)
- Improved error message when using `frac > 1` and `replace = False` (GH27451)

- Bug in numeric indexes resulted in it being possible to instantiate an *Int64Index*, *UInt64Index*, or *Float64Index* with an invalid dtype (e.g. datetime-like) (GH29539)
- Bug in *UInt64Index* precision loss while constructing from a list with values in the `np.uint64` range (GH29526)
- Bug in *NumericIndex* construction that caused indexing to fail when integers in the `np.uint64` range were used (GH28023)
- Bug in *NumericIndex* construction that caused *UInt64Index* to be casted to *Float64Index* when integers in the `np.uint64` range were used to index a *DataFrame* (GH28279)
- Bug in *Series.interpolate()* when using `method='index'` with an unsorted index, would previously return incorrect results. (GH21037)
- Bug in *DataFrame.round()* where a *DataFrame* with a *CategoricalIndex* of *IntervalIndex* columns would incorrectly raise a *TypeError* (GH30063)
- Bug in *Series.pct\_change()* and *DataFrame.pct\_change()* when there are duplicated indices (GH30463)
- Bug in *DataFrame* cumulative operations (e.g. `cumsum`, `cummax`) incorrect casting to object-dtype (GH19296)
- Bug in *diff* losing the dtype for extension types (GH30889)
- Bug in *DataFrame.diff* raising an *IndexError* when one of the columns was a nullable integer dtype (GH30967)

## Conversion

- 

## Strings

- Calling *Series.str.isalnum()* (and other “ismethods”) on an empty *Series* would return an object dtype instead of `bool` (GH29624)
- 

## Interval

- Bug in *IntervalIndex.get\_indexer()* where a *Categorical* or *CategoricalIndex* target would incorrectly raise a *TypeError* (GH30063)
- Bug in `pandas.core.dtypes.cast.infer_dtype_from_scalar` where passing `pandas_dtype=True` did not infer *IntervalDtype* (GH30337)
- Bug in *Series* constructor where constructing a *Series* from a list of *Interval* objects resulted in object dtype instead of *IntervalDtype* (GH23563)
- Bug in *IntervalDtype* where the `kind` attribute was incorrectly set as `None` instead of `"0"` (GH30568)
- Bug in *IntervalIndex*, *IntervalArray*, and *Series* with interval data where equality comparisons were incorrect (GH24112)

## Indexing

- Bug in assignment using a reverse slicer ([GH26939](#))
- Bug in `DataFrame.explode()` would duplicate frame in the presence of duplicates in the index ([GH28010](#))
- Bug in reindexing a `PeriodIndex()` with another type of index that contained a `Period` ([GH28323](#)) ([GH28337](#))
- Fix assignment of column via `.loc` with numpy non-ns datetime type ([GH27395](#))
- Bug in `Float64Index.astype()` where `np.inf` was not handled properly when casting to an integer dtype ([GH28475](#))
- `Index.union()` could fail when the left contained duplicates ([GH28257](#))
- Bug when indexing with `.loc` where the index was a `CategoricalIndex` with non-string categories didn't work ([GH17569](#), [GH30225](#))
- `Index.get_indexer_non_unique()` could fail with `TypeError` in some cases, such as when searching for ints in a string index ([GH28257](#))
- Bug in `Float64Index.get_loc()` incorrectly raising `TypeError` instead of `KeyError` ([GH29189](#))
- Bug in `DataFrame.loc()` with incorrect dtype when setting Categorical value in 1-row `DataFrame` ([GH25495](#))
- `MultiIndex.get_loc()` can't find missing values when input includes missing values ([GH19132](#))
- Bug in `Series.__setitem__()` incorrectly assigning values with boolean indexer when the length of new data matches the number of `True` values and new data is not a `Series` or an `np.array` ([GH30567](#))
- Bug in indexing with a `PeriodIndex` incorrectly accepting integers representing years, use e.g. `ser.loc["2007"]` instead of `ser.loc[2007]` ([GH30763](#))

## Missing

- 

## MultiIndex

- Constructor for `MultiIndex` verifies that the given `sortorder` is compatible with the actual `lexsort_depth` if `verify_integrity` parameter is `True` (the default) ([GH28735](#))
- `Series` and `MultiIndex` `.drop` with `MultiIndex` raise exception if labels not in given in level ([GH8594](#))
- 

## IO

- `read_csv()` now accepts binary mode file buffers when using the Python csv engine ([GH23779](#))
- Bug in `DataFrame.to_json()` where using a `Tuple` as a column or index value and using `orient="columns"` or `orient="index"` would produce invalid JSON ([GH20500](#))
- Improve infinity parsing. `read_csv()` now interprets `Infinity`, `+Infinity`, `-Infinity` as floating point values ([GH10065](#))
- Bug in `DataFrame.to_csv()` where values were truncated when the length of `na_rep` was shorter than the text input data. ([GH25099](#))

- Bug in `DataFrame.to_string()` where values were truncated using display options instead of outputting the full content (GH9784)
- Bug in `DataFrame.to_json()` where a datetime column label would not be written out in ISO format with `orient="table"` (GH28130)
- Bug in `DataFrame.to_parquet()` where writing to GCS would fail with `engine='fastparquet'` if the file did not already exist (GH28326)
- Bug in `read_hdf()` closing stores that it didn't open when Exceptions are raised (GH28699)
- Bug in `DataFrame.read_json()` where using `orient="index"` would not maintain the order (GH28557)
- Bug in `DataFrame.to_html()` where the length of the `formatters` argument was not verified (GH28469)
- Bug in `DataFrame.read_excel()` with `engine='ods'` when `sheet_name` argument references a non-existent sheet (GH27676)
- Bug in `pandas.io.formats.style.Styler()` formatting for floating values not displaying decimals correctly (GH13257)
- Bug in `DataFrame.to_html()` when using `formatters=<list>` and `max_cols` together. (GH25955)
- Bug in `Styler.background_gradient()` not able to work with dtype `Int64` (GH28869)
- Bug in `DataFrame.to_clipboard()` which did not work reliably in ipython (GH22707)
- Bug in `read_json()` where default encoding was not set to `utf-8` (GH29565)
- Bug in `PythonParser` where `str` and `bytes` were being mixed when dealing with the decimal field (GH29650)
- `read_gbq()` now accepts `progress_bar_type` to display progress bar while the data downloads. (GH29857)
- Bug in `pandas.io.json.json_normalize()` where a missing value in the location specified by `record_path` would raise a `TypeError` (GH30148)
- `read_excel()` now accepts binary data (GH15914)
- Bug in `read_csv()` in which encoding handling was limited to just the string `utf-16` for the C engine (GH24130)

## Plotting

- Bug in `Series.plot()` not able to plot boolean values (GH23719)
- Bug in `DataFrame.plot()` not able to plot when no rows (GH27758)
- Bug in `DataFrame.plot()` producing incorrect legend markers when plotting multiple series on the same axis (GH18222)
- Bug in `DataFrame.plot()` when `kind='box'` and data contains `datetime` or `timedelta` data. These types are now automatically dropped (GH22799)
- Bug in `DataFrame.plot.line()` and `DataFrame.plot.area()` produce wrong `xlim` in x-axis (GH27686, GH25160, GH24784)
- Bug where `DataFrame.boxplot()` would not accept a `color` parameter like `DataFrame.plot.box()` (GH26214)
- Bug in the `xticks` argument being ignored for `DataFrame.plot.bar()` (GH14119)
- `set_option()` now validates that the plot backend provided to `'plotting.backend'` implements the backend when the option is set, rather than when a plot is created (GH28163)

- `DataFrame.plot()` now allow a backend keyword argument to allow changing between backends in one session (GH28619).
- Bug in color validation incorrectly raising for non-color styles (GH29122).
- Allow `DataFrame.plot.scatter()` to plot objects and datetime type data (GH18755, GH30391)
- Bug in `DataFrame.hist()`, `xrot=0` does not work with `by` and subplots (GH30288).

### GroupBy/resample/rolling

- Bug in `core.groupby.DataFrameGroupBy.apply()` only showing output from a single group when function returns an `Index` (GH28652)
- Bug in `DataFrame.groupby()` with multiple groups where an `IndexError` would be raised if any group contained all NA values (GH20519)
- Bug in `pandas.core.resample.Resampler.size()` and `pandas.core.resample.Resampler.count()` returning wrong dtype when used with an empty `Series` or `DataFrame` (GH28427)
- Bug in `DataFrame.rolling()` not allowing for rolling over datetimes when `axis=1` (GH28192)
- Bug in `DataFrame.rolling()` not allowing rolling over multi-index levels (GH15584).
- Bug in `DataFrame.rolling()` not allowing rolling on monotonic decreasing time indexes (GH19248).
- Bug in `DataFrame.groupby()` not offering selection by column name when `axis=1` (GH27614)
- Bug in `core.groupby.DataFrameGroupBy.agg()` not able to use lambda function with named aggregation (GH27519)
- Bug in `DataFrame.groupby()` losing column name information when grouping by a categorical column (GH28787)
- Remove error raised due to duplicated input functions in named aggregation in `DataFrame.groupby()` and `Series.groupby()`. Previously error will be raised if the same function is applied on the same column and now it is allowed if new assigned names are different. (GH28426)
- `core.groupby.SeriesGroupBy.value_counts()` will be able to handle the case even when the  `grouper` makes empty groups (GH28479)
- Bug in `core.window.rolling.Rolling.quantile()` ignoring `interpolation` keyword argument when used within a `groupby` (GH28779)
- Bug in `DataFrame.groupby()` where `any`, `all`, `nunique` and `transform` functions would incorrectly handle duplicate column labels (GH21668)
- Bug in `core.groupby.DataFrameGroupBy.agg()` with timezone-aware `datetime64` column incorrectly casting results to the original dtype (GH29641)
- Bug in `DataFrame.groupby()` when using `axis=1` and having a single level columns index (GH30208)
- Bug in `DataFrame.groupby()` when using `nunique` on `axis=1` (GH30253)
- Bug in `GroupBy.quantile()` with multiple list-like `q` value and integer column names (GH30289)
- Bug in `GroupBy.pct_change()` and `core.groupby.SeriesGroupBy.pct_change()` causes `TypeError` when `fill_method` is `None` (GH30463)
- Bug in `Rolling.count()` and `Expanding.count()` argument where `min_periods` was ignored (GH26996)

## Reshaping

- Bug in `DataFrame.apply()` that caused incorrect output with empty `DataFrame` (GH28202, GH21959)
- Bug in `DataFrame.stack()` not handling non-unique indexes correctly when creating `MultiIndex` (GH28301)
- Bug in `pivot_table()` not returning correct type `float` when `margins=True` and `aggfunc='mean'` (GH24893)
- Bug `merge_asof()` could not use `datetime.timedelta` for tolerance kwarg (GH28098)
- Bug in `merge()`, did not append suffixes correctly with `MultiIndex` (GH28518)
- `qcut()` and `cut()` now handle boolean input (GH20303)
- Fix to ensure all int dtypes can be used in `merge_asof()` when using a tolerance value. Previously every non-int64 type would raise an erroneous `MergeError` (GH28870).
- Better error message in `get_dummies()` when `columns` isn't a list-like value (GH28383)
- Bug in `Index.join()` that caused infinite recursion error for mismatched `MultiIndex` name orders. (GH25760, GH28956)
- Bug `Series.pct_change()` where supplying an anchored frequency would throw a `ValueError` (GH28664)
- Bug where `DataFrame.equals()` returned `True` incorrectly in some cases when two `DataFrames` had the same columns in different orders (GH28839)
- Bug in `DataFrame.replace()` that caused non-numeric replacer's dtype not respected (GH26632)
- Bug in `melt()` where supplying mixed strings and numeric values for `id_vars` or `value_vars` would incorrectly raise a `ValueError` (GH29718)
- Dtypes are now preserved when transposing a `DataFrame` where each column is the same extension dtype (GH30091)
- Bug in `merge_asof()` merging on a tz-aware `left_index` and `right_on` a tz-aware column (GH29864)
- Improved error message and docstring in `cut()` and `qcut()` when `labels=True` (GH13318)
- Bug in missing `fill_na` parameter to `DataFrame.unstack()` with list of levels (GH30740)

## Sparse

- Bug in `SparseDataFrame` arithmetic operations incorrectly casting inputs to float (GH28107)
- Bug in `DataFrame.sparse` returning a `Series` when there was a column named `sparse` rather than the accessor (GH30758)
- Fixed `operator.xor()` with a boolean-dtype `SparseArray`. Now returns a sparse result, rather than object dtype (GH31025)

## ExtensionArray

- Bug in `arrays.PandasArray` when setting a scalar string (GH28118, GH28150).
- Bug where nullable integers could not be compared to strings (GH28930)
- Bug where `DataFrame` constructor raised `ValueError` with list-like data and dtype specified (GH30280)

## Other

- Trying to set the `display.precision`, `display.max_rows` or `display.max_columns` using `set_option()` to anything but a `None` or a positive int will raise a `ValueError` (GH23348)
- Using `DataFrame.replace()` with overlapping keys in a nested dictionary will no longer raise, now matching the behavior of a flat dictionary (GH27660)
- `DataFrame.to_csv()` and `Series.to_csv()` now support dicts as compression argument with key 'method' being the compression method and others as additional compression options when the compression method is 'zip'. (GH26023)
- Bug in `Series.diff()` where a boolean series would incorrectly raise a `TypeError` (GH17294)
- `Series.append()` will no longer raise a `TypeError` when passed a tuple of `Series` (GH28410)
- Fix corrupted error message when calling `pandas.libs._json.encode()` on a 0d array (GH18878)
- Backtick quoting in `DataFrame.query()` and `DataFrame.eval()` can now also be used to use invalid identifiers like names that start with a digit, are python keywords, or are using single character operators. (GH27017)
- Bug in `pd.core.util.hashing.hash_pandas_object` where arrays containing tuples were incorrectly treated as non-hashable (GH28969)
- Bug in `DataFrame.append()` that raised `IndexError` when appending with empty list (GH28769)
- Fix `AbstractHolidayCalendar` to return correct results for years after 2030 (now goes up to 2200) (GH27790)
- Fixed `IntegerArray` returning `inf` rather than `NaN` for operations dividing by 0 (GH27398)
- Fixed pow operations for `IntegerArray` when the other value is 0 or 1 (GH29997)
- Bug in `Series.count()` raises if `use_inf_as_na` is enabled (GH29478)
- Bug in `Index` where a non-hashable name could be set without raising `TypeError` (GH29069)
- Bug in `DataFrame` constructor when passing a 2D ndarray and an extension dtype (GH12513)
- Bug in `DataFrame.to_csv()` when supplied a series with a `dtype="string"` and a `na_rep`, the `na_rep` was being truncated to 2 characters. (GH29975)
- Bug where `DataFrame.itertuples()` would incorrectly determine whether or not namedtuples could be used for dataframes of 255 columns (GH28282)
- Handle nested NumPy object arrays in `testing.assert_series_equal()` for `ExtensionArray` implementations (GH30841)
- Bug in `Index` constructor incorrectly allowing 2-dimensional input arrays (GH13601, GH27125)

## 5.5 Version 0.25

### 5.5.1 What's new in 0.25.3 (October 31, 2019)

These are the changes in pandas 0.25.3. See [Release notes](#) for a full changelog including other versions of pandas.

#### Bug fixes

##### GroupBy/resample/rolling

- Bug in `DataFrameGroupBy.quantile()` where NA values in the grouping could cause segfaults or incorrect results ([GH28882](#))

## Contributors

A total of 2 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

- Will Ayd
- William Ayd

## 5.5.2 What’s new in 0.25.2 (October 15, 2019)

These are the changes in pandas 0.25.2. See [Release notes](#) for a full changelog including other versions of pandas.

---

**Note:** pandas 0.25.2 adds compatibility for Python 3.8 ([GH28147](#)).

---

### Bug fixes

#### Indexing

- Fix regression in `DataFrame.reindex()` not following the `limit` argument ([GH28631](#)).
- Fix regression in `RangeIndex.get_indexer()` for decreasing `RangeIndex` where target values may be improperly identified as missing/present ([GH28678](#))

#### IO

- Fix regression in notebook display where `<th>` tags were missing for `DataFrame.index` values ([GH28204](#)).
- Regression in `to_csv()` where writing a `Series` or `DataFrame` indexed by an `IntervalIndex` would incorrectly raise a `TypeError` ([GH28210](#))
- Fix `to_csv()` with `ExtensionArray` with list-like values ([GH28840](#)).

#### GroupBy/resample/rolling

- Bug incorrectly raising an `IndexError` when passing a list of quantiles to `pandas.core.groupby.DataFrameGroupBy.quantile()` ([GH28113](#)).
- Bug in `pandas.core.groupby.GroupBy.shift()`, `pandas.core.groupby.GroupBy.bfill()` and `pandas.core.groupby.GroupBy.ffill()` where timezone information would be dropped ([GH19995](#), [GH27992](#))

## Other

- Compatibility with Python 3.8 in `DataFrame.query()` ([GH27261](#))
- Fix to ensure that tab-completion in an IPython console does not raise warnings for deprecated attributes ([GH27900](#)).

## Contributors

A total of 6 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

- Felix Divo +
- Jeremy Schendel
- Joris Van den Bossche
- MeeseeksMachine
- Tom Augspurger
- jbrockmendel

## 5.5.3 What’s new in 0.25.1 (August 21, 2019)

These are the changes in pandas 0.25.1. See [Release notes](#) for a full changelog including other versions of pandas.

### IO and LZMA

Some users may unknowingly have an incomplete Python installation lacking the `lzma` module from the standard library. In this case, `import pandas` failed due to an `ImportError` ([GH27575](#)). pandas will now warn, rather than raising an `ImportError` if the `lzma` module is not present. Any subsequent attempt to use `lzma` methods will raise a `RuntimeError`. A possible fix for the lack of the `lzma` module is to ensure you have the necessary libraries and then re-install Python. For example, on MacOS installing Python with `pyenv` may lead to an incomplete Python installation due to unmet system dependencies at compilation time (like `xz`). Compilation will succeed, but Python might fail at run time. The issue can be solved by installing the necessary dependencies and then re-installing Python.

### Bug fixes

#### Categorical

- Bug in `Categorical.fillna()` that would replace all values, not just those that are `NaN` ([GH26215](#))

## Datetimelike

- Bug in `to_datetime()` where passing a timezone-naive `DatetimeArray` or `DatetimeIndex` and `utc=True` would incorrectly return a timezone-naive result ([GH27733](#))
- Bug in `Period.to_timestamp()` where a `Period` outside the `Timestamp` implementation bounds (roughly 1677-09-21 to 2262-04-11) would return an incorrect `Timestamp` instead of raising `OutOfBoundsDatetime` ([GH19643](#))
- Bug in iterating over `DatetimeIndex` when the underlying data is read-only ([GH28055](#))

## Timezones

- Bug in `Index` where a numpy object array with a timezone aware `Timestamp` and `np.nan` would not return a `DatetimeIndex` ([GH27011](#))

## Numeric

- Bug in `Series.interpolate()` when using a timezone aware `DatetimeIndex` ([GH27548](#))
- Bug when printing negative floating point complex numbers would raise an `IndexError` ([GH27484](#))
- Bug where `DataFrame` arithmetic operators such as `DataFrame.mul()` with a `Series` with `axis=1` would raise an `AttributeError` on `DataFrame` larger than the minimum threshold to invoke `numexpr` ([GH27636](#))
- Bug in `DataFrame` arithmetic where missing values in results were incorrectly masked with `NaN` instead of `Inf` ([GH27464](#))

## Conversion

- Improved the warnings for the deprecated methods `Series.real()` and `Series.imag()` ([GH27610](#))

## Interval

- Bug in `IntervalIndex` where `dir(obj)` would raise `ValueError` ([GH27571](#))

## Indexing

- Bug in partial-string indexing returning a NumPy array rather than a `Series` when indexing with a scalar like `.loc['2015']` ([GH27516](#))
- Break reference cycle involving `Index` and other index classes to allow garbage collection of index objects without running the GC. ([GH27585](#), [GH27840](#))
- Fix regression in assigning values to a single column of a `DataFrame` with a `MultiIndex` columns ([GH27841](#)).
- Fix regression in `.ix` fallback with an `IntervalIndex` ([GH27865](#)).

## Missing

- Bug in `pandas.isnull()` or `pandas.isna()` when the input is a type e.g. `type(pandas.Series())` (GH27482)

## IO

- Avoid calling `S3File.s3` when reading parquet, as this was removed in s3fs version 0.3.0 (GH27756)
- Better error message when a negative header is passed in `pandas.read_csv()` (GH27779)
- Follow the `min_rows` display option (introduced in v0.25.0) correctly in the HTML repr in the notebook (GH27991).

## Plotting

- Added a `pandas_plotting_backends` entrypoint group for registering plot backends. See *Plotting backends* for more (GH26747).
- Fixed the re-instatement of Matplotlib datetime converters after calling `pandas.plotting.deregister_matplotlib_converters()` (GH27481).
- Fix compatibility issue with matplotlib when passing a pandas Index to a plot call (GH27775).

## GroupBy/resample/rolling

- Fixed regression in `pandas.core.groupby.DataFrameGroupBy.quantile()` raising when multiple quantiles are given (GH27526)
- Bug in `pandas.core.groupby.DataFrameGroupBy.transform()` where applying a timezone conversion lambda function would drop timezone information (GH27496)
- Bug in `pandas.core.groupby.GroupBy.nth()` where `observed=False` was being ignored for Categorical groupers (GH26385)
- Bug in windowing over read-only arrays (GH27766)
- Fixed segfault in `pandas.core.groupby.DataFrameGroupBy.quantile` when an invalid quantile was passed (GH27470)

## Reshaping

- A `KeyError` is now raised if `.unstack()` is called on a Series or DataFrame with a flat Index passing a name which is not the correct one (GH18303)
- Bug `merge_asof()` could not merge `Timedelta` objects when passing `tolerance` kwarg (GH27642)
- Bug in `DataFrame.crosstab()` when `margins` set to `True` and `normalize` is not `False`, an error is raised. (GH27500)
- `DataFrame.join()` now suppresses the `FutureWarning` when the `sort` parameter is specified (GH21952)
- Bug in `DataFrame.join()` raising with readonly arrays (GH27943)

## Sparse

- Bug in reductions for Series with Sparse dtypes ([GH27080](#))

## Other

- Bug in Series.replace() and DataFrame.replace() when replacing timezone-aware timestamps using a dict-like replacer ([GH27720](#))
- Bug in Series.rename() when using a custom type indexer. Now any value that isn't callable or dict-like is treated as a scalar. ([GH27814](#))

## Contributors

A total of 5 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

## 5.5.4 What's new in 0.25.0 (July 18, 2019)

**Warning:** Starting with the 0.25.x series of releases, pandas only supports Python 3.5.3 and higher. See [Dropping Python 2.7](#) for more details.

**Warning:** The minimum supported Python version will be bumped to 3.6 in a future release.

**Warning:** Panel has been fully removed. For N-D labeled data structures, please use [xarray](#)

**Warning:** read\_pickle() and read\_msgpack() are only guaranteed backwards compatible back to pandas version 0.20.3 ([GH27082](#))

These are the changes in pandas 0.25.0. See [Release notes](#) for a full changelog including other versions of pandas.

## Enhancements

### GroupBy aggregation with relabeling

pandas has added special groupby behavior, known as “named aggregation”, for naming the output columns when applying multiple aggregation functions to specific columns ([GH18366](#), [GH26512](#)).

```
In [1]: animals = pd.DataFrame({'kind': ['cat', 'dog', 'cat', 'dog'],
...: 'height': [9.1, 6.0, 9.5, 34.0],
...: 'weight': [7.9, 7.5, 9.9, 198.0]})
...:
In [2]: animals
Out[2]:
 kind height weight
0 cat 9.1 7.9
1 dog 6.0 7.5
2 cat 9.5 9.9
3 dog 34.0 198.0

In [3]: animals.groupby("kind").agg(
...: min_height=pd.NamedAgg(column='height', aggfunc='min'),
...: max_height=pd.NamedAgg(column='height', aggfunc='max'),
...: average_weight=pd.NamedAgg(column='weight', aggfunc=np.mean),
...:)
Out[3]:
 min_height max_height average_weight
kind
cat 9.1 9.5 8.90
dog 6.0 34.0 102.75
```

Pass the desired columns names as the **\*\*kwargs** to `.agg`. The values of **\*\*kwargs** should be tuples where the first element is the column selection, and the second element is the aggregation function to apply. pandas provides the `pandas.NamedAgg` namedtuple to make it clearer what the arguments to the function are, but plain tuples are accepted as well.

```
In [4]: animals.groupby("kind").agg(
...: min_height=('height', 'min'),
...: max_height=('height', 'max'),
...: average_weight=('weight', np.mean),
...:)
Out[4]:
 min_height max_height average_weight
kind
cat 9.1 9.5 8.90
dog 6.0 34.0 102.75
```

Named aggregation is the recommended replacement for the deprecated “dict-of-dicts” approach to naming the output of column-specific aggregations (*Deprecate `groupby.agg()` with a dictionary when renaming*).

A similar approach is now available for Series groupby objects as well. Because there’s no need for column selection, the values can just be the functions to apply

```
In [5]: animals.groupby("kind").height.agg(
...: min_height="min",
...: max_height="max",
...:)
...:
```

```
Out[5]:
 min_height max_height
kind
cat 9.1 9.5
dog 6.0 34.0
```

This type of aggregation is the recommended alternative to the deprecated behavior when passing a dict to a Series groupby aggregation (*Deprecate groupby.agg() with a dictionary when renaming*).

See *Named aggregation* for more.

### GroupBy aggregation with multiple lambdas

You can now provide multiple lambda functions to a list-like aggregation in `pandas.core.groupby.GroupBy.agg` (GH26430).

```
In [6]: animals.groupby('kind').height.agg([
...: lambda x: x.iloc[0], lambda x: x.iloc[-1]
...:])
...:
```

```
Out[6]:
 <lambda_0> <lambda_1>
kind
cat 9.1 9.5
dog 6.0 34.0
```

```
In [7]: animals.groupby('kind').agg([
...: lambda x: x.iloc[0] - x.iloc[1],
...: lambda x: x.iloc[0] + x.iloc[1]
...:])
...:
```

```
Out[7]:
 height weight
 <lambda_0> <lambda_1> <lambda_0> <lambda_1>
kind
cat -0.4 18.6 -2.0 17.8
dog -28.0 40.0 -190.5 205.5
```

Previously, these raised a `SpecificationError`.

## Better repr for MultiIndex

Printing of *MultiIndex* instances now shows tuples of each row and ensures that the tuple items are vertically aligned, so it's now easier to understand the structure of the MultiIndex. (GH13480):

The repr now looks like this:

```
In [8]: pd.MultiIndex.from_product([['a', 'abc'], range(500)])
Out[8]:
MultiIndex([('a', 0),
 ('a', 1),
 ('a', 2),
 ('a', 3),
 ('a', 4),
 ('a', 5),
 ('a', 6),
 ('a', 7),
 ('a', 8),
 ('a', 9),
 ...
 ('abc', 490),
 ('abc', 491),
 ('abc', 492),
 ('abc', 493),
 ('abc', 494),
 ('abc', 495),
 ('abc', 496),
 ('abc', 497),
 ('abc', 498),
 ('abc', 499)],
 length=1000)
```

Previously, outputting a *MultiIndex* printed all the levels and codes of the MultiIndex, which was visually unappealing and made the output more difficult to navigate. For example (limiting the range to 5):

```
In [1]: pd.MultiIndex.from_product([['a', 'abc'], range(5)])
Out[1]: MultiIndex(levels=[['a', 'abc'], [0, 1, 2, 3]],
 : codes=[[0, 0, 0, 0, 1, 1, 1, 1], [0, 1, 2, 3, 0, 1, 2, 3]])
```

In the new repr, all values will be shown, if the number of rows is smaller than `options.display.max_seq_items` (default: 100 items). Horizontally, the output will truncate, if it's wider than `options.display.width` (default: 80 characters).

## Shorter truncated repr for Series and DataFrame

Currently, the default display options of pandas ensure that when a Series or DataFrame has more than 60 rows, its repr gets truncated to this maximum of 60 rows (the `display.max_rows` option). However, this still gives a repr that takes up a large part of the vertical screen estate. Therefore, a new option `display.min_rows` is introduced with a default of 10 which determines the number of rows showed in the truncated repr:

- For small Series or DataFrames, up to `max_rows` number of rows is shown (default: 60).
- For larger Series or DataFrame with a length above `max_rows`, only `min_rows` number of rows is shown (default: 10, i.e. the first and last 5 rows).

This dual option allows to still see the full content of relatively small objects (e.g. `df.head(20)` shows all 20 rows), while giving a brief repr for large objects.

To restore the previous behaviour of a single threshold, set `pd.options.display.min_rows = None`.

### JSON normalize with max\_level param support

`json_normalize()` normalizes the provided input dict to all nested levels. The new `max_level` parameter provides more control over which level to end normalization ([GH23843](#)):

The repr now looks like this:

```
from pandas.io.json import json_normalize
data = [{
 'CreatedBy': {'Name': 'User001'},
 'Lookup': {'TextField': 'Some text',
 'UserField': {'Id': 'ID001', 'Name': 'Name001'}},
 'Image': {'a': 'b'}
}]
json_normalize(data, max_level=1)
```

### Series.explode to split list-like values to rows

*Series* and *DataFrame* have gained the *DataFrame.explode()* methods to transform list-likes to individual rows. See [section on Exploding list-like column](#) in docs for more information ([GH16538](#), [GH10511](#))

Here is a typical usecase. You have comma separated string in a column.

```
In [9]: df = pd.DataFrame(['var1': 'a,b,c', 'var2': 1],
...: {'var1': 'd,e,f', 'var2': 2})
...:

In [10]: df
Out[10]:
 var1 var2
0 a,b,c 1
1 d,e,f 2
```

Creating a long form *DataFrame* is now straightforward using chained operations

```
In [11]: df.assign(var1=df.var1.str.split(',')).explode('var1')
Out[11]:
 var1 var2
0 a 1
0 b 1
0 c 1
1 d 2
1 e 2
1 f 2
```

## Other enhancements

- `DataFrame.plot()` keywords `logy`, `logx` and `loglog` can now accept the value `'sym'` for symlog scaling. (GH24867)
- Added support for ISO week year format (`'%G-%V-%u'`) when parsing datetimes using `to_datetime()` (GH16607)
- Indexing of `DataFrame` and `Series` now accepts zerodim `np.ndarray` (GH24919)
- `Timestamp.replace()` now supports the `fold` argument to disambiguate DST transition times (GH25017)
- `DataFrame.at_time()` and `Series.at_time()` now support `datetime.time` objects with timezones (GH24043)
- `DataFrame.pivot_table()` now accepts an `observed` parameter which is passed to underlying calls to `DataFrame.groupby()` to speed up grouping categorical data. (GH24923)
- `Series.str` has gained `Series.str.casefold()` method to removes all case distinctions present in a string (GH25405)
- `DataFrame.set_index()` now works for instances of `abc.Iterator`, provided their output is of the same length as the calling frame (GH22484, GH24984)
- `DatetimeIndex.union()` now supports the `sort` argument. The behavior of the `sort` parameter matches that of `Index.union()` (GH24994)
- `RangeIndex.union()` now supports the `sort` argument. If `sort=False` an unsorted `Int64Index` is always returned. `sort=None` is the default and returns a monotonically increasing `RangeIndex` if possible or a sorted `Int64Index` if not (GH24471)
- `TimedeltaIndex.intersection()` now also supports the `sort` keyword (GH24471)
- `DataFrame.rename()` now supports the `errors` argument to raise errors when attempting to rename non-existent keys (GH13473)
- Added `Sparse accessor` for working with a `DataFrame` whose values are sparse (GH25681)
- `RangeIndex` has gained `start`, `stop`, and `step` attributes (GH25710)
- `datetime.timezone` objects are now supported as arguments to `timezone` methods and constructors (GH25065)
- `DataFrame.query()` and `DataFrame.eval()` now supports quoting column names with backticks to refer to names with spaces (GH6508)
- `merge_asof()` now gives a more clear error message when merge keys are categoricals that are not equal (GH26136)
- `pandas.core.window.Rolling()` supports exponential (or Poisson) window type (GH21303)
- Error message for missing required imports now includes the original import error's text (GH23868)
- `DatetimeIndex` and `TimedeltaIndex` now have a `mean` method (GH24757)
- `DataFrame.describe()` now formats integer percentiles without decimal point (GH26660)
- Added support for reading SPSS `.sav` files using `read_spss()` (GH26537)
- Added new option `plotting.backend` to be able to select a plotting backend different than the existing `matplotlib` one. Use `pandas.set_option('plotting.backend', '<backend-module>')` where `<backend-module` is a library implementing the pandas plotting API (GH14130)
- `pandas.offsets.BusinessHour` supports multiple opening hours intervals (GH15481)
- `read_excel()` can now use `openpyxl` to read Excel files via the `engine='openpyxl'` argument. This will become the default in a future release (GH11499)

- `pandas.io.excel.read_excel()` supports reading OpenDocument tables. Specify `engine='odf'` to enable. Consult the *IO User Guide* for more details (GH9070)
- `Interval`, `IntervalIndex`, and `IntervalArray` have gained an `is_empty` attribute denoting if the given interval(s) are empty (GH27219)

## Backwards incompatible API changes

### Indexing with date strings with UTC offsets

Indexing a `DataFrame` or `Series` with a `DatetimeIndex` with a date string with a UTC offset would previously ignore the UTC offset. Now, the UTC offset is respected in indexing. (GH24076, GH16785)

```
In [12]: df = pd.DataFrame([0], index=pd.DatetimeIndex(['2019-01-01'], tz='US/Pacific'))
In [13]: df
Out[13]:
 0
2019-01-01 00:00:00-08:00 0
```

*Previous behavior:*

```
In [3]: df['2019-01-01 00:00:00+04:00':'2019-01-01 01:00:00+04:00']
Out[3]:
 0
2019-01-01 00:00:00-08:00 0
```

*New behavior:*

```
In [14]: df['2019-01-01 12:00:00+04:00':'2019-01-01 13:00:00+04:00']
Out[14]:
 0
2019-01-01 00:00:00-08:00 0
```

### MultiIndex constructed from levels and codes

Constructing a `MultiIndex` with NaN levels or codes value < -1 was allowed previously. Now, construction with codes value < -1 is not allowed and NaN levels' corresponding codes would be reassigned as -1. (GH19387)

*Previous behavior:*

```
In [1]: pd.MultiIndex(levels=[[np.nan, None, pd.NaT, 128, 2]],
...: codes=[[0, -1, 1, 2, 3, 4]])
...:
Out[1]: MultiIndex(levels=[[nan, None, NaT, 128, 2]],
 codes=[[0, -1, 1, 2, 3, 4]])

In [2]: pd.MultiIndex(levels=[[1, 2]], codes=[[0, -2]])
Out[2]: MultiIndex(levels=[[1, 2]],
 codes=[[0, -2]])
```

*New behavior:*

```

In [15]: pd.MultiIndex(levels=[[np.nan, None, pd.NaT, 128, 2]],
.....: codes=[[0, -1, 1, 2, 3, 4]])
.....:
Out[15]:
MultiIndex([(nan,),
 (nan,),
 (nan,),
 (nan,),
 (128,),
 (2,)],
)

In [16]: pd.MultiIndex(levels=[[1, 2]], codes=[[0, -2]])

ValueError Traceback (most recent call last)

```

### GroupBy.apply on DataFrame evaluates first group only once

The implementation of `DataFrameGroupBy.apply()` previously evaluated the supplied function consistently twice on the first group to infer if it is safe to use a fast code path. Particularly for functions with side effects, this was an undesired behavior and may have led to surprises. ([GH2936](#), [GH2656](#), [GH7739](#), [GH10519](#), [GH12155](#), [GH20084](#), [GH21417](#))

Now every group is evaluated only a single time.

```

In [17]: df = pd.DataFrame({"a": ["x", "y"], "b": [1, 2]})

In [18]: df
Out[18]:
 a b
0 x 1
1 y 2

```

(continues on next page)

(continued from previous page)

```
In [19]: def func(group):
.....: print(group.name)
.....: return group
.....:
```

*Previous behavior:*

```
In [3]: df.groupby('a').apply(func)
x
x
y
Out[3]:
 a b
0 x 1
1 y 2
```

*New behavior:*

```
In [20]: df.groupby("a").apply(func)
x
y
Out[20]:
 a b
0 x 1
1 y 2
```

## Concatenating sparse values

When passed DataFrames whose values are sparse, `concat()` will now return a *Series* or *DataFrame* with sparse values, rather than a *SparseDataFrame* (GH25702).

```
In [21]: df = pd.DataFrame({"A": pd.SparseArray([0, 1])})
```

*Previous behavior:*

```
In [2]: type(pd.concat([df, df]))
pandas.core.sparse.frame.SparseDataFrame
```

*New behavior:*

```
In [22]: type(pd.concat([df, df]))
Out[22]: pandas.core.frame.DataFrame
```

This now matches the existing behavior of `concat` on *Series* with sparse values. `concat()` will continue to return a *SparseDataFrame* when all the values are instances of *SparseDataFrame*.

This change also affects routines using `concat()` internally, like `get_dummies()`, which now returns a *DataFrame* in all cases (previously a *SparseDataFrame* was returned if all the columns were dummy encoded, and a *DataFrame* otherwise).

Providing any *SparseSeries* or *SparseDataFrame* to `concat()` will cause a *SparseSeries* or *SparseDataFrame* to be returned, as before.

## The `.str`-accessor performs stricter type checks

Due to the lack of more fine-grained dtypes, `Series.str` so far only checked whether the data was of object dtype. `Series.str` will now infer the dtype data *within* the Series; in particular, 'bytes'-only data will raise an exception (except for `Series.str.decode()`, `Series.str.get()`, `Series.str.len()`, `Series.str.slice()`), see GH23163, GH23011, GH23551.

*Previous behavior:*

```
In [1]: s = pd.Series(np.array(['a', 'ba', 'cba'], 'S'), dtype=object)

In [2]: s
Out[2]:
0 b'a'
1 b'ba'
2 b'cba'
dtype: object

In [3]: s.str.startswith(b'a')
Out[3]:
0 True
1 False
2 False
dtype: bool
```

*New behavior:*

```
In [23]: s = pd.Series(np.array(['a', 'ba', 'cba'], 'S'), dtype=object)

In [24]: s
Out[24]:
0 b'a'
1 b'ba'
2 b'cba'
dtype: object

In [25]: s.str.startswith(b'a')

TypeError Traceback (most recent call last)
<ipython-input-25-ac784692b361> in <module>
----> 1 s.str.startswith(b'a')

/pandas/pandas/core/strings/accessor.py in wrapper(self, *args, **kwargs)
 113 f"inferred dtype '{self._inferred_dtype}'."
 114)
--> 115 raise TypeError(msg)
 116 return func(self, *args, **kwargs)
 117

TypeError: Cannot use .str.startswith with values of inferred dtype 'bytes'.
```

## Categorical dtypes are preserved during GroupBy

Previously, columns that were categorical, but not the groupby key(s) would be converted to object dtype during groupby operations. pandas now will preserve these dtypes. (GH18502)

```
In [26]: cat = pd.Categorical(["foo", "bar", "bar", "qux"], ordered=True)
```

```
In [27]: df = pd.DataFrame({'payload': [-1, -2, -1, -2], 'col': cat})
```

```
In [28]: df
```

```
Out[28]:
 payload col
0 -1 foo
1 -2 bar
2 -1 bar
3 -2 qux
```

```
In [29]: df.dtypes
```

```
Out[29]:
payload int64
col category
dtype: object
```

*Previous Behavior:*

```
In [5]: df.groupby('payload').first().col.dtype
```

```
Out[5]: dtype('O')
```

*New Behavior:*

```
In [30]: df.groupby('payload').first().col.dtype
```

```
Out[30]: CategoricalDtype(categories=['bar', 'foo', 'qux'], ordered=True)
```

## Incompatible Index type unions

When performing `Index.union()` operations between objects of incompatible dtypes, the result will be a base `Index` of dtype object. This behavior holds true for unions between `Index` objects that previously would have been prohibited. The dtype of empty `Index` objects will now be evaluated before performing union operations rather than simply returning the other `Index` object. `Index.union()` can now be considered commutative, such that `A.union(B) == B.union(A)` (GH23525).

*Previous behavior:*

```
In [1]: pd.period_range('19910905', periods=2).union(pd.Int64Index([1, 2, 3]))
```

```
...
```

```
ValueError: can only call with other PeriodIndex-ed objects
```

```
In [2]: pd.Index([], dtype=object).union(pd.Index([1, 2, 3]))
```

```
Out[2]: Int64Index([1, 2, 3], dtype='int64')
```

*New behavior:*

```
In [31]: pd.period_range('19910905', periods=2).union(pd.Int64Index([1, 2, 3]))
Out[31]: Index([1991-09-05, 1991-09-06, 1, 2, 3], dtype='object')

In [32]: pd.Index([], dtype=object).union(pd.Index([1, 2, 3]))
Out[32]: Index([1, 2, 3], dtype='object')
```

Note that integer- and floating-dtype indexes are considered “compatible”. The integer values are coerced to floating point, which may result in loss of precision. See *Set operations on Index objects* for more.

### DataFrame GroupBy ffill/bfill no longer return group labels

The methods `ffill`, `bfill`, `pad` and `backfill` of `DataFrameGroupBy` previously included the group labels in the return value, which was inconsistent with other groupby transforms. Now only the filled values are returned. (GH21521)

```
In [33]: df = pd.DataFrame({"a": ["x", "y"], "b": [1, 2]})

In [34]: df
Out[34]:
 a b
0 x 1
1 y 2
```

*Previous behavior:*

```
In [3]: df.groupby("a").ffill()
Out[3]:
 a b
0 x 1
1 y 2
```

*New behavior:*

```
In [35]: df.groupby("a").ffill()
Out[35]:
 b
0 1
1 2
```

### DataFrame describe on an empty Categorical / object column will return top and freq

When calling `DataFrame.describe()` with an empty categorical / object column, the ‘top’ and ‘freq’ columns were previously omitted, which was inconsistent with the output for non-empty columns. Now the ‘top’ and ‘freq’ columns will always be included, with `numpy.nan` in the case of an empty `DataFrame` (GH26397)

```
In [36]: df = pd.DataFrame({"empty_col": pd.Categorical([])})

In [37]: df
Out[37]:
Empty DataFrame
Columns: [empty_col]
Index: []
```

*Previous behavior:*

```
In [3]: df.describe()
Out[3]:
 empty_col
count 0
unique 0
```

*New behavior:*

```
In [38]: df.describe()
Out[38]:
 empty_col
count 0
unique 0
top NaN
freq NaN
```

### `__str__` methods now call `__repr__` rather than vice versa

pandas has until now mostly defined string representations in a pandas objects' `__str__`/`__unicode__`/`__bytes__` methods, and called `__str__` from the `__repr__` method, if a specific `__repr__` method is not found. This is not needed for Python3. In pandas 0.25, the string representations of pandas objects are now generally defined in `__repr__`, and calls to `__str__` in general now pass the call on to the `__repr__`, if a specific `__str__` method doesn't exist, as is standard for Python. This change is backward compatible for direct usage of pandas, but if you subclass pandas objects *and* give your subclasses specific `__str__`/`__repr__` methods, you may have to adjust your `__str__`/`__repr__` methods (GH26495).

### Indexing an `IntervalIndex` with `Interval` objects

Indexing methods for `IntervalIndex` have been modified to require exact matches only for `Interval` queries. `IntervalIndex` methods previously matched on any overlapping `Interval`. Behavior with scalar points, e.g. querying with an integer, is unchanged (GH16316).

```
In [39]: ii = pd.IntervalIndex.from_tuples([(0, 4), (1, 5), (5, 8)])
In [40]: ii
Out[40]: IntervalIndex([(0, 4], (1, 5], (5, 8]], dtype='interval[int64, right]')
```

The `in` operator (`__contains__`) now only returns `True` for exact matches to `Intervals` in the `IntervalIndex`, whereas this would previously return `True` for any `Interval` overlapping an `Interval` in the `IntervalIndex`.

*Previous behavior:*

```
In [4]: pd.Interval(1, 2, closed='neither') in ii
Out[4]: True

In [5]: pd.Interval(-10, 10, closed='both') in ii
Out[5]: True
```

*New behavior:*

```
In [41]: pd.Interval(1, 2, closed='neither') in ii
Out[41]: False

In [42]: pd.Interval(-10, 10, closed='both') in ii
Out[42]: False
```

The `get_loc()` method now only returns locations for exact matches to `Interval` queries, as opposed to the previous behavior of returning locations for overlapping matches. A `KeyError` will be raised if an exact match is not found.

*Previous behavior:*

```
In [6]: ii.get_loc(pd.Interval(1, 5))
Out[6]: array([0, 1])

In [7]: ii.get_loc(pd.Interval(2, 6))
Out[7]: array([0, 1, 2])
```

*New behavior:*

```
In [6]: ii.get_loc(pd.Interval(1, 5))
Out[6]: 1

In [7]: ii.get_loc(pd.Interval(2, 6))

KeyError: Interval(2, 6, closed='right')
```

Likewise, `get_indexer()` and `get_indexer_non_unique()` will also only return locations for exact matches to `Interval` queries, with `-1` denoting that an exact match was not found.

These indexing changes extend to querying a `Series` or `DataFrame` with an `IntervalIndex` index.

```
In [43]: s = pd.Series(list('abc'), index=ii)

In [44]: s
Out[44]:
(0, 4] a
(1, 5] b
(5, 8] c
dtype: object
```

Selecting from a `Series` or `DataFrame` using `[]` (`__getitem__`) or `loc` now only returns exact matches for `Interval` queries.

*Previous behavior:*

```
In [8]: s[pd.Interval(1, 5)]
Out[8]:
(0, 4] a
(1, 5] b
dtype: object

In [9]: s.loc[pd.Interval(1, 5)]
Out[9]:
(0, 4] a
```

(continues on next page)

(continued from previous page)

```
(1, 5] b
dtype: object
```

*New behavior:*

```
In [45]: s[pd.Interval(1, 5)]
Out[45]: 'b'
```

```
In [46]: s.loc[pd.Interval(1, 5)]
Out[46]: 'b'
```

Similarly, a `KeyError` will be raised for non-exact matches instead of returning overlapping matches.

*Previous behavior:*

```
In [9]: s[pd.Interval(2, 3)]
Out[9]:
(0, 4] a
(1, 5] b
dtype: object

In [10]: s.loc[pd.Interval(2, 3)]
Out[10]:
(0, 4] a
(1, 5] b
dtype: object
```

*New behavior:*

```
In [6]: s[pd.Interval(2, 3)]

KeyError: Interval(2, 3, closed='right')

In [7]: s.loc[pd.Interval(2, 3)]

KeyError: Interval(2, 3, closed='right')
```

The `overlaps()` method can be used to create a boolean indexer that replicates the previous behavior of returning overlapping matches.

*New behavior:*

```
In [47]: idxr = s.index.overlaps(pd.Interval(2, 3))

In [48]: idxr
Out[48]: array([True, True, False])

In [49]: s[idxr]
Out[49]:
(0, 4] a
(1, 5] b
dtype: object

In [50]: s.loc[idxr]
```

(continues on next page)

(continued from previous page)

```
Out[50]:
(0, 4] a
(1, 5] b
dtype: object
```

### Binary ufuncs on Series now align

Applying a binary ufunc like `numpy.power()` now aligns the inputs when both are *Series* (GH23293).

```
In [51]: s1 = pd.Series([1, 2, 3], index=['a', 'b', 'c'])
```

```
In [52]: s2 = pd.Series([3, 4, 5], index=['d', 'c', 'b'])
```

```
In [53]: s1
```

```
Out[53]:
a 1
b 2
c 3
dtype: int64
```

```
In [54]: s2
```

```
Out[54]:
d 3
c 4
b 5
dtype: int64
```

#### Previous behavior

```
In [5]: np.power(s1, s2)
```

```
Out[5]:
a 1
b 16
c 243
dtype: int64
```

#### New behavior

```
In [55]: np.power(s1, s2)
```

```
Out[55]:
a 1.0
b 32.0
c 81.0
d NaN
dtype: float64
```

This matches the behavior of other binary operations in pandas, like `Series.add()`. To retain the previous behavior, convert the other *Series* to an array before applying the ufunc.

```
In [56]: np.power(s1, s2.array)
```

```
Out[56]:
```

(continues on next page)

(continued from previous page)

```
a 1
b 16
c 243
dtype: int64
```

### Categorical.argsort now places missing values at the end

`Categorical.argsort()` now places missing values at the end of the array, making it consistent with NumPy and the rest of pandas (GH21801).

```
In [57]: cat = pd.Categorical(['b', None, 'a'], categories=['a', 'b'], ordered=True)
```

*Previous behavior*

```
In [2]: cat = pd.Categorical(['b', None, 'a'], categories=['a', 'b'], ordered=True)
```

```
In [3]: cat.argsort()
```

```
Out[3]: array([1, 2, 0])
```

```
In [4]: cat[cat.argsort()]
```

```
Out[4]:
```

```
[NaN, a, b]
```

```
categories (2, object): [a < b]
```

*New behavior*

```
In [58]: cat.argsort()
```

```
Out[58]: array([2, 0, 1])
```

```
In [59]: cat[cat.argsort()]
```

```
Out[59]:
```

```
['a', 'b', NaN]
```

```
Categories (2, object): ['a' < 'b']
```

### Column order is preserved when passing a list of dicts to DataFrame

Starting with Python 3.7 the key-order of `dict` is [guaranteed](#). In practice, this has been true since Python 3.6. The `DataFrame` constructor now treats a list of dicts in the same way as it does a list of `OrderedDict`, i.e. preserving the order of the dicts. This change applies only when pandas is running on Python  $\geq 3.6$  (GH27309).

```
In [60]: data = [
.....: {'name': 'Joe', 'state': 'NY', 'age': 18},
.....: {'name': 'Jane', 'state': 'KY', 'age': 19, 'hobby': 'Minecraft'},
.....: {'name': 'Jean', 'state': 'OK', 'age': 20, 'finances': 'good'}
.....:]
.....:
```

*Previous Behavior:*

The columns were lexicographically sorted previously,

```
In [1]: pd.DataFrame(data)
Out[1]:
 age finances hobby name state
0 18 NaN NaN Joe NY
1 19 NaN Minecraft Jane KY
2 20 good NaN Jean OK
```

*New Behavior:*

The column order now matches the insertion-order of the keys in the dict, considering all the records from top to bottom. As a consequence, the column order of the resulting DataFrame has changed compared to previous pandas versions.

```
In [61]: pd.DataFrame(data)
Out[61]:
 name state age hobby finances
0 Joe NY 18 NaN NaN
1 Jane KY 19 Minecraft NaN
2 Jean OK 20 NaN good
```

### Increased minimum versions for dependencies

Due to dropping support for Python 2.7, a number of optional dependencies have updated minimum versions ([GH25725](#), [GH24942](#), [GH25752](#)). Independently, some minimum supported versions of dependencies were updated ([GH23519](#), [GH25554](#)). If installed, we now require:

| Package         | Minimum Version | Required |
|-----------------|-----------------|----------|
| numpy           | 1.13.3          | X        |
| pytz            | 2015.4          | X        |
| python-dateutil | 2.6.1           | X        |
| bottleneck      | 1.2.1           |          |
| numexpr         | 2.6.2           |          |
| pytest (dev)    | 4.0.2           |          |

For [optional libraries](#) the general recommendation is to use the latest version. The following table lists the lowest version per library that is currently being tested throughout the development of pandas. Optional libraries below the lowest tested version may still work, but are not considered supported.

| Package        | Minimum Version |
|----------------|-----------------|
| beautifulsoup4 | 4.6.0           |
| fastparquet    | 0.2.1           |
| gcsfs          | 0.2.2           |
| lxml           | 3.8.0           |
| matplotlib     | 2.2.2           |
| openpyxl       | 2.4.8           |
| pyarrow        | 0.9.0           |
| pymysql        | 0.7.1           |
| pytables       | 3.4.2           |
| scipy          | 0.19.0          |
| sqlalchemy     | 1.1.4           |
| xarray         | 0.8.2           |
| xlrd           | 1.1.0           |
| xlsxwriter     | 0.9.8           |
| xlwt           | 1.2.0           |

See *Dependencies* and *Optional dependencies* for more.

## Other API changes

- `DatetimeTZDtype` will now standardize pytz timezones to a common timezone instance (GH24713)
- `Timestamp` and `Timedelta` scalars now implement the `to_numpy()` method as aliases to `Timestamp.to_datetime64()` and `Timedelta.to_timedelta64()`, respectively. (GH24653)
- `Timestamp.strptime()` will now raise a `NotImplementedError` (GH25016)
- Comparing `Timestamp` with unsupported objects now returns `NotImplemented` instead of raising `TypeError`. This implies that unsupported rich comparisons are delegated to the other object, and are now consistent with Python 3 behavior for datetime objects (GH24011)
- Bug in `DatetimeIndex.snap()` which didn't preserving the name of the input `Index` (GH25575)
- The `arg` argument in `pandas.core.groupby.DataFrameGroupBy.agg()` has been renamed to `func` (GH26089)
- The `arg` argument in `pandas.core.window._Window.aggregate()` has been renamed to `func` (GH26372)
- Most pandas classes had a `__bytes__` method, which was used for getting a python2-style bytestring representation of the object. This method has been removed as a part of dropping Python2 (GH26447)
- The `.str`-accessor has been disabled for 1-level `MultiIndex`, use `MultiIndex.to_flat_index()` if necessary (GH23679)
- Removed support of `gtk` package for clipboards (GH26563)
- Using an unsupported version of Beautiful Soup 4 will now raise an `ImportError` instead of a `ValueError` (GH27063)
- `Series.to_excel()` and `DataFrame.to_excel()` will now raise a `ValueError` when saving timezone aware data. (GH27008, GH7056)
- `ExtensionArray.argsort()` places NA values at the end of the sorted array. (GH21801)
- `DataFrame.to_hdf()` and `Series.to_hdf()` will now raise a `NotImplementedError` when saving a `MultiIndex` with extension data types for a fixed format. (GH7775)

- Passing duplicate names in `read_csv()` will now raise a `ValueError` (GH17346)

## Deprecations

### Sparse subclasses

The `SparseSeries` and `SparseDataFrame` subclasses are deprecated. Their functionality is better-provided by a `Series` or `DataFrame` with sparse values.

#### Previous way

```
df = pd.SparseDataFrame({"A": [0, 0, 1, 2]})
df.dtypes
```

#### New way

```
In [62]: df = pd.DataFrame({"A": pd.SparseArray([0, 0, 1, 2])})
In [63]: df.dtypes
Out[63]:
A Sparse[int64, 0]
dtype: object
```

The memory usage of the two approaches is identical. See *Migrating* for more (GH19239).

### msgpack format

The msgpack format is deprecated as of 0.25 and will be removed in a future version. It is recommended to use pyarrow for on-the-wire transmission of pandas objects. (GH27084)

### Other deprecations

- The deprecated `.ix[]` indexer now raises a more visible `FutureWarning` instead of `DeprecationWarning` (GH26438).
- Deprecated the `units=M` (months) and `units=Y` (year) parameters for `units` of `pandas.to_timedelta()`, `pandas.Timedelta()` and `pandas.TimedeltaIndex()` (GH16344)
- `pandas.concat()` has deprecated the `join_axes`-keyword. Instead, use `DataFrame.reindex()` or `DataFrame.reindex_like()` on the result or on the inputs (GH21951)
- The `SparseArray.values` attribute is deprecated. You can use `np.asarray(...)` or the `SparseArray.to_dense()` method instead (GH26421).
- The functions `pandas.to_datetime()` and `pandas.to_timedelta()` have deprecated the `box` keyword. Instead, use `to_numpy()` or `Timestamp.to_datetime64()` or `Timedelta.to_timedelta64()`. (GH24416)
- The `DataFrame.compound()` and `Series.compound()` methods are deprecated and will be removed in a future version (GH26405).
- The internal attributes `_start`, `_stop` and `_step` attributes of `RangeIndex` have been deprecated. Use the public attributes `start`, `stop` and `step` instead (GH26581).
- The `Series.ftype()`, `Series.ftypes()` and `DataFrame.ftypes()` methods are deprecated and will be removed in a future version. Instead, use `Series.dtype()` and `DataFrame.dtypes()` (GH26705).

- The `Series.get_values()`, `DataFrame.get_values()`, `Index.get_values()`, `SparseArray.get_values()` and `Categorical.get_values()` methods are deprecated. One of `np.asarray(...)` or `to_numpy()` can be used instead (GH19617).
- The 'outer' method on NumPy ufuncs, e.g. `np.subtract.outer` has been deprecated on `Series` objects. Convert the input to an array with `Series.array` first (GH27186)
- `Timedelta.resolution()` is deprecated and replaced with `Timedelta.resolution_string()`. In a future version, `Timedelta.resolution()` will be changed to behave like the standard library `datetime.timedelta.resolution` (GH21344)
- `read_table()` has been undeprecated. (GH25220)
- `Index.dtype_str` is deprecated. (GH18262)
- `Series.imag` and `Series.real` are deprecated. (GH18262)
- `Series.put()` is deprecated. (GH18262)
- `Index.item()` and `Series.item()` is deprecated. (GH18262)
- The default value `ordered=None` in `CategoricalDtype` has been deprecated in favor of `ordered=False`. When converting between categorical types `ordered=True` must be explicitly passed in order to be preserved. (GH26336)
- `Index.contains()` is deprecated. Use `key in index` (`__contains__`) instead (GH17753).
- `DataFrame.get_dtype_counts()` is deprecated. (GH18262)
- `Categorical.ravel()` will return a `Categorical` instead of a `np.ndarray` (GH27199)

### Removal of prior version deprecations/changes

- Removed `Panel` (GH25047, GH25191, GH25231)
- Removed the previously deprecated `sheetname` keyword in `read_excel()` (GH16442, GH20938)
- Removed the previously deprecated `TimeGrouper` (GH16942)
- Removed the previously deprecated `parse_cols` keyword in `read_excel()` (GH16488)
- Removed the previously deprecated `pd.options.html.border` (GH16970)
- Removed the previously deprecated `convert_objects` (GH11221)
- Removed the previously deprecated `select` method of `DataFrame` and `Series` (GH17633)
- Removed the previously deprecated behavior of `Series` treated as list-like in `rename_categories()` (GH17982)
- Removed the previously deprecated `DataFrame.reindex_axis` and `Series.reindex_axis` (GH17842)
- Removed the previously deprecated behavior of altering column or index labels with `Series.rename_axis()` or `DataFrame.rename_axis()` (GH17842)
- Removed the previously deprecated `tupleize_cols` keyword argument in `read_html()`, `read_csv()`, and `DataFrame.to_csv()` (GH17877, GH17820)
- Removed the previously deprecated `DataFrame.from_csv` and `Series.from_csv` (GH17812)
- Removed the previously deprecated `raise_on_error` keyword argument in `DataFrame.where()` and `DataFrame.mask()` (GH17744)
- Removed the previously deprecated `ordered` and `categories` keyword arguments in `astype` (GH17742)
- Removed the previously deprecated `cdate_range` (GH17691)

- Removed the previously deprecated True option for the dropna keyword argument in `SeriesGroupBy.nth()` (GH17493)
- Removed the previously deprecated convert keyword argument in `Series.take()` and `DataFrame.take()` (GH17352)
- Removed the previously deprecated behavior of arithmetic operations with `datetime.date` objects (GH21152)

## Performance improvements

- Significant speedup in `SparseArray` initialization that benefits most operations, fixing performance regression introduced in v0.20.0 (GH24985)
- `DataFrame.to_stata()` is now faster when outputting data with any string or non-native endian columns (GH25045)
- Improved performance of `Series.searchsorted()`. The speedup is especially large when the dtype is `int8/int16/int32` and the searched key is within the integer bounds for the dtype (GH22034)
- Improved performance of `pandas.core.groupby.GroupBy.quantile()` (GH20405)
- Improved performance of slicing and other selected operation on a `RangeIndex` (GH26565, GH26617, GH26722)
- `RangeIndex` now performs standard lookup without instantiating an actual hashtable, hence saving memory (GH16685)
- Improved performance of `read_csv()` by faster tokenizing and faster parsing of small float numbers (GH25784)
- Improved performance of `read_csv()` by faster parsing of N/A and boolean values (GH25804)
- Improved performance of `IntervalIndex.is_monotonic`, `IntervalIndex.is_monotonic_increasing` and `IntervalIndex.is_monotonic_decreasing` by removing conversion to `MultiIndex` (GH24813)
- Improved performance of `DataFrame.to_csv()` when writing datetime dtypes (GH25708)
- Improved performance of `read_csv()` by much faster parsing of MM/YYYY and DD/MM/YYYY datetime formats (GH25922)
- Improved performance of `nanops` for dtypes that cannot store NaNs. Speedup is particularly prominent for `Series.all()` and `Series.any()` (GH25070)
- Improved performance of `Series.map()` for dictionary mappers on categorical series by mapping the categories instead of mapping all values (GH23785)
- Improved performance of `IntervalIndex.intersection()` (GH24813)
- Improved performance of `read_csv()` by faster concatenating date columns without extra conversion to string for integer/float zero and float NaN; by faster checking the string for the possibility of being a date (GH25754)
- Improved performance of `IntervalIndex.is_unique` by removing conversion to `MultiIndex` (GH24813)
- Restored performance of `DatetimeIndex.__iter__()` by re-enabling specialized code path (GH26702)
- Improved performance when building `MultiIndex` with at least one `CategoricalIndex` level (GH22044)
- Improved performance by removing the need for a garbage collect when checking for `SettingWithCopyWarning` (GH27031)
- For `to_datetime()` changed default value of cache parameter to True (GH26043)
- Improved performance of `DatetimeIndex` and `PeriodIndex` slicing given non-unique, monotonic data (GH27136).
- Improved performance of `pd.read_json()` for index-oriented data. (GH26773)

- Improved performance of `MultiIndex.shape()` (GH27384).

## Bug fixes

### Categorical

- Bug in `DataFrame.at()` and `Series.at()` that would raise exception if the index was a `CategoricalIndex` (GH20629)
- Fixed bug in comparison of ordered `Categorical` that contained missing values with a scalar which sometimes incorrectly resulted in `True` (GH26504)
- Bug in `DataFrame.dropna()` when the `DataFrame` has a `CategoricalIndex` containing `Interval` objects incorrectly raised a `TypeError` (GH25087)

### Datetimelike

- Bug in `to_datetime()` which would raise an (incorrect) `ValueError` when called with a date far into the future and the `format` argument specified instead of raising `OutOfBoundsDatetime` (GH23830)
- Bug in `to_datetime()` which would raise `InvalidIndexError: Reindexing only valid with uniquely valued Index objects` when called with `cache=True`, with `arg` including at least two different elements from the set `{None, numpy.nan, pandas.NaT}` (GH22305)
- Bug in `DataFrame` and `Series` where timezone aware data with `dtype='datetime64[ns]` was not cast to naive (GH25843)
- Improved `Timestamp` type checking in various datetime functions to prevent exceptions when using a subclassed `datetime` (GH25851)
- Bug in `Series` and `DataFrame` repr where `np.datetime64('NaT')` and `np.timedelta64('NaT')` with `dtype=object` would be represented as `NaN` (GH25445)
- Bug in `to_datetime()` which does not replace the invalid argument with `NaT` when error is set to `coerce` (GH26122)
- Bug in adding `DateOffset` with nonzero month to `DatetimeIndex` would raise `ValueError` (GH26258)
- Bug in `to_datetime()` which raises unhandled `OverflowError` when called with mix of invalid dates and `NaN` values with `format='%Y%m%d'` and `error='coerce'` (GH25512)
- Bug in `isin()` for datetimelike indexes; `DatetimeIndex`, `TimedeltaIndex` and `PeriodIndex` where the `levels` parameter was ignored. (GH26675)
- Bug in `to_datetime()` which raises `TypeError` for `format='%Y%m%d'` when called for invalid integer dates with `length >= 6` digits with `errors='ignore'`
- Bug when comparing a `PeriodIndex` against a zero-dimensional numpy array (GH26689)
- Bug in constructing a `Series` or `DataFrame` from a numpy `datetime64` array with a non-ns unit and out-of-bound timestamps generating rubbish data, which will now correctly raise an `OutOfBoundsDatetime` error (GH26206).
- Bug in `date_range()` with unnecessary `OverflowError` being raised for very large or very small dates (GH26651)
- Bug where adding `Timestamp` to a `np.timedelta64` object would raise instead of returning a `Timestamp` (GH24775)

- Bug where comparing a zero-dimensional numpy array containing a `np.datetime64` object to a *Timestamp* would incorrectly raise `TypeError` (GH26916)
- Bug in `to_datetime()` which would raise `ValueError: Tz-aware datetime.datetime cannot be converted to datetime64 unless utc=True` when called with `cache=True`, with `arg` including datetime strings with different offset (GH26097)
- 

## Timedelta

- Bug in `TimedeltaIndex.intersection()` where for non-monotonic indices in some cases an empty `Index` was returned when in fact an intersection existed (GH25913)
- Bug with comparisons between *Timedelta* and `NaT` raising `TypeError` (GH26039)
- Bug when adding or subtracting a `BusinessHour` to a *Timestamp* with the resulting time landing in a following or prior day respectively (GH26381)
- Bug when comparing a *TimedeltaIndex* against a zero-dimensional numpy array (GH26689)

## Timezones

- Bug in `DatetimeIndex.to_frame()` where timezone aware data would be converted to timezone naive data (GH25809)
- Bug in `to_datetime()` with `utc=True` and datetime strings that would apply previously parsed UTC offsets to subsequent arguments (GH24992)
- Bug in `Timestamp.tz_localize()` and `Timestamp.tz_convert()` does not propagate `freq` (GH25241)
- Bug in `Series.at()` where setting *Timestamp* with timezone raises `TypeError` (GH25506)
- Bug in `DataFrame.update()` when updating with timezone aware data would return timezone naive data (GH25807)
- Bug in `to_datetime()` where an uninformative `RuntimeError` was raised when passing a naive *Timestamp* with datetime strings with mixed UTC offsets (GH25978)
- Bug in `to_datetime()` with `unit='ns'` would drop timezone information from the parsed argument (GH26168)
- Bug in `DataFrame.join()` where joining a timezone aware index with a timezone aware column would result in a column of `NaN` (GH26335)
- Bug in `date_range()` where ambiguous or nonexistent start or end times were not handled by the `ambiguous` or `nonexistent` keywords respectively (GH27088)
- Bug in `DatetimeIndex.union()` when combining a timezone aware and timezone unaware *DatetimeIndex* (GH21671)
- Bug when applying a numpy reduction function (e.g. `numpy.minimum()`) to a timezone aware *Series* (GH15552)

## Numeric

- Bug in `to_numeric()` in which large negative numbers were being improperly handled (GH24910)
- Bug in `to_numeric()` in which numbers were being coerced to float, even though errors was not coerce (GH24910)
- Bug in `to_numeric()` in which invalid values for errors were being allowed (GH26466)
- Bug in `format` in which floating point complex numbers were not being formatted to proper display precision and trimming (GH25514)
- Bug in error messages in `DataFrame.corr()` and `Series.corr()`. Added the possibility of using a callable. (GH25729)
- Bug in `Series.divmod()` and `Series.rdivmod()` which would raise an (incorrect) `ValueError` rather than return a pair of `Series` objects as result (GH25557)
- Raises a helpful exception when a non-numeric index is sent to `interpolate()` with methods which require numeric index. (GH21662)
- Bug in `eval()` when comparing floats with scalar operators, for example: `x < -0.1` (GH25928)
- Fixed bug where casting all-boolean array to integer extension array failed (GH25211)
- Bug in `divmod` with a `Series` object containing zeros incorrectly raising `AttributeError` (GH26987)
- Inconsistency in `Series` floor-division (`//`) and `divmod` filling positive//zero with `NaN` instead of `Inf` (GH27321)
- 

## Conversion

- Bug in `DataFrame.astype()` when passing a dict of columns and types the `errors` parameter was ignored. (GH25905)
- 

## Strings

- Bug in the `__name__` attribute of several methods of `Series.str`, which were set incorrectly (GH23551)
- Improved error message when passing `Series` of wrong dtype to `Series.str.cat()` (GH22722)
- 

## Interval

- Construction of `Interval` is restricted to numeric, `Timestamp` and `Timedelta` endpoints (GH23013)
- Fixed bug in `Series/DataFrame` not displaying `NaN` in `IntervalIndex` with missing values (GH25984)
- Bug in `IntervalIndex.get_loc()` where a `KeyError` would be incorrectly raised for a decreasing `IntervalIndex` (GH25860)
- Bug in `Index` constructor where passing mixed closed `Interval` objects would result in a `ValueError` instead of an object dtype `Index` (GH27172)

## Indexing

- Improved exception message when calling `DataFrame.iloc()` with a list of non-numeric objects (GH25753).
- Improved exception message when calling `.iloc` or `.loc` with a boolean indexer with different length (GH26658).
- Bug in `KeyError` exception message when indexing a `MultiIndex` with a non-existent key not displaying the original key (GH27250).
- Bug in `.iloc` and `.loc` with a boolean indexer not raising an `IndexError` when too few items are passed (GH26658).
- Bug in `DataFrame.loc()` and `Series.loc()` where `KeyError` was not raised for a `MultiIndex` when the key was less than or equal to the number of levels in the `MultiIndex` (GH14885).
- Bug in which `DataFrame.append()` produced an erroneous warning indicating that a `KeyError` will be thrown in the future when the data to be appended contains new columns (GH22252).
- Bug in which `DataFrame.to_csv()` caused a segfault for a reindexed data frame, when the indices were single-level `MultiIndex` (GH26303).
- Fixed bug where assigning a `arrays.PandasArray` to a `pandas.core.frame.DataFrame` would raise error (GH26390)
- Allow keyword arguments for callable local reference used in the `DataFrame.query()` string (GH26426)
- Fixed a `KeyError` when indexing a `MultiIndex` level with a list containing exactly one label, which is missing (GH27148)
- Bug which produced `AttributeError` on partial matching `Timestamp` in a `MultiIndex` (GH26944)
- Bug in `Categorical` and `CategoricalIndex` with `Interval` values when using the `in` operator (`__contains`) with objects that are not comparable to the values in the `Interval` (GH23705)
- Bug in `DataFrame.loc()` and `DataFrame.iloc()` on a `DataFrame` with a single timezone-aware `date-time64[ns]` column incorrectly returning a scalar instead of a `Series` (GH27110)
- Bug in `CategoricalIndex` and `Categorical` incorrectly raising `ValueError` instead of `TypeError` when a list is passed using the `in` operator (`__contains__`) (GH21729)
- Bug in setting a new value in a `Series` with a `Timedelta` object incorrectly casting the value to an integer (GH22717)
- Bug in `Series` setting a new key (`__setitem__`) with a timezone-aware datetime incorrectly raising `ValueError` (GH12862)
- Bug in `DataFrame.iloc()` when indexing with a read-only indexer (GH17192)
- Bug in `Series` setting an existing tuple key (`__setitem__`) with timezone-aware datetime values incorrectly raising `TypeError` (GH20441)

## Missing

- Fixed misleading exception message in `Series.interpolate()` if argument order is required, but omitted (GH10633, GH24014).
- Fixed class type displayed in exception message in `DataFrame.dropna()` if invalid axis parameter passed (GH25555)
- A `ValueError` will now be thrown by `DataFrame.fillna()` when `limit` is not a positive integer (GH27042)
- 

## Multindex

- Bug in which incorrect exception raised by `Timedelta` when testing the membership of `MultiIndex` (GH24570)
- 

## IO

- Bug in `DataFrame.to_html()` where values were truncated using display options instead of outputting the full content (GH17004)
- Fixed bug in missing text when using `to_clipboard()` if copying utf-16 characters in Python 3 on Windows (GH25040)
- Bug in `read_json()` for `orient='table'` when it tries to infer dtypes by default, which is not applicable as dtypes are already defined in the JSON schema (GH21345)
- Bug in `read_json()` for `orient='table'` and float index, as it infers index dtype by default, which is not applicable because index dtype is already defined in the JSON schema (GH25433)
- Bug in `read_json()` for `orient='table'` and string of float column names, as it makes a column name type conversion to `Timestamp`, which is not applicable because column names are already defined in the JSON schema (GH25435)
- Bug in `json_normalize()` for `errors='ignore'` where missing values in the input data, were filled in resulting `DataFrame` with the string "nan" instead of `numpy.nan` (GH25468)
- `DataFrame.to_html()` now raises `TypeError` when using an invalid type for the `classes` parameter instead of `AssertionError` (GH25608)
- Bug in `DataFrame.to_string()` and `DataFrame.to_latex()` that would lead to incorrect output when the `header` keyword is used (GH16718)
- Bug in `read_csv()` not properly interpreting the UTF8 encoded filenames on Windows on Python 3.6+ (GH15086)
- Improved performance in `pandas.read_stata()` and `pandas.io.stata.StataReader` when converting columns that have missing values (GH25772)
- Bug in `DataFrame.to_html()` where header numbers would ignore display options when rounding (GH17280)
- Bug in `read_hdf()` where reading a table from an HDF5 file written directly with PyTables fails with a `ValueError` when using a sub-selection via the `start` or `stop` arguments (GH11188)
- Bug in `read_hdf()` not properly closing store after a `KeyError` is raised (GH25766)
- Improved the explanation for the failure when value labels are repeated in Stata dta files and suggested work-arounds (GH25772)

- Improved `pandas.read_stata()` and `pandas.io.stata.StataReader` to read incorrectly formatted 118 format files saved by Stata (GH25960)
- Improved the `col_space` parameter in `DataFrame.to_html()` to accept a string so CSS length values can be set correctly (GH25941)
- Fixed bug in loading objects from S3 that contain # characters in the URL (GH25945)
- Adds `use_bqstorage_api` parameter to `read_gbq()` to speed up downloads of large data frames. This feature requires version 0.10.0 of the `pandas-gbq` library as well as the `google-cloud-bigquery-storage` and `fastavro` libraries. (GH26104)
- Fixed memory leak in `DataFrame.to_json()` when dealing with numeric data (GH24889)
- Bug in `read_json()` where date strings with Z were not converted to a UTC timezone (GH26168)
- Added `cache_dates=True` parameter to `read_csv()`, which allows to cache unique dates when they are parsed (GH25990)
- `DataFrame.to_excel()` now raises a `ValueError` when the caller's dimensions exceed the limitations of Excel (GH26051)
- Fixed bug in `pandas.read_csv()` where a BOM would result in incorrect parsing using `engine='python'` (GH26545)
- `read_excel()` now raises a `ValueError` when input is of type `pandas.io.excel.ExcelFile` and `engine` param is passed since `pandas.io.excel.ExcelFile` has an engine defined (GH26566)
- Bug while selecting from `HDFStore` with `where=''` specified (GH26610).
- Fixed bug in `DataFrame.to_excel()` where custom objects (i.e. `PeriodIndex`) inside merged cells were not being converted into types safe for the Excel writer (GH27006)
- Bug in `read_hdf()` where reading a timezone aware `DatetimeIndex` would raise a `TypeError` (GH11926)
- Bug in `to_msgpack()` and `read_msgpack()` which would raise a `ValueError` rather than a `FileNotFoundError` for an invalid path (GH27160)
- Fixed bug in `DataFrame.to_parquet()` which would raise a `ValueError` when the dataframe had no columns (GH27339)
- Allow parsing of `PeriodDtype` columns when using `read_csv()` (GH26934)

## Plotting

- Fixed bug where `api.extensions.ExtensionArray` could not be used in matplotlib plotting (GH25587)
- Bug in an error message in `DataFrame.plot()`. Improved the error message if non-numeric are passed to `DataFrame.plot()` (GH25481)
- Bug in incorrect ticklabel positions when plotting an index that are non-numeric / non-datetime (GH7612, GH15912, GH22334)
- Fixed bug causing plots of `PeriodIndex` timeseries to fail if the frequency is a multiple of the frequency rule code (GH14763)
- Fixed bug when plotting a `DatetimeIndex` with `datetime.timezone.utc` timezone (GH17173)
-

## GroupBy/resample/rolling

- Bug in `pandas.core.resample.Resampler.agg()` with a timezone aware index where `OverflowError` would raise when passing a list of functions (GH22660)
- Bug in `pandas.core.groupby.DataFrameGroupBy.nunique()` in which the names of column levels were lost (GH23222)
- Bug in `pandas.core.groupby.GroupBy.agg()` when applying an aggregation function to timezone aware data (GH23683)
- Bug in `pandas.core.groupby.GroupBy.first()` and `pandas.core.groupby.GroupBy.last()` where timezone information would be dropped (GH21603)
- Bug in `pandas.core.groupby.GroupBy.size()` when grouping only NA values (GH23050)
- Bug in `Series.groupby()` where observed kwarg was previously ignored (GH24880)
- Bug in `Series.groupby()` where using groupby with a `MultiIndex` Series with a list of labels equal to the length of the series caused incorrect grouping (GH25704)
- Ensured that ordering of outputs in groupby aggregation functions is consistent across all versions of Python (GH25692)
- Ensured that result group order is correct when grouping on an ordered Categorical and specifying `observed=True` (GH25871, GH25167)
- Bug in `pandas.core.window.Rolling.min()` and `pandas.core.window.Rolling.max()` that caused a memory leak (GH25893)
- Bug in `pandas.core.window.Rolling.count()` and `pandas.core.window.Expanding.count` was previously ignoring the `axis` keyword (GH13503)
- Bug in `pandas.core.groupby.GroupBy.idxmax()` and `pandas.core.groupby.GroupBy.idxmin()` with datetime column would return incorrect dtype (GH25444, GH15306)
- Bug in `pandas.core.groupby.GroupBy.cumsum()`, `pandas.core.groupby.GroupBy.cumprod()`, `pandas.core.groupby.GroupBy.cummin()` and `pandas.core.groupby.GroupBy.cummax()` with categorical column having absent categories, would return incorrect result or segfault (GH16771)
- Bug in `pandas.core.groupby.GroupBy.nth()` where NA values in the grouping would return incorrect results (GH26011)
- Bug in `pandas.core.groupby.SeriesGroupBy.transform()` where transforming an empty group would raise a `ValueError` (GH26208)
- Bug in `pandas.core.frame.DataFrame.groupby()` where passing a `pandas.core.groupby.grouper.Grouper` would return incorrect groups when using the `.groups` accessor (GH26326)
- Bug in `pandas.core.groupby.GroupBy.agg()` where incorrect results are returned for uint64 columns. (GH26310)
- Bug in `pandas.core.window.Rolling.median()` and `pandas.core.window.Rolling.quantile()` where `MemoryError` is raised with empty window (GH26005)
- Bug in `pandas.core.window.Rolling.median()` and `pandas.core.window.Rolling.quantile()` where incorrect results are returned with `closed='left'` and `closed='neither'` (GH26005)
- Improved `pandas.core.window.Rolling`, `pandas.core.window.Window` and `pandas.core.window.ExponentialMovingWindow` functions to exclude nuisance columns from results instead of raising errors and raise a `DataError` only if all columns are nuisance (GH12537)
- Bug in `pandas.core.window.Rolling.max()` and `pandas.core.window.Rolling.min()` where incorrect results are returned with an empty variable window (GH26005)

- Raise a helpful exception when an unsupported weighted window function is used as an argument of `pandas.core.window.Window.aggregate()` (GH26597)

## Reshaping

- Bug in `pandas.merge()` adds a string of None, if None is assigned in suffixes instead of remain the column name as-is (GH24782).
- Bug in `merge()` when merging by index name would sometimes result in an incorrectly numbered index (missing index values are now assigned NA) (GH24212, GH25009)
- `to_records()` now accepts dtypes to its `column_dtypes` parameter (GH24895)
- Bug in `concat()` where order of `OrderedDict` (and `dict` in Python 3.6+) is not respected, when passed in as `objs` argument (GH21510)
- Bug in `pivot_table()` where columns with NaN values are dropped even if `dropna` argument is `False`, when the `aggfunc` argument contains a list (GH22159)
- Bug in `concat()` where the resulting `freq` of two `DatetimeIndex` with the same `freq` would be dropped (GH3232).
- Bug in `merge()` where merging with equivalent Categorical dtypes was raising an error (GH22501)
- bug in `DataFrame` instantiating with a dict of iterators or generators (e.g. `pd.DataFrame({'A': reversed(range(3))})`) raised an error (GH26349).
- Bug in `DataFrame` instantiating with a `range` (e.g. `pd.DataFrame(range(3))`) raised an error (GH26342).
- Bug in `DataFrame` constructor when passing non-empty tuples would cause a segmentation fault (GH25691)
- Bug in `Series.apply()` failed when the series is a timezone aware `DatetimeIndex` (GH25959)
- Bug in `pandas.cut()` where large bins could incorrectly raise an error due to an integer overflow (GH26045)
- Bug in `DataFrame.sort_index()` where an error is thrown when a multi-indexed `DataFrame` is sorted on all levels with the initial level sorted last (GH26053)
- Bug in `Series.nlargest()` treats `True` as smaller than `False` (GH26154)
- Bug in `DataFrame.pivot_table()` with a `IntervalIndex` as pivot index would raise `TypeError` (GH25814)
- Bug in which `DataFrame.from_dict()` ignored order of `OrderedDict` when `orient='index'` (GH8425).
- Bug in `DataFrame.transpose()` where transposing a `DataFrame` with a timezone-aware datetime column would incorrectly raise `ValueError` (GH26825)
- Bug in `pivot_table()` when pivoting a timezone aware column as the values would remove timezone information (GH14948)
- Bug in `merge_asof()` when specifying multiple by columns where one is `datetime64[ns, tz]` dtype (GH26649)

## Sparse

- Significant speedup in `SparseArray` initialization that benefits most operations, fixing performance regression introduced in v0.20.0 (GH24985)
- Bug in `SparseFrame` constructor where passing `None` as the data would cause `default_fill_value` to be ignored (GH16807)
- Bug in `SparseDataFrame` when adding a column in which the length of values does not match length of index, `AssertionError` is raised instead of raising `ValueError` (GH25484)
- Introduce a better error message in `Series.sparse.from_coo()` so it returns a `TypeError` for inputs that are not `coo` matrices (GH26554)
- Bug in `numpy.modf()` on a `SparseArray`. Now a tuple of `SparseArray` is returned (GH26946).

## Build changes

- Fix install error with PyPy on macOS (GH26536)

## ExtensionArray

- Bug in `factorize()` when passing an `ExtensionArray` with a custom `na_sentinel` (GH25696).
- `Series.count()` miscounts NA values in `ExtensionArrays` (GH26835)
- Added `Series.__array_ufunc__` to better handle NumPy ufuncs applied to `Series` backed by extension arrays (GH23293).
- Keyword argument `deep` has been removed from `ExtensionArray.copy()` (GH27083)

## Other

- Removed unused C functions from vendored UltraJSON implementation (GH26198)
- Allow `Index` and `RangeIndex` to be passed to `numpy.min` and `numpy.max` functions (GH26125)
- Use actual class name in repr of empty objects of a `Series` subclass (GH27001).
- Bug in `DataFrame` where passing an object array of timezone-aware `datetime` objects would incorrectly raise `ValueError` (GH13287)

## Contributors

A total of 231 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

## 5.6 Version 0.24

### 5.6.1 What's new in 0.24.2 (March 12, 2019)

**Warning:** The 0.24.x series of releases will be the last to support Python 2. Future feature releases will support Python 3 only. See [Dropping Python 2.7](#) for more.

These are the changes in pandas 0.24.2. See [Release notes](#) for a full changelog including other versions of pandas.

#### Fixed regressions

- Fixed regression in `DataFrame.all()` and `DataFrame.any()` where `bool_only=True` was ignored (GH25101)
- Fixed issue in `DataFrame` construction with passing a mixed list of mixed types could segfault. (GH25075)
- Fixed regression in `DataFrame.apply()` causing `RecursionError` when dict-like classes were passed as argument. (GH25196)
- Fixed regression in `DataFrame.replace()` where `regex=True` was only replacing patterns matching the start of the string (GH25259)
- Fixed regression in `DataFrame.duplicated()`, where empty dataframe was not returning a boolean dtyped Series. (GH25184)
- Fixed regression in `Series.min()` and `Series.max()` where `numeric_only=True` was ignored when the Series contained Categorical data (GH25299)
- Fixed regression in subtraction between `Series` objects with `datetime64[ns]` dtype incorrectly raising `OverflowError` when the Series on the right contains null values (GH25317)
- Fixed regression in `TimedeltaIndex` where `np.sum(index)` incorrectly returned a zero-dimensional object instead of a scalar (GH25282)
- Fixed regression in `IntervalDtype` construction where passing an incorrect string with 'Interval' as a prefix could result in a `RecursionError`. (GH25338)
- Fixed regression in creating a period-dtype array from a read-only NumPy array of period objects. (GH25403)

- Fixed regression in `Categorical`, where constructing it from a categorical Series and an explicit `categories=` that differed from that in the Series created an invalid object which could trigger segfaults. (GH25318)
- Fixed regression in `to_timedelta()` losing precision when converting floating data to Timedelta data (GH25077).
- Fixed pip installing from source into an environment without NumPy (GH25193)
- Fixed regression in `DataFrame.replace()` where large strings of numbers would be coerced into `int64`, causing an `OverflowError` (GH25616)
- Fixed regression in `factorize()` when passing a custom `na_sentinel` value with `sort=True` (GH25409).
- Fixed regression in `DataFrame.to_csv()` writing duplicate line endings with gzip compress (GH25311)

## Bug fixes

### I/O

- Better handling of terminal printing when the terminal dimensions are not known (GH25080)
- Bug in reading a HDF5 table-format DataFrame created in Python 2, in Python 3 (GH24925)
- Bug in reading a JSON with `orient='table'` generated by `DataFrame.to_json()` with `index=False` (GH25170)
- Bug where float indexes could have misaligned values when printing (GH25061)

### Categorical

- Bug where calling `Series.replace()` on categorical data could return a Series with incorrect dimensions (GH24971)
- 

### Reshaping

- Bug in `transform()` where applying a function to a timezone aware column would return a timezone naive result (GH24198)
- Bug in `DataFrame.join()` when joining on a timezone aware `DatetimeIndex` (GH23931)

### Visualization

- Bug in `Series.plot()` where a secondary y axis could not be set to log scale (GH25545)

### Other

- Bug in `Series.is_unique()` where single occurrences of NaN were not considered unique (GH25180)
- Bug in `merge()` when merging an empty DataFrame with an `Int64` column or a non-empty DataFrame with an `Int64` column that is all NaN (GH25183)
- Bug in `IntervalTree` where a `RecursionError` occurs upon construction due to an overflow when adding endpoints, which also causes `IntervalIndex` to crash during indexing operations (GH25485)
- Bug in `Series.size` raising for some extension-array-backed Series, rather than returning the size (GH25580)
- Bug in resampling raising for nullable integer-dtype columns (GH25580)

## 5.6.2 What's new in 0.24.1 (February 3, 2019)

**Warning:** The 0.24.x series of releases will be the last to support Python 2. Future feature releases will support Python 3 only. See [Dropping Python 2.7](#) for more.

These are the changes in pandas 0.24.1. See [Release notes](#) for a full changelog including other versions of pandas. See [What's new in 0.24.0 \(January 25, 2019\)](#) for the 0.24.0 changelog.

### API changes

#### Changing the sort parameter for Index set operations

The default `sort` value for `Index.union()` has changed from `True` to `None` (GH24959). The default *behavior*, however, remains the same: the result is sorted, unless

1. `self` and `other` are identical
2. `self` or `other` is empty
3. `self` or `other` contain values that can not be compared (a `RuntimeWarning` is raised).

This change will allow `sort=True` to mean “always sort” in a future release.

The same change applies to `Index.difference()` and `Index.symmetric_difference()`, which would not sort the result when the values could not be compared.

The `sort` option for `Index.intersection()` has changed in three ways.

1. The default has changed from `True` to `False`, to restore the pandas 0.23.4 and earlier behavior of not sorting by default.
2. The behavior of `sort=True` can now be obtained with `sort=None`. This will sort the result only if the values in `self` and `other` are not identical.
3. The value `sort=True` is no longer allowed. A future version of pandas will properly support `sort=True` meaning “always sort”.

### Fixed regressions

- Fixed regression in `DataFrame.to_dict()` with `records` orient raising an `AttributeError` when the `DataFrame` contained more than 255 columns, or wrongly converting column names that were not valid python identifiers (GH24939, GH24940).
- Fixed regression in `read_sql()` when passing certain queries with MySQL/pymysql (GH24988).
- Fixed regression in `Index.intersection` incorrectly sorting the values by default (GH24959).
- Fixed regression in `merge()` when merging an empty `DataFrame` with multiple timezone-aware columns on one of the timezone-aware columns (GH25014).
- Fixed regression in `Series.rename_axis()` and `DataFrame.rename_axis()` where passing `None` failed to remove the axis name (GH25034)
- Fixed regression in `to_timedelta()` with `box=False` incorrectly returning a `datetime64` object instead of a `timedelta64` object (GH24961)
- Fixed regression where custom hashable types could not be used as column keys in `DataFrame.set_index()` (GH24969)

## Bug fixes

### Reshaping

- Bug in `DataFrame.groupby()` with `Groupby` when there is a time change (DST) and grouping frequency is '1d' (GH24972)

### Visualization

- Fixed the warning for implicitly registered matplotlib converters not showing. See [Restore Matplotlib datetime converter registration](#) for more (GH24963).

### Other

- Fixed `AttributeError` when printing a `DataFrame`'s HTML repr after accessing the IPython config object (GH25036)

## Contributors

A total of 7 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

## 5.6.3 What's new in 0.24.0 (January 25, 2019)

**Warning:** The 0.24.x series of releases will be the last to support Python 2. Future feature releases will support Python 3 only. See [Dropping Python 2.7](#) for more details.

This is a major release from 0.23.4 and includes a number of API changes, new features, enhancements, and performance improvements along with a large number of bug fixes.

Highlights include:

- *Optional Integer NA Support*
- *New APIs for accessing the array backing a Series or Index*
- *A new top-level method for creating arrays*
- *Store Interval and Period data in a Series or DataFrame*
- *Support for joining on two MultiIndexes*

Check the *API Changes* and *deprecations* before updating.

These are the changes in pandas 0.24.0. See [Release notes](#) for a full changelog including other versions of pandas.

## Enhancements

### Optional integer NA support

pandas has gained the ability to hold integer dtypes with missing values. This long requested feature is enabled through the use of *extension types*.

---

**Note:** IntegerArray is currently experimental. Its API or implementation may change without warning.

---

We can construct a `Series` with the specified dtype. The dtype string `Int64` is a pandas `ExtensionDtype`. Specifying a list or array using the traditional missing value marker of `np.nan` will infer to integer dtype. The display of the `Series` will also use the `NaN` to indicate missing values in string outputs. (GH20700, GH20747, GH22441, GH21789, GH22346)

```
In [1]: s = pd.Series([1, 2, np.nan], dtype='Int64')

In [2]: s
Out[2]:
0 1
1 2
2 <NA>
dtype: Int64
```

Operations on these dtypes will propagate `NaN` as other pandas operations.

```
arithmetic
In [3]: s + 1
Out[3]:
0 2
1 3
2 <NA>
dtype: Int64

comparison
In [4]: s == 1
Out[4]:
0 True
1 False
2 <NA>
dtype: boolean

indexing
In [5]: s.iloc[1:3]
Out[5]:
1 2
2 <NA>
dtype: Int64

operate with other dtypes
In [6]: s + s.iloc[1:3].astype('Int8')
Out[6]:
0 <NA>
```

(continues on next page)

(continued from previous page)

```

1 4
2 <NA>
dtype: Int64

coerce when needed
In [7]: s + 0.01
Out[7]:
0 1.01
1 2.01
2 <NA>
dtype: Float64

```

These dtypes can operate as part of a DataFrame.

```

In [8]: df = pd.DataFrame({'A': s, 'B': [1, 1, 3], 'C': list('aab')})

In [9]: df
Out[9]:
 A B C
0 1 1 a
1 2 1 a
2 <NA> 3 b

In [10]: df.dtypes
Out[10]:
A Int64
B int64
C object
dtype: object

```

These dtypes can be merged, reshaped, and casted.

```

In [11]: pd.concat([df[['A']], df[['B', 'C']], axis=1).dtypes
Out[11]:
A Int64
B int64
C object
dtype: object

In [12]: df['A'].astype(float)
Out[12]:
0 1.0
1 2.0
2 NaN
Name: A, dtype: float64

```

Reduction and groupby operations such as `sum` work.

```

In [13]: df.sum()
Out[13]:
A 3
B 5
C aab

```

(continues on next page)

(continued from previous page)

dtype: object

**In [14]:** df.groupby('B').A.sum()**Out[14]:**

B

1 3

3 0

Name: A, dtype: Int64

**Warning:** The Integer NA support currently uses the capitalized dtype version, e.g. Int8 as compared to the traditional int8. This may be changed at a future date.

See *Nullable integer data type* for more.

## Accessing the values in a Series or Index

`Series.array` and `Index.array` have been added for extracting the array backing a Series or Index. (GH19954, GH23623)

**In [15]:** idx = pd.period\_range('2000', periods=4)**In [16]:** idx.array**Out[16]:**

&lt;PeriodArray&gt;

['2000-01-01', '2000-01-02', '2000-01-03', '2000-01-04']

Length: 4, dtype: period[D]

**In [17]:** pd.Series(idx).array**Out[17]:**

&lt;PeriodArray&gt;

['2000-01-01', '2000-01-02', '2000-01-03', '2000-01-04']

Length: 4, dtype: period[D]

Historically, this would have been done with `series.values`, but with `.values` it was unclear whether the returned value would be the actual array, some transformation of it, or one of pandas custom arrays (like Categorical). For example, with `PeriodIndex`, `.values` generates a new ndarray of period objects each time.

**In [18]:** idx.values**Out[18]:**array([Period('2000-01-01', 'D'), Period('2000-01-02', 'D'),  
Period('2000-01-03', 'D'), Period('2000-01-04', 'D')], dtype=object)**In [19]:** id(idx.values)**Out[19]:** 139800454065296**In [20]:** id(idx.values)**Out[20]:** 139800454065296

If you need an actual NumPy array, use `Series.to_numpy()` or `Index.to_numpy()`.

```
In [21]: idx.to_numpy()
Out[21]:
array([Period('2000-01-01', 'D'), Period('2000-01-02', 'D'),
 Period('2000-01-03', 'D'), Period('2000-01-04', 'D')], dtype=object)

In [22]: pd.Series(idx).to_numpy()
Out[22]:
array([Period('2000-01-01', 'D'), Period('2000-01-02', 'D'),
 Period('2000-01-03', 'D'), Period('2000-01-04', 'D')], dtype=object)
```

For Series and Indexes backed by normal NumPy arrays, `Series.array` will return a new `arrays.PandasArray`, which is a thin (no-copy) wrapper around a `numpy.ndarray`. `PandasArray` isn't especially useful on its own, but it does provide the same interface as any extension array defined in pandas or by a third-party library.

```
In [23]: ser = pd.Series([1, 2, 3])

In [24]: ser.array
Out[24]:
<PandasArray>
[1, 2, 3]
Length: 3, dtype: int64

In [25]: ser.to_numpy()
Out[25]: array([1, 2, 3])
```

We haven't removed or deprecated `Series.values` or `DataFrame.values`, but we highly recommend and using `.array` or `.to_numpy()` instead.

See *Dtypes* and *Attributes and Underlying Data* for more.

### pandas.array: a new top-level method for creating arrays

A new top-level method `array()` has been added for creating 1-dimensional arrays (GH22860). This can be used to create any *extension array*, including extension arrays registered by 3rd party libraries. See the *dtypes docs* for more on extension arrays.

```
In [26]: pd.array([1, 2, np.nan], dtype='Int64')
Out[26]:
<IntegerArray>
[1, 2, <NA>]
Length: 3, dtype: Int64

In [27]: pd.array(['a', 'b', 'c'], dtype='category')
Out[27]:
['a', 'b', 'c']
Categories (3, object): ['a', 'b', 'c']
```

Passing data for which there isn't dedicated extension type (e.g. float, integer, etc.) will return a new `arrays.PandasArray`, which is just a thin (no-copy) wrapper around a `numpy.ndarray` that satisfies the pandas extension array interface.

```
In [28]: pd.array([1, 2, 3])
Out[28]:
```

(continues on next page)

(continued from previous page)

```
<IntegerArray>
[1, 2, 3]
Length: 3, dtype: Int64
```

On their own, a *PandasArray* isn't a very useful object. But if you need write low-level code that works generically for any *ExtensionArray*, *PandasArray* satisfies that need.

Notice that by default, if no *dtype* is specified, the *dtype* of the returned array is inferred from the data. In particular, note that the first example of `[1, 2, np.nan]` would have returned a floating-point array, since `NaN` is a float.

```
In [29]: pd.array([1, 2, np.nan])
Out[29]:
<IntegerArray>
[1, 2, <NA>]
Length: 3, dtype: Int64
```

## Storing Interval and Period data in Series and DataFrame

*Interval* and *Period* data may now be stored in a *Series* or *DataFrame*, in addition to an *IntervalIndex* and *PeriodIndex* like previously (GH19453, GH22862).

```
In [30]: ser = pd.Series(pd.interval_range(0, 5))
```

```
In [31]: ser
Out[31]:
0 (0, 1]
1 (1, 2]
2 (2, 3]
3 (3, 4]
4 (4, 5]
dtype: interval
```

```
In [32]: ser.dtype
Out[32]: interval[int64, right]
```

For periods:

```
In [33]: pser = pd.Series(pd.period_range("2000", freq="D", periods=5))
```

```
In [34]: pser
Out[34]:
0 2000-01-01
1 2000-01-02
2 2000-01-03
3 2000-01-04
4 2000-01-05
dtype: period[D]
```

```
In [35]: pser.dtype
Out[35]: period[D]
```

Previously, these would be cast to a NumPy array with object dtype. In general, this should result in better performance when storing an array of intervals or periods in a *Series* or column of a *DataFrame*.

Use *Series.array* to extract the underlying array of intervals or periods from the Series:

```
In [36]: ser.array
Out[36]:
<IntervalArray>
[[0, 1], (1, 2], (2, 3], (3, 4], (4, 5]]
Length: 5, dtype: interval[int64, right]

In [37]: pser.array
Out[37]:
<PeriodArray>
['2000-01-01', '2000-01-02', '2000-01-03', '2000-01-04', '2000-01-05']
Length: 5, dtype: period[D]
```

These return an instance of *arrays.IntervalArray* or *arrays.PeriodArray*, the new extension arrays that back interval and period data.

**Warning:** For backwards compatibility, *Series.values* continues to return a NumPy array of objects for Interval and Period data. We recommend using *Series.array* when you need the array of data stored in the Series, and *Series.to\_numpy()* when you know you need a NumPy array.

See *Dtypes* and *Attributes and Underlying Data* for more.

## Joining with two multi-indexes

*DataFrame.merge()* and *DataFrame.join()* can now be used to join multi-indexed Dataframe instances on the overlapping index levels (GH6360)

See the *Merge, join, and concatenate* documentation section.

```
In [38]: index_left = pd.MultiIndex.from_tuples([('K0', 'X0'), ('K0', 'X1'),
.....: ('K1', 'X2')],
.....: names=['key', 'X'])
.....:

In [39]: left = pd.DataFrame({'A': ['A0', 'A1', 'A2'],
.....: 'B': ['B0', 'B1', 'B2']}, index=index_left)
.....:

In [40]: index_right = pd.MultiIndex.from_tuples([('K0', 'Y0'), ('K1', 'Y1'),
.....: ('K2', 'Y2'), ('K2', 'Y3')],
.....: names=['key', 'Y'])
.....:

In [41]: right = pd.DataFrame({'C': ['C0', 'C1', 'C2', 'C3'],
.....: 'D': ['D0', 'D1', 'D2', 'D3']}, index=index_right)
.....:

In [42]: left.join(right)
Out[42]:
```

(continues on next page)

(continued from previous page)

```

 A B C D
key X Y
K0 X0 Y0 A0 B0 C0 D0
 X1 Y0 A1 B1 C0 D0
K1 X2 Y1 A2 B2 C1 D1

```

For earlier versions this can be done using the following.

```

In [43]: pd.merge(left.reset_index(), right.reset_index(),
.....: on=['key'], how='inner').set_index(['key', 'X', 'Y'])
.....:

```

```

Out[43]:
 A B C D
key X Y
K0 X0 Y0 A0 B0 C0 D0
 X1 Y0 A1 B1 C0 D0
K1 X2 Y1 A2 B2 C1 D1

```

### Function `read_html` enhancements

`read_html()` previously ignored `colspan` and `rowspan` attributes. Now it understands them, treating them as sequences of cells with the same value. (GH17054)

```

In [44]: result = pd.read_html("""
.....: <table>
.....: <thead>
.....: <tr>
.....: <th>A</th><th>B</th><th>C</th>
.....: </tr>
.....: </thead>
.....: <tbody>
.....: <tr>
.....: <td colspan="2">1</td><td>2</td>
.....: </tr>
.....: </tbody>
.....: </table>""")
.....:

```

*Previous behavior:*

```

In [13]: result
Out [13]:
[A B C
0 1 2 NaN]

```

*New behavior:*

```

In [45]: result
Out[45]:
[A B C
0 1 1 2]

```

## New Styler.pipe() method

The *Styler* class has gained a *pipe()* method. This provides a convenient way to apply users' predefined styling functions, and can help reduce "boilerplate" when using DataFrame styling functionality repeatedly within a notebook. (GH23229)

```
In [46]: df = pd.DataFrame({'N': [1250, 1500, 1750], 'X': [0.25, 0.35, 0.50]})
In [47]: def format_and_align(styler):
.....: return (styler.format({'N': '{:,}', 'X': '{:.1%}'})
.....: .set_properties(**{'text-align': 'right'}))
.....:
In [48]: df.style.pipe(format_and_align).set_caption('Summary of results.')
Out[48]: <pandas.io.formats.style.Styler at 0x7f25d456e760>
```

Similar methods already exist for other classes in pandas, including *DataFrame.pipe()*, *GroupBy.pipe()*, and *Resampler.pipe()*.

## Renaming names in a MultiIndex

*DataFrame.rename\_axis()* now supports index and columns arguments and *Series.rename\_axis()* supports index argument (GH19978).

This change allows a dictionary to be passed so that some of the names of a MultiIndex can be changed.

Example:

```
In [49]: mi = pd.MultiIndex.from_product([list('AB'), list('CD'), list('EF')],
.....: names=['AB', 'CD', 'EF'])
.....:
In [50]: df = pd.DataFrame(list(range(len(mi))), index=mi, columns=['N'])

In [51]: df
Out[51]:
 N
AB CD EF
A C E 0
 F 1
 D E 2
 F 3
B C E 4
 F 5
 D E 6
 F 7

In [52]: df.rename_axis(index={'CD': 'New'})
Out[52]:
 N
AB New EF
A C E 0
 F 1
```

(continues on next page)

(continued from previous page)

|   |   |   |   |
|---|---|---|---|
|   | D | E | 2 |
|   |   | F | 3 |
| B | C | E | 4 |
|   |   | F | 5 |
|   | D | E | 6 |
|   |   | F | 7 |

See the *Advanced documentation on renaming* for more details.

## Other enhancements

- `merge()` now directly allows merge between objects of type `DataFrame` and named `Series`, without the need to convert the `Series` object into a `DataFrame` beforehand (GH21220)
- `ExcelWriter` now accepts `mode` as a keyword argument, enabling append to existing workbooks when using the `openpyxl` engine (GH3441)
- `FrozenList` has gained the `.union()` and `.difference()` methods. This functionality greatly simplifies `groupby`'s that rely on explicitly excluding certain columns. See *Splitting an object into groups* for more information (GH15475, GH15506).
- `DataFrame.to_parquet()` now accepts `index` as an argument, allowing the user to override the engine's default behavior to include or omit the dataframe's indexes from the resulting Parquet file. (GH20768)
- `read_feather()` now accepts `columns` as an argument, allowing the user to specify which columns should be read. (GH24025)
- `DataFrame.corr()` and `Series.corr()` now accept a callable for generic calculation methods of correlation, e.g. histogram intersection (GH22684)
- `DataFrame.to_string()` now accepts `decimal` as an argument, allowing the user to specify which decimal separator should be used in the output. (GH23614)
- `DataFrame.to_html()` now accepts `render_links` as an argument, allowing the user to generate HTML with links to any URLs that appear in the `DataFrame`. See the *section on writing HTML* in the IO docs for example usage. (GH2679)
- `pandas.read_csv()` now supports pandas extension types as an argument to `dtype`, allowing the user to use pandas extension types when reading CSVs. (GH23228)
- The `shift()` method now accepts `fill_value` as an argument, allowing the user to specify a value which will be used instead of `NA/NaT` in the empty periods. (GH15486)
- `to_datetime()` now supports the `%Z` and `%z` directive when passed into `format` (GH13486)
- `Series.mode()` and `DataFrame.mode()` now support the `dropna` parameter which can be used to specify whether `NaN/NaT` values should be considered (GH17534)
- `DataFrame.to_csv()` and `Series.to_csv()` now support the `compression` keyword when a file handle is passed. (GH21227)
- `Index.droplevel()` is now implemented also for flat indexes, for compatibility with `MultiIndex` (GH21115)
- `Series.droplevel()` and `DataFrame.droplevel()` are now implemented (GH20342)
- Added support for reading from/writing to Google Cloud Storage via the `gcsfs` library (GH19454, GH23094)
- `DataFrame.to_gbq()` and `read_gbq()` signature and documentation updated to reflect changes from the `pandas-gbq` library version 0.8.0. Adds a `credentials` argument, which enables the use of any kind of `google-auth` credentials. (GH21627, GH22557, GH23662)

- New method `HDFStore.walk()` will recursively walk the group hierarchy of an HDF5 file (GH10932)
- `read_html()` copies cell data across colspan and rowspan, and it treats all-th table rows as headers if header kwarg is not given and there is no thead (GH17054)
- `Series.nlargest()`, `Series.nsmallest()`, `DataFrame.nlargest()`, and `DataFrame.nsmallest()` now accept the value "all" for the keep argument. This keeps all ties for the nth largest/smallest value (GH16818)
- `IntervalIndex` has gained the `set_closed()` method to change the existing closed value (GH21670)
- `to_csv()`, `to_csv()`, `to_json()`, and `to_json()` now support `compression='infer'` to infer compression based on filename extension (GH15008). The default compression for `to_csv`, `to_json`, and `to_pickle` methods has been updated to 'infer' (GH22004).
- `DataFrame.to_sql()` now supports writing `TIMESTAMP WITH TIME ZONE` types for supported databases. For databases that don't support timezones, datetime data will be stored as timezone unaware local timestamps. See the *Datetime data types* for implications (GH9086).
- `to_timedelta()` now supports iso-formatted timedelta strings (GH21877)
- `Series` and `DataFrame` now support Iterable objects in the constructor (GH2193)
- `DatetimeIndex` has gained the `DatetimeIndex.timetz` attribute. This returns the local time with timezone information. (GH21358)
- `round()`, `ceil()`, and `floor()` for `DatetimeIndex` and `Timestamp` now support an `ambiguous` argument for handling datetimes that are rounded to ambiguous times (GH18946) and a `nonexistent` argument for handling datetimes that are rounded to nonexistent times. See *Nonexistent times when localizing* (GH22647)
- The result of `resample()` is now iterable similar to `groupby()` (GH15314).
- `Series.resample()` and `DataFrame.resample()` have gained the `pandas.core.resample.Resampler.quantile()` (GH15023).
- `DataFrame.resample()` and `Series.resample()` with a `PeriodIndex` will now respect the `base` argument in the same fashion as with a `DatetimeIndex`. (GH23882)
- `pandas.api.types.is_list_like()` has gained a keyword `allow_sets` which is True by default; if False, all instances of `set` will not be considered "list-like" anymore (GH23061)
- `Index.to_frame()` now supports overriding column name(s) (GH22580).
- `Categorical.from_codes()` now can take a `dtype` parameter as an alternative to passing `categories` and `ordered` (GH24398).
- New attribute `__git_version__` will return git commit sha of current build (GH21295).
- Compatibility with Matplotlib 3.0 (GH22790).
- Added `Interval.overlaps()`, `arrays.IntervalArray.overlaps()`, and `IntervalIndex.overlaps()` for determining overlaps between interval-like objects (GH21998)
- `read_fwf()` now accepts keyword `infer_nrows` (GH15138).
- `to_parquet()` now supports writing a `DataFrame` as a directory of parquet files partitioned by a subset of the columns when `engine = 'pyarrow'` (GH23283)
- `Timestamp.tz_localize()`, `DatetimeIndex.tz_localize()`, and `Series.tz_localize()` have gained the `nonexistent` argument for alternative handling of nonexistent times. See *Nonexistent times when localizing* (GH8917, GH24466)
- `Index.difference()`, `Index.intersection()`, `Index.union()`, and `Index.symmetric_difference()` now have an optional `sort` parameter to control whether the results should be sorted if possible (GH17839, GH24471)

- `read_excel()` now accepts `usecols` as a list of column names or callable (GH18273)
- `MultiIndex.to_flat_index()` has been added to flatten multiple levels into a single-level `Index` object.
- `DataFrame.to_stata()` and `pandas.io.stata.StataWriter117` can write mixed string columns to Stata `strl` format (GH23633)
- `DataFrame.between_time()` and `DataFrame.at_time()` have gained the `axis` parameter (GH8839)
- `DataFrame.to_records()` now accepts `index_dtypes` and `column_dtypes` parameters to allow different data types in stored column and index records (GH18146)
- `IntervalIndex` has gained the `is_overlapping` attribute to indicate if the `IntervalIndex` contains any overlapping intervals (GH23309)
- `pandas.DataFrame.to_sql()` has gained the `method` argument to control SQL insertion clause. See the *insertion method* section in the documentation. (GH8953)
- `DataFrame.corrwith()` now supports Spearman's rank correlation, Kendall's tau as well as callable correlation methods. (GH21925)
- `DataFrame.to_json()`, `DataFrame.to_csv()`, `DataFrame.to_pickle()`, and other export methods now support tilde(~) in path argument. (GH23473)

### Backwards incompatible API changes

pandas 0.24.0 includes a number of API breaking changes.

### Increased minimum versions for dependencies

We have updated our minimum supported versions of dependencies (GH21242, GH18742, GH23774, GH24767). If installed, we now require:

| Package      | Minimum Version | Required |
|--------------|-----------------|----------|
| numpy        | 1.12.0          | X        |
| bottleneck   | 1.2.0           |          |
| fastparquet  | 0.2.1           |          |
| matplotlib   | 2.0.0           |          |
| numexpr      | 2.6.1           |          |
| pandas-gbq   | 0.8.0           |          |
| pyarrow      | 0.9.0           |          |
| pytables     | 3.4.2           |          |
| scipy        | 0.18.1          |          |
| xlrd         | 1.0.0           |          |
| pytest (dev) | 3.6             |          |

Additionally we no longer depend on `feather-format` for feather based storage and replaced it with references to `pyarrow` (GH21639 and GH23053).

### os.linesep is used for line\_terminator of DataFrame.to\_csv

`DataFrame.to_csv()` now uses `os.linesep()` rather than `'\n'` for the default line terminator (GH20353). This change only affects when running on Windows, where `'\r\n'` was used for line terminator even when `'\n'` was passed in `line_terminator`.

*Previous behavior on Windows:*

```
In [1]: data = pd.DataFrame({"string_with_lf": ["a\nbc"],
...: "string_with_crlf": ["a\r\nbc"]})

In [2]: # When passing file PATH to to_csv,
...: # line_terminator does not work, and csv is saved with '\r\n'.
...: # Also, this converts all '\n's in the data to '\r\n'.
...: data.to_csv("test.csv", index=False, line_terminator='\n')

In [3]: with open("test.csv", mode='rb') as f:
...: print(f.read())
Out[3]: b'string_with_lf,string_with_crlf\r\n"a\r\nbc","a\r\nbc"\r\n'

In [4]: # When passing file OBJECT with newline option to
...: # to_csv, line_terminator works.
...: with open("test2.csv", mode='w', newline='\n') as f:
...: data.to_csv(f, index=False, line_terminator='\n')

In [5]: with open("test2.csv", mode='rb') as f:
...: print(f.read())
Out[5]: b'string_with_lf,string_with_crlf\n"a\nbc","a\r\nbc"\n'
```

*New behavior on Windows:*

Passing `line_terminator` explicitly, set the line terminator to that character.

```
In [1]: data = pd.DataFrame({"string_with_lf": ["a\nbc"],
...: "string_with_crlf": ["a\r\nbc"]})

In [2]: data.to_csv("test.csv", index=False, line_terminator='\n')

In [3]: with open("test.csv", mode='rb') as f:
...: print(f.read())
Out[3]: b'string_with_lf,string_with_crlf\n"a\nbc","a\r\nbc"\n'
```

On Windows, the value of `os.linesep` is `'\r\n'`, so if `line_terminator` is not set, `'\r\n'` is used for line terminator.

```
In [1]: data = pd.DataFrame({"string_with_lf": ["a\nbc"],
...: "string_with_crlf": ["a\r\nbc"]})

In [2]: data.to_csv("test.csv", index=False)

In [3]: with open("test.csv", mode='rb') as f:
...: print(f.read())
Out[3]: b'string_with_lf,string_with_crlf\r\n"a\nbc","a\r\nbc"\r\n'
```

For file objects, specifying `newline` is not sufficient to set the line terminator. You must pass in the `line_terminator`

explicitly, even in this case.

```
In [1]: data = pd.DataFrame({"string_with_lf": ["a\nbc"],
...: "string_with_crlf": ["a\r\nbc"]})

In [2]: with open("test2.csv", mode='w', newline='\n') as f:
...: data.to_csv(f, index=False)

In [3]: with open("test2.csv", mode='rb') as f:
...: print(f.read())
Out[3]: b'string_with_lf,string_with_crlf\r\n"a\nbc","a\r\nbc"\r\n'
```

### Proper handling of np.NaN in a string data-typed column with the Python engine

There was bug in `read_excel()` and `read_csv()` with the Python engine, where missing values turned to 'nan' with `dtype=str` and `na_filter=True`. Now, these missing values are converted to the string missing indicator, `np.nan`. (GH20377)

*Previous behavior:*

```
In [5]: data = 'a,b,c\n1,,3\n4,5,6'
In [6]: df = pd.read_csv(StringIO(data), engine='python', dtype=str, na_filter=True)
In [7]: df.loc[0, 'b']
Out[7]:
'nan'
```

*New behavior:*

```
In [53]: data = 'a,b,c\n1,,3\n4,5,6'

In [54]: df = pd.read_csv(StringIO(data), engine='python', dtype=str, na_filter=True)

In [55]: df.loc[0, 'b']
Out[55]: nan
```

Notice how we now instead output `np.nan` itself instead of a stringified form of it.

### Parsing datetime strings with timezone offsets

Previously, parsing datetime strings with UTC offsets with `to_datetime()` or `DatetimeIndex` would automatically convert the datetime to UTC without timezone localization. This is inconsistent from parsing the same datetime string with `Timestamp` which would preserve the UTC offset in the `tz` attribute. Now, `to_datetime()` preserves the UTC offset in the `tz` attribute when all the datetime strings have the same UTC offset (GH17697, GH11736, GH22457)

*Previous behavior:*

```
In [2]: pd.to_datetime("2015-11-18 15:30:00+05:30")
Out[2]: Timestamp('2015-11-18 10:00:00')

In [3]: pd.Timestamp("2015-11-18 15:30:00+05:30")
Out[3]: Timestamp('2015-11-18 15:30:00+0530', tz='pytz.FixedOffset(330)')
```

(continues on next page)

(continued from previous page)

```
Different UTC offsets would automatically convert the datetimes to UTC (without a UTC_
↳ timezone)
In [4]: pd.to_datetime(["2015-11-18 15:30:00+05:30", "2015-11-18 16:30:00+06:30"])
Out[4]: DatetimeIndex(['2015-11-18 10:00:00', '2015-11-18 10:00:00'], dtype=
↳ 'datetime64[ns]', freq=None)
```

*New behavior:*

```
In [56]: pd.to_datetime("2015-11-18 15:30:00+05:30")
Out[56]: Timestamp('2015-11-18 15:30:00+0530', tz='pytz.FixedOffset(330)')

In [57]: pd.Timestamp("2015-11-18 15:30:00+05:30")
Out[57]: Timestamp('2015-11-18 15:30:00+0530', tz='pytz.FixedOffset(330)')
```

Parsing datetime strings with the same UTC offset will preserve the UTC offset in the tz

```
In [58]: pd.to_datetime(["2015-11-18 15:30:00+05:30"] * 2)
Out[58]: DatetimeIndex(['2015-11-18 15:30:00+05:30', '2015-11-18 15:30:00+05:30'], dtype=
↳ 'datetime64[ns, pytz.FixedOffset(330)]', freq=None)
```

Parsing datetime strings with different UTC offsets will now create an Index of `datetime.datetime` objects with different UTC offsets

```
In [59]: idx = pd.to_datetime(["2015-11-18 15:30:00+05:30",
.....: "2015-11-18 16:30:00+06:30"])
.....:

In [60]: idx
Out[60]: Index([2015-11-18 15:30:00+05:30, 2015-11-18 16:30:00+06:30], dtype='object')

In [61]: idx[0]
Out[61]: datetime.datetime(2015, 11, 18, 15, 30, tzinfo=tzoffset(None, 19800))

In [62]: idx[1]
Out[62]: datetime.datetime(2015, 11, 18, 16, 30, tzinfo=tzoffset(None, 23400))
```

Passing `utc=True` will mimic the previous behavior but will correctly indicate that the dates have been converted to UTC

```
In [63]: pd.to_datetime(["2015-11-18 15:30:00+05:30",
.....: "2015-11-18 16:30:00+06:30"], utc=True)
.....:
Out[63]: DatetimeIndex(['2015-11-18 10:00:00+00:00', '2015-11-18 10:00:00+00:00'], dtype=
↳ 'datetime64[ns, UTC]', freq=None)
```

## Parsing mixed-timezones with read\_csv()

`read_csv()` no longer silently converts mixed-timezone columns to UTC (GH24987).

*Previous behavior*

```
>>> import io
>>> content = """\
... a
... 2000-01-01T00:00:00+05:00
... 2000-01-01T00:00:00+06:00"""
>>> df = pd.read_csv(io.StringIO(content), parse_dates=['a'])
>>> df.a
0 1999-12-31 19:00:00
1 1999-12-31 18:00:00
Name: a, dtype: datetime64[ns]
```

*New behavior*

```
In [64]: import io

In [65]: content = """\
.....: a
.....: 2000-01-01T00:00:00+05:00
.....: 2000-01-01T00:00:00+06:00"""
.....:

In [66]: df = pd.read_csv(io.StringIO(content), parse_dates=['a'])

In [67]: df.a
Out[67]:
0 2000-01-01 00:00:00+05:00
1 2000-01-01 00:00:00+06:00
Name: a, dtype: object
```

As can be seen, the dtype is object; each value in the column is a string. To convert the strings to an array of datetimes, the `date_parser` argument

```
In [68]: df = pd.read_csv(io.StringIO(content), parse_dates=['a'],
.....: date_parser=lambda col: pd.to_datetime(col, utc=True))
.....:

In [69]: df.a
Out[69]:
0 1999-12-31 19:00:00+00:00
1 1999-12-31 18:00:00+00:00
Name: a, dtype: datetime64[ns, UTC]
```

See *Parsing datetime strings with timezone offsets* for more.

### Time values in `dt.end_time` and `to_timestamp(how='end')`

The time values in `Period` and `PeriodIndex` objects are now set to '23:59:59.999999999' when calling `Series.dt.end_time`, `Period.end_time`, `PeriodIndex.end_time`, `Period.to_timestamp()` with `how='end'`, or `PeriodIndex.to_timestamp()` with `how='end'` (GH17157)

*Previous behavior:*

```
In [2]: p = pd.Period('2017-01-01', 'D')
In [3]: pi = pd.PeriodIndex([p])

In [4]: pd.Series(pi).dt.end_time[0]
Out[4]: Timestamp(2017-01-01 00:00:00)

In [5]: p.end_time
Out[5]: Timestamp(2017-01-01 23:59:59.999999999)
```

*New behavior:*

Calling `Series.dt.end_time` will now result in a time of '23:59:59.999999999' as is the case with `Period.end_time`, for example

```
In [70]: p = pd.Period('2017-01-01', 'D')
In [71]: pi = pd.PeriodIndex([p])

In [72]: pd.Series(pi).dt.end_time[0]
Out[72]: Timestamp('2017-01-01 23:59:59.999999999')

In [73]: p.end_time
Out[73]: Timestamp('2017-01-01 23:59:59.999999999')
```

### `Series.unique` for timezone-aware data

The return type of `Series.unique()` for datetime with timezone values has changed from an `numpy.ndarray` of `Timestamp` objects to a `arrays.DatetimeArray` (GH24024).

```
In [74]: ser = pd.Series([pd.Timestamp('2000', tz='UTC'),
.....: pd.Timestamp('2000', tz='UTC')])
.....:
```

*Previous behavior:*

```
In [3]: ser.unique()
Out[3]: array([Timestamp('2000-01-01 00:00:00+0000', tz='UTC')], dtype=object)
```

*New behavior:*

```
In [75]: ser.unique()
Out[75]:
<DatetimeArray>
['2000-01-01 00:00:00+00:00']
Length: 1, dtype: datetime64[ns, UTC]
```

## Sparse data structure refactor

`SparseArray`, the array backing `SparseSeries` and the columns in a `SparseDataFrame`, is now an extension array (GH21978, GH19056, GH22835). To conform to this interface and for consistency with the rest of pandas, some API breaking changes were made:

- `SparseArray` is no longer a subclass of `numpy.ndarray`. To convert a `SparseArray` to a NumPy array, use `numpy.asarray()`.
- `SparseArray.dtype` and `SparseSeries.dtype` are now instances of `SparseDtype`, rather than `np.dtype`. Access the underlying dtype with `SparseDtype.subtype`.
- `numpy.asarray(sparse_array)` now returns a dense array with all the values, not just the non-fill-value values (GH14167)
- `SparseArray.take` now matches the API of `pandas.api.extensions.ExtensionArray.take()` (GH19506):
  - The default value of `allow_fill` has changed from `False` to `True`.
  - The `out` and `mode` parameters are now longer accepted (previously, this raised if they were specified).
  - Passing a scalar for `indices` is no longer allowed.
- The result of `concat()` with a mix of sparse and dense Series is a Series with sparse values, rather than a `SparseSeries`.
- `SparseDataFrame.combine` and `DataFrame.combine_first` no longer supports combining a sparse column with a dense column while preserving the sparse subtype. The result will be an object-dtype `SparseArray`.
- Setting `SparseArray.fill_value` to a fill value with a different dtype is now allowed.
- `DataFrame[column]` is now a `Series` with sparse values, rather than a `SparseSeries`, when slicing a single column with sparse values (GH23559).
- The result of `Series.where()` is now a Series with sparse values, like with other extension arrays (GH24077)

Some new warnings are issued for operations that require or are likely to materialize a large dense array:

- A `errors.PerformanceWarning` is issued when using `fillna` with a method, as a dense array is constructed to create the filled array. Filling with a value is the efficient way to fill a sparse array.
- A `errors.PerformanceWarning` is now issued when concatenating sparse Series with differing fill values. The fill value from the first sparse array continues to be used.

In addition to these API breaking changes, many *Performance Improvements and Bug Fixes have been made*.

Finally, a `Series.sparse` accessor was added to provide sparse-specific methods like `Series.sparse.from_coo()`.

```
In [76]: s = pd.Series([0, 0, 1, 1, 1], dtype='Sparse[int]')
```

```
In [77]: s.sparse.density
```

```
Out[77]: 0.6
```

### `get_dummies()` always returns a `DataFrame`

Previously, when `sparse=True` was passed to `get_dummies()`, the return value could be either a `DataFrame` or a `SparseDataFrame`, depending on whether all or a just a subset of the columns were dummy-encoded. Now, a `DataFrame` is always returned (GH24284).

#### *Previous behavior*

The first `get_dummies()` returns a `DataFrame` because the column A is not dummy encoded. When just ["B", "C"] are passed to `get_dummies`, then all the columns are dummy-encoded, and a `SparseDataFrame` was returned.

```
In [2]: df = pd.DataFrame({"A": [1, 2], "B": ['a', 'b'], "C": ['a', 'a']})
```

```
In [3]: type(pd.get_dummies(df, sparse=True))
```

```
Out[3]: pandas.core.frame.DataFrame
```

```
In [4]: type(pd.get_dummies(df[['B', 'C']], sparse=True))
```

```
Out[4]: pandas.core.sparse.frame.SparseDataFrame
```

#### *New behavior*

Now, the return type is consistently a `DataFrame`.

```
In [78]: type(pd.get_dummies(df, sparse=True))
```

```
Out[78]: pandas.core.frame.DataFrame
```

```
In [79]: type(pd.get_dummies(df[['B', 'C']], sparse=True))
```

```
Out[79]: pandas.core.frame.DataFrame
```

---

**Note:** There's no difference in memory usage between a `SparseDataFrame` and a `DataFrame` with sparse values. The memory usage will be the same as in the previous version of pandas.

---

### Raise `ValueError` in `DataFrame.to_dict(orient='index')`

Bug in `DataFrame.to_dict()` raises `ValueError` when used with `orient='index'` and a non-unique index instead of losing data (GH22801)

```
In [80]: df = pd.DataFrame({'a': [1, 2], 'b': [0.5, 0.75]}, index=['A', 'A'])
```

```
In [81]: df
```

```
Out[81]:
```

```
 a b
A 1 0.50
A 2 0.75
```

```
In [82]: df.to_dict(orient='index')
```

```
ValueError Traceback (most recent call last)
```

```
<ipython-input-82-f5309a7c6adb> in <module>
```

```
----> 1 df.to_dict(orient='index')
```

```
/pandas/pandas/core/frame.py in to_dict(self, orient, into)
```

(continues on next page)

(continued from previous page)

```

1826 elif orient == "index":
1827 if not self.index.is_unique:
-> 1828 raise ValueError("DataFrame index must be unique for orient=
↪ 'index'.")
1829 return into_c(
1830 (t[0], dict(zip(self.columns, t[1:])))
ValueError: DataFrame index must be unique for orient='index'.

```

### Tick DateOffset normalize restrictions

Creating a Tick object (Day, Hour, Minute, Second, Milli, Micro, Nano) with `normalize=True` is no longer supported. This prevents unexpected behavior where addition could fail to be monotone or associative. (GH21427)

*Previous behavior:*

```

In [2]: ts = pd.Timestamp('2018-06-11 18:01:14')

In [3]: ts
Out[3]: Timestamp('2018-06-11 18:01:14')

In [4]: tic = pd.offsets.Hour(n=2, normalize=True)
 ...:

In [5]: tic
Out[5]: <2 * Hours>

In [6]: ts + tic
Out[6]: Timestamp('2018-06-11 00:00:00')

In [7]: ts + tic + tic + tic == ts + (tic + tic + tic)
Out[7]: False

```

*New behavior:*

```

In [83]: ts = pd.Timestamp('2018-06-11 18:01:14')

In [84]: tic = pd.offsets.Hour(n=2)

In [85]: ts + tic + tic + tic == ts + (tic + tic + tic)
Out[85]: True

```

## Period subtraction

Subtraction of a Period from another Period will give a DateOffset. instead of an integer (GH21314)

*Previous behavior:*

```
In [2]: june = pd.Period('June 2018')
In [3]: april = pd.Period('April 2018')
In [4]: june - april
Out [4]: 2
```

*New behavior:*

```
In [86]: june = pd.Period('June 2018')
In [87]: april = pd.Period('April 2018')
In [88]: june - april
Out[88]: <2 * MonthEnds>
```

Similarly, subtraction of a Period from a PeriodIndex will now return an Index of DateOffset objects instead of an Int64Index

*Previous behavior:*

```
In [2]: pi = pd.period_range('June 2018', freq='M', periods=3)
In [3]: pi - pi[0]
Out[3]: Int64Index([0, 1, 2], dtype='int64')
```

*New behavior:*

```
In [89]: pi = pd.period_range('June 2018', freq='M', periods=3)
In [90]: pi - pi[0]
Out[90]: Index([<0 * MonthEnds>, <MonthEnd>, <2 * MonthEnds>], dtype='object')
```

## Addition/subtraction of NaN from DataFrame

Adding or subtracting NaN from a *DataFrame* column with `timedelta64[ns]` dtype will now raise a `TypeError` instead of returning all-NaN. This is for compatibility with `TimedeltaIndex` and `Series` behavior (GH22163)

```
In [91]: df = pd.DataFrame([pd.Timedelta(days=1)])
In [92]: df
Out[92]:
 0
0 1 days
```

*Previous behavior:*

```
In [4]: df = pd.DataFrame([pd.Timedelta(days=1)])
```

```
In [5]: df - np.nan
```

```
Out[5]:
```

```
 0
0 NaT
```

*New behavior:*

```
In [2]: df - np.nan
```

```
...
```

```
TypeError: unsupported operand type(s) for -: 'TimedeltaIndex' and 'float'
```

## DataFrame comparison operations broadcasting changes

Previously, the broadcasting behavior of *DataFrame* comparison operations (`==`, `!=`, ...) was inconsistent with the behavior of arithmetic operations (`+`, `-`, ...). The behavior of the comparison operations has been changed to match the arithmetic operations in these cases. (GH22880)

The affected cases are:

- operating against a 2-dimensional `np.ndarray` with either 1 row or 1 column will now broadcast the same way a `np.ndarray` would (GH23000).
- a list or tuple with length matching the number of rows in the *DataFrame* will now raise `ValueError` instead of operating column-by-column (GH22880).
- a list or tuple with length matching the number of columns in the *DataFrame* will now operate row-by-row instead of raising `ValueError` (GH22880).

```
In [93]: arr = np.arange(6).reshape(3, 2)
```

```
In [94]: df = pd.DataFrame(arr)
```

```
In [95]: df
```

```
Out[95]:
```

```
 0 1
0 0 1
1 2 3
2 4 5
```

*Previous behavior:*

```
In [5]: df == arr[[0], :]
```

```
...: # comparison previously broadcast where arithmetic would raise
```

```
Out[5]:
```

```
 0 1
0 True True
1 False False
2 False False
```

```
In [6]: df + arr[[0], :]
```

```
...
```

```
ValueError: Unable to coerce to DataFrame, shape must be (3, 2): given (1, 2)
```

(continues on next page)

(continued from previous page)

```

In [7]: df == (1, 2)
...: # length matches number of columns;
...: # comparison previously raised where arithmetic would broadcast
...
ValueError: Invalid broadcasting comparison [(1, 2)] with block values
In [8]: df + (1, 2)
Out[8]:
 0 1
0 1 3
1 3 5
2 5 7

In [9]: df == (1, 2, 3)
...: # length matches number of rows
...: # comparison previously broadcast where arithmetic would raise
Out[9]:
 0 1
0 False True
1 True False
2 False False

In [10]: df + (1, 2, 3)
...
ValueError: Unable to coerce to Series, length must be 2: given 3

```

*New behavior:*

```

Comparison operations and arithmetic operations both broadcast.
In [96]: df == arr[[0], :]
Out[96]:
 0 1
0 True True
1 False False
2 False False

In [97]: df + arr[[0], :]
Out[97]:
 0 1
0 0 2
1 2 4
2 4 6

```

```

Comparison operations and arithmetic operations both broadcast.
In [98]: df == (1, 2)
Out[98]:
 0 1
0 False False
1 False False
2 False False

In [99]: df + (1, 2)
Out[99]:
 0 1
0 1 3

```

(continues on next page)

(continued from previous page)

```
0 1 3
1 3 5
2 5 7
```

```
Comparison operations and arithmetic operations both raise ValueError.
```

```
In [6]: df == (1, 2, 3)
```

```
...
```

```
ValueError: Unable to coerce to Series, length must be 2: given 3
```

```
In [7]: df + (1, 2, 3)
```

```
...
```

```
ValueError: Unable to coerce to Series, length must be 2: given 3
```

### DataFrame arithmetic operations broadcasting changes

`DataFrame` arithmetic operations when operating with 2-dimensional `np.ndarray` objects now broadcast in the same way as `np.ndarray` broadcast. (GH23000)

```
In [100]: arr = np.arange(6).reshape(3, 2)
```

```
In [101]: df = pd.DataFrame(arr)
```

```
In [102]: df
```

```
Out[102]:
```

```
 0 1
0 0 1
1 2 3
2 4 5
```

*Previous behavior:*

```
In [5]: df + arr[[0], :] # 1 row, 2 columns
```

```
...
```

```
ValueError: Unable to coerce to DataFrame, shape must be (3, 2): given (1, 2)
```

```
In [6]: df + arr[:, [1]] # 1 column, 3 rows
```

```
...
```

```
ValueError: Unable to coerce to DataFrame, shape must be (3, 2): given (3, 1)
```

*New behavior:*

```
In [103]: df + arr[[0], :] # 1 row, 2 columns
```

```
Out[103]:
```

```
 0 1
0 0 2
1 2 4
2 4 6
```

```
In [104]: df + arr[:, [1]] # 1 column, 3 rows
```

```
Out[104]:
```

```
 0 1
0 1 2
```

(continues on next page)

(continued from previous page)

```
1 5 6
2 9 10
```

### Series and Index data-dtype incompatibilities

Series and Index constructors now raise when the data is incompatible with a passed dtype= (GH15832)

*Previous behavior:*

```
In [4]: pd.Series([-1], dtype="uint64")
Out [4]:
0 18446744073709551615
dtype: uint64
```

*New behavior:*

```
In [4]: pd.Series([-1], dtype="uint64")
Out [4]:
...
OverflowError: Trying to coerce negative values to unsigned integers
```

### Concatenation changes

Calling `pandas.concat()` on a Categorical of ints with NA values now causes them to be processed as objects when concatenating with anything other than another Categorical of ints (GH19214)

```
In [105]: s = pd.Series([0, 1, np.nan])
In [106]: c = pd.Series([0, 1, np.nan], dtype="category")
```

*Previous behavior*

```
In [3]: pd.concat([s, c])
Out[3]:
0 0.0
1 1.0
2 NaN
0 0.0

## Datetimelike API changes

- For *DatetimeIndex* and *TimedeltaIndex* with non-None `freq` attribute, addition or subtraction of integer-typed array or *Index* will return an object of the same class (GH19959)
- *DateOffset* objects are now immutable. Attempting to alter one of these will now raise *AttributeError* (GH21341)
- *PeriodIndex* subtraction of another *PeriodIndex* will now return an object-dtype *Index* of *DateOffset* objects instead of raising a *TypeError* (GH20049)
- *cut()* and *qcut()* now returns a *DatetimeIndex* or *TimedeltaIndex* bins when the input is datetime or timedelta dtype respectively and `retbins=True` (GH19891)
- *DatetimeIndex.to\_period()* and *Timestamp.to\_period()* will issue a warning when timezone information will be lost (GH21333)
- *PeriodIndex.tz\_convert()* and *PeriodIndex.tz\_localize()* have been removed (GH21781)

## Other API changes

- A newly constructed empty *DataFrame* with integer as the dtype will now only be cast to float64 if index is specified (GH22858)
- *Series.str.cat()* will now raise if `others` is a set (GH23009)
- Passing scalar values to *DatetimeIndex* or *TimedeltaIndex* will now raise *TypeError* instead of *ValueError* (GH23539)
- `max_rows` and `max_cols` parameters removed from *HTMLFormatter* since truncation is handled by *DataFrameFormatter* (GH23818)
- *read\_csv()* will now raise a *ValueError* if a column with missing values is declared as having dtype bool (GH20591)
- The column order of the resultant *DataFrame* from *MultiIndex.to\_frame()* is now guaranteed to match the *MultiIndex.names* order. (GH22420)
- Incorrectly passing a *DatetimeIndex* to *MultiIndex.from\_tuples()*, rather than a sequence of tuples, now raises a *TypeError* rather than a *ValueError* (GH24024)
- `pd.offsets.generate_range()` argument `time_rule` has been removed; use `offset` instead (GH24157)
- In 0.23.x, pandas would raise a *ValueError* on a merge of a numeric column (e.g. `int` dtyped column) and an object dtyped column (GH9780). We have re-enabled the ability to merge object and other dtypes; pandas will still raise on a merge between a numeric and an object dtyped column that is composed only of strings (GH21681)
- Accessing a level of a *MultiIndex* with a duplicate name (e.g. in *get\_level\_values()*) now raises a *ValueError* instead of a *KeyError* (GH21678).
- Invalid construction of *IntervalDtype* will now always raise a *TypeError* rather than a *ValueError* if the subtype is invalid (GH21185)

- Trying to reindex a `DataFrame` with a non unique `MultiIndex` now raises a `ValueError` instead of an `Exception` (GH21770)
- `Index` subtraction will attempt to operate element-wise instead of raising `TypeError` (GH19369)
- `pandas.io.formats.style.Styler` supports a `number-format` property when using `to_excel()` (GH22015)
- `DataFrame.corr()` and `Series.corr()` now raise a `ValueError` along with a helpful error message instead of a `KeyError` when supplied with an invalid method (GH22298)
- `shift()` will now always return a copy, instead of the previous behaviour of returning self when shifting by 0 (GH22397)
- `DataFrame.set_index()` now gives a better (and less frequent) `KeyError`, raises a `ValueError` for incorrect types, and will not fail on duplicate column names with `drop=True`. (GH22484)
- Slicing a single row of a `DataFrame` with multiple `ExtensionArrays` of the same type now preserves the dtype, rather than coercing to object (GH22784)
- `DateOffset` attribute `_cacheable` and method `_should_cache` have been removed (GH23118)
- `Series.searchsorted()`, when supplied a scalar value to search for, now returns a scalar instead of an array (GH23801).
- `Categorical.searchsorted()`, when supplied a scalar value to search for, now returns a scalar instead of an array (GH23466).
- `Categorical.searchsorted()` now raises a `KeyError` rather than a `ValueError`, if a searched for key is not found in its categories (GH23466).
- `Index.hasnans()` and `Series.hasnans()` now always return a python boolean. Previously, a python or a numpy boolean could be returned, depending on circumstances (GH23294).
- The order of the arguments of `DataFrame.to_html()` and `DataFrame.to_string()` is rearranged to be consistent with each other. (GH23614)
- `CategoricalIndex.reindex()` now raises a `ValueError` if the target index is non-unique and not equal to the current index. It previously only raised if the target index was not of a categorical dtype (GH23963).
- `Series.to_list()` and `Index.to_list()` are now aliases of `Series.tolist` respectively `Index.tolist` (GH8826)
- The result of `SparseSeries.unstack` is now a `DataFrame` with sparse values, rather than a `SparseDataFrame` (GH24372).
- `DatetimeIndex` and `TimedeltaIndex` no longer ignore the dtype precision. Passing a non-nanosecond resolution dtype will raise a `ValueError` (GH24753)

## Extension type changes

### Equality and hashability

pandas now requires that extension dtypes be hashable (i.e. the respective `ExtensionDtype` objects; hashability is not a requirement for the values of the corresponding `ExtensionArray`). The base class implements a default `__eq__` and `__hash__`. If you have a parametrized dtype, you should update the `ExtensionDtype._metadata` tuple to match the signature of your `__init__` method. See `pandas.api.extensions.ExtensionDtype` for more (GH22476).

### New and changed methods

- `dropna()` has been added (GH21185)
- `repeat()` has been added (GH24349)

- The `ExtensionArray` constructor, `_from_sequence` now take the keyword arg `copy=False` (GH21185)
- `pandas.api.extensions.ExtensionArray.shift()` added as part of the basic `ExtensionArray` interface (GH22387).
- `searchsorted()` has been added (GH24350)
- Support for reduction operations such as `sum`, `mean` via opt-in base class method override (GH22762)
- `ExtensionArray.isna()` is allowed to return an `ExtensionArray` (GH22325).

### Dtype changes

- `ExtensionDtype` has gained the ability to instantiate from string dtypes, e.g. `decimal` would instantiate a registered `DecimalDtype`; furthermore the `ExtensionDtype` has gained the method `construct_array_type` (GH21185)
- Added `ExtensionDtype._is_numeric` for controlling whether an extension dtype is considered numeric (GH22290).
- Added `pandas.api.types.register_extension_dtype()` to register an extension type with pandas (GH22664)
- Updated the `.type` attribute for `PeriodDtype`, `DatetimeTZDtype`, and `IntervalDtype` to be instances of the dtype (`Period`, `Timestamp`, and `Interval` respectively) (GH22938)

### Operator support

A `Series` based on an `ExtensionArray` now supports arithmetic and comparison operators (GH19577). There are two approaches for providing operator support for an `ExtensionArray`:

1. Define each of the operators on your `ExtensionArray` subclass.
2. Use an operator implementation from pandas that depends on operators that are already defined on the underlying elements (scalars) of the `ExtensionArray`.

See the *ExtensionArray Operator Support* documentation section for details on both ways of adding operator support.

### Other changes

- A default repr for `pandas.api.extensions.ExtensionArray` is now provided (GH23601).
- `ExtensionArray._formatting_values()` is deprecated. Use `ExtensionArray._formatter` instead. (GH23601)
- An `ExtensionArray` with a boolean dtype now works correctly as a boolean indexer. `pandas.api.types.is_bool_dtype()` now properly considers them boolean (GH22326)

### Bug fixes

- Bug in `Series.get()` for `Series` using `ExtensionArray` and integer index (GH21257)
- `shift()` now dispatches to `ExtensionArray.shift()` (GH22386)
- `Series.combine()` works correctly with `ExtensionArray` inside of `Series` (GH20825)
- `Series.combine()` with scalar argument now works for any function type (GH21248)
- `Series.astype()` and `DataFrame.astype()` now dispatch to `ExtensionArray.astype()` (GH21185).
- Slicing a single row of a `DataFrame` with multiple `ExtensionArrays` of the same type now preserves the dtype, rather than coercing to object (GH22784)
- Bug when concatenating multiple `Series` with different extension dtypes not casting to object dtype (GH22994)
- `Series` backed by an `ExtensionArray` now work with `util.hash_pandas_object()` (GH23066)

- `DataFrame.stack()` no longer converts to object dtype for DataFrames where each column has the same extension dtype. The output Series will have the same dtype as the columns (GH23077).
- `Series.unstack()` and `DataFrame.unstack()` no longer convert extension arrays to object-dtype ndarrays. Each column in the output DataFrame will now have the same dtype as the input (GH23077).
- Bug when grouping `DataFrame.groupby()` and aggregating on `ExtensionArray` it was not returning the actual `ExtensionArray` dtype (GH23227).
- Bug in `pandas.merge()` when merging on an extension array-backed column (GH23020).

## Deprecations

- `MultiIndex.labels` has been deprecated and replaced by `MultiIndex.codes`. The functionality is unchanged. The new name better reflects the natures of these codes and makes the `MultiIndex` API more similar to the API for `CategoricalIndex` (GH13443). As a consequence, other uses of the name `labels` in `MultiIndex` have also been deprecated and replaced with `codes`:
  - You should initialize a `MultiIndex` instance using a parameter named `codes` rather than `labels`.
  - `MultiIndex.set_labels` has been deprecated in favor of `MultiIndex.set_codes()`.
  - For method `MultiIndex.copy()`, the `labels` parameter has been deprecated and replaced by a `codes` parameter.
- `DataFrame.to_stata()`, `read_stata()`, `StataReader` and `StataWriter` have deprecated the `encoding` argument. The encoding of a Stata dta file is determined by the file type and cannot be changed (GH21244)
- `MultiIndex.to_hierarchical()` is deprecated and will be removed in a future version (GH21613)
- `Series.ptp()` is deprecated. Use `numpy.ptp` instead (GH21614)
- `Series.compress()` is deprecated. Use `Series[condition]` instead (GH18262)
- The signature of `Series.to_csv()` has been uniformed to that of `DataFrame.to_csv()`: the name of the first argument is now `path_or_buf`, the order of subsequent arguments has changed, the `header` argument now defaults to `True`. (GH19715)
- `Categorical.from_codes()` has deprecated providing float values for the `codes` argument. (GH21767)
- `pandas.read_table()` is deprecated. Instead, use `read_csv()` passing `sep='\t'` if necessary. This deprecation has been removed in 0.25.0. (GH21948)
- `Series.str.cat()` has deprecated using arbitrary list-likes *within* list-likes. A list-like container may still contain many `Series`, `Index` or 1-dimensional `np.ndarray`, or alternatively, only scalar values. (GH21950)
- `FrozenNDArray.searchsorted()` has deprecated the `v` parameter in favor of `value` (GH14645)
- `DatetimeIndex.shift()` and `PeriodIndex.shift()` now accept `periods` argument instead of `n` for consistency with `Index.shift()` and `Series.shift()`. Using `n` throws a deprecation warning (GH22458, GH22912)
- The `fastpath` keyword of the different `Index` constructors is deprecated (GH23110).
- `Timestamp.tz_localize()`, `DatetimeIndex.tz_localize()`, and `Series.tz_localize()` have deprecated the `errors` argument in favor of the `nonexistent` argument (GH8917)
- The class `FrozenNDArray` has been deprecated. When unpickling, `FrozenNDArray` will be unpickled to `np.ndarray` once this class is removed (GH9031)
- The methods `DataFrame.update()` and `Panel.update()` have deprecated the `raise_conflict=False|True` keyword in favor of `errors='ignore'|'raise'` (GH23585)

- The methods `Series.str.partition()` and `Series.str.rpartition()` have deprecated the `pat` keyword in favor of `sep` (GH22676)
- Deprecated the `nthreads` keyword of `pandas.read_feather()` in favor of `use_threads` to reflect the changes in `pyarrow`  $\geq 0.11.0$ . (GH23053)
- `pandas.read_excel()` has deprecated accepting `usecols` as an integer. Please pass in a list of ints from 0 to `usecols` inclusive instead (GH23527)
- Constructing a `TimedeltaIndex` from data with `datetime64`-typed data is deprecated, will raise `TypeError` in a future version (GH23539)
- Constructing a `DatetimeIndex` from data with `timedelta64`-typed data is deprecated, will raise `TypeError` in a future version (GH23675)
- The `keep_tz=False` option (the default) of the `keep_tz` keyword of `DatetimeIndex.to_series()` is deprecated (GH17832).
- Timezone converting a tz-aware `datetime.datetime` or `Timestamp` with `Timestamp` and the `tz` argument is now deprecated. Instead, use `Timestamp.tz_convert()` (GH23579)
- `pandas.api.types.is_period()` is deprecated in favor of `pandas.api.types.is_period_dtype` (GH23917)
- `pandas.api.types.is_datetimetz()` is deprecated in favor of `pandas.api.types.is_datetime64tz` (GH23917)
- Creating a `TimedeltaIndex`, `DatetimeIndex`, or `PeriodIndex` by passing range arguments `start`, `end`, and `periods` is deprecated in favor of `timedelta_range()`, `date_range()`, or `period_range()` (GH23919)
- Passing a string alias like `'datetime64[ns, UTC]'` as the `unit` parameter to `DatetimeTZDtype` is deprecated. Use `DatetimeTZDtype.construct_from_string` instead (GH23990).
- The `skipna` parameter of `infer_dtype()` will switch to `True` by default in a future version of pandas (GH17066, GH24050)
- In `Series.where()` with Categorical data, providing an `other` that is not present in the categories is deprecated. Convert the categorical to a different dtype or add the `other` to the categories first (GH24077).
- `Series.clip_lower()`, `Series.clip_upper()`, `DataFrame.clip_lower()` and `DataFrame.clip_upper()` are deprecated and will be removed in a future version. Use `Series.clip(lower=threshold)`, `Series.clip(upper=threshold)` and the equivalent `DataFrame` methods (GH24203)
- `Series.nonzero()` is deprecated and will be removed in a future version (GH18262)
- Passing an integer to `Series.fillna()` and `DataFrame.fillna()` with `timedelta64[ns]` dtypes is deprecated, will raise `TypeError` in a future version. Use `obj.fillna(pd.Timedelta(...))` instead (GH24694)
- `Series.cat.categorical`, `Series.cat.name` and `Series.cat.index` have been deprecated. Use the attributes on `Series.cat` or `Series` directly. (GH24751).
- Passing a dtype without a precision like `np.dtype('datetime64')` or `timedelta64` to `Index`, `DatetimeIndex` and `TimedeltaIndex` is now deprecated. Use the nanosecond-precision dtype instead (GH24753).

## Integer addition/subtraction with datetimes and timedeltas is deprecated

In the past, users could—in some cases—add or subtract integers or integer-dtype arrays from *Timestamp*, *DatetimeIndex* and *TimedeltaIndex*.

This usage is now deprecated. Instead add or subtract integer multiples of the object's `freq` attribute (GH21939, GH23878).

*Previous behavior:*

```
In [5]: ts = pd.Timestamp('1994-05-06 12:15:16', freq=pd.offsets.Hour())
In [6]: ts + 2
Out[6]: Timestamp('1994-05-06 14:15:16', freq='H')

In [7]: tdi = pd.timedelta_range('1D', periods=2)
In [8]: tdi - np.array([2, 1])
Out[8]: TimedeltaIndex(['-1 days', '1 days'], dtype='timedelta64[ns]', freq=None)

In [9]: dti = pd.date_range('2001-01-01', periods=2, freq='7D')
In [10]: dti + pd.Index([1, 2])
Out[10]: DatetimeIndex(['2001-01-08', '2001-01-22'], dtype='datetime64[ns]', freq=None)
```

*New behavior:*

```
In [108]: ts = pd.Timestamp('1994-05-06 12:15:16', freq=pd.offsets.Hour())

In [109]: ts + 2 * ts.freq
Out[109]: Timestamp('1994-05-06 14:15:16', freq='H')

In [110]: tdi = pd.timedelta_range('1D', periods=2)

In [111]: tdi - np.array([2 * tdi.freq, 1 * tdi.freq])
Out[111]: TimedeltaIndex(['-1 days', '1 days'], dtype='timedelta64[ns]', freq=None)

In [112]: dti = pd.date_range('2001-01-01', periods=2, freq='7D')

In [113]: dti + pd.Index([1 * dti.freq, 2 * dti.freq])
Out[113]: DatetimeIndex(['2001-01-08', '2001-01-22'], dtype='datetime64[ns]', freq=None)
```

## Passing integer data and a timezone to DatetimeIndex

The behavior of *DatetimeIndex* when passed integer data and a timezone is changing in a future version of pandas. Previously, these were interpreted as wall times in the desired timezone. In the future, these will be interpreted as wall times in UTC, which are then converted to the desired timezone (GH24559).

The default behavior remains the same, but issues a warning:

```
In [3]: pd.DatetimeIndex([946684800000000000], tz="US/Central")
/bin/ipython:1: FutureWarning:
 Passing integer-dtype data and a timezone to DatetimeIndex. Integer values
 will be interpreted differently in a future version of pandas. Previously,
 these were viewed as datetime64[ns] values representing the wall time
 in the specified timezone. In the future, these will be viewed as
```

(continues on next page)

(continued from previous page)

```
datetime64[ns] values representing the wall time *in UTC*. This is similar
to a nanosecond-precision UNIX epoch. To accept the future behavior, use
```

```
pd.to_datetime(integer_data, utc=True).tz_convert(tz)
```

To keep the previous behavior, use

```
pd.to_datetime(integer_data).tz_localize(tz)
```

```
#!/bin/python3
```

```
Out[3]: DatetimeIndex(['2000-01-01 00:00:00-06:00'], dtype='datetime64[ns, US/Central]',
↳ freq=None)
```

As the warning message explains, opt in to the future behavior by specifying that the integer values are UTC, and then converting to the final timezone:

```
In [114]: pd.to_datetime([946684800000000000], utc=True).tz_convert('US/Central')
Out[114]: DatetimeIndex(['1999-12-31 18:00:00-06:00'], dtype='datetime64[ns, US/Central]
↳ ', freq=None)
```

The old behavior can be retained with by localizing directly to the final timezone:

```
In [115]: pd.to_datetime([946684800000000000]).tz_localize('US/Central')
Out[115]: DatetimeIndex(['2000-01-01 00:00:00-06:00'], dtype='datetime64[ns, US/Central]
↳ ', freq=None)
```

## Converting timezone-aware Series and Index to NumPy arrays

The conversion from a *Series* or *Index* with timezone-aware datetime data will change to preserve timezones by default (GH23569).

NumPy doesn't have a dedicated dtype for timezone-aware datetimes. In the past, converting a *Series* or *DatetimeIndex* with timezone-aware datetimes would convert to a NumPy array by

1. converting the tz-aware data to UTC
2. dropping the timezone-info
3. returning a `numpy.ndarray` with `datetime64[ns]` dtype

Future versions of pandas will preserve the timezone information by returning an object-dtype NumPy array where each value is a *Timestamp* with the correct timezone attached

```
In [116]: ser = pd.Series(pd.date_range('2000', periods=2, tz="CET"))
```

```
In [117]: ser
```

```
Out[117]:
0 2000-01-01 00:00:00+01:00
1 2000-01-02 00:00:00+01:00
dtype: datetime64[ns, CET]
```

The default behavior remains the same, but issues a warning

```
In [8]: np.asarray(ser)
/bin/ipython:1: FutureWarning: Converting timezone-aware DatetimeArray to timezone-naive
ndarray with 'datetime64[ns]' dtype. In the future, this will return an ndarray
with 'object' dtype where each element is a 'pandas.Timestamp' with the correct 'tz
↔'.

 To accept the future behavior, pass 'dtype=object'.
 To keep the old behavior, pass 'dtype="datetime64[ns]"'.
#!/bin/python3
Out[8]:
array(['1999-12-31T23:00:00.000000000', '2000-01-01T23:00:00.000000000'],
 dtype='datetime64[ns]')
```

The previous or future behavior can be obtained, without any warnings, by specifying the dtype

*Previous behavior*

```
In [118]: np.asarray(ser, dtype='datetime64[ns]')
Out[118]:
array(['1999-12-31T23:00:00.000000000', '2000-01-01T23:00:00.000000000'],
 dtype='datetime64[ns]')
```

*Future behavior*

```
New behavior
In [119]: np.asarray(ser, dtype=object)
Out[119]:
array([Timestamp('2000-01-01 00:00:00+0100', tz='CET'),
 Timestamp('2000-01-02 00:00:00+0100', tz='CET')], dtype=object)
```

Or by using `Series.to_numpy()`

```
In [120]: ser.to_numpy()
Out[120]:
array([Timestamp('2000-01-01 00:00:00+0100', tz='CET'),
 Timestamp('2000-01-02 00:00:00+0100', tz='CET')], dtype=object)

In [121]: ser.to_numpy(dtype="datetime64[ns]")
Out[121]:
array(['1999-12-31T23:00:00.000000000', '2000-01-01T23:00:00.000000000'],
 dtype='datetime64[ns]')
```

All the above applies to a `DatetimeIndex` with tz-aware values as well.

## Removal of prior version deprecations/changes

- The `LongPanel` and `WidePanel` classes have been removed ([GH10892](#))
- `Series.repeat()` has renamed the `reps` argument to `repeats` ([GH14645](#))
- Several private functions were removed from the (non-public) module `pandas.core.common` ([GH22001](#))
- Removal of the previously deprecated module `pandas.core.datetools` ([GH14105](#), [GH14094](#))
- Strings passed into `DataFrame.groupby()` that refer to both column and index levels will raise a `ValueError` ([GH14432](#))
- `Index.repeat()` and `MultiIndex.repeat()` have renamed the `n` argument to `repeats` ([GH14645](#))
- The `Series` constructor and `.astype` method will now raise a `ValueError` if timestamp dtypes are passed in without a unit (e.g. `np.datetime64`) for the `dtype` parameter ([GH15987](#))
- Removal of the previously deprecated `as_indexer` keyword completely from `str.match()` ([GH22356](#), [GH6581](#))
- The modules `pandas.types`, `pandas.computation`, and `pandas.util.decorators` have been removed ([GH16157](#), [GH16250](#))
- Removed the `pandas.formats.style` shim for `pandas.io.formats.style.Styler` ([GH16059](#))
- `pandas.pnow`, `pandas.match`, `pandas.groupby`, `pd.get_store`, `pd.Expr`, and `pd.Term` have been removed ([GH15538](#), [GH15940](#))
- `Categorical.searchsorted()` and `Series.searchsorted()` have renamed the `v` argument to `value` ([GH14645](#))
- `pandas.parser`, `pandas.lib`, and `pandas.tslib` have been removed ([GH15537](#))
- `Index.searchsorted()` have renamed the `key` argument to `value` ([GH14645](#))
- `DataFrame consolidate` and `Series consolidate` have been removed ([GH15501](#))
- Removal of the previously deprecated module `pandas.json` ([GH19944](#))
- The module `pandas.tools` has been removed ([GH15358](#), [GH16005](#))
- `SparseArray.get_values()` and `SparseArray.to_dense()` have dropped the `fill` parameter ([GH14686](#))
- `DataFrame.sortlevel` and `Series.sortlevel` have been removed ([GH15099](#))
- `SparseSeries.to_dense()` has dropped the `sparse_only` parameter ([GH14686](#))
- `DataFrame.astype()` and `Series.astype()` have renamed the `raise_on_error` argument to `errors` ([GH14967](#))
- `is_sequence`, `is_any_int_dtype`, and `is_floating_dtype` have been removed from `pandas.api.types` ([GH16163](#), [GH16189](#))

## Performance improvements

- Slicing Series and DataFrames with an monotonically increasing *CategoricalIndex* is now very fast and has speed comparable to slicing with an *Int64Index*. The speed increase is both when indexing by label (using *.loc*) and position (*.iloc*) (GH20395) Slicing a monotonically increasing *CategoricalIndex* itself (i.e. *ci[1000:2000]*) shows similar speed improvements as above (GH21659)
- Improved performance of *CategoricalIndex.equals()* when comparing to another *CategoricalIndex* (GH24023)
- Improved performance of *Series.describe()* in case of numeric dtypes (GH21274)
- Improved performance of *pandas.core.groupby.GroupBy.rank()* when dealing with tied rankings (GH21237)
- Improved performance of *DataFrame.set\_index()* with columns consisting of *Period* objects (GH21582, GH21606)
- Improved performance of *Series.at()* and *Index.get\_value()* for Extension Arrays values (e.g. *Categorical*) (GH24204)
- Improved performance of membership checks in *Categorical* and *CategoricalIndex* (i.e. *x in cat*-style checks are much faster). *CategoricalIndex.contains()* is likewise much faster (GH21369, GH21508)
- Improved performance of *HDFStore.groups()* (and dependent functions like *HDFStore.keys()*. (i.e. *x in store* checks are much faster) (GH21372)
- Improved the performance of *pandas.get\_dummies()* with *sparse=True* (GH21997)
- Improved performance of *IndexEngine.get\_indexer\_non\_unique()* for sorted, non-unique indexes (GH9466)
- Improved performance of *PeriodIndex.unique()* (GH23083)
- Improved performance of *concat()* for Series objects (GH23404)
- Improved performance of *DatetimeIndex.normalize()* and *Timestamp.normalize()* for timezone naive or UTC datetimes (GH23634)
- Improved performance of *DatetimeIndex.tz\_localize()* and various *DatetimeIndex* attributes with daylight UTC timezone (GH23772)
- Fixed a performance regression on Windows with Python 3.7 of *read\_csv()* (GH23516)
- Improved performance of *Categorical* constructor for Series objects (GH23814)
- Improved performance of *where()* for Categorical data (GH24077)
- Improved performance of iterating over a *Series*. Using *DataFrame.itertuples()* now creates iterators without internally allocating lists of all elements (GH20783)
- Improved performance of *Period* constructor, additionally benefitting *PeriodArray* and *PeriodIndex* creation (GH24084, GH24118)
- Improved performance of tz-aware *DatetimeArray* binary operations (GH24491)

## Bug fixes

### Categorical

- Bug in `Categorical.from_codes()` where NaN values in codes were silently converted to 0 (GH21767). In the future this will raise a `ValueError`. Also changes the behavior of `.from_codes([1.1, 2.0])`.
- Bug in `Categorical.sort_values()` where NaN values were always positioned in front regardless of `na_position` value. (GH22556).
- Bug when indexing with a boolean-valued `Categorical`. Now a boolean-valued `Categorical` is treated as a boolean mask (GH22665)
- Constructing a `CategoricalIndex` with empty values and boolean categories was raising a `ValueError` after a change to dtype coercion (GH22702).
- Bug in `Categorical.take()` with a user-provided `fill_value` not encoding the `fill_value`, which could result in a `ValueError`, incorrect results, or a segmentation fault (GH23296).
- In `Series.unstack()`, specifying a `fill_value` not present in the categories now raises a `TypeError` rather than ignoring the `fill_value` (GH23284)
- Bug when resampling `DataFrame.resample()` and aggregating on categorical data, the categorical dtype was getting lost. (GH23227)
- Bug in many methods of the `.str`-accessor, which always failed on calling the `CategoricalIndex.str` constructor (GH23555, GH23556)
- Bug in `Series.where()` losing the categorical dtype for categorical data (GH24077)
- Bug in `Categorical.apply()` where NaN values could be handled unpredictably. They now remain unchanged (GH24241)
- Bug in `Categorical` comparison methods incorrectly raising `ValueError` when operating against a `DataFrame` (GH24630)
- Bug in `Categorical.set_categories()` where setting fewer new categories with `rename=True` caused a segmentation fault (GH24675)

### Datetimelike

- Fixed bug where two `DateOffset` objects with different `normalize` attributes could evaluate as equal (GH21404)
- Fixed bug where `Timestamp.resolution()` incorrectly returned 1-microsecond `timedelta` instead of 1-nanosecond `Timedelta` (GH21336, GH21365)
- Bug in `to_datetime()` that did not consistently return an `Index` when `box=True` was specified (GH21864)
- Bug in `DatetimeIndex` comparisons where string comparisons incorrectly raises `TypeError` (GH22074)
- Bug in `DatetimeIndex` comparisons when comparing against `timedelta64[ns]` dtyped arrays; in some cases `TypeError` was incorrectly raised, in others it incorrectly failed to raise (GH22074)
- Bug in `DatetimeIndex` comparisons when comparing against object-dtyped arrays (GH22074)
- Bug in `DataFrame` with `datetime64[ns]` dtype addition and subtraction with `Timedelta`-like objects (GH22005, GH22163)
- Bug in `DataFrame` with `datetime64[ns]` dtype addition and subtraction with `DateOffset` objects returning an object dtype instead of `datetime64[ns]` dtype (GH21610, GH22163)

- Bug in `DataFrame` with `datetime64[ns]` dtype comparing against `NaT` incorrectly ([GH22242](#), [GH22163](#))
- Bug in `DataFrame` with `datetime64[ns]` dtype subtracting `Timestamp`-like object incorrectly returned `datetime64[ns]` dtype instead of `timedelta64[ns]` dtype ([GH8554](#), [GH22163](#))
- Bug in `DataFrame` with `datetime64[ns]` dtype subtracting `np.datetime64` object with non-nanosecond unit failing to convert to nanoseconds ([GH18874](#), [GH22163](#))
- Bug in `DataFrame` comparisons against `Timestamp`-like objects failing to raise `TypeError` for inequality checks with mismatched types ([GH8932](#), [GH22163](#))
- Bug in `DataFrame` with mixed dtypes including `datetime64[ns]` incorrectly raising `TypeError` on equality comparisons ([GH13128](#), [GH22163](#))
- Bug in `DataFrame.values` returning a `DatetimeIndex` for a single-column `DataFrame` with tz-aware date-time values. Now a 2-D `numpy.ndarray` of `Timestamp` objects is returned ([GH24024](#))
- Bug in `DataFrame.eq()` comparison against `NaT` incorrectly returning `True` or `NaN` ([GH15697](#), [GH22163](#))
- Bug in `DatetimeIndex` subtraction that incorrectly failed to raise `OverflowError` ([GH22492](#), [GH22508](#))
- Bug in `DatetimeIndex` incorrectly allowing indexing with `Timedelta` object ([GH20464](#))
- Bug in `DatetimeIndex` where frequency was being set if original frequency was `None` ([GH22150](#))
- Bug in rounding methods of `DatetimeIndex` (`round()`, `ceil()`, `floor()`) and `Timestamp` (`round()`, `ceil()`, `floor()`) could give rise to loss of precision ([GH22591](#))
- Bug in `to_datetime()` with an `Index` argument that would drop the name from the result ([GH21697](#))
- Bug in `PeriodIndex` where adding or subtracting a `timedelta` or `Tick` object produced incorrect results ([GH22988](#))
- Bug in the `Series` repr with period-dtype data missing a space before the data ([GH23601](#))
- Bug in `date_range()` when decrementing a start date to a past end date by a negative frequency ([GH23270](#))
- Bug in `Series.min()` which would return `NaN` instead of `NaT` when called on a series of `NaT` ([GH23282](#))
- Bug in `Series.combine_first()` not properly aligning categoricals, so that missing values in `self` were not filled by valid values from `other` ([GH24147](#))
- Bug in `DataFrame.combine()` with datetimelike values raising a `TypeError` ([GH23079](#))
- Bug in `date_range()` with frequency of `Day` or higher where dates sufficiently far in the future could wrap around to the past instead of raising `OutOfBoundsDatetime` ([GH14187](#))
- Bug in `period_range()` ignoring the frequency of `start` and `end` when those are provided as `Period` objects ([GH20535](#)).
- Bug in `PeriodIndex` with attribute `freq.n` greater than 1 where adding a `DateOffset` object would return incorrect results ([GH23215](#))
- Bug in `Series` that interpreted string indices as lists of characters when setting datetimelike values ([GH23451](#))
- Bug in `DataFrame` when creating a new column from an `ndarray` of `Timestamp` objects with timezones creating an object-dtype column, rather than `datetime` with `timezone` ([GH23932](#))
- Bug in `Timestamp` constructor which would drop the frequency of an input `Timestamp` ([GH22311](#))
- Bug in `DatetimeIndex` where calling `np.array(dtindex, dtype=object)` would incorrectly return an array of long objects ([GH23524](#))
- Bug in `Index` where passing a timezone-aware `DatetimeIndex` and `dtype=object` would incorrectly raise a `ValueError` ([GH23524](#))

- Bug in *Index* where calling `np.array(dtindex, dtype=object)` on a timezone-naive *DatetimeIndex* would return an array of *datetime* objects instead of *Timestamp* objects, potentially losing nanosecond portions of the timestamps (GH23524)
- Bug in *Categorical.\_\_setitem\_\_* not allowing setting with another *Categorical* when both are unordered and have the same categories, but in a different order (GH24142)
- Bug in *date\_range()* where using dates with millisecond resolution or higher could return incorrect values or the wrong number of values in the index (GH24110)
- Bug in *DatetimeIndex* where constructing a *DatetimeIndex* from a *Categorical* or *CategoricalIndex* would incorrectly drop timezone information (GH18664)
- Bug in *DatetimeIndex* and *TimedeltaIndex* where indexing with Ellipsis would incorrectly lose the index's *freq* attribute (GH21282)
- Clarified error message produced when passing an incorrect *freq* argument to *DatetimeIndex* with NaT as the first entry in the passed data (GH11587)
- Bug in *to\_datetime()* where *box* and *utc* arguments were ignored when passing a *DataFrame* or dict of unit mappings (GH23760)
- Bug in *Series.dt* where the cache would not update properly after an in-place operation (GH24408)
- Bug in *PeriodIndex* where comparisons against an array-like object with length 1 failed to raise *ValueError* (GH23078)
- Bug in *DatetimeIndex.astype()*, *PeriodIndex.astype()* and *TimedeltaIndex.astype()* ignoring the sign of the *dtype* for unsigned integer dtypes (GH24405).
- Fixed bug in *Series.max()* with *datetime64[ns]*-*dtype* failing to return NaT when nulls are present and *skipna=False* is passed (GH24265)
- Bug in *to\_datetime()* where arrays of *datetime* objects containing both timezone-aware and timezone-naive datetimes would fail to raise *ValueError* (GH24569)
- Bug in *to\_datetime()* with invalid *datetime* format doesn't coerce input to NaT even if *errors='coerce'* (GH24763)

## Timedelta

- Bug in *DataFrame* with *timedelta64[ns]* *dtype* division by *Timedelta*-like scalar incorrectly returning *timedelta64[ns]* *dtype* instead of *float64* *dtype* (GH20088, GH22163)
- Bug in adding a *Index* with object *dtype* to a *Series* with *timedelta64[ns]* *dtype* incorrectly raising (GH22390)
- Bug in multiplying a *Series* with numeric *dtype* against a *timedelta* object (GH22390)
- Bug in *Series* with numeric *dtype* when adding or subtracting an array or *Series* with *timedelta64* *dtype* (GH22390)
- Bug in *Index* with numeric *dtype* when multiplying or dividing an array with *dtype timedelta64* (GH22390)
- Bug in *TimedeltaIndex* incorrectly allowing indexing with *Timestamp* object (GH20464)
- Fixed bug where subtracting *Timedelta* from an object-dtyped array would raise *TypeError* (GH21980)
- Fixed bug in adding a *DataFrame* with all-*timedelta64[ns]* dtypes to a *DataFrame* with all-integer dtypes returning incorrect results instead of raising *TypeError* (GH22696)
- Bug in *TimedeltaIndex* where adding a timezone-aware *datetime* scalar incorrectly returned a timezone-naive *DatetimeIndex* (GH23215)

- Bug in *TimedeltaIndex* where adding `np.timedelta64('NaT')` incorrectly returned an all-`NaT DatetimeIndex` instead of an all-`NaT TimedeltaIndex` (GH23215)
- Bug in *Timedelta* and `to_timedelta()` have inconsistencies in supported unit string (GH21762)
- Bug in *TimedeltaIndex* division where dividing by another *TimedeltaIndex* raised `TypeError` instead of returning a *Float64Index* (GH23829, GH22631)
- Bug in *TimedeltaIndex* comparison operations where comparing against non-*Timedelta*-like objects would raise `TypeError` instead of returning all-`False` for `__eq__` and all-`True` for `__ne__` (GH24056)
- Bug in *Timedelta* comparisons when comparing with a `Tick` object incorrectly raising `TypeError` (GH24710)

## Timezones

- Bug in *Index.shift()* where an `AssertionError` would raise when shifting across DST (GH8616)
- Bug in *Timestamp* constructor where passing an invalid timezone offset designator (Z) would not raise a `ValueError` (GH8910)
- Bug in *Timestamp.replace()* where replacing at a DST boundary would retain an incorrect offset (GH7825)
- Bug in *Series.replace()* with `datetime64[ns, tz]` data when replacing `NaT` (GH11792)
- Bug in *Timestamp* when passing different string date formats with a timezone offset would produce different timezone offsets (GH12064)
- Bug when comparing a tz-naive *Timestamp* to a tz-aware *DatetimeIndex* which would coerce the *DatetimeIndex* to tz-naive (GH12601)
- Bug in *Series.truncate()* with a tz-aware *DatetimeIndex* which would cause a core dump (GH9243)
- Bug in *Series* constructor which would coerce tz-aware and tz-naive *Timestamp* to tz-aware (GH13051)
- Bug in *Index* with `datetime64[ns, tz]` dtype that did not localize integer data correctly (GH20964)
- Bug in *DatetimeIndex* where constructing with an integer and tz would not localize correctly (GH12619)
- Fixed bug where *DataFrame.describe()* and *Series.describe()* on tz-aware datetimes did not show first and last result (GH21328)
- Bug in *DatetimeIndex* comparisons failing to raise `TypeError` when comparing timezone-aware *DatetimeIndex* against `np.datetime64` (GH22074)
- Bug in *DataFrame* assignment with a timezone-aware scalar (GH19843)
- Bug in *DataFrame.asof()* that raised a `TypeError` when attempting to compare tz-naive and tz-aware timestamps (GH21194)
- Bug when constructing a *DatetimeIndex* with *Timestamp* constructed with the `replace` method across DST (GH18785)
- Bug when setting a new value with *DataFrame.loc()* with a *DatetimeIndex* with a DST transition (GH18308, GH20724)
- Bug in *Index.unique()* that did not re-localize tz-aware dates correctly (GH21737)
- Bug when indexing a *Series* with a DST transition (GH21846)
- Bug in *DataFrame.resample()* and *Series.resample()* where an `AmbiguousTimeError` or `NonExistentTimeError` would raise if a timezone aware timeseries ended on a DST transition (GH19375, GH10117)

- Bug in `DataFrame.drop()` and `Series.drop()` when specifying a tz-aware Timestamp key to drop from a `DatetimeIndex` with a DST transition (GH21761)
- Bug in `DatetimeIndex` constructor where `NaT` and `dateutil.tz.tzlocal` would raise an `OutOfBoundsDatetime` error (GH23807)
- Bug in `DatetimeIndex.tz_localize()` and `Timestamp.tz_localize()` with `dateutil.tz.tzlocal` near a DST transition that would return an incorrectly localized datetime (GH23807)
- Bug in `Timestamp` constructor where a `dateutil.tz.tzutc` timezone passed with a `datetime.datetime` argument would be converted to a `pytz.UTC` timezone (GH23807)
- Bug in `to_datetime()` where `utc=True` was not respected when specifying a unit and `errors='ignore'` (GH23758)
- Bug in `to_datetime()` where `utc=True` was not respected when passing a `Timestamp` (GH24415)
- Bug in `DataFrame.any()` returns wrong value when `axis=1` and the data is of datetimelike type (GH23070)
- Bug in `DatetimeIndex.to_period()` where a timezone aware index was converted to UTC first before creating `PeriodIndex` (GH22905)
- Bug in `DataFrame.tz_localize()`, `DataFrame.tz_convert()`, `Series.tz_localize()`, and `Series.tz_convert()` where `copy=False` would mutate the original argument inplace (GH6326)
- Bug in `DataFrame.max()` and `DataFrame.min()` with `axis=1` where a `Series` with `NaN` would be returned when all columns contained the same timezone (GH10390)

## Offsets

- Bug in FY5253 where date offsets could incorrectly raise an `AssertionError` in arithmetic operations (GH14774)
- Bug in `DateOffset` where keyword arguments `week` and `milliseconds` were accepted and ignored. Passing these will now raise `ValueError` (GH19398)
- Bug in adding `DateOffset` with `DataFrame` or `PeriodIndex` incorrectly raising `TypeError` (GH23215)
- Bug in comparing `DateOffset` objects with non-`DateOffset` objects, particularly strings, raising `ValueError` instead of returning `False` for equality checks and `True` for not-equal checks (GH23524)

## Numeric

- Bug in `Series.__rmatmul__` doesn't support matrix vector multiplication (GH21530)
- Bug in `factorize()` fails with read-only array (GH12813)
- Fixed bug in `unique()` handled signed zeros inconsistently: for some inputs `0.0` and `-0.0` were treated as equal and for some inputs as different. Now they are treated as equal for all inputs (GH21866)
- Bug in `DataFrame.agg()`, `DataFrame.transform()` and `DataFrame.apply()` where, when supplied with a list of functions and `axis=1` (e.g. `df.apply(['sum', 'mean'], axis=1)`), a `TypeError` was wrongly raised. For all three methods such calculation are now done correctly. (GH16679).
- Bug in `Series` comparison against datetime-like scalars and arrays (GH22074)
- Bug in `DataFrame` multiplication between boolean dtype and integer returning object dtype instead of integer dtype (GH22047, GH22163)
- Bug in `DataFrame.apply()` where, when supplied with a string argument and additional positional or keyword arguments (e.g. `df.apply('sum', min_count=1)`), a `TypeError` was wrongly raised (GH22376)

- Bug in `DataFrame.astype()` to extension dtype may raise `AttributeError` (GH22578)
- Bug in `DataFrame` with `timedelta64[ns]` dtype arithmetic operations with `ndarray` with integer dtype incorrectly treating the ndarray as `timedelta64[ns]` dtype (GH23114)
- Bug in `Series.rpow()` with object dtype NaN for `1 ** NA` instead of `1` (GH22922).
- `Series.agg()` can now handle numpy NaN-aware methods like `numpy.nansum()` (GH19629)
- Bug in `Series.rank()` and `DataFrame.rank()` when `pct=True` and more than  $2^{24}$  rows are present resulted in percentages greater than 1.0 (GH18271)
- Calls such as `DataFrame.round()` with a non-unique `CategoricalIndex()` now return expected data. Previously, data would be improperly duplicated (GH21809).
- Added `log10`, `floor` and `ceil` to the list of supported functions in `DataFrame.eval()` (GH24139, GH24353)
- Logical operations `&`, `|`, `^` between `Series` and `Index` will no longer raise `ValueError` (GH22092)
- Checking PEP 3141 numbers in `is_scalar()` function returns `True` (GH22903)
- Reduction methods like `Series.sum()` now accept the default value of `keepdims=False` when called from a NumPy ufunc, rather than raising a `TypeError`. Full support for `keepdims` has not been implemented (GH24356).

## Conversion

- Bug in `DataFrame.combine_first()` in which column types were unexpectedly converted to float (GH20699)
- Bug in `DataFrame.clip()` in which column types are not preserved and casted to float (GH24162)
- Bug in `DataFrame.clip()` when order of columns of dataframes doesn't match, result observed is wrong in numeric values (GH20911)
- Bug in `DataFrame.astype()` where converting to an extension dtype when duplicate column names are present causes a `RecursionError` (GH24704)

## Strings

- Bug in `Index.str.partition()` was not nan-safe (GH23558).
- Bug in `Index.str.split()` was not nan-safe (GH23677).
- Bug `Series.str.contains()` not respecting the `na` argument for a `Categorical` dtype `Series` (GH22158)
- Bug in `Index.str.cat()` when the result contained only NaN (GH24044)

## Interval

- Bug in the `IntervalIndex` constructor where the `closed` parameter did not always override the inferred `closed` (GH19370)
- Bug in the `IntervalIndex` repr where a trailing comma was missing after the list of intervals (GH20611)
- Bug in `Interval` where scalar arithmetic operations did not retain the `closed` value (GH22313)
- Bug in `IntervalIndex` where indexing with datetime-like values raised a `KeyError` (GH20636)
- Bug in `IntervalTree` where data containing NaN triggered a warning and resulted in incorrect indexing queries with `IntervalIndex` (GH23352)

## Indexing

- Bug in `DataFrame.ne()` fails if columns contain column name “dtype” (GH22383)
- The traceback from a `KeyError` when asking `.loc` for a single missing label is now shorter and more clear (GH21557)
- `PeriodIndex` now emits a `KeyError` when a malformed string is looked up, which is consistent with the behavior of `DatetimeIndex` (GH22803)
- When `.ix` is asked for a missing integer label in a `MultiIndex` with a first level of integer type, it now raises a `KeyError`, consistently with the case of a flat `Int64Index`, rather than falling back to positional indexing (GH21593)
- Bug in `Index.reindex()` when reindexing a tz-naive and tz-aware `DatetimeIndex` (GH8306)
- Bug in `Series.reindex()` when reindexing an empty series with a `datetime64[ns, tz]` dtype (GH20869)
- Bug in `DataFrame` when setting values with `.loc` and a timezone aware `DatetimeIndex` (GH11365)
- `DataFrame.__getitem__` now accepts dictionaries and dictionary keys as list-likes of labels, consistently with `Series.__getitem__` (GH21294)
- Fixed `DataFrame[np.nan]` when columns are non-unique (GH21428)
- Bug when indexing `DatetimeIndex` with nanosecond resolution dates and timezones (GH11679)
- Bug where indexing with a Numpy array containing negative values would mutate the indexer (GH21867)
- Bug where mixed indexes wouldn’t allow integers for `.at` (GH19860)
- `Float64Index.get_loc` now raises `KeyError` when boolean key passed. (GH19087)
- Bug in `DataFrame.loc()` when indexing with an `IntervalIndex` (GH19977)
- `Index` no longer mangles `None`, `NaN` and `NaT`, i.e. they are treated as three different keys. However, for numeric `Index` all three are still coerced to a `NaN` (GH22332)
- Bug in `scalar in Index` if `scalar` is a float while the `Index` is of integer dtype (GH22085)
- Bug in `MultiIndex.set_levels()` when `levels` value is not subscriptable (GH23273)
- Bug where setting a `timedelta` column by `Index` causes it to be casted to double, and therefore lose precision (GH23511)
- Bug in `Index.union()` and `Index.intersection()` where name of the `Index` of the result was not computed correctly for certain cases (GH9943, GH9862)
- Bug in `Index` slicing with boolean `Index` may raise `TypeError` (GH22533)
- Bug in `PeriodArray.__setitem__` when accepting slice and list-like value (GH23978)
- Bug in `DatetimeIndex`, `TimedeltaIndex` where indexing with `Ellipsis` would lose their `freq` attribute (GH21282)
- Bug in `iat` where using it to assign an incompatible value would create a new column (GH23236)

## Missing

- Bug in `DataFrame.fillna()` where a `ValueError` would raise when one column contained a `datetime64[ns, tz]` dtype (GH15522)
- Bug in `Series.hasnans()` that could be incorrectly cached and return incorrect answers if null elements are introduced after an initial call (GH19700)
- `Series.isin()` now treats all NaN-floats as equal also for `np.object_-dtype`. This behavior is consistent with the behavior for `float64` (GH22119)
- `unique()` no longer mangles NaN-floats and the `NaT`-object for `np.object_-dtype`, i.e. `NaT` is no longer coerced to a NaN-value and is treated as a different entity. (GH22295)
- `DataFrame` and `Series` now properly handle numpy masked arrays with hardened masks. Previously, constructing a `DataFrame` or `Series` from a masked array with a hard mask would create a pandas object containing the underlying value, rather than the expected NaN. (GH24574)
- Bug in `DataFrame` constructor where `dtype` argument was not honored when handling numpy masked record arrays. (GH24874)

## MultiIndex

- Bug in `io.formats.style.Styler.applymap()` where `subset=` with `MultiIndex` slice would reduce to `Series` (GH19861)
- Removed compatibility for `MultiIndex` pickles prior to version 0.8.0; compatibility with `MultiIndex` pickles from version 0.13 forward is maintained (GH21654)
- `MultiIndex.get_loc_level()` (and as a consequence, `.loc` on a `Series` or `DataFrame` with a `MultiIndex` index) will now raise a `KeyError`, rather than returning an empty slice, if asked a label which is present in the levels but is unused (GH22221)
- `MultiIndex` has gained the `MultiIndex.from_frame()`, it allows constructing a `MultiIndex` object from a `DataFrame` (GH22420)
- Fix `TypeError` in Python 3 when creating `MultiIndex` in which some levels have mixed types, e.g. when some labels are tuples (GH15457)

## IO

- Bug in `read_csv()` in which a column specified with `CategoricalDtype` of boolean categories was not being correctly coerced from string values to booleans (GH20498)
- Bug in `read_csv()` in which unicode column names were not being properly recognized with Python 2.x (GH13253)
- Bug in `DataFrame.to_sql()` when writing timezone aware data (`datetime64[ns, tz]` dtype) would raise a `TypeError` (GH9086)
- Bug in `DataFrame.to_sql()` where a naive `DatetimeIndex` would be written as `TIMESTAMP WITH TIMEZONE` type in supported databases, e.g. PostgreSQL (GH23510)
- Bug in `read_excel()` when `parse_cols` is specified with an empty dataset (GH9208)
- `read_html()` no longer ignores all-whitespace `<tr>` within `<thead>` when considering the `skiprows` and `header` arguments. Previously, users had to decrease their `header` and `skiprows` values on such tables to work around the issue. (GH21641)

- `read_excel()` will correctly show the deprecation warning for previously deprecated `sheetname` (GH17994)
- `read_csv()` and `read_table()` will throw `UnicodeError` and not `coredump` on badly encoded strings (GH22748)
- `read_csv()` will correctly parse timezone-aware datetimes (GH22256)
- Bug in `read_csv()` in which memory management was prematurely optimized for the C engine when the data was being read in chunks (GH23509)
- Bug in `read_csv()` in unnamed columns were being improperly identified when extracting a multi-index (GH23687)
- `read_sas()` will parse numbers in `sas7bdat`-files that have width less than 8 bytes correctly. (GH21616)
- `read_sas()` will correctly parse `sas7bdat` files with many columns (GH22628)
- `read_sas()` will correctly parse `sas7bdat` files with data page types having also bit 7 set (so page type is  $128 + 256 = 384$ ) (GH16615)
- Bug in `read_sas()` in which an incorrect error was raised on an invalid file format. (GH24548)
- Bug in `detect_client_encoding()` where potential `IOError` goes unhandled when importing in a `mod_wsgi` process due to restricted access to `stdout`. (GH21552)
- Bug in `DataFrame.to_html()` with `index=False` misses truncation indicators (...) on truncated `DataFrame` (GH15019, GH22783)
- Bug in `DataFrame.to_html()` with `index=False` when both columns and row index are `MultiIndex` (GH22579)
- Bug in `DataFrame.to_html()` with `index_names=False` displaying index name (GH22747)
- Bug in `DataFrame.to_html()` with `header=False` not displaying row index names (GH23788)
- Bug in `DataFrame.to_html()` with `sparsify=False` that caused it to raise `TypeError` (GH22887)
- Bug in `DataFrame.to_string()` that broke column alignment when `index=False` and width of first column's values is greater than the width of first column's header (GH16839, GH13032)
- Bug in `DataFrame.to_string()` that caused representations of `DataFrame` to not take up the whole window (GH22984)
- Bug in `DataFrame.to_csv()` where a single level `MultiIndex` incorrectly wrote a tuple. Now just the value of the index is written (GH19589).
- `HDFStore` will raise `ValueError` when the `format` kwarg is passed to the constructor (GH13291)
- Bug in `HDFStore.append()` when appending a `DataFrame` with an empty string column and `min_itemsize < 8` (GH12242)
- Bug in `read_csv()` in which memory leaks occurred in the C engine when parsing `NaN` values due to insufficient cleanup on completion or error (GH21353)
- Bug in `read_csv()` in which incorrect error messages were being raised when `skipfooter` was passed in along with `nrows`, `iterator`, or `chunksize` (GH23711)
- Bug in `read_csv()` in which `MultiIndex` index names were being improperly handled in the cases when they were not provided (GH23484)
- Bug in `read_csv()` in which unnecessary warnings were being raised when the `dialect`'s values conflicted with the default arguments (GH23761)
- Bug in `read_html()` in which the error message was not displaying the valid flavors when an invalid one was provided (GH23549)

- Bug in `read_excel()` in which extraneous header names were extracted, even though none were specified (GH11733)
- Bug in `read_excel()` in which column names were not being properly converted to string sometimes in Python 2.x (GH23874)
- Bug in `read_excel()` in which `index_col=None` was not being respected and parsing index columns anyway (GH18792, GH20480)
- Bug in `read_excel()` in which `usecols` was not being validated for proper column names when passed in as a string (GH20480)
- Bug in `DataFrame.to_dict()` when the resulting dict contains non-Python scalars in the case of numeric data (GH23753)
- `DataFrame.to_string()`, `DataFrame.to_html()`, `DataFrame.to_latex()` will correctly format output when a string is passed as the `float_format` argument (GH21625, GH22270)
- Bug in `read_csv()` that caused it to raise `OverflowError` when trying to use 'inf' as `na_value` with integer index column (GH17128)
- Bug in `read_csv()` that caused the C engine on Python 3.6+ on Windows to improperly read CSV filenames with accented or special characters (GH15086)
- Bug in `read_fwf()` in which the compression type of a file was not being properly inferred (GH22199)
- Bug in `pandas.io.json.json_normalize()` that caused it to raise `TypeError` when two consecutive elements of `record_path` are dicts (GH22706)
- Bug in `DataFrame.to_stata()`, `pandas.io.stata.StataWriter` and `pandas.io.stata.StataWriter117` where a exception would leave a partially written and invalid dta file (GH23573)
- Bug in `DataFrame.to_stata()` and `pandas.io.stata.StataWriter117` that produced invalid files when using strLs with non-ASCII characters (GH23573)
- Bug in `HDFStore` that caused it to raise `ValueError` when reading a Dataframe in Python 3 from fixed format written in Python 2 (GH24510)
- Bug in `DataFrame.to_string()` and more generally in the floating `repr` formatter. Zeros were not trimmed if `inf` was present in a columns while it was the case with NA values. Zeros are now trimmed as in the presence of NA (GH24861).
- Bug in the `repr` when truncating the number of columns and having a wide last column (GH24849).

## Plotting

- Bug in `DataFrame.plot.scatter()` and `DataFrame.plot.hexbin()` caused x-axis label and ticklabels to disappear when `colorbar` was on in IPython inline backend (GH10611, GH10678, and GH20455)
- Bug in plotting a Series with datetimes using `matplotlib.axes.Axes.scatter()` (GH22039)
- Bug in `DataFrame.plot.bar()` caused bars to use multiple colors instead of a single one (GH20585)
- Bug in validating color parameter caused extra color to be appended to the given color array. This happened to multiple plotting functions using `matplotlib`. (GH20726)

## GroupBy/resample/rolling

- Bug in `pandas.core.window.Rolling.min()` and `pandas.core.window.Rolling.max()` with `closed='left'`, a datetime-like index and only one entry in the series leading to segfault (GH24718)
- Bug in `pandas.core.groupby.GroupBy.first()` and `pandas.core.groupby.GroupBy.last()` with `as_index=False` leading to the loss of timezone information (GH15884)
- Bug in `DataFrame.resample()` when downsampling across a DST boundary (GH8531)
- Bug in date anchoring for `DataFrame.resample()` with offset Day when `n > 1` (GH24127)
- Bug where `ValueError` is wrongly raised when calling `count()` method of a `SeriesGroupBy` when the grouping variable only contains NaNs and numpy version `< 1.13` (GH21956).
- Multiple bugs in `pandas.core.window.Rolling.min()` with `closed='left'` and a datetime-like index leading to incorrect results and also segfault. (GH21704)
- Bug in `pandas.core.resample.Resampler.apply()` when passing positional arguments to applied func (GH14615).
- Bug in `Series.resample()` when passing `numpy.timedelta64` to `loffset` kwarg (GH7687).
- Bug in `pandas.core.resample.Resampler.asfreq()` when frequency of `TimedeltaIndex` is a subperiod of a new frequency (GH13022).
- Bug in `pandas.core.groupby.SeriesGroupBy.mean()` when values were integral but could not fit inside of `int64`, overflowing instead. (GH22487)
- `pandas.core.groupby.RollingGroupby.agg()` and `pandas.core.groupby.ExpandingGroupby.agg()` now support multiple aggregation functions as parameters (GH15072)
- Bug in `DataFrame.resample()` and `Series.resample()` when resampling by a weekly offset ('W') across a DST transition (GH9119, GH21459)
- Bug in `DataFrame.expanding()` in which the axis argument was not being respected during aggregations (GH23372)
- Bug in `pandas.core.groupby.GroupBy.transform()` which caused missing values when the input function can accept a `DataFrame` but renames it (GH23455).
- Bug in `pandas.core.groupby.GroupBy.nth()` where column order was not always preserved (GH20760)
- Bug in `pandas.core.groupby.GroupBy.rank()` with `method='dense'` and `pct=True` when a group has only one member would raise a `ZeroDivisionError` (GH23666).
- Calling `pandas.core.groupby.GroupBy.rank()` with empty groups and `pct=True` was raising a `ZeroDivisionError` (GH22519)
- Bug in `DataFrame.resample()` when resampling NaT in `TimeDeltaIndex` (GH13223).
- Bug in `DataFrame.groupby()` did not respect the `observed` argument when selecting a column and instead always used `observed=False` (GH23970)
- Bug in `pandas.core.groupby.SeriesGroupBy.pct_change()` or `pandas.core.groupby.DataFrameGroupBy.pct_change()` would previously work across groups when calculating the percent change, where it now correctly works per group (GH21200, GH21235).
- Bug preventing hash table creation with very large number ( $2^{32}$ ) of rows (GH22805)
- Bug in groupby when grouping on categorical causes `ValueError` and incorrect grouping if `observed=True` and nan is present in categorical column (GH24740, GH21151).

## Reshaping

- Bug in `pandas.concat()` when joining resampled DataFrames with timezone aware index (GH13783)
- Bug in `pandas.concat()` when joining only Series the names argument of `concat` is no longer ignored (GH23490)
- Bug in `Series.combine_first()` with `datetime64[ns, tz]` dtype which would return tz-naive result (GH21469)
- Bug in `Series.where()` and `DataFrame.where()` with `datetime64[ns, tz]` dtype (GH21546)
- Bug in `DataFrame.where()` with an empty DataFrame and empty cond having non-bool dtype (GH21947)
- Bug in `Series.mask()` and `DataFrame.mask()` with list conditionals (GH21891)
- Bug in `DataFrame.replace()` raises `RecursionError` when converting `OutOfBounds` `datetime64[ns, tz]` (GH20380)
- `pandas.core.groupby.GroupBy.rank()` now raises a `ValueError` when an invalid value is passed for argument `na_option` (GH22124)
- Bug in `get_dummies()` with Unicode attributes in Python 2 (GH22084)
- Bug in `DataFrame.replace()` raises `RecursionError` when replacing empty lists (GH22083)
- Bug in `Series.replace()` and `DataFrame.replace()` when dict is used as the `to_replace` value and one key in the dict is another key's value, the results were inconsistent between using integer key and using string key (GH20656)
- Bug in `DataFrame.drop_duplicates()` for empty DataFrame which incorrectly raises an error (GH20516)
- Bug in `pandas.wide_to_long()` when a string is passed to the `stubnames` argument and a column name is a substring of that stubname (GH22468)
- Bug in `merge()` when merging `datetime64[ns, tz]` data that contained a DST transition (GH18885)
- Bug in `merge_asof()` when merging on float values within defined tolerance (GH22981)
- Bug in `pandas.concat()` when concatenating a multicolumn DataFrame with tz-aware data against a DataFrame with a different number of columns (GH22796)
- Bug in `merge_asof()` where confusing error message raised when attempting to merge with missing values (GH23189)
- Bug in `DataFrame.nsmallest()` and `DataFrame.nlargest()` for dataframes that have a `MultiIndex` for columns (GH23033).
- Bug in `pandas.melt()` when passing column names that are not present in DataFrame (GH23575)
- Bug in `DataFrame.append()` with a `Series` with a dateutil timezone would raise a `TypeError` (GH23682)
- Bug in `Series` construction when passing no data and `dtype=str` (GH22477)
- Bug in `cut()` with bins as an overlapping `IntervalIndex` where multiple bins were returned per item instead of raising a `ValueError` (GH23980)
- Bug in `pandas.concat()` when joining `Series` `datetimetz` with `Series` category would lose timezone (GH23816)
- Bug in `DataFrame.join()` when joining on partial `MultiIndex` would drop names (GH20452).
- `DataFrame.nlargest()` and `DataFrame.nsmallest()` now returns the correct n values when `keep != 'all'` also when tied on the first columns (GH22752)

- Constructing a DataFrame with an index argument that wasn't already an instance of Index was broken (GH22227).
- Bug in `DataFrame` prevented list subclasses to be used to construction (GH21226)
- Bug in `DataFrame.unstack()` and `DataFrame.pivot_table()` returning a misleading error message when the resulting DataFrame has more elements than int32 can handle. Now, the error message is improved, pointing towards the actual problem (GH20601)
- Bug in `DataFrame.unstack()` where a `ValueError` was raised when unstacking timezone aware values (GH18338)
- Bug in `DataFrame.stack()` where timezone aware values were converted to timezone naive values (GH19420)
- Bug in `merge_asof()` where a `TypeError` was raised when `by_col` were timezone aware values (GH21184)
- Bug showing an incorrect shape when throwing error during DataFrame construction. (GH20742)

## Sparse

- Updating a boolean, datetime, or timedelta column to be Sparse now works (GH22367)
- Bug in `Series.to_sparse()` with Series already holding sparse data not constructing properly (GH22389)
- Providing a `sparse_index` to the `SparseArray` constructor no longer defaults the na-value to `np.nan` for all dtypes. The correct `na_value` for `data.dtype` is now used.
- Bug in `SparseArray.nbytes` under-reporting its memory usage by not including the size of its sparse index.
- Improved performance of `Series.shift()` for non-NA `fill_value`, as values are no longer converted to a dense array.
- Bug in `DataFrame.groupby` not including `fill_value` in the groups for non-NA `fill_value` when grouping by a sparse column (GH5078)
- Bug in unary inversion operator (`~`) on a `SparseSeries` with boolean values. The performance of this has also been improved (GH22835)
- Bug in `SparseArray.unique()` not returning the unique values (GH19595)
- Bug in `SparseArray.nonzero()` and `SparseDataFrame.dropna()` returning shifted/incorrect results (GH21172)
- Bug in `DataFrame.apply()` where dtypes would lose sparseness (GH23744)
- Bug in `concat()` when concatenating a list of `Series` with all-sparse values changing the `fill_value` and converting to a dense Series (GH24371)

## Style

- `background_gradient()` now takes a `text_color_threshold` parameter to automatically lighten the text color based on the luminance of the background color. This improves readability with dark background colors without the need to limit the background colormap range. (GH21258)
- `background_gradient()` now also supports tablewise application (in addition to rowwise and columnwise) with `axis=None` (GH15204)
- `bar()` now also supports tablewise application (in addition to rowwise and columnwise) with `axis=None` and setting clipping range with `vmin` and `vmax` (GH21548 and GH21526). NaN values are also handled properly.

### Build changes

- Building pandas for development now requires `cython >= 0.28.2` (GH21688)
- Testing pandas now requires `hypothesis>=3.58`. You can find [the Hypothesis docs here](#), and a pandas-specific introduction *in the contributing guide*. (GH22280)
- Building pandas on macOS now targets minimum macOS 10.9 if run on macOS 10.9 or above (GH23424)

### Other

- Bug where C variables were declared with external linkage causing import errors if certain other C libraries were imported before pandas. (GH24113)

## 5.7 Version 0.23

### 5.7.1 What's new in 0.23.4 (August 3, 2018)

This is a minor bug-fix release in the 0.23.x series and includes some small regression fixes and bug fixes. We recommend that all users upgrade to this version.

**Warning:** Starting January 1, 2019, pandas feature releases will support Python 3 only. See [Dropping Python 2.7](#) for more.

### What's new in v0.23.4

- *Fixed regressions*
- *Bug fixes*
- *Contributors*

### Fixed regressions

- Python 3.7 with Windows gave all missing values for rolling variance calculations ([GH21813](#))

### Bug fixes

#### Groupby/resample/rolling

- Bug where calling `DataFrameGroupBy.agg()` with a list of functions including `ohlcv` as the non-initial element would raise a `ValueError` ([GH21716](#))
- Bug in `roll_quantile` caused a memory leak when calling `.rolling(...).quantile(q)` with `q` in  $(0,1)$  ([GH21965](#))

#### Missing

- Bug in `Series.clip()` and `DataFrame.clip()` cannot accept list-like threshold containing `NaN` ([GH19992](#))

### Contributors

A total of 6 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

- Jeff Reback
- MeeseeksMachine +
- Tom Augspurger
- chris-b1
- h-vetinari
- meeseeksdev[bot]

## 5.7.2 What's new in 0.23.3 (July 7, 2018)

This release fixes a build issue with the sdist for Python 3.7 ([GH21785](#)) There are no other changes.

## Contributors

A total of 2 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

- Tom Augspurger
- meeseeksdev[bot] +

### 5.7.3 What’s new in 0.23.2 (July 5, 2018)

This is a minor bug-fix release in the 0.23.x series and includes some small regression fixes and bug fixes. We recommend that all users upgrade to this version.

**Note:** pandas 0.23.2 is first pandas release that’s compatible with Python 3.7 ([GH20552](#))

**Warning:** Starting January 1, 2019, pandas feature releases will support Python 3 only. See [Dropping Python 2.7](#) for more.

#### What’s new in v0.23.2

- *Logical reductions over entire DataFrame*
- *Fixed regressions*
- *Build changes*
- *Bug fixes*
- *Contributors*

#### Logical reductions over entire DataFrame

`DataFrame.all()` and `DataFrame.any()` now accept `axis=None` to reduce over all axes to a scalar ([GH19976](#))

```
In [1]: df = pd.DataFrame({"A": [1, 2], "B": [True, False]})
```

```
In [2]: df.all(axis=None)
```

```
Out[2]: False
```

This also provides compatibility with NumPy 1.15, which now dispatches to `DataFrame.all`. With NumPy 1.15 and pandas 0.23.1 or earlier, `numpy.all()` will no longer reduce over every axis:

```
>>> # NumPy 1.15, pandas 0.23.1
>>> np.any(pd.DataFrame({"A": [False], "B": [False]}))
A False
B False
dtype: bool
```

With pandas 0.23.2, that will correctly return False, as it did with NumPy < 1.15.

```
In [3]: np.any(pd.DataFrame({"A": [False], "B": [False]}))
Out[3]: False
```

## Fixed regressions

- Fixed regression in `to_csv()` when handling file-like object incorrectly (GH21471)
- Re-allowed duplicate level names of a `MultiIndex`. Accessing a level that has a duplicate name by name still raises an error (GH19029).
- Bug in both `DataFrame.first_valid_index()` and `Series.first_valid_index()` raised for a row index having duplicate values (GH21441)
- Fixed printing of DataFrames with hierarchical columns with long names (GH21180)
- Fixed regression in `reindex()` and `groupby()` with a `MultiIndex` or multiple keys that contains categorical datetime-like values (GH21390).
- Fixed regression in unary negative operations with object dtype (GH21380)
- Bug in `Timestamp.ceil()` and `Timestamp.floor()` when timestamp is a multiple of the rounding frequency (GH21262)
- Fixed regression in `to_clipboard()` that defaulted to copying dataframes with space delimited instead of tab delimited (GH21104)

## Build changes

- The source and binary distributions no longer include test data files, resulting in smaller download sizes. Tests relying on these data files will be skipped when using `pandas.test()`. (GH19320)

## Bug fixes

### Conversion

- Bug in constructing `Index` with an iterator or generator (GH21470)
- Bug in `Series.nlargest()` for signed and unsigned integer dtypes when the minimum value is present (GH21426)

### Indexing

- Bug in `Index.get_indexer_non_unique()` with categorical key (GH21448)
- Bug in comparison operations for `MultiIndex` where error was raised on equality / inequality comparison involving a `MultiIndex` with `nlevels == 1` (GH21149)
- Bug in `DataFrame.drop()` behaviour is not consistent for unique and non-unique indexes (GH21494)
- Bug in `DataFrame.duplicated()` with a large number of columns causing a ‘maximum recursion depth exceeded’ (GH21524).

### I/O

- Bug in `read_csv()` that caused it to incorrectly raise an error when `nrows=0`, `low_memory=True`, and `index_col` was not `None` (GH21141)
- Bug in `json_normalize()` when formatting the `record_prefix` with integer columns (GH21536)

### Categorical

- Bug in rendering *Series* with Categorical dtype in rare conditions under Python 2.7 (GH21002)

### Timezones

- Bug in *Timestamp* and *DatetimeIndex* where passing a *Timestamp* localized after a DST transition would return a datetime before the DST transition (GH20854)
- Bug in comparing *DataFrame* with tz-aware *DatetimeIndex* columns with a DST transition that raised a *KeyError* (GH19970)
- Bug in *DatetimeIndex.shift()* where an *AssertionError* would raise when shifting across DST (GH8616)
- Bug in *Timestamp* constructor where passing an invalid timezone offset designator (Z) would not raise a *ValueError* (GH8910)
- Bug in *Timestamp.replace()* where replacing at a DST boundary would retain an incorrect offset (GH7825)
- Bug in *DatetimeIndex.reindex()* when reindexing a tz-naive and tz-aware *DatetimeIndex* (GH8306)
- Bug in *DatetimeIndex.resample()* when downsampling across a DST boundary (GH8531)

### Timedelta

- Bug in *Timedelta* where non-zero timedeltas shorter than 1 microsecond were considered False (GH21484)

### Contributors

A total of 17 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

## 5.7.4 What's new in 0.23.1 (June 12, 2018)

This is a minor bug-fix release in the 0.23.x series and includes some small regression fixes and bug fixes. We recommend that all users upgrade to this version.

**Warning:** Starting January 1, 2019, pandas feature releases will support Python 3 only. See [Dropping Python 2.7](#) for more.

### What's new in v0.23.1

- *Fixed regressions*
- *Performance improvements*
- *Bug fixes*
- *Contributors*

### Fixed regressions

#### Comparing Series with `datetime.date`

We've reverted a 0.23.0 change to comparing a *Series* holding datetimes and a `datetime.date` object (GH21152). In pandas 0.22 and earlier, comparing a *Series* holding datetimes and `datetime.date` objects would coerce the `datetime.date` to a `datetime` before comparing. This was inconsistent with Python, NumPy, and *DatetimeIndex*, which never consider a `datetime` and `datetime.date` equal.

In 0.23.0, we unified operations between *DatetimeIndex* and *Series*, and in the process changed comparisons between a *Series* of datetimes and `datetime.date` without warning.

We've temporarily restored the 0.22.0 behavior, so datetimes and dates may again compare equal, but restore the 0.23.0 behavior in a future release.

To summarize, here's the behavior in 0.22.0, 0.23.0, 0.23.1:

```
0.22.0... Silently coerce the datetime.date
>>> import datetime
>>> pd.Series(pd.date_range('2017', periods=2)) == datetime.date(2017, 1, 1)
0 True
1 False
dtype: bool

0.23.0... Do not coerce the datetime.date
>>> pd.Series(pd.date_range('2017', periods=2)) == datetime.date(2017, 1, 1)
0 False
1 False
dtype: bool

0.23.1... Coerce the datetime.date with a warning
>>> pd.Series(pd.date_range('2017', periods=2)) == datetime.date(2017, 1, 1)
/bin/python:1: FutureWarning: Comparing Series of datetimes with 'datetime.date'.
Currently, the
'datetime.date' is coerced to a datetime. In the future pandas will
```

(continues on next page)

(continued from previous page)

```

not coerce, and the values not compare equal to the 'datetime.date'.
To retain the current behavior, convert the 'datetime.date' to a
datetime with 'pd.Timestamp'.
#!/bin/python3
0 True
1 False
dtype: bool

```

In addition, ordering comparisons will raise a `TypeError` in the future.

### Other fixes

- Reverted the ability of `to_sql()` to perform multivalue inserts as this caused regression in certain cases (GH21103). In the future this will be made configurable.
- Fixed regression in the `DatetimeIndex.date` and `DatetimeIndex.time` attributes in case of timezone-aware data: `DatetimeIndex.time` returned a tz-aware time instead of tz-naive (GH21267) and `DatetimeIndex.date` returned incorrect date when the input date has a non-UTC timezone (GH21230).
- Fixed regression in `pandas.io.json.json_normalize()` when called with `None` values in nested levels in JSON, and to not drop keys with value as `None` (GH21158, GH21356).
- Bug in `to_csv()` causes encoding error when compression and encoding are specified (GH21241, GH21118)
- Bug preventing pandas from being importable with `-OO` optimization (GH21071)
- Bug in `Categorical.fillna()` incorrectly raising a `TypeError` when value the individual categories are iterable and value is an iterable (GH21097, GH19788)
- Fixed regression in constructors coercing NA values like `None` to strings when passing `dtype=str` (GH21083)
- Regression in `pivot_table()` where an ordered `Categorical` with missing values for the pivot's index would give a mis-aligned result (GH21133)
- Fixed regression in merging on boolean index/columns (GH21119).

### Performance improvements

- Improved performance of `CategoricalIndex.is_monotonic_increasing()`, `CategoricalIndex.is_monotonic_decreasing()` and `CategoricalIndex.is_monotonic()` (GH21025)
- Improved performance of `CategoricalIndex.is_unique()` (GH21107)

### Bug fixes

#### Groupby/resample/rolling

- Bug in `DataFrame.agg()` where applying multiple aggregation functions to a `DataFrame` with duplicated column names would cause a stack overflow (GH21063)
- Bug in `pandas.core.groupby.GroupBy.ffill()` and `pandas.core.groupby.GroupBy.bfill()` where the fill within a grouping would not always be applied as intended due to the implementations' use of a non-stable sort (GH21207)
- Bug in `pandas.core.groupby.GroupBy.rank()` where results did not scale to 100% when specifying `method='dense'` and `pct=True`
- Bug in `pandas.DataFrame.rolling()` and `pandas.Series.rolling()` which incorrectly accepted a 0 window size rather than raising (GH21286)

### Data-type specific

- Bug in `Series.str.replace()` where the method throws `TypeError` on Python 3.5.2 (GH21078)
- Bug in `Timedelta` where passing a float with a unit would prematurely round the float precision (GH14156)
- Bug in `pandas.testing.assert_index_equal()` which raised `AssertionError` incorrectly, when comparing two `CategoricalIndex` objects with param `check_categorical=False` (GH19776)

### Sparse

- Bug in `SparseArray.shape` which previously only returned the shape `SparseArray.sp_values` (GH21126)

### Indexing

- Bug in `Series.reset_index()` where appropriate error was not raised with an invalid level name (GH20925)
- Bug in `interval_range()` when `start/periods` or `end/periods` are specified with float `start` or `end` (GH21161)
- Bug in `MultiIndex.set_names()` where error raised for a `MultiIndex` with `nlevels == 1` (GH21149)
- Bug in `IntervalIndex` constructors where creating an `IntervalIndex` from categorical data was not fully supported (GH21243, GH21253)
- Bug in `MultiIndex.sort_index()` which was not guaranteed to sort correctly with `level=1`; this was also causing data misalignment in particular `DataFrame.stack()` operations (GH20994, GH20945, GH21052)

### Plotting

- New keywords (`sharex`, `sharey`) to turn on/off sharing of x/y-axis by subplots generated with `pandas.DataFrame().groupby().boxplot()` (GH20968)

### I/O

- Bug in IO methods specifying `compression='zip'` which produced uncompressed zip archives (GH17778, GH21144)
- Bug in `DataFrame.to_stata()` which prevented exporting DataFrames to buffers and most file-like objects (GH21041)
- Bug in `read_stata()` and `StataReader` which did not correctly decode utf-8 strings on Python 3 from Stata 14 files (dta version 118) (GH21244)
- Bug in IO JSON `read_json()` reading empty JSON schema with `orient='table'` back to `DataFrame` caused an error (GH21287)

### Reshaping

- Bug in `concat()` where error was raised in concatenating `Series` with numpy scalar and tuple names (GH21015)
- Bug in `concat()` warning message providing the wrong guidance for future behavior (GH21101)

### Other

- Tab completion on `Index` in IPython no longer outputs deprecation warnings (GH21125)
- Bug preventing pandas being used on Windows without C++ redistributable installed (GH21106)

## 5.7.5 What's new in 0.23.0 (May 15, 2018)

This is a major release from 0.22.0 and includes a number of API changes, deprecations, new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

Highlights include:

- *Round-trippable JSON format with 'table' orient.*
- *Instantiation from dicts respects order for Python 3.6+.*
- *Dependent column arguments for assign.*
- *Merging / sorting on a combination of columns and index levels.*
- *Extending pandas with custom types.*
- *Excluding unobserved categories from groupby.*
- *Changes to make output shape of DataFrame.apply consistent.*

Check the *API Changes* and *deprecations* before updating.

**Warning:** Starting January 1, 2019, pandas feature releases will support Python 3 only. See [Dropping Python 2.7](#) for more.

### What's new in v0.23.0

- *New features*
  - *JSON read/write round-trippable with orient='table'*
  - *Method .assign() accepts dependent arguments*
  - *Merging on a combination of columns and index levels*
  - *Sorting by a combination of columns and index levels*
  - *Extending pandas with custom types (experimental)*
  - *New observed keyword for excluding unobserved categories in GroupBy*
  - *Rolling/Expanding.apply() accepts raw=False to pass a Series to the function*
  - *DataFrame.interpolate has gained the limit\_area kwarg*
  - *Function get\_dummies now supports dtype argument*
  - *Timedelta mod method*
  - *Method .rank() handles inf values when NaN are present*
  - *Series.str.cat has gained the join kwarg*
  - *DataFrame.astype performs column-wise conversion to Categorical*
  - *Other enhancements*
- *Backwards incompatible API changes*
  - *Dependencies have increased minimum versions*
  - *Instantiation from dicts preserves dict insertion order for Python 3.6+*

- *Deprecate Panel*
- *pandas.core.common removals*
- *Changes to make output of DataFrame.apply consistent*
- *Concatenation will no longer sort*
- *Build changes*
- *Index division by zero fills correctly*
- *Extraction of matching patterns from strings*
- *Default value for the ordered parameter of CategoricalDtype*
- *Better pretty-printing of DataFrames in a terminal*
- *Datetimelike API changes*
- *Other API changes*
- *Deprecations*
- *Removal of prior version deprecations/changes*
- *Performance improvements*
- *Documentation changes*
- *Bug fixes*
  - *Categorical*
  - *Datetimelike*
  - *Timedelta*
  - *Timezones*
  - *Offsets*
  - *Numeric*
  - *Strings*
  - *Indexing*
  - *MultiIndex*
  - *IO*
  - *Plotting*
  - *GroupBy/resample/rolling*
  - *Sparse*
  - *Reshaping*
  - *Other*
- *Contributors*

## New features

## JSON read/write round-trippable with orient='table'

A DataFrame can now be written to and subsequently read back via JSON while preserving metadata through usage of the orient='table' argument (see [GH18912](#) and [GH9146](#)). Previously, none of the available orient values guaranteed the preservation of dtypes and index names, amongst other metadata.

```
In [1]: df = pd.DataFrame({'foo': [1, 2, 3, 4],
...: 'bar': ['a', 'b', 'c', 'd'],
...: 'baz': pd.date_range('2018-01-01', freq='d', periods=4),
...: 'qux': pd.Categorical(['a', 'b', 'c', 'c'])},
...: index=pd.Index(range(4), name='idx'))
...:
```

```
In [2]: df
```

```
Out[2]:
 foo bar baz qux
idx
0 1 a 2018-01-01 a
1 2 b 2018-01-02 b
2 3 c 2018-01-03 c
3 4 d 2018-01-04 c
```

```
[4 rows x 4 columns]
```

```
In [3]: df.dtypes
```

```
Out[3]:
foo int64
bar object
baz datetime64[ns]
qux category
Length: 4, dtype: object
```

```
In [4]: df.to_json('test.json', orient='table')
```

```
In [5]: new_df = pd.read_json('test.json', orient='table')
```

```
In [6]: new_df
```

```
Out[6]:
 foo bar baz qux
idx
0 1 a 2018-01-01 a
1 2 b 2018-01-02 b
2 3 c 2018-01-03 c
3 4 d 2018-01-04 c
```

```
[4 rows x 4 columns]
```

```
In [7]: new_df.dtypes
```

```
Out[7]:
foo int64
bar object
```

(continues on next page)

(continued from previous page)

```
baz datetime64[ns]
qux category
Length: 4, dtype: object
```

Please note that the string index is not supported with the round trip format, as it is used by default in `write_json` to indicate a missing index name.

```
In [8]: df.index.name = 'index'

In [9]: df.to_json('test.json', orient='table')

In [10]: new_df = pd.read_json('test.json', orient='table')

In [11]: new_df
Out[11]:
 foo bar baz qux
0 1 a 2018-01-01 a
1 2 b 2018-01-02 b
2 3 c 2018-01-03 c
3 4 d 2018-01-04 c

[4 rows x 4 columns]

In [12]: new_df.dtypes
Out[12]:
foo int64
bar object
baz datetime64[ns]
qux category
Length: 4, dtype: object
```

### Method `.assign()` accepts dependent arguments

The `DataFrame.assign()` now accepts dependent keyword arguments for python version later than 3.6 (see also [PEP 468](#)). Later keyword arguments may now refer to earlier ones if the argument is a callable. See the [documentation here](#) (GH14207)

```
In [13]: df = pd.DataFrame({'A': [1, 2, 3]})

In [14]: df
Out[14]:
 A
0 1
1 2
2 3

[3 rows x 1 columns]

In [15]: df.assign(B=df.A, C=lambda x: x['A'] + x['B'])
Out[15]:
 A B C
0 1 1 2
1 2 2 4
2 3 3 6
```

(continues on next page)

(continued from previous page)

```

0 1 1 2
1 2 2 4
2 3 3 6

[3 rows x 3 columns]

```

**Warning:** This may subtly change the behavior of your code when you're using `.assign()` to update an existing column. Previously, callables referring to other variables being updated would get the “old” values

Previous behavior:

```

In [2]: df = pd.DataFrame({"A": [1, 2, 3]})

In [3]: df.assign(A=lambda df: df.A + 1, C=lambda df: df.A * -1)
Out[3]:
 A C
0 2 -1
1 3 -2
2 4 -3

```

New behavior:

```

In [16]: df.assign(A=df.A + 1, C=lambda df: df.A * -1)
Out[16]:
 A C
0 2 -2
1 3 -3
2 4 -4

[3 rows x 2 columns]

```

## Merging on a combination of columns and index levels

Strings passed to `DataFrame.merge()` as the `on`, `left_on`, and `right_on` parameters may now refer to either column names or index level names. This enables merging `DataFrame` instances on a combination of index levels and columns without resetting indexes. See the [Merge on columns and levels](#) documentation section. (GH14355)

```

In [17]: left_index = pd.Index(['K0', 'K0', 'K1', 'K2'], name='key1')

In [18]: left = pd.DataFrame({'A': ['A0', 'A1', 'A2', 'A3'],
.....: 'B': ['B0', 'B1', 'B2', 'B3'],
.....: 'key2': ['K0', 'K1', 'K0', 'K1']},
.....: index=left_index)
.....:

In [19]: right_index = pd.Index(['K0', 'K1', 'K2', 'K2'], name='key1')

In [20]: right = pd.DataFrame({'C': ['C0', 'C1', 'C2', 'C3'],
.....: 'D': ['D0', 'D1', 'D2', 'D3'],
.....: 'key2': ['K0', 'K0', 'K0', 'K1']},
.....: index=right_index)

```

(continues on next page)

(continued from previous page)

```

.....:
In [21]: left.merge(right, on=['key1', 'key2'])
Out[21]:
 A B key2 C D
key1
K0 A0 B0 K0 C0 D0
K1 A2 B2 K0 C1 D1
K2 A3 B3 K1 C3 D3

[3 rows x 5 columns]

```

### Sorting by a combination of columns and index levels

Strings passed to `DataFrame.sort_values()` as the `by` parameter may now refer to either column names or index level names. This enables sorting `DataFrame` instances by a combination of index levels and columns without resetting indexes. See the *Sorting by Indexes and Values* documentation section. (GH14353)

```

Build MultiIndex
In [22]: idx = pd.MultiIndex.from_tuples([('a', 1), ('a', 2), ('a', 2),
.....: ('b', 2), ('b', 1), ('b', 1)])
.....:

In [23]: idx.names = ['first', 'second']

Build DataFrame
In [24]: df_multi = pd.DataFrame({'A': np.arange(6, 0, -1)},
.....: index=idx)
.....:

In [25]: df_multi
Out[25]:
 A
first second
a 1 6
 2 5
 2 4
b 2 3
 1 2
 1 1

[6 rows x 1 columns]

Sort by 'second' (index) and 'A' (column)
In [26]: df_multi.sort_values(by=['second', 'A'])
Out[26]:
 A
first second
b 1 1
 1 2
a 1 6

```

(continues on next page)

(continued from previous page)

```
b 2 3
a 2 4
 2 5

[6 rows x 1 columns]
```

### Extending pandas with custom types (experimental)

pandas now supports storing array-like objects that aren't necessarily 1-D NumPy arrays as columns in a DataFrame or values in a Series. This allows third-party libraries to implement extensions to NumPy's types, similar to how pandas implemented categoricals, datetimes with timezones, periods, and intervals.

As a demonstration, we'll use [cyberpandas](#), which provides an `IPArray` type for storing ip addresses.

```
In [1]: from cyberpandas import IPArray

In [2]: values = IPArray([
...: 0,
...: 3232235777,
...: 42540766452641154071740215577757643572
...:])
...:
...:
...:
```

`IPArray` isn't a normal 1-D NumPy array, but because it's a pandas `ExtensionArray`, it can be stored properly inside pandas' containers.

```
In [3]: ser = pd.Series(values)

In [4]: ser
Out[4]:
0 0.0.0.0
1 192.168.1.1
2 2001:db8:85a3::8a2e:370:7334
dtype: ip
```

Notice that the dtype is `ip`. The missing value semantics of the underlying array are respected:

```
In [5]: ser.isna()
Out[5]:
0 True
1 False
2 False
dtype: bool
```

For more, see the [extension types](#) documentation. If you build an extension array, publicize it on our ecosystem page.

**New observed keyword for excluding unobserved categories in GroupBy**

Grouping by a categorical includes the unobserved categories in the output. When grouping by multiple categorical columns, this means you get the cartesian product of all the categories, including combinations where there are no observations, which can result in a large number of groups. We have added a keyword `observed` to control this behavior, it defaults to `observed=False` for backward-compatibility. (GH14942, GH8138, GH15217, GH17594, GH8669, GH20583, GH20902)

```
In [27]: cat1 = pd.Categorical(["a", "a", "b", "b"],
.....: categories=["a", "b", "z"], ordered=True)
.....:

In [28]: cat2 = pd.Categorical(["c", "d", "c", "d"],
.....: categories=["c", "d", "y"], ordered=True)
.....:

In [29]: df = pd.DataFrame({"A": cat1, "B": cat2, "values": [1, 2, 3, 4]})

In [30]: df['C'] = ['foo', 'bar'] * 2

In [31]: df
Out[31]:
 A B values C
0 a c 1 foo
1 a d 2 bar
2 b c 3 foo
3 b d 4 bar

[4 rows x 4 columns]
```

To show all values, the previous behavior:

```
In [32]: df.groupby(['A', 'B', 'C'], observed=False).count()
Out[32]:
 values
A B C
a c bar 0
 foo 1
 d bar 1
 foo 0
 y bar 0
... ...
z c foo 0
 d bar 0
 foo 0
 y bar 0
 foo 0

[18 rows x 1 columns]
```

To show only observed values:

```
In [33]: df.groupby(['A', 'B', 'C'], observed=True).count()
```

(continues on next page)

(continued from previous page)

```

Out[33]:
 values
A B C
a c foo 1
 d bar 1
b c foo 1
 d bar 1

[4 rows x 1 columns]

```

For pivoting operations, this behavior is *already* controlled by the `dropna` keyword:

```

In [34]: cat1 = pd.Categorical(["a", "a", "b", "b"],
.....: categories=["a", "b", "z"], ordered=True)
.....:

In [35]: cat2 = pd.Categorical(["c", "d", "c", "d"],
.....: categories=["c", "d", "y"], ordered=True)
.....:

In [36]: df = pd.DataFrame({"A": cat1, "B": cat2, "values": [1, 2, 3, 4]})

In [37]: df
Out[37]:
 A B values
0 a c 1
1 a d 2
2 b c 3
3 b d 4

[4 rows x 3 columns]

```

```

In [38]: pd.pivot_table(df, values='values', index=['A', 'B'],
.....: dropna=True)
.....:
Out[38]:
 values
A B
a c 1
 d 2
b c 3
 d 4

[4 rows x 1 columns]

In [39]: pd.pivot_table(df, values='values', index=['A', 'B'],
.....: dropna=False)
.....:
Out[39]:
 values
A B
a c 1.0

```

(continues on next page)

(continued from previous page)

```

d 2.0
y NaN
b c 3.0
d 4.0
y NaN
z c NaN
d NaN
y NaN

[9 rows x 1 columns]
```

### Rolling/Expanding.apply() accepts raw=False to pass a Series to the function

`Series.rolling().apply()`, `DataFrame.rolling().apply()`, `Series.expanding().apply()`, and `DataFrame.expanding().apply()` have gained a `raw=None` parameter. This is similar to `DataFrame.apply()`. This parameter, if `True` allows one to send a `np.ndarray` to the applied function. If `False` a `Series` will be passed. The default is `None`, which preserves backward compatibility, so this will default to `True`, sending an `np.ndarray`. In a future version the default will be changed to `False`, sending a `Series`. ([GH5071](#), [GH20584](#))

```
In [40]: s = pd.Series(np.arange(5), np.arange(5) + 1)
```

```
In [41]: s
```

```
Out[41]:
```

```

1 0
2 1
3 2
4 3
5 4
Length: 5, dtype: int64
```

Pass a Series:

```
In [42]: s.rolling(2, min_periods=1).apply(lambda x: x.iloc[-1], raw=False)
```

```
Out[42]:
```

```

1 0.0
2 1.0
3 2.0
4 3.0
5 4.0
Length: 5, dtype: float64
```

Mimic the original behavior of passing a ndarray:

```
In [43]: s.rolling(2, min_periods=1).apply(lambda x: x[-1], raw=True)
```

```
Out[43]:
```

```

1 0.0
2 1.0
3 2.0
4 3.0
5 4.0
Length: 5, dtype: float64
```

### DataFrame.interpolate has gained the limit\_area kwarg

`DataFrame.interpolate()` has gained a `limit_area` parameter to allow further control of which NaNs are replaced. Use `limit_area='inside'` to fill only NaNs surrounded by valid values or use `limit_area='outside'` to fill only NaNs outside the existing valid values while preserving those inside. (GH16284) See the [full documentation here](#).

```
In [44]: ser = pd.Series([np.nan, np.nan, 5, np.nan, np.nan,
.....: np.nan, 13, np.nan, np.nan])
.....:
```

```
In [45]: ser
```

```
Out[45]:
```

```
0 NaN
1 NaN
2 5.0
3 NaN
4 NaN
5 NaN
6 13.0
7 NaN
8 NaN
Length: 9, dtype: float64
```

Fill one consecutive inside value in both directions

```
In [46]: ser.interpolate(limit_direction='both', limit_area='inside', limit=1)
```

```
Out[46]:
```

```
0 NaN
1 NaN
2 5.0
3 7.0
4 NaN
5 11.0
6 13.0
7 NaN
8 NaN
Length: 9, dtype: float64
```

Fill all consecutive outside values backward

```
In [47]: ser.interpolate(limit_direction='backward', limit_area='outside')
```

```
Out[47]:
```

```
0 5.0
1 5.0
2 5.0
3 NaN
4 NaN
5 NaN
6 13.0
7 NaN
8 NaN
Length: 9, dtype: float64
```

Fill all consecutive outside values in both directions

```
In [48]: ser.interpolate(limit_direction='both', limit_area='outside')
Out[48]:
0 5.0
1 5.0
2 5.0
3 NaN
4 NaN
5 NaN
6 13.0
7 13.0
8 13.0
Length: 9, dtype: float64
```

### Function `get_dummies` now supports `dtype` argument

The `get_dummies()` now accepts a `dtype` argument, which specifies a dtype for the new columns. The default remains `uint8`. (GH18330)

```
In [49]: df = pd.DataFrame({'a': [1, 2], 'b': [3, 4], 'c': [5, 6]})

In [50]: pd.get_dummies(df, columns=['c']).dtypes
Out[50]:
a int64
b int64
c_5 uint8
c_6 uint8
Length: 4, dtype: object

In [51]: pd.get_dummies(df, columns=['c'], dtype=bool).dtypes
Out[51]:
a int64
b int64
c_5 bool
c_6 bool
Length: 4, dtype: object
```

### Timedelta mod method

`mod (%)` and `divmod` operations are now defined on `Timedelta` objects when operating with either `timedelta`-like or with numeric arguments. See the [documentation here](#). (GH19365)

```
In [52]: td = pd.Timedelta(hours=37)

In [53]: td % pd.Timedelta(minutes=45)
Out[53]: Timedelta('0 days 00:15:00')
```

### Method `.rank()` handles `inf` values when `NaN` are present

In previous versions, `.rank()` would assign `inf` elements `NaN` as their ranks. Now ranks are calculated properly. (GH6945)

```
In [54]: s = pd.Series([-np.inf, 0, 1, np.nan, np.inf])
```

```
In [55]: s
```

```
Out[55]:
```

```
0 -inf
1 0.0
2 1.0
3 NaN
4 inf
Length: 5, dtype: float64
```

Previous behavior:

```
In [11]: s.rank()
```

```
Out[11]:
```

```
0 1.0
1 2.0
2 3.0
3 NaN
4 NaN
dtype: float64
```

Current behavior:

```
In [56]: s.rank()
```

```
Out[56]:
```

```
0 1.0
1 2.0
2 3.0
3 NaN
4 4.0
Length: 5, dtype: float64
```

Furthermore, previously if you rank `inf` or `-inf` values together with `NaN` values, the calculation won't distinguish `NaN` from infinity when using 'top' or 'bottom' argument.

```
In [57]: s = pd.Series([np.nan, np.nan, -np.inf, -np.inf])
```

```
In [58]: s
```

```
Out[58]:
```

```
0 NaN
1 NaN
2 -inf
3 -inf
Length: 4, dtype: float64
```

Previous behavior:

```
In [15]: s.rank(na_option='top')
Out[15]:
0 2.5
1 2.5
2 2.5
3 2.5
dtype: float64
```

Current behavior:

```
In [59]: s.rank(na_option='top')
Out[59]:
0 1.5
1 1.5
2 3.5
3 3.5
Length: 4, dtype: float64
```

These bugs were squashed:

- Bug in `DataFrame.rank()` and `Series.rank()` when `method='dense'` and `pct=True` in which percentile ranks were not being used with the number of distinct observations ([GH15630](#))
- Bug in `Series.rank()` and `DataFrame.rank()` when `ascending=False` failed to return correct ranks for infinity if NaN were present ([GH19538](#))
- Bug in `DataFrameGroupBy.rank()` where ranks were incorrect when both infinity and NaN were present ([GH20561](#))

### Series.str.cat has gained the join kwarg

Previously, `Series.str.cat()` did not – in contrast to most of pandas – align `Series` on their index before concatenation (see [GH18657](#)). The method has now gained a keyword `join` to control the manner of alignment, see examples below and [here](#).

In v.0.23 `join` will default to `None` (meaning no alignment), but this default will change to `'left'` in a future version of pandas.

```
In [60]: s = pd.Series(['a', 'b', 'c', 'd'])
In [61]: t = pd.Series(['b', 'd', 'e', 'c'], index=[1, 3, 4, 2])
In [62]: s.str.cat(t)
Out[62]:
0 NaN
1 bb
2 cc
3 dd
Length: 4, dtype: object

In [63]: s.str.cat(t, join='left', na_rep='-')
Out[63]:
0 a-
1 bb
```

(continues on next page)

(continued from previous page)

```
2 cc
3 dd
Length: 4, dtype: object
```

Furthermore, `Series.str.cat()` now works for `CategoricalIndex` as well (previously raised a `ValueError`; see [GH20842](#)).

### `DataFrame.astype` performs column-wise conversion to `Categorical`

`DataFrame.astype()` can now perform column-wise conversion to `Categorical` by supplying the string `'category'` or a `CategoricalDtype`. Previously, attempting this would raise a `NotImplementedError`. See the *Object creation* section of the documentation for more details and examples. ([GH12860](#), [GH18099](#))

Supplying the string `'category'` performs column-wise conversion, with only labels appearing in a given column set as categories:

```
In [64]: df = pd.DataFrame({'A': list('abca'), 'B': list('bccd')})
In [65]: df = df.astype('category')
In [66]: df['A'].dtype
Out[66]: CategoricalDtype(categories=['a', 'b', 'c'], ordered=False)
In [67]: df['B'].dtype
Out[67]: CategoricalDtype(categories=['b', 'c', 'd'], ordered=False)
```

Supplying a `CategoricalDtype` will make the categories in each column consistent with the supplied dtype:

```
In [68]: from pandas.api.types import CategoricalDtype
In [69]: df = pd.DataFrame({'A': list('abca'), 'B': list('bccd')})
In [70]: cdt = CategoricalDtype(categories=list('abcd'), ordered=True)
In [71]: df = df.astype(cdt)
In [72]: df['A'].dtype
Out[72]: CategoricalDtype(categories=['a', 'b', 'c', 'd'], ordered=True)
In [73]: df['B'].dtype
Out[73]: CategoricalDtype(categories=['a', 'b', 'c', 'd'], ordered=True)
```

## Other enhancements

- Unary `+` now permitted for Series and DataFrame as numeric operator (GH16073)
- Better support for `to_excel()` output with the `xlsxwriter` engine. (GH16149)
- `pandas.tseries.frequencies.to_offset()` now accepts leading `'+'` signs e.g. `'+1h'`. (GH18171)
- `MultiIndex.unique()` now supports the `level=` argument, to get unique values from a specific index level (GH17896)
- `pandas.io.formats.style.Styler` now has method `hide_index()` to determine whether the index will be rendered in output (GH14194)
- `pandas.io.formats.style.Styler` now has method `hide_columns()` to determine whether columns will be hidden in output (GH14194)
- Improved wording of `ValueError` raised in `to_datetime()` when `unit=` is passed with a non-convertible value (GH14350)
- `Series.fillna()` now accepts a Series or a dict as a value for a categorical dtype (GH17033)
- `pandas.read_clipboard()` updated to use `qtpy`, falling back to `PyQt5` and then `PyQt4`, adding compatibility with `Python3` and multiple `python-qt` bindings (GH17722)
- Improved wording of `ValueError` raised in `read_csv()` when the `usecols` argument cannot match all columns. (GH17301)
- `DataFrame.corrwith()` now silently drops non-numeric columns when passed a Series. Before, an exception was raised (GH18570).
- `IntervalIndex` now supports time zone aware `Interval` objects (GH18537, GH18538)
- `Series()` / `DataFrame()` tab completion also returns identifiers in the first level of a `MultiIndex()`. (GH16326)
- `read_excel()` has gained the `nrows` parameter (GH16645)
- `DataFrame.append()` can now in more cases preserve the type of the calling dataframe's columns (e.g. if both are `CategoricalIndex`) (GH18359)
- `DataFrame.to_json()` and `Series.to_json()` now accept an `index` argument which allows the user to exclude the index from the JSON output (GH17394)
- `IntervalIndex.to_tuples()` has gained the `na_tuple` parameter to control whether NA is returned as a tuple of NA, or NA itself (GH18756)
- `Categorical.rename_categories`, `CategoricalIndex.rename_categories` and `Series.cat.rename_categories` can now take a callable as their argument (GH18862)
- `Interval` and `IntervalIndex` have gained a `length` attribute (GH18789)
- `Resampler` objects now have a functioning `pipe` method. Previously, calls to `pipe` were diverted to the `mean` method (GH17905).
- `is_scalar()` now returns `True` for `DateOffset` objects (GH18943).
- `DataFrame.pivot()` now accepts a list for the `values=` kwarg (GH17160).
- Added `pandas.api.extensions.register_dataframe_accessor()`, `pandas.api.extensions.register_series_accessor()`, and `pandas.api.extensions.register_index_accessor()`, accessor for libraries downstream of pandas to register custom accessors like `.cat` on pandas objects. See *Registering Custom Accessors* for more (GH14781).

- `IntervalIndex.astype` now supports conversions between subtypes when passed an `IntervalDtype` (GH19197)
- `IntervalIndex` and its associated constructor methods (`from_arrays`, `from_breaks`, `from_tuples`) have gained a `dtype` parameter (GH19262)
- Added `pandas.core.groupby.SeriesGroupBy.is_monotonic_increasing()` and `pandas.core.groupby.SeriesGroupBy.is_monotonic_decreasing()` (GH17015)
- For subclassed DataFrames, `DataFrame.apply()` will now preserve the `Series` subclass (if defined) when passing the data to the applied function (GH19822)
- `DataFrame.from_dict()` now accepts a `columns` argument that can be used to specify the column names when `orient='index'` is used (GH18529)
- Added option `display.html.use_mathjax` so `MathJax` can be disabled when rendering tables in Jupyter notebooks (GH19856, GH19824)
- `DataFrame.replace()` now supports the `method` parameter, which can be used to specify the replacement method when `to_replace` is a scalar, list or tuple and `value` is `None` (GH19632)
- `Timestamp.month_name()`, `DatetimeIndex.month_name()`, and `Series.dt.month_name()` are now available (GH12805)
- `Timestamp.day_name()` and `DatetimeIndex.day_name()` are now available to return day names with a specified locale (GH12806)
- `DataFrame.to_sql()` now performs a multi-value insert if the underlying connection supports itk rather than inserting row by row. SQLAlchemy dialects supporting multi-value inserts include: `mysql`, `postgresql`, `sqlite` and any dialect with `supports_multivalues_insert`. (GH14315, GH8953)
- `read_html()` now accepts a `displayed_only` keyword argument to controls whether or not hidden elements are parsed (True by default) (GH20027)
- `read_html()` now reads all `<tbody>` elements in a `<table>`, not just the first. (GH20690)
- `quantile()` and `quantile()` now accept the `interpolation` keyword, `linear` by default (GH20497)
- zip compression is supported via `compression=zip` in `DataFrame.to_pickle()`, `Series.to_pickle()`, `DataFrame.to_csv()`, `Series.to_csv()`, `DataFrame.to_json()`, `Series.to_json()`. (GH17778)
- `WeekOfMonth` constructor now supports `n=0` (GH20517).
- `DataFrame` and `Series` now support matrix multiplication (`@` operator) (GH10259) for Python>=3.5
- Updated `DataFrame.to_gbq()` and `pandas.read_gbq()` signature and documentation to reflect changes from the pandas-gbq library version 0.4.0. Adds intersphinx mapping to pandas-gbq library. (GH20564)
- Added new writer for exporting Stata dta files in version 117, `StataWriter117`. This format supports exporting strings with lengths up to 2,000,000 characters (GH16450)
- `to_hdf()` and `read_hdf()` now accept an `errors` keyword argument to control encoding error handling (GH20835)
- `cut()` has gained the `duplicates='raise'|'drop'` option to control whether to raise on duplicated edges (GH20947)
- `date_range()`, `timedelta_range()`, and `interval_range()` now return a linearly spaced index if `start`, `stop`, and `periods` are specified, but `freq` is not. (GH20808, GH20983, GH20976)

## Backwards incompatible API changes

### Dependencies have increased minimum versions

We have updated our minimum supported versions of dependencies ([GH15184](#)). If installed, we now require:

| Package         | Minimum Version | Required | Issue                   |
|-----------------|-----------------|----------|-------------------------|
| python-dateutil | 2.5.0           | X        | <a href="#">GH15184</a> |
| openpyxl        | 2.4.0           |          | <a href="#">GH15184</a> |
| beautifulsoup4  | 4.2.1           |          | <a href="#">GH20082</a> |
| setuptools      | 24.2.0          |          | <a href="#">GH20698</a> |

### Instantiation from dicts preserves dict insertion order for Python 3.6+

Until Python 3.6, dicts in Python had no formally defined ordering. For Python version 3.6 and later, dicts are ordered by insertion order, see [PEP 468](#). pandas will use the dict's insertion order, when creating a Series or DataFrame from a dict and you're using Python version 3.6 or higher. ([GH19884](#))

Previous behavior (and current behavior if on Python < 3.6):

```
In [16]: pd.Series({'Income': 2000,
.....: 'Expenses': -1500,
.....: 'Taxes': -200,
.....: 'Net result': 300})
Out[16]:
Expenses -1500
Income 2000
Net result 300
Taxes -200
dtype: int64
```

Note the Series above is ordered alphabetically by the index values.

New behavior (for Python >= 3.6):

```
In [74]: pd.Series({'Income': 2000,
.....: 'Expenses': -1500,
.....: 'Taxes': -200,
.....: 'Net result': 300})
Out[74]:
Income 2000
Expenses -1500
Taxes -200
Net result 300
Length: 4, dtype: int64
```

Notice that the Series is now ordered by insertion order. This new behavior is used for all relevant pandas types (Series, DataFrame, SparseSeries and SparseDataFrame).

If you wish to retain the old behavior while using Python >= 3.6, you can use `.sort_index()`:

```
In [75]: pd.Series({'Income': 2000,
.....: 'Expenses': -1500,
.....: 'Taxes': -200,
.....: 'Net result': 300}).sort_index()
.....:
Out[75]:
Expenses -1500
Income 2000
Net result 300
Taxes -200
Length: 4, dtype: int64
```

## Deprecate Panel

Panel was deprecated in the 0.20.x release, showing as a `DeprecationWarning`. Using Panel will now show a `FutureWarning`. The recommended way to represent 3-D data are with a `MultiIndex` on a `DataFrame` via the `to_frame()` or with the `xarray` package. pandas provides a `to_xarray()` method to automate this conversion (GH13563, GH18324).

```
In [75]: import pandas._testing as tm

In [76]: p = tm.makePanel()

In [77]: p
Out[77]:
<class 'pandas.core.panel.Panel'>
Dimensions: 3 (items) x 3 (major_axis) x 4 (minor_axis)
Items axis: ItemA to ItemC
Major_axis axis: 2000-01-03 00:00:00 to 2000-01-05 00:00:00
Minor_axis axis: A to D
```

Convert to a `MultiIndex` `DataFrame`

```
In [78]: p.to_frame()
Out[78]:
```

| major      | minor | ItemA     | ItemB     | ItemC     |
|------------|-------|-----------|-----------|-----------|
| 2000-01-03 | A     | 0.469112  | 0.721555  | 0.404705  |
|            | B     | -1.135632 | 0.271860  | -1.039268 |
|            | C     | 0.119209  | 0.276232  | -1.344312 |
|            | D     | -2.104569 | 0.113648  | -0.109050 |
| 2000-01-04 | A     | -0.282863 | -0.706771 | 0.577046  |
|            | B     | 1.212112  | -0.424972 | -0.370647 |
|            | C     | -1.044236 | -1.087401 | 0.844885  |
|            | D     | -0.494929 | -1.478427 | 1.643563  |
| 2000-01-05 | A     | -1.509059 | -1.039575 | -1.715002 |
|            | B     | -0.173215 | 0.567020  | -1.157892 |
|            | C     | -0.861849 | -0.673690 | 1.075770  |
|            | D     | 1.071804  | 0.524988  | -1.469388 |

```
[12 rows x 3 columns]
```

Convert to an xarray DataArray

```
In [79]: p.to_xarray()
Out[79]:
<xarray.DataArray (items: 3, major_axis: 3, minor_axis: 4)>
array([[[0.469112, -1.135632, 0.119209, -2.104569],
 [-0.282863, 1.212112, -1.044236, -0.494929],
 [-1.509059, -0.173215, -0.861849, 1.071804]],

 [[0.721555, 0.27186 , 0.276232, 0.113648],
 [-0.706771, -0.424972, -1.087401, -1.478427],
 [-1.039575, 0.56702 , -0.67369 , 0.524988]],

 [[0.404705, -1.039268, -1.344312, -0.10905],
 [0.577046, -0.370647, 0.844885, 1.643563],
 [-1.715002, -1.157892, 1.07577 , -1.469388]])
Coordinates:
 * items (items) object 'ItemA' 'ItemB' 'ItemC'
 * major_axis (major_axis) datetime64[ns] 2000-01-03 2000-01-04 2000-01-05
 * minor_axis (minor_axis) object 'A' 'B' 'C' 'D'
```

### pandas.core.common removals

The following error & warning messages are removed from `pandas.core.common` (GH13634, GH19769):

- PerformanceWarning
- UnsupportedFunctionCall
- UnsortedIndexError
- AbstractMethodError

These are available from import from `pandas.errors` (since 0.19.0).

### Changes to make output of `DataFrame.apply` consistent

`DataFrame.apply()` was inconsistent when applying an arbitrary user-defined-function that returned a list-like with `axis=1`. Several bugs and inconsistencies are resolved. If the applied function returns a Series, then pandas will return a DataFrame; otherwise a Series will be returned, this includes the case where a list-like (e.g. `tuple` or `list` is returned) (GH16353, GH17437, GH17970, GH17348, GH17892, GH18573, GH17602, GH18775, GH18901, GH18919).

```
In [76]: df = pd.DataFrame(np.tile(np.arange(3), 6).reshape(6, -1) + 1,
.....: columns=['A', 'B', 'C'])
.....:
```

```
In [77]: df
Out[77]:
 A B C
0 1 2 3
1 1 2 3
2 1 2 3
3 1 2 3
4 1 2 3
```

(continues on next page)

(continued from previous page)

```
5 1 2 3

[6 rows x 3 columns]
```

Previous behavior: if the returned shape happened to match the length of original columns, this would return a DataFrame. If the return shape did not match, a Series with lists was returned.

```
In [3]: df.apply(lambda x: [1, 2, 3], axis=1)
Out[3]:
 A B C
0 1 2 3
1 1 2 3
2 1 2 3
3 1 2 3
4 1 2 3
5 1 2 3
```

```
In [4]: df.apply(lambda x: [1, 2], axis=1)
Out[4]:
0 [1, 2]
1 [1, 2]
2 [1, 2]
3 [1, 2]
4 [1, 2]
5 [1, 2]
dtype: object
```

New behavior: When the applied function returns a list-like, this will now *always* return a Series.

```
In [78]: df.apply(lambda x: [1, 2, 3], axis=1)
Out[78]:
0 [1, 2, 3]
1 [1, 2, 3]
2 [1, 2, 3]
3 [1, 2, 3]
4 [1, 2, 3]
5 [1, 2, 3]
Length: 6, dtype: object
```

```
In [79]: df.apply(lambda x: [1, 2], axis=1)
Out[79]:
0 [1, 2]
1 [1, 2]
2 [1, 2]
3 [1, 2]
4 [1, 2]
5 [1, 2]
Length: 6, dtype: object
```

To have expanded columns, you can use `result_type='expand'`

```
In [80]: df.apply(lambda x: [1, 2, 3], axis=1, result_type='expand')
Out[80]:
```

(continues on next page)

(continued from previous page)

```

 0 1 2
0 1 2 3
1 1 2 3
2 1 2 3
3 1 2 3
4 1 2 3
5 1 2 3

[6 rows x 3 columns]
```

To broadcast the result across the original columns (the old behaviour for list-likes of the correct length), you can use `result_type='broadcast'`. The shape must match the original columns.

```

In [81]: df.apply(lambda x: [1, 2, 3], axis=1, result_type='broadcast')
Out[81]:
 A B C
0 1 2 3
1 1 2 3
2 1 2 3
3 1 2 3
4 1 2 3
5 1 2 3

[6 rows x 3 columns]
```

Returning a Series allows one to control the exact return structure and column names:

```

In [82]: df.apply(lambda x: pd.Series([1, 2, 3], index=['D', 'E', 'F']), axis=1)
Out[82]:
 D E F
0 1 2 3
1 1 2 3
2 1 2 3
3 1 2 3
4 1 2 3
5 1 2 3

[6 rows x 3 columns]
```

### Concatenation will no longer sort

In a future version of pandas `pandas.concat()` will no longer sort the non-concatenation axis when it is not already aligned. The current behavior is the same as the previous (sorting), but now a warning is issued when `sort` is not specified and the non-concatenation axis is not aligned (GH4588).

```

In [83]: df1 = pd.DataFrame({"a": [1, 2], "b": [1, 2]}, columns=['b', 'a'])
In [84]: df2 = pd.DataFrame({"a": [4, 5]})
In [85]: pd.concat([df1, df2])
Out[85]:
```

(continues on next page)

(continued from previous page)

```

 b a
0 1.0 1
1 2.0 2
0 NaN 4
1 NaN 5

[4 rows x 2 columns]
```

To keep the previous behavior (sorting) and silence the warning, pass `sort=True`

```

In [86]: pd.concat([df1, df2], sort=True)
Out[86]:
 a b
0 1 1.0
1 2 2.0
0 4 NaN
1 5 NaN

[4 rows x 2 columns]
```

To accept the future behavior (no sorting), pass `sort=False`

Note that this change also applies to `DataFrame.append()`, which has also received a `sort` keyword for controlling this behavior.

## Build changes

- Building pandas for development now requires `cython >= 0.24` (GH18613)
- Building from source now explicitly requires `setuptools` in `setup.py` (GH18113)
- Updated conda recipe to be in compliance with conda-build 3.0+ (GH18002)

## Index division by zero fills correctly

Division operations on `Index` and subclasses will now fill division of positive numbers by zero with `np.inf`, division of negative numbers by zero with `-np.inf` and `0 / 0` with `np.nan`. This matches existing `Series` behavior. (GH19322, GH19347)

Previous behavior:

```

In [6]: index = pd.Int64Index([-1, 0, 1])

In [7]: index / 0
Out[7]: Int64Index([0, 0, 0], dtype='int64')

Previous behavior yielded different results depending on the type of zero in the
↳divisor
In [8]: index / 0.0
Out[8]: Float64Index([-inf, nan, inf], dtype='float64')

In [9]: index = pd.UInt64Index([0, 1])
```

(continues on next page)

(continued from previous page)

```
In [10]: index / np.array([0, 0], dtype=np.uint64)
Out[10]: UInt64Index([0, 0], dtype='uint64')

In [11]: pd.RangeIndex(1, 5) / 0
ZeroDivisionError: integer division or modulo by zero
```

Current behavior:

```
In [87]: index = pd.Int64Index([-1, 0, 1])

division by zero gives -infinity where negative,
+infinity where positive, and NaN for 0 / 0
In [88]: index / 0
Out[88]: Float64Index([-inf, nan, inf], dtype='float64')

The result of division by zero should not depend on
whether the zero is int or float
In [89]: index / 0.0
Out[89]: Float64Index([-inf, nan, inf], dtype='float64')

In [90]: index = pd.UInt64Index([0, 1])

In [91]: index / np.array([0, 0], dtype=np.uint64)
Out[91]: Float64Index([nan, inf], dtype='float64')

In [92]: pd.RangeIndex(1, 5) / 0
Out[92]: Float64Index([inf, inf, inf, inf], dtype='float64')
```

### Extraction of matching patterns from strings

By default, extracting matching patterns from strings with `str.extract()` used to return a `Series` if a single group was being extracted (a `DataFrame` if more than one group was extracted). As of pandas 0.23.0 `str.extract()` always returns a `DataFrame`, unless `expand` is set to `False`. Finally, `None` was an accepted value for the `expand` parameter (which was equivalent to `False`), but now raises a `ValueError`. ([GH11386](#))

Previous behavior:

```
In [1]: s = pd.Series(['number 10', '12 eggs'])

In [2]: extracted = s.str.extract(r'.*(\d\d).*')

In [3]: extracted
Out [3]:
0 10
1 12
dtype: object

In [4]: type(extracted)
Out [4]:
pandas.core.series.Series
```

New behavior:

```
In [93]: s = pd.Series(['number 10', '12 eggs'])
In [94]: extracted = s.str.extract(r'.*(\d\d).*')
In [95]: extracted
Out[95]:
 0
0 10
1 12

[2 rows x 1 columns]
In [96]: type(extracted)
Out[96]: pandas.core.frame.DataFrame
```

To restore previous behavior, simply set `expand` to `False`:

```
In [97]: s = pd.Series(['number 10', '12 eggs'])
In [98]: extracted = s.str.extract(r'.*(\d\d).*', expand=False)
In [99]: extracted
Out[99]:
0 10
1 12
Length: 2, dtype: object
In [100]: type(extracted)
Out[100]: pandas.core.series.Series
```

### Default value for the ordered parameter of CategoricalDtype

The default value of the `ordered` parameter for `CategoricalDtype` has changed from `False` to `None` to allow updating of categories without impacting `ordered`. Behavior should remain consistent for downstream objects, such as *Categorical* (GH18790)

In previous versions, the default value for the `ordered` parameter was `False`. This could potentially lead to the `ordered` parameter unintentionally being changed from `True` to `False` when users attempt to update categories if `ordered` is not explicitly specified, as it would silently default to `False`. The new behavior for `ordered=None` is to retain the existing value of `ordered`.

New behavior:

```
In [2]: from pandas.api.types import CategoricalDtype
In [3]: cat = pd.Categorical(list('abcaba'), ordered=True, categories=list('cba'))
In [4]: cat
Out[4]:
[a, b, c, a, b, a]
Categories (3, object): [c < b < a]
```

(continues on next page)

(continued from previous page)

```
In [5]: cdt = CategoricalDtype(categories=list('cbad'))
```

```
In [6]: cat.astype(cdt)
```

```
Out[6]:
```

```
[a, b, c, a, b, a]
```

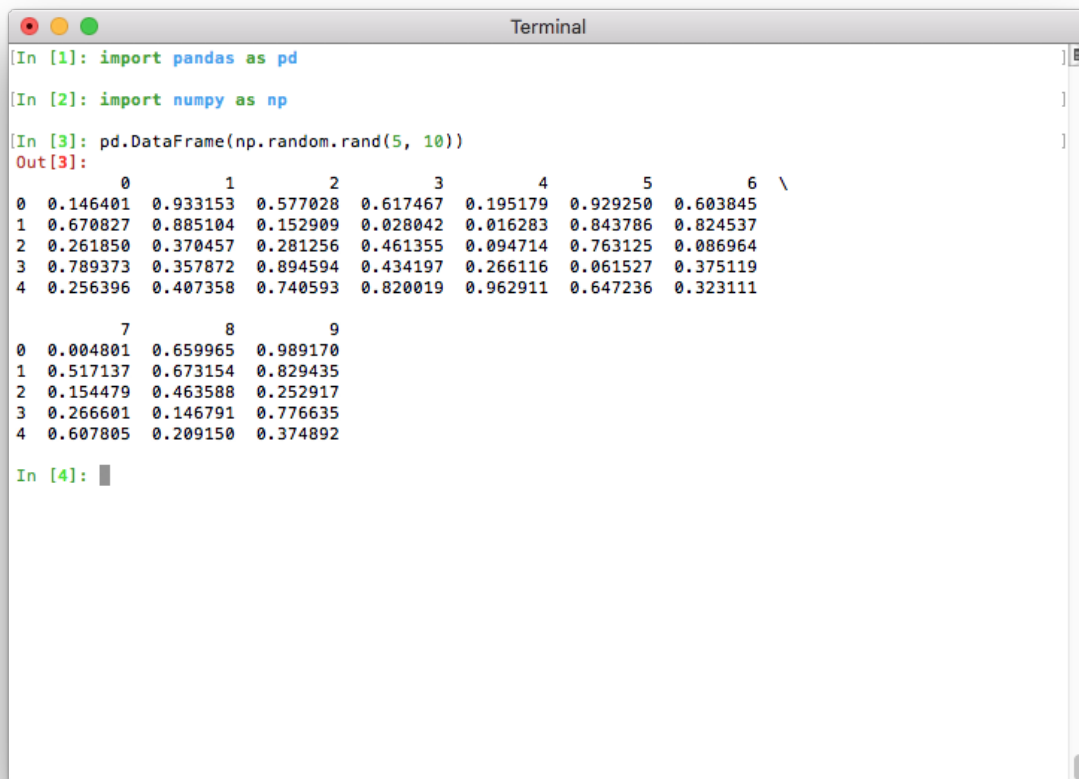

```
Categories (4, object): [c < b < a < d]
```

Notice in the example above that the converted `Categorical` has retained `ordered=True`. Had the default value for `ordered` remained as `False`, the converted `Categorical` would have become `unordered`, despite `ordered=False` never being explicitly specified. To change the value of `ordered`, explicitly pass it to the new dtype, e.g. `CategoricalDtype(categories=list('cbad'), ordered=False)`.

Note that the unintentional conversion of `ordered` discussed above did not arise in previous versions due to separate bugs that prevented `astype` from doing any type of category to category conversion ([GH10696](#), [GH18593](#)). These bugs have been fixed in this release, and motivated changing the default value of `ordered`.

## Better pretty-printing of DataFrames in a terminal

Previously, the default value for the maximum number of columns was `pd.options.display.max_columns=20`. This meant that relatively wide data frames would not fit within the terminal width, and pandas would introduce line breaks to display these 20 columns. This resulted in an output that was relatively difficult to read:

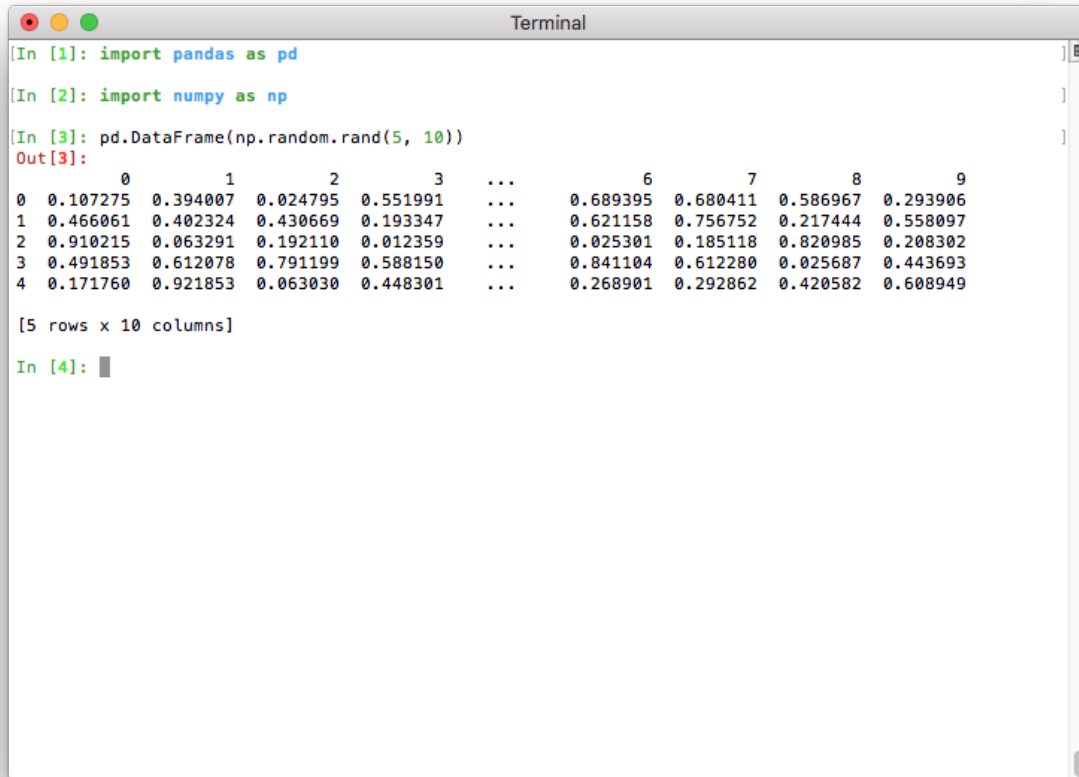

```
Terminal
[In [1]: import pandas as pd
[In [2]: import numpy as np
[In [3]: pd.DataFrame(np.random.rand(5, 10))
Out[3]:
 0 1 2 3 4 5 6 \
0 0.146401 0.933153 0.577028 0.617467 0.195179 0.929250 0.603845
1 0.670827 0.885104 0.152909 0.028042 0.016283 0.843786 0.824537
2 0.261850 0.370457 0.281256 0.461355 0.094714 0.763125 0.086964
3 0.789373 0.357872 0.894594 0.434197 0.266116 0.061527 0.375119
4 0.256396 0.407358 0.740593 0.820019 0.962911 0.647236 0.323111

 7 8 9
0 0.004801 0.659965 0.989170
1 0.517137 0.673154 0.829435
2 0.154479 0.463588 0.252917
3 0.266601 0.146791 0.776635
4 0.607805 0.209150 0.374892

In [4]:
```

If Python runs in a terminal, the maximum number of columns is now determined automatically so that the printed data frame fits within the current terminal width (`pd.options.display.max_columns=0`) (GH17023). If Python runs as a Jupyter kernel (such as the Jupyter QtConsole or a Jupyter notebook, as well as in many IDEs), this value cannot be inferred automatically and is thus set to 20 as in previous versions. In a terminal, this results in a much nicer output:

```
In [1]: import pandas as pd
In [2]: import numpy as np
In [3]: pd.DataFrame(np.random.rand(5, 10))
Out[3]:
```

|   | 0        | 1        | 2        | 3        | ... | 6        | 7        | 8        | 9        |
|---|----------|----------|----------|----------|-----|----------|----------|----------|----------|
| 0 | 0.107275 | 0.394007 | 0.024795 | 0.551991 | ... | 0.689395 | 0.680411 | 0.586967 | 0.293906 |
| 1 | 0.466061 | 0.402324 | 0.430669 | 0.193347 | ... | 0.621158 | 0.756752 | 0.217444 | 0.558097 |
| 2 | 0.910215 | 0.063291 | 0.192110 | 0.012359 | ... | 0.025301 | 0.185118 | 0.820985 | 0.208302 |
| 3 | 0.491853 | 0.612078 | 0.791199 | 0.588150 | ... | 0.841104 | 0.612280 | 0.025687 | 0.443693 |
| 4 | 0.171760 | 0.921853 | 0.063030 | 0.448301 | ... | 0.268901 | 0.292862 | 0.420582 | 0.608949 |

```
[5 rows x 10 columns]
In [4]:
```

Note that if you don't like the new default, you can always set this option yourself. To revert to the old setting, you can run this line:

```
pd.options.display.max_columns = 20
```

### Datetimelike API changes

- The default `Timedelta` constructor now accepts an ISO 8601 Duration string as an argument (GH19040)
- Subtracting `NaT` from a `Series` with `dtype='datetime64[ns]'` returns a `Series` with `dtype='timedelta64[ns]'` instead of `dtype='datetime64[ns]'` (GH18808)
- Addition or subtraction of `NaT` from `TimedeltaIndex` will return `TimedeltaIndex` instead of `DatetimeIndex` (GH19124)
- `DatetimeIndex.shift()` and `TimedeltaIndex.shift()` will now raise `NullFrequencyError` (which subclasses `ValueError`, which was raised in older versions) when the index object frequency is `None` (GH19147)
- Addition and subtraction of `NaN` from a `Series` with `dtype='timedelta64[ns]'` will raise a `TypeError` instead of treating the `NaN` as `NaT` (GH19274)

- NaT division with `datetime.timedelta` will now return NaN instead of raising (GH17876)
- Operations between a `Series` with dtype `dtype='datetime64[ns]'` and a `PeriodIndex` will correctly raises `TypeError` (GH18850)
- Subtraction of `Series` with timezone-aware `dtype='datetime64[ns]'` with mismatched timezones will raise `TypeError` instead of `ValueError` (GH18817)
- `Timestamp` will no longer silently ignore unused or invalid `tz` or `tzinfo` keyword arguments (GH17690)
- `Timestamp` will no longer silently ignore invalid `freq` arguments (GH5168)
- `CacheableOffset` and `WeekDay` are no longer available in the `pandas.tseries.offsets` module (GH17830)
- `pandas.tseries.frequencies.get_freq_group()` and `pandas.tseries.frequencies.DAYS` are removed from the public API (GH18034)
- `Series.truncate()` and `DataFrame.truncate()` will raise a `ValueError` if the index is not sorted instead of an unhelpful `KeyError` (GH17935)
- `Series.first` and `DataFrame.first` will now raise a `TypeError` rather than `NotImplementedError` when index is not a `DatetimeIndex` (GH20725).
- `Series.last` and `DataFrame.last` will now raise a `TypeError` rather than `NotImplementedError` when index is not a `DatetimeIndex` (GH20725).
- Restricted `DateOffset` keyword arguments. Previously, `DateOffset` subclasses allowed arbitrary keyword arguments which could lead to unexpected behavior. Now, only valid arguments will be accepted. (GH17176, GH18226).
- `pandas.merge()` provides a more informative error message when trying to merge on timezone-aware and timezone-naive columns (GH15800)
- For `DatetimeIndex` and `TimedeltaIndex` with `freq=None`, addition or subtraction of integer-dtyped array or `Index` will raise `NullFrequencyError` instead of `TypeError` (GH19895)
- `Timestamp` constructor now accepts a `nanosecond` keyword or positional argument (GH18898)
- `DatetimeIndex` will now raise an `AttributeError` when the `tz` attribute is set after instantiation (GH3746)
- `DatetimeIndex` with a `pytz` timezone will now return a consistent `pytz` timezone (GH18595)

## Other API changes

- `Series.astype()` and `Index.astype()` with an incompatible dtype will now raise a `TypeError` rather than a `ValueError` (GH18231)
- `Series` construction with an object dtyped tz-aware datetime and `dtype=object` specified, will now return an object dtyped `Series`, previously this would infer the datetime dtype (GH18231)
- A `Series` of `dtype=category` constructed from an empty dict will now have categories of `dtype=object` rather than `dtype=float64`, consistently with the case in which an empty list is passed (GH18515)
- All-NaN levels in a `MultiIndex` are now assigned `float` rather than `object` dtype, promoting consistency with `Index` (GH17929).
- Levels names of a `MultiIndex` (when not `None`) are now required to be unique: trying to create a `MultiIndex` with repeated names will raise a `ValueError` (GH18872)
- Both construction and renaming of `Index/MultiIndex` with non-hashable name/names will now raise `TypeError` (GH20527)
- `Index.map()` can now accept `Series` and dictionary input objects (GH12756, GH18482, GH18509).

- `DataFrame.unstack()` will now default to filling with `np.nan` for object columns. (GH12815)
- `IntervalIndex` constructor will raise if the `closed` parameter conflicts with how the input data is inferred to be closed (GH18421)
- Inserting missing values into indexes will work for all types of indexes and automatically insert the correct type of missing value (NaN, NaT, etc.) regardless of the type passed in (GH18295)
- When created with duplicate labels, `MultiIndex` now raises a `ValueError`. (GH17464)
- `Series.fillna()` now raises a `TypeError` instead of a `ValueError` when passed a list, tuple or `DataFrame` as a value (GH18293)
- `pandas.DataFrame.merge()` no longer casts a float column to object when merging on int and float columns (GH16572)
- `pandas.merge()` now raises a `ValueError` when trying to merge on incompatible data types (GH9780)
- The default NA value for `UInt64Index` has changed from 0 to NaN, which impacts methods that mask with NA, such as `UInt64Index.where()` (GH18398)
- Refactored `setup.py` to use `find_packages` instead of explicitly listing out all subpackages (GH18535)
- Rearranged the order of keyword arguments in `read_excel()` to align with `read_csv()` (GH16672)
- `wide_to_long()` previously kept numeric-like suffixes as object dtype. Now they are cast to numeric if possible (GH17627)
- In `read_excel()`, the `comment` argument is now exposed as a named parameter (GH18735)
- Rearranged the order of keyword arguments in `read_excel()` to align with `read_csv()` (GH16672)
- The options `html.border` and `mode.use_inf_as_null` were deprecated in prior versions, these will now show `FutureWarning` rather than a `DeprecationWarning` (GH19003)
- `IntervalIndex` and `IntervalDtype` no longer support categorical, object, and string subtypes (GH19016)
- `IntervalDtype` now returns `True` when compared against 'interval' regardless of subtype, and `IntervalDtype.name` now returns 'interval' regardless of subtype (GH18980)
- `KeyError` now raises instead of `ValueError` in `drop()`, `drop()`, `drop()`, `drop()` when dropping a non-existent element in an axis with duplicates (GH19186)
- `Series.to_csv()` now accepts a `compression` argument that works in the same way as the `compression` argument in `DataFrame.to_csv()` (GH18958)
- Set operations (union, difference...) on `IntervalIndex` with incompatible index types will now raise a `TypeError` rather than a `ValueError` (GH19329)
- `DateOffset` objects render more simply, e.g. `<DateOffset: days=1>` instead of `<DateOffset: kwds={'days': 1}>` (GH19403)
- `Categorical.fillna` now validates its value and method keyword arguments. It now raises when both or none are specified, matching the behavior of `Series.fillna()` (GH19682)
- `pd.to_datetime('today')` now returns a datetime, consistent with `pd.Timestamp('today')`; previously `pd.to_datetime('today')` returned a `.normalized()` datetime (GH19935)
- `Series.str.replace()` now takes an optional `regex` keyword which, when set to `False`, uses literal string replacement rather than regex replacement (GH16808)
- `DatetimeIndex.strftime()` and `PeriodIndex.strftime()` now return an `Index` instead of a numpy array to be consistent with similar accessors (GH20127)
- Constructing a `Series` from a list of length 1 no longer broadcasts this list when a longer index is specified (GH19714, GH20391).

- `DataFrame.to_dict()` with `orient='index'` no longer casts int columns to float for a DataFrame with only int and float columns (GH18580)
- A user-defined-function that is passed to `Series.rolling().aggregate()`, `DataFrame.rolling().aggregate()`, or its expanding cousins, will now *always* be passed a `Series`, rather than a `np.array`; `.apply()` only has the `raw` keyword, see [here](#). This is consistent with the signatures of `.aggregate()` across pandas (GH20584)
- Rolling and Expanding types raise `NotImplementedError` upon iteration (GH11704).

## Deprecations

- `Series.from_array` and `SparseSeries.from_array` are deprecated. Use the normal constructor `Series(. .)` and `SparseSeries(. .)` instead (GH18213).
- `DataFrame.as_matrix` is deprecated. Use `DataFrame.values` instead (GH18458).
- `Series.asobject`, `DatetimeIndex.asobject`, `PeriodIndex.asobject` and `TimeDeltaIndex.asobject` have been deprecated. Use `.astype(object)` instead (GH18572)
- Grouping by a tuple of keys now emits a `FutureWarning` and is deprecated. In the future, a tuple passed to 'by' will always refer to a single key that is the actual tuple, instead of treating the tuple as multiple keys. To retain the previous behavior, use a list instead of a tuple (GH18314)
- `Series.valid` is deprecated. Use `Series.dropna()` instead (GH18800).
- `read_excel()` has deprecated the `skip_footer` parameter. Use `skipfooter` instead (GH18836)
- `ExcelFile.parse()` has deprecated `sheetname` in favor of `sheet_name` for consistency with `read_excel()` (GH20920).
- The `is_copy` attribute is deprecated and will be removed in a future version (GH18801).
- `IntervalIndex.from_intervals` is deprecated in favor of the `IntervalIndex` constructor (GH19263)
- `DataFrame.from_items` is deprecated. Use `DataFrame.from_dict()` instead, or `DataFrame.from_dict(OrderedDict())` if you wish to preserve the key order (GH17320, GH17312)
- Indexing a `MultiIndex` or a `FloatIndex` with a list containing some missing keys will now show a `FutureWarning`, which is consistent with other types of indexes (GH17758).
- The `broadcast` parameter of `.apply()` is deprecated in favor of `result_type='broadcast'` (GH18577)
- The `reduce` parameter of `.apply()` is deprecated in favor of `result_type='reduce'` (GH18577)
- The `order` parameter of `factorize()` is deprecated and will be removed in a future release (GH19727)
- `Timestamp.weekday_name`, `DatetimeIndex.weekday_name`, and `Series.dt.weekday_name` are deprecated in favor of `Timestamp.day_name()`, `DatetimeIndex.day_name()`, and `Series.dt.day_name()` (GH12806)
- `pandas.tseries.plotting.tsplot` is deprecated. Use `Series.plot()` instead (GH18627)
- `Index.summary()` is deprecated and will be removed in a future version (GH18217)
- `NDFrame.get_ftype_counts()` is deprecated and will be removed in a future version (GH18243)
- The `convert_datetime64` parameter in `DataFrame.to_records()` has been deprecated and will be removed in a future version. The NumPy bug motivating this parameter has been resolved. The default value for this parameter has also changed from `True` to `None` (GH18160).
- `Series.rolling().apply()`, `DataFrame.rolling().apply()`, `Series.expanding().apply()`, and `DataFrame.expanding().apply()` have deprecated passing an `np.array` by default. One will need to pass the new `raw` parameter to be explicit about what is passed (GH20584)

- The `data`, `base`, `strides`, `flags` and `itemsize` properties of the `Series` and `Index` classes have been deprecated and will be removed in a future version (GH20419).
- `DatetimeIndex.offset` is deprecated. Use `DatetimeIndex.freq` instead (GH20716)
- Floor division between an integer ndarray and a `Timedelta` is deprecated. Divide by `Timedelta.value` instead (GH19761)
- Setting `PeriodIndex.freq` (which was not guaranteed to work correctly) is deprecated. Use `PeriodIndex.asfreq()` instead (GH20678)
- `Index.get_duplicates()` is deprecated and will be removed in a future version (GH20239)
- The previous default behavior of negative indices in `Categorical.take` is deprecated. In a future version it will change from meaning missing values to meaning positional indices from the right. The future behavior is consistent with `Series.take()` (GH20664).
- Passing multiple axes to the `axis` parameter in `DataFrame.dropna()` has been deprecated and will be removed in a future version (GH20987)

### Removal of prior version deprecations/changes

- Warnings against the obsolete usage `Categorical(codes, categories)`, which were emitted for instance when the first two arguments to `Categorical()` had different dtypes, and recommended the use of `Categorical.from_codes`, have now been removed (GH8074)
- The `levels` and `labels` attributes of a `MultiIndex` can no longer be set directly (GH4039).
- `pd.tseries.util.pivot_annual` has been removed (deprecated since v0.19). Use `pivot_table` instead (GH18370)
- `pd.tseries.util.isleapyear` has been removed (deprecated since v0.19). Use `.is_leap_year` property in `Datetime`-likes instead (GH18370)
- `pd.ordered_merge` has been removed (deprecated since v0.19). Use `pd.merge_ordered` instead (GH18459)
- The `SparseList` class has been removed (GH14007)
- The `pandas.io.wb` and `pandas.io.data` stub modules have been removed (GH13735)
- `Categorical.from_array` has been removed (GH13854)
- The `freq` and `how` parameters have been removed from the `rolling/expanding/ewm` methods of `DataFrame` and `Series` (deprecated since v0.18). Instead, `resample` before calling the methods. (GH18601 & GH18668)
- `DatetimeIndex.to_datetime`, `Timestamp.to_datetime`, `PeriodIndex.to_datetime`, and `Index.to_datetime` have been removed (GH8254, GH14096, GH14113)
- `read_csv()` has dropped the `skip_footer` parameter (GH13386)
- `read_csv()` has dropped the `as_rearray` parameter (GH13373)
- `read_csv()` has dropped the `buffer_lines` parameter (GH13360)
- `read_csv()` has dropped the `compact_ints` and `use_unsigned` parameters (GH13323)
- The `Timestamp` class has dropped the `offset` attribute in favor of `freq` (GH13593)
- The `Series`, `Categorical`, and `Index` classes have dropped the `reshape` method (GH13012)
- `pandas.tseries.frequencies.get_standard_freq` has been removed in favor of `pandas.tseries.frequencies.to_offset(freq).rule_code` (GH13874)
- The `freqstr` keyword has been removed from `pandas.tseries.frequencies.to_offset` in favor of `freq` (GH13874)

- The Panel4D and PanelND classes have been removed (GH13776)
- The Panel class has dropped the `to_long` and `toLong` methods (GH19077)
- The options `display.line_with` and `display.height` are removed in favor of `display.width` and `display.max_rows` respectively (GH4391, GH19107)
- The `labels` attribute of the `Categorical` class has been removed in favor of `Categorical.codes` (GH7768)
- The `flavor` parameter have been removed from `func:to_sql` method (GH13611)
- The modules `pandas.tools.hashing` and `pandas.util.hashing` have been removed (GH16223)
- The top-level functions `pd.rolling_*`, `pd.expanding_*` and `pd.ewm*` have been removed (Deprecated since v0.18). Instead, use the `DataFrame/Series` methods `rolling`, `expanding` and `ewm` (GH18723)
- Imports from `pandas.core.common` for functions such as `is_datetime64_dtype` are now removed. These are located in `pandas.api.types`. (GH13634, GH19769)
- The `infer_dst` keyword in `Series.tz_localize()`, `DatetimeIndex.tz_localize()` and `DatetimeIndex` have been removed. `infer_dst=True` is equivalent to `ambiguous='infer'`, and `infer_dst=False` to `ambiguous='raise'` (GH7963).
- When `.resample()` was changed from an eager to a lazy operation, like `.groupby()` in v0.18.0, we put in place compatibility (with a `FutureWarning`), so operations would continue to work. This is now fully removed, so a `Resampler` will no longer forward compat operations (GH20554)
- Remove long deprecated `axis=None` parameter from `.replace()` (GH20271)

## Performance improvements

- Indexers on `Series` or `DataFrame` no longer create a reference cycle (GH17956)
- Added a keyword argument, `cache`, to `to_datetime()` that improved the performance of converting duplicate datetime arguments (GH11665)
- `DateOffset` arithmetic performance is improved (GH18218)
- Converting a `Series` of `Timedelta` objects to days, seconds, etc... sped up through vectorization of underlying methods (GH18092)
- Improved performance of `.map()` with a `Series/dict` input (GH15081)
- The overridden `Timedelta` properties of days, seconds and microseconds have been removed, leveraging their built-in Python versions instead (GH18242)
- `Series` construction will reduce the number of copies made of the input data in certain cases (GH17449)
- Improved performance of `Series.dt.date()` and `DatetimeIndex.date()` (GH18058)
- Improved performance of `Series.dt.time()` and `DatetimeIndex.time()` (GH18461)
- Improved performance of `IntervalIndex.symmetric_difference()` (GH18475)
- Improved performance of `DatetimeIndex` and `Series` arithmetic operations with `Business-Month` and `Business-Quarter` frequencies (GH18489)
- `Series()` / `DataFrame()` tab completion limits to 100 values, for better performance. (GH18587)
- Improved performance of `DataFrame.median()` with `axis=1` when `bottleneck` is not installed (GH16468)
- Improved performance of `MultiIndex.get_loc()` for large indexes, at the cost of a reduction in performance for small ones (GH18519)

- Improved performance of `MultiIndex.remove_unused_levels()` when there are no unused levels, at the cost of a reduction in performance when there are (GH19289)
- Improved performance of `Index.get_loc()` for non-unique indexes (GH19478)
- Improved performance of pairwise `.rolling()` and `.expanding()` with `.cov()` and `.corr()` operations (GH17917)
- Improved performance of `pandas.core.groupby.GroupBy.rank()` (GH15779)
- Improved performance of variable `.rolling()` on `.min()` and `.max()` (GH19521)
- Improved performance of `pandas.core.groupby.GroupBy.ffill()` and `pandas.core.groupby.GroupBy.bfill()` (GH11296)
- Improved performance of `pandas.core.groupby.GroupBy.any()` and `pandas.core.groupby.GroupBy.all()` (GH15435)
- Improved performance of `pandas.core.groupby.GroupBy.pct_change()` (GH19165)
- Improved performance of `Series.isin()` in the case of categorical dtypes (GH20003)
- Improved performance of `getattr(Series, attr)` when the Series has certain index types. This manifested in slow printing of large Series with a `DatetimeIndex` (GH19764)
- Fixed a performance regression for `GroupBy.nth()` and `GroupBy.last()` with some object columns (GH19283)
- Improved performance of `pandas.core.arrays.Categorical.from_codes()` (GH18501)

### Documentation changes

Thanks to all of the contributors who participated in the pandas Documentation Sprint, which took place on March 10th. We had about 500 participants from over 30 locations across the world. You should notice that many of the *API docstrings* have greatly improved.

There were too many simultaneous contributions to include a release note for each improvement, but this [GitHub search](#) should give you an idea of how many docstrings were improved.

Special thanks to [Marc Garcia](#) for organizing the sprint. For more information, read the [NumFOCUS blogpost](#) recapping the sprint.

- Changed spelling of “numpy” to “NumPy”, and “python” to “Python”. (GH19017)
- Consistency when introducing code samples, using either colon or period. Rewrote some sentences for greater clarity, added more dynamic references to functions, methods and classes. (GH18941, GH18948, GH18973, GH19017)
- Added a reference to `DataFrame.assign()` in the concatenate section of the merging documentation (GH18665)

## Bug fixes

### Categorical

**Warning:** A class of bugs were introduced in pandas 0.21 with `CategoricalDtype` that affects the correctness of operations like `merge`, `concat`, and indexing when comparing multiple unordered `Categorical` arrays that have the same categories, but in a different order. We highly recommend upgrading or manually aligning your categories before doing these operations.

- Bug in `Categorical.equals` returning the wrong result when comparing two unordered `Categorical` arrays with the same categories, but in a different order (GH16603)
- Bug in `pandas.api.types.union_categoricals()` returning the wrong result when for unordered categoricals with the categories in a different order. This affected `pandas.concat()` with `Categorical` data (GH19096).
- Bug in `pandas.merge()` returning the wrong result when joining on an unordered `Categorical` that had the same categories but in a different order (GH19551)
- Bug in `CategoricalIndex.get_indexer()` returning the wrong result when `target` was an unordered `Categorical` that had the same categories as `self` but in a different order (GH19551)
- Bug in `Index.astype()` with a categorical dtype where the resultant index is not converted to a `CategoricalIndex` for all types of index (GH18630)
- Bug in `Series.astype()` and `Categorical.astype()` where an existing categorical data does not get updated (GH10696, GH18593)
- Bug in `Series.str.split()` with `expand=True` incorrectly raising an `IndexError` on empty strings (GH20002).
- Bug in `Index` constructor with `dtype=CategoricalDtype(...)` where `categories` and `ordered` are not maintained (GH19032)
- Bug in `Series` constructor with `scalar` and `dtype=CategoricalDtype(...)` where `categories` and `ordered` are not maintained (GH19565)
- Bug in `Categorical.__iter__` not converting to Python types (GH19909)
- Bug in `pandas.factorize()` returning the unique codes for the `uniques`. This now returns a `Categorical` with the same dtype as the input (GH19721)
- Bug in `pandas.factorize()` including an item for missing values in the `uniques` return value (GH19721)
- Bug in `Series.take()` with categorical data interpreting `-1` in indices as missing value markers, rather than the last element of the `Series` (GH20664)

### Datetimelike

- Bug in `Series.__sub__()` subtracting a non-nanosecond `np.datetime64` object from a `Series` gave incorrect results (GH7996)
- Bug in `DatetimeIndex`, `TimedeltaIndex` addition and subtraction of zero-dimensional integer arrays gave incorrect results (GH19012)
- Bug in `DatetimeIndex` and `TimedeltaIndex` where adding or subtracting an array-like of `DateOffset` objects either raised (`np.array`, `pd.Index`) or broadcast incorrectly (`pd.Series`) (GH18849)

- Bug in `Series.__add__()` adding Series with dtype `timedelta64[ns]` to a timezone-aware `DatetimeIndex` incorrectly dropped timezone information (GH13905)
- Adding a `Period` object to a `datetime` or `Timestamp` object will now correctly raise a `TypeError` (GH17983)
- Bug in `Timestamp` where comparison with an array of `Timestamp` objects would result in a `RecursionError` (GH15183)
- Bug in `Series` floor-division where operating on a scalar `timedelta` raises an exception (GH18846)
- Bug in `DatetimeIndex` where the repr was not showing high-precision time values at the end of a day (e.g., `23:59:59.999999999`) (GH19030)
- Bug in `.astype()` to non-ns `timedelta` units would hold the incorrect dtype (GH19176, GH19223, GH12425)
- Bug in subtracting `Series` from `NaT` incorrectly returning `NaT` (GH19158)
- Bug in `Series.truncate()` which raises `TypeError` with a monotonic `PeriodIndex` (GH17717)
- Bug in `pct_change()` using `periods` and `freq` returned different length outputs (GH7292)
- Bug in comparison of `DatetimeIndex` against `None` or `datetime.date` objects raising `TypeError` for `==` and `!=` comparisons instead of all-False and all-True, respectively (GH19301)
- Bug in `Timestamp` and `to_datetime()` where a string representing a barely out-of-bounds timestamp would be incorrectly rounded down instead of raising `OutOfBoundsDatetime` (GH19382)
- Bug in `Timestamp.floor()` `DatetimeIndex.floor()` where time stamps far in the future and past were not rounded correctly (GH19206)
- Bug in `to_datetime()` where passing an out-of-bounds datetime with `errors='coerce'` and `utc=True` would raise `OutOfBoundsDatetime` instead of parsing to `NaT` (GH19612)
- Bug in `DatetimeIndex` and `TimedeltaIndex` addition and subtraction where name of the returned object was not always set consistently. (GH19744)
- Bug in `DatetimeIndex` and `TimedeltaIndex` addition and subtraction where operations with numpy arrays raised `TypeError` (GH19847)
- Bug in `DatetimeIndex` and `TimedeltaIndex` where setting the `freq` attribute was not fully supported (GH20678)

## Timedelta

- Bug in `Timedelta.__mul__()` where multiplying by `NaT` returned `NaT` instead of raising a `TypeError` (GH19819)
- Bug in `Series` with dtype `'timedelta64[ns]'` where addition or subtraction of `TimedeltaIndex` had results cast to dtype `'int64'` (GH17250)
- Bug in `Series` with dtype `'timedelta64[ns]'` where addition or subtraction of `TimedeltaIndex` could return a `Series` with an incorrect name (GH19043)
- Bug in `Timedelta.__floordiv__()` and `Timedelta.__rfloordiv__()` dividing by many incompatible numpy objects was incorrectly allowed (GH18846)
- Bug where dividing a scalar `timedelta`-like object with `TimedeltaIndex` performed the reciprocal operation (GH19125)
- Bug in `TimedeltaIndex` where division by a `Series` would return a `TimedeltaIndex` instead of a `Series` (GH19042)

- Bug in `Timedelta.__add__()`, `Timedelta.__sub__()` where adding or subtracting a `np.timedelta64` object would return another `np.timedelta64` instead of a `Timedelta` (GH19738)
- Bug in `Timedelta.__floordiv__()`, `Timedelta.__rfloordiv__()` where operating with a `Tick` object would raise a `TypeError` instead of returning a numeric value (GH19738)
- Bug in `Period.asfreq()` where periods near `datetime(1, 1, 1)` could be converted incorrectly (GH19643, GH19834)
- Bug in `Timedelta.total_seconds()` causing precision errors, for example `Timedelta('30S').total_seconds()==30.000000000000004` (GH19458)
- Bug in `Timedelta.__rmod__()` where operating with a `numpy.timedelta64` returned a `timedelta64` object instead of a `Timedelta` (GH19820)
- Multiplication of `TimedeltaIndex` by `TimedeltaIndex` will now raise `TypeError` instead of raising `ValueError` in cases of length mismatch (GH19333)
- Bug in indexing a `TimedeltaIndex` with a `np.timedelta64` object which was raising a `TypeError` (GH20393)

## Timezones

- Bug in creating a `Series` from an array that contains both tz-naive and tz-aware values will result in a `Series` whose dtype is tz-aware instead of object (GH16406)
- Bug in comparison of timezone-aware `DatetimeIndex` against `NaT` incorrectly raising `TypeError` (GH19276)
- Bug in `DatetimeIndex.astype()` when converting between timezone aware dtypes, and converting from timezone aware to naive (GH18951)
- Bug in comparing `DatetimeIndex`, which failed to raise `TypeError` when attempting to compare timezone-aware and timezone-naive datetimelike objects (GH18162)
- Bug in localization of a naive, datetime string in a `Series` constructor with a `datetime64[ns, tz]` dtype (GH174151)
- `Timestamp.replace()` will now handle Daylight Savings transitions gracefully (GH18319)
- Bug in tz-aware `DatetimeIndex` where addition/subtraction with a `TimedeltaIndex` or array with dtype='timedelta64[ns]' was incorrect (GH17558)
- Bug in `DatetimeIndex.insert()` where inserting `NaT` into a timezone-aware index incorrectly raised (GH16357)
- Bug in `DataFrame` constructor, where tz-aware `DatetimeIndex` and a given column name will result in an empty `DataFrame` (GH19157)
- Bug in `Timestamp.tz_localize()` where localizing a timestamp near the minimum or maximum valid values could overflow and return a timestamp with an incorrect nanosecond value (GH12677)
- Bug when iterating over `DatetimeIndex` that was localized with fixed timezone offset that rounded nanosecond precision to microseconds (GH19603)
- Bug in `DataFrame.diff()` that raised an `IndexError` with tz-aware values (GH18578)
- Bug in `melt()` that converted tz-aware dtypes to tz-naive (GH15785)
- Bug in `DataFrame.count()` that raised a `ValueError`, if `DataFrame.dropna()` was called for a single column with timezone-aware values. (GH13407)

## Offsets

- Bug in `WeekOfMonth` and `Week` where addition and subtraction did not roll correctly ([GH18510](#), [GH18672](#), [GH18864](#))
- Bug in `WeekOfMonth` and `LastWeekOfMonth` where default keyword arguments for constructor raised `ValueError` ([GH19142](#))
- Bug in `FY5253Quarter`, `LastWeekOfMonth` where rollback and rollforward behavior was inconsistent with addition and subtraction behavior ([GH18854](#))
- Bug in `FY5253` where `datetime` addition and subtraction incremented incorrectly for dates on the year-end but not normalized to midnight ([GH18854](#))
- Bug in `FY5253` where date offsets could incorrectly raise an `AssertionError` in arithmetic operations ([GH14774](#))

## Numeric

- Bug in `Series` constructor with an int or float list where specifying `dtype=str`, `dtype='str'` or `dtype='U'` failed to convert the data elements to strings ([GH16605](#))
- Bug in `Index` multiplication and division methods where operating with a `Series` would return an `Index` object instead of a `Series` object ([GH19042](#))
- Bug in the `DataFrame` constructor in which data containing very large positive or very large negative numbers was causing `OverflowError` ([GH18584](#))
- Bug in `Index` constructor with `dtype='uint64'` where int-like floats were not coerced to `UInt64Index` ([GH18400](#))
- Bug in `DataFrame` flex arithmetic (e.g. `df.add(other, fill_value=foo)`) with a `fill_value` other than `None` failed to raise `NotImplementedError` in corner cases where either the frame or `other` has length zero ([GH19522](#))
- Multiplication and division of numeric-dtyped `Index` objects with `timedelta`-like scalars returns `TimedeltaIndex` instead of raising `TypeError` ([GH19333](#))
- Bug where `NaN` was returned instead of `0` by `Series.pct_change()` and `DataFrame.pct_change()` when `fill_method` is not `None` ([GH19873](#))

## Strings

- Bug in `Series.str.get()` with a dictionary in the values and the index not in the keys, raising `KeyError` ([GH20671](#))

## Indexing

- Bug in `Index` construction from list of mixed type tuples ([GH18505](#))
- Bug in `Index.drop()` when passing a list of both tuples and non-tuples ([GH18304](#))
- Bug in `DataFrame.drop()`, `Panel.drop()`, `Series.drop()`, `Index.drop()` where no `KeyError` is raised when dropping a non-existent element from an axis that contains duplicates ([GH19186](#))
- Bug in indexing a `datetimelike` `Index` that raised `ValueError` instead of `IndexError` ([GH18386](#)).
- `Index.to_series()` now accepts `index` and `name` kwargs ([GH18699](#))

- `DatetimeIndex.to_series()` now accepts `index` and `name` kwargs (GH18699)
- Bug in indexing non-scalar value from `Series` having non-unique `Index` will return value flattened (GH17610)
- Bug in indexing with iterator containing only missing keys, which raised no error (GH20748)
- Fixed inconsistency in `.ix` between list and scalar keys when the index has integer dtype and does not include the desired keys (GH20753)
- Bug in `__setitem__` when indexing a `DataFrame` with a 2-d boolean ndarray (GH18582)
- Bug in `str.extractall` when there were no matches empty `Index` was returned instead of appropriate `MultiIndex` (GH19034)
- Bug in `IntervalIndex` where empty and purely NA data was constructed inconsistently depending on the construction method (GH18421)
- Bug in `IntervalIndex.symmetric_difference()` where the symmetric difference with a non-`IntervalIndex` did not raise (GH18475)
- Bug in `IntervalIndex` where set operations that returned an empty `IntervalIndex` had the wrong dtype (GH19101)
- Bug in `DataFrame.drop_duplicates()` where no `KeyError` is raised when passing in columns that don't exist on the `DataFrame` (GH19726)
- Bug in `Index` subclasses constructors that ignore unexpected keyword arguments (GH19348)
- Bug in `Index.difference()` when taking difference of an `Index` with itself (GH20040)
- Bug in `DataFrame.first_valid_index()` and `DataFrame.last_valid_index()` in presence of entire rows of NaNs in the middle of values (GH20499).
- Bug in `IntervalIndex` where some indexing operations were not supported for overlapping or non-monotonic `uint64` data (GH20636)
- Bug in `Series.is_unique` where extraneous output in `stderr` is shown if `Series` contains objects with `__ne__` defined (GH20661)
- Bug in `.loc` assignment with a single-element list-like incorrectly assigns as a list (GH19474)
- Bug in partial string indexing on a `Series/DataFrame` with a monotonic decreasing `DatetimeIndex` (GH19362)
- Bug in performing in-place operations on a `DataFrame` with a duplicate `Index` (GH17105)
- Bug in `IntervalIndex.get_loc()` and `IntervalIndex.get_indexer()` when used with an `IntervalIndex` containing a single interval (GH17284, GH20921)
- Bug in `.loc` with a `uint64` indexer (GH20722)

## MultiIndex

- Bug in `MultiIndex.__contains__()` where non-tuple keys would return `True` even if they had been dropped (GH19027)
- Bug in `MultiIndex.set_labels()` which would cause casting (and potentially clipping) of the new labels if the `level` argument is not 0 or a list like `[0, 1, ... ]` (GH19057)
- Bug in `MultiIndex.get_level_values()` which would return an invalid index on level of ints with missing values (GH17924)
- Bug in `MultiIndex.unique()` when called on empty `MultiIndex` (GH20568)

- Bug in `MultiIndex.unique()` which would not preserve level names (GH20570)
- Bug in `MultiIndex.remove_unused_levels()` which would fill nan values (GH18417)
- Bug in `MultiIndex.from_tuples()` which would fail to take zipped tuples in python3 (GH18434)
- Bug in `MultiIndex.get_loc()` which would fail to automatically cast values between float and int (GH18818, GH15994)
- Bug in `MultiIndex.get_loc()` which would cast boolean to integer labels (GH19086)
- Bug in `MultiIndex.get_loc()` which would fail to locate keys containing NaN (GH18485)
- Bug in `MultiIndex.get_loc()` in large `MultiIndex`, would fail when levels had different dtypes (GH18520)
- Bug in indexing where nested indexers having only numpy arrays are handled incorrectly (GH19686)

## IO

- `read_html()` now rewinds seekable IO objects after parse failure, before attempting to parse with a new parser. If a parser errors and the object is non-seekable, an informative error is raised suggesting the use of a different parser (GH17975)
- `DataFrame.to_html()` now has an option to add an id to the leading `<table>` tag (GH8496)
- Bug in `read_msgpack()` with a non-existent file is passed in Python 2 (GH15296)
- Bug in `read_csv()` where a `MultiIndex` with duplicate columns was not being mangled appropriately (GH18062)
- Bug in `read_csv()` where missing values were not being handled properly when `keep_default_na=False` with dictionary `na_values` (GH19227)
- Bug in `read_csv()` causing heap corruption on 32-bit, big-endian architectures (GH20785)
- Bug in `read_sas()` where a file with 0 variables gave an `AttributeError` incorrectly. Now it gives an `EmptyDataError` (GH18184)
- Bug in `DataFrame.to_latex()` where pairs of braces meant to serve as invisible placeholders were escaped (GH18667)
- Bug in `DataFrame.to_latex()` where a NaN in a `MultiIndex` would cause an `IndexError` or incorrect output (GH14249)
- Bug in `DataFrame.to_latex()` where a non-string index-level name would result in an `AttributeError` (GH19981)
- Bug in `DataFrame.to_latex()` where the combination of an index name and the `index_names=False` option would result in incorrect output (GH18326)
- Bug in `DataFrame.to_latex()` where a `MultiIndex` with an empty string as its name would result in incorrect output (GH18669)
- Bug in `DataFrame.to_latex()` where missing space characters caused wrong escaping and produced non-valid latex in some cases (GH20859)
- Bug in `read_json()` where large numeric values were causing an `OverflowError` (GH18842)
- Bug in `DataFrame.to_parquet()` where an exception was raised if the write destination is S3 (GH19134)
- `Interval` now supported in `DataFrame.to_excel()` for all Excel file types (GH19242)
- `Timedelta` now supported in `DataFrame.to_excel()` for all Excel file types (GH19242, GH9155, GH19900)

- Bug in `pandas.io.stata.StataReader.value_labels()` raising an `AttributeError` when called on very old files. Now returns an empty dict (GH19417)
- Bug in `read_pickle()` when unpickling objects with `TimedeltaIndex` or `Float64Index` created with pandas prior to version 0.20 (GH19939)
- Bug in `pandas.io.json.json_normalize()` where sub-records are not properly normalized if any sub-records values are `NoneType` (GH20030)
- Bug in `usecols` parameter in `read_csv()` where error is not raised correctly when passing a string. (GH20529)
- Bug in `HDFStore.keys()` when reading a file with a soft link causes exception (GH20523)
- Bug in `HDFStore.select_column()` where a key which is not a valid store raised an `AttributeError` instead of a `KeyError` (GH17912)

## Plotting

- Better error message when attempting to plot but `matplotlib` is not installed (GH19810).
- `DataFrame.plot()` now raises a `ValueError` when the `x` or `y` argument is improperly formed (GH18671)
- Bug in `DataFrame.plot()` when `x` and `y` arguments given as positions caused incorrect referenced columns for line, bar and area plots (GH20056)
- Bug in formatting tick labels with `datetime.time()` and fractional seconds (GH18478).
- `Series.plot.kde()` has exposed the args `ind` and `bw_method` in the docstring (GH18461). The argument `ind` may now also be an integer (number of sample points).
- `DataFrame.plot()` now supports multiple columns to the `y` argument (GH19699)

## GroupBy/resample/rolling

- Bug when grouping by a single column and aggregating with a class like `list` or `tuple` (GH18079)
- Fixed regression in `DataFrame.groupby()` which would not emit an error when called with a tuple key not in the index (GH18798)
- Bug in `DataFrame.resample()` which silently ignored unsupported (or mistyped) options for `label`, `closed` and `convention` (GH19303)
- Bug in `DataFrame.groupby()` where tuples were interpreted as lists of keys rather than as keys (GH17979, GH18249)
- Bug in `DataFrame.groupby()` where aggregation by `first/last/min/max` was causing timestamps to lose precision (GH19526)
- Bug in `DataFrame.transform()` where particular aggregation functions were being incorrectly cast to match the `dtype(s)` of the grouped data (GH19200)
- Bug in `DataFrame.groupby()` passing the `on=` kwarg, and subsequently using `.apply()` (GH17813)
- Bug in `DataFrame.resample().aggregate` not raising a `KeyError` when aggregating a non-existent column (GH16766, GH19566)
- Bug in `DataFrameGroupBy.cumsum()` and `DataFrameGroupBy.cumprod()` when `skipna` was passed (GH19806)
- Bug in `DataFrame.resample()` that dropped timezone information (GH13238)

- Bug in `DataFrame.groupby()` where transformations using `np.all` and `np.any` were raising a `ValueError` (GH20653)
- Bug in `DataFrame.resample()` where `ffill`, `bfill`, `pad`, `backfill`, `fillna`, `interpolate`, and `asfreq` were ignoring `loffset`. (GH20744)
- Bug in `DataFrame.groupby()` when applying a function that has mixed data types and the user supplied function can fail on the grouping column (GH20949)
- Bug in `DataFrameGroupBy.rolling().apply()` where operations performed against the associated `DataFrameGroupBy` object could impact the inclusion of the grouped item(s) in the result (GH14013)

## Sparse

- Bug in which creating a `SparseDataFrame` from a dense `Series` or an unsupported type raised an uncontrolled exception (GH19374)
- Bug in `SparseDataFrame.to_csv` causing exception (GH19384)
- Bug in `SparseSeries.memory_usage` which caused segfault by accessing non sparse elements (GH19368)
- Bug in constructing a `SparseArray`: if `data` is a scalar and `index` is defined it will coerce to `float64` regardless of scalar's dtype. (GH19163)

## Reshaping

- Bug in `DataFrame.merge()` where referencing a `CategoricalIndex` by name, where the `by` kwarg would raise `KeyError` (GH20777)
- Bug in `DataFrame.stack()` which fails trying to sort mixed type levels under Python 3 (GH18310)
- Bug in `DataFrame.unstack()` which casts `int` to `float` if `columns` is a `MultiIndex` with unused levels (GH17845)
- Bug in `DataFrame.unstack()` which raises an error if `index` is a `MultiIndex` with unused labels on the unstacked level (GH18562)
- Fixed construction of a `Series` from a `dict` containing `NaN` as key (GH18480)
- Fixed construction of a `DataFrame` from a `dict` containing `NaN` as key (GH18455)
- Disabled construction of a `Series` where `len(index) > len(data) = 1`, which previously would broadcast the data item, and now raises a `ValueError` (GH18819)
- Suppressed error in the construction of a `DataFrame` from a `dict` containing scalar values when the corresponding keys are not included in the passed `index` (GH18600)
- Fixed (changed from `object` to `float64`) dtype of `DataFrame` initialized with axes, no data, and `dtype=int` (GH19646)
- Bug in `Series.rank()` where `Series` containing `NaT` modifies the `Series` inplace (GH18521)
- Bug in `cut()` which fails when using `readonly` arrays (GH18773)
- Bug in `DataFrame.pivot_table()` which fails when the `aggfunc` arg is of type `string`. The behavior is now consistent with other methods like `agg` and `apply` (GH18713)
- Bug in `DataFrame.merge()` in which merging using `Index` objects as vectors raised an `Exception` (GH19038)
- Bug in `DataFrame.stack()`, `DataFrame.unstack()`, `Series.unstack()` which were not returning subclasses (GH15563)

- Bug in timezone comparisons, manifesting as a conversion of the index to UTC in `.concat()` (GH18523)
- Bug in `concat()` when concatenating sparse and dense series it returns only a `SparseDataFrame`. Should be a `DataFrame`. (GH18914, GH18686, and GH16874)
- Improved error message for `DataFrame.merge()` when there is no common merge key (GH19427)
- Bug in `DataFrame.join()` which does an `outer` instead of a `left` join when being called with multiple `DataFrames` and some have non-unique indices (GH19624)
- `Series.rename()` now accepts `axis` as a kwarg (GH18589)
- Bug in `rename()` where an `Index` of same-length tuples was converted to a `MultiIndex` (GH19497)
- Comparisons between `Series` and `Index` would return a `Series` with an incorrect name, ignoring the `Index`'s name attribute (GH19582)
- Bug in `qcut()` where datetime and timedelta data with `NaT` present raised a `ValueError` (GH19768)
- Bug in `DataFrame.iterrows()`, which would infer strings not compliant to `ISO8601` to datetimes (GH19671)
- Bug in `Series` constructor with `Categorical` where a `ValueError` is not raised when an index of different length is given (GH19342)
- Bug in `DataFrame.astype()` where column metadata is lost when converting to categorical or a dictionary of dtypes (GH19920)
- Bug in `cut()` and `qcut()` where timezone information was dropped (GH19872)
- Bug in `Series` constructor with a `dtype=str`, previously raised in some cases (GH19853)
- Bug in `get_dummies()`, and `select_dtypes()`, where duplicate column names caused incorrect behavior (GH20848)
- Bug in `isna()`, which cannot handle ambiguous typed lists (GH20675)
- Bug in `concat()` which raises an error when concatenating TZ-aware dataframes and all-`NaT` dataframes (GH12396)
- Bug in `concat()` which raises an error when concatenating empty TZ-aware series (GH18447)

## Other

- Improved error message when attempting to use a Python keyword as an identifier in a `numexpr` backed query (GH18221)
- Bug in accessing a `pandas.get_option()`, which raised `KeyError` rather than `OptionError` when looking up a non-existent option key in some cases (GH19789)
- Bug in `testing.assert_series_equal()` and `testing.assert_frame_equal()` for `Series` or `DataFrames` with differing unicode data (GH20503)

## Contributors

A total of 328 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

## 5.8 Version 0.22

### 5.8.1 Version 0.22.0 (December 29, 2017)

This is a major release from 0.21.1 and includes a single, API-breaking change. We recommend that all users upgrade to this version after carefully reading the release note (singular!).

#### Backwards incompatible API changes

pandas 0.22.0 changes the handling of empty and all-*NA* sums and products. The summary is that

- The sum of an empty or all-*NA* Series is now 0
- The product of an empty or all-*NA* Series is now 1
- We've added a `min_count` parameter to `.sum()` and `.prod()` controlling the minimum number of valid values for the result to be valid. If fewer than `min_count` non-*NA* values are present, the result is *NA*. The default is 0. To return NaN, the 0.21 behavior, use `min_count=1`.

Some background: In pandas 0.21, we fixed a long-standing inconsistency in the return value of all-*NA* series depending on whether or not bottleneck was installed. See *Sum/prod of all-*NaN* or empty Series/DataFrames is now consistently *NaN**. At the same time, we changed the sum and prod of an empty Series to also be NaN.

Based on feedback, we've partially reverted those changes.

#### Arithmetic operations

The default sum for empty or all-*NA* Series is now 0.

*pandas 0.21.x*

```
In [1]: pd.Series([]).sum()
Out[1]: nan

In [2]: pd.Series([np.nan]).sum()
Out[2]: nan
```

*pandas 0.22.0*

```
In [1]: pd.Series([]).sum()
Out[1]: 0.0
```

```
In [2]: pd.Series([np.nan]).sum()
Out[2]: 0.0
```

The default behavior is the same as pandas 0.20.3 with bottleneck installed. It also matches the behavior of NumPy's `np.nansum` on empty and all-*NA* arrays.

To have the sum of an empty series return NaN (the default behavior of pandas 0.20.3 without bottleneck, or pandas 0.21.x), use the `min_count` keyword.

```
In [3]: pd.Series([]).sum(min_count=1)
Out[3]: nan
```

Thanks to the `skipna` parameter, the `.sum` on an all-*NA* series is conceptually the same as the `.sum` of an empty one with `skipna=True` (the default).

```
In [4]: pd.Series([np.nan]).sum(min_count=1) # skipna=True by default
Out[4]: nan
```

The `min_count` parameter refers to the minimum number of *non-null* values required for a non-*NA* sum or product. `Series.prod()` has been updated to behave the same as `Series.sum()`, returning 1 instead.

```
In [5]: pd.Series([]).prod()
Out[5]: 1.0

In [6]: pd.Series([np.nan]).prod()
Out[6]: 1.0

In [7]: pd.Series([]).prod(min_count=1)
Out[7]: nan
```

These changes affect `DataFrame.sum()` and `DataFrame.prod()` as well. Finally, a few less obvious places in pandas are affected by this change.

## Grouping by a Categorical

Grouping by a `Categorical` and summing now returns 0 instead of NaN for categories with no observations. The product now returns 1 instead of NaN.

*pandas 0.21.x*

```
In [8]: grouper = pd.Categorical(['a', 'a'], categories=['a', 'b'])

In [9]: pd.Series([1, 2]).groupby(grouper).sum()
Out[9]:
a 3.0
b NaN
dtype: float64
```

*pandas 0.22*

```
In [8]: grouper = pd.Categorical(["a", "a"], categories=["a", "b"])
```

```
In [9]: pd.Series([1, 2]).groupby(grouper).sum()
```

```
Out[9]:
```

```
a 3
```

```
b 0
```

```
Length: 2, dtype: int64
```

To restore the 0.21 behavior of returning NaN for unobserved groups, use `min_count>=1`.

```
In [10]: pd.Series([1, 2]).groupby(grouper).sum(min_count=1)
```

```
Out[10]:
```

```
a 3.0
```

```
b NaN
```

```
Length: 2, dtype: float64
```

## Resample

The sum and product of all-*NA* bins has changed from NaN to 0 for sum and 1 for product.

*pandas 0.21.x*

```
In [11]: s = pd.Series([1, 1, np.nan, np.nan],
.....: index=pd.date_range('2017', periods=4))
.....: s
```

```
Out[11]:
```

```
2017-01-01 1.0
```

```
2017-01-02 1.0
```

```
2017-01-03 NaN
```

```
2017-01-04 NaN
```

```
Freq: D, dtype: float64
```

```
In [12]: s.resample('2d').sum()
```

```
Out[12]:
```

```
2017-01-01 2.0
```

```
2017-01-03 NaN
```

```
Freq: 2D, dtype: float64
```

*pandas 0.22.0*

```
In [11]: s = pd.Series([1, 1, np.nan, np.nan], index=pd.date_range("2017", periods=4))
```

```
In [12]: s.resample("2d").sum()
```

```
Out[12]:
```

```
2017-01-01 2.0
```

```
2017-01-03 0.0
```

```
Freq: 2D, Length: 2, dtype: float64
```

To restore the 0.21 behavior of returning NaN, use `min_count>=1`.

```
In [13]: s.resample("2d").sum(min_count=1)
```

```
Out[13]:
```

(continues on next page)

(continued from previous page)

```
2017-01-01 2.0
2017-01-03 NaN
Freq: 2D, Length: 2, dtype: float64
```

In particular, upsampling and taking the sum or product is affected, as upsampling introduces missing values even if the original series was entirely valid.

*pandas 0.21.x*

```
In [14]: idx = pd.DatetimeIndex(['2017-01-01', '2017-01-02'])
```

```
In [15]: pd.Series([1, 2], index=idx).resample('12H').sum()
```

```
Out[15]:
2017-01-01 00:00:00 1.0
2017-01-01 12:00:00 NaN
2017-01-02 00:00:00 2.0
Freq: 12H, dtype: float64
```

*pandas 0.22.0*

```
In [14]: idx = pd.DatetimeIndex(["2017-01-01", "2017-01-02"])
```

```
In [15]: pd.Series([1, 2], index=idx).resample("12H").sum()
```

```
Out[15]:
2017-01-01 00:00:00 1
2017-01-01 12:00:00 0
2017-01-02 00:00:00 2
Freq: 12H, Length: 3, dtype: int64
```

Once again, the `min_count` keyword is available to restore the 0.21 behavior.

```
In [16]: pd.Series([1, 2], index=idx).resample("12H").sum(min_count=1)
```

```
Out[16]:
2017-01-01 00:00:00 1.0
2017-01-01 12:00:00 NaN
2017-01-02 00:00:00 2.0
Freq: 12H, Length: 3, dtype: float64
```

## Rolling and expanding

Rolling and expanding already have a `min_periods` keyword that behaves similar to `min_count`. The only case that changes is when doing a rolling or expanding sum with `min_periods=0`. Previously this returned `NaN`, when fewer than `min_periods` non-`NA` values were in the window. Now it returns `0`.

*pandas 0.21.1*

```
In [17]: s = pd.Series([np.nan, np.nan])
```

```
In [18]: s.rolling(2, min_periods=0).sum()
```

```
Out[18]:
0 NaN
1 NaN
dtype: float64
```

*pandas 0.22.0*

```
In [17]: s = pd.Series([np.nan, np.nan])
In [18]: s.rolling(2, min_periods=0).sum()
Out[18]:
0 0.0
1 0.0
Length: 2, dtype: float64
```

The default behavior of `min_periods=None`, implying that `min_periods` equals the window size, is unchanged.

## Compatibility

If you maintain a library that should work across pandas versions, it may be easiest to exclude pandas 0.21 from your requirements. Otherwise, all your `sum()` calls would need to check if the `Series` is empty before summing.

With `setuptools`, in your `setup.py` use:

```
install_requires=['pandas!=0.21.*', ...]
```

With `conda`, use

```
requirements:
run:
- pandas !=0.21.0,!=0.21.1
```

Note that the inconsistency in the return value for all-*NA* series is still there for pandas 0.20.3 and earlier. Avoiding pandas 0.21 will only help with the empty case.

## 5.9 Version 0.21

### 5.9.1 Version 0.21.1 (December 12, 2017)

This is a minor bug-fix release in the 0.21.x series and includes some small regression fixes, bug fixes and performance improvements. We recommend that all users upgrade to this version.

Highlights include:

- Temporarily restore matplotlib datetime plotting functionality. This should resolve issues for users who implicitly relied on pandas to plot datetimes with matplotlib. See [here](#).
- Improvements to the Parquet IO functions introduced in 0.21.0. See [here](#).

### What's new in v0.21.1

- *Restore Matplotlib datetime converter registration*
- *New features*
  - *Improvements to the Parquet IO functionality*
  - *Other enhancements*
- *Deprecations*
- *Performance improvements*
- *Bug fixes*
  - *Conversion*
  - *Indexing*
  - *IO*
  - *Plotting*
  - *GroupBy/resample/rolling*
  - *Reshaping*
  - *Numeric*
  - *Categorical*
  - *String*
- *Contributors*

### Restore Matplotlib datetime converter registration

pandas implements some matplotlib converters for nicely formatting the axis labels on plots with `datetime` or `Period` values. Prior to pandas 0.21.0, these were implicitly registered with matplotlib, as a side effect of `import pandas`.

In pandas 0.21.0, we required users to explicitly register the converter. This caused problems for some users who relied on those converters being present for regular `matplotlib.pyplot` plotting methods, so we're temporarily reverting that change; pandas 0.21.1 again registers the converters on import, just like before 0.21.0.

We've added a new option to control the converters: `pd.options.plotting.matplotlib.register_converters`. By default, they are registered. Toggling this to `False` removes pandas' formatters and restore any converters we overwrote when registering them (GH18301).

We're working with the matplotlib developers to make this easier. We're trying to balance user convenience (automatically registering the converters) with import performance and best practices (importing pandas shouldn't have the side effect of overwriting any custom converters you've already set). In the future we hope to have most of the datetime formatting functionality in matplotlib, with just the pandas-specific converters in pandas. We'll then gracefully deprecate the automatic registration of converters in favor of users explicitly registering them when they want them.

## New features

### Improvements to the Parquet IO functionality

- `DataFrame.to_parquet()` will now write non-default indexes when the underlying engine supports it. The indexes will be preserved when reading back in with `read_parquet()` (GH18581).
- `read_parquet()` now allows to specify the columns to read from a parquet file (GH18154)
- `read_parquet()` now allows to specify kwargs which are passed to the respective engine (GH18216)

### Other enhancements

- `Timestamp.timestamp()` is now available in Python 2.7. (GH17329)
- `Groupby` and `TimeGroupby` now have a friendly repr output (GH18203).

### Deprecations

- `pandas.tseries.register` has been renamed to `pandas.plotting.register_matplotlib_converters()` (GH18301)

### Performance improvements

- Improved performance of plotting large series/dataframes (GH18236).

### Bug fixes

#### Conversion

- Bug in `TimedeltaIndex` subtraction could incorrectly overflow when NaT is present (GH17791)
- Bug in `DatetimeIndex` subtracting datetimelike from `DatetimeIndex` could fail to overflow (GH18020)
- Bug in `IntervalIndex.copy()` when copying and `IntervalIndex` with non-default `closed` (GH18339)
- Bug in `DataFrame.to_dict()` where columns of datetime that are tz-aware were not converted to required arrays when used with `orient='records'`, raising `TypeError` (GH18372)
- Bug in `DatetimeIndex` and `date_range()` where mismatching tz-aware `start` and `end` timezones would not raise an err if `end.tzinfo` is `None` (GH18431)
- Bug in `Series.fillna()` which raised when passed a long integer on Python 2 (GH18159).

## Indexing

- Bug in a boolean comparison of a `datetime.datetime` and a `datetime64[ns]` dtype Series (GH17965)
- Bug where a `MultiIndex` with more than a million records was not raising `AttributeError` when trying to access a missing attribute (GH18165)
- Bug in `IntervalIndex` constructor when a list of intervals is passed with non-default `closed` (GH18334)
- Bug in `Index.putmask` when an invalid mask passed (GH18368)
- Bug in masked assignment of a `timedelta64[ns]` dtype Series, incorrectly coerced to float (GH18493)

## IO

- Bug in class `~pandas.io.stata.StataReader` not converting date/time columns with display formatting addressed (GH17990). Previously columns with display formatting were normally left as ordinal numbers and not converted to datetime objects.
- Bug in `read_csv()` when reading a compressed UTF-16 encoded file (GH18071)
- Bug in `read_csv()` for handling null values in index columns when specifying `na_filter=False` (GH5239)
- Bug in `read_csv()` when reading numeric category fields with high cardinality (GH18186)
- Bug in `DataFrame.to_csv()` when the table had `MultiIndex` columns, and a list of strings was passed in for header (GH5539)
- Bug in parsing integer datetime-like columns with specified format in `read_sql` (GH17855).
- Bug in `DataFrame.to_msgpack()` when serializing data of the `numpy.bool_` datatype (GH18390)
- Bug in `read_json()` not decoding when reading line delimited JSON from S3 (GH17200)
- Bug in `pandas.io.json.json_normalize()` to avoid modification of `meta` (GH18610)
- Bug in `to_latex()` where repeated `MultiIndex` values were not printed even though a higher level index differed from the previous row (GH14484)
- Bug when reading NaN-only categorical columns in `HDFStore` (GH18413)
- Bug in `DataFrame.to_latex()` with `longtable=True` where a latex multicolumn always spanned over three columns (GH17959)

## Plotting

- Bug in `DataFrame.plot()` and `Series.plot()` with `DatetimeIndex` where a figure generated by them is not pickleable in Python 3 (GH18439)

## GroupBy/resample/rolling

- Bug in `DataFrame.resample(...).apply(...)` when there is a callable that returns different columns (GH15169)
- Bug in `DataFrame.resample(...)` when there is a time change (DST) and resampling frequency is 12h or higher (GH15549)
- Bug in `pd.DataFrameGroupBy.count()` when counting over a datetimelike column (GH13393)
- Bug in `rolling.var` where calculation is inaccurate with a zero-valued array (GH18430)

## Reshaping

- Error message in `pd.merge_asof()` for key datatype mismatch now includes datatype of left and right key (GH18068)
- Bug in `pd.concat` when empty and non-empty DataFrames or Series are concatenated (GH18178 GH18187)
- Bug in `DataFrame.filter(...)` when unicode is passed as a condition in Python 2 (GH13101)
- Bug when merging empty DataFrames when `np.seterr(divide='raise')` is set (GH17776)

## Numeric

- Bug in `pd.Series.rolling.skew()` and `rolling.kurt()` with all equal values has floating issue (GH18044)

## Categorical

- Bug in `DataFrame.astype()` where casting to 'category' on an empty DataFrame causes a segmentation fault (GH18004)
- Error messages in the testing module have been improved when items have different CategoricalDtype (GH18069)
- CategoricalIndex can now correctly take a `pd.api.types.CategoricalDtype` as its dtype (GH18116)
- Bug in `Categorical.unique()` returning read-only codes array when all categories were NaN (GH18051)
- Bug in `DataFrame.groupby(axis=1)` with a CategoricalIndex (GH18432)

## String

- `Series.str.split()` will now propagate NaN values across all expanded columns instead of None (GH18450)

## 5.9.2 Version 0.21.0 (October 27, 2017)

This is a major release from 0.20.3 and includes a number of API changes, deprecations, new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

Highlights include:

- Integration with [Apache Parquet](#), including a new top-level `read_parquet()` function and `DataFrame.to_parquet()` method, see [here](#).
- New user-facing `pandas.api.types.CategoricalDtype` for specifying categoricals independent of the data, see [here](#).
- The behavior of `sum` and `prod` on all-NaN Series/DataFrames is now consistent and no longer depends on whether `bottleneck` is installed, and `sum` and `prod` on empty Series now return NaN instead of 0, see [here](#).
- Compatibility fixes for pypy, see [here](#).
- Additions to the `drop`, `reindex` and `rename` API to make them more consistent, see [here](#).
- Addition of the new methods `DataFrame.infer_objects` (see [here](#)) and `GroupBy.pipe` (see [here](#)).
- Indexing with a list of labels, where one or more of the labels is missing, is deprecated and will raise a `KeyError` in a future version, see [here](#).

Check the [API Changes](#) and [deprecations](#) before updating.

### What's new in v0.21.0

- *New features*
  - *Integration with Apache Parquet file format*
  - *Method `infer_objects` type conversion*
  - *Improved warnings when attempting to create columns*

- *Method `drop` now also accepts `index/columns` keywords*
- *Methods `rename`, `reindex` now also accept `axis` keyword*
- *`CategoricalDtype` for specifying categoricals*
- *`GroupBy` objects now have a `pipe` method*
- *`Categorical.rename_categories` accepts a dict-like*
- *Other enhancements*
- *Backwards incompatible API changes*
  - *Dependencies have increased minimum versions*
  - *Sum/prod of all-NaN or empty Series/DataFrames is now consistently NaN*
  - *Indexing with a list with missing labels is deprecated*
  - *NA naming changes*
  - *Iteration of Series/Index will now return Python scalars*
  - *Indexing with a Boolean Index*
  - *PeriodIndex resampling*
  - *Improved error handling during item assignment in `pd.eval`*
  - *Dtype conversions*
  - *MultiIndex constructor with a single level*
  - *UTC localization with Series*
  - *Consistency of range functions*
  - *No automatic Matplotlib converters*
  - *Other API changes*
- *Deprecations*
  - *Series.select and DataFrame.select*
  - *Series.argmax and Series.argmin*
- *Removal of prior version deprecations/changes*
- *Performance improvements*
- *Documentation changes*
- *Bug fixes*
  - *Conversion*
  - *Indexing*
  - *IO*
  - *Plotting*
  - *GroupBy/resample/rolling*
  - *Sparse*
  - *Reshaping*

- *Numeric*
- *Categorical*
- *PyPy*
- *Other*
- *Contributors*

## New features

### Integration with Apache Parquet file format

Integration with [Apache Parquet](#), including a new top-level `read_parquet()` and `DataFrame.to_parquet()` method, see [here](#) (GH15838, GH17438).

[Apache Parquet](#) provides a cross-language, binary file format for reading and writing data frames efficiently. Parquet is designed to faithfully serialize and de-serialize `DataFrame`s, supporting all of the pandas dtypes, including extension dtypes such as datetime with timezones.

This functionality depends on either the `pyarrow` or `fastparquet` library. For more details, see [the IO docs on Parquet](#).

### Method `infer_objects` type conversion

The `DataFrame.infer_objects()` and `Series.infer_objects()` methods have been added to perform dtype inference on object columns, replacing some of the functionality of the deprecated `convert_objects` method. See the documentation [here](#) for more details. (GH11221)

This method only performs soft conversions on object columns, converting Python objects to native types, but not any coercive conversions. For example:

```
In [1]: df = pd.DataFrame({'A': [1, 2, 3],
...: 'B': np.array([1, 2, 3], dtype='object'),
...: 'C': ['1', '2', '3']})
...:

In [2]: df.dtypes
Out[2]:
A int64
B object
C object
Length: 3, dtype: object

In [3]: df.infer_objects().dtypes
Out[3]:
A int64
B int64
C object
Length: 3, dtype: object
```

Note that column 'C' was not converted - only scalar numeric types will be converted to a new type. Other types of conversion should be accomplished using the `to_numeric()` function (or `to_datetime()`, `to_timedelta()`).

```
In [4]: df = df.infer_objects()

In [5]: df['C'] = pd.to_numeric(df['C'], errors='coerce')

In [6]: df.dtypes
Out[6]:
A int64
B int64
C int64
Length: 3, dtype: object
```

### Improved warnings when attempting to create columns

New users are often puzzled by the relationship between column operations and attribute access on `DataFrame` instances (GH7175). One specific instance of this confusion is attempting to create a new column by setting an attribute on the `DataFrame`:

```
In [1]: df = pd.DataFrame({'one': [1., 2., 3.]})
In [2]: df.two = [4, 5, 6]
```

This does not raise any obvious exceptions, but also does not create a new column:

```
In [3]: df
Out[3]:
 one
0 1.0
1 2.0
2 3.0
```

Setting a list-like data structure into a new attribute now raises a `UserWarning` about the potential for unexpected behavior. See *Attribute Access*.

### Method `drop` now also accepts `index/columns` keywords

The `drop()` method has gained `index/columns` keywords as an alternative to specifying the `axis`. This is similar to the behavior of `reindex` (GH12392).

For example:

```
In [7]: df = pd.DataFrame(np.arange(8).reshape(2, 4),
...: columns=['A', 'B', 'C', 'D'])
...:

In [8]: df
Out[8]:
 A B C D
0 0 1 2 3
1 4 5 6 7

[2 rows x 4 columns]
```

(continues on next page)

(continued from previous page)

```
In [9]: df.drop(['B', 'C'], axis=1)
```

```
Out[9]:
```

```
 A D
0 0 3
1 4 7
```

```
[2 rows x 2 columns]
```

```
the following is now equivalent
```

```
In [10]: df.drop(columns=['B', 'C'])
```

```
Out[10]:
```

```
 A D
0 0 3
1 4 7
```

```
[2 rows x 2 columns]
```

### Methods `rename`, `reindex` now also accept `axis` keyword

The `DataFrame.rename()` and `DataFrame.reindex()` methods have gained the `axis` keyword to specify the axis to target with the operation (GH12392).

Here's `rename`:

```
In [11]: df = pd.DataFrame({"A": [1, 2, 3], "B": [4, 5, 6]})
```

```
In [12]: df.rename(str.lower, axis='columns')
```

```
Out[12]:
```

```
 a b
0 1 4
1 2 5
2 3 6
```

```
[3 rows x 2 columns]
```

```
In [13]: df.rename(id, axis='index')
```

```
Out[13]:
```

```
 A B
94293413313760 1 4
94293413313792 2 5
94293413313824 3 6
```

```
[3 rows x 2 columns]
```

And `reindex`:

```
In [14]: df.reindex(['A', 'B', 'C'], axis='columns')
```

```
Out[14]:
```

```
 A B C
0 1 4 NaN
1 2 5 NaN
```

(continues on next page)

(continued from previous page)

```

2 3 6 NaN

[3 rows x 3 columns]

In [15]: df.reindex([0, 1, 3], axis='index')
Out[15]:
 A B
0 1.0 4.0
1 2.0 5.0
3 NaN NaN

[3 rows x 2 columns]

```

The “index, columns” style continues to work as before.

```

In [16]: df.rename(index=id, columns=str.lower)
Out[16]:
 a b
94293413313760 1 4
94293413313792 2 5
94293413313824 3 6

[3 rows x 2 columns]

In [17]: df.reindex(index=[0, 1, 3], columns=['A', 'B', 'C'])
Out[17]:
 A B C
0 1.0 4.0 NaN
1 2.0 5.0 NaN
3 NaN NaN NaN

[3 rows x 3 columns]

```

We *highly* encourage using named arguments to avoid confusion when using either style.

### CategoricalDtype for specifying categoricals

`pandas.api.types.CategoricalDtype` has been added to the public API and expanded to include the `categories` and `ordered` attributes. A `CategoricalDtype` can be used to specify the set of categories and orderedness of an array, independent of the data. This can be useful for example, when converting string data to a `Categorical` ([GH14711](#), [GH15078](#), [GH16015](#), [GH17643](#)):

```

In [18]: from pandas.api.types import CategoricalDtype

In [19]: s = pd.Series(['a', 'b', 'c', 'a']) # strings

In [20]: dtype = CategoricalDtype(categories=['a', 'b', 'c', 'd'], ordered=True)

In [21]: s.astype(dtype)
Out[21]:
0 a

```

(continues on next page)

(continued from previous page)

```

1 b
2 c
3 a
Length: 4, dtype: category
Categories (4, object): ['a' < 'b' < 'c' < 'd']

```

One place that deserves special mention is in `read_csv()`. Previously, with `dtype={'col': 'category'}`, the returned values and categories would always be strings.

```
In [22]: data = 'A,B\na,1\nb,2\nc,3'
```

```
In [23]: pd.read_csv(StringIO(data), dtype={'B': 'category'}).B.cat.categories
```

```
Out[23]: Index(['1', '2', '3'], dtype='object')
```

Notice the “object” dtype.

With a `CategoricalDtype` of all numerics, datetimes, or timedeltas, we can automatically convert to the correct type

```
In [24]: dtype = {'B': CategoricalDtype([1, 2, 3])}
```

```
In [25]: pd.read_csv(StringIO(data), dtype=dtype).B.cat.categories
```

```
Out[25]: Int64Index([1, 2, 3], dtype='int64')
```

The values have been correctly interpreted as integers.

The `.dtype` property of a `Categorical`, `CategoricalIndex` or a `Series` with categorical type will now return an instance of `CategoricalDtype`. While the repr has changed, `str(CategoricalDtype())` is still the string `'category'`. We’ll take this moment to remind users that the *preferred* way to detect categorical data is to use `pandas.api.types.is_categorical_dtype()`, and not `str(dtype) == 'category'`.

See the [CategoricalDtype docs](#) for more.

## GroupBy objects now have a pipe method

`GroupBy` objects now have a pipe method, similar to the one on `DataFrame` and `Series`, that allow for functions that take a `GroupBy` to be composed in a clean, readable syntax. (GH17871)

For a concrete example on combining `.groupby` and `.pipe`, imagine having a `DataFrame` with columns for stores, products, revenue and sold quantity. We’d like to do a groupwise calculation of *prices* (i.e. revenue/quantity) per store and per product. We could do this in a multi-step operation, but expressing it in terms of piping can make the code more readable.

First we set the data:

```
In [26]: import numpy as np
```

```
In [27]: n = 1000
```

```
In [28]: df = pd.DataFrame({'Store': np.random.choice(['Store_1', 'Store_2'], n),
.....: 'Product': np.random.choice(['Product_1',
.....: 'Product_2',
.....: 'Product_3']
.....:], n),
.....: 'Revenue': (np.random.random(n) * 50 + 10).round(2),
```

(continues on next page)

(continued from previous page)

```

.....: 'Quantity': np.random.randint(1, 10, size=n)})
.....:
In [29]: df.head(2)
Out[29]:
 Store Product Revenue Quantity
0 Store_2 Product_2 32.09 7
1 Store_1 Product_3 14.20 1

[2 rows x 4 columns]

```

Now, to find prices per store/product, we can simply do:

```

In [30]: (df.groupby(['Store', 'Product'])
.....: .pipe(lambda grp: grp.Revenue.sum() / grp.Quantity.sum())
.....: .unstack().round(2))
.....:
Out[30]:
Product Product_1 Product_2 Product_3
Store
Store_1 6.73 6.72 7.14
Store_2 7.59 6.98 7.23

[2 rows x 3 columns]

```

See the [documentation](#) for more.

### Categorical.rename\_categories accepts a dict-like

`rename_categories()` now accepts a dict-like argument for `new_categories`. The previous categories are looked up in the dictionary's keys and replaced if found. The behavior of missing and extra keys is the same as in `DataFrame.rename()`.

```

In [31]: c = pd.Categorical(['a', 'a', 'b'])

In [32]: c.rename_categories({"a": "eh", "b": "bee"})
Out[32]:
['eh', 'eh', 'bee']
Categories (2, object): ['eh', 'bee']

```

**Warning:** To assist with upgrading pandas, `rename_categories` treats Series as list-like. Typically, Series are considered to be dict-like (e.g. in `.rename`, `.map`). In a future version of pandas `rename_categories` will change to treat them as dict-like. Follow the warning message's recommendations for writing future-proof code.

```

In [33]: c.rename_categories(pd.Series([0, 1], index=['a', 'c']))
FutureWarning: Treating Series 'new_categories' as a list-like and using the values.
In a future version, 'rename_categories' will treat Series like a dictionary.
For dict-like, use 'new_categories.to_dict()'
For list-like, use 'new_categories.values'.
Out[33]:
[0, 0, 1]
Categories (2, int64): [0, 1]

```

## Other enhancements

### New functions or methods

- `nearest()` is added to support nearest-neighbor upsampling (GH17496).
- `Index` has added support for a `to_frame` method (GH15230).

### New keywords

- Added a `skipna` parameter to `infer_dtype()` to support type inference in the presence of missing values (GH17059).
- `Series.to_dict()` and `DataFrame.to_dict()` now support an `into` keyword which allows you to specify the `collections.Mapping` subclass that you would like returned. The default is `dict`, which is backwards compatible. (GH16122)
- `Series.set_axis()` and `DataFrame.set_axis()` now support the `inplace` parameter. (GH14636)
- `Series.to_pickle()` and `DataFrame.to_pickle()` have gained a `protocol` parameter (GH16252). By default, this parameter is set to `HIGHEST_PROTOCOL`
- `read_feather()` has gained the `nthreads` parameter for multi-threaded operations (GH16359)
- `DataFrame.clip()` and `Series.clip()` have gained an `inplace` argument. (GH15388)
- `crosstab()` has gained a `margins_name` parameter to define the name of the row / column that will contain the totals when `margins=True`. (GH15972)
- `read_json()` now accepts a `chunksize` parameter that can be used when `lines=True`. If `chunksize` is passed, `read_json` now returns an iterator which reads in `chunksize` lines with each iteration. (GH17048)
- `read_json()` and `to_json()` now accept a `compression` argument which allows them to transparently handle compressed files. (GH17798)

### Various enhancements

- Improved the import time of pandas by about 2.25x. (GH16764)
- Support for PEP 519 – Adding a file system path protocol on most readers (e.g. `read_csv()`) and writers (e.g. `DataFrame.to_csv()`) (GH13823).
- Added a `__fspath__` method to `pd.HDFStore`, `pd.ExcelFile`, and `pd.ExcelWriter` to work properly with the file system path protocol (GH13823).
- The `validate` argument for `merge()` now checks whether a merge is one-to-one, one-to-many, many-to-one, or many-to-many. If a merge is found to not be an example of specified merge type, an exception of type `MergeError` will be raised. For more, see [here](#) (GH16270)
- Added support for PEP 518 (`pyproject.toml`) to the build system (GH16745)
- `RangeIndex.append()` now returns a `RangeIndex` object when possible (GH16212)
- `Series.rename_axis()` and `DataFrame.rename_axis()` with `inplace=True` now return `None` while renaming the axis inplace. (GH15704)

- `api.types.infer_dtype()` now infers decimals. (GH15690)
- `DataFrame.select_dtypes()` now accepts scalar values for include/exclude as well as list-like. (GH16855)
- `date_range()` now accepts 'YS' in addition to 'AS' as an alias for start of year. (GH9313)
- `date_range()` now accepts 'Y' in addition to 'A' as an alias for end of year. (GH9313)
- `DataFrame.add_prefix()` and `DataFrame.add_suffix()` now accept strings containing the '%' character. (GH17151)
- Read/write methods that infer compression (`read_csv()`, `read_table()`, `read_pickle()`, and `to_pickle()`) can now infer from path-like objects, such as `pathlib.Path`. (GH17206)
- `read_sas()` now recognizes much more of the most frequently used date (datetime) formats in SAS7BDAT files. (GH15871)
- `DataFrame.items()` and `Series.items()` are now present in both Python 2 and 3 and is lazy in all cases. (GH13918, GH17213)
- `pandas.io.formats.style.Styler.where()` has been implemented as a convenience for `pandas.io.formats.style.Styler.applymap()`. (GH17474)
- `MultiIndex.is_monotonic_decreasing()` has been implemented. Previously returned False in all cases. (GH16554)
- `read_excel()` raises `ImportError` with a better message if `xlrd` is not installed. (GH17613)
- `DataFrame.assign()` will preserve the original order of `**kwargs` for Python 3.6+ users instead of sorting the column names. (GH14207)
- `Series.reindex()`, `DataFrame.reindex()`, `Index.get_indexer()` now support list-like argument for tolerance. (GH17367)

## Backwards incompatible API changes

### Dependencies have increased minimum versions

We have updated our minimum supported versions of dependencies (GH15206, GH15543, GH15214). If installed, we now require:

| Package    | Minimum Version | Required |
|------------|-----------------|----------|
| Numpy      | 1.9.0           | X        |
| Matplotlib | 1.4.3           |          |
| Scipy      | 0.14.0          |          |
| Bottleneck | 1.0.0           |          |

Additionally, support has been dropped for Python 3.4 (GH15251).

## Sum/prod of all-NaN or empty Series/DataFrames is now consistently NaN

**Note:** The changes described here have been partially reverted. See the [v0.22.0 Whatsnew](#) for more.

The behavior of `sum` and `prod` on all-NaN Series/DataFrames no longer depends on whether `bottleneck` is installed, and return value of `sum` and `prod` on an empty Series has changed (GH9422, GH15507).

Calling `sum` or `prod` on an empty or all-NaN Series, or columns of a DataFrame, will result in NaN. See the [docs](#).

```
In [33]: s = pd.Series([np.nan])
```

Previously WITHOUT `bottleneck` installed:

```
In [2]: s.sum()
Out[2]: np.nan
```

Previously WITH `bottleneck`:

```
In [2]: s.sum()
Out[2]: 0.0
```

New behavior, without regard to the `bottleneck` installation:

```
In [34]: s.sum()
Out[34]: 0.0
```

Note that this also changes the sum of an empty Series. Previously this always returned 0 regardless of a `bottleneck` installation:

```
In [1]: pd.Series([]).sum()
Out[1]: 0
```

but for consistency with the all-NaN case, this was changed to return NaN as well:

```
In [35]: pd.Series([]).sum()
Out[35]: 0.0
```

## Indexing with a list with missing labels is deprecated

Previously, selecting with a list of labels, where one or more labels were missing would always succeed, returning NaN for missing labels. This will now show a `FutureWarning`. In the future this will raise a `KeyError` (GH15747). This warning will trigger on a DataFrame or a Series for using `.loc[]` or `[][]` when passing a list-of-labels with at least 1 missing label. See the [deprecation docs](#).

```
In [36]: s = pd.Series([1, 2, 3])
```

```
In [37]: s
Out[37]:
0 1
1 2
2 3
Length: 3, dtype: int64
```

Previous behavior

```
In [4]: s.loc[[1, 2, 3]]
Out[4]:
1 2.0
2 3.0
3 NaN
dtype: float64
```

Current behavior

```
In [4]: s.loc[[1, 2, 3]]
Passing list-likes to .loc or [] with any missing label will raise
KeyError in the future, you can use .reindex() as an alternative.

See the documentation here:
https://pandas.pydata.org/pandas-docs/stable/indexing.html#deprecate-loc-reindex-listlike

Out[4]:
1 2.0
2 3.0
3 NaN
dtype: float64
```

The idiomatic way to achieve selecting potentially not-found elements is via `.reindex()`

```
In [38]: s.reindex([1, 2, 3])
Out[38]:
1 2.0
2 3.0
3 NaN
Length: 3, dtype: float64
```

Selection with all keys found is unchanged.

```
In [39]: s.loc[[1, 2]]
Out[39]:
1 2
2 3
Length: 2, dtype: int64
```

## NA naming changes

In order to promote more consistency among the pandas API, we have added additional top-level functions `isna()` and `notna()` that are aliases for `isnull()` and `notnull()`. The naming scheme is now more consistent with methods like `.dropna()` and `.fillna()`. Furthermore in all cases where `.isnull()` and `.notnull()` methods are defined, these have additional methods named `.isna()` and `.notna()`, these are included for classes `Categorical`, `Index`, `Series`, and `DataFrame`. (GH15001).

The configuration option `pd.options.mode.use_inf_as_null` is deprecated, and `pd.options.mode.use_inf_as_na` is added as a replacement.

### Iteration of Series/Index will now return Python scalars

Previously, when using certain iteration methods for a `Series` with dtype `int` or `float`, you would receive a numpy scalar, e.g. a `np.int64`, rather than a Python `int`. Issue (GH10904) corrected this for `Series.tolist()` and `list(Series)`. This change makes all iteration methods consistent, in particular, for `__iter__()` and `.map()`; note that this only affects `int/float` dtypes. (GH13236, GH13258, GH14216).

```
In [40]: s = pd.Series([1, 2, 3])
```

```
In [41]: s
```

```
Out[41]:
```

```
0 1
1 2
2 3
Length: 3, dtype: int64
```

Previously:

```
In [2]: type(list(s)[0])
```

```
Out[2]: numpy.int64
```

New behavior:

```
In [42]: type(list(s)[0])
```

```
Out[42]: int
```

Furthermore this will now correctly box the results of iteration for `DataFrame.to_dict()` as well.

```
In [43]: d = {'a': [1], 'b': ['b']}
```

```
In [44]: df = pd.DataFrame(d)
```

Previously:

```
In [8]: type(df.to_dict()['a'][0])
```

```
Out[8]: numpy.int64
```

New behavior:

```
In [45]: type(df.to_dict()['a'][0])
```

```
Out[45]: int
```

### Indexing with a Boolean Index

Previously when passing a boolean `Index` to `.loc`, if the index of the `Series/DataFrame` had boolean labels, you would get a label based selection, potentially duplicating result labels, rather than a boolean indexing selection (where `True` selects elements), this was inconsistent how a boolean numpy array indexed. The new behavior is to act like a boolean numpy array indexer. (GH17738)

Previous behavior:

```
In [46]: s = pd.Series([1, 2, 3], index=[False, True, False])
```

(continues on next page)

(continued from previous page)

```
In [47]: s
Out[47]:
False 1
True 2
False 3
Length: 3, dtype: int64
```

```
In [59]: s.loc[pd.Index([True, False, True])]
Out[59]:
True 2
False 1
False 3
True 2
dtype: int64
```

Current behavior

```
In [48]: s.loc[pd.Index([True, False, True])]
Out[48]:
False 1
False 3
Length: 2, dtype: int64
```

Furthermore, previously if you had an index that was non-numeric (e.g. strings), then a boolean Index would raise a `KeyError`. This will now be treated as a boolean indexer.

Previously behavior:

```
In [49]: s = pd.Series([1, 2, 3], index=['a', 'b', 'c'])

In [50]: s
Out[50]:
a 1
b 2
c 3
Length: 3, dtype: int64
```

```
In [39]: s.loc[pd.Index([True, False, True])]
KeyError: "None of [Index([True, False, True], dtype='object')] are in the [index]"
```

Current behavior

```
In [51]: s.loc[pd.Index([True, False, True])]
Out[51]:
a 1
c 3
Length: 2, dtype: int64
```

## PeriodIndex resampling

In previous versions of pandas, resampling a Series/DataFrame indexed by a PeriodIndex returned a DatetimeIndex in some cases (GH12884). Resampling to a multiplied frequency now returns a PeriodIndex (GH15944). As a minor enhancement, resampling a PeriodIndex can now handle NaT values (GH13224)

Previous behavior:

```
In [1]: pi = pd.period_range('2017-01', periods=12, freq='M')
In [2]: s = pd.Series(np.arange(12), index=pi)
In [3]: resampled = s.resample('2Q').mean()
In [4]: resampled
Out[4]:
2017-03-31 1.0
2017-09-30 5.5
2018-03-31 10.0
Freq: 2Q-DEC, dtype: float64
In [5]: resampled.index
Out[5]: DatetimeIndex(['2017-03-31', '2017-09-30', '2018-03-31'], dtype='datetime64[ns]',
↳ freq='2Q-DEC')
```

New behavior:

```
In [52]: pi = pd.period_range('2017-01', periods=12, freq='M')
In [53]: s = pd.Series(np.arange(12), index=pi)
In [54]: resampled = s.resample('2Q').mean()
In [55]: resampled
Out[55]:
2017Q1 2.5
2017Q3 8.5
Freq: 2Q-DEC, Length: 2, dtype: float64
In [56]: resampled.index
Out[56]: PeriodIndex(['2017Q1', '2017Q3'], dtype='period[2Q-DEC]')
```

Upsampling and calling `.ohlc()` previously returned a Series, basically identical to calling `.asfreq()`. OHLC upsampling now returns a DataFrame with columns `open`, `high`, `low` and `close` (GH13083). This is consistent with downsampling and DatetimeIndex behavior.

Previous behavior:

```
In [1]: pi = pd.period_range(start='2000-01-01', freq='D', periods=10)
In [2]: s = pd.Series(np.arange(10), index=pi)
In [3]: s.resample('H').ohlc()
Out[3]:
```

(continues on next page)

(continued from previous page)

```

### Improved error handling during item assignment in `pd.eval`

`eval()` will now raise a `ValueError` when item assignment malfunctions, or inplace operations are specified, but there is no item assignment in the expression ([GH16732](#))

```
In [61]: arr = np.array([1, 2, 3])
```

Previously, if you attempted the following expression, you would get a not very helpful error message:

```
In [3]: pd.eval("a = 1 + 2", target=arr, inplace=True)
```

```
...
```

(continues on next page)

(continued from previous page)

```
IndexError: only integers, slices (':'), ellipsis ('...'), numpy.newaxis ('None')
and integer or boolean arrays are valid indices
```

This is a very long way of saying numpy arrays don't support string-item indexing. With this change, the error message is now this:

```
In [3]: pd.eval("a = 1 + 2", target=arr, inplace=True)
...
ValueError: Cannot assign expression output to target
```

It also used to be possible to evaluate expressions inplace, even if there was no item assignment:

```
In [4]: pd.eval("1 + 2", target=arr, inplace=True)
Out[4]: 3
```

However, this input does not make much sense because the output is not being assigned to the target. Now, a `ValueError` will be raised when such an input is passed in:

```
In [4]: pd.eval("1 + 2", target=arr, inplace=True)
...
ValueError: Cannot operate inplace if there is no assignment
```

## Dtype conversions

Previously assignments, `.where()` and `.fillna()` with a `bool` assignment, would coerce to same the type (e.g. `int` / `float`), or raise for datetimelikes. These will now preserve the bools with `object` dtypes. (GH16821).

```
In [62]: s = pd.Series([1, 2, 3])
```

```
In [5]: s[1] = True
```

```
In [6]: s
Out[6]:
0 1
1 1
2 3
dtype: int64
```

New behavior

```
In [63]: s[1] = True
```

```
In [64]: s
Out[64]:
0 1
1 True
2 3
Length: 3, dtype: object
```

Previously, as assignment to a datetimelike with a non-datetimelike would coerce the non-datetime-like item being assigned (GH14145).

```
In [65]: s = pd.Series([pd.Timestamp('2011-01-01'), pd.Timestamp('2012-01-01')])
```

```
In [1]: s[1] = 1
```

```
In [2]: s
```

```
Out[2]:
```

```
0 2011-01-01 00:00:00.000000000
```

```
1 1970-01-01 00:00:00.000000001
```

```
dtype: datetime64[ns]
```

These now coerce to object dtype.

```
In [66]: s[1] = 1
```

```
In [67]: s
```

```
Out[67]:
```

```
0 2011-01-01 00:00:00
```

```
1 1
```

```
Length: 2, dtype: object
```

- Inconsistent behavior in `.where()` with datetimelikes which would raise rather than coerce to object ([GH16402](#))
- Bug in assignment against int64 data with `np.ndarray` with float64 dtype may keep int64 dtype ([GH14001](#))

### MultiIndex constructor with a single level

The `MultiIndex` constructors no longer squeezes a `MultiIndex` with all length-one levels down to a regular `Index`. This affects all the `MultiIndex` constructors. ([GH17178](#))

Previous behavior:

```
In [2]: pd.MultiIndex.from_tuples([('a',), ('b',)])
```

```
Out[2]: Index(['a', 'b'], dtype='object')
```

Length 1 levels are no longer special-cased. They behave exactly as if you had length 2+ levels, so a `MultiIndex` is always returned from all of the `MultiIndex` constructors:

```
In [68]: pd.MultiIndex.from_tuples([('a',), ('b',)])
```

```
Out[68]:
```

```
MultiIndex([('a',),
 ('b',)],
)
```

## UTC localization with Series

Previously, `to_datetime()` did not localize datetime Series data when `utc=True` was passed. Now, `to_datetime()` will correctly localize Series with a `datetime64[ns, UTC]` dtype to be consistent with how list-like and Index data are handled. (GH6415).

Previous behavior

```
In [69]: s = pd.Series(['20130101 00:00:00'] * 3)
```

```
In [12]: pd.to_datetime(s, utc=True)
```

```
Out[12]:
```

```
0 2013-01-01
1 2013-01-01
2 2013-01-01
dtype: datetime64[ns]
```

New behavior

```
In [70]: pd.to_datetime(s, utc=True)
```

```
Out[70]:
```

```
0 2013-01-01 00:00:00+00:00
1 2013-01-01 00:00:00+00:00
2 2013-01-01 00:00:00+00:00
Length: 3, dtype: datetime64[ns, UTC]
```

Additionally, DataFrames with datetime columns that were parsed by `read_sql_table()` and `read_sql_query()` will also be localized to UTC only if the original SQL columns were timezone aware datetime columns.

## Consistency of range functions

In previous versions, there were some inconsistencies between the various range functions: `date_range()`, `bdate_range()`, `period_range()`, `timedelta_range()`, and `interval_range()`. (GH17471).

One of the inconsistent behaviors occurred when the `start`, `end` and `period` parameters were all specified, potentially leading to ambiguous ranges. When all three parameters were passed, `interval_range` ignored the `period` parameter, `period_range` ignored the `end` parameter, and the other range functions raised. To promote consistency among the range functions, and avoid potentially ambiguous ranges, `interval_range` and `period_range` will now raise when all three parameters are passed.

Previous behavior:

```
In [2]: pd.interval_range(start=0, end=4, periods=6)
```

```
Out[2]:
```

```
IntervalIndex([(0, 1], (1, 2], (2, 3]]
 closed='right',
 dtype='interval[int64]')
```

```
In [3]: pd.period_range(start='2017Q1', end='2017Q4', periods=6, freq='Q')
```

```
Out[3]: PeriodIndex(['2017Q1', '2017Q2', '2017Q3', '2017Q4', '2018Q1', '2018Q2'], dtype=
→ 'period[Q-DEC]', freq='Q-DEC')
```

New behavior:

```
In [2]: pd.interval_range(start=0, end=4, periods=6)
```

```

ValueError: Of the three parameters: start, end, and periods, exactly two must be
↪specified
```

```
In [3]: pd.period_range(start='2017Q1', end='2017Q4', periods=6, freq='Q')
```

```

ValueError: Of the three parameters: start, end, and periods, exactly two must be
↪specified
```

Additionally, the endpoint parameter `end` was not included in the intervals produced by `interval_range`. However, all other range functions include `end` in their output. To promote consistency among the range functions, `interval_range` will now include `end` as the right endpoint of the final interval, except if `freq` is specified in a way which skips `end`.

Previous behavior:

```
In [4]: pd.interval_range(start=0, end=4)
```

```
Out[4]:
```

```
IntervalIndex([(0, 1], (1, 2], (2, 3]]
 closed='right',
 dtype='interval[int64]')
```

New behavior:

```
In [71]: pd.interval_range(start=0, end=4)
```

```
Out[71]: IntervalIndex([(0, 1], (1, 2], (2, 3], (3, 4]], dtype='interval[int64, right]')
```

## No automatic Matplotlib converters

pandas no longer registers our `date`, `time`, `datetime`, `datetime64`, and `Period` converters with `matplotlib` when pandas is imported. `Matplotlib` plot methods (`plt.plot`, `ax.plot`, ...) will not nicely format the x-axis for `DatetimeIndex` or `PeriodIndex` values. You must explicitly register these methods:

pandas built-in `Series.plot` and `DataFrame.plot` will register these converters on first-use (GH17710).

---

**Note:** This change has been temporarily reverted in pandas 0.21.1, for more details see [here](#).

---

## Other API changes

- The Categorical constructor no longer accepts a scalar for the `categories` keyword. (GH16022)
- Accessing a non-existent attribute on a closed `HDFStore` will now raise an `AttributeError` rather than a `ClosedFileError` (GH16301)
- `read_csv()` now issues a `UserWarning` if the `names` parameter contains duplicates (GH17095)
- `read_csv()` now treats `'null'` and `'n/a'` strings as missing values by default (GH16471, GH16078)
- `pandas.HDFStore`'s string representation is now faster and less detailed. For the previous behavior, use `pandas.HDFStore.info()`. (GH16503).

- Compression defaults in HDF stores now follow pytables standards. Default is no compression and if `complib` is missing and `complevel > 0` `zlib` is used (GH15943)
- `Index.get_indexer_non_unique()` now returns a `ndarray` indexer rather than an `Index`; this is consistent with `Index.get_indexer()` (GH16819)
- Removed the `@slow` decorator from `pandas._testing`, which caused issues for some downstream packages' test suites. Use `@pytest.mark.slow` instead, which achieves the same thing (GH16850)
- Moved definition of `MergeError` to the `pandas.errors` module.
- The signature of `Series.set_axis()` and `DataFrame.set_axis()` has been changed from `set_axis(axis, labels)` to `set_axis(labels, axis=0)`, for consistency with the rest of the API. The old signature is deprecated and will show a `FutureWarning` (GH14636)
- `Series.argmax()` and `Series.argmin()` will now raise a `TypeError` when used with `object` dtypes, instead of a `ValueError` (GH13595)
- `Period` is now immutable, and will now raise an `AttributeError` when a user tries to assign a new value to the `ordinal` or `freq` attributes (GH17116).
- `to_datetime()` when passed a tz-aware `origin=` kwarg will now raise a more informative `ValueError` rather than a `TypeError` (GH16842)
- `to_datetime()` now raises a `ValueError` when format includes `%W` or `%U` without also including day of the week and calendar year (GH16774)
- Renamed non-functional index to `index_col` in `read_stata()` to improve API consistency (GH16342)
- Bug in `DataFrame.drop()` caused boolean labels `False` and `True` to be treated as labels 0 and 1 respectively when dropping indices from a numeric index. This will now raise a `ValueError` (GH16877)
- Restricted `DateOffset` keyword arguments. Previously, `DateOffset` subclasses allowed arbitrary keyword arguments which could lead to unexpected behavior. Now, only valid arguments will be accepted. (GH17176).

## Deprecations

- `DataFrame.from_csv()` and `Series.from_csv()` have been deprecated in favor of `read_csv()` (GH4191)
- `read_excel()` has deprecated `sheetname` in favor of `sheet_name` for consistency with `.to_excel()` (GH10559).
- `read_excel()` has deprecated `parse_cols` in favor of `usecols` for consistency with `read_csv()` (GH4988)
- `read_csv()` has deprecated the `tupleize_cols` argument. Column tuples will always be converted to a `MultiIndex` (GH17060)
- `DataFrame.to_csv()` has deprecated the `tupleize_cols` argument. `MultiIndex` columns will be always written as rows in the CSV file (GH17060)
- The `convert` parameter has been deprecated in the `.take()` method, as it was not being respected (GH16948)
- `pd.options.html.border` has been deprecated in favor of `pd.options.display.html.border` (GH15793).
- `SeriesGroupBy.nth()` has deprecated `True` in favor of `'all'` for its kwarg `dropna` (GH11038).
- `DataFrame.as_blocks()` is deprecated, as this is exposing the internal implementation (GH17302)
- `pd.TimeGrouper` is deprecated in favor of `pandas.Grouper` (GH16747)
- `cdate_range` has been deprecated in favor of `bdate_range()`, which has gained `weekmask` and `holidays` parameters for building custom frequency date ranges. See the [documentation](#) for more details (GH17596)

- passing categories or ordered kwargs to `Series.astype()` is deprecated, in favor of passing a `CategoricalDtype` (GH17636)
- `.get_value` and `.set_value` on `Series`, `DataFrame`, `Panel`, `SparseSeries`, and `SparseDataFrame` are deprecated in favor of using `.iat[]` or `.at[]` accessors (GH15269)
- Passing a non-existent column in `.to_excel(..., columns=)` is deprecated and will raise a `KeyError` in the future (GH17295)
- `raise_on_error` parameter to `Series.where()`, `Series.mask()`, `DataFrame.where()`, `DataFrame.mask()` is deprecated, in favor of `errors=` (GH14968)
- Using `DataFrame.rename_axis()` and `Series.rename_axis()` to alter index or column *labels* is now deprecated in favor of using `.rename`. `rename_axis` may still be used to alter the name of the index or columns (GH17833).
- `reindex_axis()` has been deprecated in favor of `reindex()`. See [here](#) for more (GH17833).

### Series.select and DataFrame.select

The `Series.select()` and `DataFrame.select()` methods are deprecated in favor of using `df.loc[labels.map(crit)]` (GH12401)

```
In [72]: df = pd.DataFrame({'A': [1, 2, 3]}, index=['foo', 'bar', 'baz'])
```

```
In [3]: df.select(lambda x: x in ['bar', 'baz'])
```

FutureWarning: select is deprecated and will be removed in a future release. You can use `df.loc[labels]` as a replacement

```
Out[3]:
```

```
 A
bar 2
baz 3
```

```
In [73]: df.loc[df.index.map(lambda x: x in ['bar', 'baz'])]
```

```
Out[73]:
```

```
 A
bar 2
baz 3
```

```
[2 rows x 1 columns]
```

### Series.argmax and Series.argmin

The behavior of `Series.argmax()` and `Series.argmin()` have been deprecated in favor of `Series.idxmax()` and `Series.idxmin()`, respectively (GH16830).

For compatibility with NumPy arrays, `pd.Series` implements `argmax` and `argmin`. Since pandas 0.13.0, `argmax` has been an alias for `pandas.Series.idxmax()`, and `argmin` has been an alias for `pandas.Series.idxmin()`. They return the *label* of the maximum or minimum, rather than the *position*.

We've deprecated the current behavior of `Series.argmax` and `Series.argmin`. Using either of these will emit a `FutureWarning`. Use `Series.idxmax()` if you want the label of the maximum. Use `Series.values.argmax()` if you want the position of the maximum. Likewise for the minimum. In a future release `Series.argmax` and `Series.argmin` will return the position of the maximum or minimum.

## Removal of prior version deprecations/changes

- `read_excel()` has dropped the `has_index_names` parameter (GH10967)
- The `pd.options.display.height` configuration has been dropped (GH3663)
- The `pd.options.display.line_width` configuration has been dropped (GH2881)
- The `pd.options.display.mpl_style` configuration has been dropped (GH12190)
- Index has dropped the `.sym_diff()` method in favor of `.symmetric_difference()` (GH12591)
- Categorical has dropped the `.order()` and `.sort()` methods in favor of `.sort_values()` (GH12882)
- `eval()` and `DataFrame.eval()` have changed the default of `inplace` from `None` to `False` (GH11149)
- The function `get_offset_name` has been dropped in favor of the `.freqstr` attribute for an offset (GH11834)
- pandas no longer tests for compatibility with hdf5-files created with pandas < 0.11 (GH17404).

## Performance improvements

- Improved performance of instantiating `SparseDataFrame` (GH16773)
- `Series.dt` no longer performs frequency inference, yielding a large speedup when accessing the attribute (GH17210)
- Improved performance of `set_categories()` by not materializing the values (GH17508)
- `Timestamp.microsecond` no longer re-computes on attribute access (GH17331)
- Improved performance of the `CategoricalIndex` for data that is already categorical dtype (GH17513)
- Improved performance of `RangeIndex.min()` and `RangeIndex.max()` by using `RangeIndex` properties to perform the computations (GH17607)

## Documentation changes

- Several NaT method docstrings (e.g. `NaT.ctime()`) were incorrect (GH17327)
- The documentation has had references to versions < v0.17 removed and cleaned up (GH17442, GH17442, GH17404 & GH17504)

## Bug fixes

### Conversion

- Bug in assignment against datetime-like data with `int` may incorrectly convert to datetime-like (GH14145)
- Bug in assignment against `int64` data with `np.ndarray` with `float64` dtype may keep `int64` dtype (GH14001)
- Fixed the return type of `IntervalIndex.is_non_overlapping_monotonic` to be a Python `bool` for consistency with similar attributes/methods. Previously returned a `numpy.bool_`. (GH17237)
- Bug in `IntervalIndex.is_non_overlapping_monotonic` when intervals are closed on both sides and overlap at a point (GH16560)
- Bug in `Series.fillna()` returns frame when `inplace=True` and `value` is dict (GH16156)
- Bug in `Timestamp.weekday_name` returning a UTC-based weekday name when localized to a timezone (GH17354)

- Bug in `Timestamp.replace` when replacing `tzinfo` around DST changes (GH15683)
- Bug in `Timedelta` construction and arithmetic that would not propagate the `Overflow` exception (GH17367)
- Bug in `astype()` converting to object dtype when passed extension type classes (`DatetimeTZDtype`, `CategoricalDtype`) rather than instances. Now a `TypeError` is raised when a class is passed (GH17780).
- Bug in `to_numeric()` in which elements were not always being coerced to numeric when `errors='coerce'` (GH17007, GH17125)
- Bug in `DataFrame` and `Series` constructors where range objects are converted to `int32` dtype on Windows instead of `int64` (GH16804)

## Indexing

- When called with a null slice (e.g. `df.iloc[:]`), the `.iloc` and `.loc` indexers return a shallow copy of the original object. Previously they returned the original object. (GH13873).
- When called on an unsorted `MultiIndex`, the `loc` indexer now will raise `UnsortedIndexError` only if proper slicing is used on non-sorted levels (GH16734).
- Fixes regression in 0.20.3 when indexing with a string on a `TimedeltaIndex` (GH16896).
- Fixed `TimedeltaIndex.get_loc()` handling of `np.timedelta64` inputs (GH16909).
- Fix `MultiIndex.sort_index()` ordering when ascending argument is a list, but not all levels are specified, or are in a different order (GH16934).
- Fixes bug where indexing with `np.inf` caused an `OverflowError` to be raised (GH16957)
- Bug in reindexing on an empty `CategoricalIndex` (GH16770)
- Fixes `DataFrame.loc` for setting with alignment and tz-aware `DatetimeIndex` (GH16889)
- Avoids `IndexError` when passing an `Index` or `Series` to `.iloc` with older numpy (GH17193)
- Allow unicode empty strings as placeholders in multilevel columns in Python 2 (GH17099)
- Bug in `.iloc` when used with inplace addition or assignment and an int indexer on a `MultiIndex` causing the wrong indexes to be read from and written to (GH17148)
- Bug in `.isin()` in which checking membership in empty `Series` objects raised an error (GH16991)
- Bug in `CategoricalIndex` reindexing in which specified indices containing duplicates were not being respected (GH17323)
- Bug in intersection of `RangeIndex` with negative step (GH17296)
- Bug in `IntervalIndex` where performing a scalar lookup fails for included right endpoints of non-overlapping monotonic decreasing indexes (GH16417, GH17271)
- Bug in `DataFrame.first_valid_index()` and `DataFrame.last_valid_index()` when no valid entry (GH17400)
- Bug in `Series.rename()` when called with a callable, incorrectly alters the name of the `Series`, rather than the name of the `Index`. (GH17407)
- Bug in `String.str_get()` raises `IndexError` instead of inserting NaNs when using a negative index. (GH17704)

## IO

- Bug in `read_hdf()` when reading a timezone aware index from fixed format HDFStore (GH17618)
- Bug in `read_csv()` in which columns were not being thoroughly de-duplicated (GH17060)
- Bug in `read_csv()` in which specified column names were not being thoroughly de-duplicated (GH17095)
- Bug in `read_csv()` in which non integer values for the header argument generated an unhelpful / unrelated error message (GH16338)
- Bug in `read_csv()` in which memory management issues in exception handling, under certain conditions, would cause the interpreter to segfault (GH14696, GH16798).
- Bug in `read_csv()` when called with `low_memory=False` in which a CSV with at least one column > 2GB in size would incorrectly raise a `MemoryError` (GH16798).
- Bug in `read_csv()` when called with a single-element list header would return a `DataFrame` of all NaN values (GH7757)
- Bug in `DataFrame.to_csv()` defaulting to 'ascii' encoding in Python 3, instead of 'utf-8' (GH17097)
- Bug in `read_stata()` where value labels could not be read when using an iterator (GH16923)
- Bug in `read_stata()` where the index was not set (GH16342)
- Bug in `read_html()` where import check fails when run in multiple threads (GH16928)
- Bug in `read_csv()` where automatic delimiter detection caused a `TypeError` to be thrown when a bad line was encountered rather than the correct error message (GH13374)
- Bug in `DataFrame.to_html()` with `notebook=True` where `DataFrames` with named indices or non-`MultiIndex` indices had undesired horizontal or vertical alignment for column or row labels, respectively (GH16792)
- Bug in `DataFrame.to_html()` in which there was no validation of the `justify` parameter (GH17527)
- Bug in `HDFStore.select()` when reading a contiguous mixed-data table featuring `VArray` (GH17021)
- Bug in `to_json()` where several conditions (including objects with unprintable symbols, objects with deep recursion, overlong labels) caused segfaults instead of raising the appropriate exception (GH14256)

## Plotting

- Bug in plotting methods using `secondary_y` and `fontsize` not setting secondary axis font size (GH12565)
- Bug when plotting `timedelta` and `datetime` dtypes on y-axis (GH16953)
- Line plots no longer assume monotonic x data when calculating `xlims`, they show the entire lines now even for unsorted x data. (GH11310, GH11471)
- With matplotlib 2.0.0 and above, calculation of x limits for line plots is left to matplotlib, so that its new default settings are applied. (GH15495)
- Bug in `Series.plot.bar` or `DataFrame.plot.bar` with `y` not respecting user-passed `color` (GH16822)
- Bug causing `plotting.parallel_coordinates` to reset the random seed when using random colors (GH17525)

## GroupBy/resample/rolling

- Bug in `DataFrame.resample(...).size()` where an empty `DataFrame` did not return a `Series` (GH14962)
- Bug in `infer_freq()` causing indices with 2-day gaps during the working week to be wrongly inferred as business daily (GH16624)
- Bug in `.rolling(...).quantile()` which incorrectly used different defaults than `Series.quantile()` and `DataFrame.quantile()` (GH9413, GH16211)
- Bug in `groupby.transform()` that would coerce boolean dtypes back to float (GH16875)
- Bug in `Series.resample(...).apply()` where an empty `Series` modified the source index and did not return the name of a `Series` (GH14313)
- Bug in `.rolling(...).apply(...)` with a `DataFrame` with a `DatetimeIndex`, a window of a `timedelta`-convertible and `min_periods >= 1` (GH15305)
- Bug in `DataFrame.groupby` where index and column keys were not recognized correctly when the number of keys equaled the number of elements on the groupby axis (GH16859)
- Bug in `groupby.unique()` with `TimeGrouper` which cannot handle `NaT` correctly (GH17575)
- Bug in `DataFrame.groupby` where a single level selection from a `MultiIndex` unexpectedly sorts (GH17537)
- Bug in `DataFrame.groupby` where spurious warning is raised when `Grouper` object is used to override ambiguous column name (GH17383)
- Bug in `TimeGrouper` differs when passes as a list and as a scalar (GH17530)

## Sparse

- Bug in `SparseSeries` raises `AttributeError` when a dictionary is passed in as data (GH16905)
- Bug in `SparseDataFrame.fillna()` not filling all `NaNs` when frame was instantiated from SciPy sparse matrix (GH16112)
- Bug in `SparseSeries.unstack()` and `SparseDataFrame.stack()` (GH16614, GH15045)
- Bug in `make_sparse()` treating two numeric/boolean data, which have same bits, as same when array dtype is object (GH17574)
- `SparseArray.all()` and `SparseArray.any()` are now implemented to handle `SparseArray`, these were used but not implemented (GH17570)

## Reshaping

- Joining/Merging with a non unique `PeriodIndex` raised a `TypeError` (GH16871)
- Bug in `crosstab()` where non-aligned series of integers were casted to float (GH17005)
- Bug in merging with categorical dtypes with datetimelikes incorrectly raised a `TypeError` (GH16900)
- Bug when using `isin()` on a large object series and large comparison array (GH16012)
- Fixes regression from 0.20, `Series.aggregate()` and `DataFrame.aggregate()` allow dictionaries as return values again (GH16741)
- Fixes dtype of result with integer dtype input, from `pivot_table()` when called with `margins=True` (GH17013)
- Bug in `crosstab()` where passing two `Series` with the same name raised a `KeyError` (GH13279)

- `Series.argmax()`, `Series.amin()`, and their counterparts on `DataFrame` and `groupby` objects work correctly with floating point data that contains infinite values (GH13595).
- Bug in `unique()` where checking a tuple of strings raised a `TypeError` (GH17108)
- Bug in `concat()` where order of result index was unpredictable if it contained non-comparable elements (GH17344)
- Fixes regression when sorting by multiple columns on a `datetime64` dtype `Series` with `NaT` values (GH16836)
- Bug in `pivot_table()` where the result's columns did not preserve the categorical dtype of columns when `dropna` was `False` (GH17842)
- Bug in `DataFrame.drop_duplicates` where dropping with non-unique column names raised a `ValueError` (GH17836)
- Bug in `unstack()` which, when called on a list of levels, would discard the `fillna` argument (GH13971)
- Bug in the alignment of `range` objects and other list-likes with `DataFrame` leading to operations being performed row-wise instead of column-wise (GH17901)

## Numeric

- Bug in `.clip()` with `axis=1` and a list-like for `threshold` is passed; previously this raised `ValueError` (GH15390)
- `Series.clip()` and `DataFrame.clip()` now treat NA values for upper and lower arguments as `None` instead of raising `ValueError` (GH17276).

## Categorical

- Bug in `Series.isin()` when called with a categorical (GH16639)
- Bug in the categorical constructor with empty values and categories causing the `.categories` to be an empty `Float64Index` rather than an empty `Index` with object dtype (GH17248)
- Bug in categorical operations with `Series.cat` not preserving the original `Series`' name (GH17509)
- Bug in `DataFrame.merge()` failing for categorical columns with boolean/int data types (GH17187)
- Bug in constructing a `Categorical/CategoricalDtype` when the specified categories are of categorical type (GH17884).

## PyPy

- Compatibility with PyPy in `read_csv()` with `usecols=[<unsorted ints>]` and `read_json()` (GH17351)
- Split tests into cases for CPython and PyPy where needed, which highlights the fragility of index matching with `float('nan')`, `np.nan` and `NAT` (GH17351)
- Fix `DataFrame.memory_usage()` to support PyPy. Objects on PyPy do not have a fixed size, so an approximation is used instead (GH17228)

## Other

- Bug where some inplace operators were not being wrapped and produced a copy when invoked ([GH12962](#))
- Bug in `eval()` where the `inplace` parameter was being incorrectly handled ([GH16732](#))

## Contributors

## 5.10 Version 0.20

### 5.10.1 Version 0.20.3 (July 7, 2017)

This is a minor bug-fix release in the 0.20.x series and includes some small regression fixes and bug fixes. We recommend that all users upgrade to this version.

#### What's new in v0.20.3

- *Bug fixes*
  - *Conversion*
  - *Indexing*
  - *IO*
  - *Plotting*
  - *Reshaping*
  - *Categorical*
- *Contributors*

#### Bug fixes

- Fixed a bug in failing to compute rolling computations of a column-MultiIndexed DataFrame ([GH16789](#), [GH16825](#))
- Fixed a pytest marker failing downstream packages' tests suites ([GH16680](#))

#### Conversion

- Bug in pickle compat prior to the v0.20.x series, when UTC is a timezone in a Series/DataFrame/Index ([GH16608](#))
- Bug in Series construction when passing a Series with dtype='category' ([GH16524](#)).
- Bug in `DataFrame.astype()` when passing a Series as the dtype kwarg. ([GH16717](#)).

#### Indexing

- Bug in `Float64Index` causing an empty array instead of `None` to be returned from `.get(np.nan)` on a Series whose index did not contain any NaNs ([GH8569](#))
- Bug in `MultiIndex.isin` causing an error when passing an empty iterable ([GH16777](#))
- Fixed a bug in a slicing DataFrame/Series that have a `TimedeltaIndex` ([GH16637](#))

## IO

- Bug in `read_csv()` in which files weren't opened as binary files by the C engine on Windows, causing EOF characters mid-field, which would fail ([GH16039](#), [GH16559](#), [GH16675](#))
- Bug in `read_hdf()` in which reading a `Series` saved to an HDF file in 'fixed' format fails when an explicit `mode='r'` argument is supplied ([GH16583](#))
- Bug in `DataFrame.to_latex()` where `bold_rows` was wrongly specified to be `True` by default, whereas in reality row labels remained non-bold whatever parameter provided. ([GH16707](#))
- Fixed an issue with `DataFrame.style()` where generated element ids were not unique ([GH16780](#))
- Fixed loading a `DataFrame` with a `PeriodIndex`, from a `format='fixed'` `HDFStore`, in Python 3, that was written in Python 2 ([GH16781](#))

## Plotting

- Fixed regression that prevented RGB and RGBA tuples from being used as color arguments ([GH16233](#))
- Fixed an issue with `DataFrame.plot.scatter()` that incorrectly raised a `KeyError` when categorical data is used for plotting ([GH16199](#))

## Reshaping

- `PeriodIndex / TimedeltaIndex.join` was missing the `sort=` kwarg ([GH16541](#))
- Bug in joining on a `MultiIndex` with a `category` dtype for a level ([GH16627](#)).
- Bug in `merge()` when merging/joining with multiple categorical columns ([GH16767](#))

## Categorical

- Bug in `DataFrame.sort_values` not respecting the `kind` parameter with categorical data ([GH16793](#))

## Contributors

### **5.10.2 Version 0.20.2 (June 4, 2017)**

This is a minor bug-fix release in the 0.20.x series and includes some small regression fixes, bug fixes and performance improvements. We recommend that all users upgrade to this version.

#### **What's new in v0.20.2**

- *Enhancements*
- *Performance improvements*
- *Bug fixes*
  - *Conversion*
  - *Indexing*
  - *IO*
  - *Plotting*
  - *GroupBy/resample/rolling*
  - *Sparse*
  - *Reshaping*
  - *Numeric*
  - *Categorical*
  - *Other*
- *Contributors*

## Enhancements

- Unblocked access to additional compression types supported in pytables: ‘blosc:blosclz’, ‘blosc:lz4’, ‘blosc:lz4hc’, ‘blosc:snappy’, ‘blosc:zlib’, ‘blosc:zstd’ (GH14478)
- Series provides a `to_latex` method (GH16180)
- A new `groupby` method `ngroup()`, parallel to the existing `cumcount()`, has been added to return the group order (GH11642); see [here](#).

## Performance improvements

- Performance regression fix when indexing with a list-like (GH16285)
- Performance regression fix for MultiIndexes (GH16319, GH16346)
- Improved performance of `.clip()` with scalar arguments (GH15400)
- Improved performance of `groupby` with categorical groupers (GH16413)
- Improved performance of `MultiIndex.remove_unused_levels()` (GH16556)

## Bug fixes

- Silenced a warning on some Windows environments about “tput: terminal attributes: No such device or address” when detecting the terminal size. This fix only applies to python 3 (GH16496)
- Bug in using `pathlib.Path` or `py.path.local` objects with io functions (GH16291)
- Bug in `Index.symmetric_difference()` on two equal `MultiIndex`’s, results in a `TypeError` (GH13490)
- Bug in `DataFrame.update()` with `overwrite=False` and `NaN` values (GH15593)
- Passing an invalid engine to `read_csv()` now raises an informative `ValueError` rather than `UnboundLocalError`. (GH16511)
- Bug in `unique()` on an array of tuples (GH16519)
- Bug in `cut()` when `labels` are set, resulting in incorrect label ordering (GH16459)
- Fixed a compatibility issue with IPython 6.0’s tab completion showing deprecation warnings on `Categoricals` (GH16409)

## Conversion

- Bug in `to_numeric()` in which empty data inputs were causing a segfault of the interpreter (GH16302)
- Silence numpy warnings when broadcasting `DataFrame` to `Series` with comparison ops (GH16378, GH16306)

## Indexing

- Bug in `DataFrame.reset_index(level=)` with single level index (GH16263)
- Bug in partial string indexing with a monotonic, but not strictly-monotonic, index incorrectly reversing the slice bounds (GH16515)
- Bug in `MultiIndex.remove_unused_levels()` that would not return a `MultiIndex` equal to the original. (GH16556)

## IO

- Bug in `read_csv()` when `comment` is passed in a space delimited text file (GH16472)
- Bug in `read_csv()` not raising an exception with nonexistent columns in `usecols` when it had the correct length (GH14671)
- Bug that would force importing of the clipboard routines unnecessarily, potentially causing an import error on startup (GH16288)
- Bug that raised `IndexError` when HTML-rendering an empty `DataFrame` (GH15953)
- Bug in `read_csv()` in which tarfile object inputs were raising an error in Python 2.x for the C engine (GH16530)
- Bug where `DataFrame.to_html()` ignored the `index_names` parameter (GH16493)
- Bug where `pd.read_hdf()` returns numpy strings for index names (GH13492)
- Bug in `HDFStore.select_as_multiple()` where start/stop arguments were not respected (GH16209)

## Plotting

- Bug in `DataFrame.plot` with a single column and a list-like `color` (GH3486)
- Bug in plot where `NaT` in `DatetimeIndex` results in `Timestamp.min` (GH12405)
- Bug in `DataFrame.boxplot` where `figsize` keyword was not respected for non-grouped boxplots (GH11959)

## GroupBy/resample/rolling

- Bug in creating a time-based rolling window on an empty `DataFrame` (GH15819)
- Bug in `rolling.cov()` with offset window (GH16058)
- Bug in `.resample()` and `.groupby()` when aggregating on integers (GH16361)

## Sparse

- Bug in construction of `SparseDataFrame` from `scipy.sparse.dok_matrix` (GH16179)

## Reshaping

- Bug in `DataFrame.stack` with unsorted levels in `MultiIndex` columns ([GH16323](#))
- Bug in `pd.wide_to_long()` where no error was raised when `i` was not a unique identifier ([GH16382](#))
- Bug in `Series.isin(..)` with a list of tuples ([GH16394](#))
- Bug in construction of a `DataFrame` with mixed dtypes including an all-`NaT` column. ([GH16395](#))
- Bug in `DataFrame.agg()` and `Series.agg()` with aggregating on non-callable attributes ([GH16405](#))

## Numeric

- Bug in `.interpolate()`, where `limit_direction` was not respected when `limit=None` (default) was passed ([GH16282](#))

## Categorical

- Fixed comparison operations considering the order of the categories when both categoricals are unordered ([GH16014](#))

## Other

- Bug in `DataFrame.drop()` with an empty-list with non-unique indices ([GH16270](#))

## Contributors

### 5.10.3 Version 0.20.1 (May 5, 2017)

This is a major release from 0.19.2 and includes a number of API changes, deprecations, new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

Highlights include:

- New `.agg()` API for Series/DataFrame similar to the groupby-rolling-resample API’s, see [here](#)
- Integration with the `feather-format`, including a new top-level `pd.read_feather()` and `DataFrame.to_feather()` method, see [here](#).
- The `.ix` indexer has been deprecated, see [here](#)
- `Panel` has been deprecated, see [here](#)
- Addition of an `IntervalIndex` and `Interval` scalar type, see [here](#)
- Improved user API when grouping by index levels in `.groupby()`, see [here](#)
- Improved support for `UInt64` dtypes, see [here](#)
- A new orient for JSON serialization, `orient='table'`, that uses the Table Schema spec and that gives the possibility for a more interactive repr in the Jupyter Notebook, see [here](#)
- Experimental support for exporting styled DataFrames (`DataFrame.style`) to Excel, see [here](#)

- Window binary corr/cov operations now return a MultiIndexed DataFrame rather than a Panel, as Panel is now deprecated, see [here](#)
- Support for S3 handling now uses s3fs, see [here](#)
- Google BigQuery support now uses the pandas-gbq library, see [here](#)

**Warning:** pandas has changed the internal structure and layout of the code base. This can affect imports that are not from the top-level `pandas.*` namespace, please see the changes [here](#).

Check the *API Changes* and *deprecations* before updating.

**Note:** This is a combined release for 0.20.0 and 0.20.1. Version 0.20.1 contains one additional change for backwards-compatibility with downstream projects using pandas' `utils` routines. ([GH16250](#))

### What's new in v0.20.0

- *New features*
  - Method `agg` API for DataFrame/Series
  - Keyword argument `dtype` for data IO
  - Method `.to_datetime()` has gained an `origin` parameter
  - GroupBy enhancements
  - Better support for compressed URLs in `read_csv`
  - Pickle file IO now supports compression
  - UInt64 support improved
  - GroupBy on categoricals
  - Table schema output
  - SciPy sparse matrix from/to SparseDataFrame
  - Excel output for styled DataFrames
  - IntervalIndex
  - Other enhancements
- *Backwards incompatible API changes*
  - Possible incompatibility for HDF5 formats created with pandas < 0.13.0
  - Map on Index types now return other Index types
  - Accessing datetime fields of Index now return Index
  - `pd.unique` will now be consistent with extension types
  - S3 file handling
  - Partial string indexing changes
  - Concat of different float dtypes will not automatically upcast
  - pandas Google BigQuery support has moved

- *Memory usage for Index is more accurate*
- *DataFrame.sort\_index changes*
- *GroupBy describe formatting*
- *Window binary corr/cov operations return a MultiIndex DataFrame*
- *HDFStore where string comparison*
- *Index.intersection and inner join now preserve the order of the left Index*
- *Pivot table always returns a DataFrame*
- *Other API changes*
- *Reorganization of the library: privacy changes*
  - *Modules privacy has changed*
  - *pandas.errors*
  - *pandas.testing*
  - *pandas.plotting*
  - *Other development changes*
- *Deprecations*
  - *Deprecate .ix*
  - *Deprecate Panel*
  - *Deprecate groupby.agg() with a dictionary when renaming*
  - *Deprecate .plotting*
  - *Other deprecations*
- *Removal of prior version deprecations/changes*
- *Performance improvements*
- *Bug fixes*
  - *Conversion*
  - *Indexing*
  - *IO*
  - *Plotting*
  - *GroupBy/resample/rolling*
  - *Sparse*
  - *Reshaping*
  - *Numeric*
  - *Other*
- *Contributors*

## New features

### Method agg API for DataFrame/Series

Series & DataFrame have been enhanced to support the aggregation API. This is a familiar API from groupby, window operations, and resampling. This allows aggregation operations in a concise way by using `agg()` and `transform()`. The full documentation is [here](#) (GH1623).

Here is a sample

```
In [1]: df = pd.DataFrame(np.random.randn(10, 3), columns=['A', 'B', 'C'],
...: index=pd.date_range('1/1/2000', periods=10))
...:

In [2]: df.iloc[3:7] = np.nan

In [3]: df
Out[3]:
```

|            | A         | B         | C         |
|------------|-----------|-----------|-----------|
| 2000-01-01 | 0.469112  | -0.282863 | -1.509059 |
| 2000-01-02 | -1.135632 | 1.212112  | -0.173215 |
| 2000-01-03 | 0.119209  | -1.044236 | -0.861849 |
| 2000-01-04 | NaN       | NaN       | NaN       |
| 2000-01-05 | NaN       | NaN       | NaN       |
| 2000-01-06 | NaN       | NaN       | NaN       |
| 2000-01-07 | NaN       | NaN       | NaN       |
| 2000-01-08 | 0.113648  | -1.478427 | 0.524988  |
| 2000-01-09 | 0.404705  | 0.577046  | -1.715002 |
| 2000-01-10 | -1.039268 | -0.370647 | -1.157892 |

```
[10 rows x 3 columns]
```

One can operate using string function names, callables, lists, or dictionaries of these.

Using a single function is equivalent to `.apply`.

```
In [4]: df.agg('sum')
Out[4]:
```

|   |           |
|---|-----------|
| A | -1.068226 |
| B | -1.387015 |
| C | -4.892029 |

```
Length: 3, dtype: float64
```

Multiple aggregations with a list of functions.

```
In [5]: df.agg(['sum', 'min'])
Out[5]:
```

|     | A         | B         | C         |
|-----|-----------|-----------|-----------|
| sum | -1.068226 | -1.387015 | -4.892029 |
| min | -1.135632 | -1.478427 | -1.715002 |

```
[2 rows x 3 columns]
```

Using a dict provides the ability to apply specific aggregations per column. You will get a matrix-like output of all of the aggregators. The output has one column per unique function. Those functions applied to a particular column will

be NaN:

```
In [6]: df.agg({'A': ['sum', 'min'], 'B': ['min', 'max']})
```

```
Out[6]:
```

|     | A         | B         |
|-----|-----------|-----------|
| sum | -1.068226 | NaN       |
| min | -1.135632 | -1.478427 |
| max | NaN       | 1.212112  |

[3 rows x 2 columns]

The API also supports a `.transform()` function for broadcasting results.

```
In [7]: df.transform(['abs', lambda x: x - x.min()])
```

```
Out[7]:
```

|            | A        |          | B        |          | C        |          |
|------------|----------|----------|----------|----------|----------|----------|
|            | abs      | <lambda> | abs      | <lambda> | abs      | <lambda> |

[10 rows x 6 columns]

When presented with mixed dtypes that cannot be aggregated, `.agg()` will only take the valid aggregations. This is similar to how `groupby .agg()` works. (GH15015)

```
In [8]: df = pd.DataFrame({'A': [1, 2, 3],
...: 'B': [1., 2., 3.],
...: 'C': ['foo', 'bar', 'baz'],
...: 'D': pd.date_range('20130101', periods=3)})
...:
```

```
In [9]: df.dtypes
```

```
Out[9]:
```

```
A int64
B float64
C object
D datetime64[ns]
Length: 4, dtype: object
```

```
In [10]: df.agg(['min', 'sum'])
```

```
Out[10]:
```

|     | A | B   | C        | D          |
|-----|---|-----|----------|------------|
| min | 1 | 1.0 | bar      | 2013-01-01 |
| sum | 6 | 6.0 | foobabaz | NaT        |

[2 rows x 4 columns]

## Keyword argument dtype for data IO

The 'python' engine for `read_csv()`, as well as the `read_fwf()` function for parsing fixed-width text files and `read_excel()` for parsing Excel files, now accept the `dtype` keyword argument for specifying the types of specific columns (GH14295). See the *io docs* for more information.

```
In [11]: data = "a b\n1 2\n3 4"

In [12]: pd.read_fwf(StringIO(data)).dtypes
Out[12]:
a int64
b int64
Length: 2, dtype: object

In [13]: pd.read_fwf(StringIO(data), dtype={'a': 'float64', 'b': 'object'}).dtypes
Out[13]:
a float64
b object
Length: 2, dtype: object
```

## Method `.to_datetime()` has gained an origin parameter

`to_datetime()` has gained a new parameter, `origin`, to define a reference date from where to compute the resulting timestamps when parsing numerical values with a specific unit specified. (GH11276, GH11745)

For example, with 1960-01-01 as the starting date:

```
In [14]: pd.to_datetime([1, 2, 3], unit='D', origin=pd.Timestamp('1960-01-01'))
Out[14]: DatetimeIndex(['1960-01-02', '1960-01-03', '1960-01-04'], dtype='datetime64[ns]
↳', freq=None)
```

The default is set at `origin='unix'`, which defaults to 1970-01-01 00:00:00, which is commonly called 'unix epoch' or POSIX time. This was the previous default, so this is a backward compatible change.

```
In [15]: pd.to_datetime([1, 2, 3], unit='D')
Out[15]: DatetimeIndex(['1970-01-02', '1970-01-03', '1970-01-04'], dtype='datetime64[ns]
↳', freq=None)
```

## GroupBy enhancements

Strings passed to `DataFrame.groupby()` as the `by` parameter may now reference either column names or index level names. Previously, only column names could be referenced. This allows to easily group by a column and index level at the same time. (GH5677)

```
In [16]: arrays = [['bar', 'bar', 'baz', 'baz', 'foo', 'foo', 'qux', 'qux'],
.....: ['one', 'two', 'one', 'two', 'one', 'two', 'one', 'two']]
.....:

In [17]: index = pd.MultiIndex.from_arrays(arrays, names=['first', 'second'])

In [18]: df = pd.DataFrame({'A': [1, 1, 1, 1, 2, 2, 3, 3],
```

(continues on next page)

(continued from previous page)

```

.....: 'B': np.arange(8)},
.....: index=index)
.....:

In [19]: df
Out[19]:
 A B
first second
bar one 1 0
 two 1 1
baz one 1 2
 two 1 3
foo one 2 4
 two 2 5
qux one 3 6
 two 3 7

[8 rows x 2 columns]

In [20]: df.groupby(['second', 'A']).sum()
Out[20]:
 B
second A
one 1 2
 2 4
 3 6
two 1 4
 2 5
 3 7

[6 rows x 1 columns]

```

### Better support for compressed URLs in `read_csv`

The compression code was refactored (GH12688). As a result, reading dataframes from URLs in `read_csv()` or `read_table()` now supports additional compression methods: `xz`, `bz2`, and `zip` (GH14570). Previously, only `gzip` compression was supported. By default, compression of URLs and paths are now inferred using their file extensions. Additionally, support for `bz2` compression in the python 2 C-engine improved (GH14874).

```

In [21]: url = ('https://github.com/{repo}/raw/{branch}/{path}'
.....: .format(repo='pandas-dev/pandas',
.....: branch='master',
.....: path='pandas/tests/io/parser/data/salaries.csv.bz2'))
.....:

default, infer compression
In [22]: df = pd.read_csv(url, sep='\t', compression='infer')

explicitly specify compression
In [23]: df = pd.read_csv(url, sep='\t', compression='bz2')

```

(continues on next page)

(continued from previous page)

```
In [24]: df.head(2)
Out[24]:
 S X E M
0 13876 1 1 1
1 11608 1 3 0

[2 rows x 4 columns]
```

## Pickle file IO now supports compression

`read_pickle()`, `DataFrame.to_pickle()` and `Series.to_pickle()` can now read from and write to compressed pickle files. Compression methods can be an explicit parameter or be inferred from the file extension. See [the docs here](#).

```
In [25]: df = pd.DataFrame({'A': np.random.randn(1000),
.....: 'B': 'foo',
.....: 'C': pd.date_range('20130101', periods=1000, freq='s')})
.....:
```

Using an explicit compression type

```
In [26]: df.to_pickle("data.pkl.compress", compression="gzip")
In [27]: rt = pd.read_pickle("data.pkl.compress", compression="gzip")
In [28]: rt.head()
Out[28]:
 A B C
0 -1.344312 foo 2013-01-01 00:00:00
1 0.844885 foo 2013-01-01 00:00:01
2 1.075770 foo 2013-01-01 00:00:02
3 -0.109050 foo 2013-01-01 00:00:03
4 1.643563 foo 2013-01-01 00:00:04

[5 rows x 3 columns]
```

The default is to infer the compression type from the extension (`compression='infer'`):

```
In [29]: df.to_pickle("data.pkl.gz")
In [30]: rt = pd.read_pickle("data.pkl.gz")
In [31]: rt.head()
Out[31]:
 A B C
0 -1.344312 foo 2013-01-01 00:00:00
1 0.844885 foo 2013-01-01 00:00:01
2 1.075770 foo 2013-01-01 00:00:02
3 -0.109050 foo 2013-01-01 00:00:03
4 1.643563 foo 2013-01-01 00:00:04
```

(continues on next page)

(continued from previous page)

```
[5 rows x 3 columns]
In [32]: df["A"].to_pickle("s1.pkl.bz2")
In [33]: rt = pd.read_pickle("s1.pkl.bz2")
In [34]: rt.head()
Out[34]:
0 -1.344312
1 0.844885
2 1.075770
3 -0.109050
4 1.643563
Name: A, Length: 5, dtype: float64
```

### UInt64 support improved

pandas has significantly improved support for operations involving unsigned, or purely non-negative, integers. Previously, handling these integers would result in improper rounding or data-type casting, leading to incorrect results. Notably, a new numerical index, `UInt64Index`, has been created ([GH14937](#))

```
In [35]: idx = pd.UInt64Index([1, 2, 3])
In [36]: df = pd.DataFrame({'A': ['a', 'b', 'c']}, index=idx)
In [37]: df.index
Out[37]: UInt64Index([1, 2, 3], dtype='uint64')
```

- Bug in converting object elements of array-like objects to unsigned 64-bit integers ([GH4471](#), [GH14982](#))
- Bug in `Series.unique()` in which unsigned 64-bit integers were causing overflow ([GH14721](#))
- Bug in `DataFrame` construction in which unsigned 64-bit integer elements were being converted to objects ([GH14881](#))
- Bug in `pd.read_csv()` in which unsigned 64-bit integer elements were being improperly converted to the wrong data types ([GH14983](#))
- Bug in `pd.unique()` in which unsigned 64-bit integers were causing overflow ([GH14915](#))
- Bug in `pd.value_counts()` in which unsigned 64-bit integers were being erroneously truncated in the output ([GH14934](#))

### GroupBy on categoricals

In previous versions, `.groupby(..., sort=False)` would fail with a `ValueError` when grouping on a categorical series with some categories not appearing in the data. ([GH13179](#))

```
In [38]: chromosomes = np.r_[np.arange(1, 23).astype(str), ['X', 'Y']]
In [39]: df = pd.DataFrame({
.....: 'A': np.random.randint(100),
```

(continues on next page)

(continued from previous page)

```

.....: 'B': np.random.randint(100),
.....: 'C': np.random.randint(100),
.....: 'chromosomes': pd.Categorical(np.random.choice(chromosomes, 100),
.....: categories=chromosomes,
.....: ordered=True)})
.....:
In [40]: df
Out[40]:
 A B C chromosomes
0 87 22 81 4
1 87 22 81 13
2 87 22 81 22
3 87 22 81 2
4 87 22 81 6
..
95 87 22 81 8
96 87 22 81 11
97 87 22 81 X
98 87 22 81 1
99 87 22 81 19

[100 rows x 4 columns]

```

**Previous behavior:**

```

In [3]: df[df.chromosomes != '1'].groupby('chromosomes', sort=False).sum()

ValueError: items in new_categories are not the same as in old categories

```

**New behavior:**

```

In [41]: df[df.chromosomes != '1'].groupby('chromosomes', sort=False).sum()
Out[41]:
 chromosomes A B C
2 348 88 324
3 348 88 324
4 348 88 324
5 261 66 243
6 174 44 162
...
22 348 88 324
X 348 88 324
Y 435 110 405
1 0 0 0
21 0 0 0

[24 rows x 3 columns]

```

## Table schema output

The new orient 'table' for `DataFrame.to_json()` will generate a Table Schema compatible string representation of the data.

```
In [42]: df = pd.DataFrame(
.....: {'A': [1, 2, 3],
.....: 'B': ['a', 'b', 'c'],
.....: 'C': pd.date_range('2016-01-01', freq='d', periods=3)},
.....: index=pd.Index(range(3), name='idx'))
.....:

In [43]: df
Out[43]:
 A B C
idx
0 1 a 2016-01-01
1 2 b 2016-01-02
2 3 c 2016-01-03

[3 rows x 3 columns]

In [44]: df.to_json(orient='table')
Out[44]: '{"schema":{"fields":[{"name":"idx","type":"integer"}, {"name":"A","type":
↪ "integer"}, {"name":"B","type":"string"}, {"name":"C","type":"datetime"}], "primaryKey": [
↪ "idx"], "pandas_version": "0.20.0"}, "data": [{"idx": 0, "A": 1, "B": "a", "C": "2016-01-01T00:00:
↪ 00.000Z"}, {"idx": 1, "A": 2, "B": "b", "C": "2016-01-02T00:00:00.000Z"}, {"idx": 2, "A": 3, "B": "c
↪ ", "C": "2016-01-03T00:00:00.000Z"}]}'
```

See *IO: Table Schema* for more information.

Additionally, the repr for `DataFrame` and `Series` can now publish this JSON Table schema representation of the `Series` or `DataFrame` if you are using IPython (or another frontend like `nteract` using the Jupyter messaging protocol). This gives frontends like the Jupyter notebook and `nteract` more flexibility in how they display pandas objects, since they have more information about the data. You must enable this by setting the `display.html.table_schema` option to `True`.

## SciPy sparse matrix from/to SparseDataFrame

pandas now supports creating sparse dataframes directly from `scipy.sparse.spmatrix` instances. See the *documentation* for more information. (GH4343)

All sparse formats are supported, but matrices that are not in `COOrdinate` format will be converted, copying data as needed.

```
from scipy.sparse import csr_matrix
arr = np.random.random(size=(1000, 5))
arr[arr < .9] = 0
sp_arr = csr_matrix(arr)
sp_arr
sdf = pd.SparseDataFrame(sp_arr)
sdf
```

To convert a `SparseDataFrame` back to sparse SciPy matrix in COO format, you can use:

```
sdf.to_coo()
```

### Excel output for styled DataFrames

Experimental support has been added to export `DataFrame.style` formats to Excel using the `openpyxl` engine. (GH15530)

For example, after running the following, `styled.xlsx` renders as below:

```
In [45]: np.random.seed(24)

In [46]: df = pd.DataFrame({'A': np.linspace(1, 10, 10)})

In [47]: df = pd.concat([df, pd.DataFrame(np.random.RandomState(24).randn(10, 4),
.....: columns=list('BCDE'))],
.....: axis=1)
.....:

In [48]: df.iloc[0, 2] = np.nan

In [49]: df
Out[49]:
```

|   | A    | B         | C         | D         | E         |
|---|------|-----------|-----------|-----------|-----------|
| 0 | 1.0  | 1.329212  | NaN       | -0.316280 | -0.990810 |
| 1 | 2.0  | -1.070816 | -1.438713 | 0.564417  | 0.295722  |
| 2 | 3.0  | -1.626404 | 0.219565  | 0.678805  | 1.889273  |
| 3 | 4.0  | 0.961538  | 0.104011  | -0.481165 | 0.850229  |
| 4 | 5.0  | 1.453425  | 1.057737  | 0.165562  | 0.515018  |
| 5 | 6.0  | -1.336936 | 0.562861  | 1.392855  | -0.063328 |
| 6 | 7.0  | 0.121668  | 1.207603  | -0.002040 | 1.627796  |
| 7 | 8.0  | 0.354493  | 1.037528  | -0.385684 | 0.519818  |
| 8 | 9.0  | 1.686583  | -1.325963 | 1.428984  | -2.089354 |
| 9 | 10.0 | -0.129820 | 0.631523  | -0.586538 | 0.290720  |

```
[10 rows x 5 columns]

In [50]: styled = (df.style
.....: .applymap(lambda val: 'color:red;' if val < 0 else 'color:black;')
.....: .highlight_max())
.....:

In [51]: styled.to_excel('styled.xlsx', engine='openpyxl')
```

|    | A | B  | C         | D         | E         | F         |
|----|---|----|-----------|-----------|-----------|-----------|
| 1  |   | A  | B         | C         | D         | E         |
| 2  | 0 | 1  | 1.329212  |           | -0.31628  | -0.99081  |
| 3  | 1 | 2  | -1.070816 | -1.438713 | 0.564417  | 0.295722  |
| 4  | 2 | 3  | -1.626404 | 0.219565  | 0.678805  | 1.889273  |
| 5  | 3 | 4  | 0.961538  | 0.104011  | -0.481165 | 0.850229  |
| 6  | 4 | 5  | 1.453425  | 1.057737  | 0.165562  | 0.515018  |
| 7  | 5 | 6  | -1.336936 | 0.562861  | 1.392855  | -0.063328 |
| 8  | 6 | 7  | 0.121668  | 1.207603  | -0.00204  | 1.627796  |
| 9  | 7 | 8  | 0.354493  | 1.037528  | -0.385684 | 0.519818  |
| 10 | 8 | 9  | 1.686583  | -1.325963 | 1.428984  | -2.089354 |
| 11 | 9 | 10 | -0.12982  | 0.631523  | -0.586538 | 0.29072   |

See the [Style documentation](#) for more detail.

## IntervalIndex

pandas has gained an `IntervalIndex` with its own dtype, `interval` as well as the `Interval` scalar type. These allow first-class support for interval notation, specifically as a return type for the categories in `cut()` and `qcut()`. The `IntervalIndex` allows some unique indexing, see the [docs](#). ([GH7640](#), [GH8625](#))

**Warning:** These indexing behaviors of the `IntervalIndex` are provisional and may change in a future version of pandas. Feedback on usage is welcome.

Previous behavior:

The returned categories were strings, representing Intervals

```
In [1]: c = pd.cut(range(4), bins=2)

In [2]: c
Out[2]:
[(-0.003, 1.5], (-0.003, 1.5], (1.5, 3], (1.5, 3]]
Categories (2, object): [(-0.003, 1.5] < (1.5, 3]]

In [3]: c.categories
Out[3]: Index(['(-0.003, 1.5]', '(1.5, 3]'], dtype='object')
```

New behavior:

```
In [52]: c = pd.cut(range(4), bins=2)

In [53]: c
Out[53]:
[(-0.003, 1.5], (-0.003, 1.5], (1.5, 3.0], (1.5, 3.0]]
Categories (2, interval[float64, right]): [(-0.003, 1.5] < (1.5, 3.0]]

In [54]: c.categories
Out[54]: IntervalIndex([(-0.003, 1.5], (1.5, 3.0]], dtype='interval[float64, right]')
```

Furthermore, this allows one to bin *other* data with these same bins, with NaN representing a missing value similar to other dtypes.

```
In [55]: pd.cut([0, 3, 5, 1], bins=c.categories)
Out[55]:
[(-0.003, 1.5], (1.5, 3.0], NaN, (-0.003, 1.5]]
Categories (2, interval[float64, right]): [(-0.003, 1.5] < (1.5, 3.0]]
```

An IntervalIndex can also be used in Series and DataFrame as the index.

```
In [56]: df = pd.DataFrame({'A': range(4),
.....: 'B': pd.cut([0, 3, 1, 1], bins=c.categories)
.....: }).set_index('B')
.....:

In [57]: df
Out[57]:
 A
B
(-0.003, 1.5] 0
(1.5, 3.0] 1
(-0.003, 1.5] 2
(-0.003, 1.5] 3

[4 rows x 1 columns]
```

Selecting via a specific interval:

```
In [58]: df.loc[pd.Interval(1.5, 3.0)]
Out[58]:
A 1
Name: (1.5, 3.0], Length: 1, dtype: int64
```

Selecting via a scalar value that is contained *in* the intervals.

```
In [59]: df.loc[0]
Out[59]:
 A
B
(-0.003, 1.5] 0
(-0.003, 1.5] 2
(-0.003, 1.5] 3

[3 rows x 1 columns]
```

## Other enhancements

- `DataFrame.rolling()` now accepts the parameter `closed='right'|'left'|'both'|'neither'` to choose the rolling window-endpoint closedness. See the [documentation](#) (GH13965)
- Integration with the `feather-format`, including a new top-level `pd.read_feather()` and `DataFrame.to_feather()` method, see [here](#).
- `Series.str.replace()` now accepts a callable, as replacement, which is passed to `re.sub` (GH15055)
- `Series.str.replace()` now accepts a compiled regular expression as a pattern (GH15446)
- `Series.sort_index` accepts parameters `kind` and `na_position` (GH13589, GH14444)
- `DataFrame` and `DataFrame.groupby()` have gained a `nunique()` method to count the distinct values over an axis (GH14336, GH15197).
- `DataFrame` has gained a `melt()` method, equivalent to `pd.melt()`, for unpivoting from a wide to long format (GH12640).
- `pd.read_excel()` now preserves sheet order when using `sheetname=None` (GH9930)
- Multiple offset aliases with decimal points are now supported (e.g. `0.5min` is parsed as `30s`) (GH8419)
- `.isnull()` and `.notnull()` have been added to `Index` object to make them more consistent with the `Series` API (GH15300)
- New `UnsortedIndexError` (subclass of `KeyError`) raised when indexing/slicing into an unsorted `MultiIndex` (GH11897). This allows differentiation between errors due to lack of sorting or an incorrect key. See [here](#)
- `MultiIndex` has gained a `.to_frame()` method to convert to a `DataFrame` (GH12397)
- `pd.cut` and `pd.qcut` now support `datetime64` and `timedelta64` dtypes (GH14714, GH14798)
- `pd.qcut` has gained the `duplicates='raise'|'drop'` option to control whether to raise on duplicated edges (GH7751)
- `Series` provides a `to_excel` method to output Excel files (GH8825)
- The `usecols` argument in `pd.read_csv()` now accepts a callable function as a value (GH14154)
- The `skiprows` argument in `pd.read_csv()` now accepts a callable function as a value (GH10882)
- The `nrows` and `chunksize` arguments in `pd.read_csv()` are supported if both are passed (GH6774, GH15755)
- `DataFrame.plot` now prints a title above each subplot if `suplots=True` and `title` is a list of strings (GH14753)
- `DataFrame.plot` can pass the `matplotlib 2.0` default color cycle as a single string as `color` parameter, see [here](#). (GH15516)
- `Series.interpolate()` now supports `timedelta` as an index type with `method='time'` (GH6424)
- Addition of a `level` keyword to `DataFrame/Series.rename` to rename labels in the specified level of a `MultiIndex` (GH4160).
- `DataFrame.reset_index()` will now interpret a tuple `index.name` as a key spanning across levels of columns, if this is a `MultiIndex` (GH16164)
- `Timedelta.isoformat` method added for formatting `Timedeltas` as an `ISO 8601` duration. See the [Timedelta docs](#) (GH15136)
- `.select_dtypes()` now allows the string `datetimez` to generically select datetimes with `tz` (GH14910)
- The `.to_latex()` method will now accept `multicolumn` and `multirow` arguments to use the accompanying LaTeX enhancements

- `pd.merge_asof()` gained the option `direction='backward' | 'forward' | 'nearest'` (GH14887)
- `Series/DataFrame.asfreq()` have gained a `fill_value` parameter, to fill missing values (GH3715).
- `Series/DataFrame.resample.asfreq` have gained a `fill_value` parameter, to fill missing values during resampling (GH3715).
- `pandas.util.hash_pandas_object()` has gained the ability to hash a `MultiIndex` (GH15224)
- `Series/DataFrame.squeeze()` have gained the `axis` parameter. (GH15339)
- `DataFrame.to_excel()` has a new `freeze_panes` parameter to turn on Freeze Panes when exporting to Excel (GH15160)
- `pd.read_html()` will parse multiple header rows, creating a `MultiIndex` header. (GH13434).
- HTML table output skips `colspan` or `rowspan` attribute if equal to 1. (GH15403)
- `pandas.io.formats.style.Styler` template now has blocks for easier extension, see the *example notebook* (GH15649)
- `Styler.render()` now accepts `**kwargs` to allow user-defined variables in the template (GH15649)
- Compatibility with Jupyter notebook 5.0; `MultiIndex` column labels are left-aligned and `MultiIndex` row-labels are top-aligned (GH15379)
- `TimedeltaIndex` now has a custom date-tick formatter specifically designed for nanosecond level precision (GH8711)
- `pd.api.types.union_categoricals` gained the `ignore_ordered` argument to allow ignoring the ordered attribute of unioned categoricals (GH13410). See the *categorical union docs* for more information.
- `DataFrame.to_latex()` and `DataFrame.to_string()` now allow optional header aliases. (GH15536)
- Re-enable the `parse_dates` keyword of `pd.read_excel()` to parse string columns as dates (GH14326)
- Added `.empty` property to subclasses of `Index`. (GH15270)
- Enabled floor division for `Timedelta` and `TimedeltaIndex` (GH15828)
- `pandas.io.json.json_normalize()` gained the option `errors='ignore' | 'raise'`; the default is `errors='raise'` which is backward compatible. (GH14583)
- `pandas.io.json.json_normalize()` with an empty list will return an empty `DataFrame` (GH15534)
- `pandas.io.json.json_normalize()` has gained a `sep` option that accepts `str` to separate joined fields; the default is `“.”`, which is backward compatible. (GH14883)
- `MultiIndex.remove_unused_levels()` has been added to facilitate *removing unused levels*. (GH15694)
- `pd.read_csv()` will now raise a `ParserError` error whenever any parsing error occurs (GH15913, GH15925)
- `pd.read_csv()` now supports the `error_bad_lines` and `warn_bad_lines` arguments for the Python parser (GH15925)
- The `display.show_dimensions` option can now also be used to specify whether the length of a `Series` should be shown in its repr (GH7117).
- `parallel_coordinates()` has gained a `sort_labels` keyword argument that sorts class labels and the colors assigned to them (GH15908)
- Options added to allow one to turn on/off using `bottleneck` and `numexpr`, see *here* (GH16157)
- `DataFrame.style.bar()` now accepts two more options to further customize the bar chart. Bar alignment is set with `align='left' | 'mid' | 'zero'`, the default is `“left”`, which is backward compatible; You can now pass a list of `color=[color_negative, color_positive]`. (GH14757)

## Backwards incompatible API changes

### Possible incompatibility for HDF5 formats created with pandas < 0.13.0

`pd.TimeSeries` was deprecated officially in 0.17.0, though has already been an alias since 0.13.0. It has been dropped in favor of `pd.Series`. (GH15098).

This *may* cause HDF5 files that were created in prior versions to become unreadable if `pd.TimeSeries` was used. This is most likely to be for pandas < 0.13.0. If you find yourself in this situation. You can use a recent prior version of pandas to read in your HDF5 files, then write them out again after applying the procedure below.

```
In [2]: s = pd.TimeSeries([1, 2, 3], index=pd.date_range('20130101', periods=3))
```

```
In [3]: s
```

```
Out[3]:
```

```
2013-01-01 1
2013-01-02 2
2013-01-03 3
Freq: D, dtype: int64
```

```
In [4]: type(s)
```

```
Out[4]: pandas.core.series.TimeSeries
```

```
In [5]: s = pd.Series(s)
```

```
In [6]: s
```

```
Out[6]:
```

```
2013-01-01 1
2013-01-02 2
2013-01-03 3
Freq: D, dtype: int64
```

```
In [7]: type(s)
```

```
Out[7]: pandas.core.series.Series
```

### Map on Index types now return other Index types

`map` on an Index now returns an Index, not a numpy array (GH12766)

```
In [60]: idx = pd.Index([1, 2])
```

```
In [61]: idx
```

```
Out[61]: Int64Index([1, 2], dtype='int64')
```

```
In [62]: mi = pd.MultiIndex.from_tuples([(1, 2), (2, 4)])
```

```
In [63]: mi
```

```
Out[63]:
```

```
MultiIndex([(1, 2),
 (2, 4)],
)
```

Previous behavior:

```
In [5]: idx.map(lambda x: x * 2)
Out[5]: array([2, 4])

In [6]: idx.map(lambda x: (x, x * 2))
Out[6]: array([(1, 2), (2, 4)], dtype=object)

In [7]: mi.map(lambda x: x)
Out[7]: array([(1, 2), (2, 4)], dtype=object)

In [8]: mi.map(lambda x: x[0])
Out[8]: array([1, 2])
```

New behavior:

```
In [64]: idx.map(lambda x: x * 2)
Out[64]: Int64Index([2, 4], dtype='int64')

In [65]: idx.map(lambda x: (x, x * 2))
Out[65]:
MultiIndex([(1, 2),
 (2, 4)],
)

In [66]: mi.map(lambda x: x)
Out[66]:
MultiIndex([(1, 2),
 (2, 4)],
)

In [67]: mi.map(lambda x: x[0])
Out[67]: Int64Index([1, 2], dtype='int64')
```

map on a Series with datetime64 values may return int64 dtypes rather than int32

```
In [68]: s = pd.Series(pd.date_range('2011-01-02T00:00', '2011-01-02T02:00', freq='H')
.....: .tz_localize('Asia/Tokyo'))
.....:

In [69]: s
Out[69]:
0 2011-01-02 00:00:00+09:00
1 2011-01-02 01:00:00+09:00
2 2011-01-02 02:00:00+09:00
Length: 3, dtype: datetime64[ns, Asia/Tokyo]
```

Previous behavior:

```
In [9]: s.map(lambda x: x.hour)
Out[9]:
0 0
1 1
2 2
dtype: int32
```

New behavior:

```
In [70]: s.map(lambda x: x.hour)
Out[70]:
0 0
1 1
2 2
Length: 3, dtype: int64
```

### Accessing datetime fields of Index now return Index

The datetime-related attributes (see [here](#) for an overview) of `DatetimeIndex`, `PeriodIndex` and `TimedeltaIndex` previously returned numpy arrays. They will now return a new `Index` object, except in the case of a boolean field, where the result will still be a boolean ndarray. (GH15022)

Previous behaviour:

```
In [1]: idx = pd.date_range("2015-01-01", periods=5, freq='10H')

In [2]: idx.hour
Out[2]: array([0, 10, 20, 6, 16], dtype=int32)
```

New behavior:

```
In [71]: idx = pd.date_range("2015-01-01", periods=5, freq='10H')

In [72]: idx.hour
Out[72]: Int64Index([0, 10, 20, 6, 16], dtype='int64')
```

This has the advantage that specific `Index` methods are still available on the result. On the other hand, this might have backward incompatibilities: e.g. compared to numpy arrays, `Index` objects are not mutable. To get the original ndarray, you can always convert explicitly using `np.asarray(idx.hour)`.

### pd.unique will now be consistent with extension types

In prior versions, using `Series.unique()` and `pandas.unique()` on Categorical and tz-aware data-types would yield different return types. These are now made consistent. (GH15903)

- Datetime tz-aware

Previous behaviour:

```
Series
In [5]: pd.Series([pd.Timestamp('20160101', tz='US/Eastern'),
...: pd.Timestamp('20160101', tz='US/Eastern')]).unique()
Out[5]: array([Timestamp('2016-01-01 00:00:00-0500', tz='US/Eastern')],
 dtype=object)

In [6]: pd.unique(pd.Series([pd.Timestamp('20160101', tz='US/Eastern'),
...: pd.Timestamp('20160101', tz='US/Eastern')]))
Out[6]: array(['2016-01-01T05:00:00.000000000'], dtype='datetime64[ns]')

Index
```

(continues on next page)

(continued from previous page)

```

In [7]: pd.Index([pd.Timestamp('20160101', tz='US/Eastern'),
...: pd.Timestamp('20160101', tz='US/Eastern')]).unique()
Out[7]: DatetimeIndex(['2016-01-01 00:00:00-05:00'], dtype='datetime64[ns, US/
↪Eastern]', freq=None)

In [8]: pd.unique([pd.Timestamp('20160101', tz='US/Eastern'),
...: pd.Timestamp('20160101', tz='US/Eastern')])
Out[8]: array(['2016-01-01T05:00:00.000000000'], dtype='datetime64[ns]')

```

New behavior:

```

Series, returns an array of Timestamp tz-aware
In [73]: pd.Series([pd.Timestamp(r'20160101', tz=r'US/Eastern'),
...: pd.Timestamp(r'20160101', tz=r'US/Eastern')]).unique()
...:
Out[73]:
<DatetimeArray>
['2016-01-01 00:00:00-05:00']
Length: 1, dtype: datetime64[ns, US/Eastern]

In [74]: pd.unique(pd.Series([pd.Timestamp('20160101', tz='US/Eastern'),
...: pd.Timestamp('20160101', tz='US/Eastern')]))
...:
Out[74]:
<DatetimeArray>
['2016-01-01 00:00:00-05:00']
Length: 1, dtype: datetime64[ns, US/Eastern]

Index, returns a DatetimeIndex
In [75]: pd.Index([pd.Timestamp('20160101', tz='US/Eastern'),
...: pd.Timestamp('20160101', tz='US/Eastern')]).unique()
...:
Out[75]: DatetimeIndex(['2016-01-01 00:00:00-05:00'], dtype='datetime64[ns, US/
↪Eastern]', freq=None)

In [76]: pd.unique(pd.Index([pd.Timestamp('20160101', tz='US/Eastern'),
...: pd.Timestamp('20160101', tz='US/Eastern')]))
...:
Out[76]: DatetimeIndex(['2016-01-01 00:00:00-05:00'], dtype='datetime64[ns, US/
↪Eastern]', freq=None)

```

- Categoricals

Previous behaviour:

```

In [1]: pd.Series(list('baabc'), dtype='category').unique()
Out[1]:
[b, a, c]
Categories (3, object): [b, a, c]

In [2]: pd.unique(pd.Series(list('baabc'), dtype='category'))
Out[2]: array(['b', 'a', 'c'], dtype=object)

```

New behavior:

```
returns a Categorical
In [77]: pd.Series(list('baabc'), dtype='category').unique()
Out[77]:
['b', 'a', 'c']
Categories (3, object): ['a', 'b', 'c']

In [78]: pd.unique(pd.Series(list('baabc'), dtype='category'))
Out[78]:
['b', 'a', 'c']
Categories (3, object): ['a', 'b', 'c']
```

### S3 file handling

pandas now uses `s3fs` for handling S3 connections. This shouldn't break any code. However, since `s3fs` is not a required dependency, you will need to install it separately, like `boto` in prior versions of pandas. (GH11915).

### Partial string indexing changes

*DatetimeIndex Partial String Indexing* now works as an exact match, provided that string resolution coincides with index resolution, including a case when both are seconds (GH14826). See *Slice vs. Exact Match* for details.

```
In [79]: df = pd.DataFrame({'a': [1, 2, 3]}, pd.DatetimeIndex(['2011-12-31 23:59:59',
.....: '2012-01-01 00:00:00',
.....: '2012-01-01 00:00:01']))
.....:
```

Previous behavior:

```
In [4]: df['2011-12-31 23:59:59']
Out[4]:
 a
2011-12-31 23:59:59 1

In [5]: df['a']['2011-12-31 23:59:59']
Out[5]:
2011-12-31 23:59:59 1
Name: a, dtype: int64
```

New behavior:

```
In [4]: df['2011-12-31 23:59:59']
KeyError: '2011-12-31 23:59:59'

In [5]: df['a']['2011-12-31 23:59:59']
Out[5]: 1
```

## Concat of different float dtypes will not automatically upcast

Previously, concat of multiple objects with different float dtypes would automatically upcast results to a dtype of float64. Now the smallest acceptable dtype will be used ([GH13247](#))

```
In [80]: df1 = pd.DataFrame(np.array([1.0], dtype=np.float32, ndmin=2))
In [81]: df1.dtypes
Out[81]:
0 float32
Length: 1, dtype: object
In [82]: df2 = pd.DataFrame(np.array([np.nan], dtype=np.float32, ndmin=2))
In [83]: df2.dtypes
Out[83]:
0 float32
Length: 1, dtype: object
```

Previous behavior:

```
In [7]: pd.concat([df1, df2]).dtypes
Out[7]:
0 float64
dtype: object
```

New behavior:

```
In [84]: pd.concat([df1, df2]).dtypes
Out[84]:
0 float32
Length: 1, dtype: object
```

## pandas Google BigQuery support has moved

pandas has split off Google BigQuery support into a separate package `pandas-gbq`. You can `conda install pandas-gbq -c conda-forge` or `pip install pandas-gbq` to get it. The functionality of `read_gbq()` and `DataFrame.to_gbq()` remain the same with the currently released version of `pandas-gbq=0.1.4`. Documentation is now hosted [here](#) ([GH15347](#))

## Memory usage for Index is more accurate

In previous versions, showing `.memory_usage()` on a pandas structure that has an index, would only include actual index values and not include structures that facilitated fast indexing. This will generally be different for `Index` and `MultiIndex` and less-so for other index types. ([GH15237](#))

Previous behavior:

```
In [8]: index = pd.Index(['foo', 'bar', 'baz'])
In [9]: index.memory_usage(deep=True)
Out[9]: 180
```

(continues on next page)

(continued from previous page)

```
In [10]: index.get_loc('foo')
Out[10]: 0

In [11]: index.memory_usage(deep=True)
Out[11]: 180
```

New behavior:

```
In [8]: index = pd.Index(['foo', 'bar', 'baz'])

In [9]: index.memory_usage(deep=True)
Out[9]: 180

In [10]: index.get_loc('foo')
Out[10]: 0

In [11]: index.memory_usage(deep=True)
Out[11]: 260
```

### DataFrame.sort\_index changes

In certain cases, calling `.sort_index()` on a MultiIndexed DataFrame would return the *same* DataFrame without seeming to sort. This would happen with a lexicographically sorted, but non-monotonic levels. ([GH15622](#), [GH15687](#), [GH14015](#), [GH13431](#), [GH15797](#))

This is *unchanged* from prior versions, but shown for illustration purposes:

```
In [85]: df = pd.DataFrame(np.arange(6), columns=['value'],
.....: index=pd.MultiIndex.from_product([list('BA'), range(3)]))
.....:

In [86]: df
Out[86]:
 value
B 0 0
 1 1
 2 2
A 0 3
 1 4
 2 5

[6 rows x 1 columns]
```

```
In [87]: df.index.is_lexsorted()
Out[87]: False

In [88]: df.index.is_monotonic
Out[88]: False
```

Sorting works as expected

```
In [87]: df.sort_index()
```

```
Out[87]:
```

```
 value
A 0 3
 1 4
 2 5
B 0 0
 1 1
 2 2
```

```
[6 rows x 1 columns]
```

```
In [90]: df.sort_index().index.is_lexsorted()
```

```
Out[90]: True
```

```
In [91]: df.sort_index().index.is_monotonic
```

```
Out[91]: True
```

However, this example, which has a non-monotonic 2nd level, doesn't behave as desired.

```
In [88]: df = pd.DataFrame({'value': [1, 2, 3, 4]},
.....: index=pd.MultiIndex([['a', 'b'], ['bb', 'aa']],
.....: [[0, 0, 1, 1], [0, 1, 0, 1]]))
.....:
```

```
In [89]: df
```

```
Out[89]:
```

```
 value
a bb 1
 aa 2
b bb 3
 aa 4
```

```
[4 rows x 1 columns]
```

Previous behavior:

```
In [11]: df.sort_index()
```

```
Out[11]:
```

```
 value
a bb 1
 aa 2
b bb 3
 aa 4
```

```
In [14]: df.sort_index().index.is_lexsorted()
```

```
Out[14]: True
```

```
In [15]: df.sort_index().index.is_monotonic
```

```
Out[15]: False
```

New behavior:

```
In [94]: df.sort_index()
Out[94]:
 value
a aa 2
 bb 1
b aa 4
 bb 3

[4 rows x 1 columns]

In [95]: df.sort_index().index.is_lexsorted()
Out[95]: True

In [96]: df.sort_index().index.is_monotonic
Out[96]: True
```

### GroupBy describe formatting

The output formatting of `groupby.describe()` now labels the `describe()` metrics in the columns instead of the index. This format is consistent with `groupby.agg()` when applying multiple functions at once. (GH4792)

Previous behavior:

```
In [1]: df = pd.DataFrame({'A': [1, 1, 2, 2], 'B': [1, 2, 3, 4]})

In [2]: df.groupby('A').describe()
Out[2]:
 B
A
1 count 2.000000
 mean 1.500000
 std 0.707107
 min 1.000000
 25% 1.250000
 50% 1.500000
 75% 1.750000
 max 2.000000
2 count 2.000000
 mean 3.500000
 std 0.707107
 min 3.000000
 25% 3.250000
 50% 3.500000
 75% 3.750000
 max 4.000000

In [3]: df.groupby('A').agg([np.mean, np.std, np.min, np.max])
Out[3]:
 B
mean std amin amax
A
1 1.5 0.707107 1 2
```

(continues on next page)

(continued from previous page)

```
2 3.5 0.707107 3 4
```

New behavior:

```
In [90]: df = pd.DataFrame({'A': [1, 1, 2, 2], 'B': [1, 2, 3, 4]})
```

```
In [91]: df.groupby('A').describe()
```

```
Out[91]:
```

```
 B
count mean std min 25% 50% 75% max
A
1 2.0 1.5 0.707107 1.0 1.25 1.5 1.75 2.0
2 2.0 3.5 0.707107 3.0 3.25 3.5 3.75 4.0
```

```
[2 rows x 8 columns]
```

```
In [92]: df.groupby('A').agg([np.mean, np.std, np.min, np.max])
```

```
Out[92]:
```

```
 B
mean std amin amax
A
1 1.5 0.707107 1 2
2 3.5 0.707107 3 4
```

```
[2 rows x 4 columns]
```

## Window binary corr/cov operations return a MultiIndex DataFrame

A binary window operation, like `.corr()` or `.cov()`, when operating on a `.rolling(..)`, `.expanding(..)`, or `.ewm(..)` object, will now return a 2-level MultiIndexed DataFrame rather than a Panel, as Panel is now deprecated, see [here](#). These are equivalent in function, but a MultiIndexed DataFrame enjoys more support in pandas. See the section on *Windowed Binary Operations* for more information. (GH15677)

```
In [93]: np.random.seed(1234)
```

```
In [94]: df = pd.DataFrame(np.random.rand(100, 2),
.....: columns=pd.Index(['A', 'B'], name='bar'),
.....: index=pd.date_range('20160101',
.....: periods=100, freq='D', name='foo'))
```

```
In [95]: df.tail()
```

```
Out[95]:
```

```
bar A B
foo
2016-04-05 0.640880 0.126205
2016-04-06 0.171465 0.737086
2016-04-07 0.127029 0.369650
2016-04-08 0.604334 0.103104
2016-04-09 0.802374 0.945553
```

(continues on next page)

(continued from previous page)

[5 rows x 2 columns]

Previous behavior:

```
In [2]: df.rolling(12).corr()
Out[2]:
<class 'pandas.core.panel.Panel'>
Dimensions: 100 (items) x 2 (major_axis) x 2 (minor_axis)
Items axis: 2016-01-01 00:00:00 to 2016-04-09 00:00:00
Major_axis axis: A to B
Minor_axis axis: A to B
```

New behavior:

```
In [96]: res = df.rolling(12).corr()
```

```
In [97]: res.tail()
```

```
Out[97]:
bar A B
foo bar
2016-04-07 B -0.132090 1.000000
2016-04-08 A 1.000000 -0.145775
 B -0.145775 1.000000
2016-04-09 A 1.000000 0.119645
 B 0.119645 1.000000
```

[5 rows x 2 columns]

Retrieving a correlation matrix for a cross-section

```
In [98]: df.rolling(12).corr().loc['2016-04-07']
```

```
Out[98]:
bar A B
foo bar
2016-04-07 A 1.000000 -0.13209
 B -0.13209 1.00000
```

[2 rows x 2 columns]

## HDFStore where string comparison

In previous versions most types could be compared to string column in a `HDFStore` usually resulting in an invalid comparison, returning an empty result frame. These comparisons will now raise a `TypeError` ([GH15492](#))

```
In [99]: df = pd.DataFrame({'unparsed_date': ['2014-01-01', '2014-01-01']})
```

```
In [100]: df.to_hdf('store.h5', 'key', format='table', data_columns=True)
```

```
In [101]: df.dtypes
```

```
Out[101]:
unparsed_date object
Length: 1, dtype: object
```

Previous behavior:

```
In [4]: pd.read_hdf('store.h5', 'key', where='unparsed_date > ts')
File "<string>", line 1
 (unparsed_date > 1970-01-01 00:00:01.388552400)
 ^
SyntaxError: invalid token
```

New behavior:

```
In [18]: ts = pd.Timestamp('2014-01-01')

In [19]: pd.read_hdf('store.h5', 'key', where='unparsed_date > ts')
TypeError: Cannot compare 2014-01-01 00:00:00 of
type <class 'pandas.tslib.Timestamp'> to string column
```

## Index.intersection and inner join now preserve the order of the left Index

`Index.intersection()` now preserves the order of the calling Index (left) instead of the other Index (right) (GH15582). This affects inner joins, `DataFrame.join()` and `merge()`, and the `.align` method.

- `Index.intersection`

```
In [102]: left = pd.Index([2, 1, 0])

In [103]: left
Out[103]: Int64Index([2, 1, 0], dtype='int64')

In [104]: right = pd.Index([1, 2, 3])

In [105]: right
Out[105]: Int64Index([1, 2, 3], dtype='int64')
```

Previous behavior:

```
In [4]: left.intersection(right)
Out[4]: Int64Index([1, 2], dtype='int64')
```

New behavior:

```
In [106]: left.intersection(right)
Out[106]: Int64Index([2, 1], dtype='int64')
```

- `DataFrame.join` and `pd.merge`

```
In [107]: left = pd.DataFrame({'a': [20, 10, 0]}, index=[2, 1, 0])

In [108]: left
Out[108]:
 a
2 20
1 10
0 0
```

(continues on next page)

(continued from previous page)

```
[3 rows x 1 columns]
In [109]: right = pd.DataFrame({'b': [100, 200, 300]}, index=[1, 2, 3])
In [110]: right
Out[110]:
 b
1 100
2 200
3 300
[3 rows x 1 columns]
```

Previous behavior:

```
In [4]: left.join(right, how='inner')
Out[4]:
 a b
1 10 100
2 20 200
```

New behavior:

```
In [111]: left.join(right, how='inner')
Out[111]:
 a b
2 20 200
1 10 100
[2 rows x 2 columns]
```

### Pivot table always returns a DataFrame

The documentation for `pivot_table()` states that a `DataFrame` is *always* returned. Here a bug is fixed that allowed this to return a `Series` under certain circumstance. (GH4386)

```
In [112]: df = pd.DataFrame({'col1': [3, 4, 5],
.....: 'col2': ['C', 'D', 'E'],
.....: 'col3': [1, 3, 9]})
.....:

In [113]: df
Out[113]:
 col1 col2 col3
0 3 C 1
1 4 D 3
2 5 E 9
[3 rows x 3 columns]
```

Previous behavior:

```
In [2]: df.pivot_table('col1', index=['col3', 'col2'], aggfunc=np.sum)
Out[2]:
col3 col2
1 C 3
3 D 4
9 E 5
Name: col1, dtype: int64
```

New behavior:

```
In [114]: df.pivot_table('col1', index=['col3', 'col2'], aggfunc=np.sum)
Out[114]:
 col1
col3 col2
1 C 3
3 D 4
9 E 5

[3 rows x 1 columns]
```

## Other API changes

- `numexpr` version is now required to be  $\geq 2.4.6$  and it will not be used at all if this requisite is not fulfilled ([GH15213](#)).
- `CParserError` has been renamed to `ParserError` in `pd.read_csv()` and will be removed in the future ([GH12665](#)).
- `SparseArray.cumsum()` and `SparseSeries.cumsum()` will now always return `SparseArray` and `SparseSeries` respectively ([GH12855](#)).
- `DataFrame.applymap()` with an empty `DataFrame` will return a copy of the empty `DataFrame` instead of a `Series` ([GH8222](#)).
- `Series.map()` now respects default values of dictionary subclasses with a `__missing__` method, such as `collections.Counter` ([GH15999](#)).
- `.loc` has `compat` with `.ix` for accepting iterators, and `NamedTuples` ([GH15120](#)).
- `interpolate()` and `fillna()` will raise a `ValueError` if the `limit` keyword argument is not greater than 0. ([GH9217](#)).
- `pd.read_csv()` will now issue a `ParserWarning` whenever there are conflicting values provided by the `dialect` parameter and the user ([GH14898](#)).
- `pd.read_csv()` will now raise a `ValueError` for the C engine if the quote character is larger than one byte ([GH11592](#)).
- `inplace` arguments now require a boolean value, else a `ValueError` is thrown ([GH14189](#)).
- `pandas.api.types.is_datetime64_ns_dtype` will now report `True` on a tz-aware dtype, similar to `pandas.api.types.is_datetime64_any_dtype`.
- `DataFrame.asof()` will return a null filled `Series` instead the scalar `NaN` if a match is not found ([GH15118](#)).
- Specific support for `copy.copy()` and `copy.deepcopy()` functions on `NDFrame` objects ([GH15444](#)).
- `Series.sort_values()` accepts a one element list of `bool` for consistency with the behavior of `DataFrame.sort_values()` ([GH15604](#)).

- `.merge()` and `.join()` on category dtype columns will now preserve the category dtype when possible (GH10409)
- `SparseDataFrame.default_fill_value` will be 0, previously was nan in the return from `pd.get_dummies(..., sparse=True)` (GH15594)
- The default behaviour of `Series.str.match` has changed from extracting groups to matching the pattern. The extracting behaviour was deprecated since pandas version 0.13.0 and can be done with the `Series.str.extract` method (GH5224). As a consequence, the `as_indexer` keyword is ignored (no longer needed to specify the new behaviour) and is deprecated.
- NaT will now correctly report False for datetimelike boolean operations such as `is_month_start` (GH15781)
- NaT will now correctly return `np.nan` for `Timedelta` and `Period` accessors such as `days` and `quarter` (GH15782)
- NaT will now returns NaT for `tz_localize` and `tz_convert` methods (GH15830)
- `DataFrame` and `Panel` constructors with invalid input will now raise `ValueError` rather than `PandasError`, if called with scalar inputs and not axes (GH15541)
- `DataFrame` and `Panel` constructors with invalid input will now raise `ValueError` rather than `pandas.core.common.PandasError`, if called with scalar inputs and not axes; The exception `PandasError` is removed as well. (GH15541)
- The exception `pandas.core.common.AmbiguousIndexError` is removed as it is not referenced (GH15541)

### Reorganization of the library: privacy changes

#### Modules privacy has changed

Some formerly public python/c/c++/cython extension modules have been moved and/or renamed. These are all removed from the public API. Furthermore, the `pandas.core`, `pandas.compat`, and `pandas.util` top-level modules are now considered to be PRIVATE. If indicated, a deprecation warning will be issued if you reference these modules. (GH12588)

| pandas._testing      | pandas._libs.testing               |                 |
| pandas._window       | pandas._libs.window                |                 |

Some new subpackages are created with public functionality that is not directly exposed in the top-level namespace: `pandas.errors`, `pandas.plotting` and `pandas.testing` (more details below). Together with `pandas.api.types` and certain functions in the `pandas.io` and `pandas.tseries` submodules, these are now the public subpackages.

Further changes:

- The function `union_categoricals()` is now importable from `pandas.api.types`, formerly from `pandas.types.concat` (GH15998)
- The type import `pandas.tslib.NaTType` is deprecated and can be replaced by using `type(pandas.NaT)` (GH16146)
- The public functions in `pandas.tools.hashing` deprecated from that locations, but are now importable from `pandas.util` (GH16223)
- The modules in `pandas.util`: `decorators`, `print_versions`, `doctools`, `validators`, `depr_module` are now private. Only the functions exposed in `pandas.util` itself are public (GH16223)

## pandas.errors

We are adding a standard public module for all pandas exceptions & warnings `pandas.errors`. (GH14800). Previously these exceptions & warnings could be imported from `pandas.core.common` or `pandas.io.common`. These exceptions and warnings will be removed from the `*.common` locations in a future release. (GH15541)

The following are now part of this API:

```
['DtypeWarning',
 'EmptyDataError',
```

(continues on next page)

(continued from previous page)

```
'OutOfBoundsDatetime',
'ParserError',
'ParserWarning',
'PerformanceWarning',
'UnsortedIndexError',
'UnsupportedFunctionCall']
```

## pandas.testing

We are adding a standard module that exposes the public testing functions in `pandas.testing` (GH9895). Those functions can be used when writing tests for functionality using pandas objects.

The following testing functions are now part of this API:

- `testing.assert_frame_equal()`
- `testing.assert_series_equal()`
- `testing.assert_index_equal()`

## pandas.plotting

A new public `pandas.plotting` module has been added that holds plotting functionality that was previously in either `pandas.tools.plotting` or in the top-level namespace. See the *deprecations sections* for more details.

## Other development changes

- Building pandas for development now requires `cython >= 0.23` (GH14831)
- Require at least 0.23 version of cython to avoid problems with character encodings (GH14699)
- Switched the test framework to use `pytest` (GH13097)
- Reorganization of tests directory layout (GH14854, GH15707).

## Deprecations

### Deprecate `.ix`

The `.ix` indexer is deprecated, in favor of the more strict `.iloc` and `.loc` indexers. `.ix` offers a lot of magic on the inference of what the user wants to do. More specifically, `.ix` can decide to index *positionally* OR via *labels*, depending on the data type of the index. This has caused quite a bit of user confusion over the years. The full indexing documentation is *here*. (GH14218)

The recommended methods of indexing are:

- `.loc` if you want to *label* index
- `.iloc` if you want to *positionally* index.

Using `.ix` will now show a `DeprecationWarning` with a link to some examples of how to convert code *here*.

```
In [115]: df = pd.DataFrame({'A': [1, 2, 3],
.....: 'B': [4, 5, 6]},
.....: index=list('abc'))
.....:
```

```
In [116]: df
```

```
Out[116]:
```

```
 A B
a 1 4
b 2 5
c 3 6
```

```
[3 rows x 2 columns]
```

Previous behavior, where you wish to get the 0th and the 2nd elements from the index in the 'A' column.

```
In [3]: df.ix[[0, 2], 'A']
```

```
Out[3]:
```

```
a 1
c 3
```

```
Name: A, dtype: int64
```

Using `.loc`. Here we will select the appropriate indexes from the index, then use *label* indexing.

```
In [117]: df.loc[df.index[[0, 2]], 'A']
```

```
Out[117]:
```

```
a 1
c 3
```

```
Name: A, Length: 2, dtype: int64
```

Using `.iloc`. Here we will get the location of the 'A' column, then use *positional* indexing to select things.

```
In [118]: df.iloc[[0, 2], df.columns.get_loc('A')]
```

```
Out[118]:
```

```
a 1
c 3
```

```
Name: A, Length: 2, dtype: int64
```

## Deprecate Panel

Panel is deprecated and will be removed in a future version. The recommended way to represent 3-D data are with a `MultiIndex` on a `DataFrame` via the `to_frame()` or with the `xarray` package. pandas provides a `to_xarray()` method to automate this conversion (GH13563).

```
In [133]: import pandas._testing as tm
```

```
In [134]: p = tm.makePanel()
```

```
In [135]: p
```

```
Out[135]:
```

```
<class 'pandas.core.panel.Panel'>
Dimensions: 3 (items) x 3 (major_axis) x 4 (minor_axis)
```

(continues on next page)

(continued from previous page)

```
Items axis: ItemA to ItemC
Major_axis axis: 2000-01-03 00:00:00 to 2000-01-05 00:00:00
Minor_axis axis: A to D
```

Convert to a MultiIndex DataFrame

```
In [136]: p.to_frame()
```

```
Out[136]:
```

|            |       | ItemA     | ItemB     | ItemC     |
|------------|-------|-----------|-----------|-----------|
| major      | minor |           |           |           |
| 2000-01-03 | A     | 0.628776  | -1.409432 | 0.209395  |
|            | B     | 0.988138  | -1.347533 | -0.896581 |
|            | C     | -0.938153 | 1.272395  | -0.161137 |
|            | D     | -0.223019 | -0.591863 | -1.051539 |
| 2000-01-04 | A     | 0.186494  | 1.422986  | -0.592886 |
|            | B     | -0.072608 | 0.363565  | 1.104352  |
|            | C     | -1.239072 | -1.449567 | 0.889157  |
|            | D     | 2.123692  | -0.414505 | -0.319561 |
| 2000-01-05 | A     | 0.952478  | -2.147855 | -1.473116 |
|            | B     | -0.550603 | -0.014752 | -0.431550 |
|            | C     | 0.139683  | -1.195524 | 0.288377  |
|            | D     | 0.122273  | -1.425795 | -0.619993 |

```
[12 rows x 3 columns]
```

Convert to an xarray DataArray

```
In [137]: p.to_xarray()
```

```
Out[137]:
```

```
<xarray.DataArray (items: 3, major_axis: 3, minor_axis: 4)>
array([[[0.628776, 0.988138, -0.938153, -0.223019],
 [0.186494, -0.072608, -1.239072, 2.123692],
 [0.952478, -0.550603, 0.139683, 0.122273]],

 [-1.473116, -0.43155 , 0.288377, -0.619993]])])
```

```
Coordinates:
```

```
* items (items) object 'ItemA' 'ItemB' 'ItemC'
* major_axis (major_axis) datetime64[ns] 2000-01-03 2000-01-04 2000-01-05
* minor_axis (minor_axis) object 'A' 'B' 'C' 'D'
```

## Deprecate `groupby.agg()` with a dictionary when renaming

The `.groupby(...).agg(...)`, `.rolling(...).agg(...)`, and `.resample(...).agg(...)` syntax can accept a variable of inputs, including scalars, list, and a dict of column names to scalars or lists. This provides a useful syntax for constructing multiple (potentially different) aggregations.

However, `.agg(...)` can *also* accept a dict that allows ‘renaming’ of the result columns. This is a complicated and confusing syntax, as well as not consistent between `Series` and `DataFrame`. We are deprecating this ‘renaming’ functionality.

- We are deprecating passing a dict to a grouped/rolled/resampled `Series`. This allowed one to rename the resulting aggregation, but this had a completely different meaning than passing a dictionary to a grouped `DataFrame`, which accepts column-to-aggregations.
- We are deprecating passing a dict-of-dicts to a grouped/rolled/resampled `DataFrame` in a similar manner.

This is an illustrative example:

```
In [119]: df = pd.DataFrame({'A': [1, 1, 1, 2, 2],
.....: 'B': range(5),
.....: 'C': range(5)})
.....:

In [120]: df
Out[120]:
 A B C
0 1 0 0
1 1 1 1
2 1 2 2
3 2 3 3
4 2 4 4

[5 rows x 3 columns]
```

Here is a typical useful syntax for computing different aggregations for different columns. This is a natural, and useful syntax. We aggregate from the dict-to-list by taking the specified columns and applying the list of functions. This returns a `MultiIndex` for the columns (this is *not* deprecated).

```
In [121]: df.groupby('A').agg({'B': 'sum', 'C': 'min'})
Out[121]:
 B C
A
1 3 0
2 7 3

[2 rows x 2 columns]
```

Here’s an example of the first deprecation, passing a dict to a grouped `Series`. This is a combination aggregation & renaming:

```
In [6]: df.groupby('A').B.agg({'foo': 'count'})
FutureWarning: using a dict on a Series for aggregation
is deprecated and will be removed in a future version

Out[6]:
```

(continues on next page)

(continued from previous page)

```

 foo
A
1 3
2 2

```

You can accomplish the same operation, more idiomatically by:

```

In [122]: df.groupby('A').B.agg(['count']).rename(columns={'count': 'foo'})
Out[122]:
 foo
A
1 3
2 2

[2 rows x 1 columns]

```

Here's an example of the second deprecation, passing a dict-of-dict to a grouped DataFrame:

```

In [23]: (df.groupby('A')
...: .agg({'B': {'foo': 'sum'}, 'C': {'bar': 'min'}})
...:)
FutureWarning: using a dict with renaming is deprecated and
will be removed in a future version

Out[23]:
 B C
 foo bar
A
1 3 0
2 7 3

```

You can accomplish nearly the same by:

```

In [123]: (df.groupby('A')
...: .agg({'B': 'sum', 'C': 'min'})
...: .rename(columns={'B': 'foo', 'C': 'bar'})
...:)
Out[123]:
 foo bar
A
1 3 0
2 7 3

[2 rows x 2 columns]

```

## Deprecate .plotting

The `pandas.tools.plotting` module has been deprecated, in favor of the top level `pandas.plotting` module. All the public plotting functions are now available from `pandas.plotting` ([GH12548](#)).

Furthermore, the top-level `pandas.scatter_matrix` and `pandas.plot_params` are deprecated. Users can import these from `pandas.plotting` as well.

Previous script:

```
pd.tools.plotting.scatter_matrix(df)
pd.scatter_matrix(df)
```

Should be changed to:

```
pd.plotting.scatter_matrix(df)
```

## Other deprecations

- `SparseArray.to_dense()` has deprecated the `fill` parameter, as that parameter was not being respected ([GH14647](#))
- `SparseSeries.to_dense()` has deprecated the `sparse_only` parameter ([GH14647](#))
- `Series.repeat()` has deprecated the `reps` parameter in favor of `repeats` ([GH12662](#))
- The `Series` constructor and `.astype` method have deprecated accepting timestamp dtypes without a frequency (e.g. `np.datetime64`) for the `dtype` parameter ([GH15524](#))
- `Index.repeat()` and `MultiIndex.repeat()` have deprecated the `n` parameter in favor of `repeats` ([GH12662](#))
- `Categorical.searchsorted()` and `Series.searchsorted()` have deprecated the `v` parameter in favor of `value` ([GH12662](#))
- `TimedeltaIndex.searchsorted()`, `DatetimeIndex.searchsorted()`, and `PeriodIndex.searchsorted()` have deprecated the `key` parameter in favor of `value` ([GH12662](#))
- `DataFrame.astype()` has deprecated the `raise_on_error` parameter in favor of `errors` ([GH14878](#))
- `Series.sortlevel` and `DataFrame.sortlevel` have been deprecated in favor of `Series.sort_index` and `DataFrame.sort_index` ([GH15099](#))
- importing `concat` from `pandas.tools.merge` has been deprecated in favor of imports from the `pandas` namespace. This should only affect explicit imports ([GH15358](#))
- `Series/DataFrame/Panel consolidate()` been deprecated as a public method. ([GH15483](#))
- The `as_indexer` keyword of `Series.str.match()` has been deprecated (ignored keyword) ([GH15257](#)).
- The following top-level pandas functions have been deprecated and will be removed in a future version ([GH13790](#), [GH15940](#))
  - `pd.pnow()`, replaced by `Period.now()`
  - `pd.Term`, is removed, as it is not applicable to user code. Instead use in-line string expressions in the `where` clause when searching in `HDFStore`
  - `pd.Expr`, is removed, as it is not applicable to user code.
  - `pd.match()`, is removed.

- `pd.groupby()`, replaced by using the `.groupby()` method directly on a `Series/DataFrame`
- `pd.get_store()`, replaced by a direct call to `pd.HDFStore(...)`
- `is_any_int_dtype`, `is_floating_dtype`, and `is_sequence` are deprecated from `pandas.api.types` (GH16042)

### Removal of prior version deprecations/changes

- The `pandas.rpy` module is removed. Similar functionality can be accessed through the `rpy2` project. See the [interfacing docs](#) for more details.
- The `pandas.io.ga` module with a `google-analytics` interface is removed (GH11308). Similar functionality can be found in the `Google2Pandas` package.
- `pd.to_datetime` and `pd.to_timedelta` have dropped the `coerce` parameter in favor of `errors` (GH13602)
- `pandas.stats.fama_macbeth`, `pandas.stats.ols`, `pandas.stats.plm` and `pandas.stats.var`, as well as the top-level `pandas.fama_macbeth` and `pandas.ols` routines are removed. Similar functionality can be found in the `statsmodels` package. (GH11898)
- The `TimeSeries` and `SparseTimeSeries` classes, aliases of `Series` and `SparseSeries`, are removed (GH10890, GH15098).
- `Series.is_time_series` is dropped in favor of `Series.index.is_all_dates` (GH15098)
- The deprecated `irow`, `icol`, `iget` and `iget_value` methods are removed in favor of `iloc` and `iat` as explained [here](#) (GH10711).
- The deprecated `DataFrame.iterkv()` has been removed in favor of `DataFrame.iteritems()` (GH10711)
- The `Categorical` constructor has dropped the `name` parameter (GH10632)
- `Categorical` has dropped support for `NaN` categories (GH10748)
- The `take_last` parameter has been dropped from `duplicated()`, `drop_duplicates()`, `nlargest()`, and `nsmallest()` methods (GH10236, GH10792, GH10920)
- `Series`, `Index`, and `DataFrame` have dropped the `sort` and `order` methods (GH10726)
- Where clauses in `pytables` are only accepted as strings and expressions types and not other data-types (GH12027)
- `DataFrame` has dropped the `combineAdd` and `combineMult` methods in favor of `add` and `mul` respectively (GH10735)

### Performance improvements

- Improved performance of `pd.wide_to_long()` (GH14779)
- Improved performance of `pd.factorize()` by releasing the GIL with object dtype when inferred as strings (GH14859, GH16057)
- Improved performance of timeseries plotting with an irregular `DatetimeIndex` (or with `compat_x=True`) (GH15073).
- Improved performance of `groupby().cummin()` and `groupby().cummax()` (GH15048, GH15109, GH15561, GH15635)
- Improved performance and reduced memory when indexing with a `MultiIndex` (GH15245)
- When reading buffer object in `read_sas()` method without specified format, filepath string is inferred rather than buffer object. (GH14947)

- Improved performance of `.rank()` for categorical data (GH15498)
- Improved performance when using `.unstack()` (GH15503)
- Improved performance of `merge/join` on category columns (GH10409)
- Improved performance of `drop_duplicates()` on bool columns (GH12963)
- Improve performance of `pd.core.groupby.GroupBy.apply` when the applied function used the `.name` attribute of the group DataFrame (GH15062).
- Improved performance of `iloc` indexing with a list or array (GH15504).
- Improved performance of `Series.sort_index()` with a monotonic index (GH15694)
- Improved performance in `pd.read_csv()` on some platforms with buffered reads (GH16039)

## Bug fixes

### Conversion

- Bug in `Timestamp.replace` now raises `TypeError` when incorrect argument names are given; previously this raised `ValueError` (GH15240)
- Bug in `Timestamp.replace` with `compat` for passing long integers (GH15030)
- Bug in `Timestamp` returning UTC based time/date attributes when a timezone was provided (GH13303, GH6538)
- Bug in `Timestamp` incorrectly localizing timezones during construction (GH11481, GH15777)
- Bug in `TimedeltaIndex` addition where overflow was being allowed without error (GH14816)
- Bug in `TimedeltaIndex` raising a `ValueError` when boolean indexing with `loc` (GH14946)
- Bug in catching an overflow in `Timestamp + Timedelta/Offset` operations (GH15126)
- Bug in `DatetimeIndex.round()` and `Timestamp.round()` floating point accuracy when rounding by milliseconds or less (GH14440, GH15578)
- Bug in `astype()` where `inf` values were incorrectly converted to integers. Now raises error now with `astype()` for Series and DataFrames (GH14265)
- Bug in `DataFrame(...).apply(to_numeric)` when values are of type `decimal.Decimal`. (GH14827)
- Bug in `describe()` when passing a numpy array which does not contain the median to the `percentiles` keyword argument (GH14908)
- Cleaned up `PeriodIndex` constructor, including raising on floats more consistently (GH13277)
- Bug in using `__deepcopy__` on empty `NDFrame` objects (GH15370)
- Bug in `.replace()` may result in incorrect dtypes. (GH12747, GH15765)
- Bug in `Series.replace` and `DataFrame.replace` which failed on empty replacement dicts (GH15289)
- Bug in `Series.replace` which replaced a numeric by string (GH15743)
- Bug in `Index` construction with `NaN` elements and integer dtype specified (GH15187)
- Bug in `Series` construction with a `datetimetz` (GH14928)
- Bug in `Series.dt.round()` inconsistent behaviour on `NaT` 's with different arguments (GH14940)
- Bug in `Series` constructor when both `copy=True` and `dtype` arguments are provided (GH15125)

- Incorrect dtyped Series was returned by comparison methods (e.g., `lt`, `gt`, ...) against a constant for an empty DataFrame (GH15077)
- Bug in `Series.ffill()` with mixed dtypes containing tz-aware datetimes. (GH14956)
- Bug in `DataFrame.fillna()` where the argument `downcast` was ignored when `fillna` value was of type `dict` (GH15277)
- Bug in `.asfreq()`, where frequency was not set for empty Series (GH14320)
- Bug in DataFrame construction with nulls and datetimes in a list-like (GH15869)
- Bug in `DataFrame.fillna()` with tz-aware datetimes (GH15855)
- Bug in `is_string_dtype`, `is_timedelta64_ns_dtype`, and `is_string_like_dtype` in which an error was raised when `None` was passed in (GH15941)
- Bug in the return type of `pd.unique` on a Categorical, which was returning an ndarray and not a Categorical (GH15903)
- Bug in `Index.to_series()` where the index was not copied (and so mutating later would change the original), (GH15949)
- Bug in indexing with partial string indexing with a len-1 DataFrame (GH16071)
- Bug in Series construction where passing invalid dtype didn't raise an error. (GH15520)

## Indexing

- Bug in Index power operations with reversed operands (GH14973)
- Bug in `DataFrame.sort_values()` when sorting by multiple columns where one column is of type `int64` and contains `NaT` (GH14922)
- Bug in `DataFrame.reindex()` in which `method` was ignored when passing `columns` (GH14992)
- Bug in `DataFrame.loc` with indexing a `MultiIndex` with a `Series` indexer (GH14730, GH15424)
- Bug in `DataFrame.loc` with indexing a `MultiIndex` with a numpy array (GH15434)
- Bug in `Series.asof` which raised if the series contained all `np.nan` (GH15713)
- Bug in `.at` when selecting from a tz-aware column (GH15822)
- Bug in `Series.where()` and `DataFrame.where()` where array-like conditionals were being rejected (GH15414)
- Bug in `Series.where()` where TZ-aware data was converted to float representation (GH15701)
- Bug in `.loc` that would not return the correct dtype for scalar access for a DataFrame (GH11617)
- Bug in output formatting of a `MultiIndex` when names are integers (GH12223, GH15262)
- Bug in `Categorical.searchsorted()` where alphabetical instead of the provided categorical order was used (GH14522)
- Bug in `Series.iloc` where a Categorical object for list-like indexes input was returned, where a Series was expected. (GH14580)
- Bug in `DataFrame.isin` comparing datetimelike to empty frame (GH15473)
- Bug in `.reset_index()` when an all NaN level of a `MultiIndex` would fail (GH6322)
- Bug in `.reset_index()` when raising error for index name already present in `MultiIndex` columns (GH16120)

- Bug in creating a `MultiIndex` with tuples and not passing a list of names; this will now raise `ValueError` ([GH15110](#))
- Bug in the HTML display with a `MultiIndex` and truncation ([GH14882](#))
- Bug in the display of `.info()` where a qualifier (+) would always be displayed with a `MultiIndex` that contains only non-strings ([GH15245](#))
- Bug in `pd.concat()` where the names of `MultiIndex` of resulting `DataFrame` are not handled correctly when `None` is presented in the names of `MultiIndex` of input `DataFrame` ([GH15787](#))
- Bug in `DataFrame.sort_index()` and `Series.sort_index()` where `na_position` doesn't work with a `MultiIndex` ([GH14784](#), [GH16604](#))
- Bug in `pd.concat()` when combining objects with a `CategoricalIndex` ([GH16111](#))
- Bug in indexing with a scalar and a `CategoricalIndex` ([GH16123](#))

## IO

- Bug in `pd.to_numeric()` in which float and unsigned integer elements were being improperly casted ([GH14941](#), [GH15005](#))
- Bug in `pd.read_fwf()` where the `skiprows` parameter was not being respected during column width inference ([GH11256](#))
- Bug in `pd.read_csv()` in which the `dialect` parameter was not being verified before processing ([GH14898](#))
- Bug in `pd.read_csv()` in which missing data was being improperly handled with `usecols` ([GH6710](#))
- Bug in `pd.read_csv()` in which a file containing a row with many columns followed by rows with fewer columns would cause a crash ([GH14125](#))
- Bug in `pd.read_csv()` for the C engine where `usecols` were being indexed incorrectly with `parse_dates` ([GH14792](#))
- Bug in `pd.read_csv()` with `parse_dates` when multi-line headers are specified ([GH15376](#))
- Bug in `pd.read_csv()` with `float_precision='round_trip'` which caused a segfault when a text entry is parsed ([GH15140](#))
- Bug in `pd.read_csv()` when an index was specified and no values were specified as null values ([GH15835](#))
- Bug in `pd.read_csv()` in which certain invalid file objects caused the Python interpreter to crash ([GH15337](#))
- Bug in `pd.read_csv()` in which invalid values for `nrows` and `chunksizes` were allowed ([GH15767](#))
- Bug in `pd.read_csv()` for the Python engine in which unhelpful error messages were being raised when parsing errors occurred ([GH15910](#))
- Bug in `pd.read_csv()` in which the `skipfooter` parameter was not being properly validated ([GH15925](#))
- Bug in `pd.to_csv()` in which there was numeric overflow when a timestamp index was being written ([GH15982](#))
- Bug in `pd.util.hashing.hash_pandas_object()` in which hashing of categoricals depended on the ordering of categories, instead of just their values. ([GH15143](#))
- Bug in `.to_json()` where `lines=True` and contents (keys or values) contain escaped characters ([GH15096](#))
- Bug in `.to_json()` causing single byte ascii characters to be expanded to four byte unicode ([GH15344](#))
- Bug in `.to_json()` for the C engine where rollover was not correctly handled for case where `frac` is odd and `diff` is exactly 0.5 ([GH15716](#), [GH15864](#))

- Bug in `pd.read_json()` for Python 2 where `lines=True` and contents contain non-ascii unicode characters (GH15132)
- Bug in `pd.read_msgpack()` in which Series categoricals were being improperly processed (GH14901)
- Bug in `pd.read_msgpack()` which did not allow loading of a dataframe with an index of type `CategoricalIndex` (GH15487)
- Bug in `pd.read_msgpack()` when deserializing a `CategoricalIndex` (GH15487)
- Bug in `DataFrame.to_records()` with converting a `DatetimeIndex` with a timezone (GH13937)
- Bug in `DataFrame.to_records()` which failed with unicode characters in column names (GH11879)
- Bug in `.to_sql()` when writing a `DataFrame` with numeric index names (GH15404).
- Bug in `DataFrame.to_html()` with `index=False` and `max_rows` raising in `IndexError` (GH14998)
- Bug in `pd.read_hdf()` passing a `Timestamp` to the `where` parameter with a non date column (GH15492)
- Bug in `DataFrame.to_stata()` and `StataWriter` which produces incorrectly formatted files to be produced for some locales (GH13856)
- Bug in `StataReader` and `StataWriter` which allows invalid encodings (GH15723)
- Bug in the Series repr not showing the length when the output was truncated (GH15962).

## Plotting

- Bug in `DataFrame.hist` where `plt.tight_layout` caused an `AttributeError` (use `matplotlib >= 2.0.1`) (GH9351)
- Bug in `DataFrame.boxplot` where `fontsize` was not applied to the tick labels on both axes (GH15108)
- Bug in the date and time converters pandas registers with `matplotlib` not handling multiple dimensions (GH16026)
- Bug in `pd.scatter_matrix()` could accept either `color` or `c`, but not both (GH14855)

## GroupBy/resample/rolling

- Bug in `.groupby(...).resample()` when passed the `on=` kwarg. (GH15021)
- Properly set `__name__` and `__qualname__` for `Groupby.*` functions (GH14620)
- Bug in `GroupBy.get_group()` failing with a categorical grouper (GH15155)
- Bug in `.groupby(...).rolling(...)` when `on` is specified and using a `DatetimeIndex` (GH15130, GH13966)
- Bug in `groupby` operations with `timedelta64` when passing `numeric_only=False` (GH5724)
- Bug in `groupby.apply()` coercing object dtypes to numeric types, when not all values were numeric (GH14423, GH15421, GH15670)
- Bug in `resample`, where a non-string `loffset` argument would not be applied when resampling a timeseries (GH13218)
- Bug in `DataFrame.groupby().describe()` when grouping on `Index` containing tuples (GH14848)
- Bug in `groupby().nunique()` with a `datetimelike-grouper` where bins counts were incorrect (GH13453)
- Bug in `groupby.transform()` that would coerce the resultant dtypes back to the original (GH10972, GH11444)

- Bug in `groupby.agg()` incorrectly localizing timezone on `datetime` ([GH15426](#), [GH10668](#), [GH13046](#))
- Bug in `.rolling/expanding()` functions where `count()` was not counting `np.Inf`, nor handling object dtypes ([GH12541](#))
- Bug in `.rolling()` where `pd.Timedelta` or `datetime.timedelta` was not accepted as a window argument ([GH15440](#))
- Bug in `Rolling.quantile` function that caused a segmentation fault when called with a quantile value outside of the range `[0, 1]` ([GH15463](#))
- Bug in `DataFrame.resample().median()` if duplicate column names are present ([GH14233](#))

## Sparse

- Bug in `SparseSeries.reindex` on single level with list of length 1 ([GH15447](#))
- Bug in repr-formatting a `SparseDataFrame` after a value was set on (a copy of) one of its series ([GH15488](#))
- Bug in `SparseDataFrame` construction with lists not coercing to dtype ([GH15682](#))
- Bug in sparse array indexing in which indices were not being validated ([GH15863](#))

## Reshaping

- Bug in `pd.merge_asof()` where `left_index` or `right_index` caused a failure when `multiple_by` was specified ([GH15676](#))
- Bug in `pd.merge_asof()` where `left_index/right_index` together caused a failure when `tolerance` was specified ([GH15135](#))
- Bug in `DataFrame.pivot_table()` where `dropna=True` would not drop all-`NaN` columns when the columns was a category dtype ([GH15193](#))
- Bug in `pd.melt()` where passing a tuple value for `value_vars` caused a `TypeError` ([GH15348](#))
- Bug in `pd.pivot_table()` where no error was raised when `values` argument was not in the columns ([GH14938](#))
- Bug in `pd.concat()` in which concatenating with an empty dataframe with `join='inner'` was being improperly handled ([GH15328](#))
- Bug with `sort=True` in `DataFrame.join` and `pd.merge` when joining on indexes ([GH15582](#))
- Bug in `DataFrame.nsmallest` and `DataFrame.nlargest` where identical values resulted in duplicated rows ([GH15297](#))
- Bug in `pandas.pivot_table()` incorrectly raising `UnicodeError` when passing unicode input for margins keyword ([GH13292](#))

## Numeric

- Bug in `.rank()` which incorrectly ranks ordered categories (GH15420)
- Bug in `.corr()` and `.cov()` where the column and index were the same object (GH14617)
- Bug in `.mode()` where mode was not returned if was only a single value (GH15714)
- Bug in `pd.cut()` with a single bin on an all 0s array (GH15428)
- Bug in `pd.qcut()` with a single quantile and an array with identical values (GH15431)
- Bug in `pandas.tools.utils.cartesian_product()` with large input can cause overflow on windows (GH15265)
- Bug in `.eval()` which caused multi-line evals to fail with local variables not on the first line (GH15342)

## Other

- Compat with SciPy 0.19.0 for testing on `.interpolate()` (GH15662)
- Compat for 32-bit platforms for `.qcut/cut`; bins will now be `int64` dtype (GH14866)
- Bug in interactions with Qt when a `QtApplication` already exists (GH14372)
- Avoid use of `np.finfo()` during `import pandas` removed to mitigate deadlock on Python GIL misuse (GH14641)

## 5.11 Version 0.19

### 5.11.1 Version 0.19.2 (December 24, 2016)

This is a minor bug-fix release in the 0.19.x series and includes some small regression fixes, bug fixes and performance improvements. We recommend that all users upgrade to this version.

Highlights include:

- Compatibility with Python 3.6
- Added a [Pandas Cheat Sheet](#). (GH13202).

#### What's new in v0.19.2

- *Enhancements*
- *Performance improvements*
- *Bug fixes*
- *Contributors*

#### Enhancements

The `pd.merge_asof()`, added in 0.19.0, gained some improvements:

- `pd.merge_asof()` gained `left_index/right_index` and `left_by/right_by` arguments (GH14253)
- `pd.merge_asof()` can take multiple columns in `by` parameter and has specialized dtypes for better performance (GH13936)

## Performance improvements

- Performance regression with `PeriodIndex` (GH14822)
- Performance regression in indexing with `getitem` (GH14930)
- Improved performance of `.replace()` (GH12745)
- Improved performance `Series` creation with a datetime index and dictionary data (GH14894)

## Bug fixes

- Compat with python 3.6 for pickling of some offsets (GH14685)
- Compat with python 3.6 for some indexing exception types (GH14684, GH14689)
- Compat with python 3.6 for deprecation warnings in the test suite (GH14681)
- Compat with python 3.6 for `Timestamp` pickles (GH14689)
- Compat with `dateutil==2.6.0`; `segfault` reported in the testing suite (GH14621)
- Allow nanoseconds in `Timestamp.replace` as a kwarg (GH14621)
- Bug in `pd.read_csv` in which aliasing was being done for `na_values` when passed in as a dictionary (GH14203)
- Bug in `pd.read_csv` in which column indices for a dict-like `na_values` were not being respected (GH14203)
- Bug in `pd.read_csv` where reading files fails, if the number of headers is equal to the number of lines in the file (GH14515)
- Bug in `pd.read_csv` for the Python engine in which an unhelpful error message was being raised when multi-char delimiters were not being respected with quotes (GH14582)
- Fix bugs (GH14734, GH13654) in `pd.read_sas` and `pandas.io.sas.sas7bdat.SAS7BDATReader` that caused problems when reading a SAS file incrementally.
- Bug in `pd.read_csv` for the Python engine in which an unhelpful error message was being raised when `skipfooter` was not being respected by Python's CSV library (GH13879)
- Bug in `.fillna()` in which timezone aware `datetime64` values were incorrectly rounded (GH14872)
- Bug in `.groupby(..., sort=True)` of a non-lexsorted `MultiIndex` when grouping with multiple levels (GH14776)
- Bug in `pd.cut` with negative values and a single bin (GH14652)
- Bug in `pd.to_numeric` where a 0 was not unsigned on a `downcast='unsigned'` argument (GH14401)
- Bug in plotting regular and irregular timeseries using shared axes (`sharex=True` or `ax.twinx()`) (GH13341, GH14322).
- Bug in not propagating exceptions in parsing invalid datetimes, noted in python 3.6 (GH14561)
- Bug in resampling a `DatetimeIndex` in local TZ, covering a DST change, which would raise `AmbiguousTimeError` (GH14682)
- Bug in indexing that transformed `RecursionError` into `KeyError` or `IndexingError` (GH14554)
- Bug in `HDFStore` when writing a `MultiIndex` when using `data_columns=True` (GH14435)
- Bug in `HDFStore.append()` when writing a `Series` and passing a `min_itemsize` argument containing a value for the index (GH11412)

- Bug when writing to a HDFStore in table format with a `min_itemsize` value for the `index` and without asking to append ([GH10381](#))
- Bug in `Series.groupby.unique()` raising an `IndexError` for an empty `Series` ([GH12553](#))
- Bug in `DataFrame.nlargest` and `DataFrame.nsmallest` when the `index` had duplicate values ([GH13412](#))
- Bug in clipboard functions on linux with python2 with unicode and separators ([GH13747](#))
- Bug in clipboard functions on Windows 10 and python 3 ([GH14362](#), [GH12807](#))
- Bug in `.to_clipboard()` and Excel compat ([GH12529](#))
- Bug in `DataFrame.combine_first()` for integer columns ([GH14687](#)).
- Bug in `pd.read_csv()` in which the `dtype` parameter was not being respected for empty data ([GH14712](#))
- Bug in `pd.read_csv()` in which the `nrows` parameter was not being respected for large input when using the C engine for parsing ([GH7626](#))
- Bug in `pd.merge_asof()` could not handle timezone-aware `DatetimeIndex` when a tolerance was specified ([GH14844](#))
- Explicit check in `to_stata` and `StataWriter` for out-of-range values when writing doubles ([GH14618](#))
- Bug in `.plot(kind='kde')` which did not drop missing values to generate the KDE Plot, instead generating an empty plot. ([GH14821](#))
- Bug in `unstack()` if called with a list of column(s) as an argument, regardless of the dtypes of all columns, they get coerced to object ([GH11847](#))

### 5.11.2 Version 0.19.1 (November 3, 2016)

This is a minor bug-fix release from 0.19.0 and includes some small regression fixes, bug fixes and performance improvements. We recommend that all users upgrade to this version.

#### What's new in v0.19.1

- *Performance improvements*
- *Bug fixes*
- *Contributors*

#### Performance improvements

- Fixed performance regression in factorization of `Period` data (GH14338)
- Fixed performance regression in `Series.asof(where)` when `where` is a scalar (GH14461)
- Improved performance in `DataFrame.asof(where)` when `where` is a scalar (GH14461)
- Improved performance in `.to_json()` when `lines=True` (GH14408)
- Improved performance in certain types of `loc` indexing with a `MultiIndex` (GH14551).

## Bug fixes

- Source installs from PyPI will now again work without cython installed, as in previous versions (GH14204)
- Compat with Cython 0.25 for building (GH14496)
- Fixed regression where user-provided file handles were closed in `read_csv` (c engine) (GH14418).
- Fixed regression in `DataFrame.quantile` when missing values were present in some columns (GH14357).
- Fixed regression in `Index.difference` where the `freq` of a `DatetimeIndex` was incorrectly set (GH14323)
- Added back `pandas.core.common.array_equivalent` with a deprecation warning (GH14555).
- Bug in `pd.read_csv` for the C engine in which quotation marks were improperly parsed in skipped rows (GH14459)
- Bug in `pd.read_csv` for Python 2.x in which Unicode quote characters were no longer being respected (GH14477)
- Fixed regression in `Index.append` when categorical indices were appended (GH14545).
- Fixed regression in `pd.DataFrame` where constructor fails when given dict with `None` value (GH14381)
- Fixed regression in `DatetimeIndex._maybe_cast_slice_bound` when index is empty (GH14354).
- Bug in localizing an ambiguous timezone when a boolean is passed (GH14402)
- Bug in `TimedeltaIndex` addition with a `Datetime`-like object where addition overflow in the negative direction was not being caught (GH14068, GH14453)
- Bug in string indexing against data with object `Index` may raise `AttributeError` (GH14424)
- Correctly raise `ValueError` on empty input to `pd.eval()` and `df.query()` (GH13139)
- Bug in `RangeIndex.intersection` when result is a empty set (GH14364).
- Bug in groupby-transform broadcasting that could cause incorrect dtype coercion (GH14457)
- Bug in `Series.__setitem__` which allowed mutating read-only arrays (GH14359).
- Bug in `DataFrame.insert` where multiple calls with duplicate columns can fail (GH14291)
- `pd.merge()` will raise `ValueError` with non-boolean parameters in passed boolean type arguments (GH14434)
- Bug in `Timestamp` where dates very near the minimum (1677-09) could underflow on creation (GH14415)
- Bug in `pd.concat` where names of the keys were not propagated to the resulting `MultiIndex` (GH14252)
- Bug in `pd.concat` where `axis` cannot take string parameters 'rows' or 'columns' (GH14369)
- Bug in `pd.concat` with dataframes heterogeneous in length and tuple keys (GH14438)
- Bug in `MultiIndex.set_levels` where illegal level values were still set after raising an error (GH13754)
- Bug in `DataFrame.to_json` where `lines=True` and a value contained a `}` character (GH14391)
- Bug in `df.groupby` causing an `AttributeError` when grouping a single index frame by a column and the index level (GH14327)
- Bug in `df.groupby` where `TypeError` raised when `pd.Grouper(key=...)` is passed in a list (GH14334)
- Bug in `pd.pivot_table` may raise `TypeError` or `ValueError` when `index` or `columns` is not scalar and `values` is not specified (GH14380)

### 5.11.3 Version 0.19.0 (October 2, 2016)

This is a major release from 0.18.1 and includes number of API changes, several new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

Highlights include:

- `merge_asof()` for asof-style time-series joining, see [here](#)
- `.rolling()` is now time-series aware, see [here](#)
- `read_csv()` now supports parsing Categorical data, see [here](#)
- A function `union_categorical()` has been added for combining categoricals, see [here](#)
- `PeriodIndex` now has its own period dtype, and changed to be more consistent with other `Index` classes. See [here](#)
- Sparse data structures gained enhanced support of `int` and `bool` dtypes, see [here](#)
- Comparison operations with `Series` no longer ignores the index, see [here](#) for an overview of the API changes.
- Introduction of a pandas development API for utility functions, see [here](#).
- Deprecation of `Panel4D` and `PanelND`. We recommend to represent these types of n-dimensional data with the [xarray](#) package.
- Removal of the previously deprecated modules `pandas.io.data`, `pandas.io.wb`, `pandas.tools.rplot`.

**Warning:** pandas >= 0.19.0 will no longer silence numpy ufunc warnings upon import, see [here](#).

#### What's new in v0.19.0

- *New features*
  - *Function `merge_asof` for asof-style time-series joining*
  - *Method `.rolling()` is now time-series aware*
  - *Method `read_csv` has improved support for duplicate column names*
  - *Method `read_csv` supports parsing Categorical directly*
  - *Categorical concatenation*
  - *Semi-month offsets*
  - *New Index methods*
  - *Google BigQuery enhancements*
  - *Fine-grained NumPy errstate*
  - *Method `get_dummies` now returns integer dtypes*
  - *Downcast values to smallest possible dtype in `to_numeric`*
  - *pandas development API*
  - *Other enhancements*
- *API changes*

- *Series.tolist()* will now return Python types
- *Series operators for different indexes*
  - \* *Arithmetic operators*
  - \* *Comparison operators*
  - \* *Logical operators*
  - \* *Flexible comparison methods*
- *Series type promotion on assignment*
- *Function .to\_datetime() changes*
- *Merging changes*
- *Method .describe() changes*
- *Period changes*
  - \* *The PeriodIndex now has period dtype*
  - \* *Period('NaT') now returns pd.NaT*
  - \* *PeriodIndex.values now returns array of Period object*
- *Index + / - no longer used for set operations*
- *Index.difference and .symmetric\_difference changes*
- *Index.unique consistently returns Index*
- *MultiIndex constructors, groupby and set\_index preserve categorical dtypes*
- *Function read\_csv will progressively enumerate chunks*
- *Sparse changes*
  - \* *Types int64 and bool support enhancements*
  - \* *Operators now preserve dtypes*
  - \* *Other sparse fixes*
- *Indexer dtype changes*
- *Other API changes*
- *Deprecations*
- *Removal of prior version deprecations/changes*
- *Performance improvements*
- *Bug fixes*
- *Contributors*

## New features

### Function `merge_asof` for asof-style time-series joining

A long-time requested feature has been added through the `merge_asof()` function, to support asof style joining of time-series ([GH1870](#), [GH13695](#), [GH13709](#), [GH13902](#)). Full documentation is [here](#).

The `merge_asof()` performs an asof merge, which is similar to a left-join except that we match on nearest key rather than equal keys.

```
In [1]: left = pd.DataFrame({"a": [1, 5, 10], "left_val": ["a", "b", "c"]})
In [2]: right = pd.DataFrame({"a": [1, 2, 3, 6, 7], "right_val": [1, 2, 3, 6, 7]})

In [3]: left
Out[3]:
 a left_val
0 1 a
1 5 b
2 10 c

[3 rows x 2 columns]

In [4]: right
Out[4]:
 a right_val
0 1 1
1 2 2
2 3 3
3 6 6
4 7 7

[5 rows x 2 columns]
```

We typically want to match exactly when possible, and use the most recent value otherwise.

```
In [5]: pd.merge_asof(left, right, on="a")
Out[5]:
 a left_val right_val
0 1 a 1
1 5 b 3
2 10 c 7

[3 rows x 3 columns]
```

We can also match rows ONLY with prior data, and not an exact match.

```
In [6]: pd.merge_asof(left, right, on="a", allow_exact_matches=False)
Out[6]:
 a left_val right_val
0 1 a NaN
1 5 b 3.0
2 10 c 7.0
```

(continues on next page)

(continued from previous page)

[3 rows x 3 columns]

In a typical time-series example, we have trades and quotes and we want to asof-join them. This also illustrates using the by parameter to group data before merging.

```
In [7]: trades = pd.DataFrame(
...: {
...: "time": pd.to_datetime(
...: [
...: "20160525 13:30:00.023",
...: "20160525 13:30:00.038",
...: "20160525 13:30:00.048",
...: "20160525 13:30:00.048",
...: "20160525 13:30:00.048",
...:]
...:),
...: "ticker": ["MSFT", "MSFT", "GOOG", "GOOG", "AAPL"],
...: "price": [51.95, 51.95, 720.77, 720.92, 98.00],
...: "quantity": [75, 155, 100, 100, 100],
...: },
...: columns=["time", "ticker", "price", "quantity"],
...:)
...:
```

```
In [8]: quotes = pd.DataFrame(
...: {
...: "time": pd.to_datetime(
...: [
...: "20160525 13:30:00.023",
...: "20160525 13:30:00.023",
...: "20160525 13:30:00.030",
...: "20160525 13:30:00.041",
...: "20160525 13:30:00.048",
...: "20160525 13:30:00.049",
...: "20160525 13:30:00.072",
...: "20160525 13:30:00.075",
...:]
...:),
...: "ticker": ["GOOG", "MSFT", "MSFT", "MSFT", "GOOG", "AAPL", "GOOG", "MSFT
↪"],
...: "bid": [720.50, 51.95, 51.97, 51.99, 720.50, 97.99, 720.50, 52.01],
...: "ask": [720.93, 51.96, 51.98, 52.00, 720.93, 98.01, 720.88, 52.03],
...: },
...: columns=["time", "ticker", "bid", "ask"],
...:)
...:
```

In [9]: trades

Out[9]:

|   | time                    | ticker | price | quantity |
|---|-------------------------|--------|-------|----------|
| 0 | 2016-05-25 13:30:00.023 | MSFT   | 51.95 | 75       |

(continues on next page)

(continued from previous page)

```

```

```
[5 rows x 4 columns]
```

```
In [10]: quotes
```

```
Out[10]:
```

```

 time ticker bid ask
0 2016-05-25 13:30:00.023 GOOG 720.50 720.93
1 2016-05-25 13:30:00.023 MSFT 51.95 51.96
2 2016-05-25 13:30:00.030 MSFT 51.97 51.98
3 2016-05-25 13:30:00.041 MSFT 51.99 52.00
4 2016-05-25 13:30:00.048 GOOG 720.50 720.93
5 2016-05-25 13:30:00.049 AAPL 97.99 98.01
6 2016-05-25 13:30:00.072 GOOG 720.50 720.88
7 2016-05-25 13:30:00.075 MSFT 52.01 52.03

```

```
[8 rows x 4 columns]
```

An asof merge joins on the `on`, typically a datetimelike field, which is ordered, and in this case we are using a grouper in the `by` field. This is like a left-outer join, except that forward filling happens automatically taking the most recent non-`NaN` value.

```
In [11]: pd.merge_asof(trades, quotes, on="time", by="ticker")
```

```
Out[11]:
```

```

 time ticker price quantity bid ask
0 2016-05-25 13:30:00.023 MSFT 51.95 75 51.95 51.96
1 2016-05-25 13:30:00.038 MSFT 51.95 155 51.97 51.98
2 2016-05-25 13:30:00.048 GOOG 720.77 100 720.50 720.93
3 2016-05-25 13:30:00.048 GOOG 720.92 100 720.50 720.93
4 2016-05-25 13:30:00.048 AAPL 98.00 100 NaN NaN

```

```
[5 rows x 6 columns]
```

This returns a merged DataFrame with the entries in the same order as the original left passed DataFrame (`trades` in this case), with the fields of the quotes merged.

### Method `.rolling()` is now time-series aware

`.rolling()` objects are now time-series aware and can accept a time-series offset (or convertible) for the `window` argument ([GH13327](#), [GH12995](#)). See the full documentation [here](#).

```

In [12]: dft = pd.DataFrame(
.....: {"B": [0, 1, 2, np.nan, 4]},
.....: index=pd.date_range("20130101 09:00:00", periods=5, freq="s"),
.....:)
.....:

```

```
In [13]: dft
```

(continues on next page)

(continued from previous page)

**Out[13]:**

```

 B
2013-01-01 09:00:00 0.0
2013-01-01 09:00:01 1.0
2013-01-01 09:00:02 2.0
2013-01-01 09:00:03 NaN
2013-01-01 09:00:04 4.0

```

[5 rows x 1 columns]

This is a regular frequency index. Using an integer window parameter works to roll along the window frequency.

**In [14]:** `dft.rolling(2).sum()`**Out[14]:**

```

 B
2013-01-01 09:00:00 NaN
2013-01-01 09:00:01 1.0
2013-01-01 09:00:02 3.0
2013-01-01 09:00:03 NaN
2013-01-01 09:00:04 NaN

```

[5 rows x 1 columns]

**In [15]:** `dft.rolling(2, min_periods=1).sum()`**Out[15]:**

```

 B
2013-01-01 09:00:00 0.0
2013-01-01 09:00:01 1.0
2013-01-01 09:00:02 3.0
2013-01-01 09:00:03 2.0
2013-01-01 09:00:04 4.0

```

[5 rows x 1 columns]

Specifying an offset allows a more intuitive specification of the rolling frequency.

**In [16]:** `dft.rolling("2s").sum()`**Out[16]:**

```

 B
2013-01-01 09:00:00 0.0
2013-01-01 09:00:01 1.0
2013-01-01 09:00:02 3.0
2013-01-01 09:00:03 2.0
2013-01-01 09:00:04 4.0

```

[5 rows x 1 columns]

Using a non-regular, but still monotonic index, rolling with an integer window does not impart any special calculation.

```

In [17]: dft = pd.DataFrame(
.....: {"B": [0, 1, 2, np.nan, 4]},
.....: index=pd.Index(
.....: [

```

(continues on next page)

(continued from previous page)

```

.....: pd.Timestamp("20130101 09:00:00"),
.....: pd.Timestamp("20130101 09:00:02"),
.....: pd.Timestamp("20130101 09:00:03"),
.....: pd.Timestamp("20130101 09:00:05"),
.....: pd.Timestamp("20130101 09:00:06"),
.....:],
.....: name="foo",
.....:),
.....:)
.....:
In [18]: dft
Out[18]:
 B
foo
2013-01-01 09:00:00 0.0
2013-01-01 09:00:02 1.0
2013-01-01 09:00:03 2.0
2013-01-01 09:00:05 NaN
2013-01-01 09:00:06 4.0

[5 rows x 1 columns]

In [19]: dft.rolling(2).sum()
Out[19]:
 B
foo
2013-01-01 09:00:00 NaN
2013-01-01 09:00:02 1.0
2013-01-01 09:00:03 3.0
2013-01-01 09:00:05 NaN
2013-01-01 09:00:06 NaN

[5 rows x 1 columns]

```

Using the time-specification generates variable windows for this sparse data.

```

In [20]: dft.rolling("2s").sum()
Out[20]:
 B
foo
2013-01-01 09:00:00 0.0
2013-01-01 09:00:02 1.0
2013-01-01 09:00:03 3.0
2013-01-01 09:00:05 NaN
2013-01-01 09:00:06 4.0

[5 rows x 1 columns]

```

Furthermore, we now allow an optional `on` parameter to specify a column (rather than the default of the index) in a DataFrame.

```
In [21]: dft = dft.reset_index()
```

```
In [22]: dft
```

```
Out[22]:
```

```
 foo B

4 2013-01-01 09:00:06 4.0
```

```
[5 rows x 2 columns]
```

### Method `read_csv` has improved support for duplicate column names

*Duplicate column names* are now supported in `read_csv()` whether they are in the file or passed in as the names parameter (GH7160, GH9424)

```
In [24]: data = "0,1,2\n3,4,5"
```

```
In [25]: names = ["a", "b", "a"]
```

#### Previous behavior:

```
In [2]: pd.read_csv(StringIO(data), names=names)
```

```
Out[2]:
```

```
 a b a
0 2 1 2
1 5 4 5
```

The first a column contained the same data as the second a column, when it should have contained the values [0, 3].

#### New behavior:

```
In [26]: pd.read_csv(StringIO(data), names=names)
```

```

### Method `read_csv` supports parsing Categorical directly

The `read_csv()` function now supports parsing a Categorical column when specified as a dtype (GH10153). Depending on the structure of the data, this can result in a faster parse time and lower memory usage compared to converting to Categorical after parsing. See the [io docs here](#).

```

In [27]: data = """
.....: col1,col2,col3
.....: a,b,1
.....: a,b,2
.....: c,d,3
.....: """
.....:

```

(continues on next page)

(continued from previous page)

```

In [28]: pd.read_csv(StringIO(data))
Out[28]:
 col1 col2 col3
0 a b 1
1 a b 2
2 c d 3

[3 rows x 3 columns]

In [29]: pd.read_csv(StringIO(data)).dtypes
Out[29]:
col1 object
col2 object
col3 int64
Length: 3, dtype: object

In [30]: pd.read_csv(StringIO(data), dtype="category").dtypes
Out[30]:
col1 category
col2 category
col3 category
Length: 3, dtype: object

```

Individual columns can be parsed as a `Categorical` using a dict specification

```

In [31]: pd.read_csv(StringIO(data), dtype={"col1": "category"}).dtypes
Out[31]:
col1 category
col2 object
col3 int64
Length: 3, dtype: object

```

**Note:** The resulting categories will always be parsed as strings (object dtype). If the categories are numeric they can be converted using the `to_numeric()` function, or as appropriate, another converter such as `to_datetime()`.

```

In [32]: df = pd.read_csv(StringIO(data), dtype="category")

In [33]: df.dtypes
Out[33]:
col1 category
col2 category
col3 category
Length: 3, dtype: object

In [34]: df["col3"]
Out[34]:
0 1
1 2
2 3
Name: col3, Length: 3, dtype: category

```

(continues on next page)

(continued from previous page)

```
Categories (3, object): ['1', '2', '3']
```

```
In [35]: df["col3"].cat.categories = pd.to_numeric(df["col3"].cat.categories)
```

```
In [36]: df["col3"]
```

```
Out[36]:
```

```
0 1
1 2
2 3
```

```
Name: col3, Length: 3, dtype: category
```

```
Categories (3, int64): [1, 2, 3]
```

### Categorical concatenation

- A function `union_categoricals()` has been added for combining categoricals, see *Unioning Categoricals* (GH13361, GH13763, GH13846, GH14173)

```
In [37]: from pandas.api.types import union_categoricals
```

```
In [38]: a = pd.Categorical(["b", "c"])
```

```
In [39]: b = pd.Categorical(["a", "b"])
```

```
In [40]: union_categoricals([a, b])
```

```
Out[40]:
```

```
['b', 'c', 'a', 'b']
```

```
Categories (3, object): ['b', 'c', 'a']
```

- `concat` and `append` now can concat category dtypes with different categories as object dtype (GH13524)

```
In [41]: s1 = pd.Series(["a", "b"], dtype="category")
```

```
In [42]: s2 = pd.Series(["b", "c"], dtype="category")
```

#### Previous behavior:

```
In [1]: pd.concat([s1, s2])
```

```
ValueError: incompatible categories in categorical concat
```

#### New behavior:

```
In [43]: pd.concat([s1, s2])
```

```
Out[43]:
```

```
0 a
1 b
0 b
1 c
```

```
Length: 4, dtype: object
```

## Semi-month offsets

pandas has gained new frequency offsets, `SemiMonthEnd` ('SM') and `SemiMonthBegin` ('SMS'). These provide date offsets anchored (by default) to the 15th and end of month, and 15th and 1st of month respectively. (GH1543)

```
In [44]: from pandas.tseries.offsets import SemiMonthEnd, SemiMonthBegin
```

### SemiMonthEnd:

```
In [45]: pd.Timestamp("2016-01-01") + SemiMonthEnd()
```

```
Out[45]: Timestamp('2016-01-15 00:00:00')
```

```
In [46]: pd.date_range("2015-01-01", freq="SM", periods=4)
```

```
Out[46]: DatetimeIndex(['2015-01-15', '2015-01-31', '2015-02-15', '2015-02-28'], dtype=
↳ 'datetime64[ns]', freq='SM-15')
```

### SemiMonthBegin:

```
In [47]: pd.Timestamp("2016-01-01") + SemiMonthBegin()
```

```
Out[47]: Timestamp('2016-01-15 00:00:00')
```

```
In [48]: pd.date_range("2015-01-01", freq="SMS", periods=4)
```

```
Out[48]: DatetimeIndex(['2015-01-01', '2015-01-15', '2015-02-01', '2015-02-15'], dtype=
↳ 'datetime64[ns]', freq='SMS-15')
```

Using the anchoring suffix, you can also specify the day of month to use instead of the 15th.

```
In [49]: pd.date_range("2015-01-01", freq="SMS-16", periods=4)
```

```
Out[49]: DatetimeIndex(['2015-01-01', '2015-01-16', '2015-02-01', '2015-02-16'], dtype=
↳ 'datetime64[ns]', freq='SMS-16')
```

```
In [50]: pd.date_range("2015-01-01", freq="SM-14", periods=4)
```

```
Out[50]: DatetimeIndex(['2015-01-14', '2015-01-31', '2015-02-14', '2015-02-28'], dtype=
↳ 'datetime64[ns]', freq='SM-14')
```

## New Index methods

The following methods and options are added to `Index`, to be more consistent with the `Series` and `DataFrame` API.

`Index` now supports the `.where()` function for same shape indexing (GH13170)

```
In [51]: idx = pd.Index(["a", "b", "c"])
```

```
In [52]: idx.where([True, False, True])
```

```
Out[52]: Index(['a', nan, 'c'], dtype='object')
```

`Index` now supports `.dropna()` to exclude missing values (GH6194)

```
In [53]: idx = pd.Index([1, 2, np.nan, 4])
```

```
In [54]: idx.dropna()
```

```
Out[54]: Float64Index([1.0, 2.0, 4.0], dtype='float64')
```

For `MultiIndex`, values are dropped if any level is missing by default. Specifying `how='all'` only drops values where all levels are missing.

```
In [55]: midx = pd.MultiIndex.from_arrays([[1, 2, np.nan, 4], [1, 2, np.nan, np.nan]])
```

```
In [56]: midx
```

```
Out[56]:
```

```
MultiIndex([(1.0, 1.0),
 (2.0, 2.0),
 (nan, nan),
 (4.0, nan)],
)
```

```
In [57]: midx.dropna()
```

```
Out[57]:
```

```
MultiIndex([(1, 1),
 (2, 2)],
)
```

```
In [58]: midx.dropna(how="all")
```

```
Out[58]:
```

```
MultiIndex([(1, 1.0),
 (2, 2.0),
 (4, nan)],
)
```

Index now supports `.str.extractall()` which returns a `DataFrame`, see the *docs here* (GH10008, GH13156)

```
In [59]: idx = pd.Index(["a1a2", "b1", "c1"])
```

```
In [60]: idx.str.extractall(r"[ab](?P<digit>\d)")
```

```
Out[60]:
```

```
 digit
match
0 0 1
 1 2
1 0 1
```

```
[3 rows x 1 columns]
```

`Index.astype()` now accepts an optional boolean argument `copy`, which allows optional copying if the requirements on `dtype` are satisfied (GH13209)

## Google BigQuery enhancements

- The `read_gbq()` method has gained the `dialect` argument to allow users to specify whether to use BigQuery's legacy SQL or BigQuery's standard SQL. See the *docs* for more details (GH13615).
- The `to_gbq()` method now allows the `DataFrame` column order to differ from the destination table schema (GH11359).

## Fine-grained NumPy errstate

Previous versions of pandas would permanently silence numpy's ufunc error handling when pandas was imported. pandas did this in order to silence the warnings that would arise from using numpy ufuncs on missing data, which are usually represented as NaN s. Unfortunately, this silenced legitimate warnings arising in non-pandas code in the application. Starting with 0.19.0, pandas will use the `numpy.errstate` context manager to silence these warnings in a more fine-grained manner, only around where these operations are actually used in the pandas code base. (GH13109, GH13145)

After upgrading pandas, you may see *new* `RuntimeWarnings` being issued from your code. These are likely legitimate, and the underlying cause likely existed in the code when using previous versions of pandas that simply silenced the warning. Use `numpy.errstate` around the source of the `RuntimeWarning` to control how these conditions are handled.

## Method `get_dummies` now returns integer dtypes

The `pd.get_dummies` function now returns dummy-encoded columns as small integers, rather than floats (GH8725). This should provide an improved memory footprint.

### Previous behavior:

```
In [1]: pd.get_dummies(['a', 'b', 'a', 'c']).dtypes
```

```
Out[1]:
```

```
a float64
b float64
c float64
dtype: object
```

### New behavior:

```
In [61]: pd.get_dummies(["a", "b", "a", "c"]).dtypes
```

```
Out[61]:
```

```
a uint8
b uint8
c uint8
Length: 3, dtype: object
```

## Downcast values to smallest possible dtype in `to_numeric`

`pd.to_numeric()` now accepts a `downcast` parameter, which will downcast the data if possible to smallest specified numerical dtype (GH13352)

```
In [62]: s = ["1", 2, 3]
```

```
In [63]: pd.to_numeric(s, downcast="unsigned")
```

```
Out[63]: array([1, 2, 3], dtype=uint8)
```

```
In [64]: pd.to_numeric(s, downcast="integer")
```

```
Out[64]: array([1, 2, 3], dtype=int8)
```

## pandas development API

As part of making pandas API more uniform and accessible in the future, we have created a standard sub-package of pandas, `pandas.api` to hold public API's. We are starting by exposing type introspection functions in `pandas.api.types`. More sub-packages and officially sanctioned API's will be published in future versions of pandas ([GH13147](#), [GH13634](#))

The following are now part of this API:

```
In [65]: import pprint

In [66]: from pandas.api import types

In [67]: funcs = [f for f in dir(types) if not f.startswith("_")]

In [68]: pprint.pprint(funcs)
['CategoricalDtype',
 'DatetimeTZDtype',
 'IntervalDtype',
 'PeriodDtype',
 'infer_dtype',
 'is_array_like',
 'is_bool',
 'is_bool_dtype',
 'is_categorical',
 'is_categorical_dtype',
 'is_complex',
 'is_complex_dtype',
 'is_datetime64_any_dtype',
 'is_datetime64_dtype',
 'is_datetime64_ns_dtype',
 'is_datetime64tz_dtype',
 'is_dict_like',
 'is_dtype_equal',
 'is_extension_array_dtype',
 'is_extension_type',
 'is_file_like',
 'is_float',
 'is_float_dtype',
 'is_hashable',
 'is_int64_dtype',
 'is_integer',
 'is_integer_dtype',
 'is_interval',
 'is_interval_dtype',
 'is_iterator',
 'is_list_like',
 'is_named_tuple',
 'is_number',
 'is_numeric_dtype',
 'is_object_dtype',
 'is_period_dtype',
 'is_re',
```

(continues on next page)

(continued from previous page)

```
'is_re_compilable',
'is_scalar',
'is_signed_integer_dtype',
'is_sparse',
'is_string_dtype',
'is_timedelta64_dtype',
'is_timedelta64_ns_dtype',
'is_unsigned_integer_dtype',
'pandas_dtype',
'union_categoricals']
```

**Note:** Calling these functions from the internal module `pandas.core.common` will now show a `DeprecationWarning` (GH13990)

## Other enhancements

- `Timestamp` can now accept positional and keyword parameters similar to `datetime.datetime()` (GH10758, GH11630)

```
In [69]: pd.Timestamp(2012, 1, 1)
Out[69]: Timestamp('2012-01-01 00:00:00')
```

```
In [70]: pd.Timestamp(year=2012, month=1, day=1, hour=8, minute=30)
Out[70]: Timestamp('2012-01-01 08:30:00')
```

- The `.resample()` function now accepts a `on=` or `level=` parameter for resampling on a datetimelike column or `MultiIndex` level (GH13500)

```
In [71]: df = pd.DataFrame(
.....: {"date": pd.date_range("2015-01-01", freq="W", periods=5), "a": np.
↪ arange(5)},
.....: index=pd.MultiIndex.from_arrays(
.....: [[1, 2, 3, 4, 5], pd.date_range("2015-01-01", freq="W",
↪ periods=5)],
.....: names=["v", "d"],
.....:),
.....:)
.....:
```

```
In [72]: df
Out[72]:
```

|   |            | date       | a |
|---|------------|------------|---|
| v | d          |            |   |
| 1 | 2015-01-04 | 2015-01-04 | 0 |
| 2 | 2015-01-11 | 2015-01-11 | 1 |
| 3 | 2015-01-18 | 2015-01-18 | 2 |
| 4 | 2015-01-25 | 2015-01-25 | 3 |
| 5 | 2015-02-01 | 2015-02-01 | 4 |

(continues on next page)

(continued from previous page)

```
[5 rows x 2 columns]
In [73]: df.resample("M", on="date").sum()
Out[73]:
 a
date
2015-01-31 6
2015-02-28 4

[2 rows x 1 columns]
In [74]: df.resample("M", level="d").sum()
Out[74]:
 a
d
2015-01-31 6
2015-02-28 4

[2 rows x 1 columns]
```

- The `.get_credentials()` method of `GbqConnector` can now first try to fetch the application default credentials. See the docs for more details ([GH13577](#)).
- The `.tz_localize()` method of `DatetimeIndex` and `Timestamp` has gained the `errors` keyword, so you can potentially coerce nonexistent timestamps to `NaT`. The default behavior remains to raising a `NonExistentTimeError` ([GH13057](#)).
- `.to_hdf/read_hdf()` now accept path objects (e.g. `pathlib.Path`, `py.path.local`) for the file path ([GH11773](#)).
- The `pd.read_csv()` with `engine='python'` has gained support for the `decimal` ([GH12933](#)), `na_filter` ([GH13321](#)) and the `memory_map` option ([GH13381](#)).
- Consistent with the Python API, `pd.read_csv()` will now interpret `+inf` as positive infinity ([GH13274](#)).
- The `pd.read_html()` has gained support for the `na_values`, `converters`, `keep_default_na` options ([GH13461](#)).
- `Categorical.astype()` now accepts an optional boolean argument `copy`, effective when `dtype` is categorical ([GH13209](#)).
- `DataFrame` has gained the `.asof()` method to return the last non-`NaN` values according to the selected subset ([GH13358](#)).
- The `DataFrame` constructor will now respect key ordering if a list of `OrderedDict` objects are passed in ([GH13304](#)).
- `pd.read_html()` has gained support for the `decimal` option ([GH12907](#)).
- `Series` has gained the properties `.is_monotonic`, `.is_monotonic_increasing`, `.is_monotonic_decreasing`, similar to `Index` ([GH13336](#)).
- `DataFrame.to_sql()` now allows a single value as the SQL type for all columns ([GH11886](#)).
- `Series.append` now supports the `ignore_index` option ([GH13677](#)).
- `.to_stata()` and `StataWriter` can now write variable labels to Stata dta files using a dictionary to make column names to labels ([GH13535](#), [GH13536](#)).

- `.to_stata()` and `StataWriter` will automatically convert `datetime64[ns]` columns to Stata format `%tc`, rather than raising a `ValueError` (GH12259)
- `read_stata()` and `StataReader` raise with a more explicit error message when reading Stata files with repeated value labels when `convert_categoricals=True` (GH13923)
- `DataFrame.style` will now render sparsified `MultiIndexes` (GH11655)
- `DataFrame.style` will now show column level names (e.g. `DataFrame.columns.names`) (GH13775)
- `DataFrame` has gained support to re-order the columns based on the values in a row using `df.sort_values(by='...', axis=1)` (GH10806)

```
In [75]: df = pd.DataFrame({"A": [2, 7], "B": [3, 5], "C": [4, 8]}, index=["row1",
→"row2"])
```

```
In [76]: df
```

```
Out[76]:
 A B C
row1 2 3 4
row2 7 5 8
```

```
[2 rows x 3 columns]
```

```
In [77]: df.sort_values(by="row2", axis=1)
```

```
Out[77]:
 B A C
row1 3 2 4
row2 5 7 8
```

```
[2 rows x 3 columns]
```

- Added documentation to *I/O* regarding the perils of reading in columns with mixed dtypes and how to handle it (GH13746)
- `to_html()` now has a `border` argument to control the value in the opening `<table>` tag. The default is the value of the `html.border` option, which defaults to 1. This also affects the notebook HTML repr, but since Jupyter's CSS includes a `border-width` attribute, the visual effect is the same. (GH11563)
- Raise `ImportError` in the `sql` functions when `sqlalchemy` is not installed and a connection string is used (GH11920).
- Compatibility with `matplotlib` 2.0. Older versions of `pandas` should also work with `matplotlib` 2.0 (GH13333)
- `Timestamp`, `Period`, `DatetimeIndex`, `PeriodIndex` and `.dt` accessor have gained a `.is_leap_year` property to check whether the date belongs to a leap year. (GH13727)
- `astype()` will now accept a dict of column name to data types mapping as the `dtype` argument. (GH12086)
- The `pd.read_json` and `DataFrame.to_json` has gained support for reading and writing json lines with `lines` option see *Line delimited json* (GH9180)
- `read_excel()` now supports the `true_values` and `false_values` keyword arguments (GH13347)
- `groupby()` will now accept a scalar and a single-element list for specifying `level` on a non-`MultiIndex` grouper. (GH13907)
- Non-convertible dates in an excel date column will be returned without conversion and the column will be object dtype, rather than raising an exception (GH10001).
- `pd.Timedelta(None)` is now accepted and will return `NaT`, mirroring `pd.Timestamp` (GH13687)

- `pd.read_stata()` can now handle some format 111 files, which are produced by SAS when generating Stata dta files (GH11526)
- `Series` and `Index` now support `divmod` which will return a tuple of series or indices. This behaves like a standard binary operator with regards to broadcasting rules (GH14208).

### API changes

#### `Series.tolist()` will now return Python types

`Series.tolist()` will now return Python types in the output, mimicking NumPy `.tolist()` behavior (GH10904)

```
In [78]: s = pd.Series([1, 2, 3])
```

#### Previous behavior:

```
In [7]: type(s.tolist()[0])
Out[7]:
<class 'numpy.int64'>
```

#### New behavior:

```
In [79]: type(s.tolist()[0])
Out[79]: int
```

### Series operators for different indexes

Following `Series` operators have been changed to make all operators consistent, including `DataFrame` (GH1134, GH4581, GH13538)

- `Series` comparison operators now raise `ValueError` when `index` are different.
- `Series` logical operators align both `index` of left and right hand side.

**Warning:** Until 0.18.1, comparing `Series` with the same length, would succeed even if the `.index` are different (the result ignores `.index`). As of 0.19.0, this will raise `ValueError` to be more strict. This section also describes how to keep previous behavior or align different indexes, using the flexible comparison methods like `.eq`.

As a result, `Series` and `DataFrame` operators behave as below:

### Arithmetic operators

Arithmetic operators align both `index` (no changes).

```
In [80]: s1 = pd.Series([1, 2, 3], index=list("ABC"))
In [81]: s2 = pd.Series([2, 2, 2], index=list("ABD"))
In [82]: s1 + s2
Out[82]:
A 3.0
```

(continues on next page)

(continued from previous page)

```

B 4.0
C NaN
D NaN
Length: 4, dtype: float64

In [83]: df1 = pd.DataFrame([1, 2, 3], index=list("ABC"))

In [84]: df2 = pd.DataFrame([2, 2, 2], index=list("ABD"))

In [85]: df1 + df2
Out[85]:
 0
A 3.0
B 4.0
C NaN
D NaN

[4 rows x 1 columns]
```

## Comparison operators

Comparison operators raise `ValueError` when `.index` are different.

### Previous behavior (Series):

Series compared values ignoring the `.index` as long as both had the same length:

```

In [1]: s1 == s2
Out[1]:
A False
B True
C False
dtype: bool
```

### New behavior (Series):

```

In [2]: s1 == s2
Out[2]:
ValueError: Can only compare identically-labeled Series objects
```

**Note:** To achieve the same result as previous versions (compare values based on locations ignoring `.index`), compare both `.values`.

```

In [86]: s1.values == s2.values
Out[86]: array([False, True, False])
```

If you want to compare Series aligning its `.index`, see flexible comparison methods section below:

```

In [87]: s1.eq(s2)
Out[87]:
A False
```

(continues on next page)

(continued from previous page)

```
B True
C False
D False
Length: 4, dtype: bool
```

**Current behavior** (DataFrame, no change):

```
In [3]: df1 == df2
Out[3]:
ValueError: Can only compare identically-labeled DataFrame objects
```

## Logical operators

Logical operators align both `.index` of left and right hand side.

**Previous behavior** (Series), only left hand side index was kept:

```
In [4]: s1 = pd.Series([True, False, True], index=list('ABC'))
In [5]: s2 = pd.Series([True, True, True], index=list('ABD'))
In [6]: s1 & s2
Out[6]:
A True
B False
C False
dtype: bool
```

**New behavior** (Series):

```
In [88]: s1 = pd.Series([True, False, True], index=list("ABC"))
In [89]: s2 = pd.Series([True, True, True], index=list("ABD"))

In [90]: s1 & s2
Out[90]:
A True
B False
C False
D False
Length: 4, dtype: bool
```

---

**Note:** Series logical operators fill a NaN result with False.

---

**Note:** To achieve the same result as previous versions (compare values based on only left hand side index), you can use `reindex_like`:

```
In [91]: s1 & s2.reindex_like(s1)
Out[91]:
A True
```

(continues on next page)

(continued from previous page)

```
B False
C False
Length: 3, dtype: bool
```

**Current behavior** (DataFrame, no change):

```
In [92]: df1 = pd.DataFrame([True, False, True], index=list("ABC"))
In [93]: df2 = pd.DataFrame([True, True, True], index=list("ABD"))
In [94]: df1 & df2
Out[94]:
 0
A True
B False
C False
D False

[4 rows x 1 columns]
```

### Flexible comparison methods

Series flexible comparison methods like `eq`, `ne`, `le`, `lt`, `ge` and `gt` now align both index. Use these operators if you want to compare two Series which has the different index.

```
In [95]: s1 = pd.Series([1, 2, 3], index=["a", "b", "c"])
In [96]: s2 = pd.Series([2, 2, 2], index=["b", "c", "d"])
In [97]: s1.eq(s2)
Out[97]:
a False
b True
c False
d False
Length: 4, dtype: bool
In [98]: s1.ge(s2)
Out[98]:
a False
b True
c True
d False
Length: 4, dtype: bool
```

Previously, this worked the same as comparison operators (see above).

## Series type promotion on assignment

A Series will now correctly promote its dtype for assignment with incompat values to the current dtype (GH13234)

```
In [99]: s = pd.Series()
```

### Previous behavior:

```
In [2]: s["a"] = pd.Timestamp("2016-01-01")
```

```
In [3]: s["b"] = 3.0
TypeError: invalid type promotion
```

### New behavior:

```
In [100]: s["a"] = pd.Timestamp("2016-01-01")
```

```
In [101]: s["b"] = 3.0
```

```
In [102]: s
Out[102]:
a 2016-01-01 00:00:00
b 3.0
Length: 2, dtype: object
```

```
In [103]: s.dtype
Out[103]: dtype('O')
```

## Function `.to_datetime()` changes

Previously if `.to_datetime()` encountered mixed integers/floats and strings, but no datetimes with `errors='coerce'` it would convert all to NaT.

### Previous behavior:

```
In [2]: pd.to_datetime([1, 'foo'], errors='coerce')
Out[2]: DatetimeIndex(['NaT', 'NaT'], dtype='datetime64[ns]', freq=None)
```

### Current behavior:

This will now convert integers/floats with the default unit of ns.

```
In [104]: pd.to_datetime([1, "foo"], errors="coerce")
Out[104]: DatetimeIndex(['1970-01-01 00:00:00.000000001', 'NaT'], dtype='datetime64[ns]',
→ freq=None)
```

Bug fixes related to `.to_datetime()`:

- Bug in `pd.to_datetime()` when passing integers or floats, and no unit and `errors='coerce'` (GH13180).
- Bug in `pd.to_datetime()` when passing invalid data types (e.g. `bool`); will now respect the `errors` keyword (GH13176)
- Bug in `pd.to_datetime()` which overflowed on `int8`, and `int16` dtypes (GH13451)

- Bug in `pd.to_datetime()` raise `AttributeError` with `NaN` and the other string is not valid when `errors='ignore'` ([GH12424](#))
- Bug in `pd.to_datetime()` did not cast floats correctly when `unit` was specified, resulting in truncated datetime ([GH13834](#))

## Merging changes

Merging will now preserve the dtype of the join keys ([GH8596](#))

```
In [105]: df1 = pd.DataFrame({"key": [1], "v1": [10]})

In [106]: df1
Out[106]:
 key v1
0 1 10

[1 rows x 2 columns]

In [107]: df2 = pd.DataFrame({"key": [1, 2], "v1": [20, 30]})

In [108]: df2
Out[108]:
 key v1
0 1 20
1 2 30

[2 rows x 2 columns]
```

### Previous behavior:

```
In [5]: pd.merge(df1, df2, how='outer')
Out[5]:
 key v1
0 1.0 10.0
1 1.0 20.0
2 2.0 30.0

In [6]: pd.merge(df1, df2, how='outer').dtypes
Out[6]:
key float64
v1 float64
dtype: object
```

### New behavior:

We are able to preserve the join keys

```
In [109]: pd.merge(df1, df2, how="outer")
Out[109]:
 key v1
0 1 10
1 1 20
2 2 30
```

(continues on next page)

(continued from previous page)

```
[3 rows x 2 columns]
In [110]: pd.merge(df1, df2, how="outer").dtypes
Out[110]:
key int64
v1 int64
Length: 2, dtype: object
```

Of course if you have missing values that are introduced, then the resulting dtype will be upcast, which is unchanged from previous.

```
In [111]: pd.merge(df1, df2, how="outer", on="key")
Out[111]:
 key v1_x v1_y
0 1 10.0 20
1 2 NaN 30

[2 rows x 3 columns]

In [112]: pd.merge(df1, df2, how="outer", on="key").dtypes
Out[112]:
key int64
v1_x float64
v1_y int64
Length: 3, dtype: object
```

### Method `.describe()` changes

Percentile identifiers in the index of a `.describe()` output will now be rounded to the least precision that keeps them distinct ([GH13104](#))

```
In [113]: s = pd.Series([0, 1, 2, 3, 4])
In [114]: df = pd.DataFrame([0, 1, 2, 3, 4])
```

#### Previous behavior:

The percentiles were rounded to at most one decimal place, which could raise `ValueError` for a data frame if the percentiles were duplicated.

```
In [3]: s.describe(percentiles=[0.0001, 0.0005, 0.001, 0.999, 0.9995, 0.9999])
Out[3]:
count 5.000000
mean 2.000000
std 1.581139
min 0.000000
0.0% 0.000400
0.1% 0.002000
0.1% 0.004000
50% 2.000000
99.9% 3.996000
```

(continues on next page)

(continued from previous page)

```

100.0% 3.998000
100.0% 3.999600
max 4.000000
dtype: float64

```

```
In [4]: df.describe(percentiles=[0.0001, 0.0005, 0.001, 0.999, 0.9995, 0.9999])
```

```
Out[4]:
```

```
...
```

```
ValueError: cannot reindex from a duplicate axis
```

#### New behavior:

```
In [115]: s.describe(percentiles=[0.0001, 0.0005, 0.001, 0.999, 0.9995, 0.9999])
```

```
Out[115]:
```

```

count 5.000000
mean 2.000000
std 1.581139
min 0.000000
0.01% 0.000400
0.05% 0.002000
0.1% 0.004000
50% 2.000000
99.9% 3.996000
99.95% 3.998000
99.99% 3.999600
max 4.000000

```

```
Length: 12, dtype: float64
```

```
In [116]: df.describe(percentiles=[0.0001, 0.0005, 0.001, 0.999, 0.9995, 0.9999])
```

```
Out[116]:
```

```

 0
count 5.000000
mean 2.000000
std 1.581139
min 0.000000
0.01% 0.000400
0.05% 0.002000
0.1% 0.004000
50% 2.000000
99.9% 3.996000
99.95% 3.998000
99.99% 3.999600
max 4.000000

```

```
[12 rows x 1 columns]
```

#### Furthermore:

- Passing duplicated percentiles will now raise a `ValueError`.
- Bug in `.describe()` on a `DataFrame` with a mixed-dtype column index, which would previously raise a `TypeError` ([GH13288](#))

## Period changes

### The PeriodIndex now has period dtype

PeriodIndex now has its own period dtype. The period dtype is a pandas extension dtype like category or the *timezone aware dtype* (datetime64[ns, tz]) (GH13941). As a consequence of this change, PeriodIndex no longer has an integer dtype:

#### Previous behavior:

```
In [1]: pi = pd.PeriodIndex(['2016-08-01'], freq='D')
In [2]: pi
Out[2]: PeriodIndex(['2016-08-01'], dtype='int64', freq='D')
In [3]: pd.api.types.is_integer_dtype(pi)
Out[3]: True
In [4]: pi.dtype
Out[4]: dtype('int64')
```

#### New behavior:

```
In [117]: pi = pd.PeriodIndex(["2016-08-01"], freq="D")
In [118]: pi
Out[118]: PeriodIndex(['2016-08-01'], dtype='period[D]')
In [119]: pd.api.types.is_integer_dtype(pi)
Out[119]: False
In [120]: pd.api.types.is_period_dtype(pi)
Out[120]: True
In [121]: pi.dtype
Out[121]: period[D]
In [122]: type(pi.dtype)
Out[122]: pandas.core.dtypes.dtypes.PeriodDtype
```

### Period('NaT') now returns pd.NaT

Previously, Period has its own Period('NaT') representation different from pd.NaT. Now Period('NaT') has been changed to return pd.NaT. (GH12759, GH13582)

#### Previous behavior:

```
In [5]: pd.Period('NaT', freq='D')
Out[5]: Period('NaT', 'D')
```

#### New behavior:

These result in pd.NaT without providing freq option.

```
In [123]: pd.Period("NaT")
Out[123]: NaT
```

```
In [124]: pd.Period(None)
Out[124]: NaT
```

To be compatible with `Period` addition and subtraction, `pd.NaT` now supports addition and subtraction with `int`. Previously it raised `ValueError`.

#### Previous behavior:

```
In [5]: pd.NaT + 1
...
ValueError: Cannot add integral value to Timestamp without freq.
```

#### New behavior:

```
In [125]: pd.NaT + 1
Out[125]: NaT

In [126]: pd.NaT - 1
Out[126]: NaT
```

### PeriodIndex.values now returns array of Period object

`.values` is changed to return an array of `Period` objects, rather than an array of integers ([GH13988](#)).

#### Previous behavior:

```
In [6]: pi = pd.PeriodIndex(['2011-01', '2011-02'], freq='M')
In [7]: pi.values
Out[7]: array([492, 493])
```

#### New behavior:

```
In [127]: pi = pd.PeriodIndex(["2011-01", "2011-02"], freq="M")

In [128]: pi.values
Out[128]: array([Period('2011-01', 'M'), Period('2011-02', 'M')], dtype=object)
```

### Index + / - no longer used for set operations

Addition and subtraction of the base `Index` type and of `DatetimeIndex` (not the numeric index types) previously performed set operations (set union and difference). This behavior was already deprecated since 0.15.0 (in favor using the specific `.union()` and `.difference()` methods), and is now disabled. When possible, `+` and `-` are now used for element-wise operations, for example for concatenating strings or subtracting datetimes ([GH8227](#), [GH14127](#)).

#### Previous behavior:

```
In [1]: pd.Index(['a', 'b']) + pd.Index(['a', 'c'])
FutureWarning: using '+' to provide set union with Indexes is deprecated, use '|' or .
↳union()
Out[1]: Index(['a', 'b', 'c'], dtype='object')
```

**New behavior:** the same operation will now perform element-wise addition:

```
In [129]: pd.Index(["a", "b"]) + pd.Index(["a", "c"])
Out[129]: Index(['aa', 'bc'], dtype='object')
```

Note that numeric Index objects already performed element-wise operations. For example, the behavior of adding two integer Indexes is unchanged. The base Index is now made consistent with this behavior.

```
In [130]: pd.Index([1, 2, 3]) + pd.Index([2, 3, 4])
Out[130]: Int64Index([3, 5, 7], dtype='int64')
```

Further, because of this change, it is now possible to subtract two DatetimeIndex objects resulting in a TimedeltaIndex:

**Previous behavior:**

```
In [1]: (pd.DatetimeIndex(['2016-01-01', '2016-01-02'])
...: - pd.DatetimeIndex(['2016-01-02', '2016-01-03']))
FutureWarning: using '-' to provide set differences with datetimelike Indexes is
↳ deprecated, use .difference()
Out[1]: DatetimeIndex(['2016-01-01'], dtype='datetime64[ns]', freq=None)
```

**New behavior:**

```
In [131]: (
...: pd.DatetimeIndex(["2016-01-01", "2016-01-02"])
...: - pd.DatetimeIndex(["2016-01-02", "2016-01-03"])
...:)
...:
Out[131]: TimedeltaIndex(['-1 days', '-1 days'], dtype='timedelta64[ns]', freq=None)
```

### Index.difference and .symmetric\_difference changes

Index.difference and Index.symmetric\_difference will now, more consistently, treat NaN values as any other values. (GH13514)

```
In [132]: idx1 = pd.Index([1, 2, 3, np.nan])
```

```
In [133]: idx2 = pd.Index([0, 1, np.nan])
```

**Previous behavior:**

```
In [3]: idx1.difference(idx2)
Out[3]: Float64Index([nan, 2.0, 3.0], dtype='float64')

In [4]: idx1.symmetric_difference(idx2)
Out[4]: Float64Index([0.0, nan, 2.0, 3.0], dtype='float64')
```

**New behavior:**

```
In [134]: idx1.difference(idx2)
Out[134]: Float64Index([2.0, 3.0], dtype='float64')

In [135]: idx1.symmetric_difference(idx2)
Out[135]: Float64Index([0.0, 2.0, 3.0], dtype='float64')
```

### Index.unique consistently returns Index

Index.unique() now returns unique values as an Index of the appropriate dtype. (GH13395). Previously, most Index classes returned np.ndarray, and DatetimeIndex, TimedeltaIndex and PeriodIndex returned Index to keep metadata like timezone.

#### Previous behavior:

```
In [1]: pd.Index([1, 2, 3]).unique()
Out[1]: array([1, 2, 3])

In [2]: pd.DatetimeIndex(['2011-01-01', '2011-01-02',
.....: '2011-01-03'], tz='Asia/Tokyo').unique()
Out[2]:
DatetimeIndex(['2011-01-01 00:00:00+09:00', '2011-01-02 00:00:00+09:00',
 '2011-01-03 00:00:00+09:00'],
 dtype='datetime64[ns, Asia/Tokyo]', freq=None)
```

#### New behavior:

```
In [136]: pd.Index([1, 2, 3]).unique()
Out[136]: Int64Index([1, 2, 3], dtype='int64')

In [137]: pd.DatetimeIndex(
.....: ["2011-01-01", "2011-01-02", "2011-01-03"], tz="Asia/Tokyo"
.....:).unique()
.....:
Out[137]:
DatetimeIndex(['2011-01-01 00:00:00+09:00', '2011-01-02 00:00:00+09:00',
 '2011-01-03 00:00:00+09:00'],
 dtype='datetime64[ns, Asia/Tokyo]', freq=None)
```

### MultiIndex constructors, groupby and set\_index preserve categorical dtypes

MultiIndex.from\_arrays and MultiIndex.from\_product will now preserve categorical dtype in MultiIndex levels (GH13743, GH13854).

```
In [138]: cat = pd.Categorical(["a", "b"], categories=list("bac"))

In [139]: lvl1 = ["foo", "bar"]

In [140]: midx = pd.MultiIndex.from_arrays([cat, lvl1])

In [141]: midx
Out[141]:
MultiIndex([(a, 'foo'),
 (b, 'bar')],
)
```

#### Previous behavior:

```
In [4]: midx.levels[0]
Out[4]: Index(['b', 'a', 'c'], dtype='object')
```

(continues on next page)

(continued from previous page)

```
In [5]: midx.get_level_values[0]
Out[5]: Index(['a', 'b'], dtype='object')
```

**New behavior:** the single level is now a CategoricalIndex:

```
In [142]: midx.levels[0]
Out[142]: CategoricalIndex(['b', 'a', 'c'], categories=['b', 'a', 'c'], ordered=False,
↳ dtype='category')

In [143]: midx.get_level_values(0)
Out[143]: CategoricalIndex(['a', 'b'], categories=['b', 'a', 'c'], ordered=False, dtype=
↳ 'category')
```

An analogous change has been made to `MultiIndex.from_product`. As a consequence, `groupby` and `set_index` also preserve categorical dtypes in indexes

```
In [144]: df = pd.DataFrame({"A": [0, 1], "B": [10, 11], "C": cat})

In [145]: df_grouped = df.groupby(by=["A", "C"]).first()

In [146]: df_set_idx = df.set_index(["A", "C"])
```

**Previous behavior:**

```
In [11]: df_grouped.index.levels[1]
Out[11]: Index(['b', 'a', 'c'], dtype='object', name='C')
In [12]: df_grouped.reset_index().dtypes
Out[12]:
A int64
C object
B float64
dtype: object

In [13]: df_set_idx.index.levels[1]
Out[13]: Index(['b', 'a', 'c'], dtype='object', name='C')
In [14]: df_set_idx.reset_index().dtypes
Out[14]:
A int64
C object
B int64
dtype: object
```

**New behavior:**

```
In [147]: df_grouped.index.levels[1]
Out[147]: CategoricalIndex(['b', 'a', 'c'], categories=['b', 'a', 'c'], ordered=False,
↳ dtype='category', name='C')

In [148]: df_grouped.reset_index().dtypes
Out[148]:
A int64
C category
```

(continues on next page)

(continued from previous page)

```

B float64
Length: 3, dtype: object

In [149]: df_set_idx.index.levels[1]
Out[149]: CategoricalIndex(['b', 'a', 'c'], categories=['b', 'a', 'c'], ordered=False,
↳dtype='category', name='C')

In [150]: df_set_idx.reset_index().dtypes
Out[150]:
A int64
C category
B int64
Length: 3, dtype: object

```

### Function `read_csv` will progressively enumerate chunks

When `read_csv()` is called with `chunksize=n` and without specifying an index, each chunk used to have an independently generated index from 0 to n-1. They are now given instead a progressive index, starting from 0 for the first chunk, from n for the second, and so on, so that, when concatenated, they are identical to the result of calling `read_csv()` without the `chunksize=` argument (GH12185).

```
In [151]: data = "A,B\n0,1\n2,3\n4,5\n6,7"
```

#### Previous behavior:

```

In [2]: pd.concat(pd.read_csv(StringIO(data), chunksize=2))
Out[2]:
 A B
0 0 1
1 2 3
0 4 5
1 6 7

```

#### New behavior:

```

In [152]: pd.concat(pd.read_csv(StringIO(data), chunksize=2))
Out[152]:
 A B
0 0 1
1 2 3
2 4 5
3 6 7

[4 rows x 2 columns]

```

## Sparse changes

These changes allow pandas to handle sparse data with more dtypes, and for work to make a smoother experience with data handling.

### Types `int64` and `bool` support enhancements

Sparse data structures now gained enhanced support of `int64` and `bool` dtype ([GH667](#), [GH13849](#)).

Previously, sparse data were `float64` dtype by default, even if all inputs were of `int` or `bool` dtype. You had to specify dtype explicitly to create sparse data with `int64` dtype. Also, `fill_value` had to be specified explicitly because the default was `np.nan` which doesn't appear in `int64` or `bool` data.

```
In [1]: pd.SparseArray([1, 2, 0, 0])
Out[1]:
[1.0, 2.0, 0.0, 0.0]
Fill: nan
IntIndex
Indices: array([0, 1, 2, 3], dtype=int32)

specifying int64 dtype, but all values are stored in sp_values because
fill_value default is np.nan
In [2]: pd.SparseArray([1, 2, 0, 0], dtype=np.int64)
Out[2]:
[1, 2, 0, 0]
Fill: nan
IntIndex
Indices: array([0, 1, 2, 3], dtype=int32)

In [3]: pd.SparseArray([1, 2, 0, 0], dtype=np.int64, fill_value=0)
Out[3]:
[1, 2, 0, 0]
Fill: 0
IntIndex
Indices: array([0, 1], dtype=int32)
```

As of v0.19.0, sparse data keeps the input dtype, and uses more appropriate `fill_value` defaults (`0` for `int64` dtype, `False` for `bool` dtype).

```
In [153]: pd.SparseArray([1, 2, 0, 0], dtype=np.int64)
Out[153]:
[1, 2, 0, 0]
Fill: 0
IntIndex
Indices: array([0, 1], dtype=int32)

In [154]: pd.SparseArray([True, False, False, False])
Out[154]:
[True, False, False, False]
Fill: False
IntIndex
Indices: array([0], dtype=int32)
```

See the [docs](#) for more details.

## Operators now preserve dtypes

- Sparse data structure now can preserve dtype after arithmetic ops ([GH13848](#))

```
s = pd.SparseSeries([0, 2, 0, 1], fill_value=0, dtype=np.int64)
s.dtype

s + 1
```

- Sparse data structure now support astype to convert internal dtype ([GH13900](#))

```
s = pd.SparseSeries([1.0, 0.0, 2.0, 0.0], fill_value=0)
s
s.astype(np.int64)
```

astype fails if data contains values which cannot be converted to specified dtype. Note that the limitation is applied to fill\_value which default is np.nan.

```
In [7]: pd.SparseSeries([1., np.nan, 2., np.nan], fill_value=np.nan).astype(np.int64)
Out[7]:
ValueError: unable to coerce current fill_value nan to int64 dtype
```

## Other sparse fixes

- Subclassed SparseDataFrame and SparseSeries now preserve class types when slicing or transposing. ([GH13787](#))
- SparseArray with bool dtype now supports logical (bool) operators ([GH14000](#))
- Bug in SparseSeries with MultiIndex [] indexing may raise IndexError ([GH13144](#))
- Bug in SparseSeries with MultiIndex [] indexing result may have normal Index ([GH13144](#))
- Bug in SparseDataFrame in which axis=None did not default to axis=0 ([GH13048](#))
- Bug in SparseSeries and SparseDataFrame creation with object dtype may raise TypeError ([GH11633](#))
- Bug in SparseDataFrame doesn't respect passed SparseArray or SparseSeries 's dtype and fill\_value ([GH13866](#))
- Bug in SparseArray and SparseSeries don't apply ufunc to fill\_value ([GH13853](#))
- Bug in SparseSeries.abs incorrectly keeps negative fill\_value ([GH13853](#))
- Bug in single row slicing on multi-type SparseDataFrame s, types were previously forced to float ([GH13917](#))
- Bug in SparseSeries slicing changes integer dtype to float ([GH8292](#))
- Bug in SparseDataFrame comparison ops may raise TypeError ([GH13001](#))
- Bug in SparseDataFrame.isnull raises ValueError ([GH8276](#))
- Bug in SparseSeries representation with bool dtype may raise IndexError ([GH13110](#))
- Bug in SparseSeries and SparseDataFrame of bool or int64 dtype may display its values like float64 dtype ([GH13110](#))
- Bug in sparse indexing using SparseArray with bool dtype may return incorrect result ([GH13985](#))
- Bug in SparseArray created from SparseSeries may lose dtype ([GH13999](#))

- Bug in SparseSeries comparison with dense returns normal Series rather than SparseSeries (GH13999)

## Indexer dtype changes

---

**Note:** This change only affects 64 bit python running on Windows, and only affects relatively advanced indexing operations

---

Methods such as `Index.get_indexer` that return an indexer array, coerce that array to a “platform int”, so that it can be directly used in 3rd party library operations like `numpy.take`. Previously, a platform int was defined as `np.int_` which corresponds to a C integer, but the correct type, and what is being used now, is `np.intp`, which corresponds to the C integer size that can hold a pointer (GH3033, GH13972).

These types are the same on many platform, but for 64 bit python on Windows, `np.int_` is 32 bits, and `np.intp` is 64 bits. Changing this behavior improves performance for many operations on that platform.

### Previous behavior:

```
In [1]: i = pd.Index(['a', 'b', 'c'])
In [2]: i.get_indexer(['b', 'b', 'c']).dtype
Out[2]: dtype('int32')
```

### New behavior:

```
In [1]: i = pd.Index(['a', 'b', 'c'])
In [2]: i.get_indexer(['b', 'b', 'c']).dtype
Out[2]: dtype('int64')
```

## Other API changes

- `Timestamp.to_pydatetime` will issue a `UserWarning` when `warn=True`, and the instance has a non-zero number of nanoseconds, previously this would print a message to stdout (GH14101).
- `Series.unique()` with `datetime` and `timezone` now returns return array of `Timestamp` with `timezone` (GH13565).
- `Panel.to_sparse()` will raise a `NotImplementedError` exception when called (GH13778).
- `Index.reshape()` will raise a `NotImplementedError` exception when called (GH12882).
- `.filter()` enforces mutual exclusion of the keyword arguments (GH12399).
- `eval`'s upcasting rules for `float32` types have been updated to be more consistent with NumPy's rules. New behavior will not upcast to `float64` if you multiply a pandas `float32` object by a scalar `float64` (GH12388).
- An `UnsupportedFunctionCall` error is now raised if NumPy ufuncs like `np.mean` are called on `groupby` or `resample` objects (GH12811).
- `__setitem__` will no longer apply a callable rhs as a function instead of storing it. Call `where` directly to get the previous behavior (GH13299).
- Calls to `.sample()` will respect the random seed set via `numpy.random.seed(n)` (GH13161)

- `Styler.apply` is now more strict about the outputs your function must return. For `axis=0` or `axis=1`, the output shape must be identical. For `axis=None`, the output must be a `DataFrame` with identical columns and index labels (GH13222).
- `Float64Index.astype(int)` will now raise `ValueError` if `Float64Index` contains `NaN` values (GH13149)
- `TimedeltaIndex.astype(int)` and `DatetimeIndex.astype(int)` will now return `Int64Index` instead of `np.array` (GH13209)
- Passing `Period` with multiple frequencies to normal `Index` now returns `Index` with `object` dtype (GH13664)
- `PeriodIndex.fillna` with `Period` has different freq now coerces to `object` dtype (GH13664)
- Faceted boxplots from `DataFrame.boxplot(by=col)` now return a `Series` when `return_type` is not `None`. Previously these returned an `OrderedDict`. Note that when `return_type=None`, the default, these still return a 2-D NumPy array (GH12216, GH7096).
- `pd.read_hdf` will now raise a `ValueError` instead of `KeyError`, if a mode other than `r`, `r+` and `a` is supplied. (GH13623)
- `pd.read_csv()`, `pd.read_table()`, and `pd.read_hdf()` raise the builtin `FileNotFoundError` exception for Python 3.x when called on a nonexistent file; this is back-ported as `IOError` in Python 2.x (GH14086)
- More informative exceptions are passed through the csv parser. The exception type would now be the original exception type instead of `CParserError` (GH13652).
- `pd.read_csv()` in the C engine will now issue a `ParserWarning` or raise a `ValueError` when `sep` encoded is more than one character long (GH14065)
- `DataFrame.values` will now return `float64` with a `DataFrame` of mixed `int64` and `uint64` dtypes, conforming to `np.find_common_type` (GH10364, GH13917)
- `.groupby.groups` will now return a dictionary of `Index` objects, rather than a dictionary of `np.ndarray` or `lists` (GH14293)

## Deprecations

- `Series.reshape` and `Categorical.reshape` have been deprecated and will be removed in a subsequent release (GH12882, GH12882)
- `PeriodIndex.to_datetime` has been deprecated in favor of `PeriodIndex.to_timestamp` (GH8254)
- `Timestamp.to_datetime` has been deprecated in favor of `Timestamp.to_pydatetime` (GH8254)
- `Index.to_datetime` and `DatetimeIndex.to_datetime` have been deprecated in favor of `pd.to_datetime` (GH8254)
- `pandas.core.datetools` module has been deprecated and will be removed in a subsequent release (GH14094)
- `SparseList` has been deprecated and will be removed in a future version (GH13784)
- `DataFrame.to_html()` and `DataFrame.to_latex()` have dropped the `colSpace` parameter in favor of `col_space` (GH13857)
- `DataFrame.to_sql()` has deprecated the `flavor` parameter, as it is superfluous when `SQLAlchemy` is not installed (GH13611)
- Depreciated `read_csv` keywords:
  - `compact_ints` and `use_unsigned` have been deprecated and will be removed in a future version (GH13320)
  - `buffer_lines` has been deprecated and will be removed in a future version (GH13360)

- `as_reccarray` has been deprecated and will be removed in a future version ([GH13373](#))
- `skip_footer` has been deprecated in favor of `skipfooter` and will be removed in a future version ([GH13349](#))
- top-level `pd.ordered_merge()` has been renamed to `pd.merge_ordered()` and the original name will be removed in a future version ([GH13358](#))
- `Timestamp.offset` property (and named arg in the constructor), has been deprecated in favor of `freq` ([GH12160](#))
- `pd.tseries.util.pivot_annual` is deprecated. Use `pivot_table` as alternative, an example is [here](#) ([GH736](#))
- `pd.tseries.util.isleapyear` has been deprecated and will be removed in a subsequent release. Datetime-likes now have a `.is_leap_year` property ([GH13727](#))
- `Panel4D` and `PanelND` constructors are deprecated and will be removed in a future version. The recommended way to represent these types of n-dimensional data are with the `xarray` package. pandas provides a `to_xarray()` method to automate this conversion ([GH13564](#)).
- `pandas.tseries.frequencies.get_standard_freq` is deprecated. Use `pandas.tseries.frequencies.to_offset(freq).rule_code` instead ([GH13874](#))
- `pandas.tseries.frequencies.to_offset`'s `freqstr` keyword is deprecated in favor of `freq` ([GH13874](#))
- `Categorical.from_array` has been deprecated and will be removed in a future version ([GH13854](#))

### Removal of prior version deprecations/changes

- The `SparsePanel` class has been removed ([GH13778](#))
- The `pd.sandbox` module has been removed in favor of the external library `pandas-qt` ([GH13670](#))
- The `pandas.io.data` and `pandas.io.wb` modules are removed in favor of the `pandas-datareader` package ([GH13724](#)).
- The `pandas.tools.rplot` module has been removed in favor of the `seaborn` package ([GH13855](#))
- `DataFrame.to_csv()` has dropped the `engine` parameter, as was deprecated in 0.17.1 ([GH11274](#), [GH13419](#))
- `DataFrame.to_dict()` has dropped the `outtype` parameter in favor of `orient` ([GH13627](#), [GH8486](#))
- `pd.Categorical` has dropped setting of the `ordered` attribute directly in favor of the `set_ordered` method ([GH13671](#))
- `pd.Categorical` has dropped the `levels` attribute in favor of `categories` ([GH8376](#))
- `DataFrame.to_sql()` has dropped the `mysql` option for the `flavor` parameter ([GH13611](#))
- `Panel.shift()` has dropped the `lags` parameter in favor of `periods` ([GH14041](#))
- `pd.Index` has dropped the `diff` method in favor of `difference` ([GH13669](#))
- `pd.DataFrame` has dropped the `to_wide` method in favor of `to_panel` ([GH14039](#))
- `Series.to_csv` has dropped the `nanRep` parameter in favor of `na_rep` ([GH13804](#))
- `Series.xs`, `DataFrame.xs`, `Panel.xs`, `Panel.major_xs`, and `Panel.minor_xs` have dropped the `copy` parameter ([GH13781](#))
- `str.split` has dropped the `return_type` parameter in favor of `expand` ([GH13701](#))

- Removal of the legacy time rules (offset aliases), deprecated since 0.17.0 (this has been alias since 0.8.0) (GH13590, GH13868). Now legacy time rules raises ValueError. For the list of currently supported offsets, see [here](#).
- The default value for the `return_type` parameter for `DataFrame.plot.box` and `DataFrame.boxplot` changed from `None` to `"axes"`. These methods will now return a matplotlib axes by default instead of a dictionary of artists. See [here](#) (GH6581).
- The `tquery` and `uquery` functions in the `pandas.io.sql` module are removed (GH5950).

## Performance improvements

- Improved performance of sparse `IntIndex.intersect` (GH13082)
- Improved performance of sparse arithmetic with `BlockIndex` when the number of blocks are large, though recommended to use `IntIndex` in such cases (GH13082)
- Improved performance of `DataFrame.quantile()` as it now operates per-block (GH11623)
- Improved performance of float64 hash table operations, fixing some very slow indexing and groupby operations in python 3 (GH13166, GH13334)
- Improved performance of `DataFrameGroupBy.transform` (GH12737)
- Improved performance of `Index` and `Series.duplicated` (GH10235)
- Improved performance of `Index.difference` (GH12044)
- Improved performance of `RangeIndex.is_monotonic_increasing` and `is_monotonic_decreasing` (GH13749)
- Improved performance of datetime string parsing in `DatetimeIndex` (GH13692)
- Improved performance of hashing `Period` (GH12817)
- Improved performance of `factorize` of datetime with `timezone` (GH13750)
- Improved performance of by lazily creating indexing hashtables on larger `Indexes` (GH14266)
- Improved performance of `groupby.groups` (GH14293)
- Unnecessary materializing of a `MultiIndex` when introspecting for memory usage (GH14308)

## Bug fixes

- Bug in `groupby().shift()`, which could cause a segfault or corruption in rare circumstances when grouping by columns with missing values (GH13813)
- Bug in `groupby().cumsum()` calculating `cumprod` when `axis=1`. (GH13994)
- Bug in `pd.to_timedelta()` in which the `errors` parameter was not being respected (GH13613)
- Bug in `io.json.json_normalize()`, where non-ascii keys raised an exception (GH13213)
- Bug when passing a not-default-indexed `Series` as `xerr` or `yerr` in `.plot()` (GH11858)
- Bug in area plot draws legend incorrectly if subplot is enabled or legend is moved after plot (matplotlib 1.5.0 is required to draw area plot legend properly) (GH9161, GH13544)
- Bug in `DataFrame` assignment with an object-dtyped `Index` where the resultant column is mutable to the original object. (GH13522)
- Bug in matplotlib `AutoDataFormatter`; this restores the second scaled formatting and re-adds micro-second scaled formatting (GH13131)

- Bug in selection from a `HDFStore` with a fixed format and `start` and/or `stop` specified will now return the selected range ([GH8287](#))
- Bug in `Categorical.from_codes()` where an unhelpful error was raised when an invalid ordered parameter was passed in ([GH14058](#))
- Bug in `Series` construction from a tuple of integers on windows not returning default dtype (`int64`) ([GH13646](#))
- Bug in `TimedeltaIndex` addition with a `Datetime`-like object where addition overflow was not being caught ([GH14068](#))
- Bug in `.groupby(...).resample(...)` when the same object is called multiple times ([GH13174](#))
- Bug in `.to_records()` when index name is a unicode string ([GH13172](#))
- Bug in calling `.memory_usage()` on object which doesn't implement ([GH12924](#))
- Regression in `Series.quantile` with nans (also shows up in `.median()` and `.describe()`); furthermore now names the `Series` with the quantile ([GH13098](#), [GH13146](#))
- Bug in `SeriesGroupBy.transform` with datetime values and missing groups ([GH13191](#))
- Bug where empty `Series` were incorrectly coerced in datetime-like numeric operations ([GH13844](#))
- Bug in `Categorical` constructor when passed a `Categorical` containing datetimes with timezones ([GH14190](#))
- Bug in `Series.str.extractall()` with `str` index raises `ValueError` ([GH13156](#))
- Bug in `Series.str.extractall()` with single group and quantifier ([GH13382](#))
- Bug in `DatetimeIndex` and `Period` subtraction raises `ValueError` or `AttributeError` rather than `TypeError` ([GH13078](#))
- Bug in `Index` and `Series` created with `NaN` and `NaT` mixed data may not have `datetime64` dtype ([GH13324](#))
- Bug in `Index` and `Series` may ignore `np.datetime64('nat')` and `np.timedelta64('nat')` to infer dtype ([GH13324](#))
- Bug in `PeriodIndex` and `Period` subtraction raises `AttributeError` ([GH13071](#))
- Bug in `PeriodIndex` construction returning a `float64` index in some circumstances ([GH13067](#))
- Bug in `.resample(...)` with a `PeriodIndex` not changing its `freq` appropriately when empty ([GH13067](#))
- Bug in `.resample(...)` with a `PeriodIndex` not retaining its type or name with an empty `DataFrame` appropriately when empty ([GH13212](#))
- Bug in `groupby(...).apply(...)` when the passed function returns scalar values per group ([GH13468](#)).
- Bug in `groupby(...).resample(...)` where passing some keywords would raise an exception ([GH13235](#))
- Bug in `.tz_convert` on a tz-aware `DateTimeIndex` that relied on index being sorted for correct results ([GH13306](#))
- Bug in `.tz_localize` with `dateutil.tz.tzlocal` may return incorrect result ([GH13583](#))
- Bug in `DatetimeTZDtype` dtype with `dateutil.tz.tzlocal` cannot be regarded as valid dtype ([GH13583](#))
- Bug in `pd.read_hdf()` where attempting to load an HDF file with a single dataset, that had one or more categorical columns, failed unless the `key` argument was set to the name of the dataset. ([GH13231](#))
- Bug in `.rolling()` that allowed a negative integer window in construction of the `Rolling()` object, but would later fail on aggregation ([GH13383](#))
- Bug in `Series` indexing with tuple-valued data and a numeric index ([GH13509](#))
- Bug in printing `pd.DataFrame` where unusual elements with the object dtype were causing segfaults ([GH13717](#))

- Bug in ranking Series which could result in segfaults (GH13445)
- Bug in various index types, which did not propagate the name of passed index (GH12309)
- Bug in DatetimeIndex, which did not honour the copy=True (GH13205)
- Bug in DatetimeIndex.is\_normalized returns incorrectly for normalized date\_range in case of local time-zones (GH13459)
- Bug in pd.concat and .append may coerces datetime64 and timedelta to object dtype containing python built-in datetime or timedelta rather than Timestamp or Timedelta (GH13626)
- Bug in PeriodIndex.append may raises AttributeError when the result is object dtype (GH13221)
- Bug in CategoricalIndex.append may accept normal list (GH13626)
- Bug in pd.concat and .append with the same timezone get reset to UTC (GH7795)
- Bug in Series and DataFrame.append raises AmbiguousTimeError if data contains datetime near DST boundary (GH13626)
- Bug in DataFrame.to\_csv() in which float values were being quoted even though quotations were specified for non-numeric values only (GH12922, GH13259)
- Bug in DataFrame.describe() raising ValueError with only boolean columns (GH13898)
- Bug in MultiIndex slicing where extra elements were returned when level is non-unique (GH12896)
- Bug in .str.replace does not raise TypeError for invalid replacement (GH13438)
- Bug in MultiIndex.from\_arrays which didn't check for input array lengths matching (GH13599)
- Bug in cartesian\_product and MultiIndex.from\_product which may raise with empty input arrays (GH12258)
- Bug in pd.read\_csv() which may cause a segfault or corruption when iterating in large chunks over a stream/file under rare circumstances (GH13703)
- Bug in pd.read\_csv() which caused errors to be raised when a dictionary containing scalars is passed in for na\_values (GH12224)
- Bug in pd.read\_csv() which caused BOM files to be incorrectly parsed by not ignoring the BOM (GH4793)
- Bug in pd.read\_csv() with engine='python' which raised errors when a numpy array was passed in for usecols (GH12546)
- Bug in pd.read\_csv() where the index columns were being incorrectly parsed when parsed as dates with a thousands parameter (GH14066)
- Bug in pd.read\_csv() with engine='python' in which NaN values weren't being detected after data was converted to numeric values (GH13314)
- Bug in pd.read\_csv() in which the nrows argument was not properly validated for both engines (GH10476)
- Bug in pd.read\_csv() with engine='python' in which infinities of mixed-case forms were not being interpreted properly (GH13274)
- Bug in pd.read\_csv() with engine='python' in which trailing NaN values were not being parsed (GH13320)
- Bug in pd.read\_csv() with engine='python' when reading from a tempfile.TemporaryFile on Windows with Python 3 (GH13398)
- Bug in pd.read\_csv() that prevents usecols kwarg from accepting single-byte unicode strings (GH13219)
- Bug in pd.read\_csv() that prevents usecols from being an empty set (GH13402)
- Bug in pd.read\_csv() in the C engine where the NULL character was not being parsed as NULL (GH14012)

- Bug in `pd.read_csv()` with `engine='c'` in which NULL quotechar was not accepted even though quoting was specified as None (GH13411)
- Bug in `pd.read_csv()` with `engine='c'` in which fields were not properly cast to float when quoting was specified as non-numeric (GH13411)
- Bug in `pd.read_csv()` in Python 2.x with non-UTF8 encoded, multi-character separated data (GH3404)
- Bug in `pd.read_csv()`, where aliases for utf-xx (e.g. UTF-xx, UTF\_xx, utf\_xx) raised UnicodeDecodeError (GH13549)
- Bug in `pd.read_csv`, `pd.read_table`, `pd.read_fwf`, `pd.read_stata` and `pd.read_sas` where files were opened by parsers but not closed if both `chunksize` and `iterator` were None. (GH13940)
- Bug in `StataReader`, `StataWriter`, `XportReader` and `SAS7BDATReader` where a file was not properly closed when an error was raised. (GH13940)
- Bug in `pd.pivot_table()` where `margins_name` is ignored when `aggfunc` is a list (GH13354)
- Bug in `pd.Series.str.zfill`, `center`, `ljust`, `rjust`, and `pad` when passing non-integers, did not raise `TypeError` (GH13598)
- Bug in checking for any null objects in a `TimedeltaIndex`, which always returned `True` (GH13603)
- Bug in `Series` arithmetic raises `TypeError` if it contains datetime-like as `object` dtype (GH13043)
- Bug `Series.isnull()` and `Series.notnull()` ignore `Period('NaT')` (GH13737)
- Bug `Series.fillna()` and `Series.dropna()` don't affect to `Period('NaT')` (GH13737)
- Bug in `.fillna(value=np.nan)` incorrectly raises `KeyError` on a `category` dtype `Series` (GH14021)
- Bug in extension dtype creation where the created types were not is/identical (GH13285)
- Bug in `.resample(..)` where incorrect warnings were triggered by IPython introspection (GH13618)
- Bug in `NaT - Period` raises `AttributeError` (GH13071)
- Bug in `Series` comparison may output incorrect result if `rhs` contains `NaT` (GH9005)
- Bug in `Series` and `Index` comparison may output incorrect result if it contains `NaT` with `object` dtype (GH13592)
- Bug in `Period` addition raises `TypeError` if `Period` is on right hand side (GH13069)
- Bug in `Period` and `Series` or `Index` comparison raises `TypeError` (GH13200)
- Bug in `pd.set_eng_float_format()` that would prevent `NaN` and `Inf` from formatting (GH11981)
- Bug in `.unstack` with `Categorical` dtype resets `.ordered` to `True` (GH13249)
- Clean some compile time warnings in datetime parsing (GH13607)
- Bug in `factorize` raises `AmbiguousTimeError` if data contains datetime near DST boundary (GH13750)
- Bug in `.set_index` raises `AmbiguousTimeError` if new index contains DST boundary and multi levels (GH12920)
- Bug in `.shift` raises `AmbiguousTimeError` if data contains datetime near DST boundary (GH13926)
- Bug in `pd.read_hdf()` returns incorrect result when a `DataFrame` with a `categorical` column and a query which doesn't match any values (GH13792)
- Bug in `.iloc` when indexing with a non lexsorted `MultiIndex` (GH13797)
- Bug in `.loc` when indexing with date strings in a reverse sorted `DatetimeIndex` (GH14316)
- Bug in `Series` comparison operators when dealing with zero dim `NumPy` arrays (GH13006)

- Bug in `.combine_first` may return incorrect dtype ([GH7630](#), [GH10567](#))
- Bug in `groupby` where `apply` returns different result depending on whether first result is `None` or not ([GH12824](#))
- Bug in `groupby(...).nth()` where the group key is included inconsistently if called after `.head()/tail()` ([GH12839](#))
- Bug in `.to_html`, `.to_latex` and `.to_string` silently ignore custom datetime formatter passed through the `formatters` key word ([GH10690](#))
- Bug in `DataFrame.iterrows()`, not yielding a `Series` subclasse if defined ([GH13977](#))
- Bug in `pd.to_numeric` when `errors='coerce'` and input contains non-hashable objects ([GH13324](#))
- Bug in invalid `Timedelta` arithmetic and comparison may raise `ValueError` rather than `TypeError` ([GH13624](#))
- Bug in invalid datetime parsing in `to_datetime` and `DatetimeIndex` may raise `TypeError` rather than `ValueError` ([GH11169](#), [GH11287](#))
- Bug in `Index` created with tz-aware `Timestamp` and mismatched `tz` option incorrectly coerces timezone ([GH13692](#))
- Bug in `DatetimeIndex` with nanosecond frequency does not include timestamp specified with `end` ([GH13672](#))
- Bug in `Series` when setting a slice with a `np.timedelta64` ([GH14155](#))
- Bug in `Index` raises `OutOfBoundsDatetime` if datetime exceeds `datetime64[ns]` bounds, rather than coercing to object dtype ([GH13663](#))
- Bug in `Index` may ignore specified `datetime64` or `timedelta64` passed as dtype ([GH13981](#))
- Bug in `RangeIndex` can be created without no arguments rather than raises `TypeError` ([GH13793](#))
- Bug in `.value_counts()` raises `OutOfBoundsDatetime` if data exceeds `datetime64[ns]` bounds ([GH13663](#))
- Bug in `DatetimeIndex` may raise `OutOfBoundsDatetime` if input `np.datetime64` has other unit than `ns` ([GH9114](#))
- Bug in `Series` creation with `np.datetime64` which has other unit than `ns` as object dtype results in incorrect values ([GH13876](#))
- Bug in `resample` with `timedelta` data where data was casted to float ([GH13119](#)).
- Bug in `pd.isnull()` `pd.notnull()` raise `TypeError` if input datetime-like has other unit than `ns` ([GH13389](#))
- Bug in `pd.merge()` may raise `TypeError` if input datetime-like has other unit than `ns` ([GH13389](#))
- Bug in `HDFStore/read_hdf()` discarded `DatetimeIndex.name` if `tz` was set ([GH13884](#))
- Bug in `Categorical.remove_unused_categories()` changes `.codes` dtype to platform int ([GH13261](#))
- Bug in `groupby` with `as_index=False` returns all `NaN`'s when grouping on multiple columns including a categorical one ([GH13204](#))
- Bug in `df.groupby(...)[...]` where `getitem` with `Int64Index` raised an error ([GH13731](#))
- Bug in the CSS classes assigned to `DataFrame.style` for index names. Previously they were assigned `"col_heading level<n> col<c>"` where `n` was the number of levels + 1. Now they are assigned `"index_name level<n>"`, where `n` is the correct level for that `MultiIndex`.
- Bug where `pd.read_gbq()` could throw `ImportError: No module named discovery` as a result of a naming conflict with another python package called `apiclient` ([GH13454](#))
- Bug in `Index.union` returns an incorrect result with a named empty index ([GH13432](#))

- Bugs in `Index.difference` and `DataFrame.join` raise in Python3 when using mixed-integer indexes ([GH13432](#), [GH12814](#))
- Bug in subtract tz-aware `datetime.datetime` from tz-aware `datetime64` series ([GH14088](#))
- Bug in `.to_excel()` when `DataFrame` contains a `MultiIndex` which contains a label with a `NaN` value ([GH13511](#))
- Bug in invalid frequency offset string like “D1”, “-2-3H” may not raise `ValueError` ([GH13930](#))
- Bug in `concat` and `groupby` for hierarchical frames with `RangeIndex` levels ([GH13542](#)).
- Bug in `Series.str.contains()` for `Series` containing only `NaN` values of `object` dtype ([GH14171](#))
- Bug in `agg()` function on `groupby` dataframe changes dtype of `datetime64[ns]` column to `float64` ([GH12821](#))
- Bug in using `NumPy` `ufunc` with `PeriodIndex` to add or subtract integer raise `IncompatibleFrequency`. Note that using standard operator like `+` or `-` is recommended, because standard operators use more efficient path ([GH13980](#))
- Bug in operations on `NaT` returning `float` instead of `datetime64[ns]` ([GH12941](#))
- Bug in `Series` flexible arithmetic methods (like `.add()`) raises `ValueError` when `axis=None` ([GH13894](#))
- Bug in `DataFrame.to_csv()` with `MultiIndex` columns in which a stray empty line was added ([GH6618](#))
- Bug in `DatetimeIndex`, `TimedeltaIndex` and `PeriodIndex.equals()` may return `True` when input isn't `Index` but contains the same values ([GH13107](#))
- Bug in assignment against `datetime` with `timezone` may not work if it contains `datetime` near `DST` boundary ([GH14146](#))
- Bug in `pd.eval()` and `HDFStore` query truncating long float literals with python 2 ([GH14241](#))
- Bug in `Index` raises `KeyError` displaying incorrect column when column is not in the `df` and columns contains duplicate values ([GH13822](#))
- Bug in `Period` and `PeriodIndex` creating wrong dates when frequency has combined offset aliases ([GH13874](#))
- Bug in `.to_string()` when called with an integer `line_width` and `index=False` raises an `UnboundLocalError` exception because `idx` referenced before assignment.
- Bug in `eval()` where the `resolvers` argument would not accept a list ([GH14095](#))
- Bugs in `stack`, `get_dummies`, `make_axis_dummies` which don't preserve categorical dtypes in (multi)indexes ([GH13854](#))
- `PeriodIndex` can now accept `list` and `array` which contains `pd.NaT` ([GH13430](#))
- Bug in `df.groupby` where `.median()` returns arbitrary values if grouped dataframe contains empty bins ([GH13629](#))
- Bug in `Index.copy()` where `name` parameter was ignored ([GH14302](#))

## Contributors

## 5.12 Version 0.18

### 5.12.1 Version 0.18.1 (May 3, 2016)

This is a minor bug-fix release from 0.18.0 and includes a large number of bug fixes along with several new features, enhancements, and performance improvements. We recommend that all users upgrade to this version.

Highlights include:

- `.groupby(...)` has been enhanced to provide convenient syntax when working with `.rolling(...)`, `.expanding(...)` and `.resample(...)` per group, see [here](#)
- `pd.to_datetime()` has gained the ability to assemble dates from a `DataFrame`, see [here](#)
- Method chaining improvements, see [here](#).
- Custom business hour offset, see [here](#).
- Many bug fixes in the handling of `sparse`, see [here](#)
- Expanded the *Tutorials section* with a feature on modern pandas, courtesy of [@TomAugsburger](#). (GH13045).

#### What's new in v0.18.1

- *New features*
  - *Custom business hour*
  - *Method `.groupby(...)` syntax with window and resample operations*
  - *Method chaining improvements*
    - \* *Methods `.where()` and `.mask()`*
    - \* *Methods `.loc[]`, `.iloc[]`, `.ix[]`*
    - \* *Indexing with `[]`*
  - *Partial string indexing on `DatetimeIndex` when part of a `MultiIndex`*

- *Assembling datetimes*
- *Other enhancements*
- *Sparse changes*
- *API changes*
  - *Method `.groupby(..).nth()` changes*
  - *NumPy function compatibility*
  - *Using `.apply` on `GroupBy` resampling*
  - *Changes in `read_csv` exceptions*
  - *Method `to_datetime` error changes*
  - *Other API changes*
  - *Deprecations*
- *Performance improvements*
- *Bug fixes*
- *Contributors*

## New features

### Custom business hour

The `CustomBusinessHour` is a mixture of `BusinessHour` and `CustomBusinessDay` which allows you to specify arbitrary holidays. For details, see *Custom Business Hour* (GH11514)

```
In [1]: from pandas.tseries.offsets import CustomBusinessHour
In [2]: from pandas.tseries.holiday import USFederalHolidayCalendar
In [3]: bhour_us = CustomBusinessHour(calendar=USFederalHolidayCalendar())
```

Friday before MLK Day

```
In [4]: import datetime
In [5]: dt = datetime.datetime(2014, 1, 17, 15)
In [6]: dt + bhour_us
Out[6]: Timestamp('2014-01-17 16:00:00')
```

Tuesday after MLK Day (Monday is skipped because it's a holiday)

```
In [7]: dt + bhour_us * 2
Out[7]: Timestamp('2014-01-20 09:00:00')
```

### Method `.groupby(...)` syntax with window and resample operations

`.groupby(...)` has been enhanced to provide convenient syntax when working with `.rolling(...)`, `.expanding(...)` and `.resample(...)` per group, see (GH12486, GH12738).

You can now use `.rolling(...)` and `.expanding(...)` as methods on groupbys. These return another deferred object (similar to what `.rolling()` and `.expanding()` do on ungrouped pandas objects). You can then operate on these `RollingGroupby` objects in a similar manner.

Previously you would have to do this to get a rolling window mean per-group:

```
In [8]: df = pd.DataFrame({"A": [1] * 20 + [2] * 12 + [3] * 8, "B": np.arange(40)})
```

```
In [9]: df
```

```
Out[9]:
```

```
 A B
0 1 0
1 1 1
2 1 2
3 1 3
4 1 4
..
35 3 35
36 3 36
37 3 37
38 3 38
39 3 39
```

```
[40 rows x 2 columns]
```

```
In [10]: df.groupby("A").apply(lambda x: x.rolling(4).B.mean())
```

```
Out[10]:
```

```
A
1 0 NaN
 1 NaN
 2 NaN
 3 1.5
 4 2.5
 ..
3 35 33.5
 36 34.5
 37 35.5
 38 36.5
 39 37.5
```

```
Name: B, Length: 40, dtype: float64
```

Now you can do:

```
In [11]: df.groupby("A").rolling(4).B.mean()
```

```
Out[11]:
```

```
A
1 0 NaN
 1 NaN
 2 NaN
```

(continues on next page)

(continued from previous page)

```

3 1.5
4 2.5
...
3 35 33.5
36 34.5
37 35.5
38 36.5
39 37.5
Name: B, Length: 40, dtype: float64

```

For `.resample(.)` type of operations, previously you would have to:

```

In [12]: df = pd.DataFrame(
...: {
...: "date": pd.date_range(start="2016-01-01", periods=4, freq="W"),
...: "group": [1, 1, 2, 2],
...: "val": [5, 6, 7, 8],
...: }
...:).set_index("date")
...:

```

```
In [13]: df
```

```
Out[13]:
```

|            | group | val |
|------------|-------|-----|
| date       |       |     |
| 2016-01-03 | 1     | 5   |
| 2016-01-10 | 1     | 6   |
| 2016-01-17 | 2     | 7   |
| 2016-01-24 | 2     | 8   |

```
[4 rows x 2 columns]
```

```
In [14]: df.groupby("group").apply(lambda x: x.resample("1D").ffill())
```

```
Out[14]:
```

|            | group      | val |
|------------|------------|-----|
| group date |            |     |
| 1          | 2016-01-03 | 1 5 |
|            | 2016-01-04 | 1 5 |
|            | 2016-01-05 | 1 5 |
|            | 2016-01-06 | 1 5 |
|            | 2016-01-07 | 1 5 |
| ...        | ...        | ... |
| 2          | 2016-01-20 | 2 7 |
|            | 2016-01-21 | 2 7 |
|            | 2016-01-22 | 2 7 |
|            | 2016-01-23 | 2 7 |
|            | 2016-01-24 | 2 8 |

```
[16 rows x 2 columns]
```

Now you can do:

```
In [15]: df.groupby("group").resample("1D").ffill()
```

```
Out[15]:
```

```
 group val
group date
1 2016-01-03 5
 2016-01-04 5
 2016-01-05 5
 2016-01-06 5
 2016-01-07 5
...
2 2016-01-20 7
 2016-01-21 7
 2016-01-22 7
 2016-01-23 7
 2016-01-24 8
```

```
[16 rows x 2 columns]
```

## Method chaining improvements

The following methods / indexers now accept a callable. It is intended to make these more useful in method chains, see the [documentation](#). (GH11485, GH12533)

- `.where()` and `.mask()`
- `.loc[], iloc[]` and `.ix[]`
- `[]` indexing

## Methods `.where()` and `.mask()`

These can accept a callable for the condition and other arguments.

```
In [16]: df = pd.DataFrame({"A": [1, 2, 3], "B": [4, 5, 6], "C": [7, 8, 9]})
```

```
In [17]: df.where(lambda x: x > 4, lambda x: x + 10)
```

```
Out[17]:
```

```
 A B C
0 11 14 7
1 12 5 8
2 13 6 9
```

```
[3 rows x 3 columns]
```

**Methods .loc[], .iloc[], .ix[]**

These can accept a callable, and a tuple of callable as a slicer. The callable can return a valid boolean indexer or anything which is valid for these indexer's input.

```
callable returns bool indexer
In [18]: df.loc[lambda x: x.A >= 2, lambda x: x.sum() > 10]
Out[18]:
 B C
1 5 8
2 6 9

[2 rows x 2 columns]

callable returns list of labels
In [19]: df.loc[lambda x: [1, 2], lambda x: ["A", "B"]]
Out[19]:
 A B
1 2 5
2 3 6

[2 rows x 2 columns]
```

**Indexing with ``[]``**

Finally, you can use a callable in [] indexing of Series, DataFrame and Panel. The callable must return a valid input for [] indexing depending on its class and index type.

```
In [20]: df[lambda x: "A"]
Out[20]:
0 1
1 2
2 3
Name: A, Length: 3, dtype: int64
```

Using these methods / indexers, you can chain data selection operations without using temporary variable.

```
In [21]: bb = pd.read_csv("data/baseball.csv", index_col="id")
In [22]: (bb.groupby(["year", "team"]).sum().loc[lambda df: df.r > 100])
Out[22]:
 stint g ab r h X2b X3b hr rbi sb cs bb so ibb

### Partial string indexing on DatetimeIndex when part of a MultiIndex

Partial string indexing now matches on DateTimeIndex when part of a MultiIndex (GH10331)

```

In [23]: dft2 = pd.DataFrame(
.....: np.random.randn(20, 1),
.....: columns=["A"],
.....: index=pd.MultiIndex.from_product(
.....: [pd.date_range("20130101", periods=10, freq="12H"), ["a", "b"]]
.....:),
.....:)
.....:
```

In [24]: dft2

Out[24]:

```

 A
2013-01-01 00:00:00 a 0.469112
 b -0.282863
2013-01-01 12:00:00 a -1.509059
 b -1.135632
2013-01-02 00:00:00 a 1.212112
...
2013-01-04 12:00:00 b 0.271860
2013-01-05 00:00:00 a -0.424972
 b 0.567020
2013-01-05 12:00:00 a 0.276232
 b -1.087401
```

[20 rows x 1 columns]

In [25]: dft2.loc["2013-01-05"]

Out[25]:

```

 A
2013-01-05 00:00:00 a -0.424972
 b 0.567020

|     | 2013-01-05 | 12:00:00 | -1.087401 |

[20 rows x 1 columns]

```
In [29]: dft2.loc[idx[:, "2013-01-05"], :]
Out[29]:
```

|   |            |          | A         |
|---|------------|----------|-----------|
| a | 2013-01-05 | 00:00:00 | -0.424972 |
|   | 2013-01-05 | 12:00:00 | 0.276232  |
| b | 2013-01-05 | 00:00:00 | 0.567020  |
|   | 2013-01-05 | 12:00:00 | -1.087401 |

[4 rows x 1 columns]

## Assembling datetimes

`pd.to_datetime()` has gained the ability to assemble datetimes from a passed in DataFrame or a dict. (GH8158).

```
In [30]: df = pd.DataFrame(
.....: {"year": [2015, 2016], "month": [2, 3], "day": [4, 5], "hour": [2, 3]}
.....:)
.....:
In [31]: df
Out[31]:
```

|   | year | month | day | hour |
|---|------|-------|-----|------|
| 0 | 2015 | 2     | 4   | 2    |
| 1 | 2016 | 3     | 5   | 3    |

[2 rows x 4 columns]

Assembling using the passed frame.

```
In [32]: pd.to_datetime(df)
Out[32]:
0 2015-02-04 02:00:00
1 2016-03-05 03:00:00
Length: 2, dtype: datetime64[ns]
```

You can pass only the columns that you need to assemble.

```
In [33]: pd.to_datetime(df[["year", "month", "day"]])
Out[33]:
0 2015-02-04
1 2016-03-05
Length: 2, dtype: datetime64[ns]
```

## Other enhancements

- `pd.read_csv()` now supports `delim_whitespace=True` for the Python engine (GH12958)
- `pd.read_csv()` now supports opening ZIP files that contains a single CSV, via extension inference or explicit `compression='zip'` (GH12175)
- `pd.read_csv()` now supports opening files using xz compression, via extension inference or explicit `compression='xz'` is specified; xz compressions is also supported by `DataFrame.to_csv` in the same way (GH11852)
- `pd.read_msgpack()` now always gives writeable ndarrays even when compression is used (GH12359).
- `pd.read_msgpack()` now supports serializing and de-serializing categoricals with msgpack (GH12573)
- `.to_json()` now supports NDFrames that contain categorical and sparse data (GH10778)
- `interpolate()` now supports `method='akima'` (GH7588).
- `pd.read_excel()` now accepts path objects (e.g. `pathlib.Path`, `py.path.local`) for the file path, in line with other `read_*` functions (GH12655)
- Added `.weekday_name` property as a component to `DatetimeIndex` and the `.dt` accessor. (GH11128)
- `Index.take` now handles `allow_fill` and `fill_value` consistently (GH12631)

```
In [34]: idx = pd.Index([1.0, 2.0, 3.0, 4.0], dtype="float")
```

```
default, allow_fill=True, fill_value=None
```

```
In [35]: idx.take([2, -1])
```

```
Out[35]: Float64Index([3.0, 4.0], dtype='float64')
```

```
In [36]: idx.take([2, -1], fill_value=True)
```

```
Out[36]: Float64Index([3.0, nan], dtype='float64')
```

- `Index` now supports `.str.get_dummies()` which returns `MultiIndex`, see *Creating Indicator Variables* (GH10008, GH10103)

```
In [37]: idx = pd.Index(["a|b", "a|c", "b|c"])
```

```
In [38]: idx.str.get_dummies("|")
```

```
Out[38]:
```

(continues on next page)

(continued from previous page)

```
MultiIndex([(1, 1, 0),
 (1, 0, 1),
 (0, 1, 1)],
 names=['a', 'b', 'c'])
```

- `pd.crosstab()` has gained a `normalize` argument for normalizing frequency tables (GH12569). Examples in the updated docs [here](#).
- `.resample(..).interpolate()` is now supported (GH12925)
- `.isin()` now accepts passed sets (GH12988)

## Sparse changes

These changes conform sparse handling to return the correct types and work to make a smoother experience with indexing.

`SparseArray.take` now returns a scalar for scalar input, `SparseArray` for others. Furthermore, it handles a negative indexer with the same rule as `Index` (GH10560, GH12796)

```
s = pd.SparseArray([np.nan, np.nan, 1, 2, 3, np.nan, 4, 5, np.nan, 6])
s.take(0)
s.take([1, 2, 3])
```

- Bug in `SparseSeries[]` indexing with `Ellipsis` raises `KeyError` (GH9467)
- Bug in `SparseArray[]` indexing with tuples are not handled properly (GH12966)
- Bug in `SparseSeries.loc[]` with list-like input raises `TypeError` (GH10560)
- Bug in `SparseSeries.iloc[]` with scalar input may raise `IndexError` (GH10560)
- Bug in `SparseSeries.loc[], .iloc[]` with slice returns `SparseArray`, rather than `SparseSeries` (GH10560)
- Bug in `SparseDataFrame.loc[], .iloc[]` may results in dense `Series`, rather than `SparseSeries` (GH12787)
- Bug in `SparseArray` addition ignores `fill_value` of right hand side (GH12910)
- Bug in `SparseArray` mod raises `AttributeError` (GH12910)
- Bug in `SparseArray` pow calculates `1 ** np.nan` as `np.nan` which must be 1 (GH12910)
- Bug in `SparseArray` comparison output may incorrect result or raise `ValueError` (GH12971)
- Bug in `SparseSeries.__repr__` raises `TypeError` when it is longer than `max_rows` (GH10560)
- Bug in `SparseSeries.shape` ignores `fill_value` (GH10452)
- Bug in `SparseSeries` and `SparseArray` may have different `dtype` from its dense values (GH12908)
- Bug in `SparseSeries.reindex` incorrectly handle `fill_value` (GH12797)
- Bug in `SparseArray.to_frame()` results in `DataFrame`, rather than `SparseDataFrame` (GH9850)
- Bug in `SparseSeries.value_counts()` does not count `fill_value` (GH6749)
- Bug in `SparseArray.to_dense()` does not preserve `dtype` (GH10648)
- Bug in `SparseArray.to_dense()` incorrectly handle `fill_value` (GH12797)
- Bug in `pd.concat()` of `SparseSeries` results in dense (GH10536)

- Bug in `pd.concat()` of `SparseDataFrame` incorrectly handle `fill_value` (GH9765)
- Bug in `pd.concat()` of `SparseDataFrame` may raise `AttributeError` (GH12174)
- Bug in `SparseArray.shift()` may raise `NameError` or `TypeError` (GH12908)

## API changes

### Method `.groupby(..).nth()` changes

The index in `.groupby(..).nth()` output is now more consistent when the `as_index` argument is passed (GH11039):

```
In [39]: df = pd.DataFrame({"A": ["a", "b", "a"], "B": [1, 2, 3]})

In [40]: df
Out[40]:
 A B
0 a 1
1 b 2
2 a 3

[3 rows x 2 columns]
```

Previous behavior:

```
In [3]: df.groupby('A', as_index=True)['B'].nth(0)
Out[3]:
0 1
1 2
Name: B, dtype: int64

In [4]: df.groupby('A', as_index=False)['B'].nth(0)
Out[4]:
0 1
1 2
Name: B, dtype: int64
```

New behavior:

```
In [41]: df.groupby("A", as_index=True)["B"].nth(0)
Out[41]:
A
a 1
b 2
Name: B, Length: 2, dtype: int64

In [42]: df.groupby("A", as_index=False)["B"].nth(0)
Out[42]:
0 1
1 2
Name: B, Length: 2, dtype: int64
```

Furthermore, previously, a `.groupby` would always sort, regardless if `sort=False` was passed with `.nth()`.

```
In [43]: np.random.seed(1234)
```

```
In [44]: df = pd.DataFrame(np.random.randn(100, 2), columns=["a", "b"])
```

```
In [45]: df["c"] = np.random.randint(0, 4, 100)
```

Previous behavior:

```
In [4]: df.groupby('c', sort=True).nth(1)
```

```
Out[4]:
```

```
 a b
c
0 -0.334077 0.002118
1 0.036142 -2.074978
2 -0.720589 0.887163
3 0.859588 -0.636524
```

```
In [5]: df.groupby('c', sort=False).nth(1)
```

```
Out[5]:
```

```
 a b
c
0 -0.334077 0.002118
1 0.036142 -2.074978
2 -0.720589 0.887163
3 0.859588 -0.636524
```

New behavior:

```
In [46]: df.groupby("c", sort=True).nth(1)
```

```
Out[46]:
```

```
 a b
c
0 -0.334077 0.002118
1 0.036142 -2.074978
2 -0.720589 0.887163
3 0.859588 -0.636524
```

```
[4 rows x 2 columns]
```

```
In [47]: df.groupby("c", sort=False).nth(1)
```

```
Out[47]:
```

```
 a b
c
2 -0.720589 0.887163
3 0.859588 -0.636524
0 -0.334077 0.002118
1 0.036142 -2.074978
```

```
[4 rows x 2 columns]
```

## NumPy function compatibility

Compatibility between pandas array-like methods (e.g. `sum` and `take`) and their numpy counterparts has been greatly increased by augmenting the signatures of the pandas methods so as to accept arguments that can be passed in from numpy, even if they are not necessarily used in the pandas implementation (GH12644, GH12638, GH12687)

- `.searchsorted()` for `Index` and `TimedeltaIndex` now accept a `sorter` argument to maintain compatibility with numpy's `searchsorted` function (GH12238)
- Bug in numpy compatibility of `np.round()` on a `Series` (GH12600)

An example of this signature augmentation is illustrated below:

```
sp = pd.SparseDataFrame([1, 2, 3])
sp
```

Previous behaviour:

```
In [2]: np.cumsum(sp, axis=0)
...
TypeError: cumsum() takes at most 2 arguments (4 given)
```

New behaviour:

```
np.cumsum(sp, axis=0)
```

## Using `.apply` on `GroupBy` resampling

Using `apply` on resampling groupby operations (using a `pd.TimeGrouper`) now has the same output types as similar `apply` calls on other groupby operations. (GH11742).

```
In [48]: df = pd.DataFrame(
...: {"date": pd.to_datetime(["10/10/2000", "11/10/2000"]), "value": [10, 13]}
...:)
...:
```

```
In [49]: df
```

```
Out[49]:
 date value
0 2000-10-10 10
1 2000-11-10 13
```

```
[2 rows x 2 columns]
```

Previous behavior:

```
In [1]: df.groupby(pd.TimeGrouper(key='date',
...: freq='M')).apply(lambda x: x.value.sum())
```

```
Out[1]:
...
TypeError: cannot concatenate a non-NDFrame object
```

```
Output is a Series
```

```
In [2]: df.groupby(pd.TimeGrouper(key='date',
```

(continues on next page)

(continued from previous page)

```

...:
Out[2]:
date
2000-10-31 value 10
2000-11-30 value 13
dtype: int64

```

New behavior:

```

Output is a Series
In [55]: df.groupby(pd.TimeGrouper(key='date',
...: freq='M')).apply(lambda x: x.value.sum())
Out[55]:
date
2000-10-31 10
2000-11-30 13
Freq: M, dtype: int64

Output is a DataFrame
In [56]: df.groupby(pd.TimeGrouper(key='date',
...: freq='M')).apply(lambda x: x[['value']].sum())
Out[56]:
 value
date
2000-10-31 10
2000-11-30 13

```

### Changes in read\_csv exceptions

In order to standardize the read\_csv API for both the c and python engines, both will now raise an `EmptyDataError`, a subclass of `ValueError`, in response to empty columns or header ([GH12493](#), [GH12506](#))

Previous behaviour:

```

In [1]: import io

In [2]: df = pd.read_csv(io.StringIO(''), engine='c')
...
ValueError: No columns to parse from file

In [3]: df = pd.read_csv(io.StringIO(''), engine='python')
...
StopIteration

```

New behaviour:

```

In [1]: df = pd.read_csv(io.StringIO(''), engine='c')
...
pandas.io.common.EmptyDataError: No columns to parse from file

In [2]: df = pd.read_csv(io.StringIO(''), engine='python')

```

(continues on next page)

(continued from previous page)

```
...
pandas.io.common.EmptyDataError: No columns to parse from file
```

In addition to this error change, several others have been made as well:

- `CParserError` now sub-classes `ValueError` instead of just a `Exception` ([GH12551](#))
- A `CParserError` is now raised instead of a generic `Exception` in `read_csv` when the `c` engine cannot parse a column ([GH12506](#))
- A `ValueError` is now raised instead of a generic `Exception` in `read_csv` when the `c` engine encounters a `NaN` value in an integer column ([GH12506](#))
- A `ValueError` is now raised instead of a generic `Exception` in `read_csv` when `true_values` is specified, and the `c` engine encounters an element in a column containing unencodable bytes ([GH12506](#))
- `pandas.parser.OverflowError` exception has been removed and has been replaced with Python's built-in `OverflowError` exception ([GH12506](#))
- `pd.read_csv()` no longer allows a combination of strings and integers for the `usecols` parameter ([GH12678](#))

### Method `to_datetime` error changes

Bugs in `pd.to_datetime()` when passing a `unit` with convertible entries and `errors='coerce'` or non-convertible with `errors='ignore'`. Furthermore, an `OutOfBoundsDatetime` exception will be raised when an out-of-range value is encountered for that unit when `errors='raise'`. ([GH11758](#), [GH13052](#), [GH13059](#))

Previous behaviour:

```
In [27]: pd.to_datetime(1420043460, unit='s', errors='coerce')
Out[27]: NaT

In [28]: pd.to_datetime(11111111, unit='D', errors='ignore')
OverflowError: Python int too large to convert to C long

In [29]: pd.to_datetime(11111111, unit='D', errors='raise')
OverflowError: Python int too large to convert to C long
```

New behaviour:

```
In [2]: pd.to_datetime(1420043460, unit='s', errors='coerce')
Out[2]: Timestamp('2014-12-31 16:31:00')

In [3]: pd.to_datetime(11111111, unit='D', errors='ignore')
Out[3]: 11111111

In [4]: pd.to_datetime(11111111, unit='D', errors='raise')
OutOfBoundsDatetime: cannot convert input with unit 'D'
```

## Other API changes

- `.swaplevel()` for `Series`, `DataFrame`, `Panel`, and `MultiIndex` now features defaults for its first two parameters `i` and `j` that swap the two innermost levels of the index. (GH12934)
- `.searchsorted()` for `Index` and `TimedeltaIndex` now accept a `sorter` argument to maintain compatibility with `numpy`'s `searchsorted` function (GH12238)
- `Period` and `PeriodIndex` now raises `IncompatibleFrequency` error which inherits `ValueError` rather than raw `ValueError` (GH12615)
- `Series.apply` for category dtype now applies the passed function to each of the `.categories` (and not the `.codes`), and returns a category dtype if possible (GH12473)
- `read_csv` will now raise a `TypeError` if `parse_dates` is neither a boolean, list, or dictionary (matches the doc-string) (GH5636)
- The default for `.query()/eval()` is now `engine=None`, which will use `numexpr` if it's installed; otherwise it will fallback to the `python` engine. This mimics the pre-0.18.1 behavior if `numexpr` is installed (and which, previously, if `numexpr` was not installed, `.query()/eval()` would raise). (GH12749)
- `pd.show_versions()` now includes `pandas_datareader` version (GH12740)
- Provide a proper `__name__` and `__qualname__` attributes for generic functions (GH12021)
- `pd.concat(ignore_index=True)` now uses `RangeIndex` as default (GH12695)
- `pd.merge()` and `DataFrame.join()` will show a `UserWarning` when merging/joining a single- with a multi-levelled dataframe (GH9455, GH12219)
- Compat with `scipy > 0.17` for deprecated `piecewise_polynomial` interpolation method; support for the replacement `from_derivatives` method (GH12887)

## Deprecations

- The method name `Index.sym_diff()` is deprecated and can be replaced by `Index.symmetric_difference()` (GH12591)
- The method name `Categorical.sort()` is deprecated in favor of `Categorical.sort_values()` (GH12882)

## Performance improvements

- Improved speed of SAS reader (GH12656, GH12961)
- Performance improvements in `.groupby(...).cumcount()` (GH11039)
- Improved memory usage in `pd.read_csv()` when using `skiprows=an_integer` (GH13005)
- Improved performance of `DataFrame.to_sql` when checking case sensitivity for tables. Now only checks if table has been created correctly when table name is not lower case. (GH12876)
- Improved performance of `Period` construction and time series plotting (GH12903, GH11831).
- Improved performance of `.str.encode()` and `.str.decode()` methods (GH13008)
- Improved performance of `to_numeric` if input is numeric dtype (GH12777)
- Improved performance of sparse arithmetic with `IntIndex` (GH13036)

## Bug fixes

- `usecols` parameter in `pd.read_csv` is now respected even when the lines of a CSV file are not even (GH12203)
- Bug in `groupby.transform(...)` when `axis=1` is specified with a non-monotonic ordered index (GH12713)
- Bug in `Period` and `PeriodIndex` creation raises `KeyError` if `freq="Minute"` is specified. Note that “Minute” `freq` is deprecated in v0.17.0, and recommended to use `freq="T"` instead (GH11854)
- Bug in `.resample(...).count()` with a `PeriodIndex` always raising a `TypeError` (GH12774)
- Bug in `.resample(...)` with a `PeriodIndex` casting to a `DatetimeIndex` when empty (GH12868)
- Bug in `.resample(...)` with a `PeriodIndex` when resampling to an existing frequency (GH12770)
- Bug in printing data which contains `Period` with different `freq` raises `ValueError` (GH12615)
- Bug in `Series` construction with `Categorical` and `dtype='category'` is specified (GH12574)
- Bugs in concatenation with a coercible `dtype` was too aggressive, resulting in different `dtypes` in output formatting when an object was longer than `display.max_rows` (GH12411, GH12045, GH11594, GH10571, GH12211)
- Bug in `float_format` option with option not being validated as a callable. (GH12706)
- Bug in `GroupBy.filter` when `dropna=False` and no groups fulfilled the criteria (GH12768)
- Bug in `__name__` of `.cum*` functions (GH12021)
- Bug in `.astype()` of a `Float64Index/Int64Index` to an `Int64Index` (GH12881)
- Bug in round tripping an integer based index in `.to_json()/read_json()` when `orient='index'` (the default) (GH12866)
- Bug in plotting `Categorical` `dtypes` cause error when attempting stacked bar plot (GH13019)
- Compat with `>= numpy 1.11` for `NaT` comparisons (GH12969)
- Bug in `.drop()` with a non-unique `MultiIndex`. (GH12701)
- Bug in `.concat` of `datetime tz-aware` and `naive DataFrames` (GH12467)
- Bug in correctly raising a `ValueError` in `.resample(...).fillna(...)` when passing a non-string (GH12952)
- Bug fixes in various encoding and header processing issues in `pd.read_sas()` (GH12659, GH12654, GH12647, GH12809)
- Bug in `pd.crosstab()` where would silently ignore `aggfunc` if `values=None` (GH12569).
- Potential segfault in `DataFrame.to_json` when serialising `datetime.time` (GH11473).
- Potential segfault in `DataFrame.to_json` when attempting to serialise `0d` array (GH11299).
- Segfault in `to_json` when attempting to serialise a `DataFrame` or `Series` with non-ndarray values; now supports serialization of `category`, `sparse`, and `datetime64[ns, tz]` `dtypes` (GH10778).
- Bug in `DataFrame.to_json` with unsupported `dtype` not passed to default handler (GH12554).
- Bug in `.align` not returning the sub-class (GH12983)
- Bug in aligning a `Series` with a `DataFrame` (GH13037)
- Bug in `ABCPanel` in which `Panel4D` was not being considered as a valid instance of this generic type (GH12810)
- Bug in consistency of `.name` on `.groupby(...).apply(...)` cases (GH12363)
- Bug in `Timestamp.__repr__` that caused `pprint` to fail in nested structures (GH12622)
- Bug in `Timedelta.min` and `Timedelta.max`, the properties now report the true minimum/maximum `timedeltas` as recognized by pandas. See the *documentation*. (GH12727)

- Bug in `.quantile()` with interpolation may coerce to float unexpectedly (GH12772)
- Bug in `.quantile()` with empty Series may return scalar rather than empty Series (GH12772)
- Bug in `.loc` with out-of-bounds in a large indexer would raise `IndexError` rather than `KeyError` (GH12527)
- Bug in resampling when using a `TimedeltaIndex` and `.asfreq()`, would previously not include the final fencepost (GH12926)
- Bug in equality testing with a `Categorical` in a `DataFrame` (GH12564)
- Bug in `GroupBy.first()`, `.last()` returns incorrect row when `TimeGrouper` is used (GH7453)
- Bug in `pd.read_csv()` with the `c` engine when specifying `skiprows` with newlines in quoted items (GH10911, GH12775)
- Bug in `DataFrame` timezone lost when assigning tz-aware datetime Series with alignment (GH12981)
- Bug in `.value_counts()` when `normalize=True` and `dropna=True` where nulls still contributed to the normalized count (GH12558)
- Bug in `Series.value_counts()` loses name if its dtype is category (GH12835)
- Bug in `Series.value_counts()` loses timezone info (GH12835)
- Bug in `Series.value_counts(normalize=True)` with `Categorical` raises `UnboundLocalError` (GH12835)
- Bug in `Panel.fillna()` ignoring `inplace=True` (GH12633)
- Bug in `pd.read_csv()` when specifying `names`, `usecols`, and `parse_dates` simultaneously with the `c` engine (GH9755)
- Bug in `pd.read_csv()` when specifying `delim_whitespace=True` and `lineterminator` simultaneously with the `c` engine (GH12912)
- Bug in `Series.rename`, `DataFrame.rename` and `DataFrame.rename_axis` not treating Series as mappings to relabel (GH12623).
- Clean in `.rolling.min` and `.rolling.max` to enhance dtype handling (GH12373)
- Bug in `groupby` where complex types are coerced to float (GH12902)
- Bug in `Series.map` raises `TypeError` if its dtype is category or tz-aware datetime (GH12473)
- Bugs on 32bit platforms for some test comparisons (GH12972)
- Bug in index coercion when falling back from `RangeIndex` construction (GH12893)
- Better error message in window functions when invalid argument (e.g. a float window) is passed (GH12669)
- Bug in slicing subclassed `DataFrame` defined to return subclassed `Series` may return normal `Series` (GH11559)
- Bug in `.str` accessor methods may raise `ValueError` if input has name and the result is `DataFrame` or `MultiIndex` (GH12617)
- Bug in `DataFrame.last_valid_index()` and `DataFrame.first_valid_index()` on empty frames (GH12800)
- Bug in `CategoricalIndex.get_loc` returns different result from regular `Index` (GH12531)
- Bug in `PeriodIndex.resample` where name not propagated (GH12769)
- Bug in `date_range` closed keyword and timezones (GH12684).
- Bug in `pd.concat` raises `AttributeError` when input data contains tz-aware datetime and `timedelta` (GH12620)

- Bug in `pd.concat` did not handle empty Series properly (GH11082)
- Bug in `.plot.bar` alignment when `width` is specified with `int` (GH12979)
- Bug in `fill_value` is ignored if the argument to a binary operator is a constant (GH12723)
- Bug in `pd.read_html()` when using `bs4` flavor and parsing table with a header and only one column (GH9178)
- Bug in `.pivot_table` when `margins=True` and `dropna=True` where nulls still contributed to margin count (GH12577)
- Bug in `.pivot_table` when `dropna=False` where table index/column names disappear (GH12133)
- Bug in `pd.crosstab()` when `margins=True` and `dropna=False` which raised (GH12642)
- Bug in `Series.name` when `name` attribute can be a hashable type (GH12610)
- Bug in `.describe()` resets categorical columns information (GH11558)
- Bug where `loffset` argument was not applied when calling `resample().count()` on a timeseries (GH12725)
- `pd.read_excel()` now accepts column names associated with keyword argument `names` (GH12870)
- Bug in `pd.to_numeric()` with `Index` returns `np.ndarray`, rather than `Index` (GH12777)
- Bug in `pd.to_numeric()` with datetime-like may raise `TypeError` (GH12777)
- Bug in `pd.to_numeric()` with scalar raises `ValueError` (GH12777)

### 5.12.2 Version 0.18.0 (March 13, 2016)

This is a major release from 0.17.1 and includes a small number of API changes, several new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

**Warning:** pandas  $\geq$  0.18.0 no longer supports compatibility with Python version 2.6 and 3.3 ([GH7718](#), [GH11273](#))

**Warning:** numexpr version 2.4.4 will now show a warning and not be used as a computation back-end for pandas because of some buggy behavior. This does not affect other versions ( $\geq$  2.1 and  $\geq$  2.4.6). ([GH12489](#))

Highlights include:

- Moving and expanding window functions are now methods on Series and DataFrame, similar to `.groupby`, see [here](#).
- Adding support for a RangeIndex as a specialized form of the Int64Index for memory savings, see [here](#).
- API breaking change to the `.resample` method to make it more `.groupby` like, see [here](#).
- Removal of support for positional indexing with floats, which was deprecated since 0.14.0. This will now raise a `TypeError`, see [here](#).
- The `.to_xarray()` function has been added for compatibility with the `xarray` package, see [here](#).
- The `read_sas` function has been enhanced to read `sas7bdat` files, see [here](#).
- Addition of the `.str.extractall()` method, and API changes to the `.str.extract()` method and `.str.cat()` method.
- `pd.test()` top-level nose test runner is available ([GH4327](#)).

Check the [API Changes](#) and [deprecations](#) before updating.

#### What's new in v0.18.0

- *New features*
  - *Window functions are now methods*
  - *Changes to rename*
  - *Range Index*
  - *Changes to str.extract*
  - *Addition of str.extractall*

- *Changes to str.cat*
- *Datetimelike rounding*
- *Formatting of integers in FloatIndex*
- *Changes to dtype assignment behaviors*
- *Method to \_xarray*
- *Latex representation*
- *pd.read\_sas() changes*
- *Other enhancements*
- *Backwards incompatible API changes*
  - *NaT and Timedelta operations*
  - *Changes to msgpack*
  - *Signature change for .rank*
  - *Bug in QuarterBegin with n=0*
  - *Resample API*
    - \* *Downsampling*
    - \* *Upsampling*
    - \* *Previous API will work but with deprecations*
  - *Changes to eval*
  - *Other API changes*
  - *Deprecations*
  - *Removal of deprecated float indexers*
  - *Removal of prior version deprecations/changes*
- *Performance improvements*
- *Bug fixes*
- *Contributors*

## New features

### Window functions are now methods

Window functions have been refactored to be methods on `Series/DataFrame` objects, rather than top-level functions, which are now deprecated. This allows these window-type functions, to have a similar API to that of `.groupby`. See the full documentation [here](#) (GH11603, GH12373)

```
In [1]: np.random.seed(1234)
```

```
In [2]: df = pd.DataFrame({'A': range(10), 'B': np.random.randn(10)})
```

```
In [3]: df
```

| 7 | 6.0  | 1.0 | 0.370076  | 0.871850 |
| 8 | 7.0  | 1.0 | 0.079587  | 0.750099 |
| 9 | 8.0  | 1.0 | -0.954504 | 1.162285 |

```
[10 rows x 4 columns]
```

## Changes to rename

`Series.rename` and `NDFrame.rename_axis` can now take a scalar or list-like argument for altering the Series or axis *name*, in addition to their old behaviors of altering labels. (GH9494, GH11965)

```
In [9]: s = pd.Series(np.random.randn(5))
```

```
In [10]: s.rename('newname')
```

```
Out[10]:
```

```
0 1.150036
1 0.991946
2 0.953324
3 -2.021255
4 -0.334077
```

```
Name: newname, Length: 5, dtype: float64
```

```
In [11]: df = pd.DataFrame(np.random.randn(5, 2))
```

```
In [12]: (df.rename_axis("indexname")
```

```
.....: .rename_axis("columns_name", axis="columns"))
```

```
.....:
```

```
Out[12]:
```

```
columns_name 0 1
indexname
0 0.002118 0.405453
1 0.289092 1.321158
2 -1.546906 -0.202646
3 -0.655969 0.193421
4 0.553439 1.318152
```

```
[5 rows x 2 columns]
```

The new functionality works well in method chains. Previously these methods only accepted functions or dicts mapping a *label* to a new label. This continues to work as before for function or dict-like values.

## Range Index

A `RangeIndex` has been added to the `Int64Index` sub-classes to support a memory saving alternative for common use cases. This has a similar implementation to the python `range` object (`xrange` in python 2), in that it only stores the start, stop, and step values for the index. It will transparently interact with the user API, converting to `Int64Index` if needed.

This will now be the default constructed index for `NDFrame` objects, rather than previous an `Int64Index`. (GH939, GH12070, GH12071, GH12109, GH12888)

Previous behavior:

```
In [3]: s = pd.Series(range(1000))
```

```
In [4]: s.index
```

```
Out[4]:
```

```
Int64Index([0, 1, 2, 3, 4, 5, 6, 7, 8, 9,
 ...
```

(continues on next page)

(continued from previous page)

```

990, 991, 992, 993, 994, 995, 996, 997, 998, 999], dtype='int64',
↳length=1000)
In [6]: s.index.nbytes
Out[6]: 8000

```

New behavior:

```

In [13]: s = pd.Series(range(1000))

In [14]: s.index
Out[14]: RangeIndex(start=0, stop=1000, step=1)

In [15]: s.index.nbytes
Out[15]: 128

```

## Changes to `str.extract`

The `.str.extract` method takes a regular expression with capture groups, finds the first match in each subject string, and returns the contents of the capture groups (GH11386).

In v0.18.0, the `expand` argument was added to `extract`.

- `expand=False`: it returns a `Series`, `Index`, or `DataFrame`, depending on the subject and regular expression pattern (same behavior as pre-0.18.0).
- `expand=True`: it always returns a `DataFrame`, which is more consistent and less confusing from the perspective of a user.

Currently the default is `expand=None` which gives a `FutureWarning` and uses `expand=False`. To avoid this warning, please explicitly specify `expand`.

```

In [1]: pd.Series(['a1', 'b2', 'c3']).str.extract(r'[ab](\d)', expand=None)
FutureWarning: currently extract(expand=None) means expand=False (return Index/Series/
↳DataFrame)
but in a future version of pandas this will be changed to expand=True (return DataFrame)

Out[1]:
0 1
1 2
2 NaN
dtype: object

```

Extracting a regular expression with one group returns a `Series` if `expand=False`.

```

In [16]: pd.Series(['a1', 'b2', 'c3']).str.extract(r'[ab](\d)', expand=False)
Out[16]:
0 1
1 2
2 NaN
Length: 3, dtype: object

```

It returns a `DataFrame` with one column if `expand=True`.

```
In [17]: pd.Series(['a1', 'b2', 'c3']).str.extract(r'[ab](\d)', expand=True)
Out[17]:
 0
0 1
1 2
2 NaN

[3 rows x 1 columns]
```

Calling on an Index with a regex with exactly one capture group returns an Index if `expand=False`.

```
In [18]: s = pd.Series(["a1", "b2", "c3"], ["A11", "B22", "C33"])
In [19]: s.index
Out[19]: Index(['A11', 'B22', 'C33'], dtype='object')
In [20]: s.index.str.extract("(?P<letter>[a-zA-Z])", expand=False)
Out[20]: Index(['A', 'B', 'C'], dtype='object', name='letter')
```

It returns a DataFrame with one column if `expand=True`.

```
In [21]: s.index.str.extract("(?P<letter>[a-zA-Z])", expand=True)
Out[21]:
 letter
0 A
1 B
2 C

[3 rows x 1 columns]
```

Calling on an Index with a regex with more than one capture group raises `ValueError` if `expand=False`.

```
>>> s.index.str.extract("(?P<letter>[a-zA-Z])([0-9]+)", expand=False)
ValueError: only one regex group is supported with Index
```

It returns a DataFrame if `expand=True`.

```
In [22]: s.index.str.extract("(?P<letter>[a-zA-Z])([0-9]+)", expand=True)
Out[22]:
 letter 1
0 A 11
1 B 22
2 C 33

[3 rows x 2 columns]
```

In summary, `extract(expand=True)` always returns a DataFrame with a row for every subject string, and a column for every capture group.

## Addition of `str.extractall`

The `.str.extractall` method was added (GH11386). Unlike `extract`, which returns only the first match.

```
In [23]: s = pd.Series(["a1a2", "b1", "c1"], ["A", "B", "C"])

In [24]: s
Out[24]:
A a1a2
B b1
C c1
Length: 3, dtype: object

In [25]: s.str.extract(r"(?P<letter>[ab])(?P<digit>\d)", expand=False)
Out[25]:
 letter digit
A a 1
B b 1
C NaN NaN

[3 rows x 2 columns]
```

The `extractall` method returns all matches.

```
In [26]: s.str.extractall(r"(?P<letter>[ab])(?P<digit>\d)")
Out[26]:
 letter digit
match
A 0 a 1
 1 a 2
B 0 b 1

[3 rows x 2 columns]
```

## Changes to `str.cat`

The method `.str.cat()` concatenates the members of a `Series`. Before, if `NaN` values were present in the `Series`, calling `.str.cat()` on it would return `NaN`, unlike the rest of the `Series.str.*` API. This behavior has been amended to ignore `NaN` values by default. (GH11435).

A new, friendlier `ValueError` is added to protect against the mistake of supplying the `sep` as an arg, rather than as a kwarg. (GH11334).

```
In [27]: pd.Series(['a', 'b', np.nan, 'c']).str.cat(sep=' ')
Out[27]: 'a b c'

In [28]: pd.Series(['a', 'b', np.nan, 'c']).str.cat(sep=' ', na_rep='?')
Out[28]: 'a b ? c'
```

```
In [2]: pd.Series(['a', 'b', np.nan, 'c']).str.cat(' ')
ValueError: Did you mean to supply a ``sep`` keyword?
```

## Datetimelike rounding

DatetimeIndex, Timestamp, TimedeltaIndex, Timedelta have gained the `.round()`, `.floor()` and `.ceil()` method for datetimelike rounding, flooring and ceiling. (GH4314, GH11963)

Naive datetimes

```
In [29]: dr = pd.date_range('20130101 09:12:56.1234', periods=3)

In [30]: dr
Out[30]:
DatetimeIndex(['2013-01-01 09:12:56.123400', '2013-01-02 09:12:56.123400',
 '2013-01-03 09:12:56.123400'],
 dtype='datetime64[ns]', freq='D')

In [31]: dr.round('s')
Out[31]:
DatetimeIndex(['2013-01-01 09:12:56', '2013-01-02 09:12:56',
 '2013-01-03 09:12:56'],
 dtype='datetime64[ns]', freq=None)

Timestamp scalar
In [32]: dr[0]
Out[32]: Timestamp('2013-01-01 09:12:56.123400', freq='D')

In [33]: dr[0].round('10s')
Out[33]: Timestamp('2013-01-01 09:13:00')
```

Tz-aware are rounded, floored and ceiled in local times

```
In [34]: dr = dr.tz_localize('US/Eastern')

In [35]: dr
Out[35]:
DatetimeIndex(['2013-01-01 09:12:56.123400-05:00',
 '2013-01-02 09:12:56.123400-05:00',
 '2013-01-03 09:12:56.123400-05:00'],
 dtype='datetime64[ns, US/Eastern]', freq=None)

In [36]: dr.round('s')
Out[36]:
DatetimeIndex(['2013-01-01 09:12:56-05:00', '2013-01-02 09:12:56-05:00',
 '2013-01-03 09:12:56-05:00'],
 dtype='datetime64[ns, US/Eastern]', freq=None)
```

Timedeltas

```
In [37]: t = pd.timedelta_range('1 days 2 hr 13 min 45 us', periods=3, freq='d')

In [38]: t
Out[38]:
TimedeltaIndex(['1 days 02:13:00.000045', '2 days 02:13:00.000045',
 '3 days 02:13:00.000045'],
 dtype='timedelta64[ns]', freq='D')
```

(continues on next page)

(continued from previous page)

```

In [39]: t.round('10min')
Out[39]: TimedeltaIndex(['1 days 02:10:00', '2 days 02:10:00', '3 days 02:10:00'], dtype=
↳ 'timedelta64[ns]', freq=None)

Timedelta scalar
In [40]: t[0]
Out[40]: Timedelta('1 days 02:13:00.000045')

In [41]: t[0].round('2h')
Out[41]: Timedelta('1 days 02:00:00')

```

In addition, `.round()`, `.floor()` and `.ceil()` will be available through the `.dt` accessor of `Series`.

```

In [42]: s = pd.Series(dr)

In [43]: s
Out[43]:
0 2013-01-01 09:12:56.123400-05:00
1 2013-01-02 09:12:56.123400-05:00
2 2013-01-03 09:12:56.123400-05:00
Length: 3, dtype: datetime64[ns, US/Eastern]

In [44]: s.dt.round('D')
Out[44]:
0 2013-01-01 00:00:00-05:00
1 2013-01-02 00:00:00-05:00
2 2013-01-03 00:00:00-05:00
Length: 3, dtype: datetime64[ns, US/Eastern]

```

### Formatting of integers in FloatIndex

Integers in `FloatIndex`, e.g. `1.`, are now formatted with a decimal point and a `0` digit, e.g. `1.0` ([GH11713](#)) This change not only affects the display to the console, but also the output of IO methods like `.to_csv` or `.to_html`.

Previous behavior:

```

In [2]: s = pd.Series([1, 2, 3], index=np.arange(3.))

In [3]: s
Out[3]:
0 1
1 2
2 3
dtype: int64

In [4]: s.index
Out[4]: Float64Index([0.0, 1.0, 2.0], dtype='float64')

In [5]: print(s.to_csv(path=None))
0,1

```

(continues on next page)

(continued from previous page)

```
1,2
2,3
```

New behavior:

```
In [45]: s = pd.Series([1, 2, 3], index=np.arange(3.))

In [46]: s
Out[46]:
0.0 1
1.0 2
2.0 3
Length: 3, dtype: int64

In [47]: s.index
Out[47]: Float64Index([0.0, 1.0, 2.0], dtype='float64')

In [48]: print(s.to_csv(path_or_buf=None, header=False))
0.0,1
1.0,2
2.0,3
```

### Changes to dtype assignment behaviors

When a DataFrame's slice is updated with a new slice of the same dtype, the dtype of the DataFrame will now remain the same. (GH10503)

Previous behavior:

```
In [5]: df = pd.DataFrame({'a': [0, 1, 1],
 'b': pd.Series([100, 200, 300], dtype='uint32')})

In [7]: df.dtypes
Out[7]:
a int64
b uint32
dtype: object

In [8]: ix = df['a'] == 1

In [9]: df.loc[ix, 'b'] = df.loc[ix, 'b']

In [11]: df.dtypes
Out[11]:
a int64
b int64
dtype: object
```

New behavior:

```
In [49]: df = pd.DataFrame({'a': [0, 1, 1],
.....: 'b': pd.Series([100, 200, 300], dtype='uint32')})
```

(continues on next page)

(continued from previous page)

```

.....:
In [50]: df.dtypes
Out[50]:
a int64
b uint32
Length: 2, dtype: object

```

```
In [51]: ix = df['a'] == 1
```

```
In [52]: df.loc[ix, 'b'] = df.loc[ix, 'b']
```

```

In [53]: df.dtypes
Out[53]:
a int64
b uint32
Length: 2, dtype: object

```

When a DataFrame's integer slice is partially updated with a new slice of floats that could potentially be down-casted to integer without losing precision, the dtype of the slice will be set to float instead of integer.

Previous behavior:

```

In [4]: df = pd.DataFrame(np.array(range(1,10)).reshape(3,3),
 columns=list('abc'),
 index=[[4,4,8], [8,10,12]])

```

```

In [5]: df
Out[5]:
 a b c
4 8 1 2 3
10 4 4 5 6
8 12 7 8 9

```

```
In [7]: df.ix[4, 'c'] = np.array([0., 1.])
```

```

In [8]: df
Out[8]:
 a b c
4 8 1 2 0
10 4 4 5 1
8 12 7 8 9

```

New behavior:

```

In [54]: df = pd.DataFrame(np.array(range(1,10)).reshape(3,3),
.....: columns=list('abc'),
.....: index=[[4,4,8], [8,10,12]])
.....:

In [55]: df
Out[55]:
 a b c

```

(continues on next page)

(continued from previous page)

```

4 8 1 2 3
 10 4 5 6
8 12 7 8 9

[3 rows x 3 columns]

```

```
In [56]: df.loc[4, 'c'] = np.array([0., 1.])
```

```
In [57]: df
```

```

Out[57]:
 a b c
4 8 1 2 0.0
 10 4 5 1.0
8 12 7 8 9.0

[3 rows x 3 columns]

```

### Method to\_xarray

In a future version of pandas, we will be deprecating Panel and other > 2 ndim objects. In order to provide for continuity, all NDFrame objects have gained the `.to_xarray()` method in order to convert to xarray objects, which has a pandas-like interface for > 2 ndim. ([GH11972](#))

See the [xarray full-documentation](#) here.

```
In [1]: p = Panel(np.arange(2*3*4).reshape(2,3,4))
```

```
In [2]: p.to_xarray()
```

```

Out[2]:
<xarray.DataArray (items: 2, major_axis: 3, minor_axis: 4)>
array([[[0, 1, 2, 3],
 [4, 5, 6, 7],
 [8, 9, 10, 11]],

 [[12, 13, 14, 15],
 [16, 17, 18, 19],
 [20, 21, 22, 23]])
Coordinates:
 * items (items) int64 0 1
 * major_axis (major_axis) int64 0 1 2
 * minor_axis (minor_axis) int64 0 1 2 3

```

## Latex representation

DataFrame has gained a `._repr_latex_()` method in order to allow for conversion to latex in a ipython/jupyter notebook using nbconvert. (GH11778)

Note that this must be activated by setting the option `pd.display.latex.repr=True` (GH12182)

For example, if you have a jupyter notebook you plan to convert to latex using nbconvert, place the statement `pd.display.latex.repr=True` in the first cell to have the contained DataFrame output also stored as latex.

The options `display.latex.escape` and `display.latex.longtable` have also been added to the configuration and are used automatically by the `to_latex` method. See the *available options docs* for more info.

## pd.read\_sas() changes

`read_sas` has gained the ability to read SAS7BDAT files, including compressed files. The files can be read in entirety, or incrementally. For full details see *here*. (GH4052)

## Other enhancements

- Handle truncated floats in SAS xport files (GH11713)
- Added option to hide index in `Series.to_string` (GH11729)
- `read_excel` now supports s3 urls of the format `s3://bucketname/filename` (GH11447)
- add support for `AWS_S3_HOST` env variable when reading from s3 (GH12198)
- A simple version of `Panel.round()` is now implemented (GH11763)
- For Python 3.x, `round(DataFrame)`, `round(Series)`, `round(Panel)` will work (GH11763)
- `sys.getsizeof(obj)` returns the memory usage of a pandas object, including the values it contains (GH11597)
- `Series` gained an `is_unique` attribute (GH11946)
- `DataFrame.quantile` and `Series.quantile` now accept interpolation keyword (GH10174).
- Added `DataFrame.style.format` for more flexible formatting of cell values (GH11692)
- `DataFrame.select_dtypes` now allows the `np.float16` type code (GH11990)
- `pivot_table()` now accepts most iterables for the `values` parameter (GH12017)
- Added Google BigQuery service account authentication support, which enables authentication on remote servers. (GH11881, GH12572). For further details see *here*
- `HDFStore` is now iterable: `for k in store` is equivalent to `for k in store.keys()` (GH12221).
- Add missing methods/fields to `.dt` for `Period` (GH8848)
- The entire code base has been PEP-ified (GH12096)

## Backwards incompatible API changes

- the leading white spaces have been removed from the output of `.to_string(index=False)` method (GH11833)
- the `out` parameter has been removed from the `Series.round()` method. (GH11763)
- `DataFrame.round()` leaves non-numeric columns unchanged in its return, rather than raises. (GH11885)
- `DataFrame.head(0)` and `DataFrame.tail(0)` return empty frames, rather than `self`. (GH11937)
- `Series.head(0)` and `Series.tail(0)` return empty series, rather than `self`. (GH11937)
- `to_msgpack` and `read_msgpack` encoding now defaults to 'utf-8'. (GH12170)
- the order of keyword arguments to text file parsing functions (`.read_csv()`, `.read_table()`, `.read_fwf()`) changed to group related arguments. (GH11555)
- `NaTType.isoformat` now returns the string 'NaT' to allow the result to be passed to the constructor of `Timestamp`. (GH12300)

## NaT and Timedelta operations

NaT and Timedelta have expanded arithmetic operations, which are extended to Series arithmetic where applicable. Operations defined for `datetime64[ns]` or `timedelta64[ns]` are now also defined for NaT (GH11564).

NaT now supports arithmetic operations with integers and floats.

```
In [58]: pd.NaT * 1
Out[58]: NaT

In [59]: pd.NaT * 1.5
Out[59]: NaT

In [60]: pd.NaT / 2
Out[60]: NaT

In [61]: pd.NaT * np.nan
Out[61]: NaT
```

NaT defines more arithmetic operations with `datetime64[ns]` and `timedelta64[ns]`.

```
In [62]: pd.NaT / pd.NaT
Out[62]: nan

In [63]: pd.Timedelta('1s') / pd.NaT
Out[63]: nan
```

NaT may represent either a `datetime64[ns]` null or a `timedelta64[ns]` null. Given the ambiguity, it is treated as a `timedelta64[ns]`, which allows more operations to succeed.

```
In [64]: pd.NaT + pd.NaT
Out[64]: NaT

same as
In [65]: pd.Timedelta('1s') + pd.Timedelta('1s')
Out[65]: Timedelta('0 days 00:00:02')
```

as opposed to

```
In [3]: pd.Timestamp('19900315') + pd.Timestamp('19900315')
TypeError: unsupported operand type(s) for +: 'Timestamp' and 'Timestamp'
```

However, when wrapped in a Series whose dtype is datetime64[ns] or timedelta64[ns], the dtype information is respected.

```
In [1]: pd.Series([pd.NaT], dtype='<M8[ns]') + pd.Series([pd.NaT], dtype='<M8[ns]')
TypeError: can only operate on a datetimes for subtraction,
 but the operator [__add__] was passed
```

```
In [66]: pd.Series([pd.NaT], dtype='<m8[ns]') + pd.Series([pd.NaT], dtype='<m8[ns]')
Out[66]:
0 NaT
Length: 1, dtype: timedelta64[ns]
```

Timedelta division by floats now works.

```
In [67]: pd.Timedelta('1s') / 2.0
Out[67]: Timedelta('0 days 00:00:00.500000')
```

Subtraction by Timedelta in a Series by a Timestamp works (GH11925)

```
In [68]: ser = pd.Series(pd.timedelta_range('1 day', periods=3))

In [69]: ser
Out[69]:
0 1 days
1 2 days
2 3 days
Length: 3, dtype: timedelta64[ns]

In [70]: pd.Timestamp('2012-01-01') - ser
Out[70]:
0 2011-12-31
1 2011-12-30
2 2011-12-29
Length: 3, dtype: datetime64[ns]
```

NaT.isoformat() now returns 'NaT'. This change allows pd.Timestamp to rehydrate any timestamp like object from its isoformat (GH12300).

## Changes to msgpack

Forward incompatible changes in msgpack writing format were made over 0.17.0 and 0.18.0; older versions of pandas cannot read files packed by newer versions (GH12129, GH10527)

Bugs in to\_msgpack and read\_msgpack introduced in 0.17.0 and fixed in 0.18.0, caused files packed in Python 2 unreadable by Python 3 (GH12142). The following table describes the backward and forward compat of msgpacks.

**Warning:**

| Packed with         | Can be unpacked with                                                                                    |
|---------------------|---------------------------------------------------------------------------------------------------------|
| pre-0.17 / Python 2 | any                                                                                                     |
| pre-0.17 / Python 3 | any                                                                                                     |
| 0.17 / Python 2     | <ul style="list-style-type: none"> <li>• ==0.17 / Python 2</li> <li>• &gt;=0.18 / any Python</li> </ul> |
| 0.17 / Python 3     | >=0.18 / any Python                                                                                     |
| 0.18                | >= 0.18                                                                                                 |

0.18.0 is backward-compatible for reading files packed by older versions, except for files packed with 0.17 in Python 2, in which case only they can only be unpacked in Python 2.

### Signature change for .rank

Series.rank and DataFrame.rank now have the same signature (GH11759)

Previous signature

```
In [3]: pd.Series([0,1]).rank(method='average', na_option='keep',
 ascending=True, pct=False)

Out[3]:
0 1
1 2
dtype: float64

In [4]: pd.DataFrame([0,1]).rank(axis=0, numeric_only=None,
 method='average', na_option='keep',
 ascending=True, pct=False)

Out[4]:
0
0 1
1 2
```

New signature

```
In [71]: pd.Series([0,1]).rank(axis=0, method='average', numeric_only=None,
 : na_option='keep', ascending=True, pct=False)
 :

Out[71]:
0 1.0
1 2.0
Length: 2, dtype: float64

In [72]: pd.DataFrame([0,1]).rank(axis=0, method='average', numeric_only=None,
 : na_option='keep', ascending=True, pct=False)
 :

Out[72]:
0
0 1.0
1 2.0
```

(continues on next page)

(continued from previous page)

```
[2 rows x 1 columns]
```

### Bug in QuarterBegin with n=0

In previous versions, the behavior of the QuarterBegin offset was inconsistent depending on the date when the `n` parameter was 0. (GH11406)

The general semantics of anchored offsets for `n=0` is to not move the date when it is an anchor point (e.g., a quarter start date), and otherwise roll forward to the next anchor point.

```
In [73]: d = pd.Timestamp('2014-02-01')

In [74]: d
Out[74]: Timestamp('2014-02-01 00:00:00')

In [75]: d + pd.offsets.QuarterBegin(n=0, startingMonth=2)
Out[75]: Timestamp('2014-02-01 00:00:00')

In [76]: d + pd.offsets.QuarterBegin(n=0, startingMonth=1)
Out[76]: Timestamp('2014-04-01 00:00:00')
```

For the QuarterBegin offset in previous versions, the date would be rolled *backwards* if date was in the same month as the quarter start date.

```
In [3]: d = pd.Timestamp('2014-02-15')

In [4]: d + pd.offsets.QuarterBegin(n=0, startingMonth=2)
Out[4]: Timestamp('2014-02-01 00:00:00')
```

This behavior has been corrected in version 0.18.0, which is consistent with other anchored offsets like MonthBegin and YearBegin.

```
In [77]: d = pd.Timestamp('2014-02-15')

In [78]: d + pd.offsets.QuarterBegin(n=0, startingMonth=2)
Out[78]: Timestamp('2014-05-01 00:00:00')
```

### Resample API

Like the change in the window functions API *above*, `.resample(...)` is changing to have a more groupby-like API. (GH11732, GH12702, GH12202, GH12332, GH12334, GH12348, GH12448).

```
In [79]: np.random.seed(1234)

In [80]: df = pd.DataFrame(np.random.rand(10,4),
.....: columns=list('ABCD'),
.....: index=pd.date_range('2010-01-01 09:00:00',
.....: periods=10, freq='s'))
```

(continues on next page)

(continued from previous page)

**In [81]:** df**Out[81]:**

|                     | A        | B        | C        | D        |
|---------------------|----------|----------|----------|----------|
| 2010-01-01 09:00:00 | 0.191519 | 0.622109 | 0.437728 | 0.785359 |
| 2010-01-01 09:00:01 | 0.779976 | 0.272593 | 0.276464 | 0.801872 |
| 2010-01-01 09:00:02 | 0.958139 | 0.875933 | 0.357817 | 0.500995 |
| 2010-01-01 09:00:03 | 0.683463 | 0.712702 | 0.370251 | 0.561196 |
| 2010-01-01 09:00:04 | 0.503083 | 0.013768 | 0.772827 | 0.882641 |
| 2010-01-01 09:00:05 | 0.364886 | 0.615396 | 0.075381 | 0.368824 |
| 2010-01-01 09:00:06 | 0.933140 | 0.651378 | 0.397203 | 0.788730 |
| 2010-01-01 09:00:07 | 0.316836 | 0.568099 | 0.869127 | 0.436173 |
| 2010-01-01 09:00:08 | 0.802148 | 0.143767 | 0.704261 | 0.704581 |
| 2010-01-01 09:00:09 | 0.218792 | 0.924868 | 0.442141 | 0.909316 |

[10 rows x 4 columns]

**Previous API:**

You would write a resampling operation that immediately evaluates. If a `how` parameter was not provided, it would default to `how='mean'`.

**In [6]:** df.resample('2s')**Out[6]:**

|                     | A        | B        | C        | D        |
|---------------------|----------|----------|----------|----------|
| 2010-01-01 09:00:00 | 0.485748 | 0.447351 | 0.357096 | 0.793615 |
| 2010-01-01 09:00:02 | 0.820801 | 0.794317 | 0.364034 | 0.531096 |
| 2010-01-01 09:00:04 | 0.433985 | 0.314582 | 0.424104 | 0.625733 |
| 2010-01-01 09:00:06 | 0.624988 | 0.609738 | 0.633165 | 0.612452 |
| 2010-01-01 09:00:08 | 0.510470 | 0.534317 | 0.573201 | 0.806949 |

You could also specify a `how` directly

**In [7]:** df.resample('2s', how='sum')**Out[7]:**

|                     | A        | B        | C        | D        |
|---------------------|----------|----------|----------|----------|
| 2010-01-01 09:00:00 | 0.971495 | 0.894701 | 0.714192 | 1.587231 |
| 2010-01-01 09:00:02 | 1.641602 | 1.588635 | 0.728068 | 1.062191 |
| 2010-01-01 09:00:04 | 0.867969 | 0.629165 | 0.848208 | 1.251465 |
| 2010-01-01 09:00:06 | 1.249976 | 1.219477 | 1.266330 | 1.224904 |
| 2010-01-01 09:00:08 | 1.020940 | 1.068634 | 1.146402 | 1.613897 |

**New API:**

Now, you can write `.resample(..)` as a 2-stage operation like `.groupby(...)`, which yields a `Resampler`.

**In [82]:** r = df.resample('2s')**In [83]:** r**Out[83]:** <pandas.core.resample.DatetimeIndexResampler object at 0x7f2601887d30>

## Downsampling

You can then use this object to perform operations. These are downsampling operations (going from a higher frequency to a lower one).

```
In [84]: r.mean()
```

```
Out[84]:
```

|                     | A        | B        | C        | D        |
|---------------------|----------|----------|----------|----------|
| 2010-01-01 09:00:00 | 0.485748 | 0.447351 | 0.357096 | 0.793615 |
| 2010-01-01 09:00:02 | 0.820801 | 0.794317 | 0.364034 | 0.531096 |
| 2010-01-01 09:00:04 | 0.433985 | 0.314582 | 0.424104 | 0.625733 |
| 2010-01-01 09:00:06 | 0.624988 | 0.609738 | 0.633165 | 0.612452 |
| 2010-01-01 09:00:08 | 0.510470 | 0.534317 | 0.573201 | 0.806949 |

```
[5 rows x 4 columns]
```

```
In [85]: r.sum()
```

```
Out[85]:
```

|                     | A        | B        | C        | D        |
|---------------------|----------|----------|----------|----------|
| 2010-01-01 09:00:00 | 0.971495 | 0.894701 | 0.714192 | 1.587231 |
| 2010-01-01 09:00:02 | 1.641602 | 1.588635 | 0.728068 | 1.062191 |
| 2010-01-01 09:00:04 | 0.867969 | 0.629165 | 0.848208 | 1.251465 |
| 2010-01-01 09:00:06 | 1.249976 | 1.219477 | 1.266330 | 1.224904 |
| 2010-01-01 09:00:08 | 1.020940 | 1.068634 | 1.146402 | 1.613897 |

```
[5 rows x 4 columns]
```

Furthermore, `resample` now supports `getitem` operations to perform the resample on specific columns.

```
In [86]: r[['A', 'C']].mean()
```

```
Out[86]:
```

|                     | A        | C        |
|---------------------|----------|----------|
| 2010-01-01 09:00:00 | 0.485748 | 0.357096 |
| 2010-01-01 09:00:02 | 0.820801 | 0.364034 |
| 2010-01-01 09:00:04 | 0.433985 | 0.424104 |
| 2010-01-01 09:00:06 | 0.624988 | 0.633165 |
| 2010-01-01 09:00:08 | 0.510470 | 0.573201 |

```
[5 rows x 2 columns]
```

and `.aggregate` type operations.

```
In [87]: r.agg({'A' : 'mean', 'B' : 'sum'})
```

```
Out[87]:
```

|                     | A        | B        |
|---------------------|----------|----------|
| 2010-01-01 09:00:00 | 0.485748 | 0.894701 |
| 2010-01-01 09:00:02 | 0.820801 | 1.588635 |
| 2010-01-01 09:00:04 | 0.433985 | 0.629165 |
| 2010-01-01 09:00:06 | 0.624988 | 1.219477 |
| 2010-01-01 09:00:08 | 0.510470 | 1.068634 |

```
[5 rows x 2 columns]
```

These accessors can of course, be combined

```
In [88]: r[['A', 'B']].agg(['mean', 'sum'])
Out[88]:
```

|            |          | A        |          | B        |          |
|------------|----------|----------|----------|----------|----------|
|            |          | mean     | sum      | mean     | sum      |
| 2010-01-01 | 09:00:00 | 0.485748 | 0.971495 | 0.447351 | 0.894701 |
| 2010-01-01 | 09:00:02 | 0.820801 | 1.641602 | 0.794317 | 1.588635 |
| 2010-01-01 | 09:00:04 | 0.433985 | 0.867969 | 0.314582 | 0.629165 |
| 2010-01-01 | 09:00:06 | 0.624988 | 1.249976 | 0.609738 | 1.219477 |
| 2010-01-01 | 09:00:08 | 0.510470 | 1.020940 | 0.534317 | 1.068634 |

```
[5 rows x 4 columns]
```

## Upsampling

Upsampling operations take you from a lower frequency to a higher frequency. These are now performed with the Resampler objects with `backfill()`, `ffill()`, `fillna()` and `asfreq()` methods.

```
In [89]: s = pd.Series(np.arange(5, dtype='int64'),
.....: index=pd.date_range('2010-01-01', periods=5, freq='Q'))
.....:

In [90]: s
Out[90]:
```

|            |   |
|------------|---|
| 2010-03-31 | 0 |
| 2010-06-30 | 1 |
| 2010-09-30 | 2 |
| 2010-12-31 | 3 |
| 2011-03-31 | 4 |

```
Freq: Q-DEC, Length: 5, dtype: int64
```

Previously

```
In [6]: s.resample('M', fill_method='ffill')
Out[6]:
```

|            |   |
|------------|---|
| 2010-03-31 | 0 |
| 2010-04-30 | 0 |
| 2010-05-31 | 0 |
| 2010-06-30 | 1 |
| 2010-07-31 | 1 |
| 2010-08-31 | 1 |
| 2010-09-30 | 2 |
| 2010-10-31 | 2 |
| 2010-11-30 | 2 |
| 2010-12-31 | 3 |
| 2011-01-31 | 3 |
| 2011-02-28 | 3 |
| 2011-03-31 | 4 |

```
Freq: M, dtype: int64
```

New API

```
In [91]: s.resample('M').ffill()
Out[91]:
2010-03-31 0
2010-04-30 0
2010-05-31 0
2010-06-30 1
2010-07-31 1
2010-08-31 1
2010-09-30 2
2010-10-31 2
2010-11-30 2
2010-12-31 3
2011-01-31 3
2011-02-28 3
2011-03-31 4
Freq: M, Length: 13, dtype: int64
```

**Note:** In the new API, you can either downsample OR upsample. The prior implementation would allow you to pass an aggregator function (like mean) even though you were upsampling, providing a bit of confusion.

### Previous API will work but with deprecations

**Warning:** This new API for resample includes some internal changes for the prior-to-0.18.0 API, to work with a deprecation warning in most cases, as the resample operation returns a deferred object. We can intercept operations and just do what the (pre 0.18.0) API did (with a warning). Here is a typical use case:

```
In [4]: r = df.resample('2s')
```

```
In [6]: r*10
```

```
pandas/tseries/resample.py:80: FutureWarning: .resample() is now a deferred operation
use .resample(...).mean() instead of .resample(...)
```

```
Out[6]:
```

|                     | A        | B        | C        | D        |
|---------------------|----------|----------|----------|----------|
| 2010-01-01 09:00:00 | 4.857476 | 4.473507 | 3.570960 | 7.936154 |
| 2010-01-01 09:00:02 | 8.208011 | 7.943173 | 3.640340 | 5.310957 |
| 2010-01-01 09:00:04 | 4.339846 | 3.145823 | 4.241039 | 6.257326 |
| 2010-01-01 09:00:06 | 6.249881 | 6.097384 | 6.331650 | 6.124518 |
| 2010-01-01 09:00:08 | 5.104699 | 5.343172 | 5.732009 | 8.069486 |

However, getting and assignment operations directly on a Resampler will raise a ValueError:

```
In [7]: r.iloc[0] = 5
```

```
ValueError: .resample() is now a deferred operation
use .resample(...).mean() instead of .resample(...)
```

There is a situation where the new API can not perform all the operations when using original code. This code is intending to resample every 2s, take the mean AND then take the min of those results.

```
In [4]: df.resample('2s').min()
```

```
Out[4]:
```

```
A 0.433985
B 0.314582
C 0.357096
D 0.531096
dtype: float64
```

The new API will:

```
In [92]: df.resample('2s').min()
```

```
Out[92]:
```

|                     | A        | B        | C        | D        |
|---------------------|----------|----------|----------|----------|
| 2010-01-01 09:00:00 | 0.191519 | 0.272593 | 0.276464 | 0.785359 |
| 2010-01-01 09:00:02 | 0.683463 | 0.712702 | 0.357817 | 0.500995 |
| 2010-01-01 09:00:04 | 0.364886 | 0.013768 | 0.075381 | 0.368824 |
| 2010-01-01 09:00:06 | 0.316836 | 0.568099 | 0.397203 | 0.436173 |
| 2010-01-01 09:00:08 | 0.218792 | 0.143767 | 0.442141 | 0.704581 |

```
[5 rows x 4 columns]
```

The good news is the return dimensions will differ between the new API and the old API, so this should loudly raise an exception.

To replicate the original operation

```
In [93]: df.resample('2s').mean().min()
```

```
Out[93]:
```

```
A 0.433985
B 0.314582
C 0.357096
D 0.531096
Length: 4, dtype: float64
```

## Changes to eval

In prior versions, new columns assignments in an `eval` expression resulted in an inplace change to the `DataFrame`. (GH9297, GH8664, GH10486)

```
In [94]: df = pd.DataFrame({'a': np.linspace(0, 10, 5), 'b': range(5)})
```

```
In [95]: df
```

```
Out[95]:
```

|   | a    | b |
|---|------|---|
| 0 | 0.0  | 0 |
| 1 | 2.5  | 1 |
| 2 | 5.0  | 2 |
| 3 | 7.5  | 3 |
| 4 | 10.0 | 4 |

```
[5 rows x 2 columns]
```

```
In [12]: df.eval('c = a + b')
FutureWarning: eval expressions containing an assignment currently default to operating
↳ inplace.
This will change in a future version of pandas, use inplace=True to avoid this warning.
```

```
In [13]: df
```

```
Out[13]:
 a b c
0 0.0 0 0.0
1 2.5 1 3.5
2 5.0 2 7.0
3 7.5 3 10.5
4 10.0 4 14.0
```

In version 0.18.0, a new `inplace` keyword was added to choose whether the assignment should be done inplace or return a copy.

```
In [96]: df
```

```
Out[96]:
 a b c
0 0.0 0 0.0
1 2.5 1 3.5
2 5.0 2 7.0
3 7.5 3 10.5
4 10.0 4 14.0
```

```
[5 rows x 3 columns]
```

```
In [97]: df.eval('d = c - b', inplace=False)
```

```
Out[97]:
 a b c d
0 0.0 0 0.0 0.0
1 2.5 1 3.5 2.5
2 5.0 2 7.0 5.0
3 7.5 3 10.5 7.5
4 10.0 4 14.0 10.0
```

```
[5 rows x 4 columns]
```

```
In [98]: df
```

```
Out[98]:
 a b c
0 0.0 0 0.0
1 2.5 1 3.5
2 5.0 2 7.0
3 7.5 3 10.5
4 10.0 4 14.0
```

```
[5 rows x 3 columns]
```

```
In [99]: df.eval('d = c - b', inplace=True)
```

```
In [100]: df
```

(continues on next page)

(continued from previous page)

```
Out[100]:
 a b c d
0 0.0 0 0.0 0.0
1 2.5 1 3.5 2.5
2 5.0 2 7.0 5.0
3 7.5 3 10.5 7.5
4 10.0 4 14.0 10.0

[5 rows x 4 columns]
```

**Warning:** For backwards compatibility, `inplace` defaults to `True` if not specified. This will change in a future version of pandas. If your code depends on an `inplace` assignment you should update to explicitly set `inplace=True`

The `inplace` keyword parameter was also added the `query` method.

```
In [101]: df.query('a > 5')
Out[101]:
 a b c d
3 7.5 3 10.5 7.5
4 10.0 4 14.0 10.0

[2 rows x 4 columns]

In [102]: df.query('a > 5', inplace=True)

In [103]: df
Out[103]:
 a b c d
3 7.5 3 10.5 7.5
4 10.0 4 14.0 10.0

[2 rows x 4 columns]
```

**Warning:** Note that the default value for `inplace` in a query is `False`, which is consistent with prior versions.

`eval` has also been updated to allow multi-line expressions for multiple assignments. These expressions will be evaluated one at a time in order. Only assignments are valid for multi-line expressions.

```
In [104]: df
Out[104]:
 a b c d
3 7.5 3 10.5 7.5
4 10.0 4 14.0 10.0

[2 rows x 4 columns]

In [105]: df.eval("""
.....: e = d + a
.....: f = e - 22
```

(continues on next page)

(continued from previous page)

```

.....: g = f / 2.0""", inplace=True)
.....:

In [106]: df
Out[106]:
 a b c d e f g
3 7.5 3 10.5 7.5 15.0 -7.0 -3.5
4 10.0 4 14.0 10.0 20.0 -2.0 -1.0

[2 rows x 7 columns]

```

## Other API changes

- `DataFrame.between_time` and `Series.between_time` now only parse a fixed set of time strings. Parsing of date strings is no longer supported and raises a `ValueError`. (GH11818)

```

In [107]: s = pd.Series(range(10), pd.date_range('2015-01-01', freq='H',
→periods=10))

```

```

In [108]: s.between_time("7:00am", "9:00am")

```

```

Out[108]:
2015-01-01 07:00:00 7
2015-01-01 08:00:00 8
2015-01-01 09:00:00 9
Freq: H, Length: 3, dtype: int64

```

This will now raise.

```

In [2]: s.between_time('20150101 07:00:00', '20150101 09:00:00')
ValueError: Cannot convert arg ['20150101 07:00:00'] to a time.

```

- `.memory_usage()` now includes values in the index, as does `memory_usage` in `.info()` (GH11597)
- `DataFrame.to_latex()` now supports non-ascii encodings (eg `utf-8`) in Python 2 with the parameter `encoding` (GH7061)
- `pandas.merge()` and `DataFrame.merge()` will show a specific error message when trying to merge with an object that is not of type `DataFrame` or a subclass (GH12081)
- `DataFrame.unstack` and `Series.unstack` now take `fill_value` keyword to allow direct replacement of missing values when an unstack results in missing values in the resulting `DataFrame`. As an added benefit, specifying `fill_value` will preserve the data type of the original stacked data. (GH9746)
- As part of the new API for *window functions* and *resampling*, aggregation functions have been clarified, raising more informative error messages on invalid aggregations. (GH9052). A full set of examples are presented in *groupby*.
- Statistical functions for `NDFrame` objects (like `sum()`, `mean()`, `min()`) will now raise if non-numpy-compatible arguments are passed in for `**kwargs` (GH12301)
- `.to_latex` and `.to_html` gain a `decimal` parameter like `.to_csv`; the default is `'.'` (GH12031)
- More helpful error message when constructing a `DataFrame` with empty data but with indices (GH8020)
- `.describe()` will now properly handle `bool` dtype as a categorical (GH6625)

- More helpful error message with an invalid `.transform` with user defined input ([GH10165](#))
- Exponentially weighted functions now allow specifying alpha directly ([GH10789](#)) and raise `ValueError` if parameters violate  $0 < \alpha \leq 1$  ([GH12492](#))

## Deprecations

- The functions `pd.rolling_*`, `pd.expanding_*`, and `pd.ewm*` are deprecated and replaced by the corresponding method call. Note that the new suggested syntax includes all of the arguments (even if default) ([GH11603](#))

```
In [1]: s = pd.Series(range(3))

In [2]: pd.rolling_mean(s,window=2,min_periods=1)
FutureWarning: pd.rolling_mean is deprecated for Series and
 will be removed in a future version, replace with
 Series.rolling(min_periods=1,window=2,center=False).mean()

Out[2]:
0 0.0
1 0.5
2 1.5
dtype: float64

In [3]: pd.rolling_cov(s, s, window=2)
FutureWarning: pd.rolling_cov is deprecated for Series and
 will be removed in a future version, replace with
 Series.rolling(window=2).cov(other=<Series>)

Out[3]:
0 NaN
1 0.5
2 0.5
dtype: float64
```

- The `freq` and `how` arguments to the `.rolling`, `.expanding`, and `.ewm` (new) functions are deprecated, and will be removed in a future version. You can simply resample the input prior to creating a window function. ([GH11603](#)).

For example, instead of `s.rolling(window=5, freq='D').max()` to get the max value on a rolling 5 Day window, one could use `s.resample('D').mean().rolling(window=5).max()`, which first resamples the data to daily data, then provides a rolling 5 day window.

- `pd.tseries.frequencies.get_offset_name` function is deprecated. Use `offset's .freqstr` property as alternative ([GH11192](#))
- `pandas.stats.fama_macbeth` routines are deprecated and will be removed in a future version ([GH6077](#))
- `pandas.stats.ols`, `pandas.stats.plm` and `pandas.stats.var` routines are deprecated and will be removed in a future version ([GH6077](#))
- show a `FutureWarning` rather than a `DeprecationWarning` on using long-time deprecated syntax in `HDFStore.select`, where the `where` clause is not a string-like ([GH12027](#))
- The `pandas.options.display.mpl_style` configuration has been deprecated and will be removed in a future version of pandas. This functionality is better handled by matplotlib's `style sheets` ([GH11783](#)).

## Removal of deprecated float indexers

In [GH4892](#) indexing with floating point numbers on a non-Float64Index was deprecated (in version 0.14.0). In 0.18.0, this deprecation warning is removed and these will now raise a `TypeError`. ([GH12165](#), [GH12333](#))

```
In [109]: s = pd.Series([1, 2, 3], index=[4, 5, 6])
```

```
In [110]: s
```

```
Out[110]:
```

```
4 1
5 2
6 3
Length: 3, dtype: int64
```

```
In [111]: s2 = pd.Series([1, 2, 3], index=list('abc'))
```

```
In [112]: s2
```

```
Out[112]:
```

```
a 1
b 2
c 3
Length: 3, dtype: int64
```

Previous behavior:

```
this is label indexing
```

```
In [2]: s[5.0]
```

```
FutureWarning: scalar indexers for index type Int64Index should be integers and not
↳floating point
```

```
Out[2]: 2
```

```
this is positional indexing
```

```
In [3]: s.iloc[1.0]
```

```
FutureWarning: scalar indexers for index type Int64Index should be integers and not
↳floating point
```

```
Out[3]: 2
```

```
this is label indexing
```

```
In [4]: s.loc[5.0]
```

```
FutureWarning: scalar indexers for index type Int64Index should be integers and not
↳floating point
```

```
Out[4]: 2
```

```
.ix would coerce 1.0 to the positional 1, and index
```

```
In [5]: s2.ix[1.0] = 10
```

```
FutureWarning: scalar indexers for index type Index should be integers and not floating
↳point
```

```
In [6]: s2
```

```
Out[6]:
```

```
a 1
b 10
c 3
dtype: int64
```

New behavior:

For `iloc`, getting & setting via a float scalar will always raise.

```
In [3]: s.iloc[2.0]
TypeError: cannot do label indexing on <class 'pandas.indexes.numeric.Int64Index'> with
↳ these indexers [2.0] of <type 'float'>
```

Other indexers will coerce to a like integer for both getting and setting. The `FutureWarning` has been dropped for `.loc`, `.ix` and `[]`.

```
In [113]: s[5.0]
Out[113]: 2

In [114]: s.loc[5.0]
Out[114]: 2
```

and setting

```
In [115]: s_copy = s.copy()

In [116]: s_copy[5.0] = 10

In [117]: s_copy
Out[117]:
4 1
5 10
6 3
Length: 3, dtype: int64

In [118]: s_copy = s_copy.copy()

In [119]: s_copy.loc[5.0] = 10

In [120]: s_copy
Out[120]:
4 1
5 10
6 3
Length: 3, dtype: int64
```

Positional setting with `.ix` and a float indexer will ADD this value to the index, rather than previously setting the value by position.

```
In [3]: s2.ix[1.0] = 10
In [4]: s2
Out[4]:
a 1
b 2
c 3
1.0 10
dtype: int64
```

Slicing will also coerce integer-like floats to integers for a non-`Float64Index`.

```
In [121]: s.loc[5.0:6]
Out[121]:
5 2
6 3
Length: 2, dtype: int64
```

Note that for floats that are NOT coercible to ints, the label based bounds will be excluded

```
In [122]: s.loc[5.1:6]
Out[122]:
6 3
Length: 1, dtype: int64
```

Float indexing on a Float64Index is unchanged.

```
In [123]: s = pd.Series([1, 2, 3], index=np.arange(3.))

In [124]: s[1.0]
Out[124]: 2

In [125]: s[1.0:2.5]
Out[125]:
1.0 2
2.0 3
Length: 2, dtype: int64
```

## Removal of prior version deprecations/changes

- Removal of `rolling_corr_pairwise` in favor of `.rolling().corr(pairwise=True)` (GH4950)
- Removal of `expanding_corr_pairwise` in favor of `.expanding().corr(pairwise=True)` (GH4950)
- Removal of `DataMatrix` module. This was not imported into the pandas namespace in any event (GH12111)
- Removal of `cols` keyword in favor of `subset` in `DataFrame.duplicated()` and `DataFrame.drop_duplicates()` (GH6680)
- Removal of the `read_frame` and `frame_query` (both aliases for `pd.read_sql`) and `write_frame` (alias of `to_sql`) functions in the `pd.io.sql` namespace, deprecated since 0.14.0 (GH6292).
- Removal of the `order` keyword from `.factorize()` (GH6930)

## Performance improvements

- Improved performance of `andrews_curves` (GH11534)
- Improved huge `DatetimeIndex`, `PeriodIndex` and `TimedeltaIndex`'s ops performance including `NaT` (GH10277)
- Improved performance of `pandas.concat` (GH11958)
- Improved performance of `StataReader` (GH11591)
- Improved performance in construction of `Categoricals` with `Series` of datetimes containing `NaT` (GH12077)
- Improved performance of ISO 8601 date parsing for dates without separators (GH11899), leading zeros (GH11871) and with white space preceding the time zone (GH9714)

## Bug fixes

- Bug in `GroupBy.size` when data-frame is empty. (GH11699)
- Bug in `Period.end_time` when a multiple of time period is requested (GH11738)
- Regression in `.clip` with tz-aware datetimes (GH11838)
- Bug in `date_range` when the boundaries fell on the frequency (GH11804, GH12409)
- Bug in consistency of passing nested dicts to `.groupby(...).agg(...)` (GH9052)
- Accept unicode in `Timedelta` constructor (GH11995)
- Bug in value label reading for `StataReader` when reading incrementally (GH12014)
- Bug in vectorized `DateOffset` when `n` parameter is 0 (GH11370)
- Compat for numpy 1.11 w.r.t. `NaT` comparison changes (GH12049)
- Bug in `read_csv` when reading from a `StringIO` in threads (GH11790)
- Bug in not treating `NaT` as a missing value in datetimelikes when factorizing & with `Categoricals` (GH12077)
- Bug in `getitem` when the values of a `Series` were tz-aware (GH12089)
- Bug in `Series.str.get_dummies` when one of the variables was 'name' (GH12180)
- Bug in `pd.concat` while concatenating tz-aware `NaT` series. (GH11693, GH11755, GH12217)
- Bug in `pd.read_stata` with version `<= 108` files (GH12232)
- Bug in `Series.resample` using a frequency of `Nano` when the index is a `DatetimeIndex` and contains non-zero nanosecond parts (GH12037)
- Bug in resampling with `.nunique` and a sparse index (GH12352)
- Removed some compiler warnings (GH12471)
- Work around compat issues with `boto` in python 3.5 (GH11915)
- Bug in `NaT` subtraction from `Timestamp` or `DatetimeIndex` with timezones (GH11718)
- Bug in subtraction of `Series` of a single tz-aware `Timestamp` (GH12290)
- Use compat iterators in PY2 to support `.next()` (GH12299)
- Bug in `Timedelta.round` with negative values (GH11690)
- Bug in `.loc` against `CategoricalIndex` may result in normal `Index` (GH11586)
- Bug in `DataFrame.info` when duplicated column names exist (GH11761)
- Bug in `.copy` of datetime tz-aware objects (GH11794)
- Bug in `Series.apply` and `Series.map` where `timedelta64` was not boxed (GH11349)
- Bug in `DataFrame.set_index()` with tz-aware `Series` (GH12358)
- Bug in subclasses of `DataFrame` where `AttributeError` did not propagate (GH11808)
- Bug groupby on tz-aware data where selection not returning `Timestamp` (GH11616)
- Bug in `pd.read_clipboard` and `pd.to_clipboard` functions not supporting Unicode; upgrade included `pyperclip` to v1.5.15 (GH9263)
- Bug in `DataFrame.query` containing an assignment (GH8664)
- Bug in `from_msgpack` where `__contains__()` fails for columns of the unpacked `DataFrame`, if the `DataFrame` has object columns. (GH11880)

- Bug in `.resample` on categorical data with `TimedeltaIndex` (GH12169)
- Bug in timezone info lost when broadcasting scalar datetime to `DataFrame` (GH11682)
- Bug in `Index` creation from `Timestamp` with mixed tz coerces to UTC (GH11488)
- Bug in `to_numeric` where it does not raise if input is more than one dimension (GH11776)
- Bug in parsing timezone offset strings with non-zero minutes (GH11708)
- Bug in `df.plot` using incorrect colors for bar plots under matplotlib 1.5+ (GH11614)
- Bug in the `groupby` plot method when using keyword arguments (GH11805).
- Bug in `DataFrame.duplicated` and `drop_duplicates` causing spurious matches when setting `keep=False` (GH11864)
- Bug in `.loc` result with duplicated key may have `Index` with incorrect dtype (GH11497)
- Bug in `pd.rolling_median` where memory allocation failed even with sufficient memory (GH11696)
- Bug in `DataFrame.style` with spurious zeros (GH12134)
- Bug in `DataFrame.style` with integer columns not starting at 0 (GH12125)
- Bug in `.style.bar` may not rendered properly using specific browser (GH11678)
- Bug in rich comparison of `Timedelta` with a `numpy.array` of `Timedelta` that caused an infinite recursion (GH11835)
- Bug in `DataFrame.round` dropping column index name (GH11986)
- Bug in `df.replace` while replacing value in mixed dtype `Dataframe` (GH11698)
- Bug in `Index` prevents copying name of passed `Index`, when a new name is not provided (GH11193)
- Bug in `read_excel` failing to read any non-empty sheets when empty sheets exist and `sheetname=None` (GH11711)
- Bug in `read_excel` failing to raise `NotImplemented` error when keywords `parse_dates` and `date_parser` are provided (GH11544)
- Bug in `read_sql` with `pymysql` connections failing to return chunked data (GH11522)
- Bug in `.to_csv` ignoring formatting parameters `decimal`, `na_rep`, `float_format` for float indexes (GH11553)
- Bug in `Int64Index` and `Float64Index` preventing the use of the modulo operator (GH9244)
- Bug in `MultiIndex.drop` for not lexsorted `MultiIndexes` (GH12078)
- Bug in `DataFrame` when masking an empty `DataFrame` (GH11859)
- Bug in `.plot` potentially modifying the `colors` input when the number of columns didn't match the number of series provided (GH12039).
- Bug in `Series.plot` failing when index has a `CustomBusinessDay` frequency (GH7222).
- Bug in `.to_sql` for `datetime.time` values with `sqlite` fallback (GH8341)
- Bug in `read_excel` failing to read data with one column when `squeeze=True` (GH12157)
- Bug in `read_excel` failing to read one empty column (GH12292, GH9002)
- Bug in `.groupby` where a `KeyError` was not raised for a wrong column if there was only one row in the dataframe (GH11741)
- Bug in `.read_csv` with dtype specified on empty data producing an error (GH12048)
- Bug in `.read_csv` where strings like '2E' are treated as valid floats (GH12237)

- Bug in building *pandas* with debugging symbols (GH12123)
- Removed millisecond property of `DatetimeIndex`. This would always raise a `ValueError` (GH12019).
- Bug in `Series` constructor with read-only data (GH11502)
- Removed `pandas._testing.choice()`. Should use `np.random.choice()`, instead. (GH12386)
- Bug in `.loc` setitem indexer preventing the use of a TZ-aware `DatetimeIndex` (GH12050)
- Bug in `.style` indexes and `MultiIndexes` not appearing (GH11655)
- Bug in `to_msgpack` and `from_msgpack` which did not correctly serialize or deserialize `NaT` (GH12307).
- Bug in `.skew` and `.kurt` due to roundoff error for highly similar values (GH11974)
- Bug in `Timestamp` constructor where microsecond resolution was lost if `HHMMSS` were not separated with `':'` (GH10041)
- Bug in `buffer_rd_bytes` `src->buffer` could be freed more than once if reading failed, causing a segfault (GH12098)
- Bug in `crosstab` where arguments with non-overlapping indexes would return a `KeyError` (GH10291)
- Bug in `DataFrame.apply` in which reduction was not being prevented for cases in which `dtype` was not a numpy dtype (GH12244)
- Bug when initializing categorical series with a scalar value. (GH12336)
- Bug when specifying a UTC `DatetimeIndex` by setting `utc=True` in `.to_datetime` (GH11934)
- Bug when increasing the buffer size of CSV reader in `read_csv` (GH12494)
- Bug when setting columns of a `DataFrame` with duplicate column names (GH12344)

## 5.13 Version 0.17

### 5.13.1 Version 0.17.1 (November 21, 2015)

---

**Note:** We are proud to announce that *pandas* has become a sponsored project of the (NumFOCUS organization). This will help ensure the success of development of *pandas* as a world-class open-source project.

---

This is a minor bug-fix release from 0.17.0 and includes a large number of bug fixes along several new features, enhancements, and performance improvements. We recommend that all users upgrade to this version.

Highlights include:

- Support for Conditional HTML Formatting, see [here](#)
- Releasing the GIL on the csv reader & other ops, see [here](#)
- Fixed regression in `DataFrame.drop_duplicates` from 0.16.2, causing incorrect results on integer values ([GH11376](#))

#### What's new in v0.17.1

- *New features*
  - *Conditional HTML formatting*
- *Enhancements*
- *API changes*
  - *Deprecations*

- *Performance improvements*
- *Bug fixes*
- *Contributors*

## New features

### Conditional HTML formatting

**Warning:** This is a new feature and is under active development. We'll be adding features and possibly making breaking changes in future releases. Feedback is [welcome](#).

We've added *experimental* support for conditional HTML formatting: the visual styling of a DataFrame based on the data. The styling is accomplished with HTML and CSS. Accesses the styler class with the `pandas.DataFrame.style` attribute, an instance of `Styler` with your data attached.

Here's a quick example:

```
In [1]: np.random.seed(123)

In [2]: df = pd.DataFrame(np.random.randn(10, 5), columns=list("abcde"))

In [3]: html = df.style.background_gradient(cmap="viridis", low=0.5)
```

We can render the HTML to get the following table.

`Styler` interacts nicely with the Jupyter Notebook. See the [documentation](#) for more.

## Enhancements

- `DatetimeIndex` now supports conversion to strings with `astype(str)` (GH10442)
- Support for compression (`gzip/bz2`) in `pandas.DataFrame.to_csv()` (GH7615)
- `pd.read_*` functions can now also accept `pathlib.Path`, or `py._path.local.LocalPath` objects for the `filepath_or_buffer` argument. (GH11033) - The `DataFrame` and `Series` functions `.to_csv()`, `.to_html()` and `.to_latex()` can now handle paths beginning with tildes (e.g. `~/Documents/`) (GH11438)
- `DataFrame` now uses the fields of a `namedtuple` as columns, if columns are not supplied (GH11181)
- `DataFrame.itertuples()` now returns `namedtuple` objects, when possible. (GH11269, GH11625)
- Added `axvlines_kwds` to parallel coordinates plot (GH10709)
- Option to `.info()` and `.memory_usage()` to provide for deep introspection of memory consumption. Note that this can be expensive to compute and therefore is an optional parameter. (GH11595)

```
In [4]: df = pd.DataFrame({"A": ["foo"] * 1000}) # noqa: F821

In [5]: df["B"] = df["A"].astype("category")

shows the '+' as we have object dtypes
In [6]: df.info()
```

(continues on next page)

(continued from previous page)

```

<class 'pandas.core.frame.DataFrame'>
RangeIndex: 1000 entries, 0 to 999
Data columns (total 2 columns):
Column Non-Null Count Dtype
--- -
0 A 1000 non-null object
1 B 1000 non-null category
dtypes: category(1), object(1)
memory usage: 9.0+ KB

we have an accurate memory assessment (but can be expensive to compute this)
In [7]: df.info(memory_usage="deep")
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 1000 entries, 0 to 999
Data columns (total 2 columns):
Column Non-Null Count Dtype
--- -
0 A 1000 non-null object
1 B 1000 non-null category
dtypes: category(1), object(1)
memory usage: 59.9 KB

```

- Index now has a `fillna` method (GH10089)

```

In [8]: pd.Index([1, np.nan, 3]).fillna(2)
Out[8]: Float64Index([1.0, 2.0, 3.0], dtype='float64')

```

- Series of type `category` now make `.str.<...>` and `.dt.<...>` accessor methods / properties available, if the categories are of that type. (GH10661)

```

In [9]: s = pd.Series(list("aabb")).astype("category")

In [10]: s
Out[10]:
0 a
1 a
2 b
3 b
Length: 4, dtype: category
Categories (2, object): ['a', 'b']

In [11]: s.str.contains("a")
Out[11]:
0 True
1 True
2 False
3 False
Length: 4, dtype: bool

In [12]: date = pd.Series(pd.date_range("1/1/2015", periods=5)).astype("category")

In [13]: date

```

(continues on next page)

(continued from previous page)

```
Out[13]:
0 2015-01-01
1 2015-01-02
2 2015-01-03
3 2015-01-04
4 2015-01-05
Length: 5, dtype: category
Categories (5, datetime64[ns]): [2015-01-01, 2015-01-02, 2015-01-03, 2015-01-04,
→2015-01-05]

In [14]: date.dt.day
Out[14]:
0 1
1 2
2 3
3 4
4 5
Length: 5, dtype: int64
```

- `pivot_table` now has a `margins_name` argument so you can use something other than the default of 'All' ([GH3335](#))
- Implement export of `datetime64[ns, tz]` dtypes with a fixed HDF5 store ([GH11411](#))
- Pretty printing sets (e.g. in DataFrame cells) now uses set literal syntax (`{x, y}`) instead of Legacy Python syntax (`set([x, y])`) ([GH11215](#))
- Improve the error message in `pandas.io.gbq.to_gbq()` when a streaming insert fails ([GH11285](#)) and when the DataFrame does not match the schema of the destination table ([GH11359](#))

## API changes

- raise `NotImplementedError` in `Index.shift` for non-supported index types ([GH8038](#))
- `min` and `max` reductions on `datetime64` and `timedelta64` dtypes series now result in `NaT` and not `nan` ([GH11245](#)).
- Indexing with a null key will raise a `TypeError`, instead of a `ValueError` ([GH11356](#))
- `Series.ptp` will now ignore missing values by default ([GH11163](#))

## Deprecations

- The `pandas.io.ga` module which implements google-analytics support is deprecated and will be removed in a future version ([GH11308](#))
- Deprecate the `engine` keyword in `.to_csv()`, which will be removed in a future version ([GH11274](#))

## Performance improvements

- Checking monotonic-ness before sorting on an index (GH11080)
- `Series.dropna` performance improvement when its dtype can't contain NaN (GH11159)
- Release the GIL on most datetime field operations (e.g. `DatetimeIndex.year`, `Series.dt.year`), normalization, and conversion to and from `Period`, `DatetimeIndex.to_period` and `PeriodIndex.to_timestamp` (GH11263)
- Release the GIL on some rolling algos: `rolling_median`, `rolling_mean`, `rolling_max`, `rolling_min`, `rolling_var`, `rolling_kurt`, `rolling_skew` (GH11450)
- Release the GIL when reading and parsing text files in `read_csv`, `read_table` (GH11272)
- Improved performance of `rolling_median` (GH11450)
- Improved performance of `to_excel` (GH11352)
- Performance bug in repr of Categorical categories, which was rendering the strings before chopping them for display (GH11305)
- Performance improvement in `Categorical.remove_unused_categories`, (GH11643).
- Improved performance of `Series` constructor with no data and `DatetimeIndex` (GH11433)
- Improved performance of `shift`, `cumprod`, and `cumsum` with `groupby` (GH4095)

## Bug fixes

- `SparseArray.__iter__()` now does not cause `PendingDeprecationWarning` in Python 3.5 (GH11622)
- Regression from 0.16.2 for output formatting of long floats/nan, restored in (GH11302)
- `Series.sort_index()` now correctly handles the `inplace` option (GH11402)
- Incorrectly distributed `.c` file in the build on PyPi when reading a csv of floats and passing `na_values=<a scalar>` would show an exception (GH11374)
- Bug in `.to_latex()` output broken when the index has a name (GH10660)
- Bug in `HDFStore.append` with strings whose encoded length exceeded the max unencoded length (GH11234)
- Bug in merging `datetime64[ns, tz]` dtypes (GH11405)
- Bug in `HDFStore.select` when comparing with a numpy scalar in a `where` clause (GH11283)
- Bug in using `DataFrame.ix` with a `MultiIndex` indexer (GH11372)
- Bug in `date_range` with ambiguous endpoints (GH11626)
- Prevent adding new attributes to the accessors `.str`, `.dt` and `.cat`. Retrieving such a value was not possible, so error out on setting it. (GH10673)
- Bug in `tz-conversions` with an ambiguous time and `.dt` accessors (GH11295)
- Bug in output formatting when using an index of ambiguous times (GH11619)
- Bug in comparisons of `Series` vs list-likes (GH11339)
- Bug in `DataFrame.replace` with a `datetime64[ns, tz]` and a non-compatible `to_replace` (GH11326, GH11153)
- Bug in `isnull` where `numpy.datetime64('NaT')` in a `numpy.array` was not determined to be null (GH11206)

- Bug in list-like indexing with a mixed-integer Index (GH11320)
- Bug in `pivot_table` with `margins=True` when indexes are of Categorical dtype (GH10993)
- Bug in `DataFrame.plot` cannot use hex strings colors (GH10299)
- Regression in `DataFrame.drop_duplicates` from 0.16.2, causing incorrect results on integer values (GH11376)
- Bug in `pd.eval` where unary ops in a list error (GH11235)
- Bug in `squeeze()` with zero length arrays (GH11230, GH8999)
- Bug in `describe()` dropping column names for hierarchical indexes (GH11517)
- Bug in `DataFrame.pct_change()` not propagating `axis` keyword on `.fillna` method (GH11150)
- Bug in `.to_csv()` when a mix of integer and string column names are passed as the `columns` parameter (GH11637)
- Bug in indexing with a `range`, (GH11652)
- Bug in inference of numpy scalars and preserving dtype when setting columns (GH11638)
- Bug in `to_sql` using unicode column names giving `UnicodeEncodeError` with (GH11431).
- Fix regression in setting of `xticks` in `plot` (GH11529).
- Bug in `holiday.dates` where observance rules could not be applied to holiday and doc enhancement (GH11477, GH11533)
- Fix plotting issues when having plain `Axes` instances instead of `SubplotAxes` (GH11520, GH11556).
- Bug in `DataFrame.to_latex()` produces an extra rule when `header=False` (GH7124)
- Bug in `df.groupby(...).apply(func)` when a `func` returns a `Series` containing a new datetimelike column (GH11324)
- Bug in `pandas.json` when file to load is big (GH11344)
- Bugs in `to_excel` with duplicate columns (GH11007, GH10982, GH10970)
- Fixed a bug that prevented the construction of an empty series of dtype `datetime64[ns, tz]` (GH11245).
- Bug in `read_excel` with `MultiIndex` containing integers (GH11317)
- Bug in `to_excel` with `openpyxl 2.2+` and merging (GH11408)
- Bug in `DataFrame.to_dict()` produces a `np.datetime64` object instead of `Timestamp` when only datetime is present in data (GH11327)
- Bug in `DataFrame.corr()` raises exception when computes Kendall correlation for `DataFrames` with boolean and not boolean columns (GH11560)
- Bug in the link-time error caused by `C inline` functions on `FreeBSD 10+` (with `clang`) (GH10510)
- Bug in `DataFrame.to_csv` in passing through arguments for formatting `MultiIndexes`, including `date_format` (GH7791)
- Bug in `DataFrame.join()` with `how='right'` producing a `TypeError` (GH11519)
- Bug in `Series.quantile` with empty list results has `Index` with `object` dtype (GH11588)
- Bug in `pd.merge` results in empty `Int64Index` rather than `Index(dtype=object)` when the merge result is empty (GH11588)
- Bug in `Categorical.remove_unused_categories` when having `NaN` values (GH11599)
- Bug in `DataFrame.to_sparse()` loses column names for `MultiIndexes` (GH11600)

- Bug in `DataFrame.round()` with non-unique column index producing a Fatal Python error ([GH11611](#))
- Bug in `DataFrame.round()` with decimals being a non-unique indexed Series producing extra columns ([GH11618](#))

### 5.13.2 Version 0.17.0 (October 9, 2015)

This is a major release from 0.16.2 and includes a small number of API changes, several new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

**Warning:** pandas >= 0.17.0 will no longer support compatibility with Python version 3.2 (GH9118)

**Warning:** The `pandas.io.data` package is deprecated and will be replaced by the `pandas-datareader` package. This will allow the data modules to be independently updated to your pandas installation. The API for `pandas-datareader v0.1.1` is exactly the same as in `pandas v0.17.0` (GH8961, GH10861).

After installing `pandas-datareader`, you can easily change your imports:

```
from pandas.io import data, wb
```

becomes

```
from pandas_datareader import data, wb
```

Highlights include:

- Release the Global Interpreter Lock (GIL) on some cython operations, see [here](#)
- Plotting methods are now available as attributes of the `.plot` accessor, see [here](#)
- The sorting API has been revamped to remove some long-time inconsistencies, see [here](#)
- Support for a `datetime64[ns]` with timezones as a first-class dtype, see [here](#)
- The default for `to_datetime` will now be to raise when presented with unparsable formats, previously this would return the original input. Also, date parse functions now return consistent results. See [here](#)
- The default for `dropna` in `HDFStore` has changed to `False`, to store by default all rows even if they are all `NaN`, see [here](#)
- Datetime accessor (`dt`) now supports `Series.dt.strftime` to generate formatted strings for datetime-likes, and `Series.dt.total_seconds` to generate each duration of the `timedelta` in seconds. See [here](#)
- `Period` and `PeriodIndex` can handle multiplied `freq` like `3D`, which corresponding to 3 days span. See [here](#)
- Development installed versions of pandas will now have PEP440 compliant version strings (GH9518)
- Development support for benchmarking with the [Air Speed Velocity library](#) (GH8361)
- Support for reading SAS `xport` files, see [here](#)
- Documentation comparing SAS to `pandas`, see [here](#)
- Removal of the automatic `TimeSeries` broadcasting, deprecated since 0.8.0, see [here](#)
- Display format with plain text can optionally align with Unicode East Asian Width, see [here](#)
- Compatibility with Python 3.5 (GH11097)
- Compatibility with `matplotlib` 1.5.0 (GH11111)

Check the [API Changes](#) and [deprecations](#) before updating.

## What's new in v0.17.0

- *New features*
  - *Datetime with TZ*
  - *Releasing the GIL*
  - *Plot submethods*
  - *Additional methods for dt accessor*
    - \* *Series.dt.strftime*
    - \* *Series.dt.total\_seconds*
  - *Period frequency enhancement*
  - *Support for SAS XPORT files*
  - *Support for math functions in .eval()*
  - *Changes to Excel with MultiIndex*
  - *Google BigQuery enhancements*
  - *Display alignment with Unicode East Asian width*
  - *Other enhancements*
- *Backwards incompatible API changes*
  - *Changes to sorting API*
  - *Changes to to\_datetime and to\_timedelta*
    - \* *Error handling*
    - \* *Consistent parsing*
  - *Changes to Index comparisons*
  - *Changes to boolean comparisons vs. None*
  - *HDFStore dropna behavior*
  - *Changes to display.precision option*
  - *Changes to Categorical.unique*
  - *Changes to bool passed as header in parsers*
  - *Other API changes*
  - *Deprecations*
  - *Removal of prior version deprecations/changes*
- *Performance improvements*
- *Bug fixes*
- *Contributors*

## New features

### Datetime with TZ

We are adding an implementation that natively supports datetime with timezones. A Series or a DataFrame column previously *could* be assigned a datetime with timezones, and would work as an object dtype. This had performance issues with a large number rows. See the [docs](#) for more details. ([GH8260](#), [GH10763](#), [GH11034](#)).

The new implementation allows for having a single-timezone across all rows, with operations in a performant manner.

```
In [1]: df = pd.DataFrame(
...: {
...: "A": pd.date_range("20130101", periods=3),
...: "B": pd.date_range("20130101", periods=3, tz="US/Eastern"),
...: "C": pd.date_range("20130101", periods=3, tz="CET"),
...: }
...:)
...:
```

```
In [2]: df
```

```
Out[2]:
```

|   | A          | B                         | C                         |
|---|------------|---------------------------|---------------------------|
| 0 | 2013-01-01 | 2013-01-01 00:00:00-05:00 | 2013-01-01 00:00:00+01:00 |
| 1 | 2013-01-02 | 2013-01-02 00:00:00-05:00 | 2013-01-02 00:00:00+01:00 |
| 2 | 2013-01-03 | 2013-01-03 00:00:00-05:00 | 2013-01-03 00:00:00+01:00 |

```
[3 rows x 3 columns]
```

```
In [3]: df.dtypes
```

```
Out[3]:
```

|   |                            |
|---|----------------------------|
| A | datetime64[ns]             |
| B | datetime64[ns, US/Eastern] |
| C | datetime64[ns, CET]        |

Length: 3, dtype: object

```
In [4]: df.B
```

```
Out[4]:
```

|   |                           |
|---|---------------------------|
| 0 | 2013-01-01 00:00:00-05:00 |
| 1 | 2013-01-02 00:00:00-05:00 |
| 2 | 2013-01-03 00:00:00-05:00 |

Name: B, Length: 3, dtype: datetime64[ns, US/Eastern]

```
In [5]: df.B.dt.tz_localize(None)
```

```
Out[5]:
```

|   |            |
|---|------------|
| 0 | 2013-01-01 |
| 1 | 2013-01-02 |
| 2 | 2013-01-03 |

Name: B, Length: 3, dtype: datetime64[ns]

This uses a new-dtype representation as well, that is very similar in look-and-feel to its numpy cousin `datetime64[ns]`

```
In [6]: df["B"].dtype
```

```
Out[6]: datetime64[ns, US/Eastern]
```

(continues on next page)

(continued from previous page)

```
In [7]: type(df["B"].dtype)
Out[7]: pandas.core.dtypes.dtypes.DatetimeTZDtype
```

**Note:** There is a slightly different string repr for the underlying `DatetimeIndex` as a result of the dtype changes, but functionally these are the same.

Previous behavior:

```
In [1]: pd.date_range('20130101', periods=3, tz='US/Eastern')
Out[1]: DatetimeIndex(['2013-01-01 00:00:00-05:00', '2013-01-02 00:00:00-05:00',
 '2013-01-03 00:00:00-05:00'],
 dtype='datetime64[ns]', freq='D', tz='US/Eastern')

In [2]: pd.date_range('20130101', periods=3, tz='US/Eastern').dtype
Out[2]: dtype('<M8[ns]')
```

New behavior:

```
In [8]: pd.date_range("20130101", periods=3, tz="US/Eastern")
Out[8]:
DatetimeIndex(['2013-01-01 00:00:00-05:00', '2013-01-02 00:00:00-05:00',
 '2013-01-03 00:00:00-05:00'],
 dtype='datetime64[ns, US/Eastern]', freq='D')

In [9]: pd.date_range("20130101", periods=3, tz="US/Eastern").dtype
Out[9]: datetime64[ns, US/Eastern]
```

## Releasing the GIL

We are releasing the global-interpreter-lock (GIL) on some cython operations. This will allow other threads to run simultaneously during computation, potentially allowing performance improvements from multi-threading. Notably `groupby`, `nsmallest`, `value_counts` and some indexing operations benefit from this. (GH8882)

For example the `groupby` expression in the following code will have the GIL released during the factorization step, e.g. `df.groupby('key')` as well as the `.sum()` operation.

```
N = 1000000
ngroups = 10
df = DataFrame(
 {"key": np.random.randint(0, ngroups, size=N), "data": np.random.randn(N)}
)
df.groupby("key")["data"].sum()
```

Releasing of the GIL could benefit an application that uses threads for user interactions (e.g. QT), or performing multi-threaded computations. A nice example of a library that can handle these types of computation-in-parallel is the `dask` library.

## Plot submethods

The Series and DataFrame `.plot()` method allows for customizing *plot types* by supplying the `kind` keyword arguments. Unfortunately, many of these kinds of plots use different required and optional keyword arguments, which makes it difficult to discover what any given plot kind uses out of the dozens of possible arguments.

To alleviate this issue, we have added a new, optional plotting interface, which exposes each kind of plot as a method of the `.plot` attribute. Instead of writing `series.plot(kind=<kind>, ...)`, you can now also use `series.plot.<kind>(...)`:

```
In [10]: df = pd.DataFrame(np.random.rand(10, 2), columns=['a', 'b'])
```

```
In [11]: df.plot.bar()
```

As a result of this change, these methods are now all discoverable via tab-completion:

```
In [12]: df.plot.<TAB> # noqa: E225, E999
df.plot.area df.plot.barh df.plot.density df.plot.hist df.plot.line df.
↳plot.scatter
df.plot.bar df.plot.box df.plot.hexbin df.plot.kde df.plot.pie
```

Each method signature only includes relevant arguments. Currently, these are limited to required arguments, but in the future these will include optional arguments, as well. For an overview, see the new *Plotting* API documentation.

## Additional methods for dt accessor

### Series.dt.strftime

We are now supporting a `Series.dt.strftime` method for datetime-likes to generate a formatted string (GH10110). Examples:

```
DatetimeIndex
In [13]: s = pd.Series(pd.date_range("20130101", periods=4))

In [14]: s
Out[14]:
```

(continues on next page)

(continued from previous page)

```

0 2013-01-01
1 2013-01-02
2 2013-01-03
3 2013-01-04
Length: 4, dtype: datetime64[ns]

In [15]: s.dt.strftime("%Y/%m/%d")
Out[15]:
0 2013/01/01
1 2013/01/02
2 2013/01/03
3 2013/01/04
Length: 4, dtype: object

```

```

PeriodIndex
In [16]: s = pd.Series(pd.period_range("20130101", periods=4))

In [17]: s
Out[17]:
0 2013-01-01
1 2013-01-02
2 2013-01-03
3 2013-01-04
Length: 4, dtype: period[D]

In [18]: s.dt.strftime("%Y/%m/%d")
Out[18]:
0 2013/01/01
1 2013/01/02
2 2013/01/03
3 2013/01/04
Length: 4, dtype: object

```

The string format is as the python standard library and details can be found [here](#)

### Series.dt.total\_seconds

pd.Series of type timedelta64 has new method `.dt.total_seconds()` returning the duration of the timedelta in seconds ([GH10817](#))

```

TimedeltaIndex
In [19]: s = pd.Series(pd.timedelta_range("1 minutes", periods=4))

In [20]: s
Out[20]:
0 0 days 00:01:00
1 1 days 00:01:00
2 2 days 00:01:00
3 3 days 00:01:00
Length: 4, dtype: timedelta64[ns]

```

(continues on next page)

(continued from previous page)

```
In [21]: s.dt.total_seconds()
Out[21]:
0 60.0
1 86460.0
2 172860.0
3 259260.0
Length: 4, dtype: float64
```

## Period frequency enhancement

Period, PeriodIndex and period\_range can now accept multiplied freq. Also, Period.freq and PeriodIndex.freq are now stored as a DateOffset instance like DatetimeIndex, and not as str (GH7811)

A multiplied freq represents a span of corresponding length. The example below creates a period of 3 days. Addition and subtraction will shift the period by its span.

```
In [22]: p = pd.Period("2015-08-01", freq="3D")

In [23]: p
Out[23]: Period('2015-08-01', '3D')

In [24]: p + 1
Out[24]: Period('2015-08-04', '3D')

In [25]: p - 2
Out[25]: Period('2015-07-26', '3D')

In [26]: p.to_timestamp()
Out[26]: Timestamp('2015-08-01 00:00:00')

In [27]: p.to_timestamp(how="E")
Out[27]: Timestamp('2015-08-03 23:59:59.999999999')
```

You can use the multiplied freq in PeriodIndex and period\_range.

```
In [28]: idx = pd.period_range("2015-08-01", periods=4, freq="2D")

In [29]: idx
Out[29]: PeriodIndex(['2015-08-01', '2015-08-03', '2015-08-05', '2015-08-07'], dtype=
→ 'period[2D]')

In [30]: idx + 1
Out[30]: PeriodIndex(['2015-08-03', '2015-08-05', '2015-08-07', '2015-08-09'], dtype=
→ 'period[2D]')
```

## Support for SAS XPORT files

`read_sas()` provides support for reading *SAS XPORT* format files. (GH4052).

```
df = pd.read_sas("sas_xport.xpt")
```

It is also possible to obtain an iterator and read an XPORT file incrementally.

```
for df in pd.read_sas("sas_xport.xpt", chunksize=10000):
 do_something(df)
```

See the *docs* for more details.

## Support for math functions in `.eval()`

`eval()` now supports calling math functions (GH4893)

```
df = pd.DataFrame({"a": np.random.randn(10)})
df.eval("b = sin(a)")
```

The support math functions are `sin`, `cos`, `exp`, `log`, `expm1`, `log1p`, `sqrt`, `sinh`, `cosh`, `tanh`, `arcsin`, `arccos`, `arctan`, `arccosh`, `arcsinh`, `arctanh`, `abs` and `arctan2`.

These functions map to the intrinsics for the NumExpr engine. For the Python engine, they are mapped to NumPy calls.

## Changes to Excel with MultiIndex

In version 0.16.2 a `DataFrame` with `MultiIndex` columns could not be written to Excel via `to_excel`. That functionality has been added (GH10564), along with updating `read_excel` so that the data can be read back with, no loss of information, by specifying which columns/rows make up the `MultiIndex` in the `header` and `index_col` parameters (GH4679)

See the *documentation* for more details.

```
In [31]: df = pd.DataFrame(
.....: [[1, 2, 3, 4], [5, 6, 7, 8]],
.....: columns=pd.MultiIndex.from_product(
.....: ["foo", "bar"], ["a", "b"], names=["col1", "col2"]
.....:),
.....: index=pd.MultiIndex.from_product(["j", ["l", "k"]], names=["i1", "i2"]),
.....:)
.....:
```

```
In [32]: df
```

```
Out[32]:
```

```
col1 foo bar
col2 a b a b
i1 i2
j l 1 2 3 4
 k 5 6 7 8
```

```
[2 rows x 4 columns]
```

(continues on next page)

(continued from previous page)

```
In [33]: df.to_excel("test.xlsx")

In [34]: df = pd.read_excel("test.xlsx", header=[0, 1], index_col=[0, 1])

In [35]: df
Out[35]:
col1 foo bar
col2 a b a b
i1 i2
j 1 1 2 3 4
 k 5 6 7 8

[2 rows x 4 columns]
```

Previously, it was necessary to specify the `has_index_names` argument in `read_excel`, if the serialized data had index names. For version 0.17.0 the output format of `to_excel` has been changed to make this keyword unnecessary - the change is shown below.

**Old**

|   | A                   | B        | C        | D        | E        | F |
|---|---------------------|----------|----------|----------|----------|---|
| 1 |                     | <b>A</b> | <b>B</b> | <b>C</b> | <b>D</b> |   |
| 2 | <b>idx_name</b>     |          |          |          |          |   |
| 3 | 2000-01-07 00:00:00 | 0.968129 | 0.906529 | 0.05343  | 0.02619  |   |
| 4 | 2000-01-10 00:00:00 | -0.16632 | 1.981993 | 1.833093 | 0.803685 |   |
| 5 | 2000-01-11 00:00:00 | 0.121057 | 0.36946  | -0.02888 | 1.683975 |   |
| 6 | 2000-01-12 00:00:00 | -1.70456 | -0.73098 | -0.38088 | 0.020946 |   |
| 7 | 2000-01-13 00:00:00 | -1.20024 | 1.907733 | 0.629318 | 1.507033 |   |
| 8 | 2000-01-14 00:00:00 | -0.66344 | 0.073188 | 1.583482 | 0.735205 |   |
| 9 | 2000-01-17 00:00:00 | 0.716635 | -2.07952 | 1.760536 | 0.970309 |   |

**New**

|   | A                   | B        | C        | D        | E        | F |
|---|---------------------|----------|----------|----------|----------|---|
| 1 | <b>idx_name</b>     | <b>A</b> | <b>B</b> | <b>C</b> | <b>D</b> |   |
| 2 | 2000-01-07 00:00:00 | 0.968129 | 0.906529 | 0.05343  | 0.02619  |   |
| 3 | 2000-01-10 00:00:00 | -0.16632 | 1.981993 | 1.833093 | 0.803685 |   |
| 4 | 2000-01-11 00:00:00 | 0.121057 | 0.36946  | -0.02888 | 1.683975 |   |
| 5 | 2000-01-12 00:00:00 | -1.70456 | -0.73098 | -0.38088 | 0.020946 |   |
| 6 | 2000-01-13 00:00:00 | -1.20024 | 1.907733 | 0.629318 | 1.507033 |   |
| 7 | 2000-01-14 00:00:00 | -0.66344 | 0.073188 | 1.583482 | 0.735205 |   |
| 8 | 2000-01-17 00:00:00 | 0.716635 | -2.07952 | 1.760536 | 0.970309 |   |
| 9 | 2000-01-18 00:00:00 | 0.727628 | 2.22267  | 2.706276 | 0.681842 |   |

**Warning:** Excel files saved in version 0.16.2 or prior that had index names will still be able to be read in, but the `has_index_names` argument must be specified to `True`.

## Google BigQuery enhancements

- Added ability to automatically create a table/dataset using the `pandas.io.gbq.to_gbq()` function if the destination table/dataset does not exist. (GH8325, GH11121).
- Added ability to replace an existing table and schema when calling the `pandas.io.gbq.to_gbq()` function via the `if_exists` argument. See the [docs](#) for more details (GH8325).
- `InvalidColumnOrder` and `InvalidPageToken` in the `gbq` module will raise `ValueError` instead of `IOError`.
- The `generate_bq_schema()` function is now deprecated and will be removed in a future version (GH11121)
- The `gbq` module will now support Python 3 (GH11094).

## Display alignment with Unicode East Asian width

**Warning:** Enabling this option will affect the performance for printing of `DataFrame` and `Series` (about 2 times slower). Use only when it is actually required.

Some East Asian countries use Unicode characters its width is corresponding to 2 alphabets. If a `DataFrame` or `Series` contains these characters, the default output cannot be aligned properly. The following options are added to enable precise handling for these characters.

- `display.unicode.east_asian_width`: Whether to use the Unicode East Asian Width to calculate the display text width. (GH2612)
- `display.unicode.ambiguous_as_wide`: Whether to handle Unicode characters belong to Ambiguous as Wide. (GH11102)

```
In [36]: df = pd.DataFrame({u"": ["UK", u""], u"": ["Alice", u""]})
```

```
In [37]: df;
```

```
>>> df = pd.DataFrame({u'国籍': ['UK', u'日本'], u'名前': ['Alice', u'しのぶ']})
>>> df
 名前 国籍
0 Alice UK
1 しのぶ 日本
```

```
In [38]: pd.set_option("display.unicode.east_asian_width", True)
```

```
In [39]: df;
```

```
>>> pd.set_option('display.unicode.east_asian_width', True)
>>> df
 名前 国籍
0 Alice UK
1 しのぶ 日本
```

For further details, see [here](#)

## Other enhancements

- Support for openpyxl >= 2.2. The API for style support is now stable ([GH10125](#))
- `merge` now accepts the argument `indicator` which adds a Categorical-type column (by default called `_merge`) to the output object that takes on the values ([GH8790](#))

| Observation Origin              | <code>_merge</code> value |
|---------------------------------|---------------------------|
| Merge key only in 'left' frame  | <code>left_only</code>    |
| Merge key only in 'right' frame | <code>right_only</code>   |
| Merge key in both frames        | <code>both</code>         |

```
In [40]: df1 = pd.DataFrame({"col1": [0, 1], "col_left": ["a", "b"]})
In [41]: df2 = pd.DataFrame({"col1": [1, 2, 2], "col_right": [2, 2, 2]})
In [42]: pd.merge(df1, df2, on="col1", how="outer", indicator=True)
Out[42]:
 col1 col_left col_right _merge
0 0 a NaN left_only
1 1 b 2.0 both
2 2 NaN 2.0 right_only
3 2 NaN 2.0 right_only

[4 rows x 4 columns]
```

For more, see the [updated docs](#)

- `pd.to_numeric` is a new function to coerce strings to numbers (possibly with coercion) ([GH11133](#))
- `pd.merge` will now allow duplicate column names if they are not merged upon ([GH10639](#)).
- `pd.pivot` will now allow passing `index` as `None` ([GH3962](#)).
- `pd.concat` will now use existing Series names if provided ([GH10698](#)).

```
In [43]: foo = pd.Series([1, 2], name="foo")
In [44]: bar = pd.Series([1, 2])
In [45]: baz = pd.Series([4, 5])
```

Previous behavior:

```
In [1]: pd.concat([foo, bar, baz], axis=1)
Out[1]:
 0 1 2
0 1 1 4
1 2 2 5
```

New behavior:

```
In [46]: pd.concat([foo, bar, baz], axis=1)
Out[46]:
 foo 0 1
```

(continues on next page)

(continued from previous page)

```

0 1 1 4
1 2 2 5

[2 rows x 3 columns]

```

- DataFrame has gained the `nlargest` and `nsmallest` methods (GH10393)
- Add a `limit_direction` keyword argument that works with `limit` to enable `interpolate` to fill NaN values forward, backward, or both (GH9218, GH10420, GH11115)

```
In [47]: ser = pd.Series([np.nan, np.nan, 5, np.nan, np.nan, np.nan, 13])
```

```
In [48]: ser.interpolate(limit=1, limit_direction="both")
```

```
Out[48]:
```

```

0 NaN
1 5.0
2 5.0
3 7.0
4 NaN
5 11.0
6 13.0
Length: 7, dtype: float64

```

- Added a `DataFrame.round` method to round the values to a variable number of decimal places (GH10568).

```
In [49]: df = pd.DataFrame(
.....: np.random.random([3, 3]),
.....: columns=["A", "B", "C"],
.....: index=["first", "second", "third"],
.....:)
.....:
```

```
In [50]: df
```

```
Out[50]:
```

```

 A B C
first 0.126970 0.966718 0.260476
second 0.897237 0.376750 0.336222
third 0.451376 0.840255 0.123102

```

```
[3 rows x 3 columns]
```

```
In [51]: df.round(2)
```

```
Out[51]:
```

```

 A B C
first 0.13 0.97 0.26
second 0.90 0.38 0.34
third 0.45 0.84 0.12

```

```
[3 rows x 3 columns]
```

```
In [52]: df.round({"A": 0, "C": 2})
```

```
Out[52]:
```

```

 A B C

```

(continues on next page)

(continued from previous page)

```
first 0.0 0.966718 0.26
second 1.0 0.376750 0.34
third 0.0 0.840255 0.12
```

```
[3 rows x 3 columns]
```

- `drop_duplicates` and `duplicated` now accept a `keep` keyword to target first, last, and all duplicates. The `take_last` keyword is deprecated, see [here \(GH6511, GH8505\)](#)

```
In [53]: s = pd.Series(["A", "B", "C", "A", "B", "D"])
```

```
In [54]: s.drop_duplicates()
```

```
Out[54]:
```

```
0 A
1 B
2 C
5 D
```

```
Length: 4, dtype: object
```

```
In [55]: s.drop_duplicates(keep="last")
```

```
Out[55]:
```

```
2 C
3 A
4 B
5 D
```

```
Length: 4, dtype: object
```

```
In [56]: s.drop_duplicates(keep=False)
```

```
Out[56]:
```

```
2 C
5 D
```

```
Length: 2, dtype: object
```

- `Reindex` now has a `tolerance` argument that allows for finer control of *Limits on filling while reindexing* (GH10411):

```
In [57]: df = pd.DataFrame({"x": range(5), "t": pd.date_range("2000-01-01",
↳ periods=5)})
```

```
In [58]: df.reindex([0.1, 1.9, 3.5], method="nearest", tolerance=0.2)
```

```
Out[58]:
```

```
 x t
0.1 0.0 2000-01-01
1.9 2.0 2000-01-03
3.5 NaN NaT
```

```
[3 rows x 2 columns]
```

When used on a `DatetimeIndex`, `TimedeltaIndex` or `PeriodIndex`, `tolerance` will be coerced into a `Timedelta` if possible. This allows you to specify tolerance with a string:

```
In [59]: df = df.set_index("t")
```

(continues on next page)

(continued from previous page)

```
In [60]: df.reindex(pd.to_datetime(["1999-12-31"]), method="nearest", tolerance="1_
↳day")
Out[60]:
 x
1999-12-31 0

[1 rows x 1 columns]
```

tolerance is also exposed by the lower level `Index.get_indexer` and `Index.get_loc` methods.

- Added functionality to use the base argument when resampling a `TimeDeltaIndex` (GH10530)
- `DatetimeIndex` can be instantiated using strings contains NaT (GH7599)
- `to_datetime` can now accept the `yearfirst` keyword (GH7599)
- `pandas.tseries.offsets` larger than the Day offset can now be used with a `Series` for addition/subtraction (GH10699). See the *docs* for more details.
- `pd.Timedelta.total_seconds()` now returns `Timedelta` duration to ns precision (previously microsecond precision) (GH10939)
- `PeriodIndex` now supports arithmetic with `np.ndarray` (GH10638)
- Support pickling of `Period` objects (GH10439)
- `.as_blocks` will now take a `copy` optional argument to return a copy of the data, default is to copy (no change in behavior from prior versions), (GH9607)
- `regex` argument to `DataFrame.filter` now handles numeric column names instead of raising `ValueError` (GH10384).
- Enable reading `gzip` compressed files via URL, either by explicitly setting the compression parameter or by inferring from the presence of the HTTP Content-Encoding header in the response (GH8685)
- Enable writing Excel files in *memory* using `StringIO/BytesIO` (GH7074)
- Enable serialization of lists and dicts to strings in `ExcelWriter` (GH8188)
- SQL io functions now accept a `SQLAlchemy` connectable. (GH7877)
- `pd.read_sql` and `to_sql` can accept database URI as `con` parameter (GH10214)
- `read_sql_table` will now allow reading from views (GH10750).
- Enable writing complex values to `HDFStores` when using the `table` format (GH10447)
- Enable `pd.read_hdf` to be used without specifying a key when the HDF file contains a single dataset (GH10443)
- `pd.read_stata` will now read Stata 118 type files. (GH9882)
- `msgpack` submodule has been updated to 0.4.6 with backward compatibility (GH10581)
- `DataFrame.to_dict` now accepts `orient='index'` keyword argument (GH10844).
- `DataFrame.apply` will return a `Series` of dicts if the passed function returns a dict and `reduce=True` (GH8735).
- Allow passing `kwargs` to the interpolation methods (GH10378).
- Improved error message when concatenating an empty iterable of `Dataframe` objects (GH9157)
- `pd.read_csv` can now read `bz2`-compressed files incrementally, and the C parser can read `bz2`-compressed files from AWS S3 (GH11070, GH11072).
- In `pd.read_csv`, recognize `s3n://` and `s3a://` URLs as designating S3 file storage (GH11070, GH11071).

- Read CSV files from AWS S3 incrementally, instead of first downloading the entire file. (Full file download still required for compressed files in Python 2.) (GH11070, GH11073)
- `pd.read_csv` is now able to infer compression type for files read from AWS S3 storage (GH11070, GH11074).

## Backwards incompatible API changes

### Changes to sorting API

The sorting API has had some longtime inconsistencies. (GH9816, GH8239).

Here is a summary of the API **PRIOR** to 0.17.0:

- `Series.sort` is **INPLACE** while `DataFrame.sort` returns a new object.
- `Series.order` returns a new object
- It was possible to use `Series/DataFrame.sort_index` to sort by **values** by passing the `by` keyword.
- `Series/DataFrame.sortlevel` worked only on a `MultiIndex` for sorting by index.

To address these issues, we have revamped the API:

- We have introduced a new method, `DataFrame.sort_values()`, which is the merger of `DataFrame.sort()`, `Series.sort()`, and `Series.order()`, to handle sorting of **values**.
- The existing methods `Series.sort()`, `Series.order()`, and `DataFrame.sort()` have been deprecated and will be removed in a future version.
- The `by` argument of `DataFrame.sort_index()` has been deprecated and will be removed in a future version.
- The existing method `.sort_index()` will gain the `level` keyword to enable level sorting.

We now have two distinct and non-overlapping methods of sorting. A \* marks items that will show a `FutureWarning`.

To sort by the **values**:

| Previous                                   | Replacement                                   |
|--------------------------------------------|-----------------------------------------------|
| * <code>Series.order()</code>              | <code>Series.sort_values()</code>             |
| * <code>Series.sort()</code>               | <code>Series.sort_values(inplace=True)</code> |
| * <code>DataFrame.sort(columns=...)</code> | <code>DataFrame.sort_values(by=...)</code>    |

To sort by the **index**:

| Previous                                    | Replacement                                  |
|---------------------------------------------|----------------------------------------------|
| <code>Series.sort_index()</code>            | <code>Series.sort_index()</code>             |
| <code>Series.sortlevel(level=...)</code>    | <code>Series.sort_index(level=...)</code>    |
| <code>DataFrame.sort_index()</code>         | <code>DataFrame.sort_index()</code>          |
| <code>DataFrame.sortlevel(level=...)</code> | <code>DataFrame.sort_index(level=...)</code> |
| * <code>DataFrame.sort()</code>             | <code>DataFrame.sort_index()</code>          |

We have also deprecated and changed similar methods in two Series-like classes, `Index` and `Categorical`.

| Previous                           | Replacement                            |
|------------------------------------|----------------------------------------|
| * <code>Index.order()</code>       | <code>Index.sort_values()</code>       |
| * <code>Categorical.order()</code> | <code>Categorical.sort_values()</code> |

## Changes to `to_datetime` and `timedelta`

### Error handling

The default for `pd.to_datetime` error handling has changed to `errors='raise'`. In prior versions it was `errors='ignore'`. Furthermore, the `coerce` argument has been deprecated in favor of `errors='coerce'`. This means that invalid parsing will raise rather than return the original input as in previous versions. (GH10636)

Previous behavior:

```
In [2]: pd.to_datetime(['2009-07-31', 'asd'])
Out[2]: array(['2009-07-31', 'asd'], dtype=object)
```

New behavior:

```
In [3]: pd.to_datetime(['2009-07-31', 'asd'])
ValueError: Unknown string format
```

Of course you can coerce this as well.

```
In [61]: pd.to_datetime(["2009-07-31", "asd"], errors="coerce")
Out[61]: DatetimeIndex(['2009-07-31', 'NaT'], dtype='datetime64[ns]', freq=None)
```

To keep the previous behavior, you can use `errors='ignore'`:

```
In [62]: pd.to_datetime(["2009-07-31", "asd"], errors="ignore")
Out[62]: Index(['2009-07-31', 'asd'], dtype='object')
```

Furthermore, `pd.to_timedelta` has gained a similar API, of `errors='raise'|'ignore'|'coerce'`, and the `coerce` keyword has been deprecated in favor of `errors='coerce'`.

### Consistent parsing

The string parsing of `to_datetime`, `Timestamp` and `DatetimeIndex` has been made consistent. (GH7599)

Prior to v0.17.0, `Timestamp` and `to_datetime` may parse year-only datetime-string incorrectly using today's date, otherwise `DatetimeIndex` uses the beginning of the year. `Timestamp` and `to_datetime` may raise `ValueError` in some types of datetime-string which `DatetimeIndex` can parse, such as a quarterly string.

Previous behavior:

```
In [1]: pd.Timestamp('2012Q2')
Traceback
...
ValueError: Unable to parse 2012Q2

Results in today's date.
In [2]: pd.Timestamp('2014')
Out [2]: 2014-08-12 00:00:00
```

v0.17.0 can parse them as below. It works on `DatetimeIndex` also.

New behavior:

```
In [63]: pd.Timestamp("2012Q2")
Out[63]: Timestamp('2012-04-01 00:00:00')

In [64]: pd.Timestamp("2014")
Out[64]: Timestamp('2014-01-01 00:00:00')

In [65]: pd.DatetimeIndex(["2012Q2", "2014"])
Out[65]: DatetimeIndex(['2012-04-01', '2014-01-01'], dtype='datetime64[ns]', freq=None)
```

**Note:** If you want to perform calculations based on today's date, use `Timestamp.now()` and `pandas.tseries.offsets`.

```
In [66]: import pandas.tseries.offsets as offsets

In [67]: pd.Timestamp.now()
Out[67]: Timestamp('2021-09-12 10:50:28.754890')

In [68]: pd.Timestamp.now() + offsets.DateOffset(years=1)
Out[68]: Timestamp('2022-09-12 10:50:28.755650')
```

## Changes to Index comparisons

Operator equal on Index should behavior similarly to Series ([GH9947](#), [GH10637](#))

Starting in v0.17.0, comparing Index objects of different lengths will raise a `ValueError`. This is to be consistent with the behavior of Series.

Previous behavior:

```
In [2]: pd.Index([1, 2, 3]) == pd.Index([1, 4, 5])
Out[2]: array([True, False, False], dtype=bool)

In [3]: pd.Index([1, 2, 3]) == pd.Index([2])
Out[3]: array([False, True, False], dtype=bool)

In [4]: pd.Index([1, 2, 3]) == pd.Index([1, 2])
Out[4]: False
```

New behavior:

```
In [8]: pd.Index([1, 2, 3]) == pd.Index([1, 4, 5])
Out[8]: array([True, False, False], dtype=bool)

In [9]: pd.Index([1, 2, 3]) == pd.Index([2])
ValueError: Lengths must match to compare

In [10]: pd.Index([1, 2, 3]) == pd.Index([1, 2])
ValueError: Lengths must match to compare
```

Note that this is different from the numpy behavior where a comparison can be broadcast:

```
In [69]: np.array([1, 2, 3]) == np.array([1])
Out[69]: array([True, False, False])
```

or it can return False if broadcasting can not be done:

```
In [70]: np.array([1, 2, 3]) == np.array([1, 2])
Out[70]: False
```

## Changes to boolean comparisons vs. None

Boolean comparisons of a Series vs None will now be equivalent to comparing with `np.nan`, rather than raise `TypeError`. (GH1079).

```
In [71]: s = pd.Series(range(3))
```

```
In [72]: s.iloc[1] = None
```

```
In [73]: s
```

```
Out[73]:
0 0.0
1 NaN
2 2.0
Length: 3, dtype: float64
```

Previous behavior:

```
In [5]: s == None
```

```
TypeError: Could not compare <type 'NoneType'> type with Series
```

New behavior:

```
In [74]: s == None
```

```
Out[74]:
0 False
1 False
2 False
Length: 3, dtype: bool
```

Usually you simply want to know which values are null.

```
In [75]: s.isnull()
```

```
Out[75]:
0 False
1 True
2 False
Length: 3, dtype: bool
```

**Warning:** You generally will want to use `isnull/notnull` for these types of comparisons, as `isnull/notnull` tells you which elements are null. One has to be mindful that `nan`'s don't compare equal, but `None`'s do. Note that pandas/numpy uses the fact that `np.nan != np.nan`, and treats `None` like `np.nan`.

```
In [76]: None == None
Out[76]: True

In [77]: np.nan == np.nan
Out[77]: False
```

### HDFStore dropna behavior

The default behavior for HDFStore write functions with `format='table'` is now to keep rows that are all missing. Previously, the behavior was to drop rows that were all missing save the index. The previous behavior can be replicated using the `dropna=True` option. (GH9382)

Previous behavior:

```
In [78]: df_with_missing = pd.DataFrame(
.....: {"col1": [0, np.nan, 2], "col2": [1, np.nan, np.nan]}
.....:)
.....:

In [79]: df_with_missing
Out[79]:
 col1 col2
0 0.0 1.0
1 NaN NaN
2 2.0 NaN

[3 rows x 2 columns]
```

```
In [27]:
df_with_missing.to_hdf('file.h5',
 'df_with_missing',
 format='table',
 mode='w')

In [28]: pd.read_hdf('file.h5', 'df_with_missing')

Out [28]:
 col1 col2
0 0 1
2 2 NaN
```

New behavior:

```
In [80]: df_with_missing.to_hdf("file.h5", "df_with_missing", format="table", mode="w")

In [81]: pd.read_hdf("file.h5", "df_with_missing")
Out[81]:
 col1 col2
0 0.0 1.0
1 NaN NaN
2 2.0 NaN
```

(continues on next page)

(continued from previous page)

```
[3 rows x 2 columns]
```

See the *docs* for more details.

### Changes to `display.precision` option

The `display.precision` option has been clarified to refer to decimal places (GH10451).

Earlier versions of pandas would format floating point numbers to have one less decimal place than the value in `display.precision`.

```
In [1]: pd.set_option('display.precision', 2)
```

```
In [2]: pd.DataFrame({'x': [123.456789]})
```

```
Out[2]:
```

```
 x
0 123.5
```

If interpreting precision as “significant figures” this did work for scientific notation but that same interpretation did not work for values with standard formatting. It was also out of step with how numpy handles formatting.

Going forward the value of `display.precision` will directly control the number of places after the decimal, for regular formatting as well as scientific notation, similar to how numpy’s `precision` print option works.

```
In [82]: pd.set_option("display.precision", 2)
```

```
In [83]: pd.DataFrame({"x": [123.456789]})
```

```
Out[83]:
```

```
 x
0 123.46
```

```
[1 rows x 1 columns]
```

To preserve output behavior with prior versions the default value of `display.precision` has been reduced to 6 from 7.

### Changes to `Categorical.unique`

`Categorical.unique` now returns new `Categoricals` with categories and codes that are unique, rather than returning `np.array` (GH10508)

- unordered category: values and categories are sorted by appearance order.
- ordered category: values are sorted by appearance order, categories keep existing order.

```
In [84]: cat = pd.Categorical(["C", "A", "B", "C"], categories=["A", "B", "C"],
↳ ordered=True)
```

```
In [85]: cat
```

```
Out[85]:
```

```
['C', 'A', 'B', 'C']
```

(continues on next page)

(continued from previous page)

```
Categories (3, object): ['A' < 'B' < 'C']
```

```
In [86]: cat.unique()
```

```
Out[86]:
```

```
['C', 'A', 'B']
```

```
Categories (3, object): ['A' < 'B' < 'C']
```

```
In [87]: cat = pd.Categorical(["C", "A", "B", "C"], categories=["A", "B", "C"])
```

```
In [88]: cat
```

```
Out[88]:
```

```
['C', 'A', 'B', 'C']
```

```
Categories (3, object): ['A', 'B', 'C']
```

```
In [89]: cat.unique()
```

```
Out[89]:
```

```
['C', 'A', 'B']
```

```
Categories (3, object): ['A', 'B', 'C']
```

### Changes to bool passed as header in parsers

In earlier versions of pandas, if a bool was passed the header argument of `read_csv`, `read_excel`, or `read_html` it was implicitly converted to an integer, resulting in `header=0` for False and `header=1` for True ([GH6113](#))

A bool input to header will now raise a `TypeError`

```
In [29]: df = pd.read_csv('data.csv', header=False)
```

```
TypeError: Passing a bool to header is invalid. Use header=None for no header or header=int or list-like of ints to specify the row(s) making up the column names
```

### Other API changes

- Line and kde plot with `subplots=True` now uses default colors, not all black. Specify `color='k'` to draw all lines in black ([GH9894](#))
- Calling the `.value_counts()` method on a Series with a categorical dtype now returns a Series with a `CategoricalIndex` ([GH10704](#))
- The metadata properties of subclasses of pandas objects will now be serialized ([GH10553](#)).
- `groupby` using `Categorical` follows the same rule as `Categorical.unique` described above ([GH10508](#))
- When constructing `DataFrame` with an array of `complex64` dtype previously meant the corresponding column was automatically promoted to the `complex128` dtype. pandas will now preserve the `itemsized` of the input for complex data ([GH10952](#))
- some numeric reduction operators would return `ValueError`, rather than `TypeError` on object types that includes strings and numbers ([GH11131](#))
- Passing currently unsupported `chunksize` argument to `read_excel` or `ExcelFile.parse` will now raise `NotImplementedError` ([GH8011](#))
- Allow an `ExcelFile` object to be passed into `read_excel` ([GH11198](#))

- `DatetimeIndex.union` does not infer `freq` if self and the input have `None` as `freq` (GH11086)
- `NaT`'s methods now either raise `ValueError`, or return `np.nan` or `NaT` (GH9513)

| Behavior                                 | Methods                                                                                                     |
|------------------------------------------|-------------------------------------------------------------------------------------------------------------|
| return <code>np.nan</code>               | <code>weekday</code> , <code>isoweekday</code>                                                              |
| return <code>NaT</code>                  | <code>date</code> , <code>now</code> , <code>replace</code> , <code>to_datetime</code> , <code>today</code> |
| return <code>np.datetime64('NaT')</code> | <code>to_datetime64</code> (unchanged)                                                                      |
| raise <code>ValueError</code>            | All other public methods (names not beginning with underscores)                                             |

## Deprecations

- For `Series` the following indexing functions are deprecated (GH10177).

| Deprecated Function         | Replacement                                   |
|-----------------------------|-----------------------------------------------|
| <code>.irow(i)</code>       | <code>.iloc[i]</code> or <code>.iat[i]</code> |
| <code>.iget(i)</code>       | <code>.iloc[i]</code> or <code>.iat[i]</code> |
| <code>.iget_value(i)</code> | <code>.iloc[i]</code> or <code>.iat[i]</code> |

- For `DataFrame` the following indexing functions are deprecated (GH10177).

| Deprecated Function            | Replacement                                         |
|--------------------------------|-----------------------------------------------------|
| <code>.irow(i)</code>          | <code>.iloc[i]</code>                               |
| <code>.iget_value(i, j)</code> | <code>.iloc[i, j]</code> or <code>.iat[i, j]</code> |
| <code>.icol(j)</code>          | <code>.iloc[:, j]</code>                            |

---

**Note:** These indexing function have been deprecated in the documentation since 0.11.0.

---

- `Categorical.name` was deprecated to make `Categorical` more `numpy.ndarray` like. Use `Series(cat, name="whatever")` instead (GH10482).
- Setting missing values (`NaN`) in a `Categorical`'s categories will issue a warning (GH10748). You can still have missing values in the values.
- `drop_duplicates` and `duplicated`'s `take_last` keyword was deprecated in favor of `keep`. (GH6511, GH8505)
- `Series.nsmallest` and `nlargest`'s `take_last` keyword was deprecated in favor of `keep`. (GH10792)
- `DataFrame.combineAdd` and `DataFrame.combineMult` are deprecated. They can easily be replaced by using the `add` and `mul` methods: `DataFrame.add(other, fill_value=0)` and `DataFrame.mul(other, fill_value=1.)` (GH10735).
- `TimeSeries` deprecated in favor of `Series` (note that this has been an alias since 0.13.0), (GH10890)
- `SparsePanel` deprecated and will be removed in a future version (GH11157).
- `Series.is_time_series` deprecated in favor of `Series.index.is_all_dates` (GH11135)
- Legacy offsets (like `'A@JAN'`) are deprecated (note that this has been alias since 0.8.0) (GH10878)
- `WidePanel` deprecated in favor of `Panel`, `LongPanel` in favor of `DataFrame` (note these have been aliases since < 0.11.0), (GH10892)

- `DataFrame.convert_objects` has been deprecated in favor of type-specific functions `pd.to_datetime`, `pd.to_timestamp` and `pd.to_numeric` (new in 0.17.0) (GH11133).

### Removal of prior version deprecations/changes

- Removal of `na_last` parameters from `Series.order()` and `Series.sort()`, in favor of `na_position`. (GH5231)
- Remove of `percentile_width` from `.describe()`, in favor of `percentiles`. (GH7088)
- Removal of `colSpace` parameter from `DataFrame.to_string()`, in favor of `col_space`, circa 0.8.0 version.
- Removal of automatic time-series broadcasting (GH2304)

```
In [90]: np.random.seed(1234)

In [91]: df = pd.DataFrame(

[5 rows x 2 columns]

- Remove `table` keyword in `HDFStore.put/append`, in favor of using `format=` (GH4645)
- Remove `kind` in `read_excel/ExcelFile` as its unused (GH4712)
- Remove `infer_type` keyword from `pd.read_html` as its unused (GH4770, GH7032)
- Remove `offset` and `timeRule` keywords from `Series.tshift/shift`, in favor of `freq` (GH4853, GH4864)
- Remove `pd.load/pd.save` aliases in favor of `pd.to_pickle/pd.read_pickle` (GH3787)

## Performance improvements

- Development support for benchmarking with the `Air Speed Velocity` library (GH8361)
- Added `vbench` benchmarks for alternative `ExcelWriter` engines and reading Excel files (GH7171)
- Performance improvements in `Categorical.value_counts` (GH10804)
- Performance improvements in `SeriesGroupBy.nunique` and `SeriesGroupBy.value_counts` and `SeriesGroupBy.transform` (GH10820, GH11077)
- Performance improvements in `DataFrame.drop_duplicates` with integer dtypes (GH10917)
- Performance improvements in `DataFrame.duplicated` with wide frames. (GH10161, GH11180)
- 4x improvement in `timedelta` string parsing (GH6755, GH10426)
- 8x improvement in `timedelta64` and `datetime64` ops (GH6755)
- Significantly improved performance of indexing `MultiIndex` with slicers (GH10287)
- 8x improvement in `iloc` using list-like input (GH10791)
- Improved performance of `Series.isin` for datetimelike/integer Series (GH10287)
- 20x improvement in `concat` of `Categoricals` when categories are identical (GH10587)
- Improved performance of `to_datetime` when specified format string is ISO8601 (GH10178)
- 2x improvement of `Series.value_counts` for float dtype (GH10821)
- Enable `infer_datetime_format` in `to_datetime` when date components do not have 0 padding (GH11142)
- Regression from 0.16.1 in constructing `DataFrame` from nested dictionary (GH11084)
- Performance improvements in addition/subtraction operations for `DateOffset` with `Series` or `DatetimeIndex` (GH10744, GH11205)

## Bug fixes

- Bug in incorrect computation of `.mean()` on `timedelta64[ns]` because of overflow (GH9442)
- Bug in `.isin` on older numpies (GH11232)
- Bug in `DataFrame.to_html(index=False)` renders unnecessary name row (GH10344)
- Bug in `DataFrame.to_latex()` the `column_format` argument could not be passed (GH9402)
- Bug in `DatetimeIndex` when localizing with `NaT` (GH10477)
- Bug in `Series.dt` ops in preserving meta-data (GH10477)
- Bug in preserving `NaT` when passed in an otherwise invalid `to_datetime` construction (GH10477)
- Bug in `DataFrame.apply` when function returns categorical series. (GH9573)
- Bug in `to_datetime` with invalid dates and formats supplied (GH10154)
- Bug in `Index.drop_duplicates` dropping name(s) (GH10115)
- Bug in `Series.quantile` dropping name (GH10881)
- Bug in `pd.Series` when setting a value on an empty `Series` whose index has a frequency. (GH10193)
- Bug in `pd.Series.interpolate` with invalid order keyword values. (GH10633)
- Bug in `DataFrame.plot` raises `ValueError` when color name is specified by multiple characters (GH10387)
- Bug in `Index` construction with a mixed list of tuples (GH10697)
- Bug in `DataFrame.reset_index` when index contains `NaT`. (GH10388)
- Bug in `ExcelReader` when worksheet is empty (GH6403)
- Bug in `BinGrouper.group_info` where returned values are not compatible with base class (GH10914)
- Bug in clearing the cache on `DataFrame.pop` and a subsequent inplace op (GH10912)
- Bug in indexing with a mixed-integer `Index` causing an `ImportError` (GH10610)
- Bug in `Series.count` when index has nulls (GH10946)
- Bug in pickling of a non-regular freq `DatetimeIndex` (GH11002)
- Bug causing `DataFrame.where` to not respect the `axis` parameter when the frame has a symmetric shape. (GH9736)
- Bug in `Table.select_column` where name is not preserved (GH10392)
- Bug in `offsets.generate_range` where `start` and `end` have finer precision than `offset` (GH9907)
- Bug in `pd.rolling_*` where `Series.name` would be lost in the output (GH10565)
- Bug in `stack` when index or columns are not unique. (GH10417)
- Bug in setting a `Panel` when an axis has a `MultiIndex` (GH10360)
- Bug in `USFederalHolidayCalendar` where `USMemorialDay` and `USMartinLutherKingJr` were incorrect (GH10278 and GH9760)
- Bug in `.sample()` where returned object, if set, gives unnecessary `SettingWithCopyWarning` (GH10738)
- Bug in `.sample()` where weights passed as `Series` were not aligned along axis before being treated positionally, potentially causing problems if weight indices were not aligned with sampled object. (GH10738)
- Regression fixed in (GH9311, GH6620, GH9345), where `groupby` with a datetime-like converting to float with certain aggregators (GH10979)

- Bug in `DataFrame.interpolate` with `axis=1` and `inplace=True` (GH10395)
- Bug in `io.sql.get_schema` when specifying multiple columns as primary key (GH10385).
- Bug in `groupby(sort=False)` with datetime-like Categorical raises `ValueError` (GH10505)
- Bug in `groupby(axis=1)` with `filter()` throws `IndexError` (GH11041)
- Bug in `test_categorical` on big-endian builds (GH10425)
- Bug in `Series.shift` and `DataFrame.shift` not supporting categorical data (GH9416)
- Bug in `Series.map` using categorical Series raises `AttributeError` (GH10324)
- Bug in `MultiIndex.get_level_values` including Categorical raises `AttributeError` (GH10460)
- Bug in `pd.get_dummies` with `sparse=True` not returning `SparseDataFrame` (GH10531)
- Bug in Index subtypes (such as `PeriodIndex`) not returning their own type for `.drop` and `.insert` methods (GH10620)
- Bug in `algos.outer_join_indexer` when right array is empty (GH10618)
- Bug in `filter` (regression from 0.16.0) and `transform` when grouping on multiple keys, one of which is datetime-like (GH10114)
- Bug in `to_datetime` and `to_timedelta` causing Index name to be lost (GH10875)
- Bug in `len(DataFrame.groupby)` causing `IndexError` when there's a column containing only NaNs (GH11016)
- Bug that caused segfault when resampling an empty Series (GH10228)
- Bug in `DatetimeIndex` and `PeriodIndex.value_counts` resets name from its result, but retains in result's Index. (GH10150)
- Bug in `pd.eval` using `numexpr` engine coerces 1 element numpy array to scalar (GH10546)
- Bug in `pd.concat` with `axis=0` when column is of dtype category (GH10177)
- Bug in `read_msgpack` where input type is not always checked (GH10369, GH10630)
- Bug in `pd.read_csv` with kwargs `index_col=False`, `index_col=['a', 'b']` or `dtype` (GH10413, GH10467, GH10577)
- Bug in `Series.from_csv` with `header` kwarg not setting the `Series.name` or the `Series.index.name` (GH10483)
- Bug in `groupby.var` which caused variance to be inaccurate for small float values (GH10448)
- Bug in `Series.plot(kind='hist')` Y Label not informative (GH10485)
- Bug in `read_csv` when using a converter which generates a `uint8` type (GH9266)
- Bug causes memory leak in time-series line and area plot (GH9003)
- Bug when setting a `Panel` sliced along the major or minor axes when the right-hand side is a `DataFrame` (GH11014)
- Bug that returns `None` and does not raise `NotImplementedError` when operator functions (e.g. `.add`) of `Panel` are not implemented (GH7692)
- Bug in line and kde plot cannot accept multiple colors when `subplots=True` (GH9894)
- Bug in `DataFrame.plot` raises `ValueError` when color name is specified by multiple characters (GH10387)
- Bug in left and right align of Series with `MultiIndex` may be inverted (GH10665)
- Bug in left and right join of with `MultiIndex` may be inverted (GH10741)

- Bug in `read_stata` when reading a file with a different order set in `columns` (GH10757)
- Bug in `Categorical` may not representing properly when category contains `tz` or `Period` (GH10713)
- Bug in `Categorical.__iter__` may not returning correct `datetime` and `Period` (GH10713)
- Bug in indexing with a `PeriodIndex` on an object with a `PeriodIndex` (GH4125)
- Bug in `read_csv` with `engine='c'`: EOF preceded by a comment, blank line, etc. was not handled correctly (GH10728, GH10548)
- Reading “famafrench” data via `DataReader` results in HTTP 404 error because of the website url is changed (GH10591).
- Bug in `read_msgpack` where `DataFrame` to decode has duplicate column names (GH9618)
- Bug in `io.common.get_filepath_or_buffer` which caused reading of valid S3 files to fail if the bucket also contained keys for which the user does not have read permission (GH10604)
- Bug in vectorised setting of timestamp columns with `python datetime.date` and `numpy datetime64` (GH10408, GH10412)
- Bug in `Index.take` may add unnecessary `freq` attribute (GH10791)
- Bug in `merge` with empty `DataFrame` may raise `IndexError` (GH10824)
- Bug in `to_latex` where unexpected keyword argument for some documented arguments (GH10888)
- Bug in indexing of large `DataFrame` where `IndexError` is uncaught (GH10645 and GH10692)
- Bug in `read_csv` when using the `nrows` or `chunks` parameters if file contains only a header line (GH9535)
- Bug in serialization of `category` types in HDF5 in presence of alternate encodings. (GH10366)
- Bug in `pd.DataFrame` when constructing an empty `DataFrame` with a string dtype (GH9428)
- Bug in `pd.DataFrame.diff` when `DataFrame` is not consolidated (GH10907)
- Bug in `pd.unique` for arrays with the `datetime64` or `timedelta64` dtype that meant an array with object dtype was returned instead the original dtype (GH9431)
- Bug in `Timedelta` raising error when slicing from 0s (GH10583)
- Bug in `DatetimeIndex.take` and `TimedeltaIndex.take` may not raise `IndexError` against invalid index (GH10295)
- Bug in `Series([np.nan]).astype('M8[ms]')`, which now returns `Series([pd.NaT])` (GH10747)
- Bug in `PeriodIndex.order` reset `freq` (GH10295)
- Bug in `date_range` when `freq` divides `end` as `nanos` (GH10885)
- Bug in `iloc` allowing memory outside bounds of a `Series` to be accessed with negative integers (GH10779)
- Bug in `read_msgpack` where encoding is not respected (GH10581)
- Bug preventing access to the first index when using `iloc` with a list containing the appropriate negative integer (GH10547, GH10779)
- Bug in `TimedeltaIndex` formatter causing error while trying to save `DataFrame` with `TimedeltaIndex` using `to_csv` (GH10833)
- Bug in `DataFrame.where` when handling `Series` slicing (GH10218, GH9558)
- Bug where `pd.read_gbq` throws `ValueError` when `Bigquery` returns zero rows (GH10273)
- Bug in `to_json` which was causing segmentation fault when serializing 0-rank `ndarray` (GH9576)
- Bug in plotting functions may raise `IndexError` when plotted on `GridSpec` (GH10819)

- Bug in plot result may show unnecessary minor ticklabels ([GH10657](#))
- Bug in groupby incorrect computation for aggregation on DataFrame with NaT (E.g first, last, min). ([GH10590](#), [GH11010](#))
- Bug when constructing DataFrame where passing a dictionary with only scalar values and specifying columns did not raise an error ([GH10856](#))
- Bug in .var() causing roundoff errors for highly similar values ([GH10242](#))
- Bug in DataFrame.plot(subplots=True) with duplicated columns outputs incorrect result ([GH10962](#))
- Bug in Index arithmetic may result in incorrect class ([GH10638](#))
- Bug in date\_range results in empty if freq is negative annually, quarterly and monthly ([GH11018](#))
- Bug in DatetimeIndex cannot infer negative freq ([GH11018](#))
- Remove use of some deprecated numpy comparison operations, mainly in tests. ([GH10569](#))
- Bug in Index dtype may not applied properly ([GH11017](#))
- Bug in io.gbq when testing for minimum google api client version ([GH10652](#))
- Bug in DataFrame construction from nested dict with timedelta keys ([GH11129](#))
- Bug in .fillna against may raise TypeError when data contains datetime dtype ([GH7095](#), [GH11153](#))
- Bug in .groupby when number of keys to group by is same as length of index ([GH11185](#))
- Bug in convert\_objects where converted values might not be returned if all null and coerce ([GH9589](#))
- Bug in convert\_objects where copy keyword was not respected ([GH9589](#))

## 5.14 Version 0.16

### 5.14.1 Version 0.16.2 (June 12, 2015)

This is a minor bug-fix release from 0.16.1 and includes a large number of bug fixes along some new features ([`pipe\(\)`](#) method), enhancements, and performance improvements.

We recommend that all users upgrade to this version.

Highlights include:

- A new `pipe` method, see [here](#)
- Documentation on how to use `numba` with `pandas`, see [here](#)

### What's new in v0.16.2

- *New features*
  - *Pipe*
  - *Other enhancements*
- *API changes*
- *Performance improvements*
- *Bug fixes*
- *Contributors*

## New features

### Pipe

We've introduced a new method `DataFrame.pipe()`. As suggested by the name, `pipe` should be used to pipe data through a chain of function calls. The goal is to avoid confusing nested function calls like

```
df is a DataFrame
f, g, and h are functions that take and return DataFrames
f(g(h(df), arg1=1), arg2=2, arg3=3) # noqa F821
```

The logic flows from inside out, and function names are separated from their keyword arguments. This can be rewritten as

```
(
 df.pipe(h) # noqa F821
 .pipe(g, arg1=1) # noqa F821
 .pipe(f, arg2=2, arg3=3) # noqa F821
)
```

Now both the code and the logic flow from top to bottom. Keyword arguments are next to their functions. Overall the code is much more readable.

In the example above, the functions `f`, `g`, and `h` each expected the `DataFrame` as the first positional argument. When the function you wish to apply takes its data anywhere other than the first argument, pass a tuple of (`function`, `keyword`) indicating where the `DataFrame` should flow. For example:

```
In [1]: import statsmodels.formula.api as sm

In [2]: bb = pd.read_csv("data/baseball.csv", index_col="id")

sm.ols takes (formula, data)
In [3]: (
...: bb.query("h > 0")
...: .assign(ln_h=lambda df: np.log(df.h))
...: .pipe((sm.ols, "data"), "hr ~ ln_h + year + g + C(lg)")
...: .fit()
...: .summary()
```

(continues on next page)

(continued from previous page)

```

.....)
.....
Out[3]:
<class 'statsmodels.iolib.summary.Summary'>
"""

Notes:
[1] Standard Errors assume that the covariance matrix of the errors is correctly
 ↪ specified.
[2] The condition number is large, 1.49e+07. This might indicate that there are
 strong multicollinearity or other numerical problems.
"""

```

The pipe method is inspired by unix pipes, which stream text through processes. More recently `dplyr` and `magrittr` have introduced the popular `(%>%)` pipe operator for R.

See the [documentation](#) for more. (GH10129)

## Other enhancements

- Added `rsplit` to Index/Series StringMethods ([GH10303](#))
- Removed the hard-coded size limits on the DataFrame HTML representation in the IPython notebook, and leave this to IPython itself (only for IPython v3.0 or greater). This eliminates the duplicate scroll bars that appeared in the notebook with large frames ([GH10231](#)).  
Note that the notebook has a `toggle output scrolling` feature to limit the display of very large frames (by clicking left of the output). You can also configure the way DataFrames are displayed using the pandas options, see here [here](#).
- `axis` parameter of `DataFrame.quantile` now accepts also `index` and `column`. ([GH9543](#))

## API changes

- `Holiday` now raises `NotImplementedError` if both `offset` and `observance` are used in the constructor instead of returning an incorrect result ([GH10217](#)).

## Performance improvements

- Improved `Series.resample` performance with `dtype=datetime64[ns]` ([GH7754](#))
- Increase performance of `str.split` when `expand=True` ([GH10081](#))

## Bug fixes

- Bug in `Series.hist` raises an error when a one row `Series` was given ([GH10214](#))
- Bug where `HDFStore.select` modifies the passed columns list ([GH7212](#))
- Bug in `Categorical` repr with `display.width` of `None` in Python 3 ([GH10087](#))
- Bug in `to_json` with certain `orients` and a `CategoricalIndex` would segfault ([GH10317](#))
- Bug where some of the nan functions do not have consistent return dtypes ([GH10251](#))
- Bug in `DataFrame.quantile` on checking that a valid axis was passed ([GH9543](#))
- Bug in `groupby.apply` aggregation for `Categorical` not preserving categories ([GH10138](#))
- Bug in `to_csv` where `date_format` is ignored if the `datetime` is fractional ([GH10209](#))
- Bug in `DataFrame.to_json` with mixed data types ([GH10289](#))
- Bug in cache updating when consolidating ([GH10264](#))
- Bug in `mean()` where integer dtypes can overflow ([GH10172](#))
- Bug where `Panel.from_dict` does not set dtype when specified ([GH10058](#))
- Bug in `Index.union` raises `AttributeError` when passing array-likes. ([GH10149](#))
- Bug in `Timestamp`'s `microsecond`, `quarter`, `dayofyear`, `week` and `daysinmonth` properties return `np.int` type, not built-in `int`. ([GH10050](#))
- Bug in `NaT` raises `AttributeError` when accessing to `daysinmonth`, `dayofweek` properties. ([GH10096](#))
- Bug in `Index` repr when using the `max_seq_items=None` setting ([GH10182](#)).
- Bug in getting timezone data with `dateutil` on various platforms ([GH9059](#), [GH8639](#), [GH9663](#), [GH10121](#))

- Bug in displaying datetimes with mixed frequencies; display 'ms' datetimes to the proper precision. (GH10170)
- Bug in `setitem` where type promotion is applied to the entire block (GH10280)
- Bug in `Series` arithmetic methods may incorrectly hold names (GH10068)
- Bug in `GroupBy.get_group` when grouping on multiple keys, one of which is categorical. (GH10132)
- Bug in `DatetimeIndex` and `TimedeltaIndex` names are lost after `timedelta` arithmetic ( GH9926)
- Bug in `DataFrame` construction from nested dict with `datetime64` (GH10160)
- Bug in `Series` construction from dict with `datetime64` keys (GH9456)
- Bug in `Series.plot(label="LABEL")` not correctly setting the label (GH10119)
- Bug in `plot` not defaulting to `matplotlib axes.grid` setting (GH9792)
- Bug causing strings containing an exponent, but no decimal to be parsed as `int` instead of `float` in `engine='python'` for the `read_csv` parser (GH9565)
- Bug in `Series.align` resets name when `fill_value` is specified (GH10067)
- Bug in `read_csv` causing index name not to be set on an empty `DataFrame` (GH10184)
- Bug in `SparseSeries.abs` resets name (GH10241)
- Bug in `TimedeltaIndex` slicing may reset `freq` (GH10292)
- Bug in `GroupBy.get_group` raises `ValueError` when group key contains `NaT` (GH6992)
- Bug in `SparseSeries` constructor ignores input data name (GH10258)
- Bug in `Categorical.remove_categories` causing a `ValueError` when removing the `NaN` category if underlying dtype is floating-point (GH10156)
- Bug where `infer_freq` infers time rule (WOM-5XXX) unsupported by `to_offset` (GH9425)
- Bug in `DataFrame.to_hdf()` where table format would raise a seemingly unrelated error for invalid (non-string) column names. This is now explicitly forbidden. (GH9057)
- Bug to handle masking empty `DataFrame` (GH10126).
- Bug where `MySQL` interface could not handle numeric table/column names (GH10255)
- Bug in `read_csv` with a `date_parser` that returned a `datetime64` array of other time resolution than `[ns]` (GH10245)
- Bug in `Panel.apply` when the result has `ndim=0` (GH10332)
- Bug in `read_hdf` where `auto_close` could not be passed (GH9327).
- Bug in `read_hdf` where open stores could not be used (GH10330).
- Bug in adding empty `DataFrames`, now results in a `DataFrame` that `.equals` an empty `DataFrame` (GH10181).
- Bug in `to_hdf` and `HDFStore` which did not check that `complib` choices were valid (GH4582, GH8874).

### 5.14.2 Version 0.16.1 (May 11, 2015)

This is a minor bug-fix release from 0.16.0 and includes a large number of bug fixes along several new features, enhancements, and performance improvements. We recommend that all users upgrade to this version.

Highlights include:

- Support for a `CategoricalIndex`, a category based index, see [here](#)
- New section on how-to-contribute to *pandas*, see [here](#)
- Revised “Merge, join, and concatenate” documentation, including graphical examples to make it easier to understand each operations, see [here](#)
- New method `sample` for drawing random samples from Series, DataFrames and Panels. See [here](#)
- The default Index printing has changed to a more uniform format, see [here](#)
- `BusinessHour` datetime-offset is now supported, see [here](#)
- Further enhancement to the `.str` accessor to make string operations easier, see [here](#)

#### What’s new in v0.16.1

- *Enhancements*
  - *CategoricalIndex*
  - *Sample*
  - *String methods enhancements*
  - *Other enhancements*
- *API changes*
  - *Deprecations*
- *Index representation*
- *Performance improvements*
- *Bug fixes*
- *Contributors*

**Warning:** In pandas 0.17.0, the sub-package `pandas.io.data` will be removed in favor of a separately installable package (GH8961).

## Enhancements

### CategoricalIndex

We introduce a `CategoricalIndex`, a new type of index object that is useful for supporting indexing with duplicates. This is a container around a `Categorical` (introduced in v0.15.0) and allows efficient indexing and storage of an index with a large number of duplicated elements. Prior to 0.16.1, setting the index of a `DataFrame`/`Series` with a category dtype would convert this to regular object-based `Index`.

```
In [1]: df = pd.DataFrame({'A': np.arange(6),
...: 'B': pd.Series(list('aabbca'))
...: .astype('category', categories=list('cab'))
...: })
...:
```

```
In [2]: df
```

```
Out[2]:
 A B
0 0 a
1 1 a
2 2 b
3 3 b
4 4 c
5 5 a
```

```
In [3]: df.dtypes
```

```
Out[3]:
A int64
B category
dtype: object
```

```
In [4]: df.B.cat.categories
```

```
Out[4]: Index(['c', 'a', 'b'], dtype='object')
```

setting the index, will create a `CategoricalIndex`

```
In [5]: df2 = df.set_index('B')
```

```
In [6]: df2.index
```

```
Out[6]: CategoricalIndex(['a', 'a', 'b', 'b', 'c', 'a'], categories=['c', 'a', 'b'],
↳ordered=False, name='B', dtype='category')
```

indexing with `__getitem__`/`.iloc`/`.loc`/`.ix` works similarly to an `Index` with duplicates. The indexers MUST be in the category or the operation will raise.

```
In [7]: df2.loc['a']
```

```
Out[7]:
 A
B
a 0
a 1
a 5
```

and preserves the `CategoricalIndex`

```
In [8]: df2.loc['a'].index
Out[8]: CategoricalIndex(['a', 'a', 'a'], categories=['c', 'a', 'b'], ordered=False,
↳name='B', dtype='category')
```

sorting will order by the order of the categories

```
In [9]: df2.sort_index()
Out[9]:
A
B
c 4
a 0
a 1
a 5
b 2
b 3
```

groupby operations on the index will preserve the index nature as well

```
In [10]: df2.groupby(level=0).sum()
Out[10]:
A
B
c 4
a 6
b 5

In [11]: df2.groupby(level=0).sum().index
Out[11]: CategoricalIndex(['c', 'a', 'b'], categories=['c', 'a', 'b'], ordered=False,
↳name='B', dtype='category')
```

reindexing operations, will return a resulting index based on the type of the passed indexer, meaning that passing a list will return a plain-old-Index; indexing with a Categorical will return a CategoricalIndex, indexed according to the categories of the PASSED Categorical dtype. This allows one to arbitrarily index these even with values NOT in the categories, similarly to how you can reindex ANY pandas index.

```
In [12]: df2.reindex(['a', 'e'])
Out[12]:
A
B
a 0.0
a 1.0
a 5.0
e NaN

In [13]: df2.reindex(['a', 'e']).index
Out[13]: pd.Index(['a', 'a', 'a', 'e'], dtype='object', name='B')

In [14]: df2.reindex(pd.Categorical(['a', 'e'], categories=list('abcde')))
Out[14]:
A
B
a 0.0
```

(continues on next page)

(continued from previous page)

```

a 1.0
a 5.0
e NaN

In [15]: df2.reindex(pd.Categorical(['a', 'e'], categories=list('abcde'))).index
Out[15]: pd.CategoricalIndex(['a', 'a', 'a', 'e'],
 categories=['a', 'b', 'c', 'd', 'e'],
 ordered=False, name='B',
 dtype='category')
```

See the [documentation](#) for more. (GH7629, GH10038, GH10039)

## Sample

Series, DataFrames, and Panels now have a new method: `sample()`. The method accepts a specific number of rows or columns to return, or a fraction of the total number of rows or columns. It also has options for sampling with or without replacement, for passing in a column for weights for non-uniform sampling, and for setting seed values to facilitate replication. (GH2419)

```

In [1]: example_series = pd.Series([0, 1, 2, 3, 4, 5])

When no arguments are passed, returns 1
In [2]: example_series.sample()
Out[2]:
3 3
Length: 1, dtype: int64

One may specify either a number of rows:
In [3]: example_series.sample(n=3)
Out[3]:
2 2
1 1
0 0
Length: 3, dtype: int64

Or a fraction of the rows:
In [4]: example_series.sample(frac=0.5)
Out[4]:
1 1
5 5
3 3
Length: 3, dtype: int64

weights are accepted.
In [5]: example_weights = [0, 0, 0.2, 0.2, 0.2, 0.4]

In [6]: example_series.sample(n=3, weights=example_weights)
Out[6]:
2 2
4 4
3 3
```

(continues on next page)

(continued from previous page)

```

Length: 3, dtype: int64

weights will also be normalized if they do not sum to one,
and missing values will be treated as zeros.
In [7]: example_weights2 = [0.5, 0, 0, 0, None, np.nan]

In [8]: example_series.sample(n=1, weights=example_weights2)
Out[8]:
0 0
Length: 1, dtype: int64

```

When applied to a DataFrame, one may pass the name of a column to specify sampling weights when sampling from rows.

```

In [9]: df = pd.DataFrame({"col1": [9, 8, 7, 6], "weight_column": [0.5, 0.4, 0.1, 0]})

In [10]: df.sample(n=3, weights="weight_column")
Out[10]:
 col1 weight_column
0 9 0.5
1 8 0.4
2 7 0.1

[3 rows x 2 columns]

```

## String methods enhancements

*Continuing from v0.16.0*, the following enhancements make string operations easier and more consistent with standard python string operations.

- Added StringMethods (`.str` accessor) to Index (GH9068)

The `.str` accessor is now available for both Series and Index.

```

In [11]: idx = pd.Index([" jack", "jill ", " jesse ", "frank"])

In [12]: idx.str.strip()
Out[12]: Index(['jack', 'jill', 'jesse', 'frank'], dtype='object')

```

One special case for the `.str` accessor on Index is that if a string method returns `bool`, the `.str` accessor will return a `np.array` instead of a boolean Index (GH8875). This enables the following expression to work naturally:

```

In [13]: idx = pd.Index(["a1", "a2", "b1", "b2"])

In [14]: s = pd.Series(range(4), index=idx)

In [15]: s
Out[15]:
a1 0
a2 1
b1 2

```

(continues on next page)

(continued from previous page)

```

b2 3
Length: 4, dtype: int64

In [16]: idx.str.startswith("a")
Out[16]: array([True, True, False, False])

In [17]: s[s.index.str.startswith("a")]
Out[17]:
a1 0
a2 1
Length: 2, dtype: int64

```

- The following new methods are accessible via `.str` accessor to apply the function to each values. ([GH9766](#), [GH9773](#), [GH10031](#), [GH10045](#), [GH10052](#))

| Methods                   |                         |                          |                          |                           |
|---------------------------|-------------------------|--------------------------|--------------------------|---------------------------|
| <code>capitalize()</code> | <code>swapcase()</code> | <code>normalize()</code> | <code>partition()</code> | <code>rpartition()</code> |
| <code>index()</code>      | <code>rindex()</code>   | <code>translate()</code> |                          |                           |

- `split` now takes `expand` keyword to specify whether to expand dimensionality. `return_type` is deprecated. ([GH9847](#))

```

In [18]: s = pd.Series(["a,b", "a,c", "b,c"])

return Series
In [19]: s.str.split(",")
Out[19]:
0 [a, b]
1 [a, c]
2 [b, c]
Length: 3, dtype: object

return DataFrame
In [20]: s.str.split(",", expand=True)
Out[20]:
 0 1
0 a b
1 a c
2 b c

[3 rows x 2 columns]

In [21]: idx = pd.Index(["a,b", "a,c", "b,c"])

return Index
In [22]: idx.str.split(",")
Out[22]: Index([['a', 'b'], ['a', 'c'], ['b', 'c']], dtype='object')

return MultiIndex
In [23]: idx.str.split(",", expand=True)
Out[23]:
MultiIndex([('a', 'b'),

```

(continues on next page)

(continued from previous page)

```

 ('a', 'c'),
 ('b', 'c')],
)

```

- Improved `extract` and `get_dummies` methods for `Index.str` (GH9980)

## Other enhancements

- `BusinessHour` offset is now supported, which represents business hours starting from 09:00 - 17:00 on `BusinessDay` by default. See [Here](#) for details. (GH7905)

```
In [24]: pd.Timestamp("2014-08-01 09:00") + pd.tseries.offsets.BusinessHour()
```

```
Out[24]: Timestamp('2014-08-01 10:00:00')
```

```
In [25]: pd.Timestamp("2014-08-01 07:00") + pd.tseries.offsets.BusinessHour()
```

```
Out[25]: Timestamp('2014-08-01 10:00:00')
```

```
In [26]: pd.Timestamp("2014-08-01 16:30") + pd.tseries.offsets.BusinessHour()
```

```
Out[26]: Timestamp('2014-08-04 09:30:00')
```

- `DataFrame.diff` now takes an `axis` parameter that determines the direction of differencing (GH9727)
- Allow `clip`, `clip_lower`, and `clip_upper` to accept array-like arguments as thresholds (This is a regression from 0.11.0). These methods now have an `axis` parameter which determines how the Series or DataFrame will be aligned with the threshold(s). (GH6966)
- `DataFrame.mask()` and `Series.mask()` now support same keywords as `where` (GH8801)
- `drop` function can now accept `errors` keyword to suppress `ValueError` raised when any of label does not exist in the target data. (GH6736)

```
In [27]: df = pd.DataFrame(np.random.randn(3, 3), columns=["A", "B", "C"])
```

```
In [28]: df.drop(["A", "X"], axis=1, errors="ignore")
```

```
Out[28]:
```

```

 B C
0 -0.706771 -1.039575
1 -0.424972 0.567020
2 -1.087401 -0.673690

```

```
[3 rows x 2 columns]
```

- Add support for separating years and quarters using dashes, for example 2014-Q1. (GH9688)
- Allow conversion of values with dtype `datetime64` or `timedelta64` to strings using `astype(str)` (GH9757)
- `get_dummies` function now accepts `sparse` keyword. If set to `True`, the return DataFrame is sparse, e.g. `SparseDataFrame`. (GH8823)
- `Period` now accepts `datetime64` as value input. (GH9054)
- Allow `timedelta` string conversion when leading zero is missing from time definition, ie `0:00:00` vs `00:00:00`. (GH9570)
- Allow `Panel.shift` with `axis='items'` (GH9890)

- Trying to write an excel file now raises `NotImplementedError` if the `DataFrame` has a `MultiIndex` instead of writing a broken Excel file. (GH9794)
- Allow `Categorical.add_categories` to accept `Series` or `np.array`. (GH9927)
- Add/delete `str/dt/cat` accessors dynamically from `__dir__`. (GH9910)
- Add `normalize` as a `dt` accessor method. (GH10047)
- `DataFrame` and `Series` now have `_constructor_expanddim` property as overridable constructor for one higher dimensionality data. This should be used only when it is really needed, see [here](#)
- `pd.lib.infer_dtype` now returns 'bytes' in Python 3 where appropriate. (GH10032)

### API changes

- When passing in an `ax` to `df.plot(..., ax=ax)`, the `sharex` kwarg will now default to `False`. The result is that the visibility of `xlabels` and `xticklabels` will not anymore be changed. You have to do that by yourself for the right axes in your figure or set `sharex=True` explicitly (but this changes the visible for all axes in the figure, not only the one which is passed in!). If pandas creates the subplots itself (e.g. no passed in `ax` kwarg), then the default is still `sharex=True` and the visibility changes are applied.
- `assign()` now inserts new columns in alphabetical order. Previously the order was arbitrary. (GH9777)
- By default, `read_csv` and `read_table` will now try to infer the compression type based on the file extension. Set `compression=None` to restore the previous behavior (no decompression). (GH9770)

### Deprecations

- `Series.str.split`'s `return_type` keyword was removed in favor of `expand` (GH9847)

### Index representation

The string representation of `Index` and its sub-classes have now been unified. These will show a single-line display if there are few values; a wrapped multi-line display for a lot of values (but less than `display.max_seq_items`; if lots of items (`> display.max_seq_items`) will show a truncated display (the head and tail of the data). The formatting for `MultiIndex` is unchanged (a multi-line wrapped display). The display width responds to the option `display.max_seq_items`, which is defaulted to 100. (GH6482)

Previous behavior

```
In [2]: pd.Index(range(4), name='foo')
Out[2]: Int64Index([0, 1, 2, 3], dtype='int64')

In [3]: pd.Index(range(104), name='foo')
Out[3]: Int64Index([0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19,
↳ 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40,
↳ 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62,
↳ 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83,
↳ 84, 85, 86, 87, 88, 89, 90, 91, 92, 93, 94, 95, 96, 97, 98, 99, ...], dtype='int64')

In [4]: pd.date_range('20130101', periods=4, name='foo', tz='US/Eastern')
Out[4]:
<class 'pandas.tseries.index.DatetimeIndex'>
[2013-01-01 00:00:00-05:00, ..., 2013-01-04 00:00:00-05:00]
```

(continues on next page)

(continued from previous page)

 dtype='datetime64[ns, US/Eastern]', name='foo', length=104, freq='D')

```

## Performance improvements

- Improved csv write performance with mixed dtypes, including datetimes by up to 5x (GH9940)
- Improved csv write performance generally by 2x (GH9940)
- Improved the performance of `pd.lib.max_len_string_array` by 5-7x (GH10024)

## Bug fixes

- Bug where labels did not appear properly in the legend of `DataFrame.plot()`, passing `label=` arguments works, and Series indices are no longer mutated. (GH9542)
- Bug in json serialization causing a segfault when a frame had zero length. (GH9805)
- Bug in `read_csv` where missing trailing delimiters would cause segfault. (GH5664)
- Bug in retaining index name on appending (GH9862)
- Bug in `scatter_matrix` draws unexpected axis ticklabels (GH5662)
- Fixed bug in `StataWriter` resulting in changes to input `DataFrame` upon save (GH9795).
- Bug in `transform` causing length mismatch when null entries were present and a fast aggregator was being used (GH9697)
- Bug in `equals` causing false negatives when block order differed (GH9330)
- Bug in grouping with multiple `pd.Grouper` where one is non-time based (GH10063)

- Bug in `read_sql_table` error when reading postgres table with timezone (GH7139)
- Bug in `DataFrame` slicing may not retain metadata (GH9776)
- Bug where `TimedeltaIndex` were not properly serialized in fixed `HDFStore` (GH9635)
- Bug with `TimedeltaIndex` constructor ignoring name when given another `TimedeltaIndex` as data (GH10025).
- Bug in `DataFrameFormatter._get_formatted_index` with not applying `max_colwidth` to the `DataFrame` index (GH7856)
- Bug in `.loc` with a read-only `ndarray` data source (GH10043)
- Bug in `groupby.apply()` that would raise if a passed user defined function either returned only `None` (for all input). (GH9685)
- Always use temporary files in `pytables` tests (GH9992)
- Bug in plotting continuously using `secondary_y` may not show legend properly. (GH9610, GH9779)
- Bug in `DataFrame.plot(kind="hist")` results in `TypeError` when `DataFrame` contains non-numeric columns (GH9853)
- Bug where repeated plotting of `DataFrame` with a `DatetimeIndex` may raise `TypeError` (GH9852)
- Bug in `setup.py` that would allow an incompat `cython` version to build (GH9827)
- Bug in plotting `secondary_y` incorrectly attaches `right_ax` property to secondary axes specifying itself recursively. (GH9861)
- Bug in `Series.quantile` on empty `Series` of type `Datetime` or `Timedelta` (GH9675)
- Bug in `where` causing incorrect results when upcasting was required (GH9731)
- Bug in `FloatArrayFormatter` where decision boundary for displaying “small” floats in decimal format is off by one order of magnitude for a given `display.precision` (GH9764)
- Fixed bug where `DataFrame.plot()` raised an error when both `color` and `style` keywords were passed and there was no color symbol in the style strings (GH9671)
- Not showing a `DeprecationWarning` on combining list-likes with an `Index` (GH10083)
- Bug in `read_csv` and `read_table` when using `skip_rows` parameter if blank lines are present. (GH9832)
- Bug in `read_csv()` interprets `index_col=True` as 1 (GH9798)
- Bug in index equality comparisons using `==` failing on `Index/MultiIndex` type incompatibility (GH9785)
- Bug in which `SparseDataFrame` could not take `nan` as a column name (GH8822)
- Bug in `to_msgpack` and `read_msgpack` `zlib` and `blosc` compression support (GH9783)
- Bug `GroupBy.size` doesn't attach index name properly if grouped by `TimeGrouper` (GH9925)
- Bug causing an exception in slice assignments because `length_of_indexer` returns wrong results (GH9995)
- Bug in `csv` parser causing lines with initial white space plus one non-space character to be skipped. (GH9710)
- Bug in `C` `csv` parser causing spurious `NaNs` when data started with newline followed by white space. (GH10022)
- Bug causing elements with a null group to spill into the final group when grouping by a `Categorical` (GH9603)
- Bug where `.iloc` and `.loc` behavior is not consistent on empty dataframes (GH9964)
- Bug in invalid attribute access on a `TimedeltaIndex` incorrectly raised `ValueError` instead of `AttributeError` (GH9680)

- Bug in unequal comparisons between categorical data and a scalar, which was not in the categories (e.g. `Series(Categorical(list("abc")), ordered=True) > "d"`). This returned `False` for all elements, but now raises a `TypeError`. Equality comparisons also now return `False` for `==` and `True` for `!=`. (GH9848)
- Bug in `DataFrame.__setitem__` when right hand side is a dictionary (GH9874)
- Bug in `where` when `dtype` is `datetime64/timedelta64`, but `dtype` of other is not (GH9804)
- Bug in `MultiIndex.sortlevel()` results in unicode level name breaks (GH9856)
- Bug in which `groupby.transform` incorrectly enforced output dtypes to match input dtypes. (GH9807)
- Bug in `DataFrame` constructor when `columns` parameter is set, and `data` is an empty list (GH9939)
- Bug in bar plot with `log=True` raises `TypeError` if all values are less than 1 (GH9905)
- Bug in horizontal bar plot ignores `log=True` (GH9905)
- Bug in `PyTables` queries that did not return proper results using the index (GH8265, GH9676)
- Bug where dividing a dataframe containing values of type `Decimal` by another `Decimal` would raise. (GH9787)
- Bug where using `DataFrames` `asfreq` would remove the name of the index. (GH9885)
- Bug causing extra index point when `resample` BM/BQ (GH9756)
- Changed caching in `AbstractHolidayCalendar` to be at the instance level rather than at the class level as the latter can result in unexpected behaviour. (GH9552)
- Fixed latex output for `MultiIndexed` dataframes (GH9778)
- Bug causing an exception when setting an empty range using `DataFrame.loc` (GH9596)
- Bug in hiding ticklabels with subplots and shared axes when adding a new plot to an existing grid of axes (GH9158)
- Bug in `transform` and `filter` when grouping on a categorical variable (GH9921)
- Bug in `transform` when groups are equal in number and `dtype` to the input index (GH9700)
- Google BigQuery connector now imports dependencies on a per-method basis.(GH9713)
- Updated BigQuery connector to no longer use deprecated `oauth2client.tools.run()` (GH8327)
- Bug in subclassed `DataFrame`. It may not return the correct class, when slicing or subsetting it. (GH9632)
- Bug in `.median()` where non-float null values are not handled correctly (GH10040)
- Bug in `Series.fillna()` where it raises if a numerically convertible string is given (GH10092)

### 5.14.3 Version 0.16.0 (March 22, 2015)

This is a major release from 0.15.2 and includes a small number of API changes, several new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

Highlights include:

- `DataFrame.assign` method, see [here](#)
- `Series.to_coo/from_coo` methods to interact with `scipy.sparse`, see [here](#)
- Backwards incompatible change to `Timedelta` to conform the `.seconds` attribute with `datetime.timedelta`, see [here](#)
- Changes to the `.loc` slicing API to conform with the behavior of `.ix` see [here](#)
- Changes to the default for ordering in the `Categorical` constructor, see [here](#)
- Enhancement to the `.str` accessor to make string operations easier, see [here](#)
- The `pandas.tools.rplot`, `pandas.sandbox.qtpandas` and `pandas.rpy` modules are deprecated. We refer users to external packages like `seaborn`, `pandas-qt` and `rpy2` for similar or equivalent functionality, see [here](#)

Check the *API Changes* and *deprecations* before updating.

#### What's new in v0.16.0

- *New features*
  - *DataFrame assign*
  - *Interaction with scipy.sparse*
  - *String methods enhancements*

- *Other enhancements*
- *Backwards incompatible API changes*
  - *Changes in timedelta*
  - *Indexing changes*
  - *Categorical changes*
  - *Other API changes*
  - *Deprecations*
  - *Removal of prior version deprecations/changes*
- *Performance improvements*
- *Bug fixes*
- *Contributors*

## New features

### DataFrame assign

Inspired by `dplyr`'s `mutate` verb, `DataFrame` has a new `assign()` method. The function signature for `assign` is simply `**kwargs`. The keys are the column names for the new fields, and the values are either a value to be inserted (for example, a `Series` or `NumPy` array), or a function of one argument to be called on the `DataFrame`. The new values are inserted, and the entire `DataFrame` (with all original and new columns) is returned.

```
In [1]: iris = pd.read_csv('data/iris.data')
```

```
In [2]: iris.head()
```

```
Out[2]:
```

|   | SepalLength | SepalWidth | PetalLength | PetalWidth | Name        |
|---|-------------|------------|-------------|------------|-------------|
| 0 | 5.1         | 3.5        | 1.4         | 0.2        | Iris-setosa |
| 1 | 4.9         | 3.0        | 1.4         | 0.2        | Iris-setosa |
| 2 | 4.7         | 3.2        | 1.3         | 0.2        | Iris-setosa |
| 3 | 4.6         | 3.1        | 1.5         | 0.2        | Iris-setosa |
| 4 | 5.0         | 3.6        | 1.4         | 0.2        | Iris-setosa |

```
[5 rows x 5 columns]
```

```
In [3]: iris.assign(sepal_ratio=iris['SepalWidth'] / iris['SepalLength']).head()
```

```
Out[3]:
```

|   | SepalLength | SepalWidth | PetalLength | PetalWidth | Name        | sepal_ratio |
|---|-------------|------------|-------------|------------|-------------|-------------|
| 0 | 5.1         | 3.5        | 1.4         | 0.2        | Iris-setosa | 0.686275    |
| 1 | 4.9         | 3.0        | 1.4         | 0.2        | Iris-setosa | 0.612245    |
| 2 | 4.7         | 3.2        | 1.3         | 0.2        | Iris-setosa | 0.680851    |
| 3 | 4.6         | 3.1        | 1.5         | 0.2        | Iris-setosa | 0.673913    |
| 4 | 5.0         | 3.6        | 1.4         | 0.2        | Iris-setosa | 0.720000    |

```
[5 rows x 6 columns]
```

Above was an example of inserting a precomputed value. We can also pass in a function to be evaluated.

```
In [4]: iris.assign(sepal_ratio=lambda x: (x['SepalWidth']
...: / x['SepalLength'])).head()
...:
...:
```

```
Out[4]:
```

|   | SepalLength | SepalWidth | PetalLength | PetalWidth | Name        | sepal_ratio |
|---|-------------|------------|-------------|------------|-------------|-------------|
| 0 | 5.1         | 3.5        | 1.4         | 0.2        | Iris-setosa | 0.686275    |
| 1 | 4.9         | 3.0        | 1.4         | 0.2        | Iris-setosa | 0.612245    |
| 2 | 4.7         | 3.2        | 1.3         | 0.2        | Iris-setosa | 0.680851    |
| 3 | 4.6         | 3.1        | 1.5         | 0.2        | Iris-setosa | 0.673913    |
| 4 | 5.0         | 3.6        | 1.4         | 0.2        | Iris-setosa | 0.720000    |

```
[5 rows x 6 columns]
```

The power of `assign` comes when used in chains of operations. For example, we can limit the DataFrame to just those with a Sepal Length greater than 5, calculate the ratio, and plot

```
In [5]: iris = pd.read_csv('data/iris.data')
```

```
In [6]: (iris.query('SepalLength > 5')
...: .assign(SepalRatio=lambda x: x.SepalWidth / x.SepalLength,
...: PetalRatio=lambda x: x.PetalWidth / x.PetalLength)
...: .plot(kind='scatter', x='SepalRatio', y='PetalRatio'))
...:
...:
```

```
Out[6]: <AxesSubplot:xlabel='SepalRatio', ylabel='PetalRatio'>
```

See the [documentation](#) for more. (GH9229)

## Interaction with `scipy.sparse`

Added `SparseSeries.to_coo()` and `SparseSeries.from_coo()` methods (GH8048) for converting to and from `scipy.sparse.coo_matrix` instances (see [here](#)). For example, given a `SparseSeries` with `MultiIndex` we can convert to a `scipy.sparse.coo_matrix` by specifying the row and column labels as index levels:

```
s = pd.Series([3.0, np.nan, 1.0, 3.0, np.nan, np.nan])
s.index = pd.MultiIndex.from_tuples([(1, 2, 'a', 0),
...: (1, 2, 'a', 1),
...: (1, 1, 'b', 0),
...: (1, 1, 'b', 1),
...: (2, 1, 'b', 0),
...: (2, 1, 'b', 1)],
```

(continues on next page)

(continued from previous page)

```

names=['A', 'B', 'C', 'D'])

s

SparseSeries
ss = s.to_sparse()
ss

A, rows, columns = ss.to_coo(row_levels=['A', 'B'],
 column_levels=['C', 'D'],
 sort_labels=False)

A
A.todense()
rows
columns

```

The `from_coo` method is a convenience method for creating a `SparseSeries` from a `scipy.sparse.coo_matrix`:

```

from scipy import sparse
A = sparse.coo_matrix(([3.0, 1.0, 2.0], ([1, 0, 0], [0, 2, 3])),
 shape=(3, 4))

A
A.todense()

ss = pd.SparseSeries.from_coo(A)
ss

```

## String methods enhancements

- Following new methods are accessible via `.str` accessor to apply the function to each values. This is intended to make it more consistent with standard methods on strings. ([GH9282](#), [GH9352](#), [GH9386](#), [GH9387](#), [GH9439](#))

| Methods                |                        |                        |                          |                          |
|------------------------|------------------------|------------------------|--------------------------|--------------------------|
| <code>isalnum()</code> | <code>isalpha()</code> | <code>isdigit()</code> | <code>isdigit()</code>   | <code>isspace()</code>   |
| <code>islower()</code> | <code>isupper()</code> | <code>istitle()</code> | <code>isnumeric()</code> | <code>isdecimal()</code> |
| <code>find()</code>    | <code>rfind()</code>   | <code>ljust()</code>   | <code>rjust()</code>     | <code>zfill()</code>     |

```
In [7]: s = pd.Series(['abcd', '3456', 'EFGH'])
```

```
In [8]: s.str.isalpha()
```

```
Out[8]:
```

```
0 True
1 False
2 True
Length: 3, dtype: bool
```

```
In [9]: s.str.find('ab')
```

```
Out[9]:
```

```
0 0
```

(continues on next page)

(continued from previous page)

```
1 -1
2 -1
Length: 3, dtype: int64
```

- `Series.str.pad()` and `Series.str.center()` now accept `fillchar` option to specify filling character (GH9352)

```
In [10]: s = pd.Series(['12', '300', '25'])
```

```
In [11]: s.str.pad(5, fillchar='_')
```

```
Out[11]:
```

```
0 ___12
1 __300
2 ___25
Length: 3, dtype: object
```

- Added `Series.str.slice_replace()`, which previously raised `NotImplementedError` (GH8888)

```
In [12]: s = pd.Series(['ABCD', 'EFGH', 'IJK'])
```

```
In [13]: s.str.slice_replace(1, 3, 'X')
```

```
Out[13]:
```

```
0 AXD
1 EXH
2 IX
Length: 3, dtype: object
```

```
replaced with empty char
```

```
In [14]: s.str.slice_replace(0, 1)
```

```
Out[14]:
```

```
0 BCD
1 FGH
2 JK
Length: 3, dtype: object
```

## Other enhancements

- `Reindex` now supports `method='nearest'` for frames or series with a monotonic increasing or decreasing index (GH9258):

```
In [15]: df = pd.DataFrame({'x': range(5)})
```

```
In [16]: df.reindex([0.2, 1.8, 3.5], method='nearest')
```

```
Out[16]:
```

```
 x
0.2 0
1.8 2
3.5 4

[3 rows x 1 columns]
```

This method is also exposed by the lower level `Index.get_indexer` and `Index.get_loc` methods.

- The `read_excel()` function's `sheetname` argument now accepts a list and `None`, to get multiple or all sheets respectively. If more than one sheet is specified, a dictionary is returned. (GH9450)

```
Returns the 1st and 4th sheet, as a dictionary of DataFrames.
pd.read_excel('path_to_file.xls', sheetname=['Sheet1', 3])
```

- Allow Stata files to be read incrementally with an iterator; support for long strings in Stata files. See the docs [here](#) (GH9493:).
- Paths beginning with `~` will now be expanded to begin with the user's home directory (GH9066)
- Added time interval selection in `get_data_yahoo` (GH9071)
- Added `Timestamp.to_datetime64()` to complement `Timedelta.to_timedelta64()` (GH9255)
- `tseries.frequencies.to_offset()` now accepts `Timedelta` as input (GH9064)
- Lag parameter was added to the autocorrelation method of `Series`, defaults to lag-1 autocorrelation (GH9192)
- `Timedelta` will now accept nanoseconds keyword in constructor (GH9273)
- SQL code now safely escapes table and column names (GH8986)
- Added auto-complete for `Series.str.<tab>`, `Series.dt.<tab>` and `Series.cat.<tab>` (GH9322)
- `Index.get_indexer` now supports `method='pad'` and `method='backfill'` even for any target array, not just monotonic targets. These methods also work for monotonic decreasing as well as monotonic increasing indexes (GH9258).
- `Index.asof` now works on all index types (GH9258).
- A `verbose` argument has been augmented in `io.read_excel()`, defaults to `False`. Set to `True` to print sheet names as they are parsed. (GH9450)
- Added `days_in_month` (compatibility alias `daysinmonth`) property to `Timestamp`, `DatetimeIndex`, `Period`, `PeriodIndex`, and `Series.dt` (GH9572)
- Added `decimal` option in `to_csv` to provide formatting for non-`'.'` decimal separators (GH781)
- Added `normalize` option for `Timestamp` to normalized to midnight (GH8794)
- Added example for `DataFrame` import to R using HDF5 file and `rhdf5` library. See the [documentation](#) for more (GH9636).

## Backwards incompatible API changes

### Changes in `timedelta`

In v0.15.0 a new scalar type `Timedelta` was introduced, that is a sub-class of `datetime.timedelta`. Mentioned [here](#) was a notice of an API change w.r.t. the `.seconds` accessor. The intent was to provide a user-friendly set of accessors that give the 'natural' value for that unit, e.g. if you had a `Timedelta('1 day, 10:11:12')`, then `.seconds` would return 12. However, this is at odds with the definition of `datetime.timedelta`, which defines `.seconds` as  $10 * 3600 + 11 * 60 + 12 == 36672$ .

So in v0.16.0, we are restoring the API to match that of `datetime.timedelta`. Further, the component values are still available through the `.components` accessor. This affects the `.seconds` and `.microseconds` accessors, and removes the `.hours`, `.minutes`, `.milliseconds` accessors. These changes affect `TimedeltaIndex` and the `Series.dt` accessor as well. (GH9185, GH9139)

Previous behavior

```
In [2]: t = pd.Timedelta('1 day, 10:11:12.100123')
```

```
In [3]: t.days
```

```
Out[3]: 1
```

```
In [4]: t.seconds
```

```
Out[4]: 12
```

```
In [5]: t.microseconds
```

```
Out[5]: 123
```

New behavior

```
In [17]: t = pd.Timedelta('1 day, 10:11:12.100123')
```

```
In [18]: t.days
```

```
Out[18]: 1
```

```
In [19]: t.seconds
```

```
Out[19]: 36672
```

```
In [20]: t.microseconds
```

```
Out[20]: 100123
```

Using `.components` allows the full component access

```
In [21]: t.components
```

```
Out[21]: Components(days=1, hours=10, minutes=11, seconds=12, milliseconds=100,
↳microseconds=123, nanoseconds=0)
```

```
In [22]: t.components.seconds
```

```
Out[22]: 12
```

## Indexing changes

The behavior of a small sub-set of edge cases for using `.loc` have changed ([GH8613](#)). Furthermore we have improved the content of the error messages that are raised:

- Slicing with `.loc` where the start and/or stop bound is not found in the index is now allowed; this previously would raise a `KeyError`. This makes the behavior the same as `.ix` in this case. This change is only for slicing, not when indexing with a single label.

```
In [23]: df = pd.DataFrame(np.random.randn(5, 4),
.....: columns=list('ABCD'),
.....: index=pd.date_range('20130101', periods=5))
.....:
```

```
In [24]: df
```

```
Out[24]:
```

|            | A        | B         | C         | D         |
|------------|----------|-----------|-----------|-----------|
| 2013-01-01 | 0.469112 | -0.282863 | -1.509059 | -1.135632 |
| 2013-01-02 | 1.212112 | -0.173215 | 0.119209  | -1.044236 |

(continues on next page)

(continued from previous page)

```
2013-01-03 -0.861849 -2.104569 -0.494929 1.071804
2013-01-04 0.721555 -0.706771 -1.039575 0.271860
2013-01-05 -0.424972 0.567020 0.276232 -1.087401
```

```
[5 rows x 4 columns]
```

```
In [25]: s = pd.Series(range(5), [-2, -1, 1, 2, 3])
```

```
In [26]: s
```

```
Out[26]:
```

```
-2 0
-1 1
 1 2
 2 3
 3 4
```

```
Length: 5, dtype: int64
```

Previous behavior

```
In [4]: df.loc['2013-01-02':'2013-01-10']
KeyError: 'stop bound [2013-01-10] is not in the [index]'
```

```
In [6]: s.loc[-10:3]
KeyError: 'start bound [-10] is not the [index]'
```

New behavior

```
In [27]: df.loc['2013-01-02':'2013-01-10']
Out[27]:
```

|            | A         | B         | C         | D         |
|------------|-----------|-----------|-----------|-----------|
| 2013-01-02 | 1.212112  | -0.173215 | 0.119209  | -1.044236 |
| 2013-01-03 | -0.861849 | -2.104569 | -0.494929 | 1.071804  |
| 2013-01-04 | 0.721555  | -0.706771 | -1.039575 | 0.271860  |
| 2013-01-05 | -0.424972 | 0.567020  | 0.276232  | -1.087401 |

```
[4 rows x 4 columns]
```

```
In [28]: s.loc[-10:3]
```

```
Out[28]:
```

```
-2 0
-1 1
 1 2
 2 3
 3 4
```

```
Length: 5, dtype: int64
```

- Allow slicing with float-like values on an integer index for `.ix`. Previously this was only enabled for `.loc`:

Previous behavior

```
In [8]: s.ix[-1.0:2]
TypeError: the slice start value [-1.0] is not a proper indexer for this index type
↳ (Int64Index)
```

New behavior

```
In [2]: s.ix[-1.0:2]
Out[2]:
-1 1
 1 2
 2 3
dtype: int64
```

- Provide a useful exception for indexing with an invalid type for that index when using `.loc`. For example trying to use `.loc` on an index of type `DatetimeIndex` or `PeriodIndex` or `TimedeltaIndex`, with an integer (or a float).

Previous behavior

```
In [4]: df.loc[2:3]
KeyError: 'start bound [2] is not the [index]'
```

New behavior

```
In [4]: df.loc[2:3]
TypeError: Cannot do slice indexing on <class 'pandas.tseries.index.DatetimeIndex'>
↳with <type 'int'> keys
```

## Categorical changes

In prior versions, Categoricals that had an unspecified ordering (meaning no `ordered` keyword was passed) were defaulted as ordered Categoricals. Going forward, the `ordered` keyword in the `Categorical` constructor will default to `False`. Ordering must now be explicit.

Furthermore, previously you *could* change the `ordered` attribute of a Categorical by just setting the attribute, e.g. `cat.ordered=True`; This is now deprecated and you should use `cat.as_ordered()` or `cat.as_unordered()`. These will by default return a **new** object and not modify the existing object. (GH9347, GH9190)

Previous behavior

```
In [3]: s = pd.Series([0, 1, 2], dtype='category')

In [4]: s
Out[4]:
0 0
1 1
2 2
dtype: category
Categories (3, int64): [0 < 1 < 2]

In [5]: s.cat.ordered
Out[5]: True

In [6]: s.cat.ordered = False

In [7]: s
Out[7]:
0 0
```

(continues on next page)

(continued from previous page)

```

1 1
2 2
dtype: category
Categories (3, int64): [0, 1, 2]

```

New behavior

```

In [29]: s = pd.Series([0, 1, 2], dtype='category')

In [30]: s
Out[30]:
0 0
1 1
2 2
Length: 3, dtype: category
Categories (3, int64): [0, 1, 2]

In [31]: s.cat.ordered
Out[31]: False

In [32]: s = s.cat.as_ordered()

In [33]: s
Out[33]:
0 0
1 1
2 2
Length: 3, dtype: category
Categories (3, int64): [0 < 1 < 2]

In [34]: s.cat.ordered
Out[34]: True

you can set in the constructor of the Categorical
In [35]: s = pd.Series(pd.Categorical([0, 1, 2], ordered=True))

In [36]: s
Out[36]:
0 0
1 1
2 2
Length: 3, dtype: category
Categories (3, int64): [0 < 1 < 2]

In [37]: s.cat.ordered
Out[37]: True

```

For ease of creation of series of categorical data, we have added the ability to pass keywords when calling `.astype()`. These are passed directly to the constructor.

```

In [54]: s = pd.Series(["a", "b", "c", "a"]).astype('category', ordered=True)

```

(continues on next page)

(continued from previous page)

```

In [55]: s
Out[55]:
0 a
1 b
2 c
3 a
dtype: category
Categories (3, object): [a < b < c]

In [56]: s = (pd.Series(["a", "b", "c", "a"])
....: .astype('category', categories=list('abcdef'), ordered=False))

In [57]: s
Out[57]:
0 a
1 b
2 c
3 a
dtype: category
Categories (6, object): [a, b, c, d, e, f]

```

## Other API changes

- `Index.duplicated` now returns `np.array(dtype=bool)` rather than `Index(dtype=object)` containing bool values. (GH8875)
- `DataFrame.to_json` now returns accurate type serialisation for each column for frames of mixed dtype (GH9037)

Previously data was coerced to a common dtype before serialisation, which for example resulted in integers being serialised to floats:

```

In [2]: pd.DataFrame({'i': [1,2], 'f': [3.0, 4.2]}).to_json()
Out[2]: '{"f":{"0":3.0,"1":4.2},"i":{"0":1.0,"1":2.0}}'

```

Now each column is serialised using its correct dtype:

```

In [2]: pd.DataFrame({'i': [1,2], 'f': [3.0, 4.2]}).to_json()
Out[2]: '{"f":{"0":3.0,"1":4.2},"i":{"0":1,"1":2}}'

```

- `DatetimeIndex`, `PeriodIndex` and `TimedeltaIndex.summary` now output the same format. (GH9116)
- `TimedeltaIndex.freqstr` now output the same string format as `DatetimeIndex`. (GH9116)
- Bar and horizontal bar plots no longer add a dashed line along the info axis. The prior style can be achieved with matplotlib's `axhline` or `axvline` methods (GH9088).
- Series accessors `.dt`, `.cat` and `.str` now raise `AttributeError` instead of `TypeError` if the series does not contain the appropriate type of data (GH9617). This follows Python's built-in exception hierarchy more closely and ensures that tests like `hasattr(s, 'cat')` are consistent on both Python 2 and 3.
- Series now supports bitwise operation for integral types (GH9016). Previously even if the input dtypes were integral, the output dtype was coerced to `bool`.

Previous behavior

```
In [2]: pd.Series([0, 1, 2, 3], list('abcd')) | pd.Series([4, 4, 4, 4], list('abcd
↪'))
Out[2]:
a True
b True
c True
d True
dtype: bool
```

New behavior. If the input dtypes are integral, the output dtype is also integral and the output values are the result of the bitwise operation.

```
In [2]: pd.Series([0, 1, 2, 3], list('abcd')) | pd.Series([4, 4, 4, 4], list('abcd
↪'))
Out[2]:
a 4
b 5
c 6
d 7
dtype: int64
```

- During division involving a Series or DataFrame, `0/0` and `0//0` now give `np.nan` instead of `np.inf`. (GH9144, GH8445)

Previous behavior

```
In [2]: p = pd.Series([0, 1])

In [3]: p / 0
Out[3]:
0 inf
1 inf
dtype: float64

In [4]: p // 0
Out[4]:
0 inf
1 inf
dtype: float64
```

New behavior

```
In [38]: p = pd.Series([0, 1])

In [39]: p / 0
Out[39]:
0 NaN
1 inf
Length: 2, dtype: float64

In [40]: p // 0
Out[40]:
0 NaN
1 inf
```

(continues on next page)

(continued from previous page)

```
Length: 2, dtype: float64
```

- `Series.values_counts` and `Series.describe` for categorical data will now put NaN entries at the end. (GH9443)
- `Series.describe` for categorical data will now give counts and frequencies of 0, not NaN, for unused categories (GH9443)
- Due to a bug fix, looking up a partial string label with `DatetimeIndex.asof` now includes values that match the string, even if they are after the start of the partial string label (GH9258).

Old behavior:

```
In [4]: pd.to_datetime(['2000-01-31', '2000-02-28']).asof('2000-02')
Out[4]: Timestamp('2000-01-31 00:00:00')
```

Fixed behavior:

```
In [41]: pd.to_datetime(['2000-01-31', '2000-02-28']).asof('2000-02')
Out[41]: Timestamp('2000-02-28 00:00:00')
```

To reproduce the old behavior, simply add more precision to the label (e.g., use `2000-02-01` instead of `2000-02`).

## Deprecations

- The `rplot` trellis plotting interface is deprecated and will be removed in a future version. We refer to external packages like `seaborn` for similar but more refined functionality (GH3445). The documentation includes some examples how to convert your existing code from `rplot` to `seaborn` [here](#).
- The `pandas.sandbox.qtpandas` interface is deprecated and will be removed in a future version. We refer users to the external package `pandas-qt`. (GH9615)
- The `pandas.rpy` interface is deprecated and will be removed in a future version. Similar functionality can be accessed through the `rpy2` project (GH9602)
- Adding `DatetimeIndex/PeriodIndex` to another `DatetimeIndex/PeriodIndex` is being deprecated as a set-operation. This will be changed to a `TypeError` in a future version. `.union()` should be used for the union set operation. (GH9094)
- Subtracting `DatetimeIndex/PeriodIndex` from another `DatetimeIndex/PeriodIndex` is being deprecated as a set-operation. This will be changed to an actual numeric subtraction yielding a `TimeDeltaIndex` in a future version. `.difference()` should be used for the differencing set operation. (GH9094)

## Removal of prior version deprecations/changes

- `DataFrame.pivot_table` and `crosstab`'s `rows` and `cols` keyword arguments were removed in favor of `index` and `columns` (GH6581)
- `DataFrame.to_excel` and `DataFrame.to_csv` `cols` keyword argument was removed in favor of `columns` (GH6581)
- Removed `convert_dummies` in favor of `get_dummies` (GH6581)
- Removed `value_range` in favor of `describe` (GH6581)

## Performance improvements

- Fixed a performance regression for `.loc` indexing with an array or list-like (GH9126:).
- `DataFrame.to_json` 30x performance improvement for mixed dtype frames. (GH9037)
- Performance improvements in `MultiIndex.duplicated` by working with labels instead of values (GH9125)
- Improved the speed of `nunique` by calling `unique` instead of `value_counts` (GH9129, GH7771)
- Performance improvement of up to 10x in `DataFrame.count` and `DataFrame.dropna` by taking advantage of homogeneous/heterogeneous dtypes appropriately (GH9136)
- Performance improvement of up to 20x in `DataFrame.count` when using a `MultiIndex` and the `level` keyword argument (GH9163)
- Performance and memory usage improvements in `merge` when key space exceeds `int64` bounds (GH9151)
- Performance improvements in multi-key `groupby` (GH9429)
- Performance improvements in `MultiIndex.sortlevel` (GH9445)
- Performance and memory usage improvements in `DataFrame.duplicated` (GH9398)
- Cythonized `Period` (GH9440)
- Decreased memory usage on `to_hdf` (GH9648)

## Bug fixes

- Changed `.to_html` to remove leading/trailing spaces in table body (GH4987)
- Fixed issue using `read_csv` on s3 with Python 3 (GH9452)
- Fixed compatibility issue in `DatetimeIndex` affecting architectures where `numpy.int_` defaults to `numpy.int32` (GH8943)
- Bug in `Panel` indexing with an object-like (GH9140)
- Bug in the returned `Series.dt.components` index was reset to the default index (GH9247)
- Bug in `Categorical.__getitem__/_setitem__` with listlike input getting incorrect results from indexer coercion (GH9469)
- Bug in partial setting with a `DatetimeIndex` (GH9478)
- Bug in `groupby` for integer and `datetime64` columns when applying an aggregator that caused the value to be changed when the number was sufficiently large (GH9311, GH6620)
- Fixed bug in `to_sql` when mapping a `Timestamp` object column (datetime column with timezone info) to the appropriate sqlalchemy type (GH9085).
- Fixed bug in `to_sql` dtype argument not accepting an instantiated SQLAlchemy type (GH9083).
- Bug in `.loc` partial setting with a `np.datetime64` (GH9516)
- Incorrect dtypes inferred on datetimelike looking `Series` & on `.xs` slices (GH9477)
- Items in `Categorical.unique()` (and `s.unique()` if `s` is of dtype `category`) now appear in the order in which they are originally found, not in sorted order (GH9331). This is now consistent with the behavior for other dtypes in pandas.
- Fixed bug on big endian platforms which produced incorrect results in `StataReader` (GH8688).
- Bug in `MultiIndex.has_duplicates` when having many levels causes an indexer overflow (GH9075, GH5873)

- Bug in `pivot` and `unstack` where nan values would break index alignment ([GH4862](#), [GH7401](#), [GH7403](#), [GH7405](#), [GH7466](#), [GH9497](#))
- Bug in left join on `MultiIndex` with `sort=True` or null values ([GH9210](#)).
- Bug in `MultiIndex` where inserting new keys would fail ([GH9250](#)).
- Bug in `groupby` when key space exceeds `int64` bounds ([GH9096](#)).
- Bug in `unstack` with `TimedeltaIndex` or `DatetimeIndex` and nulls ([GH9491](#)).
- Bug in `rank` where comparing floats with tolerance will cause inconsistent behaviour ([GH8365](#)).
- Fixed character encoding bug in `read_stata` and `StataReader` when loading data from a URL ([GH9231](#)).
- Bug in adding offsets. `Nano` to other offsets raises `TypeError` ([GH9284](#))
- Bug in `DatetimeIndex` iteration, related to ([GH8890](#)), fixed in ([GH9100](#))
- Bugs in `resample` around DST transitions. This required fixing offset classes so they behave correctly on DST transitions. ([GH5172](#), [GH8744](#), [GH8653](#), [GH9173](#), [GH9468](#)).
- Bug in binary operator method (eg `.mul()`) alignment with integer levels ([GH9463](#)).
- Bug in `boxplot`, `scatter` and `hexbin` plot may show an unnecessary warning ([GH8877](#))
- Bug in subplot with `layout` kw may show unnecessary warning ([GH9464](#))
- Bug in using grouper functions that need passed through arguments (e.g. `axis`), when using wrapped function (e.g. `fillna`), ([GH9221](#))
- `DataFrame` now properly supports simultaneous `copy` and `dtype` arguments in constructor ([GH9099](#))
- Bug in `read_csv` when using `skiprows` on a file with CR line endings with the `c` engine. ([GH9079](#))
- `isnull` now detects `NaT` in `PeriodIndex` ([GH9129](#))
- Bug in `groupby .nth()` with a multiple column `groupby` ([GH8979](#))
- Bug in `DataFrame.where` and `Series.where` coerce numerics to string incorrectly ([GH9280](#))
- Bug in `DataFrame.where` and `Series.where` raise `ValueError` when string list-like is passed. ([GH9280](#))
- Accessing `Series.str` methods on with non-string values now raises `TypeError` instead of producing incorrect results ([GH9184](#))
- Bug in `DatetimeIndex.__contains__` when index has duplicates and is not monotonic increasing ([GH9512](#))
- Fixed division by zero error for `Series.kurt()` when all values are equal ([GH9197](#))
- Fixed issue in the `xlsxwriter` engine where it added a default 'General' format to cells if no other format was applied. This prevented other row or column formatting being applied. ([GH9167](#))
- Fixes issue with `index_col=False` when `usecols` is also specified in `read_csv`. ([GH9082](#))
- Bug where `wide_to_long` would modify the input stub names list ([GH9204](#))
- Bug in `to_sql` not storing `float64` values using double precision. ([GH9009](#))
- `SparseSeries` and `SparsePanel` now accept zero argument constructors (same as their non-sparse counterparts) ([GH9272](#)).
- Regression in merging `Categorical` and object dtypes ([GH9426](#))
- Bug in `read_csv` with buffer overflows with certain malformed input files ([GH9205](#))
- Bug in `groupby MultiIndex` with missing pair ([GH9049](#), [GH9344](#))
- Fixed bug in `Series.groupby` where grouping on `MultiIndex` levels would ignore the `sort` argument ([GH9444](#))

- Fix bug in `DataFrame.Groupby` where `sort=False` is ignored in the case of Categorical columns. (GH8868)
- Fixed bug with reading CSV files from Amazon S3 on python 3 raising a `TypeError` (GH9452)
- Bug in the Google BigQuery reader where the 'jobComplete' key may be present but False in the query results (GH8728)
- Bug in `Series.values_counts` with excluding NaN for categorical type Series with `dropna=True` (GH9443)
- Fixed missing `numeric_only` option for `DataFrame.std/var/sem` (GH9201)
- Support constructing Panel or Panel4D with scalar data (GH8285)
- Series text representation disconnected from `max_rows/max_columns` (GH7508).
- Series number formatting inconsistent when truncated (GH8532).

Previous behavior

```
In [2]: pd.options.display.max_rows = 10
In [3]: s = pd.Series([1,1,1,1,1,1,1,1,1,1,0.9999,1,1]*10)
In [4]: s
Out[4]:
0 1
1 1
2 1
...
127 0.9999
128 1.0000
129 1.0000
Length: 130, dtype: float64
```

New behavior

```
0 1.0000
1 1.0000
2 1.0000
3 1.0000
4 1.0000
...
125 1.0000
126 1.0000
127 0.9999
128 1.0000
129 1.0000
dtype: float64
```

- A Spurious `SettingWithCopy` Warning was generated when setting a new item in a frame in some cases (GH8730)

The following would previously report a `SettingWithCopy` Warning.

```
In [42]: df1 = pd.DataFrame({'x': pd.Series(['a', 'b', 'c']),
.....: 'y': pd.Series(['d', 'e', 'f'])})
.....:
In [43]: df2 = df1[['x']]
```

(continues on next page)

(continued from previous page)

```
In [44]: df2['y'] = ['g', 'h', 'i']
```

## 5.15 Version 0.15

### 5.15.1 Version 0.15.2 (December 12, 2014)

This is a minor release from 0.15.1 and includes a large number of bug fixes along with several new features, enhancements, and performance improvements. A small number of API changes were necessary to fix existing bugs. We recommend that all users upgrade to this version.

- *Enhancements*
- *API Changes*
- *Performance Improvements*
- *Bug Fixes*

#### API changes

- Indexing in MultiIndex beyond lex-sort depth is now supported, though a lexically sorted index will have a better performance. (GH2646)

```
In [1]: df = pd.DataFrame({'jim':[0, 0, 1, 1],
...: 'joe':['x', 'x', 'z', 'y'],
...: 'jolie':np.random.rand(4)}).set_index(['jim', 'joe'])
...:

In [2]: df
Out[2]:
 jolie
jim joe
0 x 0.126970
 x 0.966718
1 z 0.260476
 y 0.897237

[4 rows x 1 columns]

In [3]: df.index.lexsort_depth
Out[3]: 1

in prior versions this would raise a KeyError
will now show a PerformanceWarning
In [4]: df.loc[(1, 'z')]
Out[4]:
 jolie
jim joe
1 z 0.260476

[1 rows x 1 columns]

lexically sorting
In [5]: df2 = df.sort_index()

In [6]: df2
```

(continues on next page)

(continued from previous page)

```

Out[6]:
 jolie
jim joe
0 x 0.126970
 x 0.966718
1 y 0.897237
 z 0.260476

[4 rows x 1 columns]

In [7]: df2.index.lexsort_depth
Out[7]: 2

In [8]: df2.loc[(1, 'z')]
Out[8]:
 jolie
jim joe
1 z 0.260476

[1 rows x 1 columns]

```

- Bug in unique of Series with category dtype, which returned all categories regardless whether they were “used” or not (see [GH8559](#) for the discussion). Previous behaviour was to return all categories:

```

In [3]: cat = pd.Categorical(['a', 'b', 'a'], categories=['a', 'b', 'c'])

In [4]: cat
Out[4]:
[a, b, a]
Categories (3, object): [a < b < c]

In [5]: cat.unique()
Out[5]: array(['a', 'b', 'c'], dtype=object)

```

Now, only the categories that do effectively occur in the array are returned:

```

In [9]: cat = pd.Categorical(['a', 'b', 'a'], categories=['a', 'b', 'c'])

In [10]: cat.unique()
Out[10]:
['a', 'b']
Categories (3, object): ['a', 'b', 'c']

```

- `Series.all` and `Series.any` now support the `level` and `skipna` parameters. `Series.all`, `Series.any`, `Index.all`, and `Index.any` no longer support the `out` and `keepdims` parameters, which existed for compatibility with `ndarray`. Various index types no longer support the `all` and `any` aggregation functions and will now raise `TypeError`. ([GH8302](#)).
- Allow equality comparisons of Series with a categorical dtype and object dtype; previously these would raise `TypeError` ([GH8938](#))
- Bug in `NDFrame`: conflicting attribute/column names now behave consistently between getting and setting. Previously, when both a column and attribute named `y` existed, `data.y` would return the attribute, while `data.y = z` would update the column ([GH8994](#))

```
In [11]: data = pd.DataFrame({'x': [1, 2, 3]})
```

```
In [12]: data.y = 2
```

```
In [13]: data['y'] = [2, 4, 6]
```

```
In [14]: data
```

```
Out[14]:
```

```
 x y
0 1 2
1 2 4
2 3 6
```

```
[3 rows x 2 columns]
```

```
this assignment was inconsistent
```

```
In [15]: data.y = 5
```

Old behavior:

```
In [6]: data.y
```

```
Out[6]: 2
```

```
In [7]: data['y'].values
```

```
Out[7]: array([5, 5, 5])
```

New behavior:

```
In [16]: data.y
```

```
Out[16]: 5
```

```
In [17]: data['y'].values
```

```
Out[17]: array([2, 4, 6])
```

- `Timestamp('now')` is now equivalent to `Timestamp.now()` in that it returns the local time rather than UTC. Also, `Timestamp('today')` is now equivalent to `Timestamp.today()` and both have `tz` as a possible argument. (GH9000)
- Fix negative step support for label-based slices (GH8753)

Old behavior:

```
In [1]: s = pd.Series(np.arange(3), ['a', 'b', 'c'])
```

```
Out[1]:
```

```
a 0
b 1
c 2
dtype: int64
```

```
In [2]: s.loc['c':'a':-1]
```

```
Out[2]:
```

```
c 2
dtype: int64
```

New behavior:

```
In [18]: s = pd.Series(np.arange(3), ['a', 'b', 'c'])
```

```
In [19]: s.loc['c':'a':-1]
```

```
Out[19]:
```

```
c 2
```

```
b 1
```

```
a 0
```

```
Length: 3, dtype: int64
```

## Enhancements

Categorical enhancements:

- Added ability to export Categorical data to Stata (GH8633). See [here](#) for limitations of categorical variables exported to Stata data files.
- Added flag `order_categoricals` to `StataReader` and `read_stata` to select whether to order imported categorical data (GH8836). See [here](#) for more information on importing categorical variables from Stata data files.
- Added ability to export Categorical data to/from HDF5 (GH7621). Queries work the same as if it was an object array. However, the `category` dtyped data is stored in a more efficient manner. See [here](#) for an example and caveats w.r.t. prior versions of pandas.
- Added support for `searchsorted()` on `Categorical` class (GH8420).

Other enhancements:

- Added the ability to specify the SQL type of columns when writing a `DataFrame` to a database (GH8778). For example, specifying to use the `sqlalchemy` `String` type instead of the default `Text` type for string columns:

```
from sqlalchemy.types import String
data.to_sql('data_dtype', engine, dtype={'Col_1': String}) # noqa F821
```

- `Series.all` and `Series.any` now support the `level` and `skipna` parameters (GH8302):

```
In [20]: s = pd.Series([False, True, False], index=[0, 0, 1])
```

```
In [21]: s.any(level=0)
```

```
Out[21]:
```

```
0 True
```

```
1 False
```

```
Length: 2, dtype: bool
```

- `Panel` now supports the `all` and `any` aggregation functions. (GH8302):

```
>>> p = pd.Panel(np.random.rand(2, 5, 4) > 0.1)
```

```
>>> p.all()
```

```
 0 1 2 3
```

```
0 True True True True
```

```
1 True False True True
```

```
2 True True True True
```

```
3 False True False True
```

```
4 True True True True
```

- Added support for `utcfromtimestamp()`, `fromtimestamp()`, and `combine()` on `Timestamp` class (GH5351).

- Added Google Analytics (*pandas.io.ga*) basic documentation (GH8835). See [here](#).
- Timedelta arithmetic returns NotImplemented in unknown cases, allowing extensions by custom classes (GH8813).
- Timedelta now supports arithmetic with numpy.ndarray objects of the appropriate dtype (numpy 1.8 or newer only) (GH8884).
- Added Timedelta.to\_timedelta64() method to the public API (GH8884).
- Added gbq.generate\_bq\_schema() function to the gbq module (GH8325).
- Series now works with map objects the same way as generators (GH8909).
- Added context manager to HDFStore for automatic closing (GH8791).
- to\_datetime gains an exact keyword to allow for a format to not require an exact match for a provided format string (if its False). exact defaults to True (meaning that exact matching is still the default) (GH8904)
- Added axvlines boolean option to parallel\_coordinates plot function, determines whether vertical lines will be printed, default is True
- Added ability to read table footers to read\_html (GH8552)
- to\_sql now infers data types of non-NA values for columns that contain NA values and have dtype object (GH8778).

## Performance

- Reduce memory usage when skiprows is an integer in read\_csv (GH8681)
- Performance boost for to\_datetime conversions with a passed format=, and the exact=False (GH8904)

## Bug fixes

- Bug in concat of Series with category dtype which were coercing to object. (GH8641)
- Bug in Timestamp-Timestamp not returning a Timedelta type and datelike-datelike ops with timezones (GH8865)
- Made consistent a timezone mismatch exception (either tz operated with None or incompatible timezone), will now return TypeError rather than ValueError (a couple of edge cases only), (GH8865)
- Bug in using a pd.Grouper(key=...) with no level/axis or level only (GH8795, GH8866)
- Report a TypeError when invalid/no parameters are passed in a groupby (GH8015)
- Bug in packaging pandas with py2app/cx\_Freeze (GH8602, GH8831)
- Bug in groupby signatures that didn't include \*args or \*\*kwargs (GH8733).
- io.data.Options now raises RemoteDataError when no expiry dates are available from Yahoo and when it receives no data from Yahoo (GH8761), (GH8783).
- Unclear error message in csv parsing when passing dtype and names and the parsed data is a different data type (GH8833)
- Bug in slicing a MultiIndex with an empty list and at least one boolean indexer (GH8781)
- io.data.Options now raises RemoteDataError when no expiry dates are available from Yahoo (GH8761).
- Timedelta kwargs may now be numpy ints and floats (GH8757).
- Fixed several outstanding bugs for Timedelta arithmetic and comparisons (GH8813, GH5963, GH5436).
- sql\_schema now generates dialect appropriate CREATE TABLE statements (GH8697)

- slice string method now takes step into account (GH8754)
- Bug in BlockManager where setting values with different type would break block integrity (GH8850)
- Bug in DatetimeIndex when using time object as key (GH8667)
- Bug in merge where how='left' and sort=False would not preserve left frame order (GH7331)
- Bug in MultiIndex.reindex where reindexing at level would not reorder labels (GH4088)
- Bug in certain operations with dateutil timezones, manifesting with dateutil 2.3 (GH8639)
- Regression in DatetimeIndex iteration with a Fixed/Local offset timezone (GH8890)
- Bug in to\_datetime when parsing a nanoseconds using the %f format (GH8989)
- io.data.Options now raises RemoteDataError when no expiry dates are available from Yahoo and when it receives no data from Yahoo (GH8761), (GH8783).
- Fix: The font size was only set on x axis if vertical or the y axis if horizontal. (GH8765)
- Fixed division by 0 when reading big csv files in python 3 (GH8621)
- Bug in outputting a MultiIndex with to\_html, index=False which would add an extra column (GH8452)
- Imported categorical variables from Stata files retain the ordinal information in the underlying data (GH8836).
- Defined .size attribute across NDFrame objects to provide compat with numpy >= 1.9.1; buggy with np.array\_split (GH8846)
- Skip testing of histogram plots for matplotlib <= 1.2 (GH8648).
- Bug where get\_data\_google returned object dtypes (GH3995)
- Bug in DataFrame.stack(..., dropna=False) when the DataFrame's columns is a MultiIndex whose labels do not reference all its levels. (GH8844)
- Bug in that Option context applied on \_\_enter\_\_ (GH8514)
- Bug in resample that causes a ValueError when resampling across multiple days and the last offset is not calculated from the start of the range (GH8683)
- Bug where DataFrame.plot(kind='scatter') fails when checking if an np.array is in the DataFrame (GH8852)
- Bug in pd.infer\_freq/DataFrame.inferred\_freq that prevented proper sub-daily frequency inference when the index contained DST days (GH8772).
- Bug where index name was still used when plotting a series with use\_index=False (GH8558).
- Bugs when trying to stack multiple columns, when some (or all) of the level names are numbers (GH8584).
- Bug in MultiIndex where \_\_contains\_\_ returns wrong result if index is not lexically sorted or unique (GH7724)
- BUG CSV: fix problem with trailing white space in skipped rows, (GH8679), (GH8661), (GH8983)
- Regression in Timestamp does not parse 'Z' zone designator for UTC (GH8771)
- Bug in StataWriter the produces writes strings with 244 characters irrespective of actual size (GH8969)
- Fixed ValueError raised by cummin/cummax when datetime64 Series contains NaT. (GH8965)
- Bug in DataReader returns object dtype if there are missing values (GH8980)
- Bug in plotting if sharex was enabled and index was a timeseries, would show labels on multiple axes (GH3964).
- Bug where passing a unit to the TimedeltaIndex constructor applied the to nano-second conversion twice. (GH9011).

- Bug in plotting of a period-like array ([GH9012](#))

### 5.15.2 Version 0.15.1 (November 9, 2014)

This is a minor bug-fix release from 0.15.0 and includes a small number of API changes, several new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

- *Enhancements*
- *API Changes*
- *Bug Fixes*

#### API changes

- `s.dt.hour` and other `.dt` accessors will now return `np.nan` for missing values (rather than previously `-1`), (GH8689)

```
In [1]: s = pd.Series(pd.date_range("20130101", periods=5, freq="D"))
In [2]: s.iloc[2] = np.nan
In [3]: s
Out[3]:
0 2013-01-01
1 2013-01-02
2 NaT
```

(continues on next page)

(continued from previous page)

```
3 2013-01-04
4 2013-01-05
Length: 5, dtype: datetime64[ns]
```

previous behavior:

```
In [6]: s.dt.hour
Out[6]:
0 0
1 0
2 -1
3 0
4 0
dtype: int64
```

current behavior:

```
In [4]: s.dt.hour
Out[4]:
0 0.0
1 0.0
2 NaN
3 0.0
4 0.0
Length: 5, dtype: float64
```

- `groupby` with `as_index=False` will not add erroneous extra columns to result (GH8582):

```
In [5]: np.random.seed(2718281)

In [6]: df = pd.DataFrame(np.random.randint(0, 100, (10, 2)), columns=["jim", "joe
↪"])

In [7]: df.head()
Out[7]:
 jim joe
0 61 81
1 96 49
2 55 65
3 72 51
4 77 12

[5 rows x 2 columns]

In [8]: ts = pd.Series(5 * np.random.randint(0, 3, 10))
```

previous behavior:

```
In [4]: df.groupby(ts, as_index=False).max()
Out[4]:
 NaN jim joe
0 0 72 83
```

(continues on next page)

(continued from previous page)

|   |    |    |    |
|---|----|----|----|
| 1 | 5  | 77 | 84 |
| 2 | 10 | 96 | 65 |

current behavior:

```
In [9]: df.groupby(ts, as_index=False).max()
Out[9]:
 jim joe
0 72 83
1 77 84
2 96 65

[3 rows x 2 columns]
```

- `groupby` will not erroneously exclude columns if the column name conflicts with the grouper name (GH8112):

```
In [10]: df = pd.DataFrame({"jim": range(5), "joe": range(5, 10)})

In [11]: df
Out[11]:
 jim joe
0 0 5
1 1 6
2 2 7
3 3 8
4 4 9

[5 rows x 2 columns]

In [12]: gr = df.groupby(df["jim"] < 2)
```

previous behavior (excludes 1st column from output):

```
In [4]: gr.apply(sum)
Out[4]:
 joe
jim
False 24
True 11
```

current behavior:

```
In [13]: gr.apply(sum)
Out[13]:
 jim joe
jim
False 9 24
True 1 11

[2 rows x 2 columns]
```

- Support for slicing with monotonic decreasing indexes, even if `start` or `stop` is not found in the index (GH7860):

```
In [14]: s = pd.Series(["a", "b", "c", "d"], [4, 3, 2, 1])
```

```
In [15]: s
```

```
Out[15]:
```

```
4 a
3 b
2 c
1 d
Length: 4, dtype: object
```

previous behavior:

```
In [8]: s.loc[3.5:1.5]
```

```
KeyError: 3.5
```

current behavior:

```
In [16]: s.loc[3.5:1.5]
```

```
Out[16]:
```

```
3 b
2 c
Length: 2, dtype: object
```

- `io.data.Options` has been fixed for a change in the format of the Yahoo Options page ([GH8612](#)), ([GH8741](#))

**Note:** As a result of a change in Yahoo's option page layout, when an expiry date is given, `Options` methods now return data for a single expiry date. Previously, methods returned all data for the selected month.

The month and year parameters have been undeprecated and can be used to get all options data for a given month.

If an expiry date that is not valid is given, data for the next expiry after the given date is returned.

Option data frames are now saved on the instance as `callsYYMMDD` or `putsYYMMDD`. Previously they were saved as `callsMMYY` and `putsMMYY`. The next expiry is saved as `calls` and `puts`.

New features:

- The expiry parameter can now be a single date or a list-like object containing dates.
- A new property `expiry_dates` was added, which returns all available expiry dates.

Current behavior:

```
In [17]: from pandas.io.data import Options
```

```
In [18]: aapl = Options('aapl', 'yahoo')
```

```
In [19]: aapl.get_call_data().iloc[0:5, 0:1]
```

```
Out[19]:
```

| Strike | Expiry     | Type | Symbol              | Last  |
|--------|------------|------|---------------------|-------|
| 80     | 2014-11-14 | call | AAPL141114C00080000 | 29.05 |
| 84     | 2014-11-14 | call | AAPL141114C00084000 | 24.80 |
| 85     | 2014-11-14 | call | AAPL141114C00085000 | 24.05 |

(continues on next page)

(continued from previous page)

```
86 2014-11-14 call AAPL141114C00086000 22.76
87 2014-11-14 call AAPL141114C00087000 21.74
```

```
In [20]: aapl.expiry_dates
```

```
Out[20]:
```

```
[datetime.date(2014, 11, 14),
 datetime.date(2014, 11, 22),
 datetime.date(2014, 11, 28),
 datetime.date(2014, 12, 5),
 datetime.date(2014, 12, 12),
 datetime.date(2014, 12, 20),
 datetime.date(2015, 1, 17),
 datetime.date(2015, 2, 20),
 datetime.date(2015, 4, 17),
 datetime.date(2015, 7, 17),
 datetime.date(2016, 1, 15),
 datetime.date(2017, 1, 20)]
```

```
In [21]: aapl.get_near_stock_price(expiry=aapl.expiry_dates[0:3]).iloc[0:5, 0:1]
```

```
Out[21]:
```

|        |            |      |                     |  | Last |
|--------|------------|------|---------------------|--|------|
| Strike | Expiry     | Type | Symbol              |  |      |
| 109    | 2014-11-22 | call | AAPL141122C00109000 |  | 1.48 |
|        | 2014-11-28 | call | AAPL141128C00109000 |  | 1.79 |
| 110    | 2014-11-14 | call | AAPL141114C00110000 |  | 0.55 |
|        | 2014-11-22 | call | AAPL141122C00110000 |  | 1.02 |
|        | 2014-11-28 | call | AAPL141128C00110000 |  | 1.32 |

- pandas now also registers the `datetime64` dtype in matplotlib's units registry to plot such values as datetimes. This is activated once pandas is imported. In previous versions, plotting an array of `datetime64` values will have resulted in plotted integer values. To keep the previous behaviour, you can do `del matplotlib.units.registry[np.datetime64]` (GH8614).

## Enhancements

- `concat` permits a wider variety of iterables of pandas objects to be passed as the first parameter (GH8645):

```
In [17]: from collections import deque
```

```
In [18]: df1 = pd.DataFrame([1, 2, 3])
```

```
In [19]: df2 = pd.DataFrame([4, 5, 6])
```

previous behavior:

```
In [7]: pd.concat((df1, df2))
```

```
TypeError: first argument must be a list-like of pandas objects, you passed an
↳ object of type "deque"
```

current behavior:

```
In [20]: pd.concat(deque((df1, df2)))
```

```
Out[20]:
```

```
0
0 1
1 2
2 3
0 4
1 5
2 6
```

```
[6 rows x 1 columns]
```

- Represent MultiIndex labels with a dtype that utilizes memory based on the level size. In prior versions, the memory usage was a constant 8 bytes per element in each level. In addition, in prior versions, the *reported* memory usage was incorrect as it didn't show the usage for the memory occupied by the underlying data array. (GH8456)

```
In [21]: dfi = pd.DataFrame(
.....: 1, index=pd.MultiIndex.from_product([["a"], range(1000)]), columns=["A
↪"]
.....:)
.....:
```

previous behavior:

```
this was underreported in prior versions
In [1]: dfi.memory_usage(index=True)
Out[1]:
Index 8000 # took about 24008 bytes in < 0.15.1
A 8000
dtype: int64
```

current behavior:

```
In [22]: dfi.memory_usage(index=True)
Out[22]:
Index 44212
A 8000
Length: 2, dtype: int64
```

- Added Index properties `is_monotonic_increasing` and `is_monotonic_decreasing` (GH8680).
- Added option to select columns when importing Stata files (GH7935)
- Qualify memory usage in `DataFrame.info()` by adding + if it is a lower bound (GH8578)
- Raise errors in certain aggregation cases where an argument such as `numeric_only` is not handled (GH8592).
- Added support for 3-character ISO and non-standard country codes in `io.wb.download()` (GH8482)
- World Bank data requests now will warn/raise based on an `errors` argument, as well as a list of hard-coded country codes and the World Bank's JSON response. In prior versions, the error messages didn't look at the World Bank's JSON response. Problem-inducing input were simply dropped prior to the request. The issue was that many good countries were dropped in the hard-coded approach. All countries will work now, but some bad countries will raise exceptions because some edge cases break the entire response. (GH8482)
- Added option to `Series.str.split()` to return a `DataFrame` rather than a `Series` (GH8428)

- Added option to `df.info(null_counts=None|True|False)` to override the default display options and force showing of the null-counts (GH8701)

## Bug fixes

- Bug in unpickling of a `CustomBusinessDay` object (GH8591)
- Bug in coercing `Categorical` to a records array, e.g. `df.to_records()` (GH8626)
- Bug in `Categorical` not created properly with `Series.to_frame()` (GH8626)
- Bug in coercing in `astype` of a `Categorical` of a passed `pd.Categorical` (this now raises `TypeError` correctly), (GH8626)
- Bug in `cut/qcut` when using `Series` and `retbins=True` (GH8589)
- Bug in writing `Categorical` columns to an SQL database with `to_sql` (GH8624).
- Bug in comparing `Categorical` of `datetime` raising when being compared to a scalar `datetime` (GH8687)
- Bug in selecting from a `Categorical` with `.iloc` (GH8623)
- Bug in `groupby-transform` with a `Categorical` (GH8623)
- Bug in `deduplicated/drop_duplicates` with a `Categorical` (GH8623)
- Bug in `Categorical` reflected comparison operator raising if the first argument was a numpy array scalar (e.g. `np.int64`) (GH8658)
- Bug in `Panel` indexing with a list-like (GH8710)
- Compat issue in `DataFrame.dtypes` when `options.mode.use_inf_as_null` is `True` (GH8722)
- Bug in `read_csv`, `dialect` parameter would not take a string (GH8703)
- Bug in slicing a `MultiIndex` level with an empty-list (GH8737)
- Bug in numeric index operations of `add/sub` with `Float/Index Index` with numpy arrays (GH8608)
- Bug in `setitem` with empty indexer and unwanted coercion of dtypes (GH8669)
- Bug in `ix/loc` block splitting on `setitem` (manifests with integer-like dtypes, e.g. `datetime64`) (GH8607)
- Bug when doing label based indexing with integers not found in the index for non-unique but monotonic indexes (GH8680).
- Bug when indexing a `Float64Index` with `np.nan` on numpy 1.7 (GH8980).
- Fix `shape` attribute for `MultiIndex` (GH8609)
- Bug in `GroupBy` where a name conflict between the grouper and columns would break `groupby` operations (GH7115, GH8112)
- Fixed a bug where plotting a column `y` and specifying a label would mutate the index name of the original `DataFrame` (GH8494)
- Fix regression in plotting of a `DatetimeIndex` directly with `matplotlib` (GH8614).
- Bug in `date_range` where partially-specified dates would incorporate current date (GH6961)
- Bug in `Setting` by indexer to a scalar value with a mixed-dtype `Panel14d` was failing (GH8702)
- Bug where `DataReader`'s would fail if one of the symbols passed was invalid. Now returns data for valid symbols and `np.nan` for invalid (GH8494)
- Bug in `get_quote_yahoo` that wouldn't allow non-float return values (GH5229).

### 5.15.3 Version 0.15.0 (October 18, 2014)

This is a major release from 0.14.1 and includes a small number of API changes, several new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

**Warning:** pandas  $\geq$  0.15.0 will no longer support compatibility with NumPy versions  $<$  1.7.0. If you want to use the latest versions of pandas, please upgrade to NumPy  $\geq$  1.7.0 ([GH7711](#))

- Highlights include:
  - The Categorical type was integrated as a first-class pandas type, see [here](#)
  - New scalar type Timedelta, and a new index type TimedeltaIndex, see [here](#)

- New datetimelike properties accessor `.dt` for Series, see [Datetimelike Properties](#)
  - New DataFrame default display for `df.info()` to include memory usage, see [Memory Usage](#)
  - `read_csv` will now by default ignore blank lines when parsing, see [here](#)
  - API change in using Indexes in set operations, see [here](#)
  - Enhancements in the handling of timezones, see [here](#)
  - A lot of improvements to the rolling and expanding moment functions, see [here](#)
  - Internal refactoring of the Index class to no longer sub-class `ndarray`, see [Internal Refactoring](#)
  - dropping support for PyTables less than version 3.0.0, and numexpr less than version 2.1 (GH7990)
  - Split indexing documentation into [Indexing and Selecting Data](#) and [MultiIndex / Advanced Indexing](#)
  - Split out string methods documentation into [Working with Text Data](#)
- Check the [API Changes](#) and [deprecations](#) before updating
  - [Other Enhancements](#)
  - [Performance Improvements](#)
  - [Bug Fixes](#)

**Warning:** In 0.15.0 Index has internally been refactored to no longer sub-class `ndarray` but instead subclass `PandasObject`, similarly to the rest of the pandas objects. This change allows very easy sub-classing and creation of new index types. This should be a transparent change with only very limited API implications (See the [Internal Refactoring](#))

**Warning:** The refactoring in [Categorical](#) changed the two argument constructor from “codes/labels and levels” to “values and levels (now called ‘categories’)”. This can lead to subtle bugs. If you use [Categorical](#) directly, please audit your code before updating to this pandas version and change it to use the `from_codes()` constructor. See more on [Categorical](#) [here](#)

## New features

### Categoricals in Series/DataFrame

[Categorical](#) can now be included in Series and DataFrames and gained new methods to manipulate. Thanks to Jan Schulz for much of this API/implementation. (GH3943, GH5313, GH5314, GH7444, GH7839, GH7848, GH7864, GH7914, GH7768, GH8006, GH3678, GH8075, GH8076, GH8143, GH8453, GH8518).

For full docs, see the [categorical introduction](#) and the [API documentation](#).

```
In [1]: df = pd.DataFrame({"id": [1, 2, 3, 4, 5, 6],
...: "raw_grade": ['a', 'b', 'b', 'a', 'a', 'e']})
...:
...:

In [2]: df["grade"] = df["raw_grade"].astype("category")

In [3]: df["grade"]
Out[3]:
```

(continues on next page)

(continued from previous page)

```

0 a
1 b
2 b
3 a
4 a
5 e
Name: grade, Length: 6, dtype: category
Categories (3, object): ['a', 'b', 'e']

Rename the categories
In [4]: df["grade"].cat.categories = ["very good", "good", "very bad"]

Reorder the categories and simultaneously add the missing categories
In [5]: df["grade"] = df["grade"].cat.set_categories(["very bad", "bad",
...: "medium", "good", "very good"])
...:

In [6]: df["grade"]
Out[6]:
0 very good
1 good
2 good
3 very good
4 very good
5 very bad
Name: grade, Length: 6, dtype: category
Categories (5, object): ['very bad', 'bad', 'medium', 'good', 'very good']

In [7]: df.sort_values("grade")
Out[7]:
 id raw_grade grade
5 6 e very bad
1 2 b good
2 3 b good
0 1 a very good
3 4 a very good
4 5 a very good

[6 rows x 3 columns]

In [8]: df.groupby("grade").size()
Out[8]:
grade
very bad 1
bad 0
medium 0
good 2
very good 3
Length: 5, dtype: int64

```

- `pandas.core.group_agg` and `pandas.core.factor_agg` were removed. As an alternative, construct a dataframe and use `df.groupby(<group>).agg(<func>)`.

- Supplying “codes/labels and levels” to the `Categorical` constructor is not supported anymore. Supplying two arguments to the constructor is now interpreted as “values and levels (now called ‘categories’)”. Please change your code to use the `from_codes()` constructor.
- The `Categorical.labels` attribute was renamed to `Categorical.codes` and is read only. If you want to manipulate codes, please use one of the *API methods on Categoricals*.
- The `Categorical.levels` attribute is renamed to `Categorical.categories`.

## TimedeltaIndex/scalar

We introduce a new scalar type `Timedelta`, which is a subclass of `datetime.timedelta`, and behaves in a similar manner, but allows compatibility with `np.timedelta64` types as well as a host of custom representation, parsing, and attributes. This type is very similar to how `Timestamp` works for `datetimes`. It is a nice-API box for the type. See the *docs*. ([GH3009](#), [GH4533](#), [GH8209](#), [GH8187](#), [GH8190](#), [GH7869](#), [GH7661](#), [GH8345](#), [GH8471](#))

**Warning:** `Timedelta` scalars (and `TimedeltaIndex`) component fields are *not the same* as the component fields on a `datetime.timedelta` object. For example, `.seconds` on a `datetime.timedelta` object returns the total number of seconds combined between hours, minutes and seconds. In contrast, the pandas `Timedelta` breaks out hours, minutes, microseconds and nanoseconds separately.

```
Timedelta accessor
In [9]: tds = pd.Timedelta('31 days 5 min 3 sec')

In [10]: tds.minutes
Out[10]: 5L

In [11]: tds.seconds
Out[11]: 3L

datetime.timedelta accessor
this is 5 minutes * 60 + 3 seconds
In [12]: tds.to_pytimedelta().seconds
Out[12]: 303
```

**Note:** this is no longer true starting from v0.16.0, where full compatibility with `datetime.timedelta` is introduced. See the *0.16.0 whatsnew entry*

**Warning:** Prior to 0.15.0 `pd.to_timedelta` would return a `Series` for list-like/`Series` input, and a `np.timedelta64` for scalar input. It will now return a `TimedeltaIndex` for list-like input, `Series` for `Series` input, and `Timedelta` for scalar input.

The arguments to `pd.to_timedelta` are now `(arg, unit='ns', box=True, coerce=False)`, previously were `(arg, box=True, unit='ns')` as these are more logical.

Construct a scalar

```
In [9]: pd.Timedelta('1 days 06:05:01.00003')
Out[9]: Timedelta('1 days 06:05:01.000030')

In [10]: pd.Timedelta('15.5us')
```

(continues on next page)

(continued from previous page)

```

Out[10]: Timedelta('0 days 00:00:00.000015500')

In [11]: pd.Timedelta('1 hour 15.5us')
Out[11]: Timedelta('0 days 01:00:00.000015500')

negative Timedeltas have this string repr
to be more consistent with datetime.timedelta conventions
In [12]: pd.Timedelta('-1us')
Out[12]: Timedelta('-1 days +23:59:59.999999')

a NaT
In [13]: pd.Timedelta('nan')
Out[13]: NaT

```

Access fields for a Timedelta

```

In [14]: td = pd.Timedelta('1 hour 3m 15.5us')

In [15]: td.seconds
Out[15]: 3780

In [16]: td.microseconds
Out[16]: 15

In [17]: td.nanoseconds
Out[17]: 500

```

Construct a TimedeltaIndex

```

In [18]: pd.TimedeltaIndex(['1 days', '1 days, 00:00:05',
.....: np.timedelta64(2, 'D'),
.....: datetime.timedelta(days=2, seconds=2)])
.....:
Out[18]:
TimedeltaIndex(['1 days 00:00:00', '1 days 00:00:05', '2 days 00:00:00',
 '2 days 00:00:02'],
 dtype='timedelta64[ns]', freq=None)

```

Constructing a TimedeltaIndex with a regular range

```

In [19]: pd.timedelta_range('1 days', periods=5, freq='D')
Out[19]: TimedeltaIndex(['1 days', '2 days', '3 days', '4 days', '5 days'], dtype=
→ 'timedelta64[ns]', freq='D')

In [20]: pd.timedelta_range(start='1 days', end='2 days', freq='30T')
Out[20]:
TimedeltaIndex(['1 days 00:00:00', '1 days 00:30:00', '1 days 01:00:00',
 '1 days 01:30:00', '1 days 02:00:00', '1 days 02:30:00',
 '1 days 03:00:00', '1 days 03:30:00', '1 days 04:00:00',
 '1 days 04:30:00', '1 days 05:00:00', '1 days 05:30:00',
 '1 days 06:00:00', '1 days 06:30:00', '1 days 07:00:00',
 '1 days 07:30:00', '1 days 08:00:00', '1 days 08:30:00',
 '1 days 09:00:00', '1 days 09:30:00', '1 days 10:00:00'],
 dtype='timedelta64[ns]', freq='30T')

```

(continues on next page)

(continued from previous page)

```
'1 days 10:30:00', '1 days 11:00:00', '1 days 11:30:00',
'1 days 12:00:00', '1 days 12:30:00', '1 days 13:00:00',
'1 days 13:30:00', '1 days 14:00:00', '1 days 14:30:00',
'1 days 15:00:00', '1 days 15:30:00', '1 days 16:00:00',
'1 days 16:30:00', '1 days 17:00:00', '1 days 17:30:00',
'1 days 18:00:00', '1 days 18:30:00', '1 days 19:00:00',
'1 days 19:30:00', '1 days 20:00:00', '1 days 20:30:00',
'1 days 21:00:00', '1 days 21:30:00', '1 days 22:00:00',
'1 days 22:30:00', '1 days 23:00:00', '1 days 23:30:00',
'2 days 00:00:00'],
dtype='timedelta64[ns]', freq='30T')
```

You can now use a `TimedeltaIndex` as the index of a pandas object

```
In [21]: s = pd.Series(np.arange(5),
.....: index=pd.timedelta_range('1 days', periods=5, freq='s'))
.....:
```

```
In [22]: s
```

```
Out[22]:
1 days 00:00:00 0
1 days 00:00:01 1
1 days 00:00:02 2
1 days 00:00:03 3
1 days 00:00:04 4
Freq: S, Length: 5, dtype: int64
```

You can select with partial string selections

```
In [23]: s['1 day 00:00:02']
```

```
Out[23]: 2
```

```
In [24]: s['1 day':'1 day 00:00:02']
```

```
Out[24]:
1 days 00:00:00 0
1 days 00:00:01 1
1 days 00:00:02 2
Freq: S, Length: 3, dtype: int64
```

Finally, the combination of `TimedeltaIndex` with `DatetimeIndex` allow certain combination operations that are `NaT` preserving:

```
In [25]: tdi = pd.TimedeltaIndex(['1 days', pd.NaT, '2 days'])
```

```
In [26]: tdi.tolist()
```

```
Out[26]: [Timedelta('1 days 00:00:00'), NaT, Timedelta('2 days 00:00:00')]
```

```
In [27]: dti = pd.date_range('20130101', periods=3)
```

```
In [28]: dti.tolist()
```

```
Out[28]:
[Timestamp('2013-01-01 00:00:00', freq='D'),
 Timestamp('2013-01-02 00:00:00', freq='D'),
```

(continues on next page)

(continued from previous page)

```
Timestamp('2013-01-03 00:00:00', freq='D')]
In [29]: (dti + tdi).tolist()
Out[29]: [Timestamp('2013-01-02 00:00:00'), NaT, Timestamp('2013-01-05 00:00:00')]
In [30]: (dti - tdi).tolist()
Out[30]: [Timestamp('2012-12-31 00:00:00'), NaT, Timestamp('2013-01-01 00:00:00')]
```

- iteration of a Series e.g. `list(Series(...))` of `timedelta64[ns]` would prior to v0.15.0 return `np.timedelta64` for each element. These will now be wrapped in `Timedelta`.

## Memory usage

Implemented methods to find memory usage of a DataFrame. See the [FAQ](#) for more. (GH6852).

A new display option `display.memory_usage` (see [Options and settings](#)) sets the default behavior of the `memory_usage` argument in the `df.info()` method. By default `display.memory_usage` is `True`.

```
In [31]: dtypes = ['int64', 'float64', 'datetime64[ns]', 'timedelta64[ns]',
.....: 'complex128', 'object', 'bool']
.....:

In [32]: n = 5000

In [33]: data = {t: np.random.randint(100, size=n).astype(t) for t in dtypes}

In [34]: df = pd.DataFrame(data)

In [35]: df['categorical'] = df['object'].astype('category')

In [36]: df.info()
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 5000 entries, 0 to 4999
Data columns (total 8 columns):
Column Non-Null Count Dtype
--- --- ---
0 int64 5000 non-null int64
1 float64 5000 non-null float64
2 datetime64[ns] 5000 non-null datetime64[ns]
3 timedelta64[ns] 5000 non-null timedelta64[ns]
4 complex128 5000 non-null complex128
5 object 5000 non-null object
6 bool 5000 non-null bool
7 categorical 5000 non-null category
dtypes: bool(1), category(1), complex128(1), datetime64[ns](1), float64(1), int64(1),
→object(1), timedelta64[ns](1)
memory usage: 288.2+ KB
```

Additionally `memory_usage()` is an available method for a dataframe object which returns the memory usage of each column.

```
In [37]: df.memory_usage(index=True)
```

```
Out[37]:
```

```
Index 128
int64 40000
float64 40000
datetime64[ns] 40000
timedelta64[ns] 40000
complex128 80000
object 40000
bool 5000
categorical 9968
Length: 9, dtype: int64
```

### Series.dt accessor

Series has gained an accessor to succinctly return datetime like properties for the *values* of the Series, if its a date-time/period like Series. (GH7207) This will return a Series, indexed like the existing Series. See the [docs](#)

```
datetime
```

```
In [38]: s = pd.Series(pd.date_range('20130101 09:10:12', periods=4))
```

```
In [39]: s
```

```
Out[39]:
```

```
0 2013-01-01 09:10:12
1 2013-01-02 09:10:12
2 2013-01-03 09:10:12
3 2013-01-04 09:10:12
Length: 4, dtype: datetime64[ns]
```

```
In [40]: s.dt.hour
```

```
Out[40]:
```

```
0 9
1 9
2 9
3 9
Length: 4, dtype: int64
```

```
In [41]: s.dt.second
```

```
Out[41]:
```

```
0 12
1 12
2 12
3 12
Length: 4, dtype: int64
```

```
In [42]: s.dt.day
```

```
Out[42]:
```

```
0 1
1 2
2 3
3 4
```

(continues on next page)

(continued from previous page)

```
Length: 4, dtype: int64
```

```
In [43]: s.dt.freq
```

```
Out[43]: 'D'
```

This enables nice expressions like this:

```
In [44]: s[s.dt.day == 2]
```

```
Out[44]:
```

```
1 2013-01-02 09:10:12
```

```
Length: 1, dtype: datetime64[ns]
```

You can easily produce tz aware transformations:

```
In [45]: stz = s.dt.tz_localize('US/Eastern')
```

```
In [46]: stz
```

```
Out[46]:
```

```
0 2013-01-01 09:10:12-05:00
```

```
1 2013-01-02 09:10:12-05:00
```

```
2 2013-01-03 09:10:12-05:00
```

```
3 2013-01-04 09:10:12-05:00
```

```
Length: 4, dtype: datetime64[ns, US/Eastern]
```

```
In [47]: stz.dt.tz
```

```
Out[47]: <DstTzInfo 'US/Eastern' LMT-1 day, 19:04:00 STD>
```

You can also chain these types of operations:

```
In [48]: s.dt.tz_localize('UTC').dt.tz_convert('US/Eastern')
```

```
Out[48]:
```

```
0 2013-01-01 04:10:12-05:00
```

```
1 2013-01-02 04:10:12-05:00
```

```
2 2013-01-03 04:10:12-05:00
```

```
3 2013-01-04 04:10:12-05:00
```

```
Length: 4, dtype: datetime64[ns, US/Eastern]
```

The `.dt` accessor works for period and timedelta dtypes.

```
period
```

```
In [49]: s = pd.Series(pd.period_range('20130101', periods=4, freq='D'))
```

```
In [50]: s
```

```
Out[50]:
```

```
0 2013-01-01
```

```
1 2013-01-02
```

```
2 2013-01-03
```

```
3 2013-01-04
```

```
Length: 4, dtype: period[D]
```

```
In [51]: s.dt.year
```

```
Out[51]:
```

```
0 2013
```

(continues on next page)

(continued from previous page)

```

1 2013
2 2013
3 2013
Length: 4, dtype: int64

```

```
In [52]: s.dt.day
```

```
Out[52]:
```

```

0 1
1 2
2 3
3 4
Length: 4, dtype: int64

```

```
timedelta
```

```
In [53]: s = pd.Series(pd.timedelta_range('1 day 00:00:05', periods=4, freq='s'))
```

```
In [54]: s
```

```
Out[54]:
```

```

0 1 days 00:00:05
1 1 days 00:00:06
2 1 days 00:00:07
3 1 days 00:00:08
Length: 4, dtype: timedelta64[ns]

```

```
In [55]: s.dt.days
```

```
Out[55]:
```

```

0 1
1 1
2 1
3 1
Length: 4, dtype: int64

```

```
In [56]: s.dt.seconds
```

```
Out[56]:
```

```

0 5
1 6
2 7
3 8
Length: 4, dtype: int64

```

```
In [57]: s.dt.components
```

```
Out[57]:
```

|   | days | hours | minutes | seconds | milliseconds | microseconds | nanoseconds |
|---|------|-------|---------|---------|--------------|--------------|-------------|
| 0 | 1    | 0     | 0       | 5       | 0            | 0            | 0           |
| 1 | 1    | 0     | 0       | 6       | 0            | 0            | 0           |
| 2 | 1    | 0     | 0       | 7       | 0            | 0            | 0           |
| 3 | 1    | 0     | 0       | 8       | 0            | 0            | 0           |

```
[4 rows x 7 columns]
```

## Timezone handling improvements

- `tz_localize(None)` for `tz`-aware `Timestamp` and `DatetimeIndex` now removes timezone holding local time, previously this resulted in `Exception` or `TypeError` ([GH7812](#))

```
In [58]: ts = pd.Timestamp('2014-08-01 09:00', tz='US/Eastern')

In [59]: ts
Out[59]: Timestamp('2014-08-01 09:00:00-0400', tz='US/Eastern')

In [60]: ts.tz_localize(None)
Out[60]: Timestamp('2014-08-01 09:00:00')

In [61]: didx = pd.date_range(start='2014-08-01 09:00', freq='H',
.....: periods=10, tz='US/Eastern')
.....:

In [62]: didx
Out[62]:
DatetimeIndex(['2014-08-01 09:00:00-04:00', '2014-08-01 10:00:00-04:00',
 '2014-08-01 11:00:00-04:00', '2014-08-01 12:00:00-04:00',
 '2014-08-01 13:00:00-04:00', '2014-08-01 14:00:00-04:00',
 '2014-08-01 15:00:00-04:00', '2014-08-01 16:00:00-04:00',
 '2014-08-01 17:00:00-04:00', '2014-08-01 18:00:00-04:00'],
 dtype='datetime64[ns, US/Eastern]', freq='H')

In [63]: didx.tz_localize(None)
Out[63]:
DatetimeIndex(['2014-08-01 09:00:00', '2014-08-01 10:00:00',
 '2014-08-01 11:00:00', '2014-08-01 12:00:00',
 '2014-08-01 13:00:00', '2014-08-01 14:00:00',
 '2014-08-01 15:00:00', '2014-08-01 16:00:00',
 '2014-08-01 17:00:00', '2014-08-01 18:00:00'],
 dtype='datetime64[ns]', freq=None)
```

- `tz_localize` now accepts the `ambiguous` keyword which allows for passing an array of bools indicating whether the date belongs in DST or not, `'NaT'` for setting transition times to `NaT`, `'infer'` for inferring DST/non-DST, and `'raise'` (default) for an `AmbiguousTimeError` to be raised. See [the docs](#) for more details ([GH7943](#))
- `DataFrame.tz_localize` and `DataFrame.tz_convert` now accepts an optional `level` argument for localizing a specific level of a `MultiIndex` ([GH7846](#))
- `Timestamp.tz_localize` and `Timestamp.tz_convert` now raise `TypeError` in error cases, rather than `Exception` ([GH8025](#))
- a `timeseries/index` localized to UTC when inserted into a `Series/DataFrame` will preserve the UTC timezone (rather than being a naive `datetime64[ns]`) as object dtype ([GH8411](#))
- `Timestamp.__repr__` displays `dateutil.tz.tzoffset` info ([GH7907](#))

## Rolling/expanding moments improvements

- `rolling_min()`, `rolling_max()`, `rolling_cov()`, and `rolling_corr()` now return objects with all NaN when `len(arg) < min_periods <= window` rather than raising. (This makes all rolling functions consistent in this behavior). (GH7766)

Prior to 0.15.0

```
In [64]: s = pd.Series([10, 11, 12, 13])
```

```
In [15]: pd.rolling_min(s, window=10, min_periods=5)
ValueError: min_periods (5) must be <= window (4)
```

New behavior

```
In [4]: pd.rolling_min(s, window=10, min_periods=5)
Out[4]:
0 NaN
1 NaN
2 NaN
3 NaN
dtype: float64
```

- `rolling_max()`, `rolling_min()`, `rolling_sum()`, `rolling_mean()`, `rolling_median()`, `rolling_std()`, `rolling_var()`, `rolling_skew()`, `rolling_kurt()`, `rolling_quantile()`, `rolling_cov()`, `rolling_corr()`, `rolling_corr_pairwise()`, `rolling_window()`, and `rolling_apply()` with `center=True` previously would return a result of the same structure as the input arg with NaN in the final  $(window-1)/2$  entries.

Now the final  $(window-1)/2$  entries of the result are calculated as if the input arg were followed by  $(window-1)/2$  NaN values (or with shrinking windows, in the case of `rolling_apply()`). (GH7925, GH8269)

Prior behavior (note final value is NaN):

```
In [7]: pd.rolling_sum(Series(range(4)), window=3, min_periods=0, center=True)
Out[7]:
0 1
1 3
2 6
3 NaN
dtype: float64
```

New behavior (note final value is 5 = `sum([2, 3, NaN])`):

```
In [7]: pd.rolling_sum(pd.Series(range(4)), window=3,
.....: min_periods=0, center=True)
Out[7]:
0 1
1 3
2 6
3 5
dtype: float64
```

- `rolling_window()` now normalizes the weights properly in rolling mean mode (`mean=True`) so that the calculated weighted means (e.g. ‘triang’, ‘gaussian’) are distributed about the same means as those calculated without weighting (i.e. ‘boxcar’). See *the note on normalization* for further details. (GH7618)

```
In [65]: s = pd.Series([10.5, 8.8, 11.4, 9.7, 9.3])
```

Behavior prior to 0.15.0:

```
In [39]: pd.rolling_window(s, window=3, win_type='triang', center=True)
```

```
Out[39]:
```

```
0 NaN
1 6.583333
2 6.883333
3 6.683333
4 NaN
dtype: float64
```

New behavior

```
In [10]: pd.rolling_window(s, window=3, win_type='triang', center=True)
```

```
Out[10]:
```

```
0 NaN
1 9.875
2 10.325
3 10.025
4 NaN
dtype: float64
```

- Removed `center` argument from all `expanding_*` functions (see [list](#)), as the results produced when `center=True` did not make much sense. ([GH7925](#))
- Added optional `ddof` argument to `expanding_cov()` and `rolling_cov()`. The default value of 1 is backwards-compatible. ([GH8279](#))
- Documented the `ddof` argument to `expanding_var()`, `expanding_std()`, `rolling_var()`, and `rolling_std()`. These functions' support of a `ddof` argument (with a default value of 1) was previously undocumented. ([GH8064](#))
- `ewma()`, `ewmstd()`, `ewmvol()`, `ewmvar()`, `ewmcov()`, and `ewmcorr()` now interpret `min_periods` in the same manner that the `rolling_*`() and `expanding_*`() functions do: a given result entry will be `NaN` if the (expanding, in this case) window does not contain at least `min_periods` values. The previous behavior was to set to `NaN` the `min_periods` entries starting with the first non-`NaN` value. ([GH7977](#))

Prior behavior (note values start at index 2, which is `min_periods` after index 0 (the index of the first non-empty value)):

```
In [66]: s = pd.Series([1, None, None, None, 2, 3])
```

```
In [51]: ewma(s, com=3., min_periods=2)
```

```
Out[51]:
```

```
0 NaN
1 NaN
2 1.000000
3 1.000000
4 1.571429
5 2.189189
dtype: float64
```

New behavior (note values start at index 4, the location of the 2nd (since `min_periods=2`) non-empty value):

```
In [2]: pd.ewma(s, com=3., min_periods=2)
Out[2]:
0 NaN
1 NaN
2 NaN
3 NaN
4 1.759644
5 2.383784
dtype: float64
```

- `ewmstd()`, `ewmvol()`, `ewmvar()`, `ewmcov()`, and `ewmcorr()` now have an optional `adjust` argument, just like `ewma()` does, affecting how the weights are calculated. The default value of `adjust` is `True`, which is backwards-compatible. See *Exponentially weighted moment functions* for details. (GH7911)
- `ewma()`, `ewmstd()`, `ewmvol()`, `ewmvar()`, `ewmcov()`, and `ewmcorr()` now have an optional `ignore_na` argument. When `ignore_na=False` (the default), missing values are taken into account in the weights calculation. When `ignore_na=True` (which reproduces the pre-0.15.0 behavior), missing values are ignored in the weights calculation. (GH7543)

```
In [7]: pd.ewma(pd.Series([None, 1., 8.]), com=2.)
Out[7]:
0 NaN
1 1.0
2 5.2
dtype: float64
```

```
In [8]: pd.ewma(pd.Series([1., None, 8.]), com=2.,
....: ignore_na=True) # pre-0.15.0 behavior
Out[8]:
0 1.0
1 1.0
2 5.2
dtype: float64
```

```
In [9]: pd.ewma(pd.Series([1., None, 8.]), com=2.,
....: ignore_na=False) # new default
Out[9]:
0 1.000000
1 1.000000
2 5.846154
dtype: float64
```

**Warning:** By default (`ignore_na=False`) the `ewm*()` functions' weights calculation in the presence of missing values is different than in pre-0.15.0 versions. To reproduce the pre-0.15.0 calculation of weights in the presence of missing values one must specify explicitly `ignore_na=True`.

- Bug in `expanding_cov()`, `expanding_corr()`, `rolling_cov()`, `rolling_cor()`, `ewmcov()`, and `ewmcorr()` returning results with columns sorted by name and producing an error for non-unique columns; now handles non-unique columns and returns columns in original order (except for the case of two DataFrames with `pairwise=False`, where behavior is unchanged) (GH7542)
- Bug in `rolling_count()` and `expanding_*()` functions unnecessarily producing error message for zero-length data (GH8056)

- Bug in `rolling_apply()` and `expanding_apply()` interpreting `min_periods=0` as `min_periods=1` (GH8080)
- Bug in `expanding_std()` and `expanding_var()` for a single value producing a confusing error message (GH7900)
- Bug in `rolling_std()` and `rolling_var()` for a single value producing `0` rather than `NaN` (GH7900)
- Bug in `ewmstd()`, `ewmvol()`, `ewmvar()`, and `ewmcov()` calculation of de-biasing factors when `bias=False` (the default). Previously an incorrect constant factor was used, based on `adjust=True`, `ignore_na=True`, and an infinite number of observations. Now a different factor is used for each entry, based on the actual weights (analogous to the usual  $N/(N-1)$  factor). In particular, for a single point a value of `NaN` is returned when `bias=False`, whereas previously a value of (approximately) `0` was returned.

For example, consider the following pre-0.15.0 results for `ewmvar(..., bias=False)`, and the corresponding debiasing factors:

```
In [67]: s = pd.Series([1., 2., 0., 4.])
```

```
In [89]: ewmvar(s, com=2., bias=False)
```

```
Out[89]:
0 -2.775558e-16
1 3.000000e-01
2 9.556787e-01
3 3.585799e+00
dtype: float64
```

```
In [90]: ewmvar(s, com=2., bias=False) / ewmvar(s, com=2., bias=True)
```

```
Out[90]:
0 1.25
1 1.25
2 1.25
3 1.25
dtype: float64
```

Note that entry `0` is approximately `0`, and the debiasing factors are a constant `1.25`. By comparison, the following 0.15.0 results have a `NaN` for entry `0`, and the debiasing factors are decreasing (towards `1.25`):

```
In [14]: pd.ewmvar(s, com=2., bias=False)
```

```
Out[14]:
0 NaN
1 0.500000
2 1.210526
3 4.089069
dtype: float64
```

```
In [15]: pd.ewmvar(s, com=2., bias=False) / pd.ewmvar(s, com=2., bias=True)
```

```
Out[15]:
0 NaN
1 2.083333
2 1.583333
3 1.425439
dtype: float64
```

See *Exponentially weighted moment functions* for details. (GH7912)

## Improvements in the SQL IO module

- Added support for a `chunksize` parameter to `to_sql` function. This allows DataFrame to be written in chunks and avoid packet-size overflow errors (GH8062).
- Added support for a `chunksize` parameter to `read_sql` function. Specifying this argument will return an iterator through chunks of the query result (GH2908).
- Added support for writing `datetime.date` and `datetime.time` object columns with `to_sql` (GH6932).
- Added support for specifying a schema to read from/write to with `read_sql_table` and `to_sql` (GH7441, GH7952). For example:

```
df.to_sql('table', engine, schema='other_schema') # noqa F821
pd.read_sql_table('table', engine, schema='other_schema') # noqa F821
```

- Added support for writing NaN values with `to_sql` (GH2754).
- Added support for writing `datetime64` columns with `to_sql` for all database flavors (GH7103).

## Backwards incompatible API changes

### Breaking changes

API changes related to Categorical (see [here](#) for more details):

- The Categorical constructor with two arguments changed from “codes/labels and levels” to “values and levels (now called ‘categories’)”. This can lead to subtle bugs. If you use `Categorical` directly, please audit your code by changing it to use the `from_codes()` constructor.

An old function call like (prior to 0.15.0):

```
pd.Categorical([0,1,0,2,1], levels=['a', 'b', 'c'])
```

will have to adapted to the following to keep the same behaviour:

```
In [2]: pd.Categorical.from_codes([0,1,0,2,1], categories=['a', 'b', 'c'])
Out[2]:
[a, b, a, c, b]
Categories (3, object): [a, b, c]
```

API changes related to the introduction of the Timedelta scalar (see [above](#) for more details):

- Prior to 0.15.0 `to_timedelta()` would return a Series for list-like/Series input, and a `np.timedelta64` for scalar input. It will now return a `TimedeltaIndex` for list-like input, `Series` for Series input, and `Timedelta` for scalar input.

For API changes related to the rolling and expanding functions, see detailed overview [above](#).

Other notable API changes:

- Consistency when indexing with `.loc` and a list-like indexer when no values are found.

```
In [68]: df = pd.DataFrame([['a'], ['b']], index=[1, 2])
In [69]: df
Out[69]:
0
```

(continues on next page)

(continued from previous page)

```

1 a
2 b

[2 rows x 1 columns]

```

In prior versions there was a difference in these two constructs:

- `df.loc[[3]]` would return a frame reindexed by 3 (with all `np.nan` values)
- `df.loc[[3], :]` would raise `KeyError`.

Both will now raise a `KeyError`. The rule is that *at least 1* indexer must be found when using a list-like and `.loc` (GH7999)

Furthermore in prior versions these were also different:

- `df.loc[[1, 3]]` would return a frame reindexed by [1,3]
- `df.loc[[1, 3], :]` would raise `KeyError`.

Both will now return a frame reindex by [1,3]. E.g.

```

In [3]: df.loc[[1, 3]]
Out[3]:
 0
1 a
3 NaN

In [4]: df.loc[[1, 3], :]
Out[4]:
 0
1 a
3 NaN

```

This can also be seen in multi-axis indexing with a `Panel`.

```

>>> p = pd.Panel(np.arange(2 * 3 * 4).reshape(2, 3, 4),
... items=['ItemA', 'ItemB'],
... major_axis=[1, 2, 3],
... minor_axis=['A', 'B', 'C', 'D'])
>>> p
<class 'pandas.core.panel.Panel'>
Dimensions: 2 (items) x 3 (major_axis) x 4 (minor_axis)
Items axis: ItemA to ItemB
Major_axis axis: 1 to 3
Minor_axis axis: A to D

```

The following would raise `KeyError` prior to 0.15.0:

```

In [5]:
Out[5]:
 ItemA ItemD
1 3 NaN
2 7 NaN
3 11 NaN

```

Furthermore, `.loc` will raise `If no values are found in a MultiIndex with a list-like indexer`:

```

In [70]: s = pd.Series(np.arange(3, dtype='int64'),
.....: index=pd.MultiIndex.from_product([['A'],
.....: ['foo', 'bar', 'baz']],
.....: names=['one', 'two'])
.....:).sort_index()
.....:

In [71]: s
Out[71]:
one two
A bar 1
 baz 2
 foo 0
Length: 3, dtype: int64

In [72]: try:
.....: s.loc['D']
.....: except KeyError as e:
.....: print("KeyError: " + str(e))
.....:
KeyError: "['D'] not in index"

```

- Assigning values to `None` now considers the dtype when choosing an ‘empty’ value (GH7941).

Previously, assigning to `None` in numeric containers changed the dtype to object (or errored, depending on the call). It now uses `NaN`:

```

In [73]: s = pd.Series([1, 2, 3])

In [74]: s.loc[0] = None

In [75]: s
Out[75]:
0 NaN
1 2.0
2 3.0
Length: 3, dtype: float64

```

`NaT` is now used similarly for datetime containers.

For object containers, we now preserve `None` values (previously these were converted to `NaN` values).

```

In [76]: s = pd.Series(["a", "b", "c"])

In [77]: s.loc[0] = None

In [78]: s
Out[78]:
0 None
1 b
2 c
Length: 3, dtype: object

```

To insert a `NaN`, you must explicitly use `np.nan`. See the *docs*.

- In prior versions, updating a pandas object inplace would not reflect in other python references to this object. (GH8511, GH5104)

```
In [79]: s = pd.Series([1, 2, 3])
In [80]: s2 = s
In [81]: s += 1.5
```

Behavior prior to v0.15.0

```
the original object
In [5]: s
Out[5]:
0 2.5
1 3.5
2 4.5
dtype: float64

a reference to the original object
In [7]: s2
Out[7]:
0 1
1 2
2 3
dtype: int64
```

This is now the correct behavior

```
the original object
In [82]: s
Out[82]:
0 2.5
1 3.5
2 4.5
Length: 3, dtype: float64

a reference to the original object
In [83]: s2
Out[83]:
0 2.5
1 3.5
2 4.5
Length: 3, dtype: float64
```

- Made both the C-based and Python engines for `read_csv` and `read_table` ignore empty lines in input as well as white space-filled lines, as long as `sep` is not white space. This is an API change that can be controlled by the keyword parameter `skip_blank_lines`. See *the docs* (GH4466)
- A timeseries/index localized to UTC when inserted into a Series/DataFrame will preserve the UTC timezone and inserted as object dtype rather than being converted to a naive `datetime64[ns]` (GH8411).
- Bug in passing a `DatetimeIndex` with a timezone that was not being retained in DataFrame construction from a dict (GH7822)

In prior versions this would drop the timezone, now it retains the timezone, but gives a column of object dtype:

```
In [84]: i = pd.date_range('1/1/2011', periods=3, freq='10s', tz='US/Eastern')

In [85]: i
Out[85]:
DatetimeIndex(['2011-01-01 00:00:00-05:00', '2011-01-01 00:00:10-05:00',
 '2011-01-01 00:00:20-05:00'],
 dtype='datetime64[ns, US/Eastern]', freq='10S')

In [86]: df = pd.DataFrame({'a': i})

In [87]: df
Out[87]:
 a
0 2011-01-01 00:00:00-05:00
1 2011-01-01 00:00:10-05:00
2 2011-01-01 00:00:20-05:00

[3 rows x 1 columns]

In [88]: df.dtypes
Out[88]:
a datetime64[ns, US/Eastern]
Length: 1, dtype: object
```

Previously this would have yielded a column of `datetime64` dtype, but without timezone info.

The behaviour of assigning a column to an existing dataframe as `df['a'] = i` remains unchanged (this already returned an object column with a timezone).

- When passing multiple levels to `stack()`, it will now raise a `ValueError` when the levels aren't all level names or all level numbers (GH7660). See *Reshaping by stacking and unstacking*.
- Raise a `ValueError` in `df.to_hdf` with 'fixed' format, if `df` has non-unique columns as the resulting file will be broken (GH7761)
- `SettingWithCopy` raise/warnings (according to the option `mode.chained_assignment`) will now be issued when setting a value on a sliced mixed-dtype DataFrame using chained-assignment. (GH7845, GH7950)

```
In [1]: df = pd.DataFrame(np.arange(0, 9), columns=['count'])

In [2]: df['group'] = 'b'

In [3]: df.iloc[0:5]['group'] = 'a'
/usr/local/bin/ipython:1: SettingWithCopyWarning:
A value is trying to be set on a copy of a slice from a DataFrame.
Try using .loc[row_indexer,col_indexer] = value instead

See the caveats in the documentation: https://pandas.pydata.org/pandas-docs/stable/
->indexing.html#indexing-view-versus-copy
```

- `merge`, `DataFrame.merge`, and `ordered_merge` now return the same type as the left argument (GH7737).
- Previously an enlargement with a mixed-dtype frame would act unlike `.append` which will preserve dtypes (related GH2578, GH8176):

```
In [89]: df = pd.DataFrame([[True, 1], [False, 2]],
.....: columns=["female", "fitness"])
.....:

In [90]: df
Out[90]:
 female fitness
0 True 1
1 False 2

[2 rows x 2 columns]

In [91]: df.dtypes
Out[91]:
female bool
fitness int64
Length: 2, dtype: object

dtypes are now preserved
In [92]: df.loc[2] = df.loc[1]

In [93]: df
Out[93]:
 female fitness
0 True 1
1 False 2
2 False 2

[3 rows x 2 columns]

In [94]: df.dtypes
Out[94]:
female bool
fitness int64
Length: 2, dtype: object
```

- `Series.to_csv()` now returns a string when `path=None`, matching the behaviour of `DataFrame.to_csv()` (GH8215).
- `read_hdf` now raises `IOError` when a file that doesn't exist is passed in. Previously, a new, empty file was created, and a `KeyError` raised (GH7715).
- `DataFrame.info()` now ends its output with a newline character (GH8114)
- Concatenating no objects will now raise a `ValueError` rather than a bare `Exception`.
- Merge errors will now be sub-classes of `ValueError` rather than raw `Exception` (GH8501)
- `DataFrame.plot` and `Series.plot` keywords are now have consistent orders (GH8037)

## Internal refactoring

In 0.15.0 `Index` has internally been refactored to no longer sub-class `ndarray` but instead subclass `PandasObject`, similarly to the rest of the pandas objects. This change allows very easy sub-classing and creation of new index types. This should be a transparent change with only very limited API implications ([GH5080](#), [GH7439](#), [GH7796](#), [GH8024](#), [GH8367](#), [GH7997](#), [GH8522](#)):

- you may need to unpickle pandas version < 0.15.0 pickles using `pd.read_pickle` rather than `pickle.load`. See [pickle docs](#)
- when plotting with a `PeriodIndex`, the matplotlib internal axes will now be arrays of `Period` rather than a `PeriodIndex` (this is similar to how a `DatetimeIndex` passes arrays of datetimes now)
- `MultiIndex`s will now raise similarly to other pandas objects w.r.t. truth testing, see [here](#) ([GH7897](#)).
- When plotting a `DatetimeIndex` directly with matplotlib's `plot` function, the axis labels will no longer be formatted as dates but as integers (the internal representation of a `datetime64`). **UPDATE** This is fixed in 0.15.1, see [here](#).

## Deprecations

- The attributes `Categorical` labels and levels attributes are deprecated and renamed to `codes` and `categories`.
- The `outtype` argument to `pd.DataFrame.to_dict` has been deprecated in favor of `orient`. ([GH7840](#))
- The `convert_dummies` method has been deprecated in favor of `get_dummies` ([GH8140](#))
- The `infer_dst` argument in `tz_localize` will be deprecated in favor of `ambiguous` to allow for more flexibility in dealing with DST transitions. Replace `infer_dst=True` with `ambiguous='infer'` for the same behavior ([GH7943](#)). See [the docs](#) for more details.
- The top-level `pd.value_range` has been deprecated and can be replaced by `.describe()` ([GH8481](#))
- The `Index` set operations `+` and `-` were deprecated in order to provide these for numeric type operations on certain index types. `+` can be replaced by `.union()` or `|`, and `-` by `.difference()`. Further the method name `Index.diff()` is deprecated and can be replaced by `Index.difference()` ([GH8226](#))

```
+
pd.Index(['a', 'b', 'c']) + pd.Index(['b', 'c', 'd'])

should be replaced by
pd.Index(['a', 'b', 'c']).union(pd.Index(['b', 'c', 'd']))
```

```
-
pd.Index(['a', 'b', 'c']) - pd.Index(['b', 'c', 'd'])

should be replaced by
pd.Index(['a', 'b', 'c']).difference(pd.Index(['b', 'c', 'd']))
```

- The `infer_types` argument to `read_html()` now has no effect and is deprecated ([GH7762](#), [GH7032](#)).

## Removal of prior version deprecations/changes

- Remove `DataFrame.delevel` method in favor of `DataFrame.reset_index`

## Enhancements

Enhancements in the importing/exporting of Stata files:

- Added support for `bool`, `uint8`, `uint16` and `uint32` data types in `to_stata` (GH7097, GH7365)
- Added conversion option when importing Stata files (GH8527)
- `DataFrame.to_stata` and `StataWriter` check string length for compatibility with limitations imposed in dta files where fixed-width strings must contain 244 or fewer characters. Attempting to write Stata dta files with strings longer than 244 characters raises a `ValueError`. (GH7858)
- `read_stata` and `StataReader` can import missing data information into a `DataFrame` by setting the argument `convert_missing` to `True`. When using this options, missing values are returned as `StataMissingValue` objects and columns containing missing values have object data type. (GH8045)

Enhancements in the plotting functions:

- Added layout keyword to `DataFrame.plot`. You can pass a tuple of (`rows`, `columns`), one of which can be `-1` to automatically infer (GH6667, GH8071).
- Allow to pass multiple axes to `DataFrame.plot`, `hist` and `boxplot` (GH5353, GH6970, GH7069)
- Added support for `c`, `colormap` and `colorbar` arguments for `DataFrame.plot` with `kind='scatter'` (GH7780)
- Histogram from `DataFrame.plot` with `kind='hist'` (GH7809), See *the docs*.
- Boxplot from `DataFrame.plot` with `kind='box'` (GH7998), See *the docs*.

Other:

- `read_csv` now has a keyword parameter `float_precision` which specifies which floating-point converter the C engine should use during parsing, see *here* (GH8002, GH8044)
- Added `searchsorted` method to `Series` objects (GH7447)
- `describe()` on mixed-types `DataFrames` is more flexible. Type-based column filtering is now possible via the `include/exclude` arguments. See the *docs* (GH8164).

```
In [95]: df = pd.DataFrame({'catA': ['foo', 'foo', 'bar'] * 8,
.....: 'catB': ['a', 'b', 'c', 'd'] * 6,
.....: 'numC': np.arange(24),
.....: 'numD': np.arange(24.) + .5})
.....:

In [96]: df.describe(include=["object"])
Out[96]:
 catA catB
count 24 24
unique 2 4
top foo a
freq 16 6

[4 rows x 2 columns]
```

(continues on next page)

(continued from previous page)

```
In [97]: df.describe(include=["number", "object"], exclude=["float"])
```

```
Out[97]:
```

|        | catA | catB | numC      |
|--------|------|------|-----------|
| count  | 24   | 24   | 24.000000 |
| unique | 2    | 4    | NaN       |
| top    | foo  | a    | NaN       |
| freq   | 16   | 6    | NaN       |
| mean   | NaN  | NaN  | 11.500000 |
| std    | NaN  | NaN  | 7.071068  |
| min    | NaN  | NaN  | 0.000000  |
| 25%    | NaN  | NaN  | 5.750000  |
| 50%    | NaN  | NaN  | 11.500000 |
| 75%    | NaN  | NaN  | 17.250000 |
| max    | NaN  | NaN  | 23.000000 |

```
[11 rows x 3 columns]
```

Requesting all columns is possible with the shorthand 'all'

```
In [98]: df.describe(include='all')
```

```
Out[98]:
```

|        | catA | catB | numC      | numD      |
|--------|------|------|-----------|-----------|
| count  | 24   | 24   | 24.000000 | 24.000000 |
| unique | 2    | 4    | NaN       | NaN       |
| top    | foo  | a    | NaN       | NaN       |
| freq   | 16   | 6    | NaN       | NaN       |
| mean   | NaN  | NaN  | 11.500000 | 12.000000 |
| std    | NaN  | NaN  | 7.071068  | 7.071068  |
| min    | NaN  | NaN  | 0.000000  | 0.500000  |
| 25%    | NaN  | NaN  | 5.750000  | 6.250000  |
| 50%    | NaN  | NaN  | 11.500000 | 12.000000 |
| 75%    | NaN  | NaN  | 17.250000 | 17.750000 |
| max    | NaN  | NaN  | 23.000000 | 23.500000 |

```
[11 rows x 4 columns]
```

Without those arguments, `describe` will behave as before, including only numerical columns or, if none are, only categorical columns. See also the [docs](#)

- Added `split` as an option to the `orient` argument in `pd.DataFrame.to_dict`. ([GH7840](#))
- The `get_dummies` method can now be used on DataFrames. By default only categorical columns are encoded as 0's and 1's, while other columns are left untouched.

```
In [99]: df = pd.DataFrame({'A': ['a', 'b', 'a'], 'B': ['c', 'c', 'b'],
.....: 'C': [1, 2, 3]})
.....:
```

```
In [100]: pd.get_dummies(df)
```

```
Out[100]:
```

|   | C | A_a | A_b | B_b | B_c |
|---|---|-----|-----|-----|-----|
| 0 | 1 | 1   | 0   | 0   | 1   |

(continues on next page)

(continued from previous page)

```
1 2 0 1 0 1
2 3 1 0 1 0
```

```
[3 rows x 5 columns]
```

- `PeriodIndex` supports resolution as the same as `DatetimeIndex` (GH7708)
- `pandas.tseries.holiday` has added support for additional holidays and ways to observe holidays (GH7070)
- `pandas.tseries.holiday.Holiday` now supports a list of offsets in Python3 (GH7070)
- `pandas.tseries.holiday.Holiday` now supports a `days_of_week` parameter (GH7070)
- `GroupBy.nth()` now supports selecting multiple `nth` values (GH7910)

```
In [101]: business_dates = pd.date_range(start='4/1/2014', end='6/30/2014', freq='B
→')
```

```
In [102]: df = pd.DataFrame(1, index=business_dates, columns=['a', 'b'])
```

```
get the first, 4th, and last date index for each month
```

```
In [103]: df.groupby([df.index.year, df.index.month]).nth([0, 3, -1])
```

```
Out[103]:
```

```
 a b
2014 4 1 1
 4 1 1
 4 1 1
 5 1 1
 5 1 1
 5 1 1
 5 1 1
 6 1 1
 6 1 1
 6 1 1
```

```
[9 rows x 2 columns]
```

- `Period` and `PeriodIndex` supports addition/subtraction with `timedelta`-likes (GH7966)

If `Period` `freq` is D, H, T, S, L, U, N, `Timedelta`-like can be added if the result can have same `freq`. Otherwise, only the same offsets can be added.

```
In [104]: idx = pd.period_range('2014-07-01 09:00', periods=5, freq='H')
```

```
In [105]: idx
```

```
Out[105]:
```

```
PeriodIndex(['2014-07-01 09:00', '2014-07-01 10:00', '2014-07-01 11:00',
 '2014-07-01 12:00', '2014-07-01 13:00'],
 dtype='period[H]')
```

```
In [106]: idx + pd.offsets.Hour(2)
```

```
Out[106]:
```

```
PeriodIndex(['2014-07-01 11:00', '2014-07-01 12:00', '2014-07-01 13:00',
 '2014-07-01 14:00', '2014-07-01 15:00'],
 dtype='period[H]')
```

(continues on next page)

(continued from previous page)

```

In [107]: idx + pd.Timedelta('120m')
Out[107]:
PeriodIndex(['2014-07-01 11:00', '2014-07-01 12:00', '2014-07-01 13:00',
 '2014-07-01 14:00', '2014-07-01 15:00'],
 dtype='period[H]')

In [108]: idx = pd.period_range('2014-07', periods=5, freq='M')

In [109]: idx
Out[109]: PeriodIndex(['2014-07', '2014-08', '2014-09', '2014-10', '2014-11'],
 dtype='period[M]')

In [110]: idx + pd.offsets.MonthEnd(3)
Out[110]: PeriodIndex(['2014-10', '2014-11', '2014-12', '2015-01', '2015-02'],
 dtype='period[M]')

```

- Added experimental compatibility with `openpyxl` for versions  $\geq 2.0$ . The `DataFrame.to_excel` method engine keyword now recognizes `openpyxl1` and `openpyxl2` which will explicitly require `openpyxl v1` and `v2` respectively, failing if the requested version is not available. The `openpyxl` engine is now a meta-engine that automatically uses whichever version of `openpyxl` is installed. (GH7177)
- `DataFrame.fillna` can now accept a `DataFrame` as a fill value (GH8377)
- Passing multiple levels to `stack()` will now work when multiple level numbers are passed (GH7660). See *Reshaping by stacking and unstacking*.
- `set_names()`, `set_labels()`, and `set_levels()` methods now take an optional `level` keyword argument to all modification of specific level(s) of a `MultiIndex`. Additionally `set_names()` now accepts a scalar string value when operating on an `Index` or on a specific level of a `MultiIndex` (GH7792)

```

In [111]: idx = pd.MultiIndex.from_product(['a'], range(3), list("pqr")),
 : names=['foo', 'bar', 'baz'])
 :

In [112]: idx.set_names('qux', level=0)
Out[112]:
MultiIndex([(a, 0, 'p'),
 (a, 0, 'q'),
 (a, 0, 'r'),
 (a, 1, 'p'),
 (a, 1, 'q'),
 (a, 1, 'r'),
 (a, 2, 'p'),
 (a, 2, 'q'),
 (a, 2, 'r')],
 names=['qux', 'bar', 'baz'])

In [113]: idx.set_names(['qux', 'corge'], level=[0, 1])
Out[113]:
MultiIndex([(a, 0, 'p'),
 (a, 0, 'q'),
 (a, 0, 'r'),
 (a, 1, 'p'),
 (a, 1, 'q'),

```

(continues on next page)

(continued from previous page)

```

 ('a', 1, 'r'),
 ('a', 2, 'p'),
 ('a', 2, 'q'),
 ('a', 2, 'r')],
 names=['qux', 'corge', 'baz'])

In [114]: idx.set_levels(['a', 'b', 'c'], level='bar')
Out[114]:
MultiIndex([(a, 'a', 'p'),
 (a, 'a', 'q'),
 (a, 'a', 'r'),
 (a, 'b', 'p'),
 (a, 'b', 'q'),
 (a, 'b', 'r'),
 (a, 'c', 'p'),
 (a, 'c', 'q'),
 (a, 'c', 'r')],
 names=['foo', 'bar', 'baz'])

In [115]: idx.set_levels([[a, 'b', 'c'], [1, 2, 3]], level=[1, 2])
Out[115]:
MultiIndex([(a, 'a', 1),
 (a, 'a', 2),
 (a, 'a', 3),
 (a, 'b', 1),
 (a, 'b', 2),
 (a, 'b', 3),
 (a, 'c', 1),
 (a, 'c', 2),
 (a, 'c', 3)],
 names=['foo', 'bar', 'baz'])

```

- Index.isin now supports a level argument to specify which index level to use for membership tests (GH7892, GH7890)

```

In [1]: idx = pd.MultiIndex.from_product([[0, 1], ['a', 'b', 'c']])

In [2]: idx.values
Out[2]: array([(0, 'a'), (0, 'b'), (0, 'c'), (1, 'a'), (1, 'b'), (1, 'c')],
 dtype=object)

In [3]: idx.isin(['a', 'c', 'e'], level=1)
Out[3]: array([True, False, True, True, False, True], dtype=bool)

```

- Index now supports duplicated and drop\_duplicates. (GH4060)

```

In [116]: idx = pd.Index([1, 2, 3, 4, 1, 2])

In [117]: idx
Out[117]: Int64Index([1, 2, 3, 4, 1, 2], dtype='int64')

In [118]: idx.duplicated()

```

(continues on next page)

(continued from previous page)

```
Out[118]: array([False, False, False, False, True, True])
```

```
In [119]: idx.drop_duplicates()
```

```
Out[119]: Int64Index([1, 2, 3, 4], dtype='int64')
```

- add `copy=True` argument to `pd.concat` to enable pass through of complete blocks (GH8252)
- Added support for numpy 1.8+ data types (`bool_`, `int_`, `float_`, `string_`) for conversion to R dataframe (GH8400)

## Performance

- Performance improvements in `DatetimeIndex.__iter__` to allow faster iteration (GH7683)
- Performance improvements in `Period` creation (and `PeriodIndex` setitem) (GH5155)
- Improvements in `Series.transform` for significant performance gains (revised) (GH6496)
- Performance improvements in `StataReader` when reading large files (GH8040, GH8073)
- Performance improvements in `StataWriter` when writing large files (GH8079)
- Performance and memory usage improvements in multi-key `groupby` (GH8128)
- Performance improvements in `groupby .agg` and `.apply` where builtins `max/min` were not mapped to numpy/cythonized versions (GH7722)
- Performance improvement in writing to sql (`to_sql`) of up to 50% (GH8208).
- Performance benchmarking of `groupby` for large value of `ngroups` (GH6787)
- Performance improvement in `CustomBusinessDay`, `CustomBusinessMonth` (GH8236)
- Performance improvement for `MultiIndex.values` for multi-level indexes containing datetimes (GH8543)

## Bug fixes

- Bug in `pivot_table`, when using margins and a dict aggfunc (GH8349)
- Bug in `read_csv` where `squeeze=True` would return a view (GH8217)
- Bug in checking of table name in `read_sql` in certain cases (GH7826).
- Bug in `DataFrame.groupby` where `Groupby` does not recognize level when frequency is specified (GH7885)
- Bug in multiindexes dtypes getting mixed up when `DataFrame` is saved to SQL table (GH8021)
- Bug in `Series` 0-division with a float and integer operand dtypes (GH7785)
- Bug in `Series.astype("unicode")` not calling `unicode` on the values correctly (GH7758)
- Bug in `DataFrame.as_matrix()` with mixed `datetime64[ns]` and `timedelta64[ns]` dtypes (GH7778)
- Bug in `HDFStore.select_column()` not preserving UTC timezone info when selecting a `DatetimeIndex` (GH7777)
- Bug in `to_datetime` when `format='%Y%m%d'` and `coerce=True` are specified, where previously an object array was returned (rather than a coerced time-series with `NaT`), (GH7930)
- Bug in `DatetimeIndex` and `PeriodIndex` in-place addition and subtraction cause different result from normal one (GH6527)

- Bug in adding and subtracting `PeriodIndex` with `PeriodIndex` raise `TypeError` (GH7741)
- Bug in `combine_first` with `PeriodIndex` data raises `TypeError` (GH3367)
- Bug in `MultiIndex` slicing with missing indexers (GH7866)
- Bug in `MultiIndex` slicing with various edge cases (GH8132)
- Regression in `MultiIndex` indexing with a non-scalar type object (GH7914)
- Bug in `Timestamp` comparisons with `==` and `int64` dtype (GH8058)
- Bug in pickles contains `DateOffset` may raise `AttributeError` when `normalize` attribute is referred internally (GH7748)
- Bug in `Panel` when using `major_xs` and `copy=False` is passed (deprecation warning fails because of missing warnings) (GH8152).
- Bug in pickle deserialization that failed for pre-0.14.1 containers with dup items trying to avoid ambiguity when matching block and manager items, when there's only one block there's no ambiguity (GH7794)
- Bug in putting a `PeriodIndex` into a `Series` would convert to `int64` dtype, rather than object of `Periods` (GH7932)
- Bug in `HDFStore` iteration when passing a `where` (GH8014)
- Bug in `DataFrameGroupby.transform` when transforming with a passed non-sorted key (GH8046, GH8430)
- Bug in repeated timeseries line and area plot may result in `ValueError` or incorrect kind (GH7733)
- Bug in inference in a `MultiIndex` with `datetime.date` inputs (GH7888)
- Bug in `get` where an `IndexError` would not cause the default value to be returned (GH7725)
- Bug in `offsets.apply`, `rollforward` and `rollback` may reset nanosecond (GH7697)
- Bug in `offsets.apply`, `rollforward` and `rollback` may raise `AttributeError` if `Timestamp` has `dateutil.tzinfo` (GH7697)
- Bug in sorting a `MultiIndex` frame with a `Float64Index` (GH8017)
- Bug in inconsistent panel setitem with a rhs of a `DataFrame` for alignment (GH7763)
- Bug in `is_superperiod` and `is_subperiod` cannot handle higher frequencies than S (GH7760, GH7772, GH7803)
- Bug in 32-bit platforms with `Series.shift` (GH8129)
- Bug in `PeriodIndex.unique` returns `int64 np.ndarray` (GH7540)
- Bug in `groupby.apply` with a non-affecting mutation in the function (GH8467)
- Bug in `DataFrame.reset_index` which has `MultiIndex` contains `PeriodIndex` or `DatetimeIndex` with tz raises `ValueError` (GH7746, GH7793)
- Bug in `DataFrame.plot` with `subplots=True` may draw unnecessary minor xticks and yticks (GH7801)
- Bug in `StataReader` which did not read variable labels in 117 files due to difference between Stata documentation and implementation (GH7816)
- Bug in `StataReader` where strings were always converted to 244 characters-fixed width irrespective of underlying string size (GH7858)
- Bug in `DataFrame.plot` and `Series.plot` may ignore `rot` and `fontsize` keywords (GH7844)
- Bug in `DatetimeIndex.value_counts` doesn't preserve tz (GH7735)
- Bug in `PeriodIndex.value_counts` results in `Int64Index` (GH7735)

- Bug in `DataFrame.join` when doing left join on index and there are multiple matches (GH5391)
- Bug in `GroupBy.transform()` where int groups with a transform that didn't preserve the index were incorrectly truncated (GH7972).
- Bug in `groupby` where callable objects without name attributes would take the wrong path, and produce a `DataFrame` instead of a `Series` (GH7929)
- Bug in `groupby` error message when a `DataFrame` grouping column is duplicated (GH7511)
- Bug in `read_html` where the `infer_types` argument forced coercion of date-likes incorrectly (GH7762, GH7032).
- Bug in `Series.str.cat` with an index which was filtered as to not include the first item (GH7857)
- Bug in `Timestamp` cannot parse nanosecond from string (GH7878)
- Bug in `Timestamp` with string offset and `tz` results incorrect (GH7833)
- Bug in `tslib.tz_convert` and `tslib.tz_convert_single` may return different results (GH7798)
- Bug in `DatetimeIndex.intersection` of non-overlapping timestamps with `tz` raises `IndexError` (GH7880)
- Bug in alignment with `TimeOps` and non-unique indexes (GH8363)
- Bug in `GroupBy.filter()` where fast path vs. slow path made the filter return a non scalar value that appeared valid but wasn't (GH7870).
- Bug in `date_range()/DatetimeIndex()` when the timezone was inferred from input dates yet incorrect times were returned when crossing DST boundaries (GH7835, GH7901).
- Bug in `to_excel()` where a negative sign was being prepended to positive infinity and was absent for negative infinity (GH7949)
- Bug in area plot draws legend with incorrect alpha when `stacked=True` (GH8027)
- `Period` and `PeriodIndex` addition/subtraction with `np.timedelta64` results in incorrect internal representations (GH7740)
- Bug in `Holiday` with no offset or observance (GH7987)
- Bug in `DataFrame.to_latex` formatting when columns or index is a `MultiIndex` (GH7982).
- Bug in `DateOffset` around Daylight Savings Time produces unexpected results (GH5175).
- Bug in `DataFrame.shift` where empty columns would throw `ZeroDivisionError` on numpy 1.7 (GH8019)
- Bug in installation where `html_encoding/*.html` wasn't installed and therefore some tests were not running correctly (GH7927).
- Bug in `read_html` where bytes objects were not tested for in `_read` (GH7927).
- Bug in `DataFrame.stack()` when one of the column levels was a datelike (GH8039)
- Bug in broadcasting numpy scalars with `DataFrame` (GH8116)
- Bug in `pivot_table` performed with nameless index and columns raises `KeyError` (GH8103)
- Bug in `DataFrame.plot(kind='scatter')` draws points and errorbars with different colors when the color is specified by `c` keyword (GH8081)
- Bug in `Float64Index` where `iat` and `at` were not testing and were failing (GH8092).
- Bug in `DataFrame.boxplot()` where y-limits were not set correctly when producing multiple axes (GH7528, GH5517).
- Bug in `read_csv` where line comments were not handled correctly given a custom line terminator or `delim_whitespace=True` (GH8122).

- Bug in `read_html` where empty tables caused a `StopIteration` (GH7575)
- Bug in casting when setting a column in a same-dtype block (GH7704)
- Bug in accessing groups from a `GroupBy` when the original grouper was a tuple (GH8121).
- Bug in `.at` that would accept integer indexers on a non-integer index and do fallback (GH7814)
- Bug with kde plot and NaNs (GH8182)
- Bug in `GroupBy.count` with float32 data type where nan values were not excluded (GH8169).
- Bug with stacked barplots and NaNs (GH8175).
- Bug in `resample` with non evenly divisible offsets (e.g. '7s') (GH8371)
- Bug in interpolation methods with the `limit` keyword when no values needed interpolating (GH7173).
- Bug where `col_space` was ignored in `DataFrame.to_string()` when `header=False` (GH8230).
- Bug with `DatetimeIndex.asof` incorrectly matching partial strings and returning the wrong date (GH8245).
- Bug in plotting methods modifying the global matplotlib rcParams (GH8242).
- Bug in `DataFrame.__setitem__` that caused errors when setting a dataframe column to a sparse array (GH8131)
- Bug where `DataFrame.boxplot()` failed when entire column was empty (GH8181).
- Bug with messed variables in `radviz` visualization (GH8199).
- Bug in interpolation methods with the `limit` keyword when no values needed interpolating (GH7173).
- Bug where `col_space` was ignored in `DataFrame.to_string()` when `header=False` (GH8230).
- Bug in `to_clipboard` that would clip long column data (GH8305)
- Bug in `DataFrame` terminal display: Setting `max_column/max_rows` to zero did not trigger auto-resizing of dfs to fit terminal width/height (GH7180).
- Bug in OLS where running with "cluster" and "nw\_lags" parameters did not work correctly, but also did not throw an error (GH5884).
- Bug in `DataFrame.dropna` that interpreted non-existent columns in the subset argument as the 'last column' (GH8303)
- Bug in `Index.intersection` on non-monotonic non-unique indexes (GH8362).
- Bug in masked series assignment where mismatching types would break alignment (GH8387)
- Bug in `NDFrame.equals` gives false negatives with `dtype=object` (GH8437)
- Bug in assignment with indexer where type diversity would break alignment (GH8258)
- Bug in `NDFrame.loc` indexing when row/column names were lost when target was a list/ndarray (GH6552)
- Regression in `NDFrame.loc` indexing when rows/columns were converted to `Float64Index` if target was an empty list/ndarray (GH7774)
- Bug in `Series` that allows it to be indexed by a `DataFrame` which has unexpected results. Such indexing is no longer permitted (GH8444)
- Bug in item assignment of a `DataFrame` with `MultiIndex` columns where right-hand-side columns were not aligned (GH7655)
- Suppress `FutureWarning` generated by NumPy when comparing object arrays containing NaN for equality (GH7065)
- Bug in `DataFrame.eval()` where the dtype of the not operator (`~`) was not correctly inferred as `bool`.

## 5.16 Version 0.14

### 5.16.1 Version 0.14.1 (July 11, 2014)

This is a minor release from 0.14.0 and includes a small number of API changes, several new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

- Highlights include:
  - New methods `select_dtypes()` to select columns based on the dtype and `sem()` to calculate the standard error of the mean.
  - Support for dateutil timezones (see *docs*).
  - Support for ignoring full line comments in the `read_csv()` text parser.
  - New documentation section on *Options and Settings*.
  - Lots of bug fixes.
- *Enhancements*
- *API Changes*
- *Performance Improvements*
- *Experimental Changes*
- *Bug Fixes*

## API changes

- Openpyxl now raises a `ValueError` on construction of the openpyxl writer instead of warning on pandas import (GH7284).
- For `StringMethods.extract`, when no match is found, the result - only containing NaN values - now also has `dtype=object` instead of `float` (GH7242)
- `Period` objects no longer raise a `TypeError` when compared using `==` with another object that *isn't* a `Period`. Instead when comparing a `Period` with another object using `==` if the other object isn't a `Period` `False` is returned. (GH7376)
- Previously, the behaviour on resetting the time or not in `offsets.apply`, `rollforward` and `rollback` operations differed between offsets. With the support of the `normalize` keyword for all offsets (see below) with a default value of `False` (preserve time), the behaviour changed for certain offsets (`BusinessMonthBegin`, `MonthEnd`, `BusinessMonthEnd`, `CustomBusinessMonthEnd`, `BusinessYearBegin`, `LastWeekOfMonth`, `FY5253Quarter`, `LastWeekOfMonth`, `Easter`):

```
In [6]: from pandas.tseries import offsets

In [7]: d = pd.Timestamp('2014-01-01 09:00')

old behaviour < 0.14.1
In [8]: d + offsets.MonthEnd()
Out[8]: pd.Timestamp('2014-01-31 00:00:00')
```

Starting from 0.14.1 all offsets preserve time by default. The old behaviour can be obtained with `normalize=True`

```
new behaviour
In [1]: d + offsets.MonthEnd()
Out[1]: Timestamp('2014-01-31 09:00:00')

In [2]: d + offsets.MonthEnd(normalize=True)
Out[2]: Timestamp('2014-01-31 00:00:00')
```

Note that for the other offsets the default behaviour did not change.

- Add back `#N/A N/A` as a default NA value in text parsing, (regression from 0.12) (GH5521)
- Raise a `TypeError` on inplace-setting with a `.where` and a non `np.nan` value as this is inconsistent with a set-item expression like `df[mask] = None` (GH7656)

## Enhancements

- Add `dropna` argument to `value_counts` and `nunique` (GH5569).
- Add `select_dtypes()` method to allow selection of columns based on dtype (GH7316). See *the docs*.
- All offsets supports the `normalize` keyword to specify whether `offsets.apply`, `rollforward` and `rollback` resets the time (hour, minute, etc) or not (default `False`, preserves time) (GH7156):

```
import pandas.tseries.offsets as offsets

day = offsets.Day()
day.apply(pd.Timestamp("2014-01-01 09:00"))
```

(continues on next page)

(continued from previous page)

```
day = offsets.Day(normalize=True)
day.apply(pd.Timestamp("2014-01-01 09:00"))
```

- `PeriodIndex` is represented as the same format as `DatetimeIndex` (GH7601)
- `StringMethods` now work on empty `Series` (GH7242)
- The file parsers `read_csv` and `read_table` now ignore line comments provided by the parameter `comment`, which accepts only a single character for the C reader. In particular, they allow for comments before file data begins (GH2685)
- Add `NotImplementedError` for simultaneous use of `chunksize` and `nrows` for `read_csv()` (GH6774).
- Tests for basic reading of public S3 buckets now exist (GH7281).
- `read_html` now sports an `encoding` argument that is passed to the underlying parser library. You can use this to read non-ascii encoded web pages (GH7323).
- `read_excel` now supports reading from URLs in the same way that `read_csv` does. (GH6809)
- Support for `dateutil` timezones, which can now be used in the same way as `pytz` timezones across `pandas`. (GH4688)

```
In [3]: rng = pd.date_range(
...: "3/6/2012 00:00", periods=10, freq="D", tz="dateutil/Europe/London"
...:)
...:
```

```
In [4]: rng.tz
```

```
Out[4]: tzfile('/usr/share/zoneinfo/Europe/London')
```

See *the docs*.

- Implemented `sem` (standard error of the mean) operation for `Series`, `DataFrame`, `Panel`, and `Groupby` (GH6897)
- Add `nlargest` and `nsmallest` to the `Series groupby` allowlist, which means you can now use these methods on a `SeriesGroupBy` object (GH7053).
- All `offsets` `apply`, `rollforward` and `rollback` can now handle `np.datetime64`, previously results in `ApplyTypeError` (GH7452)
- `Period` and `PeriodIndex` can contain `NaT` in its values (GH7485)
- Support pickling `Series`, `DataFrame` and `Panel` objects with non-unique labels along *item* axis (`index`, `columns` and `items` respectively) (GH7370).
- Improved inference of `datetime/timedelta` with mixed null objects. Regression from 0.13.1 in interpretation of an object `Index` with all null elements (GH7431)

## Performance

- Improvements in dtype inference for numeric operations involving yielding performance gains for dtypes: `int64`, `timedelta64`, `datetime64` (GH7223)
- Improvements in `Series.transform` for significant performance gains (GH6496)
- Improvements in `DataFrame.transform` with `ufuncs` and built-in grouper functions for significant performance gains (GH7383)
- Regression in groupby aggregation of `datetime64` dtypes (GH7555)
- Improvements in `MultiIndex.from_product` for large iterables (GH7627)

## Experimental

- `pandas.io.data.Options` has a new method, `get_all_data` method, and now consistently returns a Multi-Indexed `DataFrame` (GH5602)
- `io.gbq.read_gbq` and `io.gbq.to_gbq` were refactored to remove the dependency on the Google `bq.py` command line client. This submodule now uses `httplib2` and the Google `apiclient` and `oauth2client` API client libraries which should be more stable and, therefore, reliable than `bq.py`. See *the docs*. (GH6937).

## Bug fixes

- Bug in `DataFrame.where` with a symmetric shaped frame and a passed other of a `DataFrame` (GH7506)
- Bug in Panel indexing with a `MultiIndex` axis (GH7516)
- Regression in datetimelike slice indexing with a duplicated index and non-exact end-points (GH7523)
- Bug in `setitem` with list-of-lists and single vs mixed types (GH7551:)
- Bug in time ops with non-aligned `Series` (GH7500)
- Bug in `timedelta` inference when assigning an incomplete `Series` (GH7592)
- Bug in groupby `.nth` with a `Series` and integer-like column name (GH7559)
- Bug in `Series.get` with a boolean accessor (GH7407)
- Bug in `value_counts` where `NaT` did not qualify as missing (`NaN`) (GH7423)
- Bug in `to_timedelta` that accepted invalid units and misinterpreted 'm/h' (GH7611, GH6423)
- Bug in line plot doesn't set correct `xlim` if `secondary_y=True` (GH7459)
- Bug in grouped `hist` and `scatter` plots use old `figsize` default (GH7394)
- Bug in plotting subplots with `DataFrame.plot`, `hist` clears passed `ax` even if the number of subplots is one (GH7391).
- Bug in plotting subplots with `DataFrame.boxplot` with `by` kw raises `ValueError` if the number of subplots exceeds 1 (GH7391).
- Bug in subplots displays `ticklabels` and `labels` in different rule (GH5897)
- Bug in `Panel.apply` with a `MultiIndex` as an axis (GH7469)
- Bug in `DatetimeIndex.insert` doesn't preserve name and `tz` (GH7299)
- Bug in `DatetimeIndex.asobject` doesn't preserve name (GH7299)
- Bug in `MultiIndex` slicing with datetimelike ranges (strings and `Timestamps`), (GH7429)

- Bug in `Index.min` and `max` doesn't handle nan and NaT properly (GH7261)
- Bug in `PeriodIndex.min/max` results in int (GH7609)
- Bug in `resample` where `fill_method` was ignored if you passed `how` (GH2073)
- Bug in `TimeGrouper` doesn't exclude column specified by key (GH7227)
- Bug in `DataFrame` and `Series` bar and `barh` plot raises `TypeError` when `bottom` and `left` keyword is specified (GH7226)
- Bug in `DataFrame.hist` raises `TypeError` when it contains non numeric column (GH7277)
- Bug in `Index.delete` does not preserve name and `freq` attributes (GH7302)
- Bug in `DataFrame.query()/eval` where local string variables with the `@` sign were being treated as temporaries attempting to be deleted (GH7300).
- Bug in `Float64Index` which didn't allow duplicates (GH7149).
- Bug in `DataFrame.replace()` where truthy values were being replaced (GH7140).
- Bug in `StringMethods.extract()` where a single match group `Series` would use the matcher's name instead of the group name (GH7313).
- Bug in `isnull()` when `mode.use_inf_as_null == True` where `isnull` wouldn't test `True` when it encountered an `inf/-inf` (GH7315).
- Bug in `inferred_freq` results in `None` for eastern hemisphere timezones (GH7310)
- Bug in `Easter` returns incorrect date when offset is negative (GH7195)
- Bug in broadcasting with `.div`, integer dtypes and divide-by-zero (GH7325)
- Bug in `CustomBusinessDay.apply` raises `NameError` when `np.datetime64` object is passed (GH7196)
- Bug in `MultiIndex.append`, `concat` and `pivot_table` don't preserve timezone (GH6606)
- Bug in `.loc` with a list of indexers on a single-multi index level (that is not nested) (GH7349)
- Bug in `Series.map` when mapping a dict with tuple keys of different lengths (GH7333)
- Bug all `StringMethods` now work on empty `Series` (GH7242)
- Fix delegation of `read_sql` to `read_sql_query` when query does not contain 'select' (GH7324).
- Bug where a string column name assignment to a `DataFrame` with a `Float64Index` raised a `TypeError` during a call to `np.isnan` (GH7366).
- Bug where `NDFrame.replace()` didn't correctly replace objects with `Period` values (GH7379).
- Bug in `.ix` `getitem` should always return a `Series` (GH7150)
- Bug in `MultiIndex` slicing with incomplete indexers (GH7399)
- Bug in `MultiIndex` slicing with a step in a sliced level (GH7400)
- Bug where negative indexers in `DatetimeIndex` were not correctly sliced (GH7408)
- Bug where `NaT` wasn't repr'd correctly in a `MultiIndex` (GH7406, GH7409).
- Bug where `bool` objects were converted to `nan` in `convert_objects` (GH7416).
- Bug in `quantile` ignoring the `axis` keyword argument (GH7306)
- Bug where `nanops._maybe_null_out` doesn't work with complex numbers (GH7353)
- Bug in several `nanops` functions when `axis==0` for 1-dimensional nan arrays (GH7354)
- Bug where `nanops.nanmedian` doesn't work when `axis==None` (GH7352)

- Bug where `nanops._has_infs` doesn't work with many dtypes (GH7357)
- Bug in `StataReader.data` where reading a 0-observation dta failed (GH7369)
- Bug in `StataReader` when reading Stata 13 (117) files containing fixed width strings (GH7360)
- Bug in `StataWriter` where encoding was ignored (GH7286)
- Bug in `DatetimeIndex` comparison doesn't handle NaT properly (GH7529)
- Bug in passing input with `tzinfo` to some offsets `apply`, `rollforward` or `rollback` resets `tzinfo` or raises `ValueError` (GH7465)
- Bug in `DatetimeIndex.to_period`, `PeriodIndex.asobject`, `PeriodIndex.to_timestamp` doesn't preserve name (GH7485)
- Bug in `DatetimeIndex.to_period` and `PeriodIndex.to_timestamp` handle NaT incorrectly (GH7228)
- Bug in `offsets.apply`, `rollforward` and `rollback` may return normal datetime (GH7502)
- Bug in `resample` raises `ValueError` when target contains NaT (GH7227)
- Bug in `Timestamp.tz_localize` resets nanosecond info (GH7534)
- Bug in `DatetimeIndex.asobject` raises `ValueError` when it contains NaT (GH7539)
- Bug in `Timestamp.__new__` doesn't preserve nanosecond properly (GH7610)
- Bug in `Index.astype(float)` where it would return an object dtype `Index` (GH7464).
- Bug in `DataFrame.reset_index` loses `tz` (GH3950)
- Bug in `DatetimeIndex.freqstr` raises `AttributeError` when `freq` is `None` (GH7606)
- Bug in `GroupBy.size` created by `TimeGrouper` raises `AttributeError` (GH7453)
- Bug in single column bar plot is misaligned (GH7498).
- Bug in area plot with tz-aware time series raises `ValueError` (GH7471)
- Bug in non-monotonic `Index.union` may preserve name incorrectly (GH7458)
- Bug in `DatetimeIndex.intersection` doesn't preserve timezone (GH4690)
- Bug in `rolling_var` where a window larger than the array would raise an error (GH7297)
- Bug with last plotted timeseries dictating `xlim` (GH2960)
- Bug with secondary\_y axis not being considered for timeseries `xlim` (GH3490)
- Bug in `Float64Index` assignment with a non scalar indexer (GH7586)
- Bug in `pandas.core.strings.str_contains` does not properly match in a case insensitive fashion when `regex=False` and `case=False` (GH7505)
- Bug in `expanding_cov`, `expanding_corr`, `rolling_cov`, and `rolling_corr` for two arguments with mismatched index (GH7512)
- Bug in `to_sql` taking the boolean column as text column (GH7678)
- Bug in grouped `hist` doesn't handle `rot` kw and `sharex` kw properly (GH7234)
- Bug in `.loc` performing fallback integer indexing with object dtype indices (GH7496)
- Bug (`regression`) in `PeriodIndex` constructor when passed `Series` objects (GH7701).

### **5.16.2 Version 0.14.0 (May 31 , 2014)**

This is a major release from 0.13.1 and includes a small number of API changes, several new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

- Highlights include:
  - Officially support Python 3.4
  - SQL interfaces updated to use sqlalchemy, See [Here](#).
  - Display interface changes, See [Here](#)
  - MultiIndexing Using Slicers, See [Here](#).
  - Ability to join a singly-indexed DataFrame with a MultiIndexed DataFrame, see [Here](#)
  - More consistency in groupby results and more flexible groupby specifications, See [Here](#)
  - Holiday calendars are now supported in CustomBusinessDay, see [Here](#)
  - Several improvements in plotting functions, including: hexbin, area and pie plots, see [Here](#).
  - Performance doc section on I/O operations, See [Here](#)
- *Other Enhancements*
- *API Changes*
- *Text Parsing API Changes*
- *Groupby API Changes*
- *Performance Improvements*
- *Prior Deprecations*
- *Deprecations*
- *Known Issues*
- *Bug Fixes*

**Warning:** In 0.14.0 all NDFrame based containers have undergone significant internal refactoring. Before that each block of homogeneous data had its own labels and extra care was necessary to keep those in sync with the parent container's labels. This should not have any visible user/API behavior changes ([GH6745](#))

## API changes

- `read_excel` uses 0 as the default sheet ([GH6573](#))
- `iloc` will now accept out-of-bounds indexers for slices, e.g. a value that exceeds the length of the object being indexed. These will be excluded. This will make pandas conform more with python/numpy indexing of out-of-bounds values. A single indexer that is out-of-bounds and drops the dimensions of the object will still raise `IndexError` ([GH6296](#), [GH6299](#)). This could result in an empty axis (e.g. an empty DataFrame being returned)

```
In [1]: dfl = pd.DataFrame(np.random.randn(5, 2), columns=list('AB'))
```

```
In [2]: dfl
```

```
Out[2]:
```

|---|-----------|-----------|
| 4 | -0.861849 | -2.104569 |

```
[1 rows x 2 columns]
```

These are out-of-bounds selections

```
>>> df1.iloc[[4, 5, 6]]
IndexError: positional indexers are out-of-bounds

>>> df1.iloc[:, 4]
IndexError: single positional indexer is out-of-bounds
```

- Slicing with negative start, stop & step values handles corner cases better (GH6531):
  - `df.iloc[:-len(df)]` is now empty
  - `df.iloc[len(df):-1]` now enumerates all elements in reverse
- The `DataFrame.interpolate()` keyword `downcast` default has been changed from `infer` to `None`. This is to preserve the original dtype unless explicitly requested otherwise (GH6290).
- When converting a dataframe to HTML it used to return `Empty DataFrame`. This special case has been removed, instead a header with the column names is returned (GH6062).
- `Series` and `Index` now internally share more common operations, e.g. `factorize()`, `nunique()`, `value_counts()` are now supported on `Index` types as well. The `Series.weekday` property from is removed from `Series` for API consistency. Using a `DatetimeIndex/PeriodIndex` method on a `Series` will now raise a `TypeError`. (GH4551, GH4056, GH5519, GH6380, GH7206).
- Add `is_month_start`, `is_month_end`, `is_quarter_start`, `is_quarter_end`, `is_year_start`, `is_year_end` accessors for `DatetimeIndex / Timestamp` which return a boolean array of whether the timestamp(s) are at the start/end of the month/quarter/year defined by the frequency of the `DatetimeIndex / Timestamp` (GH4565, GH6998)
- Local variable usage has changed in `pandas.eval()/DataFrame.eval()/DataFrame.query()` (GH5987). For the `DataFrame` methods, two things have changed
  - Column names are now given precedence over locals
  - Local variables must be referred to explicitly. This means that even if you have a local variable that is *not* a column you must still refer to it with the '@' prefix.
  - You can have an expression like `df.query('@a < a')` with no complaints from pandas about ambiguity of the name `a`.
  - The top-level `pandas.eval()` function does not allow you use the '@' prefix and provides you with an error message telling you so.
  - `NameResolutionError` was removed because it isn't necessary anymore.
- Define and document the order of column vs index names in `query/eval` (GH6676)
- `concat` will now concatenate mixed `Series` and `DataFrames` using the `Series` name or numbering columns as needed (GH2385). See *the docs*
- Slicing and advanced/boolean indexing operations on `Index` classes as well as `Index.delete()` and `Index.drop()` methods will no longer change the type of the resulting index (GH6440, GH7040)

```
In [6]: i = pd.Index([1, 2, 3, 'a', 'b', 'c'])

In [7]: i[[0, 1, 2]]
Out[7]: Index([1, 2, 3], dtype='object')

In [8]: i.drop(['a', 'b', 'c'])
Out[8]: Index([1, 2, 3], dtype='object')
```

Previously, the above operation would return `Int64Index`. If you'd like to do this manually, use `Index.astype()`

```
In [9]: i[[0, 1, 2]].astype(np.int_)
Out[9]: Int64Index([1, 2, 3], dtype='int64')
```

- `set_index` no longer converts `MultiIndex`s to an `Index` of tuples. For example, the old behavior returned an `Index` in this case ([GH6459](#)):

```
Old behavior, casted MultiIndex to an Index
In [10]: tuple_ind
Out[10]: Index([('a', 'c'), ('a', 'd'), ('b', 'c'), ('b', 'd')], dtype='object')

In [11]: df_multi.set_index(tuple_ind)
Out[11]:
```

|        | 0         | 1         |
|--------|-----------|-----------|
| (a, c) | 0.471435  | -1.190976 |
| (a, d) | 1.432707  | -0.312652 |
| (b, c) | -0.720589 | 0.887163  |
| (b, d) | 0.859588  | -0.636524 |

```
[4 rows x 2 columns]

New behavior
In [12]: mi
Out[12]:
MultiIndex([('a', 'c'),
 ('a', 'd'),
 ('b', 'c'),
 ('b', 'd')],
)

In [13]: df_multi.set_index(mi)
Out[13]:
```

|     | 0         | 1         |
|-----|-----------|-----------|
| a c | 0.471435  | -1.190976 |
| d   | 1.432707  | -0.312652 |
| b c | -0.720589 | 0.887163  |
| d   | 0.859588  | -0.636524 |

```
[4 rows x 2 columns]
```

This also applies when passing multiple indices to `set_index`:

```
Old output, 2-level MultiIndex of tuples
In [14]: df_multi.set_index([df_multi.index, df_multi.index])
Out[14]:
```

|               | 0         | 1         |
|---------------|-----------|-----------|
| (a, c) (a, c) | 0.471435  | -1.190976 |
| (a, d) (a, d) | 1.432707  | -0.312652 |
| (b, c) (b, c) | -0.720589 | 0.887163  |
| (b, d) (b, d) | 0.859588  | -0.636524 |

```
[4 rows x 2 columns]
```

(continues on next page)

(continued from previous page)

```
New output, 4-level MultiIndex
In [15]: df_multi.set_index([df_multi.index, df_multi.index])
Out[15]:
```

|         | 0         | 1         |
|---------|-----------|-----------|
| a c a c | 0.471435  | -1.190976 |
| d a d   | 1.432707  | -0.312652 |
| b c b c | -0.720589 | 0.887163  |
| d b d   | 0.859588  | -0.636524 |

```
[4 rows x 2 columns]
```

- pairwise keyword was added to the statistical moment functions `rolling_cov`, `rolling_corr`, `ewmcov`, `ewmcorr`, `expanding_cov`, `expanding_corr` to allow the calculation of moving window covariance and correlation matrices (GH4950). See *Computing rolling pairwise covariances and correlations* in the docs.

```
In [1]: df = pd.DataFrame(np.random.randn(10, 4), columns=list('ABCD'))

In [4]: covs = pd.rolling_cov(df[['A', 'B', 'C']],
.....: df[['B', 'C', 'D']],
.....: 5,
.....: pairwise=True)

In [5]: covs[df.index[-1]]
Out[5]:
```

|   | B         | C         | D         |
|---|-----------|-----------|-----------|
| A | 0.035310  | 0.326593  | -0.505430 |
| B | 0.137748  | -0.006888 | -0.005383 |
| C | -0.006888 | 0.861040  | 0.020762  |

- `Series.iteritems()` is now lazy (returns an iterator rather than a list). This was the documented behavior prior to 0.14. (GH6760)
- Added `nunique` and `value_counts` functions to `Index` for counting unique elements. (GH6734)
- `stack` and `unstack` now raise a `ValueError` when the `level` keyword refers to a non-unique item in the `Index` (previously raised a `KeyError`). (GH6738)
- drop unused `order` argument from `Series.sort`; args now are in the same order as `Series.order`; add `na_position` arg to conform to `Series.order` (GH6847)
- default sorting algorithm for `Series.order` is now `quicksort`, to conform with `Series.sort` (and numpy defaults)
- add `inplace` keyword to `Series.order/sort` to make them inverses (GH6859)
- `DataFrame.sort` now places NaNs at the beginning or end of the sort according to the `na_position` parameter. (GH3917)
- accept `TextFileReader` in `concat`, which was affecting a common user idiom (GH6583), this was a regression from 0.13.1
- Added `factorize` functions to `Index` and `Series` to get indexer and unique values (GH7090)
- `describe` on a `DataFrame` with a mix of `Timestamp` and string like objects returns a different `Index` (GH7088). Previously the index was unintentionally sorted.

- Arithmetic operations with **only** bool dtypes now give a warning indicating that they are evaluated in Python space for +, -, and \* operations and raise for all others (GH7011, GH6762, GH7015, GH7210)

```
>>> x = pd.Series(np.random.rand(10) > 0.5)
>>> y = True
>>> x + y # warning generated: should do x | y instead
UserWarning: evaluating in Python space because the '+' operator is not
supported by numexpr for the bool dtype, use '|' instead
>>> x / y # this raises because it doesn't make sense
NotImplementedError: operator '/' not implemented for bool dtypes
```

- In HDFStore, select\_as\_multiple will always raise a KeyError, when a key or the selector is not found (GH6177)
- df['col'] = value and df.loc[:, 'col'] = value are now completely equivalent; previously the .loc would not necessarily coerce the dtype of the resultant series (GH6149)
- dtypes and ftypes now return a series with dtype=object on empty containers (GH5740)
- df.to\_csv will now return a string of the CSV data if neither a target path nor a buffer is provided (GH6061)
- pd.infer\_freq() will now raise a TypeError if given an invalid Series/Index type (GH6407, GH6463)
- A tuple passed to DataFrame.sort\_index will be interpreted as the levels of the index, rather than requiring a list of tuple (GH4370)
- all offset operations now return Timestamp types (rather than datetime), Business/Week frequencies were incorrect (GH4069)
- to\_excel now converts np.inf into a string representation, customizable by the inf\_rep keyword argument (Excel has no native inf representation) (GH6782)
- Replace pandas.compat.scipy.scoreatpercentile with numpy.percentile (GH6810)
- .quantile on a datetime[ns] series now returns Timestamp instead of np.datetime64 objects (GH6810)
- change AssertionError to TypeError for invalid types passed to concat (GH6583)
- Raise a TypeError when DataFrame is passed an iterator as the data argument (GH5357)

## Display changes

- The default way of printing large DataFrames has changed. DataFrames exceeding max\_rows and/or max\_columns are now displayed in a centrally truncated view, consistent with the printing of a pandas.Series (GH5603).

In previous versions, a DataFrame was truncated once the dimension constraints were reached and an ellipse (...) signaled that part of the data was cut off.

```
In [1]: import pandas as pd
In [2]: import numpy as np
In [3]: pd.options.display.max_rows = 6
In [4]: pd.options.display.max_columns = 6
In [5]: index = pd.DatetimeIndex(start='20010101', freq='D', periods=10)
```

```
In [6]: pd.DataFrame(np.arange(10*10).reshape((10,10)), index=index)
```

```
Out[6]:
 0 1 2 3 4 5 ...
2001-01-01 0 1 2 3 4 5 ...
2001-01-02 10 11 12 13 14 15 ...
2001-01-03 20 21 22 23 24 25 ...
2001-01-04 30 31 32 33 34 35 ...
2001-01-05 40 41 42 43 44 45 ...
2001-01-06 50 51 52 53 54 55 ...
... ..
```

```
[10 rows x 10 columns]
```

In the current version, large DataFrames are centrally truncated, showing a preview of head and tail in both dimensions.

```
In [24]: pd.DataFrame(np.arange(10*10).reshape((10,10)), index=index)
```

```
Out[24]:
 0 1 2 ... 7 8 9
2001-01-01 0 1 2 ... 7 8 9
2001-01-02 10 11 12 ... 17 18 19
2001-01-03 20 21 22 ... 27 28 29
... ..
2001-01-08 70 71 72 ... 77 78 79
2001-01-09 80 81 82 ... 87 88 89
2001-01-10 90 91 92 ... 97 98 99
```

```
[10 rows x 10 columns]
```

- allow option 'truncate' for `display.show_dimensions` to only show the dimensions if the frame is truncated (GH6547).

The default for `display.show_dimensions` will now be `truncate`. This is consistent with how Series display length.

```
In [16]: dfd = pd.DataFrame(np.arange(25).reshape(-1, 5),
.....: index=[0, 1, 2, 3, 4],
.....: columns=[0, 1, 2, 3, 4])
.....:
```

```
show dimensions since this is truncated
```

```
In [17]: with pd.option_context('display.max_rows', 2, 'display.max_columns', 2,
```

(continues on next page)

(continued from previous page)

```

.....: 'display.show_dimensions', 'truncate'):
.....: print(dfd)
.....:
0 0 ... 4
..
4 20 ... 24

[5 rows x 5 columns]

will not show dimensions since it is not truncated
In [18]: with pd.option_context('display.max_rows', 10, 'display.max_columns', 40,
.....: 'display.show_dimensions', 'truncate'):
.....: print(dfd)
.....:
0 0 1 2 3 4
0 0 1 2 3 4
1 5 6 7 8 9
2 10 11 12 13 14
3 15 16 17 18 19
4 20 21 22 23 24

```

- Regression in the display of a MultiIndexed Series with `display.max_rows` is less than the length of the series (GH7101)
- Fixed a bug in the HTML repr of a truncated Series or DataFrame not showing the class name with the `large_repr` set to 'info' (GH7105)
- The `verbose` keyword in `DataFrame.info()`, which controls whether to shorten the `info` representation, is now `None` by default. This will follow the global setting in `display.max_info_columns`. The global setting can be overridden with `verbose=True` or `verbose=False`.
- Fixed a bug with the `info` repr not honoring the `display.max_info_columns` setting (GH6939)
- Offset/freq info now in `Timestamp.__repr__` (GH4553)

## Text parsing API changes

`read_csv()/read_table()` will now be noisier w.r.t invalid options rather than falling back to the `PythonParser`.

- Raise `ValueError` when `sep` specified with `delim_whitespace=True` in `read_csv()/read_table()` (GH6607)
- Raise `ValueError` when `engine='c'` specified with unsupported options in `read_csv()/read_table()` (GH6607)
- Raise `ValueError` when fallback to python parser causes options to be ignored (GH6607)
- Produce `ParserWarning` on fallback to python parser when no options are ignored (GH6607)
- Translate `sep='\s+'` to `delim_whitespace=True` in `read_csv()/read_table()` if no other C-unsupported options specified (GH6607)

## GroupBy API changes

More consistent behavior for some groupby methods:

- groupby head and tail now act more like filter rather than an aggregation:

```
In [19]: df = pd.DataFrame([[1, 2], [1, 4], [5, 6]], columns=['A', 'B'])
In [20]: g = df.groupby('A')
In [21]: g.head(1) # filters DataFrame
Out[21]:
 A B
0 1 2
2 5 6

[2 rows x 2 columns]
In [22]: g.apply(lambda x: x.head(1)) # used to simply fall-through
Out[22]:
 A B
A
1 0 1 2
5 2 5 6

[2 rows x 2 columns]
```

- groupby head and tail respect column selection:

```
In [23]: g[['B']].head(1)
Out[23]:
 B
0 2
2 6

[2 rows x 1 columns]
```

- groupby nth now reduces by default; filtering can be achieved by passing `as_index=False`. With an optional `dropna` argument to ignore NaN. See [the docs](#).

Reducing

```
In [24]: df = pd.DataFrame([[1, np.nan], [1, 4], [5, 6]], columns=['A', 'B'])
In [25]: g = df.groupby('A')
In [26]: g.nth(0)
Out[26]:
 B
A
1 NaN
5 6.0

[2 rows x 1 columns]
```

(continues on next page)

(continued from previous page)

```
this is equivalent to g.first()
In [27]: g.nth(0, dropna='any')
Out[27]:
 B
A
1 4.0
5 6.0

[2 rows x 1 columns]

this is equivalent to g.last()
In [28]: g.nth(-1, dropna='any')
Out[28]:
 B
A
1 4.0
5 6.0

[2 rows x 1 columns]
```

## Filtering

```
In [29]: gf = df.groupby('A', as_index=False)

In [30]: gf.nth(0)
Out[30]:
 A B
0 1 NaN
2 5 6.0

[2 rows x 2 columns]

In [31]: gf.nth(0, dropna='any')
Out[31]:
 A B
1 1 4.0
5 5 6.0

[2 rows x 2 columns]
```

- `groupby` will now not return the grouped column for non-cython functions ([GH5610](#), [GH5614](#), [GH6732](#)), as its already the index

```
In [32]: df = pd.DataFrame([[1, np.nan], [1, 4], [5, 6], [5, 8]], columns=['A', 'B
→'])

In [33]: g = df.groupby('A')

In [34]: g.count()
Out[34]:
 B
```

(continues on next page)

(continued from previous page)

```

A
1 1
5 2

[2 rows x 1 columns]

In [35]: g.describe()
Out[35]:
 B
count mean std min 25% 50% 75% max
A
1 1.0 4.0 NaN 4.0 4.0 4.0 4.0 4.0
5 2.0 7.0 1.414214 6.0 6.5 7.0 7.5 8.0

[2 rows x 8 columns]

```

- passing `as_index` will leave the grouped column in-place (this is not change in 0.14.0)

```

In [36]: df = pd.DataFrame([[1, np.nan], [1, 4], [5, 6], [5, 8]], columns=['A', 'B
↳'])

In [37]: g = df.groupby('A', as_index=False)

In [38]: g.count()
Out[38]:
 A B
0 1 1
1 5 2

[2 rows x 2 columns]

In [39]: g.describe()
Out[39]:
 A B
count mean std min 25% 50% 75% max count mean std min 25% 50% 75%
↳ max
0 2.0 1.0 0.0 1.0 1.0 1.0 1.0 1.0 1.0 4.0 NaN 4.0 4.0 4.0 4.0
↳ 4.0
1 2.0 5.0 0.0 5.0 5.0 5.0 5.0 5.0 2.0 7.0 1.414214 6.0 6.5 7.0 7.5
↳ 8.0

[2 rows x 16 columns]

```

- Allow specification of a more complex groupby via `pd.Grouper`, such as grouping by a Time and a string field simultaneously. See *the docs*. (GH3794)
- Better propagation/preservation of Series names when performing groupby operations:
  - `SeriesGroupBy.agg` will ensure that the name attribute of the original series is propagated to the result (GH6265).
  - If the function provided to `GroupBy.apply` returns a named series, the name of the series will be kept as the name of the column index of the DataFrame returned by `GroupBy.apply` (GH6124). This facilitates

`DataFrame.stack` operations where the name of the column index is used as the name of the inserted column containing the pivoted data.

## SQL

The SQL reading and writing functions now support more database flavors through SQLAlchemy ([GH2717](#), [GH4163](#), [GH5950](#), [GH6292](#)). All databases supported by SQLAlchemy can be used, such as PostgreSQL, MySQL, Oracle, Microsoft SQL server (see documentation of SQLAlchemy on [included dialects](#)).

The functionality of providing DBAPI connection objects will only be supported for sqlite3 in the future. The 'mysql' flavor is deprecated.

The new functions `read_sql_query()` and `read_sql_table()` are introduced. The function `read_sql()` is kept as a convenience wrapper around the other two and will delegate to specific function depending on the provided input (database table name or sql query).

In practice, you have to provide a SQLAlchemy engine to the sql functions. To connect with SQLAlchemy you use the `create_engine()` function to create an engine object from database URI. You only need to create the engine once per database you are connecting to. For an in-memory sqlite database:

```
In [40]: from sqlalchemy import create_engine
Create your connection.
In [41]: engine = create_engine('sqlite:///memory:')
```

This engine can then be used to write or read data to/from this database:

```
In [42]: df = pd.DataFrame({'A': [1, 2, 3], 'B': ['a', 'b', 'c']})
In [43]: df.to_sql('db_table', engine, index=False)
```

You can read data from a database by specifying the table name:

```
In [44]: pd.read_sql_table('db_table', engine)
Out[44]:
 A B
0 1 a
1 2 b
2 3 c

[3 rows x 2 columns]
```

or by specifying a sql query:

```
In [45]: pd.read_sql_query('SELECT * FROM db_table', engine)
Out[45]:
 A B
0 1 a
1 2 b
2 3 c

[3 rows x 2 columns]
```

Some other enhancements to the sql functions include:

- support for writing the index. This can be controlled with the `index` keyword (default is `True`).

- specify the column label to use when writing the index with `index_label`.
- specify string columns to parse as datetimes with the `parse_dates` keyword in `read_sql_query()` and `read_sql_table()`.

**Warning:** Some of the existing functions or function aliases have been deprecated and will be removed in future versions. This includes: `tquery`, `uquery`, `read_frame`, `frame_query`, `write_frame`.

**Warning:** The support for the ‘mysql’ flavor when using DBAPI connection objects has been deprecated. MySQL will be further supported with SQLAlchemy engines ([GH6900](#)).

### Multi-indexing using slicers

In 0.14.0 we added a new way to slice MultiIndexed objects. You can slice a MultiIndex by providing multiple indexers.

You can provide any of the selectors as if you are indexing by label, see *Selection by Label*, including slices, lists of labels, labels, and boolean indexers.

You can use `slice(None)` to select all the contents of *that* level. You do not need to specify all the *deeper* levels, they will be implied as `slice(None)`.

As usual, **both sides** of the slicers are included as this is label indexing.

See *the docs* See also issues ([GH6134](#), [GH4036](#), [GH3057](#), [GH2598](#), [GH5641](#), [GH7106](#))

**Warning:**

You should specify all axes in the `.loc` specifier, meaning the indexer for the **index** and for the **columns**. There are some ambiguous cases where the passed indexer could be mis-interpreted as indexing *both* axes, rather than into say the MultiIndex for the rows.

You should do this:

```
>>> df.loc[(slice('A1', 'A3'), ...), :] # noqa: E901
```

rather than this:

```
>>> df.loc[(slice('A1', 'A3'), ...)] # noqa: E901
```

**Warning:** You will need to make sure that the selection axes are fully lexsorted!

```
In [46]: def mklbl(prefix, n):
.....: return ["%s%s" % (prefix, i) for i in range(n)]
.....:

In [47]: index = pd.MultiIndex.from_product([mklbl('A', 4),
.....: mklbl('B', 2),
.....: mklbl('C', 4),
.....: mklbl('D', 2)])
.....:
```

(continues on next page)

(continued from previous page)

```
In [48]: columns = pd.MultiIndex.from_tuples([('a', 'foo'), ('a', 'bar'),
.....: ('b', 'foo'), ('b', 'bah')],
.....: names=['lvl0', 'lvl1'])
.....:

In [49]: df = pd.DataFrame(np.arange(len(index) * len(columns)).reshape((len(index),
.....: len(columns))),
.....: index=index,
.....: columns=columns).sort_index().sort_index(axis=1)
.....:

In [50]: df
Out[50]:
```

| lvl0 |    |     |     | a   |     | b   |     |
|------|----|-----|-----|-----|-----|-----|-----|
| lvl1 |    | bar | foo | bah | foo |     |     |
| A0   | B0 | C0  | D0  | 1   | 0   | 3   | 2   |
|      |    |     | D1  | 5   | 4   | 7   | 6   |
|      |    | C1  | D0  | 9   | 8   | 11  | 10  |
|      |    |     | D1  | 13  | 12  | 15  | 14  |
|      |    | C2  | D0  | 17  | 16  | 19  | 18  |
| ...  |    |     | ... | ... | ... | ... | ... |
| A3   | B1 | C1  | D1  | 237 | 236 | 239 | 238 |
|      |    | C2  | D0  | 241 | 240 | 243 | 242 |
|      |    |     | D1  | 245 | 244 | 247 | 246 |
|      |    | C3  | D0  | 249 | 248 | 251 | 250 |
|      |    |     | D1  | 253 | 252 | 255 | 254 |

[64 rows x 4 columns]

Basic MultiIndex slicing using slices, lists, and labels.

```
In [51]: df.loc[(slice('A1', 'A3'), slice(None), ['C1', 'C3']), :]
Out[51]:
```

| lvl0 |    |     |     | a   |     | b   |     |
|------|----|-----|-----|-----|-----|-----|-----|
| lvl1 |    | bar | foo | bah | foo |     |     |
| A1   | B0 | C1  | D0  | 73  | 72  | 75  | 74  |
|      |    |     | D1  | 77  | 76  | 79  | 78  |
|      |    | C3  | D0  | 89  | 88  | 91  | 90  |
|      |    |     | D1  | 93  | 92  | 95  | 94  |
|      | B1 | C1  | D0  | 105 | 104 | 107 | 106 |
| ...  |    |     | ... | ... | ... | ... | ... |
| A3   | B0 | C3  | D1  | 221 | 220 | 223 | 222 |
|      | B1 | C1  | D0  | 233 | 232 | 235 | 234 |
|      |    |     | D1  | 237 | 236 | 239 | 238 |
|      |    | C3  | D0  | 249 | 248 | 251 | 250 |
|      |    |     | D1  | 253 | 252 | 255 | 254 |

[24 rows x 4 columns]

You can use a `pd.IndexSlice` to shortcut the creation of these slices

```
In [52]: idx = pd.IndexSlice
```

```
In [53]: df.loc[idx[:, :, ['C1', 'C3']], idx[:, 'foo']]
```

```
Out[53]:
```

```
lvl0 a b
lvl1 foo foo
A0 B0 C1 D0 8 10
 D1 12 14
 C3 D0 24 26
 D1 28 30
 B1 C1 D0 40 42
...
A3 B0 C3 D1 220 222
 B1 C1 D0 232 234
 D1 236 238
 C3 D0 248 250
 D1 252 254
```

```
[32 rows x 2 columns]
```

It is possible to perform quite complicated selections using this method on multiple axes at the same time.

```
In [54]: df.loc['A1', (slice(None), 'foo')]
```

```
Out[54]:
```

```
lvl0 a b
lvl1 foo foo
B0 C0 D0 64 66
 D1 68 70
 C1 D0 72 74
 D1 76 78
 C2 D0 80 82
...
B1 C1 D1 108 110
 C2 D0 112 114
 D1 116 118
 C3 D0 120 122
 D1 124 126
```

```
[16 rows x 2 columns]
```

```
In [55]: df.loc[idx[:, :, ['C1', 'C3']], idx[:, 'foo']]
```

```
Out[55]:
```

```
lvl0 a b
lvl1 foo foo
A0 B0 C1 D0 8 10
 D1 12 14
 C3 D0 24 26
 D1 28 30
 B1 C1 D0 40 42
...
A3 B0 C3 D1 220 222
 B1 C1 D0 232 234
 D1 236 238
```

(continues on next page)

(continued from previous page)

```

C3 D0 248 250
 D1 252 254

[32 rows x 2 columns]

```

Using a boolean indexer you can provide selection related to the *values*.

```

In [56]: mask = df[('a', 'foo')] > 200

In [57]: df.loc[idx[mask, :], ['C1', 'C3']], idx[:, 'foo']]
Out[57]:
lvl0 a b
lvl1 foo foo
A3 B0 C1 D1 204 206
 C3 D0 216 218
 D1 220 222
 B1 C1 D0 232 234
 D1 236 238
 C3 D0 248 250
 D1 252 254

[7 rows x 2 columns]

```

You can also specify the `axis` argument to `.loc` to interpret the passed slicers on a single axis.

```

In [58]: df.loc(axis=0)[:, :, ['C1', 'C3']]
Out[58]:
lvl0 a b
lvl1 bar foo bah foo
A0 B0 C1 D0 9 8 11 10
 D1 13 12 15 14
 C3 D0 25 24 27 26
 D1 29 28 31 30
 B1 C1 D0 41 40 43 42
...
A3 B0 C3 D1 221 220 223 222
 B1 C1 D0 233 232 235 234
 D1 237 236 239 238
 C3 D0 249 248 251 250
 D1 253 252 255 254

[32 rows x 4 columns]

```

Furthermore you can *set* the values using these methods

```

In [59]: df2 = df.copy()

In [60]: df2.loc(axis=0)[:, :, ['C1', 'C3']] = -10

In [61]: df2
Out[61]:
lvl0 a b
lvl1 bar foo bah foo

```

(continues on next page)

(continued from previous page)

```

A0 B0 C0 D0 1 0 3 2
 D1 5 4 7 6
 C1 D0 -10 -10 -10 -10
 D1 -10 -10 -10 -10
 C2 D0 17 16 19 18
...
A3 B1 C1 D1 -10 -10 -10 -10
 C2 D0 241 240 243 242
 D1 245 244 247 246
 C3 D0 -10 -10 -10 -10
 D1 -10 -10 -10 -10

```

[64 rows x 4 columns]

You can use a right-hand-side of an alignable object as well.

```
In [62]: df2 = df.copy()
```

```
In [63]: df2.loc[idx[:, :, ['C1', 'C3']], :] = df2 * 1000
```

```
In [64]: df2
```

```
Out[64]:
```

```

lvl0 a b
lvl1 bar foo bah foo
A0 B0 C0 D0 1 0 3 2
 D1 5 4 7 6
 C1 D0 9000 8000 11000 10000
 D1 13000 12000 15000 14000
 C2 D0 17 16 19 18
...
A3 B1 C1 D1 237000 236000 239000 238000
 C2 D0 241 240 243 242
 D1 245 244 247 246
 C3 D0 249000 248000 251000 250000
 D1 253000 252000 255000 254000

```

[64 rows x 4 columns]

## Plotting

- Hexagonal bin plots from `DataFrame.plot` with `kind='hexbin'` ([GH5478](#)), See *the docs*.
- `DataFrame.plot` and `Series.plot` now supports area plot with specifying `kind='area'` ([GH6656](#)), See *the docs*
- Pie plots from `Series.plot` and `DataFrame.plot` with `kind='pie'` ([GH6976](#)), See *the docs*.
- Plotting with Error Bars is now supported in the `.plot` method of `DataFrame` and `Series` objects ([GH3796](#), [GH6834](#)), See *the docs*.
- `DataFrame.plot` and `Series.plot` now support a `table` keyword for plotting `matplotlib.Table`, See *the docs*. The `table` keyword can receive the following values.
  - `False`: Do nothing (default).

- True: Draw a table using the DataFrame or Series called plot method. Data will be transposed to meet matplotlib's default layout.
- DataFrame or Series: Draw matplotlib.table using the passed data. The data will be drawn as displayed in print method (not transposed automatically). Also, helper function pandas.tools.plotting.table is added to create a table from DataFrame and Series, and add it to an matplotlib.Axes.
- plot(legend='reverse') will now reverse the order of legend labels for most plot kinds. (GH6014)
- Line plot and area plot can be stacked by stacked=True (GH6656)
- Following keywords are now acceptable for DataFrame.plot() with kind='bar' and kind='barh':
  - width: Specify the bar width. In previous versions, static value 0.5 was passed to matplotlib and it cannot be overwritten. (GH6604)
  - align: Specify the bar alignment. Default is center (different from matplotlib). In previous versions, pandas passes align='edge' to matplotlib and adjust the location to center by itself, and it results align keyword is not applied as expected. (GH4525)
  - position: Specify relative alignments for bar plot layout. From 0 (left/bottom-end) to 1(right/top-end). Default is 0.5 (center). (GH6604)

Because of the default align value changes, coordinates of bar plots are now located on integer values (0.0, 1.0, 2.0 ...). This is intended to make bar plot be located on the same coordinates as line plot. However, bar plot may differs unexpectedly when you manually adjust the bar location or drawing area, such as using set\_xlim, set\_ylim, etc. In this cases, please modify your script to meet with new coordinates.

- The parallel\_coordinates() function now takes argument color instead of colors. A FutureWarning is raised to alert that the old colors argument will not be supported in a future release. (GH6956)
- The parallel\_coordinates() and andrews\_curves() functions now take positional argument frame instead of data. A FutureWarning is raised if the old data argument is used by name. (GH6956)
- DataFrame.boxplot() now supports layout keyword (GH6769)
- DataFrame.boxplot() has a new keyword argument, return\_type. It accepts 'dict', 'axes', or 'both', in which case a namedtuple with the matplotlib axes and a dict of matplotlib Lines is returned.

## Prior version deprecations/changes

There are prior version deprecations that are taking effect as of 0.14.0.

- Remove DateRange in favor of DatetimeIndex (GH6816)
- Remove column keyword from DataFrame.sort (GH4370)
- Remove precision keyword from set\_eng\_float\_format() (GH395)
- Remove force\_unicode keyword from DataFrame.to\_string(), DataFrame.to\_latex(), and DataFrame.to\_html(); these function encode in unicode by default (GH2224, GH2225)
- Remove nanRep keyword from DataFrame.to\_csv() and DataFrame.to\_string() (GH275)
- Remove unique keyword from HDFStore.select\_column() (GH3256)
- Remove inferTimeRule keyword from Timestamp.offset() (GH391)
- Remove name keyword from get\_data\_yahoo() and get\_data\_google() (commit b921d1a)
- Remove offset keyword from DatetimeIndex constructor (commit 3136390)
- Remove time\_rule from several rolling-moment statistical functions, such as rolling\_sum() (GH1042)

- Removed `neg` – boolean operations on numpy arrays in favor of `inv ~`, as this is going to be deprecated in numpy 1.9 (GH6960)

## Deprecations

- The `pivot_table()/DataFrame.pivot_table()` and `crosstab()` functions now take arguments `index` and `columns` instead of `rows` and `cols`. A `FutureWarning` is raised to alert that the old `rows` and `cols` arguments will not be supported in a future release (GH5505)
- The `DataFrame.drop_duplicates()` and `DataFrame.duplicated()` methods now take argument `subset` instead of `cols` to better align with `DataFrame.dropna()`. A `FutureWarning` is raised to alert that the old `cols` arguments will not be supported in a future release (GH6680)
- The `DataFrame.to_csv()` and `DataFrame.to_excel()` functions now takes argument `columns` instead of `cols`. A `FutureWarning` is raised to alert that the old `cols` arguments will not be supported in a future release (GH6645)
- Indexers will warn `FutureWarning` when used with a scalar indexer and a non-floating point `Index` (GH4892, GH6960)

```
non-floating point indexes can only be indexed by integers / labels
In [1]: pd.Series(1, np.arange(5))[3.0]
pandas/core/index.py:469: FutureWarning: scalar indexers for index type
↳Int64Index should be integers and not floating point
Out[1]: 1

In [2]: pd.Series(1, np.arange(5)).iloc[3.0]
pandas/core/index.py:469: FutureWarning: scalar indexers for index type
↳Int64Index should be integers and not floating point
Out[2]: 1

In [3]: pd.Series(1, np.arange(5)).iloc[3.0:4]
pandas/core/index.py:527: FutureWarning: slice indexers when using iloc
↳should be integers and not floating point
Out[3]:
 3 1
dtype: int64

these are Float64Indexes, so integer or floating point is acceptable
In [4]: pd.Series(1, np.arange(5.))[3]
Out[4]: 1

In [5]: pd.Series(1, np.arange(5.))[3.0]
Out[6]: 1
```

- Numpy 1.9 compat w.r.t. deprecation warnings (GH6960)
- `Panel.shift()` now has a function signature that matches `DataFrame.shift()`. The old positional argument `lags` has been changed to a keyword argument `periods` with a default value of 1. A `FutureWarning` is raised if the old argument `lags` is used by name. (GH6910)
- The order keyword argument of `factorize()` will be removed. (GH6926).
- Remove the `copy` keyword from `DataFrame.xs()`, `Panel.major_xs()`, `Panel.minor_xs()`. A view will be returned if possible, otherwise a copy will be made. Previously the user could think that `copy=False` would ALWAYS return a view. (GH6894)

- The `parallel_coordinates()` function now takes argument `color` instead of `colors`. A `FutureWarning` is raised to alert that the old `colors` argument will not be supported in a future release. (GH6956)
- The `parallel_coordinates()` and `andrews_curves()` functions now take positional argument `frame` instead of `data`. A `FutureWarning` is raised if the old `data` argument is used by name. (GH6956)
- The support for the 'mysql' flavor when using DBAPI connection objects has been deprecated. MySQL will be further supported with SQLAlchemy engines (GH6900).
- The following `io.sql` functions have been deprecated: `tquery`, `uquery`, `read_frame`, `frame_query`, `write_frame`.
- The `percentile_width` keyword argument in `describe()` has been deprecated. Use the `percentiles` keyword instead, which takes a list of percentiles to display. The default output is unchanged.
- The default return type of `boxplot()` will change from a dict to a matplotlib Axes in a future release. You can use the future behavior now by passing `return_type='axes'` to `boxplot`.

### Known issues

- OpenPyXL 2.0.0 breaks backwards compatibility (GH7169)

### Enhancements

- DataFrame and Series will create a MultiIndex object if passed a tuples dict, See *the docs* (GH3323)

```
In [65]: pd.Series({'a', 'b'): 1, ('a', 'a'): 0,
.....: ('a', 'c'): 2, ('b', 'a'): 3, ('b', 'b'): 4})
.....:
Out[65]:
a b 1
 a 0
 c 2
b a 3
 b 4
Length: 5, dtype: int64

In [66]: pd.DataFrame({'a', 'b'): {'A', 'B'): 1, ('A', 'C'): 2},
.....: ('a', 'a'): {'A', 'C'): 3, ('A', 'B'): 4},
.....: ('a', 'c'): {'A', 'B'): 5, ('A', 'C'): 6},
.....: ('b', 'a'): {'A', 'C'): 7, ('A', 'B'): 8},
.....: ('b', 'b'): {'A', 'D'): 9, ('A', 'B'): 10})
.....:
Out[66]:

A B 1.0 4.0 5.0 8.0 10.0
C 2.0 3.0 6.0 7.0 NaN
D NaN NaN NaN NaN 9.0

[3 rows x 5 columns]
```

- Added the `sym_diff` method to `Index` (GH5543)
- `DataFrame.to_latex` now takes a `longtable` keyword, which if `True` will return a table in a `longtable` environment. (GH6617)

- Add option to turn off escaping in DataFrame.to\_latex (GH6472)
- pd.read\_clipboard will, if the keyword sep is unspecified, try to detect data copied from a spreadsheet and parse accordingly. (GH6223)
- Joining a singly-indexed DataFrame with a MultiIndexed DataFrame (GH3662)

See *the docs*. Joining MultiIndex DataFrames on both the left and right is not yet supported ATM.

```
In [67]: household = pd.DataFrame({'household_id': [1, 2, 3],
.....: 'male': [0, 1, 0],

```

- `quotechar`, `doublequote`, and `escapechar` can now be specified when using `DataFrame.to_csv` (GH5414, GH4528)
- Partially sort by only the specified levels of a `MultiIndex` with the `sort_remaining` boolean kwarg. (GH3984)
- Added `to_julian_date` to `TimeStamp` and `DatetimeIndex`. The Julian Date is used primarily in astronomy and represents the number of days from noon, January 1, 4713 BC. Because nanoseconds are used to define the time in pandas the actual range of dates that you can use is 1678 AD to 2262 AD. (GH4041)
- `DataFrame.to_stata` will now check data for compatibility with Stata data types and will upcast when needed. When it is not possible to losslessly upcast, a warning is issued (GH6327)
- `DataFrame.to_stata` and `StataWriter` will accept keyword arguments `time_stamp` and `data_label` which allow the time stamp and dataset label to be set when creating a file. (GH6545)
- `pandas.io.gbq` now handles reading unicode strings properly. (GH5940)
- *Holidays Calendars* are now available and can be used with the `CustomBusinessDay` offset (GH6719)
- `Float64Index` is now backed by a `float64` dtype ndarray instead of an object dtype array (GH6471).
- Implemented `Panel.pct_change` (GH6904)
- Added `how` option to rolling-moment functions to dictate how to handle resampling; `rolling_max()` defaults to max, `rolling_min()` defaults to min, and all others default to mean (GH6297)
- `CustomBusinessMonthBegin` and `CustomBusinessMonthEnd` are now available (GH6866)
- `Series.quantile()` and `DataFrame.quantile()` now accept an array of quantiles.
- `describe()` now accepts an array of percentiles to include in the summary statistics (GH4196)
- `pivot_table` can now accept `Groupby` by `index` and `columns` keywords (GH6913)

```

In [72]: import datetime

In [73]: df = pd.DataFrame({
.....: 'Branch': 'A A A A B'.split(),

- `read_excel` can now read milliseconds in Excel dates and times with `xlrd >= 0.9.3`. ([GH5945](#))
- `pd.stats.moments.rolling_var` now uses Welford's method for increased numerical stability ([GH6817](#))
- `pd.expanding_apply` and `pd.rolling_apply` now take args and kwargs that are passed on to the func ([GH6289](#))
- `DataFrame.rank()` now has a percentage rank option ([GH5971](#))
- `Series.rank()` now has a percentage rank option ([GH5971](#))
- `Series.rank()` and `DataFrame.rank()` now accept `method='dense'` for ranks without gaps ([GH6514](#))
- Support passing encoding with `xlwt` ([GH3710](#))
- Refactor Block classes removing `Block.items` attributes to avoid duplication in item handling ([GH6745](#), [GH6988](#)).
- Testing statements updated to use specialized asserts ([GH6175](#))

## Performance

- Performance improvement when converting `DatetimeIndex` to floating ordinals using `DatetimeConverter` (GH6636)
- Performance improvement for `DataFrame.shift` (GH5609)
- Performance improvement in indexing into a `MultiIndexed Series` (GH5567)
- Performance improvements in single-dtyped indexing (GH6484)
- Improve performance of `DataFrame` construction with certain offsets, by removing faulty caching (e.g. `MonthEnd`, `BusinessMonthEnd`), (GH6479)
- Improve performance of `CustomBusinessDay` (GH6584)
- improve performance of slice indexing on `Series` with string keys (GH6341, GH6372)
- Performance improvement for `DataFrame.from_records` when reading a specified number of rows from an iterable (GH6700)
- Performance improvements in `timedelta` conversions for integer dtypes (GH6754)
- Improved performance of compatible pickles (GH6899)
- Improve performance in certain reindexing operations by optimizing `take_2d` (GH6749)
- `GroupBy.count()` is now implemented in Cython and is much faster for large numbers of groups (GH7016).

## Experimental

There are no experimental changes in 0.14.0

## Bug fixes

- Bug in `Series ValueError` when index doesn't match data (GH6532)
- Prevent segfault due to `MultiIndex` not being supported in `HDFStore` table format (GH1848)
- Bug in `pd.DataFrame.sort_index` where mergesort wasn't stable when `ascending=False` (GH6399)
- Bug in `pd.tseries.frequencies.to_offset` when argument has leading zeros (GH6391)
- Bug in version string gen. for dev versions with shallow clones / install from tarball (GH6127)
- Inconsistent tz parsing `Timestamp / to_datetime` for current year (GH5958)
- Indexing bugs with reordered indexes (GH6252, GH6254)
- Bug in `.xs` with a `Series` multiindex (GH6258, GH5684)
- Bug in conversion of a string types to a `DatetimeIndex` with a specified frequency (GH6273, GH6274)
- Bug in `eval` where type-promotion failed for large expressions (GH6205)
- Bug in `interpolate` with `inplace=True` (GH6281)
- `HDFStore.remove` now handles start and stop (GH6177)
- `HDFStore.select_as_multiple` handles start and stop the same way as `select` (GH6177)
- `HDFStore.select_as_coordinates` and `select_column` works with a `where` clause that results in filters (GH6177)
- Regression in join of non\_unique\_indexes (GH6329)

- Issue with groupby agg with a single function and a mixed-type frame (GH6337)
- Bug in DataFrame.replace() when passing a non-bool to\_replace argument (GH6332)
- Raise when trying to align on different levels of a MultiIndex assignment (GH3738)
- Bug in setting complex dtypes via boolean indexing (GH6345)
- Bug in TimeGrouper/resample when presented with a non-monotonic DatetimeIndex that would return invalid results. (GH4161)
- Bug in index name propagation in TimeGrouper/resample (GH4161)
- TimeGrouper has a more compatible API to the rest of the groupers (e.g. groups was missing) (GH3881)
- Bug in multiple grouping with a TimeGrouper depending on target column order (GH6764)
- Bug in pd.eval when parsing strings with possible tokens like '&' (GH6351)
- Bug correctly handle placements of -inf in Panels when dividing by integer 0 (GH6178)
- DataFrame.shift with axis=1 was raising (GH6371)
- Disabled clipboard tests until release time (run locally with nosetests -A disabled) (GH6048).
- Bug in DataFrame.replace() when passing a nested dict that contained keys not in the values to be replaced (GH6342)
- str.match ignored the na flag (GH6609).
- Bug in take with duplicate columns that were not consolidated (GH6240)
- Bug in interpolate changing dtypes (GH6290)
- Bug in Series.get, was using a buggy access method (GH6383)
- Bug in hdfstore queries of the form where=[('date', '>=', datetime(2013,1,1)), ('date', '<=', datetime(2014,1,1))] (GH6313)
- Bug in DataFrame.dropna with duplicate indices (GH6355)
- Regression in chained getitem indexing with embedded list-like from 0.12 (GH6394)
- Float64Index with nans not comparing correctly (GH6401)
- eval/query expressions with strings containing the @ character will now work (GH6366).
- Bug in Series.reindex when specifying a method with some nan values was inconsistent (noted on a resample) (GH6418)
- Bug in DataFrame.replace() where nested dicts were erroneously depending on the order of dictionary keys and values (GH5338).
- Performance issue in concatenating with empty objects (GH3259)
- Clarify sorting of sym\_diff on Index objects with NaN values (GH6444)
- Regression in MultiIndex.from\_product with a DatetimeIndex as input (GH6439)
- Bug in str.extract when passed a non-default index (GH6348)
- Bug in str.split when passed pat=None and n=1 (GH6466)
- Bug in io.data.DataReader when passed "F-F\_Momentum\_Factor" and data\_source="famafrench" (GH6460)
- Bug in sum of a timedelta64[ns] series (GH6462)
- Bug in resample with a timezone and certain offsets (GH6397)

- Bug in `iat/iloc` with duplicate indices on a Series ([GH6493](#))
- Bug in `read_html` where nan's were incorrectly being used to indicate missing values in text. Should use the empty string for consistency with the rest of pandas ([GH5129](#)).
- Bug in `read_html` tests where redirected invalid URLs would make one test fail ([GH6445](#)).
- Bug in multi-axis indexing using `.loc` on non-unique indices ([GH6504](#))
- Bug that caused `_ref_locs` corruption when slice indexing across columns axis of a DataFrame ([GH6525](#))
- Regression from 0.13 in the treatment of numpy `datetime64` non-ns dtypes in Series creation ([GH6529](#))
- `.names` attribute of MultiIndexes passed to `set_index` are now preserved ([GH6459](#)).
- Bug in `setitem` with a duplicate index and an alignable rhs ([GH6541](#))
- Bug in `setitem` with `.loc` on mixed integer Indexes ([GH6546](#))
- Bug in `pd.read_stata` which would use the wrong data types and missing values ([GH6327](#))
- Bug in `DataFrame.to_stata` that lead to data loss in certain cases, and could be exported using the wrong data types and missing values ([GH6335](#))
- `StataWriter` replaces missing values in string columns by empty string ([GH6802](#))
- Inconsistent types in `Timestamp` addition/subtraction ([GH6543](#))
- Bug in preserving frequency across `Timestamp` addition/subtraction ([GH4547](#))
- Bug in empty list lookup caused `IndexError` exceptions ([GH6536](#), [GH6551](#))
- `Series.quantile` raising on an object dtype ([GH6555](#))
- Bug in `.xs` with a nan in level when dropped ([GH6574](#))
- Bug in `fillna` with `method='bfill/ffill'` and `datetime64[ns]` dtype ([GH6587](#))
- Bug in sql writing with mixed dtypes possibly leading to data loss ([GH6509](#))
- Bug in `Series.pop` ([GH6600](#))
- Bug in `iloc` indexing when positional indexer matched `Int64Index` of the corresponding axis and no reordering happened ([GH6612](#))
- Bug in `fillna` with `limit` and `value` specified
- Bug in `DataFrame.to_stata` when columns have non-string names ([GH4558](#))
- Bug in `compat` with `np.compress`, surfaced in ([GH6658](#))
- Bug in binary operations with a rhs of a Series not aligning ([GH6681](#))
- Bug in `DataFrame.to_stata` which incorrectly handles nan values and ignores `with_index` keyword argument ([GH6685](#))
- Bug in `resample` with extra bins when using an evenly divisible frequency ([GH4076](#))
- Bug in consistency of `groupby` aggregation when passing a custom function ([GH6715](#))
- Bug in `resample` when `how=None` `resample` freq is the same as the axis frequency ([GH5955](#))
- Bug in downcasting inference with empty arrays ([GH6733](#))
- Bug in `obj.blocks` on sparse containers dropping all but the last items of same for dtype ([GH6748](#))
- Bug in unpickling `NaT` (`NaTType`) ([GH4606](#))
- Bug in `DataFrame.replace()` where regex meta characters were being treated as regex even when `regex=False` ([GH6777](#)).

- Bug in `timedelta` ops on 32-bit platforms (GH6808)
- Bug in setting a tz-aware index directly via `.index` (GH6785)
- Bug in `expressions.py` where `numexpr` would try to evaluate arithmetic ops (GH6762).
- Bug in Makefile where it didn't remove Cython generated C files with `make clean` (GH6768)
- Bug with `numpy < 1.7.2` when reading long strings from `HDFStore` (GH6166)
- Bug in `DataFrame._reduce` where non bool-like (0/1) integers were being converted into bools. (GH6806)
- Regression from 0.13 with `fillna` and a Series on datetime-like (GH6344)
- Bug in adding `np.timedelta64` to `DatetimeIndex` with `timezone` outputs incorrect results (GH6818)
- Bug in `DataFrame.replace()` where changing a dtype through replacement would only replace the first occurrence of a value (GH6689)
- Better error message when passing a frequency of 'MS' in `Period` construction (GH5332)
- Bug in `Series.__unicode__` when `max_rows=None` and the Series has more than 1000 rows. (GH6863)
- Bug in `groupby.get_group` where a datelike wasn't always accepted (GH5267)
- Bug in `groupBy.get_group` created by `TimeGrouper` raises `AttributeError` (GH6914)
- Bug in `DatetimeIndex.tz_localize` and `DatetimeIndex.tz_convert` converting `NaT` incorrectly (GH5546)
- Bug in arithmetic operations affecting `NaT` (GH6873)
- Bug in `Series.str.extract` where the resulting Series from a single group match wasn't renamed to the group name
- Bug in `DataFrame.to_csv` where setting `index=False` ignored the header kwarg (GH6186)
- Bug in `DataFrame.plot` and `Series.plot`, where the legend behave inconsistently when plotting to the same axes repeatedly (GH6678)
- Internal tests for patching `__finalize__` / bug in merge not finalizing (GH6923, GH6927)
- accept `TextFileReader` in `concat`, which was affecting a common user idiom (GH6583)
- Bug in C parser with leading white space (GH3374)
- Bug in C parser with `delim_whitespace=True` and `\r`-delimited lines
- Bug in python parser with explicit `MultiIndex` in row following column header (GH6893)
- Bug in `Series.rank` and `DataFrame.rank` that caused small floats ( $<1e-13$ ) to all receive the same rank (GH6886)
- Bug in `DataFrame.apply` with functions that used `*args` or `**kwargs` and returned an empty result (GH6952)
- Bug in `sum/mean` on 32-bit platforms on overflows (GH6915)
- Moved `Panel.shift` to `NDFrame.slice_shift` and fixed to respect multiple dtypes. (GH6959)
- Bug in enabling `subplots=True` in `DataFrame.plot` only has single column raises `TypeError`, and `Series.plot` raises `AttributeError` (GH6951)
- Bug in `DataFrame.plot` draws unnecessary axes when enabling `subplots` and `kind=scatter` (GH6951)
- Bug in `read_csv` from a filesystem with non-utf-8 encoding (GH6807)
- Bug in `iloc` when setting / aligning (GH6766)
- Bug causing `UnicodeEncodeError` when `get_dummies` called with unicode values and a prefix (GH6885)

- Bug in timeseries-with-frequency plot cursor display (GH5453)
- Bug surfaced in `groupby.plot` when using a `Float64Index` (GH7025)
- Stopped tests from failing if options data isn't able to be downloaded from Yahoo (GH7034)
- Bug in `parallel_coordinates` and `radviz` where reordering of class column caused possible color/class mismatch (GH6956)
- Bug in `radviz` and `andrews_curves` where multiple values of 'color' were being passed to plotting method (GH6956)
- Bug in `Float64Index.isin()` where containing nan s would make indices claim that they contained all the things (GH7066).
- Bug in `DataFrame.boxplot` where it failed to use the axis passed as the `ax` argument (GH3578)
- Bug in the `XlsxWriter` and `XlwtWriter` implementations that resulted in datetime columns being formatted without the time (GH7075) were being passed to plotting method
- `read_fwf()` treats `None` in `colspec` like regular python slices. It now reads from the beginning or until the end of the line when `colspec` contains a `None` (previously raised a `TypeError`)
- Bug in cache coherence with chained indexing and slicing; add `_is_view` property to `NDFrame` to correctly predict views; mark `is_copy` on `xs` only if its an actual copy (and not a view) (GH7084)
- Bug in `DatetimeIndex` creation from string ndarray with `dayfirst=True` (GH5917)
- Bug in `MultiIndex.from_arrays` created from `DatetimeIndex` doesn't preserve `freq` and `tz` (GH7090)
- Bug in `unstack` raises `ValueError` when `MultiIndex` contains `PeriodIndex` (GH4342)
- Bug in `boxplot` and `hist` draws unnecessary axes (GH6769)
- Regression in `groupby.nth()` for out-of-bounds indexers (GH6621)
- Bug in `quantile` with datetime values (GH6965)
- Bug in `Dataframe.set_index`, `reindex` and `pivot` don't preserve `DatetimeIndex` and `PeriodIndex` attributes (GH3950, GH5878, GH6631)
- Bug in `MultiIndex.get_level_values` doesn't preserve `DatetimeIndex` and `PeriodIndex` attributes (GH7092)
- Bug in `Groupby` doesn't preserve `tz` (GH3950)
- Bug in `PeriodIndex` partial string slicing (GH6716)
- Bug in the HTML repr of a truncated `Series` or `DataFrame` not showing the class name with the `large_repr` set to 'info' (GH7105)
- Bug in `DatetimeIndex` specifying `freq` raises `ValueError` when passed value is too short (GH7098)
- Fixed a bug with the `info` repr not honoring the `display.max_info_columns` setting (GH6939)
- Bug `PeriodIndex` string slicing with out of bounds values (GH5407)
- Fixed a memory error in the hashtable implementation/factorizer on resizing of large tables (GH7157)
- Bug in `isnull` when applied to 0-dimensional object arrays (GH7176)
- Bug in `query/eval` where global constants were not looked up correctly (GH7178)
- Bug in recognizing out-of-bounds positional list indexers with `iloc` and a multi-axis tuple indexer (GH7189)
- Bug in `setitem` with a single value, `MultiIndex` and integer indices (GH7190, GH7218)
- Bug in expressions evaluation with reversed ops, showing in series-dataframe ops (GH7198, GH7192)

- Bug in multi-axis indexing with > 2 ndim and a MultiIndex (GH7199)
- Fix a bug where invalid eval/query operations would blow the stack (GH5198)

## 5.17 Version 0.13

### 5.17.1 Version 0.13.1 (February 3, 2014)

This is a minor release from 0.13.0 and includes a small number of API changes, several new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

Highlights include:

- Added `infer_datetime_format` keyword to `read_csv/to_datetime` to allow speedups for homogeneously formatted datetimes.
- Will intelligently limit display precision for datetime/timedelta formats.
- Enhanced Panel `apply()` method.
- Suggested tutorials in new [Tutorials](#) section.
- Our pandas ecosystem is growing, We now feature related projects in a new Pandas Ecosystem section.
- Much work has been taking place on improving the docs, and a new [Contributing](#) section has been added.
- Even though it may only be of interest to devs, we <3 our new CI status page: [ScatterCI](#).

**Warning:** 0.13.1 fixes a bug that was caused by a combination of having numpy < 1.8, and doing chained assignment on a string-like array. Please review [the docs](#), chained indexing can have unexpected results and should generally be avoided.

This would previously segfault:

```
In [1]: df = pd.DataFrame({"A": np.array(["foo", "bar", "bah", "foo", "bar"])})
```

```
In [2]: df["A"].iloc[0] = np.nan
```

```
In [3]: df
```

```
Out[3]:
 A
0 NaN
1 bar
2 bah
3 foo
4 bar
```

The recommended way to do this type of assignment is:

```
In [4]: df = pd.DataFrame({"A": np.array(["foo", "bar", "bah", "foo", "bar"])})
```

```
In [5]: df.loc[0, "A"] = np.nan
```

```
In [6]: df
```

```
Out[6]:
 A
0 NaN
1 bar
2 bah
3 foo
4 bar
```

## Output formatting enhancements

- `df.info()` view now display dtype info per column (GH5682)
- `df.info()` now honors the option `max_info_rows`, to disable null counts for large frames (GH5974)

```
In [7]: max_info_rows = pd.get_option("max_info_rows")

In [8]: df = pd.DataFrame(
...: {
...: "A": np.random.randn(10),
...: "B": np.random.randn(10),
...: "C": pd.date_range("20130101", periods=10),
...: }
...:)
...:
```

```
In [9]: df.iloc[3:6, [0, 2]] = np.nan
```

```
set to not display the null counts
In [10]: pd.set_option("max_info_rows", 0)

In [11]: df.info()
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 10 entries, 0 to 9
Data columns (total 3 columns):
Column Dtype
--- ---
0 A float64
1 B float64
2 C datetime64[ns]
dtypes: datetime64[ns](1), float64(2)
memory usage: 368.0 bytes
```

```
this is the default (same as in 0.13.0)
In [12]: pd.set_option("max_info_rows", max_info_rows)

In [13]: df.info()
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 10 entries, 0 to 9
Data columns (total 3 columns):
Column Non-Null Count Dtype
--- ---
0 A 7 non-null float64
1 B 10 non-null float64
2 C 7 non-null datetime64[ns]
dtypes: datetime64[ns](1), float64(2)
memory usage: 368.0 bytes
```

- Add `show_dimensions` display option for the new DataFrame repr to control whether the dimensions print.

```
In [14]: df = pd.DataFrame([[1, 2], [3, 4]])
```

(continues on next page)

(continued from previous page)

```
In [15]: pd.set_option("show_dimensions", False)
```

```
In [16]: df
```

```
Out[16]:
```

```
 0 1
0 1 2
1 3 4
```

```
In [17]: pd.set_option("show_dimensions", True)
```

```
In [18]: df
```

```
Out[18]:
```

```
 0 1
0 1 2
1 3 4
```

```
[2 rows x 2 columns]
```

- The `ArrayFormatter` for `datetime` and `timedelta64` now intelligently limit precision based on the values in the array ([GH3401](#))

Previously output might look like:

```
 age today diff
0 2001-01-01 00:00:00 2013-04-19 00:00:00 4491 days, 00:00:00
1 2004-06-01 00:00:00 2013-04-19 00:00:00 3244 days, 00:00:00
```

Now the output looks like:

```
In [19]: df = pd.DataFrame(
.....: [pd.Timestamp("20010101"), pd.Timestamp("20040601")], columns=["age"]
.....:)
.....:
```

```
In [20]: df["today"] = pd.Timestamp("20130419")
```

```
In [21]: df["diff"] = df["today"] - df["age"]
```

```
In [22]: df
```

```
Out[22]:
```

```
 age today diff
0 2001-01-01 2013-04-19 4491 days
1 2004-06-01 2013-04-19 3244 days
```

```
[2 rows x 3 columns]
```

## API changes

- Add `-NaN` and `-nan` to the default set of NA values (GH5952). See *NA Values*.
- Added `Series.str.get_dummies` vectorized string method (GH6021), to extract dummy/indicator variables for separated string columns:

```
In [23]: s = pd.Series(["a", "a|b", np.nan, "a|c"])
```

```
In [24]: s.str.get_dummies(sep="|")
```

```
Out[24]:
```

```
 a b c
0 1 0 0
1 1 1 0
2 0 0 0
3 1 0 1
```

```
[4 rows x 3 columns]
```

- Added the `NDFrame.equals()` method to compare if two NDFrame are equal have equal axes, dtypes, and values. Added the `array_equivalent` function to compare if two ndarrays are equal. NaNs in identical locations are treated as equal. (GH5283) See also *the docs* for a motivating example.

```
df = pd.DataFrame({"col": ["foo", 0, np.nan]})
df2 = pd.DataFrame({"col": [np.nan, 0, "foo"]}, index=[2, 1, 0])
df.equals(df2)
df.equals(df2.sort_index())
```

- `DataFrame.apply` will use the `reduce` argument to determine whether a `Series` or a `DataFrame` should be returned when the `DataFrame` is empty (GH6007).

Previously, calling `DataFrame.apply` an empty `DataFrame` would return either a `DataFrame` if there were no columns, or the function being applied would be called with an empty `Series` to guess whether a `Series` or `DataFrame` should be returned:

```
In [32]: def applied_func(col):
```

```
....: print("Apply function being called with: ", col)
```

```
....: return col.sum()
```

```
....:
```

```
In [33]: empty = DataFrame(columns=['a', 'b'])
```

```
In [34]: empty.apply(applied_func)
```

```
Apply function being called with: Series([], Length: 0, dtype: float64)
```

```
Out[34]:
```

```
a NaN
```

```
b NaN
```

```
Length: 2, dtype: float64
```

Now, when `apply` is called on an empty `DataFrame`: if the `reduce` argument is `True` a `Series` will returned, if it is `False` a `DataFrame` will be returned, and if it is `None` (the default) the function being applied will be called with an empty series to try and guess the return type.

```
In [35]: empty.apply(applied_func, reduce=True)
```

```
Out[35]:
```

(continues on next page)

(continued from previous page)

```

a NaN
b NaN
Length: 2, dtype: float64

In [36]: empty.apply(applied_func, reduce=False)
Out[36]:
Empty DataFrame
Columns: [a, b]
Index: []

[0 rows x 2 columns]
```

### Prior version deprecations/changes

There are no announced changes in 0.13 or prior that are taking effect as of 0.13.1

### Deprecations

There are no deprecations of prior behavior in 0.13.1

### Enhancements

- `pd.read_csv` and `pd.to_datetime` learned a new `infer_datetime_format` keyword which greatly improves parsing perf in many cases. Thanks to @lexical for suggesting and @danbirken for rapidly implementing. (GH5490, GH6021)

If `parse_dates` is enabled and this flag is set, pandas will attempt to infer the format of the datetime strings in the columns, and if it can be inferred, switch to a faster method of parsing them. In some cases this can increase the parsing speed by ~5-10x.

```

Try to infer the format for the index column
df = pd.read_csv(
 "foo.csv", index_col=0, parse_dates=True, infer_datetime_format=True
)
```

- `date_format` and `datetime_format` keywords can now be specified when writing to excel files (GH4133)
- `MultiIndex.from_product` convenience function for creating a MultiIndex from the cartesian product of a set of iterables (GH6055):

```

In [25]: shades = ["light", "dark"]

In [26]: colors = ["red", "green", "blue"]

In [27]: pd.MultiIndex.from_product([shades, colors], names=["shade", "color"])
Out[27]:
MultiIndex([('light', 'red'),
 ('light', 'green'),
 ('light', 'blue'),
 ('dark', 'red'),
 ('dark', 'green')])
```

(continues on next page)

(continued from previous page)

```
('dark', 'blue')],
names=['shade', 'color'])
```

- Panel `apply()` will work on non-ufuncs. See *the docs*.

```
In [28]: import pandas._testing as tm
```

```
In [29]: panel = tm.makePanel(5)
```

```
In [30]: panel
```

```
Out[30]:
```

```
<class 'pandas.core.panel.Panel'>
Dimensions: 3 (items) x 5 (major_axis) x 4 (minor_axis)
Items axis: ItemA to ItemC
Major_axis axis: 2000-01-03 00:00:00 to 2000-01-07 00:00:00
Minor_axis axis: A to D
```

```
In [31]: panel['ItemA']
```

```
Out[31]:
```

|            | A         | B         | C         | D         |
|------------|-----------|-----------|-----------|-----------|
| 2000-01-03 | -0.673690 | 0.577046  | -1.344312 | -1.469388 |
| 2000-01-04 | 0.113648  | -1.715002 | 0.844885  | 0.357021  |
| 2000-01-05 | -1.478427 | -1.039268 | 1.075770  | -0.674600 |
| 2000-01-06 | 0.524988  | -0.370647 | -0.109050 | -1.776904 |
| 2000-01-07 | 0.404705  | -1.157892 | 1.643563  | -0.968914 |

```
[5 rows x 4 columns]
```

Specifying an `apply` that operates on a Series (to return a single element)

```
In [32]: panel.apply(lambda x: x.dtype, axis='items')
```

```
Out[32]:
```

|            | A       | B       | C       | D       |
|------------|---------|---------|---------|---------|
| 2000-01-03 | float64 | float64 | float64 | float64 |
| 2000-01-04 | float64 | float64 | float64 | float64 |
| 2000-01-05 | float64 | float64 | float64 | float64 |
| 2000-01-06 | float64 | float64 | float64 | float64 |
| 2000-01-07 | float64 | float64 | float64 | float64 |

```
[5 rows x 4 columns]
```

A similar reduction type operation

```
In [33]: panel.apply(lambda x: x.sum(), axis='major_axis')
```

```
Out[33]:
```

|   | ItemA     | ItemB     | ItemC     |
|---|-----------|-----------|-----------|
| A | -1.108775 | -1.090118 | -2.984435 |
| B | -3.705764 | 0.409204  | 1.866240  |
| C | 2.110856  | 2.960500  | -0.974967 |
| D | -4.532785 | 0.303202  | -3.685193 |

```
[4 rows x 3 columns]
```

This is equivalent to

```
In [34]: panel.sum('major_axis')
Out[34]:
 ItemA ItemB ItemC
A -1.108775 -1.090118 -2.984435
B -3.705764 0.409204 1.866240
C 2.110856 2.960500 -0.974967
D -4.532785 0.303202 -3.685193

[4 rows x 3 columns]
```

A transformation operation that returns a Panel, but is computing the z-score across the major\_axis

```
In [35]: result = panel.apply(lambda x: (x - x.mean()) / x.std(),
.....: axis='major_axis')
.....:

In [36]: result
Out[36]:
<class 'pandas.core.panel.Panel'>
Dimensions: 3 (items) x 5 (major_axis) x 4 (minor_axis)
Items axis: ItemA to ItemC
Major_axis axis: 2000-01-03 00:00:00 to 2000-01-07 00:00:00
Minor_axis axis: A to D

In [37]: result['ItemA'] # noqa E999
Out[37]:

[5 rows x 4 columns]

```

## Performance

Performance improvements for 0.13.1

- Series datetime/timedelta binary operations ([GH5801](#))
- DataFrame count/dropna for axis=1
- Series.str.contains now has a regex=False keyword which can be faster for plain (non-regex) string patterns. ([GH5879](#))
- Series.str.extract ([GH5944](#))
- dtypes/ftypes methods ([GH5968](#))
- indexing with object dtypes ([GH5968](#))
- DataFrame.apply ([GH6013](#))
- Regression in JSON IO ([GH5765](#))
- Index construction from Series ([GH6150](#))

## Experimental

There are no experimental changes in 0.13.1

## Bug fixes

- Bug in `io.wb.get_countries` not including all countries (GH6008)
- Bug in Series `replace` with timestamp dict (GH5797)
- `read_csv/read_table` now respects the `prefix` kwarg (GH5732).
- Bug in selection with missing values via `.ix` from a duplicate indexed DataFrame failing (GH5835)
- Fix issue of boolean comparison on empty DataFrames (GH5808)
- Bug in `isnull` handling NaT in an object array (GH5443)
- Bug in `to_datetime` when passed a `np.nan` or integer datelike and a format string (GH5863)
- Bug in groupby dtype conversion with datetimelike (GH5869)
- Regression in handling of empty Series as indexers to Series (GH5877)
- Bug in internal caching, related to (GH5727)
- Testing bug in reading JSON/msgpack from a non-filepath on windows under py3 (GH5874)
- Bug when assigning to `.ix[tuple(...)]` (GH5896)
- Bug in fully reindexing a Panel (GH5905)
- Bug in `idxmin/max` with object dtypes (GH5914)
- Bug in `BusinessDay` when adding `n` days to a date not on offset when `n>5` and `n%5==0` (GH5890)
- Bug in assigning to chained series with a series via `ix` (GH5928)
- Bug in creating an empty DataFrame, copying, then assigning (GH5932)
- Bug in `DataFrame.tail` with empty frame (GH5846)
- Bug in propagating metadata on `resample` (GH5862)
- Fixed string-representation of NaT to be “NaT” (GH5708)
- Fixed string-representation for Timestamp to show nanoseconds if present (GH5912)
- `pd.match` not returning passed sentinel
- `Panel.to_frame()` no longer fails when `major_axis` is a `MultiIndex` (GH5402).
- Bug in `pd.read_msgpack` with inferring a `DateTimeIndex` frequency incorrectly (GH5947)
- Fixed `to_datetime` for array with both Tz-aware datetimes and NaT’s (GH5961)
- Bug in rolling skew/kurtosis when passed a Series with bad data (GH5749)
- Bug in `scipy.interpolate` methods with a datetime index (GH5975)
- Bug in NaT comparison if a mixed datetime/`np.datetime64` with NaT were passed (GH5968)
- Fixed bug with `pd.concat` losing dtype information if all inputs are empty (GH5742)
- Recent changes in IPython cause warnings to be emitted when using previous versions of pandas in QTCConsole, now fixed. If you’re using an older version and need to suppress the warnings, see (GH5922).
- Bug in merging `timedelta` dtypes (GH5695)

- Bug in plotting.scatter\_matrix function. Wrong alignment among diagonal and off-diagonal plots, see (GH5497).
- Regression in Series with a MultiIndex via ix (GH6018)
- Bug in Series.xs with a MultiIndex (GH6018)
- Bug in Series construction of mixed type with datelike and an integer (which should result in object type and not automatic conversion) (GH6028)
- Possible segfault when chained indexing with an object array under NumPy 1.7.1 (GH6026, GH6056)
- Bug in setting using fancy indexing a single element with a non-scalar (e.g. a list), (GH6043)
- to\_sql did not respect if\_exists (GH4110 GH4304)
- Regression in .get(None) indexing from 0.12 (GH5652)
- Subtle iloc indexing bug, surfaced in (GH6059)
- Bug with insert of strings into DatetimeIndex (GH5818)
- Fixed unicode bug in to\_html/HTML repr (GH6098)
- Fixed missing arg validation in get\_options\_data (GH6105)
- Bug in assignment with duplicate columns in a frame where the locations are a slice (e.g. next to each other) (GH6120)
- Bug in propagating \_ref\_locs during construction of a DataFrame with dups index/columns (GH6121)
- Bug in DataFrame.apply when using mixed datelike reductions (GH6125)
- Bug in DataFrame.append when appending a row with different columns (GH6129)
- Bug in DataFrame construction with recarray and non-ns datetime dtype (GH6140)
- Bug in .loc setitem indexing with a dataframe on rhs, multiple item setting, and a datetimelike (GH6152)
- Fixed a bug in query/eval during lexicographic string comparisons (GH6155).
- Fixed a bug in query where the index of a single-element Series was being thrown away (GH6148).
- Bug in HDFStore on appending a dataframe with MultiIndexed columns to an existing table (GH6167)
- Consistency with dtypes in setting an empty DataFrame (GH6171)
- Bug in selecting on a MultiIndex HDFStore even in the presence of under specified column spec (GH6169)
- Bug in nanops.var with ddof=1 and 1 elements would sometimes return inf rather than nan on some platforms (GH6136)
- Bug in Series and DataFrame bar plots ignoring the use\_index keyword (GH6209)
- Bug in groupby with mixed str/int under python3 fixed; argsort was failing (GH6212)

### 5.17.2 Version 0.13.0 (January 3, 2014)

This is a major release from 0.12.0 and includes a number of API changes, several new features and enhancements along with a large number of bug fixes.

Highlights include:

- support for a new index type `Float64Index`, and other Indexing enhancements
- `HDFStore` has a new string based syntax for query specification
- support for new methods of interpolation
- updated `timedelta` operations
- a new string manipulation method `extract`
- Nanosecond support for Offsets
- `isin` for DataFrames

Several experimental features are added, including:

- new `eval/query` methods for expression evaluation
- support for `msgpack` serialization
- an `i/o` interface to Google's BigQuery

There are several new or updated docs sections including:

- *Comparison with SQL*, which should be useful for those familiar with SQL but still learning pandas.
- *Comparison with R*, idiom translations from R to pandas.
- *Enhancing Performance*, ways to enhance pandas performance with `eval/query`.

**Warning:** In 0.13.0 `Series` has internally been refactored to no longer sub-class `ndarray` but instead subclass `NDFrame`, similar to the rest of the pandas containers. This should be a transparent change with only very limited API implications. See *Internal Refactoring*

## API changes

- `read_excel` now supports an integer in its `sheetname` argument giving the index of the sheet to read in (GH4301).
- Text parser now treats anything that reads like inf (“inf”, “Inf”, “-Inf”, “iNf”, etc.) as infinity. (GH4220, GH4219), affecting `read_table`, `read_csv`, etc.
- pandas now is Python 2/3 compatible without the need for 2to3 thanks to @jtratner. As a result, pandas now uses iterators more extensively. This also led to the introduction of substantive parts of the Benjamin Peterson’s six library into compat. (GH4384, GH4375, GH4372)
- `pandas.util.compat` and `pandas.util.py3compat` have been merged into `pandas.compat`. `pandas.compat` now includes many functions allowing 2/3 compatibility. It contains both list and iterator versions of `range`, `filter`, `map` and `zip`, plus other necessary elements for Python 3 compatibility. `lmap`, `lzip`, `lrange` and `lfilter` all produce lists instead of iterators, for compatibility with `numpy`, subscripting and pandas constructors. (GH4384, GH4375, GH4372)
- `Series.get` with negative indexers now returns the same as `[]` (GH4390)
- Changes to how `Index` and `MultiIndex` handle metadata (`levels`, `labels`, and `names`) (GH4039):

```
previously, you would have set levels or labels directly
>>> pd.index.levels = [[1, 2, 3, 4], [1, 2, 4, 4]]

now, you use the set_levels or set_labels methods
>>> index = pd.index.set_levels([[1, 2, 3, 4], [1, 2, 4, 4]])

similarly, for names, you can rename the object
but setting names is not deprecated
>>> index = pd.index.set_names(["bob", "cranberry"])

and all methods take an inplace kwarg - but return None
>>> pd.index.set_names(["bob", "cranberry"], inplace=True)
```

- All division with `NDFrame` objects is now *truedivision*, regardless of the future import. This means that operating on pandas objects will by default use *floating point* division, and return a floating point dtype. You can use `//` and `floordiv` to do integer division.

Integer division

```
In [3]: arr = np.array([1, 2, 3, 4])

In [4]: arr2 = np.array([5, 3, 2, 1])

In [5]: arr / arr2
Out[5]: array([0, 0, 1, 4])

In [6]: pd.Series(arr) // pd.Series(arr2)
Out[6]:
0 0
1 0
2 1
3 4
dtype: int64
```

True Division

```
In [7]: pd.Series(arr) / pd.Series(arr2) # no future import required
Out[7]:
0 0.200000
1 0.666667
2 1.500000
3 4.000000
dtype: float64
```

- Infer and downcast dtype if `downcast='infer'` is passed to `fillna/ffill/bfill` (GH4604)
- `__nonzero__` for all NDFrame objects, will now raise a `ValueError`, this reverts back to (GH1073, GH4633) behavior. See *gotchas* for a more detailed discussion.

This prevents doing boolean comparison on *entire* pandas objects, which is inherently ambiguous. These all will raise a `ValueError`.

```
>>> df = pd.DataFrame({'A': np.random.randn(10),
... 'B': np.random.randn(10),
... 'C': pd.date_range('20130101', periods=10)
... })
...
>>> if df:
... pass
...
Traceback (most recent call last):
...
ValueError: The truth value of a DataFrame is ambiguous. Use a.empty,
a.bool(), a.item(), a.any() or a.all().

>>> df1 = df
>>> df2 = df
>>> df1 and df2
Traceback (most recent call last):
...
ValueError: The truth value of a DataFrame is ambiguous. Use a.empty,
a.bool(), a.item(), a.any() or a.all().

>>> d = [1, 2, 3]
>>> s1 = pd.Series(d)
>>> s2 = pd.Series(d)
>>> s1 and s2
Traceback (most recent call last):
...
ValueError: The truth value of a DataFrame is ambiguous. Use a.empty,
a.bool(), a.item(), a.any() or a.all().
```

Added the `.bool()` method to NDFrame objects to facilitate evaluating of single-element boolean Series:

```
In [1]: pd.Series([True]).bool()
Out[1]: True

In [2]: pd.Series([False]).bool()
Out[2]: False
```

(continues on next page)

(continued from previous page)

```
In [3]: pd.DataFrame([[True]]).bool()
Out[3]: True
```

```
In [4]: pd.DataFrame([[False]]).bool()
Out[4]: False
```

- All non-Index NDFrame (Series, DataFrame, Panel, Panel4D, SparsePanel, etc.), now support the entire set of arithmetic operators and arithmetic flex methods (add, sub, mul, etc.). SparsePanel does not support pow or mod with non-scalars. (GH3765)
- Series and DataFrame now have a mode() method to calculate the statistical mode(s) by axis/Series. (GH5367)
- Chained assignment will now by default warn if the user is assigning to a copy. This can be changed with the option mode.chained\_assignment, allowed options are raise/warn/None. See *the docs*.

```
In [5]: dfc = pd.DataFrame({'A': ['aaa', 'bbb', 'ccc'], 'B': [1, 2, 3]})
```

```
In [6]: pd.set_option('chained_assignment', 'warn')
```

The following warning / exception will show if this is attempted.

```
In [7]: dfc.loc[0]['A'] = 1111
```

```
Traceback (most recent call last)
```

```
...
SettingWithCopyWarning:
 A value is trying to be set on a copy of a slice from a DataFrame.
 Try using .loc[row_index,col_indexer] = value instead
```

Here is the correct method of assignment.

```
In [8]: dfc.loc[0, 'A'] = 11
```

```
In [9]: dfc
```

```
Out[9]:
 A B
0 11 1
1 bbb 2
2 ccc 3
```

- **Panel.reindex** has the following call signature `Panel.reindex(items=None, major_axis=None, minor_axis=None)`, to conform with other NDFrame objects. See *Internal Refactoring* for more information.
- **Series.argmax** and **Series.argmin** are now aliased to **Series.idxmin** and **Series.idxmax**. These return the *index* of the min or max element respectively. Prior to 0.13.0 these would return the position of the min / max element. (GH6214)

## Prior version deprecations/changes

These were announced changes in 0.12 or prior that are taking effect as of 0.13.0

- Remove deprecated `Factor` (GH3650)
- Remove deprecated `set_printoptions/reset_printoptions` (GH3046)
- Remove deprecated `_verbose_info` (GH3215)
- Remove deprecated `read_clipboard/to_clipboard/ExcelFile/ExcelWriter` from `pandas.io.parsers` (GH3717) These are available as functions in the main pandas namespace (e.g. `pd.read_clipboard`)
- default for `tupleize_cols` is now `False` for both `to_csv` and `read_csv`. Fair warning in 0.12 (GH3604)
- default for `display.max_seq_len` is now 100 rather than `None`. This activates truncated display (“...”) of long sequences in various places. (GH3391)

## Deprecations

Deprecated in 0.13.0

- deprecated `iterkv`, which will be removed in a future release (this was an alias of `iteritems` used to bypass 2to3’s changes). (GH4384, GH4375, GH4372)
- deprecated the string method `match`, whose role is now performed more idiomatically by `extract`. In a future release, the default behavior of `match` will change to become analogous to `contains`, which returns a boolean indexer. (Their distinction is strictness: `match` relies on `re.match` while `contains` relies on `re.search`.) In this release, the deprecated behavior is the default, but the new behavior is available through the keyword argument `as_indexer=True`.

## Indexing API changes

Prior to 0.13, it was impossible to use a label indexer (`.loc/.ix`) to set a value that was not contained in the index of a particular axis. (GH2578). See *the docs*

In the `Series` case this is effectively an appending operation

```
In [10]: s = pd.Series([1, 2, 3])
```

```
In [11]: s
```

```
Out[11]:
```

```
0 1
1 2
2 3
dtype: int64
```

```
In [12]: s[5] = 5.
```

```
In [13]: s
```

```
Out[13]:
```

```
0 1.0
1 2.0
2 3.0
5 5.0
dtype: float64
```

```
In [14]: dfi = pd.DataFrame(np.arange(6).reshape(3, 2),
.....: columns=['A', 'B'])
.....:
```

```
In [15]: dfi
```

```
Out[15]:
 A B
0 0 1
1 2 3
2 4 5
```

This would previously KeyError

```
In [16]: dfi.loc[:, 'C'] = dfi.loc[:, 'A']
```

```
In [17]: dfi
```

```
Out[17]:
 A B C
0 0 1 0
1 2 3 2
2 4 5 4
```

This is like an append operation.

```
In [18]: dfi.loc[3] = 5
```

```
In [19]: dfi
```

```
Out[19]:
 A B C
0 0 1 0
1 2 3 2
2 4 5 4
3 5 5 5
```

A Panel setting operation on an arbitrary axis aligns the input to the Panel

```
In [20]: p = pd.Panel(np.arange(16).reshape(2, 4, 2),
.....: items=['Item1', 'Item2'],
.....: major_axis=pd.date_range('2001/1/12', periods=4),
.....: minor_axis=['A', 'B'], dtype='float64')
.....:
```

```
In [21]: p
```

```
Out[21]:
<class 'pandas.core.panel.Panel'>
Dimensions: 2 (items) x 4 (major_axis) x 2 (minor_axis)
Items axis: Item1 to Item2
Major_axis axis: 2001-01-12 00:00:00 to 2001-01-15 00:00:00
Minor_axis axis: A to B
```

```
In [22]: p.loc[:, :, 'C'] = pd.Series([30, 32], index=p.items)
```

```
In [23]: p
```

(continues on next page)

(continued from previous page)

```

Out[23]:
<class 'pandas.core.panel.Panel'>
Dimensions: 2 (items) x 4 (major_axis) x 3 (minor_axis)
Items axis: Item1 to Item2
Major_axis axis: 2001-01-12 00:00:00 to 2001-01-15 00:00:00
Minor_axis axis: A to C

In [24]: p.loc[:, :, 'C']
Out[24]:

```

|            | Item1 | Item2 |
|------------|-------|-------|
| 2001-01-12 | 30.0  | 32.0  |
| 2001-01-13 | 30.0  | 32.0  |
| 2001-01-14 | 30.0  | 32.0  |
| 2001-01-15 | 30.0  | 32.0  |

### Float64Index API change

- Added a new index type, `Float64Index`. This will be automatically created when passing floating values in index creation. This enables a pure label-based slicing paradigm that makes `[]`, `.ix`, `.loc` for scalar indexing and slicing work exactly the same. See [the docs](#), (GH263)

Construction is by default for floating type values.

```

In [20]: index = pd.Index([1.5, 2, 3, 4.5, 5])

In [21]: index
Out[21]: Float64Index([1.5, 2.0, 3.0, 4.5, 5.0], dtype='float64')

In [22]: s = pd.Series(range(5), index=index)

In [23]: s
Out[23]:
1.5 0
2.0 1
3.0 2
4.5 3
5.0 4
dtype: int64

```

Scalar selection for `[]`, `.ix`, `.loc` will always be label based. An integer will match an equal float index (e.g. 3 is equivalent to 3.0)

```

In [24]: s[3]
Out[24]: 2

In [25]: s.loc[3]
Out[25]: 2

```

The only positional indexing is via `iloc`

```

In [26]: s.iloc[3]
Out[26]: 3

```

A scalar index that is not found will raise `KeyError`

Slicing is ALWAYS on the values of the index, for `[]`, `ix`, `loc` and ALWAYS positional with `iloc`

```
In [27]: s[2:4]
Out[27]:
2.0 1
3.0 2
dtype: int64

In [28]: s.loc[2:4]
Out[28]:
2.0 1
3.0 2
dtype: int64

In [29]: s.iloc[2:4]
Out[29]:
3.0 2
4.5 3
dtype: int64
```

In float indexes, slicing using floats are allowed

```
In [30]: s[2.1:4.6]
Out[30]:
3.0 2
4.5 3
dtype: int64

In [31]: s.loc[2.1:4.6]
Out[31]:
3.0 2
4.5 3
dtype: int64
```

- Indexing on other index types are preserved (and positional fallback for `[]`, `ix`), with the exception, that floating point slicing on indexes on non `Float64Index` will now raise a `TypeError`.

```
In [1]: pd.Series(range(5))[3.5]
TypeError: the label [3.5] is not a proper indexer for this index type (Int64Index)

In [1]: pd.Series(range(5))[3.5:4.5]
TypeError: the slice start [3.5] is not a proper indexer for this index type.
->(Int64Index)
```

Using a scalar float indexer will be deprecated in a future version, but is allowed for now.

```
In [3]: pd.Series(range(5))[3.0]
Out[3]: 3
```

## HDFStore API changes

- Query Format Changes. A much more string-like query format is now supported. See *the docs*.

```
In [32]: path = 'test.h5'

In [33]: dfq = pd.DataFrame(np.random.randn(10, 4),
.....: columns=list('ABCD'),
.....: index=pd.date_range('20130101', periods=10))
.....:

In [34]: dfq.to_hdf(path, 'dfq', format='table', data_columns=True)
```

Use boolean expressions, with in-line function evaluation.

```
In [35]: pd.read_hdf(path, 'dfq',
.....: where="index>Timestamp('20130104') & columns=['A', 'B']")
.....:
Out[35]:
```

|            | A         | B         |
|------------|-----------|-----------|
| 2013-01-05 | -0.424972 | 0.567020  |
| 2013-01-06 | -0.673690 | 0.113648  |
| 2013-01-07 | 0.404705  | 0.577046  |
| 2013-01-08 | -0.370647 | -1.157892 |
| 2013-01-09 | 1.075770  | -0.109050 |
| 2013-01-10 | 0.357021  | -0.674600 |

Use an inline column reference

```
In [36]: pd.read_hdf(path, 'dfq',
.....: where="A>0 or C>0")
.....:
Out[36]:
```

|            | A         | B         | C         | D         |
|------------|-----------|-----------|-----------|-----------|
| 2013-01-01 | 0.469112  | -0.282863 | -1.509059 | -1.135632 |
| 2013-01-02 | 1.212112  | -0.173215 | 0.119209  | -1.044236 |
| 2013-01-04 | 0.721555  | -0.706771 | -1.039575 | 0.271860  |
| 2013-01-05 | -0.424972 | 0.567020  | 0.276232  | -1.087401 |
| 2013-01-07 | 0.404705  | 0.577046  | -1.715002 | -1.039268 |
| 2013-01-09 | 1.075770  | -0.109050 | 1.643563  | -1.469388 |
| 2013-01-10 | 0.357021  | -0.674600 | -1.776904 | -0.968914 |

- the `format` keyword now replaces the `table` keyword; allowed values are `fixed(f)` or `table(t)` the same defaults as prior < 0.13.0 remain, e.g. `put` implies `fixed` format and `append` implies `table` format. This default format can be set as an option by setting `io.hdf.default_format`.

```
In [37]: path = 'test.h5'

In [38]: df = pd.DataFrame(np.random.randn(10, 2))

In [39]: df.to_hdf(path, 'df_table', format='table')

In [40]: df.to_hdf(path, 'df_table2', append=True)
```

(continues on next page)

(continued from previous page)

```
In [41]: df.to_hdf(path, 'df_fixed')

In [42]: with pd.HDFStore(path) as store:
.....: print(store)
.....:
<class 'pandas.io.pytables.HDFStore'>
File path: test.h5
```

- Significant table writing performance improvements
- handle a passed Series in table format (GH4330)
- can now serialize a timedelta64[ns] dtype in a table (GH3577), See *the docs*.
- added an `is_open` property to indicate if the underlying file handle is open; a closed store will now report 'CLOSED' when viewing the store (rather than raising an error) (GH4409)
- a close of a HDFStore now will close that instance of the HDFStore but will only close the actual file if the ref count (by PyTables) w.r.t. all of the open handles are 0. Essentially you have a local instance of HDFStore referenced by a variable. Once you close it, it will report closed. Other references (to the same file) will continue to operate until they themselves are closed. Performing an action on a closed file will raise `ClosedFileError`

```
In [43]: path = 'test.h5'

In [44]: df = pd.DataFrame(np.random.randn(10, 2))

In [45]: store1 = pd.HDFStore(path)

In [46]: store2 = pd.HDFStore(path)

In [47]: store1.append('df', df)

In [48]: store2.append('df2', df)

In [49]: store1
Out[49]:
<class 'pandas.io.pytables.HDFStore'>
File path: test.h5

In [50]: store2
Out[50]:
<class 'pandas.io.pytables.HDFStore'>
File path: test.h5

In [51]: store1.close()

In [52]: store2
Out[52]:
<class 'pandas.io.pytables.HDFStore'>
File path: test.h5

In [53]: store2.close()

In [54]: store2
```

(continues on next page)

(continued from previous page)

```
Out[54]:
<class 'pandas.io.pytables.HDFStore'>
File path: test.h5
```

- removed the `_quiet` attribute, replace by a `DuplicateWarning` if retrieving duplicate rows from a table (GH4367)
- removed the `warn` argument from `open`. Instead a `PossibleDataLossError` exception will be raised if you try to use `mode='w'` with an OPEN file handle (GH4367)
- allow a passed locations array or mask as a `where` condition (GH4467). See *the docs* for an example.
- add the keyword `dropna=True` to append to change whether ALL nan rows are not written to the store (default is True, ALL nan rows are NOT written), also settable via the option `io.hdf.dropna_table` (GH4625)
- pass through store creation arguments; can be used to support in-memory stores

## DataFrame repr changes

The HTML and plain text representations of `DataFrame` now show a truncated view of the table once it exceeds a certain size, rather than switching to the short info view (GH4886, GH5550). This makes the representation more consistent as small DataFrames get larger.

|            |       |       |       |       |           |       |
|------------|-------|-------|-------|-------|-----------|-------|
| 2010-03-29 | 13.70 | 13.88 | 13.39 | 13.57 | 158225000 | 12.98 |
| 2010-03-30 | 13.55 | 13.64 | 13.18 | 13.28 | 142055200 | 12.70 |
|            | ...   | ...   | ...   | ...   | ...       | ...   |

771 rows × 6 columns

To get the info view, call `DataFrame.info()`. If you prefer the info view as the repr for large DataFrames, you can set this by running `set_option('display.large_repr', 'info')`.

## Enhancements

- `df.to_clipboard()` learned a new `excel` keyword that let's you paste df data directly into excel (enabled by default). (GH5070).
- `read_html` now raises a `URLERror` instead of catching and raising a `ValueError` (GH4303, GH4305)
- Added a test for `read_clipboard()` and `to_clipboard()` (GH4282)
- Clipboard functionality now works with PySide (GH4282)
- Added a more informative error message when plot arguments contain overlapping color and style arguments (GH4402)
- `to_dict` now takes `records` as a possible out type. Returns an array of column-keyed dictionaries. (GH4936)
- NaN handing in `get_dummies` (GH4446) with `dummy_na`

```
previously, nan was erroneously counted as 2 here
now it is not counted at all
In [55]: pd.get_dummies([1, 2, np.nan])
Out[55]:
```

(continues on next page)

(continued from previous page)

```

 1.0 2.0
0 1 0
1 0 1
2 0 0

unless requested
In [56]: pd.get_dummies([1, 2, np.nan], dummy_na=True)
Out[56]:
 1.0 2.0 NaN
0 1 0 0
1 0 1 0
2 0 0 1

```

- `timedelta64[ns]` operations. See [the docs](#).

**Warning:** Most of these operations require `numpy >= 1.7`

Using the new top-level `to_timedelta`, you can convert a scalar or array from the standard `timedelta` format (produced by `to_csv`) into a `timedelta64` type (`np.timedelta64` in nanoseconds).

```

In [57]: pd.to_timedelta('1 days 06:05:01.000003')
Out[57]: Timedelta('1 days 06:05:01.0000030')

In [58]: pd.to_timedelta('15.5us')
Out[58]: Timedelta('0 days 00:00:00.000015500')

In [59]: pd.to_timedelta(['1 days 06:05:01.000003', '15.5us', 'nan'])
Out[59]: TimedeltaIndex(['1 days 06:05:01.0000030', '0 days 00:00:00.000015500',
↳NaT], dtype='timedelta64[ns]', freq=None)

In [60]: pd.to_timedelta(np.arange(5), unit='s')
Out[60]:
TimedeltaIndex(['0 days 00:00:00', '0 days 00:00:01', '0 days 00:00:02',
 '0 days 00:00:03', '0 days 00:00:04'],
 dtype='timedelta64[ns]', freq=None)

In [61]: pd.to_timedelta(np.arange(5), unit='d')
Out[61]: TimedeltaIndex(['0 days', '1 days', '2 days', '3 days', '4 days'], dtype=
↳'timedelta64[ns]', freq=None)

```

A Series of dtype `timedelta64[ns]` can now be divided by another `timedelta64[ns]` object, or astyped to yield a `float64` dtyped Series. This is frequency conversion. See [the docs](#) for the docs.

```

In [62]: import datetime

In [63]: td = pd.Series(pd.date_range('20130101', periods=4)) - pd.Series(
.....: pd.date_range('20121201', periods=4))
.....:

In [64]: td[2] += np.timedelta64(datetime.timedelta(minutes=5, seconds=3))

```

(continues on next page)

(continued from previous page)

```

In [65]: td[3] = np.nan

In [66]: td
Out[66]:
0 31 days 00:00:00
1 31 days 00:00:00
2 31 days 00:05:03
3 NaT
dtype: timedelta64[ns]

to days
In [67]: td / np.timedelta64(1, 'D')
Out[67]:
0 31.000000
1 31.000000
2 31.003507
3 NaN
dtype: float64

In [68]: td.astype('timedelta64[D]')
Out[68]:
0 31.0
1 31.0
2 31.0
3 NaN
dtype: float64

to seconds
In [69]: td / np.timedelta64(1, 's')
Out[69]:
0 2678400.0
1 2678400.0
2 2678703.0
3 NaN
dtype: float64

In [70]: td.astype('timedelta64[s]')
Out[70]:
0 2678400.0
1 2678400.0
2 2678703.0
3 NaN
dtype: float64

```

Dividing or multiplying a `timedelta64[ns]` Series by an integer or integer Series

```

In [71]: td * -1
Out[71]:
0 -31 days +00:00:00
1 -31 days +00:00:00
2 -32 days +23:54:57
3 NaT

```

(continues on next page)

(continued from previous page)

```
dtype: timedelta64[ns]
In [72]: td * pd.Series([1, 2, 3, 4])
Out[72]:
0 31 days 00:00:00
1 62 days 00:00:00
2 93 days 00:15:09
3 NaT
dtype: timedelta64[ns]
```

Absolute DateOffset objects can act equivalently to timedeltas

```
In [73]: from pandas import offsets

In [74]: td + offsets.Minute(5) + offsets.Milli(5)
Out[74]:
0 31 days 00:05:00.005000
1 31 days 00:05:00.005000
2 31 days 00:10:03.005000
3 NaT
dtype: timedelta64[ns]
```

Fillna is now supported for timedeltas

```
In [75]: td.fillna(pd.Timedelta(0))
Out[75]:
0 31 days 00:00:00
1 31 days 00:00:00
2 31 days 00:05:03
3 0 days 00:00:00
dtype: timedelta64[ns]

In [76]: td.fillna(datetime.timedelta(days=1, seconds=5))
Out[76]:
0 31 days 00:00:00
1 31 days 00:00:00
2 31 days 00:05:03
3 1 days 00:00:05
dtype: timedelta64[ns]
```

You can do numeric reduction operations on timedeltas.

```
In [77]: td.mean()
Out[77]: Timedelta('31 days 00:01:41')

In [78]: td.quantile(.1)
Out[78]: Timedelta('31 days 00:00:00')
```

- `plot(kind='kde')` now accepts the optional parameters `bw_method` and `ind`, passed to `scipy.stats.gaussian_kde()` (for `scipy >= 0.11.0`) to set the bandwidth, and to `gkde.evaluate()` to specify the indices at which it is evaluated, respectively. See [scipy docs](#). ([GH4298](#))
- `DataFrame` constructor now accepts a numpy masked record array ([GH3478](#))

- The new vectorized string method `extract` return regular expression matches more conveniently.

```
In [79]: pd.Series(['a1', 'b2', 'c3']).str.extract('[ab](\d)')
Out[79]:
 0
0 1
1 2
2 NaN
```

Elements that do not match return `NaN`. Extracting a regular expression with more than one group returns a `DataFrame` with one column per group.

```
In [80]: pd.Series(['a1', 'b2', 'c3']).str.extract('([ab])(\d)')
Out[80]:
 0 1
0 a 1
1 b 2
2 NaN NaN
```

Elements that do not match return a row of `NaN`. Thus, a `Series` of messy strings can be *converted* into a like-indexed `Series` or `DataFrame` of cleaned-up or more useful strings, without necessitating `get()` to access tuples or `re.match` objects.

Named groups like

```
In [81]: pd.Series(['a1', 'b2', 'c3']).str.extract(
.....: '(?P<letter>[ab])(?P<digit>\d)')
.....:
Out[81]:
 letter digit
0 a 1
1 b 2
2 NaN NaN
```

and optional groups can also be used.

```
In [82]: pd.Series(['a1', 'b2', '3']).str.extract(
.....: '(?P<letter>[ab])?(?P<digit>\d)')
.....:
Out[82]:
 letter digit
0 a 1
1 b 2
2 NaN 3
```

- `read_stata` now accepts Stata 13 format ([GH4291](#))
- `read_fwf` now infers the column specifications from the first 100 rows of the file if the data has correctly separated and properly aligned columns using the delimiter provided to the function ([GH4488](#)).
- support for nanosecond times as an offset

**Warning:** These operations require `numpy >= 1.7`

Period conversions in the range of seconds and below were reworked and extended up to nanoseconds. Periods in the nanosecond range are now available.

```
In [83]: pd.date_range('2013-01-01', periods=5, freq='5N')
Out[83]:
DatetimeIndex([
 '2013-01-01 00:00:00',
 '2013-01-01 00:00:00.000000005',
 '2013-01-01 00:00:00.000000010',
 '2013-01-01 00:00:00.000000015',
 '2013-01-01 00:00:00.000000020'],
 dtype='datetime64[ns]', freq='5N')
```

or with frequency as offset

```
In [84]: pd.date_range('2013-01-01', periods=5, freq=pd.offsets.Nano(5))
Out[84]:
DatetimeIndex([
 '2013-01-01 00:00:00',
 '2013-01-01 00:00:00.000000005',
 '2013-01-01 00:00:00.000000010',
 '2013-01-01 00:00:00.000000015',
 '2013-01-01 00:00:00.000000020'],
 dtype='datetime64[ns]', freq='5N')
```

Timestamps can be modified in the nanosecond range

```
In [85]: t = pd.Timestamp('20130101 09:01:02')
In [86]: t + pd.tseries.offsets.Nano(123)
Out[86]: Timestamp('2013-01-01 09:01:02.000000123')
```

- A new method, `isin` for DataFrames, which plays nicely with boolean indexing. The argument to `isin`, what we're comparing the DataFrame to, can be a DataFrame, Series, dict, or array of values. See *the docs* for more.

To get the rows where any of the conditions are met:

```
In [87]: dfi = pd.DataFrame({'A': [1, 2, 3, 4], 'B': ['a', 'b', 'f', 'n']})
In [88]: dfi
Out[88]:
 A B
0 1 a
1 2 b
2 3 f
3 4 n

In [89]: other = pd.DataFrame({'A': [1, 3, 3, 7], 'B': ['e', 'f', 'f', 'e']})
In [90]: mask = dfi.isin(other)
In [91]: mask
Out[91]:
 A B
0 True False
1 False False
2 True True
```

(continues on next page)

(continued from previous page)

```

3 False False

In [92]: dfi[mask.any(1)]
Out[92]:
 A B
0 1 a
2 3 f

```

- Series now supports a `to_frame` method to convert it to a single-column DataFrame (GH5164)
- All R datasets listed here <http://stat.ethz.ch/R-manual/R-devel/library/datasets/html/00Index.html> can now be loaded into pandas objects

```

note that pandas.rpy was deprecated in v0.16.0
import pandas.rpy.common as com
com.load_data('Titanic')

```

- `tz_localize` can infer a fall daylight savings transition based on the structure of the unlocalized data (GH4230), see *the docs*
- `DatetimeIndex` is now in the API documentation, see *the docs*
- `json_normalize()` is a new method to allow you to create a flat table from semi-structured JSON data. See *the docs* (GH1067)
- Added PySide support for the `qt pandas DataFrameModel` and `DataFrameWidget`.
- Python csv parser now supports `usecols` (GH4335)
- Frequencies gained several new offsets:
  - `LastWeekOfMonth` (GH4637)
  - `FY5253`, and `FY5253Quarter` (GH4511)
- DataFrame has a new `interpolate` method, similar to Series (GH4434, GH1892)

```

In [93]: df = pd.DataFrame({'A': [1, 2.1, np.nan, 4.7, 5.6, 6.8],
.....: 'B': [.25, np.nan, np.nan, 4, 12.2, 14.4]})
.....:

In [94]: df.interpolate()
Out[94]:
 A B
0 1.0 0.25
1 2.1 1.50
2 3.4 2.75
3 4.7 4.00
4 5.6 12.20
5 6.8 14.40

```

Additionally, the method argument to `interpolate` has been expanded to include 'nearest', 'zero', 'slinear', 'quadratic', 'cubic', 'barycentric', 'krogh', 'piecewise\_polynomial', 'pchip', 'polynomial', 'spline' The new methods require `scipy`. Consult the Scipy reference [guide](#) and [documentation](#) for more information about when the various methods are appropriate. See *the docs*.

`interpolate` now also accepts a `limit` keyword argument. This works similar to `fillna`'s `limit`:

```
In [95]: ser = pd.Series([1, 3, np.nan, np.nan, np.nan, 11])
```

```
In [96]: ser.interpolate(limit=2)
```

```
Out[96]:
```

```
0 1.0
1 3.0
2 5.0
3 7.0
4 NaN
5 11.0
dtype: float64
```

- Added `wide_to_long` panel data convenience function. See [the docs](#).

```
In [97]: np.random.seed(123)
```

```
In [98]: df = pd.DataFrame({"A1970": {0: "a", 1: "b", 2: "c"},
.....: "A1980": {0: "d", 1: "e", 2: "f"},
.....: "B1970": {0: 2.5, 1: 1.2, 2: .7},
.....: "B1980": {0: 3.2, 1: 1.3, 2: .1},
.....: "X": dict(zip(range(3), np.random.randn(3)))
.....: })
```

```
In [99]: df["id"] = df.index
```

```
In [100]: df
```

```
Out[100]:
```

```
 A1970 A1980 B1970 B1980 X id
0 a d 2.5 3.2 -1.085631 0
1 b e 1.2 1.3 0.997345 1
2 c f 0.7 0.1 0.282978 2
```

```
In [101]: pd.wide_to_long(df, ["A", "B"], i="id", j="year")
```

```
Out[101]:
```

```
 X A B
id year
0 1970 -1.085631 a 2.5
1 1970 0.997345 b 1.2
2 1970 0.282978 c 0.7
0 1980 -1.085631 d 3.2
1 1980 0.997345 e 1.3
2 1980 0.282978 f 0.1
```

- `to_csv` now takes a `date_format` keyword argument that specifies how output datetime objects should be formatted. Datetimes encountered in the index, columns, and values will all have this formatting applied. (GH4313)
- `DataFrame.plot` will scatter plot x versus y by passing `kind='scatter'` (GH2215)
- Added support for Google Analytics v3 API segment IDs that also supports v2 IDs. (GH5271)

## Experimental

- The new `eval()` function implements expression evaluation using numexpr behind the scenes. This results in large speedups for complicated expressions involving large DataFrames/Series. For example,

```
In [102]: nrows, ncols = 20000, 100
```

```
In [103]: df1, df2, df3, df4 = [pd.DataFrame(np.random.randn(nrows, ncols))
.....: for _ in range(4)]
.....:
```

```
eval with NumExpr backend
```

```
In [104]: %timeit pd.eval('df1 + df2 + df3 + df4')
4.04 ms +- 38.1 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

```
pure Python evaluation
```

```
In [105]: %timeit df1 + df2 + df3 + df4
5.8 ms +- 130 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

For more details, see the [the docs](#)

- Similar to `pandas.eval`, `DataFrame` has a new `DataFrame.eval` method that evaluates an expression in the context of the `DataFrame`. For example,

```
In [106]: df = pd.DataFrame(np.random.randn(10, 2), columns=['a', 'b'])
```

```
In [107]: df.eval('a + b')
```

```
Out[107]:
0 -0.685204
1 1.589745
2 0.325441
3 -1.784153
4 -0.432893
5 0.171850
6 1.895919
7 3.065587
8 -0.092759
9 1.391365
dtype: float64
```

- `query()` method has been added that allows you to select elements of a `DataFrame` using a natural query syntax nearly identical to Python syntax. For example,

```
In [108]: n = 20
```

```
In [109]: df = pd.DataFrame(np.random.randint(n, size=(n, 3)), columns=['a', 'b', 'c
→'])
```

```
In [110]: df.query('a < b < c')
```

```
Out[110]:
 a b c
11 1 5 8
15 8 16 19
```

selects all the rows of `df` where `a < b < c` evaluates to `True`. For more details see the [the docs](#).

- `pd.read_msgpack()` and `pd.to_msgpack()` are now a supported method of serialization of arbitrary pandas (and python objects) in a lightweight portable binary format. See *the docs*

**Warning:** Since this is an EXPERIMENTAL LIBRARY, the storage format may not be stable until a future release.

```
df = pd.DataFrame(np.random.rand(5, 2), columns=list('AB'))
df.to_msgpack('foo.msg')
pd.read_msgpack('foo.msg')

s = pd.Series(np.random.rand(5), index=pd.date_range('20130101', periods=5))
pd.to_msgpack('foo.msg', df, s)
pd.read_msgpack('foo.msg')
```

You can pass `iterator=True` to iterator over the unpacked results

```
for o in pd.read_msgpack('foo.msg', iterator=True):
 print(o)
```

- `pandas.io.gbq` provides a simple way to extract from, and load data into, Google's BigQuery Data Sets by way of pandas DataFrames. BigQuery is a high performance SQL-like database service, useful for performing ad-hoc queries against extremely large datasets. See *the docs*

```
from pandas.io import gbq

A query to select the average monthly temperatures in the
in the year 2000 across the USA. The dataset,
publicdata:samples.gsod, is available on all BigQuery accounts,
and is based on NOAA gsod data.

query = """SELECT station_number as STATION,
month as MONTH, AVG(mean_temp) as MEAN_TEMP
FROM publicdata:samples.gsod
WHERE YEAR = 2000
GROUP BY STATION, MONTH
ORDER BY STATION, MONTH ASC"""

Fetch the result set for this query

Your Google BigQuery Project ID
To find this, see your dashboard:
https://console.developers.google.com/iam-admin/projects?authuser=0
projectid = 'xxxxxxxx'
df = gbq.read_gbq(query, project_id=projectid)

Use pandas to process and reshape the dataset

df2 = df.pivot(index='STATION', columns='MONTH', values='MEAN_TEMP')
df3 = pd.concat([df2.min(), df2.mean(), df2.max()],
 axis=1, keys=["Min Tem", "Mean Temp", "Max Temp"])
```

The resulting DataFrame is:

```
> df3
 Min Tem Mean Temp Max Temp
MONTH
1 -53.336667 39.827892 89.770968
2 -49.837500 43.685219 93.437932
3 -77.926087 48.708355 96.099998
4 -82.892858 55.070087 97.317240
5 -92.378261 61.428117 102.042856
6 -77.703334 65.858888 102.900000
7 -87.821428 68.169663 106.510714
8 -89.431999 68.614215 105.500000
9 -86.611112 63.436935 107.142856
10 -78.209677 56.880838 92.103333
11 -50.125000 48.861228 94.996428
12 -50.332258 42.286879 94.396774
```

**Warning:** To use this module, you will need a BigQuery account. See <<https://cloud.google.com/products/big-query>> for details.

As of 10/10/13, there is a bug in Google's API preventing result sets from being larger than 100,000 rows. A patch is scheduled for the week of 10/14/13.

## Internal refactoring

In 0.13.0 there is a major refactor primarily to subclass `Series` from `NDFrame`, which is the base class currently for `DataFrame` and `Panel`, to unify methods and behaviors. `Series` formerly subclassed directly from `ndarray`. (GH4080, GH3862, GH816)

**Warning:** There are two potential incompatibilities from < 0.13.0

- Using certain numpy functions would previously return a `Series` if passed a `Series` as an argument. This seems only to affect `np.ones_like`, `np.empty_like`, `np.diff` and `np.where`. These now return `ndarrays`.

```
In [111]: s = pd.Series([1, 2, 3, 4])
```

Numpy Usage

```
In [112]: np.ones_like(s)
Out[112]: array([1, 1, 1, 1])
```

```
In [113]: np.diff(s)
Out[113]: array([1, 1, 1])
```

```
In [114]: np.where(s > 1, s, np.nan)
Out[114]: array([nan, 2., 3., 4.])
```

Pandonic Usage

```
In [115]: pd.Series(1, index=s.index)
```

```
Out[115]:
0 1
1 1
```

```
2 1
3 1
dtype: int64
```

```
In [116]: s.diff()
```

```
Out[116]:
```

```
0 NaN
1 1.0
2 1.0
3 1.0
dtype: float64
```

```
In [117]: s.where(s > 1)
```

```
Out[117]:
```

```
0 NaN
1 2.0
2 3.0
3 4.0
dtype: float64
```

- Passing a Series directly to a cython function expecting an ndarray type will no longer work directly, you must pass Series.values, See [Enhancing Performance](#)
- Series(0.5) would previously return the scalar 0.5, instead this will return a 1-element Series
- This change breaks rpy2<=2.3.8. an Issue has been opened against rpy2 and a workaround is detailed in [GH5698](#). Thanks @JanSchulz.

- Pickle compatibility is preserved for pickles created prior to 0.13. These must be unpickled with pd.read\_pickle, see [Pickling](#).
- Refactor of series.py/frame.py/panel.py to move common code to generic.py
  - added \_setup\_axes to create generic NDFrame structures
  - moved methods
    - \* from\_axes, \_wrap\_array, axes, ix, loc, iloc, shape, empty, swapaxes, transpose, pop
    - \* \_\_iter\_\_, keys, \_\_contains\_\_, \_\_len\_\_, \_\_neg\_\_, \_\_invert\_\_
    - \* convert\_objects, as\_blocks, as\_matrix, values
    - \* \_\_getstate\_\_, \_\_setstate\_\_ (compat remains in frame/panel)
    - \* \_\_getattr\_\_, \_\_setattr\_\_
    - \* \_indexed\_same, reindex\_like, align, where, mask
    - \* fillna, replace (Series replace is now consistent with DataFrame)
    - \* filter (also added axis argument to selectively filter on a different axis)
    - \* reindex, reindex\_axis, take
    - \* truncate (moved to become part of NDFrame)
- These are API changes which make Panel more consistent with DataFrame
  - swapaxes on a Panel with the same axes specified now return a copy
  - support attribute access for setting

- filter supports the same API as the original DataFrame filter
- Reindex called with no arguments will now return a copy of the input object
- TimeSeries is now an alias for Series. the property `is_time_series` can be used to distinguish (if desired)
- Refactor of Sparse objects to use BlockManager
  - Created a new block type in internals, `SparseBlock`, which can hold multi-dtypes and is non-consolidatable. `SparseSeries` and `SparseDataFrame` now inherit more methods from there hierarchy (Series/DataFrame), and no longer inherit from `SparseArray` (which instead is the object of the `SparseBlock`)
  - Sparse suite now supports integration with non-sparse data. Non-float sparse data is supportable (partially implemented)
  - Operations on sparse structures within DataFrames should preserve sparseness, merging type operations will convert to dense (and back to sparse), so might be somewhat inefficient
  - enable `setitem` on `SparseSeries` for boolean/integer/slices
  - `SparsePanel`s implementation is unchanged (e.g. not using `BlockManager`, needs work)
- added `ftypes` method to Series/DataFrame, similar to `dtypes`, but indicates if the underlying is sparse/dense (as well as the dtype)
- All NDFrame objects can now use `__finalize__()` to specify various values to propagate to new objects from an existing one (e.g. `name` in `Series` will follow more automatically now)
- Internal type checking is now done via a suite of generated classes, allowing `isinstance(value, klass)` without having to directly import the class, courtesy of `@jtratner`
- Bug in `Series` update where the parent frame is not updating its cache based on changes ([GH4080](#)) or types ([GH3217](#)), `fillna` ([GH3386](#))
- Indexing with dtype conversions fixed ([GH4463](#), [GH4204](#))
- Refactor `Series.reindex` to `core/generic.py` ([GH4604](#), [GH4618](#)), allow `method=` in reindexing on a `Series` to work
- `Series.copy` no longer accepts the `order` parameter and is now consistent with `NDFrame` copy
- Refactor `rename` methods to `core/generic.py`; fixes `Series.rename` for ([GH4605](#)), and adds `rename` with the same signature for `Panel`
- Refactor `clip` methods to `core/generic.py` ([GH4798](#))
- Refactor of `_get_numeric_data/_get_bool_data` to `core/generic.py`, allowing `Series/Panel` functionality
- `Series` (for index) / `Panel` (for items) now allow attribute access to its elements ([GH1903](#))

```
In [118]: s = pd.Series([1, 2, 3], index=list('abc'))

In [119]: s.b
Out[119]: 2

In [120]: s.a = 5

In [121]: s
Out[121]:
a 5
b 2
```

(continues on next page)

```
c 3
dtype: int64
```

## Bug fixes

- `HDFStore`
  - raising an invalid `TypeError` rather than `ValueError` when appending with a different block ordering ([GH4096](#))
  - `read_hdf` was not respecting `as` passed mode ([GH4504](#))
  - appending a 0-len table will work correctly ([GH4273](#))
  - `to_hdf` was raising when passing both arguments `append` and `table` ([GH4584](#))
  - reading from a store with duplicate columns across dtypes would raise ([GH4767](#))
  - Fixed a bug where `ValueError` wasn't correctly raised when column names weren't strings ([GH4956](#))
  - A zero length series written in Fixed format not deserializing properly. ([GH4708](#))
  - Fixed decoding perf issue on py3 ([GH5441](#))
  - Validate levels in a `MultiIndex` before storing ([GH5527](#))
  - Correctly handle `data_columns` with a `Panel` ([GH5717](#))
- Fixed bug in `tslib.tz_convert(vals, tz1, tz2)`: it could raise `IndexError` exception while trying to access `trans[pos + 1]` ([GH4496](#))
- The `by` argument now works correctly with the `layout` argument ([GH4102](#), [GH4014](#)) in `*.hist` plotting methods
- Fixed bug in `PeriodIndex.map` where using `str` would return the `str` representation of the index ([GH4136](#))
- Fixed test failure `test_time_series_plot_color_with_empty_kwargs` when using custom matplotlib default colors ([GH4345](#))
- Fix running of stata IO tests. Now uses temporary files to write ([GH4353](#))
- Fixed an issue where `DataFrame.sum` was slower than `DataFrame.mean` for integer valued frames ([GH4365](#))
- `read_html` tests now work with Python 2.6 ([GH4351](#))
- Fixed bug where `network` testing was throwing `NameError` because a local variable was undefined ([GH4381](#))
- In `to_json`, raise if a passed `orient` would cause loss of data because of a duplicate index ([GH4359](#))
- In `to_json`, fix date handling so milliseconds are the default timestamp as the docstring says ([GH4362](#)).
- `as_index` is no longer ignored when doing `groupby` apply ([GH4648](#), [GH3417](#))
- JSON NaT handling fixed, NaTs are now serialized to `null` ([GH4498](#))
- Fixed JSON handling of escapable characters in JSON object keys ([GH4593](#))
- Fixed passing `keep_default_na=False` when `na_values=None` ([GH4318](#))
- Fixed bug with `values` raising an error on a `DataFrame` with duplicate columns and mixed dtypes, surfaced in ([GH4377](#))
- Fixed bug with duplicate columns and type conversion in `read_json` when `orient='split'` ([GH4377](#))

- Fixed JSON bug where locales with decimal separators other than ‘.’ threw exceptions when encoding / decoding certain values. (GH4918)
- Fix `.iat` indexing with a `PeriodIndex` (GH4390)
- Fixed an issue where `PeriodIndex` joining with self was returning a new instance rather than the same instance (GH4379); also adds a test for this for the other index types
- Fixed a bug with all the dtypes being converted to object when using the CSV parser with the `usecols` parameter (GH3192)
- Fix an issue in merging blocks where the resulting `DataFrame` had partially set `_ref_locs` (GH4403)
- Fixed an issue where hist subplots were being overwritten when they were called using the top level matplotlib API (GH4408)
- Fixed a bug where calling `Series.astype(str)` would truncate the string (GH4405, GH4437)
- Fixed a py3 compat issue where bytes were being repr’d as tuples (GH4455)
- Fixed Panel attribute naming conflict if item is named ‘a’ (GH3440)
- Fixed an issue where duplicate indexes were raising when plotting (GH4486)
- Fixed an issue where `cumsum` and `cumprod` didn’t work with bool dtypes (GH4170, GH4440)
- Fixed Panel slicing issued in `xs` that was returning an incorrect dimmed object (GH4016)
- Fix resampling bug where custom reduce function not used if only one group (GH3849, GH4494)
- Fixed Panel assignment with a transposed frame (GH3830)
- Raise on set indexing with a Panel and a Panel as a value which needs alignment (GH3777)
- frozenset objects now raise in the `Series` constructor (GH4482, GH4480)
- Fixed issue with sorting a duplicate `MultiIndex` that has multiple dtypes (GH4516)
- Fixed bug in `DataFrame.set_values` which was causing name attributes to be lost when expanding the index. (GH3742, GH4039)
- Fixed issue where individual names, levels and labels could be set on `MultiIndex` without validation (GH3714, GH4039)
- Fixed (GH3334) in `pivot_table`. Margins did not compute if values is the index.
- Fix bug in having a rhs of `np.timedelta64` or `np.offsets.DateOffset` when operating with datetimes (GH4532)
- Fix arithmetic with `series/datetimeindex` and `np.timedelta64` not working the same (GH4134) and buggy `timedelta` in NumPy 1.6 (GH4135)
- Fix bug in `pd.read_clipboard` on windows with PY3 (GH4561); not decoding properly
- `tslib.get_period_field()` and `tslib.get_period_field_arr()` now raise if code argument out of range (GH4519, GH4520)
- Fix boolean indexing on an empty series loses index names (GH4235), `infer_dtype` works with empty arrays.
- Fix reindexing with multiple axes; if an axes match was not replacing the current axes, leading to a possible lazy frequency inference issue (GH3317)
- Fixed issue where `DataFrame.apply` was reraising exceptions incorrectly (causing the original stack trace to be truncated).
- Fix selection with `ix/loc` and `non_unique` selectors (GH4619)

- Fix assignment with `iloc/loc` involving a dtype change in an existing column ([GH4312](#), [GH5702](#)) have internal `setitem_with_indexer` in `core/indexing` to use `Block.setitem`
- Fixed bug where thousands operator was not handled correctly for floating point numbers in `csv_import` ([GH4322](#))
- Fix an issue with `CacheableOffset` not properly being used by many `DateOffset`; this prevented the `DateOffset` from being cached ([GH4609](#))
- Fix boolean comparison with a `DataFrame` on the lhs, and a list/tuple on the rhs ([GH4576](#))
- Fix error/dtype conversion with `setitem` of `None` on `Series/DataFrame` ([GH4667](#))
- Fix decoding based on a passed in non-default encoding in `pd.read_stata` ([GH4626](#))
- Fix `DataFrame.from_records` with a plain-vanilla `ndarray`. ([GH4727](#))
- Fix some inconsistencies with `Index.rename` and `MultiIndex.rename`, etc. ([GH4718](#), [GH4628](#))
- Bug in using `iloc/loc` with a cross-sectional and duplicate indices ([GH4726](#))
- Bug with using `QUOTE_NONE` with `to_csv` causing `Exception`. ([GH4328](#))
- Bug with `Series` indexing not raising an error when the right-hand-side has an incorrect length ([GH2702](#))
- Bug in `MultiIndexing` with a partial string selection as one part of a `MultiIndex` ([GH4758](#))
- Bug with reindexing on the index with a non-unique index will now raise `ValueError` ([GH4746](#))
- Bug in setting with `loc/ix` a single indexer with a `MultiIndex` axis and a `NumPy` array, related to ([GH3777](#))
- Bug in concatenation with duplicate columns across dtypes not merging with `axis=0` ([GH4771](#), [GH4975](#))
- Bug in `iloc` with a slice index failing ([GH4771](#))
- Incorrect error message with no `colspecs` or `width` in `read_fwf`. ([GH4774](#))
- Fix bugs in indexing in a `Series` with a duplicate index ([GH4548](#), [GH4550](#))
- Fixed bug with reading compressed files with `read_fwf` in Python 3. ([GH3963](#))
- Fixed an issue with a duplicate index and assignment with a dtype change ([GH4686](#))
- Fixed bug with reading compressed files in as `bytes` rather than `str` in Python 3. Simplifies bytes-producing file-handling in Python 3 ([GH3963](#), [GH4785](#)).
- Fixed an issue related to `ticklocs/ticklabels` with log scale bar plots across different versions of `matplotlib` ([GH4789](#))
- Suppressed `DeprecationWarning` associated with internal calls issued by `repr()` ([GH4391](#))
- Fixed an issue with a duplicate index and duplicate selector with `.loc` ([GH4825](#))
- Fixed an issue with `DataFrame.sort_index` where, when sorting by a single column and passing a list for `ascending`, the argument for `ascending` was being interpreted as `True` ([GH4839](#), [GH4846](#))
- Fixed `Panel.tshift` not working. Added `freq` support to `Panel.shift` ([GH4853](#))
- Fix an issue in `TextFileReader` w/ Python engine (i.e. `PythonParser`) with thousands `!= “,”` ([GH4596](#))
- Bug in `getitem` with a duplicate index when using `where` ([GH4879](#))
- Fix `Type` inference code coerces float column into `datetime` ([GH4601](#))
- Fixed `_ensure_numeric` does not check for complex numbers ([GH4902](#))
- Fixed a bug in `Series.hist` where two figures were being created when the `by` argument was passed ([GH4112](#), [GH4113](#)).

- Fixed a bug in `convert_objects` for `> 2` ndims (GH4937)
- Fixed a bug in DataFrame/Panel cache insertion and subsequent indexing (GH4939, GH5424)
- Fixed string methods for `FrozenNDArray` and `FrozenList` (GH4929)
- Fixed a bug with setting invalid or out-of-range values in indexing enlargement scenarios (GH4940)
- Tests for `fillna` on empty Series (GH4346), thanks @immerrr
- Fixed `copy()` to shallow copy axes/indices as well and thereby keep separate metadata. (GH4202, GH4830)
- Fixed `skiprows` option in Python parser for `read_csv` (GH4382)
- Fixed bug preventing `cut` from working with `np.inf` levels without explicitly passing labels (GH3415)
- Fixed wrong check for overlapping in `DatetimeIndex.union` (GH4564)
- Fixed conflict between thousands separator and date parser in `csv_parser` (GH4678)
- Fix appending when dtypes are not the same (error showing mixing float/np.datetime64) (GH4993)
- Fix repr for `DateOffset`. No longer show duplicate entries in kwds. Removed unused offset fields. (GH4638)
- Fixed wrong index name during `read_csv` if using `usecols`. Applies to `c` parser only. (GH4201)
- `Timestamp` objects can now appear in the left hand side of a comparison operation with a `Series` or `DataFrame` object (GH4982).
- Fix a bug when indexing with `np.nan` via `iloc/loc` (GH5016)
- Fixed a bug where low memory `c` parser could create different types in different chunks of the same file. Now coerces to numerical type or raises warning. (GH3866)
- Fix a bug where reshaping a `Series` to its own shape raised `TypeError` (GH4554) and other reshaping issues.
- Bug in setting with `ix/loc` and a mixed int/string index (GH4544)
- Make sure series-series boolean comparisons are label based (GH4947)
- Bug in multi-level indexing with a `Timestamp` partial indexer (GH4294)
- Tests/fix for `MultiIndex` construction of an all-nan frame (GH4078)
- Fixed a bug where `read_html()` wasn't correctly inferring values of tables with commas (GH5029)
- Fixed a bug where `read_html()` wasn't providing a stable ordering of returned tables (GH4770, GH5029).
- Fixed a bug where `read_html()` was incorrectly parsing when passed `index_col=0` (GH5066).
- Fixed a bug where `read_html()` was incorrectly inferring the type of headers (GH5048).
- Fixed a bug where `DatetimeIndex` joins with `PeriodIndex` caused a stack overflow (GH3899).
- Fixed a bug where `groupby` objects didn't allow plots (GH5102).
- Fixed a bug where `groupby` objects weren't tab-completing column names (GH5102).
- Fixed a bug where `groupby.plot()` and friends were duplicating figures multiple times (GH5102).
- Provide automatic conversion of object dtypes on `fillna`, related (GH5103)
- Fixed a bug where default options were being overwritten in the option parser cleaning (GH5121).
- Treat a list/ndarray identically for `iloc` indexing with list-like (GH5006)
- Fix `MultiIndex.get_level_values()` with missing values (GH5074)
- Fix bound checking for `Timestamp()` with `datetime64` input (GH4065)
- Fix a bug where `TestReadHtml` wasn't calling the correct `read_html()` function (GH5150).

- Fix a bug with `NDFrame.replace()` which made replacement appear as though it was (incorrectly) using regular expressions (GH5143).
- Fix better error message for `to_datetime` (GH4928)
- Made sure different locales are tested on travis-ci (GH4918). Also adds a couple of utilities for getting locales and setting locales with a context manager.
- Fixed segfault on `isnull(MultiIndex)` (now raises an error instead) (GH5123, GH5125)
- Allow duplicate indices when performing operations that align (GH5185, GH5639)
- Compound dtypes in a constructor raise `NotImplementedError` (GH5191)
- Bug in comparing duplicate frames (GH4421) related
- Bug in describe on duplicate frames
- Bug in `to_datetime` with a format and `coerce=True` not raising (GH5195)
- Bug in loc setting with multiple indexers and a rhs of a Series that needs broadcasting (GH5206)
- Fixed bug where inplace setting of levels or labels on `MultiIndex` would not clear cached values property and therefore return wrong values. (GH5215)
- Fixed bug where filtering a grouped `DataFrame` or `Series` did not maintain the original ordering (GH4621).
- Fixed `Period` with a business date freq to always roll-forward if on a non-business date. (GH5203)
- Fixed bug in Excel writers where frames with duplicate column names weren't written correctly. (GH5235)
- Fixed issue with `drop` and a non-unique index on `Series` (GH5248)
- Fixed segfault in C parser caused by passing more names than columns in the file. (GH5156)
- Fix `Series.isin` with date/time-like dtypes (GH5021)
- C and Python Parser can now handle the more common `MultiIndex` column format which doesn't have a row for index names (GH4702)
- Bug when trying to use an out-of-bounds date as an object dtype (GH5312)
- Bug when trying to display an embedded `PandasObject` (GH5324)
- Allows operating of `Timestamps` to return a datetime if the result is out-of-bounds related (GH5312)
- Fix return value/type signature of `initObjToJSON()` to be compatible with numpy's `import_array()` (GH5334, GH5326)
- Bug when renaming then `set_index` on a `DataFrame` (GH5344)
- Test suite no longer leaves around temporary files when testing graphics. (GH5347) (thanks for catching this @yarikoptic!)
- Fixed html tests on win32. (GH4580)
- Make sure that `head/tail` are `iloc` based, (GH5370)
- Fixed bug for `PeriodIndex` string representation if there are 1 or 2 elements. (GH5372)
- The `GroupBy` methods `transform` and `filter` can be used on `Series` and `DataFrames` that have repeated (non-unique) indices. (GH4620)
- Fix empty series not printing name in repr (GH4651)
- Make tests create temp files in temp directory by default. (GH5419)
- `pd.to_timedelta` of a scalar returns a scalar (GH5410)

- `pd.to_timedelta` accepts NaN and NaT, returning NaT instead of raising (GH5437)
- performance improvements in `isnull` on larger size pandas objects
- Fixed various setitem with 1d ndarray that does not have a matching length to the indexer (GH5508)
- Bug in `getitem` with a MultiIndex and `iloc` (GH5528)
- Bug in `delitem` on a Series (GH5542)
- Bug fix in `apply` when using custom function and objects are not mutated (GH5545)
- Bug in selecting from a non-unique index with `loc` (GH5553)
- Bug in `groupby` returning non-consistent types when user function returns a `None`, (GH5592)
- Work around regression in numpy 1.7.0 which erroneously raises `IndexError` from `ndarray.item` (GH5666)
- Bug in repeated indexing of object with resultant non-unique index (GH5678)
- Bug in `fillna` with Series and a passed series/dict (GH5703)
- Bug in `groupby` transform with a datetime-like grouper (GH5712)
- Bug in MultiIndex selection in PY3 when using certain keys (GH5725)
- Row-wise concat of differing dtypes failing in certain cases (GH5754)

## 5.18 Version 0.12

### 5.18.1 Version 0.12.0 (July 24, 2013)

This is a major release from 0.11.0 and includes several new features and enhancements along with a large number of bug fixes.

Highlights include a consistent I/O API naming scheme, routines to read html, write MultiIndexes to csv files, read & write STATA data files, read & write JSON format files, Python 3 support for HDFStore, filtering of groupby expressions via `filter`, and a revamped `replace` routine that accepts regular expressions.

## API changes

- The I/O API is now much more consistent with a set of top level reader functions accessed like `pd.read_csv()` that generally return a pandas object.

```
- read_csv
- read_excel
- read_hdf
- read_sql
- read_json
- read_html
- read_stata
- read_clipboard
```

The corresponding writer functions are object methods that are accessed like `df.to_csv()`

```
- to_csv
- to_excel
- to_hdf
- to_sql
- to_json
- to_html
- to_stata
- to_clipboard
```

- Fix modulo and integer division on Series,DataFrames to act similarly to float dtypes to return `np.nan` or `np.inf` as appropriate (GH3590). This correct a numpy bug that treats integer and float dtypes differently.

```
In [1]: p = pd.DataFrame({"first": [4, 5, 8], "second": [0, 0, 3]})
```

```
In [2]: p % 0
```

```
Out[2]:
 first second
0 NaN NaN
1 NaN NaN
2 NaN NaN
```

```
In [3]: p % p
```

```
Out[3]:
 first second
0 0.0 NaN
1 0.0 NaN
2 0.0 0.0
```

```
In [4]: p / p
```

```
Out[4]:
 first second
0 1.0 NaN
```

(continues on next page)

(continued from previous page)

```
1 1.0 NaN
2 1.0 1.0
```

```
In [5]: p / 0
```

```
Out[5]:
 first second
0 inf NaN
1 inf NaN
2 inf inf
```

- Add `squeeze` keyword to `groupby` to allow reduction from `DataFrame` -> `Series` if groups are unique. This is a Regression from 0.10.1. We are reverting back to the prior behavior. This means `groupby` will return the same shaped objects whether the groups are unique or not. Revert this issue (GH2893) with (GH3596).

```
In [2]: df2 = pd.DataFrame([{"val1": 1, "val2": 20},
...: {"val1": 1, "val2": 19},
...: {"val1": 1, "val2": 27},
...: {"val1": 1, "val2": 12}])
```

```
In [3]: def func(dataf):
...: return dataf["val2"] - dataf["val2"].mean()
...:
```

```
In [4]: # squeezing the result frame to a series (because we have unique groups)
...: df2.groupby("val1", squeeze=True).apply(func)
```

```
Out[4]:
0 0.5
1 -0.5
2 7.5
3 -7.5
Name: 1, dtype: float64
```

```
In [5]: # no squeezing (the default, and behavior in 0.10.1)
...: df2.groupby("val1").apply(func)
```

```
Out[5]:
val2 0 1 2 3
val1
1 0.5 -0.5 7.5 -7.5
```

- Raise on `iloc` when boolean indexing with a label based indexer mask e.g. a boolean `Series`, even with integer labels, will raise. Since `iloc` is purely positional based, the labels on the `Series` are not alignable (GH3631)

This case is rarely used, and there are plenty of alternatives. This preserves the `iloc` API to be *purely* positional based.

```
In [6]: df = pd.DataFrame(range(5), index=list("ABCDE"), columns=["a"])
```

```
In [7]: mask = df.a % 2 == 0
```

```
In [8]: mask
```

```
Out[8]:
A True
B False
```

(continues on next page)

(continued from previous page)

```

C True
D False
E True
Name: a, dtype: bool

this is what you should use
In [9]: df.loc[mask]
Out[9]:
 a
A 0
C 2
E 4

this will work as well
In [10]: df.iloc[mask.values]
Out[10]:
 a
A 0
C 2
E 4

```

`df.iloc[mask]` will raise a `ValueError`

- The `raise_on_error` argument to plotting functions is removed. Instead, plotting functions raise a `TypeError` when the `dtype` of the object is `object` to remind you to avoid `object` arrays whenever possible and thus you should cast to an appropriate numeric `dtype` if you need to plot something.
- Add `colormap` keyword to `DataFrame` plotting methods. Accepts either a `matplotlib` colormap object (ie, `matplotlib.cm.jet`) or a string name of such an object (ie, `'jet'`). The colormap is sampled to select the color for each column. Please see *Colormaps* for more information. (GH3860)
- `DataFrame.interpolate()` is now deprecated. Please use `DataFrame.fillna()` and `DataFrame.replace()` instead. (GH3582, GH3675, GH3676)
- the `method` and `axis` arguments of `DataFrame.replace()` are deprecated
- `DataFrame.replace` 's `infer_types` parameter is removed and now performs conversion by default. (GH3907)
- Add the keyword `allow_duplicates` to `DataFrame.insert` to allow a duplicate column to be inserted if `True`, default is `False` (same as prior to 0.12) (GH3679)
- Implement `__nonzero__` for `NDFrame` objects (GH3691, GH3696)
- IO api
  - added top-level function `read_excel` to replace the following, The original API is deprecated and will be removed in a future version

```

from pandas.io.parsers import ExcelFile

xls = ExcelFile("path_to_file.xls")
xls.parse("Sheet1", index_col=None, na_values=["NA"])

```

With

```
import pandas as pd

pd.read_excel("path_to_file.xls", "Sheet1", index_col=None, na_values=["NA"])
```

- added top-level function `read_sql` that is equivalent to the following

```
from pandas.io.sql import read_frame

read_frame(...)
```

- `DataFrame.to_html` and `DataFrame.to_latex` now accept a path for their first argument (GH3702)
- Do not allow astypes on `datetime64[ns]` except to object, and `timedelta64[ns]` to object/int (GH3425)
- The behavior of `datetime64` dtypes has changed with respect to certain so-called reduction operations (GH3726). The following operations now raise a `TypeError` when performed on a `Series` and return an *empty Series* when performed on a `DataFrame` similar to performing these operations on, for example, a `DataFrame` of slice objects:
  - `sum`, `prod`, `mean`, `std`, `var`, `skew`, `kurt`, `corr`, and `cov`
- `read_html` now defaults to `None` when reading, and falls back on `bs4` + `html5lib` when `lxml` fails to parse. a list of parsers to try until success is also valid
- The internal pandas class hierarchy has changed (slightly). The previous `PandasObject` now is called `PandasContainer` and a new `PandasObject` has become the base class for `PandasContainer` as well as `Index`, `Categorical`, `GroupBy`, `SparseList`, and `SparseArray` (+ their base classes). Currently, `PandasObject` provides string methods (from `StringMixin`). (GH4090, GH4092)
- New `StringMixin` that, given a `__unicode__` method, gets python 2 and python 3 compatible string methods (`__str__`, `__bytes__`, and `__repr__`). Plus string safety throughout. Now employed in many places throughout the pandas library. (GH4090, GH4092)

## IO enhancements

- `pd.read_html()` can now parse HTML strings, files or urls and return `DataFrames`, courtesy of @cpcloud. (GH3477, GH3605, GH3606, GH3616). It works with a *single* parser backend: `BeautifulSoup4` + `html5lib` *See the docs*

You can use `pd.read_html()` to read the output from `DataFrame.to_html()` like so

```
In [11]: df = pd.DataFrame({"a": range(3), "b": list("abc")})

In [12]: print(df)
 a b
0 0 a
1 1 b
2 2 c

In [13]: html = df.to_html()

In [14]: alist = pd.read_html(html, index_col=0)

In [15]: print(df == alist[0])
 a b
0 True True
```

(continues on next page)

(continued from previous page)

```
1 True True
2 True True
```

Note that `alist` here is a Python list so `pd.read_html()` and `DataFrame.to_html()` are not inverses.

- `pd.read_html()` no longer performs hard conversion of date strings (GH3656).

**Warning:** You may have to install an older version of BeautifulSoup4, *See the installation docs*

- Added module for reading and writing Stata files: `pandas.io.stata` (GH1512) accessible via `read_stata` top-level function for reading, and `to_stata` DataFrame method for writing, *See the docs*
- Added module for reading and writing json format files: `pandas.io.json` accessible via `read_json` top-level function for reading, and `to_json` DataFrame method for writing, *See the docs* various issues (GH1226, GH3804, GH3876, GH3867, GH1305)
- MultiIndex column support for reading and writing csv format files
  - The header option in `read_csv` now accepts a list of the rows from which to read the index.
  - The option, `tupleize_cols` can now be specified in both `to_csv` and `read_csv`, to provide compatibility for the pre 0.12 behavior of writing and reading MultiIndex columns via a list of tuples. The default in 0.12 is to write lists of tuples and *not* interpret list of tuples as a MultiIndex column.

Note: The default behavior in 0.12 remains unchanged from prior versions, but starting with 0.13, the default *to* write and read MultiIndex columns will be in the new format. (GH3571, GH1651, GH3141)

- If an `index_col` is not specified (e.g. you don't have an index, or wrote it with `df.to_csv(..., index=False)`), then any names on the columns index will be *lost*.

```
In [16]: from pandas._testing import makeCustomDataframe as mkdf

In [17]: df = mkdf(5, 3, r_idx_nlevels=2, c_idx_nlevels=4)

In [18]: df.to_csv("mi.csv")

In [19]: print(open("mi.csv").read())

- Support for HDFStore (via PyTables 3.0.0) on Python3
- Iterator support via `read_hdf` that automatically opens and closes the store when iteration is finished. This is only for *tables*

```
In [25]: path = 'store_iterator.h5'
```

```
In [26]: pd.DataFrame(np.random.randn(10, 2)).to_hdf(path, 'df', table=True)
```

```
In [27]: for df in pd.read_hdf(path, 'df', chunksize=3):
```

```
.....: print(df)
```

```
.....:
```

```

 0 1
0 0.713216 -0.778461
1 -0.661062 0.862877
2 0.344342 0.149565
 0 1
3 -0.626968 -0.875772
4 -0.930687 -0.218983
5 0.949965 -0.442354
 0 1
6 -0.402985 1.111358
7 -0.241527 -0.670477
8 0.049355 0.632633
 0 1
9 -1.502767 -1.225492
```

- `read_csv` will now throw a more informative error message when a file contains no columns, e.g., all newline characters

## Other enhancements

- `DataFrame.replace()` now allows regular expressions on contained Series with object dtype. See the examples section in the regular docs *Replacing via String Expression*

For example you can do

```
In [21]: df = pd.DataFrame({"a": list("ab.."), "b": [1, 2, 3, 4]})
```

```
In [22]: df.replace(regex=r"\s*\.\s*", value=np.nan)
```

```
Out[22]:
```

```

 a b
0 a 1
1 b 2
```

(continues on next page)

(continued from previous page)

```
2 NaN 3
3 NaN 4
```

to replace all occurrences of the string '.' with zero or more instances of surrounding white space with NaN.

Regular string replacement still works as expected. For example, you can do

```
In [23]: df.replace(".", np.nan)
Out[23]:
 a b
0 a 1
1 b 2
2 NaN 3
3 NaN 4
```

to replace all occurrences of the string '.' with NaN.

- `pd.melt()` now accepts the optional parameters `var_name` and `value_name` to specify custom column names of the returned DataFrame.
- `pd.set_option()` now allows N option, value pairs ([GH3667](#)).

Let's say that we had an option 'a.b' and another option 'b.c'. We can set them at the same time:

```
In [31]: pd.get_option('a.b')
Out[31]: 2

In [32]: pd.get_option('b.c')
Out[32]: 3

In [33]: pd.set_option('a.b', 1, 'b.c', 4)

In [34]: pd.get_option('a.b')
Out[34]: 1

In [35]: pd.get_option('b.c')
Out[35]: 4
```

- The `filter` method for group objects returns a subset of the original object. Suppose we want to take only elements that belong to groups with a group sum greater than 2.

```
In [24]: sf = pd.Series([1, 1, 2, 3, 3, 3])

In [25]: sf.groupby(sf).filter(lambda x: x.sum() > 2)
Out[25]:
3 3
4 3
5 3
dtype: int64
```

The argument of `filter` must a function that, applied to the group as a whole, returns True or False.

Another useful operation is filtering out elements that belong to groups with only a couple members.

```
In [26]: dff = pd.DataFrame({"A": np.arange(8), "B": list("aabbbbcc")})
```

```
In [27]: dff.groupby("B").filter(lambda x: len(x) > 2)
```

```
Out[27]:
```

```
 A B
2 2 b
3 3 b
4 4 b
5 5 b
```

Alternatively, instead of dropping the offending groups, we can return a like-indexed objects where the groups that do not pass the filter are filled with NaNs.

```
In [28]: dff.groupby("B").filter(lambda x: len(x) > 2, dropna=False)
```

```
Out[28]:
```

```
 A B
0 NaN NaN
1 NaN NaN
2 2.0 b
3 3.0 b
4 4.0 b
5 5.0 b
6 NaN NaN
7 NaN NaN
```

- Series and DataFrame hist methods now take a `figsize` argument (GH3834)
- DatetimeIndexes no longer try to convert mixed-integer indexes during join operations (GH3877)
- Timestamp.min and Timestamp.max now represent valid Timestamp instances instead of the default datetime.min and datetime.max (respectively), thanks @SleepingPills
- read\_html now raises when no tables are found and BeautifulSoup==4.2.0 is detected (GH4214)

## Experimental features

- Added experimental CustomBusinessDay class to support DateOffsets with custom holiday calendars and custom weekmasks. (GH2301)

---

**Note:** This uses the `numpy.busdaycalendar` API introduced in Numpy 1.7 and therefore requires Numpy 1.7.0 or newer.

---

```
In [29]: from pandas.tseries.offsets import CustomBusinessDay
```

```
In [30]: from datetime import datetime
```

```
As an interesting example, let's look at Egypt where
a Friday-Saturday weekend is observed.
```

```
In [31]: weekmask_egypt = "Sun Mon Tue Wed Thu"
```

```
They also observe International Workers' Day so let's
add that for a couple of years
```

(continues on next page)

(continued from previous page)

```

In [32]: holidays = ["2012-05-01", datetime(2013, 5, 1), np.datetime64("2014-05-01
↪")]

In [33]: bday_egypt = CustomBusinessDay(holidays=holidays, weekmask=weekmask_egypt)

In [34]: dt = datetime(2013, 4, 30)

In [35]: print(dt + 2 * bday_egypt)
2013-05-05 00:00:00

In [36]: dts = pd.date_range(dt, periods=5, freq=bday_egypt)

In [37]: print(pd.Series(dts.weekday, dts).map(pd.Series("Mon Tue Wed Thu Fri Sat
↪Sun".split()))
2013-04-30 Tue
2013-05-02 Thu
2013-05-05 Sun
2013-05-06 Mon
2013-05-07 Tue
Freq: C, dtype: object

```

## Bug fixes

- Plotting functions now raise a `TypeError` before trying to plot anything if the associated objects have a dtype of `object` (GH1818, GH3572, GH3911, GH3912), but they will try to convert object arrays to numeric arrays if possible so that you can still plot, for example, an object array with floats. This happens before any drawing takes place which eliminates any spurious plots from showing up.
- `fillna` methods now raise a `TypeError` if the `value` parameter is a list or tuple.
- `Series.str` now supports iteration (GH3638). You can iterate over the individual elements of each string in the `Series`. Each iteration yields a `Series` with either a single character at each index of the original `Series` or `NaN`. For example,

```

In [38]: strs = "go", "bow", "joe", "slow"

In [39]: ds = pd.Series(strs)

In [40]: for s in ds.str:
.....: print(s)
.....:
0 g
1 b
2 j
3 s
dtype: object
0 o
1 o
2 o
3 l
dtype: object
0 NaN

```

(continues on next page)

(continued from previous page)

```

1 w
2 e
3 o
dtype: object
0 NaN
1 NaN
2 NaN
3 w
dtype: object

In [41]: s
Out[41]:
0 NaN
1 NaN
2 NaN
3 w
dtype: object

In [42]: s.dropna().values.item() == "w"
Out[42]: True

```

The last element yielded by the iterator will be a `Series` containing the last element of the longest string in the `Series` with all other elements being `NaN`. Here since `'slow'` is the longest string and there are no other strings with the same length `'w'` is the only non-null string in the yielded `Series`.

- `HDFStore`
  - will retain index attributes (`freq,tz,name`) on recreation ([GH3499](#))
  - will warn with a `AttributeConflictWarning` if you are attempting to append an index with a different frequency than the existing, or attempting to append an index with a different name than the existing
  - support datelike columns with a timezone as `data_columns` ([GH2852](#))
- Non-unique index support clarified ([GH3468](#)).
  - Fix assigning a new index to a duplicate index in a `DataFrame` would fail ([GH3468](#))
  - Fix construction of a `DataFrame` with a duplicate index
  - `ref_locs` support to allow duplicative indices across dtypes, allows `iget` support to always find the index (even across dtypes) ([GH2194](#))
  - `applymap` on a `DataFrame` with a non-unique index now works (removed warning) ([GH2786](#)), and fix ([GH3230](#))
  - Fix `to_csv` to handle non-unique columns ([GH3495](#))
  - Duplicate indexes with `getitem` will return items in the correct order ([GH3455](#), [GH3457](#)) and handle missing elements like unique indices ([GH3561](#))
  - Duplicate indexes with an empty `DataFrame.from_records` will return a correct frame ([GH3562](#))
  - `Concat` to produce a non-unique columns when duplicates are across dtypes is fixed ([GH3602](#))
  - Allow `insert/delete` to non-unique columns ([GH3679](#))
  - Non-unique indexing with a slice via `loc` and friends fixed ([GH3659](#))
  - Allow `insert/delete` to non-unique columns ([GH3679](#))

- Extend `reindex` to correctly deal with non-unique indices (GH3679)
- `DataFrame.itertuples()` now works with frames with duplicate column names (GH3873)
- Bug in non-unique indexing via `iloc` (GH4017); added `takeable` argument to `reindex` for location-based taking
- Allow non-unique indexing in series via `.ix/.loc` and `__getitem__` (GH4246)
- Fixed non-unique indexing memory allocation issue with `.ix/.loc` (GH4280)
- `DataFrame.from_records` did not accept empty recarrays (GH3682)
- `read_html` now correctly skips tests (GH3741)
- Fixed a bug where `DataFrame.replace` with a compiled regular expression in the `to_replace` argument wasn't working (GH3907)
- Improved `network` test decorator to catch `IOError` (and therefore `URLError` as well). Added `with_connectivity_check` decorator to allow explicitly checking a website as a proxy for seeing if there is network connectivity. Plus, new `optional_args` decorator factory for decorators. (GH3910, GH3914)
- Fixed testing issue where too many sockets were open thus leading to a connection reset issue (GH3982, GH3985, GH4028, GH4054)
- Fixed failing tests in `test_yahoo`, `test_google` where symbols were not retrieved but were being accessed (GH3982, GH3985, GH4028, GH4054)
- `Series.hist` will now take the figure from the current environment if one is not passed
- Fixed bug where a 1xN `DataFrame` would barf on a 1xN mask (GH4071)
- Fixed running of `tox` under `python3` where the `pickle` import was getting rewritten in an incompatible way (GH4062, GH4063)
- Fixed bug where `sharex` and `sharey` were not being passed to `grouped_hist` (GH4089)
- Fixed bug in `DataFrame.replace` where a nested dict wasn't being iterated over when `regex=False` (GH4115)
- Fixed bug in the parsing of microseconds when using the `format` argument in `to_datetime` (GH4152)
- Fixed bug in `PandasAutoDateLocator` where `invert_xaxis` triggered incorrectly `MillisecondLocator` (GH3990)
- Fixed bug in plotting that wasn't raising on invalid colormap for `matplotlib 1.1.1` (GH4215)
- Fixed the legend displaying in `DataFrame.plot(kind='kde')` (GH4216)
- Fixed bug where `Index` slices weren't carrying the name attribute (GH4226)
- Fixed bug in initializing `DatetimeIndex` with an array of strings in a certain time zone (GH4229)
- Fixed bug where `html5lib` wasn't being properly skipped (GH4265)
- Fixed bug where `get_data_famafrench` wasn't using the correct file edges (GH4281)

See the [full release notes](#) or issue tracker on GitHub for a complete list.

## 5.19 Version 0.11

### 5.19.1 Version 0.11.0 (April 22, 2013)

This is a major release from 0.10.1 and includes many new features and enhancements along with a large number of bug fixes. The methods of Selecting Data have had quite a number of additions, and Dtype support is now full-fledged. There are also a number of important API changes that long-time pandas users should pay close attention to.

There is a new section in the documentation, *10 Minutes to Pandas*, primarily geared to new users.

There is a new section in the documentation, *Cookbook*, a collection of useful recipes in pandas (and that we want contributions!).

There are several libraries that are now *Recommended Dependencies*

#### Selection choices

Starting in 0.11.0, object selection has had a number of user-requested additions in order to support more explicit location based indexing. pandas now supports three types of multi-axis indexing.

- `.loc` is strictly label based, will raise `KeyError` when the items are not found, allowed inputs are:
  - A single label, e.g. 5 or 'a', (note that 5 is interpreted as a *label* of the index. This use is **not** an integer position along the index)
  - A list or array of labels ['a', 'b', 'c']
  - A slice object with labels 'a':'f', (note that contrary to usual python slices, **both** the start and the stop are included!)

- A boolean array

See more at [Selection by Label](#)

- `.iloc` is strictly integer position based (from 0 to length-1 of the axis), will raise `IndexError` when the requested indices are out of bounds. Allowed inputs are:
  - An integer e.g. 5
  - A list or array of integers [4, 3, 0]
  - A slice object with ints 1:7
  - A boolean array

See more at [Selection by Position](#)

- `.ix` supports mixed integer and label based access. It is primarily label based, but will fallback to integer positional access. `.ix` is the most general and will support any of the inputs to `.loc` and `.iloc`, as well as support for floating point label schemes. `.ix` is especially useful when dealing with mixed positional and label based hierarchical indexes.

As using integer slices with `.ix` have different behavior depending on whether the slice is interpreted as position based or label based, it's usually better to be explicit and use `.iloc` or `.loc`.

See more at [Advanced Indexing](#) and [Advanced Hierarchical](#).

## Selection deprecations

Starting in version 0.11.0, these methods *may* be deprecated in future versions.

- `irow`
- `icol`
- `iget_value`

See the section [Selection by Position](#) for substitutes.

## Dtypes

Numeric dtypes will propagate and can coexist in DataFrames. If a dtype is passed (either directly via the `dtype` keyword, a passed `ndarray`, or a passed `Series`, then it will be preserved in DataFrame operations. Furthermore, different numeric dtypes will **NOT** be combined. The following example will give you a taste.

```
In [1]: df1 = pd.DataFrame(np.random.randn(8, 1), columns=['A'], dtype='float32')
```

```
In [2]: df1
```

```
Out[2]:
```

```
 A
0 0.469112
1 -0.282863
2 -1.509058
3 -1.135632
4 1.212112
5 -0.173215
6 0.119209
7 -1.044236
```

(continues on next page)

(continued from previous page)

```
In [3]: df1.dtypes

```

```
In [9]: df3.dtypes
```

```
Out[9]:
```

```
A float32
B float64
C float64
dtype: object
```

## Dtype conversion

This is lower-common-denominator upcasting, meaning you get the dtype which can accommodate all of the types

```
In [10]: df3.values.dtype
Out[10]: dtype('float64')
```

Conversion

```
In [11]: df3.astype('float32').dtypes
Out[11]:
A float32
B float32
C float32
dtype: object
```

Mixed conversion

```
In [12]: df3['D'] = '1.'
In [13]: df3['E'] = '1'
In [14]: df3.convert_objects(convert_numeric=True).dtypes
Out[14]:
A float32
B float64
C float64
D float64
E int64
dtype: object

same, but specific dtype conversion
In [15]: df3['D'] = df3['D'].astype('float16')
In [16]: df3['E'] = df3['E'].astype('int32')
In [17]: df3.dtypes
Out[17]:
A float32
B float64
C float64
D float16
E int32
dtype: object
```

Forcing date coercion (and setting NaT when not datelike)

```
In [18]: import datetime
In [19]: s = pd.Series([datetime.datetime(2001, 1, 1, 0, 0), 'foo', 1.0, 1,
.....: pd.Timestamp('20010104'), '20010105'], dtype='O')
.....:
In [20]: s.convert_objects(convert_dates='coerce')
```

(continues on next page)

(continued from previous page)

```

Out[20]:
0 2001-01-01
1 NaT
2 NaT
3 NaT
4 2001-01-04
5 2001-01-05
dtype: datetime64[ns]

```

## Dtype gotchas

### Platform gotchas

Starting in 0.11.0, construction of DataFrame/Series will use default dtypes of `int64` and `float64`, *regardless of platform*. This is not an apparent change from earlier versions of pandas. If you specify dtypes, they *WILL* be respected, however (GH2837)

The following will all result in `int64` dtypes

```

In [21]: pd.DataFrame([1, 2], columns=['a']).dtypes
Out[21]:
a int64
dtype: object

In [22]: pd.DataFrame({'a': [1, 2]}).dtypes
Out[22]:
a int64
dtype: object

In [23]: pd.DataFrame({'a': 1}, index=range(2)).dtypes
Out[23]:
a int64
dtype: object

```

Keep in mind that `DataFrame(np.array([1, 2]))` **WILL** result in `int32` on 32-bit platforms!

### Upcasting gotchas

Performing indexing operations on integer type data can easily upcast the data. The dtype of the input data will be preserved in cases where nans are not introduced.

```

In [24]: dfi = df3.astype('int32')

In [25]: dfi['D'] = dfi['D'].astype('int64')

In [26]: dfi
Out[26]:
 A B C D E
0 0 0 0 0 1 1
1 -2 0 1 1 1
2 -2 0 2 1 1
3 0 -1 3 1 1
4 1 0 4 1 1

```

(continues on next page)

(continued from previous page)

```
5 0 0 5 1 1
6 0 -1 6 1 1
7 0 0 7 1 1
```

```
In [27]: dfi.dtypes
```

```
Out[27]:
```

```
A int32
B int32
C int32
D int64
E int32
dtype: object
```

```
In [28]: casted = dfi[dfi > 0]
```

```
In [29]: casted
```

```
Out[29]:
```

```
 A B C D E
0 NaN NaN NaN 1 1
1 NaN NaN 1.0 1 1
2 NaN NaN 2.0 1 1
3 NaN NaN 3.0 1 1
4 1.0 NaN 4.0 1 1
5 NaN NaN 5.0 1 1
6 NaN NaN 6.0 1 1
7 NaN NaN 7.0 1 1
```

```
In [30]: casted.dtypes
```

```
Out[30]:
```

```
A float64

| E      | int32   |
| dtype: | object  |

## Datetimes conversion

Datetime64[ns] columns in a DataFrame (or a Series) allow the use of `np.nan` to indicate a nan value, in addition to the traditional NaT, or not-a-time. This allows convenient nan setting in a generic way. Furthermore `datetime64[ns]` columns are created by default, when passed datetimelike objects (*this change was introduced in 0.10.1*) ([GH2809](#), [GH2810](#))

```
In [12]: df = pd.DataFrame(np.random.randn(6, 2), pd.date_range('20010102', periods=6),
.....: columns=['A', 'B'])
.....:
```

```
In [13]: df['timestamp'] = pd.Timestamp('20010103')
```

```
In [14]: df
Out[14]:
```

|            | A         | B         | timestamp  |
|------------|-----------|-----------|------------|
| 2001-01-02 | 0.404705  | 0.577046  | 2001-01-03 |
| 2001-01-03 | -1.715002 | -1.039268 | 2001-01-03 |
| 2001-01-04 | -0.370647 | -1.157892 | 2001-01-03 |
| 2001-01-05 | -1.344312 | 0.844885  | 2001-01-03 |
| 2001-01-06 | 1.075770  | -0.109050 | 2001-01-03 |
| 2001-01-07 | 1.643563  | -1.469388 | 2001-01-03 |

```
datetime64[ns] out of the box
```

```
In [15]: df.dtypes.value_counts()
```

```
Out[15]:
```

|                |       |
|----------------|-------|
| float64        | 2     |
| datetime64[ns] | 1     |
| dtype:         | int64 |

(continues on next page)

(continued from previous page)

```
use the traditional nan, which is mapped to NaT internally
In [16]: df.loc[df.index[2:4], ['A', 'timestamp']] = np.nan
```

```
In [17]: df
```

```
Out[17]:
```

```
 A B timestamp
2001-01-02 0.404705 0.577046 2001-01-03
2001-01-03 -1.715002 -1.039268 2001-01-03
2001-01-04 NaN -1.157892 NaT
2001-01-05 NaN 0.844885 NaT
2001-01-06 1.075770 -0.109050 2001-01-03
2001-01-07 1.643563 -1.469388 2001-01-03
```

Astype conversion on datetime64[ns] to object, implicitly converts NaT to np.nan

```
In [18]: import datetime
```

```
In [19]: s = pd.Series([datetime.datetime(2001, 1, 2, 0, 0) for i in range(3)])
```

```
In [20]: s.dtype
```

```
Out[20]: dtype('<M8[ns]')
```

```
In [21]: s[1] = np.nan
```

```
In [22]: s
```

```
Out[22]:
```

```
0 2001-01-02
1 NaT
2 2001-01-02
dtype: datetime64[ns]
```

```
In [23]: s.dtype
```

```
Out[23]: dtype('<M8[ns]')
```

```
In [24]: s = s.astype('O')
```

```
In [25]: s
```

```
Out[25]:
```

```
0 2001-01-02 00:00:00
1 NaT
2 2001-01-02 00:00:00
dtype: object
```

```
In [26]: s.dtype
```

```
Out[26]: dtype('O')
```

## API changes

- Added `to_series()` method to indices, to facilitate the creation of indexers ([GH3275](#))
- `HDFStore`
  - added the method `select_column` to select a single column from a table as a Series.
  - deprecated the `unique` method, can be replicated by `select_column(key, column).unique()`
  - `min_itemsize` parameter to `append` will now automatically create data columns for passed keys

## Enhancements

- Improved performance of `df.to_csv()` by up to 10x in some cases. ([GH3059](#))
- `Numexpr` is now a *Recommended Dependencies*, to accelerate certain types of numerical and boolean operations
- `Bottleneck` is now a *Recommended Dependencies*, to accelerate certain types of nan operations
- `HDFStore`
  - support `read_hdf/to_hdf` API similar to `read_csv/to_csv`

```
In [27]: df = pd.DataFrame({'A': range(5), 'B': range(5)})
In [28]: df.to_hdf('store.h5', 'table', append=True)
In [29]: pd.read_hdf('store.h5', 'table', where=['index > 2'])
Out[29]:
 A B
3 3 3
4 4 4
```

- provide dotted attribute access to get from stores, e.g. `store.df == store['df']`
  - new keywords `iterator=boolean`, and `chunks=number_in_a_chunk` are provided to support iteration on `select` and `select_as_multiple` ([GH3076](#))
- You can now select timestamps from an *unordered* timeseries similarly to an *ordered* timeseries ([GH2437](#))
- You can now select with a string from a DataFrame with a datelike index, in a similar way to a Series ([GH3070](#))

```
In [30]: idx = pd.date_range("2001-10-1", periods=5, freq='M')
In [31]: ts = pd.Series(np.random.rand(len(idx)), index=idx)
In [32]: ts['2001']
Out[32]:
2001-10-31 0.117967
2001-11-30 0.702184
2001-12-31 0.414034
Freq: M, dtype: float64
In [33]: df = pd.DataFrame({'A': ts})
In [34]: df['2001']
Out[34]:
```

(continues on next page)

(continued from previous page)

2001-01-04 -0.185352
2001-01-05 0.669934
Freq: D, Name: B, dtype: float64

```

- In `pd.io.data.Options`,
  - Fix bug when trying to fetch data for the current month when already past expiry.
  - Now using `lxml` to scrape html instead of `BeautifulSoup` (`lxml` was faster).
  - New instance variables for calls and puts are automatically created when a method that creates them is called. This works for current month where the instance variables are simply `calls` and `puts`. Also works for future expiry months and save the instance variable as `callsMMYY` or `putsMMYY`, where `MMYY` are, respectively, the month and year of the option's expiry.
  - `Options.get_near_stock_price` now allows the user to specify the month for which to get relevant options data.
  - `Options.get_forward_data` now has optional kwargs `near` and `above_below`. This allows the user to specify if they would like to only return forward looking data for options near the current stock price. This just obtains the data from `Options.get_near_stock_price` instead of `Options.get_xxx_data()` ([GH2758](#)).
- Cursor coordinate information is now displayed in time-series plots.
- added option `display.max_seq_items` to control the number of elements printed per sequence pprinting it. ([GH2979](#))
- added option `display.chop_threshold` to control display of small numerical values. ([GH2739](#))

- added option `display.max_info_rows` to prevent `verbose_info` from being calculated for frames above 1M rows (configurable). (GH2807, GH2918)
- `value_counts()` now accepts a “normalize” argument, for normalized histograms. (GH2710).
- `DataFrame.from_records` now accepts not only dicts but any instance of the `collections.Mapping` ABC.
- added option `display.mpl_style` providing a sleeker visual style for plots. Based on <https://gist.github.com/huyng/816622> (GH3075).
- Treat boolean values as integers (values 1 and 0) for numeric operations. (GH2641)
- `to_html()` now accepts an optional “escape” argument to control reserved HTML character escaping (enabled by default) and escapes `&`, in addition to `<` and `>`. (GH2919)

See the *full release notes* or issue tracker on GitHub for a complete list.

## 5.20 Version 0.10

### 5.20.1 Version 0.10.1 (January 22, 2013)

This is a minor release from 0.10.0 and includes new features, enhancements, and bug fixes. In particular, there is substantial new HDFStore functionality contributed by Jeff Reback.

An undesired API breakage with functions taking the `inplace` option has been reverted and deprecation warnings added.

## API changes

- Functions taking an `inplace` option return the calling object as before. A deprecation message has been added
- Groupby aggregations Max/Min no longer exclude non-numeric data (GH2700)
- Resampling an empty DataFrame now returns an empty DataFrame instead of raising an exception (GH2640)
- The file reader will now raise an exception when NA values are found in an explicitly specified integer column instead of converting the column to float (GH2631)
- `DatetimeIndex.unique` now returns a `DatetimeIndex` with the same name and `timezone` instead of an array (GH2563)

## New features

- MySQL support for database (contribution from Dan Allan)

## HDFStore

You may need to upgrade your existing data files. Please visit the **compatibility** section in the main docs.

You can designate (and index) certain columns that you want to be able to perform queries on a table, by passing a list to `data_columns`

```
In [1]: store = pd.HDFStore("store.h5")

In [2]: df = pd.DataFrame(
...: np.random.randn(8, 3),
...: index=pd.date_range("1/1/2000", periods=8),
...: columns=["A", "B", "C"],
...:)
...:

In [3]: df["string"] = "foo"

In [4]: df.loc[df.index[4:6], "string"] = np.nan

In [5]: df.loc[df.index[7:9], "string"] = "bar"

In [6]: df["string2"] = "cool"

In [7]: df
Out[7]:
```

|            | A         | B         | C         | string | string2 |
|------------|-----------|-----------|-----------|--------|---------|
| 2000-01-01 | 0.469112  | -0.282863 | -1.509059 | foo    | cool    |
| 2000-01-02 | -1.135632 | 1.212112  | -0.173215 | foo    | cool    |
| 2000-01-03 | 0.119209  | -1.044236 | -0.861849 | foo    | cool    |
| 2000-01-04 | -2.104569 | -0.494929 | 1.071804  | foo    | cool    |
| 2000-01-05 | 0.721555  | -0.706771 | -1.039575 | NaN    | cool    |
| 2000-01-06 | 0.271860  | -0.424972 | 0.567020  | NaN    | cool    |
| 2000-01-07 | 0.276232  | -1.087401 | -0.673690 | foo    | cool    |
| 2000-01-08 | 0.113648  | -1.478427 | 0.524988  | bar    | cool    |

(continues on next page)

(continued from previous page)

```
on-disk operations
In [8]: store.append("df", df, data_columns=["B", "C", "string", "string2"])

In [9]: store.select("df", "B>0 and string=='foo'")
Out[9]:
 A B C string string2
2000-01-02 -1.135632 1.212112 -0.173215 foo cool

this is in-memory version of this type of selection
In [10]: df[(df.B > 0) & (df.string == "foo")]
Out[10]:
 A B C string string2
2000-01-02 -1.135632 1.212112 -0.173215 foo cool
```

Retrieving unique values in an indexable or data column.

```
note that this is deprecated as of 0.14.0
can be replicated by: store.select_column('df','index').unique()
store.unique("df", "index")
store.unique("df", "string")
```

You can now store datetime64 in data columns

```
In [11]: df_mixed = df.copy()

In [12]: df_mixed["datetime64"] = pd.Timestamp("20010102")

In [13]: df_mixed.loc[df_mixed.index[3:4], ["A", "B"]] = np.nan

In [14]: store.append("df_mixed", df_mixed)

In [15]: df_mixed1 = store.select("df_mixed")

In [16]: df_mixed1
Out[16]:
 A B C string string2 datetime64
2000-01-01 0.469112 -0.282863 -1.509059 foo cool 2001-01-02
2000-01-02 -1.135632 1.212112 -0.173215 foo cool 2001-01-02
2000-01-03 0.119209 -1.044236 -0.861849 foo cool 2001-01-02
2000-01-04 NaN NaN 1.071804 foo cool 2001-01-02

2000-01-06 0.271860 -0.424972 0.567020 NaN cool 2001-01-02
2000-01-07 0.276232 -1.087401 -0.673690 foo cool 2001-01-02
2000-01-08 0.113648 -1.478427 0.524988 bar cool 2001-01-02

In [17]: df_mixed1.dtypes.value_counts()
Out[17]:
float64 3
object 2
datetime64[ns] 1
dtype: int64
```

You can pass columns keyword to select to filter a list of the return columns, this is equivalent to passing a

```
Term('columns',list_of_columns_to_filter)
```

```
In [18]: store.select("df", columns=["A", "B"])
```

```
Out[18]:
```

|            | A         | B         |
|------------|-----------|-----------|

HDFStore now serializes MultiIndex dataframes when appending tables.

```
In [19]: index = pd.MultiIndex(levels=[['foo', 'bar', 'baz', 'qux'],
....: ['one', 'two', 'three']],
....: labels=[[0, 0, 0, 1, 1, 2, 2, 3, 3, 3],
....: [0, 1, 2, 0, 1, 1, 2, 0, 1, 2]],
....: names=['foo', 'bar'])
....:
```

```
In [20]: df = pd.DataFrame(np.random.randn(10, 3), index=index,
```

```
....: columns=['A', 'B', 'C'])
....:
```

```
In [21]: df
```

```
Out[21]:
```

|         | A         | B         | C         |
|---------|-----------|-----------|-----------|
| foo bar |           |           |           |
| foo one | -0.116619 | 0.295575  | -1.047704 |
| two     | 1.640556  | 1.905836  | 2.772115  |
| three   | 0.088787  | -1.144197 | -0.633372 |
| bar one | 0.925372  | -0.006438 | -0.820408 |
| two     | -0.600874 | -1.039266 | 0.824758  |
| baz two | -0.824095 | -0.337730 | -0.927764 |
| three   | -0.840123 | 0.248505  | -0.109250 |

| bar one | 0.925372  | -0.006438 | -0.820408 |
| two     | -0.600874 | -1.039266 | 0.824758  |
| baz two | -0.824095 | -0.337730 | -0.927764 |

(continues on next page)

(continued from previous page)

```

 three -0.840123 0.248505 -0.109250
qux one 0.431977 -0.460710 0.336505
 two -3.207595 -1.535854 0.409769
 three -0.673145 -0.741113 -0.110891

the levels are automatically included as data columns
In [24]: store.select('mi', "foo='bar'")
Out[24]:
 A B C
foo bar
bar one 0.925372 -0.006438 -0.820408
 two -0.600874 -1.039266 0.824758

```

Multi-table creation via `append_to_multiple` and selection via `select_as_multiple` can create/select from multiple tables and return a combined result, by using `where` on a selector table.

```

In [19]: df_mt = pd.DataFrame(
.....: np.random.randn(8, 6),
.....: index=pd.date_range("1/1/2000", periods=8),
.....: columns=["A", "B", "C", "D", "E", "F"],
.....:)
.....:

In [20]: df_mt["foo"] = "bar"

you can also create the tables individually
In [21]: store.append_to_multiple(
.....: {"df1_mt": ["A", "B"], "df2_mt": None}, df_mt, selector="df1_mt"
.....:)
.....:

In [22]: store
Out[22]:
<class 'pandas.io.pytables.HDFStore'>
File path: store.h5

individual tables were created
In [23]: store.select("df1_mt")
Out[23]:
 A B

```

### Enhancements

- HDFStore now can read native PyTables table format tables
- You can pass `nan_rep = 'my_nan_rep'` to `append`, to change the default nan representation on disk (which converts to/from `np.nan`), this defaults to `nan`.
- You can pass `index` to `append`. This defaults to `True`. This will automatically create indices on the *indexables* and *data columns* of the table
- You can pass `chunksize=an integer` to `append`, to change the writing chunksize (default is 50000). This will significantly lower your memory usage on writing.
- You can pass `expectedrows=an integer` to the first `append`, to set the TOTAL number of expected rows that PyTables will expect. This will optimize read/write performance.
- `Select` now supports passing `start` and `stop` to provide selection space limiting in selection.
- Greatly improved ISO8601 (e.g., yyyy-mm-dd) date parsing for file parsers ([GH2698](#))
- Allow `DataFrame.merge` to handle combinatorial sizes too large for 64-bit integer ([GH2690](#))
- `Series` now has unary negation (`-series`) and inversion (`~series`) operators ([GH2686](#))
- `DataFrame.plot` now includes a `logx` parameter to change the x-axis to log scale ([GH2327](#))
- `Series` arithmetic operators can now handle constant and `ndarray` input ([GH2574](#))
- `ExcelFile` now takes a `kind` argument to specify the file type ([GH2613](#))
- A faster implementation for `Series.str` methods ([GH2602](#))

### Bug Fixes

- `HDFStore` tables can now store `float32` types correctly (cannot be mixed with `float64` however)
- Fixed Google Analytics prefix when specifying request segment ([GH2713](#)).
- Function to reset Google Analytics token store so users can recover from improperly setup client secrets ([GH2687](#)).
- Fixed `groupby` bug resulting in segfault when passing in `MultiIndex` ([GH2706](#))

- Fixed bug where passing a Series with datetime64 values into `to_datetime` results in bogus output values (GH2699)
- Fixed bug in `pattern` in `HDFStore` expressions when `pattern` is not a valid regex (GH2694)
- Fixed performance issues while aggregating boolean data (GH2692)
- When given a boolean mask key and a Series of new values, Series `__setitem__` will now align the incoming values with the original Series (GH2686)
- Fixed `MemoryError` caused by performing counting sort on sorting `MultiIndex` levels with a very large number of combinatorial values (GH2684)
- Fixed bug that causes plotting to fail when the index is a `DatetimeIndex` with a fixed-offset timezone (GH2683)
- Corrected business day subtraction logic when the offset is more than 5 bdays and the starting date is on a weekend (GH2680)
- Fixed C file parser behavior when the file has more columns than data (GH2668)
- Fixed file reader bug that misaligned columns with data in the presence of an implicit column and a specified `usecols` value
- `DataFrames` with numerical or datetime indices are now sorted prior to plotting (GH2609)
- Fixed `DataFrame.from_records` error when passed columns, index, but empty records (GH2633)
- Several bug fixed for Series operations when dtype is `datetime64` (GH2689, GH2629, GH2626)

See the [full release notes](#) or issue tracker on GitHub for a complete list.

## 5.20.2 Version 0.10.0 (December 17, 2012)

This is a major release from 0.9.1 and includes many new features and enhancements along with a large number of bug fixes. There are also a number of important API changes that long-time pandas users should pay close attention to.

### File parsing new features

The delimited file parsing engine (the guts of `read_csv` and `read_table`) has been rewritten from the ground up and now uses a fraction the amount of memory while parsing, while being 40% or more faster in most use cases (in some cases much faster).

There are also many new features:

- Much-improved Unicode handling via the `encoding` option.
- Column filtering (`usecols`)
- Dtype specification (`dtype` argument)
- Ability to specify strings to be recognized as True/False
- Ability to yield NumPy record arrays (`as_recarray`)
- High performance `delim_whitespace` option
- Decimal format (e.g. European format) specification
- Easier CSV dialect options: `escapechar`, `lineterminator`, `quotechar`, etc.
- More robust handling of many exceptional kinds of files observed in the wild

### API changes

#### Deprecated DataFrame BINOP TimeSeries special case behavior

The default behavior of binary operations between a DataFrame and a Series has always been to align on the DataFrame's columns and broadcast down the rows, **except** in the special case that the DataFrame contains time series. Since there are now method for each binary operator enabling you to specify how you want to broadcast, we are phasing out this special case (Zen of Python: *Special cases aren't special enough to break the rules*). Here's what I'm talking about:

```
In [1]: import pandas as pd

In [2]: df = pd.DataFrame(np.random.randn(6, 4), index=pd.date_range("1/1/2000",
↳ periods=6))

In [3]: df
Out[3]:
```

|            | 0         | 1         | 2         | 3         |

Change your code to
In [5]: df.sub(df[0], axis=0) # align on axis 0 (rows)
Out[5]:
 0 1 2 3
2000-01-01 0.0 -0.751976 -1.978171 -1.604745
2000-01-02 0.0 -1.385327 -1.092903 -2.256348
2000-01-03 0.0 -1.242720 0.366920 1.933653
2000-01-04 0.0 -1.428326 -1.761130 -0.449695
2000-01-05 0.0 0.991993 0.701204 -0.662428
2000-01-06 0.0 0.787338 -0.804737 1.198677

```

You will get a deprecation warning in the 0.10.x series, and the deprecated functionality will be removed in 0.11 or later.

### Altered resample default behavior

The default time series resample binning behavior of daily D and *higher* frequencies has been changed to `closed='left'`, `label='left'`. Lower frequencies are unaffected. The prior defaults were causing a great deal of confusion for users, especially resampling data to daily frequency (which labeled the aggregated group with the end of the interval: the next day).

```
In [1]: dates = pd.date_range('1/1/2000', '1/5/2000', freq='4h')
```

```
In [2]: series = pd.Series(np.arange(len(dates)), index=dates)
```

```
In [3]: series
```

```

2000-01-05 129
Freq: D, dtype: int64

```

- Infinity and negative infinity are no longer treated as NA by `isnull` and `notnull`. That they ever were was a relic of early pandas. This behavior can be re-enabled globally by the `mode.use_inf_as_null` option:

```
In [6]: s = pd.Series([1.5, np.inf, 3.4, -np.inf])
```

```
In [7]: pd.isnull(s)
```

```
Out[7]:
```

```

0 False
1 False
2 False
3 False

```

(continues on next page)

(continued from previous page)

```
Length: 4, dtype: bool
```

```
In [8]: s.fillna(0)
```

```
Out[8]:
```

```
0 1.500000
1 inf
2 3.400000
3 -inf
```

```
Length: 4, dtype: float64
```

```
In [9]: pd.set_option('use_inf_as_null', True)
```

```
In [10]: pd.isnull(s)
```

```
Out[10]:
```

```
0 False
1 True
2 False
3 True
```

```
Length: 4, dtype: bool
```

```
In [11]: s.fillna(0)
```

```
Out[11]:
```

```
0 1.5
1 0.0
2 3.4
3 0.0
```

```
Length: 4, dtype: float64
```

```
In [12]: pd.reset_option('use_inf_as_null')
```

- Methods with the `inplace` option now all return `None` instead of the calling object. E.g. code written like `df = df.fillna(0, inplace=True)` may stop working. To fix, simply delete the unnecessary variable assignment.
- `pandas.merge` no longer sorts the group keys (`sort=False`) by default. This was done for performance reasons: the group-key sorting is often one of the more expensive parts of the computation and is often unnecessary.
- The default column names for a file with no header have been changed to the integers `0` through `N - 1`. This is to create consistency with the `DataFrame` constructor with no columns specified. The `v0.9.0` behavior (names `X0, X1, ...`) can be reproduced by specifying `prefix='X'`:

```
In [6]: import io
```

```
In [7]: data = """
```

```
...: a,b,c
...: 1,Yes,2
...: 3,No,4
...: """
...:
```

```
In [8]: print(data)
```

```
a,b,c
1,Yes,2
```

(continues on next page)

(continued from previous page)

3, No, 4

**In [9]:** `pd.read_csv(io.StringIO(data), header=None)`**Out[9]:**

```

 0 1 2
0 a b c
1 1 Yes 2
2 3 No 4

```

**In [10]:** `pd.read_csv(io.StringIO(data), header=None, prefix="X")`**Out[10]:**

```

 X0 X1 X2
0 a b c
1 1 Yes 2
2 3 No 4

```

- Values like 'Yes' and 'No' are not interpreted as boolean by default, though this can be controlled by new `true_values` and `false_values` arguments:

**In [11]:** `print(data)`

```

a,b,c
1,Yes,2
3,No,4

```

**In [12]:** `pd.read_csv(io.StringIO(data))`**Out[12]:**

```

 a b c
0 1 Yes 2
1 3 No 4

```

**In [13]:** `pd.read_csv(io.StringIO(data), true_values=["Yes"], false_values=["No"])`**Out[13]:**

```

 a b c
0 1 True 2
1 3 False 4

```

- The file parsers will not recognize non-string values arising from a converter function as NA if passed in the `na_values` argument. It's better to do post-processing using the `replace` function instead.
- Calling `fillna` on Series or DataFrame with no arguments is no longer valid code. You must either specify a fill value or an interpolation method:

**In [14]:** `s = pd.Series([np.nan, 1.0, 2.0, np.nan, 4])`**In [15]:** `s`**Out[15]:**

```

0 NaN
1 1.0
2 2.0
3 NaN

```

(continues on next page)

(continued from previous page)

```
4 4.0
dtype: float64

In [16]: s.fillna(0)
Out[16]:
0 0.0
1 1.0
2 2.0
3 0.0
4 4.0
dtype: float64
```

```
In [17]: s.fillna(method="pad")
Out[17]:
0 NaN
1 1.0
2 2.0
3 2.0
4 4.0
dtype: float64
```

Convenience methods `ffill` and `bfill` have been added:

```
In [18]: s.fffll()
Out[18]:
0 NaN
1 1.0
2 2.0
3 2.0
4 4.0
dtype: float64
```

- `Series.apply` will now operate on a returned value from the applied function, that is itself a series, and possibly upcast the result to a `DataFrame`

```
In [19]: def f(x):
.....: return pd.Series([x, x ** 2], index=["x", "x^2"])
.....:

In [20]: s = pd.Series(np.random.rand(5))

In [21]: s
Out[21]:
0 0.340445
1 0.984729
2 0.919540
3 0.037772
4 0.861549
dtype: float64

In [22]: s.apply(f)
Out[22]:
```

(continues on next page)

(continued from previous page)

|---|----------|----------|
| 0 | 0.340445 | 0.115903 |
| 1 | 0.984729 | 0.969691 |
| 2 | 0.919540 | 0.845555 |
| 3 | 0.037772 | 0.001427 |
| 4 | 0.861549 | 0.742267 |

- New API functions for working with pandas options ([GH2097](#)):
  - `get_option/ set_option` - get/set the value of an option. Partial names are accepted. - `reset_option` - reset one or more options to their default value. Partial names are accepted. - `describe_option` - print a description of one or more options. When called with no arguments, print all registered options.

Note: `set_printoptions/ reset_printoptions` are now deprecated (but functioning), the print options now live under “`display.XYZ`”. For example:

```
In [23]: pd.get_option("display.max_rows")
Out[23]: 15
```

- `to_string()` methods now always return unicode strings ([GH2224](#)).

## New features

### Wide DataFrame printing

Instead of printing the summary information, pandas now splits the string representation across multiple rows by default:

```
In [24]: wide_frame = pd.DataFrame(np.random.randn(5, 16))

In [25]: wide_frame
Out[25]:
```

|   | 0         | 1         | 2         | 3         | 4         | 5         | 6         | ... | 9         |
|---|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----|-----------|
| ↪ | 10        | 11        | 12        | 13        | 14        | 15        |           |     |           |
| 0 | -0.548702 | 1.467327  | -1.015962 | -0.483075 | 1.637550  | -1.217659 | -0.291519 | ... | 0.991460  |
| ↪ | 0.919069  | 0.266046  | -0.709661 | 1.669052  | 1.037882  | -1.705775 |           |     |           |
| 1 | -0.919854 | -0.042379 | 1.247642  | -0.009920 | 0.290213  | 0.495767  | 0.362949  | ... | -0.089329 |

| ↪ | 1.018601  | -0.595447 | 1.395433  | -0.392670 | 0.007207  | 1.928123  |           |     |           |

[5 rows x 16 columns]

The old behavior of printing out summary information can be achieved via the ‘`expand_frame_repr`’ print option:

```
In [26]: pd.set_option("expand_frame_repr", False)

In [27]: wide_frame
Out[27]:
```

|   | 0 | 1 | 2  | 3  | 4  | 5  | 6  | 7                           |
|---|---|---|----|----|----|----|----|-----------------------------|
| ↪ | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 (continues on next page) |

(continued from previous page)

```

```

### Enhancements

- added ability to hierarchical keys

```

In [58]: store.put('foo/bar/bah', df)

In [59]: store.append('food/orange', df)

In [60]: store.append('food/apple', df)

In [61]: store
Out[61]:
<class 'pandas.io.pytables.HDFStore'>
File path: store.h5
/foo/bar/bah frame (shape->[8,3])
/food/apple frame_table (typ->appendable,nrows->8,ncols->3,
↳indexers->[index])
/food/orange frame_table (typ->appendable,nrows->8,ncols->3,
↳indexers->[index])
/wp wide_table (typ->appendable,nrows->12,ncols->2,
↳indexers->[major_axis,minor_axis])

remove all nodes under this level
In [62]: store.remove('food')

In [63]: store
Out[63]:
<class 'pandas.io.pytables.HDFStore'>
File path: store.h5
/foo/bar/bah frame (shape->[8,3])
/wp wide_table (typ->appendable,nrows->12,ncols->2,
↳indexers->[major_axis,minor_axis])

```

- added mixed-dtype support!

```
In [64]: df['string'] = 'string'
```

(continues on next page)

(continued from previous page)

```

In [65]: df['int'] = 1

In [66]: store.append('df', df)

In [67]: df1 = store.select('df')

In [68]: df1
Out[68]:
 A B C string int

[8 rows x 5 columns]

In [69]: df1.get_dtype_counts()
Out[69]:
float64 3
int64 1
object 1
dtype: int64

```

- performance improvements on table writing
- support for arbitrarily indexed dimensions
- SparseSeries now has a density property ([GH2384](#))
- enable Series.str.strip/lstrip/rstrip methods to take an input argument to strip arbitrary characters ([GH2411](#))
- implement value\_vars in melt to limit values to certain columns and add melt to pandas namespace ([GH2412](#))

### Bug Fixes

- added Term method of specifying where conditions ([GH1996](#)).
- del store['df'] now call store.remove('df') for store deletion
- deleting of consecutive rows is much faster than before
- min\_itemsize parameter can be specified in table creation to force a minimum size for indexing columns (the previous implementation would set the column size based on the first append)
- indexing support via create\_table\_index (requires PyTables >= 2.3) ([GH698](#)).
- appending on a store would fail if the table was not first created via put
- fixed issue with missing attributes after loading a pickled dataframe ([GH2431](#))
- minor change to select and remove: require a table ONLY if where is also provided (and not None)

### Compatibility

0.10 of HDFStore is backwards compatible for reading tables created in a prior version of pandas, however, query terms using the prior (undocumented) methodology are unsupported. You must read in the entire file and write it out using the new format to take advantage of the updates.

## N dimensional panels (experimental)

Adding experimental support for Panel4D and factory functions to create n-dimensional named panels. Here is a taste of what to expect.

```
In [58]: p4d = Panel4D(np.random.randn(2, 2, 5, 4),
.....: labels=['Label1', 'Label2'],
.....: items=['Item1', 'Item2'],
.....: major_axis=date_range('1/1/2000', periods=5),
.....: minor_axis=['A', 'B', 'C', 'D'])
.....:

In [59]: p4d
Out[59]:
<class 'pandas.core.panelnd.Panel4D'>
Dimensions: 2 (labels) x 2 (items) x 5 (major_axis) x 4 (minor_axis)
Labels axis: Label1 to Label2
Items axis: Item1 to Item2
Major_axis axis: 2000-01-01 00:00:00 to 2000-01-05 00:00:00
Minor_axis axis: A to D
```

See the [full release notes](#) or issue tracker on GitHub for a complete list.

## 5.21 Version 0.9

### 5.21.1 Version 0.9.1 (November 14, 2012)

This is a bug fix release from 0.9.0 and includes several new features and enhancements along with a large number of bug fixes. The new features include by-column sort order for DataFrame and Series, improved NA handling for the rank method, masking functions for DataFrame, and intraday time-series filtering for DataFrame.

#### New features

- `Series.sort`, `DataFrame.sort`, and `DataFrame.sort_index` can now be specified in a per-column manner to support multiple sort orders ([GH928](#))

```
In [2]: df = pd.DataFrame(np.random.randint(0, 2, (6, 3)),
...: columns=['A', 'B', 'C'])
```

```
In [3]: df.sort(['A', 'B'], ascending=[1, 0])
```

```
Out[3]:
```

```
 A B C
3 0 1 1
4 0 1 1
2 0 0 1
0 1 0 0
1 1 0 0
5 1 0 0
```

- `DataFrame.rank` now supports additional argument values for the `na_option` parameter so missing values can be assigned either the largest or the smallest rank ([GH1508](#), [GH2159](#))

```
In [1]: df = pd.DataFrame(np.random.randn(6, 3), columns=['A', 'B', 'C'])
```

```
In [2]: df.loc[2:4] = np.nan
```

```
In [3]: df.rank()
```

```
Out[3]:
```

|   | A   | B   | C   |
|---|-----|-----|-----|
| 0 | 3.0 | 2.0 | 1.0 |
| 1 | 1.0 | 3.0 | 2.0 |
| 2 | NaN | NaN | NaN |
| 3 | NaN | NaN | NaN |
| 4 | NaN | NaN | NaN |
| 5 | 2.0 | 1.0 | 3.0 |

```
In [4]: df.rank(na_option='top')
```

```
Out[4]:
```

|   | A   | B   | C   |
|---|-----|-----|-----|
| 0 | 6.0 | 5.0 | 4.0 |
| 1 | 4.0 | 6.0 | 5.0 |
| 2 | 2.0 | 2.0 | 2.0 |
| 3 | 2.0 | 2.0 | 2.0 |
| 4 | 2.0 | 2.0 | 2.0 |
| 5 | 5.0 | 4.0 | 6.0 |

```
In [5]: df.rank(na_option='bottom')
```

```
Out[5]:
```

|   | A   | B   | C   |
|---|-----|-----|-----|
| 0 | 3.0 | 2.0 | 1.0 |
| 1 | 1.0 | 3.0 | 2.0 |
| 2 | 5.0 | 5.0 | 5.0 |
| 3 | 5.0 | 5.0 | 5.0 |
| 4 | 5.0 | 5.0 | 5.0 |
| 5 | 2.0 | 1.0 | 3.0 |

- DataFrame has new `where` and `mask` methods to select values according to a given boolean mask (GH2109, GH2151)

DataFrame currently supports slicing via a boolean vector the same length as the DataFrame (inside the `[]`). The returned DataFrame has the same number of columns as the original, but is sliced on its index.

```
In [6]: df = DataFrame(np.random.randn(5, 3), columns = ['A', 'B', 'C'])

NameError Traceback (most recent call last)
<ipython-input-6-b548a30a7bce> in <module>

5 0.271860 -0.424972 0.567020

```

If a DataFrame is sliced with a DataFrame based boolean condition (with the same size as the original DataFrame), then a DataFrame the same size (index and columns) as the original is returned, with elements that do not meet the boolean condition as NaN. This is accomplished via the new method `DataFrame.where`. In addition, `where` takes an optional `other` argument for replacement.

```
In [9]: df[df>0]
```

```
Out[9]:

```

```
Out[11]:
```

```

 A B C
0 0.469112 0.282863 1.509059
1 1.135632 1.212112 0.173215
2 NaN NaN NaN
3 NaN NaN NaN
4 NaN NaN NaN
5 0.271860 0.424972 0.567020

```

Furthermore, `where` now aligns the input boolean condition (ndarray or DataFrame), such that partial selection with setting is possible. This is analogous to partial setting via `.ix` (but on the contents rather than the axis labels)

```
In [12]: df2 = df.copy()
```

(continues on next page)

(continued from previous page)

```
In [13]: df2[df2[1:4] > 0] = 3
```

```
In [14]: df2
```

```
Out[14]:
```

|   | A         | B         | C         |
|---|-----------|-----------|-----------|

| 4 | NaN      | NaN      | NaN     |
| 5 | 0.271860 | NaN      | 0.56702 |

- Enable referencing of Excel columns by their column names (GH1936)

```
In [16]: xl = pd.ExcelFile('data/test.xls')
```

```
In [17]: xl.parse('Sheet1', index_col=0, parse_dates=True,
.....: parse_cols='A:D')
```

```
.....:
Out[17]:
```

|            | A         | B         | C         | D         |
|------------|-----------|-----------|-----------|-----------|
| 2000-01-03 | 0.980269  | 3.685731  | -0.364217 | -1.159738 |
| 2000-01-04 | 1.047916  | -0.041232 | -0.161812 | 0.212549  |
| 2000-01-05 | 0.498581  | 0.731168  | -0.537677 | 1.346270  |
| 2000-01-06 | 1.120202  | 1.567621  | 0.003641  | 0.675253  |
| 2000-01-07 | -0.487094 | 0.571455  | -1.611639 | 0.103469  |
| 2000-01-10 | 0.836649  | 0.246462  | 0.588543  | 1.062782  |
| 2000-01-11 | -0.157161 | 1.340307  | 1.195778  | -1.097007 |

- Added option to disable pandas-style tick locators and formatters using `series.plot(x_compat=True)` or `pandas.plot_params['x_compat'] = True` (GH2205)
- Existing TimeSeries methods `at_time` and `between_time` were added to DataFrame (GH2149)
- DataFrame.dot can now accept ndarrays (GH2042)
- DataFrame.drop now supports non-unique indexes (GH2101)
- Panel.shift now supports negative periods (GH2164)
- DataFrame now support unary `~` operator (GH2110)

## API changes

- Upsampling data with a PeriodIndex will result in a higher frequency TimeSeries that spans the original time window

```
In [1]: prng = pd.period_range('2012Q1', periods=2, freq='Q')
In [2]: s = pd.Series(np.random.randn(len(prng)), prng)
In [4]: s.resample('M')
Out[4]:
2012-01 -1.471992
2012-02 NaN
2012-03 NaN
2012-04 -0.493593
2012-05 NaN
2012-06 NaN
Freq: M, dtype: float64
```

- Period.end\_time now returns the last nanosecond in the time interval ([GH2124](#), [GH2125](#), [GH1764](#))

```
In [18]: p = pd.Period('2012')
In [19]: p.end_time
Out[19]: Timestamp('2012-12-31 23:59:59.999999999')
```

- File parsers no longer coerce to float or bool for columns that have custom converters specified ([GH2184](#))

```
In [20]: import io
In [21]: data = ('A,B,C\n'
.....: '00001,001,5\n'
.....: '00002,002,6')
.....:
In [22]: pd.read_csv(io.StringIO(data), converters={'A': lambda x: x.strip()})
Out[22]:
 A B C
0 00001 1 5
1 00002 2 6
```

See the [full release notes](#) or issue tracker on GitHub for a complete list.

### 5.21.2 Version 0.9.0 (October 7, 2012)

This is a major release from 0.8.1 and includes several new features and enhancements along with a large number of bug fixes. New features include vectorized unicode encoding/decoding for `Series.str`, `to_latex` method to `DataFrame`, more flexible parsing of boolean values, and enabling the download of options data from Yahoo! Finance.

#### New features

- Add `encode` and `decode` for unicode handling to *vectorized string processing methods* in `Series.str` (GH1706)
- Add `DataFrame.to_latex` method (GH1735)
- Add convenient expanding window equivalents of all `rolling_*` ops (GH1785)
- Add `Options` class to `pandas.io.data` for fetching options data from Yahoo! Finance (GH1748, GH1739)
- More flexible parsing of boolean values (Yes, No, TRUE, FALSE, etc) (GH1691, GH1295)
- Add `level` parameter to `Series.reset_index`
- `TimeSeries.between_time` can now select times across midnight (GH1871)
- `Series` constructor can now handle generator as input (GH1679)
- `DataFrame.dropna` can now take multiple axes (tuple/list) as input (GH924)
- Enable `skip_footer` parameter in `ExcelFile.parse` (GH1843)

#### API changes

- The default column names when `header=None` and no columns names passed to functions like `read_csv` has changed to be more Pythonic and amenable to attribute access:

```
In [1]: import io

In [2]: data = """
...: 0,0,1
...: 1,1,0
...: 0,1,0
...: """
...:

In [3]: df = pd.read_csv(io.StringIO(data), header=None)

In [4]: df
```

(continues on next page)

(continued from previous page)

```
Out[4]:
 0 1 2
0 0 0 1
1 1 1 0
2 0 1 0
```

- Creating a Series from another Series, passing an index, will cause reindexing to happen inside rather than treating the Series like an ndarray. Technically improper usages like `Series(df[col1], index=df[col2])` that worked before “by accident” (this was never intended) will lead to all NA Series in some cases. To be perfectly clear:

```
In [5]: s1 = pd.Series([1, 2, 3])
```

```
In [6]: s1
```

```
Out[6]:
0 1
1 2
2 3
dtype: int64
```

```
In [7]: s2 = pd.Series(s1, index=["foo", "bar", "baz"])
```

```
In [8]: s2
```

```
Out[8]:
foo NaN
bar NaN
baz NaN
dtype: float64
```

- Deprecated `day_of_year` API removed from `PeriodIndex`, use `dayofyear` ([GH1723](#))
- Don't modify NumPy suppress printoption to True at import time
- The internal HDF5 data arrangement for DataFrames has been transposed. Legacy files will still be readable by `HDFStore` ([GH1834](#), [GH1824](#))
- Legacy cruft removed: `pandas.stats.misc.quantileTS`
- Use ISO8601 format for `Period` repr: `monthly`, `daily`, and on down ([GH1776](#))
- Empty `DataFrame` columns are now created as `object` dtype. This will prevent a class of `TypeError`s that was occurring in code where the dtype of a column would depend on the presence of data or not (e.g. a SQL query having results) ([GH1783](#))
- Setting parts of `DataFrame/Panel` using `ix` now aligns input `Series/DataFrame` ([GH1630](#))
- `first` and `last` methods in `GroupBy` no longer drop non-numeric columns ([GH1809](#))
- Resolved inconsistencies in specifying custom NA values in text parser. `na_values` of type `dict` no longer override default NAs unless `keep_default_na` is set to `false` explicitly ([GH1657](#))
- `DataFrame.dot` will not do data alignment, and also work with `Series` ([GH1915](#))

See the [full release notes](#) or issue tracker on GitHub for a complete list.

## 5.22 Version 0.8

### 5.22.1 Version 0.8.1 (July 22, 2012)

This release includes a few new features, performance enhancements, and over 30 bug fixes from 0.8.0. New features include notably NA friendly string processing functionality and a series of new plot types and options.

## New features

- Add *vectorized string processing methods* accessible via Series.str (GH620)
- Add option to disable adjustment in EWMA (GH1584)
- *Radviz plot* (GH1566)
- *Parallel coordinates plot*
- *Bootstrap plot*
- Per column styles and secondary y-axis plotting (GH1559)
- New datetime converters millisecond plotting (GH1599)
- Add option to disable “sparse” display of hierarchical indexes (GH1538)
- Series/DataFrame’s set\_index method can *append levels* to an existing Index/MultiIndex (GH1569, GH1577)

## Performance improvements

- Improved implementation of rolling min and max (thanks to Bottleneck !)
- Add accelerated 'median' GroupBy option (GH1358)
- Significantly improve the performance of parsing ISO8601-format date strings with DatetimeIndex or to\_datetime (GH1571)
- Improve the performance of GroupBy on single-key aggregations and use with Categorical types
- Significant datetime parsing performance improvements

## Contributors

A total of 5 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

- Chang She
- Skipper Seabold

- Vytautas Jancauskas
- Wes McKinney

### 5.22.2 Version 0.8.0 (June 29, 2012)

This is a major release from 0.7.3 and includes extensive work on the time series handling and processing infrastructure as well as a great deal of new functionality throughout the library. It includes over 700 commits from more than 20 distinct authors. Most pandas 0.7.3 and earlier users should not experience any issues upgrading, but due to the migration to the NumPy datetime64 dtype, there may be a number of bugs and incompatibilities lurking. Lingering incompatibilities will be fixed ASAP in a 0.8.1 release if necessary. See the *full release notes* or issue tracker on GitHub for a complete list.

## Support for non-unique indexes

All objects can now work with non-unique indexes. Data alignment / join operations work according to SQL join semantics (including, if application, index duplication in many-to-many joins)

## NumPy datetime64 dtype and 1.6 dependency

Time series data are now represented using NumPy's datetime64 dtype; thus, pandas 0.8.0 now requires at least NumPy 1.6. It has been tested and verified to work with the development version (1.7+) of NumPy as well which includes some significant user-facing API changes. NumPy 1.6 also has a number of bugs having to do with nanosecond resolution data, so I recommend that you steer clear of NumPy 1.6's datetime64 API functions (though limited as they are) and only interact with this data using the interface that pandas provides.

See the end of the 0.8.0 section for a "porting" guide listing potential issues for users migrating legacy code bases from pandas 0.7 or earlier to 0.8.0.

Bug fixes to the 0.7.x series for legacy NumPy < 1.6 users will be provided as they arise. There will be no more further development in 0.7.x beyond bug fixes.

## Time Series changes and improvements

---

**Note:** With this release, legacy scikits.timeseries users should be able to port their code to use pandas.

---

---

**Note:** See [documentation](#) for overview of pandas timeseries API.

---

- New datetime64 representation **speeds up join operations and data alignment, reduces memory usage**, and improve serialization / deserialization performance significantly over datetime.datetime
- High performance and flexible **resample** method for converting from high-to-low and low-to-high frequency. Supports interpolation, user-defined aggregation functions, and control over how the intervals and result labeling are defined. A suite of high performance Cython/C-based resampling functions (including Open-High-Low-Close) have also been implemented.
- Revamp of *frequency aliases* and support for **frequency shortcuts** like '15min', or '1h30min'
- New *DatetimeIndex class* supports both fixed frequency and irregular time series. Replaces now deprecated DateRange class
- New PeriodIndex and Period classes for representing *time spans* and performing **calendar logic**, including the 12 fiscal quarterly frequencies <timeseries.quarterly>. This is a partial port of, and a substantial enhancement to, elements of the scikits.timeseries code base. Support for conversion between PeriodIndex and DatetimeIndex
- New Timestamp data type subclasses datetime.datetime, providing the same interface while enabling working with nanosecond-resolution data. Also provides *easy time zone conversions*.
- Enhanced support for *time zones*. Add tz\_convert and tz\_localize methods to TimeSeries and DataFrame. All timestamps are stored as UTC; Timestamps from DatetimeIndex objects with time zone set will be localized to local time. Time zone conversions are therefore essentially free. User needs to know very little about pytz library now; only time zone names as strings are required. Time zone-aware timestamps are equal if and only if their UTC timestamps match. Operations between time zone-aware time series with different time zones will result in a UTC-indexed time series.
- Time series **string indexing conveniences** / shortcuts: slice years, year and month, and index values with strings

- Enhanced time series **plotting**; adaptation of scikits.timeseries matplotlib-based plotting code
- New `date_range`, `bdate_range`, and `period_range` *factory functions*
- Robust **frequency inference** function `infer_freq` and `inferred_freq` property of `DatetimeIndex`, with option to infer frequency on construction of `DatetimeIndex`
- `to_datetime` function efficiently **parses array of strings** to `DatetimeIndex`. `DatetimeIndex` will parse array or list of strings to `datetime64`
- **Optimized** support for `datetime64-dtype` data in `Series` and `DataFrame` columns
- New `NaT` (Not-a-Time) type to represent **NA** in timestamp arrays
- Optimize `Series.asof` for looking up **“as of” values** for arrays of timestamps
- Milli, Micro, Nano date offset objects
- Can index time series with `datetime.time` objects to select all data at particular **time of day** (`TimeSeries.at_time`) or **between two times** (`TimeSeries.between_time`)
- Add `tshift` method for leading/lagging using the frequency (if any) of the index, as opposed to a naive lead/lag using `shift`

### Other new features

- New `cut` and `qcut` functions (like R’s `cut` function) for computing a categorical variable from a continuous variable by binning values either into value-based (`cut`) or quantile-based (`qcut`) bins
- Rename `Factor` to `Categorical` and add a number of usability features
- Add `limit` argument to `fillna/reindex`
- More flexible multiple function application in `GroupBy`, and can pass list (name, function) tuples to get result in particular order with given names
- Add flexible `replace` method for efficiently substituting values
- Enhanced `read_csv/read_table` for reading time series data and converting multiple columns to dates
- Add `comments` option to parser functions: `read_csv`, etc.
- Add `dayfirst` option to parser functions for parsing international DD/MM/YYYY dates
- Allow the user to specify the CSV reader `dialect` to control quoting etc.
- Handling *thousands* separators in `read_csv` to improve integer parsing.
- Enable unstacking of multiple levels in one shot. Alleviate `pivot_table` bugs (empty columns being introduced)
- Move to `klib`-based hash tables for indexing; better performance and less memory usage than Python’s `dict`
- Add `first`, `last`, `min`, `max`, and `prod` optimized `GroupBy` functions
- New `ordered_merge` function
- Add flexible `comparison` instance methods `eq`, `ne`, `lt`, `gt`, etc. to `DataFrame`, `Series`
- Improve `scatter_matrix` plotting function and add histogram or kernel density estimates to diagonal
- Add `‘kde’` plot option for density plots
- Support for converting `DataFrame` to R `data.frame` through `rpy2`
- Improved support for complex numbers in `Series` and `DataFrame`

- Add `pct_change` method to all data structures
- Add `max_colwidth` configuration option for DataFrame console output
- *Interpolate* Series values using index values
- Can select multiple columns from GroupBy
- Add `update` methods to Series/DataFrame for updating values in place
- Add `any` and `all` method to DataFrame

## New plotting methods

```
import pandas as pd

fx = pd.read_pickle("data/fx_prices")
import matplotlib.pyplot as plt
```

`Series.plot` now supports a `secondary_y` option:

```
plt.figure()

fx["FR"].plot(style="g")

fx["IT"].plot(style="k--", secondary_y=True)
```

Vytautas Jancauskas, the 2012 GSOC participant, has added many new plot types. For example, 'kde' is a new option:

```
s = pd.Series(
 np.concatenate((np.random.randn(1000), np.random.randn(1000) * 0.5 + 3))
)
plt.figure()
s.hist(density=True, alpha=0.2)
s.plot(kind="kde")
```

See [the plotting page](#) for much more.

## Other API changes

- Deprecation of `offset`, `time_rule`, and `timeRule` arguments names in time series functions. Warnings will be printed until pandas 0.9 or 1.0.

## Potential porting issues for pandas <= 0.7.3 users

The major change that may affect you in pandas 0.8.0 is that time series indexes use NumPy's `datetime64` data type instead of `dtype=object` arrays of Python's built-in `datetime.datetime` objects. `DateRange` has been replaced by `DatetimeIndex` but otherwise behaved identically. But, if you have code that converts `DateRange` or `Index` objects that used to contain `datetime.datetime` values to plain NumPy arrays, you may have bugs lurking with code using scalar values because you are handing control over to NumPy:

```
In [1]: import datetime

In [2]: rng = pd.date_range("1/1/2000", periods=10)
```

(continues on next page)

(continued from previous page)

```
In [3]: rng[5]
Out[3]: Timestamp('2000-01-06 00:00:00', freq='D')

In [4]: isinstance(rng[5], datetime.datetime)
Out[4]: True

In [5]: rng_asarray = np.asarray(rng)

In [6]: scalar_val = rng_asarray[5]

In [7]: type(scalar_val)
Out[7]: numpy.datetime64
```

pandas's `Timestamp` object is a subclass of `datetime.datetime` that has nanosecond support (the nanosecond field store the nanosecond value between 0 and 999). It should substitute directly into any code that used `datetime.datetime` values before. Thus, I recommend not casting `DatetimeIndex` to regular NumPy arrays.

If you have code that requires an array of `datetime.datetime` objects, you have a couple of options. First, the `astype(object)` method of `DatetimeIndex` produces an array of `Timestamp` objects:

```
In [8]: stamp_array = rng.astype(object)

In [9]: stamp_array
Out[9]:
Index([2000-01-01 00:00:00, 2000-01-02 00:00:00, 2000-01-03 00:00:00,
 2000-01-04 00:00:00, 2000-01-05 00:00:00, 2000-01-06 00:00:00,
 2000-01-07 00:00:00, 2000-01-08 00:00:00, 2000-01-09 00:00:00,
 2000-01-10 00:00:00],
 dtype='object')

In [10]: stamp_array[5]
Out[10]: Timestamp('2000-01-06 00:00:00', freq='D')
```

To get an array of proper `datetime.datetime` objects, use the `to_pydatetime` method:

```
In [11]: dt_array = rng.to_pydatetime()

In [12]: dt_array
Out[12]:
array([datetime.datetime(2000, 1, 1, 0, 0),
 datetime.datetime(2000, 1, 2, 0, 0),
 datetime.datetime(2000, 1, 3, 0, 0),
 datetime.datetime(2000, 1, 4, 0, 0),
 datetime.datetime(2000, 1, 5, 0, 0),
 datetime.datetime(2000, 1, 6, 0, 0),
 datetime.datetime(2000, 1, 7, 0, 0),
 datetime.datetime(2000, 1, 8, 0, 0),
 datetime.datetime(2000, 1, 9, 0, 0),
 datetime.datetime(2000, 1, 10, 0, 0)], dtype=object)

In [13]: dt_array[5]
Out[13]: datetime.datetime(2000, 1, 6, 0, 0)
```

matplotlib knows how to handle `datetime.datetime` but not `Timestamp` objects. While I recommend that you plot time series using `TimeSeries.plot`, you can either use `to_pydatetime` or register a converter for the `Timestamp` type. See [matplotlib documentation](#) for more on this.

**Warning:** There are bugs in the user-facing API with the nanosecond `datetime64` unit in NumPy 1.6. In particular, the string version of the array shows garbage values, and conversion to `dtype=object` is similarly broken.

```
In [14]: rng = pd.date_range("1/1/2000", periods=10)
```

```
In [15]: rng
```

```
Out[15]:
```

```
DatetimeIndex(['2000-01-01', '2000-01-02', '2000-01-03', '2000-01-04',
 '2000-01-05', '2000-01-06', '2000-01-07', '2000-01-08',
 '2000-01-09', '2000-01-10'],
 dtype='datetime64[ns]', freq='D')
```

```
In [16]: np.asarray(rng)
```

```
Out[16]:
```

```
array(['2000-01-01T00:00:00.000000000', '2000-01-02T00:00:00.000000000',
 '2000-01-03T00:00:00.000000000', '2000-01-04T00:00:00.000000000',
 '2000-01-05T00:00:00.000000000', '2000-01-06T00:00:00.000000000',
 '2000-01-07T00:00:00.000000000', '2000-01-08T00:00:00.000000000',
 '2000-01-09T00:00:00.000000000', '2000-01-10T00:00:00.000000000'],
 dtype='datetime64[ns]')
```

```
In [17]: converted = np.asarray(rng, dtype=object)
```

```
In [18]: converted[5]
```

```
Out[18]: Timestamp('2000-01-06 00:00:00', freq='D')
```

**Trust me: don't panic.** If you are using NumPy 1.6 and restrict your interaction with `datetime64` values to pandas's API you will be just fine. There is nothing wrong with the data-type (a 64-bit integer internally); all of the important data processing happens in pandas and is heavily tested. I strongly recommend that you **do not work directly with `datetime64` arrays in NumPy 1.6** and only use the pandas API.

**Support for non-unique indexes:** In the latter case, you may have code inside a `try: ... catch:` block that failed due to the index not being unique. In many cases it will no longer fail (some method like `append` still check for uniqueness unless disabled). However, all is not lost: you can inspect `index.is_unique` and raise an exception explicitly if it is `False` or go to a different code branch.

## 5.23 Version 0.7

### 5.23.1 Version 0.7.3 (April 12, 2012)

This is a minor release from 0.7.2 and fixes many minor bugs and adds a number of nice new features. There are also a couple of API changes to note; these should not affect very many users, and we are inclined to call them “bug fixes” even though they do constitute a change in behavior. See the [full release notes](#) or issue tracker on GitHub for a complete list.

#### New features

- New *fixed width file reader*, `read_fwf`
- New *scatter\_matrix* function for making a scatter plot matrix

```
from pandas.tools.plotting import scatter_matrix

scatter_matrix(df, alpha=0.2) # noqa F821
```

- Add `stacked` argument to Series and DataFrame’s `plot` method for *stacked bar plots*.

```
df.plot(kind="bar", stacked=True) # noqa F821
```

```
df.plot(kind="barh", stacked=True) # noqa F821
```

- Add log x and y *scaling options* to DataFrame.plot and Series.plot
- Add kurt methods to Series and DataFrame for computing kurtosis

### NA boolean comparison API change

Reverted some changes to how NA values (represented typically as NaN or None) are handled in non-numeric Series:

```
In [1]: series = pd.Series(["Steve", np.nan, "Joe"])
```

```
In [2]: series == "Steve"
```

```
Out[2]:
```

```
0 True
1 False
2 False
Length: 3, dtype: bool
```

```
In [3]: series != "Steve"
```

```
Out[3]:
```

```
0 False
1 True
2 True
Length: 3, dtype: bool
```

In comparisons, NA / NaN will always come through as False except with != which is True. *Be very careful* with boolean arithmetic, especially negation, in the presence of NA data. You may wish to add an explicit NA filter into boolean array operations if you are worried about this:

```
In [4]: mask = series == "Steve"
```

```
In [5]: series[mask & series.notnull()]
```

```
Out[5]:
```

```
0 Steve
Length: 1, dtype: object
```

While propagating NA in comparisons may seem like the right behavior to some users (and you could argue on purely technical grounds that this is the right thing to do), the evaluation was made that propagating NA everywhere, including in numerical arrays, would cause a large amount of problems for users. Thus, a “practicality beats purity” approach was taken. This issue may be revisited at some point in the future.

## Other API changes

When calling `apply` on a grouped Series, the return value will also be a Series, to be more consistent with the groupby behavior with DataFrame:

```
In [6]: df = pd.DataFrame(
...: {
...: "A": ["foo", "bar", "foo", "bar", "foo", "bar", "foo", "foo"],
...: "B": ["one", "one", "two", "three", "two", "two", "one", "three"],
...: "C": np.random.randn(8),
...: "D": np.random.randn(8),
...: }
...:)
...:
```

```
In [7]: df
```

```
Out[7]:
```

|   | A   | B     | C         | D         |
|---|-----|-------|-----------|-----------|
| 0 | foo | one   | 0.469112  | -0.861849 |
| 1 | bar | one   | -0.282863 | -2.104569 |
| 2 | foo | two   | -1.509059 | -0.494929 |
| 3 | bar | three | -1.135632 | 1.071804  |
| 4 | foo | two   | 1.212112  | 0.721555  |
| 5 | bar | two   | -0.173215 | -0.706771 |
| 6 | foo | one   | 0.119209  | -1.039575 |
| 7 | foo | three | -1.044236 | 0.271860  |

```
[8 rows x 4 columns]
```

```
In [8]: grouped = df.groupby("A")["C"]
```

```
In [9]: grouped.describe()
```

```
Out[9]:
```

|     | count | mean      | std      | min       | 25%       | 50%       | 75%       | max       |
|-----|-------|-----------|----------|-----------|-----------|-----------|-----------|-----------|
| A   |       |           |          |           |           |           |           |           |
| bar | 3.0   | -0.530570 | 0.526860 | -1.135632 | -0.709248 | -0.282863 | -0.228039 | -0.173215 |
| foo | 5.0   | -0.150572 | 1.113308 | -1.509059 | -1.044236 | 0.119209  | 0.469112  | 1.212112  |

```
[2 rows x 8 columns]
```

```
In [10]: grouped.apply(lambda x: x.sort_values()[-2:]) # top 2 values
```

```
Out[10]:
```

| A   |   |           |
|-----|---|-----------|
| bar | 1 | -0.282863 |
|     | 5 | -0.173215 |
| foo | 0 | 0.469112  |
|     | 4 | 1.212112  |

Name: C, Length: 4, dtype: float64

### 5.23.2 Version 0.7.2 (March 16, 2012)

This release targets bugs in 0.7.1, and adds a few minor features.

#### New features

- Add additional tie-breaking methods in `DataFrame.rank` (GH874)
- Add ascending parameter to rank in `Series`, `DataFrame` (GH875)
- Add `coerce_float` option to `DataFrame.from_records` (GH893)
- Add `sort_columns` parameter to allow unsorted plots (GH918)
- Enable column access via attributes on `GroupBy` (GH882)
- Can pass dict of values to `DataFrame.fillna` (GH661)
- Can select multiple hierarchical groups by passing list of values in `.ix` (GH134)
- Add `axis` option to `DataFrame.fillna` (GH174)
- Add `level` keyword to `drop` for dropping values from a level (GH159)

## Performance improvements

- Use khash for Series.value\_counts, add raw function to algorithms.py (GH861)
- Intercept `__builtin__.sum` in groupby (GH885)

## Contributors

A total of 12 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

### 5.23.3 Version 0.7.1 (February 29, 2012)

This release includes a few new features and addresses over a dozen bugs in 0.7.0.

#### New features

- Add `to_clipboard` function to pandas namespace for writing objects to the system clipboard (GH774)
- Add `itertuples` method to DataFrame for iterating through the rows of a dataframe as tuples (GH818)
- Add ability to pass `fill_value` and method to DataFrame and Series `align` method (GH806, GH807)
- Add `fill_value` option to `reindex`, `align` methods (GH784)
- Enable `concat` to produce DataFrame from Series (GH787)
- Add `between` method to Series (GH802)
- Add HTML representation hook to DataFrame for the IPython HTML notebook (GH773)
- Support for reading Excel 2007 XML documents using `openpyxl`

## Performance improvements

- Improve performance and memory usage of fillna on DataFrame
- Can concatenate a list of Series along axis=1 to obtain a DataFrame ([GH787](#))

## Contributors

A total of 9 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

- Adam Klein
- Brian Granger +
- Chang She
- Dieter Vandenbussche
- Josh Klein
- Steve +
- Wes McKinney
- Wouter Overmeire

### 5.23.4 Version 0.7.0 (February 9, 2012)

#### New features

- New unified *merge function* for efficiently performing full gamut of database / relational-algebra operations. Refactored existing join methods to use the new infrastructure, resulting in substantial performance gains ([GH220](#), [GH249](#), [GH267](#))
- New *unified concatenation function* for concatenating Series, DataFrame or Panel objects along an axis. Can form union or intersection of the other axes. Improves performance of `Series.append` and `DataFrame.append` ([GH468](#), [GH479](#), [GH273](#))
- *Can* pass multiple DataFrames to `DataFrame.append` to concatenate (stack) and multiple Series to `Series.append` too
- *Can* pass list of dicts (e.g., a list of JSON objects) to DataFrame constructor ([GH526](#))
- You can now *set multiple columns* in a DataFrame via `__getitem__`, useful for transformation ([GH342](#))
- Handle differently-indexed output values in `DataFrame.apply` ([GH498](#))

```
In [1]: df = pd.DataFrame(np.random.randn(10, 4))
In [2]: df.apply(lambda x: x.describe())
Out[2]:
```

|       | 0         | 1         | 2         | 3         |
|-------|-----------|-----------|-----------|-----------|
| count | 10.000000 | 10.000000 | 10.000000 | 10.000000 |
| mean  | 0.190912  | -0.395125 | -0.731920 | -0.403130 |
| std   | 0.730951  | 0.813266  | 1.112016  | 0.961912  |
| min   | -0.861849 | -2.104569 | -1.776904 | -1.469388 |
| 25%   | -0.411391 | -0.698728 | -1.501401 | -1.076610 |

(continues on next page)

(continued from previous page)

```
50% 0.380863 -0.228039 -1.191943 -1.004091
75% 0.658444 0.057974 -0.034326 0.461706
max 1.212112 0.577046 1.643563 1.071804
```

```
[8 rows x 4 columns]
```

- *Add* `reorder_levels` method to Series and DataFrame (GH534)
- *Add* dict-like `get` function to DataFrame and Panel (GH521)
- *Add* `DataFrame.iterrows` method for efficiently iterating through the rows of a DataFrame
- Add `DataFrame.to_panel` with code adapted from `LongPanel.to_long`
- *Add* `reindex_axis` method added to DataFrame
- *Add* `level` option to binary arithmetic functions on DataFrame and Series
- *Add* `level` option to the `reindex` and `align` methods on Series and DataFrame for broadcasting values across a level (GH542, GH552, others)
- Add attribute-based item access to Panel and add IPython completion (GH563)
- *Add* `logy` option to `Series.plot` for log-scaling on the Y axis
- *Add* `index` and `header` options to `DataFrame.to_string`
- *Can* pass multiple DataFrames to `DataFrame.join` to join on index (GH115)
- *Can* pass multiple Panels to `Panel.join` (GH115)
- *Added* `justify` argument to `DataFrame.to_string` to allow different alignment of column headers
- *Add* `sort` option to `GroupBy` to allow disabling sorting of the group keys for potential speedups (GH595)
- *Can* pass `MaskedArray` to Series constructor (GH563)
- Add Panel item access via attributes and IPython completion (GH554)
- Implement `DataFrame.lookup`, fancy-indexing analogue for retrieving values given a sequence of row and column labels (GH338)
- *Can* pass a *list of functions* to aggregate with `groupby` on a DataFrame, yielding an aggregated result with hierarchical columns (GH166)
- *Can* call `cummin` and `cummax` on Series and DataFrame to get cumulative minimum and maximum, respectively (GH647)
- `value_range` added as utility function to get min and max of a dataframe (GH288)
- Added encoding argument to `read_csv`, `read_table`, `to_csv` and `from_csv` for non-ascii text (GH717)
- *Added* `abs` method to pandas objects
- *Added* `crosstab` function for easily computing frequency tables
- *Added* `isin` method to index objects
- *Added* `level` argument to `xs` method of DataFrame.

## API changes to integer indexing

One of the potentially riskiest API changes in 0.7.0, but also one of the most important, was a complete review of how **integer indexes** are handled with regard to label-based indexing. Here is an example:

```
In [3]: s = pd.Series(np.random.randn(10), index=range(0, 20, 2))
In [4]: s
Out[4]:
0 -1.294524
2 0.413738
4 0.276662
6 -0.472035
8 -0.013960
10 -0.362543
12 -0.006154
14 -0.923061
16 0.895717
18 0.805244
Length: 10, dtype: float64

In [5]: s[0]
Out[5]: -1.2945235902555294

In [6]: s[2]
Out[6]: 0.41373810535784006

In [7]: s[4]
Out[7]: 0.2766617129497566
```

This is all exactly identical to the behavior before. However, if you ask for a key **not** contained in the Series, in versions 0.6.1 and prior, Series would *fall back* on a location-based lookup. This now raises a `KeyError`:

```
In [2]: s[1]
KeyError: 1
```

This change also has the same impact on DataFrame:

```
In [3]: df = pd.DataFrame(np.random.randn(8, 4), index=range(0, 16, 2))
In [4]: df
 0 1 2 3
0 0.88427 0.3363 -0.1787 0.03162
2 0.14451 -0.1415 0.2504 0.58374
4 -1.44779 -0.9186 -1.4996 0.27163
6 -0.26598 -2.4184 -0.2658 0.11503
8 -0.58776 0.3144 -0.8566 0.61941
10 0.10940 -0.7175 -1.0108 0.47990
12 -1.16919 -0.3087 -0.6049 -0.43544
14 -0.07337 0.3410 0.0424 -0.16037

In [5]: df.ix[3]
KeyError: 3
```

In order to support purely integer-based indexing, the following methods have been added:

| Method                                  | Description                                                        |
|-----------------------------------------|--------------------------------------------------------------------|
| <code>Series.iget_value(i)</code>       | Retrieve value stored at location <code>i</code>                   |
| <code>Series.iget(i)</code>             | Alias for <code>iget_value</code>                                  |
| <code>DataFrame.irow(i)</code>          | Retrieve the <code>i</code> -th row                                |
| <code>DataFrame.icol(j)</code>          | Retrieve the <code>j</code> -th column                             |
| <code>DataFrame.iget_value(i, j)</code> | Retrieve the value at row <code>i</code> and column <code>j</code> |

### API tweaks regarding label-based slicing

Label-based slicing using `ix` now requires that the index be sorted (monotonic) **unless** both the start and endpoint are contained in the index:

```
In [1]: s = pd.Series(np.random.randn(6), index=list('gmkaec'))

In [2]: s
Out[2]:
g -1.182230
m -0.276183
k -0.243550
a 1.628992
e 0.073308
c -0.539890
dtype: float64
```

Then this is OK:

```
In [3]: s.ix['k':'e']
Out[3]:
k -0.243550
a 1.628992
e 0.073308
dtype: float64
```

But this is not:

```
In [12]: s.ix['b':'h']
KeyError 'b'
```

If the index had been sorted, the “range selection” would have been possible:

```
In [4]: s2 = s.sort_index()

In [5]: s2
Out[5]:
a 1.628992
c -0.539890
e 0.073308
g -1.182230
k -0.243550
m -0.276183
dtype: float64
```

(continues on next page)

(continued from previous page)

```
In [6]: s2.ix['b':'h']
```

```
Out[6]:
```

```
c -0.539890
```

```
e 0.073308
```

```
g -1.182230
```

```
dtype: float64
```

## Changes to Series [] operator

As a notational convenience, you can pass a sequence of labels or a label slice to a Series when getting and setting values via [] (i.e. the `__getitem__` and `__setitem__` methods). The behavior will be the same as passing similar input to `ix` **except in the case of integer indexing**:

```
In [8]: s = pd.Series(np.random.randn(6), index=list('acegkm'))
```

```
In [9]: s
```

```
Out[9]:
```

```
a -1.206412
```

```
c 2.565646
```

```
e 1.431256
```

```
g 1.340309
```

```
k -1.170299
```

```
m -0.226169
```

```
Length: 6, dtype: float64
```

```
In [10]: s[['m', 'a', 'c', 'e']]
```

```
Out[10]:
```

```
m -0.226169
```

```
a -1.206412
```

```
c 2.565646
```

```
e 1.431256
```

```
Length: 4, dtype: float64
```

```
In [11]: s['b':'l']
```

```
Out[11]:
```

```
c 2.565646
```

```
e 1.431256
```

```
g 1.340309
```

```
k -1.170299
```

```
Length: 4, dtype: float64
```

```
In [12]: s['c':'k']
```

```
Out[12]:
```

```
c 2.565646
```

```
e 1.431256
```

```
g 1.340309
```

```
k -1.170299
```

```
Length: 4, dtype: float64
```

In the case of integer indexes, the behavior will be exactly as before (shadowing ndarray):

```
In [13]: s = pd.Series(np.random.randn(6), index=range(0, 12, 2))
```

```
In [14]: s[[4, 0, 2]]
```

```
Out[14]:
```

```
4 0.132003
0 0.410835
2 0.813850
Length: 3, dtype: float64
```

```
In [15]: s[1:5]
```

```
Out[15]:
```

```
2 0.813850
4 0.132003
6 -0.827317
8 -0.076467
Length: 4, dtype: float64
```

If you wish to do indexing with sequences and slicing on an integer index with label semantics, use `ix`.

### Other API changes

- The deprecated `LongPanel` class has been completely removed
- If `Series.sort` is called on a column of a `DataFrame`, an exception will now be raised. Before it was possible to accidentally mutate a `DataFrame`'s column by doing `df[col].sort()` instead of the side-effect free method `df[col].order()` ([GH316](#))
- Miscellaneous renames and deprecations which will (harmlessly) raise `FutureWarning`
- `drop` added as an optional parameter to `DataFrame.reset_index` ([GH699](#))

### Performance improvements

- *Cythonized GroupBy aggregations* no longer presort the data, thus achieving a significant speedup ([GH93](#)). `GroupBy` aggregations with Python functions significantly sped up by clever manipulation of the `ndarray` data type in Cython ([GH496](#)).
- Better error message in `DataFrame` constructor when passed column labels don't match data ([GH497](#))
- Substantially improve performance of multi-`GroupBy` aggregation when a Python function is passed, reuse `ndarray` object in Cython ([GH496](#))
- Can store objects indexed by tuples and floats in `HDFStore` ([GH492](#))
- Don't print length by default in `Series.to_string`, add `length` option ([GH489](#))
- Improve Cython code for multi-groupby to aggregate without having to sort the data ([GH93](#))
- Improve `MultiIndex` reindexing speed by storing tuples in the `MultiIndex`, test for backwards unpickling compatibility
- Improve column reindexing performance by using specialized Cython take function
- Further performance tweaking of `Series.__getitem__` for standard use cases
- Avoid `Index` dict creation in some cases (i.e. when getting slices, etc.), regression from prior versions
- Friendlier error message in `setup.py` if `NumPy` not installed

- Use common set of NA-handling operations (sum, mean, etc.) in Panel class also (GH536)
- Default name assignment when calling `reset_index` on DataFrame with a regular (non-hierarchical) index (GH476)
- Use Cythonized groupers when possible in Series/DataFrame stat ops with `level` parameter passed (GH545)
- Ported skiplist data structure to C to speed up `rolling_median` by about 5-10x in most typical use cases (GH374)

## 5.24 Version 0.6

### 5.24.1 Version 0.6.1 (December 13, 2011)

#### New features

- Can *append single rows* (as Series) to a DataFrame
- Add Spearman and Kendall rank *correlation* options to `Series.corr` and `DataFrame.corr` (GH428)

- *Added* `get_value` and `set_value` methods to Series, DataFrame, and Panel for very low-overhead access (>2x faster in many cases) to scalar elements (GH437, GH438). `set_value` is capable of producing an enlarged object.
- Add PyQt table widget to sandbox (GH435)
- `DataFrame.align` can *accept Series arguments* and an *axis option* (GH461)
- Implement new *SparseArray* and *SparseList* data structures. `SparseSeries` now derives from `SparseArray` (GH463)
- *Better console printing options* (GH453)
- Implement fast *data ranking* for Series and DataFrame, fast versions of `scipy.stats.rankdata` (GH428)
- Implement `DataFrame.from_items` alternate constructor (GH444)
- `DataFrame.convert_objects` method for *inferring better dtypes* for object columns (GH302)
- Add *rolling\_corr\_pairwise* function for computing Panel of correlation matrices (GH189)
- Add *margins* option to *pivot\_table* for computing subgroup aggregates (GH114)
- Add `Series.from_csv` function (GH482)
- *Can pass* DataFrame/DataFrame and DataFrame/Series to `rolling_corr/rolling_cov` (GH #462)
- `MultiIndex.get_level_values` can *accept the level name*

### Performance improvements

- Improve memory usage of `DataFrame.describe` (do not copy data unnecessarily) (PR #425)
- Optimize scalar value lookups in the general case by 25% or more in Series and DataFrame
- Fix performance regression in cross-sectional count in DataFrame, affecting `DataFrame.dropna` speed
- Column deletion in DataFrame copies no data (computes views on blocks) (GH #158)

## 5.24.2 Version 0.6.0 (November 25, 2011)

### New features

- *Added* `melt` function to `pandas.core.reshape`
- *Added* `level` parameter to `group by level` in `Series` and `DataFrame` descriptive statistics (GH313)
- *Added* `head` and `tail` methods to `Series`, analogous to `DataFrame` (GH296)
- *Added* `Series.isin` function which checks if each value is contained in a passed sequence (GH289)
- *Added* `float_format` option to `Series.to_string`
- *Added* `skip_footer` (GH291) and `converters` (GH343) options to `read_csv` and `read_table`
- *Added* `drop_duplicates` and `duplicated` functions for removing duplicate `DataFrame` rows and checking for duplicate rows, respectively (GH319)
- *Implemented* operators `&`, `|`, `^`, `-` on `DataFrame` (GH347)
- *Added* `Series.mad`, mean absolute deviation
- *Added* `QuarterEnd` `DateOffset` (GH321)
- *Added* `dot` to `DataFrame` (GH65)
- *Added* `orient` option to `Panel.from_dict` (GH359, GH301)
- *Added* `orient` option to `DataFrame.from_dict`
- *Added* passing list of tuples or list of lists to `DataFrame.from_records` (GH357)
- *Added* multiple levels to `groupby` (GH103)
- *Allow* multiple columns in `by` argument of `DataFrame.sort_index` (GH92, GH362)
- *Added* fast `get_value` and `put_value` methods to `DataFrame` (GH360)
- *Added* `cov` instance methods to `Series` and `DataFrame` (GH194, GH362)
- *Added* `kind='bar'` option to `DataFrame.plot` (GH348)
- *Added* `idxmin` and `idxmax` to `Series` and `DataFrame` (GH286)
- *Added* `read_clipboard` function to parse `DataFrame` from clipboard (GH300)
- *Added* `nunique` function to `Series` for counting unique elements (GH297)
- *Made* `DataFrame` constructor use `Series` name if no columns passed (GH373)
- *Support* regular expressions in `read_table/read_csv` (GH364)
- *Added* `DataFrame.to_html` for writing `DataFrame` to HTML (GH387)
- *Added* support for `MaskedArray` data in `DataFrame`, masked values converted to `NaN` (GH396)
- *Added* `DataFrame.boxplot` function (GH368)
- *Can* pass extra args, `kwds` to `DataFrame.apply` (GH376)
- *Implement* `DataFrame.join` with vector on argument (GH312)
- *Added* `legend` boolean flag to `DataFrame.plot` (GH324)
- *Can* pass multiple levels to `stack` and `unstack` (GH370)
- *Can* pass multiple values columns to `pivot_table` (GH381)
- *Use* `Series` name in `GroupBy` for result index (GH363)

- *Added* `raw` option to `DataFrame.apply` for performance if only need ndarray (GH309)
- Added proper, tested weighted least squares to standard and panel OLS (GH303)

### Performance enhancements

- VBENCH Cythonized `cache_readonly`, resulting in substantial micro-performance enhancements throughout the code base (GH361)
- VBENCH Special Cython matrix iterator for applying arbitrary reduction operations with 3-5x better performance than `np.apply_along_axis` (GH309)
- VBENCH Improved performance of `MultiIndex.from_tuples`
- VBENCH Special Cython matrix iterator for applying arbitrary reduction operations
- VBENCH + DOCUMENT Add `raw` option to `DataFrame.apply` for getting better performance when
- VBENCH Faster cythonized count by level in `Series` and `DataFrame` (GH341)
- VBENCH? Significant `GroupBy` performance enhancement with multiple keys with many “empty” combinations
- VBENCH New Cython vectorized function `map_infer` speeds up `Series.apply` and `Series.map` significantly when passed elementwise Python function, motivated by (GH355)
- VBENCH Significantly improved performance of `Series.order`, which also makes `np.unique` called on a `Series` faster (GH327)
- VBENCH Vastly improved performance of `GroupBy` on axes with a `MultiIndex` (GH299)

## 5.25 Version 0.5

### 5.25.1 Version 0.5.0 (October 24, 2011)

#### New features

- *Added* `DataFrame.align` method with standard join options

- *Added* `parse_dates` option to `read_csv` and `read_table` methods to optionally try to parse dates in the index columns
- *Added* `nrows`, `chunksize`, and `iterator` arguments to `read_csv` and `read_table`. The last two return a new `TextParser` class capable of lazily iterating through chunks of a flat file (GH242)
- *Added* ability to join on multiple columns in `DataFrame.join` (GH214)
- Added private `_get_duplicates` function to `Index` for identifying duplicate values more easily (ENH5c)
- *Added* column attribute access to `DataFrame`.
- *Added* Python tab completion hook for `DataFrame` columns. (GH233, GH230)
- *Implemented* `Series.describe` for `Series` containing objects (GH241)
- *Added* inner join option to `DataFrame.join` when joining on key(s) (GH248)
- *Implemented* selecting `DataFrame` columns by passing a list to `__getitem__` (GH253)
- *Implemented* `&` and `|` to intersect / union `Index` objects, respectively (GH261)
- *Added* `pivot_table` convenience function to pandas namespace (GH234)
- *Implemented* `Panel.rename_axis` function (GH243)
- `DataFrame` will show index level names in console output (GH334)
- *Implemented* `Panel.take`
- *Added* `set_eng_float_format` for alternate `DataFrame` floating point string formatting (ENH61)
- *Added* convenience `set_index` function for creating a `DataFrame` index from its existing columns
- *Implemented* `groupby` hierarchical index level name (GH223)
- *Added* support for different delimiters in `DataFrame.to_csv` (GH244)
- TODO: DOCS ABOUT TAKE METHODS

## Performance enhancements

- VBENCH Major performance improvements in file parsing functions `read_csv` and `read_table`
- VBENCH Added Cython function for converting tuples to `ndarray` very fast. Speeds up many `MultiIndex`-related operations
- VBENCH Refactored merging / joining code into a tidy class and disabled unnecessary computations in the float/object case, thus getting about 10% better performance (GH211)
- VBENCH Improved speed of `DataFrame.xs` on mixed-type `DataFrame` objects by about 5x, regression from 0.3.0 (GH215)
- VBENCH With new `DataFrame.align` method, speeding up binary operations between differently-indexed `DataFrame` objects by 10-25%.
- VBENCH Significantly sped up conversion of nested dict into `DataFrame` (GH212)
- VBENCH Significantly speed up `DataFrame.__repr__` and `count` on large mixed-type `DataFrame` objects

## Contributors

A total of 9 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

## 5.26 Version 0.4

### 5.26.1 Versions 0.4.1 through 0.4.3 (September 25 - October 9, 2011)

#### New features

- Added Python 3 support using 2to3 (GH200)
- *Added* name attribute to Series, now prints as part of Series.\_\_repr\_\_
- *Added* instance methods isnull and notnull to Series (GH209, GH203)
- *Added* Series.align method for aligning two series with choice of join method (ENH56)
- *Added* method get\_level\_values to MultiIndex (GH188)
- Set values in mixed-type DataFrame objects via .ix indexing attribute (GH135)
- Added new DataFrame *methods* get\_dtype\_counts and property dtypes (ENHdc)
- Added *ignore\_index* option to DataFrame.append to stack DataFrames (ENH1b)
- read\_csv tries to *sniff* delimiters using csv.Sniffer (GH146)
- read\_csv can *read* multiple columns into a MultiIndex; DataFrame’s to\_csv method writes out a corresponding MultiIndex (GH151)
- DataFrame.rename has a new copy parameter to *rename* a DataFrame in place (ENHed)
- *Enable* unstacking by name (GH142)
- *Enable* sortlevel to work by level (GH141)

## Performance enhancements

- Altered binary operations on differently-indexed SparseSeries objects to use the integer-based (dense) alignment logic which is faster with a larger number of blocks (GH205)
- Wrote faster Cython data alignment / merging routines resulting in substantial speed increases
- Improved performance of `isnull` and `notnull`, a regression from v0.3.0 (GH187)
- Refactored code related to `DataFrame.join` so that intermediate aligned copies of the data in each `DataFrame` argument do not need to be created. Substantial performance increases result (GH176)
- Substantially improved performance of generic `Index.intersection` and `Index.union`
- Implemented `BlockManager.take` resulting in significantly faster `take` performance on mixed-type `DataFrame` objects (GH104)
- Improved performance of `Series.sort_index`
- Significant groupby performance enhancement: removed unnecessary integrity checks in `DataFrame` internals that were slowing down slicing operations to retrieve groups
- Optimized `_ensure_index` function resulting in performance savings in type-checking `Index` objects
- Wrote fast time series merging / joining methods in Cython. Will be integrated later into `DataFrame.join` and related functions
