The [`canvas`](#)^{p645} element has two attributes to control the size of the element's bitmap: **width** and **height**. These attributes, when specified, must have values that are [valid non-negative integers](#)^{p70}. The [rules for parsing non-negative integers](#)^{p70} must be used to **obtain their numeric values**. If an attribute is missing, or if parsing its value returns an error, then the default value must be used instead. The [width](#)^{p647} attribute defaults to 300, and the [height](#)^{p647} attribute defaults to 150.

When setting the value of the [width](#)^{p647} or [height](#)^{p647} attribute, if the [context mode](#)^{p647} of the [`canvas`](#)^{p645} element is set to [placeholder](#)^{p647}, the user agent must throw an `"InvalidStateError"` [DOMException](#) and leave the attribute's value unchanged.

The [intrinsic dimensions](#) of the [`canvas`](#)^{p645} element when it [represents embedded content](#)^{p137} are equal to the dimensions of the element's bitmap.

The user agent must use a square pixel density consisting of one pixel of image data per coordinate space unit for the bitmaps of a [`canvas`](#)^{p645} and its rendering contexts.

Note

A [`canvas`](#)^{p645} element can be sized arbitrarily by a style sheet, its bitmap is then subject to the `'object-fit'` CSS property.

The bitmaps of [`canvas`](#)^{p645} elements, the bitmaps of [ImageBitmap](#)^{p1016} objects, as well as some of the bitmaps of rendering contexts, such as those described in the sections on the [CanvasRenderingContext2D](#)^{p650} and [ImageBitmapRenderingContext](#)^{p710} objects below, have an **origin-clean** flag, which can be set to true or false. Initially, when the [`canvas`](#)^{p645} element or [ImageBitmap](#)^{p1016} object is created, its bitmap's [origin-clean](#)^{p647} flag must be set to true.

A [`canvas`](#)^{p645} element can have a rendering context bound to it. Initially, it does not have a bound rendering context. To keep track of whether it has a rendering context or not, and what kind of rendering context it is, a [`canvas`](#)^{p645} also has a **canvas context mode**, which is initially **none** but can be changed to either **placeholder**, **2d**, **bitmaprenderer**, **webgl**, **webgl2**, or **webgpu** by algorithms defined in this specification.

When its [canvas context mode](#)^{p647} is [none](#)^{p647}, a [`canvas`](#)^{p645} element has no rendering context, and its bitmap must be [transparent black](#) with an [intrinsic width](#) equal to [the numeric value](#)^{p647} of the element's [width](#)^{p647} attribute and an [intrinsic height](#) equal to [the numeric value](#)^{p647} of the element's [height](#)^{p647} attribute, those values being interpreted in [CSS pixels](#), and being updated as the attributes are set, changed, or removed.

When its [canvas context mode](#)^{p647} is [placeholder](#)^{p647}, a [`canvas`](#)^{p645} element has no rendering context. It serves as a placeholder for an [OffscreenCanvas](#)^{p712} object, and the content of the [`canvas`](#)^{p645} element is updated by calling the [commit\(\)](#)^{p712} method of the [OffscreenCanvas](#)^{p712} object's rendering context.

When a [`canvas`](#)^{p645} element represents [embedded content](#)^{p137}, it provides a [paint source](#) whose width is the element's [intrinsic width](#), whose height is the element's [intrinsic height](#), and whose appearance is the element's bitmap.

Whenever the [width](#)^{p647} and [height](#)^{p647} content attributes are set, removed, changed, or redundantly set to the value they already have, then the user agent must perform the action from the row of the following table that corresponds to the [`canvas`](#)^{p645} element's [context mode](#)^{p647}.

Context Mode ^{p647}	Action
2d ^{p647}	Follow the steps to set bitmap dimensions ^{p657} to the numeric values ^{p647} of the width ^{p647} and height ^{p647} content attributes.
webgl ^{p647} or webgl2 ^{p647}	Follow the behavior defined in the WebGL specifications. [WEBGL] ^{p1313}
webgpu ^{p647}	Follow the behavior defined in <i>WebGPU</i> . [WEBGPU] ^{p1313}
bitmaprenderer ^{p647}	If the context's bitmap mode ^{p710} is set to blank ^{p710} , run the steps to set an ImageBitmapRenderingContext's output bitmap ^{p711} , passing the <code>canvas</code> ^{p645} element's rendering context.

Context Mode ^{p647}	Action
placeholder ^{p647}	Do nothing.
none ^{p647}	Do nothing.

The **width** and **height** IDL attributes must [reflect](#)^{p97} the respective content attributes of the same name, with the same defaults. MDN

For web developers (non-normative)

context = **canvas.getContext**^{p648}(**contextId** [, **options**])

Returns an object that exposes an API for drawing on the canvas. *contextId* specifies the desired API: "[2d](#)^{p648}", "[bitmaprenderer](#)^{p648}", "[webgl](#)^{p648}", "[webgl2](#)^{p648}", or "[webgpu](#)^{p649}". *options* is handled by that API.

This specification defines the "[2d](#)^{p648}" and "[bitmaprenderer](#)^{p648}" contexts below. The WebGL specifications define the "[webgl](#)^{p648}" and "[webgl2](#)^{p648}" contexts. *WebGPU* defines the "[webgpu](#)^{p649}" context. [[WEBGL](#)]^{p1313} [[WEBGPU](#)]^{p1313}

Returns null if *contextId* is not supported, or if the canvas has already been initialized with another context type (e.g., trying to get a "[2d](#)^{p648}" context after getting a "[webgl](#)^{p648}" context).

The **getContext**(*contextId*, *options*) method of the [canvas](#)^{p645} element, when invoked, must run these steps:

- If *options* is not an [object](#), then set *options* to null.
- Set *options* to the result of [converting](#) *options* to a JavaScript value.
- Run the steps in the cell of the following table whose column header matches this [canvas](#)^{p645} element's [canvas context mode](#)^{p647} and whose row header matches *contextId*:

	none ^{p647}	2d ^{p647}	bitmaprenderer ^{p647}	webgl ^{p647} or webgl2 ^{p647}	webgpu ^{p647}	placeholder ^{p647}
"2d"	Follow the 2D context creation algorithm ^{p657} defined in the section below, passing it this canvas ^{p645} element and <i>options</i> , to obtain a CanvasRenderingContext2D ^{p650} object; if this does not throw an exception, then set this canvas ^{p645} element's context mode ^{p647} to 2d ^{p647} , and return the CanvasRenderingContext2D ^{p650} object.	Return the same object as was returned the last time the method was invoked with this same first argument.	Return null.	Return null.	Return null.	Throw an "InvalidStateError" ^{p647} DOMException .
"bitmaprenderer"	Follow the ImageBitmapRenderingContext creation algorithm ^{p711} defined in the section below, passing it this canvas ^{p645} element and <i>options</i> , to obtain an ImageBitmapRenderingContext ^{p710} object; then set this canvas ^{p645} element's context mode ^{p647} to bitmaprenderer ^{p647} , and return the ImageBitmapRenderingContext ^{p710} object.	Return null.	Return the same object as was returned the last time the method was invoked with this same first argument.	Return null.	Return null.	Throw an "InvalidStateError" ^{p647} DOMException .
"webgl" or "webgl2", if the user agent supports the WebGL feature in its current configuration	Follow the instructions given in the WebGL specifications' <i>Context Creation</i> sections to obtain a WebGLRenderingContext , WebGL2RenderingContext , or null; if the returned value is null, then return null; otherwise, set this canvas ^{p645} element's context mode ^{p647} to webgl ^{p647} or webgl2 ^{p647} , and return the WebGLRenderingContext or WebGL2RenderingContext object. [WEBGL] ^{p1313}	Return null.	Return null.	Return the same object as was returned the last time the method was invoked with this same first argument.	Return null.	Throw an "InvalidStateError" ^{p647} DOMException .

	none ^{p647}	2d ^{p647}	bitmaprenderer ^{p647}	webgl ^{p647} or webgl2 ^{p647}	webgpu ^{p647}	placeholder ^{p647}
"webgpu", if the user agent supports the WebGPU feature in its current configuration	Follow the instructions given in <i>WebGPU's Canvas Rendering</i> section to obtain a GPUCanvasContext or null; if the returned value is null, then return null; otherwise, set this canvas ^{p645} element's context mode ^{p647} to webgpu ^{p647} and return the GPUCanvasContext object. [WEBGPU] ^{p1313}	Return null.	Return null.	Return null.	Return the same object as was returned the last time the method was invoked with this same first argument.	Throw an "InvalidStateError" DOMException .
An unsupported value*	Return null.	Return null.	Return null.	Return null.	Return null.	Throw an "InvalidStateError" DOMException .

* For example, the "[webgl](#)^{p648}" or "[webgl2](#)^{p648}" value in the case of a user agent having exhausted the graphics hardware's abilities and having no software fallback implementation.

For web developers (non-normative)

`url = canvas.toDataURL`^{p649} (`[type [, quality]]`)

Returns a [data: URL](#) for the image in the canvas.

The first argument, if provided, controls the type of the image to be returned (e.g. PNG or JPEG). The default is "[image/png](#)^{p1303}"; that type is also used if the given type isn't supported. The second argument applies if the type is an image format that supports variable quality (such as "[image/jpeg](#)^{p1303}"), and is a number in the range 0.0 to 1.0 inclusive indicating the desired quality level for the resulting image.

When trying to use types other than "[image/png](#)^{p1303}", authors can check if the image was really returned in the requested format by checking to see if the returned string starts with one of the exact strings "[data:image/png,](#)" or "[data:image/png;](#)". If it does, the image is PNG, and thus the requested type was not supported. (The one exception to this is if the canvas has either no height or no width, in which case the result might simply be "[data: ,](#)".)

`canvas.toBlob`^{p649} (`callback [, type [, quality]]`)

Creates a [Blob](#) object representing a file containing the image in the canvas, and invokes a callback with a handle to that object.

The second argument, if provided, controls the type of the image to be returned (e.g. PNG or JPEG). The default is "[image/png](#)^{p1303}"; that type is also used if the given type isn't supported. The third argument applies if the type is an image format that supports variable quality (such as "[image/jpeg](#)^{p1303}"), and is a number in the range 0.0 to 1.0 inclusive indicating the desired quality level for the resulting image.

`canvas.transferControlToOffscreen`^{p650} ()

Returns a newly created [OffscreenCanvas](#)^{p712} object that uses the [canvas](#)^{p645} element as a placeholder. Once the [canvas](#)^{p645} element has become a placeholder for an [OffscreenCanvas](#)^{p712} object, its intrinsic size can no longer be changed, and it cannot have a rendering context. The content of the placeholder canvas is updated by calling the [commit\(\)](#)^{p712} method of the [OffscreenCanvas](#)^{p712} object's rendering context.

The [toDataURL](#)(*type*, *quality*) method, when invoked, must run these steps:

1. If this [canvas](#)^{p645} element's [origin-clean](#)^{p647} flag is set to false, then throw a ["SecurityError"](#) [DOMException](#).
2. If this [canvas](#)^{p645} element's bitmap has no pixels (i.e. either its horizontal dimension or its vertical dimension is zero) then return the string "[data: ,](#)". (This is the shortest [data: URL](#); it represents the empty string in a [text/plain](#) resource.)
3. Let *file* be a [serialization of this canvas element's bitmap as a file](#)^{p718}, passing *type* and *quality* if given.
4. If *file* is null then return "[data: ,](#)".
5. Return a [data: URL](#) representing *file*. [\[RFC2397\]](#)^{p1311}

The [toBlob](#)(*callback*, *type*, *quality*) method, when invoked, must run these steps:

1. If this [canvas](#)^{p645} element's [origin-clean](#)^{p647} flag is set to false, then throw a ["SecurityError"](#) [DOMException](#).
2. Let *result* be null.

3. If this [canvas](#)^{p645} element's bitmap has pixels (i.e., neither its horizontal dimension nor its vertical dimension is zero), then set *result* to a copy of this [canvas](#)^{p645} element's bitmap.
4. Run these steps [in parallel](#)^{p42}:
 1. If *result* is non-null, then set *result* to [a serialization of result as a file](#)^{p718} with *type* and *quality* if given.
 2. [Queue an element task](#)^{p970} on the **canvas blob serialization task source** given the [canvas](#)^{p645} element to run these steps:
 1. If *result* is non-null, then set *result* to a new **Blob** object, created in the [relevant Realm](#)^{p944} of this [canvas](#)^{p645} element, representing *result*. [\[FILEAPI\]](#)^{p1308}
 2. [Invoke callback](#) with « *result* ».

The **transferControlToOffscreen()** method, when invoked, must run these steps:

1. If this [canvas](#)^{p645} element's [context mode](#)^{p647} is not set to [none](#)^{p647}, throw an **"InvalidStateError" DOMException**.
2. Let *offscreenCanvas* be a new **OffscreenCanvas**^{p712} object with its width and height equal to the values of the [width](#)^{p647} and [height](#)^{p647} content attributes of this [canvas](#)^{p645} element.
3. Set the [placeholder canvas element](#)^{p712} of *offscreenCanvas* to be a weak reference to this [canvas](#)^{p645} element.
4. Set this [canvas](#)^{p645} element's [context mode](#)^{p647} to [placeholder](#)^{p647}.
5. Return *offscreenCanvas*.

Note

To maintain compatibility with existing web content, user agents need to enumerate methods defined in [CanvasUserInterface](#)^{p652} immediately after the [stroke\(\)](#)^{p688} method on [CanvasRenderingContext2D](#)^{p650} objects.

For web developers (non-normative)

context = [canvas.getContext\(\)](#)^{p648}('2d' [, { [[alpha](#)^{p657}: true] [, [desynchronized](#)^{p657}: false] [, [colorSpace](#)^{p657}: 'srgb'] [, [willReadFrequently](#)^{p657}: false] }])

Returns a [CanvasRenderingContext2D](#)^{p650} object that is permanently bound to a particular [canvas](#)^{p645} element.

If the [alpha](#)^{p657} member is false, then the context is forced to always be opaque.

If the [desynchronized](#)^{p657} member is true, then the context might be [desynchronized](#)^{p656}.

The [colorSpace](#)^{p657} member specifies the [color space](#)^{p656} of the rendering context.

If the [willReadFrequently](#)^{p657} member is true, then the context is marked for [readback optimization](#)^{p656}.

context.canvas^{p657}

Returns the [canvas](#)^{p645} element.

attributes = [context.getContextAttributes\(\)](#)^{p656} ()

Returns an object whose:

- [alpha](#)^{p655} member is true if the context has an alpha channel, or false if it was forced to be opaque.
- [desynchronized](#)^{p657} member is true if the context can be [desynchronized](#)^{p656}.
- [colorSpace](#)^{p657} member is a string indicating the context's [color space](#)^{p656}.
- [willReadFrequently](#)^{p657} member is true if the context is marked for [readback optimization](#)^{p656}.

A [CanvasRenderingContext2D](#)^{p650} object has an **output bitmap** that is initialized when the object is created.

The [output bitmap](#)^{p655} has an [origin-clean](#)^{p647} flag, which can be set to true or false. Initially, when one of these bitmaps is created, its [origin-clean](#)^{p647} flag must be set to true.

The [CanvasRenderingContext2D](#)^{p650} object also has an **alpha** boolean. When a [CanvasRenderingContext2D](#)^{p650} object's [alpha](#)^{p655} is false, then its alpha channel must be fixed to 1.0 (fully opaque) for all pixels, and attempts to change the alpha component of any pixel must be silently ignored.

Note

Thus, the bitmap of such a context starts off as [opaque black](#) instead of [transparent black](#); [clearRect\(\)](#)^{p685} always results in [opaque black](#) pixels, every fourth byte from [getImageData\(\)](#)^{p695} is always 255, the [putImageData\(\)](#)^{p696} method effectively ignores every fourth byte in its input, and so on. However, the alpha component of styles and images drawn onto the canvas are still honoured up to the point where they would impact the [output bitmap](#)^{p655}'s alpha channel; for instance, drawing a 50% transparent white square on a freshly created [output bitmap](#)^{p655} with its [alpha](#)^{p655} set to false will result in a fully-opaque gray square.

The [CanvasRenderingContext2D](#)^{p650} object also has a **desynchronized** boolean. When a [CanvasRenderingContext2D](#)^{p650} object's [desynchronized](#)^{p656} is true, then the user agent may optimize the rendering of the canvas to reduce the latency, as measured from input events to rasterization, by desynchronizing the canvas paint cycle from the event loop, bypassing the ordinary user agent rendering algorithm, or both. Insofar as this mode involves bypassing the usual paint mechanisms, rasterization, or both, it might introduce visible tearing artifacts.

Note

The user agent usually renders on a buffer which is not being displayed, quickly swapping it and the one being scanned out for presentation; the former buffer is called back buffer and the latter front buffer. A popular technique for reducing latency is called front buffer rendering, also known as single buffer rendering, where rendering happens in parallel and rapidly with the scanning out process. This technique reduces the latency at the price of potentially introducing tearing artifacts and can be used to implement in total or part of the [desynchronized](#)^{p656} boolean. [\[MULTIPLEBUFFERING\]](#)^{p1309}

Note

The [desynchronized](#)^{p656} boolean can be useful when implementing certain kinds of applications, such as drawing applications, where the latency between input and rasterization is critical.

The [CanvasRenderingContext2D](#)^{p650} object also has a **will read frequently** boolean. When a [CanvasRenderingContext2D](#)^{p650} object's [will read frequently](#)^{p656} is true, the user agent may optimize the canvas for readback operations.

Note

On most devices the user agent needs to decide whether to store the canvas's [output bitmap](#)^{p655} on the GPU (this is also called "hardware accelerated"), or on the CPU (also called "software"). Most rendering operations are more performant for accelerated canvases, with the major exception being readback with [getImageData\(\)](#)^{p695}, [toDataURL\(\)](#)^{p649}, or [toBlob\(\)](#)^{p649}. [CanvasRenderingContext2D](#)^{p650} objects with [will read frequently](#)^{p656} equal to true tell the user agent that the webpage is likely to perform many readback operations and that it is advantageous to use a software canvas.

The [CanvasRenderingContext2D](#)^{p650} object also has a **color space** setting of type [PredefinedColorSpace](#)^{p650}. The [CanvasRenderingContext2D](#)^{p650} object's [color space](#)^{p656} indicates the color space for the [output bitmap](#)^{p655}.

The [getContextAttributes\(\)](#) method steps are to return «["[alpha](#)^{p657}" → this's [alpha](#)^{p655}, "[desynchronized](#)^{p657}" → this's [desynchronized](#)^{p656}, "[colorSpace](#)^{p657}" → this's [color space](#)^{p656}, "[willReadFrequently](#)^{p657}" → this's [will read frequently](#)^{p656}]».

The [CanvasRenderingContext2D](#)^{p650} 2D rendering context represents a flat linear Cartesian surface whose origin (0,0) is at the top left corner, with the coordinate space having x values increasing when going right, and y values increasing when going down. The x-coordinate of the right-most edge is equal to the width of the rendering context's [output bitmap](#)^{p655} in [CSS pixels](#); similarly, the y-coordinate of the bottom-most edge is equal to the height of the rendering context's [output bitmap](#)^{p655} in [CSS pixels](#).

The size of the coordinate space does not necessarily represent the size of the actual bitmaps that the user agent will use internally or during rendering. On high-definition displays, for instance, the user agent may internally use bitmaps with four device pixels per unit in the coordinate space, so that the rendering remains at high quality throughout. Anti-aliasing can similarly be implemented using oversampling with bitmaps of a higher resolution than the final image on the display.

Example

Using [CSS pixels](#) to describe the size of a rendering context's [output bitmap](#)^{p655} does not mean that when rendered the canvas will cover an equivalent area in [CSS pixels](#). [CSS pixels](#) are reused for ease of integration with CSS features, such as text layout.

In other words, the [canvas](#)^{p645} element below's rendering context has a 200x200 [output bitmap](#)^{p655} (which internally uses [CSS pixels](#) as a unit for ease of integration with CSS) and is rendered as 100x100 [CSS pixels](#):

```
<canvas width=200 height=200 style=width:100px;height:100px>
```

The **2D context creation algorithm**, which is passed a *target* (a [canvas](#)^{p645} element) and *options*, consists of running these steps:

1. Let *settings* be the result of [converting](#) *options* to the dictionary type [CanvasRenderingContext2DSettings](#)^{p650}. (This can throw an exception.).
2. Let *context* be a new [CanvasRenderingContext2D](#)^{p650} object.
3. Initialize *context*'s [canvas](#)^{p657} attribute to point to *target*.
4. Set *context*'s [output_bitmap](#)^{p655} to the same bitmap as *target*'s bitmap (so that they are shared).
5. [Set bitmap dimensions](#)^{p657} to [the numeric values](#)^{p647} of *target*'s [width](#)^{p647} and [height](#)^{p647} content attributes.
6. Set *context*'s [alpha](#)^{p655} to *settings*["[alpha](#)"].
7. Set *context*'s [desynchronized](#)^{p656} to *settings*["[desynchronized](#)"].
8. Set *context*'s [color_space](#)^{p656} to *settings*["[colorSpace](#)"].
9. Set *context*'s [will_read_frequently](#)^{p656} to *settings*["[willReadFrequently](#)"].
10. Return *context*.

When the user agent is to **set bitmap dimensions** to *width* and *height*, it must run these steps:

1. [Reset the rendering context to its default state](#)^{p659}.
2. Resize the [output_bitmap](#)^{p655} to the new *width* and *height*.
3. Let *canvas* be the [canvas](#)^{p645} element to which the rendering context's [canvas](#)^{p657} attribute was initialized.
4. If [the numeric value](#)^{p647} of *canvas*'s [width](#)^{p647} content attribute differs from *width*, then set *canvas*'s [width](#)^{p647} content attribute to the shortest possible string representing *width* as a [valid non-negative integer](#)^{p70}.
5. If [the numeric value](#)^{p647} of *canvas*'s [height](#)^{p647} content attribute differs from *height*, then set *canvas*'s [height](#)^{p647} content attribute to the shortest possible string representing *height* as a [valid non-negative integer](#)^{p70}.

Example

Only one square appears to be drawn in the following example:

```
// canvas is a reference to a <canvas> element
var context = canvas.getContext('2d');
context.fillRect(0,0,50,50);
canvas.setAttribute('width', '300'); // clears the canvas
context.fillRect(0,100,50,50);
canvas.width = canvas.width; // clears the canvas
context.fillRect(100,0,50,50); // only this square remains
```

The [canvas](#) attribute must return the value it was initialized to when the object was created.

The [PredefinedColorSpace](#)^{p650} enumeration is used to specify the [color_space](#)^{p656} of the canvas's backing store.

The "[srgb](#)" value indicates the '[srgb](#)' color space.

The "[display-p3](#)" value indicates the '[display-p3](#)' color space.

Note

Algorithms for converting between color spaces are found in the [Predefined color spaces](#) section of CSS Color. [[CSSCOLOR](#)]^{p1306}

The [CanvasFillRule](#)^{p650} enumeration is used to select the **fill rule** algorithm by which to determine if a point is inside or outside a path.

The value **"nonzero"** value indicates the nonzero winding rule, wherein a point is considered to be outside a shape if the number of times a half-infinite straight line drawn from that point crosses the shape's path going in one direction is equal to the number of times it crosses the path going in the other direction.

The **"evenodd"** value indicates the even-odd rule, wherein a point is considered to be outside a shape if the number of times a half-infinite straight line drawn from that point crosses the shape's path is even.

If a point is not outside a shape, it is inside the shape.

The [ImageSmoothingQuality](#)^{p650} enumeration is used to express a preference for the interpolation quality to use when smoothing images.

The **"low"** value indicates a preference for a low level of image interpolation quality. Low-quality image interpolation may be more computationally efficient than higher settings.

The **"medium"** value indicates a preference for a medium level of image interpolation quality.

The **"high"** value indicates a preference for a high level of image interpolation quality. High-quality image interpolation may be more computationally expensive than lower settings.

Note

Bilinear scaling is an example of a relatively fast, lower-quality image-smoothing algorithm. Bicubic or Lanczos scaling are examples of image-smoothing algorithms that produce higher-quality output. This specification does not mandate that specific interpolation algorithms be used.

4.12.5.1.1 Implementation notes § p65

This section is non-normative.

The [output bitmap](#)^{p655}, when it is not directly displayed by the user agent, implementations can, instead of updating this bitmap, merely remember the sequence of drawing operations that have been applied to it until such time as the bitmap's actual data is needed (for example because of a call to [drawImage\(\)](#)^{p692}, or the [createImageBitmap\(\)](#)^{p1018} factory method). In many cases, this will be more memory efficient.

The bitmap of a [canvas](#)^{p645} element is the one bitmap that's pretty much always going to be needed in practice. The [output bitmap](#)^{p655} of a rendering context, when it has one, is always just an alias to a [canvas](#)^{p645} element's bitmap.

Additional bitmaps are sometimes needed, e.g. to enable fast drawing when the canvas is being painted at a different size than its [intrinsic size](#), or to enable double buffering so that graphics updates, like page scrolling for example, can be processed concurrently while canvas draw commands are being executed.

4.12.5.1.2 The canvas state § p65

Objects that implement the [CanvasState](#)^{p651} interface maintain a stack of drawing states. **Drawing states** consist of:

- The current [transformation matrix](#)^{p677}.
- The current [clipping region](#)^{p689}.
- The current [letter spacing](#)^{p666}, [word spacing](#)^{p666}, [fill style](#)^{p681}, [stroke style](#)^{p681}, [filter](#)^{p701}, [global alpha](#)^{p699}, and [compositing and blending operator](#)^{p699}.
- The current values of the following attributes: [lineWidth](#)^{p660}, [lineCap](#)^{p660}, [lineJoin](#)^{p660}, [miterLimit](#)^{p660}, [lineDashOffset](#)^{p661}, [shadowOffsetX](#)^{p700}, [shadowOffsetY](#)^{p700}, [shadowBlur](#)^{p700}, [shadowColor](#)^{p700}, [font](#)^{p665}, [textAlign](#)^{p665}, [textBaseline](#)^{p665}, [direction](#)^{p666}, [fontKerning](#)^{p666}, [fontStretch](#)^{p666}, [fontVariantCaps](#)^{p666}, [textRendering](#)^{p666}, [imageSmoothingEnabled](#)^{p700}, [imageSmoothingQuality](#)^{p700}.
- The current [dash list](#)^{p660}.

Note

The rendering context's bitmaps are not part of the drawing state, as they depend on whether and how the rendering context is bound to a [canvas](#)^{p645} element.

Objects that implement the [CanvasState](#)^{p651} mixin have a **context lost** boolean, that is initialized to false when the object is created. The [context lost](#)^{p659} value is updated in the [context lost steps](#)^{p973}.

For web developers (non-normative)

context.save^{p659} ()

Pushes the current state onto the stack.

context.restore^{p659} ()

Pops the top state on the stack, restoring the context to that state.

context.reset^{p659} ()

Resets the rendering context, which includes the backing buffer, the drawing state stack, path, and styles.

context.isContextLost^{p659} ()

Returns true if the rendering context was lost. Context loss can occur due to driver crashes, running out of memory, etc. In these cases, the canvas loses its backing storage and takes steps to [reset the rendering context to its default state](#)^{p659}.

The **save()** method steps are to push a copy of the current drawing state onto the drawing state stack.

The **restore()** method steps are to pop the top entry in the drawing state stack, and reset the drawing state it describes. If there is no saved state, then the method must do nothing.

The **reset()** method steps are to [reset the rendering context to its default state](#)^{p659}.

To **reset the rendering context to its default state**:

1. Clear canvas's bitmap to [transparent black](#).
2. Empty the list of subpaths in context's [current default path](#)^{p688}.
3. Clear the context's drawing state stack.
4. Reset everything that [drawing state](#)^{p658} consists of to their initial values.

The **isContextLost()** method steps are to return [this's context lost](#)^{p659}.

4.12.5.1.3 Line styles ^{p65}₉

For web developers (non-normative)

context.lineWidth^{p660} [= value]

styles.lineWidth^{p660} [= value]

Returns the current line width.

Can be set, to change the line width. Values that are not finite values greater than zero are ignored.

context.lineCap^{p660} [= value]

styles.lineCap^{p660} [= value]

Returns the current line cap style.

Can be set, to change the line cap style.

The possible line cap styles are "butt", "round", and "square". Other values are ignored.

context.lineJoin^{p660} [= value]

styles.lineJoin^{p660} [= value]

Returns the current line join style.

Can be set, to change the line join style.

The possible line join styles are "bevel", "round", and "miter". Other values are ignored.

context.miterLimit^{p660} [= value]

styles.miterLimit^{p660} [= value]

Returns the current miter limit ratio.

Can be set, to change the miter limit ratio. Values that are not finite values greater than zero are ignored.

context.setLineDash^{p660}(*segments*)

styles.setLineDash^{p660}(*segments*)

Sets the current line dash pattern (as used when stroking). The argument is a list of distances for which to alternately have the line on and the line off.

segments = **context.getLineDash**^{p661}()

segments = **styles.getLineDash**^{p661}()

Returns a copy of the current line dash pattern. The array returned will always have an even number of entries (i.e. the pattern is normalized).

context.lineDashOffset^{p661}

styles.lineDashOffset^{p661}

Returns the phase offset (in the same units as the line dash pattern).

Can be set, to change the phase offset. Values that are not finite values are ignored.

Objects that implement the [CanvasPathDrawingStyles](#)^{p653} interface have attributes and methods (defined in this section) that control how lines are treated by the object.

The **lineWidth** attribute gives the width of lines, in coordinate space units. On getting, it must return the current value. On setting, zero, negative, infinite, and NaN values must be ignored, leaving the value unchanged; other values must change the current value to the new value.

When the object implementing the [CanvasPathDrawingStyles](#)^{p653} interface is created, the **lineWidth**^{p660} attribute must initially have the value 1.0.

The **lineCap** attribute defines the type of endings that UAs will place on the end of lines. The three valid values are "butt", "round", and "square".

On getting, it must return the current value. On setting, the current value must be changed to the new value.

When the object implementing the [CanvasPathDrawingStyles](#)^{p653} interface is created, the **lineCap**^{p660} attribute must initially have the value "butt".

The **lineJoin** attribute defines the type of corners that UAs will place where two lines meet. The three valid values are "bevel", "round", and "miter".

On getting, it must return the current value. On setting, the current value must be changed to the new value.

When the object implementing the [CanvasPathDrawingStyles](#)^{p653} interface is created, the **lineJoin**^{p660} attribute must initially have the value "miter".

When the **lineJoin**^{p660} attribute has the value "miter", strokes use the miter limit ratio to decide how to render joins. The miter limit ratio can be explicitly set using the **miterLimit** attribute. On getting, it must return the current value. On setting, zero, negative, infinite, and NaN values must be ignored, leaving the value unchanged; other values must change the current value to the new value.

When the object implementing the [CanvasPathDrawingStyles](#)^{p653} interface is created, the **miterLimit**^{p660} attribute must initially have the value 10.0.

Each [CanvasPathDrawingStyles](#)^{p653} object has a **dash list**, which is either empty or consists of an even number of non-negative numbers. Initially, the **dash list**^{p660} must be empty.

The **setLineDash(*segments*)** method, when invoked, must run these steps:

1. If any value in *segments* is not finite (e.g. an Infinity or a NaN value), or if any value is negative (less than zero), then return (without throwing an exception; user agents could show a message on a developer console, though, as that would be helpful for debugging).

2. If the number of elements in *segments* is odd, then let *segments* be the concatenation of two copies of *segments*.
3. Let the object's [dash list](#)^{p660} be *segments*.

When the `getLineDash()` method is invoked, it must return a sequence whose values are the values of the object's [dash list](#)^{p660}, in the same order.

It is sometimes useful to change the "phase" of the dash pattern, e.g. to achieve a "marching ants" effect. The phase can be set using the `lineDashOffset` attribute. On getting, it must return the current value. On setting, infinite and NaN values must be ignored, leaving the value unchanged; other values must change the current value to the new value.

When the object implementing the [CanvasPathDrawingStyles](#)^{p653} interface is created, the `lineDashOffset`^{p661} attribute must initially have the value 0.0.

When a user agent is to **trace a path**, given an object *style* that implements the [CanvasPathDrawingStyles](#)^{p653} interface, it must run the following algorithm. This algorithm returns a new [path](#)^{p670}.

1. Let *path* be a copy of the path being traced.
2. Prune all zero-length [line segments](#)^{p670} from *path*.
3. Remove from *path* any subpaths containing no lines (i.e. subpaths with just one point).
4. Replace each point in each subpath of *path* other than the first point and the last point of each subpath by a *join* that joins the line leading to that point to the line leading out of that point, such that the subpaths all consist of two points (a starting point with a line leading out of it, and an ending point with a line leading into it), one or more lines (connecting the points and the joins), and zero or more joins (each connecting one line to another), connected together such that each subpath is a series of one or more lines with a join between each one and a point on each end.
5. Add a straight closing line to each closed subpath in *path* connecting the last point and the first point of that subpath; change the last point to a join (from the previously last line to the newly added closing line), and change the first point to a join (from the newly added closing line to the first line).
6. If *style*'s [dash list](#)^{p660} is empty, then jump to the step labeled *convert*.
7. Let *pattern width* be the concatenation of all the entries of *style*'s [dash list](#)^{p660}, in coordinate space units.
8. For each subpath *subpath* in *path*, run the following substeps. These substeps mutate the subpaths in *path in vivo*.
 1. Let *subpath width* be the length of all the lines of *subpath*, in coordinate space units.
 2. Let *offset* be the value of *style*'s `lineDashOffset`^{p661}, in coordinate space units.
 3. While *offset* is greater than *pattern width*, decrement it by *pattern width*.
While *offset* is less than zero, increment it by *pattern width*.
 4. Define *L* to be a linear coordinate line defined along all lines in *subpath*, such that the start of the first line in the subpath is defined as coordinate 0, and the end of the last line in the subpath is defined as coordinate *subpath width*.
 5. Let *position* be zero minus *offset*.
 6. Let *index* be 0.
 7. Let *current state* be *off* (the other states being *on* and *zero-on*).
 8. *Dash on*: Let *segment length* be the value of *style*'s [dash list](#)^{p660}'s *index*th entry.
 9. Increment *position* by *segment length*.
 10. If *position* is greater than *subpath width*, then end these substeps for this subpath and start them again for the next subpath; if there are no more subpaths, then jump to the step labeled *convert* instead.
 11. If *segment length* is nonzero, then let *current state* be *on*.
 12. Increment *index* by one.
 13. *Dash off*: Let *segment length* be the value of *style*'s [dash list](#)^{p660}'s *index*th entry.

14. Let *start* be the offset *position* on *L*.
15. Increment *position* by *segment length*.
16. If *position* is less than zero, then jump to the step labeled *post-cut*.
17. If *start* is less than zero, then let *start* be zero.
18. If *position* is greater than *subpath width*, then let *end* be the offset *subpath width* on *L*. Otherwise, let *end* be the offset *position* on *L*.
19. Jump to the first appropriate step:

↪ **If segment length is zero and current state is off**

Do nothing, just continue to the next step.

↪ **If current state is off**

Cut the line on which *end* finds itself short at *end* and place a point there, cutting in two the subpath that it was in; remove all line segments, joins, points, and subpaths that are between *start* and *end*; and finally place a single point at *start* with no lines connecting to it.

The point has a *directionality* for the purposes of drawing line caps (see below). The directionality is the direction that the original line had at that point (i.e. when *L* was defined above).

↪ **Otherwise**

Cut the line on which *start* finds itself into two at *start* and place a point there, cutting in two the subpath that it was in, and similarly cut the line on which *end* finds itself short at *end* and place a point there, cutting in two the subpath that it was in, and then remove all line segments, joins, points, and subpaths that are between *start* and *end*.

If *start* and *end* are the same point, then this results in just the line being cut in two and two points being inserted there, with nothing being removed, unless a join also happens to be at that point, in which case the join must be removed.

20. *Post-cut*: If *position* is greater than *subpath width*, then jump to the step labeled *convert*.
21. If *segment length* is greater than zero, then let *positioned-at-on-dash* be false.
22. Increment *index* by one. If it is equal to the number of entries in *style*'s [dash list^{p660}](#), then let *index* be 0.
23. Return to the step labeled *dash on*.

9. *Convert*: This is the step that converts the path to a new path that represents its stroke.

Create a new [path^{p670}](#) that describes the edge of the areas that would be covered if a straight line of length equal to *style*'s [lineWidth^{p660}](#) was swept along each subpath in *path* while being kept at an angle such that the line is orthogonal to the path being swept, replacing each point with the end cap necessary to satisfy *style*'s [lineCap^{p660}](#) attribute as described previously and elaborated below, and replacing each join with the join necessary to satisfy *style*'s [lineJoin^{p660}](#) type, as defined below.

Caps: Each point has a flat edge perpendicular to the direction of the line coming out of it. This is then augmented according to the value of *style*'s [lineCap^{p660}](#). The "butt" value means that no additional line cap is added. The "round" value means that a semi-circle with the diameter equal to *style*'s [lineWidth^{p660}](#) width must additionally be placed on to the line coming out of each point. The "square" value means that a rectangle with the length of *style*'s [lineWidth^{p660}](#) width and the width of half *style*'s [lineWidth^{p660}](#) width, placed flat against the edge perpendicular to the direction of the line coming out of the point, must be added at each point.

Points with no lines coming out of them must have two caps placed back-to-back as if it was really two points connected to each other by an infinitesimally short straight line in the direction of the point's *directionality* (as defined above).

Joins: In addition to the point where a join occurs, two additional points are relevant to each join, one for each line: the two corners found half the line width away from the join point, one perpendicular to each line, each on the side furthest from the other line.

A triangle connecting these two opposite corners with a straight line, with the third point of the triangle being the join point, must be added at all joins. The [lineJoin^{p660}](#) attribute controls whether anything else is rendered. The three aforementioned values have the following meanings:

The "bevel" value means that this is all that is rendered at joins.

The "round" value means that an arc connecting the two aforementioned corners of the join, abutting (and not overlapping) the aforementioned triangle, with the diameter equal to the line width and the origin at the point of the join, must be added at joins.

The "miter" value means that a second triangle must (if it can given the miter length) be added at the join, with one line being the line between the two aforementioned corners, abutting the first triangle, and the other two being continuations of the outside edges of the two joining lines, as long as required to intersect without going over the miter length.

The miter length is the distance from the point where the join occurs to the intersection of the line edges on the outside of the join. The miter limit ratio is the maximum allowed ratio of the miter length to half the line width. If the miter length would cause the miter limit ratio (as set by style's `miterLimit`^{p660} attribute) to be exceeded, then this second triangle must not be added.

The subpaths in the newly created path must be oriented such that for any point, the number of times a half-infinite straight line drawn from that point crosses a subpath is even if and only if the number of times a half-infinite straight line drawn from that same point crosses a subpath going in one direction is equal to the number of times it crosses a subpath going in the other direction.

10. Return the newly created path.

4.12.5.1.4 Text styles ^{§ p66}₃

For web developers (non-normative)

`context.font`^{p665} [= *value*]

`styles.font`^{p665} [= *value*]

Returns the current font settings.

Can be set, to change the font. The syntax is the same as for the CSS `font` property; values that cannot be parsed as CSS font values are ignored.

Relative keywords and lengths are computed relative to the font of the `canvas`^{p645} element.

`context.textAlign`^{p665} [= *value*]

`styles.textAlign`^{p665} [= *value*]

Returns the current text alignment settings.

Can be set, to change the alignment. The possible values are and their meanings are given below. Other values are ignored. The default is "start".

`context.textBaseline`^{p665} [= *value*]

`styles.textBaseline`^{p665} [= *value*]

Returns the current baseline alignment settings.

Can be set, to change the baseline alignment. The possible values and their meanings are given below. Other values are ignored. The default is "alphabetic"^{p667}.

`context.direction`^{p666} [= *value*]

`styles.direction`^{p666} [= *value*]

Returns the current directionality.

Can be set, to change the directionality. The possible values and their meanings are given below. Other values are ignored. The default is "inherit"^{p667}.

`context.letterSpacing`^{p666} [= *value*]

`styles.letterSpacing`^{p666} [= *value*]

Returns the current spacing between characters in the text.

Can be set, to change spacing between characters. Values that cannot be parsed as a CSS `<length>` are ignored. The default is "0px".

`context.fontKerning`^{p666} [= *value*]

`styles.fontKerning`^{p666} [= *value*]

Returns the current font kerning settings.

Can be set, to change the font kerning. The possible values and their meanings are given below. Other values are ignored. The default is "auto"^{p667}.

context.fontStretch^{p666} [= value]

styles.fontStretch^{p666} [= value]

Returns the current font stretch settings.

Can be set, to change the font stretch. The possible values and their meanings are given below. Other values are ignored. The default is "normal"^{p668}.

context.fontVariantCaps^{p666} [= value]

styles.fontVariantCaps^{p666} [= value]

Returns the current font variant caps settings.

Can be set, to change the font variant caps. The possible values and their meanings are given below. Other values are ignored. The default is "normal"^{p668}.

context.textRendering^{p666} [= value]

styles.textRendering^{p666} [= value]

Returns the current text rendering settings.

Can be set, to change the text rendering. The possible values and their meanings are given below. Other values are ignored. The default is "auto"^{p668}.

context.wordSpacing^{p666} [= value]

styles.wordSpacing^{p666} [= value]

Returns the current spacing between words in the text.

Can be set, to change spacing between words. Values that cannot be parsed as a CSS `<length>` are ignored. The default is "0px".

Objects that implement the [CanvasTextDrawingStyles](#)^{p653} interface have attributes (defined in this section) that control how text is laid out (rasterized or outlined) by the object. Such objects can also have a **font style source object**. For [CanvasRenderingContext2D](#)^{p650} objects, this is the [canvas](#)^{p645} element given by the value of the context's [canvas](#)^{p657} attribute. For [OffscreenCanvasRenderingContext2D](#)^{p716} objects, this is the [associated OffscreenCanvas object](#)^{p716}.

Font resolution for the [font style source object](#)^{p664} requires a [font source](#). This is determined for a given *object* implementing [CanvasTextDrawingStyles](#)^{p653} by the following steps: [\[CSSFONTLOAD\]](#)^{p1306}

1. If *object*'s [font style source object](#)^{p664} is a [canvas](#)^{p645} element, return the element's [node document](#).
2. Otherwise, *object*'s [font style source object](#)^{p664} is an [OffscreenCanvas](#)^{p712} object:
 1. Let *global* be *object*'s [relevant global object](#)^{p944}.
 2. If *global* is a [Window](#)^{p855} object, then return *global*'s [associated Document](#)^{p856}.
 3. Assert: *global* implements [WorkerGlobalScope](#)^{p1062}.
 4. Return *global*.

Example

This is an example of font resolution with a regular [canvas](#)^{p645} element with ID c1.

```
const font = new FontFace("MyCanvasFont", "url(mycanvasfont.ttf)");
documents.fonts.add(font);

const context = document.getElementById("c1").getContext("2d");
document.fonts.ready.then(function() {
  context.font = "64px MyCanvasFont";
  context.fillText("hello", 0, 0);
});
```

In this example, the canvas will display text using `mycanvasfont.ttf` as its font.

Example

This is an example of how font resolution can happen using [OffscreenCanvas](#)^{p712}. Assuming a [canvas](#)^{p645} element with ID c2 which is transferred to a worker like so:

```
const offscreenCanvas = document.getElementById("c2").transferControlToOffscreen();
worker.postMessage(offscreenCanvas, [offscreenCanvas]);
```

Then, in the worker:

```
self.onmessage = function(ev) {
  const transferredCanvas = ev.data;
  const context = transferredCanvas.getContext("2d");
  const font = new FontFace("MyFont", "url(myfont.ttf)");
  self.fonts.add(font);
  self.fonts.ready.then(function() {
    context.font = "64px MyFont";
    context.fillText("hello", 0, 0);
  });
};
```

In this example, the canvas will display a text using `myfont.ttf`. Notice that the font is only loaded inside the worker, and not in the document context.

The **font** IDL attribute, on setting, must be [parsed as a CSS <'font'> value](#) (but without supporting property-independent style sheet syntax like 'inherit'), and the resulting font must be assigned to the context, with the ['line-height'](#) component forced to 'normal', with the ['font-size'](#) component converted to [CSS pixels](#), and with system fonts being computed to explicit values. If the new value is syntactically incorrect (including using property-independent style sheet syntax like 'inherit' or 'initial'), then it must be ignored, without assigning a new font value. [\[CSS\]](#)^{p1305}

Font family names must be interpreted in the context of the [font style source object](#)^{p664} when the font is to be used; any fonts embedded using `@font-face` or loaded using [FontFace](#)^{p63} objects that are visible to the [font style source object](#)^{p664} must therefore be available once they are loaded. (Each [font style source object](#)^{p664} has a [font source](#), which determines what fonts are available.) If a font is used before it is fully loaded, or if the [font style source object](#)^{p664} does not have that font in scope at the time the font is to be used, then it must be treated as if it was an unknown font, falling back to another as described by the relevant CSS specifications. [\[CSSFONT\]](#)^{p1306} [\[CSSFONTLOAD\]](#)^{p1306}

On getting, the [font](#)^{p665} attribute must return the [serialized form](#) of the current font of the context (with no ['line-height'](#) component). [\[CSSOM\]](#)^{p1306}

Example

For example, after the following statement:

```
context.font = 'italic 400 12px/2 Unknown Font, sans-serif';
```

...the expression `context.font` would evaluate to the string `'italic 12px "Unknown Font", sans-serif'`. The "400" font-weight doesn't appear because that is the default value. The line-height doesn't appear because it is forced to "normal", the default value.

When the object implementing the [CanvasTextDrawingStyles](#)^{p653} interface is created, the font of the context must be set to 10px sans-serif. When the ['font-size'](#) component is set to lengths using percentages, `'em'` or `'ex'` units, or the `'larger'` or `'smaller'` keywords, these must be interpreted relative to the [computed value](#) of the ['font-size'](#) property of the [font style source object](#)^{p664} at the time that the attribute is set, if it is an element. When the ['font-weight'](#) component is set to the relative values `'bolder'` and `'lighter'`, these must be interpreted relative to the [computed value](#) of the ['font-weight'](#) property of the [font style source object](#)^{p664} at the time that the attribute is set, if it is an element. If the [computed values](#) are undefined for a particular case (e.g. because the [font style source object](#)^{p664} is not an element or is not [being rendered](#)^{p1221}), then the relative keywords must be interpreted relative to the normal-weight 10px sans-serif default.

The **textAlign** IDL attribute, on getting, must return the current value. On setting, the current value must be changed to the new value. When the object implementing the [CanvasTextDrawingStyles](#)^{p653} interface is created, the [textAlign](#)^{p665} attribute must initially have the value `start`^{p666}.

The **textBaseline** IDL attribute, on getting, must return the current value. On setting, the current value must be changed to the new

value. When the object implementing the [CanvasTextDrawingStyles](#)^{p653} interface is created, the [textBaseline](#)^{p665} attribute must initially have the value [alphabetic](#)^{p667}.

The [direction](#) IDL attribute, on getting, must return the current value. On setting, the current value must be changed to the new value. When the object implementing the [CanvasTextDrawingStyles](#)^{p653} interface is created, the [direction](#)^{p666} attribute must initially have the value "[inherit](#)^{p667}".

Objects that implement the [CanvasTextDrawingStyles](#)^{p653} interface have attributes that control the spacing between letters and words. Such objects have associated **letter spacing** and **word spacing** values, which are CSS [<length>](#) values. Initially, both must be the result of [parsing](#) "0px" as a CSS [<length>](#).

The [letterSpacing](#)^{p666} getter steps are to return the [serialized form](#) of this's [letter spacing](#)^{p666}.

The [letterSpacing](#)^{p666} setter steps are:

1. Let *parsed* be the result of [parsing](#) the given value as a CSS [<length>](#).
2. If *parsed* is failure, then return.
3. Set this's [letter spacing](#)^{p666} to *parsed*.

The [wordSpacing](#)^{p666} getter steps are to return the [serialized form](#) of this's [word spacing](#)^{p666}.

The [wordSpacing](#)^{p666} setter steps are:

1. Let *parsed* be the result of [parsing](#) the given value as a CSS [<length>](#).
2. If *parsed* is failure, then return.
3. Set this's [word spacing](#)^{p666} to *parsed*.

The [fontKerning](#) IDL attribute, on getting, must return the current value. On setting, the current value must be changed to the new value. When the object implementing the [CanvasTextDrawingStyles](#)^{p653} interface is created, the [fontKerning](#)^{p666} attribute must initially have the value "[auto](#)^{p667}".

The [fontStretch](#) IDL attribute, on getting, must return the current value. On setting, the current value must be changed to the new value. When the object implementing the [CanvasTextDrawingStyles](#)^{p653} interface is created, the [fontStretch](#)^{p666} attribute must initially have the value "[normal](#)^{p668}".

The [fontVariantCaps](#) IDL attribute, on getting, must return the current value. On setting, the current value must be changed to the new value. When the object implementing the [CanvasTextDrawingStyles](#)^{p653} interface is created, the [fontVariantCaps](#)^{p666} attribute must initially have the value "[normal](#)^{p668}".

The [textRendering](#) IDL attribute, on getting, must return the current value. On setting, the current value must be changed to the new value. When the object implementing the [CanvasTextDrawingStyles](#)^{p653} interface is created, the [textRendering](#)^{p666} attribute must initially have the value "[auto](#)^{p668}".

The [textAlign](#)^{p665} attribute's allowed keywords are as follows:

start

Align to the start edge of the text (left side in left-to-right text, right side in right-to-left text).

end

Align to the end edge of the text (right side in left-to-right text, left side in right-to-left text).

left

Align to the left.

right

Align to the right.

center

Align to the center.

The [textBaseline](#)^{p665} attribute's allowed keywords correspond to alignment points in the font:

The keywords map to these alignment points as follows:

top

The top of the em square

hanging

The [hanging_baseline](#)

middle

The middle of the em square

alphabetic

The [alphabetic_baseline](#)

ideographic

The [ideographic-under_baseline](#)

bottom

The bottom of the em square

The [direction^{p666}](#) attribute's allowed keywords are as follows:

ltr

Treat input to the [text_preparation_algorithm^{p669}](#) as left-to-right text.

rtl

Treat input to the [text_preparation_algorithm^{p669}](#) as right-to-left text.

inherit

Default to the directionality of the [canvas^{p645}](#) element or [Document^{p117}](#) as appropriate.

The [fontKerning^{p666}](#) attribute's allowed keywords are as follows:

auto

Kerning is applied at the discretion of the user agent.

normal

Kerning is applied.

none

Kerning is not applied.

The [fontStretch^{p666}](#) attribute's allowed keywords are as follows:

ultra-condensed

Same as CSS ['font-stretch' 'ultra-condensed'](#) setting.

extra-condensed

Same as CSS ['font-stretch' 'extra-condensed'](#) setting.

condensed

Same as CSS ['font-stretch' 'condensed'](#) setting.

semi-condensed

Same as CSS ['font-stretch' 'semi-condensed'](#) setting.

normal

The default setting, where width of the glyphs is at 100%.

semi-expanded

Same as CSS ['font-stretch' 'semi-expanded'](#) setting.

expanded

Same as CSS ['font-stretch' 'expanded'](#) setting.

extra-expanded

Same as CSS ['font-stretch' 'extra-expanded'](#) setting.

ultra-expanded

Same as CSS ['font-stretch' 'ultra-expanded'](#) setting.

The [fontVariantCaps^{p666}](#) attribute's allowed keywords are as follows:

normal

None of the features listed below are enabled.

small-caps

Same as CSS ['font-variant-caps' 'small-caps'](#) setting.

all-small-caps

Same as CSS ['font-variant-caps' 'all-small-caps'](#) setting.

petite-caps

Same as CSS ['font-variant-caps' 'petite-caps'](#) setting.

all-petite-caps

Same as CSS ['font-variant-caps' 'all-petite-caps'](#) setting.

unicase

Same as CSS ['font-variant-caps' 'unicase'](#) setting.

titling-caps

Same as CSS ['font-variant-caps' 'titling-caps'](#) setting.

The [textRendering^{p666}](#) attribute's allowed keywords are as follows:

auto

Same as 'auto' in [SVG text-rendering](#) property.

optimizeSpeed

Same as 'optimizeSpeed' in [SVG text-rendering](#) property.

optimizeLegibility

Same as 'optimizeLegibility' in [SVG text-rendering](#) property.

geometricPrecision

Same as 'geometricPrecision' in [SVG text-rendering](#) property.

The **text preparation algorithm** is as follows. It takes as input a string *text*, a [CanvasTextDrawingStyles](#)^{p653} object *target*, and an optional length *maxWidth*. It returns an array of glyph shapes, each positioned on a common coordinate space, a *physical alignment* whose value is one of *left*, *right*, and *center*, and an [inline box](#). (Most callers of this algorithm ignore the *physical alignment* and the [inline box](#).)

1. If *maxWidth* was provided but is less than or equal to zero or equal to NaN, then return an empty array.
2. Replace all [ASCII whitespace](#) in *text* with U+0020 SPACE characters.
3. Let *font* be the current font of *target*, as given by that object's [font](#)^{p665} attribute.
4. Apply the appropriate step from the following list to determine the value of *direction*:
 - ↪ **If the *target* object's [direction](#)^{p666} attribute has the value "[ltr](#)^{p667}"**
Let *direction* be '[ltr](#)^{p146}'.
 - ↪ **If the *target* object's [direction](#)^{p666} attribute has the value "[rtl](#)^{p667}"**
Let *direction* be '[rtl](#)^{p146}'.
 - ↪ **If the *target* object's [font style source object](#)^{p664} is an element**
Let *direction* be [the directionality](#)^{p146} of the *target* object's [font style source object](#)^{p664}.
 - ↪ **If the *target* object's [font style source object](#)^{p664} is a [Document](#)^{p117} with a non-null [document element](#)**
Let *direction* be [the directionality](#)^{p146} of the *target* object's [font style source object](#)^{p664}'s [document element](#).
 - ↪ **Otherwise**
Let *direction* be '[ltr](#)^{p146}'.
5. Form a hypothetical infinitely-wide CSS [line box](#) containing a single [inline box](#) containing the text *text*, with its CSS properties set as follows:

Property	Source
' direction '	<i>direction</i>
' font '	<i>font</i>
' font-kerning '	<i>target</i> 's fontKerning ^{p666}
' font-stretch '	<i>target</i> 's fontStretch ^{p666}
' font-variant-caps '	<i>target</i> 's fontVariantCaps ^{p666}
' letter-spacing '	<i>target</i> 's letter spacing ^{p666}
SVG text-rendering	<i>target</i> 's textRendering ^{p666}
' white-space '	'pre'
' word-spacing '	<i>target</i> 's word spacing ^{p666}

and with all other properties set to their initial values.

6. If *maxWidth* was provided and the hypothetical width of the [inline box](#) in the hypothetical [line box](#) is greater than *maxWidth* [CSS pixels](#), then change *font* to have a more condensed font (if one is available or if a reasonably readable one can be synthesized by applying a horizontal scale factor to the font) or a smaller font, and return to the previous step.
7. The *anchor point* is a point on the [inline box](#), and the *physical alignment* is one of the values *left*, *right*, and *center*. These variables are determined by the [textAlign](#)^{p665} and [textBaseline](#)^{p665} values as follows:

Horizontal position:

If [textAlign](#)^{p665} is [left](#)^{p666}

If [textAlign](#)^{p665} is [start](#)^{p666} and *direction* is 'ltr'

If [textAlign](#)^{p665} is [end](#)^{p666} and *direction* is 'rtl'

Let the *anchor point*'s horizontal position be the left edge of the [inline box](#), and let *physical alignment* be *left*.

If [textAlign](#)^{p665} is [right](#)^{p666}

If [textAlign](#)^{p665} is [end](#)^{p666} and *direction* is 'ltr'

If [textAlign](#)^{p665} is [start](#)^{p666} and *direction* is 'rtl'

Let the *anchor point*'s horizontal position be the right edge of the [inline box](#), and let *physical alignment* be *right*.

If `textAlign`^{p665} is `center`^{p666}

Let the *anchor point*'s horizontal position be half way between the left and right edges of the [inline box](#), and let *physical alignment* be *center*.

Vertical position:

If `textBaseline`^{p665} is `top`^{p667}

Let the *anchor point*'s vertical position be the top of the em box of the [first available font](#) of the [inline box](#).

If `textBaseline`^{p665} is `hanging`^{p667}

Let the *anchor point*'s vertical position be the [hanging baseline](#) of the [first available font](#) of the [inline box](#).

If `textBaseline`^{p665} is `middle`^{p667}

Let the *anchor point*'s vertical position be half way between the bottom and the top of the em box of the [first available font](#) of the [inline box](#).

If `textBaseline`^{p665} is `alphabetic`^{p667}

Let the *anchor point*'s vertical position be the [alphabetic baseline](#) of the [first available font](#) of the [inline box](#).

If `textBaseline`^{p665} is `ideographic`^{p667}

Let the *anchor point*'s vertical position be the [ideographic-under baseline](#) of the [first available font](#) of the [inline box](#).

If `textBaseline`^{p665} is `bottom`^{p667}

Let the *anchor point*'s vertical position be the bottom of the em box of the [first available font](#) of the [inline box](#).

8. Let *result* be an array constructed by iterating over each glyph in the [inline box](#) from left to right (if any), adding to the array, for each glyph, the shape of the glyph as it is in the [inline box](#), positioned on a coordinate space using [CSS pixels](#) with its origin is at the *anchor point*.
9. Return *result*, *physical alignment*, and the inline box.

4.12.5.1.5 Building paths §^{p67}₀

Objects that implement the [CanvasPath](#)^{p654} interface have a [path](#)^{p670}. A **path** has a list of zero or more subpaths. Each subpath consists of a list of one or more points, connected by straight or curved **line segments**, and a flag indicating whether the subpath is closed or not. A closed subpath is one where the last point of the subpath is connected to the first point of the subpath by a straight line. Subpaths with only one point are ignored when painting the path.

[Paths](#)^{p670} have a **need new subpath** flag. When this flag is set, certain APIs create a new subpath rather than extending the previous one. When a [path](#)^{p670} is created, its [need new subpath](#)^{p670} flag must be set.

When an object implementing the [CanvasPath](#)^{p654} interface is created, its [path](#)^{p670} must be initialized to zero subpaths.

For web developers (non-normative)

`context.moveTo`^{p673}(*x*, *y*)

`path.moveTo`^{p673}(*x*, *y*)

Creates a new subpath with the given point.

`context.closePath`^{p673}()

`path.closePath`^{p673}()

Marks the current subpath as closed, and starts a new subpath with a point the same as the start and end of the newly closed subpath.

`context.lineTo`^{p673}(*x*, *y*)

`path.lineTo`^{p673}(*x*, *y*)

Adds the given point to the current subpath, connected to the previous one by a straight line.

`context.quadraticCurveTo`^{p673}(*cpx*, *cpy*, *x*, *y*)

`path.quadraticCurveTo`^{p673}(*cpx*, *cpy*, *x*, *y*)

Adds the given point to the current subpath, connected to the previous one by a quadratic Bézier curve with the given control point.

`context.bezierCurveTop674(cp1x, cp1y, cp2x, cp2y, x, y)`

`path.bezierCurveTop674(cp1x, cp1y, cp2x, cp2y, x, y)`

Adds the given point to the current subpath, connected to the previous one by a cubic Bézier curve with the given control points.

`context.arcTop674(x1, y1, x2, y2, radius)`

`path.arcTop674(x1, y1, x2, y2, radius)`

Adds an arc with the given control points and radius to the current subpath, connected to the previous point by a straight line.

Throws an `"IndexSizeError" DOMException` if the given radius is negative.

context.arc^{p674}(*x*, *y*, *radius*, *startAngle*, *endAngle* [, *counterclockwise*])

path.arc^{p674}(*x*, *y*, *radius*, *startAngle*, *endAngle* [, *counterclockwise*])

Adds points to the subpath such that the arc described by the circumference of the circle described by the arguments, starting at the given start angle and ending at the given end angle, going in the given direction (defaulting to clockwise), is added to the path, connected to the previous point by a straight line.

Throws an ["IndexSizeError" DOMException](#) if the given radius is negative.

context.ellipse^{p674}(*x*, *y*, *radiusX*, *radiusY*, *rotation*, *startAngle*, *endAngle* [, *counterclockwise*])

path.ellipse^{p674}(*x*, *y*, *radiusX*, *radiusY*, *rotation*, *startAngle*, *endAngle* [, *counterclockwise*])

Adds points to the subpath such that the arc described by the circumference of the ellipse described by the arguments, starting at the given start angle and ending at the given end angle, going in the given direction (defaulting to clockwise), is added to the path, connected to the previous point by a straight line.

Throws an ["IndexSizeError" DOMException](#) if the given radius is negative.

context.rect^{p675}(*x*, *y*, *w*, *h*)

path.rect^{p675}(*x*, *y*, *w*, *h*)

Adds a new closed subpath to the path, representing the given rectangle.

context.roundRect^{p675}(*x*, *y*, *w*, *h*, *radii*)

path.roundRect^{p675}(*x*, *y*, *w*, *h*, *radii*)

Adds a new closed subpath to the path representing the given rounded rectangle. *radii* is either a list of radii or a single radius representing the corners of the rectangle in pixels. If a list is provided, the number and order of these radii function in the same

way as the CSS `'border-radius'` property. A single radius behaves the same way as a list with a single element.

If w and h are both greater than or equal to 0, or if both are smaller than 0, then the path is drawn clockwise. Otherwise, it is drawn counterclockwise.

When w is negative, the rounded rectangle is flipped horizontally, which means that the radius values that normally apply to the left corners are used on the right and vice versa. Similarly, when h is negative, the rounded rect is flipped vertically.

When a value r in `radii` is a number, the corresponding corner(s) are drawn as circular arcs of radius r .

When a value r in `radii` is an object with `{ x, y }` properties, the corresponding corner(s) are drawn as elliptical arcs whose x and y radii are equal to $r.x$ and $r.y$, respectively.

When the sum of the `radii` of two corners of the same edge is greater than the length of the edge, all the `radii` of the rounded rectangle are scaled by a factor of $\text{length} / (r1 + r2)$. If multiple edges have this property, the scale factor of the edge with the smallest scale factor is used. This is consistent with CSS behavior.

Throws a `RangeError` if `radii` is a list whose size is not one, two, three, or four.

Throws a `RangeError` if a value in `radii` is a negative number, or is an `{ x, y }` object whose x or y properties are negative numbers.

The following methods allow authors to manipulate the [paths](#)^{p670} of objects implementing the [CanvasPath](#)^{p654} interface.

For objects implementing the [CanvasDrawPath](#)^{p652} and [CanvasTransform](#)^{p651} interfaces, the points passed to the methods, and the resulting lines added to [current default path](#)^{p688} by these methods, must be transformed according to the [current transformation matrix](#)^{p677} before being added to the path.

The `moveTo(x, y)` method, when invoked, must run these steps:

1. If either of the arguments are infinite or NaN, then return.
2. Create a new subpath with the specified point as its first (and only) point.

When the user agent is to **ensure there is a subpath** for a coordinate (x, y) on a [path](#)^{p670}, the user agent must check to see if the [path](#)^{p670} has its [need new subpath](#)^{p670} flag set. If it does, then the user agent must create a new subpath with the point (x, y) as its first (and only) point, as if the [moveTo\(.\)](#)^{p673} method had been called, and must then unset the [path](#)^{p670}'s [need new subpath](#)^{p670} flag.

The `closePath()` method, when invoked, must do nothing if the object's path has no subpaths. Otherwise, it must mark the last subpath as closed, create a new subpath whose first point is the same as the previous subpath's first point, and finally add this new subpath to the path.

Note

If the last subpath had more than one point in its list of points, then this is equivalent to adding a straight line connecting the last point back to the first point of the last subpath, thus "closing" the subpath.

New points and the lines connecting them are added to subpaths using the methods described below. In all cases, the methods only modify the last subpath in the object's path.

The `lineTo(x, y)` method, when invoked, must run these steps:

1. If either of the arguments are infinite or NaN, then return.
2. If the object's path has no subpaths, then [ensure there is a subpath](#)^{p673} for (x, y) .
3. Otherwise, connect the last point in the subpath to the given point (x, y) using a straight line, and then add the given point (x, y) to the subpath.

The `quadraticCurveTo(cpx, cpy, x, y)` method, when invoked, must run these steps:

1. If any of the arguments are infinite or NaN, then return.
2. [Ensure there is a subpath](#)^{p673} for (cpx, cpy)
3. Connect the last point in the subpath to the given point (x, y) using a quadratic Bézier curve with control point (cpx, cpy) .
[\[BEZIER\]](#)^{p1305}

4. Add the given point (x, y) to the subpath.

The `bezierCurveTo(cp1x, cp1y, cp2x, cp2y, x, y)` method, when invoked, must run these steps:

1. If any of the arguments are infinite or NaN, then return.
2. [Ensure there is a subpath](#)^{p673} for (cp1x, cp1y).
3. Connect the last point in the subpath to the given point (x, y) using a cubic Bézier curve with control points (cp1x, cp1y) and (cp2x, cp2y). [\[BEZIER\]](#)^{p1305}
4. Add the point (x, y) to the subpath.

The `arcTo(x1, y1, x2, y2, radius)` method, when invoked, must run these steps:

1. If any of the arguments are infinite or NaN, then return.
2. [Ensure there is a subpath](#)^{p673} for (x1, y1).
3. If *radius* is negative, then throw an `"IndexSizeError" DOMException`.
4. Let the point (x0, y0) be the last point in the subpath, transformed by the inverse of the [current transformation matrix](#)^{p677} (so that it is in the same coordinate system as the points passed to the method).
5. If the point (x0, y0) is equal to the point (x1, y1), or if the point (x1, y1) is equal to the point (x2, y2), or if *radius* is zero, then add the point (x1, y1) to the subpath, and connect that point to the previous point (x0, y0) by a straight line.
6. Otherwise, if the points (x0, y0), (x1, y1), and (x2, y2) all lie on a single straight line, then add the point (x1, y1) to the subpath, and connect that point to the previous point (x0, y0) by a straight line.
7. Otherwise, let *The Arc* be the shortest arc given by circumference of the circle that has radius *radius*, and that has one point tangent to the half-infinite line that crosses the point (x0, y0) and ends at the point (x1, y1), and that has a different point tangent to the half-infinite line that ends at the point (x1, y1) and crosses the point (x2, y2). The points at which this circle touches these two lines are called the start and end tangent points respectively. Connect the point (x0, y0) to the start tangent point by a straight line, adding the start tangent point to the subpath, and then connect the start tangent point to the end tangent point by *The Arc*, adding the end tangent point to the subpath.

The `arc(x, y, radius, startAngle, endAngle, counterclockwise)` method, when invoked, must run the [ellipse method steps](#)^{p674} with this, x, y, radius, radius, 0, startAngle, endAngle, and counterclockwise.

Note

This makes it equivalent to `ellipse()`^{p674} except that both radii are equal and rotation is 0.

The `ellipse(x, y, radiusX, radiusY, rotation, startAngle, endAngle, counterclockwise)` method, when invoked, must run the [ellipse method steps](#)^{p674} with this, x, y, radiusX, radiusY, rotation, startAngle, endAngle, and counterclockwise.

The **ellipse method steps**, given *canvasPath*, x, y, radiusX, radiusY, rotation, startAngle, endAngle, and counterclockwise, are:

1. If any of the arguments are infinite or NaN, then return.
2. If either *radiusX* or *radiusY* are negative, then throw an `"IndexSizeError" DOMException`.
3. If *canvasPath*'s path has any subpaths, then add a straight line from the last point in the subpath to the start point of the arc.
4. Add the start and end points of the arc to the subpath, and connect them with an arc. The arc and its start and end points are defined as follows:

Consider an ellipse that has its origin at (x, y), that has a major-axis radius *radiusX* and a minor-axis radius *radiusY*, and that is rotated about its origin such that its semi-major axis is inclined *rotation* radians clockwise from the x-axis.

If *counterclockwise* is false and *endAngle*-*startAngle* is equal to or greater than 2π , or, if *counterclockwise* is true and *startAngle*-*endAngle* is equal to or greater than 2π , then the arc is the whole circumference of this ellipse, and the point at *startAngle* along this circle's circumference, measured in radians clockwise from the ellipse's semi-major axis, acts as both the start point and the end point.

Otherwise, the points at *startAngle* and *endAngle* along this circle's circumference, measured in radians clockwise from the ellipse's semi-major axis, are the start and end points respectively, and the arc is the path along the circumference of this ellipse from the start point to the end point, going counterclockwise if *counterclockwise* is true, and clockwise otherwise. Since the points are on the ellipse, as opposed to being simply angles from zero, the arc can never cover an angle greater than 2π radians.

Note

Even if the arc covers the entire circumference of the ellipse and there are no other points in the subpath, the path is not closed unless the `closePath()`^{p673} method is appropriately invoked.

The `rect(x, y, w, h)` method, when invoked, must run these steps:

1. If any of the arguments are infinite or NaN, then return.
2. Create a new subpath containing just the four points (x, y) , $(x+w, y)$, $(x+w, y+h)$, $(x, y+h)$, in that order, with those four points connected by straight lines.
3. Mark the subpath as closed.
4. Create a new subpath with the point (x, y) as the only point in the subpath.

The `roundRect(x, y, w, h, radii)` method steps are:

1. If any of x , y , w , or h are infinite or NaN, then return.
2. If *radii* is an `unrestricted_double` or `DOMPointInit`, then set *radii* to « *radii* ».
3. If *radii* is not a list of size one, two, three, or four, then throw a `RangeError`.
4. Let *normalizedRadii* be an empty list.
5. For each *radius* of *radii*:
 1. If *radius* is a `DOMPointInit`:
 1. If *radius*["x^{p63}"] or *radius*["y^{p63}"] is infinite or NaN, then return.
 2. If *radius*["x^{p63}"] or *radius*["y^{p63}"] is negative, then throw a `RangeError`.
 3. Otherwise, append *radius* to *normalizedRadii*.
 2. If *radius* is a `unrestricted_double`:
 1. If *radius* is infinite or NaN, then return.
 2. If *radius* is negative, then throw a `RangeError`.
 3. Otherwise append « ["x^{p63}" → *radius*, "y^{p63}" → *radius*] » to *normalizedRadii*.
6. Let *upperLeft*, *upperRight*, *lowerRight*, and *lowerLeft* be null.
7. If *normalizedRadii*'s size is 4, then set *upperLeft* to *normalizedRadii*[0], set *upperRight* to *normalizedRadii*[1], set *lowerRight* to *normalizedRadii*[2], and set *lowerLeft* to *normalizedRadii*[3].
8. If *normalizedRadii*'s size is 3, then set *upperLeft* to *normalizedRadii*[0], set *upperRight* and *lowerLeft* to *normalizedRadii*[1], and set *lowerRight* to *normalizedRadii*[2].
9. If *normalizedRadii*'s size is 2, then set *upperLeft* and *lowerRight* to *normalizedRadii*[0] and set *upperRight* and *lowerLeft* to *normalizedRadii*[1].
10. If *normalizedRadii*'s size is 1, then set *upperLeft*, *upperRight*, *lowerRight*, and *lowerLeft* to *normalizedRadii*[0].
11. Corner curves must not overlap. Scale all radii to prevent this:
 1. Let *top* be *upperLeft*["x^{p63}"] + *upperRight*["x^{p63}"].
 2. Let *right* be *upperRight*["y^{p63}"] + *lowerRight*["y^{p63}"].
 3. Let *bottom* be *lowerRight*["x^{p63}"] + *lowerLeft*["x^{p63}"].

4. Let *left* be `upperLeft["yp63"] + lowerLeft["yp63"]`.
 5. Let *scale* be the minimum value of the ratios *w / top*, *h / right*, *w / bottom*, *h / left*.
 6. If *scale* is less than 1, then set the `xp63` and `yp63` members of *upperLeft*, *upperRight*, *lowerLeft*, and *lowerRight* to their current values multiplied by *scale*.
12. Create a new subpath:
 1. Move to the point $(x + \text{upperLeft}["x^{\text{p63}}"], y)$.
 2. Draw a straight line to the point $(x + w - \text{upperRight}["x^{\text{p63}}"], y)$.
 3. Draw an arc to the point $(x + w, y + \text{upperRight}["y^{\text{p63}}"])$.
 4. Draw a straight line to the point $(x + w, y + h - \text{lowerRight}["y^{\text{p63}}"])$.
 5. Draw an arc to the point $(x + w - \text{lowerRight}["x^{\text{p63}}"], y + h)$.
 6. Draw a straight line to the point $(x + \text{lowerLeft}["x^{\text{p63}}"], y + h)$.
 7. Draw an arc to the point $(x, y + h - \text{lowerLeft}["y^{\text{p63}}"])$.
 8. Draw a straight line to the point $(x, y + \text{upperLeft}["y^{\text{p63}}"])$.
 9. Draw an arc to the point $(x + \text{upperLeft}["x^{\text{p63}}"], y)$.
 13. Mark the subpath as closed.
 14. Create a new subpath with the point (x, y) as the only point in the subpath.

Note

This is designed to behave similarly to the CSS `'border-radius'` property.

4.12.5.1.6 Path2D^{p655} objects §^{p67}₆

`Path2Dp655` objects can be used to declare paths that are then later used on objects implementing the `CanvasDrawPathp652` interface. In addition to many of the APIs described in earlier sections, `Path2Dp655` objects have methods to combine paths, and to add text to paths.

For web developers (non-normative)

`path = new Path2Dp676()`

Creates a new empty `Path2Dp655` object.

`path = new Path2Dp676(path)`

When *path* is a `Path2Dp655` object, returns a copy.

When *path* is a string, creates the path described by the argument, interpreted as SVG path data. [\[SVG\]^{p1312}](#)

`path.addPathp677(path [, transform])`

Adds to the path the path given by the argument.

The `Path2D(path)` constructor, when invoked, must run these steps:

1. Let *output* be a new `Path2Dp655` object.
2. If *path* is not given, then return *output*.
3. If *path* is a `Path2Dp655` object, then add all subpaths of *path* to *output* and return *output*. (In other words, it returns a copy of the argument.)
4. Let *svgPath* be the result of parsing and interpreting *path* according to SVG 2's rules for path data. [\[SVG\]^{p1312}](#)

Note

The resulting path could be empty. SVG defines error handling rules for parsing and applying path data.

5. Let (x, y) be the last point in `svgPath`.
6. Add all the subpaths, if any, from `svgPath` to `output`.
7. Create a new subpath in `output` with (x, y) as the only point in the subpath.
8. Return `output`.

The `addPath(path, transform)` method, when invoked on a `Path2D`^{p655} object *a*, must run these steps:

1. If the `Path2D`^{p655} object *path* has no subpaths, then return.
2. Let *matrix* be the result of [creating a DOMMatrix from the 2D dictionary](#) *transform*.
3. If one or more of *matrix*'s [m11 element](#), [m12 element](#), [m21 element](#), [m22 element](#), [m41 element](#), or [m42 element](#) are infinite or NaN, then return.
4. Create a copy of all the subpaths in *path*. Let this copy be known as *c*.
5. Transform all the coordinates and lines in *c* by the transform matrix *matrix*.
6. Let (x, y) be the last point in the last subpath of *c*.
7. Add all the subpaths in *c* to *a*.
8. Create a new subpath in *a* with (x, y) as the only point in the subpath.

4.12.5.1.7 Transformations §^{p67}₇

Objects that implement the `CanvasTransform`^{p651} interface have a **current transformation matrix**, as well as methods (described in this section) to manipulate it. When an object implementing the `CanvasTransform`^{p651} interface is created, its transformation matrix must be initialized to the identity matrix.

The [current transformation matrix](#)^{p677} is applied to coordinates when creating the [current default path](#)^{p688}, and when painting text, shapes, and `Path2D`^{p655} objects, on objects implementing the `CanvasTransform`^{p651} interface.

The transformations must be performed in reverse order.

Note

For instance, if a scale transformation that doubles the width is applied to the canvas, followed by a rotation transformation that rotates drawing operations by a quarter turn, and a rectangle twice as wide as it is tall is then drawn on the canvas, the actual result will be a square.

For web developers (non-normative)

`context.scale`^{p678}(*x*, *y*)

Changes the [current transformation matrix](#)^{p677} to apply a scaling transformation with the given characteristics.

`context.rotate`^{p678}(*angle*)

Changes the [current transformation matrix](#)^{p677} to apply a rotation transformation with the given characteristics. The angle is in radians.

`context.translate`^{p678}(*x*, *y*)

Changes the [current transformation matrix](#)^{p677} to apply a translation transformation with the given characteristics.

`context.transform`^{p678}(*a*, *b*, *c*, *d*, *e*, *f*)

Changes the [current transformation matrix](#)^{p677} to apply the matrix given by the arguments as described below.

`matrix = context.getTransform`^{p678}()

Returns a copy of the [current transformation matrix](#)^{p677}, as a newly created `DOMMatrix` object.

`context.setTransform`^{p678}(*a*, *b*, *c*, *d*, *e*, *f*)

Changes the [current transformation matrix](#)^{p677} to the matrix given by the arguments as described below.

context.setTransform^{p678}(*transform*)

Changes the [current transformation matrix](#)^{p677} to the matrix represented by the passed `DOMMatrix2DInit` dictionary.

context.resetTransform^{p679}()

Changes the [current transformation matrix](#)^{p677} to the identity matrix.

The **scale**(*x*, *y*) method, when invoked, must run these steps:

1. If either of the arguments are infinite or NaN, then return.
2. Add the scaling transformation described by the arguments to the [current transformation matrix](#)^{p677}. The *x* argument represents the scale factor in the horizontal direction and the *y* argument represents the scale factor in the vertical direction. The factors are multiples.

The **rotate**(*angle*) method, when invoked, must run these steps:

1. If *angle* is infinite or NaN, then return.
2. Add the rotation transformation described by the argument to the [current transformation matrix](#)^{p677}. The *angle* argument represents a clockwise rotation angle expressed in radians.

The **translate**(*x*, *y*) method, when invoked, must run these steps:

1. If either of the arguments are infinite or NaN, then return.
2. Add the translation transformation described by the arguments to the [current transformation matrix](#)^{p677}. The *x* argument represents the translation distance in the horizontal direction and the *y* argument represents the translation distance in the vertical direction. The arguments are in coordinate space units.

The **transform**(*a*, *b*, *c*, *d*, *e*, *f*) method, when invoked, must run these steps:

1. If any of the arguments are infinite or NaN, then return.
2. Replace the [current transformation matrix](#)^{p677} with the result of multiplying the current transformation matrix with the matrix described by:

```
a c e
b d f
0 0 1
```

Note

The arguments a, b, c, d, e, and f are sometimes called m11, m12, m21, m22, dx, and dy or m11, m21, m12, m22, dx, and dy. Care ought to be taken in particular with the order of the second and third arguments (b and c) as their order varies from API to API and APIs sometimes use the notation m12/m21 and sometimes m21/m12 for those positions.

The **getTransform**() method, when invoked, must return a newly created `DOMMatrix` representing a copy of the [current transformation matrix](#)^{p677} matrix of the context.

Note

This returned object is not live, so updating it will not affect the [current transformation matrix](#)^{p677}, and updating the [current transformation matrix](#)^{p677} will not affect an already returned `DOMMatrix`.

The **setTransform**(*a*, *b*, *c*, *d*, *e*, *f*) method, when invoked, must run these steps:

1. If any of the arguments are infinite or NaN, then return.
2. Reset the [current transformation matrix](#)^{p677} to the identity matrix.
3. Invoke the [transform](#)^{p678}(*a*, *b*, *c*, *d*, *e*, *f*) method with the same arguments.

The **setTransform**(*transform*) method, when invoked, must run these steps:

1. Let *matrix* be the result of [creating a DOMMatrix from the 2D dictionary transform](#).
2. If one or more of *matrix*'s [m11 element](#), [m12 element](#), [m21 element](#), [m22 element](#), [m41 element](#), or [m42 element](#) are infinite or NaN, then return.
3. Reset the [current transformation matrix](#)^{p677} to *matrix*.

The `resetTransform()` method, when invoked, must reset the [current transformation matrix](#)^{p677} to the identity matrix.

Note

Given a matrix of the form created by the [transform\(\)](#)^{p678} and [setTransform\(\)](#)^{p678} methods, i.e.,

$$\begin{matrix} a & c & e \\ b & d & f \\ 0 & 0 & 1 \end{matrix}$$

the resulting transformed coordinates after transform matrix multiplication will be

$$\begin{aligned} x_{new} &= a x + c y + e \\ y_{new} &= b x + d y + f \end{aligned}$$

4.12.5.1.8 Image sources for 2D rendering contexts §^{p67}₉

Some methods on the [CanvasDrawImage](#)^{p653} and [CanvasFillStrokeStyles](#)^{p651} interfaces take the union type [CanvasImageSource](#)^{p650} as an argument.

This union type allows objects implementing any of the following interfaces to be used as image sources:

- [HTMLOrSVGImageElement](#)^{p650} ([img](#)^{p327} or [SVG image](#) elements)
- [HTMLVideoElement](#)^{p389} ([video](#)^{p388} elements)
- [HTMLCanvasElement](#)^{p646} ([canvas](#)^{p645} elements)
- [ImageBitmap](#)^{p1016}
- [VideoFrame](#)

Note

Although not formally specified as such, [SVG image](#) elements are expected to be implemented nearly identical to [img](#)^{p327} elements. That is, [SVG image](#) elements share the fundamental concepts and features of [img](#)^{p327} elements.

Note

The [ImageBitmap](#)^{p1016} interface can be created from a number of other image-representing types, including [ImageData](#)^{p655}.

To **check the usability of the *image* argument**, where *image* is a [CanvasImageSource](#)^{p650} object, run these steps:

1. Switch on *image*:
 - ↪ [HTMLOrSVGImageElement](#)^{p650}
 - If *image*'s [current request](#)^{p344}'s [state](#)^{p344} is [broken](#)^{p344}, then throw an `"InvalidStateError"` [DOMException](#).
 - If *image* is not [fully decodable](#)^{p344}, then return *bad*.
 - If *image* has an [intrinsic width](#) or [intrinsic height](#) (or both) equal to zero, then return *bad*.
 - ↪ [HTMLVideoElement](#)^{p389}
 - If *image*'s [readyState](#)^{p416} attribute is either [HAVE_NOTHING](#)^{p414} or [HAVE_METADATA](#)^{p414}, then return *bad*.

↪ [HTMLCanvasElement](#)^{p646}

↪ [OffscreenCanvas](#)^{p712}

If *image* has either a horizontal dimension or a vertical dimension equal to zero, then throw an ["InvalidStateError"](#) [DOMException](#).

↪ [ImageBitmap](#)^{p1016}

↪ [VideoFrame](#)

If *image*'s [\[\[Detached\]\]](#)^{p107} internal slot value is set to true, then throw an ["InvalidStateError"](#) [DOMException](#).

2. Return *good*.

When a [CanvasImageSource](#)^{p650} object represents an [HTMLCanvasElement](#)^{p650}, the element's image must be used as the source image.

Specifically, when a [CanvasImageSource](#)^{p650} object represents an animated image in an [HTMLCanvasElement](#)^{p650}, the user agent must use the default image of the animation (the one that the format defines is to be used when animation is not supported or is disabled), or, if there is no such image, the first frame of the animation, when rendering the image for [CanvasRenderingContext2D](#)^{p650} APIs.

When a [CanvasImageSource](#)^{p650} object represents an [HTMLVideoElement](#)^{p389}, then the frame at the [current playback position](#)^{p412} when the method with the argument is invoked must be used as the source image when rendering the image for [CanvasRenderingContext2D](#)^{p650} APIs, and the source image's dimensions must be the [intrinsic width](#)^{p390} and [intrinsic height](#)^{p390} of the [media resource](#)^{p397} (i.e., after any aspect-ratio correction has been applied).

When a [CanvasImageSource](#)^{p650} object represents an [HTMLCanvasElement](#)^{p646}, the element's bitmap must be used as the source image.

When a [CanvasImageSource](#)^{p650} object represents an element that is [being rendered](#)^{p1221} and that element has been resized, the original image data of the source image must be used, not the image as it is rendered (e.g. [width](#)^{p458} and [height](#)^{p458} attributes on the source element have no effect on how the object is interpreted when rendering the image for [CanvasRenderingContext2D](#)^{p650} APIs).

When a [CanvasImageSource](#)^{p650} object represents an [ImageBitmap](#)^{p1016}, the object's bitmap image data must be used as the source image.

When a [CanvasImageSource](#)^{p650} object represents a [VideoFrame](#), the object's pixel data must be used as the source image, and the source image's dimensions must be the object's [\[\[display width\]\]](#) and [\[\[display height\]\]](#).

An object *image* is **not origin-clean** if, switching on *image*'s type:

↪ [HTMLCanvasElement](#)^{p650}

image's [current request](#)^{p344}'s [image data](#)^{p344} is [CORS-cross-origin](#)^{p92}.

↪ [HTMLVideoElement](#)^{p389}

image's [media data](#)^{p397} is [CORS-cross-origin](#)^{p92}.

↪ [HTMLCanvasElement](#)^{p646}

↪ [ImageBitmap](#)^{p1016}

image's bitmap's [origin-clean](#)^{p647} flag is false.

4.12.5.1.9 Fill and stroke styles § p68

For web developers (non-normative)

`context.fillStyle`^{p681} [= *value*]

Returns the current style used for filling shapes.

Can be set, to change the [fill style](#)^{p681}.

The style can be either a string containing a CSS color, or a [CanvasGradient](#)^{p654} or [CanvasPattern](#)^{p654} object. Invalid values are ignored.

`context.strokeStyle`^{p681} [= *value*]

Returns the current style used for stroking shapes.

Can be set, to change the [stroke style](#).^{p681}

The style can be either a string containing a CSS color, or a [CanvasGradient](#).^{p654} or [CanvasPattern](#).^{p654} object. Invalid values are ignored.

Objects that implement the [CanvasFillStrokeStyles](#).^{p651} interface have attributes and methods (defined in this section) that control how shapes are treated by the object.

Such objects have associated **fill style** and **stroke style** values, which are either CSS colors, [CanvasPattern](#).^{p654}s, or [CanvasGradient](#).^{p654}s. Initially, both must be the result of [parsing](#).^{p59} the string "#000000".

When the value is a CSS color, it must not be affected by the transformation matrix when used to draw on bitmaps.

Note

When set to a [CanvasPattern](#).^{p654} or [CanvasGradient](#).^{p654} object, changes made to the object after the assignment do affect subsequent stroking or filling of shapes.

The **fillStyle** getter steps are:

1. If [this's fill style](#).^{p681} is a CSS color, then return the [serialization](#).^{p681} of that color.
2. Return [this's fill style](#).^{p681}.

The **fillStyle**.^{p681} setter steps are:

1. If the given value is a string, then:
 1. Let *parsedValue* be the result of [parsing](#).^{p59} the given value with [this's canvas](#).^{p657} attribute's value.
 2. If *parsedValue* is failure, then return.
 3. Set [this's fill style](#).^{p681} to *parsedValue*.
 4. Return.
2. If the given value is a [CanvasPattern](#).^{p654} object that is marked as [not origin-clean](#).^{p684}, then set [this's origin-clean](#).^{p647} flag to false.
3. Set [this's fill style](#).^{p681} to the given value.

The **strokeStyle** getter steps are:

1. If [this's stroke style](#).^{p681} is a CSS color, then return the [serialization](#).^{p681} of that color.
2. Return [this's stroke style](#).^{p681}.

The **strokeStyle**.^{p681} setter steps are:

1. If the given value is a string, then:
 1. Let *parsedValue* be the result of [parsing](#).^{p59} the given value with [this's canvas](#).^{p657} attribute's value.
 2. If *parsedValue* is failure, then return.
 3. Set [this's stroke style](#).^{p681} to *parsedValue*.
 4. Return.
2. If the given value is a [CanvasPattern](#).^{p654} object that is marked as [not origin-clean](#).^{p684}, then set [this's origin-clean](#).^{p647} flag to false.
3. Set [this's stroke style](#).^{p681} to the given value.

The **serialization of a color** for a color value is a string, computed as follows: if it has alpha equal to 1.0, then the string is a lowercase six-digit hex value, prefixed with a "#" character (U+0023 NUMBER SIGN), with the first two digits representing the red component, the next two digits representing the green component, and the last two digits representing the blue component, the digits

being [ASCII lower hex digits](#). Otherwise, the color value has alpha less than 1.0, and the string is the color value in the CSS `rgba()` functional-notation format: the literal string `"rgba"` (U+0072 U+0067 U+0062 U+0061) followed by a U+0028 LEFT PARENTHESIS, a base-ten integer in the range 0-255 representing the red component (using [ASCII digits](#) in the shortest form possible), a literal U+002C COMMA and U+0020 SPACE, an integer for the green component, a comma and a space, an integer for the blue component, another comma and space, a U+0030 DIGIT ZERO, if the alpha value is greater than zero then a U+002E FULL STOP (representing the decimal point), if the alpha value is greater than zero then one or more [ASCII digits](#) representing the fractional part of the alpha, and finally a U+0029 RIGHT PARENTHESIS. User agents must express the fractional part of the alpha value, if any, with the level of precision necessary for the alpha value, when reparsed, to be interpreted as the same alpha value.

There are three types of gradients, linear gradients, radial gradients, and conic gradients, represented by objects implementing the opaque [CanvasGradient](#)^{p654} interface.

Once a gradient has been created (see below), stops are placed along it to define how the colors are distributed along the gradient. The color of the gradient at each stop is the color specified for that stop. Between each such stop, the colors and the alpha component must be linearly interpolated over the RGBA space without premultiplying the alpha value to find the color to use at that offset. Before the first stop, the color must be the color of the first stop. After the last stop, the color must be the color of the last stop. When there are no stops, the gradient is [transparent black](#).

For web developers (non-normative)

`gradient.addColorStop`^{p682}(*offset*, *color*)

Adds a color stop with the given color to the gradient at the given offset. 0.0 is the offset at one end of the gradient, 1.0 is the offset at the other end.

Throws an ["IndexSizeError"](#) `DOMException` if the offset is out of range. Throws a ["SyntaxError"](#) `DOMException` if the color cannot be parsed.

`gradient = context.createLinearGradient`^{p682}(*x0*, *y0*, *x1*, *y1*)

Returns a [CanvasGradient](#)^{p654} object that represents a linear gradient that paints along the line given by the coordinates represented by the arguments.

`gradient = context.createRadialGradient`^{p683}(*x0*, *y0*, *r0*, *x1*, *y1*, *r1*)

Returns a [CanvasGradient](#)^{p654} object that represents a radial gradient that paints along the cone given by the circles represented by the arguments.

If either of the radii are negative, throws an ["IndexSizeError"](#) `DOMException` exception.

`gradient = context.createConicGradient`^{p683}(*startAngle*, *x*, *y*)

Returns a [CanvasGradient](#)^{p654} object that represents a conic gradient that paints clockwise along the rotation around the center represented by the arguments.

The [addColorStop](#)(*offset*, *color*) method on the [CanvasGradient](#)^{p654}, when invoked, must run these steps:

1. If the *offset* is less than 0 or greater than 1, then throw an ["IndexSizeError"](#) `DOMException`.
2. Let *parsed color* be the result of [parsing](#)^{p59} *color*.

Note

No element is passed to the parser because [CanvasGradient](#)^{p654} objects are [canvas](#)^{p645}-neutral — a [CanvasGradient](#)^{p654} object created by one [canvas](#)^{p645} can be used by another, and there is therefore no way to know which is the "element in question" at the time that the color is specified.

3. If *parsed color* is failure, throw a ["SyntaxError"](#) `DOMException`.
4. Place a new stop on the gradient, at offset *offset* relative to the whole gradient, and with the color *parsed color*.

If multiple stops are added at the same offset on a gradient, then they must be placed in the order added, with the first one closest to the start of the gradient, and each subsequent one infinitesimally further along towards the end point (in effect causing all but the first and last stop added at each point to be ignored).

The [createLinearGradient](#)(*x0*, *y0*, *x1*, *y1*) method takes four arguments that represent the start point (*x0*, *y0*) and end point (*x1*, *y1*) of the gradient. The method, when invoked, must return a linear [CanvasGradient](#)^{p654} initialized with the specified line.

Linear gradients must be rendered such that all points on a line perpendicular to the line that crosses the start and end points have the color at the point where those two lines cross (with the colors coming from the [interpolation and extrapolation](#)^{p682} described above).

The points in the linear gradient must be transformed as described by the [current transformation matrix](#)^{p677} when rendering.

If $x_0 = x_1$ and $y_0 = y_1$, then the linear gradient must paint nothing.

The `createRadialGradient(x_0 , y_0 , r_0 , x_1 , y_1 , r_1)` method takes six arguments, the first three representing the start circle with origin (x_0 , y_0) and radius r_0 , and the last three representing the end circle with origin (x_1 , y_1) and radius r_1 . The values are in coordinate space units. If either of r_0 or r_1 are negative, then an ["IndexSizeError" DOMException](#) must be thrown. Otherwise, the method, when invoked, must return a radial [CanvasGradient](#)^{p654} initialized with the two specified circles.

Radial gradients must be rendered by following these steps:

1. If $x_0 = x_1$ and $y_0 = y_1$ and $r_0 = r_1$, then the radial gradient must paint nothing. Return.
2. Let $x(\omega) = (x_1 - x_0)\omega + x_0$
Let $y(\omega) = (y_1 - y_0)\omega + y_0$
Let $r(\omega) = (r_1 - r_0)\omega + r_0$

Let the color at ω be the color at that position on the gradient (with the colors coming from the [interpolation and extrapolation](#)^{p682} described above).
3. For all values of ω where $r(\omega) > 0$, starting with the value of ω nearest to positive infinity and ending with the value of ω nearest to negative infinity, draw the circumference of the circle with radius $r(\omega)$ at position $(x(\omega), y(\omega))$, with the color at ω , but only painting on the parts of the bitmap that have not yet been painted on by earlier circles in this step for this rendering of the gradient.

Note

This effectively creates a cone, touched by the two circles defined in the creation of the gradient, with the part of the cone before the start circle (0.0) using the color of the first offset, the part of the cone after the end circle (1.0) using the color of the last offset, and areas outside the cone untouched by the gradient (transparent black).

The resulting radial gradient must then be transformed as described by the [current transformation matrix](#)^{p677} when rendering.

The `createConicGradient($startAngle$, x , y)` method takes three arguments, the first argument, *startAngle*, represents the angle in radians at which the gradient begins, and the last two arguments, (x , y), represent the center of the gradient in [CSS pixels](#). The method, when invoked, must return a conic [CanvasGradient](#)^{p654} initialized with the specified center and angle.

It follows the same rendering rule as CSS '[conic-gradient](#)' and it is equivalent to CSS 'conic-gradient(from *adjustedStartAngle*rad at *xpx ypx*, *angularColorStopList*)'. Here:

- *adjustedStartAngle* is given by $startAngle + \pi/2$;
- *angularColorStopList* is given by the color stops that have been added to the [CanvasGradient](#)^{p654} using [addColorStop\(\)](#)^{p682}, with the color stop offsets interpreted as percentages.

Gradients must be painted only where the relevant stroking or filling effects requires that they be drawn.

Patterns are represented by objects implementing the opaque [CanvasPattern](#)^{p654} interface.

For web developers (non-normative)

`pattern = context.createPattern`^{p683}(*image*, *repetition*)

Returns a [CanvasPattern](#)^{p654} object that uses the given image and repeats in the direction(s) given by the *repetition* argument.

The allowed values for *repetition* are `repeat` (both directions), `repeat-x` (horizontal only), `repeat-y` (vertical only), and `no-repeat` (neither). If the *repetition* argument is empty, the value `repeat` is used.

If the image isn't yet fully decoded, then nothing is drawn. If the image is a canvas with no data, throws an ["InvalidStateError" DOMException](#).

`pattern.setTransform`^{p684}(*transform*)

Sets the transformation matrix that will be used when rendering the pattern during a fill or stroke painting operation.

The `createPattern(image, repetition)` method, when invoked, must run these steps:

1. Let *usability* be the result of [checking the usability of](#)^{p679} *image*.
2. If *usability* is *bad*, then return null.
3. Assert: *usability* is *good*.
4. If *repetition* is the empty string, then set it to "repeat".
5. If *repetition* is not [identical to](#) one of "repeat", "repeat-x", "repeat-y", or "no-repeat", then throw a ["SyntaxError" DOMException](#).
6. Let *pattern* be a new [CanvasPattern](#)^{p654} object with the image *image* and the repetition behavior given by *repetition*.
7. If *image* is [not origin-clean](#)^{p680}, then mark *pattern* as **not origin-clean**.
8. Return *pattern*.

Modifying the *image* used when creating a [CanvasPattern](#)^{p654} object after calling the [createPattern\(\)](#)^{p683} method must not affect the pattern(s) rendered by the [CanvasPattern](#)^{p654} object.

Patterns have a transformation matrix, which controls how the pattern is used when it is painted. Initially, a pattern's transformation matrix must be the identity matrix.

The [setTransform\(*transform*\)](#) method, when invoked, must run these steps:

1. Let *matrix* be the result of [creating a DOMMatrix from the 2D dictionary](#) *transform*.
2. If one or more of *matrix*'s [m11 element](#), [m12 element](#), [m21 element](#), [m22 element](#), [m41 element](#), or [m42 element](#) are infinite or NaN, then return.
3. Reset the pattern's transformation matrix to *matrix*.

When a pattern is to be rendered within an area, the user agent must run the following steps to determine what is rendered:

1. Create an infinite [transparent black](#) bitmap.
2. Place a copy of the image on the bitmap, anchored such that its top left corner is at the origin of the coordinate space, with one coordinate space unit per [CSS pixel](#) of the image, then place repeated copies of this image horizontally to the left and right, if the repetition behavior is "repeat-x", or vertically up and down, if the repetition behavior is "repeat-y", or in all four directions all over the bitmap, if the repetition behavior is "repeat".

If the original image data is a bitmap image, then the value painted at a point in the area of the repetitions is computed by filtering the original image data. When scaling up, if the [imageSmoothingEnabled](#)^{p700} attribute is set to false, then the image must be rendered using nearest-neighbor interpolation. Otherwise, the user agent may use any filtering algorithm (for example bilinear interpolation or nearest-neighbor). User agents which support multiple filtering algorithms may use the value of the [imageSmoothingQuality](#)^{p700} attribute to guide the choice of filtering algorithm. When such a filtering algorithm requires a pixel value from outside the original image data, it must instead use the value from wrapping the pixel's coordinates to the original image's dimensions. (That is, the filter uses 'repeat' behavior, regardless of the value of the pattern's repetition behavior.)

3. Transform the resulting bitmap according to the pattern's transformation matrix.
4. Transform the resulting bitmap again, this time according to the [current transformation matrix](#)^{p677}.
5. Replace any part of the image outside the area in which the pattern is to be rendered with [transparent black](#).
6. The resulting bitmap is what is to be rendered, with the same origin and same scale.

If a radial gradient or repeated pattern is used when the transformation matrix is singular, then the resulting style must be [transparent black](#) (otherwise the gradient or pattern would be collapsed to a point or line, leaving the other pixels undefined). Linear gradients and solid colors always define all points even with singular transformation matrices.

4.12.5.1.10 Drawing rectangles to the bitmap §^{p68}₄

Objects that implement the [CanvasRect](#)^{p652} interface provide the following methods for immediately drawing rectangles to the bitmap.

The methods each take four arguments; the first two give the x and y coordinates of the top left of the rectangle, and the second two give the width w and height h of the rectangle, respectively.

The [current transformation matrix](#)^{p677} must be applied to the following four coordinates, which form the path that must then be closed to get the specified rectangle: (x, y) , $(x+w, y)$, $(x+w, y+h)$, $(x, y+h)$.

Shapes are painted without affecting the [current default path](#)^{p688}, and are subject to the [clipping region](#)^{p689}, and, with the exception of [clearRect\(\)](#)^{p685}, also [shadow effects](#)^{p700}, [global alpha](#)^{p699}, and the [current compositing and blending operator](#)^{p699}.

For web developers (non-normative)

`context.clearRect`^{p685}(x, y, w, h)

Clears all pixels on the bitmap in the given rectangle to [transparent black](#).

`context.fillRect`^{p685}(x, y, w, h)

Paints the given rectangle onto the bitmap, using the current fill style.

`context.strokeRect`^{p685}(x, y, w, h)

Paints the box that outlines the given rectangle onto the bitmap, using the current stroke style.

The **`clearRect(x, y, w, h)`** method, when invoked, must run these steps:

1. If any of the arguments are infinite or NaN, then return.
2. Let *pixels* be the set of pixels in the specified rectangle that also intersect the current [clipping region](#)^{p689}.
3. Clear the pixels in *pixels* to a [transparent black](#), erasing any previous image.

Note

If either height or width are zero, this method has no effect, since the set of pixels would be empty.

The **`fillRect(x, y, w, h)`** method, when invoked, must run these steps:

1. If any of the arguments are infinite or NaN, then return.
2. If either w or h are zero, then return.
3. Paint the specified rectangular area using [this's fill style](#)^{p681}.

The **`strokeRect(x, y, w, h)`** method, when invoked, must run these steps:

1. If any of the arguments are infinite or NaN, then return.
2. Take the result of [tracing the path](#)^{p661} described below, using the [CanvasPathDrawingStyles](#)^{p653} interface's line styles, and fill it with [this's stroke style](#)^{p681}.

If both w and h are zero, the path has a single subpath with just one point (x, y) , and no lines, and this method thus has no effect (the [trace a path](#)^{p661} algorithm returns an empty path in that case).

If just one of either w or h is zero, then the path has a single subpath consisting of two points, with coordinates (x, y) and $(x+w, y+h)$, in that order, connected by a single straight line.

Otherwise, the path has a single subpath consisting of four points, with coordinates (x, y) , $(x+w, y)$, $(x+w, y+h)$, and $(x, y+h)$, connected to each other in that order by straight lines.

4.12.5.1.11 Drawing text to the bitmap §^{p68}₅

For web developers (non-normative)

`context.fillText`^{p686}($text, x, y$ [, $maxWidth$])

`context.strokeText`^{p686}($text, x, y$ [, $maxWidth$])

Fills or strokes (respectively) the given text at the given position. If a maximum width is provided, the text will be scaled to fit that width if necessary.

```
metrics = context.measureTextp686(text)
```

Returns a [TextMetrics](#)^{p654} object with the metrics of the given text in the current font.

```
metrics.widthp686
```

```
metrics.actualBoundingBoxLeftp686
```

```
metrics.actualBoundingBoxRightp686
```

```
metrics.fontBoundingBoxAscentp687
```

```
metrics.fontBoundingBoxDescentp687
```

```
metrics.actualBoundingBoxAscentp687
```

```
metrics.actualBoundingBoxDescentp687
```

```
metrics.emHeightAscentp687
```

```
metrics.emHeightDescentp687
```

```
metrics.hangingBaselinep687
```

```
metrics.alphabeticBaselinep687
```

```
metrics.ideographicBaselinep687
```

Returns the measurement described below.

Objects that implement the [CanvasText](#)^{p652} interface provide the following methods for rendering text.

The [fillText\(text, x, y, maxWidth\)](#) and [strokeText\(text, x, y, maxWidth\)](#) methods render the given *text* at the given (x, y) coordinates ensuring that the text isn't wider than *maxWidth* if specified, using the current [font](#)^{p665}, [textAlign](#)^{p665}, and [textBaseline](#)^{p665} values. Specifically, when the methods are invoked, the user agent must run these steps:

1. If any of the arguments are infinite or NaN, then return.
2. Run the [text preparation algorithm](#)^{p669}, passing it *text*, the object implementing the [CanvasText](#)^{p652} interface, and, if the *maxWidth* argument was provided, that argument. Let *glyphs* be the result.
3. Move all the shapes in *glyphs* to the right by *x* [CSS pixels](#) and down by *y* [CSS pixels](#).
4. Paint the shapes given in *glyphs*, as transformed by the [current transformation matrix](#)^{p677}, with each [CSS pixel](#) in the coordinate space of *glyphs* mapped to one coordinate space unit.

For [fillText\(\)](#)^{p686}, [this](#)'s [fill style](#)^{p681} must be applied to the shapes and [this](#)'s [stroke style](#)^{p681} must be ignored. For [strokeText\(\)](#)^{p686}, the reverse holds: [this](#)'s [stroke style](#)^{p681} must be applied to the result of [tracing](#)^{p661} the shapes using the object implementing the [CanvasText](#)^{p652} interface for the line styles, and [this](#)'s [fill style](#)^{p681} must be ignored.

These shapes are painted without affecting the current path, and are subject to [shadow effects](#)^{p700}, [global alpha](#)^{p699}, the [clipping region](#)^{p689}, and the [current compositing and blending operator](#)^{p699}.

The [measureText\(text\)](#) method steps are to run the [text preparation algorithm](#)^{p669}, passing it *text* and the object implementing the [CanvasText](#)^{p652} interface, and then using the returned [inline box](#) must return a new [TextMetrics](#)^{p654} object with members behaving as described in the following list: [\[CSS\]](#)^{p1305}

width attribute

The width of that [inline box](#), in [CSS pixels](#). (The text's advance width.)

actualBoundingBoxLeft attribute

The distance parallel to the baseline from the alignment point given by the [textAlign](#)^{p665} attribute to the left side of the bounding rectangle of the given text, in [CSS pixels](#); positive numbers indicating a distance going left from the given alignment point.

Note

The sum of this value and the next ([actualBoundingBoxRight](#)^{p686}) can be wider than the width of the [inline box](#) ([width](#)^{p686}), in particular with slanted fonts where characters overhang their advance width.

actualBoundingBoxRight attribute

The distance parallel to the baseline from the alignment point given by the [textAlign](#)^{p665} attribute to the right side of the bounding rectangle of the given text, in [CSS pixels](#); positive numbers indicating a distance going right from the given alignment point.

fontBoundingBoxAscent attribute

The distance from the horizontal line indicated by the [textBaseline^{p665}](#) attribute to the [ascent metric](#) of the [first available font](#), in [CSS pixels](#); positive numbers indicating a distance going up from the given baseline.

Note

This value and the next are useful when rendering a background that have to have a consistent height even if the exact text being rendered changes. The [actualBoundingBoxAscent^{p687}](#) attribute (and its corresponding attribute for the descent) are useful when drawing a bounding box around specific text.

fontBoundingBoxDescent attribute

The distance from the horizontal line indicated by the [textBaseline^{p665}](#) attribute to the [descent metric](#) of the [first available font](#), in [CSS pixels](#); positive numbers indicating a distance going down from the given baseline.

actualBoundingBoxAscent attribute

The distance from the horizontal line indicated by the [textBaseline^{p665}](#) attribute to the top of the bounding rectangle of the given text, in [CSS pixels](#); positive numbers indicating a distance going up from the given baseline.

Note

This number can vary greatly based on the input text, even if the first font specified covers all the characters in the input. For example, the [actualBoundingBoxAscent^{p687}](#) of a lowercase "o" from an [alphabetic baseline](#) would be less than that of an uppercase "F". The value can easily be negative; for example, the distance from the top of the em box ([textBaseline^{p665}](#) value "[top^{p667}](#)") to the top of the bounding rectangle when the given text is just a single comma ", " would likely (unless the font is quite unusual) be negative.

actualBoundingBoxDescent attribute

The distance from the horizontal line indicated by the [textBaseline^{p665}](#) attribute to the bottom of the bounding rectangle of the given text, in [CSS pixels](#); positive numbers indicating a distance going down from the given baseline.

emHeightAscent attribute

The distance from the horizontal line indicated by the [textBaseline^{p665}](#) attribute to the highest top of the em squares in the [inline box](#), in [CSS pixels](#); positive numbers indicating that the given baseline is below the top of that em square (so this value will usually be positive). Zero if the given baseline is the top of that em square; half the font size if the given baseline is the middle of that em square.

emHeightDescent attribute

The distance from the horizontal line indicated by the [textBaseline^{p665}](#) attribute to the lowest bottom of the em squares in the [inline box](#), in [CSS pixels](#); positive numbers indicating that the given baseline is above the bottom of that em square. (Zero if the given baseline is the bottom of that em square.)

hangingBaseline attribute

The distance from the horizontal line indicated by the [textBaseline^{p665}](#) attribute to the [hanging baseline](#) of the [inline box](#), in [CSS pixels](#); positive numbers indicating that the given baseline is below the [hanging baseline](#). (Zero if the given baseline is the [hanging baseline](#).)

alphabeticBaseline attribute

The distance from the horizontal line indicated by the [textBaseline^{p665}](#) attribute to the [alphabetic baseline](#) of the [inline box](#), in [CSS pixels](#); positive numbers indicating that the given baseline is below the [alphabetic baseline](#). (Zero if the given baseline is the [alphabetic baseline](#).)

ideographicBaseline attribute

The distance from the horizontal line indicated by the [textBaseline^{p665}](#) attribute to the [ideographic-under baseline](#) of the [inline box](#), in [CSS pixels](#); positive numbers indicating that the given baseline is below the [ideographic-under baseline](#). (Zero if the given baseline is the [ideographic-under baseline](#).)

Note

Glyphs rendered using [fillText\(\)^{p686}](#) and [strokeText\(\)^{p686}](#) can spill out of the box given by the font size (the em square size) and the width returned by [measureText\(\)^{p686}](#) (the text width). Authors are encouraged to use the bounding box values described above if this is an issue.

Note

A future version of the 2D context API might provide a way to render fragments of documents, rendered using CSS, straight to the canvas. This would be provided in preference to a dedicated way of doing multiline layout.

4.12.5.1.12 Drawing paths to the canvas ^{§[p688](#)}

Objects that implement the [CanvasDrawPath](#)^{p652} interface have a **current default path**. There is only one [current default path](#)^{p688}, it is not part of the [drawing state](#)^{p658}. The [current default path](#)^{p688} is a [path](#)^{p670}, as described above.

For web developers (non-normative)

context.beginPath^{p688} ()

Resets the [current default path](#)^{p688}.

context.fill^{p688} ([*fillRule*])

context.fill^{p688} (*path* [, *fillRule*])

Fills the subpaths of the [current default path](#)^{p688} or the given path with the current fill style, obeying the given fill rule.

context.stroke^{p688} ()

context.stroke^{p688} (*path*)

Strokes the subpaths of the [current default path](#)^{p688} or the given path with the current stroke style.

context.clip^{p689} ([*fillRule*])

context.clip^{p689} (*path* [, *fillRule*])

Further constrains the clipping region to the [current default path](#)^{p688} or the given path, using the given fill rule to determine what points are in the path.

context.isPointInPath^{p689} (*x*, *y* [, *fillRule*])

context.isPointInPath^{p689} (*path*, *x*, *y* [, *fillRule*])

Returns true if the given point is in the [current default path](#)^{p688} or the given path, using the given fill rule to determine what points are in the path.

context.isPointInStroke^{p689} (*x*, *y*)

context.isPointInStroke^{p689} (*path*, *x*, *y*)

Returns true if the given point would be in the region covered by the stroke of the [current default path](#)^{p688} or the given path, given the current stroke style.

The **beginPath()** method steps are to empty the list of subpaths in [this's current default path](#)^{p688} so that it once again has zero subpaths.

Where the following method definitions use the term **intended path** for a [Path2D](#)^{p655}-or-null *path*, it means *path* itself if it is a [Path2D](#)^{p655} object, or the [current default path](#)^{p688} otherwise.

When the [intended path](#)^{p688} is a [Path2D](#)^{p655} object, the coordinates and lines of its subpaths must be transformed according to the [current transformation matrix](#)^{p677} on the object implementing the [CanvasTransform](#)^{p651} interface when used by these methods (without affecting the [Path2D](#)^{p655} object itself). When the intended path is the [current default path](#)^{p688}, it is not affected by the transform. (This is because transformations already affect the [current default path](#)^{p688} when it is constructed, so applying it when it is painted as well would result in a double transformation.)

The **fill(*fillRule*)** method steps are to run the [fill steps](#)^{p688} given [this](#), null, and *fillRule*.

The **fill(*path*, *fillRule*)** method steps are to run the [fill steps](#)^{p688} given [this](#), *path*, and *fillRule*.

The **fill steps**, given a [CanvasDrawPath](#)^{p652} *context*, a [Path2D](#)^{p655}-or-null *path*, and a [fill rule](#)^{p657} *fillRule*, are to fill all the subpaths of the [intended path](#)^{p688} for *path*, using *context's fill style*^{p681}, and using the [fill rule](#)^{p657} indicated by *fillRule*. Open subpaths must be implicitly closed when being filled (without affecting the actual subpaths).

The **stroke()** method steps are to run the [stroke steps](#)^{p688} given [this](#) and null.

The **stroke(*path*)** method steps are to run the [stroke steps](#)^{p688} given [this](#) and *path*.

The **stroke steps**, given a [CanvasDrawPath](#)^{p652} *context* and a [Path2D](#)^{p655}-or-null *path*, are to [trace](#)^{p661} the [intended path](#)^{p688} for *path*,

using *context*'s line styles as set by its [CanvasPathDrawingStyles](#)^{p653} mixin, and then fill the resulting path using *context*'s [stroke style](#)^{p681}, using the [nonzero winding rule](#)^{p658}.

Note

As a result of how the algorithm to [trace a path](#)^{p661} is defined, overlapping parts of the paths in one stroke operation are treated as if their union was what was painted.

Note

The stroke style is affected by the transformation during painting, even if the [current default path](#)^{p688} is used.

Paths, when filled or stroked, must be painted without affecting the [current default path](#)^{p688} or any [Path2D](#)^{p655} objects, and must be subject to [shadow effects](#)^{p700}, [global alpha](#)^{p699}, the [clipping region](#)^{p689}, and the [current compositing and blending operator](#)^{p699}. (The effect of transformations is described above and varies based on which path is being used.)

The [clip\(fillRule\)](#) method steps are to run the [clip steps](#)^{p689} given [this](#), null, and *fillRule*.

The [clip\(path, fillRule\)](#) method steps are to run the [clip steps](#)^{p689} given [this](#), *path*, and *fillRule*.

The **clip steps**, given a [CanvasDrawPath](#)^{p652} *context*, a [Path2D](#)^{p655}-or-null *path*, and a [fill rule](#)^{p657} *fillRule*, are to create a new **clipping region** by calculating the intersection of *context*'s current clipping region and the area described by the [intended path](#)^{p688} for *path*, using the [fill rule](#)^{p657} indicated by *fillRule*. Open subpaths must be implicitly closed when computing the clipping region, without affecting the actual subpaths. The new clipping region replaces the current clipping region.

When the context is initialized, its current clipping region must be set to the largest infinite surface (i.e. by default, no clipping occurs).

The [isPointInPath\(x, y, fillRule\)](#) method steps are to return the result of the [is point in path steps](#)^{p689} given [this](#), null, *x*, *y*, and *fillRule*.

The [isPointInPath\(path, x, y, fillRule\)](#) method steps are to return the result of the [is point in path steps](#)^{p689} given [this](#), null, *x*, *y*, and *fillRule*.

The **is point in path steps**, given a [CanvasDrawPath](#)^{p652} *context*, a [Path2D](#)^{p655}-or-null *path*, two numbers *x* and *y*, and a [fill rule](#)^{p657} *fillRule*, are:

1. If *x* or *y* are infinite or NaN, then return false.
2. If the point given by the *x* and *y* coordinates, when treated as coordinates in the canvas coordinate space unaffected by the current transformation, is inside the [intended path](#)^{p688} for *path* as determined by the [fill rule](#)^{p657} indicated by *fillRule*, then return true. Open subpaths must be implicitly closed when computing the area inside the path, without affecting the actual subpaths. Points on the path itself must be considered to be inside the path.
3. Return false.

The [isPointInStroke\(x, y\)](#) method steps are to return the result of the [is point in stroke steps](#)^{p689} given [this](#), null, *x*, and *y*.

The [isPointInStroke\(path, x, y\)](#) method steps are to return the result of the [is point in stroke steps](#)^{p689} given [this](#), *path*, *x*, and *y*.

The **is point in stroke steps**, given a [CanvasDrawPath](#)^{p652} *context*, a [Path2D](#)^{p655}-or-null *path*, and two numbers *x* and *y*, are:

1. If *x* or *y* are infinite or NaN, then return false.
2. If the point given by the *x* and *y* coordinates, when treated as coordinates in the canvas coordinate space unaffected by the current transformation, is inside the path that results from [tracing](#)^{p661} the [intended path](#)^{p688} for *path*, using the [nonzero winding rule](#)^{p658}, and using *context*'s line styles as set by its [CanvasPathDrawingStyles](#)^{p653} mixin, then return true. Points on the resulting path must be considered to be inside the path.
3. Return false.

Example

This [canvas^{p645}](#) element has a couple of checkboxes. The path-related commands are highlighted:

```
<canvas height=400 width=750>
  <label><input type=checkbox id=showA> Show As</label>
  <label><input type=checkbox id=showB> Show Bs</label>
  <!-- ... -->
</canvas>
<script>
  function drawCheckbox(context, element, x, y, paint) {
    context.save();
    context.font = '10px sans-serif';
    context.textAlign = 'left';
    context.textBaseline = 'middle';
    var metrics = context.measureText(element.labels[0].textContent);
    if (paint) {

```

4.12.5.1.13 Drawing focus rings and scrolling paths into view §^{p69}

For web developers (non-normative)

context.drawFocusIfNeeded^{p691}(*element*)

context.drawFocusIfNeeded^{p691}(*path*, *element*)

If the given element is [focused](#)^{p799}, draws a focus ring around the [current default path](#)^{p688} or the given path, following the platform conventions for focus rings.

context.scrollPathIntoView^{p692}()

context.scrollPathIntoView^{p692}(*path*)

Scrolls the [current default path](#)^{p688} or the given path into view. This is especially useful on devices with small screens, where the whole canvas might not be visible at once.

Objects that implement the [CanvasUserInterface](#)^{p652} interface provide the following methods to control drawing focus rings and scrolling paths into view.

The **drawFocusIfNeeded(*element*)** method, when invoked, must run these steps:

1. If *element* is not [focused](#)^{p799} or is not a descendant of the element with whose context the method is associated, then return.
2. Draw a focus ring of the appropriate style along the intended path, following platform conventions.

Note

Some platforms only draw focus rings around elements that have been focused from the keyboard, and not those focused from the mouse. Other platforms simply don't draw focus rings around some elements at all unless relevant accessibility features are enabled. This API is intended to follow these conventions. User agents that implement distinctions based on the manner in which the element was focused are encouraged to classify focus driven by the [focus\(\)](#)^{p810} method based on the kind of user interaction event from which the call was triggered (if any).

The focus ring should not be subject to the [shadow effects](#)^{p700}, the [global alpha](#)^{p699}, the [current compositing and blending operator](#)^{p699}, the [fill style](#)^{p681}, the [stroke style](#)^{p681}, or any of the members in the [CanvasPathDrawingStyles](#)^{p653}, [CanvasTextDrawingStyles](#)^{p653} interfaces, but *should* be subject to the [clipping region](#)^{p689}. (The effect of transformations is described above and varies based on which path is being used.)

3. [Inform the user](#)^{p692} that the focus is at the location given by the intended path. User agents may wait until the next time the [event loop](#)^{p968} reaches its [update the rendering](#)^{p972} step to optionally inform the user.

User agents should not implicitly close open subpaths in the intended path when drawing the focus ring.

Note

This might be a moot point, however. For example, if the focus ring is drawn as an axis-aligned bounding rectangle around the points in the intended path, then whether the subpaths are closed or not has no effect. This specification intentionally does not specify precisely how focus rings are to be drawn: user agents are expected to honor their platform's native conventions.

The `scrollPathIntoView()` method, when invoked, must run these steps:

1. Let *specifiedRectangle* be the rectangle of the bounding box of the intended path.
2. Let *notionalChild* be a hypothetical element that is a rendered child of the `canvas`^{p645} element whose dimensions are those of *specifiedRectangle*.
3. [Scroll *notionalChild* into view](#) with *behavior* set to "auto", *block* set to "start", and *inline* set to "nearest".
4. Optionally, [inform the user](#)^{p692} that the caret or selection (or both) cover *specifiedRectangle* of the canvas. The user agent may wait until the next time the [event loop](#)^{p968} reaches its [update the rendering](#)^{p972} step to optionally inform the user.

"Inform the user", as used in this section, does not imply any persistent state change. It could mean, for instance, calling a system accessibility API to notify assistive technologies such as magnification tools so that the user's magnifier moves to the given area of the canvas. However, it does not associate the path with the element, or provide a region for tactile feedback, etc.

4.12.5.1.14 Drawing images §^{p69}₂

Objects that implement the `CanvasDrawImage`^{p653} interface have the `drawImage` method to draw images.

This method can be invoked with three different sets of arguments:

- `drawImage(image, dx, dy)`
- `drawImage(image, dx, dy, dw, dh)`
- `drawImage(image, sx, sy, sw, sh, dx, dy, dw, dh)`

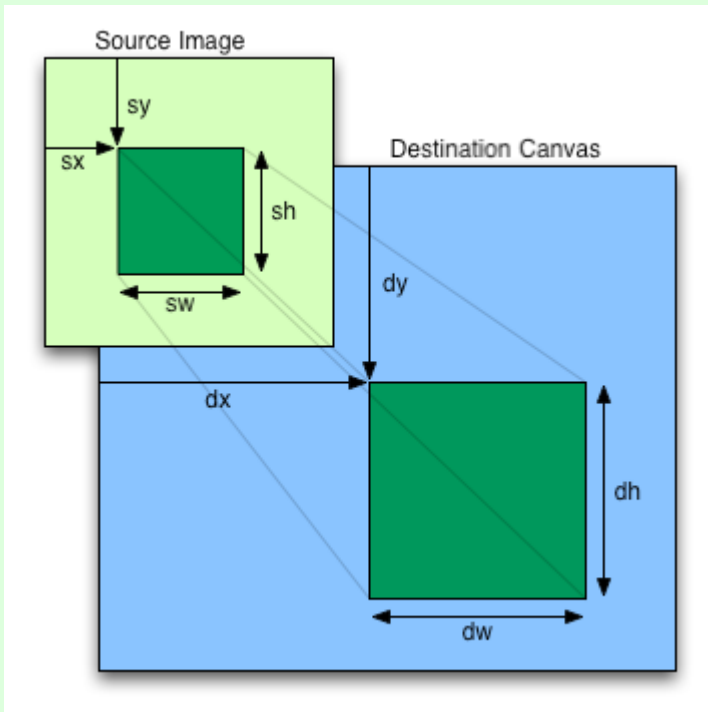

For web developers (non-normative)

`context.drawImage`^{p692}(*image*, *dx*, *dy*)

`context.drawImage`^{p692}(*image*, *dx*, *dy*, *dw*, *dh*)

`context.drawImage`^{p692}(*image*, *sx*, *sy*, *sw*, *sh*, *dx*, *dy*, *dw*, *dh*)

Draws the given image onto the canvas. The arguments are interpreted as follows:

If the image isn't yet fully decoded, then nothing is drawn. If the image is a canvas with no data, throws an `"InvalidStateError" DOMException`.

When the `drawImage()`^{p692} method is invoked, the user agent must run these steps:

1. If any of the arguments are infinite or NaN, then return.

- Let *usability* be the result of [checking the usability of image](#)^{p679}.
- If *usability* is *bad*, then return (without drawing anything).
- Establish the source and destination rectangles as follows:

If not specified, the *dw* and *dh* arguments must default to the values of *sw* and *sh*, interpreted such that one [CSS pixel](#) in the image is treated as one unit in the [output bitmap](#)^{p655}'s coordinate space. If the *sx*, *sy*, *sw*, and *sh* arguments are omitted, then they must default to 0, 0, the image's [intrinsic width](#) in image pixels, and the image's [intrinsic height](#) in image pixels, respectively. If the image has no [intrinsic dimensions](#), then the *concrete object size* must be used instead, as determined using the CSS "[Concrete Object Size Resolution](#)" algorithm, with the *specified size* having neither a definite width nor height, nor any additional constraints, the object's intrinsic properties being those of the *image* argument, and the [default object size](#) being the size of the [output bitmap](#)^{p655}. [\[CSSIMAGES\]](#)^{p1306}

The source rectangle is the rectangle whose corners are the four points (*sx*, *sy*), (*sx*+*sw*, *sy*), (*sx*+*sw*, *sy*+*sh*), (*sx*, *sy*+*sh*).

The destination rectangle is the rectangle whose corners are the four points (*dx*, *dy*), (*dx*+*dw*, *dy*), (*dx*+*dw*, *dy*+*dh*), (*dx*, *dy*+*dh*).

When the source rectangle is outside the source image, the source rectangle must be clipped to the source image and the destination rectangle must be clipped in the same proportion.

Note

When the destination rectangle is outside the destination image (the [output bitmap](#)^{p655}), the pixels that land outside the [output bitmap](#)^{p655} are discarded, as if the destination was an infinite canvas whose rendering was clipped to the dimensions of the [output bitmap](#)^{p655}.

- If one of the *sw* or *sh* arguments is zero, then return. Nothing is painted.
- Paint the region of the *image* argument specified by the source rectangle on the region of the rendering context's [output bitmap](#)^{p655} specified by the destination rectangle, after applying the [current transformation matrix](#)^{p677} to the destination rectangle.

The image data must be processed in the original direction, even if the dimensions given are negative.

When scaling up, if the [imageSmoothingEnabled](#)^{p700} attribute is set to true, the user agent should attempt to apply a smoothing algorithm to the image data when it is scaled. User agents which support multiple filtering algorithms may use the value of the [imageSmoothingQuality](#)^{p700} attribute to guide the choice of filtering algorithm when the [imageSmoothingEnabled](#)^{p700} attribute is set to true. Otherwise, the image must be rendered using nearest-neighbor interpolation.

Note

This specification does not define the precise algorithm to use when scaling an image down, or when scaling an image up when the [imageSmoothingEnabled](#)^{p700} attribute is set to true.

Note

When a [canvas](#)^{p645} element is drawn onto itself, the [drawing model](#)^{p704} requires the source to be copied before the image is drawn, so it is possible to copy parts of a [canvas](#)^{p645} element onto overlapping parts of itself.

If the original image data is a bitmap image, then the value painted at a point in the destination rectangle is computed by filtering the original image data. The user agent may use any filtering algorithm (for example bilinear interpolation or nearest-neighbor). When the filtering algorithm requires a pixel value from outside the original image data, it must instead use the value from the nearest edge pixel. (That is, the filter uses 'clamp-to-edge' behavior.) When the filtering algorithm requires a pixel value from outside the source rectangle but inside the original image data, then the value from the original image data must be used.

Note

Thus, scaling an image in parts or in whole will have the same effect. This does mean that when sprites coming from a single sprite sheet are to be scaled, adjacent images in the sprite sheet can interfere. This can be avoided by ensuring each sprite in the sheet is surrounded by a border of [transparent black](#), or by copying sprites to be scaled into temporary [canvas](#)^{p645} elements and drawing the scaled sprites from there.

Images are painted without affecting the current path, and are subject to [shadow effects](#)^{p700}, [global alpha](#)^{p699}, the [clipping region](#)^{p689}, and the [current compositing and blending operator](#)^{p699}.

7. If `image` is `not origin-clean`^{p680}, then set the `CanvasRenderingContext2D`^{p650}'s `origin-clean`^{p647} flag to false.

4.12.5.1.15 Pixel manipulation ^{p69}₄

For web developers (non-normative)

`imagedata = new ImageData`^{p694}`(sw, sh [, settings])`

Returns an `ImageData`^{p655} object with the given dimensions and the color space indicated by `settings`. All the pixels in the returned object are `transparent black`.

Throws an `"IndexSizeError" DOMException` if either of the width or height arguments are zero.

`imagedata = new ImageData`^{p695}`(data, sw [, sh [, settings]])`

Returns an `ImageData`^{p655} object using the data provided in the `Uint8ClampedArray` argument, interpreted using the given dimensions and the color space indicated by `settings`.

As each pixel in the data is represented by four numbers, the length of the data needs to be a multiple of four times the given width. If the height is provided as well, then the length needs to be exactly the width times the height times 4.

Throws an `"IndexSizeError" DOMException` if the given data and dimensions can't be interpreted consistently, or if either dimension is zero.

`imagedata = context.createImageData`^{p695}`(imagedata)`

Returns an `ImageData`^{p655} object with the same dimensions and color space as the argument. All the pixels in the returned object are `transparent black`.

`imagedata = context.createImageData`^{p695}`(sw, sh [, settings])`

Returns an `ImageData`^{p655} object with the given dimensions. The color space of the returned object is the `color space`^{p656} of `context` unless overridden by `settings`. All the pixels in the returned object are `transparent black`.

Throws an `"IndexSizeError" DOMException` if either of the width or height arguments are zero.

`imagedata = context.getImageData`^{p695}`(sx, sy, sw, sh [, settings])`

Returns an `ImageData`^{p655} object containing the image data for the given rectangle of the bitmap. The color space of the returned object is the `color space`^{p656} of `context` unless overridden by `settings`.

Throws an `"IndexSizeError" DOMException` if the either of the width or height arguments are zero.

`imagedata.width`^{p696}

`imagedata.height`^{p696}

Returns the actual dimensions of the data in the `ImageData`^{p655} object, in pixels.

`imagedata.data`^{p696}

Returns the one-dimensional array containing the data in RGBA order, as integers in the range 0 to 255.

`imagedata.colorSpace`^{p696}

Returns the color space of the pixels.

`context.putImageData`^{p696}`(imagedata, dx, dy [, dirtyX, dirtyY, dirtyWidth, dirtyHeight])`

Paints the data from the given `ImageData`^{p655} object onto the bitmap. If a dirty rectangle is provided, only the pixels from that rectangle are painted.

The `globalAlpha`^{p699} and `globalCompositeOperation`^{p699} properties, as well as the `shadow attributes`^{p700}, are ignored for the purposes of this method call; pixels in the canvas are replaced wholesale, with no composition, alpha blending, no shadows, etc.

Throws an `"InvalidStateError" DOMException` if the `imagedata` object's `data`^{p696} attribute value's `[[ViewedArrayBuffer]]` internal slot is detached.

Objects that implement the `CanvasImageData`^{p653} interface provide the following methods for reading and writing pixel data to the bitmap.

The `new ImageData(sw, sh, settings)` constructor steps are:

1. If one or both of `sw` and `sh` are zero, then throw an `"IndexSizeError" DOMException`.
2. `Initialize`^{p696} `this` given `sw`, `sh`, and `settings`^{p696} set to `settings`.
3. Initialize the image data of `this` to `transparent black`.

The **new ImageData(data, sw, sh, settings)** constructor steps are:

1. Let *length* be the number of bytes in *data*.
2. If *length* is not a nonzero integral multiple of four, then throw an **"InvalidStateError"** DOMException.
3. Let *length* be *length* divided by four.
4. If *length* is not an integral multiple of *sw*, then throw an **"IndexSizeError"** DOMException.

Note

At this step, the length is guaranteed to be greater than zero (otherwise the second step above would have aborted the steps), so if sw is zero, this step will throw the exception and return.

5. Let *height* be *length* divided by *sw*.
6. If *sh* was given and its value is not equal to *height*, then throw an **"IndexSizeError"** DOMException.
7. **Initialize**^{p696} **this** given *sw*, *sh*, **settings**^{p696} set to *settings*, and **source**^{p696} set to *data*.

Note

*This step does not set **this**'s data to a copy of data. It sets it to the actual Uint8ClampedArray object passed as data.*

The **createImageData(sw, sh, settings)** method steps are:

1. If one or both of *sw* and *sh* are zero, then throw an **"IndexSizeError"** DOMException.
2. Let *newImageData* be a **new ImageData**^{p655} object.
3. **Initialize**^{p696} *newImageData* given the absolute magnitude of *sw*, the absolute magnitude of *sh*, **settings**^{p696} set to *settings*, and **defaultColorSpace**^{p696} set to **this**'s **color space**^{p656}.
4. Initialize the image data of *newImageData* to **transparent black**.
5. Return *newImageData*.

The **createImageData(imagedata)** method steps are:

1. Let *newImageData* be a **new ImageData**^{p655} object.
2. **Initialize**^{p696} *newImageData* given the value of *imagedata*'s **width**^{p696} attribute, the value of *imagedata*'s **height**^{p696} attribute, and **defaultColorSpace**^{p696} set to the value of *imagedata*'s **colorSpace**^{p696} attribute.
3. Initialize the image data of *newImageData* to **transparent black**.
4. Return *newImageData*.

The **getImageData(sx, sy, sw, sh, settings)** method steps are:

1. If either the *sw* or *sh* arguments are zero, then throw an **"IndexSizeError"** DOMException.
2. If the **CanvasRenderingContext2D**^{p650}'s **origin-clean**^{p647} flag is set to false, then throw a **"SecurityError"** DOMException.
3. Let *imageData* be a **new ImageData**^{p655} object.
4. **Initialize**^{p696} *imageData* given *sw*, *sh*, **settings**^{p696} set to *settings*, and **defaultColorSpace**^{p696} set to **this**'s **color space**^{p656}.
5. Let the source rectangle be the rectangle whose corners are the four points (*sx*, *sy*), (*sx*+*sw*, *sy*), (*sx*+*sw*, *sy*+*sh*), (*sx*, *sy*+*sh*).
6. Set the pixel values of *imageData* to be the pixels of **this**'s **output bitmap**^{p655} in the area specified by the source rectangle in the bitmap's coordinate space units, converted from **this**'s **color space**^{p656} to *imageData*'s **colorSpace**^{p696} using 'relative-colorimetric' rendering intent.
7. Set the pixels values of *imageData* for areas of the source rectangle that are outside of the **output bitmap**^{p655} to **transparent black**.
8. Return *imageData*.

To **initialize an `ImageData` object** *imageData*, given a positive integer number of rows *rows*, a positive integer number of pixels per row *pixelsPerRow*, an optional `ImageDataSettings`^{p654} *settings*, an optional `Uint8ClampedArray` *source*, and an optional `PredefinedColorSpace`^{p659} *defaultColorSpace*:

1. If *source* was given, then initialize the `data` attribute of *imageData* to *source*.
2. Otherwise (*source* was not given), initialize the `data`^{p696} attribute of *imageData* to a new `Uint8ClampedArray` object. The `Uint8ClampedArray` object must use a new `Canvas Pixel ArrayBuffer`^{p696} for its storage, and must have a zero start offset and a length equal to the length of its storage, in bytes. The `Canvas Pixel ArrayBuffer`^{p696} must have the correct size to store *rows* × *pixelsPerRow* pixels.

If the `Canvas Pixel ArrayBuffer`^{p696} cannot be allocated, then rethrow the `RangeError` thrown by JavaScript, and return.
3. Initialize the `width` attribute of *imageData* to *pixelsPerRow*.
4. Initialize the `height` attribute of *imageData* to *rows*.
5. If *settings* was given and *settings*["`colorSpace`^{p696}"] *exists*, then initialize the `colorSpace` attribute of *imageData* to *settings*["`colorSpace`"].
6. Otherwise, if *defaultColorSpace* was given, then initialize the `colorSpace`^{p696} attribute of *imageData* to *defaultColorSpace*.
7. Otherwise, initialize the `colorSpace`^{p696} attribute of *imageData* to "`srgb`^{p657}".

`ImageData`^{p655} objects are `serializable objects`^{p105}. Their `serialization steps`^{p105}, given *value* and *serialized*, are:

1. Set *serialized*.[[Data]] to the `sub-serialization`^{p110} of the value of *value*'s `data`^{p696} attribute.
2. Set *serialized*.[[Width]] to the value of *value*'s `width`^{p696} attribute.
3. Set *serialized*.[[Height]] to the value of *value*'s `height`^{p696} attribute.
4. Set *serialized*.[[ColorSpace]] to the value of *value*'s `colorSpace`^{p696} attribute.

Their `deserialization steps`^{p105}, given *serialized* and *value*, are:

1. Initialize *value*'s `data`^{p696} attribute to the `sub-deserialization`^{p113} of *serialized*.[[Data]].
2. Initialize *value*'s `width`^{p696} attribute to *serialized*.[[Width]].
3. Initialize *value*'s `height`^{p696} attribute to *serialized*.[[Height]].
4. Initialize *value*'s `colorSpace`^{p696} attribute to *serialized*.[[ColorSpace]].

A **Canvas Pixel ArrayBuffer** is an `ArrayBuffer` whose data is represented in left-to-right order, row by row top to bottom, starting with the top left, with each pixel's red, green, blue, and alpha components being given in that order for each pixel. Each component of each pixel represented in this array must be in the range 0..255, representing the 8 bit value for that component. The components must be assigned consecutive indices starting with 0 for the top left pixel's red component.

The `putImageData()` method writes data from `ImageData`^{p655} structures back to the rendering context's `output bitmap`^{p655}. Its arguments are: *imagedata*, *dx*, *dy*, *dirtyX*, *dirtyY*, *dirtyWidth*, and *dirtyHeight*.

When the last four arguments to this method are omitted, they must be assumed to have the values 0, 0, the `width`^{p696} member of the *imagedata* structure, and the `height`^{p696} member of the *imagedata* structure, respectively.

The method, when invoked, must act as follows:

1. Let *buffer* be *imagedata*'s `data`^{p696} attribute value's [[ViewedArrayBuffer]] internal slot.
2. If `IsDetachedBuffer(buffer)` is true, then throw an "`InvalidStateError`" `DOMException`.
3. If *dirtyWidth* is negative, then let *dirtyX* be *dirtyX*+*dirtyWidth*, and let *dirtyWidth* be equal to the absolute magnitude of *dirtyWidth*.

If *dirtyHeight* is negative, then let *dirtyY* be *dirtyY*+*dirtyHeight*, and let *dirtyHeight* be equal to the absolute magnitude of *dirtyHeight*.
4. If *dirtyX* is negative, then let *dirtyWidth* be *dirtyWidth*+*dirtyX*, and let *dirtyX* be zero.

If *dirtyY* is negative, then let *dirtyHeight* be *dirtyHeight+dirtyY*, and let *dirtyY* be zero.

5. If *dirtyX+dirtyWidth* is greater than the [width^{p696}](#) attribute of the *imagedata* argument, then let *dirtyWidth* be the value of that [width^{p696}](#) attribute, minus the value of *dirtyX*.

If *dirtyY+dirtyHeight* is greater than the [height^{p696}](#) attribute of the *imagedata* argument, then let *dirtyHeight* be the value of that [height^{p696}](#) attribute, minus the value of *dirtyY*.

6. If, after those changes, either *dirtyWidth* or *dirtyHeight* are negative or zero, then return without affecting any bitmaps.
7. For all integer values of *x* and *y* where $dirtyX \leq x < dirtyX+dirtyWidth$ and $dirtyY \leq y < dirtyY+dirtyHeight$, copy the four channels of the pixel with coordinate (*x*, *y*) in the *imagedata* data structure's [Canvas Pixel ArrayBuffer^{p696}](#) to the pixel with coordinate (*dx+x*, *dy+y*) in the rendering context's [output_bitmap^{p655}](#).

Note

Due to the lossy nature of converting between color spaces and converting to and from [premultiplied alpha^{p719}](#) color values, pixels that have just been set using [putImageData\(\)^{p696}](#), and are not completely opaque, might be returned to an equivalent [getImageData\(\)^{p695}](#) as different values.

The current path, [transformation matrix^{p677}](#), [shadow attributes^{p700}](#), [global alpha^{p699}](#), the [clipping region^{p689}](#), and [current compositing and blending operator^{p699}](#) must not affect the methods described in this section.

Example

In the following example, the script generates an [ImageData^{p655}](#) object so that it can draw onto it.

```
// canvas is a reference to a <canvas> element
var context = canvas.getContext('2d');

// create a blank slate
var data = context.createImageData(canvas.width, canvas.height);

// create some plasma
FillPlasma(data, 'green'); // green plasma

// add a cloud to the plasma
AddCloud(data, data.width/2, data.height/2); // put a cloud in the middle

// paint the plasma+cloud on the canvas
context.putImageData(data, 0, 0);

// support methods
function FillPlasma(data, color) { ... }
function AddCloud(data, x, y) { ... }
```

Example

Here is an example of using [getImageData\(\)^{p695}](#) and [putImageData\(\)^{p696}](#) to implement an edge detection filter.

```
<!DOCTYPE HTML>
<html lang="en">
<head>
<title>Edge detection demo</title>
<script>
var image = new Image();
function init() {
  image.onload = demo;
  image.src = "image.jpeg";
}
function demo() {
  var canvas = document.getElementsByTagName('canvas')[0];
  var context = canvas.getContext('2d');
```

```

// draw the image onto the canvas
context.drawImage(image, 0, 0);

// get the image data to manipulate
var input = context.getImageData(0, 0, canvas.width, canvas.height);

// get an empty slate to put the data into
var output = context.createImageData(canvas.width, canvas.height);

// alias some variables for convenience
// In this case input.width and input.height
// match canvas.width and canvas.height
// but we'll use the former to keep the code generic.
var w = input.width, h = input.height;
var inputData = input.data;
var outputData = output.data;

// edge detection
for (var y = 1; y < h-1; y += 1) {
  for (var x = 1; x < w-1; x += 1) {
    for (var c = 0; c < 3; c += 1) {
      var i = (y*w + x)*4 + c;
      outputData[i] = 127 + -inputData[i - w*4 - 4] -  inputData[i - w*4] - inputData[i -
w*4 + 4] +
                                -inputData[i - 4]          + 8*inputData[i]          - inputData[i + 4]
+
                                -inputData[i + w*4 - 4] -  inputData[i + w*4] - inputData[i +
w*4 + 4];
    }
    outputData[(y*w + x)*4 + 3] = 255; // alpha
  }
}

// put the image data back after manipulation
context.putImageData(output, 0, 0);
}
</script>
</head>
<body onload="init()">
  <canvas></canvas>
</body>
</html>

```

Example

Here is an example of color space conversion applied when drawing a solid color and reading the result back using and [getImageData\(\)](#)^{p695}.

```

<!DOCTYPE HTML>
<html lang="en">
<title>Color space image data demo</title>

<canvas></canvas>

<script>
const canvas = document.querySelector('canvas');
const context = canvas.getContext('2d', {colorSpace: 'display-p3'});

// Draw a red rectangle. Note that the hex color notation

```

```

// specifies sRGB colors.
context.fillStyle = "#FF0000";
context.fillRect(0, 0, 64, 64);

// Get the image data.
const pixels = context.getImageData(0, 0, 1, 1);

// This will print 'display-p3', reflecting the default behavior
// of returning image data in the canvas's color space.
console.log(pixels.colorSpace);

// This will print the values 234, 51, and 35, reflecting the
// red fill color, converted to 'display-p3'.
console.log(pixels.data[0]);
console.log(pixels.data[1]);
console.log(pixels.data[2]);
</script>

```

4.12.5.1.16 Compositing §^{p69}₉

For web developers (non-normative)

context.globalAlpha^{p699} [= value]

Returns the current [global alpha](#)^{p699} value applied to rendering operations.

Can be set, to change the [global alpha](#)^{p699} value. Values outside of the range 0.0 .. 1.0 are ignored.

context.globalCompositeOperation^{p699} [= value]

Returns the [current compositing and blending operator](#)^{p699}, from the values defined in *Compositing and Blending*.
[COMPOSITE]^{p1305}

Can be set, to change the [current compositing and blending operator](#)^{p699}. Unknown values are ignored.

Objects that implement the [CanvasCompositing](#)^{p651} interface have a [global alpha](#)^{p699} value and a [current compositing and blending operator](#)^{p699} value that both affect all the drawing operations on this object.

The **global alpha** value gives an alpha value that is applied to shapes and images before they are composited onto the [output bitmap](#)^{p655}. The value ranges from 0.0 (fully transparent) to 1.0 (no additional transparency). It must initially have the value 1.0.

The **globalAlpha** getter steps are to return [this's global alpha](#)^{p699}.

The **globalAlpha**^{p699} setter steps are:

1. If the given value is either infinite, NaN, or not in the range 0.0 to 1.0, then return.
2. Otherwise, set [this's global alpha](#)^{p699} to the given value.

The **current compositing and blending operator** value controls how shapes and images are drawn onto the [output bitmap](#)^{p655}, once they have had the [global alpha](#)^{p699} and the [current transformation matrix](#)^{p677} applied. Initially, it must be set to "[source-over](#)".

The **globalCompositeOperation** getter steps are to return [this's current compositing and blending operator](#)^{p699}.

The **globalCompositeOperation**^{p699} setter steps are:

1. If the given value is not [identical to](#) any of the values that the [<blend-mode>](#) or the [<composite-mode>](#) properties are defined to take, then return. [COMPOSITE]^{p1305}
2. Otherwise, set [this's current compositing and blending operator](#)^{p699} to the given value.

4.12.5.1.17 Image smoothing §^{p70}₀

For web developers (non-normative)

context.imageSmoothingEnabled^{p700} [= *value*]

Returns whether pattern fills and the [drawImage\(\)](#)^{p692} method will attempt to smooth images if their pixels don't line up exactly with the display, when scaling images up.

Can be set, to change whether images are smoothed (true) or not (false).

context.imageSmoothingQuality^{p700} [= *value*]

Returns the current image-smoothing-quality preference.

Can be set, to change the preferred quality of image smoothing. The possible values are "[low](#)^{p658}", "[medium](#)^{p658}" and "[high](#)^{p658}". Unknown values are ignored.

Objects that implement the [CanvasImageSmoothing](#)^{p651} interface have attributes that control how image smoothing is performed.

The **imageSmoothingEnabled** attribute, on getting, must return the last value it was set to. On setting, it must be set to the new value. When the object implementing the [CanvasImageSmoothing](#)^{p651} interface is created, the attribute must be set to true.

The **imageSmoothingQuality** attribute, on getting, must return the last value it was set to. On setting, it must be set to the new value. When the object implementing the [CanvasImageSmoothing](#)^{p651} interface is created, the attribute must be set to "[low](#)^{p658}".

4.12.5.1.18 Shadows §^{p70}₀

All drawing operations on an object which implements the [CanvasShadowStyles](#)^{p652} interface are affected by the four global shadow attributes.

For web developers (non-normative)

context.shadowColor^{p700} [= *value*]

Returns the current shadow color.

Can be set, to change the shadow color. Values that cannot be parsed as CSS colors are ignored.

context.shadowOffsetX^{p700} [= *value*]

context.shadowOffsetY^{p700} [= *value*]

Returns the current shadow offset.

Can be set, to change the shadow offset. Values that are not finite numbers are ignored.

context.shadowBlur^{p700} [= *value*]

Returns the current level of blur applied to shadows.

Can be set, to change the blur level. Values that are not finite numbers greater than or equal to zero are ignored.

The **shadowColor** attribute sets the color of the shadow.

When the context is created, the [shadowColor](#)^{p700} attribute initially must be [transparent black](#).

On getting, the [serialization of the color](#)^{p681} must be returned.

On setting, the new value must be [parsed](#)^{p59} with this [canvas](#)^{p645} element and the color assigned. If parsing the value results in failure then it must be ignored, and the attribute must retain its previous value. [\[CSSCOLOR\]](#)^{p1306}

The **shadowOffsetX** and **shadowOffsetY** attributes specify the distance that the shadow will be offset in the positive horizontal and positive vertical distance respectively. Their values are in coordinate space units. They are not affected by the current transformation matrix.

When the context is created, the shadow offset attributes must initially have the value 0.

On getting, they must return their current value. On setting, the attribute being set must be set to the new value, except if the value is infinite or NaN, in which case the new value must be ignored.

The **shadowBlur** attribute specifies the level of the blurring effect. (The units do not map to coordinate space units, and are not

affected by the current transformation matrix.)

When the context is created, the `shadowBlur`^{p700} attribute must initially have the value 0.

On getting, the attribute must return its current value. On setting the attribute must be set to the new value, except if the value is negative, infinite or NaN, in which case the new value must be ignored.

Shadows are only drawn if the opacity component of the alpha component of the color of `shadowColor`^{p700} is nonzero and either the `shadowBlur`^{p700} is nonzero, or the `shadowOffsetX`^{p700} is nonzero, or the `shadowOffsetY`^{p700} is nonzero.

[When shadows are drawn](#)^{p701}, they must be rendered as follows:

1. Let *A* be an infinite [transparent black](#) bitmap on which the source image for which a shadow is being created has been rendered.
2. Let *B* be an infinite [transparent black](#) bitmap, with a coordinate space and an origin identical to *A*.
3. Copy the alpha channel of *A* to *B*, offset by `shadowOffsetX`^{p700} in the positive x direction, and `shadowOffsetY`^{p700} in the positive y direction.
4. If `shadowBlur`^{p700} is greater than 0:
 1. Let σ be half the value of `shadowBlur`^{p700}.
 2. Perform a 2D Gaussian Blur on *B*, using σ as the standard deviation.

User agents may limit values of σ to an implementation-specific maximum value to avoid exceeding hardware limitations during the Gaussian blur operation.

5. Set the red, green, and blue components of every pixel in *B* to the red, green, and blue components (respectively) of the color of `shadowColor`^{p700}.
6. Multiply the alpha component of every pixel in *B* by the alpha component of the color of `shadowColor`^{p700}.
7. The shadow is in the bitmap *B*, and is rendered as part of the [drawing model](#)^{p704} described below.

If the [current compositing and blending operator](#)^{p699} is "copy", then shadows effectively won't render (since the shape will overwrite the shadow).

4.12.5.1.19 Filters § p70 1

All drawing operations on an object which implements the `CanvasFilters`^{p652} interface are affected by the global `filter` attribute.

For web developers (non-normative)

`context.filter`^{p701} [= *value*]

Returns the current filter.

Can be set, to change the filter. Values can either be the string "none", a string parseable as a [<filter-value-list>](#), or a `CanvasFilter`^{p652} object.

`filter = new CanvasFilter`^{p702} (*input*)

Constructs a new `CanvasFilter`^{p702} from the properties of the *input* object. These properties include a `filter` property, whose value is one of the [supported filter names](#)^{p702}, and additionally can include properties corresponding to the settings for the filter. These latter properties are the same as the XML attribute names when using the corresponding SVG filters.

`filter = new CanvasFilter`^{p702} (*inputs*)

Constructs a new `CanvasFilter`^{p702} from the *inputs* array. Each element in the array is an input as described for the previous overload. They are composed in sequence to create the final filter.

Such objects have an associated **current filter**, which is either a string or a `CanvasFilter`^{p652}. Initially the [current filter](#)^{p701} is set to the string "none". Whenever the value of the [current filter](#)^{p701} is the string "none" filters will be disabled for the context.

A `CanvasFilter`^{p652} is an interface for creating SVG filters using JavaScript. A `CanvasFilter`^{p652} has an associated **XML filter list**. An [XML filter list](#)^{p701} is a [list of XML element data for filters](#)^{p702} that fully describes an SVG filter network. It is set during construction of the `CanvasFilter`^{p652}.

The `filterp701` getter steps are to return `this's current filterp701`.

The `filterp701` setter steps are:

1. If the given value is a string, then:
 1. If the given value is "none", then set `this's current filterp701` to "none" and return.
 2. Let `parsedValue` be the result of `parsing` the given values as a `<filter-value-list>`. If any property-independent style sheet syntax like 'inherit' or 'initial' is present, then this parsing must return failure.
 3. If `parsedValue` is failure, then return.
 4. Set `this's current filterp701` to the given value.
2. Otherwise, set `this's current filterp701` to the given value.

Note

Though `context.filterp701 = "none"` will disable filters for the context, `context.filterp701 = ""`, `context.filterp701 = null`, and `context.filterp701 = undefined` are all treated as unparseable inputs and the value of the `current filterp701` is left unchanged.

For the construction of `CanvasFilterp652` objects, the following definitions are needed:

The **supported filter names** are "gaussianBlur", "colorMatrix", "convolveMatrix", and "componentTransfer".

The **XML element data for filters** is a `struct`, with the following `items`:

- A string **name**
- An `ordered map` of strings to strings **attributes**
- A list of `XML element data for filtersp702` **children**

To get the **IDL type for a canvas filter attribute** `attrName`:

1. Let `type` be the type listed for `attrName` in `Filter Effects`. [\[FILTERS\]^{p1308}](#)
2. If `type` is "false | true", then return `boolean`.
3. If `type` is "list of <number>s", then return `sequence<long long>`.
4. If `type` is "<number-optional-number>", "<number>", or "<integer>", then return `long long`.
5. Return `DOMString`.

To **generate an XML value** from a `key, value` pair:

1. Let `type` be the result of getting the `IDL type for a canvas filter attributep702` for `key`.
2. Let `idlValue` be the result of `converting` `value` to `type`.
3. Let `xmlValue` be the result of `converting` `idlValue` to an ECMAScript value, and then `converting` that result to a `DOMString`.
4. Return `xmlValue`.

The `new CanvasFilter(filters)` constructor steps are:

1. Let `xmlFilters` be an empty list.
2. If `filters` is a `CanvasFilterInputp652`, then set `filters` to « `filters` ».
3. For each `filterDict` of `filters`:
 1. If `filterDict["filter"]` does not `exist`, then throw a `TypeError`.
 2. Let `filterName` be the value of `filterDict["filter"]`.
 3. If `filterName` is not one of `supported filter namesp702`, then `continue`.

4. Let *xmlName* be the concatenation of "fe", the first code unit of *filterName* [converted to ASCII uppercase](#), and all code units of *filterName* after the first one.
5. Let *xmlFilter* be a new [XML element data for filters](#)^{p702} whose [name](#)^{p702} is *xmlName*, whose [attributes](#)^{p702} is an empty ordered map, and whose [children](#)^{p702} is an empty list.
6. [Append](#) *xmlFilter* to *xmlFilters*.
7. [For each](#) *key* → *value* of *filterDict*:
 1. If any of the following are true:
 - *key* is not the local name of an attribute listed for the filter primitive given by *xmlName* [\[FILTERS\]](#)^{p1308}
 - *key* is the local name of a [core attribute](#)
 - *key* is the local name of a [presentation attribute](#)
 - *key* is the local name of a [filter primitive attribute](#)
 - *key* is "in" or "filter"
 - *key* contains U+003A (:)
 then [continue](#).
 2. If *key* is one of "funcR", "funcG", "funcB", "funcA":
 1. Set *value* to the result of [converting value](#) to `record<DOMString, any>`.
 2. Let *xmlTransferName* be the concatenation of "fe", the first code unit of *key* [converted to ASCII uppercase](#), and all code units of *key* after the first one.
 3. Let *transferFunction* be a new [XML element data for filters](#)^{p702} whose [name](#)^{p702} is *xmlTransferName*, whose [attributes](#)^{p702} is an empty ordered map, and whose [children](#)^{p702} is an empty list.
 4. For each *transferName* → *transferValue* of *value*:
 1. Let *transferFunctionValue* be the result of [generating an XML value](#)^{p702} from *transferName* and *transferValue*.
 2. Set *transferFunction*'s [attributes](#)^{p702}[*key*] to *transferFunctionValue*.
 5. [Append](#) *transferFunction* to *xmlFilter*'s [children](#)^{p702}.
 3. Otherwise:
 1. Let *attrXMLValue* be the result of [generating an XML value](#)^{p702} from *key* and *value*.
 2. Set *xmlFilter*'s [attributes](#)^{p702}[*key*] to *attrXMLValue*.
4. Set *this*'s [XML filter list](#)^{p701} to *xmlFilters*.

Example

The following example will set the canvas's filter to a `colorMatrix` filter that swaps the green and red channels, then blurs the result by 5 pixels:

```
// canvas is a reference to a <canvas> element
const context = canvas.getContext('2d');
context.filter = new CanvasFilter([
  {
    filter: "colorMatrix",
    type: "matrix",
    values: [
      0, 1, 0, 0, 0,
      1, 0, 0, 0, 0,
```

```

    0, 0, 1, 0, 0,
    0, 0, 0, 1, 0
  ],
},
{
  filter: "gaussianBlur",
  stdDeviation: 5,
}
]);

```

Note

Currently, [CanvasFilter^{p652}](#)s can only be linked lists. Full filter graphs are a planned expansion of this feature.

Coordinates used in the value of the [current filter^{p701}](#) are interpreted such that one pixel is equivalent to one SVG user space unit and to one canvas coordinate space unit. Filter coordinates are not affected by the [current transformation matrix^{p677}](#). The current transformation matrix affects only the input to the filter. Filters are applied in the [output bitmap^{p655}](#)'s coordinate space.

When the value of the [current filter^{p701}](#) is a string parseable as a [<filter-value-list>](#) which defines lengths using percentages or using 'em' or 'ex' units, these must be interpreted relative to the [computed value](#) of the 'font-size' property of the [font style source object^{p664}](#) at the time that the attribute is set. If the [computed values](#) are undefined for a particular case (e.g. because the [font style source object^{p664}](#) is not an element or is not [being rendered^{p1221}](#)), then the relative keywords must be interpreted relative to the default value of the [font^{p665}](#) attribute. The 'larger' and 'smaller' keywords are not supported.

If the value of the [current filter^{p701}](#) is a string parseable as a [<filter-value-list>](#) with a reference to an SVG filter in the same document, and this SVG filter changes, then the changed filter is used for the next draw operation.

If the value of the [current filter^{p701}](#) is a string parseable as a [<filter-value-list>](#) with a reference to an SVG filter in an external resource document and that document is not loaded when a drawing operation is invoked, then the drawing operation must proceed with no filtering.

4.12.5.1.20 Working with externally-defined SVG filters §^{p70}₄

This section is non-normative.

Since drawing is performed using filter value "none" until an externally-defined filter has finished loading, authors might wish to determine whether such a filter has finished loading before proceeding with a drawing operation. One way to accomplish this is to load the externally-defined filter elsewhere within the same page in some element that sends a `load` event (for example, an [SVG use](#) element), and wait for the `load` event to be dispatched.

4.12.5.1.21 Drawing model §^{p70}₄

When a shape or image is painted, user agents must follow these steps, in the order given (or act as if they do):

1. Render the shape or image onto an infinite [transparent black](#) bitmap, creating image *A*, as described in the previous sections. For shapes, the current fill, stroke, and line styles must be honored, and the stroke must itself also be subjected to the current transformation matrix.
2. When the [current filter^{p701}](#) is set to a value other than "none" and all the externally-defined filters it references, if any, are in documents that are currently loaded, then use image *A* as the input to the [current filter^{p701}](#), creating image *B*. If the [current filter^{p701}](#) is a string parseable as a [<filter-value-list>](#), then draw using the [current filter^{p701}](#) in the same manner as SVG. If the [current filter^{p701}](#) is a [CanvasFilter^{p652}](#), draw using the equivalent SVG for the XML structure stored in the [current filter^{p701}](#)'s by mapping each [filter property](#) of the [XML filter list^{p701}](#).

Otherwise, let *B* be an alias for *A*.

3. [When shadows are drawn^{p701}](#), render the shadow from image *B*, using the current shadow styles, creating image *C*.
4. [When shadows are drawn^{p701}](#), multiply the alpha component of every pixel in *C* by [global alpha^{p699}](#).

5. [When shadows are drawn](#)^{p701}, composite *C* within the [clipping region](#)^{p689} over the current [output bitmap](#)^{p655} using the [current compositing and blending operator](#)^{p699}.
6. Multiply the alpha component of every pixel in *B* by [global_alpha](#)^{p699}.
7. Composite *B* within the [clipping region](#)^{p689} over the current [output bitmap](#)^{p655} using the [current compositing and blending operator](#)^{p699}.

When compositing onto the [output bitmap](#)^{p655}, pixels that would fall outside of the [output bitmap](#)^{p655} must be discarded.

4.12.5.1.22 Best practices §^{p70}₅

When a canvas is interactive, authors should include [focusable](#)^{p800} elements in the element's fallback content corresponding to each [focusable](#)^{p800} part of the canvas, as in the [example above](#)^{p689}.

When rendering focus rings, to ensure that focus rings have the appearance of native focus rings, authors should use the [drawFocusIfNeeded\(\)](#)^{p691} method, passing it the element for which a ring is being drawn. This method only draws the focus ring if the element is [focused](#)^{p799}, so that it can simply be called whenever drawing the element, without checking whether the element is focused or not first.

In addition to drawing focus rings, authors should use the [scrollPathIntoView\(\)](#)^{p692} method when an element in the canvas is focused, to make sure it is visible on the screen (if applicable).

Authors should avoid implementing text editing controls using the [canvas](#)^{p645} element. Doing so has a large number of disadvantages:

- Mouse placement of the caret has to be reimplemented.
- Keyboard movement of the caret has to be reimplemented (possibly across lines, for multiline text input).
- Scrolling of the text control has to be implemented (horizontally for long lines, vertically for multiline input).
- Native features such as copy-and-paste have to be reimplemented.
- Native features such as spell-checking have to be reimplemented.
- Native features such as drag-and-drop have to be reimplemented.
- Native features such as page-wide text search have to be reimplemented.
- Native features specific to the user, for example custom text services, have to be reimplemented. This is close to impossible since each user might have different services installed, and there is an unbounded set of possible such services.
- Bidirectional text editing has to be reimplemented.
- For multiline text editing, line wrapping has to be implemented for all relevant languages.
- Text selection has to be reimplemented.
- Dragging of bidirectional text selections has to be reimplemented.
- Platform-native keyboard shortcuts have to be reimplemented.
- Platform-native input method editors (IMEs) have to be reimplemented.
- Undo and redo functionality has to be reimplemented.
- Accessibility features such as magnification following the caret or selection have to be reimplemented.

This is a huge amount of work, and authors are most strongly encouraged to avoid doing any of it by instead using the [input](#)^{p501} element, the [textarea](#)^{p558} element, or the [contenteditable](#)^{p815} attribute.

4.12.5.1.23 Examples §^{p70}₅

This section is non-normative.

Example

Here is an example of a script that uses canvas to draw [pretty glowing lines](#).

```
<canvas width="800" height="450"></canvas>
<script>

var context = document.getElementsByTagName('canvas')[0].getContext('2d');

var lastX = context.canvas.width * Math.random();
var lastY = context.canvas.height * Math.random();
var hue = 0;
function line() {
  context.save();
  context.translate(context.canvas.width/2, context.canvas.height/2);
  context.scale(0.9, 0.9);
  context.translate(-context.canvas.width/2, -context.canvas.height/2);
  context.beginPath();
  context.lineWidth = 5 + Math.random() * 10;
  context.moveTo(lastX, lastY);
  lastX = context.canvas.width * Math.random();
  lastY = context.canvas.height * Math.random();
  context.bezierCurveTo(context.canvas.width * Math.random(),
                        context.canvas.height * Math.random(),
                        context.canvas.width * Math.random(),
                        context.canvas.height * Math.random(),
                        lastX, lastY);

  hue = hue + 10 * Math.random();
  context.strokeStyle = 'hsl(' + hue + ', 50%, 50%)';
  context.shadowColor = 'white';
  context.shadowBlur = 10;
  context.stroke();
  context.restore();
}
setInterval(line, 50);

function blank() {
  context.fillStyle = 'rgba(0,0,0,0.1)';
  context.fillRect(0, 0, context.canvas.width, context.canvas.height);
}
setInterval(blank, 40);

</script>
```

Example

The 2D rendering context for [canvas^{p645}](#) is often used for sprite-based games. The following example demonstrates this:

Walk

Stop

Here is the source for this example:

```
<!DOCTYPE HTML>
<html lang="en">
<meta charset="utf-8">
<title>Blue Robot Demo</title>
<style>
  html { overflow: hidden; min-height: 200px; min-width: 380px; }
  body { height: 200px; position: relative; margin: 8px; }
  .buttons { position: absolute; bottom: 0px; left: 0px; margin: 4px; }
</style>
<canvas width="380" height="200"></canvas>
<script>
var Landscape = function (context, width, height) {
  this.offset = 0;
  this.width = width;
  this.advance = function (dx) {
    this.offset += dx;
  };
  this.horizon = height * 0.7;
  // This creates the sky gradient (from a darker blue to white at the bottom)
  this.sky = context.createLinearGradient(0, 0, 0, this.horizon);
  this.sky.addColorStop(0.0, 'rgb(55,121,179)');
  this.sky.addColorStop(0.7, 'rgb(121,194,245)');
  this.sky.addColorStop(1.0, 'rgb(164,200,214)');
  // this creates the grass gradient (from a darker green to a lighter green)
  this.earth = context.createLinearGradient(0, this.horizon, 0, height);
  this.earth.addColorStop(0.0, 'rgb(81,140,20)');
  this.earth.addColorStop(1.0, 'rgb(123,177,57)');
  this.paintBackground = function (context, width, height) {
    // first, paint the sky and grass rectangles
    context.fillStyle = this.sky;
    context.fillRect(0, 0, width, this.horizon);
    context.fillStyle = this.earth;
    context.fillRect(0, this.horizon, width, height-this.horizon);
    // then, draw the cloudy banner
    // we make it cloudy by having the draw text off the top of the
    // canvas, and just having the blurred shadow shown on the canvas
    context.save();
    context.translate(width-((this.offset+(this.width*3.2)) % (this.width*4.0))+0, 0);
    context.shadowColor = 'white';
    context.shadowOffsetY = 30+this.horizon/3; // offset down on canvas
    context.shadowBlur = '5';
    context.fillStyle = 'white';
    context.textAlign = 'left';
    context.textBaseline = 'top';
    context.font = '20px sans-serif';
    context.fillText('WHATWG ROCKS', 10, -30); // text up above canvas
    context.restore();
    // then, draw the background tree
    context.save();
    context.translate(width-((this.offset+(this.width*0.2)) % (this.width*1.5))+30, 0);
    context.beginPath();
    context.fillStyle = 'rgb(143,89,2)';
    context.strokeStyle = 'rgb(10,10,10)';
    context.lineWidth = 2;
    context.rect(0, this.horizon+5, 10, -50); // trunk
    context.fill();
    context.stroke();
    context.beginPath();
```

```

context.fillStyle = 'rgb(78,154,6)';
context.arc(5, this.horizon-60, 30, 0, Math.PI*2); // leaves
context.fill();
context.stroke();
context.restore();
};
this.paintForeground = function (context, width, height) {
// draw the box that goes in front
context.save();
context.translate(width-((this.offset+(this.width*0.7)) % (this.width*1.1))+0, 0);
context.beginPath();
context.rect(0, this.horizon - 5, 25, 25);
context.fillStyle = 'rgb(220,154,94)';
context.strokeStyle = 'rgb(10,10,10)';
context.lineWidth = 2;
context.fill();
context.stroke();
context.restore();
};
};
</script>
<script>
var BlueRobot = function () {
this.sprites = new Image();
this.sprites.src = 'blue-robot.png'; // this sprite sheet has 8 cells
this.targetMode = 'idle';

}
}
}
};
};

```

Using an [img^{p327}](#) element as an intermediate for getting an image resource into a canvas, for example, would result in two copies of the decoded image existing in memory at the same time: the [img^{p327}](#) element's copy, and the one in the canvas's backing store. This memory cost can be prohibitive when dealing with extremely large images. This can be avoided by using [ImageBitmapRenderingContext^{p710}](#).

Example

Using [ImageBitmapRenderingContext^{p710}](#), here is how to transcode an image to the JPEG format in a memory- and CPU-efficient way:

```
createImageBitmap(inputImageBlob).then(image => {
  const canvas = document.createElement('canvas');
  const context = canvas.getContext('bitmaprenderer');
  context.transferFromImageBitmap(image);

  canvas.toBlob(outputJPEGBlob => {
    // Do something with outputJPEGBlob.
  }, 'image/jpeg');
});
```

✓ MDN

4.12.5.2.2 The [ImageBitmapRenderingContext^{p710}](#) interface §^{p71}₀

```
IDL [Exposed=(Window,Worker)]
interface ImageBitmapRenderingContext {
  readonly attribute (HTMLCanvasElement or OffscreenCanvas) canvas;
  undefined transferFromImageBitmap(ImageBitmap? bitmap);
};

dictionary ImageBitmapRenderingContextSettings {
  boolean alpha = true;
};
```

For web developers (non-normative)

context = canvas.getContext^{p648}('bitmaprenderer' [, { [alpha^{p711}: false] }])

Returns an [ImageBitmapRenderingContext^{p710}](#) object that is permanently bound to a particular [canvas^{p645}](#) element. If the [alpha^{p711}](#) setting is provided and set to false, then the canvas is forced to always be opaque.

context.canvas^{p710}

Returns the [canvas^{p645}](#) element that the context is bound to.

context.transferFromImageBitmap^{p711}(imageBitmap)

Transfers the underlying [bitmap data^{p1017}](#) from *imageBitmap* to *context*, and the bitmap becomes the contents of the [canvas^{p645}](#) element to which *context* is bound.

context.transferFromImageBitmap^{p711}(null)

Replaces contents of the [canvas^{p645}](#) element to which *context* is bound with a [transparent black](#) bitmap whose size corresponds to the [width^{p647}](#) and [height^{p647}](#) content attributes of the [canvas^{p645}](#) element.

The [canvas](#) attribute must return the value it was initialized to when the object was created.

An [ImageBitmapRenderingContext^{p710}](#) object has an **output bitmap**, which is a reference to [bitmap data^{p1017}](#).

An [ImageBitmapRenderingContext^{p710}](#) object has a **bitmap mode**, which can be set to **valid** or **blank**. A value of [valid^{p710}](#) indicates that the context's [output bitmap^{p710}](#) refers to [bitmap data^{p1017}](#) that was acquired via [transferFromImageBitmap\(\)^{p711}](#). A value [blank^{p710}](#) indicates that the context's [output bitmap^{p710}](#) is a default transparent bitmap.

An [ImageBitmapRenderingContext^{p710}](#) object also has an **alpha** flag, which can be set to true or false. When an [ImageBitmapRenderingContext^{p710}](#) object has its [alpha^{p710}](#) flag set to false, the contents of the [canvas^{p645}](#) element to which the context is bound are obtained by compositing the context's [output bitmap^{p710}](#) onto an [opaque black](#) bitmap of the same size using the [source-over](#) compositing operator. If the [alpha^{p710}](#) flag is set to true, then the [output bitmap^{p710}](#) is used as the contents of the

[canvas](#)^{p645} element to which the context is bound. [\[COMPOSITE\]](#)^{p1305}

Note

The step of compositing over an *opaque black* bitmap ought to be elided whenever equivalent results can be obtained more efficiently by other means.

When a user agent is required to **set an [ImageBitmapRenderingContext](#)'s output bitmap**, with a *context* argument that is an [ImageBitmapRenderingContext](#)^{p710} object and an optional argument *bitmap* that refers to [bitmap data](#)^{p1017}, it must run these steps:

1. If a *bitmap* argument was not provided, then:
 1. Set *context*'s [bitmap mode](#)^{p710} to [blank](#)^{p710}.
 2. Let *canvas* be the [canvas](#)^{p645} element to which *context* is bound.
 3. Set *context*'s [output bitmap](#)^{p710} to be [transparent black](#) with an [intrinsic width](#) equal to [the numeric value](#)^{p647} of *canvas*'s [width](#)^{p647} attribute and an [intrinsic height](#) equal to [the numeric value](#)^{p647} of *canvas*'s [height](#)^{p647} attribute, those values being interpreted in [CSS pixels](#).
 4. Set the [output bitmap](#)^{p710}'s [origin-clean](#)^{p647} flag to true.
2. If a *bitmap* argument was provided, then:
 1. Set *context*'s [bitmap mode](#)^{p710} to [valid](#)^{p710}.
 2. Set *context*'s [output bitmap](#)^{p710} to refer to the same underlying bitmap data as *bitmap*, without making a copy.

Note

The [origin-clean](#)^{p647} flag of bitmap is included in the bitmap data to be referenced by *context*'s [output bitmap](#)^{p710}.

The **[ImageBitmapRenderingContext](#) creation algorithm**, which is passed a *target* and *options*, consists of running these steps:

1. Let *settings* be the result of [converting](#) *options* to the dictionary type [ImageBitmapRenderingContextSettings](#)^{p710}. (This can throw an exception.)
2. Let *context* be a new [ImageBitmapRenderingContext](#)^{p710} object.
3. Initialize *context*'s [canvas](#)^{p657} attribute to point to *target*.
4. Set *context*'s [output bitmap](#)^{p710} to the same bitmap as *target*'s bitmap (so that they are shared).
5. Run the steps to [set an ImageBitmapRenderingContext's output bitmap](#)^{p711} with *context*.
6. Initialize *context*'s [alpha](#)^{p710} flag to true.
7. Process each of the members of *settings* as follows:

alpha

If false, then set *context*'s [alpha](#)^{p710} flag to false.
8. Return *context*.

The **[transferFromImageBitmap\(bitmap\)](#)** method, when invoked, must run these steps:

1. Let *bitmapContext* be the [ImageBitmapRenderingContext](#)^{p710} object on which the [transferFromImageBitmap\(\)](#)^{p711} method was called.
2. If *bitmap* is null, then run the steps to [set an ImageBitmapRenderingContext's output bitmap](#)^{p711}, with *bitmapContext* as the *context* argument and no *bitmap* argument, then return.
3. If the value of *bitmap*'s [\[\[Detached\]\]](#)^{p107} internal slot is set to true, then throw an ["InvalidStateError" DOMException](#).
4. Run the steps to [set an ImageBitmapRenderingContext's output bitmap](#)^{p711}, with the *context* argument equal to

bitmapContext, and the *bitmap* argument referring to *bitmap*'s underlying [bitmap_data](#)^{p1017}.

5. Set the value of *bitmap*'s [\[\[Detached\]\]](#)^{p107} internal slot to true.
6. Unset *bitmap*'s [bitmap_data](#)^{p1017}.

4.12.5.3 The [OffscreenCanvas](#)^{p712} interface §^{p71}₂

```
IDL
typedef (OffscreenCanvasRenderingContext2D or ImageBitmapRenderingContext or WebGLRenderingContext or
WebGL2RenderingContext or GPUCanvasContext) OffscreenRenderingContext;

dictionary ImageEncodeOptions {
  DOMString type = "image/png";
  unrestricted double quality;
};

enum OffscreenRenderingContextId { "2d", "bitmaprenderer", "webgl", "webgl2", "webgpu" };

[Exposed=(Window,Worker), Transferable]
interface OffscreenCanvas : EventTarget {
  constructor([EnforceRange] unsigned long long width, [EnforceRange] unsigned long long height);

  attribute [EnforceRange] unsigned long long width;
  attribute [EnforceRange] unsigned long long height;

  OffscreenRenderingContext? getContext(OffscreenRenderingContextId contextId, optional any options =
null);
  ImageBitmap transferToImageBitmap();
  Promise<Blob> convertToBlob(optional ImageEncodeOptions options = {});

  attribute EventHandler oncontextlost;
  attribute EventHandler oncontextrestored;
};
```

Note

[OffscreenCanvas](#)^{p712} is an [EventTarget](#), so both [OffscreenCanvasRenderingContext2D](#)^{p716} and [WebGL](#) can fire events at it. [OffscreenCanvasRenderingContext2D](#)^{p716} can fire [contextlost](#)^{p1301} and [contextrestored](#)^{p1301}, and [WebGL](#) can fire [webglcontextlost](#) and [webglcontextrestored](#). [\[WEBGL\]](#)^{p1313}

[OffscreenCanvas](#)^{p712} objects are used to create rendering contexts, much like an [HTMLCanvasElement](#)^{p646}, but with no connection to the DOM. This makes it possible to use canvas rendering contexts in [workers](#)^{p1046}.

An [OffscreenCanvas](#)^{p712} object may hold a weak reference to a **placeholder canvas element**, which is typically in the DOM, whose embedded content is provided by the [OffscreenCanvas](#)^{p712} object. The bitmap of the [OffscreenCanvas](#)^{p712} object is pushed to the [placeholder canvas element](#)^{p712} by calling the [commit\(\)](#) method of the [OffscreenCanvas](#)^{p712} object's rendering context. All rendering context types that can be created by an [OffscreenCanvas](#)^{p712} object must implement a [commit\(\)](#)^{p712} method. The exact behavior of the commit method (e.g. whether it copies or transfers bitmaps) may vary, as defined by the rendering contexts' respective specifications. Only the [2D context for offscreen canvases](#)^{p716} is defined in this specification.

For web developers (non-normative)

`offscreenCanvas = new OffscreenCanvas`^{p713}(*width*, *height*)

Returns a new [OffscreenCanvas](#)^{p712} object that is not linked to a [placeholder canvas element](#)^{p712}, and whose bitmap's size is determined by the *width* and *height* arguments.

`context = offscreenCanvas.getContext`^{p713}(*contextId* [, *options*])

Returns an object that exposes an API for drawing on the [OffscreenCanvas](#)^{p712} object. *contextId* specifies the desired API: "[2d](#)^{p713}", "[bitmaprenderer](#)^{p714}", "[webgl](#)^{p714}", "[webgl2](#)^{p714}", or "[webgpu](#)^{p714}". *options* is handled by that API.

This specification defines the "[2d](#)^{p648}" context below, which is similar but distinct from the "[2d](#)^{p713}" context that is created from a

`canvas`^{p645} element. The WebGL specifications define the `"webgl"`^{p714} and `"webgl2"`^{p714} contexts. *WebGPU* defines the `"webgpu"`^{p714} context. [WEBGL]^{p1313} [WEBGPU]^{p1313}

Returns null if the canvas has already been initialized with another context type (e.g., trying to get a `"2d"`^{p713} context after getting a `"webgl"`^{p714} context).

An `OffscreenCanvas`^{p712} object has an internal **bitmap** that is initialized when the object is created. The width and height of the `bitmap`^{p713} are equal to the values of the `width`^{p714} and `height`^{p714} attributes of the `OffscreenCanvas`^{p712} object. Initially, all the `bitmap`'s pixels are `transparent black`.

An `OffscreenCanvas`^{p712} object can have a rendering context bound to it. Initially, it does not have a bound rendering context. To keep track of whether it has a rendering context or not, and what kind of rendering context it is, an `OffscreenCanvas`^{p712} object also has a **context mode**, which is initially `none` but can be changed to either `2d`, `bitmaprenderer`, `webgl`, `webgl2`, `webgpu`, or `detached` by algorithms defined in this specification.

The constructor `OffscreenCanvas(width, height)`, when invoked, must create a new `OffscreenCanvas`^{p712} object with its `bitmap`^{p713} initialized to a rectangular array of `transparent black` pixels of the dimensions specified by `width` and `height`; and its `width`^{p714} and `height`^{p714} attributes initialized to `width` and `height` respectively.

`OffscreenCanvas`^{p712} objects are `transferable`^{p106}. Their `transfer steps`^{p106}, given `value` and `dataHolder`, are as follows:

1. If `value`'s `context mode`^{p713} is not equal to `none`^{p713}, then throw an `"InvalidStateError"` `DOMException`.
2. Set `value`'s `context mode`^{p713} to `detached`^{p713}.
3. Let `width` and `height` be the dimensions of `value`'s `bitmap`^{p713}.
4. Unset `value`'s `bitmap`^{p713}.
5. Set `dataHolder`.`[[Width]]` to `width` and `dataHolder`.`[[Height]]` to `height`.
6. Set `dataHolder`.`[[PlaceholderCanvas]]` to be a weak reference to `value`'s `placeholder canvas element`^{p712}, if `value` has one, or null if it does not.

Their `transfer-receiving steps`^{p106}, given `dataHolder` and `value`, are:

1. Initialize `value`'s `bitmap`^{p713} to a rectangular array of `transparent black` pixels with width given by `dataHolder`.`[[Width]]` and height given by `dataHolder`.`[[Height]]`.
2. If `dataHolder`.`[[PlaceholderCanvas]]` is not null, set `value`'s `placeholder canvas element`^{p712} to `dataHolder`.`[[PlaceholderCanvas]]` (while maintaining the weak reference semantics).

The `getContext(contextId, options)` method of an `OffscreenCanvas`^{p712} object, when invoked, must run these steps:

1. If `options` is not an `object`, then set `options` to null.
2. Set `options` to the result of `converting options` to a JavaScript value.
3. Run the steps in the cell of the following table whose column header matches this `OffscreenCanvas`^{p712} object's `context mode`^{p713} and whose row header matches `contextId`:

	<code>none</code> ^{p713}	<code>2d</code> ^{p713}	<code>bitmaprenderer</code> ^{p713}	<code>webgl</code> ^{p713} or <code>webgl2</code> ^{p713}	<code>webgpu</code> ^{p713}	<code>detached</code> ^{p713}
<code>"2d"</code>	Follow the <code>offscreen 2D context creation algorithm</code> ^{p716} defined in the section below, passing it this <code>OffscreenCanvas</code> ^{p712} object and <code>options</code> , to obtain an <code>OffscreenCanvasRenderingContext2D</code> ^{p716} object; if this does not throw an exception, then set this <code>OffscreenCanvas</code> ^{p712} object's <code>context mode</code> ^{p713} to <code>2d</code> ^{p713} , and return the new <code>OffscreenCanvasRenderingContext2D</code> ^{p716}	Return the same object as was returned the last time the method was invoked	Return null.	Return null.	Return null.	Throw an <code>"InvalidStateError"</code> <code>DOMException</code> .

	none ^{p713}	2d ^{p713}	bitmaprenderer ^{p713}	webgl ^{p713} or webgl2 ^{p713}	webgpu ^{p713}	detached ^{p713}
	object.	with this same first argument.				
" bitmaprenderer "	Follow the ImageBitmapRenderingContext creation algorithm ^{p711} defined in the section above, passing it this OffscreenCanvas ^{p712} object and <i>options</i> , to obtain an ImageBitmapRenderingContext ^{p710} object; if this does not throw an exception, then set this OffscreenCanvas ^{p712} object's context mode ^{p713} to bitmaprenderer ^{p713} , and return the new ImageBitmapRenderingContext ^{p710} object.	Return null.	Return the same object as was returned the last time the method was invoked with this same first argument.	Return null.	Return null.	Throw an "InvalidStateError" DOMException .
" webgl " or " webgl2 "	Follow the instructions given in the WebGL specifications' <i>Context Creation</i> sections to obtain either a WebGLRenderingContext , WebGL2RenderingContext , or null; if the returned value is null, then return null; otherwise, set this OffscreenCanvas ^{p712} object's context mode ^{p713} to webgl ^{p713} or webgl2 ^{p713} , and return the WebGLRenderingContext or WebGL2RenderingContext object. [WEBGL] ^{p1313}	Return null.	Return null.	Return the same value as was returned the last time the method was invoked with this same first argument.	Return null.	Throw an "InvalidStateError" DOMException .
" webgpu "	Follow the instructions given in <i>WebGPU's Canvas Rendering</i> section to obtain a GPUCanvasContext or null; if the returned value is null, then return null; otherwise, set this OffscreenCanvas ^{p712} object's context mode ^{p713} to webgpu ^{p713} and return the GPUCanvasContext object. [WEBGPU] ^{p1313}	Return null.	Return null.	Return null.	Return the same value as was returned the last time the method was invoked with this same first argument.	Throw an "InvalidStateError" DOMException .

For web developers (non-normative)

`offscreenCanvas.widthp714 [= value]`

`offscreenCanvas.heightp714 [= value]`

These attributes return the dimensions of the [OffscreenCanvas](#)^{p712} object's [bitmap](#)^{p713}.

They can be set, to replace the [bitmap](#)^{p713} with a new, [transparent_black](#) bitmap of the specified dimensions (effectively resizing it).

If either the [width](#) or [height](#) attributes of an [OffscreenCanvas](#)^{p712} object are set (to a new value or to the same value as before) and the [OffscreenCanvas](#)^{p712} object's [context mode](#)^{p713} is [2d](#)^{p713}, then [reset the rendering context to its default state](#)^{p659} and resize the [OffscreenCanvas](#)^{p712} object's [bitmap](#)^{p713} to the new values of the [width](#)^{p714} and [height](#)^{p714} attributes.

The resizing behavior for "[webgl](#)^{p714}" and "[webgl2](#)^{p714}" contexts is defined in the WebGL specifications. [\[WEBGL\]](#)^{p1313}

The resizing behavior for "[webgpu](#)^{p714}" context is defined in *WebGPU*. [\[WEBGPU\]](#)^{p1313}

Note

If an [OffscreenCanvas](#)^{p712} object whose dimensions were changed has a [placeholder canvas element](#)^{p712}, then the [placeholder canvas element](#)^{p712}'s [intrinsic size](#) will only be updated via the [commit\(\)](#)^{p712} method of the [OffscreenCanvas](#)^{p712} object's rendering context.

For web developers (non-normative)

`promise = offscreenCanvas.convertToBlobp715 ([options])`

Returns a promise that will fulfill with a new [Blob](#) object representing a file containing the image in the [OffscreenCanvas](#)^{p712}

object.

The argument, if provided, is a dictionary that controls the encoding options of the image file to be created. The `type` field specifies the file format and has a default value of `"image/png"`; that type is also used if the requested type isn't supported. If the image format supports variable quality (such as `"image/jpeg"`), then the `quality` field is a number in the range 0.0 to 1.0 inclusive indicating the desired quality level for the resulting image.

`canvas.transferToImageBitmap()`

Returns a newly created `ImageBitmap` object with the image in the `OffscreenCanvas` object. The image in the `OffscreenCanvas` object is replaced with a new blank image.

The `convertToBlob(options)` method, when invoked, must run the following steps:

1. If the value of this `OffscreenCanvas` object's `[[Detached]]` internal slot is set to true, then return a promise rejected with an `"InvalidStateError"` `DOMException`.
2. If this `OffscreenCanvas` object's `context mode` is `2d` and the rendering context's `bitmap`'s `origin-clean` flag is set to false, then return a promise rejected with a `"SecurityError"` `DOMException`.
3. If this `OffscreenCanvas` object's `bitmap` has no pixels (i.e., either its horizontal dimension or its vertical dimension is zero) then return a promise rejected with an `"IndexSizeError"` `DOMException`.
4. Let `bitmap` be a copy of this `OffscreenCanvas` object's `bitmap`.
5. Let `result` be a new promise object.
6. Run these steps in parallel:
 1. Let `file` be a `serialization of bitmap as a file`, with `options`'s `type` and `quality` if present.
 2. `Queue an element task` on the `canvas blob serialization task source` given the `canvas` element to run these steps:
 1. If `file` is null, then reject `result` with an `"EncodingError"` `DOMException`.
 2. Otherwise, resolve `result` with a new `Blob` object, created in the `relevant Realm` of this `OffscreenCanvas` object, representing `file`.
7. Return `result`.

The `transferToImageBitmap()` method, when invoked, must run the following steps:

1. If the value of this `OffscreenCanvas` object's `[[Detached]]` internal slot is set to true, then throw an `"InvalidStateError"` `DOMException`.
2. If this `OffscreenCanvas` object's `context mode` is set to `none`, then throw an `"InvalidStateError"` `DOMException`.
3. Let `image` be a newly created `ImageBitmap` object that references the same underlying bitmap data as this `OffscreenCanvas` object's `bitmap`.
4. Set this `OffscreenCanvas` object's `bitmap` to reference a newly created bitmap of the same dimensions and color space as the previous bitmap, and with its pixels initialized to `transparent black`, or `opaque black` if the rendering context's `alpha` flag is set to false.

Note

This means that if the rendering context of this `OffscreenCanvas` is a `WebGLRenderingContext`, the value of `preserveDrawingBuffer` will have no effect.

5. Return `image`.

The following are the `event handlers` (and their corresponding `event handler event types`) that must be supported, as `event handler IDL attributes`, by all objects implementing the `OffscreenCanvas` interface:

<code>Event handler</code>	<code>Event handler event type</code>
<code>oncontextlost</code>	<code>contextlost</code>
<code>oncontextrestored</code>	<code>contextrestored</code>

4.12.5.3.1 The offscreen 2D rendering context ^{§[p71](#)}₆

```
IDL [Exposed=(Window,Worker)]
interface OffscreenCanvasRenderingContext2D {
  undefined commit();
  readonly attribute OffscreenCanvas canvas;
};

OffscreenCanvasRenderingContext2D includes CanvasState;
OffscreenCanvasRenderingContext2D includes CanvasTransform;
OffscreenCanvasRenderingContext2D includes CanvasCompositing;
OffscreenCanvasRenderingContext2D includes CanvasImageSmoothing;
OffscreenCanvasRenderingContext2D includes CanvasFillStrokeStyles;
OffscreenCanvasRenderingContext2D includes CanvasShadowStyles;
OffscreenCanvasRenderingContext2D includes CanvasFilters;
OffscreenCanvasRenderingContext2D includes CanvasRect;
OffscreenCanvasRenderingContext2D includes CanvasDrawPath;
OffscreenCanvasRenderingContext2D includes CanvasText;
OffscreenCanvasRenderingContext2D includes CanvasDrawImage;
OffscreenCanvasRenderingContext2D includes CanvasImageData;
OffscreenCanvasRenderingContext2D includes CanvasPathDrawingStyles;
OffscreenCanvasRenderingContext2D includes CanvasTextDrawingStyles;
OffscreenCanvasRenderingContext2D includes CanvasPath;
```

The [OffscreenCanvasRenderingContext2D](#)^{p716} object is a rendering context for drawing to the [bitmap](#)^{p713} of an [OffscreenCanvas](#)^{p712} object. It is similar to the [CanvasRenderingContext2D](#)^{p650} object, with the following differences:

- there is no support for [user interface](#)^{p652} features;
- its [canvas](#)^{p717} attribute refers to an [OffscreenCanvas](#)^{p712} object rather than a [canvas](#)^{p645} element;
- it has a [commit\(\)](#)^{p717} method for pushing the rendered image to the context's [OffscreenCanvas](#)^{p712} object's [placeholder canvas element](#)^{p712}.

An [OffscreenCanvasRenderingContext2D](#)^{p716} object has a **bitmap** that is initialized when the object is created.

The [bitmap](#)^{p716} has an **origin-clean** flag, which can be set to true or false. Initially, when one of these bitmaps is created, its [origin-clean](#)^{p716} flag must be set to true.

An [OffscreenCanvasRenderingContext2D](#)^{p716} object also has an **alpha** flag, which can be set to true or false. Initially, when the context is created, its alpha flag must be set to true. When an [OffscreenCanvasRenderingContext2D](#)^{p716} object has its [alpha](#)^{p716} flag set to false, then its alpha channel must be fixed to 1.0 (fully opaque) for all pixels, and attempts to change the alpha component of any pixel must be silently ignored.

An [OffscreenCanvasRenderingContext2D](#)^{p716} object also has a **color space** setting of type [PredefinedColorSpace](#)^{p650}. The color space for the context's [bitmap](#)^{p716} is set to the context's [color space](#)^{p716}.

An [OffscreenCanvasRenderingContext2D](#)^{p716} object has an **associated OffscreenCanvas object**, which is the [OffscreenCanvas](#)^{p712} object from which the [OffscreenCanvasRenderingContext2D](#)^{p716} object was created.

For web developers (non-normative)

[offscreenCanvasRenderingContext2D.commit](#)^{p717} ()

Copies the rendering context's [bitmap](#)^{p716} to the bitmap of the [placeholder canvas element](#)^{p712} of the [associated OffscreenCanvas object](#)^{p716}. The copy operation is synchronous. Calling this method is not needed for the transfer, since it happens automatically during the [event loop](#)^{p968} execution.

[offscreenCanvas](#) = **[offscreenCanvasRenderingContext2D.canvas](#)**^{p717}

Returns the [associated OffscreenCanvas object](#)^{p716}.

The **offscreen 2D context creation algorithm**, which is passed a *target* (an [OffscreenCanvas](#)^{p712} object) and optionally some arguments, consists of running the following steps:

1. If the algorithm was passed some arguments, let *arg* be the first such argument. Otherwise, let *arg* be undefined.

- Let *settings* be the result of [converting](#) *arg* to the dictionary type [CanvasRenderingContext2DSettings](#)^{p650}. (This can throw an exception.).
- Let *context* be a new [OffscreenCanvasRenderingContext2D](#)^{p716} object.
- Set *context*'s [associated OffscreenCanvas object](#)^{p716} to *target*.
- If *settings*["[alpha](#)^{p657}"] is false, then set *context*'s [alpha](#)^{p716} flag to false.
- Set *context*'s [color space](#)^{p716} to *settings*["[colorSpace](#)^{p657}"].
- Set *context*'s [bitmap](#)^{p716} to a newly created bitmap with the dimensions specified by the [width](#)^{p714} and [height](#)^{p714} attributes of *target*, and set *target*'s bitmap to the same bitmap (so that they are shared).
- If *context*'s [alpha](#)^{p716} flag is set to true, initialize all the pixels of *context*'s [bitmap](#)^{p716} to [transparent black](#). Otherwise, initialize the pixels to [opaque black](#).
- Return *context*.

The [commit\(\)](#) method, when invoked, must run the following steps:

- If this [OffscreenCanvasRenderingContext2D](#)^{p716}'s [associated OffscreenCanvas object](#)^{p716} does not have a [placeholder canvas element](#)^{p712}, then return.
- Let *image* be a copy of this [OffscreenCanvasRenderingContext2D](#)^{p716}'s [bitmap](#)^{p716}, including the value of its [origin-clean](#)^{p716} flag.
- [Queue an element task](#)^{p970} on the [DOM manipulation task source](#)^{p977} given the [placeholder canvas element](#)^{p712} to set the [placeholder canvas element](#)^{p712}'s [output bitmap](#)^{p655} to be a reference to *image*.

Note

If *image* has different dimensions than the bitmap previously referenced as the [placeholder canvas element](#)^{p712}'s [output bitmap](#)^{p655}, then this task will result in a change in the [placeholder canvas element](#)^{p712}'s [intrinsic size](#), which can affect document layout.

Note

Implementations are encouraged to short-circuit the graphics update steps of the [window event loop](#)^{p968} for the purposes of updating the contents of a [placeholder canvas element](#)^{p712} to the display. This could mean, for example, that the [commit\(\)](#)^{p717} method can copy the bitmap contents directly to a graphics buffer that is mapped to the physical display location of the [placeholder canvas element](#)^{p712}. This or similar short-circuiting approaches can significantly reduce display latency, especially in cases where the [commit\(\)](#)^{p717} method is invoked from a [worker event loop](#)^{p968} and the [window event loop](#)^{p968} of the [placeholder canvas element](#)^{p712} is busy. However, such shortcuts cannot have any script-observable side-effects. This means that the committed bitmap still needs to be sent to the [placeholder canvas element](#)^{p712}, in case the element is used as a [CanvasImageSource](#)^{p650}, as an [ImageBitmapSource](#)^{p1016}, or in case [toDataURL\(\)](#)^{p649} or [toBlob\(\)](#)^{p649} are called on it.

The [canvas](#) attribute, on getting, must return this [OffscreenCanvasRenderingContext2D](#)^{p716}'s [associated OffscreenCanvas object](#)^{p716}.

4.12.5.4 Color spaces and color space conversion §^{p71}₇

The [canvas](#)^{p645} APIs provide mechanisms for specifying the color space of the canvas's backing store. The default backing store color space for all canvas APIs is `'srgb'`.

Color space conversion must be applied to the canvas's backing store when rendering the canvas to the output device. This color space conversion must be identical to the color space conversion that would be applied to an [img](#)^{p327} element with a color profile that specifies the same [color space](#)^{p656} as the canvas's backing store.

When drawing content to a 2D context, all inputs must be converted to the [context's color space](#)^{p656} before drawing. Interpolation of gradient color stops must be performed on color values after conversion to the [context's color space](#)^{p656}. Alpha blending must be performed on values after conversion to the [context's color space](#)^{p656}.

Note

There do not exist any inputs to a 2D context for which the color space is undefined. The color space for CSS colors is defined in

CSS Color. The color space for images that specify no color profile information is assumed to be 'srgb', as specified in the [Color Spaces of Untagged Colors](#) section of CSS Color. [CSSCOLOR]^{p1306}

4.12.5.5 Serializing bitmaps to a file ^{§ p71}₈

When a user agent is to create a **serialization of the bitmap as a file**, given a *type* and an optional *quality*, it must create an image file in the format given by *type*. If an error occurs during the creation of the image file (e.g. an internal encoder error), then the result of the serialization is null. [PNG]^{p1310}

The image file's pixel data must be the bitmap's pixel data scaled to one image pixel per coordinate space unit, and if the file format used supports encoding resolution metadata, the resolution must be given as 96dpi (one image pixel per [CSS pixel](#)).

If *type* is supplied, then it must be interpreted as a [MIME type](#) giving the format to use. If the type has any parameters, then it must be treated as not supported.

Example

For example, the value "[image/png](#)^{p1303}" would mean to generate a PNG image, the value "[image/jpeg](#)^{p1303}" would mean to generate a JPEG image, and the value "[image/svg+xml](#)^{p1303}" would mean to generate an SVG image (which would require that the user agent track how the bitmap was generated, an unlikely, though potentially awesome, feature).

User agents must support PNG ("[image/png](#)^{p1303}"). User agents may support other types. If the user agent does not support the requested type, then it must create the file using the PNG format. [PNG]^{p1310}

User agents must [convert the provided type to ASCII lowercase](#) before establishing if they support that type.

For image types that do not support an alpha channel, the serialized image must be the bitmap image composited onto an [opaque black](#) background using the [source-over](#) compositing operator.

For image types that support color profiles, the serialized image must include a color profile indicating the color space of the underlying bitmap. For image types that do not support color profiles, the serialized image must be converted to the 'srgb' color space using '[relative-colorimetric](#)' rendering intent.

Note

Thus, in the 2D context, calling the [drawImage\(\)](#)^{p692} method to render the output of the [toDataURL\(\)](#)^{p649} or [toBlob\(\)](#)^{p649} method to the canvas, given the appropriate dimensions, has no visible effect beyond, at most, clipping colors of the canvas to a more narrow gamut.

If *type* is an image format that supports variable quality (such as "[image/jpeg](#)^{p1303}"), *quality* is given, and *type* is not "[image/png](#)^{p1303}", then, if [Type\(quality\)](#) is Number, and *quality* is in the range 0.0 to 1.0 inclusive, the user agent must treat *quality* as the desired quality level. Otherwise, the user agent must use its default quality value, as if the *quality* argument had not been given.

Note

The use of type-testing here, instead of simply declaring quality as a Web IDL double, is a historical artifact.

Note

Different implementations can have slightly different interpretations of "quality". When the quality is not specified, an implementation-specific default is used that represents a reasonable compromise between compression ratio, image quality, and encoding time.

4.12.5.6 Security with [canvas](#)^{p645} elements ^{§ p71}₈

This section is non-normative.

Information leakage can occur if scripts from one [origin](#)^{p868} can access information (e.g. read pixels) from images from another origin (one that isn't the [same](#)^{p869}).

To mitigate this, bitmaps used with [canvas^{p645}](#) elements and [ImageBitmap^{p1016}](#) objects are defined to have a flag indicating whether they are [origin-clean^{p647}](#). All bitmaps start with their [origin-clean^{p647}](#) set to true. The flag is set to false when cross-origin images are used.

The [toDataURL\(\)^{p649}](#), [toBlob\(\)^{p649}](#), and [getImageData\(\)^{p695}](#) methods check the flag and will throw a `"SecurityError"` [DOMException](#) rather than leak cross-origin data.

The value of the [origin-clean^{p647}](#) flag is propagated from a source [canvas^{p645}](#) element's bitmap to a new [ImageBitmap^{p1016}](#) object by [createImageBitmap\(\)^{p1018}](#). Conversely, a destination [canvas^{p645}](#) element's bitmap will have its [origin-clean^{p647}](#) flags set to false by [drawImage^{p692}](#) if the source image is an [ImageBitmap^{p1016}](#) object whose bitmap has its [origin-clean^{p647}](#) flag set to false.

The flag can be reset in certain situations; for example, when changing the value of the [width^{p647}](#) or the [height^{p647}](#) content attribute of the [canvas^{p645}](#) element to which a [CanvasRenderingContext2D^{p659}](#) is bound, the bitmap is cleared and its [origin-clean^{p647}](#) flag is reset.

When using an [ImageBitmapRenderingContext^{p710}](#), the value of the [origin-clean^{p647}](#) flag is propagated from [ImageBitmap^{p1016}](#) objects when they are transferred to the [canvas^{p645}](#) via [transferFromImageBitmap\(\)^{p711}](#).

4.12.5.7 Premultiplied alpha and the 2D rendering context §^{p71}₉

Premultiplied alpha refers to one way of representing transparency in an image, the other being non-premultiplied alpha.

Under non-premultiplied alpha, the red, green, and blue channels of a pixel represent that pixel's color, and its alpha channel represents that pixel's opacity.

Under premultiplied alpha, however, the red, green, and blue channels of a pixel represent the amounts of color that the pixel adds to the image, and its alpha channel represents the amount that the pixel obscures whatever is behind it.

Example

For instance, assuming the color channels range from 0 (off) to 255 (full intensity), these example colors are represented in the following ways:

CSS color representation	Premultiplied representation	Non-premultiplied representation	Description of color	Image of color blended above other content
<code>rgba(255, 127, 0, 1)</code>	255, 127, 0, 255	255, 127, 0, 255	Completely-opaque orange	
<code>rgba(255, 255, 0, 0.5)</code>	127, 127, 0, 127	255, 255, 0, 127	Halfway-opaque yellow	
Unrepresentable	255, 127, 0, 127	Unrepresentable	Additive halfway-opaque orange	
Unrepresentable	255, 127, 0, 0	Unrepresentable	Additive fully-transparent orange	

CSS color representation	Premultiplied representation	Non-premultiplied representation	Description of color	Image of color blended above other content
rgba(255, 127, 0, 0)	0, 0, 0, 0	255, 127, 0, 0	Fully-transparent ("invisible") orange	
rgba(0, 127, 255, 0)	0, 0, 0, 0	255, 127, 0, 0	Fully-transparent ("invisible") turquoise	

Converting a color value from a non-premultiplied representation to a premultiplied one involves multiplying the color's red, green, and blue channels by its alpha channel (remapping the range of the alpha channel such that "fully transparent" is 0, and "fully opaque" is 1).

Converting a color value from a premultiplied representation to a non-premultiplied one involves the inverse: dividing the color's red, green, and blue channels by its alpha channel.

As certain colors can only be represented under premultiplied alpha (for instance, additive colors), and others can only be represented under non-premultiplied alpha (for instance, "invisible" colors which hold certain red, green, and blue values even with no opacity); and division and multiplication on 8-bit integers (which is how canvas's colors are currently stored) entails a loss of precision, converting between premultiplied and non-premultiplied alpha is a lossy operation on colors that are not fully opaque.

A [CanvasRenderingContext2D](#)'s [output_bitmap](#) and an [OffscreenCanvasRenderingContext2D](#)'s [bitmap](#) must use premultiplied alpha to represent transparent colors.

Note *It is important for canvas bitmaps to represent colors using premultiplied alpha because it affects the range of representable colors. While additive colors cannot currently be drawn onto canvases directly because CSS colors are non-premultiplied and cannot represent them, it is still possible to, for instance, draw additive colors onto a WebGL canvas and then draw that WebGL canvas onto a 2D canvas via [drawImage\(\)](#).*

4.13 Custom elements §^{p72}₀

4.13.1 Introduction §^{p72}₀

This section is non-normative.

[Custom elements](#) provide a way for authors to build their own fully-featured DOM elements. Although authors could always use non-standard elements in their documents, with application-specific behavior added after the fact by scripting or similar, such elements have historically been non-conforming and not very functional. By [defining](#) a custom element, authors can inform the parser how to properly construct an element and how elements of that class should react to changes.

Custom elements are part of a larger effort to "rationalise the platform", by explaining existing platform features (like the elements of HTML) in terms of lower-level author-exposed extensibility points (like custom element definition). Although today there are many limitations on the capabilities of custom elements—both functionally and semantically—that prevent them from fully explaining the behaviors of HTML's existing elements, we hope to shrink this gap over time.

4.13.1.1 Creating an autonomous custom element ^{s p72}₁

This section is non-normative.

For the purposes of illustrating how to create an [autonomous custom element](#)^{p728}, let's define a custom element that encapsulates rendering a small icon for a country flag. Our goal is to be able to use it like so:

```
<flag-icon country="nl"></flag-icon>
```

To do this, we first declare a class for the custom element, extending [HTMLElement](#)^{p128}:

```
class FlagIcon extends HTMLElement {
  constructor() {
    super();
    this._countryCode = null;
  }

  static observedAttributes = ["country"];

  attributeChangedCallback(name, oldValue, newValue) {
    // name will always be "country" due to observedAttributes
    this._countryCode = newValue;
    this._updateRendering();
  }
  connectedCallback() {
    this._updateRendering();
  }

  get country() {
    return this._countryCode;
  }
  set country(v) {
    this.setAttribute("country", v);
  }

  _updateRendering() {
    // Left as an exercise for the reader. But, you'll probably want to
    // check this.ownerDocument.defaultView to see if we've been
    // inserted into a document with a browsing context, and avoid
    // doing any work if not.
  }
}
```

We then need to use this class to define the element:

```
customElements.define("flag-icon", FlagIcon);
```

At this point, our above code will work! The parser, whenever it sees the `flag-icon` tag, will construct a new instance of our `FlagIcon` class, and tell our code about its new `country` attribute, which we then use to set the element's internal state and update its rendering (when appropriate).

You can also create `flag-icon` elements using the DOM API:

```
const flagIcon = document.createElement("flag-icon")
flagIcon.country = "jp"
document.body.appendChild(flagIcon)
```

Finally, we can also use the [custom element constructor](#)^{p728} itself. That is, the above code is equivalent to:

```
const flagIcon = new FlagIcon()
flagIcon.country = "jp"
```

```
document.body.appendChild(flagIcon)
```

4.13.1.2 Creating a form-associated custom element §^{p72}₂

This section is non-normative.

Adding a static `formAssociated` property, with a true value, makes an [autonomous custom element](#)^{p728} a [form-associated custom element](#)^{p729}. The [ElementInternals](#)^{p740} interface helps you to implement functions and properties common to form control elements.

```
class MyCheckbox extends HTMLElement {
  static formAssociated = true;
  static observedAttributes = ['checked'];

  constructor() {
    super();
    this._internals = this.attachInternals();
    this.addEventListener('click', this._onClick.bind(this));
  }

  get form() { return this._internals.form; }
  get name() { return this.getAttribute('name'); }
  get type() { return this.localName; }

  get checked() { return this.hasAttribute('checked'); }
  set checked(flag) { this.toggleAttribute('checked', Boolean(flag)); }

  attributeChangedCallback(name, oldValue, newValue) {
    // name will always be "checked" due to observedAttributes
    this._internals.setFormValue(this.checked ? 'on' : null);
  }

  _onClick(event) {
    this.checked = !this.checked;
  }
}
customElements.define('my-checkbox', MyCheckbox);
```

You can use the custom element `my-checkbox` like a built-in form-associated element. For example, putting it in [form](#)^{p494} or [label](#)^{p498} associates the `my-checkbox` element with them, and submitting the [form](#)^{p494} will send data provided by `my-checkbox` implementation.

```
<form action="..." method="...">
  <label><my-checkbox name="agreed"></my-checkbox> I read the agreement.</label>
  <input type="submit">
</form>
```

4.13.1.3 Creating a custom element with default accessible roles, states, and properties §^{p72}₂

This section is non-normative.

By using the appropriate properties of [ElementInternals](#)^{p740}, your custom element can have default accessibility semantics. The following code expands our form-associated checkbox from the previous section to properly set its default role and checkedness, as viewed by accessibility technology:

```
class MyCheckbox extends HTMLElement {
  static formAssociated = true;
  static observedAttributes = ['checked'];
```

```

constructor() {
  super();
  this._internals = this.attachInternals();
  this.addEventListener('click', this._onClick.bind(this));

  this._internals.role = 'checkbox';
  this._internals.ariaChecked = false;
}

get form() { return this._internals.form; }
get name() { return this.getAttribute('name'); }
get type() { return this.localName; }

get checked() { return this.getAttribute('checked'); }
set checked(flag) { this.toggleAttribute('checked', Boolean(flag)); }

attributeChangedCallback(name, oldValue, newValue) {
  // name will always be "checked" due to observedAttributes
  this._internals.setFormValue(this.checked ? 'on' : null);
  this._internals.ariaChecked = this.checked;
}

_onClick(event) {
  this.checked = !this.checked;
}
}
customElements.define('my-checkbox', MyCheckbox);

```

Note that, like for built-in elements, these are only defaults, and can be overridden by the page author using the [role^{p64}](#) and [aria-*^{p64}](#) attributes:

```

<!-- This markup is non-conforming -->
<input type="checkbox" checked role="button" aria-checked="false">

```

```

<!-- This markup is probably not what the custom element author intended -->
<my-checkbox role="button" checked aria-checked="false">

```

Custom element authors are encouraged to state what aspects of their accessibility semantics are strong native semantics, i.e., should not be overridden by users of the custom element. In our example, the author of the `my-checkbox` element would state that its [role](#) and [aria-checked](#) values are strong native semantics, thus discouraging code such as the above.

4.13.1.4 Creating a customized built-in element ^{§^{p72}}₃

This section is non-normative.

[Customized built-in elements^{p728}](#) are a distinct kind of [custom element^{p728}](#), which are defined slightly differently and used very differently compared to [autonomous custom elements^{p728}](#). They exist to allow reuse of behaviors from the existing elements of HTML, by extending those elements with new custom functionality. This is important since many of the existing behaviors of HTML elements can unfortunately not be duplicated by using purely [autonomous custom elements^{p728}](#). Instead, [customized built-in elements^{p728}](#) allow the installation of custom construction behavior, lifecycle hooks, and prototype chain onto existing elements, essentially "mixing in" these capabilities on top of the already-existing element.

[Customized built-in elements^{p728}](#) require a distinct syntax from [autonomous custom elements^{p728}](#) because user agents and other software key off an element's local name in order to identify the element's semantics and behavior. That is, the concept of [customized built-in elements^{p728}](#) building on top of existing behavior depends crucially on the extended elements retaining their original local name.

In this example, we'll be creating a [customized built-in element^{p728}](#) named `plastic-button`, which behaves like a normal button but gets fancy animation effects added whenever you click on it. We start by defining a class, just like before, although this time we extend [HTMLButtonElement^{p546}](#) instead of [HTMLElement^{p128}](#):

```
class PlasticButton extends HTMLElement {
  constructor() {
    super();

    this.addEventListener("click", () => {
      // Draw some fancy animation effects!
    });
  }
}
```

When defining our custom element, we have to also specify the `extends` option:

```
customElements.define("plastic-button", PlasticButton, { extends: "button" });
```

In general, the name of the element being extended cannot be determined simply by looking at what element interface it extends, as many elements share the same interface (such as `q`^{p254} and `blockquote`^{p224} both sharing `HTMLQuoteElement`^{p224}).

To construct our [customized built-in element](#)^{p728} from parsed HTML source text, we use the `is`^{p728} attribute on a `button`^{p545} element:

```
<button is="plastic-button">Click Me!</button>
```

Trying to use a [customized built-in element](#)^{p728} as an [autonomous custom element](#)^{p728} will *not* work; that is, `<plastic-button>Click me?</plastic-button>` will simply create an `HTMLElement`^{p128} with no special behavior.

If you need to create a customized built-in element programmatically, you can use the following form of `createElement()`:

```
const plasticButton = document.createElement("button", { is: "plastic-button" });
plasticButton.textContent = "Click me!";
```

And as before, the constructor will also work:

```
const plasticButton2 = new PlasticButton();
console.log(plasticButton2.localName); // will output "button"
console.assert(plasticButton2 instanceof PlasticButton);
console.assert(plasticButton2 instanceof HTMLElement);
```

Note that when creating a customized built-in element programmatically, the `is`^{p728} attribute will not be present in the DOM, since it was not explicitly set. However, [it will be added to the output when serializing](#)^{p1205}:

```
console.assert(!plasticButton.hasAttribute("is"));
console.log(plasticButton.outerHTML); // will output '<button is="plastic-button"></button>'
```

Regardless of how it is created, all of the ways in which `button`^{p545} is special apply to such "plastic buttons" as well: their focus behavior, ability to participate in [form submission](#)^{p606}, the `disabled`^{p580} attribute, and so on.

[Customized built-in elements](#)^{p728} are designed to allow extension of existing HTML elements that have useful user-agent supplied behavior or APIs. As such, they can only extend existing HTML elements defined in this specification, and cannot extend legacy elements such as `bgsound`^{p1257}, `blink`^{p1258}, `isindex`^{p1257}, `keygen`^{p1257}, `multicol`^{p1258}, `nextid`^{p1257}, or `spacer`^{p1258} that have been defined to use `HTMLUnknownElement`^{p129} as their [element interface](#).

One reason for this requirement is future-compatibility: if a [customized built-in element](#)^{p728} was defined that extended a currently-unknown element, for example `combobox`, this would prevent this specification from defining a `combobox` element in the future, as consumers of the derived [customized built-in element](#)^{p728} would have come to depend on their base element having no interesting user-agent-supplied behavior.

4.13.1.5 Drawbacks of autonomous custom elements §^{p72}₄

This section is non-normative.

As specified below, and alluded to above, simply defining and using an element called `taco-button` does not mean that such elements [represent](#)^{p128} buttons. That is, tools such as web browsers, search engines, or accessibility technology will not automatically treat the resulting element as a button just based on its defined name.

To convey the desired button semantics to a variety of users, while still using an [autonomous custom element](#)^{p728}, a number of techniques would need to be employed:

- The addition of the [tabindex](#)^{p801} attribute would make the `taco-button` [focusable](#)^{p800}. Note that if the `taco-button` were to become logically disabled, the [tabindex](#)^{p801} attribute would need to be removed.
- The addition of an ARIA role and various ARIA states and properties helps convey semantics to accessibility technology. For example, setting the [role](#) to `"button"` will convey the semantics that this is a button, enabling users to successfully interact with the control using usual button-like interactions in their accessibility technology. Setting the [aria-label](#) property is necessary to give the button an [accessible name](#), instead of having accessibility technology traverse its child text nodes and announce them. And setting the [aria-disabled](#) state to `"true"` when the button is logically disabled conveys to accessibility technology the button's disabled state.
- The addition of event handlers to handle commonly-expected button behaviors helps convey the semantics of the button to web browser users. In this case, the most relevant event handler would be one that proxies appropriate [keydown](#) events to become [click](#) events, so that you can activate the button both with keyboard and by clicking.
- In addition to any default visual styling provided for `taco-button` elements, the visual styling will also need to be updated to reflect changes in logical state, such as becoming disabled; that is, whatever style sheet has rules for `taco-button` will also need to have rules for `taco-button[disabled]`.

With these points in mind, a full-featured `taco-button` that took on the responsibility of conveying button semantics (including the ability to be disabled) might look something like this:

```
class TacoButton extends HTMLElement {
  static observedAttributes = ["disabled"];

  constructor() {
    super();
    this._internals = this.attachInternals();
    this._internals.role = "button";

    this.addEventListener("keydown", e => {
      if (e.code === "Enter" || e.code === "Space") {
        this.dispatchEvent(new PointerEvent("click", {
          bubbles: true,
          cancelable: true
        }));
      }
    });

    this.addEventListener("click", e => {
      if (this.disabled) {
        e.preventDefault();
        e.stopImmediatePropagation();
      }
    });

    this._observer = new MutationObserver(() => {
      this._internals.ariaLabel = this.textContent;
    });
  }

  connectedCallback() {
    this.setAttribute("tabindex", "0");

    this._observer.observe(this, {
      childList: true,
      characterData: true,
      subtree: true
    });
  }
}
```

```

    });
  }

  disconnectedCallback() {
    this._observer.disconnect();
  }

  get disabled() {
    return this.hasAttribute("disabled");
  }
  set disabled(flag) {
    this.toggleAttribute("disabled", Boolean(flag));
  }

  attributeChangedCallback(name, oldValue, newValue) {
    // name will always be "disabled" due to observedAttributes
    if (this.disabled) {
      this.removeAttribute("tabindex");
      this._internals.ariaDisabled = "true";
    } else {
      this.setAttribute("tabindex", "0");
      this._internals.ariaDisabled = "false";
    }
  }
}

```

Even with this rather-complicated element definition, the element is not a pleasure to use for consumers: it will be continually "sprouting" [tabindex^{p801}](#) attributes of its own volition, and its choice of `tabindex="0"` focusability behavior may not match the [button^{p545}](#) behavior on the current platform. This is because as of now there is no way to specify default focus behavior for custom elements, forcing the use of the [tabindex^{p801}](#) attribute to do so (even though it is usually reserved for allowing the consumer to override default behavior).

In contrast, a simple [customized built-in element^{p728}](#), as shown in the previous section, would automatically inherit the semantics and behavior of the [button^{p545}](#) element, with no need to implement these behaviors manually. In general, for any elements with nontrivial behavior and semantics that build on top of existing elements of HTML, [customized built-in elements^{p728}](#) will be easier to develop, maintain, and consume.

4.13.1.6 Upgrading elements after their creation §^{p72}₆

This section is non-normative.

Because [element definition^{p732}](#) can occur at any time, a non-custom element could be [created](#), and then later become a [custom element^{p728}](#) after an appropriate [definition^{p730}](#) is registered. We call this process "upgrading" the element, from a normal element into a custom element.

[Upgrades^{p734}](#) enable scenarios where it may be preferable for [custom element definitions^{p730}](#) to be registered after relevant elements have been initially created, such as by the parser. They allow progressive enhancement of the content in the custom element. For example, in the following HTML document the element definition for `img-viewer` is loaded asynchronously:

```

<!DOCTYPE html>
<html lang="en">
<title>Image viewer example</title>

<img-viewer filter="Kelvin">
  
</img-viewer>

<script src="js/elements/img-viewer.js" async</script>

```

The definition for the `img-viewer` element here is loaded using a [script^{p624}](#) element marked with the [async^{p625}](#) attribute, placed after

the `<img-viewer>` tag in the markup. While the script is loading, the `img-viewer` element will be treated as an undefined element, similar to a ``^{p285}. Once the script loads, it will define the `img-viewer` element, and the existing `img-viewer` element on the page will be upgraded, applying the custom element's definition (which presumably includes applying an image filter identified by the string "Kelvin", enhancing the image's visual appearance).

Note that [upgrades](#)^{p734} only apply to elements in the document tree. (Formally, elements that are [connected](#).) An element that is not inserted into a document will stay un-upgraded. An example illustrates this point:

```
<!DOCTYPE html>
<html lang="en">
<title>Upgrade edge-cases example</title>

<example-element></example-element>

<script>
  "use strict";

  const inDocument = document.querySelector("example-element");
  const outOfDocument = document.createElement("example-element");

  // Before the element definition, both are HTMLElement:
  console.assert(inDocument instanceof HTMLElement);
  console.assert(outOfDocument instanceof HTMLElement);

  class ExampleElement extends HTMLElement {}
  customElements.define("example-element", ExampleElement);

  // After element definition, the in-document element was upgraded:
  console.assert(inDocument instanceof ExampleElement);
  console.assert(!(outOfDocument instanceof ExampleElement));

  document.body.appendChild(outOfDocument);

  // Now that we've moved the element into the document, it too was upgraded:
  console.assert(outOfDocument instanceof ExampleElement);
</script>
```

4.13.2 Requirements for custom element constructors and reactions § p72 7

When authoring [custom element constructors](#)^{p728}, authors are bound by the following conformance requirements:

- A parameter-less call to `super()` must be the first statement in the constructor body, to establish the correct prototype chain and **this** value before any further code is run.
- A return statement must not appear anywhere inside the constructor body, unless it is a simple early-return (`return` or `return this`).
- The constructor must not use the `document.write()`^{p996} or `document.open()`^{p995} methods.
- The element's attributes and children must not be inspected, as in the non-[upgrade](#)^{p734} case none will be present, and relying on upgrades makes the element less usable.
- The element must not gain any attributes or children, as this violates the expectations of consumers who use the `createElement` or `createElementNS` methods.
- In general, work should be deferred to `connectedCallback` as much as possible—especially work involving fetching resources or rendering. However, note that `connectedCallback` can be called more than once, so any initialization work that is truly one-time will need a guard to prevent it from running twice.
- In general, the constructor should be used to set up initial state and default values, and to set up event listeners and possibly a [shadow root](#).

Several of these requirements are checked during [element creation](#), either directly or indirectly, and failing to follow them will result in a custom element that cannot be instantiated by the parser or DOM APIs. This is true even if the work is done inside a constructor-initiated [microtask](#)^{p970}, as a [microtask checkpoint](#)^{p974} can occur immediately after construction.

When authoring [custom element reactions](#)^{p737}, authors should avoid manipulating the node tree as this can lead to unexpected results.

Example

An element's `connectedCallback` can be queued before the element is disconnected, but as the callback queue is still processed, it results in a `connectedCallback` for an element that is no longer connected:

```
class CParent extends HTMLElement {
  connectedCallback() {
    this.firstChild.remove();
  }
}
customElements.define("c-parent", CParent);

class CChild extends HTMLElement {
  connectedCallback() {
    console.log("CChild connectedCallback: isConnected =", this.isConnected);
  }
}
customElements.define("c-child", CChild);

const parent = new CParent(),
      child = new CChild();
parent.appendChild(child);
document.body.appendChild(parent);

// Logs:
// CChild connectedCallback: isConnected = false
```

4.13.3 Core concepts § p72

A **custom element** is an element that is [custom](#). Informally, this means that its constructor and prototype are defined by the author, instead of by the user agent. This author-supplied constructor function is called the **custom element constructor**.

MDN

Two distinct types of [custom elements](#)^{p728} can be defined:

1. An **autonomous custom element**, which is defined with no `extends` option. These types of custom elements have a local name equal to their [defined name](#)^{p730}.
2. A **customized built-in element**, which is defined with an `extends` option. These types of custom elements have a local name equal to the value passed in their `extends` option, and their [defined name](#)^{p730} is used as the value of the `is` attribute, which therefore must be a [valid custom element name](#)^{p729}.

After a [custom element](#)^{p728} is [created](#), changing the value of the `is`^{p728} attribute does not change the element's behavior, as it is saved on the element as its [is value](#).

[Autonomous custom elements](#)^{p728} have the following element definition:

Categories^{p133}:

[Flow content](#)^{p136}.

[Phrasing content](#)^{p136}.

[Palpable content](#)^{p137}.

For [form-associated custom elements](#)^{p729}: [Listed](#)^{p494}, [labelable](#)^{p494}, [submittable](#)^{p494}, and [resettable](#)^{p494} [form-associated element](#)^{p494}.

Contexts in which this element can be used^{p133}:

Where [phrasing content](#)^{p136} is expected.

Content model^{p133}:

[Transparent^{p138}](#).

Content attributes^{p133}:

[Global attributes^{p140}](#), except the [is^{p728}](#) attribute

[form^{p576}](#), for [form-associated custom elements^{p729}](#) — Associates the element with a [form^{p494}](#) element

[disabled^{p580}](#), for [form-associated custom elements^{p729}](#) — Whether the form control is disabled

[readonly^{p729}](#), for [form-associated custom elements^{p729}](#) — Affects [willValidate^{p602}](#), plus any behavior added by the custom element author

[name^{p577}](#), for [form-associated custom elements^{p729}](#) — Name of the element to use for [form submission^{p605}](#) and in the

[form.elements^{p496}](#) API

Any other attribute that has no namespace (see prose).

Accessibility considerations^{p133}:

For [form-associated custom elements^{p729}](#): [for authors](#); [for implementers](#).

Otherwise: [for authors](#); [for implementers](#).

DOM interface^{p133}:

Supplied by the element's author (inherits from [HTMLElement^{p128}](#))

An [autonomous custom element^{p728}](#) does not have any special meaning: it [represents^{p128}](#) its children. A [customized built-in element^{p728}](#) inherits the semantics of the element that it extends.

Any namespace-less attribute that is relevant to the element's functioning, as determined by the element's author, may be specified on an [autonomous custom element^{p728}](#), so long as the attribute name is [XML-compatible^{p44}](#) and contains no [ASCII upper alphas](#). The exception is the [is^{p728}](#) attribute, which must not be specified on an [autonomous custom element^{p728}](#) (and which will have no effect if it is).

[Customized built-in elements^{p728}](#) follow the normal requirements for attributes, based on the elements they extend. To add custom attribute-based behavior, use [data-*^{p149}](#) attributes.

An [autonomous custom element^{p728}](#) is called a **form-associated custom element** if the element is associated with a [custom element definition^{p730}](#) whose [form-associated^{p730}](#) field is set to true.

The [name^{p577}](#) attribute represents the [form-associated custom element^{p729}](#)'s name. The [disabled^{p580}](#) attribute is used to make the [form-associated custom element^{p729}](#) non-interactive and to prevent its [submission value^{p742}](#) from being submitted. The [form^{p576}](#) attribute is used to explicitly associate the [form-associated custom element^{p729}](#) with its [form owner^{p576}](#).

The [readonly](#) attribute of [form-associated custom elements^{p729}](#) specifies that the element is [barred from constraint validation^{p599}](#). User agents don't provide any other behavior for the attribute, but custom element authors should, where possible, use its presence to make their control non-editable in some appropriate fashion, similar to the behavior for the [readonly^{p531}](#) attribute on built-in form controls.

Constraint validation: If the [readonly^{p729}](#) attribute is specified on a [form-associated custom element^{p729}](#), the element is [barred from constraint validation^{p599}](#).

The [reset algorithm^{p614}](#) for [form-associated custom elements^{p729}](#) is to [enqueue a custom element callback reaction^{p738}](#) with the element, callback name "formResetCallback", and an empty argument list.

A **valid custom element name** is a sequence of characters *name* that meets all of the following requirements:

- name* must match the [PotentialCustomElementName^{p729}](#) production:

```
PotentialCustomElementName ::=
```

```
[a-z] (PCENCharp729)* '-' (PCENCharp729)*
```

```
PCENChar ::=
```

```
"-" | "." | [0-9] | "_" | [a-z] | #xB7 | [#xC0-#xD6] | [#xD8-#xF6] | [#xF8-#x37D] | [#x37F-#x1FFF] |  
[#x200C-#x200D] | [#x203F-#x2040] | [#x2070-#x218F] | [#x2C00-#x2FEF] | [#x3001-#xD7FF] |  
[#xF900-#xFDCF] | [#xFDF0-#xFFFD] | [#x10000-#xEFFFF]
```

This uses the [EBNF notation](#) from the XML specification. [\[XML\]^{p1313}](#)

- *name* must not be any of the following:

- `annotation-xml`
- `color-profile`
- `font-face`
- `font-face-src`
- `font-face-uri`
- `font-face-format`
- `font-face-name`
- `missing-glyph`

Note

The list of names above is the summary of all hyphen-containing element names from the [applicable specifications](#)^{p67}, namely SVG 2 and MathML. [\[SVG\]](#)^{p1312} [\[MATHML\]](#)^{p1309}

Note

These requirements ensure a number of goals for [valid custom element names](#)^{p729}:

- They start with an [ASCII lower alpha](#), ensuring that the HTML parser will treat them as tags instead of as text.
- They do not contain any [ASCII upper alphas](#), ensuring that the user agent can always treat HTML elements ASCII-case-insensitively.
- They contain a hyphen, used for namespacing and to ensure forward compatibility (since no elements will be added to HTML, SVG, or MathML with hyphen-containing local names in the future).
- They can always be created with `createElement()` and `createElementNS()`, which have restrictions that go beyond the parser's.

Apart from these restrictions, a large variety of names is allowed, to give maximum flexibility for use cases like `<math-α>` or `<emotion-☺>`.

A **custom element definition** describes a [custom element](#)^{p728} and consists of:

A **name**

A [valid custom element name](#)^{p729}

A **local name**

A local name

A **constructor**

A Web IDL [CustomElementConstructor](#)^{p731} callback function type value wrapping the [custom element constructor](#)^{p728}

A **list of observed attributes**

A sequence<DOMString>

A **collection of lifecycle callbacks**

A map, whose keys are the strings "connectedCallback", "disconnectedCallback", "adoptedCallback", "attributeChangedCallback", "formAssociatedCallback", "formDisabledCallback", "formResetCallback", and "formStateRestoreCallback". The corresponding values are either a Web IDL [Function](#) callback function type value, or null. By default the value of each entry is null.

A **construction stack**

A list, initially empty, that is manipulated by the [upgrade an element](#)^{p734} algorithm and the [HTML element constructors](#)^{p130}. Each entry in the list will be either an element or an **already constructed marker**.

A **form-associated boolean**

If this is true, user agent treats elements associated to this [custom element definition](#)^{p730} as [form-associated custom elements](#)^{p729}.

A **disable internals boolean**

Controls [attachInternals\(\)](#)^{p740}.

A **disable shadow boolean**

Controls [attachShadow\(\)](#).

To **look up a custom element definition**, given a *document*, *namespace*, *localName*, and *is*, perform the following steps. They will return either a [custom element definition](#)^{p730} or null:

1. If *namespace* is not the [HTML namespace](#), return null.
2. If *document's* [browsing_context](#)^{p840} is null, return null.
3. Let *registry* be *document's* [relevant global object](#)^{p944}'s [CustomElementRegistry](#)^{p731} object.
4. If there is a [custom element definition](#)^{p730} in *registry* with [name](#)^{p730} and [local name](#)^{p730} both equal to *localName*, return that [custom element definition](#)^{p730}.
5. If there is a [custom element definition](#)^{p730} in *registry* with [name](#)^{p730} equal to *is* and [local name](#)^{p730} equal to *localName*, return that [custom element definition](#)^{p730}.
6. Return null.

4.13.4 The [CustomElementRegistry](#)^{p731} interface §^{p73}₁

Each [Window](#)^{p855} object is associated with a unique instance of a [CustomElementRegistry](#)^{p731} object, allocated when the [Window](#)^{p855} object is created.

Note

Custom element registries are associated with [Window](#)^{p855} objects, instead of [Document](#)^{p117} objects, since each [custom element constructor](#)^{p728} inherits from the [HTMLElement](#)^{p128} interface, and there is exactly one [HTMLElement](#)^{p128} interface per [Window](#)^{p855} object.

The `customElements` attribute of the [Window](#)^{p855} interface must return the [CustomElementRegistry](#)^{p731} object for that [Window](#)^{p855} object.

```
IDL [Exposed=Window]
interface CustomElementRegistry {
  [CEReactions] undefined define(DOMString name, CustomElementConstructor constructor, optional
  ElementDefinitionOptions options = {});
  (CustomElementConstructor or undefined) get(DOMString name);
  Promise<CustomElementConstructor> whenDefined(DOMString name);
  [CEReactions] undefined upgrade(Node root);
};

callback CustomElementConstructor = HTMLElement ();

dictionary ElementDefinitionOptions {
  DOMString extends;
};
```

Every [CustomElementRegistry](#)^{p731} has a set of [custom element definitions](#)^{p730}, initially empty. In general, algorithms in this specification look up elements in the registry by any of [name](#)^{p730}, [local name](#)^{p730}, or [constructor](#)^{p730}.

Every [CustomElementRegistry](#)^{p731} also has an **element definition is running** flag which is used to prevent reentrant invocations of [element definition](#)^{p732}. It is initially unset.

Every [CustomElementRegistry](#)^{p731} also has a **when-defined promise map**, mapping [valid custom element names](#)^{p729} to promises. It is used to implement the [whenDefined\(\)](#)^{p733} method.

For web developers (non-normative)

`window.customElements`^{p731}.`define`^{p732}(*name*, *constructor*)

Defines a new [custom element](#)^{p728}, mapping the given name to the given constructor as an [autonomous custom element](#)^{p728}.

`window.customElements`^{p731}.`define`^{p732}(*name*, *constructor*, { *extends*: *baseLocalName* })

Defines a new [custom element](#)^{p728}, mapping the given name to the given constructor as a [customized built-in element](#)^{p728} for the [element type](#)^{p44} identified by the supplied *baseLocalName*. A ["NotSupportedError"](#) [DOMException](#) will be thrown upon trying to extend a [custom element](#)^{p728} or an unknown element.

`window.customElementsp731.getp733(name)`

Retrieves the [custom element constructor^{p728}](#) defined for the given [name^{p730}](#). Returns undefined if there is no [custom element definition^{p730}](#) with the given [name^{p730}](#).

`window.customElementsp731.whenDefinedp733(name)`

Returns a promise that will be fulfilled with the [custom element^{p728}](#)'s constructor when a [custom element^{p728}](#) becomes defined with the given name. (If such a [custom element^{p728}](#) is already defined, the returned promise will be immediately fulfilled.) Returns a promise rejected with a ["SyntaxError" DOMException](#) if not given a [valid custom element name^{p729}](#).

`window.customElementsp731.upgradep734(root)`

Tries to upgrade^{p736} all [shadow-including inclusive descendant](#) elements of *root*, even if they are not [connected](#).

Element definition is a process of adding a [custom element definition^{p730}](#) to the [CustomElementRegistry^{p731}](#). This is accomplished by the [define\(\)^{p732}](#) method. When invoked, the [define\(name, constructor, options\)](#) method must run these steps:

1. If [isConstructor\(constructor\)](#) is false, then throw a [TypeError](#).
2. If *name* is not a [valid custom element name^{p729}](#), then throw a ["SyntaxError" DOMException](#).
3. If this [CustomElementRegistry^{p731}](#) contains an entry with [name^{p730}](#) *name*, then throw a ["NotSupportedError" DOMException](#).
4. If this [CustomElementRegistry^{p731}](#) contains an entry with [constructor^{p730}](#) *constructor*, then throw a ["NotSupportedError" DOMException](#).
5. Let *localName* be *name*.
6. Let *extends* be the value of the *extends* member of *options*, or null if no such member exists.
7. If *extends* is not null, then:
 1. If *extends* is a [valid custom element name^{p729}](#), then throw a ["NotSupportedError" DOMException](#).
 2. If the [element interface](#) for *extends* and the [HTML namespace](#) is [HTMLUnknownElement^{p129}](#) (e.g., if *extends* does not indicate an element definition in this specification), then throw a ["NotSupportedError" DOMException](#).
 3. Set *localName* to *extends*.
8. If this [CustomElementRegistry^{p731}](#)'s [element definition is running^{p731}](#) flag is set, then throw a ["NotSupportedError" DOMException](#).
9. Set this [CustomElementRegistry^{p731}](#)'s [element definition is running^{p731}](#) flag.
10. Let *formAssociated* be false.
11. Let *disableInternals* be false.
12. Let *disableShadow* be false.
13. Let *observedAttributes* be an empty [sequence<DOMString>](#).
14. Run the following substeps while catching any exceptions:
 1. Let *prototype* be ? [Get\(constructor, "prototype"\)](#).
 2. If [Type\(prototype\)](#) is not Object, then throw a [TypeError](#) exception.
 3. Let *lifecycleCallbacks* be a map with the keys "connectedCallback", "disconnectedCallback", "adoptedCallback", and "attributeChangedCallback", each of which belongs to an entry whose value is null.
 4. For each of the keys *callbackName* in *lifecycleCallbacks*, in the order listed in the previous step:
 1. Let *callbackValue* be ? [Get\(prototype, callbackName\)](#).
 2. If *callbackValue* is not undefined, then set the value of the entry in *lifecycleCallbacks* with key *callbackName* to the result of [converting](#) *callbackValue* to the Web IDL [Function](#) callback type. Rethrow any exceptions from the conversion.

5. If the value of the entry in *lifecycleCallbacks* with key "attributeChangedCallback" is not null, then:
 1. Let *observedAttributesIterable* be ? [Get](#)(*constructor*, "observedAttributes").
 2. If *observedAttributesIterable* is not undefined, then set *observedAttributes* to the result of [converting](#) *observedAttributesIterable* to a [sequence](#)<DOMString>. Rethrow any exceptions from the conversion.
6. Let *disabledFeatures* be an empty [sequence](#)<DOMString>.
7. Let *disabledFeaturesIterable* be ? [Get](#)(*constructor*, "disabledFeatures").
8. If *disabledFeaturesIterable* is not undefined, then set *disabledFeatures* to the result of [converting](#) *disabledFeaturesIterable* to a [sequence](#)<DOMString>. Rethrow any exceptions from the conversion.
9. Set *disableInternals* to true if *disabledFeatures* [contains](#) "internals".
10. Set *disableShadow* to true if *disabledFeatures* [contains](#) "shadow".
11. Let *formAssociatedValue* be ? [Get](#)(*constructor*, "formAssociated").
12. Set *formAssociated* to the result of [converting](#) *formAssociatedValue* to a [boolean](#). Rethrow any exceptions from the conversion.
13. If *formAssociated* is true, for each of "formAssociatedCallback", "formResetCallback", "formDisabledCallback", and "formStateRestoreCallback" *callbackName*:
 1. Let *callbackValue* be ? [Get](#)(*prototype*, *callbackName*).
 2. If *callbackValue* is not undefined, then set the value of the entry in *lifecycleCallbacks* with key *callbackName* to the result of [converting](#) *callbackValue* to the Web IDL [Function](#) callback type. Rethrow any exceptions from the conversion.

Then, perform the following substep, regardless of whether the above steps threw an exception or not:

1. Unset this [CustomElementRegistry](#)^{p731}'s [element definition is running](#)^{p731} flag.

Finally, if the first set of substeps threw an exception, then rethrow that exception (thus terminating this algorithm). Otherwise, continue onward.

15. Let *definition* be a new [custom element definition](#)^{p730} with [name](#)^{p730} *name*, [local name](#)^{p730} *localName*, [constructor](#)^{p730} *constructor*, [observed attributes](#)^{p730} *observedAttributes*, [lifecycle callbacks](#)^{p730} *lifecycleCallbacks*, [form-associated](#)^{p730} *formAssociated*, [disable internals](#)^{p730} *disableInternals*, and [disable shadow](#)^{p730} *disableShadow*.
16. Add *definition* to this [CustomElementRegistry](#)^{p731}.
17. Let *document* be this [CustomElementRegistry](#)^{p731}'s [relevant global object](#)^{p944}'s [associated Document](#)^{p856}.
18. Let *upgrade candidates* be all elements that are [shadow-including descendants](#) of *document*, whose namespace is the [HTML namespace](#) and whose local name is *localName*, in [shadow-including tree order](#). Additionally, if *extends* is non-null, only include elements whose [is value](#) is equal to *name*.
19. For each element *element* in *upgrade candidates*, [enqueue a custom element upgrade reaction](#)^{p738} given *element* and *definition*.
20. If this [CustomElementRegistry](#)^{p731}'s [when-defined promise map](#)^{p731} contains an entry with key *name*:
 1. Let *promise* be the value of that entry.
 2. Resolve *promise* with *constructor*.
 3. Delete the entry with key *name* from this [CustomElementRegistry](#)^{p731}'s [when-defined promise map](#)^{p731}.

When invoked, the [get\(name\)](#) method must run these steps:

1. If this [CustomElementRegistry](#)^{p731} contains an entry with [name](#)^{p730} *name*, then return that entry's [constructor](#)^{p730}.
2. Otherwise, return undefined.

When invoked, the [whenDefined\(name\)](#) method must run these steps:

1. If *name* is not a [valid custom element name](#)^{p729}, then return a new promise rejected with a ["SyntaxError" DOMException](#).

2. If this [CustomElementRegistry](#)^{p731} contains an entry with [name](#)^{p730} *name*, then return a new promise resolved with that entry's [constructor](#)^{p730}.
3. Let *map* be this [CustomElementRegistry](#)^{p731}'s [when-defined promise map](#)^{p731}.
4. If *map* does not contain an entry with key *name*, create an entry in *map* with key *name* and whose value is a new promise.
5. Let *promise* be the value of the entry in *map* with key *name*.
6. Return *promise*.

Example

The [whenDefined\(\)](#)^{p733} method can be used to avoid performing an action until all appropriate [custom elements](#)^{p728} are [defined](#). In this example, we combine it with the [.defined](#)^{p751} pseudo-class to hide a dynamically-loaded article's contents until we're sure that all of the [autonomous custom elements](#)^{p728} it uses are defined.

```
articleContainer.hidden = true;

fetch(articleURL)
  .then(response => response.text())
  .then(text => {
    articleContainer.innerHTML = text;

    return Promise.all(
      [...articleContainer.querySelectorAll(":not(:defined)")]
        .map(el => customElements.whenDefined(el.localName))
    );
  })
  .then(() => {
    articleContainer.hidden = false;
  });
```

When invoked, the [upgrade\(root\)](#) method must run these steps:

1. Let *candidates* be a [list](#) of all of *root*'s [shadow-including inclusive descendant](#) elements, in [shadow-including tree order](#).
2. [For each](#) *candidate* of *candidates*, [try to upgrade](#)^{p736} *candidate*.

Example

The [upgrade\(\)](#)^{p734} method allows upgrading of elements at will. Normally elements are automatically upgraded when they become [connected](#), but this method can be used if you need to upgrade before you're ready to connect the element.

```
const el = document.createElement("spider-man");

class SpiderMan extends HTMLElement {}
customElements.define("spider-man", SpiderMan);

console.assert(!(el instanceof SpiderMan)); // not yet upgraded

customElements.upgrade(el);
console.assert(el instanceof SpiderMan); // upgraded!
```

4.13.5 Upgrades §^{p73}₄

To **upgrade an element**, given as input a [custom element definition](#)^{p730} *definition* and an element *element*, run the following steps:

1. If *element*'s [custom element state](#) is not "undefined" or "uncustomized", then return.

Example

One scenario where this can occur due to reentrant invocation of this algorithm, as in the following example:

```
<!DOCTYPE html>
<x-foo id="a"></x-foo>
<x-foo id="b"></x-foo>

<script>
// Defining enqueues upgrade reactions for both "a" and "b"
customElements.define("x-foo", class extends HTMLElement {
  constructor() {
    super();

    const b = document.querySelector("#b");
    b.remove();

    // While this constructor is running for "a", "b" is still
    // undefined, and so inserting it into the document will enqueue a
    // second upgrade reaction for "b" in addition to the one enqueued
    // by defining x-foo.
    document.body.appendChild(b);
  }
});
</script>
```

This step will thus bail out the algorithm early when [upgrade an element](#)^{p734} is invoked with "b" a second time.

2. Set *element*'s [custom element definition](#) to *definition*.
3. Set *element*'s [custom element state](#) to "failed".

Note

It will be set to "custom" [after the upgrade succeeds](#)^{p736}. For now, we set it to "failed" so that any reentrant invocations will hit [the above early-exit step](#)^{p734}.

4. For each *attribute* in *element*'s [attribute list](#), in order, [enqueue a custom element callback reaction](#)^{p738} with *element*, callback name "attributeChangedCallback", and an argument list containing *attribute*'s local name, null, *attribute*'s value, and *attribute*'s namespace.
5. If *element* is [connected](#), then [enqueue a custom element callback reaction](#)^{p738} with *element*, callback name "connectedCallback", and an empty argument list.
6. Add *element* to the end of *definition*'s [construction stack](#)^{p730}.
7. Let *C* be *definition*'s [constructor](#)^{p730}.
8. Run the following substeps while catching any exceptions:
 1. If *definition*'s [disable shadow](#)^{p730} is true and *element*'s [shadow root](#) is non-null, then throw a **NotSupportedError** [DOMException](#).

Note

This is needed as [attachShadow\(\)](#) does not use [look up a custom element definition](#)^{p730} while [attachInternals\(\)](#)^{p740} does.

2. Set *element*'s [custom element state](#) to "precustomized".
3. Let *constructResult* be the result of [constructing](#) *C*, with no arguments.

Note

If *C* [non-conformantly](#)^{p727} uses an API decorated with the [\[CEReactions\]](#)^{p739} extended attribute, then the reactions enqueued at the beginning of this algorithm will execute during this step, before *C* finishes and control returns to this algorithm. Otherwise, they will execute after *C* and the rest of the upgrade process finishes.

4. If `SameValue(constructResult, element)` is false, then throw a `TypeError`.

Note

This can occur if *C* constructs another instance of the same custom element before calling `super()`, or if *C* uses JavaScript's return-override feature to return an arbitrary `HTMLElement`^{p128} object from the constructor.

Then, perform the following substep, regardless of whether the above steps threw an exception or not:

1. Remove the last entry from the end of *definition*'s `construction stack`^{p730}.

Note

Assuming *C* calls `super()` (as it will if it is `conformant`^{p727}), and that the call succeeds, this will be the `already constructed marker`^{p730} that replaced the element we pushed at the beginning of this algorithm. (The `HTML element constructor`^{p130} carries out this replacement.)

If *C* does not call `super()` (i.e. it is not `conformant`^{p727}), or if any step in the `HTML element constructor`^{p130} throws, then this entry will still be `element`.

Finally, if the above steps threw an exception, then:

1. Set *element*'s `custom element definition` to null.
2. Empty *element*'s `custom element reaction queue`^{p737}.
3. Rethrow the exception (thus terminating this algorithm).

Note

If the above steps threw an exception, then *element*'s `custom element state` will remain "failed" or "precustomized".

9. If *element* is a `form-associated custom element`^{p729}, then:
 1. `Reset the form owner`^{p576} of *element*. If *element* is associated with a `form`^{p494} element, then `enqueue a custom element callback reaction`^{p738} with *element*, callback name "formAssociatedCallback", and « the associated `form`^{p494} ».
 2. If *element* is `disabled`^{p580}, then `enqueue a custom element callback reaction`^{p738} with *element*, callback name "formDisabledCallback" and « true ».
10. Set *element*'s `custom element state` to "custom".

To **try to upgrade an element**, given as input an element *element*, run the following steps:

1. Let *definition* be the result of `looking up a custom element definition`^{p730} given *element*'s `node document`, *element*'s namespace, *element*'s local name, and *element*'s `is value`.
2. If *definition* is not null, then `enqueue a custom element upgrade reaction`^{p738} given *element* and *definition*.

4.13.6 Custom element reactions §^{p73}₆

A `custom element`^{p728} possesses the ability to respond to certain occurrences by running author code:

- When `upgraded`^{p734}, its `constructor`^{p728} is run, with no arguments.
- When it `becomes connected`^{p45}, its `connectedCallback` is called, with no arguments.
- When it `becomes disconnected`^{p45}, its `disconnectedCallback` is called, with no arguments.
- When it is `adopted` into a new document, its `adoptedCallback` is called, given the old document and new document as arguments.
- When any of its attributes are `changed`, `appended`, `removed`, or `replaced`, its `attributeChangedCallback` is called, given the attribute's local name, old value, new value, and namespace as arguments. (An attribute's old or new value is considered to be null when the attribute is added or removed, respectively.)
- When the user agent `resets the form owner`^{p576} of a `form-associated custom element`^{p729} and doing so changes the form

owner, its `formAssociatedCallback` is called, given the new form owner (or null if no owner) as an argument.

- When the form owner of a [form-associated custom element](#)^{p729} is [reset](#)^{p614}, its `formResetCallback` is called.
- When the [disabled](#)^{p580} state of a [form-associated custom element](#)^{p729} is changed, its `formDisabledCallback` is called, given the new state as an argument.
- When user agent updates a [form-associated custom element](#)^{p729}'s value on behalf of a user or [as part of navigation](#)^{p925}, its `formStateRestoreCallback` is called, given the new value and a string indicating a reason, "autocomplete" or "restore", as arguments.

We call these reactions collectively **custom element reactions**.

The way in which [custom element reactions](#)^{p737} are invoked is done with special care, to avoid running author code during the middle of delicate operations. Effectively, they are delayed until "just before returning to user script". This means that for most purposes they appear to execute synchronously, but in the case of complicated composite operations (like [cloning](#), or [range](#) manipulation), they will instead be delayed until after all the relevant user agent processing steps have completed, and then run together as a batch.

Additionally, the precise ordering of these reactions is managed via a somewhat-complicated stack-of-queues system, described below. The intention behind this system is to guarantee that [custom element reactions](#)^{p737} always are invoked in the same order as their triggering actions, at least within the local context of a single [custom element](#)^{p728}. (Because [custom element reaction](#)^{p737} code can perform its own mutations, it is not possible to give a global ordering guarantee across multiple elements.)

Each [similar-origin window agent](#)^{p933} has a **custom element reactions stack**, which is initially empty. A [similar-origin window agent](#)^{p933}'s **current element queue** is the [element queue](#)^{p737} at the top of its [custom element reactions stack](#)^{p737}. Each item in the stack is an **element queue**, which is initially empty as well. Each item in an [element queue](#)^{p737} is an element. (The elements are not necessarily [custom](#) yet, since this queue is used for [upgrades](#)^{p734} as well.)

Each [custom element reactions stack](#)^{p737} has an associated **backup element queue**, which is an initially-empty [element queue](#)^{p737}. Elements are pushed onto the [backup element queue](#)^{p737} during operations that affect the DOM without going through an API decorated with `[CEReactions]`^{p739}, or through the parser's [create an element for the token](#)^{p1154} algorithm. An example of this is a user-initiated editing operation which modifies the descendants or attributes of an [editable](#) element. To prevent reentrancy when processing the [backup element queue](#)^{p737}, each [custom element reactions stack](#)^{p737} also has a **processing the backup element queue** flag, initially unset.

All elements have an associated **custom element reaction queue**, initially empty. Each item in the [custom element reaction queue](#)^{p737} is of one of two types:

- An **upgrade reaction**, which will [upgrade](#)^{p734} the custom element and contains a [custom element definition](#)^{p730}; or
- A **callback reaction**, which will call a lifecycle callback, and contains a callback function as well as a list of arguments.

This is all summarized in the following schematic diagram:

custom element reactions stack

element queue

custom element reaction queue

backup element queue

processing backup
element queue flag

To **enqueue an element on the appropriate element queue**, given an element *element*, run the following steps:

1. Let *reactionsStack* be *element*'s [relevant agent^{p934}](#)'s [custom element reactions stack^{p737}](#).
2. If *reactionsStack* is empty, then:
 1. Add *element* to *reactionsStack*'s [backup element queue^{p737}](#).
 2. If *reactionsStack*'s [processing the backup element queue^{p737}](#) flag is set, then return.
 3. Set *reactionsStack*'s [processing the backup element queue^{p737}](#) flag.
 4. [Queue a microtask^{p970}](#) to perform the following steps:
 1. [Invoke custom element reactions^{p739}](#) in *reactionsStack*'s [backup element queue^{p737}](#).
 2. Unset *reactionsStack*'s [processing the backup element queue^{p737}](#) flag.
3. Otherwise, add *element* to *element*'s [relevant agent^{p934}](#)'s [current element queue^{p737}](#).

To **enqueue a custom element callback reaction**, given a [custom element^{p728}](#) *element*, a callback name *callbackName*, and a list of arguments *args*, run the following steps:

1. Let *definition* be *element*'s [custom element definition](#).
2. Let *callback* be the value of the entry in *definition*'s [lifecycle callbacks^{p730}](#) with key *callbackName*.
3. If *callback* is null, then return.
4. If *callbackName* is "attributeChangedCallback", then:
 1. Let *attributeName* be the first element of *args*.
 2. If *definition*'s [observed attributes^{p730}](#) does not contain *attributeName*, then return.
5. Add a new [callback reaction^{p737}](#) to *element*'s [custom element reaction queue^{p737}](#), with callback function *callback* and arguments *args*.
6. [Enqueue an element on the appropriate element queue^{p738}](#) given *element*.

To **enqueue a custom element upgrade reaction**, given an element *element* and [custom element definition^{p730}](#) *definition*, run the

following steps:

1. Add a new [upgrade reaction](#)^{p737} to *element*'s [custom element reaction queue](#)^{p737}, with [custom element definition](#)^{p730} definition.
2. [Enqueue an element on the appropriate element queue](#)^{p738} given *element*.

To **invoke custom element reactions** in an [element queue](#)^{p737} *queue*, run the following steps:

1. While *queue* is not [empty](#):
 1. Let *element* be the result of [dequeuing](#) from *queue*.
 2. Let *reactions* be *element*'s [custom element reaction queue](#)^{p737}.
 3. Repeat until *reactions* is empty:
 1. Remove the first element of *reactions*, and let *reaction* be that element. Switch on *reaction*'s type:
 - ↪ [upgrade reaction](#)^{p737}
[Upgrade](#)^{p734} *element* using *reaction*'s [custom element definition](#)^{p730}.
 - ↪ [callback reaction](#)^{p737}
[Invoke](#) *reaction*'s callback function with *reaction*'s arguments, and with *element* as the [callback this value](#).

If this throws an exception, catch it, and [report the exception](#)^{p959}.

To ensure [custom element reactions](#)^{p737} are triggered appropriately, we introduce the **[CEReactions]** IDL [extended attribute](#). It indicates that the relevant algorithm is to be supplemented with additional steps in order to appropriately track and invoke [custom element reactions](#)^{p737}.

The **[CEReactions]**^{p739} extended attribute must take no arguments, and must not appear on anything other than an operation, attribute, setter, or deleter. Additionally, it must not appear on readonly attributes.

Operations, attributes, setters, or deleters annotated with the **[CEReactions]**^{p739} extended attribute must run the following steps in place of the ones specified in their description:

1. [Push](#) a new [element queue](#)^{p737} onto this object's [relevant agent](#)^{p934}'s [custom element reactions stack](#)^{p737}.
2. Run the originally-specified steps for this construct, catching any exceptions. If the steps return a value, let *value* be the returned value. If they throw an exception, let *exception* be the thrown exception.
3. Let *queue* be the result of [popping](#) from this object's [relevant agent](#)^{p934}'s [custom element reactions stack](#)^{p737}.
4. [Invoke custom element reactions](#)^{p739} in *queue*.
5. If an exception *exception* was thrown by the original steps, rethrow *exception*.
6. If a value *value* was returned from the original steps, return *value*.

Note

The intent behind this extended attribute is somewhat subtle. One way of accomplishing its goals would be to say that every operation, attribute, setter, and deleter on the platform must have these steps inserted, and to allow implementers to optimize away unnecessary cases (where no DOM mutation is possible that could cause [custom element reactions](#)^{p737} to occur).

However, in practice this imprecision could lead to non-interoperable implementations of [custom element reactions](#)^{p737}, as some implementations might forget to invoke these steps in some cases. Instead, we settled on the approach of explicitly annotating all relevant IDL constructs, as a way of ensuring interoperable behavior and helping implementations easily pinpoint all cases where these steps are necessary.

Any nonstandard APIs introduced by the user agent that could modify the DOM in such a way as to cause [enqueueing a custom element callback reaction](#)^{p738} or [enqueueing a custom element upgrade reaction](#)^{p738}, for example by modifying any attributes or child elements, must also be decorated with the **[CEReactions]**^{p739} attribute.

Note

As of the time of this writing, the following nonstandard or not-yet-standardized APIs are known to fall into this category:

- [HTMLInputElement](#)^{p502}'s `webkitdirectory` and incremental IDL attributes
- [HTMLLinkElement](#)^{p162}'s `scope` IDL attribute

4.13.7 Element internals § p74₀

Certain capabilities are meant to be available to a custom element author, but not to a custom element consumer. These are provided by the `element.attachInternals()`^{p740} method, which returns an instance of [ElementInternals](#)^{p740}. The properties and methods of [ElementInternals](#)^{p740} allow control over internal features which the user agent provides to all elements.

For web developers (non-normative)

`element.attachInternals()`^{p740}

Returns an [ElementInternals](#)^{p740} object targeting the [custom element](#)^{p728} `element`. Throws an exception if `element` is not a [custom element](#)^{p728}, if the "internals" feature was disabled as part of the element definition, or if it is called twice on the same element.

MDN

Each [HTMLElement](#)^{p128} has an **attached internals** boolean, initially false.

The `attachInternals()` method steps are:

1. If `this`'s `is_value` is not null, then throw a `"NotSupportedError"` `DOMException`.
2. Let `definition` be the result of [looking up a custom element definition](#)^{p730} given `this`'s `node document`, its namespace, its local name, and null as the `is_value`.
3. If `definition` is null, then throw an `"NotSupportedError"` `DOMException`.
4. If `definition`'s `disable internals`^{p730} is true, then throw a `"NotSupportedError"` `DOMException`.
5. If `this`'s `attached internals`^{p740} is true, then throw an `"NotSupportedError"` `DOMException`.
6. If `this`'s `custom element state` is not "precustomized" or "custom", then throw a `"NotSupportedError"` `DOMException`.
7. Set `this`'s `attached internals`^{p740} to true.
8. Return a new [ElementInternals](#)^{p740} instance whose `target element`^{p741} is `this`.

MDN

4.13.7.1 The [ElementInternals](#)^{p740} interface § p74₀

The IDL for the [ElementInternals](#)^{p740} interface is as follows, with the various operations and attributes defined in the following sections:

```
IDL [Exposed=Window]
interface ElementInternals {
  // Shadow root access
  readonly attribute ShadowRoot? shadowRoot;

  // Form-associated custom elements
  undefined setFormValue((File or USVString or FormData)? value,
                        optional (File or USVString or FormData)? state);

  readonly attribute HTMLFormElement? form;

  undefined setValidity(optional ValidityStateFlags flags = {},
                       optional DOMString message,
                       optional HTMLElement anchor);
```

```

readonly attribute boolean willValidate;
readonly attribute ValidityState validity;
readonly attribute DOMString validationMessage;
boolean checkValidity();
boolean reportValidity();

readonly attribute NodeList labels;
};

// Accessibility semantics
ElementInternals includes ARIAMixin;

dictionary ValidityStateFlags {
  boolean valueMissing = false;
  boolean typeMismatch = false;
  boolean patternMismatch = false;
  boolean tooLong = false;
  boolean tooShort = false;
  boolean rangeUnderflow = false;
  boolean rangeOverflow = false;
  boolean stepMismatch = false;
  boolean badInput = false;
  boolean customError = false;
};

```

Each [ElementInternals](#)^{p749} has a **target element**, which is a [custom element](#)^{p728}.

4.13.7.2 Shadow root access § p74 1

For web developers (non-normative)

[internals.shadowRoot](#)^{p741}

Returns the [ShadowRoot](#) for *internals*'s [target element](#)^{p741}, if the [target element](#)^{p741} is a [shadow host](#), or null otherwise.

The **shadowRoot** getter steps are:

MDN

1. Let *target* be *this*'s [target element](#)^{p741}.
2. If *target* is not a [shadow host](#), then return null.
3. Let *shadow* be *target*'s [shadow root](#).
4. If *shadow*'s [available to element internals](#) is false, then return null.
5. Return *shadow*.

4.13.7.3 Form-associated custom elements § p74 1

For web developers (non-normative)

[internals.setFormValue](#)^{p742} (*value*)

Sets both the [state](#)^{p742} and [submission value](#)^{p742} of *internals*'s [target element](#)^{p741} to *value*.

If *value* is null, the element won't participate in form submission.

[internals.setFormValue](#)^{p742} (*value*, *state*)

Sets the [submission value](#)^{p742} of *internals*'s [target element](#)^{p741} to *value*, and its [state](#)^{p742} to *state*.

If *value* is null, the element won't participate in form submission.

`internals.form`^{p577}

Returns the [form owner](#)^{p576} of *internals*'s [target element](#)^{p741}.

`internals.setValidity`^{p743}(*flags*, *message* [, *anchor*])

Marks *internals*'s [target element](#)^{p741} as suffering from the constraints indicated by the *flags* argument, and sets the element's validation message to *message*. If *anchor* is specified, the user agent might use it to indicate problems with the constraints of *internals*'s [target element](#)^{p741} when the [form owner](#)^{p576} is validated interactively or [reportValidity\(\)](#)^{p604} is called.

`internals.setValidity`^{p743}({})

Marks *internals*'s [target element](#)^{p741} as [satisfying its constraints](#)^{p601}.

`internals . willValidate`^{p602}

Returns true if *internals*'s [target element](#)^{p741} will be validated when the form is submitted; false otherwise.

`internals.validity`^{p603}

Returns the [ValidityState](#)^{p603} object for *internals*'s [target element](#)^{p741}.

`internals . validationMessage`^{p743}

Returns the error message that would be shown to the user if *internals*'s [target element](#)^{p741} was to be checked for validity.

`valid = internals . checkValidity()`^{p604}

Returns true if *internals*'s [target element](#)^{p741} has no validity problems; false otherwise. Fires an [invalid](#)^{p1301} event at the element in the latter case.

`valid = internals . reportValidity()`^{p604}

Returns true if *internals*'s [target element](#)^{p741} has no validity problems; otherwise, returns false, fires an [invalid](#)^{p1301} event at the element, and (if the event isn't canceled) reports the problem to the user.

`internals.labels`^{p500}

Returns a [NodeList](#) of all the [label](#)^{p498} elements that *internals*'s [target element](#)^{p741} is associated with.

Each [form-associated custom element](#)^{p729} has **submission value**. It is used to provide one or more [entries](#)^{p609} on form submission. The initial value of [submission value](#)^{p742} is null, and [submission value](#)^{p742} can be null, a string, a [File](#), or a [list](#) of [entries](#)^{p609}.

Each [form-associated custom element](#)^{p729} has **state**. It is information with which the user agent can restore a user's input for the element. The initial value of [state](#)^{p742} is null, and [state](#)^{p742} can be null, a string, a [File](#), or a [list](#) of [entries](#)^{p609}.

The [setFormValue\(\)](#)^{p742} method is used by the custom element author to set the element's [submission value](#)^{p742} and [state](#)^{p742}, thus communicating these to the user agent.

When the user agent believes it is a good idea to restore a [form-associated custom element](#)^{p729}'s [state](#)^{p742}, for example [after navigation](#)^{p925} or restarting the user agent, they may [enqueue a custom element callback reaction](#)^{p738} with that element, callback name "formStateRestoreCallback", an argument list containing the state to be restored, and "restore".

If the user agent has a form-filling assist feature, then when the feature is invoked, it may [enqueue a custom element callback reaction](#)^{p738} with a [form-associated custom element](#)^{p729}, callback name "formStateRestoreCallback", an argument list containing the state value determined by history of state value and some heuristics, and "autocomplete".

In general, the [state](#)^{p742} is information specified by a user, and the [submission value](#)^{p742} is a value after canonicalization or sanitization, suitable for submission to the server. The following examples makes this concrete:

Example

Suppose that we have a [form-associated custom element](#)^{p729} which asks a user to specify a date. The user specifies "3/15/2019", but the control wishes to submit "2019-03-15" to the server. "3/15/2019" would be a [state](#)^{p742} of the element, and "2019-03-15" would be a [submission value](#)^{p742}.

Example

Suppose you develop a custom element emulating a the behavior of the existing [checkbox](#)^{p521} [input](#)^{p501} type. Its [submission value](#)^{p742} would be the value of its `value` content attribute, or the string "on". Its [state](#)^{p742} would be one of "checked", "unchecked", "checked/indeterminate", or "unchecked/indeterminate".

The `setFormValue(value, state)` method steps are:

1. Let *element* be [this's target element](#)^{p741}.
2. If *element* is not a [form-associated custom element](#)^{p729}, then throw a `"NotSupportedError"` `DOMException`.
3. Set [target element](#)^{p741}'s [submission value](#)^{p742} to *value* if *value* is not a `FormData` object, or to a [clone](#) of *value*'s [entry list](#) otherwise.
4. If the *state* argument of the function is omitted, set *element*'s [state](#)^{p742} to its [submission value](#)^{p742}.
5. Otherwise, if *state* is a `FormData` object, set *element*'s [state](#)^{p742} to a [clone](#) of *state*'s [entry list](#).
6. Otherwise, set *element*'s [state](#)^{p742} to *state*.

Each [form-associated custom element](#)^{p729} has validity flags named `valueMissing`, `typeMismatch`, `patternMismatch`, `tooLong`, `tooShort`, `rangeUnderflow`, `rangeOverflow`, `stepMismatch`, and `customError`. They are false initially.

Each [form-associated custom element](#)^{p729} has a **validation message** string. It is the empty string initially.

Each [form-associated custom element](#)^{p729} has a **validation anchor** element. It is null initially.

The `setValidity(flags, message, anchor)` method steps are:

1. Let *element* be [this's target element](#)^{p741}.
2. If *element* is not a [form-associated custom element](#)^{p729}, then throw a `"NotSupportedError"` `DOMException`.
3. If *flags* contains one or more true values and *message* is not given or is the empty string, then throw a `TypeError`.
4. For each entry *flag* → *value* of *flags*, set *element*'s validity flag with the name *flag* to *value*.
5. Set *element*'s [validation message](#)^{p743} to the empty string if *message* is not given or all of *element*'s validity flags are false, or to *message* otherwise.
6. If *element*'s `customError` validity flag is true, then set *element*'s [custom validity error message](#)^{p599} to *element*'s [validation message](#)^{p743}. Otherwise, set *element*'s [custom validity error message](#)^{p599} to the empty string.
7. Set *element*'s [validation anchor](#)^{p743} to null if *anchor* is not given. Otherwise, if *anchor* is not a [shadow-including descendant](#) of *element*, then throw a `"NotFoundError"` `DOMException`. Otherwise, set *element*'s [validation anchor](#)^{p743} to *anchor*.

The `validationMessage` getter steps are:

1. Let *element* be [this's target element](#)^{p741}.
2. If *element* is not a [form-associated custom element](#)^{p729}, then throw a `"NotSupportedError"` `DOMException`.
3. Return *element*'s [validation message](#)^{p743}.

The **entry construction algorithm** for a [form-associated custom element](#)^{p729}, given an element *element* and an [entry list](#)^{p609} *entry list*, consists of the following steps:

1. If *element*'s [submission value](#)^{p742} is a [list](#) of [entries](#)^{p609}, then [append](#) each item of *element*'s [submission value](#)^{p742} to *entry list*, and return.

Note

In this case, user agent does not refer to the [name](#)^{p577} content attribute value. An implementation of [form-associated custom element](#)^{p729} is responsible to decide names of [entries](#)^{p609}. They can be the [name](#)^{p577} content attribute value, they can be strings based on the [name](#)^{p577} content attribute value, or they can be unrelated to the [name](#)^{p577} content attribute.

2. If the element does not have a [name](#)^{p577} attribute specified, or its [name](#)^{p577} attribute's value is the empty string, then return.
3. If the element's [submission value](#)^{p742} is not null, [create an entry](#)^{p609} with the [name](#)^{p577} attribute value and the [submission value](#)^{p742}, and [append](#) it to *entry list*.

4.13.7.4 Accessibility semantics §^{p74}₄

For web developers (non-normative)

`internals.role`^{p0} [= *value*]

Sets or retrieves the default ARIA role for *internals*'s [target element](#)^{p741}, which will be used unless the page author overrides it using the [role](#)^{p64} attribute.

`internals.aria*`^{p0} [= *value*]

Sets or retrieves various default ARIA states or property values for *internals*'s [target element](#)^{p741}, which will be used unless the page author overrides them using the [aria-*](#)^{p64} attributes.

Each [custom element](#)^{p728} has a **native accessibility semantics map**, which is a [map](#)^{p450}, initially empty. See the [Requirements related to ARIA and to platform accessibility APIs](#)^{p155} section for information on how this impacts platform accessibility APIs.

[ElementInternals](#)^{p740} includes the [ARIAMixin](#) mixin. The accessors provided by this mixin are used to manipulate the [target element](#)^{p741}'s [native accessibility semantics map](#)^{p744}, as follows:

The [ARIAMixin getter steps](#) for [ElementInternals](#)^{p740}, given *internals*, *idAttribute*, and *contentAttribute*, are:

1. Let *map* be *internals*'s [target element](#)^{p741}'s [native accessibility semantics map](#)^{p744}.
2. If *map*[*contentAttribute*] [exists](#), then return it.
3. Return null.

The [ARIAMixin setter steps](#) for [ElementInternals](#)^{p740}, given *internals*, *idAttribute*, *contentAttribute*, and *value*, are:

1. Let *map* be *internals*'s [target element](#)^{p741}'s [native accessibility semantics map](#)^{p744}.
2. If *value* is null, then [remove](#) *map*[*contentAttribute*].
3. Otherwise, [set](#) *map*[*contentAttribute*] to *value*.

4.14 Common idioms without dedicated elements §^{p74}₄

4.14.1 Breadcrumb navigation §^{p74}₄

This specification does not provide a machine-readable way of describing breadcrumb navigation menus. Authors are encouraged to just use a series of links in a paragraph. The [nav](#)^{p191} element can be used to mark the section containing these paragraphs as being navigation blocks.

Example

In the following example, the current page can be reached via two paths.

```
<nav>
  <p>
    <a href="/">Main</a> ▶
    <a href="/products/">Products</a> ▶
    <a href="/products/dishwashers/">Dishwashers</a> ▶
    <a>Second hand</a>
  </p>
  <p>
    <a href="/">Main</a> ▶
    <a href="/second-hand/">Second hand</a> ▶
    <a>Dishwashers</a>
  </p>
</nav>
```

4.14.2 Tag clouds § p74 5

This specification does not define any markup specifically for marking up lists of keywords that apply to a group of pages (also known as *tag clouds*). In general, authors are encouraged to either mark up such lists using [ul](#) p228 elements with explicit inline counts that are then hidden and turned into a presentational effect using a style sheet, or to use SVG.

Example

Here, three tags are included in a short tag cloud:

```
<style>
.tag-cloud > li > span { display: none; }
.tag-cloud > li { display: inline; }
.tag-cloud-1 { font-size: 0.7em; }
.tag-cloud-2 { font-size: 0.9em; }
.tag-cloud-3 { font-size: 1.1em; }
.tag-cloud-4 { font-size: 1.3em; }
.tag-cloud-5 { font-size: 1.5em; }

@media speech {
.tag-cloud > li > span { display:inline }
}
</style>
...
<ul class="tag-cloud">
<li class="tag-cloud-4"><a title="28 instances" href="/t/apple">apple</a> <span>(popular)</span>
<li class="tag-cloud-2"><a title="6 instances" href="/t/kiwi">kiwi</a> <span>(rare)</span>
<li class="tag-cloud-5"><a title="41 instances" href="/t/pear">pear</a> <span>(very
popular)</span>
</ul>
```

The actual frequency of each tag is given using the [title](#) p143 attribute. A CSS style sheet is provided to convert the markup into a cloud of differently-sized words, but for user agents that do not support CSS or are not visual, the markup contains annotations like "(popular)" or "(rare)" to categorize the various tags by frequency, thus enabling all users to benefit from the information.

The [ul](#) p228 element is used (rather than [ol](#) p226) because the order is not particularly important: while the list is in fact ordered alphabetically, it would convey the same information if ordered by, say, the length of the tag.

The [tag](#) p315 [rel](#) p290-keyword is *not* used on these [a](#) p244 elements because they do not represent tags that apply to the page itself; they are just part of an index listing the tags themselves.

4.14.3 Conversations § p74 5

This specification does not define a specific element for marking up conversations, meeting minutes, chat transcripts, dialogues in screenplays, instant message logs, and other situations where different players take turns in discourse.

Instead, authors are encouraged to mark up conversations using [p](#) p218 elements and punctuation. Authors who need to mark the speaker for styling purposes are encouraged to use [span](#) p285 or [b](#) p279. Paragraphs with their text wrapped in the [i](#) p278 element can be used for marking up stage directions.

Example

This example demonstrates this using an extract from Abbot and Costello's famous sketch, *Who's on first*:

```
<p> Costello: Look, you gotta first baseman?
<p> Abbott: Certainly.
<p> Costello: Who's playing first?
<p> Abbott: That's right.
<p> Costello becomes exasperated.
<p> Costello: When you pay off the first baseman every month, who gets the money?
<p> Abbott: Every dollar of it.
```

Example

The following extract shows how an IM conversation log could be marked up, using the [data^{p265}](#) element to provide Unix timestamps for each line. Note that the timestamps are provided in a format that the [time^{p266}](#) element does not support, so the [data^{p265}](#) element is used instead (namely, Unix `time_t` timestamps). Had the author wished to mark up the data using one of the date and time formats supported by the [time^{p266}](#) element, that element could have been used instead of [data^{p265}](#). This could be advantageous as it would allow data analysis tools to detect the timestamps unambiguously, without coordination with the page author.

```
<p> <data value="1319898155">14:22</data> <b>egof</b> I'm not that nerdy, I've only seen 30% of
the star trek episodes
<p> <data value="1319898192">14:23</data> <b>kaj</b> if you know what percentage of the star trek
episodes you have seen, you are inarguably nerdy
<p> <data value="1319898200">14:23</data> <b>egof</b> it's unarguably
<p> <data value="1319898228">14:23</data> <i>* kaj blinks</i>
<p> <data value="1319898260">14:24</data> <b>kaj</b> you are not helping your case
```

Example

HTML does not have a good way to mark up graphs, so descriptions of interactive conversations from games are more difficult to mark up. This example shows one possible convention using [dl^{p233}](#) elements to list the possible responses at each point in the conversation. Another option to consider is describing the conversation in the form of a DOT file, and outputting the result as an SVG image to place in the document. [\[DOT\]^{p1307}](#)

```
<p> Next, you meet a fisher. You can say one of several greetings:
<dl>
  <dt> "Hello there!"
  <dd>
    <p> She responds with "Hello, how may I help you?"; you can respond with:
    <dl>
      <dt> "I would like to buy a fish."
      <dd> <p> She sells you a fish and the conversation finishes.
      <dt> "Can I borrow your boat?"
      <dd>
        <p> She is surprised and asks "What are you offering in return?".
        <dl>
          <dt> "Five gold." (if you have enough)
          <dt> "Ten gold." (if you have enough)
          <dt> "Fifteen gold." (if you have enough)
          <dd> <p> She lends you her boat. The conversation ends.
          <dt> "A fish." (if you have one)
          <dt> "A newspaper." (if you have one)
          <dt> "A pebble." (if you have one)
          <dd> <p> "No thanks", she replies. Your conversation options
            at this point are the same as they were after asking to borrow
            her boat, minus any options you've suggested before.
        </dl>
      </dd>
    </dl>
  </dd>
  <dt> "Vote for me in the next election!"
  <dd> <p> She turns away. The conversation finishes.
  <dt> "Madam, are you aware that your fish are running away?"
  <dd>
    <p> She looks at you skeptically and says "Fish cannot run, miss".
    <dl>
      <dt> "You got me!"
      <dd> <p> The fisher sighs and the conversation ends.
      <dt> "Only kidding."
      <dd> <p> "Good one!" she retorts. Your conversation options at this
        point are the same as those following "Hello there!" above.
      <dt> "Oh, then what are they doing?"
```

```

<dd> <p> She looks at her fish, giving you an opportunity to steal
her boat, which you do. The conversation ends.
</dl>
</dd>
</dl>

```

Example

In some games, conversations are simpler: each character merely has a fixed set of lines that they say. In this example, a game FAQ/walkthrough lists some of the known possible responses for each character:

```

<section>
<h1>Dialogue</h1>
<p><small>Some characters repeat their lines in order each time you interact
with them, others randomly pick from amongst their lines. Those who respond in
order have numbered entries in the lists below.</small>
<h2>The Shopkeeper</h2>
<ul>
<li>How may I help you?
<li>Fresh apples!
<li>A loaf of bread for madam?
</ul>
<h2>The pilot</h2>
<p>Before the accident:
<ul>
<li>I'm about to fly out, sorry!
<li>Sorry, I'm just waiting for flight clearance and then I'll be off!
</ul>
<p>After the accident:
<ol>
<li>I'm about to fly out, sorry!
<li>Ok, I'm not leaving right now, my plane is being cleaned.
<li>Ok, it's not being cleaned, it needs a minor repair first.
<li>Ok, ok, stop bothering me! Truth is, I had a crash.
</ol>
<h2>Clan Leader</h2>
<p>During the first clan meeting:
<ul>
<li>Hey, have you seen my daughter? I bet she's up to something nefarious again...
<li>Nice weather we're having today, eh?
<li>The name is Bailey, Jeff Bailey. How can I help you today?
<li>A glass of water? Fresh from the well!
</ul>
<p>After the earthquake:
<ol>
<li>Everyone is safe in the shelter, we just have to put out the fire!
<li>I'll go and tell the fire brigade, you keep hosing it down!
</ol>
</section>

```

4.14.4 Footnotes ^{p74}

HTML does not have a dedicated mechanism for marking up footnotes. Here are the suggested alternatives.

For short inline annotations, the `titlep143` attribute could be used.

Example

In this example, two parts of a dialogue are annotated with footnote-like content using the `titlep143` attribute.

```
<p> <b>Customer</b>: Hello! I wish to register a complaint. Hello. Miss?
<p> <b>Shopkeeper</b>: <span title="Colloquial pronunciation of 'What do you'"
>Watcha</span> mean, miss?
<p> <b>Customer</b>: Uh, I'm sorry, I have a cold. I wish to make a complaint.
<p> <b>Shopkeeper</b>: Sorry, <span title="This is, of course, a lie.">we're
closing for lunch</span>.
```

Note

Unfortunately, relying on the `titlep143` attribute is currently discouraged as many user agents do not expose the attribute in an accessible manner as required by this specification (e.g. requiring a pointing device such as a mouse to cause a tooltip to appear, which excludes keyboard-only users and touch-only users, such as anyone with a modern phone or tablet).

Note

If the `titlep143` attribute is used, CSS can be used to draw the reader's attention to the elements with the attribute.

Example

For example, the following CSS places a dashed line below elements that have a `titlep143` attribute.

```
CSS [title] { border-bottom: thin dashed; }
```

For longer annotations, the `ap244` element should be used, pointing to an element later in the document. The convention is that the contents of the link be a number in square brackets.

Example

In this example, a footnote in the dialogue links to a paragraph below the dialogue. The paragraph then reciprocally links back to the dialogue, allowing the user to return to the location of the footnote.

```
<p> Announcer: Number 16: The <i>hand</i>.
<p> Interviewer: Good evening. I have with me in the studio tonight
Mr Norman St John Polevaulter, who for the past few years has been
contradicting people. Mr Polevaulter, why <em>do</em> you
contradict people?
<p> Norman: I don't. <sup><a href="#fn1" id="r1">[1]</a></sup>
<p> Interviewer: You told me you did!
...
<section>
  <p id="fn1"><a href="#r1">[1]</a> This is, naturally, a lie,
  but paradoxically if it were true he could not say so without
  contradicting the interviewer and thus making it false.</p>
</section>
```

For side notes, longer annotations that apply to entire sections of the text rather than just specific words or sentences, the `asidep194` element should be used.

Example

In this example, a sidebar is given after a dialogue, giving it some context.

```
<p> <span class="speaker">Customer</span>: I will not buy this record, it is scratched.
<p> <span class="speaker">Shopkeeper</span>: I'm sorry?
<p> <span class="speaker">Customer</span>: I will not buy this record, it is scratched.
<p> <span class="speaker">Shopkeeper</span>: No no no, this's'a tobacconist's.
```

```

<aside>
  <p>In 1970, the British Empire lay in ruins, and foreign
  nationalists frequented the streets – many of them Hungarians
  (not the streets – the foreign nationals). Sadly, Alexander
  Yalt has been publishing incompetently-written phrase books.
</aside>

```

For figures or tables, footnotes can be included in the relevant [figcaption^{p241}](#) or [caption^{p466}](#) element, or in surrounding prose.

Example

In this example, a table has cells with footnotes that are given in prose. A [figure^{p238}](#) element is used to give a single legend to the combination of the table and its footnotes.

```

<figure>
  <figcaption>Table 1. Alternative activities for knights.</figcaption>
  <table>
    <tr>
      <th> Activity
      <th> Location
      <th> Cost
    <tr>
      <td> Dance
      <td> Wherever possible
      <td> £0<sup><a href="#fn1">1</a></sup>
    <tr>
      <td> Routines, chorus scenes<sup><a href="#fn2">2</a></sup>
      <td> Undisclosed
      <td> Undisclosed
    <tr>
      <td> Dining<sup><a href="#fn3">3</a></sup>
      <td> Camelot
      <td> Cost of ham, jam, and spam<sup><a href="#fn4">4</a></sup>
    </table>
    <p id="fn1">1. Assumed.</p>
    <p id="fn2">2. Footwork impeccable.</p>
    <p id="fn3">3. Quality described as "well".</p>
    <p id="fn4">4. A lot.</p>
  </figure>

```

4.15 Disabled elements ^{§^{p74}}₉

An element is said to be **actually disabled** if it is one of the following:

- a [button^{p545}](#) element that is [disabled^{p580}](#)
- an [input^{p501}](#) element that is [disabled^{p580}](#)
- a [select^{p547}](#) element that is [disabled^{p580}](#)
- a [textarea^{p558}](#) element that is [disabled^{p580}](#)
- an [optgroup^{p554}](#) element that has a [disabled^{p555}](#) attribute
- an [option^{p555}](#) element that is [disabled^{p556}](#)
- a [fieldset^{p572}](#) element that is a [disabled fieldset^{p573}](#)

- a [form-associated custom element](#)^{p729} that is [disabled](#)^{p580}

Note

This definition is used to determine what elements are [focusable](#)^{p800} and which elements match the [:enabled](#)^{p753} and [:disabled](#)^{p753} pseudo classes.

4.16 Matching HTML elements using selectors and CSS ^{§ p75}₀

4.16.1 Case-sensitivity of the CSS ['attr\(\)'](#) function ^{§ p75}₀

CSS Values and Units leaves the case-sensitivity of attribute names for the purpose of the ['attr\(\)'](#) function to be defined by the host language. [\[CSSVALUES\]](#)^{p1307}

When comparing the attribute name part of a CSS ['attr\(\)'](#) function to the names of namespace-less attributes on [HTML elements](#)^{p44} in [HTML documents](#), the name part of the CSS ['attr\(\)'](#) function must first be [converted to ASCII lowercase](#). The same function when compared to other attributes must be compared according to its original case. In both cases, to match the values must be [identical to](#) each other (and therefore the comparison is case sensitive).

Note

This is the same as comparing the name part of a CSS [attribute selector](#), specified in the next section.

4.16.2 Case-sensitivity of selectors ^{§ p75}₀

Selectors leaves the case-sensitivity of element names, attribute names, and attribute values to be defined by the host language. [\[SELECTORS\]](#)^{p1311}

When comparing a CSS element [type selector](#) to the names of [HTML elements](#)^{p44} in [HTML documents](#), the CSS element [type selector](#) must first be [converted to ASCII lowercase](#). The same selector when compared to other elements must be compared according to its original case. In both cases, to match the values must be [identical to](#) each other (and therefore the comparison is case sensitive).

When comparing the name part of a CSS [attribute selector](#) to the names of attributes on [HTML elements](#)^{p44} in [HTML documents](#), the name part of the CSS [attribute selector](#) must first be [converted to ASCII lowercase](#). The same selector when compared to other attributes must be compared according to its original case. In both cases, the comparison is case-sensitive.

[Attribute selectors](#) on an [HTML element](#)^{p44} in an [HTML document](#) must treat the *values* of attributes with the following names as [ASCII case-insensitive](#):

- accept
- accept-charset
- align
- alink
- axis
- bgcolor
- charset
- checked
- clear
- codetype
- color
- compact
- declare
- defer
- dir
- direction
- disabled
- enctype
- face
- frame
- hreflang
- http-equiv
- lang
- language
- link
- media
- method

- multiple
- nohref
- noresize
- noshade
- nowrap
- readonly
- rel
- rev
- rules
- scope
- scrolling
- selected
- shape
- target
- text
- type
- valign
- valuetype
- vlink

Example

For example, the selector `[bgcolor="#ffffff"]` will match any HTML element with a `bgcolor` attribute with values including `#ffffff`, `#FFFFFF` and `#fffFFF`. This happens even if `bgcolor` has no effect for a given element (e.g., [div](#)^{p243}).

The selector `[type=a s]` will match any HTML element with a `type` attribute whose value is `a`, but not whose value is `A`, due to the `s` flag.

All other attribute values and everything else must be treated as entirely [identical to](#) each other for the purposes of selector matching. This includes:

- [IDs](#) and [classes](#) in [no-quirks mode](#) and [limited-quirks mode](#)
- the names of elements not in the [HTML namespace](#)
- the names of [HTML elements](#)^{p44} in [XML documents](#)
- the names of attributes of elements not in the [HTML namespace](#)
- the names of attributes of [HTML elements](#)^{p44} in [XML documents](#)
- the names of attributes that themselves have namespaces

Note

Selectors defines that ID and class selectors (such as `#foo` and `.bar`), when matched against elements in documents that are in [quirks mode](#), will be matched in an [ASCII case-insensitive](#) manner. However, this does not apply for attribute selectors with "id" or "class" as the name part. The selector `[class="foobar"]` will treat its value as case-sensitive even in [quirks mode](#).

4.16.3 Pseudo-classes §^{p75}₁

MDN

There are a number of dynamic selectors that can be used with HTML. This section defines when these selectors match HTML elements. [\[SELECTORS\]](#)^{p1311} [\[CSSUI\]](#)^{p1307}

:defined

✓ MDN

The [:defined](#)^{p751} [pseudo-class](#) must match any element that is [defined](#).

:link

✓ MDN

:visited

✓ MDN

All [a](#)^{p244} elements that have an [href](#)^{p290} attribute, and all [area](#)^{p452} elements that have an [href](#)^{p290} attribute, must match one of [:link](#)^{p751} and [:visited](#)^{p751}.

Other specifications might apply more specific rules regarding how these elements are to match these [pseudo-classes](#), to mitigate some privacy concerns that apply with straightforward implementations of this requirement.

:active

✓ MDN

The [:active](#)^{p751} [pseudo-class](#) is defined to match an element “while an element is **being activated** by the user”.

To determine whether a particular element is [being activated](#)^{p751} for the purposes of defining the [:active](#)^{p751} [pseudo-class](#) only, an HTML user agent must use the first relevant entry in the following list.

If the element is a [button](#)^{p545} element

If the element is an [input](#)^{p501} element whose [type](#)^{p503} attribute is in the [Submit Button](#)^{p526}, [Image Button](#)^{p526}, [Reset Button](#)^{p529}, or [Button](#)^{p529} state

If the element is an [a](#)^{p244} element that has an [href](#)^{p290} attribute

If the element is an [area](#)^{p452} element that has an [href](#)^{p290} attribute

If the element is [focusable](#)^{p800}

The element is [being activated](#)^{p751} if it is in a [formal activation state](#)^{p752}.

Example

For example, if the user is using a keyboard to push a [button](#)^{p545} element by pressing the space bar, the element would match this [pseudo-class](#) in between the time that the element received the [keydown](#) event and the time the element received the [keyup](#) event.

If the element is [being actively pointed at](#)^{p752}

The element is [being activated](#)^{p751}.

An element is said to be **in a formal activation state** between the time the user begins to indicate an intent to trigger the element's [activation behavior](#) and either the time the user stops indicating an intent to trigger the element's [activation behavior](#), or the time the element's [activation behavior](#) has finished running, whichever comes first.

An element is said to be **being actively pointed at** while the user indicates the element using a pointing device while that pointing device is in the "down" state (e.g. for a mouse, between the time the mouse button is pressed and the time it is depressed; for a finger in a multitouch environment, while the finger is touching the display surface).

Note

Per the definition in [Selectors](#), [:active](#)^{p751} also matches [flat tree](#) ancestors of elements that are [being activated](#)^{p751}.
[\[SELECTORS\]](#)^{p1311}

Additionally, any element that is the [labeled control](#)^{p499} of a [label](#)^{p498} element that is currently matching [:active](#)^{p751}, also matches [:active](#)^{p751}. (But, it does not count as being [being activated](#)^{p751}.)

:hover

The [:hover](#)^{p752} [pseudo-class](#) is defined to match an element "while the user **designates** an element with a pointing device". For the purposes of defining the [:hover](#)^{p752} [pseudo-class](#) only, an HTML user agent must consider an element as being one that the user [designates](#)^{p752} if it is an element that the user indicates using a pointing device.

Note

Per the definition in [Selectors](#), [:hover](#)^{p752} also matches [flat tree](#) ancestors of elements that are [designated](#)^{p752}.
[\[SELECTORS\]](#)^{p1311}

Additionally, any element that is the [labeled control](#)^{p499} of a [label](#)^{p498} element that is currently matching [:hover](#)^{p752}, also matches [:hover](#)^{p752}. (But, it does not count as being [designated](#)^{p752}.)

Example

Consider in particular a fragment such as:

```
<p> <label for=c> <input id=a> </label> <span id=b> <input id=c> </span> </p>
```

If the user designates the element with ID "a" with their pointing device, then the [p](#)^{p218} element (and all its ancestors not shown in the snippet above), the [label](#)^{p498} element, the element with ID "a", and the element with ID "c" will match the [:hover](#)^{p752} [pseudo-class](#). The element with ID "a" matches it by being [designated](#)^{p752}; the [label](#)^{p498} and [p](#)^{p218} elements match it because of the condition in [Selectors](#) about flat tree ancestors; and the element with ID "c" matches it through the additional condition above on [labeled controls](#)^{p499} (i.e., its [label](#)^{p498} element matches [:hover](#)^{p752}). However, the element with ID "b" does *not* match [:hover](#)^{p752}: its flat tree descendant is not designated, even though that flat tree descendant matches [:hover](#)^{p752}.

:focus

For the purposes of the CSS [:focus](#)^{p752} [pseudo-class](#), an **element has the focus** when:

- it is not itself a [browsing context container](#)^{p843}; and

- at least one of the following is true:
 - it is one of the elements listed in the [current focus chain of the top-level browsing context](#)^{p799}, or
 - its [shadow root](#) `shadowRoot` is not null and `shadowRoot` is the [root](#) of at least one element that [has the focus](#)^{p752}.

:target

For the purposes of the CSS [:target](#)^{p752} [pseudo-class](#), the [Document](#)^{p117}'s *target elements* are a list containing the [Document](#)^{p117}'s [target element](#)^{p922}, if it is not null, or containing no elements, if it is. [\[SELECTORS\]](#)^{p1311}

:enabled

The [:enabled](#)^{p753} [pseudo-class](#) must match any [button](#)^{p545}, [input](#)^{p501}, [select](#)^{p547}, [textarea](#)^{p558}, [optgroup](#)^{p554}, [option](#)^{p555}, [fieldset](#)^{p572} element, or [form-associated custom element](#)^{p729} that is not [actually disabled](#)^{p749}.

:disabled

The [:disabled](#)^{p753} [pseudo-class](#) must match any element that is [actually disabled](#)^{p749}.

:checked

The [:checked](#)^{p753} [pseudo-class](#) must match any element falling into one of the following categories:

- [input](#)^{p501} elements whose [type](#)^{p503} attribute is in the [Checkbox](#)^{p521} state and whose [checkedness](#)^{p575} state is true
- [input](#)^{p501} elements whose [type](#)^{p503} attribute is in the [Radio Button](#)^{p522} state and whose [checkedness](#)^{p575} state is true
- [option](#)^{p555} elements whose [selectedness](#)^{p556} is true

:indeterminate

The [:indeterminate](#)^{p753} [pseudo-class](#) must match any element falling into one of the following categories:

- [input](#)^{p501} elements whose [type](#)^{p503} attribute is in the [Checkbox](#)^{p521} state and whose [indeterminate](#)^{p507} IDL attribute is set to true
- [input](#)^{p501} elements whose [type](#)^{p503} attribute is in the [Radio Button](#)^{p522} state and whose [radio button group](#)^{p522} contains no [input](#)^{p501} elements whose [checkedness](#)^{p575} state is true.
- [progress](#)^{p565} elements with no [value](#)^{p566} content attribute

:default

The [:default](#)^{p753} [pseudo-class](#) must match any element falling into one of the following categories:

- [Submit buttons](#)^{p494} that are [default buttons](#)^{p605} of their [form owner](#)^{p576}.
- [input](#)^{p501} elements to which the [checked](#)^{p505} attribute applies and that have a [checked](#)^{p505} attribute
- [option](#)^{p555} elements that have a [selected](#)^{p556} attribute

:placeholder-shown

The [:placeholder-shown](#)^{p753} [pseudo-class](#) must match any element falling into one of the following categories:

- [input](#)^{p501} elements that have a [placeholder](#)^{p539} attribute whose value is currently being presented to the user.
- [textarea](#)^{p558} elements that have a [placeholder](#)^{p561} attribute whose value is currently being presented to the user.

:valid

The [:valid](#)^{p753} [pseudo-class](#) must match any element falling into one of the following categories:

- elements that are [candidates for constraint validation](#)^{p599} and that [satisfy their constraints](#)^{p601}
- [form](#)^{p494} elements that are not the [form owner](#)^{p576} of any elements that themselves are [candidates for constraint validation](#)^{p599} but do not [satisfy their constraints](#)^{p601}
- [fieldset](#)^{p572} elements that have no descendant elements that themselves are [candidates for constraint validation](#)^{p599} but do not [satisfy their constraints](#)^{p601}

:invalid

The [:invalid](#)^{p753} [pseudo-class](#) must match any element falling into one of the following categories:

- elements that are [candidates for constraint validation](#)^{p599} but that do not [satisfy their constraints](#)^{p601}
- [form](#)^{p494} elements that are the [form owner](#)^{p576} of one or more elements that themselves are [candidates for constraint validation](#)^{p599} but do not [satisfy their constraints](#)^{p601}
- [fieldset](#)^{p572} elements that have one or more descendant elements that themselves are [candidates for constraint validation](#)^{p599} but do not [satisfy their constraints](#)^{p601}

:in-range

The [:in-range](#)^{p754} [pseudo-class](#) must match all elements that are [candidates for constraint validation](#)^{p599}, [have range limitations](#)^{p535}, and that are neither [suffering from an underflow](#)^{p600} nor [suffering from an overflow](#)^{p600}.

:out-of-range

The [:out-of-range](#)^{p754} [pseudo-class](#) must match all elements that are [candidates for constraint validation](#)^{p599}, [have range limitations](#)^{p535}, and that are either [suffering from an underflow](#)^{p600} or [suffering from an overflow](#)^{p600}.

:required

The [:required](#)^{p754} [pseudo-class](#) must match any element falling into one of the following categories:

- [input](#)^{p501} elements that are [required](#)^{p531}
- [select](#)^{p547} elements that have a [required](#)^{p549} attribute
- [textarea](#)^{p558} elements that have a [required](#)^{p561} attribute

:optional

The [:optional](#)^{p754} [pseudo-class](#) must match any element falling into one of the following categories:

- [input](#)^{p501} elements to which the [required](#)^{p531} attribute applies that are not [required](#)^{p531}
- [select](#)^{p547} elements that do not have a [required](#)^{p549} attribute
- [textarea](#)^{p558} elements that do not have a [required](#)^{p561} attribute

:autofill

:-webkit-autofill

The [:autofill](#)^{p754} and [:-webkit-autofill](#)^{p754} [pseudo-classes](#) must match [input](#)^{p501} elements which have been autofilled by user agent. These pseudo-classes must stop matching if the user edits the autofilled field.

Note

One way such autofilling might happen is via the [autocomplete](#)^{p582} attribute, but user agents could autofill even without that attribute being involved.

:read-only

:read-write

The [:read-write](#)^{p754} [pseudo-class](#) must match any element falling into one of the following categories, which for the purposes of Selectors are thus considered *user-alterable*: [\[SELECTORS\]](#)^{p1311}

- [input](#)^{p501} elements to which the [readonly](#)^{p531} attribute applies, and that are [mutable](#)^{p576} (i.e. that do not have the [readonly](#)^{p531} attribute specified and that are not [disabled](#)^{p580})
- [textarea](#)^{p558} elements that do not have a [readonly](#)^{p559} attribute, and that are not [disabled](#)^{p580}
- elements that are [editing hosts](#)^{p817} or [editable](#) and are neither [input](#)^{p501} elements nor [textarea](#)^{p558} elements

The [:read-only](#)^{p754} [pseudo-class](#) must match all other [HTML elements](#)^{p44}.

:dir(ltr)

The [:dir\(ltr\)](#)^{p754} [pseudo-class](#) must match all elements whose [directionality](#)^{p146} is '[ltr](#)^{p146}'.

:dir(rtl)

The [:dir\(rtl\)](#)^{p754} [pseudo-class](#) must match all elements whose [directionality](#)^{p146} is '[rtl](#)^{p146}'.

Note

This specification does not define when an element matches the `:lang()` dynamic *pseudo-class*, as it is defined in sufficient detail in a language-agnostic fashion in Selectors. [\[SELECTORS\]#p1311](#)

5 Microdata §^{p75}₆

5.1 Introduction §^{p75}₆

5.1.1 Overview §^{p75}₆

This section is non-normative.

Sometimes, it is desirable to annotate content with specific machine-readable labels, e.g. to allow generic scripts to provide services that are customized to the page, or to enable content from a variety of cooperating authors to be processed by a single script in a consistent manner.

For this purpose, authors can use the microdata features described in this section. Microdata allows nested groups of name-value pairs to be added to documents, in parallel with the existing content.

5.1.2 The basic syntax §^{p75}₆

This section is non-normative.

At a high level, microdata consists of a group of name-value pairs. The groups are called [items^{p761}](#), and each name-value pair is a property. Items and properties are represented by regular elements.

To create an item, the [itemscope^{p761}](#) attribute is used.

To add a property to an item, the [itemprop^{p763}](#) attribute is used on one of the [item's^{p761}](#) descendants.

Example

Here there are two items, each of which has the property "name":

```
<div itemscope>
  <p>My name is <span itemprop="name">Elizabeth</span>.</p>
</div>

<div itemscope>
  <p>My name is <span itemprop="name">Daniel</span>.</p>
</div>
```

Markup without the microdata-related attributes does not have any effect on the microdata model.

Example

These two examples are exactly equivalent, at a microdata level, as the previous two examples respectively:

```
<div itemscope>
  <p>My <em>name</em> is <span itemprop="name">E<strong>liz</strong>abeth</span>.</p>
</div>

<section>
  <div itemscope>
    <aside>
      <p>My name is <span itemprop="name"><a href="/?user=daniel">Daniel</a></span>.</p>
    </aside>
  </div>
</section>
```

Properties generally have values that are strings.

Example

Here the item has three properties:

```
<div itemscope>
  <p>My name is <span itemprop="name">Neil</span>.</p>
  <p>My band is called <span itemprop="band">Four Parts Water</span>.</p>
  <p>I am <span itemprop="nationality">British</span>.</p>
</div>
```

When a string value is a [URL](#), it is expressed using the [a^{p244}](#) element and its [href^{p290}](#) attribute, the [img^{p327}](#) element and its [src^{p328}](#) attribute, or other elements that link to or embed external resources.

Example

In this example, the item has one property, "image", whose value is a URL:

```
<div itemscope>
  
</div>
```

When a string value is in some machine-readable format unsuitable for human consumption, it is expressed using the [value^{p266}](#) attribute of the [data^{p265}](#) element, with the human-readable version given in the element's contents.

Example

Here, there is an item with a property whose value is a product ID. The ID is not human-friendly, so the product's name is used the human-visible text instead of the ID.

```
<h1 itemscope>
  <data itemprop="product-id" value="9678A0U879">The Instigator 2000</data>
</h1>
```

For numeric data, the [meter^{p567}](#) element and its [value^{p568}](#) attribute can be used instead.

Example

Here a rating is given using a [meter^{p567}](#) element.

```
<div itemscope itemtype="http://schema.org/Product">
  <span itemprop="name">Panasonic White 60L Refrigerator</span>
  
  <div itemprop="aggregateRating"
    itemscope itemtype="http://schema.org/AggregateRating">
    <meter itemprop="ratingValue" min=0 value=3.5 max=5>Rated 3.5/5</meter>
    (based on <span itemprop="reviewCount">11</span> customer reviews)
  </div>
</div>
```

Similarly, for date- and time-related data, the [time^{p266}](#) element and its [datetime^{p267}](#) attribute can be used instead.

Example

In this example, the item has one property, "birthday", whose value is a date:

```
<div itemscope>
  I was born on <time itemprop="birthday" datetime="2009-05-10">May 10th 2009</time>.
</div>
```

Properties can also themselves be groups of name-value pairs, by putting the [itemscope^{p761}](#) attribute on the element that declares the property.

Items that are not part of others are called [top-level microdata items](#)^{p766}.

Example

In this example, the outer item represents a person, and the inner one represents a band:

```
<div itemscope>
  <p>Name: <span itemprop="name">Amanda</span></p>
  <p>Band: <span itemprop="band" itemscope> <span itemprop="name">Jazz Band</span> (<span
itemprop="size">12</span> players)</span></p>
</div>
```

The outer item here has two properties, "name" and "band". The "name" is "Amanda", and the "band" is an item in its own right, with two properties, "name" and "size". The "name" of the band is "Jazz Band", and the "size" is "12".

The outer item in this example is a top-level microdata item.

Properties that are not descendants of the element with the [itemscope](#)^{p761} attribute can be associated with the [item](#)^{p761} using the [itemref](#)^{p762} attribute. This attribute takes a list of IDs of elements to crawl in addition to crawling the children of the element with the [itemscope](#)^{p761} attribute.

Example

This example is the same as the previous one, but all the properties are separated from their [items](#)^{p761}:

```
<div itemscope id="amanda" itemref="a b"></div>
<p id="a">Name: <span itemprop="name">Amanda</span></p>
<div id="b" itemprop="band" itemscope itemref="c"></div>
<div id="c">
  <p>Band: <span itemprop="name">Jazz Band</span></p>
  <p>Size: <span itemprop="size">12</span> players</p>
</div>
```

This gives the same result as the previous example. The first item has two properties, "name", set to "Amanda", and "band", set to another item. That second item has two further properties, "name", set to "Jazz Band", and "size", set to "12".

An [item](#)^{p761} can have multiple properties with the same name and different values.

Example

This example describes an ice cream, with two flavors:

```
<div itemscope>
  <p>Flavors in my favorite ice cream:</p>
  <ul>
    <li itemprop="flavor">Lemon sorbet</li>
    <li itemprop="flavor">Apricot sorbet</li>
  </ul>
</div>
```

This thus results in an item with two properties, both "flavor", having the values "Lemon sorbet" and "Apricot sorbet".

An element introducing a property can also introduce multiple properties at once, to avoid duplication when some of the properties have the same value.

Example

Here we see an item with two properties, "favorite-color" and "favorite-fruit", both set to the value "orange":

```
<div itemscope>
  <span itemprop="favorite-color favorite-fruit">orange</span>
</div>
```

It's important to note that there is no relationship between the microdata and the content of the document where the microdata is marked up.

Example

There is no semantic difference, for instance, between the following two examples:

```
<figure>
  
  <figcaption><span itemscope><span itemprop="name">The Castle</span></span> (1986)</figcaption>
</figure>
```

```
<span itemscope><meta itemprop="name" content="The Castle"></span>
<figure>
  
  <figcaption>The Castle (1986)</figcaption>
</figure>
```

Both have a figure with a caption, and both, completely unrelated to the figure, have an item with a name-value pair with the name "name" and the value "The Castle". The only difference is that if the user drags the caption out of the document, in the former case, the item will be included in the drag-and-drop data. In neither case is the image in any way associated with the item.

5.1.3 Typed items §^{p75}₉

This section is non-normative.

The examples in the previous section show how information could be marked up on a page that doesn't expect its microdata to be re-used. Microdata is most useful, though, when it is used in contexts where other authors and readers are able to cooperate to make new uses of the markup.

For this purpose, it is necessary to give each [item^{p761}](#) a type, such as "https://example.com/person", or "https://example.org/cat", or "https://band.example.net/". Types are identified as [URLs](#).

The type for an [item^{p761}](#) is given as the value of an [itemtype^{p761}](#) attribute on the same element as the [itemscope^{p761}](#) attribute.

Example

Here, the item's type is "https://example.org/animals#cat":

```
<section itemscope itemtype="https://example.org/animals#cat">
  <h1 itemprop="name">Hedral</h1>
  <p itemprop="desc">Hedral is a male american domestic
  shorthair, with a fluffy black fur with white paws and belly.</p>
  
</section>
```

In this example the "https://example.org/animals#cat" item has three properties, a "name" ("Hedral"), a "desc" ("Hedral is..."), and an "img" ("hedral.jpeg").

The type gives the context for the properties, thus selecting a vocabulary: a property named "class" given for an item with the type "https://census.example/person" might refer to the economic class of an individual, while a property named "class" given for an item with the type "https://example.com/school/teacher" might refer to the classroom a teacher has been assigned. Several types can share a vocabulary. For example, the types "https://example.org/people/teacher" and "https://example.org/people/engineer" could be defined to use the same vocabulary (though maybe some properties would not be especially useful in both cases, e.g. maybe the "https://example.org/people/engineer" type might not typically be used with the "classroom" property). Multiple types defined to use the same vocabulary can be given for a single item by listing the URLs as a space-separated list in the attribute's value. An item cannot be given two types if they do not use the same vocabulary, however.

5.1.4 Global identifiers for items ^{§ p76}₀

This section is non-normative.

Sometimes, an [item^{p761}](#) gives information about a topic that has a global identifier. For example, books can be identified by their ISBN number.

Vocabularies (as identified by the [itemtype^{p761}](#) attribute) can be designed such that [items^{p761}](#) get associated with their global identifier in an unambiguous way by expressing the global identifiers as [URLs](#) given in an [itemid^{p762}](#) attribute.

The exact meaning of the [URLs](#) given in [itemid^{p762}](#) attributes depends on the vocabulary used.

Example

Here, an item is talking about a particular book:

```
<dl itemscope
  itemtype="https://vocab.example.net/book"
  itemid="urn:isbn:0-330-34032-8">
  <dt>Title
  <dd itemprop="title">The Reality Dysfunction
  <dt>Author
  <dd itemprop="author">Peter F. Hamilton
  <dt>Publication date
  <dd><time itemprop="pubdate" datetime="1996-01-26">26 January 1996</time>
</dl>
```

The "https://vocab.example.net/book" vocabulary in this example would define that the [itemid^{p762}](#) attribute takes a [urn: URL](#) pointing to the ISBN of the book.

5.1.5 Selecting names when defining vocabularies ^{§ p76}₀

This section is non-normative.

Using microdata means using a vocabulary. For some purposes, an ad-hoc vocabulary is adequate. For others, a vocabulary will need to be designed. Where possible, authors are encouraged to re-use existing vocabularies, as this makes content re-use easier.

When designing new vocabularies, identifiers can be created either using [URLs](#), or, for properties, as plain words (with no dots or colons). For URLs, conflicts with other vocabularies can be avoided by only using identifiers that correspond to pages that the author has control over.

Example

For instance, if Jon and Adam both write content at example.com, at <https://example.com/~jon/>... and <https://example.com/~adam/>... respectively, then they could select identifiers of the form "https://example.com/~jon/name" and "https://example.com/~adam/name" respectively.

Properties whose names are just plain words can only be used within the context of the types for which they are intended; properties named using URLs can be reused in items of any type. If an item has no type, and is not part of another item, then if its properties have names that are just plain words, they are not intended to be globally unique, and are instead only intended for limited use. Generally speaking, authors are encouraged to use either properties with globally unique names (URLs) or ensure that their items are typed.

Example

Here, an item is an "https://example.org/animals#cat", and most of the properties have names that are words defined in the context of that type. There are also a few additional properties whose names come from other vocabularies.

```
<section itemscope itemtype="https://example.org/animals#cat">
  <h1 itemprop="name https://example.com/fn">Hedral</h1>
  <p itemprop="desc">Hedral is a male American domestic
```

```

shorthair, with a fluffy <span
itemprop="https://example.com/color">black</span> fur with <span
itemprop="https://example.com/color">white</span> paws and belly.</p>

</section>

```

This example has one item with the type "https://example.org/animals#cat" and the following properties:

Property	Value
name	Hedral
https://example.com/fn	Hedral
desc	Hedral is a male American domestic shorthair, with a fluffy black fur with white paws and belly.
https://example.com/color	black
https://example.com/color	white
img	.../hedral.jpeg

5.2 Encoding microdata §^{p76}₁

5.2.1 The microdata model §^{p76}₁

The microdata model consists of groups of name-value pairs known as [items](#)^{p761}.

Each group is known as an [item](#)^{p761}. Each [item](#)^{p761} can have [item types](#)^{p761}, a [global identifier](#)^{p762} (if the vocabulary specified by the [item types](#)^{p761} [support global identifiers for items](#)^{p762}), and a list of name-value pairs. Each name in the name-value pair is known as a [property](#)^{p766}, and each [property](#)^{p766} has one or more [values](#)^{p765}. Each [value](#)^{p765} is either a string or itself a group of name-value pairs (an [item](#)^{p761}). The names are unordered relative to each other, but if a particular name has multiple values, they do have a relative order.

5.2.2 Items §^{p76}₁

Every [HTML element](#)^{p44} may have an [itemscope](#) attribute specified. The [itemscope](#)^{p761} attribute is a [boolean attribute](#)^{p69}. ✓ MDN

An element with the [itemscope](#)^{p761} attribute specified creates a new **item**, a group of name-value pairs.

Elements with an [itemscope](#)^{p761} attribute may have an [itemtype](#) attribute specified, to give the [item types](#)^{p761} of the [item](#)^{p761}. ✓ MDN

The [itemtype](#)^{p761} attribute, if specified, must have a value that is an [unordered set of unique space-separated tokens](#)^{p89}, none of which are [identical to](#) another token and each of which is a [valid URL string](#) that is an [absolute URL](#), and all of which are defined to use the same vocabulary. The attribute's value must have at least one token.

The **item types** of an [item](#)^{p761} are the tokens obtained by [splitting the element's itemtype attribute's value on ASCII whitespace](#). If the [itemtype](#)^{p761} attribute is missing or parsing it in this way finds no tokens, the [item](#)^{p761} is said to have no [item types](#)^{p761}.

The [item types](#)^{p761} must all be types defined in [applicable specifications](#)^{p67} and must all be defined to use the same vocabulary.

Except if otherwise specified by that specification, the [URLs](#) given as the [item types](#)^{p761} should not be automatically dereferenced.

Note

A specification could define that its [item type](#)^{p761} can be dereferenced to provide the user with help information, for example. In fact, vocabulary authors are encouraged to provide useful information at the given [URL](#).

[Item types](#)^{p761} are opaque identifiers, and user agents must not dereference unknown [item types](#)^{p761}, or otherwise deconstruct them, in order to determine how to process [items](#)^{p761} that use them.

The [itemtype](#)^{p761} attribute must not be specified on elements that do not have an [itemscope](#)^{p761} attribute specified.

An [item^{p761}](#) is said to be a **typed item** when either it has an [item type^{p761}](#), or it is the [value^{p765}](#) of a [property^{p766}](#) of a [typed item^{p762}](#). The **relevant types** for a [typed item^{p762}](#) is the [item^{p761}](#)'s [item types^{p761}](#), if it has any, or else is the [relevant types^{p762}](#) of the [item^{p761}](#) for which it is a [property^{p766}](#)'s [value^{p765}](#).

Elements with an [itemscope^{p761}](#) attribute and an [itemtype^{p761}](#) attribute that references a vocabulary that is defined to **support global identifiers for items** may also have an **itemid** attribute specified, to give a global identifier for the [item^{p761}](#), so that it can be related to other [items^{p761}](#) on pages elsewhere on the web.

The [itemid^{p762}](#) attribute, if specified, must have a value that is a [valid URL potentially surrounded by spaces^{p90}](#).

The **global identifier** of an [item^{p761}](#) is the value of its element's [itemid^{p762}](#) attribute, if it has one, [parsed^{p91}](#) relative to the [node document](#) of the element on which the attribute is specified. If the [itemid^{p762}](#) attribute is missing or if resolving it fails, it is said to have no [global identifier^{p762}](#).

The [itemid^{p762}](#) attribute must not be specified on elements that do not have both an [itemscope^{p761}](#) attribute and an [itemtype^{p761}](#) attribute specified, and must not be specified on elements with an [itemscope^{p761}](#) attribute whose [itemtype^{p761}](#) attribute specifies a vocabulary that does not [support global identifiers for items^{p762}](#), as defined by that vocabulary's specification.

The exact meaning of a [global identifier^{p762}](#) is determined by the vocabulary's specification. It is up to such specifications to define whether multiple items with the same global identifier (whether on the same page or on different pages) are allowed to exist, and what the processing rules for that vocabulary are with respect to handling the case of multiple items with the same ID.

Elements with an [itemscope^{p761}](#) attribute may have an **itemref** attribute specified, to give a list of additional elements to crawl to find the name-value pairs of the [item^{p761}](#).

The [itemref^{p762}](#) attribute, if specified, must have a value that is an [unordered set of unique space-separated tokens^{p89}](#) none of which are [identical to](#) another token and consisting of [IDs](#) of elements in the same [tree](#).

The [itemref^{p762}](#) attribute must not be specified on elements that do not have an [itemscope^{p761}](#) attribute specified.

Note

The [itemref^{p762}](#) attribute is not part of the microdata data model. It is merely a syntactic construct to aid authors in adding annotations to pages where the data to be annotated does not follow a convenient tree structure. For example, it allows authors to mark up data in a table so that each column defines a separate [item^{p761}](#), while keeping the properties in the cells.

Example

This example shows a simple vocabulary used to describe the products of a model railway manufacturer. The vocabulary has just five property names:

product-code

An integer that names the product in the manufacturer's catalog.

name

A brief description of the product.

scale

One of "HO", "1", or "Z" (potentially with leading or trailing whitespace), indicating the scale of the product.

digital

If present, one of "Digital", "Delta", or "Systems" (potentially with leading or trailing whitespace) indicating that the product has a digital decoder of the given type.

track-type

For track-specific products, one of "K", "M", "C" (potentially with leading or trailing whitespace) indicating the type of track for which the product is intended.

This vocabulary has four defined [item types^{p761}](#):

https://md.example.com/loco

Rolling stock with an engine

<https://md.example.com/passengers>

Passenger rolling stock

<https://md.example.com/track>

Track pieces

<https://md.example.com/lighting>

Equipment with lighting

Each [item^{p761}](#) that uses this vocabulary can be given one or more of these types, depending on what the product is.

Thus, a locomotive might be marked up as:

```
<dl itemscope itemtype="https://md.example.com/loco
                        https://md.example.com/lighting">
  <dt>Name:
  <dd itemprop="name">Tank Locomotive (DB 80)
  <dt>Product code:
  <dd itemprop="product-code">33041
  <dt>Scale:
  <dd itemprop="scale">H0
  <dt>Digital:
  <dd itemprop="digital">Delta
</dl>
```

A turnout lantern retrofit kit might be marked up as:

```
<dl itemscope itemtype="https://md.example.com/track
                        https://md.example.com/lighting">
  <dt>Name:
  <dd itemprop="name">Turnout Lantern Kit
  <dt>Product code:
  <dd itemprop="product-code">74470
  <dt>Purpose:
  <dd>For retrofitting 2 <span itemprop="track-type">C</span> Track
  turnouts. <meta itemprop="scale" content="H0">
</dl>
```

A passenger car with no lighting might be marked up as:

```
<dl itemscope itemtype="https://md.example.com/passengers">
  <dt>Name:
  <dd itemprop="name">Express Train Passenger Car (DB Am 203)
  <dt>Product code:
  <dd itemprop="product-code">8710
  <dt>Scale:
  <dd itemprop="scale">Z
</dl>
```

Great care is necessary when creating new vocabularies. Often, a hierarchical approach to types can be taken that results in a vocabulary where each item only ever has a single type, which is generally much simpler to manage.

5.2.3 Names: the `itemprop` attribute §^{p76}₃

Every [HTML element^{p44}](#) may have an [`itemprop`^{p763}](#) attribute specified, if doing so [adds one or more properties^{p766}](#) to one or more [items^{p761}](#) (as defined below).

The [`itemprop`^{p763}](#) attribute, if specified, must have a value that is an [unordered set of unique space-separated tokens^{p89}](#) none of which

are [identical to](#) another token, representing the names of the name-value pairs that it adds. The attribute's value must have at least one token.

Each token must be either:

- If the item is a [typed item](#)^{p762}: a **defined property name** allowed in this situation according to the specification that defines the [relevant types](#)^{p762} for the item, or
- A [valid URL string](#) that is an [absolute URL](#) defined as an item property name allowed in this situation by a vocabulary specification, or
- A [valid URL string](#) that is an [absolute URL](#), used as a proprietary item property name (i.e. one used by the author for private purposes, not defined in a public specification), or
- If the item is not a [typed item](#)^{p762}: a string that contains no U+002E FULL STOP characters (.) and no U+003A COLON characters (:), used as a proprietary item property name (i.e. one used by the author for private purposes, not defined in a public specification).

Specifications that introduce [defined property names](#)^{p764} must ensure all such property names contain no U+002E FULL STOP characters (.), no U+003A COLON characters (:), and no [ASCII whitespace](#).

Note

The rules above disallow U+003A COLON characters (:) in non-URL values because otherwise they could not be distinguished from URLs. Values with U+002E FULL STOP characters (.) are reserved for future extensions. [ASCII whitespace](#) are disallowed because otherwise the values would be parsed as multiple tokens.

When an element with an [itemprop](#)^{p763} attribute [adds a property](#)^{p766} to multiple [items](#)^{p761}, the requirement above regarding the tokens applies for each [item](#)^{p761} individually.

The **property names** of an element are the tokens that the element's [itemprop](#)^{p763} attribute is found to contain when its value is [split on ASCII whitespace](#), with the order preserved but with duplicates removed (leaving only the first occurrence of each name).

Within an [item](#)^{p761}, the properties are unordered with respect to each other, except for properties with the same name, which are ordered in the order they are given by the algorithm that defines [the properties of an item](#)^{p766}.

Example

In the following example, the "a" property has the values "1" and "2", *in that order*, but whether the "a" property comes before the "b" property or not is not important:

```
<div itemscope>
  <p itemprop="a">1</p>
  <p itemprop="a">2</p>
  <p itemprop="b">test</p>
</div>
```

Thus, the following is equivalent:

```
<div itemscope>
  <p itemprop="b">test</p>
  <p itemprop="a">1</p>
  <p itemprop="a">2</p>
</div>
```

As is the following:

```
<div itemscope>
  <p itemprop="a">1</p>
  <p itemprop="b">test</p>
  <p itemprop="a">2</p>
</div>
```

And the following:

```
<div id="x">
  <p itemprop="a">1</p>
</div>
<div itemscope itemref="x">
  <p itemprop="b">test</p>
  <p itemprop="a">2</p>
</div>
```

5.2.4 Values ^{§ p76}₅

The **property value** of a name-value pair added by an element with an `itemprop`^{p763} attribute is as given for the first matching case in the following list:

↪ **If the element also has an `itemscope`^{p761} attribute**

The value is the `item`^{p761} created by the element.

↪ **If the element is a `meta`^{p170} element**

The value is the value of the element's `content`^{p171} attribute, if any, or the empty string if there is no such attribute.

↪ **If the element is an `audio`^{p392}, `embed`^{p378}, `iframe`^{p369}, `img`^{p327}, `source`^{p324}, `track`^{p393}, or `video`^{p388} element**

The value is the `resulting URL string`^{p91} that results from `parsing`^{p91} the value of the element's `src` attribute relative to the `node document` of the element at the time the attribute is set, or the empty string if there is no such attribute or if `parsing`^{p91} it results in an error.

↪ **If the element is an `a`^{p244}, `area`^{p452}, or `link`^{p162} element**

The value is the `resulting URL string`^{p91} that results from `parsing`^{p91} the value of the element's `href` attribute relative to the `node document` of the element at the time the attribute is set, or the empty string if there is no such attribute or if `parsing`^{p91} it results in an error.

↪ **If the element is an `object`^{p381} element**

The value is the `resulting URL string`^{p91} that results from `parsing`^{p91} the value of the element's `data` attribute relative to the `node document` of the element at the time the attribute is set, or the empty string if there is no such attribute or if `parsing`^{p91} it results in an error.

↪ **If the element is a `data`^{p265} element**

The value is the value of the element's `value`^{p266} attribute, if it has one, or the empty string otherwise.

↪ **If the element is a `meter`^{p567} element**

The value is the value of the element's `value`^{p568} attribute, if it has one, or the empty string otherwise.

↪ **If the element is a `time`^{p266} element**

The value is the element's `datetime value`^{p267}.

↪ **Otherwise**

The value is the element's `descendant text content`.

The **URL property elements** are the `a`^{p244}, `area`^{p452}, `audio`^{p392}, `embed`^{p378}, `iframe`^{p369}, `img`^{p327}, `link`^{p162}, `object`^{p381}, `source`^{p324}, `track`^{p393}, and `video`^{p388} elements.

If a property's `value`^{p765}, as defined by the property's definition, is an `absolute URL`, the property must be specified using a `URL property element`^{p765}.

Note

These requirements do not apply just because a property value happens to match the syntax for a URL. They only apply if the property is explicitly defined as taking such a value.

Example

For example, a book about the first moon landing could be called "mission:moon". A "title" property from a vocabulary that defines a title as being a string would not expect the title to be given in an [a^{p244}](#) element, even though it looks like a [URL](#). On the other hand, if there was a (rather narrowly scoped!) vocabulary for "books whose titles look like URLs" which had a "title" property defined to take a URL, then the property *would* expect the title to be given in an [a^{p244}](#) element (or one of the other [URL property elements^{p765}](#)), because of the requirement above.

5.2.5 Associating names with items ^{§^{p76}}₆

To find **the properties of an item** defined by the element *root*, the user agent must run the following steps. These steps are also used to flag [microdata errors^{p766}](#).

1. Let *results*, *memory*, and *pending* be empty lists of elements.
2. Add the element *root* to *memory*.
3. Add the child elements of *root*, if any, to *pending*.
4. If *root* has an [itemref^{p762}](#) attribute, [split the value of that itemref attribute on ASCII whitespace](#). For each resulting token *ID*, if there is an element in the [tree](#) of *root* with the [ID](#) *ID*, then add the first such element to *pending*.
5. While *pending* is not empty:
 1. Remove an element from *pending* and let *current* be that element.
 2. If *current* is already in *memory*, there is a [microdata error^{p766}](#); [continue](#).
 3. Add *current* to *memory*.
 4. If *current* does not have an [itemscope^{p761}](#) attribute, then: add all the child elements of *current* to *pending*.
 5. If *current* has an [itemprop^{p763}](#) attribute specified and has one or more [property names^{p764}](#), then add *current* to *results*.
6. Sort *results* in [tree order](#).
7. Return *results*.

A document must not contain any [items^{p761}](#) for which the algorithm to find [the properties of an item^{p766}](#) finds any **microdata errors**.

An [item^{p761}](#) is a **top-level microdata item** if its element does not have an [itemprop^{p763}](#) attribute.

All [itemref^{p762}](#) attributes in a [Document^{p117}](#) must be such that there are no cycles in the graph formed from representing each [item^{p761}](#) in the [Document^{p117}](#) as a node in the graph and each [property^{p766}](#) of an item whose [value^{p765}](#) is another item as an edge in the graph connecting those two items.

A document must not contain any elements that have an [itemprop^{p763}](#) attribute that would not be found to be a property of any of the [items^{p761}](#) in that document were their [properties^{p766}](#) all to be determined.

Example

In this example, a single license statement is applied to two works, using [itemref^{p762}](#) from the items representing the works:

```
<!DOCTYPE HTML>
<html lang="en">
  <head>
    <title>Photo gallery</title>
  </head>
  <body>
    <h1>My photos</h1>
    <figure itemscope itemtype="http://n.whatwg.org/work" itemref="licenses">
      
      <figcaption itemprop="title">The house I found.</figcaption>
    </figure>
  </body>
</html>
```

```

</figure>
<figure itemscope itemtype="http://n.whatwg.org/work" itemref="licenses">
  
  <figcaption itemprop="title">The mailbox.</figcaption>
</figure>
<footer>
  <p id="licenses">All images licensed under the <a itemprop="license"
href="http://www.opensource.org/licenses/mit-license.php">MIT
license</a>.</p>
</footer>
</body>
</html>

```

The above results in two items with the type "http://n.whatwg.org/work", one with:

```

work
  images/house.jpeg
title
  The house I found.
license
  http://www.opensource.org/licenses/mit-license.php

```

...and one with:

```

work
  images/mailbox.jpeg
title
  The mailbox.
license
  http://www.opensource.org/licenses/mit-license.php

```

5.2.6 Microdata and other namespaces §^{p76}₇

Currently, the [itemscope^{p761}](#), [itemprop^{p763}](#), and other microdata attributes are only defined for [HTML elements^{p44}](#). This means that attributes with the literal names "itemscope", "itemprop", etc, do not cause microdata processing to occur on elements in other namespaces, such as SVG.

Example

Thus, in the following example there is only one item, not two.

```

<p itemscope></p> <!-- this is an item (with no properties and no type) -->
<svg itemscope></svg> <!-- this is not, it's just an SVG svg element with an invalid unknown
attribute -->

```

5.3 Sample microdata vocabularies §^{p76}₇

The vocabularies in this section are primarily intended to demonstrate how a vocabulary is specified, though they are also usable in their own right.

5.3.1 vCard §^{p76}₈

An item with the [item type^{p761} http://microformats.org/profile/hcard](#) represents a person's or organization's contact information.

This vocabulary does not [support global identifiers for items^{p762}](#).

The following are the type's [defined property names^{p764}](#). They are based on the vocabulary defined in *vCard Format Specification* (vCard) and its extensions, where more information on how to interpret the values can be found. [\[RFC6350\]^{p1311}](#)

kind

Describes what kind of contact the item represents.

The [value^{p765}](#) must be text that is [identical to](#) one of the [kind strings^{p775}](#).

A single property with the name [kind^{p768}](#) may be present within each [item^{p761}](#) with the type [http://microformats.org/profile/hcard^{p768}](#).

fn

Gives the formatted text corresponding to the name of the person or organization.

The [value^{p765}](#) must be text.

Exactly one property with the name [fn^{p768}](#) must be present within each [item^{p761}](#) with the type [http://microformats.org/profile/hcard^{p768}](#).

n

Gives the structured name of the person or organization.

The [value^{p765}](#) must be an [item^{p761}](#) with zero or more of each of the [family-name^{p768}](#), [given-name^{p768}](#), [additional-name^{p768}](#), [honorific-prefix^{p768}](#), and [honorific-suffix^{p769}](#) properties.

Exactly one property with the name [n^{p768}](#) must be present within each [item^{p761}](#) with the type [http://microformats.org/profile/hcard^{p768}](#).

family-name (inside [n^{p768}](#))

Gives the family name of the person, or the full name of the organization.

The [value^{p765}](#) must be text.

Any number of properties with the name [family-name^{p768}](#) may be present within the [item^{p761}](#) that forms the [value^{p765}](#) of the [n^{p768}](#) property of an [item^{p761}](#) with the type [http://microformats.org/profile/hcard^{p768}](#).

given-name (inside [n^{p768}](#))

Gives the given-name of the person.

The [value^{p765}](#) must be text.

Any number of properties with the name [given-name^{p768}](#) may be present within the [item^{p761}](#) that forms the [value^{p765}](#) of the [n^{p768}](#) property of an [item^{p761}](#) with the type [http://microformats.org/profile/hcard^{p768}](#).

additional-name (inside [n^{p768}](#))

Gives the any additional names of the person.

The [value^{p765}](#) must be text.

Any number of properties with the name [additional-name^{p768}](#) may be present within the [item^{p761}](#) that forms the [value^{p765}](#) of the [n^{p768}](#) property of an [item^{p761}](#) with the type [http://microformats.org/profile/hcard^{p768}](#).

honorific-prefix (inside [n^{p768}](#))

Gives the honorific prefix of the person.

The [value^{p765}](#) must be text.

Any number of properties with the name [honorific-prefix^{p768}](#) may be present within the [item^{p761}](#) that forms the [value^{p765}](#) of the

[n^{p768}](#) property of an [item^{p761}](#) with the type <http://microformats.org/profile/hcard^{p768}>.

honorific-suffix (inside [n^{p768}](#))

Gives the honorific suffix of the person.

The [value^{p765}](#) must be text.

Any number of properties with the name [honorific-suffix^{p769}](#) may be present within the [item^{p761}](#) that forms the [value^{p765}](#) of the [n^{p768}](#) property of an [item^{p761}](#) with the type <http://microformats.org/profile/hcard^{p768}>.

nickname

Gives the nickname of the person or organization.

Note

The nickname is the descriptive name given instead of or in addition to the one belonging to a person, place, or thing. It can also be used to specify a familiar form of a proper name specified by the [fn^{p768}](#) or [n^{p768}](#) properties.

The [value^{p765}](#) must be text.

Any number of properties with the name [nickname^{p769}](#) may be present within each [item^{p761}](#) with the type <http://microformats.org/profile/hcard^{p768}>.

photo

Gives a photograph of the person or organization.

The [value^{p765}](#) must be an [absolute URL](#).

Any number of properties with the name [photo^{p769}](#) may be present within each [item^{p761}](#) with the type <http://microformats.org/profile/hcard^{p768}>.

bday

Gives the birth date of the person or organization.

The [value^{p765}](#) must be a [valid date string^{p76}](#).

A single property with the name [bday^{p769}](#) may be present within each [item^{p761}](#) with the type <http://microformats.org/profile/hcard^{p768}>.

anniversary

Gives the birth date of the person or organization.

The [value^{p765}](#) must be a [valid date string^{p76}](#).

A single property with the name [anniversary^{p769}](#) may be present within each [item^{p761}](#) with the type <http://microformats.org/profile/hcard^{p768}>.

sex

Gives the biological sex of the person.

The [value^{p765}](#) must be one of F, meaning "female", M, meaning "male", N, meaning "none or not applicable", O, meaning "other", or U, meaning "unknown".

A single property with the name [sex^{p769}](#) may be present within each [item^{p761}](#) with the type <http://microformats.org/profile/hcard^{p768}>.

gender-identity

Gives the gender identity of the person.

The [value^{p765}](#) must be text.

A single property with the name [gender-identity^{p769}](#) may be present within each [item^{p761}](#) with the type <http://microformats.org/profile/hcard^{p768}>.

adr

Gives the delivery address of the person or organization.

The [value](#)^{p765} must be an [item](#)^{p761} with zero or more [type](#)^{p770}, [post-office-box](#)^{p770}, [extended-address](#)^{p770}, and [street-address](#)^{p770} properties, and optionally a [locality](#)^{p770} property, optionally a [region](#)^{p770} property, optionally a [postal-code](#)^{p771} property, and optionally a [country-name](#)^{p771} property.

If no [type](#)^{p770} properties are present within an [item](#)^{p761} that forms the [value](#)^{p765} of an [adr](#)^{p770} property of an [item](#)^{p761} with the type <http://microformats.org/profile/hcard>^{p768}, then the [address-type-string](#)^{p775} [work](#)^{p775} is implied.

Any number of properties with the name [adr](#)^{p770} may be present within each [item](#)^{p761} with the type <http://microformats.org/profile/hcard>^{p768}.

type (inside [adr](#)^{p770})

Gives the type of delivery address.

The [value](#)^{p765} must be text that is [identical to](#) one of the [address-type-strings](#)^{p775}.

Any number of properties with the name [type](#)^{p770} may be present within the [item](#)^{p761} that forms the [value](#)^{p765} of an [adr](#)^{p770} property of an [item](#)^{p761} with the type <http://microformats.org/profile/hcard>^{p768}, but within each such [adr](#)^{p770} property [item](#)^{p761} there must only be one [type](#)^{p770} property per distinct value.

post-office-box (inside [adr](#)^{p770})

Gives the post office box component of the delivery address of the person or organization.

The [value](#)^{p765} must be text.

Any number of properties with the name [post-office-box](#)^{p770} may be present within the [item](#)^{p761} that forms the [value](#)^{p765} of an [adr](#)^{p770} property of an [item](#)^{p761} with the type <http://microformats.org/profile/hcard>^{p768}.

Note

vCard urges authors not to use this field.

extended-address (inside [adr](#)^{p770})

Gives an additional component of the delivery address of the person or organization.

The [value](#)^{p765} must be text.

Any number of properties with the name [extended-address](#)^{p770} may be present within the [item](#)^{p761} that forms the [value](#)^{p765} of an [adr](#)^{p770} property of an [item](#)^{p761} with the type <http://microformats.org/profile/hcard>^{p768}.

Note

vCard urges authors not to use this field.

street-address (inside [adr](#)^{p770})

Gives the street address component of the delivery address of the person or organization.

The [value](#)^{p765} must be text.

Any number of properties with the name [street-address](#)^{p770} may be present within the [item](#)^{p761} that forms the [value](#)^{p765} of an [adr](#)^{p770} property of an [item](#)^{p761} with the type <http://microformats.org/profile/hcard>^{p768}.

locality (inside [adr](#)^{p770})

Gives the locality component (e.g. city) of the delivery address of the person or organization.

The [value](#)^{p765} must be text.

A single property with the name [locality](#)^{p770} may be present within the [item](#)^{p761} that forms the [value](#)^{p765} of an [adr](#)^{p770} property of an [item](#)^{p761} with the type <http://microformats.org/profile/hcard>^{p768}.

region (inside [adr](#)^{p770})

Gives the region component (e.g. state or province) of the delivery address of the person or organization.

The [value^{p765}](#) must be text.

A single property with the name [region^{p770}](#) may be present within the [item^{p761}](#) that forms the [value^{p765}](#) of an [adr^{p770}](#) property of an [item^{p761}](#) with the type [http://microformats.org/profile/hcard^{p768}](http://microformats.org/profile/hcard).

postal-code (inside [adr^{p770}](#))

Gives the postal code component of the delivery address of the person or organization.

The [value^{p765}](#) must be text.

A single property with the name [postal-code^{p771}](#) may be present within the [item^{p761}](#) that forms the [value^{p765}](#) of an [adr^{p770}](#) property of an [item^{p761}](#) with the type [http://microformats.org/profile/hcard^{p768}](http://microformats.org/profile/hcard).

country-name (inside [adr^{p770}](#))

Gives the country name component of the delivery address of the person or organization.

The [value^{p765}](#) must be text.

A single property with the name [country-name^{p771}](#) may be present within the [item^{p761}](#) that forms the [value^{p765}](#) of an [adr^{p770}](#) property of an [item^{p761}](#) with the type [http://microformats.org/profile/hcard^{p768}](http://microformats.org/profile/hcard).

tel

Gives the telephone number of the person or organization.

The [value^{p765}](#) must be either text that can be interpreted as a telephone number as defined in the CCITT specifications E.163 and X.121, or an [item^{p761}](#) with zero or more [type^{p771}](#) properties and exactly one [value^{p771}](#) property. [\[E163\]^{p1307}](#) [\[X121\]^{p1313}](#)

If no [type^{p771}](#) properties are present within an [item^{p761}](#) that forms the [value^{p765}](#) of a [tel^{p771}](#) property of an [item^{p761}](#) with the type [http://microformats.org/profile/hcard^{p768}](http://microformats.org/profile/hcard), or if the [value^{p765}](#) of such a [tel^{p771}](#) property is text, then the [telephone type string^{p775}](#) [voice^{p775}](#) is implied.

Any number of properties with the name [tel^{p771}](#) may be present within each [item^{p761}](#) with the type [http://microformats.org/profile/hcard^{p768}](http://microformats.org/profile/hcard).

type (inside [tel^{p771}](#))

Gives the type of telephone number.

The [value^{p765}](#) must be text that is [identical to](#) one of the [telephone type strings^{p775}](#).

Any number of properties with the name [type^{p771}](#) may be present within the [item^{p761}](#) that forms the [value^{p765}](#) of a [tel^{p771}](#) property of an [item^{p761}](#) with the type [http://microformats.org/profile/hcard^{p768}](http://microformats.org/profile/hcard), but within each such [tel^{p771}](#) property [item^{p761}](#) there must only be one [type^{p771}](#) property per distinct value.

value (inside [tel^{p771}](#))

Gives the actual telephone number of the person or organization.

The [value^{p765}](#) must be text that can be interpreted as a telephone number as defined in the CCITT specifications E.163 and X.121. [\[E163\]^{p1307}](#) [\[X121\]^{p1313}](#)

Exactly one property with the name [value^{p771}](#) must be present within the [item^{p761}](#) that forms the [value^{p765}](#) of a [tel^{p771}](#) property of an [item^{p761}](#) with the type [http://microformats.org/profile/hcard^{p768}](http://microformats.org/profile/hcard).

email

Gives the email address of the person or organization.

The [value^{p765}](#) must be text.

Any number of properties with the name [email^{p771}](#) may be present within each [item^{p761}](#) with the type [http://microformats.org/profile/hcard^{p768}](http://microformats.org/profile/hcard).

imp

Gives a [URL](#) for instant messaging and presence protocol communications with the person or organization.

The [value^{p765}](#) must be an [absolute URL](#).

Any number of properties with the name [impp^{p771}](#) may be present within each [item^{p761}](#) with the type <http://microformats.org/profile/hcard^{p768}>.

lang

Gives a language understood by the person or organization.

The [value^{p765}](#) must be a valid BCP 47 language tag. [\[BCP47\]^{p1305}](#).

Any number of properties with the name [lang^{p772}](#) may be present within each [item^{p761}](#) with the type <http://microformats.org/profile/hcard^{p768}>.

tz

Gives the time zone of the person or organization.

The [value^{p765}](#) must be text and must match the following syntax:

1. Either a U+002B PLUS SIGN character (+) or a U+002D HYPHEN-MINUS character (-).
2. A [valid non-negative integer^{p70}](#) that is exactly two digits long and that represents a number in the range 00..23.
3. A U+003A COLON character (:).
4. A [valid non-negative integer^{p70}](#) that is exactly two digits long and that represents a number in the range 00..59.

Any number of properties with the name [tz^{p772}](#) may be present within each [item^{p761}](#) with the type <http://microformats.org/profile/hcard^{p768}>.

geo

Gives the geographical position of the person or organization.

The [value^{p765}](#) must be text and must match the following syntax:

1. Optionally, either a U+002B PLUS SIGN character (+) or a U+002D HYPHEN-MINUS character (-).
2. One or more [ASCII digits](#).
3. Optionally*, a U+002E FULL STOP character (.) followed by one or more [ASCII digits](#).
4. A U+003B SEMICOLON character (;).
5. Optionally, either a U+002B PLUS SIGN character (+) or a U+002D HYPHEN-MINUS character (-).
6. One or more [ASCII digits](#).
7. Optionally*, a U+002E FULL STOP character (.) followed by one or more [ASCII digits](#).

The optional components marked with an asterisk (*) should be included, and should have six digits each.

Note

The value specifies latitude and longitude, in that order (i.e., "LAT LON" ordering), in decimal degrees. The longitude represents the location east and west of the prime meridian as a positive or negative real number, respectively. The latitude represents the location north and south of the equator as a positive or negative real number, respectively.

Any number of properties with the name [geo^{p772}](#) may be present within each [item^{p761}](#) with the type <http://microformats.org/profile/hcard^{p768}>.

title

Gives the job title, functional position or function of the person or organization.

The [value^{p765}](#) must be text.

Any number of properties with the name [title^{p772}](#) may be present within each [item^{p761}](#) with the type <http://microformats.org/profile/hcard^{p768}>.

role

Gives the role, occupation, or business category of the person or organization.

The [value^{p765}](#) must be text.

Any number of properties with the name [role^{p772}](#) may be present within each [item^{p761}](#) with the type [http://microformats.org/profile/hcard^{p768}](http://microformats.org/profile/hcard).

Logo

Gives the logo of the person or organization.

The [value^{p765}](#) must be an [absolute URL](#).

Any number of properties with the name [logo^{p773}](#) may be present within each [item^{p761}](#) with the type [http://microformats.org/profile/hcard^{p768}](http://microformats.org/profile/hcard).

agent

Gives the contact information of another person who will act on behalf of the person or organization.

The [value^{p765}](#) must be either an [item^{p761}](#) with the type [http://microformats.org/profile/hcard^{p768}](http://microformats.org/profile/hcard), or an [absolute URL](#), or text.

Any number of properties with the name [agent^{p773}](#) may be present within each [item^{p761}](#) with the type [http://microformats.org/profile/hcard^{p768}](http://microformats.org/profile/hcard).

org

Gives the name and units of the organization.

The [value^{p765}](#) must be either text or an [item^{p761}](#) with one [organization-name^{p773}](#) property and zero or more [organization-unit^{p773}](#) properties.

Any number of properties with the name [org^{p773}](#) may be present within each [item^{p761}](#) with the type [http://microformats.org/profile/hcard^{p768}](http://microformats.org/profile/hcard).

organization-name (inside [org^{p773}](#))

Gives the name of the organization.

The [value^{p765}](#) must be text.

Exactly one property with the name [organization-name^{p773}](#) must be present within the [item^{p761}](#) that forms the [value^{p765}](#) of an [org^{p773}](#) property of an [item^{p761}](#) with the type [http://microformats.org/profile/hcard^{p768}](http://microformats.org/profile/hcard).

organization-unit (inside [org^{p773}](#))

Gives the name of the organization unit.

The [value^{p765}](#) must be text.

Any number of properties with the name [organization-unit^{p773}](#) may be present within the [item^{p761}](#) that forms the [value^{p765}](#) of the [org^{p773}](#) property of an [item^{p761}](#) with the type [http://microformats.org/profile/hcard^{p768}](http://microformats.org/profile/hcard).

member

Gives a [URL](#) that represents a member of the group.

The [value^{p765}](#) must be an [absolute URL](#).

Any number of properties with the name [member^{p773}](#) may be present within each [item^{p761}](#) with the type [http://microformats.org/profile/hcard^{p768}](http://microformats.org/profile/hcard) if the [item^{p761}](#) also has a property with the name [kind^{p768}](#) whose value is "[group^{p775}](#)".

related

Gives a relationship to another entity.

The [value^{p765}](#) must be an [item^{p761}](#) with one [url^{p773}](#) property and one [rel^{p774}](#) properties.

Any number of properties with the name [related^{p773}](#) may be present within each [item^{p761}](#) with the type [http://microformats.org/profile/hcard^{p768}](http://microformats.org/profile/hcard).

url (inside [related^{p773}](#))

Gives the [URL](#) for the related entity.

The [value^{p765}](#) must be an [absolute URL](#).

Exactly one property with the name [url^{p773}](#) must be present within the [item^{p761}](#) that forms the [value^{p765}](#) of a [related^{p773}](#) property of an [item^{p761}](#) with the type [http://microformats.org/profile/hcard^{p768}](#).

rel (inside [related^{p773}](#))

Gives the relationship between the entity and the related entity.

The [value^{p765}](#) must be text that is [identical to](#) one of the [relationship strings^{p775}](#).

Exactly one property with the name [rel^{p774}](#) must be present within the [item^{p761}](#) that forms the [value^{p765}](#) of a [related^{p773}](#) property of an [item^{p761}](#) with the type [http://microformats.org/profile/hcard^{p768}](#).

categories

Gives the name of a category or tag that the person or organization could be classified as.

The [value^{p765}](#) must be text.

Any number of properties with the name [categories^{p774}](#) may be present within each [item^{p761}](#) with the type [http://microformats.org/profile/hcard^{p768}](#).

note

Gives supplemental information or a comment about the person or organization.

The [value^{p765}](#) must be text.

Any number of properties with the name [note^{p774}](#) may be present within each [item^{p761}](#) with the type [http://microformats.org/profile/hcard^{p768}](#).

rev

Gives the revision date and time of the contact information.

The [value^{p765}](#) must be text that is a [valid global date and time string^{p81}](#).

Note

The value distinguishes the current revision of the information for other renditions of the information.

Any number of properties with the name [rev^{p774}](#) may be present within each [item^{p761}](#) with the type [http://microformats.org/profile/hcard^{p768}](#).

sound

Gives a sound file relating to the person or organization.

The [value^{p765}](#) must be an [absolute URL](#).

Any number of properties with the name [sound^{p774}](#) may be present within each [item^{p761}](#) with the type [http://microformats.org/profile/hcard^{p768}](#).

uid

Gives a globally unique identifier corresponding to the person or organization.

The [value^{p765}](#) must be text.

A single property with the name [uid^{p774}](#) may be present within each [item^{p761}](#) with the type [http://microformats.org/profile/hcard^{p768}](#).

url

Gives a [URL](#) relating to the person or organization.

The [value^{p765}](#) must be an [absolute URL](#).

Any number of properties with the name [url^{p774}](#) may be present within each [item^{p761}](#) with the type [http://microformats.org/profile/hcard^{p768}](#).

The **kind strings** are:

individual

Indicates a single entity (e.g. a person).

group

Indicates multiple entities (e.g. a mailing list).

org

Indicates a single entity that is not a person (e.g. a company).

location

Indicates a geographical place (e.g. an office building).

The **address type strings** are:

home

Indicates a delivery address for a residence.

work

Indicates a delivery address for a place of work.

The **telephone type strings** are:

home

Indicates a residential number.

work

Indicates a telephone number for a place of work.

text

Indicates that the telephone number supports text messages (SMS).

voice

Indicates a voice telephone number.

fax

Indicates a facsimile telephone number.

cell

Indicates a cellular telephone number.

video

Indicates a video conferencing telephone number.

pager

Indicates a paging device telephone number.

textphone

Indicates a telecommunication device for people with hearing or speech difficulties.

The **relationship strings** are:

emergency

An emergency contact.

agent

Another entity that acts on behalf of this entity.

contact
acquaintance
friend
met
worker
colleague
resident
neighbor
child
parent
sibling
spouse
kin
muse
crush
date
sweetheart
me

Has the meaning defined in XFN. [\[XFN\]^{p1313}](#)

5.3.1.1 Conversion to vCard ^{§^{p77}}₆

Given a list of nodes *nodes* in a [Document^{p117}](#), a user agent must run the following algorithm to **extract any vCard data represented by those nodes** (only the first vCard is returned):

1. If none of the nodes in *nodes* are [items^{p761}](#) with the [item type^{p761}](#) [http://microformats.org/profile/hcard^{p768}](http://microformats.org/profile/hcard), then there is no vCard. Abort the algorithm, returning nothing.
2. Let *node* be the first node in *nodes* that is an [item^{p761}](#) with the [item type^{p761}](#) [http://microformats.org/profile/hcard^{p768}](http://microformats.org/profile/hcard).
3. Let *output* be an empty string.
4. [Add a vCard line^{p778}](#) with the type "BEGIN" and the value "VCARD" to *output*.
5. [Add a vCard line^{p778}](#) with the type "PROFILE" and the value "VCARD" to *output*.
6. [Add a vCard line^{p778}](#) with the type "VERSION" and the value "4.0" to *output*.
7. [Add a vCard line^{p778}](#) with the type "SOURCE" and the result of [escaping the vCard text string^{p779}](#) that is the document's URL as the value to *output*.
8. If [the title element^{p122}](#) is not null, [add a vCard line^{p778}](#) with the type "NAME" and with the result of [escaping the vCard text string^{p779}](#) obtained from [the title element^{p122}](#)'s [descendant text content](#) as the value to *output*.
9. Let *sex* be the empty string.
10. Let *gender-identity* be the empty string.
11. For each element *element* that is [a property of the item^{p766}](#) *node*: for each name *name* in *element*'s [property names^{p764}](#), run the following substeps:
 1. Let *parameters* be an empty set of name-value pairs.
 2. Run the appropriate set of substeps from the following list. The steps will set a variable *value*, which is used in the next step.

If the property's [value^{p765}](#) is an [item^{p761}](#) *subitem* and *name* is [n^{p768}](#)

1. Let *value* be the empty string.
2. Append to *value* the result of [collecting the first vCard subproperty^{p779}](#) named [family-name^{p768}](#) in *subitem*.

3. Append a U+003B SEMICOLON character (;) to *value*.
4. Append to *value* the result of [collecting the first vCard subproperty^{p779}](#) named [given-name^{p768}](#) in *subitem*.
5. Append a U+003B SEMICOLON character (;) to *value*.
6. Append to *value* the result of [collecting the first vCard subproperty^{p779}](#) named [additional-name^{p768}](#) in *subitem*.
7. Append a U+003B SEMICOLON character (;) to *value*.
8. Append to *value* the result of [collecting the first vCard subproperty^{p779}](#) named [honorific-prefix^{p768}](#) in *subitem*.
9. Append a U+003B SEMICOLON character (;) to *value*.
10. Append to *value* the result of [collecting the first vCard subproperty^{p779}](#) named [honorific-suffix^{p769}](#) in *subitem*.

If the property's [value^{p765}](#) is an [item^{p761}](#) *subitem* and *name* is [adr^{p778}](#)

1. Let *value* be the empty string.
2. Append to *value* the result of [collecting vCard subproperties^{p779}](#) named [post-office-box^{p770}](#) in *subitem*.
3. Append a U+003B SEMICOLON character (;) to *value*.
4. Append to *value* the result of [collecting vCard subproperties^{p779}](#) named [extended-address^{p770}](#) in *subitem*.
5. Append a U+003B SEMICOLON character (;) to *value*.
6. Append to *value* the result of [collecting vCard subproperties^{p779}](#) named [street-address^{p770}](#) in *subitem*.
7. Append a U+003B SEMICOLON character (;) to *value*.
8. Append to *value* the result of [collecting the first vCard subproperty^{p779}](#) named [locality^{p770}](#) in *subitem*.
9. Append a U+003B SEMICOLON character (;) to *value*.
10. Append to *value* the result of [collecting the first vCard subproperty^{p779}](#) named [region^{p770}](#) in *subitem*.
11. Append a U+003B SEMICOLON character (;) to *value*.
12. Append to *value* the result of [collecting the first vCard subproperty^{p779}](#) named [postal-code^{p771}](#) in *subitem*.
13. Append a U+003B SEMICOLON character (;) to *value*.
14. Append to *value* the result of [collecting the first vCard subproperty^{p779}](#) named [country-name^{p771}](#) in *subitem*.
15. If there is a property named [type^{p770}](#) in *subitem*, and the first such property has a [value^{p765}](#) that is not an [item^{p761}](#) and whose value consists only of [ASCII alphanumerics](#), then add a parameter named "TYPE" whose value is the [value^{p765}](#) of that property to *parameters*.

If the property's [value^{p765}](#) is an [item^{p761}](#) *subitem* and *name* is [org^{p773}](#)

1. Let *value* be the empty string.
2. Append to *value* the result of [collecting the first vCard subproperty^{p779}](#) named [organization-name^{p773}](#) in *subitem*.
3. For each property named [organization-unit^{p773}](#) in *subitem*, run the following steps:
 1. If the [value^{p765}](#) of the property is an [item^{p761}](#), then skip this property.

2. Append a U+003B SEMICOLON character (;) to *value*.
3. Append the result of [escaping the vCard text string](#)^{p779} given by the [value](#)^{p765} of the property to *value*.

If the property's [value](#)^{p765} is an [item](#)^{p761} *subitem* with the [item type](#)^{p761} <http://microformats.org/profile/hcard>^{p768} and [name](#) is [related](#)^{p773}

1. Let *value* be the empty string.
2. If there is a property named [url](#)^{p773} in *subitem*, and its element is a [URL property element](#)^{p765}, then append the result of [escaping the vCard text string](#)^{p779} given by the [value](#)^{p765} of the first such property to *value*, and add a parameter with the name "VALUE" and the value "URI" to *parameters*.
3. If there is a property named [rel](#)^{p774} in *subitem*, and the first such property has a [value](#)^{p765} that is not an [item](#)^{p761} and whose value consists only of [ASCII alphanumerics](#), then add a parameter named "RELATION" whose value is the [value](#)^{p765} of that property to *parameters*.

If the property's [value](#)^{p765} is an [item](#)^{p761} and [name](#) is none of the above

1. Let *value* be the result of [collecting the first vCard subproperty](#)^{p779} named *value* in *subitem*.
2. If there is a property named *type* in *subitem*, and the first such property has a [value](#)^{p765} that is not an [item](#)^{p761} and whose value consists only of [ASCII alphanumeric](#), then add a parameter named "TYPE" whose value is the [value](#)^{p765} of that property to *parameters*.

If the property's [value](#)^{p765} is not an [item](#)^{p761} and its [name](#) is [sex](#)^{p769}

If this is the first such property to be found, set *sex* to the property's [value](#)^{p765}.

If the property's [value](#)^{p765} is not an [item](#)^{p761} and its [name](#) is [gender-identity](#)^{p769}

If this is the first such property to be found, set *gender-identity* to the property's [value](#)^{p765}.

Otherwise (the property's [value](#)^{p765} is not an [item](#)^{p761})

1. Let *value* be the property's [value](#)^{p765}.
2. If *element* is one of the [URL property elements](#)^{p765}, add a parameter with the name "VALUE" and the value "URI" to *parameters*.
3. Otherwise, if *name* is [bday](#)^{p769} or [anniversary](#)^{p769} and the *value* is a [valid date string](#)^{p76}, add a parameter with the name "VALUE" and the value "DATE" to *parameters*.
4. Otherwise, if *name* is [rev](#)^{p774} and the *value* is a [valid global date and time string](#)^{p81}, add a parameter with the name "VALUE" and the value "DATE-TIME" to *parameters*.
5. Prefix every U+005C REVERSE SOLIDUS character (\) in *value* with another U+005C REVERSE SOLIDUS character (\).
6. Prefix every U+002C COMMA character (,) in *value* with a U+005C REVERSE SOLIDUS character (\).
7. Unless *name* is [geo](#)^{p772}, prefix every U+003B SEMICOLON character (;) in *value* with a U+005C REVERSE SOLIDUS character (\).
8. Replace every U+000D CARRIAGE RETURN U+000A LINE FEED character pair (CRLF) in *value* with a U+005C REVERSE SOLIDUS character (\) followed by a U+006E LATIN SMALL LETTER N character (n).
9. Replace every remaining U+000D CARRIAGE RETURN (CR) or U+000A LINE FEED (LF) character in *value* with a U+005C REVERSE SOLIDUS character (\) followed by a U+006E LATIN SMALL LETTER N character (n).

3. [Add a vCard line](#)^{p778} with the type *name*, the parameters *parameters*, and the value *value* to *output*.

12. If either *sex* or *gender-identity* has a value that is not the empty string, [add a vCard line](#)^{p778} with the type "GENDER" and the value consisting of the concatenation of *sex*, a U+003B SEMICOLON character (;), and *gender-identity* to *output*.

13. [Add a vCard line](#)^{p778} with the type "END" and the value "VCARD" to *output*.

When the above algorithm says that the user agent is to **add a vCard line** consisting of a type *type*, optionally some parameters, and a value *value* to a string *output*, it must run the following steps:

1. Let *line* be an empty string.
2. Append *type*, [converted to ASCII uppercase](#), to *line*.
3. If there are any parameters, then for each parameter, in the order that they were added, run these substeps:
 1. Append a U+003B SEMICOLON character (;) to *line*.
 2. Append the parameter's name to *line*.
 3. Append a U+003D EQUALS SIGN character (=) to *line*.
 4. Append the parameter's value to *line*.
4. Append a U+003A COLON character (:) to *line*.
5. Append *value* to *line*.
6. Let *maximum length* be 75.
7. While *line*'s [code point length](#) is greater than *maximum length*:
 1. Append the first *maximum length* code points of *line* to *output*.
 2. Remove the first *maximum length* code points from *line*.
 3. Append a U+000D CARRIAGE RETURN character (CR) to *output*.
 4. Append a U+000A LINE FEED character (LF) to *output*.
 5. Append a U+0020 SPACE character to *output*.
 6. Let *maximum length* be 74.
8. Append (what remains of) *line* to *output*.
9. Append a U+000D CARRIAGE RETURN character (CR) to *output*.
10. Append a U+000A LINE FEED character (LF) to *output*.

When the steps above require the user agent to obtain the result of **collecting vCard subproperties** named *subname* in *subitem*, the user agent must run the following steps:

1. Let *value* be the empty string.
2. For each property named *subname* in the item *subitem*, run the following substeps:
 1. If the [value^{p765}](#) of the property is itself an [item^{p761}](#), then skip this property.
 2. If this is not the first property named *subname* in *subitem* (ignoring any that were skipped by the previous step), then append a U+002C COMMA character (,) to *value*.
 3. Append the result of [escaping the vCard text string^{p779}](#) given by the [value^{p765}](#) of the property to *value*.
3. Return *value*.

When the steps above require the user agent to obtain the result of **collecting the first vCard subproperty** named *subname* in *subitem*, the user agent must run the following steps:

1. If there are no properties named *subname* in *subitem*, then return the empty string.
2. If the [value^{p765}](#) of the first property named *subname* in *subitem* is an [item^{p761}](#), then return the empty string.
3. Return the result of [escaping the vCard text string^{p779}](#) given by the [value^{p765}](#) of the first property named *subname* in *subitem*.

When the above algorithms say the user agent is to **escape the vCard text string** *value*, the user agent must use the following steps:

1. Prefix every U+005C REVERSE SOLIDUS character (\) in *value* with another U+005C REVERSE SOLIDUS character (\).
2. Prefix every U+002C COMMA character (,) in *value* with a U+005C REVERSE SOLIDUS character (\).

3. Prefix every U+003B SEMICOLON character (;) in *value* with a U+005C REVERSE SOLIDUS character (\).
4. Replace every U+000D CARRIAGE RETURN U+000A LINE FEED character pair (CRLF) in *value* with a U+005C REVERSE SOLIDUS character (\) followed by a U+006E LATIN SMALL LETTER N character (n).
5. Replace every remaining U+000D CARRIAGE RETURN (CR) or U+000A LINE FEED (LF) character in *value* with a U+005C REVERSE SOLIDUS character (\) followed by a U+006E LATIN SMALL LETTER N character (n).
6. Return the mutated *value*.

Note

This algorithm can generate invalid vCard output, if the input does not conform to the rules described for the <http://microformats.org/profile/hcard>^{p768} [item type](#)^{p761} and [defined property names](#)^{p764}.

5.3.1.2 Examples § p78

This section is non-normative.

Example

Here is a long example vCard for a fictional character called "Jack Bauer":

```
<section id="jack" itemscope itemtype="http://microformats.org/profile/hcard">
  <h1 itemprop="fn">
    <span itemprop="n" itemscope>
      <span itemprop="given-name">Jack</span>
      <span itemprop="family-name">Bauer</span>
    </span>
  </h1>
  
  <p itemprop="org" itemscope>
    <span itemprop="organization-name">Counter-Terrorist Unit</span>
    (<span itemprop="organization-unit">Los Angeles Division</span>)
  </p>
  <p>
    <span itemprop="adr" itemscope>
      <span itemprop="street-address">10201 W. Pico Blvd.</span><br>
      <span itemprop="locality">Los Angeles</span>,
      <span itemprop="region">CA</span>
      <span itemprop="postal-code">90064</span><br>
      <span itemprop="country-name">United States</span><br>
    </span>
    <span itemprop="geo">34.052339; -118.410623</span>
  </p>
  <h2>Assorted Contact Methods</h2>
  <ul>
    <li itemprop="tel" itemscope>
      <span itemprop="value">+1 (310) 597 3781</span> <span itemprop="type">work</span>
      <meta itemprop="type" content="voice">
    </li>
    <li><a itemprop="url" href="https://en.wikipedia.org/wiki/Jack_Bauer">I'm on Wikipedia</a>
    so you can leave a message on my user talk page.</li>
    <li><a itemprop="url" href="http://www.jackbauerfacts.com/">Jack Bauer Facts</a></li>
    <li itemprop="email"><a
href="mailto:j.bauer@la.ctu.gov.invalid">j.bauer@la.ctu.gov.invalid</a></li>
    <li itemprop="tel" itemscope>
      <span itemprop="value">+1 (310) 555 3781</span> <span>
      <meta itemprop="type" content="cell">mobile phone</span>
    </li>
  </ul>
  <ins datetime="2008-07-20 21:00:00+01:00">
```

```

<meta itemprop="rev" content="2008-07-20 21:00:00+01:00">
<p itemprop="tel" itemscope><strong>Update!</strong>
My new <span itemprop="type">home</span> phone number is
<span itemprop="value">01632 960 123</span>.</p>
</ins>
</section>

```

The odd line wrapping is needed because newlines are meaningful in microdata: newlines would be preserved in a conversion to, for example, the vCard format.

Example

This example shows a site's contact details (using the [address](#)^{p204} element) containing an address with two street components:

```

<address itemscope itemType="http://microformats.org/profile/hcard">
<strong itemprop="fn"><span itemprop="n" itemscope><span itemprop="given-name">Alfred</span>
<span itemprop="family-name">Person</span></span></strong> <br>
<span itemprop="adr" itemscope>
<span itemprop="street-address">1600 Amphitheatre Parkway</span> <br>
<span itemprop="street-address">Building 43, Second Floor</span> <br>
<span itemprop="locality">Mountain View</span>,
<span itemprop="region">CA</span> <span itemprop="postal-code">94043</span>
</span>
</address>

```

Example

The vCard vocabulary can be used to just mark up people's names:

```

<span itemscope itemType="http://microformats.org/profile/hcard"
><span itemprop="fn"><span itemprop="n" itemscope><span itemprop="given-name"
>George</span> <span itemprop="family-name">Washington</span></span></span>
</span></span>

```

This creates a single item with a two name-value pairs, one with the name "fn" and the value "George Washington", and the other with the name "n" and a second item as its value, the second item having the two name-value pairs "given-name" and "family-name" with the values "George" and "Washington" respectively. This is defined to map to the following vCard:

```

BEGIN:VCARD
PROFILE:VCARD
VERSION:4.0
SOURCE:document's address
FN:George Washington
N:Washington;George;;;
END:VCARD

```

5.3.2 vEvent ^{p78}₁

An item with the [item type](#)^{p761} <http://microformats.org/profile/hcalendar#vevent> represents an event.

This vocabulary does not [support global identifiers for items](#)^{p762}.

The following are the type's [defined property names](#)^{p764}. They are based on the vocabulary defined in *Internet Calendaring and Scheduling Core Object Specification (iCalendar)*, where more information on how to interpret the values can be found. [\[RFC5545\]](#)^{p1311}

Note

Only the parts of the iCalendar vocabulary relating to events are used here; this vocabulary cannot express a complete iCalendar instance.

attach

Gives the address of an associated document for the event.

The [value^{p765}](#) must be an [absolute URL](#).

Any number of properties with the name [attach^{p782}](#) may be present within each [item^{p761}](#) with the type [http://microformats.org/profile/hcalendar#vevent^{p781}](http://microformats.org/profile/hcalendar#vevent).

categories

Gives the name of a category or tag that the event could be classified as.

The [value^{p765}](#) must be text.

Any number of properties with the name [categories^{p782}](#) may be present within each [item^{p761}](#) with the type [http://microformats.org/profile/hcalendar#vevent^{p781}](http://microformats.org/profile/hcalendar#vevent).

class

Gives the access classification of the information regarding the event.

The [value^{p765}](#) must be text with one of the following values:

- public
- private
- confidential

⚠Warning!

This is merely advisory and cannot be considered a confidentiality measure.

A single property with the name [class^{p782}](#) may be present within each [item^{p761}](#) with the type [http://microformats.org/profile/hcalendar#vevent^{p781}](http://microformats.org/profile/hcalendar#vevent).

comment

Gives a comment regarding the event.

The [value^{p765}](#) must be text.

Any number of properties with the name [comment^{p782}](#) may be present within each [item^{p761}](#) with the type [http://microformats.org/profile/hcalendar#vevent^{p781}](http://microformats.org/profile/hcalendar#vevent).

description

Gives a detailed description of the event.

The [value^{p765}](#) must be text.

A single property with the name [description^{p782}](#) may be present within each [item^{p761}](#) with the type [http://microformats.org/profile/hcalendar#vevent^{p781}](http://microformats.org/profile/hcalendar#vevent).

geo

Gives the geographical position of the event.

The [value^{p765}](#) must be text and must match the following syntax:

1. Optionally, either a U+002B PLUS SIGN character (+) or a U+002D HYPHEN-MINUS character (-).
2. One or more [ASCII digits](#).
3. Optionally*, a U+002E FULL STOP character (.) followed by one or more [ASCII digits](#).
4. A U+003B SEMICOLON character (;).
5. Optionally, either a U+002B PLUS SIGN character (+) or a U+002D HYPHEN-MINUS character (-).
6. One or more [ASCII digits](#).
7. Optionally*, a U+002E FULL STOP character (.) followed by one or more [ASCII digits](#).

The optional components marked with an asterisk (*) should be included, and should have six digits each.

Note

The value specifies latitude and longitude, in that order (i.e., "LAT LON" ordering), in decimal degrees. The longitude represents the location east and west of the prime meridian as a positive or negative real number, respectively. The latitude represents the location north and south of the equator as a positive or negative real number, respectively.

A single property with the name [geo](#)^{p782} may be present within each [item](#)^{p761} with the type <http://microformats.org/profile/hcalendar#vevent>^{p781}.

Location

Gives the location of the event.

The [value](#)^{p765} must be text.

A single property with the name [location](#)^{p783} may be present within each [item](#)^{p761} with the type <http://microformats.org/profile/hcalendar#vevent>^{p781}.

resources

Gives a resource that will be needed for the event.

The [value](#)^{p765} must be text.

Any number of properties with the name [resources](#)^{p783} may be present within each [item](#)^{p761} with the type <http://microformats.org/profile/hcalendar#vevent>^{p781}.

status

Gives the confirmation status of the event.

The [value](#)^{p765} must be text with one of the following values:

- tentative
- confirmed
- cancelled

A single property with the name [status](#)^{p783} may be present within each [item](#)^{p761} with the type <http://microformats.org/profile/hcalendar#vevent>^{p781}.

summary

Gives a short summary of the event.

The [value](#)^{p765} must be text.

User agents should replace U+000A LINE FEED (LF) characters in the [value](#)^{p765} by U+0020 SPACE characters when using the value.

A single property with the name [summary](#)^{p783} may be present within each [item](#)^{p761} with the type <http://microformats.org/profile/hcalendar#vevent>^{p781}.

dtend

Gives the date and time by which the event ends.

If the property with the name [dtend](#)^{p783} is present within an [item](#)^{p761} with the type <http://microformats.org/profile/hcalendar#vevent>^{p781} that has a property with the name [dtstart](#)^{p784} whose value is a [valid date string](#)^{p76}, then the [value](#)^{p765} of the property with the name [dtend](#)^{p783} must be text that is a [valid date string](#)^{p76} also. Otherwise, the [value](#)^{p765} of the property must be text that is a [valid global date and time string](#)^{p81}.

In either case, the [value](#)^{p765} be later in time than the value of the [dtstart](#)^{p784} property of the same [item](#)^{p761}.

Note

The time given by the [dtend](#)^{p783} property is not inclusive. For day-long events, therefore, the [dtend](#)^{p783} property's [value](#)^{p765} will be the day after the end of the event.

A single property with the name [dtend](#)^{p783} may be present within each [item](#)^{p761} with the type <http://microformats.org/profile/>

[hcalendar#vevent](http://microformats.org/profile/hcalendar#vevent)^{p781}, so long as that <http://microformats.org/profile/hcalendar#vevent>^{p781} does not have a property with the name [duration](http://microformats.org/profile/hcalendar#vevent)^{p784}.

dtstart

Gives the date and time at which the event starts.

The [value](#)^{p765} must be text that is either a [valid date string](#)^{p76} or a [valid global date and time string](#)^{p81}.

Exactly one property with the name [dtstart](#)^{p784} must be present within each [item](#)^{p761} with the type <http://microformats.org/profile/hcalendar#vevent>^{p781}.

duration

Gives the duration of the event.

The [value](#)^{p765} must be text that is a [valid vevent duration string](#)^{p785}.

The duration represented is the sum of all the durations represented by integers in the value.

A single property with the name [duration](#)^{p784} may be present within each [item](#)^{p761} with the type <http://microformats.org/profile/hcalendar#vevent>^{p781}, so long as that <http://microformats.org/profile/hcalendar#vevent>^{p781} does not have a property with the name [dtend](#)^{p783}.

transp

Gives whether the event is to be considered as consuming time on a calendar, for the purpose of free-busy time searches.

The [value](#)^{p765} must be text with one of the following values:

- opaque
- transparent

A single property with the name [transp](#)^{p784} may be present within each [item](#)^{p761} with the type <http://microformats.org/profile/hcalendar#vevent>^{p781}.

contact

Gives the contact information for the event.

The [value](#)^{p765} must be text.

Any number of properties with the name [contact](#)^{p784} may be present within each [item](#)^{p761} with the type <http://microformats.org/profile/hcalendar#vevent>^{p781}.

url

Gives a [URL](#) for the event.

The [value](#)^{p765} must be an [absolute URL](#).

A single property with the name [url](#)^{p784} may be present within each [item](#)^{p761} with the type <http://microformats.org/profile/hcalendar#vevent>^{p781}.

uid

Gives a globally unique identifier corresponding to the event.

The [value](#)^{p765} must be text.

A single property with the name [uid](#)^{p784} may be present within each [item](#)^{p761} with the type <http://microformats.org/profile/hcalendar#vevent>^{p781}.

exdate

Gives a date and time at which the event does not occur despite the recurrence rules.

The [value](#)^{p765} must be text that is either a [valid date string](#)^{p76} or a [valid global date and time string](#)^{p81}.

Any number of properties with the name [exdate](#)^{p784} may be present within each [item](#)^{p761} with the type <http://microformats.org/profile/hcalendar#vevent>^{p781}.

rdate

Gives a date and time at which the event recurs.

The [value](#)^{p765} must be text that is one of the following:

- A [valid date string](#)^{p76}.
- A [valid global date and time string](#)^{p81}.
- A [valid global date and time string](#)^{p81} followed by a U+002F SOLIDUS character (/) followed by a second [valid global date and time string](#)^{p81} representing a later time.
- A [valid global date and time string](#)^{p81} followed by a U+002F SOLIDUS character (/) followed by a [valid vevent duration string](#)^{p785}.

Any number of properties with the name [rdate](#)^{p785} may be present within each [item](#)^{p761} with the type <http://microformats.org/profile/hcalendar#vevent>^{p781}.

rrule

Gives a rule for finding dates and times at which the event occurs.

The [value](#)^{p765} must be text that matches the RECUR value type defined in *iCalendar*. [\[RFC5545\]](#)^{p1311}

A single property with the name [rrule](#)^{p785} may be present within each [item](#)^{p761} with the type <http://microformats.org/profile/hcalendar#vevent>^{p781}.

created

Gives the date and time at which the event information was first created in a calendaring system.

The [value](#)^{p765} must be text that is a [valid global date and time string](#)^{p81}.

A single property with the name [created](#)^{p785} may be present within each [item](#)^{p761} with the type <http://microformats.org/profile/hcalendar#vevent>^{p781}.

last-modified

Gives the date and time at which the event information was last modified in a calendaring system.

The [value](#)^{p765} must be text that is a [valid global date and time string](#)^{p81}.

A single property with the name [last-modified](#)^{p785} may be present within each [item](#)^{p761} with the type <http://microformats.org/profile/hcalendar#vevent>^{p781}.

sequence

Gives a revision number for the event information.

The [value](#)^{p765} must be text that is a [valid non-negative integer](#)^{p70}.

A single property with the name [sequence](#)^{p785} may be present within each [item](#)^{p761} with the type <http://microformats.org/profile/hcalendar#vevent>^{p781}.

A string is a **valid vevent duration string** if it matches the following pattern:

1. A U+0050 LATIN CAPITAL LETTER P character (P).
2. One of the following:
 - A [valid non-negative integer](#)^{p70} followed by a U+0057 LATIN CAPITAL LETTER W character (W). The integer represents a duration of that number of weeks.
 - At least one, and possible both in this order, of the following:
 1. A [valid non-negative integer](#)^{p70} followed by a U+0044 LATIN CAPITAL LETTER D character (D). The integer represents a duration of that number of days.
 2. A U+0054 LATIN CAPITAL LETTER T character (T) followed by any one of the following, or the first and second of the following in that order, or the second and third of the following in that order, or all three of the following in this order:
 1. A [valid non-negative integer](#)^{p70} followed by a U+0048 LATIN CAPITAL LETTER H character (H). The integer represents a duration of that number of hours.

2. A [valid non-negative integer](#)^{p70} followed by a U+004D LATIN CAPITAL LETTER M character (M). The integer represents a duration of that number of minutes.
3. A [valid non-negative integer](#)^{p70} followed by a U+0053 LATIN CAPITAL LETTER S character (S). The integer represents a duration of that number of seconds.

5.3.2.1 Conversion to iCalendar §^{p78}₆

Given a list of nodes *nodes* in a [Document](#)^{p117}, a user agent must run the following algorithm to **extract any vEvent data represented by those nodes**:

1. If none of the nodes in *nodes* are [items](#)^{p761} with the type [http://microformats.org/profile/hcalendar#vevent](#)^{p781}, then there is no vEvent data. Abort the algorithm, returning nothing.
2. Let *output* be an empty string.
3. [Add an iCalendar line](#)^{p786} with the type "BEGIN" and the value "VCALENDAR" to *output*.
4. [Add an iCalendar line](#)^{p786} with the type "PRODID" and the value equal to a user-agent-specific string representing the user agent to *output*.
5. [Add an iCalendar line](#)^{p786} with the type "VERSION" and the value "2.0" to *output*.
6. For each node *node* in *nodes* that is an [item](#)^{p761} with the type [http://microformats.org/profile/hcalendar#vevent](#)^{p781}, run the following steps:

1. [Add an iCalendar line](#)^{p786} with the type "BEGIN" and the value "VEVENT" to *output*.
2. [Add an iCalendar line](#)^{p786} with the type "DTSTAMP" and a value consisting of an iCalendar DATE-TIME string representing the current date and time, with the annotation "VALUE=DATE-TIME", to *output*. [\[RFC5545\]](#)^{p1311}
3. For each element *element* that is [a property of the item](#)^{p766} *node*: for each name *name* in *element*'s [property names](#)^{p764}, run the appropriate set of substeps from the following list:

If the property's [value](#)^{p765} is an [item](#)^{p761}

Skip the property.

If the property is [dtend](#)^{p783}

If the property is [dtstart](#)^{p784}

If the property is [exdate](#)^{p784}

If the property is [rdate](#)^{p785}

If the property is [created](#)^{p785}

If the property is [last-modified](#)^{p785}

Let *value* be the result of stripping all U+002D HYPHEN-MINUS (-) and U+003A COLON (:) characters from the property's [value](#)^{p765}.

If the property's [value](#)^{p765} is a [valid date string](#)^{p76} then [add an iCalendar line](#)^{p786} with the type *name* and the value *value* to *output*, with the annotation "VALUE=DATE".

Otherwise, if the property's [value](#)^{p765} is a [valid global date and time string](#)^{p81} then [add an iCalendar line](#)^{p786} with the type *name* and the value *value* to *output*, with the annotation "VALUE=DATE-TIME".

Otherwise skip the property.

Otherwise

[Add an iCalendar line](#)^{p786} with the type *name* and the property's [value](#)^{p765} to *output*.

4. [Add an iCalendar line](#)^{p786} with the type "END" and the value "VEVENT" to *output*.
7. [Add an iCalendar line](#)^{p786} with the type "END" and the value "VCALENDAR" to *output*.

When the above algorithm says that the user agent is to **add an iCalendar line** consisting of a type *type*, a value *value*, and optionally an annotation, to a string *output*, it must run the following steps:

1. Let *line* be an empty string.
2. Append *type*, [converted to ASCII uppercase](#), to *line*.
3. If there is an annotation:
 1. Append a U+003B SEMICOLON character (;) to *line*.
 2. Append the annotation to *line*.
4. Append a U+003A COLON character (:) to *line*.
5. Prefix every U+005C REVERSE SOLIDUS character (\) in *value* with another U+005C REVERSE SOLIDUS character (\).
6. Prefix every U+002C COMMA character (,) in *value* with a U+005C REVERSE SOLIDUS character (\).
7. Prefix every U+003B SEMICOLON character (;) in *value* with a U+005C REVERSE SOLIDUS character (\).
8. Replace every U+000D CARRIAGE RETURN U+000A LINE FEED character pair (CRLF) in *value* with a U+005C REVERSE SOLIDUS character (\) followed by a U+006E LATIN SMALL LETTER N character (n).
9. Replace every remaining U+000D CARRIAGE RETURN (CR) or U+000A LINE FEED (LF) character in *value* with a U+005C REVERSE SOLIDUS character (\) followed by a U+006E LATIN SMALL LETTER N character (n).
10. Append *value* to *line*.
11. Let *maximum length* be 75.
12. While *line*'s [code point length](#) is greater than *maximum length*:
 1. Append the first *maximum length* code points of *line* to *output*.
 2. Remove the first *maximum length* code points from *line*.
 3. Append a U+000D CARRIAGE RETURN character (CR) to *output*.
 4. Append a U+000A LINE FEED character (LF) to *output*.
 5. Append a U+0020 SPACE character to *output*.
 6. Let *maximum length* be 74.
13. Append (what remains of) *line* to *output*.
14. Append a U+000D CARRIAGE RETURN character (CR) to *output*.
15. Append a U+000A LINE FEED character (LF) to *output*.

Note

This algorithm can generate invalid iCalendar output, if the input does not conform to the rules described for the <http://microformats.org/profile/hcalendar#vevent>^{p781} [item type](#)^{p761} and [defined property names](#)^{p764}.

5.3.2.2 Examples § p78

This section is non-normative.

Example

Here is an example of a page that uses the vEvent vocabulary to mark up an event:

```
<body itemscope itemtype="http://microformats.org/profile/hcalendar#vevent">
...
<h1 itemprop="summary">Bluesday Tuesday: Money Road</h1>
...
<time itemprop="dtstart" datetime="2009-05-05T19:00:00Z">May 5th @ 7pm</time>
(until <time itemprop="dtend" datetime="2009-05-05T21:00:00Z">9pm</time>)
...
```

```

<a href="http://livebrum.co.uk/2009/05/05/bluesday-tuesday-money-road"
  rel="bookmark" itemprop="url">Link to this page</a>
...
<p>Location: <span itemprop="location">The RoadHouse</span></p>
...
<p><input type="button" value="Add to Calendar"
  onclick="location = getCalendar(this)"></p>
...
<meta itemprop="description" content="via livebrum.co.uk">
</body>

```

The `getCalendar()` function is left as an exercise for the reader.

The same page could offer some markup, such as the following, for copy-and-pasting into blogs:

```

<div itemscope itemType="http://microformats.org/profile/hcalendar#vevent">
  <p>I'm going to
  <strong itemprop="summary">Bluesday Tuesday: Money Road</strong>,
  <time itemprop="dtstart" datetime="2009-05-05T19:00:00Z">May 5th at 7pm</time>
  to <time itemprop="dtend" datetime="2009-05-05T21:00:00Z">9pm</time>,
  at <span itemprop="location">The RoadHouse</span>!</p>
  <p><a href="http://livebrum.co.uk/2009/05/05/bluesday-tuesday-money-road"
    itemprop="url">See this event on livebrum.co.uk</a>.</p>
  <meta itemprop="description" content="via livebrum.co.uk">
</div>

```

5.3.3 Licensing works ^{§^{p78}}₈

An item with the [item type](#)^{p761} `http://n.whatwg.org/work` represents a work (e.g. an article, an image, a video, a song, etc.). This type is primarily intended to allow authors to include licensing information for works.

The following are the type's [defined property names](#)^{p764}.

work

Identifies the work being described.

The [value](#)^{p765} must be an [absolute URL](#).

Exactly one property with the name [work](#)^{p788} must be present within each [item](#)^{p761} with the type [http://n.whatwg.org/work](#)^{p788}.

title

Gives the name of the work.

A single property with the name [title](#)^{p788} may be present within each [item](#)^{p761} with the type [http://n.whatwg.org/work](#)^{p788}.

author

Gives the name or contact information of one of the authors or creators of the work.

The [value](#)^{p765} must be either an [item](#)^{p761} with the type [http://microformats.org/profile/hcard](#)^{p768}, or text.

Any number of properties with the name [author](#)^{p788} may be present within each [item](#)^{p761} with the type [http://n.whatwg.org/work](#)^{p788}.

license

Identifies one of the licenses under which the work is available.

The [value](#)^{p765} must be an [absolute URL](#).

Any number of properties with the name [license](#)^{p788} may be present within each [item](#)^{p761} with the type [http://n.whatwg.org/](#)

5.3.3.1 Examples ^{§ p78}₉

This section is non-normative.

Example

This example shows an embedded image entitled *My Pond*, licensed under the Creative Commons Attribution-Share Alike 4.0 International License and the MIT license simultaneously.

```
<figure itemscope itemtype="http://n.whatwg.org/work">
  
  <figcaption>
    <p><cite itemprop="title">My Pond</cite></p>
    <p><small>Licensed under the <a itemprop="license"
      href="https://creativecommons.org/licenses/by-sa/4.0/">Creative
      Commons Attribution-Share Alike 4.0 International License</a>
      and the <a itemprop="license"
      href="http://www.opensource.org/licenses/mit-license.php">MIT
      license</a>.</small>
    </figcaption>
  </figure>
```

5.4 Converting HTML to other formats ^{§ p78}₉

5.4.1 JSON ^{§ p78}₉

Given a list of nodes *nodes* in a [Document](#)^{p117}, a user agent must run the following algorithm to **extract the microdata from those nodes into a JSON form**:

1. Let *result* be an empty object.
2. Let *items* be an empty array.
3. For each *node* in *nodes*, check if the element is a [top-level microdata item](#)^{p766}, and if it is then [get the object](#)^{p789} for that element and add it to *items*.
4. Add an entry to *result* called "items" whose value is the array *items*.
5. Return the result of serializing *result* to JSON in the shortest possible way (meaning no whitespace between tokens, no unnecessary zero digits in numbers, and only using Unicode escapes in strings for characters that do not have a dedicated escape sequence), and with a lowercase "e" used, when appropriate, in the representation of any numbers. [\[JSON\]](#)^{p1309}

Note

This algorithm returns an object with a single property that is an array, instead of just returning an array, so that it is possible to extend the algorithm in the future if necessary.

When the user agent is to **get the object** for an item *item*, optionally with a list of elements *memory*, it must run the following substeps:

1. Let *result* be an empty object.
2. If no *memory* was passed to the algorithm, let *memory* be an empty list.
3. Add *item* to *memory*.
4. If the *item* has any [item types](#)^{p761}, add an entry to *result* called "type" whose value is an array listing the [item types](#)^{p761} of *item*, in the order they were specified on the [itemtype](#)^{p761} attribute.

5. If the *item* has a [global identifier^{p762}](#), add an entry to *result* called "id" whose value is the [global identifier^{p762}](#) of *item*.
6. Let *properties* be an empty object.
7. For each element *element* that has one or more [property names^{p764}](#) and is one of [the properties of the item^{p766}](#) *item*, in the order those elements are given by the algorithm that returns [the properties of an item^{p766}](#), run the following substeps:
 1. Let *value* be the [property value^{p765}](#) of *element*.
 2. If *value* is an [item^{p761}](#), then: If *value* is in *memory*, then let *value* be the string "ERROR". Otherwise, [get the object^{p789}](#) for *value*, passing a copy of *memory*, and then replace *value* with the object returned from those steps.
 3. For each name *name* in *element*'s [property names^{p764}](#), run the following substeps:
 1. If there is no entry named *name* in *properties*, then add an entry named *name* to *properties* whose value is an empty array.
 2. Append *value* to the entry named *name* in *properties*.
8. Add an entry to *result* called "properties" whose value is the object *properties*.
9. Return *result*.

Example

For example, take this markup:

```

<!DOCTYPE HTML>
<html lang="en">
<title>My Blog</title>
<article itemscope itemtype="http://schema.org/BlogPosting">
  <header>
    <h1 itemprop="headline">Progress report</h1>
    <p><time itemprop="datePublished" datetime="2013-08-29">today</time></p>
    <link itemprop="url" href="?comments=0">
  </header>
  <p>All in all, he's doing well with his swim lessons. The biggest thing was he had trouble putting his head in, but we got it down.</p>
  <section>
    <h1>Comments</h1>
    <article itemprop="comment" itemscope itemtype="http://schema.org/UserComments" id="c1">
      <link itemprop="url" href="#c1">
      <footer>
        <p>Posted by: <span itemprop="creator" itemscope itemtype="http://schema.org/Person">
          <span itemprop="name">Greg</span>
        </span></p>

6 User interaction §^{p79}₂

6.1 The `hidden` attribute §^{p79}₂

All [HTML elements](#)^{p44} may have the `hidden` content attribute set. The `hidden`^{p792} attribute is a [boolean attribute](#)^{p69}. When specified on an element, it indicates that the element is not yet, or is no longer, directly relevant to the page's current state, or that it is being used to declare content to be reused by other parts of the page as opposed to being directly accessed by the user. User agents should not render elements that have the `hidden`^{p792} attribute specified. This requirement may be implemented indirectly through the style layer. For example, an HTML+CSS user agent could implement these requirements [using the rules suggested in the Rendering section](#)^{p1222}.

Note

Because this attribute is typically implemented using CSS, it's also possible to override it using CSS. For instance, a rule that applies 'display: block' to all elements will cancel the effects of the `hidden`^{p792} attribute. Authors therefore have to take care when writing their style sheets to make sure that the attribute is still styled as expected.

Example

In the following skeletal example, the attribute is used to hide the web game's main screen until the user logs in:

```
<h1>The Example Game</h1>
<section id="login">
  <h2>Login</h2>
  <form>
    ...
    <!-- calls login() once the user's credentials have been checked -->
  </form>
  <script>
    function login() {
      // switch screens
      document.getElementById('login').hidden = true;
      document.getElementById('game').hidden = false;
    }
  </script>
</section>
<section id="game" hidden>
  ...
</section>
```

The `hidden`^{p792} attribute must not be used to hide content that could legitimately be shown in another presentation. For example, it is incorrect to use `hidden`^{p792} to hide panels in a tabbed dialog, because the tabbed interface is merely a kind of overflow presentation — one could equally well just show all the form controls in one big page with a scrollbar. It is similarly incorrect to use this attribute to hide content just from one presentation — if something is marked `hidden`^{p792}, it is hidden from all presentations, including, for instance, screen readers.

Elements that are not themselves `hidden`^{p792} must not [hyperlink](#)^{p289} to elements that are `hidden`^{p792}. The `for` attributes of [Label](#)^{p498} and [output](#)^{p563} elements that are not themselves `hidden`^{p792} must similarly not refer to elements that are `hidden`^{p792}. In both cases, such references would cause user confusion.

Elements and scripts may, however, refer to elements that are `hidden`^{p792} in other contexts.

Example

For example, it would be incorrect to use the `href`^{p290} attribute to link to a section marked with the `hidden`^{p792} attribute. If the content is not applicable or relevant, then there is no reason to link to it.

It would be fine, however, to use the ARIA `aria-describedby` attribute to refer to descriptions that are themselves `hidden`^{p792}. While hiding the descriptions implies that they are not useful alone, they could be written in such a way that they are useful in the specific context of being referenced from the elements that they describe.

Similarly, a [`canvas`](#)^{p645} element with the [`hidden`](#)^{p792} attribute could be used by a scripted graphics engine as an off-screen buffer, and a form control could refer to a hidden [`form`](#)^{p494} element using its [`form`](#)^{p576} attribute.

Elements in a section hidden by the [`hidden`](#)^{p792} attribute are still active, e.g. scripts and form controls in such sections still execute and submit respectively. Only their presentation to the user changes.

The [`hidden`](#) IDL attribute must [reflect](#)^{p97} the content attribute of the same name.

6.2 Page visibility §^{p79}₃

A [top-level browsing context](#)^{p844} has a **system visibility state**, which is either "hidden" or "visible".

Note

The [system visibility state](#)^{p793} is determined by the user-agent, and represents, for example, whether the browser window is minimized, a browser tab is currently in the background, or a system element such as a task switcher obscures the page.

When a user-agent determines that the [system visibility state](#)^{p793} for [top-level browsing context](#)^{p844} context has changed to *newState*, it must [queue a task](#)^{p970} on the [user interaction task source](#)^{p977} to [update the visibility state](#)^{p793} of all the [Document](#)^{p117} objects in the [top-level browsing context](#)^{p844}'s [document family](#)^{p845} with *newState*.

A [Document](#)^{p117} has a **visibility state**, which is either "hidden" or "visible", initially set to "hidden".

The [visibilityState](#) getter steps are to return [this](#)'s [visibility state](#)^{p793}.

The [hidden](#) getter steps are to return true if [this](#)'s [visibility state](#)^{p793} is "hidden", otherwise false.

To **update the visibility state** of [Document](#)^{p117} *document* to *visibilityState*:

1. If *document*'s [visibility state](#)^{p793} equals *visibilityState*, then return.
2. Set *document*'s [visibility state](#)^{p793} to *visibilityState*.
3. Run any **page visibility change steps** which may be defined in other specifications, with [visibility state](#)^{p793} and *document*.

It would be better if specification authors sent a pull request to add calls from here into their specifications directly, instead of using the [page visibility change steps](#)^{p793} hook, to ensure well-defined cross-specification call order. As of the time of this writing the following specifications are known to have [page visibility change steps](#)^{p793}, which will be run in an unspecified order: *Device Posture API*, *Screen Orientation API*, and *Web NFC*. [\[DEVICEPOSTURE\]](#)^{p1307} [\[SCREENORIENTATION\]](#)^{p1311} [\[WEBNFC\]](#)^{p1313}

4. Fire an event named [visibilitychange](#)^{p1302} at *document*, with its [bubbles](#) attribute initialized to true.

6.3 Inert subtrees §^{p79}₃

Note

See also [inert](#)^{p794} for an explanation of the attribute of the same name.

A node (in particular elements and text nodes) can be **inert**. When a node is [inert](#)^{p793}:

- Hit-testing must act as if the ['pointer-events'](#) CSS property were set to 'none'.
- Text selection functionality must act as if the ['user-select'](#) CSS property were set to 'none'.
- If it is [editable](#), the node behaves as if it were non-editable.

- The user agent may ignore the node for the purposes of [find-in-page](#)^{p822}.

Note

Inert nodes generally cannot be focused. Inert nodes that are [commands](#)^{p618} will also get disabled.

User agents may allow the user to override the restrictions on search and text selection, however.

By default, a node is not [inert](#)^{p793}.

6.3.1 Modal dialogs and inert subtrees §^{p79}₄

A [Document](#)^{p117} *document* is **blocked by a modal dialog** *subject* if *subject* is the topmost [dialog](#)^{p620} element in *document*'s [top layer](#). While *document* is so blocked, every node that is [connected](#) to *document*, with the exception of the *subject* element and its [flat tree](#) descendants, must become [inert](#)^{p793}. (The elements excepted by this paragraph can additionally become [inert](#)^{p793} through other means; being part of a modal dialog does not "protect" a node from being [inert](#)^{p793}.)

Note

The [dialog](#)^{p620} element's [showModal\(\)](#)^{p622} method causes this mechanism to trigger, by [adding the dialog](#)^{p620} element to its [node document's top layer](#).

6.3.2 The **inert** attribute §^{p79}₄

The [inert](#)^{p794} attribute is a [boolean attribute](#)^{p69} that indicates, by its presence, that the element and all its [flat tree](#) descendants are to be made [inert](#)^{p793} by the user agent.

Note

By default, there is no persistent visual indication of a subtree being inert. Authors are encouraged to clearly mark what parts of their document are active and which are inert, to avoid user confusion. In particular, it is worth remembering that not all users can see all parts of a page at once; for example, users of screen readers, users on small devices or with magnifiers, and even users using particularly small windows might not be able to see the active part of a page and might get frustrated if inert sections are not obviously inert. For individual controls, the [disabled](#)^{p580} attribute is probably more appropriate.

MDN

The **inert** IDL attribute must [reflect](#)^{p97} the content attribute of the same name.

6.4 Tracking user activation §^{p79}₄

To prevent abuse of certain APIs that could be annoying to users (e.g., opening popups or vibrating phones), user agents allow these APIs only when the user is actively interacting with the web page or has interacted with the page at least once. This "active interaction" state is maintained through the mechanisms defined in this section.

6.4.1 Data model §^{p79}₄

For the purpose of tracking user activation, each [Window](#)^{p855} *W* has a **last activation timestamp**. This is a number indicating the last time *W* got an [activation notification](#)^{p795}. It corresponds to a [DOMHighResTimeStamp](#) value except for two cases: positive infinity indicates that *W* has never been activated, while negative infinity indicates that a [user activation-gated API](#)^{p796} has [consumed](#)^{p795} the last user activation of *W*. The initial value is positive infinity.

A user agent also defines a **transient activation duration**, which is a constant number indicating how long a user activation is available for certain [user activation-gated APIs](#)^{p796} (e.g., for opening popups).

Note

The [transient activation duration](#)^{p794} is expected to be at most a few seconds, so that the user can possibly perceive the link between an interaction with the page and the page calling the activation-gated API.

These two values imply two boolean user activation states for W :

Sticky activation

When the [current high resolution time](#) given W is greater than or equal to the [last activation timestamp](#)^{p794} in W , W is said to have [sticky activation](#)^{p795}.

This is W 's historical activation state, indicating whether the user has ever interacted in W . It starts false, then changes to true (and never changes back to false) when W gets the very first [activation notification](#)^{p795}.

Transient activation

When the [current high resolution time](#) given W is greater than or equal to the [last activation timestamp](#)^{p794} in W , and less than the [last activation timestamp](#)^{p794} in W plus the [transient activation duration](#)^{p794}, then W is said to have [transient activation](#)^{p795}.

This is W 's current activation state, indicating whether the user has interacted in W recently. This starts with a false value, and remains true for a limited time after every [activation notification](#)^{p795} W gets.

The [transient activation](#)^{p795} state is considered **expired** if it becomes false because the [transient activation duration](#)^{p794} time has elapsed since the last user activation. Note that it can become false even before the expiry time through an [activation consumption](#)^{p795}.

6.4.2 Processing model ^{p79}₅

When a user interaction in a [browsing context](#)^{p840} B causes firing of an [activation triggering input event](#)^{p795} in B 's [active document](#)^{p840} D , the user agent must perform the following **activation notification** steps *before dispatching* the event:

1. Let *browsingContexts* be a list consisting of:
 - B ,
 - all [ancestor browsing contexts](#)^{p843} of B , and
 - all the [descendant browsing contexts](#)^{p844} of D that have [active documents](#)^{p840} from the [same origin](#)^{p869} as that of D .
2. Let *windows* be the list of [Window](#)^{p855} objects constructed by taking the [active window](#)^{p840} of each item in *browsingContexts*.
3. **For each** *window* in *windows*, set *window*'s [last activation timestamp](#)^{p794} to the [current high resolution time](#).

An **activation triggering input event** is any event whose `isTrusted` attribute is true and whose `type` is one of:

- `keydown`, provided the key is neither the Esc key nor a shortcut key reserved by the user agent.
- `mousedown`.
- `pointerdown`, provided the event's `pointerType` is "mouse".
- `pointerup`, provided the event's `pointerType` is not "mouse".
- `touchend`.

[Activation consuming APIs](#)^{p796} defined in this and other specifications can **consume user activation** by performing the following steps, given a [Window](#)^{p855} W :

1. If W 's [browsing context](#)^{p856} is null, then return.
2. Let *top* be W 's [browsing context](#)^{p856}'s [top-level browsing context](#)^{p844}.
3. Let *browsingContexts* be the [list of the descendant browsing contexts](#)^{p844} of *top*'s [active document](#)^{p840}.
4. **Append** *top* to *browsingContexts*.
5. Let *windows* be the list of [Window](#)^{p855} objects constructed by taking the [active window](#)^{p840} of each item in *browsingContexts*.
6. **For each** *window* in *windows*, if *window*'s [last activation timestamp](#)^{p794} is not positive infinity, then set *window*'s [last activation timestamp](#)^{p794} to negative infinity.

The spec is not clear about how to traverse a tree of documents. See [issue #5020](#).

Note

Note the asymmetry in the sets of [browsing contexts](#)^{p840} in the page that are affected by an [activation notification](#)^{p795} vs an [activation consumption](#)^{p795}: an activation consumption changes (to false) the [transient activation](#)^{p795} states for all browsing contexts in the page, but an activation notification changes (to true) the states for a subset of those browsing contexts. The exhaustive nature of consumption here is deliberate: it prevents malicious sites from making multiple calls to an [activation consuming API](#)^{p796} from a single user activation (possibly by exploiting a deep hierarchy of [iframe](#)^{p369}s).

6.4.3 APIs gated by user activation § p796

APIs that are dependent on user activation are classified into three different levels. The levels are as follows, sorted by their "strength of dependence" on user activation (from weakest to strongest):

Sticky activation-gated APIs

These APIs require the [sticky activation](#)^{p795} state to be true, so they are blocked until the very first user activation.

Transient activation-gated APIs

These APIs require the [transient activation](#)^{p795} state to be true, but they don't [consume](#)^{p795} it, so multiple calls are allowed per user activation until the transient state [expires](#)^{p795}.

Transient activation-consuming APIs

These APIs require the [transient activation](#)^{p795} state to be true, and they [consume user activation](#)^{p795} in each call to prevent multiple calls per user activation.

6.5 Activation behavior of elements § p796

Certain elements in HTML have an [activation behavior](#), which means that the user can activate them. This is always caused by a [click](#) event.

The user agent should allow the user to manually trigger elements that have an [activation behavior](#), for instance using keyboard or voice input, or through mouse clicks. When the user triggers an element with a defined [activation behavior](#) in a manner other than clicking it, the default action of the interaction event must be to [fire a click event](#)^{p991} at the element.

For web developers (non-normative)

`element.click`^{p796} ()

Acts as if the element was clicked.

Each element has an associated **click in progress flag**, which is initially unset.

The `click()` method must run the following steps:

1. If this element is a form control that is [disabled](#)^{p580}, then return.
2. If this element's [click in progress flag](#)^{p796} is set, then return.
3. Set this element's [click in progress flag](#)^{p796}.
4. [Fire a synthetic pointer event](#)^{p991} named `click` at this element, with the *not trusted flag* set.
5. Unset this element's [click in progress flag](#)^{p796}.

6.6 Focus ^{§p79}₇

6.6.1 Introduction ^{§p79}₇

This section is non-normative.

An HTML user interface typically consists of multiple interactive widgets, such as form controls, scrollable regions, links, dialog boxes, browser tabs, and so forth. These widgets form a hierarchy, with some (e.g. browser tabs, dialog boxes) containing others (e.g. links, form controls).

When interacting with an interface using a keyboard, key input is channeled from the system, through the hierarchy of interactive widgets, to an active widget, which is said to be [focused](#)^{p799}.

Example

Consider an HTML application running in a browser tab running in a graphical environment. Suppose this application had a page with some text controls and links, and was currently showing a modal dialog, which itself had a text control and a button.

The hierarchy of focusable widgets, in this scenario, would include the browser window, which would have, amongst its children, the browser tab containing the HTML application. The tab itself would have as its children the various links and text controls, as well as the dialog. The dialog itself would have as its children the text control and the button.

If the widget with [focus](#)^{p799} in this example was the text control in the dialog box, then key input would be channeled from the graphical system to ① the web browser, then to ② the tab, then to ③ the dialog, and finally to ④ the text control.

Keyboard events are always targeted at this [focused](#)^{p799} element.

6.6.2 Data model ^{§p79}₇

A [top-level browsing context](#)^{b844} has **system focus** when it can receive keyboard input channeled from the operating system.

Note

System focus is lost when a browser window loses focus, but might also be lost to other system widgets in the browser window such as a URL bar.

The term **focusable area** is used to refer to regions of the interface that can further become the target of such keyboard input. Focusable areas can be elements, parts of elements, or other regions managed by the user agent.

Each [focusable area](#)^{p798} has a **DOM anchor**, which is a [Node](#) object that represents the position of the [focusable area](#)^{p798} in the DOM. (When the [focusable area](#)^{p798} is itself a [Node](#), it is its own [DOM anchor](#)^{p798}.) The [DOM anchor](#)^{p798} is used in some APIs as a substitute for the [focusable area](#)^{p798} when there is no other DOM object to represent the [focusable area](#)^{p798}.

The following table describes what objects can be [focusable areas](#)^{p798}. The cells in the left column describe objects that can be [focusable areas](#)^{p798}; the cells in the right column describe the [DOM anchors](#)^{p798} for those elements. (The cells that span both columns are non-normative examples.)

Focusable area ^{p798}	DOM anchor ^{p798}
Examples	
Elements that meet all the following criteria: <ul style="list-style-type: none"> the element's tabindex value^{p802} is non-null, or the element is determined by the user agent to be focusable; the element is either not a shadow host, or has a shadow root whose delegates focus is false; the element is not actually disabled^{p749}; the element is not inert^{p793}; the element is either being rendered^{p1221} or being used as relevant canvas fallback content^{p647}. 	The element itself.
Example	
iframe ^{p369} , <input type= text > ^{p508} , sometimes <a href=" " > ^{p244} (depending on platform conventions).	
The shapes of area^{p452} elements in an image map^{p454} associated with an img^{p327} element that is being rendered^{p1221} and is not inert^{p793}.	The img ^{p327} element.
Example	
In the following example, the area ^{p452} element creates two shapes, one on each image. The DOM anchor ^{p798} of the first shape is the first img ^{p327} element, and the DOM anchor ^{p798} of the second shape is the second img ^{p327} element.	
<pre> <map id=wallmap><area alt="Enter Door" coords="10,10,100,200" href="door.html"></map> </pre>	
The user-agent provided subwidgets of elements that are being rendered^{p1221} and are not actually disabled^{p749} or inert^{p793}.	The element for which the focusable area ^{p798} is a subwidget.
Example	
The controls in the user interface ^{p444} for a video ^{p388} element, the up and down buttons in a spin-control version of <input type= number > ^{p517} , the part of a details ^{p614} element's rendering that enables the element to be opened or closed using keyboard input.	
The scrollable regions of elements that are being rendered^{p1221} and are not inert^{p793}.	The element for which the box that the scrollable region scrolls was created.
Example	
The CSS 'overflow' property's 'scroll' value typically creates a scrollable region.	
The viewport of a Document^{p117} that has a non-null browsing context^{p840} and is not inert^{p793}.	The Document ^{p117} for which the viewport was created.
Example	
The contents of an iframe ^{p369} .	
Any other element or part of an element determined by the user agent to be a focusable area, especially to aid with accessibility or to better match platform conventions.	The element.

Examples

Example

A user agent could make all list item bullets [sequentially focusable](#)^{p800}, so that a user can more easily navigate lists.

Example

Similarly, a user agent could make all elements with [title](#)^{p143} attributes [sequentially focusable](#)^{p800}, so that their advisory information can be accessed.

Note

A [browsing context container](#)^{p843} (e.g. an [iframe](#)^{p369}) is a [focusable area](#)^{p798}, but key events routed to a [browsing context container](#)^{p843} get immediately routed to its [nested browsing context](#)^{p843}'s [active document](#)^{p840}. Similarly, in sequential focus navigation a [browsing context container](#)^{p843} essentially acts merely as a placeholder for its [nested browsing context](#)^{p843}'s [active document](#)^{p840}.

One [focusable area](#)^{p798} in each [Document](#)^{p117} is designated the **focused area of the document**. Which control is so designated changes over time, based on algorithms in this specification.

Note

Even if a document is not [fully active](#)^{p844} and not shown to the user, it can still have a [focused area of the document](#)^{p799}. If a document's [fully active](#)^{p844} state changes, its [focused area of the document](#)^{p799} will stay the same.

The **currently focused area of a top-level browsing context** *topLevelBC* at any particular time is the [focusable area](#)^{p798}-or-null returned by this algorithm:

1. If *topLevelBC* does not have [system focus](#)^{p797}, then return null.
2. Let *candidate* be *topLevelBC*'s [active document](#)^{p840}.
3. While *candidate*'s [focused area](#)^{p799} is a [browsing context container](#)^{p843} with a non-null [nested browsing context](#)^{p843}: set *candidate* to the [active document](#)^{p840} of that [browsing context container](#)^{p843}'s [nested browsing context](#)^{p843}.
4. If *candidate*'s [focused area](#)^{p799} is non-null, set *candidate* to *candidate*'s [focused area](#)^{p799}.
5. Return *candidate*.

The **current focus chain of a top-level browsing context** *topLevelBC* at any particular time is the [focus chain](#)^{p799} of the [currently focused area](#)^{p799} of *topLevelBC*, if *topLevelBC* is non-null, or an empty list otherwise.

An element that is the [DOM anchor](#)^{p798} of a [focusable area](#)^{p798} is said to **gain focus** when that [focusable area](#)^{p798} becomes the [currently focused area of a top-level browsing context](#)^{p799}. When an element is the [DOM anchor](#)^{p798} of a [focusable area](#)^{p798} of the [currently focused area of a top-level browsing context](#)^{p799}, it is **focused**.

The **focus chain** of a [focusable area](#)^{p798} *subject* is the ordered list constructed as follows:

1. Let *output* be an empty [list](#).
2. Let *currentObject* be *subject*.
3. While true:
 1. [Append](#) *currentObject* to *output*.
 2. If *currentObject* is an [area](#)^{p452} element's shape, then [append](#) that [area](#)^{p452} element to *output*.
Otherwise, if *currentObject*'s [DOM anchor](#)^{p798} is an element that is not *currentObject* itself, then [append](#) *currentObject*'s [DOM anchor](#)^{p798} to *output*.
 3. If *currentObject* is a [focusable area](#)^{p798}, then set *currentObject* to *currentObject*'s [DOM anchor](#)^{p798}'s [node document](#).
Otherwise, if *currentObject* is a [Document](#)^{p117} whose [browsing context](#)^{p840} is a [child browsing context](#)^{p843}, then set *currentObject* to *currentObject*'s [browsing context](#)^{p840}'s [container](#)^{p843}.

Otherwise, [break](#).

4. Return *output*.

Note

The chain starts with *subject* and (if *subject* is or can be the [currently focused area of a top-level browsing context](#)^{p799}) continues up the focus hierarchy up to the [Document](#)^{p117} of the [top-level browsing context](#)^{p844}.

All elements that are [focusable areas](#)^{p798} are said to be **focusable**.

There are two special types of focusability for [focusable areas](#)^{p798}:

- A [focusable area](#)^{p798} is said to be **sequentially focusable** if it is included in its [Document](#)^{p117}'s [sequential focus navigation order](#)^{p807} and the user agent determines that it is sequentially focusable.
- A [focusable area](#)^{p798} is said to be **click focusable** if the user agent determines that it is click focusable. User agents should consider focusable areas with non-null [tabindex values](#)^{p802} to be click focusable.

Note

Elements which are not [focusable](#)^{p800} are not [focusable areas](#)^{p798}, and thus not [sequentially focusable](#)^{p800} and not [click focusable](#)^{p800}.

Note

Being [focusable](#)^{p800} is a statement about whether an element can be focused programmatically, e.g. via the [focus\(\)](#)^{p810} method or [autofocus](#)^{p810} attribute. In contrast, [sequentially focusable](#)^{p800} and [click focusable](#)^{p800} govern how the user agent responds to user interaction: respectively, to [sequential focus navigation](#)^{p807} and as [activation behavior](#)^{p0}.

The user agent might determine that an element is not [sequentially focusable](#)^{p800} even if it is [focusable](#)^{p800} and is included in its [Document](#)^{p117}'s [sequential focus navigation order](#)^{p807}, according to user preferences. For example, macOS users can set the user agent to skip non-form control elements, or can skip links when doing [sequential focus navigation](#)^{p807} with just the Tab key (as opposed to using both the Option and Tab keys).

Similarly, the user agent might determine that an element is not [click focusable](#)^{p800} even if it is [focusable](#)^{p800}. For example, in some user agents, clicking on a non-editable form control does not focus it, i.e. the user agent has determined that such controls are not click focusable.

Thus, an element can be [focusable](#)^{p800}, but neither [sequentially focusable](#)^{p800} nor [click focusable](#)^{p800}. For example, in some user agents, a non-editable form-control with a negative-integer [tabindex value](#)^{p802} would not be focusable via user interaction, only via programmatic APIs.

When a user [activates](#)^{p796} a [click focusable](#)^{p800} [focusable area](#)^{p798}, the user agent must run the [focusing steps](#)^{p805} on the [focusable area](#)^{p798} with *focus trigger* set to "click".

Note

Note that focusing is not an [activation behavior](#), i.e. calling the [click\(\)](#)^{p796} method on an element or dispatching a synthetic [click](#) event on it won't cause the element to get focused.

A node is a **focus navigation scope owner** if it is a [document](#)^{p117}, a [shadow host](#) or a [slot](#)^{p644}.

Each [focus navigation scope owner](#)^{p800} has a **focus navigation scope**, which is a list of elements. Its contents are determined as follows:

Every element *element* has an **associated focus navigation owner**, which is either null or a [focus navigation scope owner](#)^{p800}. It is determined by the following algorithm:

1. If *element*'s parent is null, then return null.
2. If *element*'s parent is a [shadow host](#), then return *element*'s [assigned slot](#).
3. If *element*'s parent is a [shadow root](#), then return the parent's [host](#).

4. If *element*'s parent is the [document element](#), then return the parent's [node document](#).
5. Return *element*'s parent's [associated focus navigation owner](#)^{p800}.

Then, the contents of a given [focus navigation scope owner](#)^{p800} *owner*'s [focus navigation scope](#)^{p800} are all elements whose [associated focus navigation owner](#)^{p800} is *owner*.

Note

The order of elements within a [focus navigation scope](#)^{p800} does not impact any of the algorithms in this specification. Ordering only becomes important for the [tabindex-ordered focus navigation scope](#)^{p801} and [flattened tabindex-ordered focus navigation scope](#)^{p801} concepts defined below.

A **tabindex-ordered focus navigation scope** is a list of [focusable areas](#)^{p798} and [focus navigation scope owners](#)^{p800}. Every [focus navigation scope owner](#)^{p800} *owner* has [tabindex-ordered focus navigation scope](#)^{p801}, whose contents are determined as follows:

- It contains all elements in *owner*'s [focus navigation scope](#)^{p800} that are themselves [focus navigation scope owners](#)^{p800}, except the elements whose [tabindex value](#)^{p802} is a negative integer.
- It contains all of the [focusable areas](#)^{p798} whose [DOM anchor](#)^{p798} is an element in *owner*'s [focus navigation scope](#)^{p800}, except the [focusable areas](#)^{p798} whose [tabindex value](#)^{p802} is a negative integer.

The order within a [tabindex-ordered focus navigation scope](#)^{p801} is determined by each element's [tabindex value](#)^{p802}, as described in the section below.

Note

The rules there do not give a precise ordering, as they are composed mostly of "should" statements and relative orderings.

A **flattened tabindex-ordered focus navigation scope** is a list of [focusable areas](#)^{p798}. Every [focus navigation scope owner](#)^{p800} *owner* owns a distinct [flattened tabindex-ordered focus navigation scope](#)^{p801}, whose contents are determined by the following algorithm:

1. Let *result* be a [clone](#) of *owner*'s [tabindex-ordered focus navigation scope](#)^{p801}.
2. For each *item* of *result*:
 1. If *item* is not a [focus navigation scope owner](#)^{p800}, then [continue](#).
 2. If *item* is not a [focusable area](#)^{p798}, then replace *item* with all of the items in *item*'s [flattened tabindex-ordered focus navigation scope](#)^{p801}.
 3. Otherwise, insert the contents of *item*'s [flattened tabindex-ordered focus navigation scope](#)^{p801} after *item*.

6.6.3 The [tabindex](#)^{p801} attribute § p801

The [tabindex](#) content attribute allows authors to make an element and regions that have the element as its [DOM anchor](#)^{p798} be [focusable areas](#)^{p798}, allow or prevent them from being [sequentially focusable](#)^{p800}, and determine their relative ordering for [sequential focus navigation](#)^{p807}.

The name "tab index" comes from the common use of the Tab key to navigate through the focusable elements. The term "tabbing" refers to moving forward through [sequentially focusable](#)^{p800} [focusable areas](#)^{p798}.

The [tabindex](#)^{p801} attribute, if specified, must have a value that is a [valid integer](#)^{p70}. Positive numbers specify the relative position of the element's [focusable areas](#)^{p798} in the [sequential focus navigation order](#)^{p807}, and negative numbers indicate that the control is not [sequentially focusable](#)^{p800}.

Developers should use caution when using values other than 0 or -1 for their [tabindex](#)^{p801} attributes as this is complicated to do correctly.

Note

The following provides a non-normative summary of the behaviors of the possible [tabindex](#)^{p801} attribute values. The below

processing model gives the more precise rules.

omitted (or non-integer values)

The user agent will decide whether the element is [focusable^{p800}](#), and if it is, whether it is [sequentially focusable^{p800}](#) or [click focusable^{p800}](#) (or both).

-1 (or other negative integer values)

Causes the element to be [focusable^{p800}](#), and indicates that the author would prefer the element to be [click focusable^{p800}](#) but not [sequentially focusable^{p800}](#). The user agent might ignore this preference for click and sequential focusability, e.g., for specific element types according to platform conventions, or for keyboard-only users.

0

Causes the element to be [focusable^{p800}](#), and indicates that the author would prefer the element to be both [click focusable^{p800}](#) and [sequentially focusable^{p800}](#). The user agent might ignore this preference for click and sequential focusability.

positive integer values

Behaves the same as 0, but in addition creates a relative ordering within a [tabindex-ordered focus navigation scope^{p801}](#), so that elements with higher [tabindex^{p801}](#) attribute value come later.

Note that the [tabindex^{p801}](#) attribute cannot be used to make an element non-focusable. The only way a page author can do that is by [disabling^{p749}](#) the element, or making it [inert^{p793}](#).

The **tabindex value** of an element is the value of its [tabindex^{p801}](#) attribute, parsed using the [rules for parsing integers^{p70}](#). If parsing fails or the attribute is not specified, then the [tabindex value^{p802}](#) is null.

The [tabindex value^{p802}](#) of a [focusable area^{p798}](#) is the [tabindex value^{p802}](#) of its [DOM anchor^{p798}](#).

The [tabindex value^{p802}](#) of an element must be interpreted as follows:

If the value is null

The user agent should follow platform conventions to determine if the element should be considered as a [focusable area^{p798}](#) and if so, whether the element and any [focusable areas^{p798}](#) that have the element as their [DOM anchor^{p798}](#) are [sequentially focusable^{p800}](#), and if so, what their relative position in their [tabindex-ordered focus navigation scope^{p801}](#) is to be. If the element is a [focus navigation scope owner^{p800}](#), it must be included in its [tabindex-ordered focus navigation scope^{p801}](#) even if it is not a [focusable area^{p798}](#).

The relative ordering within a [tabindex-ordered focus navigation scope^{p801}](#) for elements and [focusable areas^{p798}](#) that belong to the same [focus navigation scope^{p800}](#) and whose [tabindex value^{p802}](#) is null should be in [shadow-including tree order](#).

Modulo platform conventions, it is suggested that the following elements should be considered as [focusable areas^{p798}](#) and be [sequentially focusable^{p800}](#):

- [a^{p244}](#) elements that have an [href^{p290}](#) attribute
- [button^{p545}](#) elements
- [input^{p501}](#) elements whose [type^{p503}](#) attribute are not in the [Hidden^{p507}](#) state
- [select^{p547}](#) elements
- [textarea^{p558}](#) elements
- [summary^{p617}](#) elements that are the first [summary^{p617}](#) element child of a [details^{p614}](#) element
- Elements with a [draggable^{p838}](#) attribute set, if that would enable the user agent to allow the user to begin drag operations for those elements without the use of a pointing device
- [Editing hosts^{p817}](#)
- [Browsing context containers^{p843}](#)

If the value is a negative integer

The user agent must consider the element as a [focusable area^{p798}](#), but should omit the element from any [tabindex-ordered focus navigation scope^{p801}](#).

Note

One valid reason to ignore the requirement that sequential focus navigation not allow the author to lead to the element would be if the user's only mechanism for moving the focus is sequential focus navigation. For instance, a keyboard-only user would be unable to click on a text control with a negative `tabindex`^{p801}, so that user's user agent would be well justified in allowing the user to tab to the control regardless.

If the value is a zero

The user agent must allow the element to be considered as a [focusable area](#)^{p798} and should allow the element and any [focusable areas](#)^{p798} that have the element as their [DOM anchor](#)^{p798} to be [sequentially focusable](#)^{p800}.

The relative ordering within a [tabindex-ordered focus navigation scope](#)^{p801} for elements and [focusable areas](#)^{p798} that belong to the same [focus navigation scope](#)^{p800} and whose [tabindex value](#)^{p802} is zero should be in [shadow-including tree order](#).

If the value is greater than zero

The user agent must allow the element to be considered as a [focusable area](#)^{p798} and should allow the element and any [focusable areas](#)^{p798} that have the element as their [DOM anchor](#)^{p798} to be [sequentially focusable](#)^{p800}, and should place the element — referenced as *candidate* below — and the aforementioned [focusable areas](#)^{p798} in the [tabindex-ordered focus navigation scope](#)^{p801} where the element is a part of so that, relative to other elements and [focusable areas](#)^{p798} that belong to the same [focus navigation scope](#)^{p800}, they are:

- before any [focusable area](#)^{p798} whose [DOM anchor](#)^{p798} is an element whose [tabindex](#)^{p801} attribute has been omitted or whose value, when parsed, returns an error,
- before any [focusable area](#)^{p798} whose [DOM anchor](#)^{p798} is an element whose [tabindex](#)^{p801} attribute has a value equal to or less than zero,
- after any [focusable area](#)^{p798} whose [DOM anchor](#)^{p798} is an element whose [tabindex](#)^{p801} attribute has a value greater than zero but less than the value of the [tabindex](#)^{p801} attribute on *candidate*,
- after any [focusable area](#)^{p798} whose [DOM anchor](#)^{p798} is an element whose [tabindex](#)^{p801} attribute has a value equal to the value of the [tabindex](#)^{p801} attribute on *candidate* but that is located earlier than *candidate* in [shadow-including tree order](#),
- before any [focusable area](#)^{p798} whose [DOM anchor](#)^{p798} is an element whose [tabindex](#)^{p801} attribute has a value equal to the value of the [tabindex](#)^{p801} attribute on *candidate* but that is located later than *candidate* in [shadow-including tree order](#), and
- before any [focusable area](#)^{p798} whose [DOM anchor](#)^{p798} is an element whose [tabindex](#)^{p801} attribute has a value greater than the value of the [tabindex](#)^{p801} attribute on *candidate*.

The `tabIndex` IDL attribute must [reflect](#)^{p97} the value of the [tabindex](#)^{p801} content attribute. The default value is 0 if the element is an [a](#)^{p244}, [area](#)^{p452}, [button](#)^{p545}, [frame](#)^{p1264}, [iframe](#)^{p369}, [input](#)^{p501}, [object](#)^{p381}, [select](#)^{p547}, [textarea](#)^{p558}, or [SVG a](#) element, or is a [summary](#)^{p617} element that is a [summary for its parent details](#)^{p617}. The default value is `-1` otherwise.

Note

The varying default value based on element type is a historical artifact.

6.6.4 Processing model ^{p80}₃

To **get the focusable area** for a *focus target* that is either an element that is not a [focusable area](#)^{p798}, or is a [browsing context](#)^{p840}, given an optional string *focus trigger* (default "other"), run the first matching set of steps from the following list:

↪ If *focus target* is an [area](#)^{p452} element with one or more shapes that are [focusable areas](#)^{p798}

Return the shape corresponding to the first [img](#)^{p327} element in [tree order](#) that uses the image map to which the [area](#)^{p452} element belongs.

↪ If *focus target* is an element with one or more scrollable regions that are [focusable areas](#)^{p798}

Return the element's first scrollable region, according to a pre-order, depth-first traversal of the [flat tree](#). [\[CSSSCOPING\]](#)^{p1307}

↪ If *focus target* is the [document element](#) of its [Document](#)^{p117}

Return the [Document](#)^{p117}'s [viewport](#).

↪ If **focus target** is a [browsing context](#)^{p840}

Return the [browsing context](#)^{p840}'s [active document](#)^{p840}.

↪ If **focus target** is a [browsing context container](#)^{p843} with a non-null [nested browsing context](#)^{p843}

Return the [browsing context container](#)^{p843}'s [nested browsing context](#)^{p843}'s [active document](#)^{p840}.

↪ If **focus target** is a [shadow host](#) whose [shadow root](#)'s [delegates focus](#) is true

1. If *focus target* is a [shadow-including inclusive ancestor](#) of the [currently focused area of a top-level browsing context](#)^{p799}'s [DOM anchor](#)^{p798}, then return null.
2. Return the [focus delegate](#)^{p804} for *focus target* given *focus trigger*.

Note

For [sequential focusability](#)^{p800}, the handling of [shadow hosts](#) and [delegates focus](#) is done when constructing the [sequential focus navigation order](#)^{p807}. That is, the [focusing steps](#)^{p805} will never be called on such [shadow hosts](#) as part of sequential focus navigation.

↪ Otherwise

Return null.

The **focus delegate** for a *focus target*, given an optional string *focus trigger* (default "other"), is given by the following steps:

1. Let *autofocus delegate* be the [autofocus delegate](#)^{p804} for *focus target* given *focus trigger*.
2. If *autofocus delegate* is not null, then return *autofocus delegate*.
3. If *focus target* is a [shadow host](#) and its [shadow root](#)'s [delegates focus](#) is false, then return null.
4. Let *parent* be *focus target*.
5. If *parent* is a [shadow host](#), then set *parent* to *parent*'s [shadow root](#).
6. For each *child* of *parent*'s [children](#):
 1. Let *focusable area* be *child*, if *child* is a [focusable area](#)^{p798}; otherwise let *focusable area* be the result of [getting the focusable area](#)^{p803} for *child* given *focus trigger*.

Note

This step can end up recursing, i.e., the [get the focusable area](#)^{p803} steps might return the [focus delegate](#)^{p804} of *child*.

2. If *focusable area* is not null, then return *focusable area*.
7. Return null.

Note

The above algorithm essentially returns the first suitable [focusable area](#)^{p798} where the path between its [DOM anchor](#)^{p798} and *focus target* [delegates focus](#) at any [shadow tree boundaries](#).

The **autofocus delegate** for a *focus target* given a *focus trigger* is given by the following steps:

1. For each [descendant](#) descendant of *focus target*, in [tree order](#):
 1. If *descendant* does not have an [autofocus](#)^{p810} content attribute, then [continue](#).
 2. Let *focusable area* be *descendant*, if *descendant* is a [focusable area](#)^{p798}; otherwise let *focusable area* be the result of [getting the focusable area](#)^{p803} for *descendant* given *focus trigger*.
 3. If *focusable area* is null, then [continue](#).
 4. If *focusable area* is not [click focusable](#)^{p800} and *focus trigger* is "click", then [continue](#).
 5. Return *focusable area*.
2. Return null.

The **focusing steps** for an object *new focus target* that is either a [focusable area](#)^{p798}, or an element that is not a [focusable area](#)^{p798}, or a [browsing context](#)^{p840}, are as follows. They can optionally be run with a *fallback target* and a string *focus trigger*.

1. If *new focus target* is not a [focusable area](#)^{p798}, then set *new focus target* to the result of [getting the focusable area](#)^{p803} for *new focus target*, given *focus trigger* if it was passed.
2. If *new focus target* is null, then:
 1. If no *fallback target* was specified, then return.
 2. Otherwise, set *new focus target* to the *fallback target*.
3. If *new focus target* is a [browsing context container](#)^{p843} with non-null [nested browsing context](#)^{p843}, then set *new focus target* to the [nested browsing context](#)^{p843}'s [active document](#)^{p840}.
4. If *new focus target* is a [focusable area](#)^{p798} and its [DOM anchor](#)^{p798} is [inert](#)^{p793}, then return.
5. If *new focus target* is the [currently focused area of a top-level browsing context](#)^{p799}, then return.
6. Let *old chain* be the [current focus chain of the top-level browsing context](#)^{p799} in which *new focus target* finds itself.
7. Let *new chain* be the [focus chain](#)^{p799} of *new focus target*.
8. Run the [focus update steps](#)^{p806} with *old chain*, *new chain*, and *new focus target* respectively.

User agents must [immediately](#)^{p42} run the [focusing steps](#)^{p805} for a [focusable area](#)^{p798} or [browsing context](#)^{p840} *candidate* whenever the user attempts to move the focus to *candidate*.

The **unfocusing steps** for an object *old focus target* that is either a [focusable area](#)^{p798} or an element that is not a [focusable area](#)^{p798} are as follows:

1. If *old focus target* is a [shadow host](#) whose [shadow root](#)'s [delegates focus](#) is true, and *old focus target*'s [shadow root](#) is a [shadow-including inclusive ancestor](#) of the [currently focused area of a top-level browsing context](#)^{p799}'s [DOM anchor](#)^{p798}, then set *old focus target* to that [currently focused area of a top-level browsing context](#)^{p799}.
2. If *old focus target* is [inert](#)^{p793}, then return.
3. If *old focus target* is an [area](#)^{p452} element and one of its shapes is the [currently focused area of a top-level browsing context](#)^{p799}, or, if *old focus target* is an element with one or more scrollable regions, and one of them is the [currently focused area of a top-level browsing context](#)^{p799}, then let *old focus target* be that [currently focused area of a top-level browsing context](#)^{p799}.
4. Let *old chain* be the [current focus chain of the top-level browsing context](#)^{p799} in which *old focus target* finds itself.
5. If *old focus target* is not one of the entries in *old chain*, then return.
6. If *old focus target* is not a [focusable area](#)^{p798}, then return.
7. Let *topDocument* be *old chain*'s last entry.
8. If *topDocument*'s [browsing context](#)^{p840} has [system focus](#)^{p797}, then run the [focusing steps](#)^{p805} for *topDocument*'s [viewport](#).

Otherwise, apply any relevant platform-specific conventions for removing [system focus](#)^{p797} from *topDocument*'s [browsing context](#)^{p840}, and run the [focus update steps](#)^{p806} with *old chain*, an empty list, and null respectively.

When the [currently focused area of a top-level browsing context](#)^{p799} is somehow unfocused without another element being explicitly focused in its stead, the user agent must [immediately](#)^{p42} run the [unfocusing steps](#)^{p805} for that object.

Note

The [unfocusing steps](#)^{p805} do not always result in the focus changing, even when applied to the [currently focused area of a top-level browsing context](#)^{p799}. For example, if the [currently focused area of a top-level browsing context](#)^{p799} is a [viewport](#), then it will usually keep its focus regardless until another [focusable area](#)^{p798} is explicitly focused with the [focusing steps](#)^{p805}.

Focus fixup rule: When the designated [focused area of the document](#)^{p799} is removed from that [Document](#)^{p117} in some way (e.g. it stops being a [focusable area](#)^{p798}, it is removed from the DOM, it becomes [inert](#)^{p793}, etc.), designate the [Document](#)^{p117}'s [viewport](#) to be the new [focused area of the document](#)^{p799}.

Example

For example, this might happen because an element is removed from its [Document](#)^{p117}, or has a [hidden](#)^{p792} attribute added. It might also happen to an [input](#)^{p501} element when the element gets [disabled](#)^{p580}.

Example

In a [Document](#)^{p117} whose [focused area](#)^{p799} is a [button](#)^{p545} element, removing, disabling, or hiding that button would cause the page's new [focused area](#)^{p799} to be the [viewport](#) of the [Document](#)^{p117}. This would, in turn, be reflected through the [activeElement](#)^{p810} API as [the body element](#)^{p123}.

The **focus update steps**, given an *old chain*, a *new chain*, and a *new focus target* respectively, are as follows:

1. If the last entry in *old chain* and the last entry in *new chain* are the same, pop the last entry from *old chain* and the last entry from *new chain* and redo this step.
2. For each entry *entry* in *old chain*, in order, run these substeps:
 1. If *entry* is an [input](#)^{p501} element, and the [change](#)^{p1301} event [applies](#)^{p504} to the element, and the element does not have a defined [activation behavior](#), and the user has changed the element's [value](#)^{p575} or its list of [selected files](#)^{p523} while the control was focused without committing that change (such that it is different to what it was when the control was first focused), then [fire an event](#) named [change](#)^{p1301} at the element, with the [bubbles](#) attribute initialized to true.
 2. If *entry* is an element, let *blur event target* be *entry*.
If *entry* is a [Document](#)^{p117} object, let *blur event target* be that [Document](#)^{p117} object's [relevant global object](#)^{p944}.
Otherwise, let *blur event target* be null.
 3. If *entry* is the last entry in *old chain*, and *entry* is an [Element](#), and the last entry in *new chain* is also an [Element](#), then let *related blur target* be the last entry in *new chain*. Otherwise, let *related blur target* be null.
 4. If *blur event target* is not null, [fire a focus event](#)^{p806} named [blur](#)^{p1301} at *blur event target*, with *related blur target* as the related target.

Note

In some cases, e.g. if entry is an [area](#)^{p452} element's shape, a scrollable region, or a [viewport](#), no event is fired.

3. Apply any relevant platform-specific conventions for focusing *new focus target*. (For example, some platforms select the contents of a text control when that control is focused.)
4. For each entry *entry* in *new chain*, in reverse order, run these substeps:
 1. If *entry* is a [focusable area](#)^{p798}: designate *entry* as the [focused area of the document](#)^{p799}.
 2. If *entry* is an element, let *focus event target* be *entry*.
If *entry* is a [Document](#)^{p117} object, let *focus event target* be that [Document](#)^{p117} object's [relevant global object](#)^{p944}.
Otherwise, let *focus event target* be null.
 3. If *entry* is the last entry in *new chain*, and *entry* is an [Element](#), and the last entry in *old chain* is also an [Element](#), then let *related focus target* be the last entry in *old chain*. Otherwise, let *related focus target* be null.
 4. If *focus event target* is not null, [fire a focus event](#)^{p806} named [focus](#)^{p1301} at *focus event target*, with *related focus target* as the related target.

Note

In some cases, e.g. if entry is an [area](#)^{p452} element's shape, a scrollable region, or a [viewport](#), no event is fired.

To **fire a focus event** named *e* at an element *t* with a given related target *r*, [fire an event](#) named *e* at *t*, using [FocusEvent](#), with the [relatedTarget](#) attribute initialized to *r*, the [view](#) attribute initialized to *t*'s [node document](#)'s [relevant global object](#)^{p944}, and the [composed flag](#) set.

When a key event is to be routed in a [top-level browsing context](#)^{p844}, the user agent must run the following steps:

1. Let *target area* be the [currently focused area of the top-level browsing context](#)^{p799}.
2. Assert: *target area* is not null, since key events are only routed to [top-level browsing contexts](#)^{p844} that have [system focus](#)^{p797}. Therefore, *target area* is a [focusable area](#)^{p798}.
3. Let *target node* be *target area*'s [DOM anchor](#)^{p798}.
4. If *target node* is a [Document](#)^{p117} that has a [body element](#)^{p123}, then let *target node* be [the body element](#)^{p123} of that [Document](#)^{p117}.
Otherwise, if *target node* is a [Document](#)^{p117} object that has a non-null [document element](#), then let *target node* be that [document element](#).
5. If *target node* is not [inert](#)^{p793}, then:
 1. Let *canHandle* be the result of [dispatching](#) the key event at *target node*.
 2. If *canHandle* is true, then let *target area* handle the key event. This might include [firing a click event](#)^{p991} at *target node*.

The **has focus steps**, given a [Document](#)^{p117} object *target*, are as follows:

1. If *target*'s [browsing context](#)^{p840}'s [top-level browsing context](#)^{p844} does not have [system focus](#)^{p797}, then return false.
2. Let *candidate* be *target*'s [browsing context](#)^{p840}'s [top-level browsing context](#)^{p844}'s [active document](#)^{p840}.
3. While true:
 1. If *candidate* is *target*, then return true.
 2. If the [focused area](#)^{p799} of *candidate* is a [browsing context container](#)^{p843} with a non-null [nested browsing context](#)^{p843}, then set *candidate* to the [active document](#)^{p840} of that [browsing context container](#)^{p843}'s [nested browsing context](#)^{p843}.
 3. Otherwise, return false.

6.6.5 Sequential focus navigation § p807

Each [Document](#)^{p117} has a **sequential focus navigation order**, which orders some or all of the [focusable areas](#)^{p798} in the [Document](#)^{p117} relative to each other. Its contents and ordering are given by the [flattened tabindex-ordered focus navigation scope](#)^{p801} of the [Document](#)^{p117}.

Note

Per the rules defining the [flattened tabindex-ordered focus navigation scope](#)^{p801}, the ordering is not necessarily related to the [tree order](#) of the [Document](#)^{p117}.

If a [focusable area](#)^{p798} is omitted from the [sequential focus navigation order](#)^{p807} of its [Document](#)^{p117}, then it is unreachable via [sequential focus navigation](#)^{p807}.

There can also be a **sequential focus navigation starting point**. It is initially unset. The user agent may set it when the user indicates that it should be moved.

Example

For example, the user agent could set it to the position of the user's click if the user clicks on the document contents.

Note

User agents are required to set the [sequential focus navigation starting point](#)^{p807} to the [target element](#)^{p922} when navigating to a [fragment](#)^{p921}.

When the user requests that focus move from the [currently focused area of a top-level browsing context](#)^{p799} to the next or previous

[focusable area](#)^{p798} (e.g. as the default action of pressing the tab key), or when the user requests that focus sequentially move to a [top-level browsing context](#)^{p844} in the first place (e.g. from the browser's location bar), the user agent must use the following algorithm:

1. Let *starting point* be the [currently focused area of a top-level browsing context](#)^{p799}, if the user requested to move focus sequentially from there, or else the [top-level browsing context](#)^{p844} itself, if the user instead requested to move focus from outside the [top-level browsing context](#)^{p844}.
2. If there is a [sequential focus navigation starting point](#)^{p807} defined and it is inside *starting point*, then let *starting point* be the [sequential focus navigation starting point](#)^{p807} instead.
3. Let *direction* be *forward* if the user requested the *next* control, and *backward* if the user requested the previous control.

Note

Typically, pressing tab requests the next control, and pressing shift + tab requests the previous control.

4. *Loop*: Let *selection mechanism* be *sequential* if the *starting point* is a [browsing context](#)^{p840} or if *starting point* is in its [Document](#)^{p117}'s [sequential focus navigation order](#)^{p807}.
Otherwise, *starting point* is not in its [Document](#)^{p117}'s [sequential focus navigation order](#)^{p807}; let *selection mechanism* be *DOM*.
5. Let *candidate* be the result of running the [sequential navigation search algorithm](#)^{p808} with *starting point*, *direction*, and *selection mechanism* as the arguments.
6. If *candidate* is not null, then run the [focusing steps](#)^{p805} for *candidate* and return.
7. Otherwise, unset the [sequential focus navigation starting point](#)^{p807}.
8. If *starting point* is the [top-level browsing context](#)^{p844}, or a [focusable area](#)^{p798} in the [top-level browsing context](#)^{p844}, the user agent should transfer focus to its own controls appropriately (if any), honouring *direction*, and then return.

Example

For example, if *direction* is *backward*, then the last [sequentially focusable](#)^{p800} control before the browser's rendering area would be the control to focus.

If the user agent has no [sequentially focusable](#)^{p800} controls — a kiosk-mode browser, for instance — then the user agent may instead restart these steps with the *starting point* being the [top-level browsing context](#)^{p844} itself.

9. Otherwise, *starting point* is a [focusable area](#)^{p798} in a [child browsing context](#)^{p843}. Set *starting point* to that [child browsing context](#)^{p843}'s [container](#)^{p843} and return to the step labeled *loop*.

The **sequential navigation search algorithm** consists of the following steps. This algorithm takes three arguments: *starting point*, *direction*, and *selection mechanism*.

1. Pick the appropriate cell from the following table, and follow the instructions in that cell.

The appropriate cell is the one that is from the column whose header describes *direction* and from the first row whose header describes *starting point* and *selection mechanism*.

	<i>direction is forward</i>	<i>direction is backward</i>
<i>starting point</i> is a browsing context ^{p840}	Let <i>candidate</i> be the first suitable sequentially focusable area ^{p808} in <i>starting point</i> 's active document ^{p840} , if any; or else null	Let <i>candidate</i> be the last suitable sequentially focusable area ^{p808} in <i>starting point</i> 's active document ^{p840} , if any; or else null
<i>selection mechanism</i> is <i>DOM</i>	Let <i>candidate</i> be the first suitable sequentially focusable area ^{p808} in the home document ^{p808} following <i>starting point</i> , if any; or else null	Let <i>candidate</i> be the last suitable sequentially focusable area ^{p808} in the home document ^{p808} preceding <i>starting point</i> , if any; or else null
<i>selection mechanism</i> is <i>sequential</i>	Let <i>candidate</i> be the first suitable sequentially focusable area ^{p808} in the home sequential focus navigation order ^{p808} following <i>starting point</i> , if any; or else null	Let <i>candidate</i> be the last suitable sequentially focusable area ^{p808} in the home sequential focus navigation order ^{p808} preceding <i>starting point</i> , if any; or else null

A **suitable sequentially focusable area** is a [focusable area](#)^{p798} whose [DOM anchor](#)^{p798} is not [inert](#)^{p793} and is [sequentially focusable](#)^{p800}.

The **home document** is the [Document](#)^{p117} to which *starting point* belongs.

The **home sequential focus navigation order** is the [sequential focus navigation order](#)^{p807} to which *starting point* belongs.

Note

The [home sequential focus navigation order](#)^{p808} is the [home document](#)^{p808}'s [sequential focus navigation order](#)^{p807}, but is only used when the starting point is in that [sequential focus navigation order](#)^{p807} (when it's not, selection mechanism will be DOM).

2. If *candidate* is a [browsing context container](#)^{p843} with a non-null [nested browsing context](#)^{p843}, then let *new candidate* be the result of running the [sequential navigation search algorithm](#)^{p808} with *candidate*'s [nested browsing context](#)^{p843} as the first argument, *direction* as the second, and *sequential* as the third.

If *new candidate* is null, then let *starting point* be *candidate*, and return to the top of this algorithm. Otherwise, let *candidate* be *new candidate*.

3. Return *candidate*.

6.6.6 Focus management APIs §^{p80}₉

```
IDL dictionary FocusOptions {  
  boolean preventScroll = false;  
};
```

For web developers (non-normative)

`documentOrShadowRoot.activeElement`^{p810}

Returns the deepest element in the document through which or to which key events are being routed. This is, roughly speaking, the focused element in the document.

For the purposes of this API, when a [child browsing context](#)^{p843} is focused, its [container](#)^{p843} is [focused](#)^{p799} in the [parent browsing context](#)^{p843}. For example, if the user moves the focus to a text control in an [iframe](#)^{p369}, the [iframe](#)^{p369} is the element returned by the [activeElement](#)^{p810} API in the [iframe](#)^{p369}'s [node document](#).

Similarly, when the focused element is in a different [node tree](#) than `documentOrShadowRoot`, the element returned will be the [host](#) that's located in the same [node tree](#) as `documentOrShadowRoot` if `documentOrShadowRoot` is a [shadow-including inclusive ancestor](#) of the focused element, and null if not.

`document.hasFocus`^{p810} ()

Returns true if key events are being routed through or to the document; otherwise, returns false. Roughly speaking, this corresponds to the document, or a document nested inside this one, being focused.

`window.focus`^{p810} ()

Moves the focus to the window's [browsing context](#)^{p856}, if any.

`element.focus`^{p810} ([{ `preventScroll`^{p810}: true }])

Moves the focus to the element.

If the element is a [browsing context container](#)^{p843}, moves the focus to its [nested browsing context](#)^{p843} instead.

By default, this method also scrolls the element into view. Providing the [preventScroll](#)^{p810} option and setting it to true prevents this behavior.

`element.blur`^{p810} ()

Moves the focus to the [viewport](#). Use of this method is discouraged; if you want to focus the [viewport](#), call the [focus\(\)](#)^{p810} method on the [Document](#)^{p117}'s [document element](#).

Do not use this method to hide the focus ring if you find the focus ring unsightly. Instead, use the `:focus-visible` pseudo-class to override the `'outline'` property, and provide a different way to show what element is focused. Be aware that if an alternative focusing style isn't made available, the page will be significantly less usable for people who primarily navigate pages using a keyboard, or those with reduced vision who use focus outlines to help them navigate the page.

Example

For example, to hide the outline from [textarea](#)^{p558} elements and instead use a yellow background to indicate focus, you could use:

```
CSS textarea:focus-visible { outline: none; background: yellow; color: black; }
```

The `activeElement` attribute's getter must run these steps:

1. Let *candidate* be the [DOM anchor](#)^{p798} of the [focused area](#)^{p799} of this [DocumentOrShadowRoot](#)^{p118}'s [node document](#).
2. Set *candidate* to the result of [retargeting candidate](#) against this [DocumentOrShadowRoot](#)^{p118}.
3. If *candidate*'s [root](#) is not this [DocumentOrShadowRoot](#)^{p118}, then return null.
4. If *candidate* is not a [Document](#)^{p117} object, then return *candidate*.
5. If *candidate* has a [body element](#)^{p123}, then return that [body element](#)^{p123}.
6. If *candidate*'s [document element](#) is non-null, then return that [document element](#).
7. Return null.

The `hasFocus()` method on the [Document](#)^{p117} object, when invoked, must return the result of running the [has focus steps](#)^{p807} with the [Document](#)^{p117} object as the argument.

The `focus()` method, when invoked, must run these steps:

1. Let *current* be this [Window](#)^{p855} object's [browsing context](#)^{p856}.
2. If *current* is null, then return.
3. Run the [focusing steps](#)^{p805} with *current*.
4. If *current* is a [top-level browsing context](#)^{p844}, user agents are encouraged to trigger some sort of notification to indicate to the user that the page is attempting to gain focus.

The `blur()` method, when invoked, provides a hint to the user agent that the script believes the user probably is not currently interested in the contents of this [Window](#)^{p855} object's [browsing context](#)^{p856}, if non-null, but that the contents might become interesting again in the future. ✓ MDN

User agents are encouraged to ignore calls to this [blur\(\)](#)^{p810} method entirely.

Note

Historically, the [focus\(\)](#)^{p810} and [blur\(\)](#)^{p810} methods actually affected the system-level focus of the system widget (e.g., tab or window) that contained the [browsing context](#)^{p840}, but hostile sites widely abuse this behavior to the user's detriment.

The `focus(options)` method on elements, when invoked, must run the following steps:

1. If the element is marked as [locked for focus](#)^{p810}, then return.
2. Mark the element as **locked for focus**.
3. Run the [focusing steps](#)^{p805} for the element.
4. If the value of the `preventScroll` dictionary member of *options* is false, then [scroll the element into view](#) with scroll behavior "auto", block flow direction position set to an [implementation-defined](#) value, and inline base direction position set to an [implementation-defined](#) value.
5. Unmark the element as [locked for focus](#)^{p810}.

The `blur()` method, when invoked, should run the [unfocusing steps](#)^{p805} for the element on which the method was called. User agents may selectively or uniformly ignore calls to this method for usability reasons.

Example

For example, if the [blur\(\)](#)^{p810} method is unwisely being used to remove the focus ring for aesthetics reasons, the page would become unusable by keyboard users. Ignoring calls to this method would thus allow keyboard users to interact with the page.

6.6.7 The [autofocus](#)^{p810} attribute § p810

The `autofocus` content attribute allows the author to indicate that an element is to be focused as soon as the page is loaded or as

soon as the [dialog](#)^{p620} within which it finds itself is shown, allowing the user to just start typing without having to manually focus the main element.

The [autofocus](#)^{p810} attribute is a [boolean attribute](#)^{p69}.

An element's **nearest ancestor autofocus scoping root element** is the element itself if the element is a [dialog](#)^{p620} element, or else is the element's nearest ancestor [dialog](#)^{p620} element, if any, or else is the element's last [inclusive ancestor](#) element.

There must not be two elements with the same [nearest ancestor autofocus scoping root element](#)^{p811} that both have the [autofocus](#)^{p810} attribute specified.

Each [Document](#)^{p117} has an **autofocus candidates list**, initially empty.

Each [Document](#)^{p117} has an **autofocus processed flag** boolean, initially false.

When an element with the [autofocus](#)^{p810} attribute specified is [inserted into a document](#)^{p44}, run the following steps:

1. If the user has indicated (for example, by starting to type in a form control) that they do not wish focus to be changed, then optionally return.
2. Let *target* be the element's [node document](#).
3. If *target*'s [browsing context](#)^{p840} is null, then return.
4. If *target*'s [active sandboxing flag set](#)^{p875} has the [sandboxed automatic features browsing context flag](#)^{p874}, then return.
5. For each *ancestorBC* of *target*'s [browsing context](#)^{p840}'s [ancestor browsing contexts](#)^{p843}: if *ancestorBC*'s [active document](#)^{p840}'s [origin](#) is not [same origin](#)^{p869} with *target*'s [origin](#), then return.
6. Let *topDocument* be the [active document](#)^{p840} of *target*'s [browsing context](#)^{p840}'s [top-level browsing context](#)^{p844}.
7. If *topDocument*'s [autofocus processed flag](#)^{p811} is false, then [remove](#) the element from *topDocument*'s [autofocus candidates](#)^{p811}, and [append](#) the element to *topDocument*'s [autofocus candidates](#)^{p811}.

Note

We do not check if an element is a [focusable area](#)^{p798} before storing it in the [autofocus candidates](#)^{p811} list, because even if it is not a focusable area when it is inserted, it could become one by the time [flush autofocus candidates](#)^{p811} sees it.

To **flush autofocus candidates** for a document *topDocument*, run these steps:

1. If *topDocument*'s [autofocus processed flag](#)^{p811} is true, then return.
2. Let *candidates* be *topDocument*'s [autofocus candidates](#)^{p811}.
3. If *candidates* is empty, then return.
4. If *topDocument*'s [focused area](#)^{p799} is not *topDocument* itself, or *topDocument* has non-null [target element](#)^{p922}, then:
 1. [Empty candidates](#).
 2. Set *topDocument*'s [autofocus processed flag](#)^{p811} to true.
 3. Return.
5. While *candidates* is not [empty](#):
 1. Let *element* be *candidates*[0].
 2. Let *doc* be *element*'s [node document](#).
 3. If *doc* is not [fully active](#)^{p844}, then [remove](#) *element* from *candidates*, and [continue](#).
 4. If *doc*'s [browsing context](#)^{p840}'s [top-level browsing context](#)^{p844} is not same as *topDocument*'s [browsing context](#)^{p840}, then [remove](#) *element* from *candidates*, and [continue](#).
 5. If *doc*'s [script-blocking style sheet counter](#)^{p184} is greater than 0, then return.

Note

In this case, element is the currently-best candidate, but doc is not ready for autofocusing. We'll try again next time [flush autofocus candidates](#)^{p811} is called.

6. [Remove](#) element from candidates.
7. Let `inclusiveAncestorDocuments` be a [list](#) consisting of `doc`, plus the [active documents](#)^{p840} of each of `doc`'s [browsing context](#)^{p840}'s [ancestor browsing contexts](#)^{p843}.
8. If any [Document](#)^{p117} in `inclusiveAncestorDocuments` has non-null [target element](#)^{p922}, then [continue](#).
9. Let `target` be `element`.
10. If `target` is not a [focusable area](#)^{p798}, then set `target` to the result of [getting the focusable area](#)^{p803} for `target`.

Note

[Autofocus candidates](#)^{p811} can contain elements which are not [focusable areas](#)^{p798}. In addition to the special cases handled in the [get the focusable area](#)^{p803} algorithm, this can happen because a non-[focusable area](#)^{p798} element with an [autofocus](#)^{p810} attribute was [inserted into a document](#)^{p44} and it never became focusable, or because the element was focusable but its status changed while it was stored in [autofocus candidates](#)^{p811}.

11. If `target` is not null, then:
 1. [Empty](#) candidates.
 2. Set `topDocument`'s [autofocus processed flag](#)^{p811} to true.
 3. Run the [focusing steps](#)^{p805} for `target`.

Note

This handles the automatic focusing during document load. The [show\(\)](#)^{p621} and [showModal\(\)](#)^{p622} methods of [dialog](#)^{p620} elements also processes the [autofocus](#)^{p810} attribute.

Note

Focusing the element does not imply that the user agent has to focus the browser window if it has lost focus.

The [autofocus](#) IDL attribute must [reflect](#)^{p97} the content attribute of the same name.

Example

In the following snippet, the text control would be focused when the document was loaded.

```
<input maxlength="256" name="q" value="" autofocus>
<input type="submit" value="Search">
```

Example

The [autofocus](#)^{p810} attribute applies to all elements, not just to form controls. This allows examples such as the following:

```
<div contenteditable autofocus>Edit <strong>me!</strong></div>
```

6.7 Assigning keyboard shortcuts ^{§ p81}₂

6.7.1 Introduction ^{§ p81}₂

This section is non-normative.

Each element that can be activated or focused can be assigned a single key combination to activate it, using the [accesskey](#)^{p813} attribute.

The exact shortcut is determined by the user agent, based on information about the user's keyboard, what keyboard shortcuts already exist on the platform, and what other shortcuts have been specified on the page, using the information provided in the [accesskey^{p813}](#) attribute as a guide.

In order to ensure that a relevant keyboard shortcut is available on a wide variety of input devices, the author can provide a number of alternatives in the [accesskey^{p813}](#) attribute.

Each alternative consists of a single character, such as a letter or digit.

User agents can provide users with a list of the keyboard shortcuts, but authors are encouraged to do so also. The [accessKeyLabel^{p815}](#) IDL attribute returns a string representing the actual key combination assigned by the user agent.

Example

In this example, an author has provided a button that can be invoked using a shortcut key. To support full keyboards, the author has provided "C" as a possible key. To support devices equipped only with numeric keypads, the author has provided "1" as another possible key.

```
<input type=button value=Collect onclick="collect()"
      accesskey="C 1" id=c>
```

Example

To tell the user what the shortcut key is, the author has this script here opted to explicitly add the key combination to the button's label:

```
function addShortcutKeyLabel(button) {
  if (button.accessKeyLabel != '')
    button.value += ' (' + button.accessKeyLabel + ')';
}
addShortcutKeyLabel(document.getElementById('c'));
```

Browsers on different platforms will show different labels, even for the same key combination, based on the convention prevalent on that platform. For example, if the key combination is the Control key, the Shift key, and the letter C, a Windows browser might display "Ctrl+Shift+C", whereas a Mac browser might display "⌘⇧C", while an Emacs browser might just display "C-C". Similarly, if the key combination is the Alt key and the Escape key, Windows might use "Alt+Esc", Mac might use "⌘⏏", and an Emacs browser might use "M-ESC" or "ESC ESC".

In general, therefore, it is unwise to attempt to parse the value returned from the [accessKeyLabel^{p815}](#) IDL attribute.

6.7.2 The [accesskey](#) attribute §^{p81}₃

All [HTML elements^{p44}](#) may have the [accesskey^{p813}](#) content attribute set. The [accesskey^{p813}](#) attribute's value is used by the user agent as a guide for creating a keyboard shortcut that activates or focuses the element.

If specified, the value must be an [ordered set of unique space-separated tokens^{p89}](#) none of which are [identical to](#) another token and each of which must be exactly one code point in length.

Example

In the following example, a variety of links are given with access keys so that keyboard users familiar with the site can more quickly navigate to the relevant pages:

```
<nav>
  <p>
    <a title="Consortium Activities" accesskey="A" href="/Consortium/activities">Activities</a> |
    <a title="Technical Reports and Recommendations" accesskey="T" href="/TR/">Technical Reports</a>
  |
    <a title="Alphabetical Site Index" accesskey="S" href="/Consortium/siteindex">Site Index</a> |
    <a title="About This Site" accesskey="B" href="/Consortium/">About Consortium</a> |
```

```
<a title="Contact Consortium" accesskey="C" href="/Consortium/contact">Contact</a>
</p>
</nav>
```

Example

In the following example, the search field is given two possible access keys, "s" and "0" (in that order). A user agent on a device with a full keyboard might pick Ctrl + Alt + S as the shortcut key, while a user agent on a small device with just a numeric keypad might pick just the plain unadorned key 0:

```
<form action="/search">
  <label>Search: <input type="search" name="q" accesskey="s 0"></label>
  <input type="submit">
</form>
```

Example

In the following example, a button has possible access keys described. A script then tries to update the button's label to advertise the key combination the user agent selected.

```
<input type=submit accesskey="N @ 1" value="Compose">
...
<script>
  function labelButton(button) {
    if (button.accessKeyLabel)
      button.value += ' (' + button.accessKeyLabel + ')';
  }
  var inputs = document.getElementsByTagName('input');
  for (var i = 0; i < inputs.length; i += 1) {
    if (inputs[i].type == "submit")
      labelButton(inputs[i]);
  }
</script>
```

On one user agent, the button's label might become "Compose (N)". On another, it might become "Compose (Alt+1)". If the user agent doesn't assign a key, it will be just "Compose". The exact string depends on what the [assigned access key](#)^{p814} is, and on how the user agent represents that key combination.

6.7.3 Processing model ^{p81}₄

An element's **assigned access key** is a key combination derived from the element's [accesskey](#)^{p813} content attribute. Initially, an element must not have an [assigned access key](#)^{p814}.

Whenever an element's [accesskey](#)^{p813} attribute is set, changed, or removed, the user agent must update the element's [assigned access key](#)^{p814} by running the following steps:

1. If the element has no [accesskey](#)^{p813} attribute, then skip to the *fallback* step below.
2. Otherwise, [split the attribute's value on ASCII whitespace](#), and let *keys* be the resulting tokens.
3. For each value in *keys* in turn, in the order the tokens appeared in the attribute's value, run the following substeps:
 1. If the value is not a string exactly one code point in length, then skip the remainder of these steps for this value.
 2. If the value does not correspond to a key on the system's keyboard, then skip the remainder of these steps for this value.

3. If the user agent can find a mix of zero or more modifier keys that, combined with the key that corresponds to the value given in the attribute, can be used as the access key, then the user agent may assign that combination of keys as the element's [assigned access key](#)^{p814} and return.
4. *Fallback*: Optionally, the user agent may assign a key combination of its choosing as the element's [assigned access key](#)^{p814} and then return.
5. If this step is reached, the element has no [assigned access key](#)^{p814}.

Once a user agent has selected and assigned an access key for an element, the user agent should not change the element's [assigned access key](#)^{p814} unless the [accesskey](#)^{p813} content attribute is changed or the element is moved to another [Document](#)^{p117}.

When the user presses the key combination corresponding to the [assigned access key](#)^{p814} for an element, if the element [defines a command](#)^{p618}, the command's [Hidden State](#)^{p618} facet is false (visible), the command's [Disabled State](#)^{p618} facet is also false (enabled), the element is [in a document](#) that has a non-null [browsing context](#)^{p840}, and neither the element nor any of its ancestors has a [hidden](#)^{p792} attribute specified, then the user agent must trigger the [Action](#)^{p618} of the command.

Note

User agents [might expose](#)^{p618} elements that have an [accesskey](#)^{p813} attribute in other ways as well, e.g. in a menu displayed in response to a specific key combination.

The [accessKey](#) IDL attribute must [reflect](#)^{p97} the [accesskey](#)^{p813} content attribute.

The [accessKeyLabel](#) IDL attribute must return a string that represents the element's [assigned access key](#)^{p814}, if any. If the element does not have one, then the IDL attribute must return the empty string.

6.8 Editing ^{p81}₅

6.8.1 Making document regions editable: The [contenteditable](#)^{p815} content attribute ^{p81}₅

```
IDL interface mixin ElementContentEditable {
  [CEReactions] attribute DOMString contentEditable;
  [CEReactions] attribute DOMString enterKeyHint;
  readonly attribute boolean isContentEditable;
  [CEReactions] attribute DOMString inputMode;
};
```

The [contenteditable](#) content attribute is an [enumerated attribute](#)^{p69} whose keywords are the empty string, `true`, and `false`. The empty string and the `true` keyword map to the *true* state. The `false` keyword maps to the *false* state. In addition, there is a third state, the *inherit* state, which is the [missing value default](#)^{p69} and the [invalid value default](#)^{p69}.

The *true* state indicates that the element is editable. The *inherit* state indicates that the element is editable if its parent is. The *false* state indicates that the element is not editable.

Example

For example, consider a page that has a [form](#)^{p494} and a [textarea](#)^{p558} to publish a new article, where the user is expected to write the article using HTML:

```
<form method=POST>
  <fieldset>
    <legend>New article</legend>
    <textarea name=article>&lt;p>Hello world.&lt;/p></textarea>
  </fieldset>
  <p><button>Publish</button></p>
</form>
```

When scripting is enabled, the [textarea](#)^{p558} element could be replaced with a rich text control instead, using the

[contentEditable](#)^{p815} attribute:

```
<form method=POST>
  <fieldset>
    <legend>New article</legend>
    <textarea id=textarea name=article>&lt;p>Hello world.&lt;/p></textarea>
    <div id=div style="white-space: pre-wrap" hidden><p>Hello world.</p></div>
    <script>
      let textarea = document.getElementById("textarea");
      let div = document.getElementById("div");
      textarea.hidden = true;
      div.hidden = false;
      div.contentEditable = "true";
      div.oninput = (e) => {
        textarea.value = div.innerHTML;
      };
    </script>
  </fieldset>
  <p><button>Publish</button></p>
</form>
```

Features to enable, e.g., inserting links, can be implemented using the [document.execCommand\(\)](#) API, or using [Selection](#) APIs and other DOM APIs. [\[EXECCOMMAND\]](#)^{p1307} [\[SELECTION\]](#)^{p1311} [\[DOM\]](#)^{p1307}

Example

The [contentEditable](#)^{p815} attribute can also be used to great effect:

```
<!doctype html>
<html lang=en>
<title>Live CSS editing!</title>
<style style=white-space:pre contentEditable>
html { margin:.2em; font-size:2em; color:lime; background:purple }
head, title, style { display:block }
body { display:none }
</style>
```

For web developers (non-normative)

[element.contentEditable](#)^{p816} [= value]

Returns "true", "false", or "inherit", based on the state of the [contentEditable](#)^{p815} attribute.

Can be set, to change that state.

Throws a ["SyntaxError" DOMException](#) if the new value isn't one of those strings.

[element.isContentEditable](#)^{p816}

Returns true if the element is editable; otherwise, returns false.

The [contentEditable](#) IDL attribute, on getting, must return the string "true" if the content attribute is set to the true state, "false" if the content attribute is set to the false state, and "inherit" otherwise. On setting, if the new value is an [ASCII case-insensitive](#) match for the string "inherit" then the content attribute must be removed, if the new value is an [ASCII case-insensitive](#) match for the string "true" then the content attribute must be set to the string "true", if the new value is an [ASCII case-insensitive](#) match for the string "false" then the content attribute must be set to the string "false", and otherwise the attribute setter must throw a ["SyntaxError" DOMException](#).

The [isContentEditable](#) IDL attribute, on getting, must return true if the element is either an [editing host](#)^{p817} or [editable](#), and false otherwise.

6.8.2 Making entire documents editable: the `designMode`^{p817} getter and setter §^{p81}₇

For web developers (non-normative)

`document.designMode`^{p817} [= *value*]

Returns "on" if the document is editable, and "off" if it isn't.

Can be set, to change the document's current state. This focuses the document and resets the selection in that document.

`Document`^{p117} objects have an associated **design mode enabled**, which is a boolean. It is initially false.

The `designMode` getter steps are to return "on" if `this`'s `design_mode_enabled`^{p817} is true; otherwise "off".

The `designMode`^{p817} setter steps are:

1. Let *value* be the given value, [converted to ASCII lowercase](#).
2. If *value* is "on" and `this`'s `design_mode_enabled`^{p817} is false, then:
 1. Set `this`'s `design_mode_enabled`^{p817} to true.
 2. Reset `this`'s `active range`'s start and end boundary points to be at the start of `this`.
 3. Run the `focusing_steps`^{p805} for `this`'s `document element`, if non-null.
3. If *value* is "off", then set `this`'s `design_mode_enabled`^{p817} to false.

6.8.3 Best practices for in-page editors §^{p81}₇

Authors are encouraged to set the `'white-space'` property on `editing hosts`^{p817} and on markup that was originally created through these editing mechanisms to the value 'pre-wrap'. Default HTML whitespace handling is not well suited to WYSIWYG editing, and line wrapping will not work correctly in some corner cases if `'white-space'` is left at its default value.

Example

As an example of problems that occur if the default 'normal' value is used instead, consider the case of the user typing "yellow_␣ball", with two spaces (here represented by "_␣") between the words. With the editing rules in place for the default value of `'white-space'` ('normal'), the resulting markup will either consist of "yellow ball" or "yellow ball"; i.e., there will be a non-breaking space between the two words in addition to the regular space. This is necessary because the 'normal' value for `'white-space'` requires adjacent regular spaces to be collapsed together.

In the former case, "yellow_␣" might wrap to the next line ("_␣" being used here to represent a non-breaking space) even though "yellow" alone might fit at the end of the line; in the latter case, "_␣ball", if wrapped to the start of the line, would have visible indentation from the non-breaking space.

When `'white-space'` is set to 'pre-wrap', however, the editing rules will instead simply put two regular spaces between the words, and should the two words be split at the end of a line, the spaces would be neatly removed from the rendering.

6.8.4 Editing APIs §^{p81}₇

An **editing host** is either an `HTML element`^{p44} with its `contenteditable`^{p815} attribute in the *true* state, or a `child HTML element`^{p44} of a `Document`^{p117} whose `design_mode_enabled`^{p817} is true.

The definition of the terms **active range**, **editing host of**, and **editable**, the user interface requirements of elements that are `editing hosts`^{p817} or `editable`, the `execCommand()`, `queryCommandEnabled()`, `queryCommandIndeterm()`, `queryCommandState()`, `queryCommandSupported()`, and `queryCommandValue()` methods, text selections, and the **delete the selection** algorithm are defined in `execCommand`. [\[EXECCOMMAND\]](#)^{p1307}

6.8.5 Spelling and grammar checking ^{p81}_B

User agents can support the checking of spelling and grammar of editable text, either in form controls (such as the value of [textarea](#)^{p558} elements), or in elements in an [editing host](#)^{p817} (e.g. using [contenteditable](#)^{p815}).

For each element, user agents must establish a **default behavior**, either through defaults or through preferences expressed by the user. There are three possible default behaviors for each element:

true-by-default

The element will be checked for spelling and grammar if its contents are editable and spellchecking is not explicitly disabled through the [spellcheck](#)^{p818} attribute.

false-by-default

The element will never be checked for spelling and grammar unless spellchecking is explicitly enabled through the [spellcheck](#)^{p818} attribute.

inherit-by-default

The element's default behavior is the same as its parent element's. Elements that have no parent element cannot have this as their default behavior.

The [spellcheck](#) attribute is an [enumerated attribute](#)^{p69} whose keywords are the empty string, `true` and `false`. The empty string and the `true` keyword map to the *true* state. The `false` keyword maps to the *false* state. In addition, there is a third state, the *default* state, which is the [missing value default](#)^{p69} and the [invalid value default](#)^{p69}.

Note

The true state indicates that the element is to have its spelling and grammar checked. The default state indicates that the element is to act according to a default behavior, possibly based on the parent element's own [spellcheck](#)^{p818} state, as defined below. The false state indicates that the element is not to be checked.

For web developers (non-normative)

`element.spellcheck`^{p818} [= *value*]

Returns true if the element is to have its spelling and grammar checked; otherwise, returns false.

Can be set, to override the default and set the [spellcheck](#)^{p818} content attribute.

The [spellcheck](#) IDL attribute, on getting, must return true if the element's [spellcheck](#)^{p818} content attribute is in the *true* state, or if the element's [spellcheck](#)^{p818} content attribute is in the *default* state and the element's [default behavior](#)^{p818} is [true-by-default](#)^{p818}, or if the element's [spellcheck](#)^{p818} content attribute is in the *default* state and the element's [default behavior](#)^{p818} is [inherit-by-default](#)^{p818} and the element's parent element's [spellcheck](#)^{p818} IDL attribute would return true; otherwise, if none of those conditions applies, then the attribute must instead return false.

Note

The [spellcheck](#)^{p818} IDL attribute is not affected by user preferences that override the [spellcheck](#)^{p818} content attribute, and therefore might not reflect the actual spellchecking state.

On setting, if the new value is `true`, then the element's [spellcheck](#)^{p818} content attribute must be set to the literal string `"true"`, otherwise it must be set to the literal string `"false"`.

User agents must only consider the following pieces of text as checkable for the purposes of this feature:

- The [value](#)^{p575} of [input](#)^{p501} elements whose [type](#)^{p503} attributes are in the [Text](#)^{p508}, [Search](#)^{p508}, [URL](#)^{p509}, or [Email](#)^{p510} states and that are [mutable](#)^{p576} (i.e. that do not have the [readonly](#)^{p531} attribute specified and that are not [disabled](#)^{p580}).
- The [value](#)^{p575} of [textarea](#)^{p558} elements that do not have a [readonly](#)^{p559} attribute and that are not [disabled](#)^{p580}.
- Text in [Text](#) nodes that are children of [editing hosts](#)^{p817} or [editable](#) elements.
- Text in attributes of [editable](#) elements.

For text that is part of a [Text](#) node, the element with which the text is associated is the element that is the immediate parent of the

first character of the word, sentence, or other piece of text. For text in attributes, it is the attribute's element. For the values of [input^{p501}](#) and [textarea^{p558}](#) elements, it is the element itself.

To determine if a word, sentence, or other piece of text in an applicable element (as defined above) is to have spelling- and grammar-checking enabled, the UA must use the following algorithm:

1. If the user has disabled the checking for this text, then the checking is disabled.
2. Otherwise, if the user has forced the checking for this text to always be enabled, then the checking is enabled.
3. Otherwise, if the element with which the text is associated has a [spellcheck^{p818}](#) content attribute, then: if that attribute is in the *true* state, then checking is enabled; otherwise, if that attribute is in the *false* state, then checking is disabled.
4. Otherwise, if there is an ancestor element with a [spellcheck^{p818}](#) content attribute that is not in the *default* state, then: if the nearest such ancestor's [spellcheck^{p818}](#) content attribute is in the *true* state, then checking is enabled; otherwise, checking is disabled.
5. Otherwise, if the element's [default behavior^{p818}](#) is [true-by-default^{p818}](#), then checking is enabled.
6. Otherwise, if the element's [default behavior^{p818}](#) is [false-by-default^{p818}](#), then checking is disabled.
7. Otherwise, if the element's parent element has *its* checking enabled, then checking is enabled.
8. Otherwise, checking is disabled.

If the checking is enabled for a word/sentence/text, the user agent should indicate spelling and grammar errors in that text. User agents should take into account the other semantics given in the document when suggesting spelling and grammar corrections. User agents may use the language of the element to determine what spelling and grammar rules to use, or may use the user's preferred language settings. UAs should use [input^{p501}](#) element attributes such as [pattern^{p533}](#) to ensure that the resulting value is valid, where possible.

If checking is disabled, the user agent should not indicate spelling or grammar errors for that text.

Example

The element with ID "a" in the following example would be the one used to determine if the word "Hello" is checked for spelling errors. In this example, it would not be.

```
<div contenteditable="true">
  <span spellcheck="false" id="a">Hell</span><em>o!</em>
</div>
```

The element with ID "b" in the following example would have checking enabled (the leading space character in the attribute's value on the [input^{p501}](#) element causes the attribute to be ignored, so the ancestor's value is used instead, regardless of the default).

```
<p spellcheck="true">
  <label>Name: <input spellcheck=" false" id="b"></label>
</p>
```

Note

This specification does not define the user interface for spelling and grammar checkers. A user agent could offer on-demand checking, could perform continuous checking while the checking is enabled, or could use other interfaces.

6.8.6 Autocapitalization ^{p81}₉

Some methods of entering text, for example virtual keyboards on mobile devices, and also voice input, often assist users by automatically capitalizing the first letter of sentences (when composing text in a language with this convention). A virtual keyboard that implements autocapitalization might automatically switch to showing uppercase letters (but allow the user to toggle it back to lowercase) when a letter that should be autocapitalized is about to be typed. Other types of input, for example voice input, may perform autocapitalization in a way that does not give users an option to intervene first. The [autocapitalize^{p820}](#) attribute allows authors to control such behavior.

The [autocapitalize^{p820}](#) attribute, as typically implemented, does not affect behavior when typing on a physical keyboard. (For this reason, as well as the ability for users to override the autocapitalization behavior in some cases or edit the text after initial input, the attribute must not be relied on for any sort of input validation.)

The [autocapitalize^{p820}](#) attribute can be used on an [editing host^{p817}](#) to control autocapitalization behavior for the hosted editable region, on an [input^{p501}](#) or [textarea^{p558}](#) element to control the behavior for inputting text into that element, or on a [form^{p494}](#) element to control the default behavior for all [autocapitalize-inheriting elements^{p494}](#) associated with the [form^{p494}](#) element.

The [autocapitalize^{p820}](#) attribute never causes autocapitalization to be enabled for [input^{p501}](#) elements whose [type^{p503}](#) attribute is in one of the [URL^{p509}](#), [Email^{p510}](#), or [Password^{p512}](#) states. (This behavior is included in the [used autocapitalization hint^{p821}](#) algorithm below.)

The autocapitalization processing model is based on selecting among five **autocapitalization hints**, defined as follows:

default

The user agent and input method should use make their own determination of whether or not to enable autocapitalization.

none

No autocapitalization should be applied (all letters should default to lowercase).

sentences

The first letter of each sentence should default to a capital letter; all other letters should default to lowercase.

words

The first letter of each word should default to a capital letter; all other letters should default to lowercase.

characters

All letters should default to uppercase.

The **autocapitalize** attribute is an [enumerated attribute^{p69}](#) whose states are the possible [autocapitalization hints^{p820}](#). The [autocapitalization hint^{p820}](#) specified by the attribute's state combines with other considerations to form the [used autocapitalization hint^{p821}](#), which informs the behavior of the user agent. The keywords for this attribute and their state mappings are as follows:

Keyword	State
off	none^{p820}
none	
on	sentences^{p820}
sentences	
words	words^{p820}
characters	characters^{p820}

The [invalid value default^{p69}](#) is the [sentences^{p820}](#) state. The [missing value default^{p69}](#) is the [default^{p820}](#) state.

For web developers (non-normative)

`element.autocapitalizep820 [= value]`

Returns the current autocapitalization state for the element, or an empty string if it hasn't been set. Note that for [input^{p501}](#) and [textarea^{p558}](#) elements that inherit their state from a [form^{p494}](#) element, this will return the autocapitalization state of the [form^{p494}](#) element, but for an element in an editable region, this will not return the autocapitalization state of the editing host (unless this element is, in fact, the [editing host^{p817}](#)).

Can be set, to set the [autocapitalize^{p820}](#) content attribute (and thereby change the autocapitalization behavior for the element).

To compute the **own autocapitalization hint** of an element *element*, run the following steps:

1. If the [autocapitalize^{p820}](#) content attribute is present on *element*, and its value is not the empty string, return the state of the attribute.
2. If *element* is an [autocapitalize-inheriting element^{p494}](#) and has a non-null [form owner^{p576}](#), return the [own autocapitalization hint^{p820}](#) of *element*'s [form owner^{p576}](#).
3. Return [default^{p820}](#).

The **autocapitalize** getter steps are to:

1. Let *state* be the [own autocapitalization hint](#)^{p820} of [this](#).
2. If *state* is [default](#)^{p820}, then return the empty string.
3. If *state* is [none](#)^{p820}, then return "[none](#)^{p820}".
4. If *state* is [sentences](#)^{p820}, then return "[sentences](#)^{p820}".
5. Return the keyword value corresponding to *state*.

The [autocapitalize](#)^{p820} setter steps are to set the [autocapitalize](#)^{p820} content attribute to the given value.

User agents that support customizable autocapitalization behavior for a text input method and wish to allow web developers to control this functionality should, during text input into an element, compute the **used autocapitalization hint** for the element. This will be an [autocapitalization hint](#)^{p820} that describes the recommended autocapitalization behavior for text input into the element.

User agents or input methods may choose to ignore or override the [used autocapitalization hint](#)^{p821} in certain circumstances.

The [used autocapitalization hint](#)^{p821} for an element *element* is computed using the following algorithm:

1. If *element* is an [input](#)^{p501} element whose [type](#)^{p503} attribute is in one of the [URL](#)^{p509}, [Email](#)^{p510}, or [Password](#)^{p512} states, then return [default](#)^{p820}.
2. If *element* is an [input](#)^{p501} element or a [textarea](#)^{p558} element, then return *element*'s [own autocapitalization hint](#)^{p820}.
3. If *element* is an [editing host](#)^{p817} or an [editable](#) element, then return the [own autocapitalization hint](#)^{p820} of the [editing host of element](#).
4. Assert: this step is never reached, since text input only occurs in elements that meet one of the above criteria.

6.8.7 Input modalities: the [inputmode](#)^{p821} attribute §^{p82}₁

User agents can support the [inputmode](#)^{p821} attribute on form controls (such as the value of [textarea](#)^{p558} elements), or in elements in an [editing host](#)^{p817} (e.g., using [contenteditable](#)^{p815}).

The [inputmode](#) content attribute is an [enumerated attribute](#)^{p69} that specifies what kind of input mechanism would be most helpful for users entering content.

Keyword	Description
none	The user agent should not display a virtual keyboard. This keyword is useful for content that renders its own keyboard control.
text	The user agent should display a virtual keyboard capable of text input in the user's locale.
tel	The user agent should display a virtual keyboard capable of telephone number input. This should including keys for the digits 0 to 9, the "#" character, and the "*" character. In some locales, this can also include alphabetic mnemonic labels (e.g., in the US, the key labeled "2" is historically also labeled with the letters A, B, and C).
url	The user agent should display a virtual keyboard capable of text input in the user's locale, with keys for aiding in the input of URLs , such as that for the "/" and "." characters and for quick input of strings commonly found in domain names such as "www." or ".com".
email	The user agent should display a virtual keyboard capable of text input in the user's locale, with keys for aiding in the input of email addresses, such as that for the "@" character and the "." character.
numeric	The user agent should display a virtual keyboard capable of numeric input. This keyword is useful for PIN entry.
decimal	The user agent should display a virtual keyboard capable of fractional numeric input. Numeric keys and the format separator for the locale should be shown.
search	The user agent should display a virtual keyboard optimized for search.

The [inputMode](#) IDL attribute must [reflect](#)^{p97} the [inputmode](#)^{p821} content attribute, [limited to only known values](#)^{p97}.

When [inputmode](#)^{p821} is unspecified (or is in a state not supported by the user agent), the user agent should determine the default virtual keyboard to be shown. Contextual information such as the input [type](#)^{p503} or [pattern](#)^{p533} attributes should be used to determine which type of virtual keyboard should be presented to the user.

6.8.8 Input modalities: the [enterkeyhint^{p822}](#) attribute § p822

User agents can support the [enterkeyhint^{p822}](#) attribute on form controls (such as the value of [textarea^{p558}](#) elements), or in elements in an [editing host^{p817}](#) (e.g., using [contenteditable^{p815}](#)).

The [enterkeyhint](#) content attribute is an [enumerated attribute^{p69}](#) that specifies what action label (or icon) to present for the enter key on virtual keyboards. This allows authors to customize the presentation of the enter key in order to make it more helpful for users.

Keyword	Description
enter	The user agent should present a cue for the operation 'enter', typically inserting a new line.
done	The user agent should present a cue for the operation 'done', typically meaning there is nothing more to input and the input method editor (IME) will be closed.
go	The user agent should present a cue for the operation 'go', typically meaning to take the user to the target of the text they typed.
next	The user agent should present a cue for the operation 'next', typically taking the user to the next field that will accept text.
previous	The user agent should present a cue for the operation 'previous', typically taking the user to the previous field that will accept text.
search	The user agent should present a cue for the operation 'search', typically taking the user to the results of searching for the text they have typed.
send	The user agent should present a cue for the operation 'send', typically delivering the text to its target.

The [enterKeyHint](#) IDL attribute must [reflect^{p97}](#) the [enterkeyhint^{p822}](#) content attribute, [limited to only known values^{p97}](#). MDN

When [enterkeyhint^{p822}](#) is unspecified (or is in a state not supported by the user agent), the user agent should determine the default action label (or icon) to present. Contextual information such as the [inputmode^{p821}](#), [type^{p503}](#), or [pattern^{p533}](#) attributes should be used to determine which action label (or icon) to present on the virtual keyboard.

6.9 Find-in-page § p822

6.9.1 Introduction § p822

This section defines **find-in-page** — a common user-agent mechanism which allows users to search through the contents of the page for particular information.

Access to [find-in-page^{p822}](#) feature is provided via a **find-in-page interface**. This is a user-agent provided user interface, which allows the user to specify input and the parameters of the search. This interface can appear as a result of a shortcut or a menu selection.

A combination of text input and settings in the [find-in-page interface^{p822}](#) represents the user **query**. This typically includes the text that the user wants to search for, as well as optional settings (e.g., the ability to restrict the search to whole words only).

The user-agent processes page contents for a given [query^{p822}](#), and identifies zero or more **matches**, which are content ranges that satisfy the user [query^{p822}](#).

One of the [matches^{p822}](#) is identified to the user as the **active match**. It is highlighted and scrolled into view. The user can navigate through the [matches^{p822}](#) by advancing the [active match^{p822}](#) using the [find-in-page interface^{p822}](#).

[Issue #3539](#) tracks standardizing how [find-in-page^{p822}](#) underlies the currently-unspecified `window.find()` API.

6.9.2 Interaction with [details^{p614}](#) § p822

When find-in-page begins searching for matches, all [details^{p614}](#) elements in the page which do not have their [open^{p615}](#) attribute set should have the [skipped contents](#) of their second slot become accessible, without modifying the [open^{p615}](#) attribute, in order to make find-in-page able to search through it. After find-in-page finishes searching for matches, those [details^{p614}](#) elements should have their contents become skipped again. This entire process must happen synchronously (and so is not observable to users or to author code). [\[CSSCONTAIN\]^{p1306}](#)

When find-in-page chooses a new [active match^{p822}](#), perform the following steps:

1. Let *node* be the first node in the [active match^{p822}](#).
2. [Queue a global task^{p970}](#) on the [user interaction task source^{p977}](#) given *node*'s [relevant global object^{p944}](#) to run the [ancestor](#)

[details_revealing_algorithm^{p615}](#) on *node*.

⚠Warning!

When *find-in-page* auto-expands a [details^{p614}](#) element like this, it will fire a [toggle^{p1302}](#) event. As with the separate `scroll` event that *find-in-page* fires, this event could be used by the page to discover what the user is typing into the *find-in-page* dialog. If the page creates a tiny scrollable area with the current search term and every possible next character the user could type separated by a gap, and observes which one the browser scrolls to, it can add that character to the search term and update the scrollable area to incrementally build the search term. By wrapping each possible next match in a closed [details^{p614}](#) element, the page could listen to [toggle^{p1302}](#) events instead of `scroll` events. This attack could be addressed for both events by not acting on every character the user types into the *find-in-page* dialog.

6.9.3 Interaction with selection §^{p82}₃

The *find-in-page* process is invoked in the context of a document, and may have an effect on the [selection](#) of that document. Specifically, the range that defines the [active match^{p822}](#) can dictate the current selection. These selection updates, however, can happen at different times during the *find-in-page* process (e.g. upon the [find-in-page interface^{p822}](#) dismissal or upon a change in the [active match^{p822}](#) range).

6.10 Drag and drop §^{p82}₃

This section defines an event-based drag-and-drop mechanism.

This specification does not define exactly what a *drag-and-drop operation* actually is.

On a visual medium with a pointing device, a drag operation could be the default action of a `mousedown` event that is followed by a series of `mousemove` events, and the drop could be triggered by the mouse being released.

When using an input modality other than a pointing device, users would probably have to explicitly indicate their intention to perform a drag-and-drop operation, stating what they wish to drag and where they wish to drop it, respectively.

However it is implemented, drag-and-drop operations must have a starting point (e.g. where the mouse was clicked, or the start of the selection or element that was selected for the drag), may have any number of intermediate steps (elements that the mouse moves over during a drag, or elements that the user picks as possible drop points as they cycle through possibilities), and must either have an end point (the element above which the mouse button was released, or the element that was finally selected), or be canceled. The end point must be the last element selected as a possible drop point before the drop occurs (so if the operation is not canceled, there must be at least one element in the middle step).

6.10.1 Introduction §^{p82}₃

This section is non-normative.

To make an element draggable, give the element a [draggable^{p838}](#) attribute, and set an event listener for [dragstart^{p838}](#) that stores the data being dragged.

The event handler typically needs to check that it's not a text selection that is being dragged, and then needs to store data into the [DataTransfer^{p826}](#) object and set the allowed effects (copy, move, link, or some combination).

For example:

```
<p>What fruits do you like?</p>
<ol ondragstart="dragStartHandler(event)">
  <li draggable="true" data-value="fruit-apple">Apples</li>
  <li draggable="true" data-value="fruit-orange">Oranges</li>
  <li draggable="true" data-value="fruit-pear">Pears</li>
</ol>
```

```

</ol>
<script>
  var internalDNDType = 'text/x-example'; // set this to something specific to your site
  function dragStartHandler(event) {
    if (event.target instanceof HTMLLIElement) {
      // use the element's data-value="" attribute as the value to be moving:
      event.dataTransfer.setData(internalDNDType, event.target.dataset.value);
      event.dataTransfer.effectAllowed = 'move'; // only allow moves
    } else {
      event.preventDefault(); // don't allow selection to be dragged
    }
  }
</script>

```

To accept a drop, the drop target has to listen to the following events:

1. The [dragenter^{p838}](#) event handler reports whether or not the drop target is potentially willing to accept the drop, by canceling the event.
2. The [dragover^{p838}](#) event handler specifies what feedback will be shown to the user, by setting the [dropEffect^{p827}](#) attribute of the [DataTransfer^{p826}](#) associated with the event. This event also needs to be canceled.
3. The [drop^{p838}](#) event handler has a final chance to accept or reject the drop. If the drop is accepted, the event handler must perform the drop operation on the target. This event needs to be canceled, so that the [dropEffect^{p827}](#) attribute's value can be used by the source. Otherwise, the drop operation is rejected.

For example:

```

<p>Drop your favorite fruits below:</p>
<ol ondragenter="dragEnterHandler(event)" ondragover="dragOverHandler(event)"
  ondrop="dropHandler(event)">
</ol>
<script>
  var internalDNDType = 'text/x-example'; // set this to something specific to your site
  function dragEnterHandler(event) {
    var items = event.dataTransfer.items;
    for (var i = 0; i < items.length; ++i) {
      var item = items[i];
      if (item.kind == 'string' && item.type == internalDNDType) {
        event.preventDefault();
        return;
      }
    }
  }
  function dragOverHandler(event) {
    event.dataTransfer.dropEffect = 'move';
    event.preventDefault();
  }
  function dropHandler(event) {
    var li = document.createElement('li');
    var data = event.dataTransfer.getData(internalDNDType);
    if (data == 'fruit-apple') {
      li.textContent = 'Apples';
    } else if (data == 'fruit-orange') {
      li.textContent = 'Oranges';
    } else if (data == 'fruit-pear') {
      li.textContent = 'Pears';
    } else {
      li.textContent = 'Unknown Fruit';
    }
    event.target.appendChild(li);
  }

```

```
}  
</script>
```

To remove the original element (the one that was dragged) from the display, the [dragend](#)^{p838} event can be used.

For our example here, that means updating the original markup to handle that event:

```
<p>What fruits do you like?</p>  
<ol ondragstart="dragStartHandler(event)" ondragend="dragEndHandler(event)">  
  ...as before...  
</ol>  
<script>  
  function dragStartHandler(event) {  
    // ...as before...  
  }  
  function dragEndHandler(event) {  
    if (event.dataTransfer.dropEffect == 'move') {  
      // remove the dragged element  
      event.target.parentNode.removeChild(event.target);  
    }  
  }  
</script>
```

6.10.2 The drag data store ^{§p82}₅

The data that underlies a drag-and-drop operation, known as the **drag data store**, consists of the following information:

- A **drag data store item list**, which is a list of items representing the dragged data, each consisting of the following information:

The drag data item kind

The kind of data:

Text

Text.

File

Binary data with a filename.

The drag data item type string

A Unicode string giving the type or format of the data, generally given by a [MIME type](#). Some values that are not [MIME types](#) are special-cased for legacy reasons. The API does not enforce the use of [MIME types](#); other values can be used as well. In all cases, however, the values are all [converted to ASCII lowercase](#) by the API.

There is a limit of one *text* item per [item type string](#)^{p825}.

The actual data

A Unicode or binary string, in some cases with a filename (itself a Unicode string), as per [the drag data item kind](#)^{p825}.

The [drag data store item list](#)^{p825} is ordered in the order that the items were added to the list; most recently added last.

- The following information, used to generate the UI feedback during the drag:
 - User-agent-defined default feedback information, known as the **drag data store default feedback**.
 - Optionally, a bitmap image and the coordinate of a point within that image, known as the **drag data store bitmap** and **drag data store hot spot coordinate**.
- A **drag data store mode**, which is one of the following:

Read/write mode

For the [dragstart](#)^{p838} event. New data can be added to the [drag data store](#)^{p825}.

Read-only mode

For the [drop](#)^{p838} event. The list of items representing dragged data can be read, including the data. No new data can be added.

Protected mode

For all other events. The formats and kinds in the [drag data store](#)^{p825} list of items representing dragged data can be enumerated, but the data itself is unavailable and no new data can be added.

- A **drag data store allowed effects state**, which is a string.

When a [drag data store](#)^{p825} is **created**, it must be initialized such that its [drag data store item list](#)^{p825} is empty, it has no [drag data store default feedback](#)^{p825}, it has no [drag data store bitmap](#)^{p825} and [drag data store hot spot coordinate](#)^{p825}, its [drag data store mode](#)^{p825} is [protected mode](#)^{p826}, and its [drag data store allowed effects state](#)^{p826} is the string "[uninitialized](#)^{p827}".

6.10.3 The [DataTransfer](#)^{p826} interface §^{p82}₆

[DataTransfer](#)^{p826} objects are used to expose the [drag data store](#)^{p825} that underlies a drag-and-drop operation.

```
IDL [Exposed=Window]
interface DataTransfer {
  constructor();

  attribute DOMString dropEffect;
  attribute DOMString effectAllowed;

  [SameObject] readonly attribute DataTransferItemList items;

  undefined setDragImage(Element image, long x, long y);

  /* old interface */
  readonly attribute FrozenArray<DOMString> types;
  DOMString getData(DOMString format);
  undefined setData(DOMString format, DOMString data);
  undefined clearData(optional DOMString format);
  [SameObject] readonly attribute FileList files;
};
```

For web developers (non-normative)

[dataTransfer](#) = new [DataTransfer](#)^{p827} ()

Creates a new [DataTransfer](#)^{p826} object with an empty [drag data store](#)^{p825}.

[dataTransfer.dropEffect](#)^{p827} [= value]

Returns the kind of operation that is currently selected. If the kind of operation isn't one of those that is allowed by the [effectAllowed](#)^{p827} attribute, then the operation will fail.

Can be set, to change the selected operation.

The possible values are "[none](#)^{p827}", "[copy](#)^{p827}", "[link](#)^{p827}", and "[move](#)^{p827}".

[dataTransfer.effectAllowed](#)^{p827} [= value]

Returns the kinds of operations that are to be allowed.

Can be set (during the [dragstart](#)^{p838} event), to change the allowed operations.

The possible values are "[none](#)^{p827}", "[copy](#)^{p827}", "[copyLink](#)^{p827}", "[copyMove](#)^{p827}", "[link](#)^{p827}", "[linkMove](#)^{p827}", "[move](#)^{p827}", "[all](#)^{p827}", and "[uninitialized](#)^{p827}".

[dataTransfer.items](#)^{p827}

Returns a [DataTransferItemList](#)^{p829} object, with the drag data.

`dataTransfer.setDragImage`^{p827}(*element*, *x*, *y*)

Uses the given element to update the drag feedback, replacing any previously specified feedback.

`dataTransfer.types`^{p828}

Returns a [frozen array](#) listing the formats that were set in the [dragstart](#)^{p838} event. In addition, if any files are being dragged, then one of the types will be the string "Files".

`data = dataTransfer.getData`^{p828}(*format*)

Returns the specified data. If there is no such data, returns the empty string.

`dataTransfer.setData`^{p828}(*format*, *data*)

Adds the specified data.

`dataTransfer.clearData`^{p828}([*format*])

Removes the data of the specified formats. Removes all data if the argument is omitted.

`dataTransfer.files`^{p829}

Returns a [FileList](#) of the files being dragged, if any.

[DataTransfer](#)^{p826} objects that are created as part of [drag-and-drop events](#)^{p838} are only valid while those events are being fired.

A [DataTransfer](#)^{p826} object is associated with a [drag data store](#)^{p825} while it is valid.

A [DataTransfer](#)^{p826} object has an associated **types array**, which is a [FrozenArray<DOMString>](#), initially empty. When the contents of the [DataTransfer](#)^{p826} object's [drag data store item list](#)^{p825} change, or when the [DataTransfer](#)^{p826} object becomes no longer associated with a [drag data store](#)^{p825}, run the following steps:

1. Let *L* be an empty sequence.
2. If the [DataTransfer](#)^{p826} object is still associated with a [drag data store](#)^{p825}, then:
 1. For each item in the [DataTransfer](#)^{p826} object's [drag data store item list](#)^{p825} whose [kind](#)^{p825} is *text*, add an entry to *L* consisting of the item's [type string](#)^{p825}.
 2. If there are any items in the [DataTransfer](#)^{p826} object's [drag data store item list](#)^{p825} whose [kind](#)^{p825} is *File*, then add an entry to *L* consisting of the string "Files". (This value can be distinguished from the other values because it is not lowercase.)
3. Set the [DataTransfer](#)^{p826} object's [types array](#)^{p827} to the result of [creating a frozen array](#) from *L*.

The [DataTransfer\(\)](#) constructor, when invoked, must return a newly created [DataTransfer](#)^{p826} object initialized as follows:

1. Set the [drag data store](#)^{p825}'s [item list](#)^{p825} to be an empty list.
2. Set the [drag data store](#)^{p825}'s [mode](#)^{p825} to [read/write mode](#)^{p826}.
3. Set the [dropEffect](#)^{p827} and [effectAllowed](#)^{p827} to "none".

The [dropEffect](#) attribute controls the drag-and-drop feedback that the user is given during a drag-and-drop operation. When the [DataTransfer](#)^{p826} object is created, the [dropEffect](#)^{p827} attribute is set to a string value. On getting, it must return its current value. On setting, if the new value is one of "none", "copy", "link", or "move", then the attribute's current value must be set to the new value. Other values must be ignored.

The [effectAllowed](#) attribute is used in the drag-and-drop processing model to initialize the [dropEffect](#)^{p827} attribute during the [dragenter](#)^{p838} and [dragover](#)^{p838} events. When the [DataTransfer](#)^{p826} object is created, the [effectAllowed](#)^{p827} attribute is set to a string value. On getting, it must return its current value. On setting, if [drag data store](#)^{p825}'s [mode](#)^{p825} is the [read/write mode](#)^{p826} and the new value is one of "none", "copy", "copyLink", "copyMove", "link", "linkMove", "move", "all", or "uninitialized", then the attribute's current value must be set to the new value. Otherwise it must be left unchanged.

The [items](#) attribute must return a [DataTransferItemList](#)^{p829} object associated with the [DataTransfer](#)^{p826} object.

The [setDragImage](#)(*image*, *x*, *y*) method must run the following steps:

1. If the [DataTransfer](#)^{p826} object is no longer associated with a [drag data store](#)^{p825}, return. Nothing happens.

2. If the [drag_data_store](#)^{p825}'s [mode](#)^{p825} is not the [read/write mode](#)^{p826}, return. Nothing happens.
3. If *image* is an [img](#)^{p327} element, then set the [drag_data_store bitmap](#)^{p825} to the element's image (at its [intrinsic size](#)); otherwise, set the [drag_data_store bitmap](#)^{p825} to an image generated from the given element (the exact mechanism for doing so is not currently specified).
4. Set the [drag_data_store hot spot coordinate](#)^{p825} to the given x, y coordinate.

The **types** attribute must return this [DataTransfer](#)^{p826} object's [types array](#)^{p827}.

The **getData(*format*)** method must run the following steps:

1. If the [DataTransfer](#)^{p826} object is no longer associated with a [drag_data_store](#)^{p825}, then return the empty string.
2. If the [drag_data_store](#)^{p825}'s [mode](#)^{p825} is the [protected mode](#)^{p826}, then return the empty string.
3. Let *format* be the first argument, [converted to ASCII lowercase](#).
4. Let *convert-to-URL* be false.
5. If *format* equals "text", change it to "text/plain".
6. If *format* equals "url", change it to "text/uri-list" and set *convert-to-URL* to true.
7. If there is no item in the [drag_data_store item list](#)^{p825} whose [kind](#)^{p825} is *text* and whose [type string](#)^{p825} is equal to *format*, return the empty string.
8. Let *result* be the data of the item in the [drag_data_store item list](#)^{p825} whose [kind](#)^{p825} is *Plain Unicode string* and whose [type string](#)^{p825} is equal to *format*.
9. If *convert-to-URL* is true, then parse *result* as appropriate for text/uri-list data, and then set *result* to the first URL from the list, if any, or the empty string otherwise. [\[RFC2483\]](#)^{p1311}
10. Return *result*.

The **setData(*format*, *data*)** method must run the following steps:

1. If the [DataTransfer](#)^{p826} object is no longer associated with a [drag_data_store](#)^{p825}, return. Nothing happens.
2. If the [drag_data_store](#)^{p825}'s [mode](#)^{p825} is not the [read/write mode](#)^{p826}, return. Nothing happens.
3. Let *format* be the first argument, [converted to ASCII lowercase](#).
4. If *format* equals "text", change it to "text/plain".
If *format* equals "url", change it to "text/uri-list".
5. Remove the item in the [drag_data_store item list](#)^{p825} whose [kind](#)^{p825} is *text* and whose [type string](#)^{p825} is equal to *format*, if there is one.
6. Add an item to the [drag_data_store item list](#)^{p825} whose [kind](#)^{p825} is *text*, whose [type string](#)^{p825} is equal to *format*, and whose data is the string given by the method's second argument.

The **clearData(*format*)** method must run the following steps:

1. If the [DataTransfer](#)^{p826} object is no longer associated with a [drag_data_store](#)^{p825}, return. Nothing happens.
2. If the [drag_data_store](#)^{p825}'s [mode](#)^{p825} is not the [read/write mode](#)^{p826}, return. Nothing happens.
3. If the method was called with no arguments, remove each item in the [drag_data_store item list](#)^{p825} whose [kind](#)^{p825} is *Plain Unicode string*, and return.
4. Set *format* to *format*, [converted to ASCII lowercase](#).
5. If *format* equals "text", change it to "text/plain".
If *format* equals "url", change it to "text/uri-list".
6. Remove the item in the [drag_data_store item list](#)^{p825} whose [kind](#)^{p825} is *text* and whose [type string](#)^{p825} is equal to *format*, if there is one.

Note

The `clearData()`^{p828} method does not affect whether any files were included in the drag, so the `types`^{p828} attribute's list might still not be empty after calling `clearData()`^{p828} (it would still contain the "Files" string if any files were included in the drag).

The `files` attribute must return a `live`^{p45} `FileList` sequence consisting of `File` objects representing the files found by the following steps. Furthermore, for a given `FileList` object and a given underlying file, the same `File` object must be used each time.

1. Start with an empty list *L*.
2. If the `DataTransfer`^{p826} object is no longer associated with a `drag_data_store`^{p825}, the `FileList` is empty. Return the empty list *L*.
3. If the `drag_data_store`^{p825}'s `mode`^{p825} is the `protected_mode`^{p826}, Return the empty list *L*.
4. For each item in the `drag_data_store_item_list`^{p825} whose `kind`^{p825} is `File`, add the item's data (the file, in particular its name and contents, as well as its `type`^{p825}) to the list *L*.
5. The files found by these steps are those in the list *L*.

Note

This version of the API does not expose the types of the files during the drag.

6.10.3.1 The `DataTransferItemList`^{p829} interface §^{p82}₉

Each `DataTransfer`^{p826} object is associated with a `DataTransferItemList`^{p829} object.

```
IDL [Exposed=Window]
interface DataTransferItemList {
  readonly attribute unsigned long length;
  getter DataTransferItem (unsigned long index);
  DataTransferItem? add(DOMString data, DOMString type);
  DataTransferItem? add(File data);
  undefined remove(unsigned long index);
  undefined clear();
};
```

For web developers (non-normative)

`items.length`^{p829}

Returns the number of items in the `drag_data_store`^{p825}.

`items[index]`

Returns the `DataTransferItem`^{p830} object representing the *index*th entry in the `drag_data_store`^{p825}.

`items.remove`^{p830} (*index*)

Removes the *index*th entry in the `drag_data_store`^{p825}.

`items.clear`^{p830} ()

Removes all the entries in the `drag_data_store`^{p825}.

`items.add`^{p830} (*data*)

`items.add`^{p830} (*data*, *type*)

Adds a new entry for the given data to the `drag_data_store`^{p825}. If the data is plain text then a *type* string has to be provided also.

While the `DataTransferItemList`^{p829} object's `DataTransfer`^{p826} object is associated with a `drag_data_store`^{p825}, the `DataTransferItemList`^{p829} object's `mode` is the same as the `drag_data_store_mode`^{p825}. When the `DataTransferItemList`^{p829} object's `DataTransfer`^{p826} object is *not* associated with a `drag_data_store`^{p825}, the `DataTransferItemList`^{p829} object's `mode` is the *disabled mode*. The `drag_data_store`^{p825} referenced in this section (which is used only when the `DataTransferItemList`^{p829} object is not in the *disabled mode*) is the `drag_data_store`^{p825} with which the `DataTransferItemList`^{p829} object's `DataTransfer`^{p826} object is associated.

The `length` attribute must return zero if the object is in the *disabled mode*; otherwise it must return the number of items in the `drag`

[data store item list](#)^{p825}.

When a [DataTransferItemList](#)^{p829} object is not in the *disabled mode*, its [supported property indices](#) are the [indices](#) of the [drag data store item list](#)^{p825}.

To [determine the value of an indexed property](#) *i* of a [DataTransferItemList](#)^{p829} object, the user agent must return a [DataTransferItem](#)^{p830} object representing the *i*th item in the [drag data store](#)^{p825}. The same object must be returned each time a particular item is obtained from this [DataTransferItemList](#)^{p829} object. The [DataTransferItem](#)^{p830} object must be associated with the same [DataTransfer](#)^{p826} object as the [DataTransferItemList](#)^{p829} object when it is first created.

The `add()` method must run the following steps:

1. If the [DataTransferItemList](#)^{p829} object is not in the [read/write mode](#)^{p826}, return null.
2. Jump to the appropriate set of steps from the following list:

↪ **If the first argument to the method is a string**

If there is already an item in the [drag data store item list](#)^{p825} whose [kind](#)^{p825} is *text* and whose [type string](#)^{p825} is equal to the value of the method's second argument, [converted to ASCII lowercase](#), then throw a `"NotSupportedError"` `DOMException`.

Otherwise, add an item to the [drag data store item list](#)^{p825} whose [kind](#)^{p825} is *text*, whose [type string](#)^{p825} is equal to the value of the method's second argument, [converted to ASCII lowercase](#), and whose data is the string given by the method's first argument.

↪ **If the first argument to the method is a File**

Add an item to the [drag data store item list](#)^{p825} whose [kind](#)^{p825} is *File*, whose [type string](#)^{p825} is the *type* of the *File*, [converted to ASCII lowercase](#), and whose data is the same as the *File*'s data.

3. [Determine the value of the indexed property](#)^{p830} corresponding to the newly added item, and return that value (a newly created [DataTransferItem](#)^{p830} object).

The `remove(index)` method must run these steps:

1. If the [DataTransferItemList](#)^{p829} object is not in the [read/write mode](#)^{p826}, throw an `"InvalidStateError"` `DOMException`.
2. Remove the *index*th item from the [drag data store](#)^{p825}.

The `clear()` method, if the [DataTransferItemList](#)^{p829} object is in the [read/write mode](#)^{p826}, must remove all the items from the [drag data store](#)^{p825}. Otherwise, it must do nothing.

6.10.3.2 The [DataTransferItem](#)^{p830} interface § p830

Each [DataTransferItem](#)^{p830} object is associated with a [DataTransfer](#)^{p826} object.

```
IDL [Exposed=Window]
interface DataTransferItem {
  readonly attribute DOMString kind;
  readonly attribute DOMString type;
  undefined getAsString(FunctionStringCallback? _callback);
  File? getAsFile();
};

callback FunctionStringCallback = undefined (DOMString data);
```

For web developers (non-normative)

`item.kind`^{p831}

Returns [the drag data item kind](#)^{p825}, one of: "string", "file".

`item.type`^{p831}

Returns [the drag data item type string](#)^{p825}.

`item.getAsString`^{p831}(*callback*)

Invokes the *callback* with the string data as the argument, if [the drag data item kind](#)^{p825} is *text*.

`file = item.getAsFile`^{p831}()

Returns a *File* object, if [the drag data item kind](#)^{p825} is *File*.

While the [DataTransferItem](#)^{p830} object's [DataTransfer](#)^{p826} object is associated with a [drag data store](#)^{p825} and that [drag data store](#)^{p825}'s [drag data store item list](#)^{p825} still contains the item that the [DataTransferItem](#)^{p830} object represents, the [DataTransferItem](#)^{p830} object's *mode* is the same as the [drag data store mode](#)^{p825}. When the [DataTransferItem](#)^{p830} object's [DataTransfer](#)^{p826} object is *not* associated with a [drag data store](#)^{p825}, or if the item that the [DataTransferItem](#)^{p830} object represents has been removed from the relevant [drag data store item list](#)^{p825}, the [DataTransferItem](#)^{p830} object's *mode* is the *disabled mode*. The [drag data store](#)^{p825} referenced in this section (which is used only when the [DataTransferItem](#)^{p830} object is not in the *disabled mode*) is the [drag data store](#)^{p825} with which the [DataTransferItem](#)^{p830} object's [DataTransfer](#)^{p826} object is associated.

The *kind* attribute must return the empty string if the [DataTransferItem](#)^{p830} object is in the *disabled mode*; otherwise it must return the string given in the cell from the second column of the following table from the row whose cell in the first column contains [the drag data item kind](#)^{p825} of the item represented by the [DataTransferItem](#)^{p830} object:

Kind	String
Text	"string"
File	"file"

The *type* attribute must return the empty string if the [DataTransferItem](#)^{p830} object is in the *disabled mode*; otherwise it must return [the drag data item type string](#)^{p825} of the item represented by the [DataTransferItem](#)^{p830} object.

The `getAsString(callback)` method must run the following steps:

1. If the *callback* is null, return.
2. If the [DataTransferItem](#)^{p830} object is not in the [read/write mode](#)^{p826} or the [read-only mode](#)^{p826}, return. The *callback* is never invoked.
3. If [the drag data item kind](#)^{p825} is not *text*, then return. The *callback* is never invoked.
4. Otherwise, [queue a task](#)^{p970} to invoke *callback*, passing the actual data of the item represented by the [DataTransferItem](#)^{p830} object as the argument.

The `getAsFile()` method must run the following steps:

1. If the [DataTransferItem](#)^{p830} object is not in the [read/write mode](#)^{p826} or the [read-only mode](#)^{p826}, then return null.
2. If [the drag data item kind](#)^{p825} is not *File*, then return null.
3. Return a new *File* object representing the actual data of the item represented by the [DataTransferItem](#)^{p830} object.

6.10.4 The [DragEvent](#)^{p831} interface §^{p83}₁

The drag-and-drop processing model involves several events. They all use the [DragEvent](#)^{p831} interface.

```
IDL [Exposed=Window]
interface DragEvent : MouseEvent {
  constructor(DOMString type, optional DragEventInit eventInitDict = {});

  readonly attribute DataTransfer? dataTransfer;
};

dictionary DragEventInit : MouseEventInit {
  DataTransfer? dataTransfer = null;
};
```

event.dataTransfer^{p832}

Returns the [DataTransfer](#)^{p826} object for the event.

Note

Although, for consistency with other event interfaces, the [DragEvent](#)^{p831} interface has a constructor, it is not particularly useful. In particular, there's no way to create a useful [DataTransfer](#)^{p826} object from script, as [DataTransfer](#)^{p826} objects have a processing and security model that is coordinated by the browser during drag-and-drops.

The **dataTransfer** attribute of the [DragEvent](#)^{p831} interface must return the value it was initialized to. It represents the context information for the event.

When a user agent is required to **fire a DND event** named *e* at an element, using a particular [drag data store](#)^{p825}, and optionally with a specific *related target*, the user agent must run the following steps:

- Let *dataDragStoreWasChanged* be false.
- If no specific *related target* was provided, set *related target* to null.
- Let *window* be the [relevant global object](#)^{p944} of the [Document](#)^{p117} object of the specified target element.
- If *e* is [dragstart](#)^{p838}, then set the [drag data store mode](#)^{p825} to the [read/write mode](#)^{p826} and set *dataDragStoreWasChanged* to true.
If *e* is [drop](#)^{p838}, set the [drag data store mode](#)^{p825} to the [read-only mode](#)^{p826}.
- Let *dataTransfer* be a newly created [DataTransfer](#)^{p826} object associated with the given [drag data store](#)^{p825}.
- Set the [effectAllowed](#)^{p827} attribute to the [drag data store](#)^{p825}'s [drag data store allowed effects state](#)^{p826}.
- Set the [dropEffect](#)^{p827} attribute to "none"^{p827} if *e* is [dragstart](#)^{p838}, [drag](#)^{p838}, or [dragleave](#)^{p838}; to the value corresponding to the [current drag operation](#)^{p835} if *e* is [drop](#)^{p838} or [dragend](#)^{p838}; and to a value based on the [effectAllowed](#)^{p827} attribute's value and the drag-and-drop source, as given by the following table, otherwise (i.e. if *e* is [dragerter](#)^{p838} or [dragover](#)^{p838}):

effectAllowed ^{p827}	dropEffect ^{p827}
"none" ^{p827}	"none" ^{p827}
"copy" ^{p827}	"copy" ^{p827}
"copylink" ^{p827}	"copy" ^{p827} , or, if appropriate ^{p832} , "link" ^{p827}
"copyMove" ^{p827}	"copy" ^{p827} , or, if appropriate ^{p832} , "move" ^{p827}
"all" ^{p827}	"copy" ^{p827} , or, if appropriate ^{p832} , either "link" ^{p827} or "move" ^{p827}
"link" ^{p827}	"link" ^{p827}
"linkMove" ^{p827}	"link" ^{p827} , or, if appropriate ^{p832} , "move" ^{p827}
"move" ^{p827}	"move" ^{p827}
"uninitialized" ^{p827} when what is being dragged is a selection from a text control	"move" ^{p827} , or, if appropriate ^{p832} , either "copy" ^{p827} or "link" ^{p827}
"uninitialized" ^{p827} when what is being dragged is a selection	"copy" ^{p827} , or, if appropriate ^{p832} , either "link" ^{p827} or "move" ^{p827}
"uninitialized" ^{p827} when what is being dragged is an a ^{p244} element with an href ^{p290} attribute	"link" ^{p827} , or, if appropriate ^{p832} , either "copy" ^{p827} or "move" ^{p827}
Any other case	"copy" ^{p827} , or, if appropriate ^{p832} , either "link" ^{p827} or "move" ^{p827}

Where the table above provides **possibly appropriate alternatives**, user agents may instead use the listed alternative values if platform conventions dictate that the user has requested those alternate effects.

Example

For example, Windows platform conventions are such that dragging while holding the "alt" key indicates a preference for linking the data, rather than moving or copying it. Therefore, on a Windows system, if "link"^{p827} is an option according to the table above while the "alt" key is depressed, the user agent could select that instead of "copy"^{p827} or "move"^{p827}.

- Let *event* be the result of [creating an event](#) using [DragEvent](#)^{p831}.

9. Initialize *event*'s `type` attribute to *e*, its `bubbles` attribute to `true`, its `view` attribute to *window*, its `relatedTarget` attribute to *related target*, and its `dataTransfer`^{p832} attribute to *dataTransfer*.
10. If *e* is not `dragleave`^{p838} or `dragend`^{p838}, then initialize *event*'s `cancelable` attribute to `true`.
11. Initialize *event*'s mouse and key attributes initialized according to the state of the input devices as they would be for user interaction events.

If there is no relevant pointing device, then initialize *event*'s `screenX`, `screenY`, `clientX`, `clientY`, and `button` attributes to 0.
12. `Dispatch` *event* at the specified target element.
13. Set the `drag data store allowed effects state`^{p826} to the current value of *dataTransfer*'s `effectAllowed`^{p827} attribute. (It can only have changed value if *e* is `dragstart`^{p838}.)
14. If *dataDragStoreWasChanged* is `true`, then set the `drag data store mode`^{p825} back to the `protected mode`^{p826}.
15. Break the association between *dataTransfer* and the `drag data store`^{p825}.

6.10.5 Processing model ^{p83}₃

When the user attempts to begin a drag operation, the user agent must run the following steps. User agents must act as if these steps were run even if the drag actually started in another document or application and the user agent was not aware that the drag was occurring until it intersected with a document under the user agent's purview.

1. Determine what is being dragged, as follows:

If the drag operation was invoked on a selection, then it is the selection that is being dragged.

Otherwise, if the drag operation was invoked on a `Document`^{p117}, it is the first element, going up the ancestor chain, starting at the node that the user tried to drag, that has the IDL attribute `draggable`^{p839} set to `true`. If there is no such element, then nothing is being dragged; return, the drag-and-drop operation is never started.

Otherwise, the drag operation was invoked outside the user agent's purview. What is being dragged is defined by the document or application where the drag was started.

Note

`img`^{p327} elements and `a`^{p244} elements with an `href`^{p290} attribute have their `draggable`^{p839} attribute set to `true` by default.

2. `Create a drag data store`^{p826}. All the DND events fired subsequently by the steps in this section must use this `drag data store`^{p825}.
3. Establish which DOM node is the **source node**, as follows:

If it is a selection that is being dragged, then the `source node`^{p833} is the `Text` node that the user started the drag on (typically the `Text` node that the user originally clicked). If the user did not specify a particular node, for example if the user just told the user agent to begin a drag of "the selection", then the `source node`^{p833} is the first `Text` node containing a part of the selection.

Otherwise, if it is an element that is being dragged, then the `source node`^{p833} is the element that is being dragged.

Otherwise, the `source node`^{p833} is part of another document or application. When this specification requires that an event be dispatched at the `source node`^{p833} in this case, the user agent must instead follow the platform-specific conventions relevant to that situation.

Note

Multiple events are fired on the `source node`^{p833} during the course of the drag-and-drop operation.

4. Determine the **list of dragged nodes**, as follows:

If it is a selection that is being dragged, then the `list of dragged nodes`^{p833} contains, in `tree order`, every node that is partially or completely included in the selection (including all their ancestors).

Otherwise, the `list of dragged nodes`^{p833} contains only the `source node`^{p833}, if any.

5. If it is a selection that is being dragged, then add an item to the [drag_data_store_item_list](#)^{p825}, with its properties set as follows:

The drag_data_item_type_string^{p825}

"text/plain"

The drag_data_item_kind^{p825}

Text

The actual data

The text of the selection

Otherwise, if any files are being dragged, then add one item per file to the [drag_data_store_item_list](#)^{p825}, with their properties set as follows:

The drag_data_item_type_string^{p825}

The MIME type of the file, if known, or "application/octet-stream" otherwise.

The drag_data_item_kind^{p825}

File

The actual data

The file's contents and name.

Note

Dragging files can currently only happen from outside a [browsing context](#)^{p840}, for example from a file system manager application.

If the drag initiated outside of the application, the user agent must add items to the [drag_data_store_item_list](#)^{p825} as appropriate for the data being dragged, honoring platform conventions where appropriate; however, if the platform conventions do not use [MIME types](#) to label dragged data, the user agent must make a best-effort attempt to map the types to MIME types, and, in any case, all the [drag_data_item_type_strings](#)^{p825} must be [converted to ASCII lowercase](#).

User agents may also add one or more items representing the selection or dragged element(s) in other forms, e.g. as HTML.

6. If the [list of dragged nodes](#)^{p833} is not empty, then [extract the microdata from those nodes into a JSON form](#)^{p789}, and add one item to the [drag_data_store_item_list](#)^{p825}, with its properties set as follows:

The drag_data_item_type_string^{p825}

application/microdata+json^{p1279}

The drag_data_item_kind^{p825}

Text

The actual data

The resulting JSON string.

7. Run the following substeps:

1. Let *urls* be an empty list of [absolute URLs](#).
2. For each *node* in the [list of dragged nodes](#)^{p833}:

If the node is an [a](#)^{p244} element with an [href](#)^{p290} attribute

Add to *urls* the result of [parsing](#)^{p91} the element's [href](#)^{p290} content attribute relative to the element's [node document](#).

If the node is an [img](#)^{p327} element with a [src](#)^{p328} attribute

Add to *urls* the result of [parsing](#)^{p91} the element's [src](#)^{p328} content attribute relative to the element's [node document](#).

3. If *urls* is still empty, then return.
4. Let *url string* be the result of concatenating the strings in *urls*, in the order they were added, separated by a U+000D CARRIAGE RETURN U+000A LINE FEED character pair (CRLF).
5. Add one item to the [drag_data_store_item_list](#)^{p825}, with its properties set as follows:

[The drag data item type string](#)^{p825}

[text/uri-list](#)^{p1304}

[The drag data item kind](#)^{p825}

Text

The actual data

url string

8. Update the [drag data store default feedback](#)^{p825} as appropriate for the user agent (if the user is dragging the selection, then the selection would likely be the basis for this feedback; if the user is dragging an element, then that element's rendering would be used; if the drag began outside the user agent, then the platform conventions for determining the drag feedback should be used).
9. [Fire a DND event](#)^{p832} named [dragstart](#)^{p838} at the [source node](#)^{p833}.

If the event is canceled, then the drag-and-drop operation should not occur; return.

Note

Since events with no event listeners registered are, almost by definition, never canceled, drag-and-drop is always available to the user if the author does not specifically prevent it.

10. [Fire a pointer event](#) at the [source node](#)^{p833} named [pointercancel](#), and fire any other follow-up events as required by [Pointer Events](#). [[POINTEREVENTS](#)]^{p1310}
11. [Initiate the drag-and-drop operation](#)^{p835} in a manner consistent with platform conventions, and as described below.

The drag-and-drop feedback must be generated from the first of the following sources that is available:

1. The [drag data store bitmap](#)^{p825}, if any. In this case, the [drag data store hot spot coordinate](#)^{p825} should be used as hints for where to put the cursor relative to the resulting image. The values are expressed as distances in [CSS pixels](#) from the left side and from the top side of the image respectively. [[CSS](#)]^{p1305}
2. The [drag data store default feedback](#)^{p825}.

From the moment that the user agent is to **initiate the drag-and-drop operation**, until the end of the drag-and-drop operation, device input events (e.g. mouse and keyboard events) must be suppressed.

During the drag operation, the element directly indicated by the user as the drop target is called the **immediate user selection**. (Only elements can be selected by the user; other nodes must not be made available as drop targets.) However, the [immediate user selection](#)^{p835} is not necessarily the **current target element**, which is the element currently selected for the drop part of the drag-and-drop operation.

The [immediate user selection](#)^{p835} changes as the user selects different elements (either by pointing at them with a pointing device, or by selecting them in some other way). The [current target element](#)^{p835} changes when the [immediate user selection](#)^{p835} changes, based on the results of event listeners in the document, as described below.

Both the [current target element](#)^{p835} and the [immediate user selection](#)^{p835} can be null, which means no target element is selected. They can also both be elements in other (DOM-based) documents, or other (non-web) programs altogether. (For example, a user could drag text to a word-processor.) The [current target element](#)^{p835} is initially null.

In addition, there is also a **current drag operation**, which can take on the values "none", "copy", "link", and "move". Initially, it has the value "none"^{p835}. It is updated by the user agent as described in the steps below.

User agents must, as soon as the drag operation is [initiated](#)^{p835} and every 350ms (± 200 ms) thereafter for as long as the drag operation is ongoing, [queue a task](#)^{p970} to perform the following steps in sequence:

1. If the user agent is still performing the previous iteration of the sequence (if any) when the next iteration becomes due, return for this iteration (effectively "skipping missed frames" of the drag-and-drop operation).
2. [Fire a DND event](#)^{p832} named [drag](#)^{p838} at the [source node](#)^{p833}. If this event is canceled, the user agent must set the [current drag operation](#)^{p835} to "none"^{p835} (no drag operation).
3. If the [drag](#)^{p838} event was not canceled and the user has not ended the drag-and-drop operation, check the state of the drag-and-drop operation, as follows:
 1. If the user is indicating a different [immediate user selection](#)^{p835} than during the last iteration (or if this is the first

iteration), and if this [immediate user selection](#)^{p835} is not the same as the [current target element](#)^{p835}, then update the [current target element](#)^{p835} as follows:

- ↪ If the new [immediate user selection](#)^{p835} is null
 - Set the [current target element](#)^{p835} to null also.
- ↪ If the new [immediate user selection](#)^{p835} is in a non-DOM document or application
 - Set the [current target element](#)^{p835} to the [immediate user selection](#)^{p835}.

↪ **Otherwise**

Fire a [DND event](#)^{p832} named [dragenter](#)^{p838} at the [immediate user selection](#)^{p835}.

If the event is canceled, then set the [current target element](#)^{p835} to the [immediate user selection](#)^{p835}.

Otherwise, run the appropriate step from the following list:

- ↪ If the [immediate user selection](#)^{p835} is a text control (e.g., [textarea](#)^{p558}, or an [input](#)^{p501} element whose [type](#)^{p503} attribute is in the [Text](#)^{p508} state) or an [editing host](#)^{p817} or [editable](#) element, and the [drag data store item list](#)^{p825} has an item with the [drag data item type string](#)^{p825} "[text/plain](#)" and the [drag data item kind](#)^{p825} [text](#)
 - Set the [current target element](#)^{p835} to the [immediate user selection](#)^{p835} anyway.
- ↪ If the [immediate user selection](#)^{p835} is the [body element](#)^{p123}
 - Leave the [current target element](#)^{p835} unchanged.
- ↪ **Otherwise**
 - Fire a [DND event](#)^{p832} named [dragenter](#)^{p838} at the [body element](#)^{p123}, if there is one, or at the [Document](#)^{p117} object, if not. Then, set the [current target element](#)^{p835} to the [body element](#)^{p123}, regardless of whether that event was canceled or not.

2. If the previous step caused the [current target element](#)^{p835} to change, and if the previous target element was not null or a part of a non-DOM document, then fire a [DND event](#)^{p832} named [dragleave](#)^{p838} at the previous target element, with the new [current target element](#)^{p835} as the specific *related target*.
3. If the [current target element](#)^{p835} is a DOM element, then fire a [DND event](#)^{p832} named [dragover](#)^{p838} at this [current target element](#)^{p835}.

If the [dragover](#)^{p838} event is not canceled, run the appropriate step from the following list:

- ↪ If the [current target element](#)^{p835} is a text control (e.g., [textarea](#)^{p558}, or an [input](#)^{p501} element whose [type](#)^{p503} attribute is in the [Text](#)^{p508} state) or an [editing host](#)^{p817} or [editable](#) element, and the [drag data store item list](#)^{p825} has an item with the [drag data item type string](#)^{p825} "[text/plain](#)" and the [drag data item kind](#)^{p825} [text](#)
 - Set the [current drag operation](#)^{p835} to either "[copy](#)^{p835}" or "[move](#)^{p835}", as appropriate given the platform conventions.
- ↪ **Otherwise**
 - Reset the [current drag operation](#)^{p835} to "[none](#)^{p835}".

Otherwise (if the [dragover](#)^{p838} event is canceled), set the [current drag operation](#)^{p835} based on the values of the [effectAllowed](#)^{p827} and [dropEffect](#)^{p827} attributes of the [DragEvent](#)^{p831} object's [dataTransfer](#)^{p832} object as they stood after the event [dispatch](#) finished, as per the following table:

effectAllowed ^{p827}	dropEffect ^{p827}	Drag operation
" uninitialized ^{p827} ", " copy ^{p827} ", " copyLink ^{p827} ", " copyMove ^{p827} ", or " all ^{p827} "	" copy ^{p827} "	" copy ^{p835} "
" uninitialized ^{p827} ", " link ^{p827} ", " copyLink ^{p827} ", " linkMove ^{p827} ", or " all ^{p827} "	" link ^{p827} "	" link ^{p835} "
" uninitialized ^{p827} ", " move ^{p827} ", " copyMove ^{p827} ", " linkMove ^{p827} ", or " all ^{p827} "	" move ^{p827} "	" move ^{p835} "
Any other case		" none ^{p835} "

4. Otherwise, if the [current target element](#)^{p835} is not a DOM element, use platform-specific mechanisms to determine what drag operation is being performed (none, copy, link, or move), and set the [current drag operation](#)^{p835} accordingly.
5. Update the drag feedback (e.g. the mouse cursor) to match the [current drag operation](#)^{p835}, as follows:

Drag operation	Feedback
"copy" ^{p835}	Data will be copied if dropped here.
"link" ^{p835}	Data will be linked if dropped here.
"move" ^{p835}	Data will be moved if dropped here.
"none" ^{p835}	No operation allowed, dropping here will cancel the drag-and-drop operation.

4. Otherwise, if the user ended the drag-and-drop operation (e.g. by releasing the mouse button in a mouse-driven drag-and-drop interface), or if the [drag^{p838}](#) event was canceled, then this will be the last iteration. Run the following steps, then stop the drag-and-drop operation:

1. If the [current drag operation^{p835}](#) is "[none^{p835}](#)" (no drag operation), or, if the user ended the drag-and-drop operation by canceling it (e.g. by hitting the Escape key), or if the [current target element^{p835}](#) is null, then the drag operation failed. Run these substeps:
 1. Let *dropped* be false.
 2. If the [current target element^{p835}](#) is a DOM element, [fire a DND event^{p832}](#) named [dragleave^{p838}](#) at it; otherwise, if it is not null, use platform-specific conventions for drag cancelation.
 3. Set the [current drag operation^{p835}](#) to "[none^{p835}](#)".

Otherwise, the drag operation might be a success; run these substeps:

1. Let *dropped* be true.
2. If the [current target element^{p835}](#) is a DOM element, [fire a DND event^{p832}](#) named [drop^{p838}](#) at it; otherwise, use platform-specific conventions for indicating a drop.
3. If the event is canceled, set the [current drag operation^{p835}](#) to the value of the [dropEffect^{p827}](#) attribute of the [DragEvent^{p831}](#) object's [dataTransfer^{p832}](#) object as it stood after the event [dispatch](#) finished.

Otherwise, the event is not canceled; perform the event's default action, which depends on the exact target as follows:

↪ If the [current target element^{p835}](#) is a text control (e.g., [textarea^{p558}](#), or an [input^{p501}](#) element whose [type^{p503}](#) attribute is in the [Text^{p508}](#) state) or an [editing host^{p817}](#) or [editable element](#), and the [drag data store item list^{p825}](#) has an item with the [drag data item type string^{p825}](#) "[text/plain](#)" and the [drag data item kind^{p825}](#) [text](#)

Insert the actual data of the first item in the [drag data store item list^{p825}](#) to have a [drag data item type string^{p825}](#) of "[text/plain](#)" and a [drag data item kind^{p825}](#) that is *text* into the text control or [editing host^{p817}](#) or [editable](#) element in a manner consistent with platform-specific conventions (e.g. inserting it at the current mouse cursor position, or inserting it at the end of the field).

↪ **Otherwise**

Reset the [current drag operation^{p835}](#) to "[none^{p835}](#)".

2. [Fire a DND event^{p832}](#) named [dragend^{p838}](#) at the [source node^{p833}](#).
3. Run the appropriate steps from the following list as the default action of the [dragend^{p838}](#) event:
 - ↪ If *dropped* is true, the [current target element^{p835}](#) is a text control (see below), the [current drag operation^{p835}](#) is "[move^{p835}](#)", and the source of the drag-and-drop operation is a selection in the DOM that is entirely contained within an [editing host^{p817}](#)
[Delete the selection.](#)
 - ↪ If *dropped* is true, the [current target element^{p835}](#) is a text control (see below), the [current drag operation^{p835}](#) is "[move^{p835}](#)", and the source of the drag-and-drop operation is a selection in a text control
The user agent should delete the dragged selection from the relevant text control.
 - ↪ If *dropped* is false or if the [current drag operation^{p835}](#) is "[none^{p835}](#)"
The drag was canceled. If the platform conventions dictate that this be represented to the user (e.g. by animating the dragged selection going back to the source of the drag-and-drop operation), then do so.

↔ Otherwise

The event has no default action.

For the purposes of this step, a *text control* is a [textarea](#)^{p558} element or an [input](#)^{p501} element whose [type](#)^{p503} attribute is in one of the [Text](#)^{p508}, [Search](#)^{p508}, [Tel](#)^{p508}, [URL](#)^{p509}, [Email](#)^{p510}, [Password](#)^{p512}, or [Number](#)^{p517} states.

Note

User agents are encouraged to consider how to react to drags near the edge of scrollable regions. For example, if a user drags a link to the bottom of the [viewport](#) on a long page, it might make sense to scroll the page so that the user can drop the link lower on the page.

Note

This model is independent of which [Document](#)^{p117} object the nodes involved are from; the events are fired as described above and the rest of the processing model runs as described above, irrespective of how many documents are involved in the operation.

6.10.6 Events summary § p83

This section is non-normative.

The following events are involved in the drag-and-drop model.

Event name	Target	Cancelable?	Drag data store mode ^{p825}	dropEffect ^{p827}	Default Action
dragstart	Source node ^{p833}	✓ Cancelable	Read/write mode ^{p826}	"none" ^{p827}	Initiate the drag-and-drop operation
drag	Source node ^{p833}	✓ Cancelable	Protected mode ^{p826}	"none" ^{p827}	Continue the drag-and-drop operation
dragenter	Immediate user selection ^{p835} or the body element ^{p123}	✓ Cancelable	Protected mode ^{p826}	Based on effectAllowed value ^{p832}	Reject immediate user selection ^{p835} as potential target element ^{p835}
dragleave	Previous target element ^{p835}	—	Protected mode ^{p826}	"none" ^{p827}	None
dragover	Current target element ^{p835}	✓ Cancelable	Protected mode ^{p826}	Based on effectAllowed value ^{p832}	Reset the current drag operation ^{p835} to "none"
drop	Current target element ^{p835}	✓ Cancelable	Read-only mode ^{p826}	Current drag operation ^{p835}	Varies
dragend	Source node ^{p833}	—	Protected mode ^{p826}	Current drag operation ^{p835}	Varies

All of these events bubble, are composed, and the [effectAllowed](#)^{p827} attribute always has the value it had after the [dragstart](#)^{p838} event, defaulting to "[uninitialized](#)^{p827}" in the [dragstart](#)^{p838} event.

6.10.7 The [draggable](#)^{p838} attribute § p83

All [HTML elements](#)^{p44} may have the [draggable](#) content attribute set. The [draggable](#)^{p838} attribute is an [enumerated attribute](#)^{p69}. It has three states. The first state is *true* and it has the keyword *true*. The second state is *false* and it has the keyword *false*. The third state is *auto*; it has no keywords but it is the [missing value default](#)^{p69} and the [invalid value default](#)^{p69}.

The *true* state means the element is draggable; the *false* state means that it is not. The *auto* state uses the default behavior of the user agent.

An element with a [draggable](#)^{p838} attribute should also have a [title](#)^{p143} attribute that names the element for the purpose of non-visual interactions.

For web developers (non-normative)

`element.draggablep839 [= value]`

Returns true if the element is draggable; otherwise, returns false.

Can be set, to override the default and set the [draggable^{p838}](#) content attribute.

The **draggable** IDL attribute, whose value depends on the content attribute's in the way described below, controls whether or not the element is draggable. Generally, only text selections are draggable, but elements whose [draggable^{p839}](#) IDL attribute is true become draggable as well.

If an element's [draggable^{p838}](#) content attribute has the state *true*, the [draggable^{p839}](#) IDL attribute must return true.

Otherwise, if the element's [draggable^{p838}](#) content attribute has the state *false*, the [draggable^{p839}](#) IDL attribute must return false.

Otherwise, the element's [draggable^{p838}](#) content attribute has the state *auto*. If the element is an [img^{p327}](#) element, an [object^{p381}](#) element that [represents^{p128}](#) an image, or an [a^{p244}](#) element with an [href^{p290}](#) content attribute, the [draggable^{p839}](#) IDL attribute must return true; otherwise, the [draggable^{p839}](#) IDL attribute must return false.

If the [draggable^{p839}](#) IDL attribute is set to the value false, the [draggable^{p838}](#) content attribute must be set to the literal value "false".

If the [draggable^{p839}](#) IDL attribute is set to the value true, the [draggable^{p838}](#) content attribute must be set to the literal value "true".

6.10.8 Security risks in the drag-and-drop model §^{p83}

User agents must not make the data added to the [DataTransfer^{p826}](#) object during the [dragstart^{p838}](#) event available to scripts until the [drop^{p838}](#) event, because otherwise, if a user were to drag sensitive information from one document to a second document, crossing a hostile third document in the process, the hostile document could intercept the data.

For the same reason, user agents must consider a drop to be successful only if the user specifically ended the drag operation — if any scripts end the drag operation, it must be considered unsuccessful (canceled) and the [drop^{p838}](#) event must not be fired.

User agents should take care to not start drag-and-drop operations in response to script actions. For example, in a mouse-and-window environment, if a script moves a window while the user has their mouse button depressed, the UA would not consider that to start a drag. This is important because otherwise UAs could cause data to be dragged from sensitive sources and dropped into hostile documents without the user's consent.

User agents should filter potentially active (scripted) content (e.g. HTML) when it is dragged and when it is dropped, using a safelist of known-safe features. Similarly, [relative URLs](#) should be turned into absolute URLs to avoid references changing in unexpected ways. This specification does not specify how this is performed.

Example

Consider a hostile page providing some content and getting the user to select and drag and drop (or indeed, copy and paste) that content to a victim page's [contenteditable^{p815}](#) region. If the browser does not ensure that only safe content is dragged, potentially unsafe content such as scripts and event handlers in the selection, once dropped (or pasted) into the victim site, get the privileges of the victim site. This would thus enable a cross-site scripting attack.

7 Loading web pages §^{p84}₀

This section describes features that apply most directly to web browsers. Having said that, except where specified otherwise, the requirements defined in this section *do* apply to all user agents, whether they are web browsers or not.

7.1 Browsing contexts §^{p84}₀

A **browsing context** is an environment in which [Document^{p117}](#) objects are presented to the user.

Note

A tab or window in a web browser typically contains a [browsing context^{p840}](#), as does an [iframe^{p369}](#) or [frame^{p1264}](#)s in a [frameset^{p1264}](#).

A [browsing context^{p840}](#) has a corresponding [WindowProxy^{p865}](#) object.

A [browsing context^{p840}](#) has an **opener browsing context**, which is null or a [browsing context^{p840}](#). It is initially null.

A [browsing context^{p840}](#) has a **disowned** boolean. It is initially false.

A [browsing context^{p840}](#) has an **is closing** boolean. It is initially false.

Example

The following example illustrates the various possibilities of a [browsing context^{p840}](#). It can be [disowned^{p840}](#), [is closing^{p840}](#), neither, or both.

```
// Neither disowned nor is closing:
const popup1 = window.open();

// Disowned, but not is closing:
const popup2 = window.open();
popup2.opener = null;

// Not disowned, but is closing:
const popup3 = window.open();
popup3.close();

// Disowned, is closing:
const popup4 = window.open();
popup4.opener = null;
popup4.close();
```

A [browsing context^{p840}](#) has a [session history^{p888}](#), which lists the [Document^{p117}](#) objects that the [browsing context^{p840}](#) has presented, is presenting, or will present. A **Document's browsing context** is the [browsing context^{p840}](#) whose [session history^{p888}](#) contains the [Document^{p117}](#), if any such browsing context exists and has not been [discarded^{p862}](#), and null otherwise.

Note

A [Document^{p117}](#) does not necessarily have a non-null [browsing context^{p840}](#). In particular, data mining tools are likely to never instantiate browsing contexts. A [Document^{p117}](#) created using an API such as [createDocument\(\)](#) never has a non-null [browsing context^{p840}](#). And the [Document^{p117}](#) originally created for an [iframe^{p369}](#) element, which has since been [removed from the document^{p44}](#), has no associated browsing context, since that browsing context was [discarded^{p862}](#).

A [browsing context^{p840}](#)'s **active window** is its [WindowProxy^{p865}](#) object's [\[\[Window\]\]^{p865}](#) internal slot value. A [browsing context^{p840}](#)'s **active document** is its [active window^{p840}](#)'s [associated Document^{p856}](#).

Note

In general, there is a 1-to-1 mapping from the [Window^{p855}](#) object to the [Document^{p117}](#) object, as long as the [Document^{p117}](#) object has a non-null [browsing context^{p840}](#). There is one exception. A [Window^{p855}](#) can be reused for the presentation of a second [Document^{p117}](#) in the same [browsing context^{p840}](#), such that the mapping is then 1-to-2. This occurs when a [browsing context^{p840}](#) is [navigated^{p906}](#) from the [initial about:blank^{p118}](#) [Document^{p117}](#) to another, with [historyHandling^{p906}](#) set to "[replace^{p906}](#)".

A [browsing context^{p840}](#) has a **virtual browsing context group ID** integer. It is initially 0. This is used by [cross-origin opener policy reporting^{p876}](#), to keep track of the browsing context group switches that would have happened if the report-only policy had been enforced.

A [browsing context^{p840}](#) has an **initial URL**, which is a [URL](#) or null. It is initially null.

A [browsing context^{p840}](#) has an **opener origin at creation**, which is an [origin^{p868}](#) or null. It is initially null.

7.1.1 Creating browsing contexts §^{p84}₁

To **set the active document** of a [browsing context^{p840}](#) *browsingContext* to a [Document^{p117}](#) object *document*, run these steps:

1. Let *window* be *document*'s [relevant global object^{p944}](#).
2. Set *document*'s [visibility state^{p793}](#) to *browsingContext*'s [top-level browsing context^{p844}](#)'s [system visibility state^{p793}](#).
3. Set *browsingContext*'s [active window^{p840}](#) to *window*.
4. Set *window*'s [associated Document^{p856}](#) to *document*.
5. Set *window*'s [relevant settings object^{p944}](#)'s [execution ready flag^{p937}](#).

A [browsing context^{p840}](#) has an associated **creator origin** (null or returns an [origin^{p868}](#)), **creator URL** (null or returns a [URL](#)), and **creator base URL** (null or returns a [URL](#)). These are all initially null.

To **determine the origin**, given [browsing context^{p840}](#) *browsingContext*, [URL](#) *url*, [sandboxing flag set^{p873}](#) *sandboxFlags*, and an [origin^{p868}](#) *invocationOrigin*:

1. If *sandboxFlags* has its [sandboxed origin browsing context flag^{p873}](#) set, then return a new [opaque origin^{p868}](#).
2. If *url* is null, then return a new [opaque origin^{p868}](#).
3. If *invocationOrigin* is non-null and *url* [matches about:blank^{p90}](#), then return *invocationOrigin*.

Note

The result here is that two documents end up with the same underlying [origin^{p868}](#), meaning that [document.domain^{p871}](#) affects both.

4. If *url* is [about:srcdoc^{p90}](#), then return the [origin](#) of *browsingContext*'s [container document^{p843}](#).
5. Return *url*'s [origin](#).

To **create a new browsing context**, given null or a [Document^{p117}](#) object *creator*, null or an element *embedder*, and a [browsing context group^{p848}](#) *group*, run these steps:

1. Let *browsingContext* be a new [browsing context^{p840}](#).
2. Let *unsafeContextCreationTime* be the [unsafe shared current time](#).
3. If *creator* is non-null, then set *browsingContext*'s [creator origin^{p841}](#) to return *creator*'s [origin](#), *browsingContext*'s [creator URL^{p841}](#) to return *creator*'s [URL](#), *browsingContext*'s [creator base URL^{p841}](#) to return *creator*'s [base URL^{p90}](#), and *browsingContext*'s [virtual browsing context group ID^{p841}](#) to *creator*'s [top-level browsing context^{p844}](#)'s [virtual browsing context group ID^{p841}](#).
4. Let *sandboxFlags* be the result of [determining the creation sandboxing flags^{p876}](#) given *browsingContext* and *embedder*.
5. Let *origin* be the result of [determining the origin^{p841}](#) given *browsingContext*, [about:blank^{p51}](#), *sandboxFlags*, and

browsingContext's [creator_origin](#)^{p841}.

- Let *permissionsPolicy* be the result of [creating a permissions policy](#) given *browsingContext* and *origin*.
[\[PERMISSIONSPOLICY\]](#)^{p1310}

This needs to use *embedder*.

- Let *agent* be the result of [obtaining a similar-origin window agent](#)^{p934} given *origin*, *group*, and false.
- Let *realm execution context* be the result of [creating a new JavaScript realm](#)^{p938} given *agent* and the following customizations:
 - For the global object, create a new [Window](#)^{p855} object.
 - For the global **this** binding, use *browsingContext*'s [WindowProxy](#)^{p865} object.
- Let *topLevelCreationURL* be [about:blank](#)^{p51} if *embedder* is null; otherwise *embedder*'s [relevant settings object](#)^{p944}'s [top-level creation URL](#)^{p936}.
- Let *topLevelOrigin* be *origin* if *embedder* is null; otherwise *embedder*'s [relevant settings object](#)^{p944}'s [top-level origin](#)^{p936}.
- [Set up a window environment settings object](#)^{p864} with [about:blank](#)^{p51}, *realm execution context*, null, *topLevelCreationURL*, and *topLevelOrigin*.
- Let *loadTimingInfo* be a new [document load timing info](#)^{p121} with its [navigation start time](#)^{p121} set to the result of calling [coarsen time](#) with *unsafeContextCreationTime* and the new [environment settings object](#)^{p937}'s [cross-origin isolated capability](#)^{p937}.
- Let *coop* be a new [cross-origin opener policy](#)^{p876}.
- If *creator* is non-null and *creator*'s [origin](#) is [same origin](#)^{p869} with *creator*'s [relevant settings object](#)^{p944}'s [top-level origin](#)^{p936}, then set *coop* to *creator*'s [browsing context](#)^{p840}'s [top-level browsing context](#)^{p844}'s [active document](#)^{p840}'s [cross-origin opener policy](#)^{p118}.
- Let *document* be a new [Document](#)^{p117}, marked as an [HTML document](#) in [quirks mode](#), whose [content type](#) is "text/html", [origin](#) is *origin*, [active sandboxing flag set](#)^{p875} is *sandboxFlags*, [permissions policy](#)^{p118} is *permissionsPolicy*, [cross-origin opener policy](#)^{p118} is *coop*, [load timing info](#)^{p121} is *loadTimingInfo*, [navigation id](#)^{p118} is null, and which is [ready for post-load tasks](#)^{p1193}.
- Assert: *document*'s [URL](#) and *document*'s [relevant settings object](#)^{p944}'s [creation URL](#)^{p936} are [about:blank](#)^{p51}.
- Set *document*'s [is initial about:blank](#)^{p118} to true.
- Ensure that *document* has a single child [html](#)^{p157} node, which itself has two empty child nodes: a [head](#)^{p158} element, and a [body](#)^{p184} element.
- [Set the active document](#)^{p841} of *browsingContext* to *document*.
- If *browsingContext*'s [creator URL](#)^{p841} is non-null, then set *document*'s [referrer](#)^{p117} to the [serialization](#) of it.
- If *creator* is non-null, then set *document*'s [policy container](#)^{p118} to a [clone](#)^{p887} of *creator*'s [policy container](#)^{p118}.
- Append a new [session history entry](#)^{p888} to *browsingContext*'s [session history](#)^{p888} whose [URL](#)^{p888} is [about:blank](#)^{p51} and [document](#)^{p888} is *document*.
- [Completely finish loading](#)^{p927} *document*.
- Return *browsingContext*.

To create a new top-level browsing context:

- Let *group* be the result of [creating a new browsing context group](#)^{p848}.
- Return *group*'s [browsing context set](#)^{p848}[0].

Note

This creates a [top-level browsing context](#)^{p844}.

To create a new auxiliary browsing context, given a [browsing context](#)^{p840} opener:

1. Let *group* be *opener*'s [top-level browsing context](#)^{p844}'s [group](#)^{p844}.
2. Assert: *group* is non-null, as [navigating](#)^{p906} invokes this directly.
3. Let *browsingContext* be the result of [creating a new browsing context](#)^{p841} with *opener*'s [active document](#)^{p840}, null, and *group*.
4. [Append](#)^{p848} *browsingContext* to *group*.
5. Set *browsingContext*'s [opener browsing context](#)^{p840} to *opener*.
6. Set *browsingContext*'s [virtual browsing context group ID](#)^{p841} to *opener*'s [top-level browsing context](#)^{p844}'s [virtual browsing context group ID](#)^{p841}.
7. Set *browsingContext*'s [opener origin at creation](#)^{p841} to *opener*'s [active document](#)^{p840}'s [origin](#).
8. [Legacy-clone a browsing session storage shed](#) with *opener*'s [browsing session](#)^{p888} and *browsingContext*'s [browsing session](#)^{p888}. [STORAGE]^{p1312}
9. Return *browsingContext*.

Note

This creates a [top-level browsing context](#)^{p844} that is also an [auxiliary browsing context](#)^{p844}.

To **create a new nested browsing context**, given an element *element*:

1. Let *group* be *element*'s [node document](#)'s [browsing context](#)^{p840}'s [top-level browsing context](#)^{p844}'s [group](#)^{p844}.
2. Let *browsingContext* be the result of [creating a new browsing context](#)^{p841} with *element*'s [node document](#), *element*, and *group*.
3. Set *element*'s [nested browsing context](#)^{p843} to *browsingContext*.
4. If *element* has a `name` attribute, then set *browsingContext*'s [name](#)^{p849} to the value of this attribute.

7.1.2 Related browsing contexts §^{p84}₃

Certain elements (for example, [iframe](#)^{p369} elements) can instantiate further [browsing contexts](#)^{p840}. These elements are called **browsing context containers**.

Each [browsing context container](#)^{p843} has a **nested browsing context**, which is either a [browsing context](#)^{p840} or null. It is initially null.

The **container** of a [browsing context](#)^{p840} *bc* is the [browsing context container](#)^{p843} whose [nested browsing context](#)^{p843} is *bc*, or null if there is no such element.

Each [browsing context](#)^{p840} *bc* has a **container document**, which is the result of running these steps:

1. If *bc*'s [container](#)^{p843} is null, then return null.
2. Return *bc*'s [container](#)^{p843}'s [node document](#).

Note

This is equal to *bc*'s [container](#)^{p843}'s [shadow-including root](#) as *bc*'s [container](#)^{p843} has to be [connected](#).

A [browsing context](#)^{p840} *child* is said to be a **child browsing context** of another [browsing context](#)^{p840} *parent*, if *child*'s [container document](#)^{p843} is non-null and *child*'s [container document](#)^{p843}'s [browsing context](#)^{p840} is *parent*.

A [browsing context](#)^{p840} *child* is a **document-tree child browsing context** of *parent* if *child* is a [child browsing context](#)^{p843} and *child*'s [container](#)^{p843} is [in a document tree](#).

A [browsing context](#)^{p840} *child* may have a **parent browsing context**. This is the unique [browsing context](#)^{p840} that has *child* as a [child browsing context](#)^{p843}, if any such browsing context exists. Otherwise, the [browsing context](#)^{p840} has no [parent browsing context](#)^{p843}.

A [browsing context](#)^{p840} *A* is said to be an **ancestor** of a browsing context *B* if there exists a browsing context *A'* that is a [child browsing context](#)^{p843} of *A* and that is itself an [ancestor](#)^{p843} of *B*, or if the browsing context *A* is the [parent browsing context](#)^{p843} of *B*.

A [browsing context](#)^{p840} that has no [parent browsing context](#)^{p843} is the **top-level browsing context** for itself and all of the browsing contexts for which it is an [ancestor browsing context](#)^{p843}.

A [top-level browsing context](#)^{p844} has an associated **group** (null or a [browsing context group](#)^{p848}). It is initially null.

A [top-level browsing context](#)^{p844} has an **is popup** boolean. It is initially false.

Note

The only mandatory impact in this specification of [is popup](#)^{p844} is on the [visible](#)^{p863} getter of the relevant [BarProp](#)^{p863} objects. However, user agents might also use it in the following ways:

- Deciding whether or not to provide a minimal web browser user interface for the [browsing context](#)^{p840}.
- Performing the optional steps in [set up browsing context features](#).

In both cases user agents might additionally incorporate user preferences, or present a choice as to whether to go down the popup route.

User agents that provides a minimal web browser user interface for such popups are encouraged to not hide the browser's location bar.

It is possible to create new browsing contexts that are related to a [top-level browsing context](#)^{p844} while their [container](#)^{p843} is null. Such browsing contexts are called **auxiliary browsing contexts**. Auxiliary browsing contexts are always [top-level browsing contexts](#)^{p844}.

The transitive closure of [parent browsing contexts](#)^{p843} for a [browsing context](#)^{p840} that is a [child browsing context](#)^{p843} gives the list of [ancestor browsing contexts](#)^{p843}.

The **list of the descendant browsing contexts** of a [Document](#)^{p117} *d* is the (ordered) list returned by the following algorithm:

1. Let *list* be an empty [list](#).
2. For each [browsing context container](#)^{p843} *container*, whose [nested browsing context](#)^{p843} is non-null and whose [shadow-including root](#) is *d*, in [shadow-including tree order](#):
 1. Let *nestedBC* be *container*'s [nested browsing context](#)^{p843}.
 2. [Append](#) *nestedBC* to *list*.
 3. [Extend](#) *list* with the [list of the descendant browsing contexts](#)^{p844} of *nestedBC*'s [active document](#)^{p840}.
3. Return *list*.

A [Document](#)^{p117} *d* is said to be **fully active** when *d*'s [browsing context](#)^{p840} is non-null, *d*'s [browsing context](#)^{p840}'s [active document](#)^{p840} is *d*, and either *d*'s [browsing context](#)^{p840} is a [top-level browsing context](#)^{p844}, or *d*'s [browsing context](#)^{p840}'s [container document](#)^{p843} is [fully active](#)^{p844}.

Because they are associated with an element, [child browsing contexts](#)^{p843} are always tied to a specific [Document](#)^{p117} in their [parent browsing context](#)^{p843}. User agents must not allow the user to interact with [child browsing contexts](#)^{p843} of elements that are in [Document](#)^{p117}s that are not themselves [fully active](#)^{p844}.

Example

The following example illustrates the differences between [active](#)^{p840} and [fully active](#)^{p844} [Document](#)^{p117} objects. Here a.html is loaded into a browser window, b-1.html starts out loaded into an [iframe](#)^{p369} as shown, and b-2.html and c.html are omitted (they can simply be an empty document).

```
<!-- a.html -->
<!DOCTYPE html>
<html lang="en">
<title>Browsing context A</title>

<iframe src="b-1.html"></iframe>
```

```

<button onclick="frames[0].location.href = 'b-2.html'">Click me</button>

<!-- b-1.html -->
<!DOCTYPE html>
<html lang="en">
<title>Browsing context B</title>

<iframe src="c.html"></iframe>

```

At this point, the documents given by a.html, b-1.html, and c.html are all the [active documents](#)^{p840} of their respective [browsing contexts](#)^{p840}. They are also all [fully active](#)^{p844}.

After clicking on the [button](#)^{p545}, and thus loading a new [Document](#)^{p117} from b-2.html into browsing context B, we have the following results:

- The a.html [Document](#)^{p117} remains both the [active document](#)^{p840} of browsing context A, and [fully active](#)^{p844}.
- The b-1.html [Document](#)^{p117} is now *not* the [active document](#)^{p840} of browsing context B. As such it is also not [fully active](#)^{p844}.
- The new b-2.html [Document](#)^{p117} is now the [active document](#)^{p840} of browsing context B, and is also [fully active](#)^{p844}.
- The c.html [Document](#)^{p117} is still the [active document](#)^{p840} of browsing context C. However, since C's [container document](#)^{p843} is the b-1.html [Document](#)^{p117}, which is itself not [fully active](#)^{p844}, this means the c.html [Document](#)^{p117} is now not [fully active](#)^{p844} (even though it is [active](#)^{p840}).

For more explorations of the complexities involved here, especially as it impacts [the session history](#)^{p888}, see *A Model of Navigation History*. [[NAVMODEL](#)]^{p1310}

A [child browsing context](#)^{p843} can be put into a **delaying load events mode**. This is used when it is [navigated](#)^{p906}, to [delay the load event](#)^{p1192} of its [container](#)^{p843} before the new [Document](#)^{p117} is created.

The **document family** of a [browsing context](#)^{p840} consists of the union of all the [Document](#)^{p117} objects in that [browsing context](#)^{p840}'s [session history](#)^{p888} and the [document families](#)^{p845} of all those [Document](#)^{p117} objects. The [document family](#)^{p845} of a [Document](#)^{p117} object consists of the union of all the [document families](#)^{p845} of the [browsing contexts](#)^{p840} in the [list of the descendant browsing contexts](#)^{p844} of the [Document](#)^{p117} object.

The **content document** of a [browsing context container](#)^{p843} *container* is the result of the following algorithm:

1. If *container*'s [nested browsing context](#)^{p843} is null, then return null.
2. Let *context* be *container*'s [nested browsing context](#)^{p843}.
3. Let *document* be *context*'s [active document](#)^{p840}.
4. If *document*'s [origin](#) and *container*'s [node document](#)'s [origin](#) are not [same origin-domain](#)^{p869}, then return null.
5. Return *document*.

7.1.2.1 Navigating related browsing contexts in the DOM §^{p84}₅

For web developers (non-normative)

window.top^{p846}

Returns the [WindowProxy](#)^{p865} for the [top-level browsing context](#)^{p844}.

window.opener^{p846} [= value]

Returns the [WindowProxy](#)^{p865} for the [opener browsing context](#)^{p840}.

Returns null if there isn't one or if it has been set to null.

Can be set to null.

`window.parent`^{p846}

Returns the [WindowProxy](#)^{p865} for the [parent browsing context](#)^{p843}.

`window.frameElement`^{p846}

Returns the [Element](#) for the [browsing context container](#)^{p843}.

Returns null if there isn't one, and in cross-origin situations.

The **top** attribute's getter must run these steps:

1. If this [Window](#)^{p855} object's [browsing context](#)^{p856} is null, then return null.
2. Return this [Window](#)^{p855} object's [browsing context](#)^{p856}'s [top-level browsing context](#)^{p844}'s [WindowProxy](#)^{p865} object.

The **opener** getter steps are:

1. Let *current* be [this](#)'s [browsing context](#)^{p856}.
2. If *current* is null, then return null.
3. If *current*'s [disowned](#)^{p840} is true, then return null.
4. If *current*'s [opener browsing context](#)^{p840} is null, then return null.
5. Return *current*'s [opener browsing context](#)^{p840}'s [WindowProxy](#)^{p865} object.

The **opener**^{p846} setter steps are:

1. If the given value is null and [this](#)'s [browsing context](#)^{p856} is non-null, then set [this](#)'s [browsing context](#)^{p856}'s [disowned](#)^{p840} to true.
2. If the given value is non-null, then return ? [OrdinaryDefineOwnProperty](#)([this](#), "opener", { [[Value]]: the given value, [[Writable]]: true, [[Enumerable]]: true, [[Configurable]]: true }).

Note

If a [browsing context](#)^{p840}'s [disowned](#)^{p840} is true, its [window.opener](#)^{p846} attribute is null. That prevents scripts in the [browsing context](#)^{p840} from changing any properties of its [opener browsing context](#)^{p840}'s [Window](#)^{p855} object (i.e., the [Window](#)^{p855} object from which the [browsing context](#)^{p840} was created).

Otherwise, if a [browsing context](#)^{p840}'s [disowned](#)^{p840} is false, then scripts in that [browsing context](#)^{p840} can use [window.opener](#)^{p846} to change properties of its [opener browsing context](#)^{p840}'s [Window](#)^{p855} object. For example, a script running in the [browsing context](#)^{p840} can change the value of `window.opener.location`, causing the [opener browsing context](#)^{p840} to navigate to a completely different document.

The **parent** attribute's getter must run these steps:

1. Let *current* be this [Window](#)^{p855} object's [browsing context](#)^{p856}.
2. If *current* is null, then return null.
3. If *current* is a [child browsing context](#)^{p843} of another [browsing context](#)^{p840} *parent*, then return *parent*'s [WindowProxy](#)^{p865} object.
4. Assert: *current* is a [top-level browsing context](#)^{p844}.
5. Return *current*'s [WindowProxy](#)^{p865} object.

The **frameElement** getter steps are:

1. Let *current* be this [Window](#)^{p855} object's [browsing context](#)^{p856}.
2. If *current* is null, then return null.
3. Let *container* be *current*'s [container](#)^{p843}.
4. If *container* is null, then return null.
5. If *container*'s [node document](#)'s [origin](#) is not [same origin-domain](#)^{p869} with the [current settings object](#)^{p944}'s [origin](#)^{p937}, then

return null.

6. Return *container*.

Example

An example of when these IDL attributes can return null is as follows:

```
<!DOCTYPE html>
<iframe></iframe>

<script>
"use strict";
const element = document.querySelector("iframe");
const iframeWindow = element.contentWindow;
element.remove();

console.assert(iframeWindow.top === null);
console.assert(iframeWindow.parent === null);
console.assert(iframeWindow.frameElement === null);
</script>
```

Here the [browsing context](#)^{p840} corresponding to `iframeWindow` was [discarded](#)^{p862} when `element` was removed from the document.

7.1.3 Security ^{p84}

A [browsing context](#)^{p840} *A* is **familiar with** a second [browsing context](#)^{p840} *B* if one of the following conditions is true:

- Either the [origin](#) of the [active document](#)^{p840} of *A* is the [same](#)^{p869} as the [origin](#) of the [active document](#)^{p840} of *B*, or
- The browsing context *A* is a [child browsing context](#)^{p843} and its [top-level browsing context](#)^{p844} is *B*, or
- The browsing context *B* is an [auxiliary browsing context](#)^{p844} and *A* is [familiar with](#)^{p847} *B*'s [opener browsing context](#)^{p840}, or
- The browsing context *B* is not a [top-level browsing context](#)^{p844}, but there exists an [ancestor browsing context](#)^{p843} of *B* whose [active document](#)^{p840} has the [same](#)^{p869} [origin](#) as the [active document](#)^{p840} of *A* (possibly in fact being *A* itself).

A [browsing context](#)^{p840} *A* is **allowed to navigate** a second [browsing context](#)^{p840} *B* if the following algorithm returns true:

1. If *A* is not the same [browsing context](#)^{p840} as *B*, and *A* is not one of the [ancestor browsing contexts](#)^{p843} of *B*, and *B* is not a [top-level browsing context](#)^{p844}, and *A*'s [active document](#)^{p840}'s [active sandboxing flag set](#)^{p875} has its [sandboxed navigation browsing context flag](#)^{p873} set, then return false.
2. Otherwise, if *B* is a [top-level browsing context](#)^{p844}, and is one of the [ancestor browsing contexts](#)^{p843} of *A*, then:
 1. If *A*'s [active window](#)^{p840} has [transient activation](#)^{p795} and *A*'s [active document](#)^{p840}'s [active sandboxing flag set](#)^{p875} has its [sandboxed top-level navigation with user activation browsing context flag](#)^{p873} set, then return false.
 2. Otherwise, if *A*'s [active window](#)^{p840} does not have [transient activation](#)^{p795} and *A*'s [active document](#)^{p840}'s [active sandboxing flag set](#)^{p875} has its [sandboxed top-level navigation without user activation browsing context flag](#)^{p873} set, then return false.
3. Otherwise, if *B* is a [top-level browsing context](#)^{p844}, and is neither *A* nor one of the [ancestor browsing contexts](#)^{p843} of *A*, and *A*'s [Document](#)^{p117}'s [active sandboxing flag set](#)^{p875} has its [sandboxed navigation browsing context flag](#)^{p873} set, and *A* is not the [one permitted sandboxed navigator](#)^{p873} of *B*, then return false.
4. Return true.

An element has a **browsing context scope origin** if its [Document](#)^{p117}'s [browsing context](#)^{p840} is a [top-level browsing context](#)^{p844} or if all of its [Document](#)^{p117}'s [ancestor browsing contexts](#)^{p843} all have [active documents](#)^{p840} whose [origins](#) are the [same origin](#)^{p869} as the element's [node document](#)'s [origin](#). If an element has a [browsing context scope origin](#)^{p847}, then its value is the [origin](#) of the element's

[node document](#).

7.1.4 Groupings of browsing contexts §^{p84}₈

A user agent holds a **browsing context group set** (a [set](#) of [browsing context groups](#)^{p848}).

A **browsing context group** holds a **browsing context set** (a [set](#) of [top-level browsing contexts](#)^{p844}).

Note

A [top-level browsing context](#)^{p844} is added to the [group](#)^{p848} when the group is [created](#)^{p848}. All subsequent [top-level browsing contexts](#)^{p844} added to the [group](#)^{p848} will be [auxiliary browsing contexts](#)^{p844}.

A [browsing context group](#)^{p848} has an associated **agent cluster map** (a weak [map](#) of [agent cluster keys](#)^{p934} to [agent clusters](#)). User agents are responsible for collecting agent clusters when it is deemed that nothing can access them anymore.

A [browsing context group](#)^{p848} has an associated **historical agent cluster key map**, which is a [map](#) of [origins](#)^{p868} to [agent cluster keys](#)^{p934}. This map is used to ensure the consistency of the [origin-keyed agent clusters](#)^{p872} feature by recording what agent cluster keys were previously used for a given origin.

Note

The [historical agent cluster key map](#)^{p848} only ever gains entries over the lifetime of the browsing context group.

A [browsing context group](#)^{p848} has a **cross-origin isolation mode**, which is a [cross-origin isolation mode](#)^{p848}. It is initially ["none"](#)^{p848}.

A **cross-origin isolation mode** is one of three possible values: ["none"](#), ["logical"](#), or ["concrete"](#).

Note

["logical"](#)^{p848} and ["concrete"](#)^{p848} are similar. They are both used for [browsing context groups](#)^{p848} where:

- every top-level [Document](#)^{p117} has `Cross-Origin-Opener-Policy`^{p877}: [same-origin](#)^{p876}, and
- every [Document](#)^{p117} has a `Cross-Origin-Embedder-Policy`^{p885} header whose value is [compatible with cross-origin isolation](#)^{p884}.

On some platforms, it is difficult to provide the security properties required to grant safe access to the APIs gated by the [cross-origin isolated capability](#)^{p937}. As a result, only ["concrete"](#)^{p848} can grant access that capability. ["logical"](#)^{p848} is used on platform not supporting this capability, where various restrictions imposed by cross-origin isolation will still apply, but the capability is not granted.

To **create a new browsing context group**, run these steps:

- Let *group* be a new [browsing context group](#)^{p848}.
- [Append](#) *group* to the user agent's [browsing context group set](#)^{p848}.
- Let *browsingContext* be the result of [creating a new browsing context](#)^{p841} with null, null, and *group*.
- [Append](#)^{p848} *browsingContext* to *group*.
- Return *group*.

To **append** a [top-level browsing context](#)^{p844} *browsingContext* to a [browsing context group](#)^{p848} *group*, run these steps:

- [Append](#) *browsingContext* to *group*'s [browsing context set](#)^{p848}.
- Set *browsingContext*'s [group](#)^{p844} to *group*.

To **remove** a [top-level browsing context](#)^{p844} *browsingContext*, run these steps:

- Assert: *browsingContext*'s [group](#)^{p844} is non-null, because a [browsing context](#)^{p840} only gets [discarded](#)^{p862} once.

- Let *group* be *browsingContext*'s [group](#)^{p844}.
- Set *browsingContext*'s [group](#)^{p844} to null.
- [Remove](#) *browsingContext* from *group*'s [browsing context set](#)^{p848}.
- If *group*'s [browsing context set](#)^{p848} is empty, then [remove](#) *group* from the user agent's [browsing context group set](#)^{p848}.

Note

[Append](#)^{p848} and [remove](#)^{p848} are primitive operations that help define the lifetime of a [browsing context group](#)^{p848}. They are called from [creating a new browsing context group](#)^{p848}, [creating a new auxiliary browsing context](#)^{p842}, and [discarding a browsing context](#)^{p862}.

Note

The HTML Standard used to define "unit of related browsing contexts" and "unit of related similar-origin browsing contexts". These have been removed as they were not adequate.

7.1.5 Browsing context names §^{p84}₉

Browsing contexts can have a **browsing context name**. Unless stated otherwise, it is the empty string.

A **valid browsing context name** is any string with at least one character that does not start with a U+005F LOW LINE character. (Names starting with an underscore are reserved for special keywords.)

A **valid browsing context name or keyword** is any string that is either a [valid browsing context name](#)^{p849} or that is an [ASCII case-insensitive](#) match for one of: `_blank`, `_self`, `_parent`, or `_top`.

These values have different meanings based on whether the page is sandboxed or not, as summarized in the following (non-normative) table. In this table, "current" means the [browsing context](#)^{p840} that the link or script is in, "parent" means the [parent browsing context](#)^{p843} of the one the link or script is in, "top" means the [top-level browsing context](#)^{p844} of the one the link or script is in, "new" means a new [top-level browsing context](#)^{p844} or [auxiliary browsing context](#)^{p844} is to be created, subject to various user preferences and user agent policies, "none" means that nothing will happen, and "maybe new" means the same as "new" if the ["allow-popups"](#)^{p874} keyword is also specified on the [sandbox](#)^{p374} attribute (or if the user overrode the sandboxing), and the same as "none" otherwise.

Keyword	Ordinary effect	Effect in an iframe ^{p369} with...	
		<code>sandbox=""</code>	<code>sandbox="allow-top-navigation"</code>
none specified, for links and form submissions	current	current	current
empty string	current	current	current
<code>_blank</code>	new	maybe new	maybe new
<code>_self</code>	current	current	current
<code>_parent</code> if there isn't a parent	current	current	current
<code>_parent</code> if parent is also top	parent/top	none	parent/top
<code>_parent</code> if there is one and it's not top	parent	none	none
<code>_top</code> if top is current	current	current	current
<code>_top</code> if top is not current	top	none	top
name that doesn't exist	new	maybe new	maybe new
name that exists and is a descendant	specified descendant	specified descendant	specified descendant
name that exists and is current	current	current	current
name that exists and is an ancestor that is top	specified ancestor	none	specified ancestor/top
name that exists and is an ancestor that is not top	specified ancestor	none	none
other name that exists with common top	specified	none	none
name that exists with different top, if familiar ^{p847} and one permitted sandboxed navigator ^{p873}	specified	specified	specified
name that exists with different top, if familiar ^{p847} but not one permitted sandboxed navigator ^{p873}	specified	none	none
name that exists with different top, not familiar ^{p847}	new	maybe new	maybe new

Most of the restrictions on sandboxed browsing contexts are applied by other algorithms, e.g. the [navigation](#)^{p906} algorithm, not [the rules for choosing a browsing context](#)^{p850} given below.

The rules for choosing a browsing context, given a [browsing context name](#)^{p849} *name*, a [browsing context](#)^{p840} *current*, and a boolean *noopener* are as follows:

1. Let *chosen* be null.
2. Let *windowType* be "existing or none".
3. Let *sandboxingFlagSet* be *current*'s [active document](#)^{p840}'s [active sandboxing flag set](#)^{p875}.
4. If *name* is the empty string or an [ASCII case-insensitive](#) match for "_self", then set *chosen* to *current*.
5. Otherwise, if *name* is an [ASCII case-insensitive](#) match for "_parent", set *chosen* to *current*'s [parent browsing context](#)^{p843}, if any, and *current* otherwise.
6. Otherwise, if *name* is an [ASCII case-insensitive](#) match for "_top", set *chosen* to *current*'s [top-level browsing context](#)^{p844}, if any, and *current* otherwise.
7. Otherwise, if *name* is not an [ASCII case-insensitive](#) match for "_blank", there exists a browsing context whose [name](#)^{p849} is the same as *name*, *current* is [familiar with](#)^{p847} that browsing context, and the user agent determines that the two browsing contexts are related enough that it is ok if they reach each other, set *chosen* to that browsing context. If there are multiple matching browsing contexts, the user agent should set *chosen* to one in some arbitrary consistent manner, such as the most recently opened, most recently focused, or more closely related.

This will be made more precise in [issue #313](#).

8. Otherwise, a new browsing context is being requested, and what happens depends on the user agent's configuration and abilities — it is determined by the rules given for the first applicable option from the following list:
 - ↪ **If *current*'s [active window](#)^{p840} does not have [transient activation](#)^{p795} and the user agent has been configured to not show popups (i.e., the user agent has a "popup blocker" enabled)**
The user agent may inform the user that a popup has been blocked.
 - ↪ **If *sandboxingFlagSet* has the [sandboxed auxiliary navigation browsing context flag](#)^{p873} set**
The user agent may report to a developer console that a popup has been blocked.
 - ↪ **If the user agent has been configured such that in this instance it will create a new browsing context**
 1. Set *windowType* to "new and unrestricted".
 2. If *current*'s [top-level browsing context](#)^{p844}'s [active document](#)^{p840}'s [cross-origin opener policy](#)^{p118}'s [value](#)^{p876} is "[same-origin](#)^{p876}" or "[same-origin-plus-COEP](#)^{p876}", then:
 1. Let *currentDocument* be *current*'s [active document](#)^{p840}.
 2. If *currentDocument*'s [origin](#) is not [same origin](#)^{p869} with *currentDocument*'s [relevant settings object](#)^{p944}'s [top-level origin](#)^{p936}, then set *noopener* to true, *name* to "_blank", and *windowType* to "new with no opener".

Note

In the presence of a [cross-origin opener policy](#)^{p876}, nested documents that are cross-origin with their top-level browsing context's active document always set *noopener* to true.

 3. If *noopener* is true, then set *chosen* to the result of [creating a new top-level browsing context](#)^{p842}.
 4. Otherwise:
 1. Set *chosen* to the result of [creating a new auxiliary browsing context](#)^{p842} with *current*.
 2. If *sandboxingFlagSet*'s [sandboxed navigation browsing context flag](#)^{p873} is set, then *current* must be set as *chosen*'s [one permitted sandboxed navigator](#)^{p873}.
 5. If *sandboxingFlagSet*'s [sandbox propagates to auxiliary browsing contexts flag](#)^{p874} is set, then all the flags that are set in *sandboxingFlagSet* must be set in *chosen*'s [popup sandboxing flag set](#)^{p875}.

6. If *name* is not an [ASCII case-insensitive](#) match for "_blank", then set *chosen*'s [name](#)^{p849} to *name*.

Note

If the newly created [browsing context](#)^{p840} is immediately [navigated](#)^{p906}, then the navigation will be done with a ["replace"](#)^{p906} [history handling behavior](#)^{p906}.

↪ **If the user agent has been configured such that in this instance it will reuse *current***

Set *chosen* to *current*.

↪ **If the user agent has been configured such that in this instance it will not find a browsing context**

Do nothing.

Note

User agents are encouraged to provide a way for users to configure the user agent to always reuse *current*.

9. Return *chosen* and *windowType*.

7.2 Security infrastructure for [Window](#)^{p855}, [WindowProxy](#)^{p865}, and [Location](#)^{p897} objects § p85 1

Although typically objects cannot be accessed across [origins](#)^{p868}, the web platform would not be true to itself if it did not have some legacy exceptions to that rule that the web depends upon.

7.2.1 Integration with IDL § p85 1

When [perform a security check](#) is invoked, with a *platformObject*, *identifier*, and *type*, run these steps:

1. If *platformObject* is not a [Window](#)^{p855} or [Location](#)^{p897} object, then return.
2. For each *e* of [CrossOriginProperties](#)^{p852}(*platformObject*):
 1. If [SameValue](#)(*e*.[[Property]], *identifier*) is true, then:
 1. If *type* is "method" and *e* has neither [[NeedsGet]] nor [[NeedsSet]], then return.
 2. Otherwise, if *type* is "getter" and *e*.[[NeedsGet]] is true, then return.
 3. Otherwise, if *type* is "setter" and *e*.[[NeedsSet]] is true, then return.
3. If [IsPlatformObjectSameOrigin](#)^{p852}(*platformObject*) is false, then throw a ["SecurityError"](#) [DOMException](#).

7.2.2 Shared internal slot: [\[\[CrossOriginPropertyDescriptorMap\]\]](#) § p85 1

[Window](#)^{p855} and [Location](#)^{p897} objects both have a [\[\[CrossOriginPropertyDescriptorMap\]\]](#) internal slot, whose value is initially an empty map.

Note

The [\[\[CrossOriginPropertyDescriptorMap\]\]](#)^{p851} internal slot contains a map with entries whose keys are (currentGlobal, objectGlobal, propertyKey)-tuples and values are property descriptors, as a memoization of what is visible to scripts when currentGlobal inspects a [Window](#)^{p855} or [Location](#)^{p897} object from objectGlobal. It is filled lazily by [CrossOriginGetOwnPropertyHelper](#)^{p853}, which consults it on future lookups.

User agents should allow a value held in the map to be garbage collected along with its corresponding key when nothing holds a reference to any part of the value. That is, as long as garbage collection is not observable.

Example

For example, with `const href = Object.getOwnPropertyDescriptor(crossOriginLocation, "href").set` the value and its corresponding key in the map cannot be garbage collected as that would be observable.

User agents may have an optimization whereby they remove key-value pairs from the map when `document.domainp871` is set. This is not observable as `document.domainp871` cannot revisit an earlier value.

Example

For example, setting `document.domainp871` to "example.com" on `www.example.com` means user agents can remove all key-value pairs from the map where part of the key is `www.example.com`, as that can never be part of the `originp868` again and therefore the corresponding value could never be retrieved from the map.

7.2.3 Shared abstract operations \S^{p85}_2

7.2.3.1 CrossOriginProperties (O) \S^{p85}_2

1. Assert: *O* is a `Locationp897` or `Windowp855` object.
2. If *O* is a `Locationp897` object, then return `« { [[Property]]: "href", [[NeedsGet]]: false, [[NeedsSet]]: true }, { [[Property]]: "replace" } »`.
3. Return `« { [[Property]]: "window", [[NeedsGet]]: true, [[NeedsSet]]: false }, { [[Property]]: "self", [[NeedsGet]]: true, [[NeedsSet]]: false }, { [[Property]]: "location", [[NeedsGet]]: true, [[NeedsSet]]: true }, { [[Property]]: "close" }, { [[Property]]: "closed", [[NeedsGet]]: true, [[NeedsSet]]: false }, { [[Property]]: "focus" }, { [[Property]]: "blur" }, { [[Property]]: "frames", [[NeedsGet]]: true, [[NeedsSet]]: false }, { [[Property]]: "length", [[NeedsGet]]: true, [[NeedsSet]]: false }, { [[Property]]: "top", [[NeedsGet]]: true, [[NeedsSet]]: false }, { [[Property]]: "opener", [[NeedsGet]]: true, [[NeedsSet]]: false }, { [[Property]]: "parent", [[NeedsGet]]: true, [[NeedsSet]]: false }, { [[Property]]: "postMessage" } »`.

Note

This abstract operation does not return a [Completion Record](#).

Note

Indexed properties do not need to be safelisted in this algorithm, as they are handled directly by the `WindowProxyp865` object.

A JavaScript property name *P* is a **cross-origin accessible window property name** if it is "window", "self", "location", "close", "closed", "focus", "blur", "frames", "length", "top", "opener", "parent", "postMessage", or an [array index property name](#).

7.2.3.2 CrossOriginPropertyFallback (P) \S^{p85}_2

1. If *P* is "then", `@@toStringTagp54`, `@@hasInstancep54`, or `@@isConcatSpreadablep54`, then return `PropertyDescriptor{ [[Value]]: undefined, [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: true }`.
2. Throw a `"SecurityError" DOMException`.

7.2.3.3 IsPlatformObjectSameOrigin (O) \S^{p85}_2

1. Return true if the `current settings objectp944`'s `originp937` is `same origin-domainp869` with *O*'s `relevant settings objectp944`'s `originp937`, and false otherwise.

Note

This abstract operation does not return a [Completion Record](#).

Note

Here the `current settings objectp944` roughly corresponds to the "caller", because this check occurs before the [execution context](#) for

the getter/setter/method in question makes its way onto the [JavaScript execution context stack](#). For example, in the code `w.document`, this step is invoked before the [document](#)^{p856} getter is reached as part of the [\[\[Get\]\]](#)^{p867} algorithm for the [WindowProxy](#)^{p865} `w`.

7.2.3.4 CrossOriginGetOwnPropertyHelper (*O*, *P*) ^{p85}₃

Note

If this abstract operation returns undefined and there is no custom behavior, the caller needs to throw a ["SecurityError" DOMException](#). In practice this is handled by the caller calling [CrossOriginPropertyFallback](#)^{p852}.

1. Let *crossOriginKey* be a tuple consisting of the [current settings object](#)^{p944}, *O*'s [relevant settings object](#)^{p944}, and *P*.
2. For each *e* of [CrossOriginProperties](#)^{p852}(*O*):
 1. If [SameValue](#)(*e*.[[Property]], *P*) is true, then:
 1. If the value of the [\[\[CrossOriginPropertyDescriptorMap\]\]](#)^{p851} internal slot of *O* contains an entry whose key is *crossOriginKey*, then return that entry's value.
 2. Let *originalDesc* be [OrdinaryGetOwnProperty](#)(*O*, *P*).
 3. Let *crossOriginDesc* be undefined.
 4. If *e*.[[NeedsGet]] and *e*.[[NeedsSet]] are absent, then:
 1. Let *value* be *originalDesc*.[[Value]].
 2. If [IsCallable](#)(*value*) is true, then set *value* to an anonymous built-in function, created in the [current Realm Record](#), that performs the same steps as the IDL operation *P* on object *O*.
 3. Set *crossOriginDesc* to [PropertyDescriptor](#){ [[Value]]: *value*, [[Enumerable]]: false, [[Writable]]: false, [[Configurable]]: true }.
 5. Otherwise:
 1. Let *crossOriginGet* be undefined.
 2. If *e*.[[NeedsGet]] is true, then set *crossOriginGet* to an anonymous built-in function, created in the [current Realm Record](#), that performs the same steps as the getter of the IDL attribute *P* on object *O*.
 3. Let *crossOriginSet* be undefined.
 4. If *e*.[[NeedsSet]] is true, then set *crossOriginSet* to an anonymous built-in function, created in the [current Realm Record](#), that performs the same steps as the setter of the IDL attribute *P* on object *O*.
 5. Set *crossOriginDesc* to [PropertyDescriptor](#){ [[Get]]: *crossOriginGet*, [[Set]]: *crossOriginSet*, [[Enumerable]]: false, [[Configurable]]: true }.
 6. Create an entry in the value of the [\[\[CrossOriginPropertyDescriptorMap\]\]](#)^{p851} internal slot of *O* with key *crossOriginKey* and value *crossOriginDesc*.
 7. Return *crossOriginDesc*.
3. Return undefined.

Note

This abstract operation does not return a [Completion Record](#).

Note

The reason that the property descriptors produced here are configurable is to preserve the [invariants of the essential internal methods](#) required by the JavaScript specification. In particular, since the value of the property can change as a consequence of

navigation, it is required that the property be configurable. (However, see [tc39/ecma262 issue #672](#) and references to it elsewhere in this specification for cases where we are not able to preserve these invariants, for compatibility with existing web content.)

[\[JAVASCRIPT\] p1308](#)

Note

The reason the property descriptors are non-enumerable, despite this mismatching the same-origin behavior, is for compatibility with existing web content. See [issue #3183](#) for details.

7.2.3.5 CrossOriginGet (O, P, Receiver) § p85₄

1. Let *desc* be ? *O*.[[GetOwnProperty]](*P*).
2. Assert: *desc* is not undefined.
3. If [IsDataDescriptor](#)(*desc*) is true, then return *desc*.[[Value]].
4. Assert: [IsAccessorDescriptor](#)(*desc*) is true.
5. Let *getter* be *desc*.[[Get]].
6. If *getter* is undefined, then throw a ["SecurityError" DOMException](#).
7. Return ? [Call](#)(*getter*, *Receiver*).

7.2.3.6 CrossOriginSet (O, P, V, Receiver) § p85₄

1. Let *desc* be ? *O*.[[GetOwnProperty]](*P*).
2. Assert: *desc* is not undefined.
3. If *desc*.[[Set]] is present and its value is not undefined, then:
 1. Perform ? [Call](#)(*setter*, *Receiver*, «*V*»).
 2. Return true.
4. Throw a ["SecurityError" DOMException](#).

7.2.3.7 CrossOriginOwnPropertyKeys (O) § p85₄

1. Let *keys* be a new empty [List](#).
2. For each *e* of [CrossOriginProperties](#)^{p852}(*O*), [append](#) *e*.[[Property]] to *keys*.
3. Return the concatenation of *keys* and « "then", [@@toStringTag](#)^{p54}, [@@hasInstance](#)^{p54}, [@@isConcatSpreadable](#)^{p54} ».

Note

This abstract operation does not return a [Completion Record](#).

7.3 The [Window](#)^{p855} object § p85₄

✓ MDN

IDL [Global=[Window](#),
Exposed=[Window](#),

```

LegacyUnenumerableNamedProperties]
interface Window : EventTarget {
  // the current browsing context
  [LegacyUnforgeable] readonly attribute WindowProxy window;
  [Replaceable] readonly attribute WindowProxy self;
  [LegacyUnforgeable] readonly attribute Document document;
  attribute DOMString name;
  [PutForwards=href, LegacyUnforgeable] readonly attribute Location location;
  readonly attribute History history;
  readonly attribute CustomElementRegistry customElements;
  [Replaceable] readonly attribute BarProp locationbar;
  [Replaceable] readonly attribute BarProp menubar;
  [Replaceable] readonly attribute BarProp personalbar;
  [Replaceable] readonly attribute BarProp scrollbars;
  [Replaceable] readonly attribute BarProp statusbar;
  [Replaceable] readonly attribute BarProp toolbar;
  attribute DOMString status;
  undefined close();
  readonly attribute boolean closed;
  undefined stop();
  undefined focus();
  undefined blur();

  // other browsing contexts
  [Replaceable] readonly attribute WindowProxy frames;
  [Replaceable] readonly attribute unsigned long length;
  [LegacyUnforgeable] readonly attribute WindowProxy? top;
  attribute any opener;
  [Replaceable] readonly attribute WindowProxy? parent;
  readonly attribute Element? frameElement;
  WindowProxy? open(optional USVString url = "", optional DOMString target = "_blank", optional
[LegacyNullToEmptyString] DOMString features = "");
  getter object (DOMString name);
  // Since this is the global object, the IDL named getter adds a NamedPropertiesObject exotic
  // object on the prototype chain. Indeed, this does not make the global object an exotic object.
  // Indexed access is taken care of by the WindowProxy exotic object.

  // the user agent
  readonly attribute Navigator navigator;
  readonly attribute Navigator clientInformation; // legacy alias of .navigator
  readonly attribute boolean originAgentCluster;

  // user prompts
  undefined alert();
  undefined alert(DOMString message);
  boolean confirm(optional DOMString message = "");
  DOMString? prompt(optional DOMString message = "", optional DOMString default = "");
  undefined print();

  undefined postMessage(any message, USVString targetOrigin, optional sequence<object> transfer = []);
  undefined postMessage(any message, optional WindowPostMessageOptions options = {});

  // also has obsolete members
};
Window includes GlobalEventHandlers;
Window includes WindowEventHandlers;

dictionary WindowPostMessageOptions : StructuredSerializeOptions {
  USVString targetOrigin = "/";
};

```

Note web developers (non-normative)

`window.window`^{p856}

`window.frames`^{p856}

`window.self`^{p856}

These attributes all return *window*.

`window.document`^{p856}

Returns the [Document](#)^{p117} associated with *window*.

`document.defaultView`^{p856}

Returns the [Window](#)^{p855} object of the [active document](#)^{p840}.

The [Window](#)^{p855} object has an **associated Document**, which is a [Document](#)^{p117} object. It is set when the [Window](#)^{p855} object is created, and only ever changed during [navigation](#)^{p906} from the [initial about:blank](#)^{p118} [Document](#)^{p117}.

The [Window](#)^{p855} object's **browsing context** is the [Window](#)^{p855} object's [associated Document](#)^{p856}'s [browsing context](#)^{p840}. *It is either null or a [browsing context](#)^{p840}.*

The **window**, **frames**, and **self** getter steps are to return *this*'s [relevant Realm](#)^{p944}.`[[GlobalEnv]].[[GlobalThisValue]]`.

The **document** getter steps are to return *this*'s [associated Document](#)^{p856}.

Note

The [Document](#)^{p117} object associated with a [Window](#)^{p855} object can change in exactly one case: when the [navigate](#)^{p906} algorithm creates a new [Document](#) object^{p914} for the first page loaded in a [browsing context](#)^{p840}. In that specific case, the [Window](#)^{p855} object of the [initial about:blank](#)^{p118} page is reused and gets a new [Document](#)^{p117} object.

The **defaultView** getter steps are:

1. If *this*'s [browsing context](#)^{p840} is null, then return null.
2. Return *this*'s [browsing context](#)^{p840}'s [WindowProxy](#)^{p865} object.

For historical reasons, [Window](#)^{p855} objects must also have a writable, configurable, non-enumerable property named **HTMLDocument**^{MDN} whose value is the [Document](#)^{p117} interface object.

7.3.1 APIs for creating and navigating browsing contexts by name ^{§ p85}₆

For web developers (non-normative)

`window = window.open`^{p858}([*url* [, *target* [, *features*]]])

Opens a window to show *url* (defaults to "[about:blank](#)^{p51}"), and returns it. *target* (defaults to "_blank") gives the name of the new window. If a window already exists with that name, it is reused. The *features* argument can contain a [set of comma-separated tokens](#)^{p89}:

"noopener"

"noreferrer"

These behave equivalently to the [noopener](#)^{p309} and [noreferrer](#)^{p310} link types on [hyperlinks](#)^{p289}.

"popup"

Encourages user agents to provide a minimal web browser user interface for the new window. (Impacts the [visible](#)^{p863} getter on all [BarProp](#)^{p863} objects as well.)

Example

```
globalThis.open("https://email.example/message/CA000kFcWW97r8yg=SsWg7GgCmp4suVX9o85y8BvNRqMjuc5PXg", undefined, "noopener,popup");
```

window.name^{p860} [= value]

Returns the name of the window.

Can be set, to change the name.

window.close^{p860} ()

Closes the window.

window.closed^{p860}

Returns true if the window has been closed, false otherwise.

window.stop^{p860} ()

Cancels the document load.

The **window open steps**, given a string *url*, a string *target*, and a string *features*, are as follows:

1. If the [event loop](#)^{p968}'s [termination nesting level](#)^{p928} is nonzero, return null.
2. Let *source browsing context* be the [entry global object](#)^{p941}'s [browsing context](#)^{p856}.
3. If *target* is the empty string, then set *target* to "_blank".
4. Let *tokenizedFeatures* be the result of [tokenizing](#)^{p858} *features*.
5. Let *noopener* and *noreferrer* be false.
6. If *tokenizedFeatures*["noopener"] [exists](#), then:
 1. Set *noopener* to the result of [parsing tokenizedFeatures\["noopener"\] as a boolean feature](#)^{p860}.
 2. [Remove](#) *tokenizedFeatures*["noopener"].
7. If *tokenizedFeatures*["noreferrer"] [exists](#), then:
 1. Set *noreferrer* to the result of [parsing tokenizedFeatures\["noreferrer"\] as a boolean feature](#)^{p860}.
 2. [Remove](#) *tokenizedFeatures*["noreferrer"].
8. If *noreferrer* is true, then set *noopener* to true.
9. Let *target browsing context* and *windowType* be the result of applying [the rules for choosing a browsing context](#)^{p850} given *target*, *source browsing context*, and *noopener*.

Example

If there is a user agent that supports control-clicking a link to open it in a new tab, and the user control-clicks on an element whose [onclick](#)^{p987} handler uses the [window.open\(\)](#)^{p858} API to open a page in an [iframe](#)^{p369} element, the user agent could override the selection of the target browsing context to instead target a new tab.

10. If *target browsing context* is null, then return null.
11. If *windowType* is either "new and unrestricted" or "new with no opener", then:
 1. Set the *target browsing context*'s [is popup](#)^{p844} to the result of [checking if a popup window is requested](#)^{p859}, given *tokenizedFeatures*.
 2. [Set up browsing context features](#) for *target browsing context* given *tokenizedFeatures*. [\[CSSOMVIEW\]](#)^{p1307}
 3. Let *urlRecord* be the [URL record](#) [about:blank](#)^{p51}.
 4. If *url* is not the empty string, then [parse](#)^{p91} *url* relative to the [entry settings object](#)^{p941}, and set *urlRecord* to the [resulting URL record](#)^{p91}, if any. If the [parse a URL](#)^{p91} algorithm failed, then throw a ["SyntaxError" DOMException](#).
 5. If *urlRecord* [matches about:blank](#)^{p90}, then perform the [URL and history update steps](#)^{p893} given *target browsing context*'s [active document](#)^{p840} and *urlRecord*.

Note

This is necessary in case url is something like about:blank?foo. If url is just plain about:blank, this will do

nothing.

6. Otherwise:

1. Let *request* be a new [request](#) whose [URL](#) is *urlRecord*.
2. If *noreferrer* is true, then set *request*'s [referrer](#) to "no-referrer".
3. [Navigate](#)^{p906} *target browsing context* to *request*, with [exceptionsEnabled](#)^{p906} set to true and the [source browsing context](#)^{p906} set to *source browsing context*.

12. Otherwise:

1. If *url* is not the empty string, then:

1. Let *urlRecord* be the [URL record](#) [about:blank](#)^{p51}.
2. [Parse](#)^{p91} *url* relative to the [entry settings object](#)^{p941}, and set *urlRecord* to the [resulting URL record](#)^{p91}, if any. If the [parse a URL](#)^{p91} algorithm failed, then throw a ["SyntaxError" DOMException](#).
3. Let *request* be a new [request](#) whose [URL](#) is *urlRecord*.
4. If *noreferrer* is true, then set *request*'s [referrer](#) to "noreferrer".
5. [Navigate](#)^{p906} *target browsing context* to *request*, with [exceptionsEnabled](#)^{p906} set to true and the [source browsing context](#)^{p906} set to *source browsing context*.

2. If *noopener* is false, then set *target browsing context*'s [opener browsing context](#)^{p840} to *source browsing context*.

13. If *noopener* is true or *windowType* is "new with no opener", then return null.

14. Return *target browsing context*'s [WindowProxy](#)^{p865} object.

The [open\(*url*, *target*, *features*\)](#) method steps are to run the [window open steps](#)^{p857} with *url*, *target*, and *features*.

Note

The method provides a mechanism for [navigating](#)^{p906} an existing [browsing context](#)^{p840} or opening and navigating an [auxiliary browsing context](#)^{p844}.

To tokenize the *features* argument:

1. Let *tokenizedFeatures* be a new [ordered map](#).
2. Let *position* point at the first code point of *features*.
3. [While](#) *position* is not past the end of *features*:
 1. Let *name* be the empty string.
 2. Let *value* be the empty string.
 3. [Collect a sequence of code points](#) that are [feature separators](#)^{p859} from *features* given *position*. This skips past leading separators before the name.
 4. [Collect a sequence of code points](#) that are not [feature separators](#)^{p859} from *features* given *position*. Set *name* to the collected characters, [converted to ASCII lowercase](#).
 5. Set *name* to the result of [normalizing the feature name](#)^{p859} *name*.
 6. [While](#) *position* is not past the end of *features* and the code point at *position* in *features* is not U+003D (=):
 1. If the code point at *position* in *features* is U+002C (,), or if it is not a [feature separator](#)^{p859}, then [break](#).
 2. Advance *position* by 1.

Note

This skips to the first U+003D (=) but does not skip past a U+002C (,) or a non-separator.

7. If the code point at *position* in *features* is a [feature separator](#)^{p859}:
 1. While *position* is not past the end of *features* and the code point at *position* in *features* is a [feature separator](#)^{p859}:
 1. If the code point at *position* in *features* is U+002C (,), then [break](#).
 2. Advance *position* by 1.

Note

This skips to the first non-separator but does not skip past a U+002C (,).

2. [Collect a sequence of code points](#) that are not [feature separators](#)^{p859} code points from *features* given *position*. Set *value* to the collected code points, [converted to ASCII lowercase](#).
8. If *name* is not the empty string, then set *tokenizedFeatures*[*name*] to *value*.
4. Return *tokenizedFeatures*.

To **check if a window feature is set**, given *tokenizedFeatures*, *featureName*, and *defaultValue*:

1. If *tokenizedFeatures*[*featureName*] [exists](#), then return the result of [parsing tokenizedFeatures\[featureName\] as a boolean feature](#)^{p860}.
2. Return *defaultValue*.

To **check if a popup window is requested**, given *tokenizedFeatures*:

1. If *tokenizedFeatures* is [empty](#), then return false.
2. If *tokenizedFeatures*["popup"] [exists](#), then return the result of [parsing tokenizedFeatures\["popup"\] as a boolean feature](#)^{p860}.
3. Let *location* be the result of [checking if a window feature is set](#)^{p859}, given *tokenizedFeatures*, "location", and false.
4. Let *toolbar* be the result of [checking if a window feature is set](#)^{p859}, given *tokenizedFeatures*, "toolbar", and false.
5. If *location* and *toolbar* are both false, then return true.
6. Let *menubar* be the result of [checking if a window feature is set](#)^{p859}, given *tokenizedFeatures*, "menubar", and false.
7. If *menubar* is false, then return true.
8. Let *resizable* be the result of [checking if a window feature is set](#)^{p859}, given *tokenizedFeatures*, "resizable", and true.
9. If *resizable* is false, then return true.
10. Let *scrollbars* be the result of [checking if a window feature is set](#)^{p859}, given *tokenizedFeatures*, "scrollbars", and false.
11. If *scrollbars* is false, then return true.
12. Let *status* be the result of [checking if a window feature is set](#)^{p859}, given *tokenizedFeatures*, "status", and false.
13. If *status* is false, then return true.
14. Return false.

A code point is a **feature separator** if it is [ASCII whitespace](#), U+003D (=), or U+002C (,).

For legacy reasons, there are some aliases of some feature names. To **normalize a feature name** *name*, switch on *name*:

- ↪ "screenx"
Return "left".
- ↪ "screeny"
Return "top".
- ↪ "innerwidth"
Return "width".

↪ "innerheight"

Return "height".

↪ **Anything else**

Return *name*.

To **parse a boolean feature** given a string *value*:

1. If *value* is the empty string, then return true.
2. If *value* is "yes", then return true.
3. If *value* is "true", then return true.
4. Let *parsed* be the result of [parsing value as an integer](#)^{p70}.
5. If *parsed* is an error, then set it to 0.
6. Return false if *parsed* is 0, and true otherwise.

The **name** getter steps are:

1. If [this's browsing context](#)^{p856} is null, then return the empty string.
2. Return [this's browsing context](#)^{p856}'s [name](#)^{p849}.

The [name](#)^{p860} setter steps are:

1. If [this's browsing context](#)^{p856} is null, then return.
2. Set [this's browsing context](#)^{p856}'s [name](#)^{p849} to the given value.

Note

The name [gets reset](#)^{p924} when the browsing context is [navigated](#)^{p906} to another [origin](#)^{p868}.

The **close()** method steps are:

1. Let *current* be [this's browsing context](#)^{p856}.
2. If *current* is null or its [is closing](#)^{p840} is true, then return.
3. If all the following are true
 - *current* is [script-closable](#)^{p860}
 - the [incumbent global object](#)^{p942}'s [browsing context](#)^{p856} is [familiar with](#)^{p847} *current*
 - the [incumbent global object](#)^{p942}'s [browsing context](#)^{p856} is [allowed to navigate](#)^{p847} *current*

then:

1. Set *current*'s [is closing](#)^{p840} to true.
2. [Queue a task](#)^{p970} on the [DOM manipulation task source](#)^{p977} to [close](#)^{p863} *current*.

A [browsing context](#)^{p840} is **script-closable** if it is an [auxiliary browsing context](#)^{p844} that was created by a script (as opposed to by an action of the user), or if it is a [top-level browsing context](#)^{p844} whose [session history](#)^{p888} contains only one [Document](#)^{p117}.

The **closed** getter steps are to return true if [this's browsing context](#)^{p856} is null or its [is closing](#)^{p840} is true; otherwise false.

The **stop()** method steps are to [stop document loading](#)^{p930} given [this's associated Document](#)^{p856}.

7.3.2 Accessing other browsing contexts § p86

1

For web developers (non-normative)

`window.length` p861

Returns the number of [document-tree child browsing contexts](#) p843.

`window[index]`

Returns the indicated [document-tree child browsing context](#) p843.

The **number of document-tree child browsing contexts** of a [Window](#) p855 object *W* is the result of running these steps:

1. If *W*'s [browsing context](#) p856 is null, then return 0.
2. Return the number of [document-tree child browsing contexts](#) p843 of *W*'s [browsing context](#) p856.

The **length** getter steps are to return the [number of document-tree child browsing contexts](#) p861 of [this](#).

Note

Indexed access to [document-tree child browsing contexts](#) p843 is defined through the [\[\[GetOwnProperty\]\]](#) p866 internal method of the [WindowProxy](#) p865 object.

7.3.3 Named access on the [Window](#) p855 object § p86

1

For web developers (non-normative)

`window[name]`

Returns the indicated element or collection of elements.

As a general rule, relying on this will lead to brittle code. Which IDs end up mapping to this API can vary over time, as new features are added to the web platform, for example. Instead of this, use `document.getElementById()` or `document.querySelector()`.

The **document-tree child browsing context name property set** of a [Window](#) p855 object *window* is the return value of running these steps:

1. If *window*'s [browsing context](#) p856 is null, then return the empty list.
2. Let *childBrowsingContexts* be all [document-tree child browsing contexts](#) p843 of *window*'s [browsing context](#) p856 whose [browsing context name](#) p849 is not the empty string, in order, and including only the first [document-tree child browsing context](#) p843 with a given [name](#) p849 if multiple [document-tree child browsing contexts](#) p843 have the same one.
3. Remove each [browsing context](#) p840 from *childBrowsingContexts* whose [active document](#) p840's [origin](#) is not [same origin](#) p869 with *window*'s [relevant settings object](#) p944's [origin](#) p937 and whose [browsing context name](#) p849 does not match the name of its [container](#) p843's name content attribute value.
4. Return the [browsing context names](#) p849 of *childBrowsingContexts*, in the same order.

Example

This means that in the following example, hosted on `https://example.org/`, assuming `https://elsewhere.example/` sets [window.name](#) p860 to "spices", evaluating `window.spices` after everything has loaded will yield undefined:

```
<iframe src=https://elsewhere.example.com/></iframe>
<iframe name=spices></iframe>
```

The [Window](#) p855 object [supports named properties](#). The [supported property names](#) of a [Window](#) p855 object *window* at any moment consist of the following, in [tree order](#) according to the element that contributed them, ignoring later duplicates:

- *window*'s [document-tree child browsing context name property set](#) p861;
- the value of the name content attribute for all [embed](#) p378, [form](#) p494, [img](#) p327, and [object](#) p381 elements that have a non-empty

name content attribute and are [in a document tree](#) with *window*'s [associated Document](#)^{p856} as their [root](#); and

- the value of the [id](#)^{p141} content attribute for all [HTML elements](#)^{p44} that have a non-empty [id](#)^{p141} content attribute and are [in a document tree](#) with *window*'s [associated Document](#)^{p856} as their [root](#).

To [determine the value of a named property](#) *name* in a [Window](#)^{p855} object *window*, the user agent must return the value obtained using the following steps:

1. Let *objects* be the list of [named objects](#)^{p862} of *window* with the name *name*.

Note

There will be at least one such object, by definition.

2. If *objects* contains a [browsing context](#)^{p840}, then return the [WindowProxy](#)^{p865} object of the [nested browsing context](#)^{p843} of the first [browsing context container](#)^{p843} in [tree order](#) whose [nested browsing context](#)^{p843} is in *objects*.
3. Otherwise, if *objects* has only one element, return that element.
4. Otherwise return an [HTMLCollection](#) rooted at *window*'s [associated Document](#)^{p856}, whose filter matches only [named objects](#)^{p862} of *window* with the name *name*. (By definition, these will all be elements.)

Named objects of [Window](#)^{p855} object *window* with the name *name*, for the purposes of the above algorithm, consist of the following:

- [document-tree child browsing contexts](#)^{p843} of *window*'s [associated Document](#)^{p856} whose [name](#)^{p849} is *name*;
- [embed](#)^{p378}, [form](#)^{p494}, [img](#)^{p327}, or [object](#)^{p381} elements that have a [name](#) content attribute whose value is *name* and are [in a document tree](#) with *window*'s [associated Document](#)^{p856} as their [root](#); and
- [HTML elements](#)^{p44} that have an [id](#)^{p141} content attribute whose value is *name* and are [in a document tree](#) with *window*'s [associated Document](#)^{p856} as their [root](#).

7.3.4 Discarding browsing contexts §^{p86}₂

To **discard** a [Document](#)^{p117} *document*:

1. Set *document*'s [salvageable](#)^{p928} state to false.
2. Run any [unloading document cleanup steps](#)^{p929} for *document* that are defined by this specification and [other applicable specifications](#)^{p67}.
3. [Abort](#)^{p930} *document*.
4. Remove any [tasks](#)^{p969} associated with *document* in any [task source](#)^{p969}, without running those tasks.
5. [Discard](#)^{p862} all the [child browsing contexts](#)^{p843} of *document*.
6. For each [session history entry](#)^{p888} *entry* whose [document](#)^{p888} is equal to *document*, set *entry*'s [document](#)^{p888} to null.
7. Set *document*'s [browsing context](#)^{p840} to null.
8. [Remove](#) *document* from the [owner set](#)^{p1062} of each [WorkerGlobalScope](#)^{p1062} object whose set [contains](#) *document*.
9. [For each](#) *workletGlobalScope* in *document*'s [worklet global scopes](#)^{p1085}, [terminate](#)^{p1081} *workletGlobalScope*.

To **discard** a [browsing context](#)^{p840} *browsingContext*, run these steps:

1. [Discard](#)^{p862} all [Document](#)^{p117} objects for all the entries in *browsingContext*'s [session history](#)^{p888}.
2. If *browsingContext* is a [top-level browsing context](#)^{p844}, then [remove](#)^{p848} *browsingContext*.

User agents may [discard](#)^{p862} [top-level browsing contexts](#)^{p844} at any time (typically, in response to user requests, e.g., when a user force-closes a window containing one or more [top-level browsing contexts](#)^{p844}). Other [browsing contexts](#)^{p840} must be discarded once their [WindowProxy](#)^{p865} object is eligible for garbage collection, in addition to the other places where this specification requires them to be discarded.

7.3.5 Closing browsing contexts ^{§ p86}₃

To **close a browsing context** *browsingContext*, run these steps:

1. If the result of calling [prompt to unload](#)^{p928} with *browsingContext*'s [active document](#)^{p840} is "refuse", then return.
2. [Unload](#)^{p928} *browsingContext*'s [active document](#)^{p840}.
3. Remove *browsingContext* from the user interface (e.g., close or hide its tab in a tabbed browser).
4. [Discard](#)^{p862} *browsingContext*.

User agents should offer users the ability to arbitrarily [close](#)^{p863} any [top-level browsing context](#)^{p844}.

7.3.6 Browser interface elements ^{§ p86}₃

For historical reasons, the [Window](#)^{p855} interface had some attributes that represented the visibility of certain web browser interface elements.

For privacy and interoperability reasons, those attributes now return values that represent whether the [Window](#)^{p855}'s [browsing context](#)^{p856}'s [is popup](#)^{p844} property is true or false.

Each interface element is represented by a [BarProp](#)^{p863} object:

```
IDL [Exposed=Window]
interface BarProp {
  readonly attribute boolean visible;
};
```

For web developers (non-normative)

```
window.locationbarp864.visiblep863
window.menubarp864.visiblep863
window.personalbarp864.visiblep863
window.scrollbarsp864.visiblep863
window.statusbarp864.visiblep863
window.toolbarp864.visiblep863
```

Returns true if the [top-level browsing context](#)^{p844} is not a popup; otherwise, returns false.

The **visible** getter steps are:

1. Let *browsingContext* be [this](#)'s [relevant global object](#)^{p944}'s [browsing context](#)^{p856}.
2. If *browsingContext* is null, then return true.
3. Return the negation of *browsingContext*'s [top-level browsing context](#)^{p844}'s [is popup](#)^{p844}.

The following [BarProp](#)^{p863} objects must exist for each [Window](#)^{p855} object:

The location bar BarProp object

Historically represented the user interface element that contains a control that displays the browser's location bar.

The menu bar BarProp object

Historically represented the user interface element that contains a list of commands in menu form, or some similar interface concept.

The personal bar BarProp object

Historically represented the user interface element that contains links to the user's favorite pages, or some similar interface concept.

The scrollbar BarProp object

Historically represented the user interface element that contains a scrolling mechanism, or some similar interface concept.

The **status bar** **BarProp** object

Historically represented a user interface element found immediately below or after the document, as appropriate for the user's media, which typically provides information about ongoing network activity or information about elements that the user's pointing device is currently indicating.

The **toolbar** **BarProp** object

Historically represented the user interface element found immediately above or before the document, as appropriate for the user's media, which typically provides [session history](#)^{p888} traversal controls (back and forward buttons, reload buttons, etc.).

The **locationbar** attribute must return [the location bar BarProp object](#)^{p863}.

The **menubar** attribute must return [the menu bar BarProp object](#)^{p863}.

The **personalbar** attribute must return [the personal bar BarProp object](#)^{p863}.

The **scrollbars** attribute must return [the scrollbar BarProp object](#)^{p863}.

The **statusbar** attribute must return [the status bar BarProp object](#)^{p864}.

The **toolbar** attribute must return [the toolbar BarProp object](#)^{p864}.

For historical reasons, the **status** attribute on the [Window](#)^{p855} object must, on getting, return the last string it was set to, and on setting, must set itself to the new value. When the [Window](#)^{p855} object is created, the attribute must be set to the empty string. It does not do anything else.

7.3.7 Script settings for [Window](#)^{p855} objects §^{p86}₄

To **set up a window environment settings object**, given a [URL creationURL](#), a [JavaScript execution context](#) *execution context*, null or an [environment](#)^{p936} *reservedEnvironment*, a [URL topLevelCreationURL](#), and an [origin](#)^{p868} *topLevelOrigin*, run these steps:

1. Let *realm* be the value of *execution context*'s *Realm* component.
2. Let *window* be *realm*'s [global object](#)^{p938}.
3. Let *settings object* be a new [environment settings object](#)^{p937} whose algorithms are defined as follows:

The [realm execution context](#)^{p937}

Return *execution context*.

The [module map](#)^{p937}

Return the [module map](#)^{p118} of *window*'s [associated Document](#)^{p856}.

The [responsible document](#)^{p937}

Return *window*'s [associated Document](#)^{p856}.

The [API URL character encoding](#)^{p937}

Return the current [character encoding](#) of *window*'s [associated Document](#)^{p856}.

The [API base URL](#)^{p937}

Return the current [base URL](#)^{p90} of *window*'s [associated Document](#)^{p856}.

The [origin](#)^{p937}

Return the [origin](#) of *window*'s [associated Document](#)^{p856}.

The [policy container](#)^{p937}

Return the [policy container](#)^{p118} of *window*'s [associated Document](#)^{p856}.

The [cross-origin isolated capability](#)^{p937}

Return true if both of the following hold, and false otherwise:

1. *realm*'s [agent cluster](#)'s [cross-origin-isolation mode](#)^{p934} is "[concrete](#)^{p848}", and

2. `window`'s `associated Document`^{p856} is allowed to use^{p376} the "`cross-origin-isolated`^{p68}" feature.

The `time origin`^{p937}

Return `window`'s `associated Document`^{p856}'s `load timing info`^{p121}'s `navigation start time`^{p121}.

4. If `reservedEnvironment` is non-null, then:

1. Set `settings object`'s `id`^{p936} to `reservedEnvironment`'s `id`^{p936}, `target browsing context`^{p937} to `reservedEnvironment`'s `target browsing context`^{p937}, and `active service worker`^{p937} to `reservedEnvironment`'s `active service worker`^{p937}.
2. Set `reservedEnvironment`'s `id`^{p936} to the empty string.

Note

The identity of the reserved environment is considered to be fully transferred to the created `environment settings object`^{p937}. The reserved environment is not searchable by the `environment`^{p936}'s `id`^{p936} from this point on.

5. Otherwise, set `settings object`'s `id`^{p936} to a new unique opaque string, `settings object`'s `target browsing context`^{p937} to null, and `settings object`'s `active service worker`^{p937} to null.
6. Set `settings object`'s `creation URL`^{p936} to `creationURL`, `settings object`'s `top-level creation URL`^{p936} to `topLevelCreationURL`, and `settings object`'s `top-level origin`^{p936} to `topLevelOrigin`.
7. Set `realm`'s `[[HostDefined]]` field to `settings object`.

7.4 The `WindowProxy`^{p865} exotic object §^{p86}₅

A `WindowProxy` is an exotic object that wraps a `Window`^{p855} ordinary object, indirecting most operations through to the wrapped object. Each `browsing context`^{p840} has an associated `WindowProxy`^{p865} object. When the `browsing context`^{p840} is `navigated`^{p906}, the `Window`^{p855} object wrapped by the `browsing context`^{p840}'s associated `WindowProxy`^{p865} object is changed.

The `WindowProxy`^{p865} exotic object must use the ordinary internal methods except where it is explicitly specified otherwise below.

There is no `WindowProxy`^{p865} interface object.

Every `WindowProxy`^{p865} object has a `[[Window]]` internal slot representing the wrapped `Window`^{p855} object.

Note

Although `WindowProxy`^{p865} is named as a "proxy", it does not do polymorphic dispatch on its target's internal methods as a real proxy would, due to a desire to reuse machinery between `WindowProxy`^{p865} and `Location`^{p897} objects. As long as the `Window`^{p855} object remains an ordinary object this is unobservable and can be implemented either way.

7.4.1 `[[GetPrototypeOf]]` () §^{p86}₅

1. Let W be the value of the `[[Window]]`^{p865} internal slot of **this**.
2. If `IsPlatformObjectSameOrigin`^{p852}(W) is true, then return ! `OrdinaryGetPrototypeOf`(W).
3. Return null.

7.4.2 `[[SetPrototypeOf]]` (V) §^{p86}₅

1. Return ! `SetImmutablePrototype`(**this**, V).

7.4.3 **[[IsExtensible]]** () §^{p86}₆

1. Return true.

7.4.4 **[[PreventExtensions]]** () §^{p86}₆

1. Return false.

7.4.5 **[[GetOwnProperty]]** (*P*) §^{p86}₆

1. Let *W* be the value of the [\[\[Window\]\]](#)^{p865} internal slot of **this**.
2. If *P* is an [array index property name](#), then:
 1. Let *index* be ! [ToUint32](#)(*P*).
 2. Let *maxProperties* be the [number of document-tree child browsing contexts](#)^{p861} of *W*.
 3. Let *value* be undefined.
 4. If *maxProperties* is greater than 0 and *index* is less than *maxProperties*, then set *value* to the [WindowProxy](#)^{p865} object of the *index*th [document-tree child browsing context](#)^{p843} of *W*'s [browsing context](#)^{p856}, sorted in the order that their [browsing context container](#)^{p843} elements were most recently inserted into *W*'s [associated Document](#)^{p856}, the [WindowProxy](#)^{p865} object of the most recently inserted [browsing context container](#)^{p843}'s [nested browsing context](#)^{p843} being last.
 5. If *value* is undefined, then:
 1. If [IsPlatformObjectSameOrigin](#)^{p852}(*W*) is true, then return undefined.
 2. Throw a ["SecurityError" DOMException](#).
 6. Return [PropertyDescriptor](#){ [\[\[Value\]\]](#): *value*, [\[\[Writable\]\]](#): false, [\[\[Enumerable\]\]](#): true, [\[\[Configurable\]\]](#): true }.
3. If [IsPlatformObjectSameOrigin](#)^{p852}(*W*) is true, then return ! [OrdinaryGetOwnProperty](#)(*W*, *P*).

Note

This is a [willful violation](#)^{p27} of the JavaScript specification's [invariants of the essential internal methods to maintain compatibility with existing web content](#). See [tc39/ecma262 issue #672](#) for more information. [\[JAVASCRIPT\]](#)^{p1308}

4. Let *property* be [CrossOriginGetOwnPropertyHelper](#)^{p853}(*W*, *P*).
5. If *property* is not undefined, then return *property*.
6. If *property* is undefined and *P* is in *W*'s [document-tree child browsing context name property set](#)^{p861}, then:
 1. Let *value* be the [WindowProxy](#)^{p865} object of the [named object](#)^{p862} of *W* with the name *P*.
 2. Return [PropertyDescriptor](#){ [\[\[Value\]\]](#): *value*, [\[\[Enumerable\]\]](#): false, [\[\[Writable\]\]](#): false, [\[\[Configurable\]\]](#): true }.

Note

The reason the property descriptors are non-enumerable, despite this mismatching the same-origin behavior, is for compatibility with existing web content. See [issue #3183](#) for details.

7. Return ? [CrossOriginPropertyFallback](#)^{p852}(*P*).

7.4.6 **[[DefineOwnProperty]]** (*P*, *Desc*) §^{p86}₆

1. Let *W* be the value of the [\[\[Window\]\]](#)^{p865} internal slot of **this**.

2. If [IsPlatformObjectSameOrigin](#)^{p852}(*W*) is true, then:
 1. If *P* is an [array index property name](#), return false.
 2. Return ? [OrdinaryDefineOwnProperty](#)(*W*, *P*, *Desc*).

Note

This is a [willful violation](#)^{p27} of the JavaScript specification's [invariants of the essential internal methods](#) to maintain compatibility with existing web content. See [tc39/ecma262 issue #672](#) for more information. [\[JAVASCRIPT\]](#)^{p1308}

3. Throw a ["SecurityError" DOMException](#).

7.4.7 [\[\[Get\]\]](#) (*P*, *Receiver*) §^{p86}₇

1. Let *W* be the value of the [\[\[Window\]\]](#)^{p865} internal slot of **this**.
2. [Check if an access between two browsing contexts should be reported](#)^{p880}, given the [current global object](#)^{p944}'s [browsing context](#)^{p856}, *W*'s [browsing context](#)^{p856}, *P*, and the [current settings object](#)^{p944}.
3. If [IsPlatformObjectSameOrigin](#)^{p852}(*W*) is true, then return ? [OrdinaryGet](#)(**this**, *P*, *Receiver*).
4. Return ? [CrossOriginGet](#)^{p854}(**this**, *P*, *Receiver*).

Note

this is passed rather than *W* as [OrdinaryGet](#) and [CrossOriginGet](#)^{p854} will invoke the [\[\[GetOwnProperty\]\]](#)^{p866} internal method.

7.4.8 [\[\[Set\]\]](#) (*P*, *V*, *Receiver*) §^{p86}₇

1. Let *W* be the value of the [\[\[Window\]\]](#)^{p865} internal slot of **this**.
2. [Check if an access between two browsing contexts should be reported](#)^{p880}, given the [current global object](#)^{p944}'s [browsing context](#)^{p840}, *W*'s [browsing context](#)^{p840}, *P*, and the [current settings object](#)^{p944}.
3. If [IsPlatformObjectSameOrigin](#)^{p852}(*W*) is true, then:
 1. If *P* is an [array index property name](#), then return false.
 2. Return ? [OrdinarySet](#)(*W*, *P*, *V*, *Receiver*).
4. Return ? [CrossOriginSet](#)^{p854}(**this**, *P*, *V*, *Receiver*).

Note

this is passed rather than *W* as [CrossOriginSet](#)^{p854} will invoke the [\[\[GetOwnProperty\]\]](#)^{p866} internal method.

7.4.9 [\[\[Delete\]\]](#) (*P*) §^{p86}₇

1. Let *W* be the value of the [\[\[Window\]\]](#)^{p865} internal slot of **this**.
2. If [IsPlatformObjectSameOrigin](#)^{p852}(*W*) is true, then:
 1. If *P* is an [array index property name](#), then:
 1. Let *desc* be ! **this**.[\[\[GetOwnProperty\]\]](#)(*P*).
 2. If *desc* is undefined, then return true.

3. Return false.
2. Return ? [OrdinaryDelete](#)(*W*, *P*).
3. Throw a "[SecurityError](#)" [DOMException](#).

7.4.10 [\[\[OwnPropertyKeys\]\]](#) () §^{p86}₈

1. Let *W* be the value of the [\[\[Window\]\]](#)^{p865} internal slot of **this**.
2. Let *keys* be a new empty [List](#).
3. Let *maxProperties* be the [number of document-tree child browsing contexts](#)^{p861} of *W*.
4. Let *index* be 0.
5. Repeat while *index* < *maxProperties*,
 1. Add ! [ToString](#)(*index*) as the last element of *keys*.
 2. Increment *index* by 1.
6. If [IsPlatformObjectSameOrigin](#)^{p852}(*W*) is true, then return the concatenation of *keys* and [OrdinaryOwnPropertyKeys](#)(*W*).
7. Return the concatenation of *keys* and ! [CrossOriginOwnPropertyKeys](#)^{p854}(*W*).

7.5 Origin §^{p86}₈

Origins are the fundamental currency of the web's security model. Two actors in the web platform that share an origin are assumed to trust each other and to have the same authority. Actors with differing origins are considered potentially hostile versus each other, and are isolated from each other to varying degrees.

Example

For example, if Example Bank's web site, hosted at `bank.example.com`, tries to examine the DOM of Example Charity's web site, hosted at `charity.example.org`, a "[SecurityError](#)" [DOMException](#) will be raised.

An **origin** is one of the following:

An opaque origin

An internal value, with no serialization it can be recreated from (it is serialized as "null" per [serialization of an origin](#)^{p869}), for which the only meaningful operation is testing for equality.

A tuple origin

A [tuple](#)^{p868} consists of:

- A **scheme** (an [ASCII string](#)).
- A **host** (a [host](#)).
- A **port** (null or a 16-bit unsigned integer).
- A **domain** (null or a [domain](#)). Null unless stated otherwise.

Note

[Origins](#)^{p868} can be shared, e.g., among multiple [Document](#)^{p117} objects. Furthermore, [origins](#)^{p868} are generally immutable. Only the [domain](#)^{p868} of a [tuple origin](#)^{p868} can be changed, and only through the [document.domain](#)^{p871} API.

The **effective domain** of an [origin](#)^{p868} origin is computed as follows:

1. If *origin* is an [opaque origin](#)^{p868}, then return null.

- If *origin*'s [domain^{p868}](#) is non-null, then return *origin*'s [domain^{p868}](#).
- Return *origin*'s [host^{p868}](#).

The **serialization of an origin** is the string obtained by applying the following algorithm to the given [origin^{p868}](#) *origin*:

- If *origin* is an [opaque origin^{p868}](#), then return "null".
- Otherwise, let *result* be *origin*'s [scheme^{p868}](#).
- Append "://" to *result*.
- Append *origin*'s [host^{p868}](#), [serialized](#), to *result*.
- If *origin*'s [port^{p868}](#) is non-null, append a U+003A COLON character (:), and *origin*'s [port^{p868}](#), [serialized](#), to *result*.
- Return *result*.

Example

The [serialization^{p869}](#) of ("https", "xn--maraa-rta.example", null, null) is "https://xn--maraa-rta.example".

Note

There used to also be a Unicode serialization of an origin. However, it was never widely adopted.

Two [origins^{p868}](#), *A* and *B*, are said to be **same origin** if the following algorithm returns true:

- If *A* and *B* are the same [opaque origin^{p868}](#), then return true.
- If *A* and *B* are both [tuple origins^{p868}](#) and their [schemes^{p868}](#), [hosts^{p868}](#), and [port^{p868}](#) are identical, then return true.
- Return false.

Two [origins^{p868}](#), *A* and *B*, are said to be **same origin-domain** if the following algorithm returns true:

- If *A* and *B* are the same [opaque origin^{p868}](#), then return true.
- If *A* and *B* are both [tuple origins^{p868}](#), run these substeps:
 - If *A* and *B*'s [schemes^{p868}](#) are identical, and their [domains^{p868}](#) are identical and non-null, then return true.
 - Otherwise, if *A* and *B* are [same origin^{p869}](#) and their [domains^{p868}](#) are identical and null, then return true.
- Return false.

Example

A	B	same origin^{p869}	same origin-domain^{p869}
("https", "example.org", null, null)	("https", "example.org", null, null)	✓	✓
("https", "example.org", 314, null)	("https", "example.org", 420, null)	✗	✗
("https", "example.org", 314, "example.org")	("https", "example.org", 420, "example.org")	✗	✓
("https", "example.org", null, null)	("https", "example.org", null, "example.org")	✓	✗
("https", "example.org", null, "example.org")	("http", "example.org", null, "example.org")	✗	✗

7.5.1 Sites §^{p86}₉

A **scheme-and-host** is a [tuple](#) of an [ASCII string](#) and a [host](#).

A **site** is an [opaque origin^{p868}](#) or a [scheme-and-host^{p869}](#).

To **obtain a site**, given an origin *origin*, run these steps:

- If *origin* is an [opaque origin^{p868}](#), then return *origin*.

- If *origin*'s [host^{p868}](#)'s [registrable domain](#) is null, then return (*origin*'s [scheme^{p868}](#), *origin*'s [host^{p868}](#)).
- Return (*origin*'s [scheme^{p868}](#), *origin*'s [host^{p868}](#)'s [registrable domain](#)).

The **serialization of a site** is the string obtained by applying the following algorithm to the given [site^{p869}](#) *site*:

- If *site* is an [opaque origin^{p868}](#), then return "null".
- Let *result* be *site*[0].
- Append "://" to *result*.
- Append *site*[1], [serialized](#), to *result*.
- Return *result*.

Warning!

It needs to be clear from context that the serialized value is a site, not an origin, as there is not necessarily a syntactic difference between the two. For example, the origin ("https", "shop.example", null, null) and the site ("https", "shop.example") have the same serialization: "https://shop.example".

Two [origins^{p868}](#), *A* and *B*, are said to be **schemelessly same site** if the following algorithm returns true:

- If *A* and *B* are the same [opaque origin^{p868}](#), then return true.
- If *A* and *B* are both [tuple origins^{p868}](#), then:
 - Let *hostA* be *A*'s [host^{p868}](#), and let *hostB* be *B*'s [host^{p868}](#).
 - If *hostA* [equals](#) *hostB* and *hostA*'s [registrable domain](#) is null, then return true.
 - If *hostA*'s [registrable domain](#) [equals](#) *hostB*'s [registrable domain](#) and is non-null, then return true.
- Return false.

Two [origins^{p868}](#), *A* and *B*, are said to be **same site** if both of the following statements are true:

- A* and *B* are [schemelessly same site^{p870}](#)
- A* and *B* are either both [opaque origins^{p868}](#), or both [tuple origins^{p868}](#) with the same [scheme^{p868}](#)

Note

Unlike the [same origin^{p869}](#) and [same origin-domain^{p869}](#) concepts, for [schemelessly same site^{p870}](#) and [same site^{p870}](#), the [port^{p868}](#) and [domain^{p868}](#) components are ignored.

Warning!

For the reasons explained in URL, the [same site^{p870}](#) and [schemelessly same site^{p870}](#) concepts should be avoided when possible, in favor of [same origin^{p869}](#) checks.

Example

Given that [wildlife.museum](#), [museum](#), and [com](#) are [public suffixes](#) and that [example.com](#) is not:

A	B	schemelessly same site^{p870}	same site^{p870}
("https", "example.com")	("https", "sub.example.com")	✓	✓
("https", "example.com")	("https", "sub.other.example.com")	✓	✓
("https", "example.com")	("http", "non-secure.example.com")	✓	✗
("https", "r.wildlife.museum")	("https", "sub.r.wildlife.museum")	✓	✓
("https", "r.wildlife.museum")	("https", "sub.other.r.wildlife.museum")	✓	✓
("https", "r.wildlife.museum")	("https", "other.wildlife.museum")	✗	✗
("https", "r.wildlife.museum")	("https", "wildlife.museum")	✗	✗
("https", "wildlife.museum")	("https", "wildlife.museum")	✓	✓

(Here we have omitted the [port^{p868}](#) and [domain^{p868}](#) components since they are not considered.)

7.5.2 Relaxing the same-origin restriction § p87

1

For web developers (non-normative)

`document.domain`^{p871} [= *domain*]

Returns the current domain used for security checks.

Can be set to a value that removes subdomains, to change the [origin](#)^{p868}'s [domain](#)^{p868} to allow pages on other subdomains of the same domain (if they do the same thing) to access each other. This enables pages on different hosts of a domain to synchronously access each other's DOMs.

In sandboxed [iframe](#)^{p369}s, [Document](#)^{p117}s with [opaque origins](#)^{p868}, [Document](#)^{p117}s without a [browsing context](#)^{p840}, and when the "[document-domain](#)^{p68}" feature is disabled, the setter will throw a ["SecurityError"](#) exception. In cases where [crossOriginIsolated](#)^{p993} or [originAgentCluster](#)^{p873} return true, the setter will do nothing.

Avoid using the [document.domain](#)^{p871} setter. It undermines the security protections provided by the same-origin policy. This is especially acute when using shared hosting; for example, if an untrusted third party is able to host an HTTP server at the same IP address but on a different port, then the same-origin protection that normally protects two different sites on the same host will fail, as the ports are ignored when comparing origins after the [document.domain](#)^{p871} setter has been used.

Because of these security pitfalls, this feature is in the process of being removed from the web platform. (This is a long process that takes many years.)

Instead, use [postMessage\(\)](#)^{p1036} or [MessageChannel](#)^{p1039} objects to communicate across origins in a safe manner.

The [domain](#) getter steps are:

1. Let *effectiveDomain* be [this](#)'s [origin](#)'s [effective domain](#)^{p868}.
2. If *effectiveDomain* is null, then return the empty string.
3. Return *effectiveDomain*, [serialized](#).

The [domain](#)^{p871} setter steps are:

1. If [this](#)'s [browsing context](#)^{p840} is null, then throw a ["SecurityError"](#) [DOMException](#).
2. If [this](#)'s [active sandboxing flag set](#)^{p875} has its [sandboxed document.domain browsing context flag](#)^{p874} set, then throw a ["SecurityError"](#) [DOMException](#).
3. If [this](#) is not [allowed to use](#)^{p376} the "[document-domain](#)^{p68}" feature, then throw a ["SecurityError"](#) [DOMException](#).
4. Let *effectiveDomain* be [this](#)'s [origin](#)'s [effective domain](#)^{p868}.
5. If *effectiveDomain* is null, then throw a ["SecurityError"](#) [DOMException](#).
6. If the given value [is not a registrable domain suffix of and is not equal to](#)^{p871} *effectiveDomain*, then throw a ["SecurityError"](#) [DOMException](#).
7. If the [surrounding agent](#)'s [agent cluster](#)'s [is origin-keyed](#)^{p934} is true, then return.
8. Set [this](#)'s [origin](#)'s [domain](#)^{p868} to the result of [parsing](#) the given value.

To determine if a string *hostSuffixString* is a **registrable domain suffix of** or **is equal to** a [host](#) *originalHost*, run these steps:

1. If *hostSuffixString* is the empty string, then return false.
2. Let *hostSuffix* be the result of [parsing](#) *hostSuffixString*.
3. If *hostSuffix* is failure, then return false.
4. If *hostSuffix* does not [equal](#) *originalHost*, then:
 1. If *hostSuffix* or *originalHost* is not a [domain](#), then return false.

Note

This excludes [hosts](#) that are [IP addresses](#).

2. If *hostSuffix*, prefixed by U+002E (.), does not match the end of *originalHost*, then return false.
3. If one of the following is true
 - *hostSuffix* equals *hostSuffix*'s [public suffix](#)
 - *hostSuffix*, prefixed by U+002E (.), matches the end of *originalHost*'s [public suffix](#)
 then return false. [\[URL\]^{p1312}](#)
4. Assert: *originalHost*'s [public suffix](#), prefixed by U+002E (.), matches the end of *hostSuffix*.
5. Return true.

Example

<i>hostSuffixString</i>	<i>originalHost</i>	Outcome of is a registrable domain suffix of or is equal to ^{p871}	Notes
"0.0.0.0"	0.0.0.0	✓	
"0x10203"	0.1.2.3	✓	
"[0::1]"	::1	✓	
"example.com"	example.com	✓	
"example.com"	example.com.	✗	Trailing dot is significant.
"example.com."	example.com	✗	
"example.com"	www.example.com	✓	
"com"	example.com	✗	At the time of writing, com is a public suffix.
"example"	example	✓	
"compute.amazonaws.com"	example.compute.amazonaws.com	✗	At the time of writing, *.compute.amazonaws.com is a public suffix.
"example.compute.amazonaws.com"	www.example.compute.amazonaws.com	✗	
"amazonaws.com"	www.example.compute.amazonaws.com	✗	
"amazonaws.com"	test.amazonaws.com	✓	At the time of writing, amazonaws.com is a registrable domain.

7.5.3 Origin-keyed agent clusters ^{p87}₂

For web developers (non-normative)

Window.originAgentCluster^{p873}

Returns true if this [Window](#)^{p855} belongs to an [agent cluster](#) which is [origin](#)^{p868}-[keyed](#)^{p934}, in the manner described in this section.

A [Document](#)^{p117} delivered over a [secure context](#)^{p944} can request that it be placed in an [origin](#)^{p868}-[keyed](#)^{p934} [agent cluster](#), by using the `Origin-Agent-Cluster` HTTP response header. This header is a [structured header](#) whose value must be a [boolean](#). [\[STRUCTURED-FIELDS\]](#)^{p1311}

Per the processing model in the [create and initialize a new Document object](#)^{p914}, values that are not the [structured header boolean](#) true value (i.e., `?1`) will be ignored.

The consequences of using this header are that the resulting [Document](#)^{p117}'s [agent cluster key](#)^{p934} is its [origin](#), instead of the [corresponding site](#)^{p869}. In terms of observable effects, this means that attempting to [relax the same-origin restriction](#)^{p871} using [document.domain](#)^{p871} will instead do nothing, and it will not be possible to send [WebAssembly.Module](#) objects to cross-origin [Document](#)^{p117}s (even if they are [same site](#)^{p870}). Behind the scenes, this isolation can allow user agents to allocate implementation-specific resources corresponding to [agent clusters](#), such as processes or threads, more efficiently.

Note that within a [browsing context group](#)^{p848}, the `Origin-Agent-Cluster`^{p872} header can never cause same-origin [Document](#)^{p117} objects to end up in different [agent clusters](#), even if one sends the header and the other doesn't. This is prevented by means of the [historical agent cluster key map](#)^{p848}.

Note

This means that the [originAgentCluster](#)^{p873} getter can return false, even if the header is set, if the header was omitted on a previously-loaded same-origin page in the same [browsing context group](#)^{p848}. Similarly, it can return true even when the header is not set.

The `originAgentCluster` getter steps are to return the `surrounding_agent`'s `agent cluster`'s `is origin-keyed`^{p934}.

Note

`Document`^{p117}s with an `opaque origin`^{p868} can be considered unconditionally origin-keyed; for them the header has no effect, and the `originAgentCluster`^{p873} getter will always return true.

Note

Similarly, `Document`^{p117}s whose `agent cluster`'s `cross-origin isolation mode`^{p934} is not "none"^{p848} are automatically origin-keyed. The ``Origin-Agent-Cluster``^{p872} header might be useful as an additional hint to implementations about resource allocation, since the ``Cross-Origin-Opener-Policy``^{p877} and ``Cross-Origin-Embedder-Policy``^{p885} headers used to achieve cross-origin isolation are more about ensuring that everything in the same address space opts in to being there. But adding it would have no additional observable effects on author code.

7.6 Sandboxing §^{p87}₃

A **sandboxing flag set** is a set of zero or more of the following flags, which are used to restrict the abilities that potentially untrusted resources have:

The *sandboxed navigation browsing context flag*

This flag prevents content from navigating browsing contexts other than the `sandboxed browsing context itself`^{p906} (or browsing contexts further nested inside it), `auxiliary browsing contexts`^{p844} (which are protected by the `sandboxed auxiliary navigation browsing context flag`^{p873} defined next), and the `top-level browsing context`^{p844} (which is protected by the `sandboxed top-level navigation without user activation browsing context flag`^{p873} and `sandboxed top-level navigation with user activation browsing context flag`^{p873} defined below).

If the `sandboxed auxiliary navigation browsing context flag`^{p873} is not set, then in certain cases the restrictions nonetheless allow popups (new `top-level browsing contexts`^{p844}) to be opened. These `browsing contexts`^{p840} always have **one permitted sandboxed navigator**, set when the browsing context is created, which allows the `browsing context`^{p840} that created them to actually navigate them. (Otherwise, the `sandboxed navigation browsing context flag`^{p873} would prevent them from being navigated even if they were opened.)

The *sandboxed auxiliary navigation browsing context flag*

This flag prevents content from creating new auxiliary browsing contexts^{p850}, e.g. using the `target`^{p290} attribute or the `window.open()`^{p858} method.

The *sandboxed top-level navigation without user activation browsing context flag*

This flag prevents content from navigating their top-level browsing context^{p906} and prevents content from closing their top-level browsing context^{p860}. It is consulted only when the sandboxed browsing context's `active window`^{p840} does not have `transient activation`^{p795}.

When the `sandboxed top-level navigation without user activation browsing context flag`^{p873} is not set, content can navigate its `top-level browsing context`^{p844}, but other `browsing contexts`^{p840} are still protected by the `sandboxed navigation browsing context flag`^{p873} and possibly the `sandboxed auxiliary navigation browsing context flag`^{p873}.

The *sandboxed top-level navigation with user activation browsing context flag*

This flag prevents content from navigating their top-level browsing context^{p906} and prevents content from closing their top-level browsing context^{p860}. It is consulted only when the sandboxed browsing context's `active window`^{p840} has `transient activation`^{p795}.

As with the `sandboxed top-level navigation without user activation browsing context flag`^{p873}, this flag only affects the `top-level browsing context`^{p844}; if it is not set, other `browsing contexts`^{p840} might still be protected by other flags.

The *sandboxed plugins browsing context flag*

This flag prevents content from instantiating `plugins`^{p45}, whether using `the embed element`^{p381}, `the object element`^{p386}, or through `navigation`^{p921} of their `nested browsing context`^{p843}.

The *sandboxed origin browsing context flag*

This flag forces content into a unique origin^{p841}, thus preventing it from accessing other content from the same origin^{p868}.

This flag also [prevents script from reading from or writing to the document.cookie IDL attribute](#)^{p119}, and blocks access to [localStorage](#)^{p1898}.

The sandboxed forms browsing context flag

This flag [blocks form submission](#)^{p606}.

The sandboxed pointer lock browsing context flag

This flag disables the Pointer Lock API. [\[POINTERLOCK\]](#)^{p1310}

The sandboxed scripts browsing context flag

This flag [blocks script execution](#)^{p944}.

The sandboxed automatic features browsing context flag

This flag blocks features that trigger automatically, such as [automatically playing a video](#)^{p416} or [automatically focusing a form control](#)^{p810}.

The sandboxed document.domain browsing context flag

This flag prevents content from using the [document.domain](#)^{p871} setter.

The sandbox propagates to auxiliary browsing contexts flag

This flag prevents content from escaping the sandbox by ensuring that any [auxiliary browsing context](#)^{p844} it creates inherits the content's [active sandboxing flag set](#)^{p875}.

The sandboxed modals flag

This flag prevents content from using any of the following features to produce modal dialogs:

- [window.alert\(\)](#)^{p1004}
- [window.confirm\(\)](#)^{p1004}
- [window.print\(\)](#)^{p1005}
- [window.prompt\(\)](#)^{p1004}
- the [beforeunload](#)^{p1300} event

The sandboxed orientation lock browsing context flag

This flag disables the ability to lock the screen orientation. [\[SCREENORIENTATION\]](#)^{p1311}

The sandboxed presentation browsing context flag

This flag disables the Presentation API. [\[PRESENTATION\]](#)^{p1310}

The sandboxed downloads browsing context flag

This flag prevents content from initiating or instantiating downloads, whether through [downloading hyperlinks](#)^{p297} or through [navigation](#)^{p911} that gets handled [as a download](#)^{p297}.

The sandboxed custom protocols navigation browsing context flag

This flag prevents navigations toward non [fetch schemes](#) from being [handed off to external software](#)^{p913}.

When the user agent is to **parse a sandboxing directive**, given a string *input*, a [sandboxing flag set](#)^{p873} *output*, it must run the following steps:

1. [Split input on ASCII whitespace](#), to obtain *tokens*.
2. Let *output* be empty.
3. Add the following flags to *output*:
 - The [sandboxed navigation browsing context flag](#)^{p873}.
 - The [sandboxed auxiliary navigation browsing context flag](#)^{p873}, unless *tokens* contains the **allow-popups** keyword.
 - The [sandboxed top-level navigation without user activation browsing context flag](#)^{p873}, unless *tokens* contains the **allow-top-navigation** keyword.
 - The [sandboxed top-level navigation with user activation browsing context flag](#)^{p873}, unless *tokens* contains either

the [allow-top-navigation-by-user-activation](#) keyword or the [allow-top-navigation](#)^{p874} keyword.

Note

This means that if the [allow-top-navigation](#)^{p874} is present, the [allow-top-navigation-by-user-activation](#)^{p875} keyword will have no effect. For this reason, specifying both is a document conformance error.

- The [sandboxed plugins browsing context flag](#)^{p873}.
- The [sandboxed origin browsing context flag](#)^{p873}, unless the `tokens` contains the [allow-same-origin](#) keyword.

Note

The [allow-same-origin](#)^{p875} keyword is intended for two cases.

First, it can be used to allow content from the same site to be sandboxed to disable scripting, while still allowing access to the DOM of the sandboxed content.

Second, it can be used to embed content from a third-party site, sandboxed to prevent that site from opening popups, etc, without preventing the embedded page from communicating back to its originating site, using the database APIs to store data, etc.

- The [sandboxed forms browsing context flag](#)^{p874}, unless `tokens` contains the [allow-forms](#) keyword.
- The [sandboxed pointer lock browsing context flag](#)^{p874}, unless `tokens` contains the [allow-pointer-lock](#) keyword.
- The [sandboxed scripts browsing context flag](#)^{p874}, unless `tokens` contains the [allow-scripts](#) keyword.
- The [sandboxed automatic features browsing context flag](#)^{p874}, unless `tokens` contains the [allow-scripts](#)^{p875} keyword (defined above).

Note

This flag is relaxed by the same keyword as `scripts`, because when `scripts` are enabled these features are trivially possible anyway, and it would be unfortunate to force authors to use `script` to do them when sandboxed rather than allowing them to use the declarative features.

- The [sandboxed document.domain browsing context flag](#)^{p874}.
- The [sandbox propagates to auxiliary browsing contexts flag](#)^{p874}, unless `tokens` contains the [allow-popups-to-escape-sandbox](#) keyword.
- The [sandboxed modals flag](#)^{p874}, unless `tokens` contains the [allow-modals](#) keyword.
- The [sandboxed orientation lock browsing context flag](#)^{p874}, unless `tokens` contains the [allow-orientation-lock](#) keyword.
- The [sandboxed presentation browsing context flag](#)^{p874}, unless `tokens` contains the [allow-presentation](#) keyword.
- The [sandboxed downloads browsing context flag](#)^{p874}, unless `tokens` contains the [allow-downloads](#) keyword.
- The [sandboxed custom protocols navigation browsing context flag](#)^{p874}, unless `tokens` contains either the [allow-top-navigation-to-custom-protocols](#) keyword, the [allow-popups](#)^{p874} keyword, or the [allow-top-navigation](#)^{p874} keyword.

Every [top-level browsing context](#)^{p844} has a **popup sandboxing flag set**, which is a [sandboxing flag set](#)^{p873}. When a [browsing context](#)^{p840} is created, its [popup sandboxing flag set](#)^{p875} must be empty. It is populated by [the rules for choosing a browsing context](#)^{p850} and the [obtain a browsing context to use for a navigation response](#)^{p879} algorithm.

Every [iframe](#)^{p369} element has an **iframe sandboxing flag set**, which is a [sandboxing flag set](#)^{p873}. Which flags in an [iframe sandboxing flag set](#)^{p875} are set at any particular time is determined by the [iframe](#)^{p369} element's [sandbox](#)^{p374} attribute.

Every [Document](#)^{p117} has an **active sandboxing flag set**, which is a [sandboxing flag set](#)^{p873}. When the [Document](#)^{p117} is created, its [active sandboxing flag set](#)^{p875} must be empty. It is populated by the [navigation algorithm](#)^{p906}.

Every resource that is obtained by the [navigation algorithm](#)^{p906} has a **forced sandboxing flag set**, which is a [sandboxing flag set](#)^{p873}. A resource by default has no flags set in its [forced sandboxing flag set](#)^{p875}, but other specifications can define that certain flags are set.

Note

In particular, the [forced sandboxing flag set](#)^{p875} is used by Content Security Policy. [\[CSP\]](#)^{p1305}

To **determine the creation sandboxing flags** for a [browsing context](#)^{p840} *browsing context*, given null or an element *embedder*, return the [union](#) of the flags that are present in the following [sandboxing flag sets](#)^{p873}:

- If *embedder* is null, then: the flags set on *browsing context*'s [popup sandboxing flag set](#)^{p875}.
- If *embedder* is an element, then: the flags set on *embedder*'s [iframe sandboxing flag set](#)^{p875}.
- If *embedder* is an element, then: the flags set on *embedder*'s [node document](#)'s [active sandboxing flag set](#)^{p875}.

After creation, the **sandboxing flags** for a [browsing context](#)^{p840} *browsing context* are the result of [determining the creation sandboxing flags](#)^{p876} given *browsing context* and *browsing context*'s [container](#)^{p843}.

7.7 Cross-origin opener policies §^{p87}₆

A **cross-origin opener policy value** allows a document which is navigated to in a [top-level browsing context](#)^{p844} to force the creation of a new [top-level browsing context](#)^{p844}, and a corresponding [group](#)^{p844}. The possible values are:

"unsafe-none"

This is the (current) default and means that the document will occupy the same [top-level browsing context](#)^{p844} as its predecessor, unless that document specified a different [cross-origin opener policy](#)^{p876}.

"same-origin-allow-popups"

This forces the creation of a new [top-level browsing context](#)^{p844} for the document, unless its predecessor specified the same [cross-origin opener policy](#)^{p876} and they are [same origin](#)^{p869}.

"same-origin"

This behaves the same as "[same-origin-allow-popups](#)^{p876}", with the addition that any [auxiliary browsing context](#)^{p844} created needs to contain [same origin](#)^{p869} documents that also have the same [cross-origin opener policy](#)^{p876} or it will appear closed to the opener.

"same-origin-plus-COEP"

This behaves the same as "[same-origin](#)^{p876}", with the addition that it sets the (new) [top-level browsing context](#)^{p844}'s [group](#)^{p844}'s [cross-origin isolation mode](#)^{p848} to one of "[logical](#)^{p848}" or "[concrete](#)^{p848}".

Note

"[same-origin-plus-COEP](#)^{p876}" cannot be directly set via the ``Cross-Origin-Opener-Policy`^{p877} header, but results from a combination of setting both ``Cross-Origin-Opener-Policy`^{p877}: `same-origin`^{p876} and a ``Cross-Origin-Embedder-Policy`^{p885} header whose value is [compatible with cross-origin isolation](#)^{p884} together.

A **cross-origin opener policy** consists of:

- A **value**, which is a [cross-origin opener policy value](#)^{p876}, initially "[unsafe-none](#)^{p876}".
- A **reporting endpoint**, which is string or null, initially null.
- A **report-only value**, which is a [cross-origin opener policy value](#)^{p876}, initially "[unsafe-none](#)^{p876}".
- A **report-only reporting endpoint**, which is a string or null, initially null.

To **match cross-origin opener policy values**, given a [cross-origin opener policy value](#)^{p876} *A*, an [origin](#)^{p868} *originA*, a [cross-origin opener policy value](#)^{p876} *B*, and an [origin](#)^{p868} *originB*:

1. If *A* is "[unsafe-none](#)^{p876}" and *B* is "[unsafe-none](#)^{p876}", then return true.
2. If *A* is "[unsafe-none](#)^{p876}" or *B* is "[unsafe-none](#)^{p876}", then return false.
3. If *A* is *B* and *originA* is [same origin](#)^{p869} with *originB*, then return true.

- Return false.

7.7.1 The headers ^{§ p87}₇

A [Document](#)^{p117}'s [cross-origin opener policy](#)^{p118} is derived from the ``Cross-Origin-Opener-Policy`` and ``Cross-Origin-Opener-Policy-Report-Only`` HTTP response headers. These headers are [structured headers](#) whose value must be a [token](#). [\[STRUCTURED-FIELDS\]](#)^{p1311}

The valid [token](#) values are the [opener policy values](#)^{p876}. The token may also have attached [parameters](#); of these, the `"report-to"` parameter can have a [valid URL string](#) identifying an appropriate reporting endpoint. [\[REPORTING\]](#)^{p1309}

Note

Per the processing model described below, user agents will ignore this header if it contains an invalid value. Likewise, user agents will ignore this header if the value cannot be parsed as a [token](#).

To **obtain a cross-origin opener policy** given a [response](#) *response* and an [environment](#)^{p936} *reservedEnvironment*:

- Let *policy* be a new [cross-origin opener policy](#)^{p876}.
- If *reservedEnvironment* is a [non-secure context](#)^{p945}, then return *policy*.
- Let *value* be the result of [getting a structured field value](#) given ``Cross-Origin-Opener-Policy``^{p877} and "item" from *response*'s [header list](#).
- If *parsedItem* is not null, then:
 - If *parsedItem*[0] is `"same-origin"`^{p876}, then:
 - Let *coop* be the result of [obtaining a cross-origin embedder policy](#)^{p885} from *response* and *reservedEnvironment*.
 - If *coop*'s [value](#)^{p885} is [compatible with cross-origin isolation](#)^{p884}, then set *policy*'s [value](#)^{p876} to `"same-origin-plus-COEP"`^{p876}.
 - Otherwise, set *policy*'s [value](#)^{p876} to `"same-origin"`^{p876}.
 - If *parsedItem*[0] is `"same-origin-allow-popups"`^{p876}, then set *policy*'s [value](#)^{p876} to `"same-origin-allow-popups"`^{p876}.
 - If *parsedItem*[1][`"report-to"`^{p877}] [exists](#) and it is a string, then set *policy*'s [reporting endpoint](#)^{p876} to *parsedItem*[1][`"report-to"`^{p877}].
- Set *parsedItem* to the result of [getting a structured field value](#) given ``Cross-Origin-Opener-Policy-Report-Only``^{p877} and "item" from *response*'s [header list](#).
- If *parsedItem* is not null, then:
 - If *parsedItem*[0] is `"same-origin"`^{p876}, then:
 - Let *coop* be the result of [obtaining a cross-origin embedder policy](#)^{p885} from *response* and *reservedEnvironment*.
 - If *coop*'s [value](#)^{p885} is [compatible with cross-origin isolation](#)^{p884} or *coop*'s [report-only value](#)^{p885} is [compatible with cross-origin isolation](#)^{p884}, then set *policy*'s [report-only value](#)^{p876} to `"same-origin-plus-COEP"`^{p876}.
 - Otherwise, set *policy*'s [report-only value](#)^{p876} to `"same-origin"`^{p876}.
 - If *parsedItem*[0] is `"same-origin-allow-popups"`^{p876}, then set *policy*'s [report-only value](#)^{p876} to `"same-origin-`

Note

Report only COOP also considers report-only COEP to assign the special `"same-origin-plus-COEP"`^{p876} value. This allows developers more freedom in the order of deployment of COOP and COEP.

- Otherwise, set *policy*'s [report-only value](#)^{p876} to `"same-origin"`^{p876}.
- If *parsedItem*[0] is `"same-origin-allow-popups"`^{p876}, then set *policy*'s [report-only value](#)^{p876} to `"same-origin-`

`allow-popupsp876`.

3. If `parsedItem[1][report-top877]` exists and it is a string, then set `policy`'s `report-only reporting endpointp876` to `parsedItem[1][report-top877]`.

7. Return `policy`.

7.7.2 Browsing context group switches due to cross-origin opener policy ^{§^{p87}₈}

To check if COOP values require a browsing context group switch, given a boolean `isInitialAboutBlank`, two `originsp868` `responseOrigin` and `activeDocumentNavigationOrigin`, and two `cross-origin opener policy valuesp876` `responseCOOPValue` and `activeDocumentCOOPValue`:

1. If the result of `matchingp876` `activeDocumentCOOPValue`, `activeDocumentNavigationOrigin`, `responseCOOPValue`, and `responseOrigin` is true, return false.
2. If all of the following are true:
 - `isInitialAboutBlank`,
 - `activeDocumentCOOPValue`'s `valuep876` is `"same-origin-allow-popupsp876"`.
 - `responseCOOPValue` is `"unsafe-nonep876"`,then return false.
3. Return true.

To check if enforcing report-only COOP would require a browsing context group switch, given a boolean `isInitialAboutBlank`, two `originsp868` `responseOrigin`, `activeDocumentNavigationOrigin`, and two `cross-origin opener policiesp876` `responseCOOP` and `activeDocumentCOOP`:

1. If the result of `checking if COOP values require a browsing context group switchp878` given `isInitialAboutBlank`, `responseOrigin`, `activeDocumentNavigationOrigin`, `responseCOOP`'s `report-only valuep876` and `activeDocumentCOOPReportOnly`'s `report-only valuep876` is false, then return false.

Note

Matching report-only policies allows a website to specify the same report-only cross-origin opener policy on all its pages and not receive violation reports for navigations between these pages.

2. If the result of `checking if COOP values require a browsing context group switchp878` given `isInitialAboutBlank`, `responseOrigin`, `activeDocumentNavigationOrigin`, `responseCOOP`'s `valuep876` and `activeDocumentCOOPReportOnly`'s `report-only valuep876` is true, then return true.
3. If the result of `checking if COOP values require a browsing context group switchp878` given `isInitialAboutBlank`, `responseOrigin`, `activeDocumentNavigationOrigin`, `responseCOOP`'s `report-only valuep876` and `activeDocumentCOOPReportOnly`'s `valuep876` is true, then return true.
4. Return false.

A **cross-origin opener policy enforcement result** is a `struct` with the following `items`:

- A boolean **needs a browsing context group switch**, initially false.
- A boolean **would need a browsing context group switch due to report-only**, initially false.
- A `URL` `url`.
- An `originp868` `origin`.
- A `cross-origin opener policyp876` `cross-origin opener policy`.
- A boolean **current context is navigation source**.

To enforce a response's cross-origin opener policy, given a `browsing contextp840` `browsingContext`, a `URL` `responseURL`, an `originp868` `responseOrigin`, a `cross-origin opener policyp876` `responseCOOP`, a `cross-origin opener policy enforcement resultp878` `currentCOOPEnforcementResult`, and a `referrer` `referrer`:

1. Let *newCOOPEnforcementResult* be a new [cross-origin opener policy enforcement result](#)^{p878} whose [needs a browsing context group switch](#)^{p878} is *currentCOOPEnforcementResult*'s [needs a browsing context group switch](#)^{p878}, [would need a browsing context group switch due to report-only](#)^{p878} is *currentCOOPEnforcementResult*'s [would need a browsing context group switch due to report-only](#)^{p878}, [url](#)^{p878} is *responseURL*, [origin](#)^{p878} is *responseOrigin*, [coop](#)^{p878} is *responseCOOP*, and [current context is navigation source](#)^{p878} is true.
2. Let *isInitialAboutBlank* be true if *browsingContext* is [still on its initial about:blank Document](#)^{p118}; otherwise, false.
3. If *isInitialAboutBlank* is true and *browsingContext*'s [initial URL](#)^{p841} is null, set *browsingContext*'s [initial URL](#)^{p841} to *responseURL*.
4. If the result of [checking if COOP values require a browsing context group switch](#)^{p878} given *isInitialAboutBlank*, *currentCOOPEnforcementResult*'s [cross-origin opener policy](#)^{p878}'s [value](#)^{p876}, *currentCOOPEnforcementResult*'s [origin](#)^{p878}, *responseCOOP*'s [value](#)^{p876}, and *responseOrigin* is true, then:
 1. Set *newCOOPEnforcementResult*'s [needs a browsing context group switch](#)^{p878} to true.
 2. If *browsingContext*'s [group](#)^{p844}'s [browsing context set](#)^{p848}'s [size](#) is greater than 1, then:
 1. [Queue a violation report for browsing context group switch when navigating to a COOP response](#)^{p881} with *responseCOOP*, "enforce", *responseURL*, *currentCOOPEnforcementResult*'s [url](#)^{p878}, *currentCOOPEnforcementResult*'s [origin](#)^{p878}, *responseOrigin*, and *referrer*.
 2. [Queue a violation report for browsing context group switch when navigating away from a COOP response](#)^{p881} with *currentCOOPEnforcementResult*'s [cross-origin opener policy](#)^{p878}, "enforce", *currentCOOPEnforcementResult*'s [url](#)^{p878}, *responseURL*, *currentCOOPEnforcementResult*'s [origin](#)^{p878}, *responseOrigin*, and *currentCOOPEnforcementResult*'s [current context is navigation source](#)^{p878}.
5. If the result of [checking if enforcing report-only COOP would require a browsing context group switch](#)^{p878} given *isInitialAboutBlank*, *responseOrigin*, *currentCOOPEnforcementResult*'s [origin](#)^{p878}, *responseCOOP*, and *currentCOOPEnforcementResult*'s [cross-origin opener policy](#)^{p878}, is true, then:
 1. Set *result*'s [would need a browsing context group switch due to report-only](#)^{p878} to true.
 2. If *browsingContext*'s [group](#)^{p844}'s [browsing context set](#)^{p848}'s [size](#) is greater than 1, then:
 1. [Queue a violation report for browsing context group switch when navigating to a COOP response](#)^{p881} with *responseCOOP*, "reporting", *responseURL*, *currentCOOPEnforcementResult*'s [url](#)^{p878}, *currentCOOPEnforcementResult*'s [origin](#)^{p878}, *responseOrigin*, and *referrer*.
 2. [Queue a violation report for browsing context group switch when navigating away from a COOP response](#)^{p881} with *currentCOOPEnforcementResult*'s [cross-origin opener policy](#)^{p878}, "reporting", *currentCOOPEnforcementResult*'s [url](#)^{p878}, *responseURL*, *currentCOOPEnforcementResult*'s [origin](#)^{p878}, *responseOrigin*, and *currentCOOPEnforcementResult*'s [current context is navigation source](#)^{p878}.
6. Return *newCOOPEnforcementResult*.

To **obtain a browsing context to use for a navigation response**, given a [browsing context](#)^{p840} *browsingContext*, a [sandboxing flag set](#)^{p873} *sandboxFlags*, a [cross-origin opener policy](#)^{p876} *navigationCOOP*, and a [cross-origin opener policy enforcement result](#)^{p878} *coopEnforcementResult*:

1. If *browsingContext* is not a [top-level browsing context](#)^{p844}, return *browsingContext*.
2. If *coopEnforcementResult*'s [needs a browsing context group switch](#)^{p878} is false, then:
 1. If *coopEnforcementResult*'s [would need a browsing context group switch due to report-only](#)^{p878} is true, set *browsingContext*'s [virtual browsing context group ID](#)^{p841} to a new unique identifier.
 2. Return *browsingContext*.
3. Let *newBrowsingContext* be the result of [creating a new top-level browsing context](#)^{p842}.
4. If *navigationCOOP*'s [value](#)^{p876} is "[same-origin-plus-COEP](#)^{p876}", then set *newBrowsingContext*'s [group](#)^{p844}'s [cross-origin isolation mode](#)^{p848} to either "[logical](#)^{p848}" or "[concrete](#)^{p848}". The choice of which is [implementation-defined](#).

Note

It is difficult on some platforms to provide the security properties required by the [cross-origin isolated capability](#)^{p937}.

"concrete^{p848}" grants access to it and "logical^{p848}" does not.

5. If `sandboxFlags` is not empty, then:
 1. Assert `navigationCOOP`'s `value`^{p876} is "`unsafe-none`^{p876}".
 2. Assert: `newBrowsingContext`'s `popup sandboxing flag set`^{p875} is empty.
 3. Set `newBrowsingContext`'s `popup sandboxing flag set`^{p875} to a clone of `sandboxFlags`.
6. Discard^{p862} `browsingContext`.

Note

This has no effect on `browsingContext`'s `group`^{p844}, unless `browsingContext` was its sole `top-level browsing context`^{p844}. In that case, the user agent might delete the `browsing context group`^{p848} which no longer contains any `browsing contexts`^{p840}.

7. Return `newBrowsingContext`.

The impact of swapping browsing context groups following a navigation is not fully defined. It is currently under discussion in [issue #5350](#).

7.7.3 Reporting ^{p880}

An **accessor-accessed relationship** is an enum that describes the relationship between two `browsing contexts`^{p840} between which an access happened. It can take the following values:

accessor is opener

The accessor `browsing context`^{p840} or one of its `ancestors`^{p843} is the `opener browsing context`^{p840} of the accessed `browsing context`^{p840}'s `top-level browsing context`^{p844}.

accessor is openee

The accessed `browsing context`^{p840} or one of its `ancestors`^{p843} is the `opener browsing context`^{p840} of the accessor `browsing context`^{p840}'s `top-level browsing context`^{p844}.

none

There is no opener relationship between the accessor `browsing context`^{p840}, the accessor `browsing context`^{p840}, or any of their `ancestors`^{p843}.

To **check if an access between two browsing contexts should be reported**, given two `browsing contexts`^{p840} `accessor` and `accessed`, a JavaScript property name `P`, and an `environment settings object`^{p937} `environment`:

1. If `P` is not a `cross-origin accessible window property name`^{p852}, then return.
2. If `accessor`'s `active document`^{p840}'s `origin` or any of its `ancestors`^{p843}' `active document`^{p840}'s `origins` are not `same origin`^{p869} with `accessor`'s `top-level browsing context`^{p844}'s `active document`^{p840}'s `origin`, or if `accessed`'s `active document`^{p840}'s `origin` or any of its `ancestors`^{p843}' `active document`^{p840}'s `origins` are not `same origin`^{p869} with `accessed`'s `top-level browsing context`^{p844}'s `active document`^{p840}'s `origin`, then return.

Note

This avoids leaking information about cross-origin iframes to a top level frame with cross-origin opener policy reporting.

3. If `accessor`'s `top-level browsing context`^{p844}'s `virtual browsing context group ID`^{p841} is `accessed`'s `top-level browsing context`^{p844}'s `virtual browsing context group ID`^{p841}, then return.
4. Let `accessorAccessedRelationship` be a new `accessor-accessed relationship`^{p880} with value `none`^{p880}.
5. If `accessed`'s `top-level browsing context`^{p844}'s `opener browsing context`^{p840} is `accessor` or an `ancestor`^{p843} of `accessor`, then set `accessorAccessedRelationship` to `accessor is opener`^{p880}.

- If [accessor's top-level browsing context^{p844}](#)'s [opener browsing context^{p840}](#) is accessed or an [ancestor^{p843}](#) of accessed, then set [accessorAccessedRelationship](#) to [accessor is openee^{p880}](#).
- [Queue violation reports for accesses^{p882}](#), given [accessorAccessedRelationship](#), [accessor's top-level browsing context^{p844}](#)'s [active document^{p840}](#)'s [cross-origin opener policy^{p118}](#), [accessed's top-level browsing context^{p844}](#)'s [active document^{p840}](#)'s [cross-origin opener policy^{p118}](#), [accessor's active document^{p840}](#)'s [URL](#), [accessed's active document^{p840}](#)'s [URL](#), [accessor's top-level browsing context^{p844}](#)'s [initial URL^{p841}](#), [accessed's top-level browsing context^{p844}](#)'s [initial URL^{p841}](#), [accessor's active document^{p840}](#)'s [origin](#), [accessed's active document^{p840}](#)'s [origin](#), [accessor's top-level browsing context^{p844}](#)'s [opener origin at creation^{p841}](#), [accessed's top-level browsing context^{p844}](#)'s [opener origin at creation^{p841}](#), [accessor's top-level browsing context^{p844}](#)'s [active document^{p840}](#)'s [referrer^{p119}](#), [accessed's top-level browsing context^{p844}](#)'s [active document^{p840}](#)'s [referrer^{p119}](#), [P](#), and [environment](#).

To **sanitize a URL to send in a report** given a [URL url](#):

- Let [sanitizedURL](#) be a copy of [url](#).
- [Set the username](#) given [sanitizedURL](#) and the empty string.
- [Set the password](#) given [sanitizedURL](#) and the empty string.
- Return the [serialization](#) of [sanitizedURL](#) with [exclude fragment](#) set to true.

To **queue a violation report for browsing context group switch when navigating to a COOP response** given a [cross-origin opener policy^{p876}](#) [coop](#), a string [disposition](#), a [URL coopURL](#), a [URL previousResponseURL](#), two [origins^{p868}](#) [coopOrigin](#) and [previousResponseOrigin](#), and a [referrer](#) [referrer](#):

- If [coop's reporting endpoint^{p876}](#) is null, return.
- Let [coopValue](#) be [coop's value^{p876}](#).
- If [disposition](#) is "reporting", then set [coopValue](#) to [coop's report-only value^{p876}](#).
- Let [serializedReferrer](#) be an empty string.
- If [referrer](#) is a [URL](#), set [serializedReferrer](#) to the [serialization](#) of [referrer](#).
- Let [body](#) be a new object containing the following properties:

key	value
disposition	disposition
effectivePolicy	coopValue
previousResponseURL	If coopOrigin and previousResponseOrigin are same origin^{p869} this is the sanitization^{p881} of previousResponseURL , null otherwise.
referrer	serializedReferrer
type	"navigation-to-response"

- [Queue body](#) as "coop" for [coop's reporting endpoint^{p876}](#) with [coopURL](#).

To **queue a violation report for browsing context group switch when navigating away from a COOP response** given a [cross-origin opener policy^{p876}](#) [coop](#), a string [disposition](#), a [URL coopURL](#), a [URL nextResponseURL](#), two [origins^{p868}](#) [coopOrigin](#) and [nextResponseOrigin](#), and a boolean [isCOOPResponseNavigationSource](#):

- If [coop's reporting endpoint^{p876}](#) is null, return.
- Let [coopValue](#) be [coop's value^{p876}](#).
- If [disposition](#) is "reporting", then set [coopValue](#) to [coop's report-only value^{p876}](#).
- Let [body](#) be a new object containing the following properties:

key	value
disposition	disposition
effectivePolicy	coopValue
nextResponseURL	If coopOrigin and nextResponseOrigin are same origin^{p869} or isCOOPResponseNavigationSource is true, this is the sanitization^{p881} of previousResponseURL , null otherwise.
type	"navigation-from-response"

5. [Queue](#) *body* as "coop" for *coop*'s [reporting endpoint](#)^{p876} with *coopURL*.

To **queue violation reports for accesses**, given an [accessor-accessed relationship](#)^{p880} *accessorAccessedRelationship*, two [cross-origin opener policies](#)^{p876} *accessorCOOP* and *accessedCOOP*, four [URLs](#) *accessorURL*, *accessedURL*, *accessorInitialURL*, *accessedInitialURL*, four [origins](#)^{p868} *accessorOrigin*, *accessedOrigin*, *accessorCreatorOrigin* and *accessedCreatorOrigin*, two [referrers](#)^{p119} *accessorReferrer* and *accessedReferrer*, a string *propertyName*, and an [environment settings object](#)^{p937} *environment*:

1. If *coop*'s [reporting endpoint](#)^{p876} is null, return.
2. Let *coopValue* be *coop*'s [value](#)^{p876}.
3. If *disposition* is "reporting", then set *coopValue* to *coop*'s [report-only value](#)^{p876}.
4. If *accessorAccessedRelationship* is [accessor is opener](#)^{p880}:
 1. [Queue a violation report for access to an opened window](#)^{p882}, given *accessorCOOP*, *accessorURL*, *accessedURL*, *accessedInitialURL*, *accessorOrigin*, *accessedOrigin*, *accessedCreatorOrigin*, *propertyName*, and *environment*.
 2. [Queue a violation report for access from the opener](#)^{p883}, given *accessedCOOP*, *accessedURL*, *accessorURL*, *accessedOrigin*, *accessorOrigin*, *propertyName*, and *accessedReferrer*.
5. Otherwise, if *accessorAccessedRelationship* is [accessor is openee](#)^{p880}:
 1. [Queue a violation report for access to the opener](#)^{p882}, given *accessorCOOP*, *accessorURL*, *accessedURL*, *accessorOrigin*, *accessedOrigin*, *propertyName*, *accessorReferrer*, and *environment*.
 2. [Queue a violation report for access from an opened window](#)^{p883}, given *accessedCOOP*, *accessedURL*, *accessorURL*, *accessorInitialURL*, *accessedOrigin*, *accessorOrigin*, *accessorCreatorOrigin*, and *propertyName*.
6. Otherwise:
 1. [Queue a violation report for access to another window](#)^{p882}, given *accessorCOOP*, *accessorURL*, *accessedURL*, *accessorOrigin*, *accessedOrigin*, *propertyName*, and *environment*.
 2. [Queue a violation report for access from another window](#)^{p884}, given *accessedCOOP*, *accessedURL*, *accessorURL*, *accessedOrigin*, *accessorOrigin*, and *propertyName*.

To **queue a violation report for access to the opener**, given a [cross-origin opener policy](#)^{p876} *coop*, two [URLs](#) *coopURL* and *openerURL*, two [origins](#)^{p868} *coopOrigin* and *openerOrigin*, a string *propertyName*, a [referrer](#) *referrer*, and an [environment settings object](#)^{p937} *environment*:

1. Let *sourceFile*, *lineNumber* and *columnNumber* be the relevant script URL and problematic position which triggered this report.
2. Let *serializedReferrer* be an empty string.
3. If *referrer* is a [URL](#), set *serializedReferrer* to the [serialization](#) of *referrer*.
4. Let *body* be a new object containing the following properties:

key	value
disposition	"reporting"
effectivePolicy	<i>coop</i> 's report-only value ^{p876}
property	<i>propertyName</i>
openerURL	If <i>coopOrigin</i> and <i>openerOrigin</i> are same origin ^{p869} , this is the sanitization ^{p881} of <i>openerURL</i> , null otherwise.
referrer	<i>serializedReferrer</i>
sourceFile	<i>sourceFile</i>
lineNumber	<i>lineNumber</i>
columnNumber	<i>columnNumber</i>
type	"access-to-opener"

5. [Queue](#) *body* as "coop" for *coop*'s [reporting endpoint](#)^{p876} with *coopURL* and *environment*.

To **queue a violation report for access to an opened window**, given a [cross-origin opener policy](#)^{p876} *coop*, three [URLs](#) *coopURL*, *openedWindowURL* and *initialWindowURL*, three [origins](#)^{p868} *coopOrigin*, *openedWindowOrigin*, and *openerInitialOrigin*, a string *propertyName*, and an [environment settings object](#)^{p937} *environment*:

1. Let *sourceFile*, *lineNumber* and *columnNumber* be the relevant script URL and problematic position which triggered this report.
2. Let *body* be a new object containing the following properties:

key	value
disposition	"reporting"
effectivePolicy	coop's report-only value ^{p876}
property	<i>propertyName</i>
openedWindowURL	If <i>coopOrigin</i> and <i>openedWindowOrigin</i> are same origin ^{p869} , this is the sanitization ^{p881} of <i>openedWindowURL</i> , null otherwise.
openedWindowInitialURL	If <i>coopOrigin</i> and <i>openerInitialOrigin</i> are same origin ^{p869} , this is the sanitization ^{p881} of <i>initialWindowURL</i> , null otherwise.
sourceFile	<i>sourceFile</i>
lineNumber	<i>lineNumber</i>
columnNumber	<i>columnNumber</i>
type	"access-to-opener"

3. [Queue](#) *body* as "coop" for coop's [reporting endpoint](#)^{p876} with *coopURL* and *environment*.

To **queue a violation report for access to another window**, given a [cross-origin opener policy](#)^{p876} *coop*, two [URLs](#) *coopURL* and *otherURL*, two [origins](#)^{p868} *coopOrigin* and *otherOrigin*, a string *propertyName*, and an [environment settings object](#)^{p937} *environment*:

1. Let *sourceFile*, *lineNumber* and *columnNumber* be the relevant script URL and problematic position which triggered this report.
2. Let *body* be a new object containing the following properties:

key	value
disposition	"reporting"
effectivePolicy	coop's report-only value ^{p876}
property	<i>propertyName</i>
otherURL	If <i>coopOrigin</i> and <i>otherOrigin</i> are same origin ^{p869} , this is the sanitization ^{p881} of <i>otherURL</i> , null otherwise.
sourceFile	<i>sourceFile</i>
lineNumber	<i>lineNumber</i>
columnNumber	<i>columnNumber</i>
type	"access-to-opener"

3. [Queue](#) *body* as "coop" for coop's [reporting endpoint](#)^{p876} with *coopURL* and *environment*.

To **queue a violation report for access from the opener**, given a [cross-origin opener policy](#)^{p876} *coop*, two [URLs](#) *coopURL* and *openerURL*, two [origins](#)^{p868} *coopOrigin* and *openerOrigin*, a string *propertyName*, and a [referrer](#) *referrer*:

1. If coop's [reporting endpoint](#)^{p876} is null, return.
2. Let *serializedReferrer* be an empty string.
3. If *referrer* is a [URL](#), set *serializedReferrer* to the [serialization](#) of *referrer*.
4. Let *body* be a new object containing the following properties:

key	value
disposition	"reporting"
effectivePolicy	coop's report-only value ^{p876}
property	<i>propertyName</i>
openerURL	If <i>coopOrigin</i> and <i>openerOrigin</i> are same origin ^{p869} , this is the sanitization ^{p881} of <i>openerURL</i> , null otherwise.
referrer	<i>serializedReferrer</i>
type	"access-to-opener"

5. [Queue](#) *body* as "coop" for coop's [reporting endpoint](#)^{p876} with *coopURL*.

To **queue a violation report for access from an opened window**, given a [cross-origin opener policy](#)^{p876} *coop*, three [URLs](#) *coopURL*, *openedWindowURL* and *initialWindowURL*, three [origins](#)^{p868} *coopOrigin*, *openedWindowOrigin*, and *openerInitialOrigin*, and a string *propertyName*:

1. If *coop*'s [reporting_endpoint](#)^{p876} is null, return.
2. Let *body* be a new object containing the following properties:

key	value
disposition	"reporting"
effectivePolicy	<i>coopValue</i>
property	<i>coop</i> 's report-only_value ^{p876}
openedWindowURL	If <i>coopOrigin</i> and <i>openedWindowOrigin</i> are same origin ^{p869} , this is the sanitization ^{p881} of <i>openedWindowURL</i> , null otherwise.
openedWindowInitialURL	If <i>coopOrigin</i> and <i>openerInitialOrigin</i> are same origin ^{p869} , this is the sanitization ^{p881} of <i>initialWindowURL</i> , null otherwise.
type	"access-to-opener"

3. [Queue](#) *body* as "coop" for *coop*'s [reporting_endpoint](#)^{p876} with *coopURL*.

To **queue a violation report for access from another window**, given a [cross-origin opener policy](#)^{p876} *coop*, two URLs *coopURL* and *otherURL*, two [origins](#)^{p868} *coopOrigin* and *otherOrigin*, and a string *propertyName*:

1. If *coop*'s [reporting_endpoint](#)^{p876} is null, return.
2. Let *body* be a new object containing the following properties:

key	value
disposition	"reporting"
effectivePolicy	<i>coop</i> 's report-only_value ^{p876}
property	<i>propertyName</i>
otherURL	If <i>coopOrigin</i> and <i>otherOrigin</i> are same origin ^{p869} , this is the sanitization ^{p881} of <i>otherURL</i> , null otherwise.
type	access-to-opener

3. [Queue](#) *body* as "coop" for *coop*'s [reporting_endpoint](#)^{p876} with *coopURL*.

7.8 Cross-origin embedder policies §^{p88}₄

An **embedder policy value** is one of three strings that controls the fetching of cross-origin resources without explicit permission from resource owners.

"unsafe-none"

This is the default value. When this value is used, cross-origin resources can be fetched without giving explicit permission through the [CORS protocol](#) or the ``Cross-Origin-Resource-Policy`` header.

"require-corp"

When this value is used, fetching cross-origin resources requires the server's explicit permission through the [CORS protocol](#) or the ``Cross-Origin-Resource-Policy`` header.

"credentialless"

When this value is used, fetching cross-origin no-CORS resources omits credentials. In exchange, an explicit ``Cross-Origin-Resource-Policy`` header is not required. Other requests sent with credentials require the server's explicit permission through the [CORS protocol](#) or the ``Cross-Origin-Resource-Policy`` header.

⚠Warning!

Before supporting "credentialless"^{p884}, implementers are strongly encouraged to support both:

- [Private Network Access](#)
- [Opaque Response Blocking](#)

Otherwise, it would allow attackers to leverage the client's network position to read non public resources, using the [cross-origin isolated capability](#)^{p937}.

An [embedder_policy_value](#)^{p884} is **compatible with cross-origin isolation** if it is "credentialless"^{p884} or "require-corp"^{p884}.

An **embedder policy** consists of:

- A **value**, which is an [embedder policy value](#)^{p884}, initially "[unsafe-none](#)^{p884}".
- A **reporting endpoint** string, initially the empty string.
- A **report only value**, which is an [embedder policy value](#)^{p884}, initially "[unsafe-none](#)^{p884}".
- A **report only reporting endpoint** string, initially the empty string.

The "**coep**" **report type** is a [report type](#) whose value is "coep". It is [visible to ReportingObservers](#).

7.8.1 The headers ^{p88}₅

The ``Cross-Origin-Embedder-Policy`` and ``Cross-Origin-Embedder-Policy-Report-Only`` HTTP response headers allow a server to declare an [embedder policy](#)^{p884} for an [environment settings object](#)^{p937}. These headers are [structured headers](#) whose values must be [token](#). [\[STRUCTURED-FIELDS\]](#)^{p1311}

The valid [token](#) values are the [embedder policy values](#)^{p884}. The token may also have attached [parameters](#); of these, the "**report-to**" parameter can have a [valid URL string](#) identifying an appropriate reporting endpoint. [\[REPORTING\]](#)^{p1309}

Note

The [processing model](#)^{p885} fails open (by defaulting to "[unsafe-none](#)^{p884}") in the presence of a header that cannot be parsed as a token. This includes inadvertent lists created by combining multiple instances of the ``Cross-Origin-Embedder-Policy``^{p885} header present in a given response:

<code>`Cross-Origin-Embedder-Policy`</code> ^{p885}	Final embedder policy value ^{p884}
No header delivered	" unsafe-none ^{p884} "
<code>`require-corp`</code>	" require-corp ^{p884} "
<code>`unknown-value`</code>	" unsafe-none ^{p884} "
<code>`require-corp, unknown-value`</code>	" unsafe-none ^{p884} "
<code>`unknown-value, unknown-value`</code>	" unsafe-none ^{p884} "
<code>`unknown-value, require-corp`</code>	" unsafe-none ^{p884} "
<code>`require-corp, require-corp`</code>	" unsafe-none ^{p884} "

(The same applies to ``Cross-Origin-Embedder-Policy-Report-Only``^{p885}.)

To **obtain an embedder policy** from a [response](#) and an [environment](#)^{p936} environment:

1. Let *policy* be a new [embedder policy](#)^{p884}.
2. If *environment* is a [non-secure context](#)^{p945}, then return *policy*.
3. Let *parsedItem* be the result of [getting a structured field value](#) with ``Cross-Origin-Embedder-Policy``^{p885} and "item" from *response*'s [header list](#).
4. If *parsedItem* is non-null and *parsedItem*[0] is [compatible with cross-origin isolation](#)^{p884}:
 1. Set *policy*'s [value](#)^{p885} to *parsedItem*[0].
 2. If *parsedItem*[1][`"report-to"`]^{p885} exists, then set *policy*'s [endpoint](#)^{p885} to *parsedItem*[1][`"report-to"`]^{p885}.
5. Set *parsedItem* to the result of [getting a structured field value](#) with ``Cross-Origin-Embedder-Policy-Report-Only``^{p885} and "item" from *response*'s [header list](#).
6. If *parsedItem* is non-null and *parsedItem*[0] is [compatible with cross-origin isolation](#)^{p884}:
 1. Set *policy*'s [value](#)^{p885} to *parsedItem*[0].
 2. If *parsedItem*[1][`"report-to"`]^{p885} exists, then set *policy*'s [endpoint](#)^{p885} to *parsedItem*[1][`"report-to"`]^{p885}.
7. Return *policy*.

7.8.2 Embedder policy checks § p88 6

To **check a navigation response's adherence to its embedder policy** given a [response](#) *response*, a [browsing context](#)^{p840} *target*, and an [embedder policy](#)^{p884} *responsePolicy*:

1. If *target* is not a [child browsing context](#)^{p843}, then return true.
2. Let *parentPolicy* be *target*'s [container document](#)^{p843}'s [policy container](#)^{p118}'s [embedder policy](#)^{p886}.
3. If *parentPolicy*'s [report-only value](#)^{p885} is [compatible with cross-origin isolation](#)^{p884} and *responsePolicy*'s [value](#)^{p885} is not, then [queue a cross-origin embedder policy inheritance violation](#)^{p886} with *response*, "navigation", *parentPolicy*'s [report only reporting endpoint](#)^{p885}, "reporting", and *target*'s [container document](#)^{p843}'s [relevant settings object](#)^{p944}.
4. If *parentPolicy*'s [value](#)^{p885} is not [compatible with cross-origin isolation](#)^{p884} or *responsePolicy*'s [value](#)^{p885} is [compatible with cross-origin isolation](#)^{p884}, then return true.
5. [Queue a cross-origin embedder policy inheritance violation](#)^{p886} with *response*, "navigation", *parentPolicy*'s [reporting endpoint](#)^{p885}, "enforce", and *target*'s [container document](#)^{p843}'s [relevant settings object](#)^{p944}.
6. Return false.

To **check a global object's embedder policy** given a [WorkerGlobalScope](#)^{p1062} *workerGlobalScope*, an [environment settings object](#)^{p937} *owner*, and a [response](#) *response*:

1. If *workerGlobalScope* is not a [DedicatedWorkerGlobalScope](#)^{p1064} object, then return true.
2. Let *policy* be *workerGlobalScope*'s [embedder policy](#)^{p1063}.
3. Let *ownerPolicy* be *owner*'s [policy container](#)^{p937}'s [embedder policy](#)^{p886}.
4. If *ownerPolicy*'s [report-only value](#)^{p885} is [compatible with cross-origin isolation](#)^{p884} and *policy*'s [value](#)^{p885} is not, then [queue a cross-origin embedder policy inheritance violation](#)^{p886} with *response*, "worker initialization", *owner*'s *policy*'s [report only reporting endpoint](#)^{p885}, "reporting", and *owner*.
5. If *ownerPolicy*'s [value](#)^{p885} is not [compatible with cross-origin isolation](#)^{p884} or *policy*'s [value](#)^{p885} is [compatible with cross-origin isolation](#)^{p884}, then return true.
6. [Queue a cross-origin embedder policy inheritance violation](#)^{p886} with *response*, "worker initialization", *owner*'s *policy*'s [reporting endpoint](#)^{p885}, "enforce", and *owner*.
7. Return false.

To **queue a cross-origin embedder policy inheritance violation** given a [response](#) *response*, a string *type*, a string *endpoint*, a string *disposition*, and an [environment settings object](#)^{p937} *settings*:

1. Let *serialized* be the result of [serializing a response URL for reporting](#) with *response*.
2. Let *body* be a new object containing the following properties:

key	value
type	<i>type</i>
blockedURL	<i>serialized</i>
disposition	<i>disposition</i>

3. [Queue](#) *body* as the ["coep" report type](#)^{p885} for *endpoint* on *settings*.

7.9 Policy containers § p88 6

A **policy container** is a [struct](#) containing policies that apply to a [Document](#)^{p117}, a [WorkerGlobalScope](#)^{p1062}, or a [WorkletGlobalScope](#)^{p1089}. It has the following [items](#):

- A **CSP list**, which is a [CSP list](#). It is initially empty.
- An **embedder policy**, which is an [embedder policy](#)^{p884}. It is initially a new [embedder policy](#)^{p884}.

- A **referrer policy**, which is a [referrer policy](#). It is initially the [default referrer policy](#).

Move other policies into the policy container.

To **clone a policy container** given a [policy container](#)^{p886} *policyContainer*:

1. Let *clone* be a new [policy container](#)^{p886}.
2. **For each** *policy* in *policyContainer*'s [CSP list](#)^{p886}, **append** a copy of *policy* into *clone*'s [CSP list](#)^{p886}.
3. Set *clone*'s [embedder policy](#)^{p886} to a copy of *policyContainer*'s [embedder policy](#)^{p886}.
4. Set *clone*'s [referrer policy](#)^{p887} to *policyContainer*'s [referrer policy](#)^{p887}.
5. Return *clone*.

To determine whether a [URL](#) *url* **requires storing the policy container in history**:

1. If *url*'s [scheme](#) is "blob", then return false.
2. If *url* is [about:srcdoc](#)^{p90}, then return false.
3. If *url* is [local](#), then return true.
4. Return false.

To **create a policy container from a fetch response** given a [response](#) *response* and an [environment](#)^{p936}-or-null *environment*:

1. If *response*'s [URL](#)'s [scheme](#) is "blob", then return a [clone](#)^{p887} of *response*'s [URL](#)'s [blob URL entry](#)'s [environment](#)'s [policy container](#)^{p886}.
2. Let *result* be a new [policy container](#)^{p886}.
3. Set *result*'s [CSP list](#)^{p886} to the result of [parsing a response's Content Security Policies](#) given *response*.
4. If *environment* is non-null, then set *result*'s [embedder policy](#)^{p886} to the result of [obtaining an embedder policy](#)^{p885} given *response* and *environment*. Otherwise, set it to "[unsafe-none](#)^{p884}".
5. Set *result*'s [referrer policy](#)^{p887} to the result of [parsing the `Referrer-Policy` header](#) given *response*. [\[REFERRERPOLICY\]](#)^{p1310}
6. Return *result*.

To **determine navigation params policy container** given a [URL](#) *responseURL* and four [policy container](#)^{p886}-or-nulls *historyPolicyContainer*, *initiatorPolicyContainer*, *parentPolicyContainer*, and *responsePolicyContainer*:

1. If *historyPolicyContainer* is not null, then:
 1. Assert: *responseURL* [requires storing the policy container in history](#)^{p887}.
 2. Return a [clone](#)^{p887} of *historyPolicyContainer*.
2. If *responseURL* is [about:srcdoc](#)^{p90}, then:
 1. Assert: *parentPolicyContainer* is not null.
 2. Return a [clone](#)^{p887} of *parentPolicyContainer*.
3. If *responseURL* is [local](#) and *initiatorPolicyContainer* is not null, then return a [clone](#)^{p887} of *initiatorPolicyContainer*.
4. If *responsePolicyContainer* is not null, then return *responsePolicyContainer*.
5. Return a new [policy container](#)^{p886}.

To **initialize a worker global scope's policy container** given a [WorkerGlobalScope](#)^{p1062} *workerGlobalScope*, a [response](#) *response*, and an [environment](#)^{p936} *environment*:

1. If *workerGlobalScope*'s [url](#)^{p1063} is [local](#) but its [scheme](#) is not "blob":
 1. Assert: *workerGlobalScope*'s [owner set](#)^{p1062}'s [size](#) is 1.

2. Set `workerGlobalScope`'s `policy_container`^{p1063} to a `clone`^{p887} of `workerGlobalScope`'s `owner_set`^{p1062}[0]'s `relevant_settings_object`^{p944}'s `policy_container`^{p937}.
2. Otherwise, set `workerGlobalScope`'s `policy_container`^{p1063} to the result of `creating a policy container from a fetch response`^{p887} given `response` and `environment`.

7.10 Session history and navigation ^{p888}

7.10.1 Browsing sessions ^{p888}

A **browsing session** is See [whatwg/html issue #4782](#) and [whatwg/html issue #5350](#) for defining `browsing_session`^{p888}. It is roughly analogous to a `top-level browsing context`^{p844} except that it cannot be replaced due to a ``Cross-Origin-Opener-Policy`^{p877} header or navigation.

A `top-level browsing context`^{p844} has an associated **browsing session** which is a `browsing_session`^{p888}.

The **browsing session** of an `environment_settings_object`^{p937} `environment` is the result of running these steps:

1. Assert: `environment` has a `responsible document`^{p937}.
2. Return `environment`'s `responsible document`^{p937}'s `browsing context`^{p840}'s `top-level browsing context`^{p844}'s `browsing session`^{p888}.

7.10.2 The session history of browsing contexts ^{p888}

The sequence of `Document`^{p117}s in a `browsing context`^{p840} is its **session history**. Each `browsing context`^{p840}, including `child browsing contexts`^{p843}, has a distinct session history. A `browsing context`^{p840}'s session history consists of a flat list of `session history entries`^{p888}.

Each `Document`^{p117} object in a `browsing context`^{p840}'s `session history`^{p888} is associated with a unique `History`^{p890} object which must all model the same underlying `session history`^{p888}.

The `history` getter steps are to return `this`'s `associated Document`^{p856}'s `History`^{p890} instance.

A **session history entry** is a `struct` with the following `items`:

- **URL**, a `URL`
- **document**, a `Document`^{p117} or null

Note

Each entry, when first created, has a `Document`^{p117} for its `document`^{p888}. However, when a `Document`^{p117} is not `active`^{p844}, it's possible for it to be `discarded`^{p862} to free resources. The `URL`^{p888} and other data in the `session history entry`^{p888} is then used to bring a new `Document`^{p117} into being to take the place of the original, in the case where the user agent finds itself having to navigate to the entry.

Note

If a history navigation occurs, and the `Document`^{p117} for the destination `session history entry`^{p888} is not null (i.e., the predicate in step 1 of `traversing the history`^{p923} is false), that means the browser has cached that `Document`^{p117}. This cache is often called a back-forward cache, or bfcache (or perhaps "`blazingly fast`" cache).

- **serialized state**, which is `serialized state`^{p889} or null, initially null
- **policy container**, a `policy_container`^{p886} or null
- **scroll restoration mode**, a `scroll restoration mode`^{p889}, initially "`auto`^{p889}"
- **scroll position data**, which is scroll position data for the `document`^{p888}'s `restorable scrollable regions`^{p925}

- **browsing context name**, a [browsing context name](#)^{p849} or null, initially null
- **persisted user state**, which is [implementation-defined](#), initially null

Example

For example, some user agents might want to persist the values of form controls.

Note

User agents that persist the value of form controls are encouraged to also persist their directionality (the value of the element's [dir](#)^{p146} attribute). This prevents values from being displayed incorrectly after a history traversal when the user had originally entered the values with an explicit, non-default directionality.

Serialized state is a serialization (via [StructuredSerializeForStorage](#)^{p110}) of an object representing a user interface state. We sometimes informally refer to "state objects", which are the objects representing user interface state supplied by the author, or alternately the objects created by deserializing (via [StructuredDeserialize](#)^{p110}) serialized state.

Pages can [add](#)^{p894} [serialized state](#)^{p889} to the session history. These are then [deserialized](#)^{p110} and [returned to the script](#)^{p1302} when the user (or script) goes back in the history, thus enabling authors to use the "navigation" metaphor even in one-page applications.

Note

[Serialized state](#)^{p889} is intended to be used for two main purposes: first, storing a prepared description of the state in the [URL](#) so that in the simple case an author doesn't have to do the parsing (though one would still need the parsing for handling [URLs](#) passed around by users, so it's only a minor optimization). Second, so that the author can store state that one wouldn't store in the [URL](#) because it only applies to the current [Document](#)^{p117} instance and it would have to be reconstructed if a new [Document](#)^{p117} were opened.

An example of the latter would be something like keeping track of the precise coordinate from which a popup [div](#)^{p243} was made to animate, so that if the user goes back, it can be made to animate to the same location. Or alternatively, it could be used to keep a pointer into a cache of data that would be fetched from the server based on the information in the [URL](#), so that when going back and forward, the information doesn't have to be fetched again.

A **scroll restoration mode** indicates whether the user agent should restore the persisted scroll position (if any) when traversing to an [entry](#)^{p888}. A scroll restoration mode is one of the following:

"auto"

The user agent is responsible for restoring the scroll position upon navigation.

"manual"

The page is responsible for restoring the scroll position and the user agent does not attempt to do so automatically

Several contiguous entries in a session history can share the same [document](#)^{p888}. This can occur when the initial entry is reached via normal [navigation](#)^{p906}, and the following entry is added via [history.pushState\(\)](#)^{p894}. Or it can occur via [navigation to a fragment](#)^{p921}.

Note

All entries that share the same [document](#)^{p888} (and that are therefore merely different states of one particular document) are contiguous by definition.

User agents may [discard](#)^{p862} the [documents](#)^{p888} of entries with non-null [documents](#)^{p888}, as long as the following conditions are met:

- They must not discard the [document](#)^{p888} of the [current entry](#)^{p890}.
- They must not discard any [Document](#)^{p117} objects which are referenced from script.

Apart from these restrictions, this standard does not specify when user agents should discard an entry's [document](#)^{p888}, versus keeping it cached.

Note

[Discarding](#)^{p862} a [Document](#)^{p117} will set the corresponding [document](#)^{p888} item of any [session history entries](#)^{p888} to null. Subsequent navigations to those entries will result in the creation of a new [Document](#)^{p117} object, and set the [document](#)^{p888} item to it.

At any point, one of the entries in the session history is the **current entry**. This is the entry representing the [active document](#)^{p840} of the [browsing context](#)^{p840}. Which entry is the [current entry](#)^{p890} is changed by the algorithms defined in this specification, e.g., during [session history traversal](#)^{p923}.

Note

The [current entry](#)^{p890} is usually the initial entry created upon navigation. However, it can also be one of the contiguous entries that share the same [document](#)^{p888}, as described above.

Each [Document](#)^{p117} in a [browsing context](#)^{p840} can also have a **latest entry**. This is the entry for that [Document](#)^{p117} to which the [browsing context](#)^{p840}'s [session history](#)^{p888} was most recently traversed. When a [Document](#)^{p117} is created, it initially has no [latest entry](#)^{p890}.

7.10.3 The [History](#)^{p890} interface § p890

```
IDL enum ScrollRestoration { "auto", "manual" };

[Exposed=Window]
interface History {
  readonly attribute unsigned long length;
  attribute ScrollRestoration scrollRestoration;
  readonly attribute any state;
  undefined go(optional long delta = 0);
  undefined back();
  undefined forward();
  undefined pushState(any data, DOMString unused, optional USVString? url = null);
  undefined replaceState(any data, DOMString unused, optional USVString? url = null);
};
```

For web developers (non-normative)

[window.history](#)^{p888}.[length](#)^{p891}

Returns the number of entries in the [joint session history](#)^{p891}.

[window.history](#)^{p888}.[scrollRestoration](#)^{p891} [= value]

Returns the [scroll restoration mode](#)^{p888} of the current entry in the [session history](#)^{p888}.

Can be set, to change the [scroll restoration mode](#)^{p888} of the current entry in the [session history](#)^{p888}.

[window.history](#)^{p888}.[state](#)^{p891}

Returns the current [serialized state](#)^{p889}, deserialized into an object.

[window.history](#)^{p888}.[go](#)^{p891}([delta])

Goes back or forward the specified number of steps in the [joint session history](#)^{p891}.

A zero delta will reload the current page.

If the delta is out of range, does nothing.

[window.history](#)^{p888}.[back](#)^{p892}()

Goes back one step in the [joint session history](#)^{p891}.

If there is no previous page, does nothing.

[window.history](#)^{p888}.[forward](#)^{p892}()

Goes forward one step in the [joint session history](#)^{p891}.

If there is no next page, does nothing.

[window.history](#)^{p888}.[pushState](#)^{p894}(data, "")

Push a new entry into session history with the given *data* associated. The current entry's URL will be copied over and used for the new entry's URL.

(The second parameter exists for historical reasons, and cannot be omitted; passing the empty string is traditional.)

`window.historyp888.pushStatep894(data, "", url)`

Push a new entry into session history with the given *data* associated, and with its URL set to *url*.

If the current [Document^{p117}](#) cannot have its URL rewritten^{p894} to *url*, a `"SecurityError" DOMException` will be thrown. (The second parameter exists for historical reasons, and cannot be omitted; passing the empty string is traditional.)

`window.historyp888.replaceStatep894(data, "", url)`

Updates the data stored in the current session history entry to *data*.

(The second parameter exists for historical reasons, and cannot be omitted; passing the empty string is traditional.)

`window.historyp888.replaceStatep894(data, "", url)`

Updates the data stored in the current session history entry to *data*, and its URL to *url*.

If the current [Document^{p117}](#) cannot have its URL rewritten^{p894} to *url*, a `"SecurityError" DOMException` will be thrown. (The second parameter exists for historical reasons, and cannot be omitted; passing the empty string is traditional.)

The **joint session history** of a [top-level browsing context^{p844}](#) is the union of all the [session histories^{p888}](#) of all [browsing contexts^{p840}](#) of all the [fully active^{p844} Document^{p117}](#) objects that share that [top-level browsing context^{p844}](#), with all the entries that are [current entries^{p890}](#) in their respective [session histories^{p888}](#) removed except for the [current entry of the joint session history^{p891}](#).

The **current entry of the joint session history** is the entry that most recently became a [current entry^{p890}](#) in its [session history^{p888}](#).

Entries in the [joint session history^{p891}](#) are ordered chronologically by the time they were added to their respective [session histories^{p888}](#). Each entry has an index; the earliest entry has index 0, and the subsequent entries are numbered with consecutively increasing integers (1, 2, 3, etc.).

Note

Since each [Document^{p117}](#) in a [browsing context^{p840}](#) might have a different [event loop^{p968}](#), the actual state of the [joint session history^{p891}](#) can be somewhat nebulous. For example, two sibling [iframe^{p369}](#) elements could both [traverse^{p923}](#) from one unique origin to another at the same time, so their precise order might not be well-defined; similarly, since they might only find out about each other later, they might disagree about the length of the [joint session history^{p891}](#).

Each [History^{p890}](#) object has **state**, initially null.

The **length** getter steps are:

1. If *this*'s associated [Document^{p117}](#) is not [fully active^{p844}](#), then throw a `"SecurityError" DOMException`.
2. Return the number of entries in the [top-level browsing context^{p844}](#)'s [joint session history^{p891}](#).

The actual entries are not accessible from script.

The **scrollRestoration** getter steps are:

1. If *this*'s associated [Document^{p117}](#) is not [fully active^{p844}](#), then throw a `"SecurityError" DOMException`.
2. Return *this*'s [session history^{p888}](#)'s [current entry^{p890}](#)'s [scroll restoration mode^{p888}](#).

The **scrollRestoration^{p891}** setter steps are:

1. If *this*'s associated [Document^{p117}](#) is not [fully active^{p844}](#), then throw a `"SecurityError" DOMException`.
2. Set *this*'s [session history^{p888}](#)'s [current entry^{p890}](#)'s [scroll restoration mode^{p888}](#) to the given value.

The **state** getter steps are:

1. If *this*'s associated [Document^{p117}](#) is not [fully active^{p844}](#), then throw a `"SecurityError" DOMException`.
2. Return *this*'s [state^{p891}](#).

The **go(delta)** method steps are:

1. Let *document* be *this*'s associated [Document^{p117}](#).

2. If *document* is not [fully active](#)^{p844}, then throw a ["SecurityError" DOMException](#).
3. If *delta* is 0, then act as if the [location.reload\(\)](#)^{p983} method was called, and return.
4. [Traverse the history by a delta](#)^{p892} with *delta* and *document*'s [browsing context](#)^{p840}.

The [back\(\)](#) method steps are:

1. Let *document* be *this*'s associated [Document](#)^{p117}.
2. If *document* is not [fully active](#)^{p844}, then throw a ["SecurityError" DOMException](#).
3. [Traverse the history by a delta](#)^{p892} with -1 and *document*'s [browsing context](#)^{p840}.

The [forward\(\)](#) method steps are:

1. Let *document* be *this*'s associated [Document](#)^{p117}.
2. If *document* is not [fully active](#)^{p844}, then throw a ["SecurityError" DOMException](#).
3. [Traverse the history by a delta](#)^{p892} with $+1$ and *document*'s [browsing context](#)^{p840}.

Each [top-level browsing context](#)^{p844} has a **session history traversal queue**, initially empty, to which [tasks](#)^{p969} can be added.

Each [top-level browsing context](#)^{p844}, when created, must begin running the following algorithm, known as the **session history event loop** for that [top-level browsing context](#)^{p844}, [in parallel](#)^{p42}:

1. Wait until this [top-level browsing context](#)^{p844}'s [session history traversal queue](#)^{p892} is not empty.
2. Pull the first [task](#)^{p969} from this [top-level browsing context](#)^{p844}'s [session history traversal queue](#)^{p892}, and execute it.
3. Return to the first step of this algorithm.

The [session history event loop](#)^{p892} helps coordinate cross-browsing-context transitions of the [joint session history](#)^{p891}: since each [browsing context](#)^{p840} might, at any particular time, have a different [event loop](#)^{p968} (this can happen if the user navigates from `example.com` to `shop.example`), transitions would otherwise have to involve cross-event-loop synchronization.

To **traverse the history by a delta** given *delta* and [browsing context](#)^{p840} *source browsing context*, the user agent must append a [task](#)^{p969} to this [top-level browsing context](#)^{p844}'s [session history traversal queue](#)^{p892}, the [task](#)^{p969} consisting of running the following steps:

1. If the index of the [current entry of the joint session history](#)^{p891} plus *delta* is less than zero or greater than or equal to the number of items in the [joint session history](#)^{p891}, then return.
2. Let *specified entry* be the entry in the [joint session history](#)^{p891} whose index is the sum of *delta* and the index of the [current entry of the joint session history](#)^{p891}.
3. Let *specified browsing context* be the [browsing context](#)^{p840} of the *specified entry*.
4. If *source browsing context* is not [allowed to navigate](#)^{p847} *specified browsing context*, then return.
5. If the *specified browsing context*'s [active document](#)^{p840}'s [unload counter](#)^{p928} is greater than 0, then return.
6. [Queue a global task](#)^{p970} on the [history traversal task source](#)^{p978} given *specified browsing context*'s [active window](#)^{p840} to perform the following steps:
 1. If there is an ongoing attempt to navigate *specified browsing context* that has not yet [matured](#)^{p918} (i.e. it has not passed the point of making its [Document](#)^{p117} the [active document](#)^{p840}), then cancel that attempt to navigate the [browsing context](#)^{p840}.
 2. If the *specified browsing context*'s [active document](#)^{p840} is not the same [Document](#)^{p117} as the [Document](#)^{p117} of the *specified entry*, then run these substeps:
 1. If the result of calling [prompt to unload](#)^{p928} with the [active document](#)^{p840} of the *specified browsing context* is "refuse", then abort these steps.

2. [Unload](#)^{p928} the [active document](#)^{p840} of the *specified browsing context*.
3. [Traverse the history](#)^{p923} of the *specified browsing context* to the *specified entry* with [explicitHistoryNavigation](#)^{p923} set to true.

When the user navigates through a [browsing context](#)^{p840}, e.g. using a browser's back and forward buttons, the user agent must [traverse the history by a delta](#)^{p892} with a delta equivalent to the action specified by the user and the browsing context being operated on.

The **URL and history update steps**, given a [Document](#)^{p117} *document*, a [URL](#) *newURL*, an optional [serialized state](#)^{p889}-or-null **serializedData** (default null), and an optional boolean **isPush** (default false), are:

1. Let *browsingContext* be *document*'s [browsing context](#)^{p840}.
2. If *browsingContext* is [still on its initial about:blank Document](#)^{p118}, then set *isPush* to false.

Note

This means that [pushState\(\)](#)^{p894} on an [initial about:blank](#)^{p118} [Document](#)^{p117} behaves as a [replaceState\(\)](#)^{p894} call.

3. If *isPush* is true, then:
 1. Remove all the entries in *browsingContext*'s [session history](#)^{p888} after the [current entry](#)^{p890}. If the [current entry](#)^{p890} is the last entry in the session history, then no entries are removed.

Note

This [doesn't necessarily have to affect](#)^{p896} the user agent's user interface.

4. Add a [session history entry](#)^{p888} entry to *browsingContext*'s [session history](#)^{p888}, after the [current entry](#)^{p890}, with
 - *newURL* as the [URL](#)^{p888};
 - *document* as the [document](#)^{p888};
 - *serializedData* as the [serialized state](#)^{p888};
 - the [scroll restoration mode](#)^{p888} of the current entry in the [session history](#)^{p888} as the [scroll restoration mode](#)^{p888}.
5. Update the [current entry](#)^{p890} to be this newly added entry.
4. Otherwise:
 1. Let *entry* be *browsingContext*'s [session history](#)^{p888}'s [current entry](#)^{p890}.
 2. Set *entry*'s [URL](#)^{p888} to *newURL*.
 3. If *serializedData* is not null, then set *entry*'s [serialized state](#)^{p888} to *serializedData*.
 4. Update *entry* so that it represents a GET request, if it currently represents a non-GET request (e.g. it was the result of a POST submission).

What does this mean? This is not a part of the definition of [session history entry](#)^{p888}.

5. Set *document*'s [URL](#) to *newURL*.

Note

Since this is neither a [navigation](#)^{p906} of the [browsing context](#)^{p840} nor a [history traversal](#)^{p923}, it does not cause a [hashchange](#)^{p1301} event to be fired.

6. If *serializedData* is not null, then:

1. Let *state* be [StructuredDeserialize^{p110}](#)(*serializedData*, *document*'s [relevant Realm^{p944}](#)). If this throws an exception, catch it, ignore the exception, and set *state* to null.
2. Set *document*'s [History^{p890}](#) instance's [state^{p891}](#) to *state*.
7. Set the [current entry^{p890}](#)'s [document^{p888}](#)'s [latest entry^{p890}](#) to the [current entry^{p890}](#).

The [pushState\(*data*, *unused*, *url*\)](#) method steps are to run the [shared history push/replace state steps^{p894}](#) given [this](#), *data*, *url*, and true.

The [replaceState\(*data*, *unused*, *url*\)](#) method steps are to run the [shared history push/replace state steps^{p894}](#) given [this](#), *data*, *url*, and false.

The **shared history push/replace state steps**, given a [History^{p890}](#) *history*, a value *data*, a [scalar value string](#)-or-null *url*, and a boolean *isPush*, are:

1. Let *document* be *history*'s associated [Document^{p117}](#).
2. If *document* is not [fully active^{p844}](#), then throw a ["SecurityError" DOMException](#).
3. Optionally, return. (For example, the user agent might disallow calls to these methods that are invoked on a timer, or from event listeners that are not triggered in response to a clear user action, or that are invoked in rapid succession.)
4. Let *serializedData* be ? [StructuredSerializeForStorage^{p110}](#)(*data*).
5. Let *newURL* be the [session history^{p888}](#)'s [current entry^{p890}](#)'s [URL^{p888}](#).
6. If *url* is not null, then:
 1. [Parse^{p91}](#) *url*, relative to the [relevant settings object^{p944}](#) of *history*.
 2. If that fails, then throw a ["SecurityError" DOMException](#).
 3. Set *newURL* to the [resulting URL record^{p91}](#).
 4. If *document* [cannot have its URL rewritten^{p894}](#) to *newURL*, then throw a ["SecurityError" DOMException](#).
7. Run the [URL and history update steps^{p893}](#) given *document* and *newURL*, with [serializedData^{p893}](#) set to *serializedData* and [isPush^{p893}](#) set to *isPush*.

User agents may limit the number of state objects added to the session history per page. If a page hits the [implementation-defined](#) limit, user agents must remove the entry immediately after the first entry for that [Document^{p117}](#) object in the session history after having added the new entry. (Thus the state history acts as a FIFO buffer for eviction, but as a LIFO buffer for navigation.)

A [Document^{p117}](#) *document* **can have its URL rewritten** to a [URL](#) *targetURL* if the following algorithm returns true:

1. Let *documentURL* be *document*'s [URL](#).
2. If *targetURL* and *documentURL* differ in their [scheme](#), [username](#), [password](#), [host](#), or [port](#) components, then return false.
3. If *targetURL*'s [scheme](#) is an [HTTP\(S\) scheme](#), then return true. (Differences in [path](#), [query](#), and [fragment](#) are allowed for [http:](#) and [https:](#) URLs.)
4. If *targetURL*'s [scheme](#) is "file", and *targetURL* and *documentURL* differ in their [path](#) component, then return false. (Differences in [query](#) and [fragment](#) are allowed for file: URLs.)
5. If *targetURL* and *documentURL* differ in their [path](#) component or [query](#) components, then return false. (Only differences in [fragment](#) are allowed for other types of URLs.)
6. Return true.

Example

<i>document</i> 's URL	<i>targetURL</i>	can have its URL rewritten^{p894}
https://example.com/home	https://example.com/home#about	✓
https://example.com/home	https://example.com/home?page=shop	✓
https://example.com/home	https://example.com/shop	✓

document's URL	targetURL	can have its URL rewritten ^{p894}
https://example.com/home	https://user:pass@example.com/home	✗
https://example.com/home	http://example.com/home	✗
file:///path/to/x	file:///path/to/x#hash	✓
file:///path/to/x	file:///path/to/x?search	✓
file:///path/to/x	file:///path/to/y	✗
about:blank	about:blank#hash	✓
about:blank	about:blank?search	✗
about:blank	about:srcdoc	✗
data:text/html,foo	data:text/html,foo#hash	✓
data:text/html,foo	data:text/html,foo?search	✗
data:text/html,foo	data:text/html,bar	✗
data:text/html,foo	data:bar	✗
blob:https://example.com/77becafe-657b-4fdc-8bd3-e83aaa5e8f43	blob:https://example.com/77becafe-657b-4fdc-8bd3-e83aaa5e8f43#hash	✓
blob:https://example.com/77becafe-657b-4fdc-8bd3-e83aaa5e8f43	blob:https://example.com/77becafe-657b-4fdc-8bd3-e83aaa5e8f43?search	✗
blob:https://example.com/77becafe-657b-4fdc-8bd3-e83aaa5e8f43	blob:https://example.com/anything	✗
blob:https://example.com/77becafe-657b-4fdc-8bd3-e83aaa5e8f43	blob:path	✗

Note how only the [URL](#) of the [Document](#)^{p117} matters, and not its [origin](#). They can mismatch in cases like [about:blank](#)^{p51} [Document](#)^{p117}s with inherited origins, in sandboxed [iframe](#)^{p369}s, or when the [document.domain](#)^{p871} setter has been used.

Example

Consider a game where the user can navigate along a line, such that the user is always at some coordinate, and such that the user can bookmark the page corresponding to a particular coordinate, to return to it later.

A static page implementing the x=5 position in such a game could look like the following:

```
<!DOCTYPE HTML>
<!-- this is https://example.com/line?x=5 -->
<html lang="en">
<title>Line Game - 5</title>
<p>You are at coordinate 5 on the line.</p>
<p>
  <a href="?x=6">Advance to 6</a> or
  <a href="?x=4">retreat to 4</a>?
</p>
```

The problem with such a system is that each time the user clicks, the whole page has to be reloaded. Here instead is another way of doing it, using script:

```
<!DOCTYPE HTML>
<!-- this starts off as https://example.com/line?x=5 -->
<html lang="en">
<title>Line Game - 5</title>
<p>You are at coordinate <span id="coord">5</span> on the line.</p>
<p>
  <a href="?x=6" onclick="go(1); return false;">Advance to 6</a> or
  <a href="?x=4" onclick="go(-1); return false;">retreat to 4</a>?
</p>
<script>
  var currentPage = 5; // prefilled by server
  function go(d) {
    setupPage(currentPage + d);
```

```

    history.pushState(currentPage, "", '?x=' + currentPage);
  }
  onpopstate = function(event) {
    setupPage(event.state);
  }
  function setupPage(page) {
    currentPage = page;
    document.title = 'Line Game - ' + currentPage;
    document.getElementById('coord').textContent = currentPage;
    document.links[0].href = '?x=' + (currentPage+1);
    document.links[0].textContent = 'Advance to ' + (currentPage+1);
    document.links[1].href = '?x=' + (currentPage-1);
    document.links[1].textContent = 'retreat to ' + (currentPage-1);
  }
</script>

```

In systems without script, this still works like the previous example. However, users that *do* have script support can now navigate much faster, since there is no network access for the same experience. Furthermore, contrary to the experience the user would have with just a naïve script-based approach, bookmarking and navigating the session history still work.

In the example above, the *data* argument to the `pushState()`^{p894} method is the same information as would be sent to the server, but in a more convenient form, so that the script doesn't have to parse the URL each time the user navigates.

Example

Most applications want to use the same `scrollRestorationMode`^{p889} value for all of their history entries. To achieve this they can set the `scrollRestoration`^{p891} attribute as soon as possible (e.g., in the first `script`^{p624} element in the document's `head`^{p158} element) to ensure that any entry added to the history session gets the desired scroll restoration mode.

```

<head>
  <script>
    if ('scrollRestoration' in history)
      history.scrollRestoration = 'manual';
  </script>
</head>

```

7.10.4 Implementation notes for session history §^{p89}₆

This section is non-normative.

The `History`^{p890} interface is not meant to place restrictions on how implementations represent the session history to the user.

For example, session history could be implemented in a tree-like manner, with each page having multiple "forward" pages. This specification doesn't define how the linear list of pages in the `history`^{p888} object are derived from the actual session history as seen from the user's perspective.

Similarly, a page containing two `iframe`^{p369}s has a `history`^{p888} object distinct from the `iframe`^{p369}'s `history`^{p888} objects, despite the fact that typical web browsers present the user with just one "Back" button, with a session history that interleaves the navigation of the two inner frames and the outer page.

Security: It is suggested that to avoid letting a page "hijack" the history navigation facilities of a UA by abusing `pushState()`^{p894}, the UA provide the user with a way to jump back to the previous page (rather than just going back to the previous state). For example, the back button could have a drop down showing just the pages in the session history, and not showing any of the states. Similarly, an aural browser could have two "back" commands, one that goes back to the previous state, and one that jumps straight back to the previous page.

For both `pushState()`^{p894} and `replaceState()`^{p894}, user agents are encouraged to prevent abuse of these APIs via too-frequent calls or over-large state objects. As detailed above, the algorithm explicitly allows user agents to ignore any such calls when appropriate.

7.10.5 The [Location](#)^{p897} interface § p897

Each [Window](#)^{p855} object is associated with a unique instance of a [Location](#)^{p897} object, allocated when the [Window](#)^{p855} object is created.

⚠ Warning!

The [Location](#)^{p897} exotic object is defined through a mishmash of IDL, invocation of JavaScript internal methods post-creation, and overridden JavaScript internal methods. Coupled with its scary security policy, please take extra care while implementing this excrescence.

To create a [Location](#)^{p897} object, run these steps:

1. Let *location* be a new [Location](#)^{p897} platform object.
2. Let *valueOf* be *location*'s [relevant Realm](#)^{p944}.[\[\[Intrinsics\]\].\[\[%Object.prototype.valueOf%\]\]](#).
3. Perform ! *location*.[\[\[DefineOwnProperty\]\]](#)("valueOf", { [\[\[Value\]\]](#): *valueOf*, [\[\[Writable\]\]](#): false, [\[\[Enumerable\]\]](#): false, [\[\[Configurable\]\]](#): false }).
4. Perform ! *location*.[\[\[DefineOwnProperty\]\]](#)([@@toPrimitive](#)^{p54}, { [\[\[Value\]\]](#): undefined, [\[\[Writable\]\]](#): false, [\[\[Enumerable\]\]](#): false, [\[\[Configurable\]\]](#): false }).
5. Set the value of the [\[\[DefaultProperties\]\]](#)^{p903} internal slot of *location* to *location*.[\[\[OwnPropertyKeys\]\]](#)()
6. Return *location*.

Note

The addition of *valueOf* and [@@toPrimitive](#)^{p54} own data properties, as well as the fact that all of [Location](#)^{p897}'s IDL attributes are marked [\[LegacyUnforgeable\]](#), is required by legacy code that consulted the [Location](#)^{p897} interface, or stringified it, to determine the [document URL](#), and then used it in a security-sensitive way. In particular, the *valueOf*, [@@toPrimitive](#)^{p54}, and [\[LegacyUnforgeable\]](#) stringifier mitigations ensure that code such as `foo[location] = bar` or `location + ""` cannot be misdirected.

For web developers (non-normative)

`document.location`^{p897} [= value]

`window.location`^{p897} [= value]

Returns a [Location](#)^{p897} object with the current page's location.

Can be set, to navigate to another page.

The [Document](#)^{p117} object's **location** getter steps are to return [this](#)'s [relevant global object](#)^{p944}'s [Location](#)^{p897} object, if [this](#) is [fully active](#)^{p844}, and null otherwise.

The [Window](#)^{p855} object's **location** getter steps are to return [this](#)'s [Location](#)^{p897} object.

[Location](#)^{p897} objects provide a representation of the [URL](#) of the [active document](#)^{p840} of their [Document](#)^{p117}'s [browsing context](#)^{p840}, and allow the [current entry](#)^{p890} of the [browsing context](#)^{p840}'s session history to be changed, by adding or replacing entries in the [history](#)^{p888} object.

```
IDL [Exposed=Window]
interface Location { // but see also additional creation steps and overridden internal methods
  [LegacyUnforgeable] stringifier attribute USVString href;
  [LegacyUnforgeable] readonly attribute USVString origin;
  [LegacyUnforgeable] attribute USVString protocol;
  [LegacyUnforgeable] attribute USVString host;
  [LegacyUnforgeable] attribute USVString hostname;
  [LegacyUnforgeable] attribute USVString port;
  [LegacyUnforgeable] attribute USVString pathname;
  [LegacyUnforgeable] attribute USVString search;
  [LegacyUnforgeable] attribute USVString hash;

  [LegacyUnforgeable] undefined assign(USVString url);
  [LegacyUnforgeable] undefined replace(USVString url);
```

```
[LegacyUnforgeable] undefined reload();

[LegacyUnforgeable, SameObject] readonly attribute DOMStringList ancestorOrigins;
};
```

For web developers (non-normative)

`Location.toString()`

`Location.href`^{p899}

Returns the [Location](#)^{p897} object's URL.

Can be set, to navigate to the given URL.

`Location.origin`^{p899}

Returns the [Location](#)^{p897} object's URL's origin.

`Location.protocol`^{p899}

Returns the [Location](#)^{p897} object's URL's scheme.

Can be set, to navigate to the same URL with a changed scheme.

`Location.host`^{p900}

Returns the [Location](#)^{p897} object's URL's host and port (if different from the default port for the scheme).

Can be set, to navigate to the same URL with a changed host and port.

`Location.hostname`^{p900}

Returns the [Location](#)^{p897} object's URL's host.

Can be set, to navigate to the same URL with a changed host.

`Location.port`^{p900}

Returns the [Location](#)^{p897} object's URL's port.

Can be set, to navigate to the same URL with a changed port.

`Location.pathname`^{p901}

Returns the [Location](#)^{p897} object's URL's path.

Can be set, to navigate to the same URL with a changed path.

`Location.search`^{p901}

Returns the [Location](#)^{p897} object's URL's query (includes leading "?" if non-empty).

Can be set, to navigate to the same URL with a changed query (ignores leading "?").

`Location.hash`^{p902}

Returns the [Location](#)^{p897} object's URL's fragment (includes leading "#" if non-empty).

Can be set, to navigate to the same URL with a changed fragment (ignores leading "#").

`Location.assign`^{p902} (*url*)

Navigates to the given URL.

`Location.replace`^{p902} (*url*)

Removes the current page from the session history and navigates to the given URL.

`Location.reload`^{p903} ()

Reloads the current page.

`Location.ancestorOrigins`^{p903}

Returns a [DOMStringList](#)^{p104} object listing the origins of the ancestor [browsing contexts](#)^{p840}, from the [parent browsing context](#)^{p843} to the [top-level browsing context](#)^{p844}.

A [Location](#)^{p897} object has an associated **relevant Document**, which is this [Location](#)^{p897} object's [relevant global object](#)^{p944}'s [browsing context](#)^{p856}'s [active document](#)^{p840}, if this [Location](#)^{p897} object's [relevant global object](#)^{p944}'s [browsing context](#)^{p856} is non-null, and null otherwise.

A [Location](#)^{p897} object has an associated **url**, which is this [Location](#)^{p897} object's [relevant Document](#)^{p898}'s **URL**, if this [Location](#)^{p897} object's [relevant Document](#)^{p898} is non-null, and [about:blank](#)^{p51} otherwise.

A [Location](#)^{p897} object has an associated **ancestor origins list**. When a [Location](#)^{p897} object is created, its [ancestor origins list](#)^{p899} must be set to a [DOMStringList](#)^{p104} object whose associated list is the [list](#) of strings that the following steps would produce:

1. Let *output* be a new [list](#) of strings.
2. Let *current* be the [browsing context](#)^{p840} of the [Document](#)^{p117} with which this [Location](#)^{p897} object is associated.
3. *Loop*: If *current* has no [parent browsing context](#)^{p843}, jump to the step labeled *end*.
4. Let *current* be *current*'s [parent browsing context](#)^{p843}.
5. [Append](#) the [serialization](#)^{p869} of *current*'s [active document](#)^{p840}'s [origin](#) to *output*.
6. Return to the step labeled *loop*.
7. *End*: Return *output*.

To **Location-object navigate**, given a [URL](#) *url* and an optional [history handling behavior](#)^{p906} *historyHandling* (default "[default](#)^{p906}"):

1. Let *browsingContext* be this [Location](#)^{p897} object's [relevant global object](#)^{p944}'s [browsing context](#)^{p856}.
2. Let *sourceBrowsingContext* be the [incumbent global object](#)^{p942}'s [browsing context](#)^{p856}.
3. If this [Location](#)^{p897} object's [relevant Document](#)^{p898} is not yet [completely loaded](#)^{p927}, and the [incumbent global object](#)^{p942} does not have [transient activation](#)^{p795}, then set *historyHandling* to "[replace](#)^{p906}".
4. [Navigate](#)^{p906} *browsingContext* to *url*, with [exceptionsEnabled](#)^{p906} set to true, [historyHandling](#)^{p906} set to *historyHandling*, and the [source browsing context](#)^{p906} set to *sourceBrowsingContext*.

The **href** getter steps are:

1. If *this*'s [relevant Document](#)^{p898} is non-null and its [origin](#) is not [same origin-domain](#)^{p869} with the [entry settings object](#)^{p941}'s [origin](#)^{p937}, then throw a "[SecurityError](#)" [DOMException](#).
2. Return *this*'s [url](#)^{p898}, [serialized](#).

The **href**^{p899} setter steps are:

1. If *this*'s [relevant Document](#)^{p898} is null, then return.
2. [Parse](#)^{p91} the given value relative to the [entry settings object](#)^{p941}. If that failed, throw a [TypeError](#) exception.
3. [Location-object navigate](#)^{p899} given the [resulting URL record](#)^{p91}.

Note

The **href**^{p899} setter intentionally has no security check.

The **origin** getter steps are:

1. If *this*'s [relevant Document](#)^{p898} is non-null and its [origin](#) is not [same origin-domain](#)^{p869} with the [entry settings object](#)^{p941}'s [origin](#)^{p937}, then throw a "[SecurityError](#)" [DOMException](#).
2. Return the [serialization](#)^{p869} of *this*'s [url](#)^{p898}'s [origin](#).

The **protocol** getter steps are:

1. If *this*'s [relevant Document](#)^{p898} is non-null and its [origin](#) is not [same origin-domain](#)^{p869} with the [entry settings object](#)^{p941}'s [origin](#)^{p937}, then throw a "[SecurityError](#)" [DOMException](#).
2. Return *this*'s [url](#)^{p898}'s [scheme](#), followed by " : ".

The **protocol**^{p899} setter steps are:

1. If *this*'s [relevant Document](#)^{p898} is null, then return.
2. If *this*'s [relevant Document](#)^{p898}'s [origin](#) is not [same origin-domain](#)^{p869} with the [entry settings object](#)^{p941}'s [origin](#)^{p937}, then throw a "[SecurityError](#)" [DOMException](#).

3. Let *copyURL* be a copy of [this's url^{p898}](#).
4. Let *possibleFailure* be the result of [basic URL parsing](#) the given value, followed by ":", with *copyURL* as *url* and [scheme start state](#) as *state override*.

Note

Because the URL parser ignores multiple consecutive colons, providing a value of "https:" (or even "https:::") is the same as providing a value of "https".

5. If *possibleFailure* is failure, then throw a ["SyntaxError" DOMException](#).
6. If *copyURL*'s [scheme](#) is not an [HTTP\(S\) scheme](#), then terminate these steps.
7. [Location-object navigate^{p899}](#) to *copyURL*.

The **host** getter steps are:

1. If [this's relevant Document^{p898}](#) is non-null and its [origin](#) is not [same origin-domain^{p869}](#) with the [entry settings object^{p941}](#)'s [origin^{p937}](#), then throw a ["SecurityError" DOMException](#).
2. Let *url* be [this's url^{p898}](#).
3. If *url*'s [host](#) is null, return the empty string.
4. If *url*'s [port](#) is null, return *url*'s [host, serialized](#).
5. Return *url*'s [host, serialized](#), followed by ":" and *url*'s [port, serialized](#).

The [host^{p900}](#) setter steps are:

1. If [this's relevant Document^{p898}](#) is null, then return.
2. If [this's relevant Document^{p898}](#)'s [origin](#) is not [same origin-domain^{p869}](#) with the [entry settings object^{p941}](#)'s [origin^{p937}](#), then throw a ["SecurityError" DOMException](#).
3. Let *copyURL* be a copy of [this's url^{p898}](#).
4. If *copyURL* has an [opaque path](#), then return.
5. [Basic URL parse](#) the given value, with *copyURL* as *url* and [host state](#) as *state override*.
6. [Location-object navigate^{p899}](#) to *copyURL*.

The **hostname** getter steps are:

1. If [this's relevant Document^{p898}](#) is non-null and its [origin](#) is not [same origin-domain^{p869}](#) with the [entry settings object^{p941}](#)'s [origin^{p937}](#), then throw a ["SecurityError" DOMException](#).
2. If [this's url^{p898}](#)'s [host](#) is null, return the empty string.
3. Return [this's url^{p898}](#)'s [host, serialized](#).

The [hostname^{p900}](#) setter steps are:

1. If [this's relevant Document^{p898}](#) is null, then return.
2. If [this's relevant Document^{p898}](#)'s [origin](#) is not [same origin-domain^{p869}](#) with the [entry settings object^{p941}](#)'s [origin^{p937}](#), then throw a ["SecurityError" DOMException](#).
3. Let *copyURL* be a copy of [this's url^{p898}](#).
4. If *copyURL* has an [opaque path](#), then return.
5. [Basic URL parse](#) the given value, with *copyURL* as *url* and [hostname state](#) as *state override*.
6. [Location-object navigate^{p899}](#) to *copyURL*.

The **port** getter steps are:

1. If [this's relevant Document^{p898}](#) is non-null and its [origin](#) is not [same origin-domain^{p869}](#) with the [entry settings object^{p941}](#)'s

[origin^{p937}](#), then throw a ["SecurityError" DOMException](#).

2. If [this's url^{p898}'s port](#) is null, return the empty string.
3. Return [this's url^{p898}'s port, serialized](#).

The [port^{p900}](#) setter steps are:

1. If [this's relevant Document^{p898}](#) is null, then return.
2. If [this's relevant Document^{p898}'s origin](#) is not [same origin-domain^{p869}](#) with the [entry settings object^{p941}'s origin^{p937}](#), then throw a ["SecurityError" DOMException](#).
3. Let *copyURL* be a copy of [this's url^{p898}](#).
4. If *copyURL* [cannot have a username/password/port](#), then return.
5. If the given value is the empty string, then set *copyURL*'s [port](#) to null.
6. Otherwise, [basic URL parse](#) the given value, with *copyURL* as *url* and [port state](#) as *state override*.
7. [Location-object navigate^{p899}](#) to *copyURL*.

The [pathname](#) getter steps are:

1. If [this's relevant Document^{p898}](#) is non-null and its [origin](#) is not [same origin-domain^{p869}](#) with the [entry settings object^{p941}'s origin^{p937}](#), then throw a ["SecurityError" DOMException](#).
2. Return the result of [URL path serializing](#) this [Location^{p897}](#) object's [url^{p898}](#).

The [pathname^{p901}](#) setter steps are:

1. If [this's relevant Document^{p898}](#) is null, then return.
2. If [this's relevant Document^{p898}'s origin](#) is not [same origin-domain^{p869}](#) with the [entry settings object^{p941}'s origin^{p937}](#), then throw a ["SecurityError" DOMException](#).
3. Let *copyURL* be a copy of [this's url^{p898}](#).
4. If *copyURL* has an [opaque path](#), then return.
5. Set *copyURL*'s [path](#) to the empty list.
6. [Basic URL parse](#) the given value, with *copyURL* as *url* and [path start state](#) as *state override*.
7. [Location-object navigate^{p899}](#) to *copyURL*.

The [search](#) getter steps are:

1. If [this's relevant Document^{p898}](#) is non-null and its [origin](#) is not [same origin-domain^{p869}](#) with the [entry settings object^{p941}'s origin^{p937}](#), then throw a ["SecurityError" DOMException](#).
2. If [this's url^{p898}'s query](#) is either null or the empty string, return the empty string.
3. Return "?", followed by [this's url^{p898}'s query](#).

The [search^{p901}](#) setter steps are:

1. If [this's relevant Document^{p898}](#) is null, then return.
2. If [this's relevant Document^{p898}'s origin](#) is not [same origin-domain^{p869}](#) with the [entry settings object^{p941}'s origin^{p937}](#), then throw a ["SecurityError" DOMException](#).
3. Let *copyURL* be a copy of [this's url^{p898}](#).
4. If the given value is the empty string, set *copyURL*'s [query](#) to null.
5. Otherwise, run these substeps:
 1. Let *input* be the given value with a single leading "?" removed, if any.

2. Set `copyURL`'s `query` to the empty string.
3. `Basic URL parse input`, with null, the `relevant Document`'s `document's character encoding`, `copyURL` as `url`, and `query state` as `state override`.
6. `Location-object navigate` to `copyURL`.

The `hash` getter steps are:

1. If `this`'s `relevant Document` is non-null and its `origin` is not `same origin-domain` with the `entry settings object`'s `origin`, then throw a `"SecurityError" DOMException`.
2. If `this`'s `url`'s `fragment` is either null or the empty string, return the empty string.
3. Return `"#"`, followed by `this`'s `url`'s `fragment`.

The `hash` setter steps are:

1. If `this`'s `relevant Document` is null, then return.
2. If `this`'s `relevant Document`'s `origin` is not `same origin-domain` with the `entry settings object`'s `origin`, then throw a `"SecurityError" DOMException`.
3. Let `copyURL` be a copy of `this`'s `url`.
4. Let `input` be the given value with a single leading `"#"` removed, if any.
5. Set `copyURL`'s `fragment` to the empty string.
6. `Basic URL parse input`, with `copyURL` as `url` and `fragment state` as `state override`.
7. If `copyURL`'s `fragment` is `this`'s `url`'s `fragment`, then return.

Note

This bailout is necessary for compatibility with deployed content, which redundantly sets `location.hash` on scroll. It does not apply to other mechanisms of fragment navigation, such as the `location.href` setter or `location.assign()`.

8. `Location-object navigate` to `copyURL`.

Note

Unlike the equivalent API for the `a` and `area` elements, the `hash` setter does not special case the empty string, to remain compatible with deployed scripts.

The `assign(url)` method steps are:

1. If `this`'s `relevant Document` is null, then return.
2. If `this`'s `relevant Document`'s `origin` is not `same origin-domain` with the `entry settings object`'s `origin`, then throw a `"SecurityError" DOMException`.
3. `Parse url` relative to the `entry settings object`. If that failed, throw a `"SyntaxError" DOMException`.
4. `Location-object navigate` given the `resulting URL record`.

The `replace(url)` method steps are:

1. If `this`'s `relevant Document` is null, then return.
2. `Parse url` relative to the `entry settings object`. If that failed, throw a `"SyntaxError" DOMException`.
3. `Location-object navigate` given the `resulting URL record` and `"replace"`.

Note

The `replace()` method intentionally has no security check.

The `reload()` method steps are to run the appropriate steps from the following list:

- ↪ If [this's relevant Document](#)^{p898} is null
Return.
- ↪ If [this's relevant Document](#)^{p898}'s [origin](#) is not [same origin-domain](#)^{p869} with the [entry settings object](#)^{p941}'s [origin](#)^{p937}
Throw a `"SecurityError"` `DOMException`.
- ↪ If the currently executing [task](#)^{p969} is the dispatch of a `resize` event in response to the user resizing the [browsing context](#)^{p840}
Repaint the [browsing context](#)^{p840} and return.
- ↪ If the [browsing context](#)^{p840}'s [active document](#)^{p840} is an [iframe srcdoc document](#)^{p370}
Reprocess the [iframe attributes](#)^{p372} of the [browsing context](#)^{p840}'s [container](#)^{p843}.
- ↪ Otherwise
[Navigate](#)^{p906} the [browsing context](#)^{p840} to [this's relevant Document](#)^{p898}'s [URL](#), with [exceptionsEnabled](#)^{p906} set to true, [historyHandling](#)^{p906} set to `"reload"`^{p906}, and the [source browsing context](#)^{p906} set to the [browsing context](#)^{p840} being navigated.

When a user requests that the [active document](#)^{p840} of a [browsing context](#)^{p840} be reloaded through a user interface element, the user agent should [navigate](#)^{p906} the [browsing context](#)^{p840} to the same resource as that [Document](#)^{p117}, with [historyHandling](#)^{p906} set to `"reload"`^{p906}. In the case of non-idempotent methods (e.g., HTTP POST), the user agent should prompt the user to confirm the operation first, since otherwise transactions (e.g., purchases or database modifications) could be repeated. User agents may allow the user to explicitly override any caches when reloading.

The `ancestorOrigins` getter steps are:

1. If [this's relevant Document](#)^{p898} is null, then return an empty [list](#).
2. If [this's relevant Document](#)^{p898}'s [origin](#) is not [same origin-domain](#)^{p869} with the [entry settings object](#)^{p941}'s [origin](#)^{p937}, then throw a `"SecurityError"` `DOMException`.
3. Otherwise, return [this's ancestor origins list](#)^{p899}.

⚠Warning!

The details of how the `ancestorOrigins`^{p983} attribute works are still controversial and might change. See [issue #1918](#) for more information.

As explained earlier, the [Location](#)^{p897} exotic object requires additional logic beyond IDL for security purposes. The [Location](#)^{p897} object must use the ordinary internal methods except where it is explicitly specified otherwise below.

Also, every [Location](#)^{p897} object has a **[[DefaultProperties]]** internal slot representing its own properties at time of its creation.

7.10.5.1 **[[GetPrototypeOf]]** () §^{p90}₃

1. If [IsPlatformObjectSameOrigin](#)^{p852}(**this**) is true, then return ! [OrdinaryGetPrototypeOf](#)(**this**).
2. Return null.

7.10.5.2 **[[SetPrototypeOf]]** (V) §^{p90}₃

1. Return ! [SetImmutablePrototype](#)(**this**, V).

7.10.5.3 **[[IsExtensible]]** () §^{p90}₄

1. Return true.

7.10.5.4 **[[PreventExtensions]]** () §^{p90}₄

1. Return false.

7.10.5.5 **[[GetOwnProperty]]** (*P*) §^{p90}₄

1. If [IsPlatformObjectSameOrigin^{p852}](#)(**this**) is true, then:
 1. Let *desc* be [OrdinaryGetOwnProperty](#)(**this**, *P*).
 2. If the value of the [\[\[DefaultProperties\]\]^{p903}](#) internal slot of **this** contains *P*, then set *desc*.[[Configurable]] to true.
 3. Return *desc*.
2. Let *property* be [CrossOriginGetOwnPropertyHelper^{p853}](#)(**this**, *P*).
3. If *property* is not undefined, then return *property*.
4. Return ? [CrossOriginPropertyFallback^{p852}](#)(*P*).

7.10.5.6 **[[DefineOwnProperty]]** (*P*, *Desc*) §^{p90}₄

1. If [IsPlatformObjectSameOrigin^{p852}](#)(**this**) is true, then:
 1. If the value of the [\[\[DefaultProperties\]\]^{p903}](#) internal slot of **this** contains *P*, then return false.
 2. Return ? [OrdinaryDefineOwnProperty](#)(**this**, *P*, *Desc*).
2. Throw a ["SecurityError" DOMException](#).

7.10.5.7 **[[Get]]** (*P*, *Receiver*) §^{p90}₄

1. If [IsPlatformObjectSameOrigin^{p852}](#)(**this**) is true, then return ? [OrdinaryGet](#)(**this**, *P*, *Receiver*).
2. Return ? [CrossOriginGet^{p854}](#)(**this**, *P*, *Receiver*).

7.10.5.8 **[[Set]]** (*P*, *V*, *Receiver*) §^{p90}₄

1. If [IsPlatformObjectSameOrigin^{p852}](#)(**this**) is true, then return ? [OrdinarySet](#)(**this**, *P*, *V*, *Receiver*).
2. Return ? [CrossOriginSet^{p854}](#)(**this**, *P*, *V*, *Receiver*).

7.10.5.9 **[[Delete]]** (*P*) §^{p90}₄

1. If [IsPlatformObjectSameOrigin^{p852}](#)(**this**) is true, then return ? [OrdinaryDelete](#)(**this**, *P*).
2. Throw a ["SecurityError" DOMException](#).

7.10.5.10 `[[OwnPropertyKeys]]` () §^{p90}₅

1. If `IsPlatformObjectSameOrigin`^{p852}(**this**) is true, then return `OrdinaryOwnPropertyKeys`(**this**).
2. Return `CrossOriginOwnPropertyKeys`^{p854}(**this**).

7.11 Browsing the web §^{p90}₅

7.11.1 Navigating across documents §^{p90}₅

Certain actions cause the `browsing context`^{p840} to `navigate`^{p906} to a new resource. A user agent may provide various ways for the user to explicitly cause a browsing context to navigate, in addition to those defined in this specification.

Example

For example, `following a hyperlink`^{p296}, `form submission`^{p606}, and the `window.open()`^{p858} and `location.assign()`^{p902} methods can all cause a browsing context to navigate.

Note

A resource has a URL, but that might not be the only information necessary to identify it. For example, a form submission that uses HTTP POST would also have the HTTP method and payload. Similarly, `an iframe srcdoc document`^{p370} needs to know the data it is to use.

Much of the navigation process is concerned with determining how to create a new `Document`^{p117}, which ultimately happens in the `create and initialize a Document object`^{p914} algorithm. The parameters to this algorithm are tracked via a **navigation params struct**, which has the following `items`:

id

a `navigation id`^{p906}

request

null or a `request` that started the navigation

response

a `response` that ultimately was navigated to (potentially a `network error`)

origin

an `origin`^{p868} to use for the new `Document`^{p117}

policy container

a `policy container`^{p886} to use for the new `Document`^{p117}

final sandboxing flag set

a `sandboxing flag set`^{p873} to impose on the new `Document`^{p117}

cross-origin opener policy

a `cross-origin opener policy`^{p876} to use for the new `Document`^{p117}

COOP enforcement result

a `cross-origin opener policy enforcement result`^{p878}, used for reporting and potentially for causing a `browsing context group switch`^{p878}

reserved environment

null or an `environment`^{p936} reserved for the new `Document`^{p117}

browsing context

the `browsing context`^{p840} to be navigated (or discarded, if a `browsing context group switch`^{p878} occurs)

history handling

a `history handling behavior`^{p906}

has cross-origin redirects

a boolean

unsafe start time

a number, representing a value of the [unsafe shared current time](#) when the navigation has started

Note

Once a [navigation params](#)^{p905} struct is created, this standard does not mutate any of its [items](#). They are only passed onward to other algorithms.

After [Document](#)^{p117} creation, the [session history](#)^{p888} gets updated. A **history handling behavior** is used to track the desired type of session history update throughout the navigation process. It is one of the following:

"default"

A regular navigation which adds a new entry to the session history.

"entry update"

A navigation to an existing [session history entry](#)^{p888} to recreate that entry's [document](#)^{p888}, which was previously [discarded](#)^{p862}.

"reload"

A navigation intended to reload the current page and replace the [current session history entry](#)^{p890}.

"replace"

A non-reload navigation that will replace the [current session history entry](#)^{p890}.

Navigation always involves **source browsing context**, which is the browsing context which was responsible for starting the navigation.

As explained in [issue #1130](#) the use of a browsing context as source might not be the correct architecture.

A navigation has a **navigation id**, which is a unique string.

To **navigate** a browsing context *browsingContext* to a resource *resource*, with an optional boolean **exceptionsEnabled** (default false), an optional [history handling behavior](#)^{p906} **historyHandling** (default ["default"](#)^{p906}), an optional [policy container](#)^{p886}-or-null **historyPolicyContainer** (default null), an optional string **navigationType** (default "other"), and an optional [navigation id](#)^{p906} **navigationId** (default null):

1. Let *unsafeNavigationStartTime* be the [unsafe shared current time](#).
2. If *resource* is a [URL](#), then set *resource* to a new [request](#) whose [URL](#) is *resource*.
3. If *resource* is a [request](#) and *historyHandling* is ["reload"](#)^{p906}, then set *resource*'s [reload-navigation flag](#).
4. If the [source browsing context](#)^{p906} is not [allowed to navigate](#)^{p847} *browsingContext*, then:
 1. If *exceptionsEnabled* is given and is true, then throw a ["SecurityError" DOMException](#).
 2. Otherwise, the user agent may instead offer to open *resource* in a new [top-level browsing context](#)^{p844} or in the [top-level browsing context](#)^{p844} of the [source browsing context](#)^{p906}, at the user's option, in which case the user agent must [navigate](#)^{p906} that designated [top-level browsing context](#)^{p844} to *resource* as if the user had requested it independently.

Note

Doing so, however, can be dangerous, as it means that the user is overriding the author's explicit request to sandbox the content.

5. If *navigationId* is null:
 1. *historyHandling* is ["reload"](#)^{p906}, and *browsingContext*'s [active document](#)^{p840}'s [navigation id](#)^{p118} is not null, let *navigationId* be *browsingContext*'s [active document](#)^{p840}'s [navigation id](#)^{p118}. Otherwise let *navigation id* be the result of [generating a random UUID](#). [UUID]^{p1312}
6. If *browsingContext*'s [active document](#)^{p840}'s [unload counter](#)^{p928} is greater than 0, then invoke [WebDriver BiDi navigation failed](#) with a [WebDriver BiDi navigation status](#) whose *id* is *navigationId*, *status* is ["canceled"](#), and *url* is *resource*'s *url*, and return.
7. If *historyHandling* is ["default"](#)^{p906}, and any of the following are true:

- *browsingContext* is [still on its initial about:blank Document](#)^{p118}
- *resource* is a [request](#) whose [URL equals](#) *browsingContext*'s [active document](#)^{p840}'s [URL](#)
- *resource* is a [request](#) whose [URL's scheme](#) is "[javascript](#)^{p913}"

then set *historyHandling* to "[replace](#)^{p906}".

- If *historyHandling* is not "[reload](#)^{p906}", *resource* is a [request](#), *resource*'s [URL equals](#) *browsingContext*'s [active document](#)^{p840}'s [URL](#) with [exclude fragments](#) set to true, and *resource*'s [URL's fragment](#) is non-null, then:
 - [Navigate to a fragment](#)^{p921} given *browsingContext*, *resource*'s [URL](#), *historyHandling*, and *navigationId*.
 - Return.
- Let *incumbentNavigationOrigin* be the [origin](#)^{p868} of the [incumbent settings object](#)^{p941}, or if no [script](#)^{p624} was involved, the [origin](#) of the [node document](#) of the element that initiated the [navigation](#)^{p906}.
- Let *initiatorPolicyContainer* be a [clone](#)^{p887} of the [source browsing context](#)^{p906}'s [active document](#)^{p840}'s [policy container](#)^{p118}.
- If *resource* is a [request](#), then set *resource*'s [policy container](#) to *initiatorPolicyContainer*.
- Cancel any preexisting but not yet [mature](#)^{p918} attempt to navigate *browsingContext*, including canceling any instances of the [fetch](#) algorithm started by those attempts. If one of those attempts has already [created and initialized a new Document object](#)^{p914}, [abort](#)^{p930} that [Document](#)^{p117} also. (Navigation attempts that have [matured](#)^{p918} already have session history entries, and are therefore handled during the [update the session history with the new page](#)^{p917} algorithm, later.)
- Let *unloadPromptResult* be the result of calling [prompt to unload](#)^{p928} with the [active document](#)^{p840} of *browsingContext*.
If this instance of the [navigation](#)^{p906} algorithm gets canceled while this step is running, the [prompt to unload](#)^{p928} algorithm must nonetheless be run to completion.
- Switch on *unloadPromptResult*:
 - ↪ "no-prompt"
Do nothing.
 - ↪ "confirm"
Set *unsafeNavigationStartTime* to the [unsafe shared current time](#).
 - ↪ "refuse"
Return a new [WebDriver BiDi navigation status](#) whose [id](#) is *navigationId* and [status](#) is "[canceled](#)".
- [Abort](#)^{p930} the [active document](#)^{p840} of *browsingContext*.
- If *browsingContext* is a [child browsing context](#)^{p843}, then put it in the [delaying load events mode](#)^{p845}.
The user agent must take this [child browsing context](#)^{p843} out of the [delaying load events mode](#)^{p845} when this [navigation](#)^{p906} algorithm later [matures](#)^{p918}, or when it terminates (whether due to having run all the steps, or being canceled, or being aborted), whichever happens first.
- Let *sandboxFlags* be the result of [determining the creation sandboxing flags](#)^{p876} given *browsingContext* and *browsingContext*'s [container](#)^{p843}.
- Let *allowedToDownload* be the result of running the [allowed to download](#)^{p296} algorithm given the [source browsing context](#)^{p906} and *browsingContext*.
- Let *hasTransientActivation* be true if the [source browsing context](#)^{p906}'s [active window](#)^{p840} has [transient activation](#)^{p795}; otherwise false.
- Invoke [WebDriver BiDi navigation started](#) with *browsingContext*, and a new [WebDriver BiDi navigation status](#) whose [id](#) is *navigationId*, [url](#) is *resource*'s [url](#), and [status](#) is "[pending](#)".
- Return, and continue running these steps [in parallel](#)^{p42}.
- This is the step that attempts to obtain *resource*, if necessary. Jump to the first appropriate substep:

If *resource* is a [response](#)

1. Assert: *browsingContext* is not a [top-level browsing context](#)^{p844}.

2. Let *finalSandboxFlags* be the [union](#) of *browsingContext*'s [sandboxing flags](#)^{p876} and *resource*'s [forced sandboxing flag set](#)^{p875}.
3. Let *responseOrigin* be the result of [determining the origin](#)^{p841} given *browsingContext*, *resource*'s [url](#), *finalSandboxFlags*, and *incumbentNavigationOrigin*.
4. Let *coop* be a new [cross-origin opener policy](#)^{p876}.
5. Let *coopEnforcementResult* be a new [cross-origin opener policy enforcement result](#)^{p878} whose [needs a browsing context group switch](#)^{p878} is false, [would need a browsing context group switch due to report-only](#)^{p878} is false, [url](#)^{p878} is *resource*'s [url](#), [origin](#)^{p878} is *responseOrigin*, [cross-origin opener policy](#)^{p878} is *coop*, and [current context is navigation source](#)^{p878} is false.
6. Let *policyContainer* be the result of [determining navigation params policy container](#)^{p887} given *resource*'s [url](#), *historyPolicyContainer*, *initiatorPolicyContainer*, *browsingContext*'s [parent browsing context](#)^{p843}'s [active document](#)^{p840}'s [policy container](#)^{p118}, and null.
7. Let *navigationParams* be a new [navigation params](#)^{p905} whose [id](#)^{p905} is *navigationId*, [request](#)^{p905} is null, [response](#)^{p905} is *resource*, [origin](#)^{p905} is *responseOrigin*, [policy container](#)^{p905} is *policyContainer*, [final sandboxing flag set](#)^{p905} is *finalSandboxFlags*, [cross-origin opener policy](#)^{p905} is *coop*, [COOP enforcement result](#)^{p905} is *coopEnforcementResult*, [reserved environment](#)^{p905} is null, [browsing context](#)^{p905} is *browsingContext*, [history handling](#)^{p905} is *historyHandling*, [unsafe start time](#)^{p906} is *unsafeNavigationStartTime*, and [has cross-origin redirects](#)^{p905} is false.
8. Run [process a navigate response](#)^{p911} with *navigationType*, *allowedToDownload*, *hasTransientActivation*, and *navigationParams*.

If *resource* is a [request](#) whose [URL's scheme](#) is "[javascript](#)^{p913}"

[Queue a global task](#)^{p970} on the [DOM manipulation task source](#)^{p977} given *browsingContext*'s [active window](#)^{p840} to run these steps:

1. Let *response* be the result of [executing a javascript: URL request](#)^{p913} given *resource*, *browsingContext*, and *incumbentNavigationOrigin*.
2. Let *finalSandboxFlags* be the [union](#) of *browsingContext*'s [sandboxing flags](#)^{p876} and *response*'s [forced sandboxing flag set](#)^{p875}.
3. Let *coopEnforcementResult* be a new [cross-origin opener policy enforcement result](#)^{p878} whose [needs a browsing context group switch](#)^{p878} is false, [would need a browsing context group switch due to report-only](#)^{p878} is false, [url](#)^{p878} is *resource*'s [URL](#), [origin](#)^{p878} is *browsingContext*'s [active document](#)^{p840}'s [origin](#), [cross-origin opener policy](#)^{p878} is *browsingContext*'s [active document](#)^{p840}'s [cross-origin opener policy](#)^{p118}, and [current context is navigation source](#)^{p878} is false.
4. Let *navigationParams* be a new [navigation params](#)^{p905} whose [id](#)^{p905} is *navigationId*, [request](#)^{p905} is *resource*, [response](#)^{p905} is *response*, [origin](#)^{p905} is *browsingContext*'s [active document](#)^{p840}'s [origin](#), [policy container](#)^{p905} is *browsingContext*'s [active document](#)^{p840}'s [policy container](#)^{p886}, [final sandboxing flag set](#)^{p905} is *finalSandboxFlags*, [cross-origin opener policy](#)^{p905} is *browsingContext*'s [active document](#)^{p840}'s [cross-origin opener policy](#)^{p118}, [COOP enforcement result](#)^{p905} is *coopEnforcementResult*, [reserved environment](#)^{p905} is null, [browsing context](#)^{p905} is *browsingContext*, [history handling](#)^{p905} is *historyHandling*, [unsafe start time](#)^{p906} is *unsafeNavigationStartTime*, and [has cross-origin redirects](#)^{p905} is false.
5. Run [process a navigate response](#)^{p911} with *navigationType*, *allowedToDownload*, *hasTransientActivation*, and *navigationParams*.

Example

So for example a [javascript: URL](#)^{p913} in an [href](#)^{p290} attribute of an [a](#)^{p244} element would only be evaluated when the link was [followed](#)^{p296}, while such a URL in the [src](#)^{p370} attribute of an [iframe](#)^{p369} element would be evaluated in the context of the [iframe](#)^{p369}'s [nested browsing context](#)^{p843} when the [iframe](#)^{p369} is being set up. Once evaluated, its return value (if it was a string) would replace that [browsing context](#)^{p840}'s [active document](#)^{p840}, thus also changing the corresponding [Window](#)^{p855} object.

If *resource* is a [request](#) whose [URL's scheme](#) is a [fetch scheme](#)

Run [process a navigate fetch](#)^{p909} given *navigationId*, *resource*, the [source browsing context](#)^{p906}, *browsingContext*, *navigationType*, *sandboxFlags*, *historyPolicyContainer*, *initiatorPolicyContainer*, *allowedToDownload*,

hasTransientActivation, *incumbentNavigationOrigin*, *historyHandling*, and *unsafeNavigationStartTime*.

Otherwise, **resource** is a **request** whose **URL's scheme** is neither "**javascript**^{p913}" nor a **fetch scheme**

Run **process a navigate URL scheme**^{p913} given resource's **URL**, *browsingContext*, *sandboxFlags*, and *hasTransientActivation*.

To **process a navigate fetch**, given a **navigation id**^{p906} *navigationId*, **request** *request*, two **browsing contexts**^{p840} *sourceBrowsingContext* and *browsingContext*, a string *navigationType*, a **sandboxing flag set**^{p873} *sandboxFlags*, two **policy containers**^{p886} *historyPolicyContainer* and *initiatorPolicyContainer*, a boolean *allowedToDownload*, a boolean *hasTransientActivation*, an **origin**^{p868} *incumbentNavigationOrigin*, a **history handling behavior**^{p906} *historyHandling*, and a number *unsafeNavigationStartTime*:

1. Let *response* be null.
2. Set *request*'s **client** to *sourceBrowsingContext*'s **active document**^{p840}'s **relevant settings object**^{p944}, **destination** to "document", **mode** to "navigate", **credentials mode** to "include", **use-URL-credentials flag**, **redirect mode** to "manual", and **replaces client id** to *browsingContext*'s **active document**^{p840}'s **relevant settings object**^{p944}'s **id**^{p936}.
3. If *hasTransientActivation* is true, then set *request*'s **user-activation** to true.
4. If *browsingContext*'s **container**^{p843} is non-null:
 1. If the *browsingContext*'s **container**^{p843} has a **browsing context scope origin**^{p847}, then set *request*'s **origin** to that **browsing context scope origin**^{p847}.
 2. Set *request*'s **destination** to *browsingContext*'s **container**^{p843}'s **local name**.
5. Let *responseOrigin* be null.
6. Let *currentContextIsSource* be the result of whether *browsingContext*'s **active document**^{p840} is **same origin**^{p869} with *sourceBrowsingContext*'s **active document**^{p840}.
7. Let *coopEnforcementResult* be a new **cross-origin opener policy enforcement result**^{p878} whose **needs a browsing context group switch**^{p878} is false, **would need a browsing context group switch due to report-only**^{p878} is false, **url**^{p878} is *browsingContext*'s **active document**^{p840}'s **url**, **origin**^{p878} is *browsingContext*'s **active document**^{p840}'s **origin**, **cross-origin opener policy**^{p878} is *browsingContext*'s **active document**^{p840}'s **cross-origin opener policy**^{p118}, and **current context is navigation source**^{p878} is *currentContextIsSource*.
8. Let *finalSandboxFlags* be an empty **sandboxing flag set**^{p873}.
9. Let *responseCOOP* be a new **cross-origin opener policy**^{p876}.
10. Let *locationURL* be null.
11. Let *currentURL* be *request*'s **current URL**.
12. Let *hasCrossOriginRedirects* be false.
13. While true:
 1. If *locationURL* is non-null, then:
 1. If *locationURL*'s **origin** is not the **same**^{p869} as *currentURL*'s **origin**, then set *hasCrossOriginRedirects* to true.
 2. Set *currentURL* to *locationURL*.
 2. If *request*'s **reserved client** is not null and *currentURL*'s **origin** is not the **same**^{p869} as *request*'s **reserved client**'s **creation URL**^{p936}'s **origin**, then:
 1. Run the **environment discarding steps**^{p937} for *request*'s **reserved client**.
 2. Set *request*'s **reserved client** to null.
 3. If *request*'s **reserved client** is null, then:
 1. Let *topLevelCreationURL* be *currentURL*.
 2. Let *topLevelOrigin* be null.
 3. If *browsingContext* is not a **top-level browsing context**^{p844}, then:

1. Let `parentEnvironment` be `browsingContext`'s [container](#)^{p843}'s [relevant settings object](#)^{p944}.
2. Set `topLevelCreationURL` to `parentEnvironment`'s [top-level creation URL](#)^{p936} and `topLevelOrigin` to `parentEnvironment`'s [top-level origin](#)^{p936}.
4. Set `request`'s [reserved client](#) to a new [environment](#)^{p936} whose [id](#)^{p936} is a unique opaque string, [target browsing context](#)^{p937} is `browsingContext`, [creation URL](#)^{p936} is `currentURL`, [top-level creation URL](#)^{p936} is `topLevelCreationURL`, and [top-level origin](#)^{p936} is `topLevelOrigin`.

Note

The created environment's [active service worker](#)^{p937} is set in the [Handle Fetch](#) algorithm during the fetch if the request URL matches a service worker registration. [\[SW\]](#)^{p1312}

4. If the result of [Should navigation request of type be blocked by Content Security Policy?](#) given `request` and `navigationType` is "Blocked", then set `response` to a [network error](#) and [break](#). [\[CSP\]](#)^{p1305}
5. Otherwise:
 1. If `response` is null, [fetch request](#).
 2. Otherwise, perform [HTTP-redirect fetch](#) using `request` and `response`.
 3. Wait for the [task](#)^{p969} on the [networking task source](#)^{p977} to [process response](#) and set `response` to the result.
 4. Set `finalSandboxFlags` to the [union](#) of `browsingContext`'s [sandboxing flags](#)^{p876} and `response`'s [forced sandboxing flag set](#)^{p875}.
 5. Set `responseOrigin` to the result of [determining the origin](#)^{p841} given `browsingContext`, `request`'s [URL](#), `finalSandboxFlags`, and `incumbentNavigationOrigin`.
 6. If `browsingContext` is a [top-level browsing context](#)^{p844}, then:
 1. Set `responseCOOP` to the result of [obtaining a cross-origin opener policy](#)^{p877} given `response` and `request`'s [reserved client](#).
 2. Set `coopEnforcementResult` to the result of [enforcing the response's cross-origin opener policy](#)^{p878} given `browsingContext`, `request`'s [URL](#), `responseOrigin`, `responseCOOP`, `coopEnforcementResult` and `request`'s [referrer](#).
 3. If `sandboxFlags` is not empty and `responseCOOP`'s [value](#)^{p876} is not "[unsafe-none](#)^{p876}", then set `response` to an appropriate [network error](#) and [break](#).

Note

This results in a network error as one cannot simultaneously provide a clean slate to a response using cross-origin opener policy and sandbox the result of navigating to that response.

7. If `response` is not a [network error](#), `browsingContext` is a [child browsing context](#)^{p843}, and the result of performing a [cross-origin resource policy check](#) with `browsingContext`'s [container document](#)^{p843}'s [origin](#), `browsingContext`'s [container document](#)^{p843}'s [relevant settings object](#)^{p944}, `request`'s [destination](#), `response`, and `true` is **blocked**, then set `response` to a [network error](#) and [break](#).

Note

Here we're running the [cross-origin resource policy check](#) against the [parent browsing context](#)^{p843} rather than `sourceBrowsingContext`. This is because we care about the same-originness of the embedded content against the parent context, not the navigation source.

8. Set `locationURL` to `response`'s [location URL](#) given `currentURL`'s [fragment](#).
9. If `locationURL` is not a [URL](#) whose [scheme](#) is an [HTTP\(S\) scheme](#), then [break](#).

Note

Navigation handles redirects manually as navigation is the only place in the web platform that cares for redirects to [mailto:](#) URLs and such.

Note

By the end of this loop we will be in one of these scenarios:

- response is a [network error](#).
- locationURL is failure, because of an unparseable `Location` header.
- locationURL is null, because we successfully fetched a non-[network error](#) HTTP(S) response with no `Location` header.
- locationURL is a [URL](#) with a non-HTTP(S) scheme.

14. If `locationURL` is failure, then set `response` to a [network error](#).
15. Otherwise, if `locationURL` is a [URL](#) whose `scheme` is a [fetch scheme](#) or "javascript", then set `response` to a [network error](#).
16. Otherwise, if `locationURL` is a [URL](#), then [process a navigate URL scheme](#)^{p913} given `locationURL`, `browsingContext`, `sandboxFlags`, and `hasTransientActivation`, and return.
17. Let `responsePolicyContainer` be the result of [creating a policy container from a fetch response](#)^{p887} given `response` and `request`'s [reserved client](#).
18. Let `resultPolicyContainer` be the result of [determining navigation params policy container](#)^{p887} given `response`'s [URL](#), `historyPolicyContainer`, `initiatorPolicyContainer`, null, and `responsePolicyContainer`.
19. Let `navigationParams` be a new [navigation params](#)^{p905} whose `id`^{p905} is `navigationId`, `request`^{p905} is `request`, `response`^{p905} is `response`, `origin`^{p905} is `responseOrigin`, `policy container`^{p905} is `resultPolicyContainer`, `final sandboxing flag set`^{p905} is `finalSandboxFlags`, `cross-origin opener policy`^{p905} is `responseCOOP`, `COOP enforcement result`^{p905} is `coopEnforcementResult`, `reserved environment`^{p905} is `request`'s [reserved client](#), `browsing context`^{p905} is `browsingContext`, `history handling`^{p905} is `historyHandling`, `unsafe start time`^{p906} is `unsafeNavigationStartTime`, and `has cross-origin redirects`^{p905} is `hasCrossOriginRedirects`.
20. Run [process a navigate response](#)^{p911} with `navigationType`, `allowedToDownload`, `hasTransientActivation`, and `navigationParams`.

To **process a navigate response**, given a string `navigationType`, a boolean `allowedToDownload`, a boolean `hasTransientActivation`, and a [navigation params](#)^{p905} `navigationParams`:

1. Let `response` be `navigationParams`'s [response](#)^{p905}.
2. Let `browsingContext` be `navigationParams`'s [browsing context](#)^{p905}.
3. Let `failure` be false.
4. If `response` is a [network error](#), then set `failure` to true.

Otherwise, if the result of [Should navigation response to navigation request of type in target be blocked by Content Security Policy?](#) given `navigationParams`'s [request](#)^{p905}, `response`, `navigationParams`'s [policy container](#)^{p905}'s [CSP list](#)^{p886}, `navigationType`, and `browsingContext` is "Blocked", then set `failure` to true. [\[CSP\]](#)^{p1305}

Otherwise, if `navigationParams`'s [reserved environment](#)^{p905} is non-null and the result of [checking a navigation response's adherence to its embedder policy](#)^{p886} given `response`, `browsingContext`, and `navigationParams`'s [policy container](#)^{p905}'s [embedder policy](#)^{p886} is false, then set `failure` to true.

Otherwise, if the result of [checking a navigation response's adherence to `X-Frame-Options`](#)^{p931} given `response`, `browsingContext`, and `navigationParams`'s [origin](#)^{p905} is false, then set `failure` to true.

5. If `failure` is true, then:
 1. [Display the inline content with an appropriate error shown to the user](#)^{p921} given `browsingContext`.
 2. Run the [environment discarding steps](#)^{p937} for `navigationParams`'s [reserved environment](#)^{p905}.
 3. Invoke [WebDriver BiDi navigation failed](#) with `browsingContext` and a new [WebDriver BiDi navigation status](#) whose `id` is `navigationParams`'s [id](#)^{p905}, `status` is "cancel", and `url` is `response`'s [URL](#).
 4. Return.

Note

This is where the network errors defined and propagated by Fetch, such as DNS or TLS errors, end up being displayed to users. [FETCH]^{p1308}

6. If response's [status](#) is 204 or 205, then return.
7. If response has a ``Content-Disposition`` header specifying the attachment disposition type, then:
 1. If `allowedToDownload` is true, then handle response [as a download](#)^{p297}.
 2. Invoke [WebDriver BiDi download_started](#) with `browsingContext` and a new [WebDriver BiDi navigation_status](#) whose `id` is `navigationParams`'s `id`^{p905}, `status` is `"complete"`, and `url` is response's `URL`.
 3. Return.
8. Let `type` be the [computed type of response](#).
9. If the user agent has been configured to process resources of the given `type` using some mechanism other than rendering the content in a [browsing_context](#)^{p840}, then skip this step. Otherwise, if the `type` is one of the following types, jump to the appropriate entry in the following list, and process `response` as described there:
 - ↪ **an HTML MIME type**
Follow the steps given in the [HTML document](#)^{p918} section providing `navigationParams`. Once the steps have completed, return.
 - ↪ **an XML MIME type that is not an explicitly supported XML MIME type**^{p912}
Follow the steps given in the [XML document](#)^{p918} section providing `navigationParams` and `type`. Once the steps have completed, return.
 - ↪ **a JavaScript MIME type**
 - ↪ **a JSON MIME type that is not an explicitly supported JSON MIME type**^{p912}
 - ↪ `"text/css"`^{p1303}
 - ↪ `"text/plain"`
 - ↪ `"text/vtt"`^{p1304}
Follow the steps given in the [plain text file](#)^{p919} section providing `navigationParams` and `type`. Once the steps have completed, return.
 - ↪ `"multipart/x-mixed-replace"`^{p1276}
Follow the steps given in the [multipart/x-mixed-replace](#)^{p919} section providing `navigationParams`. Once the steps have completed, return.
 - ↪ **A supported image, video, or audio type**
Follow the steps given in the [media](#)^{p920} section providing `navigationParams` and `type`. Once the steps have completed, return.
 - ↪ `"application/pdf"`
 - ↪ `"text/pdf"`
If the user agent's [PDF viewer supported](#)^{p1014} is true, then either follow the steps given in the [plugin](#)^{p920} section providing `navigationParams` and `type`, or [display the inline content](#)^{p921} given `browsingContext`. Once the steps have completed, return.

See [issue #6003](#) for discussion on picking one of these two behaviors to standardize.

Otherwise, proceed onward.

An **explicitly supported XML MIME type** is an [XML MIME type](#) for which the user agent is configured to use an external application to render the content (either a [plugin](#)^{p45} rendering directly in `browsingContext`, or a separate application), or one for which the user agent has dedicated processing rules (e.g., a web browser with a built-in Atom feed viewer would be said to explicitly support the `application/atom+xml`^{p1303} MIME type), or one for which the user agent has a dedicated handler.

An **explicitly supported JSON MIME type** is a [JSON MIME type](#) for which the user agent is configured to use an external application to render the content (either a [plugin](#)^{p45} rendering directly in `browsingContext`, or a separate application), or one for which the user agent has dedicated processing rules, or one for which the user agent has a dedicated handler.

10. If, given `type`, the new resource is to be handled by displaying some sort of inline content, e.g., a native rendering of the

content or an error message because the specified type is not supported, then [display the inline content](#)^{p921} given *browsingContext*, and then return.

11. Otherwise, the document's *type* is such that the resource will not affect *browsingContext*, e.g., because the resource is to be handed to an external application or because it is an unknown type that will be processed [as a download](#)^{p297}. [Hand-off to external software](#)^{p913} given *response*, *browsingContext*, *navigationParams*'s [final sandboxing flag set](#)^{p905}, and *hasTransientActivation*.

To **process a navigate URL scheme**, given a [URL](#) *url*, a [browsing context](#)^{p840} *browsingContext*, a [sandboxing flag set](#)^{p873} *sandboxFlags*, and a boolean *hasTransientActivation*:

1. If *url* is to be handled using a mechanism that does not affect *browsingContext*, e.g., because *url*'s [scheme](#) is handled externally, then [hand-off to external software](#)^{p913} given *url*, *browsingContext*, *sandboxFlags*, and *hasTransientActivation*.
2. Otherwise, *url* is to be handled by displaying some sort of inline content, e.g., an error message because the specified scheme is not one of the supported protocols, or an inline prompt to allow the user to select [a registered handler](#)^{p1010} for the given scheme. [Display the inline content](#)^{p921} given *browsingContext*.

Note

In the case of a registered handler being used, [navigate](#)^{p906} will be invoked with a new URL.

To **hand-off to external software** given a [URL](#) or [response](#) *resource*, a [browsing context](#)^{p840} *browsingContext*, a [sandboxing flag set](#)^{p873} *sandboxFlags*, and a boolean *hasTransientActivation*, user agents should:

1. Return without invoking the external software package if all of these conditions hold:
 - *browsingContext* is not a [top-level browsing context](#)^{p844};
 - *sandboxFlags* has its [sandboxed custom protocols navigation browsing context flag](#)^{p874} set; and
 - *sandboxFlags* has its [sandboxed top-level navigation with user activation browsing context flag](#)^{p873} set, or *hasTransientActivation* is false.

Note

Navigation inside an [iframe](#) toward external software can be seen by users as a new popup or a new top-level navigation. That's why its is allowed in sandboxed [iframe](#)^{p369} only when one of [allow-popups](#)^{p874}, [allow-top-navigation](#)^{p874}, [allow-top-navigation-by-user-activation](#)^{p875}, or [allow-top-navigation-to-custom-protocols](#)^{p875} is specified.

2. Perform the appropriate handoff of *resource* while attempting to mitigate the risk that this is an attempt to exploit the target software. For example, user agents could prompt the user to confirm that the [source browsing context](#)^{p906}'s [active document](#)^{p840}'s [origin](#) is to be allowed to invoke the external software in question. In particular, if *hasTransientActivation* is false, then the user agent should not invoke the external software package without prior user confirmation.

Example

For example, there could be a vulnerability in the target software's URL handler which a hostile page would attempt to exploit by tricking a user into clicking a link.

To **execute a javascript: URL request**, given a [request](#) *request*, a [browsing context](#)^{p840} *browsingContext*, and an [origin](#)^{p868} *initiatorOrigin*:

1. Let *response* be a [response](#) whose [status](#) is 204.
2. If both of the following are true:
 - *initiatorOrigin* is [same origin-domain](#)^{p869} with *browsingContext*'s [active document](#)^{p840}'s [origin](#).
 - The result of [Should navigation request of type be blocked by Content Security Policy?](#) given *request* and *navigationType* is "Allowed". [\[CSP\]](#)^{p1305}

then:

1. Let *urlString* be the result of running the [URL serializer](#) on *request*'s [URL](#).
2. Let *encodedScriptSource* be the result of removing the leading "javascript:" from *urlString*.
3. Let *scriptSource* be the [UTF-8 decoding](#) of the [percent-decoding](#) of *encodedScriptSource*.
4. [Append](#) *browsingContext*'s [active document](#)^{p840}'s [URL](#) to *request*'s [URL list](#).

5. Let *settings* be *browsingContext*'s [active document](#)^{p840}'s [relevant settings object](#)^{p944}.
6. Let *baseURL* be *settings*'s [API base URL](#)^{p937}.
7. Let *script* be the result of [creating a classic script](#)^{p954} given *scriptSource*, *settings*, *baseURL*, and the [default classic script fetch options](#)^{p946}.
8. Let *evaluationStatus* be the result of [running the classic script](#)^{p956} *script*.
9. Let *result* be undefined if *evaluationStatus* is an [abrupt completion](#) or *evaluationStatus*.[[Value]] is empty, or *evaluationStatus*.[[Value]] otherwise.
10. If [Type](#)(*result*) is String, then set *response* to a [response](#) whose [header list](#) is « (``Content-Type``^{p92}, ``text/html; charset=utf-8``) », and whose [body](#) is the result of [UTF-8 encoding](#) *result*.

Note

The encoding to UTF-8 means that unpaired [surrogates](#) will not roundtrip, once the HTML parser decodes the response body.

3. Return *response*.

In addition to the specific issues linked above, [javascript:](#)^{p913} URLs have a [dedicated label](#) on the issue tracker documenting various problems with their specification.

Some of the sections below, to which the above algorithm defers in certain cases, use the following steps to **create and initialize a Document object**, given a [type](#) *type*, [content type](#) *contentType*, and [navigation params](#)^{p905} *navigationParams*:

1. Let *browsingContext* be the result of the [obtaining a browsing context to use for a navigation response](#)^{p879} given *navigationParams*'s [browsing context](#)^{p905}, *navigationParams*'s [final sandboxing flag set](#)^{p905}, *navigationParams*'s [cross-origin opener policy](#)^{p905}, and *navigationParams*'s [COOP enforcement result](#)^{p905}.
2. Let *permissionsPolicy* be the result of [creating a permissions policy from a response](#) given *browsingContext*, *navigationParams*'s [origin](#)^{p905}, and *navigationParams*'s [response](#)^{p905}. [\[PERMISSIONSPOLICY\]](#)^{p1310}

Note

The [creating a permissions policy from a response](#) algorithm makes use of the passed [origin](#)^{p868}. If [document.domain](#)^{p871} has been used for *browsingContext*'s [container document](#)^{p843}, then its [origin](#) cannot be [same origin-domain](#)^{p869} with the passed [origin](#), because these steps run before the document is created, so it cannot itself yet have used [document.domain](#)^{p871}. Note that this means that Permissions Policy checks are less permissive compared to doing a [same origin](#)^{p869} check instead.

See below for some examples of this in action.

3. Let *creationURL* be *navigationParams*'s [response](#)^{p905}'s [URL](#).
4. If *navigationParams*'s [request](#)^{p905} is non-null, then set *creationURL* to *navigationParams*'s [request](#)^{p905}'s [current URL](#).
5. If *browsingContext* is [still on its initial about:blank Document](#)^{p118}, and *navigationParams*'s [history handling](#)^{p905} is `"replace"`^{p906}, and *browsingContext*'s [active document](#)^{p840}'s [origin](#) is [same origin-domain](#)^{p869} with *navigationParams*'s [origin](#)^{p905}, then do nothing.

Note

This means that both the [initial about:blank](#)^{p118} [Document](#)^{p117}, and the new [Document](#)^{p117} that is about to be created, will share the same [Window](#)^{p855} object.

6. Otherwise:
 1. Let *oacHeader* be the result of [getting a structured field value](#) given ``Origin-Agent-Cluster``^{p872} and "item" from *response*'s [header list](#).
 2. Let *requestsOAC* be true if *oacHeader* is not null and *oacHeader*[0] is the [boolean](#) true; otherwise false.
 3. If *navigationParams*'s [reserved environment](#)^{p905} is a [non-secure context](#)^{p945}, then set *requestsOAC* to false.

4. Let *agent* be the result of [obtaining a similar-origin window agent](#)^{p934} given *navigationParams*'s [origin](#)^{p905}, *browsingContext*'s [group](#)^{p844}, and *requestsOAC*.
5. Let *realm execution context* be the result of [creating a new JavaScript realm](#)^{p938} given *agent* and the following customizations:
 - For the global object, create a new [Window](#)^{p855} object.
 - For the global **this** binding, use *browsingContext*'s [WindowProxy](#)^{p865} object.
6. Let *topLevelCreationURL* be *creationURL*.
7. Let *topLevelOrigin* be *navigationParams*'s [origin](#)^{p905}.
8. If *browsingContext* is not a [top-level browsing context](#)^{p844}, then:
 1. Let *parentEnvironment* be *browsingContext*'s [container](#)^{p843}'s [relevant settings object](#)^{p944}.
 2. Set *topLevelCreationURL* to *parentEnvironment*'s [top-level creation URL](#)^{p936}.
 3. Set *topLevelOrigin* to *parentEnvironment*'s [top-level origin](#)^{p936}.
9. [Set up a window environment settings object](#)^{p864} with *creationURL*, *realm execution context*, *navigationParams*'s [reserved environment](#)^{p905}, *topLevelCreationURL*, and *topLevelOrigin*.

Note

This is the usual case, where the new [Document](#)^{p117} we're about to create gets a new [Window](#)^{p855} to go along with it.

7. Let *loadTimingInfo* be a new [document load timing info](#)^{p121} with its [navigation start time](#)^{p121} set to the result of calling [coarsen time](#) with *navigationParams*'s [unsafe start time](#)^{p906} and *document*'s [relevant settings object](#)^{p944}'s [cross-origin isolated capability](#)^{p937}.
8. Let *document* be a new [Document](#)^{p117}, whose [type](#) is *type*, [content type](#) is *contentType*, [origin](#) is *navigationParams*'s [origin](#)^{p905}, [policy container](#)^{p118} is *navigationParams*'s [policy container](#)^{p905}, [permissions policy](#)^{p118} is *permissionsPolicy*, [active sandboxing flag set](#)^{p875} is *navigationParams*'s [final sandboxing flag set](#)^{p905}, and [cross-origin opener policy](#)^{p118} is *navigationParams*'s [cross-origin opener policy](#)^{p905}, [load timing info](#)^{p121} is *loadTimingInfo*, and [navigation id](#)^{p118} is *navigationParams*'s [id](#)^{p905}.

Note

*The new [Window](#)^{p855}'s [associated Document](#)^{p856} is set to *document* later, when the caller of this algorithm [updates the session history with the new page](#)^{p917}. That algorithm [sets the active document](#)^{p841} as part of its larger role of [synchronizing the \[Window\]\(#\)^{p855}, \[Document\]\(#\)^{p117}, \[browsing context\]\(#\)^{p840}, and \[session history\]\(#\)^{p888}.](#)*

9. Set *document*'s [URL](#) to *creationURL*.
10. Set *document*'s [current document readiness](#)^{p120} to "loading".
11. [Run CSP initialization for a Document](#) given *document*. [[CSP](#)]^{p1305}
12. If *navigationParams*'s [request](#)^{p905} is non-null, then:
 1. Set *document*'s [referrer](#)^{p117} to the empty string.
 2. Let *referrer* be *navigationParams*'s [request](#)^{p905}'s [referrer](#).
 3. If *referrer* is a [URL record](#), then set *document*'s [referrer](#)^{p117} to the [serialization](#) of *referrer*.

Note

*Per Fetch, *referrer* will be either a [URL record](#) or "no-referrer" at this point.*

13. Let *historyHandling* be *navigationParams*'s [history handling](#)^{p905}.
14. Let *navigationType* be the result of switching on *navigationParams*'s [history handling](#)^{p905}:
 - ↪ ["default"](#)^{p906}
 - ↪ ["replace"](#)^{p906}
 - ↪ ["navigate"](#)

```
↪ "reload"p906
   "reload"
↪ "entry_update"p906
   "back_forward"
```

- Let *redirectCount* be 0 if *navigationParams*'s [has cross-origin redirects](#)^{p905} is true; otherwise *navigationParams*'s [request](#)^{p905}'s [redirect count](#).
- Create the [navigation timing entry](#) for *document*, with *navigationParams*'s [response](#)^{p905}'s [timing info](#), *redirectCount*, *navigationType*, and *navigationParams*'s [response](#)^{p905}'s [service worker timing info](#).
- If *navigationParams*'s [response](#)^{p905} has a ``Refresh`p932` header, then:
 - Let *value* be the [isomorphic decoding](#) of the value of the header.
 - Run the [shared declarative refresh steps](#)^{p177} with *document* and *value*.

We do not currently have a spec for how to handle multiple ``Refresh`p932` headers. This is tracked as [issue #2900](#).

- [Process link headers](#)^{p169} given *document*, *navigationParams*'s [response](#)^{p905}, and "pre-media".
- Return *document*.

Example

In this example, the child document is not allowed to use [PaymentRequest](#), despite being [same origin-domain](#)^{p869} at the time the child document tries to use it. At the time the child document is initialized, only the parent document has set [document.domain](#)^{p871}, and the child document has not.

```
<!-- https://foo.example.com/a.html -->
<!doctype html>
<script>
document.domain = 'example.com';
</script>
<iframe src=b.html></iframe>
```

```
<!-- https://bar.example.com/b.html -->
<!doctype html>
<script>
document.domain = 'example.com'; // This happens after the document is initialized
new PaymentRequest(...); // Not allowed to use
</script>
```

Example

In this example, the child document *is* allowed to use [PaymentRequest](#), despite not being [same origin-domain](#)^{p869} at the time the child document tries to use it. At the time the child document is initialized, none of the documents have set [document.domain](#)^{p871} yet so [same origin-domain](#)^{p869} falls back to a normal [same origin](#)^{p869} check.

```
<!-- https://example.com/a.html -->
<!doctype html>
<iframe src=b.html></iframe>
<!-- The child document is now initialized, before the script below is run. -->
<script>
document.domain = 'example.com';
</script>
```

```
<!-- https://example.com/b.html -->
<!doctype html>
<script>
new PaymentRequest(...); // Allowed to use
</script>
```

Some of the sections below, to which the above algorithm defers in certain cases, require the user agent to **update the session history with the new page**, given some [navigation params](#)^{p905} *navigationParams* and a [Document](#)^{p117} *newDocument*. When a user agent is required to do this, it must [queue a global task](#)^{p970} on the [networking task source](#)^{p977}, given the [relevant global object](#)^{p944} of the [Document](#)^{p117} object of the [current entry](#)^{p890} (not the new one), to run the following steps:

1. Let *sessionHistory* be *navigationParams*'s [browsing context](#)^{p905}'s [session history](#)^{p888}.
2. Let *unloadTimingInfo* be a new [document unload timing info](#)^{p121}.
3. Let *previousDocument* be *sessionHistory*'s [current entry](#)^{p890}'s [document](#)^{p888}.
4. [Unload](#)^{p928} *previousDocument* with *unloadTimingInfo*.

If this instance of the [navigation](#)^{p906} algorithm is canceled while this step is running the [unload a document](#)^{p928} algorithm, then the [unload a document](#)^{p928} algorithm must be allowed to run to completion, but this instance of the [navigation](#)^{p906} algorithm must not run beyond this step. (In particular, for instance, the cancelation of this algorithm does not abort any event dispatch or script execution occurring as part of unloading the document or its descendants.)

5. If *navigationParams*'s [has cross-origin redirects](#)^{p905} is false, and *newDocument*'s [origin](#) is the [same](#)^{p869} as *previousDocument*'s [origin](#), then set *newDocument*'s [previous document unload timing](#)^{p121} to *unloadTimingInfo*.
6. Switch on *navigationParams*'s [history handling](#)^{p905}:

↳ "[entry update](#)^{p966}"

↳ "[reload](#)^{p966}"

1. Let *oldDocument* be *sessionHistory*'s [current entry](#)^{p890}'s [document](#)^{p888}.
2. [For each](#) *entry* of *sessionHistory*: if *entry*'s [document](#)^{p888} is *oldDocument*, then set *entry*'s [document](#)^{p888} to *newDocument*.
3. [Traverse the history](#)^{p923} to *sessionHistory*'s [current entry](#)^{p890} with [historyHandling](#)^{p923} set to *navigationParams*'s [history handling](#)^{p905}.

↳ "[replace](#)^{p966}"

1. Let *newEntry* be a new [session history entry](#)^{p888} whose [URL](#)^{p888} is *newDocument*'s [URL](#) and [document](#)^{p888} is *newDocument*.

Some browsers copy over the serialized state *sessionHistory*'s [current entry](#)^{p890} in cases where its [URL](#)^{p888} equals that of *newDocument*, but this is inconsistent. See [issue #6213](#) for more discussion on this.

2. If *newDocument*'s [URL requires storing the policy container in history](#)^{p887}, set *newEntry*'s [policy container](#)^{p888} to *navigationParams*'s [policy container](#)^{p905}.
3. Insert *newEntry* into *sessionHistory* after its [current entry](#)^{p890}.
4. [Traverse the history](#)^{p923} to *newEntry* with [historyHandling](#)^{p923} set to "[replace](#)^{p966}".

↳ "[default](#)^{p966}"

1. Remove all the entries in *sessionHistory* after its [current entry](#)^{p890}. (If the [current entry](#)^{p890} is the last entry in the session history, then no entries are removed.)

Note

This doesn't necessarily have to affect^{p896} the user agent's user interface.

2. Let *newEntry* be a new [session history entry](#)^{p888} whose [URL](#)^{p888} is *newDocument*'s [URL](#) and [document](#)^{p888} is *newDocument*.
3. If *newDocument*'s [URL requires storing the policy container in history](#)^{p887}, then set *newEntry*'s [policy container](#)^{p888} to *navigationParams*'s [policy container](#)^{p905}.
4. [Append](#) *newEntry* to *sessionHistory*.
5. [Traverse the history](#)^{p923} to *newEntry*.

7. The [navigation algorithm](#)^{p906} has now **matured**.
8. [Try to scroll to the fragment](#)^{p918} for `newDocument`.

To **try to scroll to the fragment** for a [Document](#)^{p117} `document`, perform the following steps [in parallel](#)^{p42}:

1. Wait for an [implementation-defined](#) amount of time. (This is intended to allow the user agent to optimize the user experience in the face of performance concerns.)
2. [Queue a global task](#)^{p970} on the [networking task source](#)^{p977} given `document`'s [relevant global object](#)^{p944} to run these steps:
 1. If `document` has no parser, or its parser has [stopped parsing](#)^{p1192}, or the user agent has reason to believe the user is no longer interested in scrolling to the [fragment](#), then abort these steps.
 2. [Scroll to the fragment](#)^{p922} given in `document`'s [URL](#). If this does not find [an indicated part of the document](#)^{p922}, then [try to scroll to the fragment](#)^{p918} for `document`.

7.11.2 Page load processing model for HTML files §^{p91}₈

When an **HTML document is to be loaded**, given [navigation params](#)^{p905} `navigationParams`, the user agent must [queue a task](#)^{p970} on the [networking task source](#)^{p977} to:

1. Let `document` be the result of [creating and initializing a Document object](#)^{p914} given "html", "text/html", and `navigationParams`.
2. Create an [HTML parser](#)^{p1106} and associate it with the `document`. Each [task](#)^{p969} that the [networking task source](#)^{p977} places on the [task queue](#)^{p969} while fetching runs must then fill the parser's [input byte stream](#)^{p1112} with the fetched bytes and cause the [HTML parser](#)^{p1106} to perform the appropriate processing of the input stream.

The first [task](#)^{p969} that the [networking task source](#)^{p977} places on the [task queue](#)^{p969} while fetching runs must [process link headers](#)^{p169} given `document`, `navigationParams`'s [response](#)^{p905}, and "media", after the task has been processed by the [HTML parser](#)^{p1106}.

Note

The [input byte stream](#)^{p1112} converts bytes into characters for use in the [tokenizer](#)^{p1124}. This process relies, in part, on character encoding information found in the real [Content-Type metadata](#)^{p92} of the resource; the computed type is not used for this purpose.

When no more bytes are available, the user agent must [queue a global task](#)^{p970} on the [networking task source](#)^{p977} given the newly-created [Document](#)^{p117}'s [relevant global object](#)^{p944} for the parser to process the implied EOF character, which eventually causes a [load](#)^{p1301} event to be fired.

After creating the [Document](#)^{p117} object, but before any script execution, certainly before the parser [stops](#)^{p1192}, the user agent must [update the session history with the new page](#)^{p917} given `navigationParams` and the newly-created [Document](#)^{p117}.

7.11.3 Page load processing model for XML files §^{p91}₈

When faced with displaying an XML file inline, provided [navigation params](#)^{p905} `navigationParams` and a string `type`, user agents must follow the requirements defined in *XML and Namespaces in XML*, *XML Media Types*, *DOM*, and other relevant specifications to [create and initialize a Document object](#)^{p914} `document`, given "xml", `type`, and `navigationParams`. They must also create a corresponding [XML parser](#)^{p1217}. [[XML](#)]^{p1313} [[XMLNS](#)]^{p1313} [[RFC7303](#)]^{p1311} [[DOM](#)]^{p1307}

The first [task](#)^{p969} that the [networking task source](#)^{p977} places on the [task queue](#)^{p969} while fetching runs must [process link headers](#)^{p169} given `document`, `navigationParams`'s [response](#)^{p905}, and "media", after the task has been processed by the [XML parser](#)^{p1217}.

Note

At the time of writing, the XML specification community had not actually yet specified how XML and the DOM interact.

The actual HTTP headers and other metadata, not the headers as mutated or implied by the algorithms given in this specification, are

the ones that must be used when determining the character encoding according to the rules given in the above specifications. Once the character encoding is established, the [document's character encoding](#) must be set to that character encoding.

Then, with *document*, the user agent must [update the session history with the new page](#)^{p917} given *navigationParams* and *document*. User agents may do this before the complete document has been parsed (thus achieving *incremental rendering*), and must do this before any scripts are to be executed.

Once parsing is complete, the user agent must set *document's navigation id*^{p118} to null.

Note

For HTML documents this is reset when parsing is complete, after firing the load event.

Error messages from the parse process (e.g., XML namespace well-formedness errors) may be reported inline by mutating the [Document](#)^{p117}.

7.11.4 Page load processing model for text files §^{p91}₉

When a plain text document is to be loaded, provided [navigation params](#)^{p905} *navigationParams* and a string *type*, the user agent must [queue a task](#)^{p970} on the [networking task source](#)^{p977} to:

1. Let *document* be the result of [creating and initializing a Document object](#)^{p914} given "html", *type*, and *navigationParams*.
2. Set *document's parser cannot change the mode flag*^{p1159} to true.
3. Set *document's mode* to "no-quirks".
4. Create an [HTML parser](#)^{p1106} and associate it with the *document*. Act as if the tokenizer had emitted a start tag token with the tag name "pre" followed by a single U+000A LINE FEED (LF) character, and switch the [HTML parser](#)^{p1106}'s tokenizer to the [PLAINTEXT state](#)^{p1127}. Each [task](#)^{p969} that the [networking task source](#)^{p977} places on the [task queue](#)^{p969} while fetching runs must then fill the parser's [input byte stream](#)^{p1112} with the fetched bytes and cause the [HTML parser](#)^{p1106} to perform the appropriate processing of the input stream.

The rules for how to convert the bytes of the plain text document into actual characters, and the rules for actually rendering the text to the user, are defined by the specifications for the [computed MIME type](#) of the resource (i.e., *type*).

The [document's character encoding](#) must be set to the character encoding used to decode the document.

The first [task](#)^{p969} that the [networking task source](#)^{p977} places on the [task queue](#)^{p969} while fetching runs must [process link headers](#)^{p169} given *document*, *navigationParams's response*^{p905}, and "media", after the task has been processed by the [HTML parser](#)^{p1106}.

When no more bytes are available, the user agent must [queue a global task](#)^{p970} on the [networking task source](#)^{p977} given the newly-created [Document](#)^{p117}'s [relevant global object](#)^{p944} for the parser to process the implied EOF character, which eventually causes a [load](#)^{p1301} event to be fired.

After creating the [Document](#)^{p117} object, but potentially before the page has finished parsing, the user agent must [update the session history with the new page](#)^{p917} given *navigationParams* and the newly-created [Document](#)^{p117}.

User agents may add content to the [head](#)^{p158} element of the [Document](#)^{p117}, e.g., linking to a style sheet, providing script, or giving the document a [title](#)^{p159}.

Note

In particular, if the user agent supports the Format=Flowed feature of RFC 3676 then the user agent would need to apply extra styling to cause the text to wrap correctly and to handle the quoting feature. This could be performed using, e.g., a CSS extension.

7.11.5 Page load processing model for multipart/x-mixed-replace resources §^{p91}₉

When a resource with the type [multipart/x-mixed-replace](#)^{p1276} is to be loaded in a [browsing context](#)^{p840}, the user agent must parse the resource using the rules for multipart types. [\[RFC2046\]](#)^{p1310}

This algorithm is passed [navigation_params^{p905}](#), but it's unclear how exactly to use them.

For each body part obtained from the resource, the user agent must run [process a navigate response^{p911}](#) using the new body part and the same [browsing_context^{p840}](#), with [history_handling^{p905}](#) set to "[replace^{p986}](#)" if a previous body part from the same resource resulted in a [creating and initializing a Document object^{p914}](#), and otherwise using the same setup as the [navigate^{p906}](#) attempt that caused this section to be invoked in the first place.

For the purposes of algorithms processing these body parts as if they were complete stand-alone resources, the user agent must act as if there were no more bytes for those resources whenever the boundary following the body part is reached.

Note

Thus, [load^{p1381}](#) events (and for that matter [unload^{p1382}](#) events) do fire for each body part loaded.

7.11.6 Page load processing model for media §^{p92}₀

When an image, video, or audio resource is to be loaded, provided [navigation_params^{p905}](#) *navigationParams* and a string *type*, the user agent should:

1. Let *document* be the result of [creating and initializing a Document object^{p914}](#) given "html", *type*, and *navigationParams*.
2. Set *document*'s *mode* to "no-quirks".
3. Append an [html^{p157}](#) element to *document*.
4. Append a [head^{p158}](#) element to the [html^{p157}](#) element.
5. Append a [body^{p184}](#) element to the [html^{p157}](#) element.
6. Append an element *host element* for the media, as described below, to the [body^{p184}](#) element.
7. Set the appropriate attribute of the element *host element*, as described below, to the address of the image, video, or audio resource.
8. [Process link headers^{p169}](#) given *document*, *navigationParams*'s [response^{p905}](#), and "media".

The element *host element* to create for the media is the element given in the table below in the second cell of the row whose first cell describes the media. The appropriate attribute to set is the one given by the third cell in that same row.

Type of media	Element for the media	Appropriate attribute
Image	img^{p327}	src^{p328}
Video	video^{p388}	src^{p398}
Audio	audio^{p392}	src^{p398}

Then, the user agent must act as if it had [stopped parsing^{p1192}](#).

After creating the [Document^{p117}](#) object, but potentially before the page has finished fully loading, the user agent must [update the session history with the new page^{p917}](#) given *navigationParams* and the newly-created [Document^{p117}](#).

User agents may add content to the [head^{p158}](#) element of the [Document^{p117}](#), or attributes to the element *host element*, e.g., to link to a style sheet, to provide a script, to give the document a [title^{p159}](#), or to make the media [autoplay^{p416}](#).

7.11.7 Page load processing model for content that uses plugins §^{p92}₀

When a resource that requires an external resource to be rendered is to be loaded, provided [navigation_params^{p905}](#) *navigationParams* and a string *type*, the user agent should:

1. Let *document* be the result of [creating and initializing a Document object^{p914}](#) given "html", *type*, and *navigationParams*.
2. Set *document*'s *mode* to "no-quirks".

3. Mark *document* as being a **plugin document**
4. Append an [html^{p157}](#) element to *document*.
5. Append a [head^{p158}](#) element to the [html^{p157}](#) element.
6. Append a [body^{p184}](#) element to the [html^{p157}](#) element.
7. Append an [embed^{p378}](#) to the [body^{p184}](#) element.
8. Set the [src^{p378}](#) attribute of the [embed^{p378}](#) element to the address of the resource.
9. [Process link headers^{p169}](#) given *document*, *navigationParams*'s [response^{p905}](#), and "media".

Note

The term [plugin document^{p921}](#) is used by Content Security Policy as part of the mechanism that ensures [iframe^{p369}](#)s can't be used to evade plugin-types directives. [\[CSP\]^{p1305}](#)

Then, the user agent must act as if it had [stopped parsing^{p1192}](#).

After creating the [Document^{p117}](#) object, but potentially before the page has finished fully loading, the user agent must [update the session history with the new page^{p917}](#) given *navigationParams* and the newly-created [Document^{p117}](#).

User agents may add content to the [head^{p158}](#) element of the [Document^{p117}](#), or attributes to the [embed^{p378}](#) element, e.g. to link to a style sheet or to give the document a [title^{p159}](#).

Note

If the [Document^{p117}](#)'s [active sandboxing flag set^{p875}](#) has its [sandboxed plugins browsing context flag^{p873}](#) set, the synthesized [embed^{p378}](#) element will [fail to render the content^{p381}](#).

7.11.8 Page load processing model for inline content that doesn't have a DOM § ^{p92}₁

When the user agent is to display a user agent page inline, provided a [browsing context^{p840}](#) *browsingContext*, the user agent should:

1. Let *navigationParams* be a new [navigation params^{p905}](#) whose [request^{p905}](#) is null, [response^{p905}](#) is null, [origin^{p905}](#) is a new [opaque origin^{p868}](#), [final sandboxing flag set^{p905}](#) is an empty set, [cross-origin opener policy^{p905}](#) is a new [cross-origin opener policy^{p876}](#), [COOP enforcement result^{p905}](#) is a new [cross-origin opener policy enforcement result^{p878}](#), [reserved environment^{p905}](#) is null, [unsafe start time^{p906}](#) is the [unsafe shared current time](#), and [browsing context^{p905}](#) is *browsingContext*.

The algorithm called in the next step is not prepared to deal with a null [response^{p905}](#). Probably we should synthesize one instead.

2. Let *document* be the result of [creating and initializing a Document object^{p914}](#) given "html", "text/html", and *navigationParams*.
3. Set *document*'s [mode](#) to "no-quirks".
4. Either associate *document* with a custom rendering that is not rendered using the normal [Document^{p117}](#) rendering rules, or mutate *document* until it represents the content the user agent wants to render.

Once the page has been set up, the user agent must act as if it had [stopped parsing^{p1192}](#).

After creating the [Document^{p117}](#) object, but potentially before the page has been completely set up, the user agent must [update the session history with the new page^{p917}](#) given *navigationParams* and the newly-created [Document^{p117}](#).

7.11.9 Navigating to a fragment § ^{p92}₁

To [navigate to a fragment](#) given a [browsing context^{p840}](#) *browsingContext*, a [URL url](#), a [history handling behavior^{p906}](#) *historyHandling*, and a [navigation id^{p906}](#) *navigationId*:

1. If *historyHandling* is not "[replace](#)^{p906}", then remove all the entries in *browsingContext*'s [session history](#)^{p888} after the [current entry](#)^{p890}. (If the [current entry](#)^{p890} is the last entry in the session history, then no entries are removed.)

Note

This [doesn't necessarily have to affect](#)^{p896} the user agent's user interface.

2. Remove any [tasks](#)^{p969} queued by the [history traversal task source](#)^{p978} that are associated with any [Document](#)^{p117} objects in *browsingContext*'s [top-level browsing context](#)^{p844}'s [document family](#)^{p845}.
3. Append a new [session history entry](#)^{p888} to the [session history](#)^{p888} whose [URL](#)^{p888} is *url*, [document](#)^{p888} is the [current entry](#)^{p890}'s [document](#)^{p888}, [policy container](#)^{p888} is the [current entry](#)^{p890}'s [policy-container](#)^{p888} and [scroll restoration mode](#)^{p888} is the [current entry](#)^{p890}'s [scroll restoration mode](#)^{p888}.
4. [Traverse the history](#)^{p923} to the new entry, with [historyHandling](#)^{p923} set to *historyHandling* and with [nonBlockingEvents](#)^{p923} set to true. This will [scroll to the fragment](#)^{p922} given in what is now the document's [URL](#).
5. Invoke [WebDriver BiDi fragment navigated](#) with *browsingContext*, and a new [WebDriver BiDi navigation status](#) whose [id](#) is *navigationId*, [url](#) is *resource's url*, and [status](#) is "[complete](#)".

Note

If the scrolling fails because the relevant [ID](#) has not yet been parsed, then the original [navigation](#)^{p906} algorithm will take care of the scrolling instead, as the last few steps of its [update the session history with the new page](#)^{p917} algorithm.

When the user agent is required to **scroll to the fragment** and [the indicated part of the document](#)^{p922}, if any, is [being rendered](#)^{p1221}, the user agent must either change the scrolling position of the document using the following algorithm, or perform some other action such that [the indicated part of the document](#)^{p922} is brought to the user's attention. If there is no indicated part, or if the indicated part is not [being rendered](#)^{p1221}, then the user agent must do nothing. The aforementioned algorithm is as follows:

1. If there is no [indicated part of the document](#)^{p922}, set the [Document](#)^{p117}'s [target element](#)^{p922} to null.
2. If the [indicated part of the document](#)^{p922} is the top of the document, then:
 1. Set the [Document](#)^{p117}'s [target element](#)^{p922} to null.
 2. [Scroll to the beginning of the document](#) for the [Document](#)^{p117}. [\[CSSOMVIEW\]](#)^{p1307}
3. Otherwise:
 1. Let *target* be element that is [the indicated part of the document](#)^{p922}.
 2. Set the [Document](#)^{p117}'s [target element](#)^{p922} to *target*.
 3. Run the [ancestor details revealing algorithm](#)^{p615} on *target*.
 4. [Scroll target into view](#), with *behavior* set to "auto", *block* set to "start", and *inline* set to "nearest". [\[CSSOMVIEW\]](#)^{p1307}
 5. Run the [focusing steps](#)^{p805} for *target*, with the [Document](#)^{p117}'s [viewport](#) as the *fallback target*.
 6. Move the [sequential focus navigation starting point](#)^{p807} to *target*.

The indicated part of the document is the one that the [fragment](#), if any, identifies. The semantics of the [fragment](#) in terms of mapping it to a node is defined by the specification that defines the [MIME type](#) used by the [Document](#)^{p117} (for example, the processing of [fragments](#) for [XML MIME types](#) is the responsibility of RFC7303). [\[RFC7303\]](#)^{p1311}

There is also a **target element** for each [Document](#)^{p117}, which is used in defining the [:target](#)^{p753} pseudo-class and is updated by the above algorithm. It is initially null.

For HTML documents (and [HTML MIME types](#)), the following processing model must be followed to determine what [the indicated part of the document](#)^{p922} is.

1. Let *fragment* be the document's [URL](#)'s [fragment](#).
2. If *fragment* is the empty string, then [the indicated part of the document](#)^{p922} is the top of the document; return.
3. If [find a potential indicated element](#)^{p923} with *fragment* returns non-null, then the return value is [the indicated part of the](#)

[document](#)^{p922}; return.

- Let *fragmentBytes* be the result of [percent-decoding](#) *fragment*.
- Let *decodedFragment* be the result of running [UTF-8 decode without BOM](#) on *fragmentBytes*.
- If [find a potential indicated element](#)^{p923} with *decodedFragment* returns non-null, then the return value is [the indicated part of the document](#)^{p922}; return.
- If *decodedFragment* is an [ASCII case-insensitive](#) match for the string *top*, then [the indicated part of the document](#)^{p922} is the top of the document; return.
- There is no [indicated part of the document](#)^{p922}.

To **find a potential indicated element** given a string *fragment*, run these steps:

- If there is an element [in the document tree](#) that has an [ID](#) equal to *fragment*, then return the first such element in [tree order](#).
- If there is an [a](#)^{p244} element [in the document tree](#) that has a [name](#)^{p1258} attribute whose value is equal to *fragment*, then return the first such element in [tree order](#).
- Return null.

7.11.10 History traversal §^{p92} 3

To **traverse the history** to a [session history entry](#)^{p888} entry, with an optional [history handling behavior](#)^{p906} **historyHandling** (default "[default](#)^{p906}"), an optional boolean **nonBlockingEvents** (default false), and an optional boolean **explicitHistoryNavigation** (default false):

Note

This algorithm is not just invoked when [explicitly going back or forwards in the session history](#)^{p892} — it is also invoked in other situations, for example when [navigating a browsing context](#)^{p906}, as part of [updating the session history with the new page](#)^{p917}.

- If entry's [document](#)^{p888} is null, then:
 - Assert: *historyHandling* is "[default](#)^{p906}".
 - Let *request* be a new [request](#) whose [URL](#) is entry's [URL](#)^{p888}.
 - If *explicitHistoryNavigation* is true, then set *request*'s [history-navigation flag](#).
 - [Navigate](#)^{p906} the [browsing context](#)^{p840} to *request* with [historyHandling](#)^{p906} set to "[entry update](#)^{p906}" and with [historyPolicyContainer](#)^{p906} set to entry's [policy container](#)^{p888}. The navigation must be done using the same [source browsing context](#)^{p906} as was used the first time *entry* was created.

Note

The "[navigate](#)^{p906}" algorithm reinvokes this "traverse" algorithm to complete the traversal, at which point entry's [document](#)^{p888} is non-null.

Note

If the resource was obtained using a non-idempotent action, for example a POST form submission, or if the resource is no longer available, for example because the computer is now offline and the page wasn't cached, navigating to it again might not be possible. In this case, the navigation will result in a different page than previously; for example, it might be an error message explaining the problem or offering to resubmit the form.

- Return.
- [Save persisted state](#)^{p925} to the [current entry](#)^{p890}.
- Let *newDocument* be entry's [document](#)^{p888}.
- Assert: *newDocument*'s [is initial about:blank](#)^{p118} is false, i.e., we never traverse back to the [initial about:blank](#)^{p118} [Document](#)^{p117} because it always gets [replaced](#)^{p906} when we navigate away from it.

5. If *newDocument* is different than the [current entry](#)^{p890}'s [document](#)^{p888}, or *historyHandling* is "[entry_update](#)^{p906}" or "[reload](#)^{p906}", then:
 1. If *newDocument*'s [suspended timer handles](#)^{p928} is not [empty](#):
 1. Assert: *newDocument*'s [suspension time](#)^{p928} is not zero.
 2. Let *suspendDuration* be the [current high resolution time](#) minus *newDocument*'s [suspension time](#)^{p928}.
 3. Let *activeTimers* be *newDocument*'s [relevant global object](#)^{p944}'s [map of active timers](#)^{p999}.
 4. For each *handle* in *newDocument*'s [suspended timer handles](#)^{p928}, if *activeTimers*[*handle*] [exists](#), then increase *activeTimers*[*handle*] by *suspendDuration*.
 2. Remove any [tasks](#)^{p969} queued by the [history traversal task source](#)^{p978} that are associated with any [Document](#)^{p117} objects in the [top-level browsing context](#)^{p844}'s [document family](#)^{p845}.
 3. If *newDocument*'s [origin](#) is not [same origin](#)^{p869} with the [current entry](#)^{p890}'s [document](#)^{p888}'s [origin](#), then:
 1. Let *entriesToUpdate* be all [entries](#)^{p888} in the [session history](#)^{p888} whose [document](#)^{p888}'s [origin](#) is [same origin](#)^{p869} as the [active document](#)^{p840} and that are contiguous with the [current entry](#)^{p890}.
 2. **For each** *entryToUpdate* of *entriesToUpdate*, set *entryToUpdate*'s [browsing context name](#)^{p889} to the current [browsing context name](#)^{p849}.
 3. If the browsing context is a [top-level browsing context](#)^{p844}, but not an [auxiliary browsing context](#)^{p844} whose [disowned](#)^{p840} is false, then set the browsing context's [name](#)^{p849} to the empty string.
 4. **Set the active document**^{p841} of the [browsing context](#)^{p840} to *newDocument*.
5. If *entry*'s [browsing context name](#)^{p889} is not null, then:
 1. Set the browsing context's [name](#)^{p849} to *entry*'s [browsing context name](#)^{p889}.
 2. Let *entriesToUpdate* be all [entries](#)^{p888} in the [session history](#)^{p888} whose [document](#)^{p888}'s [origin](#) is [same origin](#)^{p869} as the new [active document](#)^{p840}'s [origin](#) and that are contiguous with *entry*.
 3. **For each** *entryToUpdate* of *entriesToUpdate*, set *entryToUpdate*'s [browsing context name](#)^{p889} to null.
6. If *newDocument* has any form controls whose [autofill field name](#)^{p588} is "[off](#)^{p584}", invoke the [reset algorithm](#)^{p614} of each of those elements.
7. If *newDocument*'s [current document readiness](#)^{p120} "complete", then **queue a global task**^{p970} on the [DOM manipulation task source](#)^{p977} given *newDocument*'s [relevant global object](#)^{p944} to run the following steps:
 1. If *newDocument*'s [page showing](#)^{p928} flag is true, then abort these steps.
 2. Set *newDocument*'s [page showing](#)^{p928} flag to true.
 3. **Update the visibility state**^{p793} of *newDocument* to "hidden".
 4. **Fire a page transition event**^{p927} named [pageshow](#)^{p1301} at *newDocument*'s [relevant global object](#)^{p944} with true.
6. Set *newDocument*'s [URL](#) to *entry*'s [URL](#)^{p888}.
7. Let *hashChanged* be false, and let *oldURL* and *newURL* be null.
8. If *entry*'s [URL](#)^{p888}'s [fragment](#) is not [identical to](#) the [current entry](#)^{p890}'s [URL](#)^{p888}'s [fragment](#), and *entry*'s [document](#)^{p888} equals the [current entry](#)^{p890}'s [document](#)^{p888}, then set *hashChanged* to true, set *oldURL* to the [current entry](#)^{p890}'s [URL](#)^{p888}, and set *newURL* to *entry*'s [URL](#)^{p888}.
9. If *historyHandling* is "[replace](#)^{p906}", then remove the entry immediately before *entry* in the [session history](#)^{p888}.
10. If *entry*'s [persisted user state](#)^{p889} is null, and its [URL](#)^{p888}'s [fragment](#) is non-null, then **scroll to the fragment**^{p922}.
11. Set the [current entry](#)^{p890} to *entry*.
12. Let *targetRealm* be the [current Realm Record](#).
13. Let *state* be null.

14. If `entry`'s [serialized state](#)^{p888} is not null, then set `state` to [StructuredDeserialize](#)^{p110}(`entry`'s [serialized state](#)^{p888}, `targetRealm`). If this throws an exception, catch it and ignore the exception.
15. Set `newDocument`'s [History](#)^{p890} object's [state](#)^{p891} to `state`.
16. Let `stateChanged` be true if `newDocument` has a [latest entry](#)^{p890}, and that entry is not `entry`; otherwise let it be false.
17. Set `newDocument`'s [latest entry](#)^{p890} to `entry`.
18. If `nonBlockingEvents` is false, then run the following steps [immediately](#)^{p42}. Otherwise, [queue a global task](#)^{p970} on the [DOM manipulation task source](#)^{p977} given `newDocument`'s [relevant global object](#)^{p944} to run the following steps instead.
 1. If `stateChanged` is true, then [fire an event](#) named [popstate](#)^{p1302} at `newDocument`'s [relevant global object](#)^{p944}, using [PopStateEvent](#)^{p926}, with the [state](#)^{p926} attribute initialized to `state`.
 2. [Restore persisted state](#)^{p925} from `entry`.
 3. If `hashChanged` is true, then [fire an event](#) named [hashchange](#)^{p1301} at the [browsing context](#)^{p840}'s [active window](#)^{p840}, using [HashChangeEvent](#)^{p926}, with the [oldURL](#)^{p926} attribute initialized to `oldURL` and the [newURL](#)^{p926} attribute initialized to `newURL`.

7.11.10.1 Persisted history entry state §^{p92}₅

To **save persisted state** to a [session history entry](#)^{p888} `entry`:

1. Set the [scroll position data](#)^{p888} of `entry` to contain the scroll positions for all of `entry`'s [document](#)^{p888}'s [restorable scrollable regions](#)^{p925}.
2. Optionally, update `entry`'s [persisted user state](#)^{p889} to reflect any state that the user agent wishes to persist, such as the values of form fields.

To **restore persisted state** from a [session history entry](#)^{p888} `entry`:

1. If `entry`'s [scroll restoration mode](#)^{p888} is `"auto"`^{p889}, then the user agent may use `entry`'s [scroll position data](#)^{p888} to restore the scroll positions of `entry`'s [document](#)^{p888}'s [restorable scrollable regions](#)^{p925}.

Note

The user agent not restoring scroll positions does not imply that scroll positions will be left at any particular value (e.g., (0,0)). The actual scroll position depends on the navigation type and the user agent's particular caching strategy. So web applications cannot assume any particular scroll position but rather are urged to set it to what they want it to be.

2. Optionally, update other aspects of `entry`'s [document](#)^{p888} and its rendering, for instance values of form fields, that the user agent had previously recorded in `entry`'s [persisted user state](#)^{p889}.

Note

This can even include updating the [dir](#)^{p146} attribute of [textarea](#)^{p558} elements or [input](#)^{p501} elements whose [type](#)^{p503} attribute is in either the [Text](#)^{p508} state or the [Search](#)^{p508} state, if the persisted state includes the directionality of user input in such controls.

Note

Restoring the value of form controls as part of this process does not fire any [input](#)^{p1301} or [change](#)^{p1301} events, but can trigger the `formStateRestoreCallback` of [form-associated custom elements](#)^{p729}.

The **restorable scrollable regions** of a [Document](#)^{p117} `document` are `document`'s [viewport](#), and all of `document`'s scrollable regions excepting any [child browsing contexts](#)^{p843} of `document`.

Note

[Child browsing context](#)^{p843} scroll restoration is handled by the history entry for those browsing contexts' [Document](#)^{p117}s.

7.11.10.2 The [PopStateEvent](#)^{p926} interface § p926

```
IDL [Exposed=Window]
interface PopStateEvent : Event {
  constructor(DOMString type, optional PopStateEventInit eventInitDict = {});

  readonly attribute any state;
};

dictionary PopStateEventInit : EventInit {
  any state = null;
};
```

For web developers (non-normative)

`event.state`^{p926}

Returns a copy of the information that was provided to [pushState\(\)](#)^{p894} or [replaceState\(\)](#)^{p894}.

The **state** attribute must return the value it was initialized to. It represents the context information for the event, or null, if the state represented is the initial state of the [Document](#)^{p117}.

7.11.10.3 The [HashChangeEvent](#)^{p926} interface § p926

```
IDL [Exposed=Window]
interface HashChangeEvent : Event {
  constructor(DOMString type, optional HashChangeEventInit eventInitDict = {});

  readonly attribute USVString oldURL;
  readonly attribute USVString newURL;
};

dictionary HashChangeEventInit : EventInit {
  USVString oldURL = "";
  USVString newURL = "";
};
```

For web developers (non-normative)

`event.oldURL`^{p926}

Returns the [URL](#) of the [session history entry](#)^{p888} that was previously current.

`event.newURL`^{p926}

Returns the [URL](#) of the [session history entry](#)^{p888} that is now current.

The **oldURL** attribute must return the value it was initialized to. It represents context information for the event, specifically the URL of the [session history entry](#)^{p888} that was traversed from.

The **newURL** attribute must return the value it was initialized to. It represents context information for the event, specifically the URL of the [session history entry](#)^{p888} that was traversed to.

7.11.10.4 The [PageTransitionEvent](#)^{p926} interface § p926

```
IDL [Exposed=Window]
interface PageTransitionEvent : Event {
  constructor(DOMString type, optional PageTransitionEventInit eventInitDict = {});

  readonly attribute boolean persisted;
};
```

```
dictionary PageTransitionEventInit : EventInit {
  boolean persisted = false;
};
```

For web developers (non-normative)

event.persisted^{p927}

For the [pageshow](#)^{p1301} event, returns false if the page is newly being loaded (and the [load](#)^{p1301} event will fire). Otherwise, returns true.

For the [pagehide](#)^{p1301} event, returns false if the page is going away for the last time. Otherwise, returns true, meaning that the page might be reused if the user navigates back to this page (if the [Document](#)^{p117}'s [salvageable](#)^{p928} state stays true).

Things that can cause the page to be unsalvageable include:

- The user agent decided to not keep the [Document](#)^{p117} alive in a [session history entry](#)^{p888} after [unload](#)^{p928}
- Having [iframe](#)^{p369}s that are not [salvageable](#)^{p928}
- Active [WebSocket](#) objects
- [Aborting a Document](#)^{p930}

The **persisted** attribute must return the value it was initialized to. It represents the context information for the event.

To **fire a page transition event** named *eventName* at a [Window](#)^{p855} *window* with a boolean *persisted*, [fire an event](#) named *eventName* at *window*, using [PageTransitionEvent](#)^{p926}, with the **persisted** attribute initialized to *persisted*, the **cancelable** attribute initialized to true, the **bubbles** attribute initialized to true, and *legacy target override flag* set.

Note

*The values for **cancelable** and **bubbles** don't make any sense, since canceling the event does nothing and it's not possible to bubble past the [Window](#)^{p855} object. They are set to true for historical reasons.*

7.11.11 Loading documents ^{p92}₇

A [Document](#)^{p117} has a **completely loaded time** (a time or null), which is initially null.

A [Document](#)^{p117} is considered **completely loaded** if its [completely loaded time](#)^{p927} is non-null.

To **completely finish loading** a [Document](#)^{p117} *document*:

1. Assert: *document*'s [browsing context](#)^{p840} is non-null.
2. Set *document*'s [completely loaded time](#)^{p927} to the current time.
3. Let *container* be *document*'s [browsing context](#)^{p840}'s [container](#)^{p843}.

Note

This will be null in the case where document is the [initial about:blank](#)^{p118} [Document](#)^{p117} in a [frame](#)^{p1264} or [iframe](#)^{p369}, since at the point of [browsing context creation](#)^{p841} which calls this algorithm, the container relationship has not yet been established. (That happens in a subsequent step of [create a new nested browsing context](#)^{p843}.)

The consequence of this is that the following steps do nothing, i.e., we do not fire an asynchronous [load](#)^{p1301} event on the container element for such cases. Instead, a synchronous [load](#)^{p1301} event is fired in a special initial-insertion case in the [shared attribute processing steps for iframe and frame elements](#)^{p372}.

4. If *container* is an [iframe](#)^{p369} element, then [queue an element task](#)^{p970} on the [DOM manipulation task source](#)^{p977} given *container* to run the [iframe load event steps](#)^{p373} given *container*.
5. Otherwise, if *container* is non-null, then [queue an element task](#)^{p970} on the [DOM manipulation task source](#)^{p977} given *container* to [fire an event](#) named [load](#)^{p1301} at *container*.

7.11.12 Unloading documents §^{p92}₈

A [Document](#)^{p117} has a **salvageable** state, which must initially be true, and a **page showing** flag, which must initially be false. The [page showing](#)^{p928} flag is used to ensure that scripts receive [pageshow](#)^{p1301} and [pagehide](#)^{p1301} events in a consistent manner (e.g. that they never receive two [pagehide](#)^{p1301} events in a row without an intervening [pageshow](#)^{p1301}, or vice versa).

A [Document](#)^{p117} has a [DOMHighResTimeStamp](#) **suspension time**, initially 0.

A [Document](#)^{p117} has a [list](#) of **suspended timer handles**, initially empty.

[Event loops](#)^{p968} have a **termination nesting level** counter, which must initially be 0.

[Document](#)^{p117} objects have an **unload counter**, which is used to ignore certain operations while the below algorithms run. Initially, the counter must be set to zero.

To **prompt to unload**, given a [Document](#)^{p117} object *document* and optionally a *recursiveFlag*, run these steps:

1. Increase the [event loop](#)^{p968}'s [termination nesting level](#)^{p928} by 1.
2. Increase the *document*'s [unload counter](#)^{p928} by 1.
3. Let *event* be the result of [creating an event](#) using [BeforeUnloadEvent](#)^{p930}.
4. Initialize *event*'s **type** attribute to [beforeunload](#)^{p1300} and its **cancelable** attribute true.
5. [Dispatch](#) *event* at *document*'s [relevant global object](#)^{p944}.
6. Decrease the [event loop](#)^{p968}'s [termination nesting level](#)^{p928} by 1.
7. Let *result* be "no-prompt".
8. If all of the following are true:
 - *document*'s [active sandboxing flag set](#)^{p875} does not have its [sandboxed modals flag](#)^{p874} set
 - *document*'s [relevant global object](#)^{p944} has [sticky activation](#)^{p795}
 - *event*'s [canceled flag](#) is set, or the [returnValue](#)^{p930} attribute of *event* is not the empty string

then the user agent may ask the user to confirm that they wish to unload the document.

Note

The message shown to the user is not customizable, but instead determined by the user agent. In particular, the actual value of the [returnValue](#)^{p930} attribute is ignored.

The user agent is encouraged to avoid asking the user for confirmation if it judges that doing so would be annoying, deceptive, or pointless.

If the user agent asks the user for confirmation, it must [pause](#)^{p977} while waiting for the user's response.

If the user confirmed the page navigation, then set *result* to "confirm"; otherwise return "refuse".

9. If the *recursiveFlag* is not set, then:
 1. Let *descendants* be the [list of the descendant browsing contexts](#)^{p844} of *document*.
 2. For each *browsingContext* in *descendants*:
 1. Let *internalResult* be the result of calling [prompt to unload](#)^{p928} for *browsingContext*'s [active document](#)^{p840} with the *recursiveFlag* set.
 2. If *internalResult* is "refuse", then return *internalResult*.
 3. Otherwise, if *internalResult* is "confirm", set *result* to *internalResult*.
10. Decrease the *document*'s [unload counter](#)^{p928} by 1.
11. Return *result*.

To **unload** a [Document](#)^{p117} *document*, given an optional *recursiveFlag* and a [document unload timing info](#)^{p121}-or-null *unloadTimingInfo* (default null):

1. Increase the [event loop](#)^{p968}'s [termination nesting level](#)^{p928} by one.
2. Increase *document*'s [unload counter](#)^{p928} by 1.
3. If the user agent does not intend to keep *document* alive in a [session history entry](#)^{p888} (such that it can be reused later on [history traversal](#)^{p923}), set *document*'s [salvageable](#)^{p928} state to false.
4. If *document*'s [page showing](#)^{p928} flag is true:
 1. Set *document*'s [page showing](#)^{p928} flag to false.
 2. [Fire a page transition event](#)^{p927} named [pagehide](#)^{p1301} at *document*'s [relevant global object](#)^{p944} with *document*'s [salvageable](#)^{p928} state.
 3. [Update the visibility state](#)^{p793} of *newDocument* to "hidden".
5. If *unloadTimingInfo* is not null, then set *unloadTimingInfo*'s [unload event start time](#)^{p121} to the [current high resolution time](#) given *document*'s [relevant global object](#)^{p944}.
6. If *document*'s [salvageable](#)^{p928} state is false, then [fire an event](#) named [unload](#)^{p1302} at *document*'s [relevant global object](#)^{p944}, with *legacy target override flag* set.
7. If *unloadTimingInfo* is not null, then set *unloadTimingInfo*'s [unload event end time](#)^{p121} to the [current high resolution time](#) given *document*'s [relevant global object](#)^{p944}.
8. Decrease the [event loop](#)^{p968}'s [termination nesting level](#)^{p928} by one.
9. Set *document*'s [suspension time](#)^{p928} to the [current high resolution time](#).
10. Set *document*'s [suspended timer handles](#)^{p928} to the result of [getting the keys](#) for the [map of active timers](#)^{p999}.
11. Run any [unloading document cleanup steps](#)^{p929} for *document* that are defined by this specification and [other applicable specifications](#)^{p67}.
12. If the *recursiveFlag* is not set, then:
 1. Let *descendants* be the [list of the descendant browsing contexts](#)^{p844} of *document*.
 2. For each *browsingContext* in *descendants*:
 1. [Unload](#)^{p928} the [active document](#)^{p840} of *browsingContext* with the *recursiveFlag* set.
 2. If the [salvageable](#)^{p928} state of the [active document](#)^{p840} of *browsingContext* is false, then set the [salvageable](#)^{p928} state of *document* to false also.
 3. If *document*'s [salvageable](#)^{p928} state is false, then [discard](#)^{p862} *document*.
13. Decrease *document*'s [unload counter](#)^{p928} by 1.

This specification defines the following **unloading document cleanup steps**. Other specifications can define more. Given a [Document](#)^{p117} *document*:

1. Let *window* be *document*'s [relevant global object](#)^{p944}.
2. For each [WebSocket](#) object *websocket* whose [relevant global object](#)^{p944} is *window*, [make disappear](#) *websocket*.
If this affected any [WebSocket](#) objects, then set *document*'s [salvageable](#)^{p928} state to false.
3. If *document*'s [salvageable](#)^{p928} state is false, then:
 1. For each [EventSource](#)^{p1026} object *eventSource* whose [relevant global object](#)^{p944} is equal to *window*, [forcibly close](#)^{p1033} *eventSource*.
 2. [Clear](#) *window*'s [map of active timers](#)^{p999}.

7.11.12.1 The [BeforeUnloadEvent](#)^{p930} interface § 9.2

IDL [Exposed=Window]

```
interface BeforeUnloadEvent : Event {
  attribute DOMString returnValue;
};
```

Note

There are no [BeforeUnloadEvent](#)^{p930}-specific initialization methods.

The [BeforeUnloadEvent](#)^{p930} interface is a legacy interface which allows [prompting to unload](#)^{p928} to be controlled not only by canceling the event, but by setting the [returnValue](#)^{p930} attribute to a value besides the empty string. Authors should use the [preventDefault\(\)](#) method, or other means of canceling events, instead of using [returnValue](#)^{p930}.

The [returnValue](#) attribute controls the process of [prompting to unload](#)^{p928}. When the event is created, the attribute must be set to the empty string. On getting, it must return the last value it was set to. On setting, the attribute must be set to the new value.

Note

This attribute is a `DOMString` only for historical reasons. Any value besides the empty string will be treated as a request to ask the user for confirmation.

7.11.13 Aborting a document load §^{p93}₀

To **abort** a [Document](#)^{p117} *document*:

1. [Abort](#)^{p930} the [active documents](#)^{p840} of every [child browsing context](#)^{p843}. If this results in any of those [Document](#)^{p117} objects having their [salvageable](#)^{p928} state set to false, then set *document*'s [salvageable](#)^{p928} state to false also.
2. Cancel any instances of the [fetch](#) algorithm in the context of *document*, discarding any [tasks](#)^{p969} [queued](#)^{p970} for them, and discarding any further data received from the network for them. If this resulted in any instances of the [fetch](#) algorithm being canceled or any [queued](#)^{p970} [tasks](#)^{p969} or any network data getting discarded, then set *document*'s [salvageable](#)^{p928} state to false.
3. If *document*'s [navigation id](#)^{p118} is non-null, then:
 1. Invoke [WebDriver BiDi navigation aborted](#) with *document*'s [browsing context](#)^{p840}, and new [WebDriver BiDi navigation status](#) whose [id](#) is *document*'s [navigation id](#)^{p118}, [status](#) is "canceled", and [url](#) is *document*'s [URL](#).
 2. Set *document*'s [navigation id](#)^{p118} to null.
4. If *document* has an [active parser](#)^{p121}, then:
 1. Set *document*'s [active parser was aborted](#)^{p994} to true.
 2. [Abort that parser](#)^{p1193}.
 3. Set *document*'s [salvageable](#)^{p928} state to false.

User agents may allow users to explicitly invoke the [stop document loading](#)^{p930} for a [Document](#)^{p117}.

To **stop document loading** given a [Document](#)^{p117} object *document*, run these steps:

1. Let *browsingContext* be *document*'s [browsing context](#)^{p840}.
2. If *browsingContext*'s [active document](#)^{p840} is not *document*, then return.
3. If there is an existing attempt to [navigate](#)^{p906} *browsingContext* and *document*'s [unload counter](#)^{p928} is 0, then cancel that [navigation](#)^{p906}.
4. [Abort](#)^{p930} *document*.

7.11.14 The `X-Frame-Options` header § 93

The `X-Frame-Options` HTTP response header is a legacy way of controlling whether and how a [Document](#) may be loaded inside of a [child browsing context](#). It is obsoleted by the `frame-ancestors` CSP directive, which provides more granular control over the same situations. It was originally defined in *HTTP Header Field X-Frame-Options*, but the definition and processing model here supersedes that document. [\[CSP\]](#) [\[RFC7034\]](#)

Note

In particular, HTTP Header Field X-Frame-Options specified an `ALLOW-FROM` variant of the header, but that is not to be implemented.

Note

Per the below processing model, if both a CSP `frame-ancestors` directive and an `X-Frame-Options` header are used in the same response, then `X-Frame-Options` is ignored.

For web developers and conformance checkers, its value ABNF is:

```
X-Frame-Options = "DENY" / "SAMEORIGIN"
```

To check a navigation response's adherence to `X-Frame-Options`, given [navigationParams](#), a [browsing context](#), and an [origin](#) [destinationOrigin](#):

1. If [browsingContext](#) is not a [child browsing context](#), then return true.
2. For each policy of [navigationParams](#)'s [policy container](#)'s [CSP list](#):
 1. If policy's [disposition](#) is not "enforce", then [continue](#).
 2. If policy's [directive set](#) contains a `frame-ancestors` directive, then return true.
3. Let [rawXFrameOptions](#) be the result of [getting, decoding, and splitting](#) `X-Frame-Options` from [navigationParams](#)'s [response](#)'s [header list](#).
4. Let [xFrameOptions](#) be a new [set](#).
5. For each value of [rawXFrameOptions](#), [append value, converted to ASCII lowercase](#), to [xFrameOptions](#).
6. If [xFrameOptions](#)'s [size](#) is greater than 1, and [xFrameOptions](#) contains any of "deny", "allowall", or "sameorigin", then return false.

Note

The intention here is to block any attempts at applying `X-Frame-Options` which were trying to do something valid, but appear confused.

Note

This is the only impact of the legacy `ALLOWALL` value on the processing model.

7. If [xFrameOptions](#)'s [size](#) is greater than 1, then return true.

Note

This means it contains multiple invalid values, which we treat the same way as if the header was omitted entirely.

8. If [xFrameOptions](#)[0] is "deny", then return false.
9. If [xFrameOptions](#)[0] is "sameorigin", then:
 1. Let [containerDocument](#) be [browsingContext](#)'s [container document](#).
 2. While [containerDocument](#) is not null:
 1. If [containerDocument](#)'s [origin](#) is not [same origin](#) with [destinationOrigin](#), then return false.
 2. Let [containerBC](#) be [containerDocument](#)'s [browsing context](#).

- Set `containerDocument` to `containerBC`'s [container document](#)^{p843}, if `containerBC` is non-null; otherwise, null.

10. Return true.

Note

If we've reached this point then we have a lone invalid value (which could potentially be one the legacy `ALLOWALL` or `ALLOW-FROM` forms). These are treated as if the header were omitted entirely.

Example

The following table illustrates the processing of various values for the header, including non-conformant ones:

<code>`X-Frame-Options`</code> ^{p931}	Valid	Result
<code>`DENY`</code>	✓	embedding disallowed
<code>`SAMEORIGIN`</code>	✓	same-origin embedding allowed
<code>`INVALID`</code>	✗	embedding allowed
<code>`ALLOWALL`</code>	✗	embedding allowed
<code>`ALLOW-FROM=https://example.com/`</code>	✗	embedding allowed (from anywhere)

Example

The following table illustrates how various non-conformant cases involving multiple values are processed:

<code>`X-Frame-Options`</code> ^{p931}	Result
<code>`SAMEORIGIN, SAMEORIGIN`</code>	same-origin embedding allowed
<code>`SAMEORIGIN, DENY`</code>	embedding disallowed
<code>`SAMEORIGIN, `</code>	embedding disallowed
<code>`SAMEORIGIN, ALLOWALL`</code>	embedding disallowed
<code>`SAMEORIGIN, INVALID`</code>	embedding disallowed
<code>`ALLOWALL, INVALID`</code>	embedding disallowed
<code>`ALLOWALL, `</code>	embedding disallowed
<code>`INVALID, INVALID`</code>	embedding allowed

The same results are obtained whether the values are delivered in a single header whose value is comma-delimited, or in multiple headers.

7.11.15 The ``Refresh``^{p932} header ^{§ p93}₂

The ``Refresh`` HTTP response header is the HTTP-equivalent to a [meta](#)^{p170} element with an [http-equiv](#)^{p176} attribute in the [Refresh state](#)^{p177}. It takes [the same value](#)^{p178} and works largely the same. Its processing model is detailed in [create and initialize a Document object](#)^{p914}.

8 Web application APIs §^{p93}₃

8.1 Scripting §^{p93}₃

8.1.1 Introduction §^{p93}₃

Various mechanisms can cause author-provided executable code to run in the context of a document. These mechanisms include, but are probably not limited to:

- Processing of [script^{p624}](#) elements.
- Navigating to [javascript: URLs^{p913}](#).
- Event handlers, whether registered through the DOM using `addEventListener()`, by explicit [event handler content attributes^{p981}](#), by [event handler IDL attributes^{p981}](#), or otherwise.
- Processing of technologies like SVG that have their own scripting features.

8.1.2 Agents and agent clusters §^{p93}₃

8.1.2.1 Integration with the JavaScript agent formalism §^{p93}₃

JavaScript defines the concept of an [agent](#). This section gives the mapping of that language-level concept on to the web platform.

Note

Conceptually, the [agent](#) concept is an architecture-independent, idealized "thread" in which JavaScript code runs. Such code can involve multiple [globals/realms^{p938}](#) that can synchronously access each other, and thus needs to run in a single execution thread.

Two [Window^{p855}](#) objects having the same [agent](#) does not indicate they can directly access all objects created in each other's realms. They would have to be [same origin-domain^{p869}](#); see [IsPlatformObjectSameOrigin^{p852}](#).

The following types of agents exist on the web platform:

Similar-origin window agent

Contains various [Window^{p855}](#) objects which can potentially reach each other, either directly or by using [document.domain^{p871}](#).

If the encompassing [agent cluster](#)'s [is origin-keyed^{p934}](#) is true, then all the [Window^{p855}](#) objects will be [same origin^{p869}](#), can reach each other directly, and [document.domain^{p871}](#) will no-op.

Note

Two [Window^{p855}](#) objects that are [same origin^{p869}](#) can be in different [similar-origin window agents^{p933}](#), for instance if they are each in their own [browsing context group^{p848}](#).

Dedicated worker agent

Contains a single [DedicatedWorkerGlobalScope^{p1064}](#).

Shared worker agent

Contains a single [SharedWorkerGlobalScope^{p1064}](#).

Service worker agent

Contains a single [ServiceWorkerGlobalScope](#).

Worklet agent

Contains a single [WorkletGlobalScope^{p1080}](#) object.

Note

Although a given worklet can have multiple realms, each such realm needs its own agent, as each realm can be executing code independently and at the same time as the others.

Only [shared^{p933}](#) and [dedicated worker agents^{p933}](#) allow the use of JavaScript [Atomics](#) APIs to potentially [block](#).

To **create an agent**, given a boolean *canBlock*:

1. Let *signifier* be a new unique internal value.
2. Let *candidateExecution* be a new [candidate execution](#).
3. Let *agent* be a new [agent](#) whose `[[CanBlock]]` is *canBlock*, `[[Signifier]]` is *signifier*, `[[CandidateExecution]]` is *candidateExecution*, and `[[IsLockFree1]]`, `[[IsLockFree2]]`, and `[[LittleEndian]]` are set at the implementation's discretion.
4. Set *agent*'s [event loop^{p968}](#) to a new [event loop^{p968}](#).
5. Return *agent*.

The **relevant agent** for a [platform object](#) *platformObject* is *platformObject*'s [relevant Realm^{p944}](#)'s [agent](#). This pointer is not yet defined in the JavaScript specification; see [tc39/ecma262#1357](#).

Note

The agent equivalent of the [current Realm Record](#) is the [surrounding agent](#).

8.1.2.2 Integration with the JavaScript agent cluster formalism ^{p93}₄

JavaScript also defines the concept of an [agent cluster](#), which this standard maps to the web platform by placing agents appropriately when they are created using the [obtain a similar-origin window agent^{p934}](#) or [obtain a worker/worklet agent^{p935}](#) algorithms.

The [agent cluster](#) concept is crucial for defining the JavaScript memory model, and in particular among which [agents](#) the backing data of [SharedArrayBuffer](#) objects can be shared.

Note

Conceptually, the [agent cluster](#) concept is an architecture-independent, idealized "process boundary" that groups together multiple "threads" ([agents](#)). The [agent clusters](#) defined by the specification are generally more restrictive than the actual process boundaries implemented in user agents. By enforcing these idealized divisions at the specification level, we ensure that web developers see interoperable behavior with regard to shared memory, even in the face of varying and changing user agent process models.

An [agent cluster](#) has an associated **cross-origin isolation mode**, which is a [cross-origin isolation mode^{p848}](#). It is initially "[none^{p848}](#)".

An [agent cluster](#) has an associated **is origin-keyed** (a boolean), which is initially false.

The following defines the allocation of the [agent clusters](#) of [similar-origin window agents^{p933}](#).

An **agent cluster key** is a [site^{p869}](#) or [tuple origin^{p868}](#). Without web developer action to achieve [origin-keyed agent clusters^{p872}](#), it will be a [site^{p869}](#).

Note

An equivalent formulation is that an [agent cluster key^{p934}](#) can be a [scheme-and-host^{p869}](#) or an [origin^{p868}](#).

To **obtain a similar-origin window agent**, given an [origin^{p868}](#) *origin*, a [browsing context group^{p848}](#) *group*, and a boolean *requestsOAC*, run these steps:

1. Let *site* be the result of [obtaining a site^{p869}](#) with *origin*.
2. Let *key* be *site*.
3. If *group*'s [cross-origin isolation mode^{p848}](#) is not "[none^{p848}](#)", then set *key* to *origin*.

4. Otherwise, if *group*'s [historical agent cluster key map](#)^{p848}[*origin*] *exists*, then set *key* to *group*'s [historical agent cluster key map](#)^{p848}[*origin*].
5. Otherwise:
 1. If *requestsOAC* is true, then set *key* to *origin*.
 2. Set *group*'s [historical agent cluster key map](#)^{p848}[*origin*] to *key*.
6. If *group*'s [agent cluster map](#)^{p848}[*key*] *does not exist*, then:
 1. Let *agentCluster* be a new [agent cluster](#).
 2. Set *agentCluster*'s [cross-origin isolation mode](#)^{p934} to *group*'s [cross-origin isolation mode](#)^{p848}.
 3. Set *agentCluster*'s [is origin-keyed](#)^{p934} to true if *key* equals *origin*; otherwise false.
 4. Add the result of [creating an agent](#)^{p934}, given false, to *agentCluster*.
 5. Set *group*'s [agent cluster map](#)^{p848}[*key*] to *agentCluster*.
7. Return the single [similar-origin window agent](#)^{p933} contained in *group*'s [agent cluster map](#)^{p848}[*key*].

Note

This means that there is only one [similar-origin window agent](#)^{p933} per browsing context agent cluster. (However, [dedicated worker](#)^{p933} and [worklet agents](#)^{p933} might be in the same cluster.)

The following defines the allocation of the [agent clusters](#) of all other types of agents.

To **obtain a worker/worklet agent**, given an [environment settings object](#)^{p937} or null *outside settings*, a boolean *isTopLevel*, and a boolean *canBlock*, run these steps:

1. Let *agentCluster* be null.
2. If *isTopLevel* is true, then:
 1. Set *agentCluster* to a new [agent cluster](#).
 2. Set *agentCluster*'s [is origin-keyed](#)^{p934} to true.

Note

These workers can be considered to be origin-keyed. However, this is not exposed through any APIs (in the way that [originAgentCluster](#)^{p873} exposes the origin-keyedness for windows).

3. Otherwise:
 1. Assert: *outside settings* is not null.
 2. Let *ownerAgent* be *outside settings*'s [Realm](#)^{p938}'s agent.
 3. Set *agentCluster* to the agent cluster which contains *ownerAgent*.
4. Let *agent* be the result of [creating an agent](#)^{p934} given *canBlock*.
5. Add *agent* to *agentCluster*.
6. Return *agent*.

To **obtain a dedicated/shared worker agent**, given an [environment settings object](#)^{p937} *outside settings* and a boolean *isShared*, return the result of [obtaining a worker/worklet agent](#)^{p935} given *outside settings*, *isShared*, and true.

To **obtain a worklet agent**, given an [environment settings object](#)^{p937} *outside settings*, return the result of [obtaining a worker/worklet agent](#)^{p935} given *outside settings*, false, and false.

To **obtain a service worker agent**, return the result of [obtaining a worker/worklet agent](#)^{p935} given null, true, and false.

Example

The following pairs of global objects are each within the same [agent cluster](#), and thus can use [SharedArrayBuffer](#) instances to share memory with each other:

- A [Window](#)^{p855} object and a dedicated worker that it created.
- A worker (of any type) and a dedicated worker it created.
- A [Window](#)^{p855} object A and the [Window](#)^{p855} object of an [iframe](#)^{p369} element that A created that could be [same-origin-domain](#)^{p869} with A.
- A [Window](#)^{p855} object and a [same-origin-domain](#)^{p869} [Window](#)^{p855} object that opened it.
- A [Window](#)^{p855} object and a worklet that it created.

The following pairs of global objects are *not* within the same [agent cluster](#), and thus cannot share memory:

- A [Window](#)^{p855} object and a shared worker it created.
- A worker (of any type) and a shared worker it created.
- A [Window](#)^{p855} object and a service worker it created.
- A [Window](#)^{p855} object and the [Window](#)^{p855} object of an [iframe](#)^{p369} element that A created that cannot be [same-origin-domain](#)^{p869} with A.
- Any two [Window](#)^{p855} objects whose [browsing contexts](#)^{p840} do not have a non-null [opener](#)^{p840} or [ancestor](#)^{p843} relationship. This holds even if the two [Window](#)^{p855} objects are [same-origin](#)^{p869}.

8.1.3 Realms and their counterparts §^{p93}₆

The JavaScript specification introduces the [realm](#) concept, representing a global environment in which script is run. Each realm comes with an [implementation-defined global object](#)^{p938}; much of this specification is devoted to defining that global object and its properties.

For web specifications, it is often useful to associate values or algorithms with a realm/global object pair. When the values are specific to a particular type of realm, they are associated directly with the global object in question, e.g., in the definition of the [Window](#)^{p855} or [WorkerGlobalScope](#)^{p1062} interfaces. When the values have utility across multiple realms, we use the [environment settings object](#)^{p937} concept.

Finally, in some cases it is necessary to track associated values before a realm/global object/environment settings object even comes into existence (for example, during [navigation](#)^{p906}). These values are tracked in the [environment](#)^{p936} concept.

8.1.3.1 Environments §^{p93}₆

An **environment** is an object that identifies the settings of a current or potential execution environment. An [environment](#)^{p936} has the following fields:

An *id*

An opaque string that uniquely identifies this [environment](#)^{p936}.

A *creation URL*

A [URL](#) that represents the location of the resource with which this [environment](#)^{p936} is associated.

Note

In the case of an [environment settings object](#)^{p937}, this URL might be distinct from the [environment settings object](#)^{p937}'s [responsible document](#)^{p937}'s URL, due to mechanisms such as [history.pushState\(\)](#)^{p894}.

A *top-level creation URL*

Null or a [URL](#) that represents the [creation URL](#)^{p936} of the "top-level" [environment](#)^{p936}. It is null for workers and worklets.

A *top-level origin*

A [for now](#) [implementation-defined](#) value, null, or an [origin](#)^{p868}. For a "top-level" potential execution environment it is null (i.e., when there is no response yet); otherwise it is the "top-level" [environment](#)^{p936}'s [origin](#)^{p937}. For a dedicated worker or worklet it is the [top-level origin](#)^{p936} of its creator. For a shared or service worker it is an [implementation-defined](#) value.

Note

This is distinct from the [top-level creation URL](#)^{p936}'s [origin](#) when sandboxing, workers, and worklets are involved.

A target browsing context

Null or a target [browsing context](#)^{p840} for a [navigation request](#).

An active service worker

Null or a [service worker](#) that [controls](#) the [environment](#)^{p936}.

An execution ready flag

A flag that indicates whether the environment setup is done. It is initially unset.

Specifications may define **environment discarding steps** for environments. The steps take an [environment](#)^{p936} as input.

Note

The [environment discarding steps](#)^{p937} are run for only a select few environments: the ones that will never become execution ready because, for example, they failed to load.

8.1.3.2 Environment settings objects ^{§ p933}₇

An **environment settings object** is an [environment](#)^{p936} that additionally specifies algorithms for:

A realm execution context

A [JavaScript execution context](#) shared by all [scripts](#)^{p624} that use this settings object, i.e. all scripts in a given [JavaScript realm](#). When we [run a classic script](#)^{p956} or [run a module script](#)^{p957}, this execution context becomes the top of the [JavaScript execution context stack](#), on top of which another execution context specific to the script in question is pushed. (This setup ensures [ParseScript](#) and [Source Text Module Record](#)'s [Evaluate](#) know which Realm to use.)

A module map

A [module map](#)^{p965} that is used when importing JavaScript modules.

A responsible document

A [Document](#)^{p117} that is assigned responsibility for actions taken by the scripts that use this [environment settings object](#)^{p937}.

Example

For example, the [URL](#) of the [responsible document](#)^{p937} is used to set the [URL](#) of the [Document](#)^{p117} after it has been reset using [document.open\(\)](#)^{p995}.

If the [responsible event loop](#)^{p938} is not a [window event loop](#)^{p968}, then the [environment settings object](#)^{p937} has no [responsible document](#)^{p937}.

An API URL character encoding

A character encoding used to encode URLs by APIs called by scripts that use this [environment settings object](#)^{p937}.

An API base URL

A [URL](#) used by APIs called by scripts that use this [environment settings object](#)^{p937} to [parse URLs](#)^{p91}.

An origin

An [origin](#)^{p868} used in security checks.

A policy container

A [policy container](#)^{p886} containing policies used for security checks.

A cross-origin isolated capability

A boolean representing whether scripts that use this [environment settings object](#)^{p937} are allowed to use APIs that require cross-origin isolation.

A time origin

A number used as the baseline for performance-related timestamps. [\[HRT\]](#)^{p1308}

An [environment settings object](#)^{p937} also has an **outstanding rejected promises weak set** and an **about-to-be-notified rejected promises list**, used to track [unhandled promise rejections](#)^{p960}. The [outstanding rejected promises weak set](#)^{p937} must not create strong

references to any of its members, and implementations are free to limit its size, e.g. by removing old entries from it when new ones are added.

An [environment settings object](#)^{p937}'s **responsible event loop** is its [global object](#)^{p938}'s [relevant agent](#)^{p934}'s [event loop](#)^{p968}.

8.1.3.3 Realms, settings objects, and global objects §^{p93}₈

A **global object** is a JavaScript object that is the `[[GlobalObject]]` field of a [JavaScript realm](#).

Note

In this specification, all [JavaScript realms](#) are created^{p938} with [global objects](#)^{p938} that are either [Window](#)^{p855} or [WorkerGlobalScope](#)^{p1062} objects.

There is always a 1-to-1-to-1 mapping between [JavaScript realms](#), [global objects](#)^{p938}, and [environment settings objects](#)^{p937}:

- A [JavaScript realm](#) has a `[[HostDefined]]` field, which contains **the Realm's settings object**.
- A [JavaScript realm](#) has a `[[GlobalObject]]` field, which contains **the Realm's global object**.
- Each [global object](#)^{p938} in this specification is created during the [creation](#)^{p938} of a corresponding [JavaScript realm](#), known as **the global object's Realm**.
- Each [global object](#)^{p938} in this specification is created alongside a corresponding [environment settings object](#)^{p937}, known as its [relevant settings object](#)^{p944}.
- An [environment settings object](#)^{p937}'s [realm execution context](#)^{p937}'s Realm component is **the environment settings object's Realm**.
- An [environment settings object](#)^{p937}'s [Realm](#)^{p938} then has a `[[GlobalObject]]` field, which contains **the environment settings object's global object**.

To **create a new JavaScript realm** in an [agent](#) *agent*, optionally with instructions to create a global object or a global **this** binding (or both), the following steps are taken:

1. Perform [InitializeHostDefinedRealm\(\)](#) with the provided customizations for creating the global object and the global **this** binding.
2. Let *realm execution context* be the [running JavaScript execution context](#).

Note

This is the [JavaScript execution context](#) created in the previous step.

3. Remove *realm execution context* from the [JavaScript execution context stack](#).
4. Let *realm* be *realm execution context*'s Realm component.
5. Set *realm*'s agent to *agent*. This pointer is not yet defined in the JavaScript specification; see [tc39/ecma262#1357](#).
6. If *agent*'s [agent cluster](#)'s [cross-origin isolation mode](#)^{p934} is "[none](#)^{p848}", then:
 1. Let *global* be *realm*'s [global object](#)^{p938}.
 2. Let *status* be `! global.[[Delete]]("SharedArrayBuffer")`.
 3. Assert: *status* is true.

Note

This is done for compatibility with web content and there is some hope that this can be removed in the future. Web developers can still get at the constructor through `new WebAssembly.Memory({ shared:true, initial:0, maximum:0 }).buffer.constructor`.

7. Return *realm execution context*.

When defining algorithm steps throughout this specification, it is often important to indicate what [JavaScript realm](#) is to be used—or, equivalently, what [global object](#)^{p938} or [environment settings object](#)^{p937} is to be used. In general, there are at least four possibilities:

Entry

This corresponds to the script that initiated the currently running script action: i.e., the function or script that the user agent called into when it called into author code.

Incumbent

This corresponds to the most-recently-entered author function or script on the stack, or the author function or script that originally scheduled the currently-running callback.

Current

This corresponds to the currently-running function object, including built-in user-agent functions which might not be implemented as JavaScript. (It is derived from the [current JavaScript realm](#).)

Relevant

Every [platform object](#) has a [relevant Realm](#)^{p944}, which is roughly the [JavaScript realm](#) in which it was created. When writing algorithms, the most prominent [platform object](#) whose [relevant Realm](#)^{p944} might be important is the **this** value of the currently-running function object. In some cases, there can be other important [relevant Realms](#)^{p944}, such as those of any arguments.

Note how the [entry](#)^{p939}, [incumbent](#)^{p939}, and [current](#)^{p939} concepts are usable without qualification, whereas the [relevant](#)^{p939} concept must be applied to a particular [platform object](#).

⚠Warning!

The [incumbent](#)^{p939} and [entry](#)^{p939} concepts should not be used by new specifications, as they are excessively complicated and unintuitive to work with. We are working to remove almost all existing uses from the platform: see [issue #1430](#) for [incumbent](#)^{p939}, and [issue #1431](#) for [entry](#)^{p939}.

In general, web platform specifications should use the [relevant](#)^{p939} concept, applied to the object being operated on (usually the **this** value of the current method). This mismatches the JavaScript specification, where [current](#)^{p939} is generally used as the default (e.g. in determining the [JavaScript realm](#) whose `Array` constructor should be used to construct the result in `Array.prototype.map`). But this inconsistency is so embedded in the platform that we have to accept it going forward.

Example

Consider the following pages, with `a.html` being loaded in a browser window, `b.html` being loaded in an [iframe](#)^{p369} as shown, and `c.html` and `d.html` omitted (they can simply be empty documents):

```
<!-- a.html -->
<!DOCTYPE html>
<html lang="en">
<title>Entry page</title>

<iframe src="b.html"></iframe>
<button onclick="frames[0].hello()">Hello</button>

<!-- b.html -->
<!DOCTYPE html>
<html lang="en">
<title>Incumbent page</title>

<iframe src="c.html" id="c"></iframe>
<iframe src="d.html" id="d"></iframe>

<script>
  const c = document.querySelector("#c").contentWindow;
  const d = document.querySelector("#d").contentWindow;

  window.hello = () => {
    c.print.call(d);
  };
</script>
```

Each page has its own [browsing context](#)^{p840}, and thus its own [JavaScript realm](#), [global object](#)^{p938}, and [environment settings object](#)^{p937}.

When the [print\(\)](#)^{p1005} method is called in response to pressing the button in a.html, then:

- The [entry Realm](#)^{p941} is that of a.html.
- The [incumbent Realm](#)^{p942} is that of b.html.
- The [current Realm](#) is that of c.html (since it is the [print\(\)](#)^{p1005} method from c.html whose code is running).
- The [relevant Realm](#)^{p944} of the object on which the [print\(\)](#)^{p1005} method is being called is that of d.html.

Example

One reason why the [relevant](#)^{p939} concept is generally a better default choice than the [current](#)^{p939} concept is that it is more suitable for creating an object that is to be persisted and returned multiple times. For example, the [navigator.getBattery\(\)](#) method creates promises in the [relevant Realm](#)^{p944} for the [Navigator](#)^{p1006} object on which it is invoked. This has the following impact: [\[BATTERY\]](#)^{p1305}

```
<!-- outer.html -->
<!DOCTYPE html>
<html lang="en">
<title>Relevant Realm demo: outer page</title>
<script>
  function doTest() {
    const promise = navigator.getBattery.call(frames[0].navigator);

    console.log(promise instanceof Promise);          // logs false
    console.log(promise instanceof frames[0].Promise); // logs true

    frames[0].hello();
  }
</script>
<iframe src="inner.html" onload="doTest()"></iframe>

<!-- inner.html -->
<!DOCTYPE html>
<html lang="en">
<title>Relevant Realm demo: inner page</title>
<script>
  function hello() {
    const promise = navigator.getBattery();

    console.log(promise instanceof Promise);          // logs true
    console.log(promise instanceof parent.Promise);   // logs false
  }
</script>
```

If the algorithm for the [getBattery\(\)](#) method had instead used the [current Realm](#), all the results would be reversed. That is, after the first call to [getBattery\(\)](#) in outer.html, the [Navigator](#)^{p1006} object in inner.html would be permanently storing a Promise object created in outer.html's [JavaScript realm](#), and calls like that inside the [hello\(\)](#) function would thus return a promise from the "wrong" realm. Since this is undesirable, the algorithm instead uses the [relevant Realm](#)^{p944}, giving the sensible results indicated in the comments above.

The rest of this section deals with formally defining the [entry](#)^{p939}, [incumbent](#)^{p939}, [current](#)^{p939}, and [relevant](#)^{p939} concepts.

8.1.3.3.1 Entry ^{§^{p94}}₁

The process of [calling scripts^{p956}](#) will push or pop [realm execution contexts^{p937}](#) onto the [JavaScript execution context stack](#), interspersed with other [execution contexts](#).

With this in hand, we define the **entry execution context** to be the most recently pushed item in the [JavaScript execution context stack](#) that is a [realm execution context^{p937}](#). The **entry Realm** is the [entry execution context^{p941}](#)'s Realm component.

Then, the **entry settings object** is the [environment settings object^{p938}](#) of the [entry Realm^{p941}](#).

Similarly, the **entry global object** is the [global object^{p938}](#) of the [entry Realm^{p941}](#).

8.1.3.3.2 Incumbent ^{§^{p94}}₁

All [JavaScript execution contexts](#) must contain, as part of their code evaluation state, a **skip-when-determining-incumbent counter** value, which is initially zero. In the process of [preparing to run a callback^{p941}](#) and [cleaning up after running a callback^{p941}](#), this value will be incremented and decremented.

Every [event loop^{p968}](#) has an associated **backup incumbent settings object stack**, initially empty. Roughly speaking, it is used to determine the [incumbent settings object^{p941}](#) when no author code is on the stack, but author code is responsible for the current algorithm having been run in some way. The process of [preparing to run a callback^{p941}](#) and [cleaning up after running a callback^{p941}](#) manipulate this stack. [\[WEBIDL\]^{p1313}](#)

When Web IDL is used to [invoke](#) author code, or when [HostEnqueuePromiseJob^{p963}](#) invokes a promise job, they use the following algorithms to track relevant data for determining the [incumbent settings object^{p941}](#):

To **prepare to run a callback** with an [environment settings object^{p937}](#) *settings*:

1. Push *settings* onto the [backup incumbent settings object stack^{p941}](#).
2. Let *context* be the [topmost script-having execution context^{p941}](#).
3. If *context* is not null, increment *context*'s [skip-when-determining-incumbent counter^{p941}](#).

To **clean up after running a callback** with an [environment settings object^{p937}](#) *settings*:

1. Let *context* be the [topmost script-having execution context^{p941}](#).

Note

This will be the same as the [topmost script-having execution context^{p941}](#) inside the corresponding invocation of [prepare to run a callback^{p941}](#).

2. If *context* is not null, decrement *context*'s [skip-when-determining-incumbent counter^{p941}](#).
3. Assert: the topmost entry of the [backup incumbent settings object stack^{p941}](#) is *settings*.
4. Remove *settings* from the [backup incumbent settings object stack^{p941}](#).

Here, the **topmost script-having execution context** is the topmost entry of the [JavaScript execution context stack](#) that has a non-null ScriptOrModule component, or null if there is no such entry in the [JavaScript execution context stack](#).

With all this in place, the **incumbent settings object** is determined as follows:

1. Let *context* be the [topmost script-having execution context^{p941}](#).
2. If *context* is null, or if *context*'s [skip-when-determining-incumbent counter^{p941}](#) is greater than zero, then:
 1. Assert: the [backup incumbent settings object stack^{p941}](#) is not empty.

Note

This assert would fail if you try to obtain the [incumbent settings object^{p941}](#) from inside an algorithm that was triggered neither by [calling scripts^{p956}](#) nor by Web IDL [invoking](#) a callback. For example, it would trigger if you tried to obtain the [incumbent settings object^{p941}](#) inside an algorithm that ran periodically as part of the [event loop^{p968}](#), with no involvement of author code. In such cases the [incumbent^{p939}](#) concept cannot be used.

2. Return the topmost entry of the [backup incumbent settings object stack](#)^{p941}.

3. Return *context*'s Realm component's [settings object](#)^{p938}.

Then, the **incumbent Realm** is the [Realm](#)^{p938} of the [incumbent settings object](#)^{p941}.

Similarly, the **incumbent global object** is the [global object](#)^{p938} of the [incumbent settings object](#)^{p941}.

The following series of examples is intended to make it clear how all of the different mechanisms contribute to the definition of the [incumbent](#)^{p941} concept:

Example

Consider the following starter example:

```
<!DOCTYPE html>
<iframe></iframe>
<script>
  frames[0].postMessage("some data", "*");
</script>
```

There are two interesting [environment settings objects](#)^{p937} here: that of `window`, and that of `frames[0]`. Our concern is: what is the [incumbent settings object](#)^{p941} at the time that the algorithm for [postMessage\(\)](#)^{p1036} executes?

It should be that of `window`, to capture the intuitive notion that the author script responsible for causing the algorithm to happen is executing in `window`, not `frames[0]`. This makes sense: the [window post message steps](#)^{p1036} use the [incumbent settings object](#)^{p941} to determine the [source](#)^{p1025} property of the resulting [MessageEvent](#)^{p1024}, and in this case `window` is definitely the source of the message.

Let us now explain how the steps given above give us our intuitively-desired result of `window`'s [relevant settings object](#)^{p944}.

When the [window post message steps](#)^{p1036} look up the [incumbent settings object](#)^{p941}, the [topmost script-having execution context](#)^{p941} will be that corresponding to the [script](#)^{p624} element: it was pushed onto the [JavaScript execution context stack](#) as part of [ScriptEvaluation](#) during the [run a classic script](#)^{p956} algorithm. Since there are no Web IDL callback invocations involved, the context's [skip-when-determining-incumbent-counter](#)^{p941} is zero, so it is used to determine the [incumbent settings object](#)^{p941}; the result is the [environment settings object](#)^{p937} of `window`.

(Note how the [environment settings object](#)^{p937} of `frames[0]` is the [relevant settings object](#)^{p944} of *this* at the time the [postMessage\(\)](#)^{p1036} method is called, and thus is involved in determining the *target* of the message. Whereas the incumbent is used to determine the *source*.)

Example

Consider the following more complicated example:

```
<!DOCTYPE html>
<iframe></iframe>
<script>
  const bound = frames[0].postMessage.bind(frames[0], "some data", "*");
  window.setTimeout(bound);
</script>
```

This example is very similar to the previous one, but with an extra indirection through `Function.prototype.bind` as well as [setTimeout\(\)](#)^{p999}. But, the answer should be the same: invoking algorithms asynchronously should not change the [incumbent](#)^{p941} concept.

This time, the result involves more complicated mechanisms:

When `bound` is [converted](#) to a Web IDL callback type, the [incumbent settings object](#)^{p941} is that corresponding to `window` (in the same manner as in our starter example above). Web IDL stores this as the resulting callback value's [callback context](#).

When the [task](#)^{p969} posted by [setTimeout\(\)](#)^{p999} executes, the algorithm for that task uses Web IDL to [invoke](#) the stored callback

value. Web IDL in turn calls the above [prepare to run a callback](#)^{p941} algorithm. This pushes the stored [callback context](#) onto the [backup incumbent settings object stack](#)^{p941}. At this time (inside the timer task) there is no author code on the stack, so the [topmost script-having execution context](#)^{p941} is null, and nothing gets its [skip-when-determining-incumbent counter](#)^{p941} incremented.

Invoking the callback then calls `bound`, which in turn calls the `postMessage()`^{p1036} method of `frames[0]`. When the `postMessage()`^{p1036} algorithm looks up the [incumbent settings object](#)^{p941}, there is still no author code on the stack, since the bound function just directly calls the built-in method. So the [topmost script-having execution context](#)^{p941} will be null: the [JavaScript execution context](#) stack only contains an execution context corresponding to `postMessage()`^{p1036}, with no [ScriptEvaluation](#) context or similar below it.

This is where we fall back to the [backup incumbent settings object stack](#)^{p941}. As noted above, it will contain as its topmost entry the [relevant settings object](#)^{p944} of `window`. So that is what is used as the [incumbent settings object](#)^{p941} while executing the `postMessage()`^{p1036} algorithm.

Example

Consider this final, even more convoluted example:

```
<!-- a.html -->
<!DOCTYPE html>
<button>click me</button>
<iframe></iframe>
<script>
const bound = frames[0].location.assign.bind(frames[0].location, "https://example.com/");
document.querySelector("button").addEventListener("click", bound);
</script>
```

```
<!-- b.html -->
<!DOCTYPE html>
<iframe src="a.html"></iframe>
<script>
  const iframe = document.querySelector("iframe");
  iframe.onload = function onLoad() {
    iframe.contentWindow.document.querySelector("button").click();
  };
</script>
```

Again there are two interesting [environment settings objects](#)^{p937} in play: that of `a.html`, and that of `b.html`. When the `location.assign()`^{p992} method triggers the [Location-object navigate](#)^{p899} algorithm, what will be the [incumbent settings object](#)^{p941}? As before, it should intuitively be that of `a.html`: the `click` listener was originally scheduled by `a.html`, so even if something involving `b.html` causes the listener to fire, the [incumbent](#)^{p939} responsible is that of `a.html`.

The callback setup is similar to the previous example: when `bound` is [converted](#) to a Web IDL callback type, the [incumbent settings object](#)^{p941} is that corresponding to `a.html`, which is stored as the callback's [callback context](#).

When the `click()`^{p796} method is called inside `b.html`, it [dispatches](#) a `click` event on the button that is inside `a.html`. This time, when the [prepare to run a callback](#)^{p941} algorithm executes as part of event dispatch, there *is* author code on the stack; the [topmost script-having execution context](#)^{p941} is that of the `onLoad` function, whose [skip-when-determining-incumbent counter](#)^{p941} gets incremented. Additionally, `a.html`'s [environment settings object](#)^{p937} (stored as the [EventHandler](#)^{p984}'s [callback context](#)) is pushed onto the [backup incumbent settings object stack](#)^{p941}.

Now, when the [Location-object navigate](#)^{p899} algorithm looks up the [incumbent settings object](#)^{p941}, the [topmost script-having execution context](#)^{p941} is still that of the `onLoad` function (due to the fact we are using a bound function as the callback). Its [skip-when-determining-incumbent counter](#)^{p941} value is one, however, so we fall back to the [backup incumbent settings object stack](#)^{p941}. This gives us the [environment settings object](#)^{p937} of `a.html`, as expected.

Note that this means that even though it is the `iframe`^{p369} inside `a.html` that navigates, it is `a.html` itself that is used as the [source browsing context](#)^{p906}, which determines among other things the [request client](#). This is [perhaps the only justifiable use of the incumbent concept on the web platform](#); in all other cases the consequences of using it are simply confusing and we hope to one day switch them to use [current](#)^{p939} or [relevant](#)^{p939} as appropriate.

8.1.3.3.3 Current § p94 4

The JavaScript specification defines the [current Realm Record](#), sometimes abbreviated to the "current Realm". [\[JAVASCRIPT\] p1308](#)

Then, the **current settings object** is the [environment settings object p938](#) of the [current Realm Record](#).

Similarly, the **current global object** is the [global object p938](#) of the [current Realm Record](#).

8.1.3.3.4 Relevant § p94 4

The **relevant Realm** for a [platform object](#) is the value of its `[[Realm]]` field.

Then, the **relevant settings object** for a [platform object](#) *o* is the [environment settings object p938](#) of the [relevant Realm p944](#) for *o*.

Similarly, the **relevant global object** for a [platform object](#) *o* is the [global object p938](#) of the [relevant Realm p944](#) for *o*.

8.1.3.4 Enabling and disabling scripting § p94 4

Scripting is enabled for an [environment settings object p937](#) *settings* when all of the following conditions are true:

- The user agent supports scripting.
- The user has not disabled scripting for *settings* at this time. (User agents may provide users with the option to disable scripting globally, or in a finer-grained manner, e.g., on a per-origin basis, down to the level of individual [environment settings objects p937](#).)
- Either *settings*'s [global object p938](#) is not a [Window p855](#) object, or *settings*'s [global object p938](#)'s [associated Document p856](#)'s [active sandboxing flag set p875](#) does not have its [sandboxed scripts browsing context flag p874](#) set.

Scripting is disabled for an [environment settings object p937](#) when scripting is not [enabled p944](#) for it, i.e., when any of the above conditions are false.

Scripting is enabled for a node *node* if *node*'s [node document](#)'s [browsing context p840](#) is non-null, and [scripting is enabled p944](#) for *node*'s [relevant settings object p944](#).

Scripting is disabled for a node when scripting is not [enabled p944](#), i.e., when its [node document](#)'s [browsing context p840](#) is null or when [scripting is disabled p944](#) for its [relevant settings object p944](#).

8.1.3.5 Secure contexts § p94 4

An [environment p936](#) *environment* is a **secure context** if the following algorithm returns true:

1. If *environment* is an [environment settings object p937](#), then:
 1. Let *global* be *environment*'s [global object p938](#).
 2. If *global* is a [WorkerGlobalScope p1062](#), then:
 1. If *global*'s [owner set p1062](#)[0]'s [relevant settings object p944](#) is a [secure context p944](#), then return true.
 2. Return false.
3. If *global* is a [WorkletGlobalScope p1080](#), then return true.

Note

We only need to check the 0th item since they will necessarily all be consistent.

Note

Worklets can only be created in secure contexts.

2. If the result of [Is url potentially trustworthy?](#) given *environment*'s [top-level creation URL](#)^{p936} is "Potentially Trustworthy", then return true.
3. Return false.

An [environment](#)^{p936} is a **non-secure context** if it is not a [secure context](#)^{p944}.

8.1.4 Script processing model § p94

8.1.4.1 Scripts § p94

A **script** is one of three possible [structs](#). All scripts have:

A *settings object*

An [environment settings object](#)^{p937}, containing various settings that are shared with other [scripts](#)^{p945} in the same context.

A *record*

One of the following:

- a [script record](#), for [classic scripts](#)^{p945};
- a [Source Text Module Record](#), for [JavaScript module scripts](#)^{p946};
- a [Synthetic Module Record](#), for [CSS module scripts](#)^{p946} and [JSON module scripts](#)^{p946}
- null, representing a parsing failure.

A *parse error*

A JavaScript value, which has meaning only if the [record](#)^{p945} is null, indicating that the corresponding script source text could not be parsed.

Note

This value is used for internal tracking of immediate parse errors when [creating scripts](#)^{p954}, and is not to be used directly. Instead, consult the [error to rethrow](#)^{p945} when determining "what went wrong" for this script.

An *error to rethrow*

A JavaScript value representing an error that will prevent evaluation from succeeding. It will be re-thrown by any attempts to [run](#)^{p956} the script.

Note

This could be the script's [parse error](#)^{p945}, but in the case of a [module script](#)^{p946} it could instead be the [parse error](#)^{p945} from one of its dependencies, or an error from [resolve a module specifier](#)^{p966}.

Note

Since this exception value is provided by the JavaScript specification, we know that it is never null, so we use null to signal that no error has occurred.

Fetch options

A [script fetch options](#)^{p946}, containing various options related to fetching this script or [module scripts](#)^{p946} that it imports.

A *base URL*

A base [URL](#) used for [resolving module specifiers](#)^{p966}. This will either be the URL from which the script was obtained, for external scripts, or the [document base URL](#)^{p90} of the containing document, for inline scripts.

A **classic script** is a type of [script](#)^{p945} that has the following additional [item](#):

A *muted errors boolean*

A boolean which, if true, means that error information will not be provided for errors in this script. This is used to mute errors for cross-origin scripts, since that can leak private information.

A **module script** is another type of [script](#)^{p945}. It has no additional [items](#).

[Module scripts](#)^{p946} can be classified into three types:

- A [module script](#)^{p946} is a **JavaScript module script** if its [record](#)^{p945} is a [Source Text Module Record](#).
- A [module script](#)^{p946} is a **CSS module script** if its [record](#)^{p945} is a [Synthetic Module Record](#), and it was created via the [create a CSS module script](#)^{p955} algorithm. CSS module scripts represent a parsed CSS stylesheet.
- A [module script](#)^{p946} is a **JSON module script** if its [record](#)^{p945} is a [Synthetic Module Record](#), and it was created via the [create a JSON module script](#)^{p956} algorithm. JSON module scripts represent a parsed JSON document.

Note

As CSS stylesheets and JSON documents do not import dependent modules, and do not throw exceptions on evaluation, the [fetch options](#)^{p945} and [base URL](#)^{p945} of [CSS module scripts](#)^{p946} and [JSON module scripts](#)^{p946} are always null.

The **active script** is determined by the following algorithm:

1. Let *record* be [GetActiveScriptOrModule](#)() .
2. If *record* is null, return null.
3. Return *record* .[[HostDefined]] .

Note

The [active script](#)^{p946} concept is so far only used by the [import\(\)](#) feature, to determine the [base URL](#)^{p945} to use for resolving relative module specifiers.

8.1.4.2 Fetching scripts § p946

This section introduces a number of algorithms for fetching scripts, taking various necessary inputs and resulting in [classic](#)^{p945} or [module scripts](#)^{p946}.

Script fetch options is a [struct](#) with the following [items](#):

cryptographic nonce

The [cryptographic nonce metadata](#) used for the initial fetch and for fetching any imported modules

integrity metadata

The [integrity metadata](#) used for the initial fetch

parser metadata

The [parser metadata](#) used for the initial fetch and for fetching any imported modules

credentials mode

The [credentials mode](#) used for the initial fetch (for [module scripts](#)^{p946}) and for fetching any imported modules (for both [module scripts](#)^{p946} and [classic scripts](#)^{p945})

referrer policy

The [referrer policy](#) used for the initial fetch and for fetching any imported modules

Note

Recall that via the [import\(\)](#) feature, [classic scripts](#)^{p945} can import [module scripts](#)^{p946}.

The **default classic script fetch options** are a [script fetch options](#)^{p946} whose [cryptographic nonce](#)^{p946} is the empty string, [integrity metadata](#)^{p946} is the empty string, [parser metadata](#)^{p946} is "not-parser-inserted", [credentials mode](#)^{p946} is "same-origin", and [referrer policy](#)^{p946} is the empty string.

Given a [request](#) *request* and a [script fetch options](#)^{p946} *options*, we define:

set up the classic script request

Set *request*'s [cryptographic nonce metadata](#) to *options*'s [cryptographic nonce](#)^{p946}, its [integrity metadata](#) to *options*'s [integrity metadata](#)^{p946}, its [parser metadata](#) to *options*'s [parser metadata](#)^{p946}, and its [referrer policy](#) to *options*'s [referrer policy](#)^{p946}.

set up the module script request

Set *request*'s [cryptographic nonce metadata](#) to *options*'s [cryptographic nonce](#)^{p946}, its [integrity metadata](#) to *options*'s [integrity metadata](#)^{p946}, its [parser metadata](#) to *options*'s [parser metadata](#)^{p946}, its [credentials mode](#) to *options*'s [credentials mode](#)^{p946}, and its [referrer policy](#) to *options*'s [referrer policy](#)^{p946}.

For any given [script fetch options](#)^{p946} *options*, the **descendant script fetch options** are a new [script fetch options](#)^{p946} whose [items](#) all have the same values, except for the [integrity metadata](#)^{p946}, which is instead the empty string.

The algorithms below can be customized by optionally supplying a custom **perform the fetch** hook, which takes a [request](#) and an **is top-level** flag. The algorithm must complete with a [response](#) (which may be a [network error](#)), either synchronously (when using [fetch a classic worker-imported script](#)^{p948}) or asynchronously (otherwise). The **is top-level**^{p947} flag will be set for all [classic script](#)^{p945} fetches, and for the initial fetch when [fetching an external module script graph](#)^{p949}, [fetching a module worker script graph](#)^{p950}, or [fetching an import\(\) module script graph](#)^{p949}, but not for the fetches resulting from `import` statements encountered throughout the graph.

Note

By default, not supplying the [perform the fetch](#)^{p947} will cause the below algorithms to simply [fetch](#) the given [request](#), with algorithm-specific customizations to the [request](#) and validations of the resulting [response](#).

To layer your own customizations on top of these algorithm-specific ones, supply a [perform the fetch](#)^{p947} hook that modifies the given [request](#), [fetches](#) it, and then performs specific validations of the resulting [response](#) (completing with a [network error](#) if the validations fail).

The hook can also be used to perform more subtle customizations, such as keeping a cache of [responses](#) and avoiding performing a [fetch](#) at all.

Note

Service Workers is an example of a specification that runs these algorithms with its own options for the hook. [\[SW\]](#)^{p1312}

Now for the algorithms themselves.

To **fetch a classic script** given a *url*, a *settings object*, some *options*, a *CORS setting*, and a *character encoding*, run these steps. The algorithm will asynchronously complete with either null (on failure) or a new [classic script](#)^{p945} (on success).

1. Let *request* be the result of [creating a potential-CORS request](#)^{p92} given *url*, "script", and *CORS setting*.
2. Set *request*'s [client](#) to *settings object*.
3. [Set up the classic script request](#)^{p947} given *request* and *options*.
4. If the caller specified custom steps to [perform the fetch](#)^{p947}, perform them on *request*, with the **is top-level**^{p947} flag set. Return from this algorithm, and when the custom [perform the fetch](#)^{p947} steps complete with [response](#) *response*, run the remaining steps.

Otherwise, [fetch](#) *request*. Return from this algorithm, and run the remaining steps as part of the fetch's [processResponseConsumeBody](#) given [response](#) *response*.

Note

response can be either [CORS-same-origin](#)^{p92} or [CORS-cross-origin](#)^{p92}. This only affects how error reporting happens.

5. [Finalize and report timing](#) with *response*, *settings object*'s [global object](#)^{p938}, and "script".
6. Set *response* to *response*'s [unsafe response](#)^{p92}.
7. If *response*'s [type](#) is "error", or *response*'s [status](#) is not an [ok status](#), then asynchronously complete this algorithm with null, and return.

Note

For historical reasons, this algorithm does not include MIME type checking, unlike the other script-fetching algorithms in this section.

8. If *response*'s [Content Type metadata](#)^{p92}, if any, specifies a character encoding, and the user agent supports that encoding, then set *character encoding* to that encoding (ignoring the passed-in value).
9. Let *source text* be the result of [decoding](#) *response*'s [body](#) to Unicode, using *character encoding* as the fallback encoding.

Note

The [decode](#) algorithm overrides character encoding if the file contains a BOM.

10. Let *muted errors* be true if *response* was [CORS-cross-origin](#)^{p92}, and false otherwise.
11. Let *script* be the result of [creating a classic script](#)^{p954} given *source text*, *settings object*, *response*'s [url](#), *options*, and *muted errors*.
12. Asynchronously complete this algorithm with *script*.

To **fetch a classic worker script** given a *url*, a *fetch client settings object*, a *destination*, and a *script settings object*, run these steps. The algorithm will asynchronously complete with either null (on failure) or a new [classic script](#)^{p945} (on success).

1. Let *request* be a new [request](#) whose [URL](#) is *url*, [client](#) is *fetch client settings object*, [destination](#) is *destination*, [mode](#) is "same-origin", [credentials mode](#) is "same-origin", [parser metadata](#) is "not parser-inserted", and whose [use-URL-credentials flag](#) is set.
2. If the caller specified custom steps to [perform the fetch](#)^{p947}, perform them on *request*, with the [is top-level](#)^{p947} flag set. Return from this algorithm, and when the custom [perform the fetch](#)^{p947} steps complete with [response](#) *response*, run the remaining steps.

Otherwise, [fetch](#) *request*. Return from this algorithm, and run the remaining steps as part of the fetch's [processResponseConsumeBody](#) given [response](#) *response*.

3. [Finalize and report timing](#) with *response*, *fetch client settings object*'s [global object](#)^{p938}, and "other".
4. Set *response* to *response*'s [unsafe response](#)^{p92}.
5. If either of the following conditions are met:
 - *response*'s [type](#) is "error"; or
 - *response*'s [status](#) is not an [ok status](#),

then asynchronously complete this algorithm with null, and return.

6. If both of the following conditions are met:
 - *response*'s [url](#)'s [scheme](#) is an [HTTP\(S\) scheme](#); and
 - the result of [extracting a MIME type](#) from *response*'s [header list](#) is not a [JavaScript MIME type](#),

then asynchronously complete this algorithm with null, and return.

Note

Other [fetch schemes](#) are exempted from MIME type checking for historical web-compatibility reasons. We might be able to tighten this in the future; see [issue #3255](#).

7. Let *source text* be the result of [UTF-8 decoding](#) *response*'s [body](#).
8. Let *script* be the result of [creating a classic script](#)^{p954} using *source text*, *script settings object*, *response*'s [url](#), and the [default classic script fetch options](#)^{p946}.
9. Asynchronously complete this algorithm with *script*.

To **fetch a classic worker-imported script** given a *url* and a *settings object*, run these steps. The algorithm will synchronously complete with a [classic script](#)^{p945} on success, or throw an exception on failure.

1. Let *request* be a new [request](#) whose [URL](#) is *url*, [client](#) is *settings object*, [destination](#) is "script", [parser metadata](#) is "not

parser-inserted", [synchronous flag](#) is set, and whose [use-URL-credentials flag](#) is set.

2. If the caller specified custom steps to [perform the fetch](#)^{p947}, perform them on *request*, with the [is top-level](#)^{p947} flag set. Let *response* be the result.

Otherwise, [fetch](#) *request*, and let *response* be the result.

Note

Unlike other algorithms in this section, the fetching process is synchronous here. Thus any [perform the fetch](#)^{p947} steps will also finish their work synchronously.

3. [Finalize and report timing](#) with *response*, *settings object*'s [global object](#)^{p938}, and "other".
4. Set *response* to *response*'s [unsafe response](#)^{p92}.
5. If any of the following conditions are met:
 - *response*'s [type](#) is "error"; or
 - *response*'s [status](#) is not an [ok status](#); or
 - the result of [extracting a MIME type](#) from *response*'s [header list](#) is not a [JavaScript MIME type](#),then throw a ["NetworkError" DOMException](#).
6. Let *source text* be the result of [UTF-8 decoding](#) *response*'s [body](#).
7. Let *muted errors* be true if *response* was [CORS-cross-origin](#)^{p92}, and false otherwise.
8. Let *script* be the result of [creating a classic script](#)^{p954} given *source text*, *settings object*, *response*'s [url](#), the [default classic script fetch options](#)^{p946}, and *muted errors*.
9. Return *script*.

To **fetch an external module script graph** given a *url*, a *settings object*, and some *options*, run these steps. The algorithm will asynchronously complete with either null (on failure) or a [module script](#)^{p946} (on success).

1. [Fetch a single module script](#)^{p952} given *url*, *settings object*, "script", *options*, *settings object*, "client", and with the *top-level module fetch flag* set. If the caller of this algorithm specified custom [perform the fetch](#)^{p947} steps, pass those along as well. Wait until the algorithm asynchronously completes with *result*.
2. If *result* is null, asynchronously complete this algorithm with null, and return.
3. Let *visited set* be « (*url*, "javascript") ».
4. [Fetch the descendants of and link](#)^{p951} *result* given *settings object*, *destination*, and *visited set*. When this asynchronously completes with *final result*, asynchronously complete this algorithm with *final result*.

To **fetch an import() module script graph** given a *moduleRequest*, a *base URL*, a *settings object*, and some *options*, run these steps. The algorithm will asynchronously complete with either null (on failure) or a [module script](#)^{p946} (on success).

1. Let *url* be the result of [resolving a module specifier](#)^{p966} given *base URL* and *moduleRequest*.[[Specifier]].
2. If *url* is failure, then asynchronously complete this algorithm with null, and return.
3. Assert: *moduleRequest*.[[Assertions]] does not contain any [Record](#) entry such that *entry*.[[Key]] is not "type", because we only asked for "type" assertions in [HostGetSupportedImportAssertions](#)^{p968}.
4. Let *moduleType* be the result of running the [module type from module request](#)^{p956} steps given *moduleRequest*.
5. If the result of running the [module type allowed](#)^{p956} steps given *moduleType* and *settings object* is false, then asynchronously complete this algorithm with null, and return.
6. [Fetch a single module script](#)^{p952} given *url*, *settings object*, "script", *options*, *settings object*, "client", *moduleRequest*, and with the *top-level module fetch flag* set. If the caller of this algorithm specified custom [perform the fetch](#)^{p947} steps, pass those along as well. Wait until the algorithm asynchronously completes with *result*.
7. If *result* is null, asynchronously complete this algorithm with null, and return.
8. Let *visited set* be « (*url*, *moduleType*) ».

9. [Fetch the descendants of and link](#)^{p951} result given *settings object*, *destination*, and *visited set*. When this asynchronously completes with *final result*, asynchronously complete this algorithm with *final result*.

To **fetch a modulepreload module script graph** given a *url*, a *destination*, a *settings object*, and some *options*, run these steps. The algorithm will asynchronously complete with either null (on failure) or a [module script](#)^{p946} (on success), although it will perform optional steps even after completing.

1. [Fetch a single module script](#)^{p952} given *url*, *settings object*, *destination*, *options*, *settings object*, "client", and with the *top-level module fetch* flag set. Wait until algorithm asynchronously completes with *result*.
2. Asynchronously complete this algorithm with *result*, but do *not* return.
3. If *result* is not null, optionally perform the following steps:
 1. Let *visited set* be « (*url*, "javascript") ».
 2. [Fetch the descendants of and link](#)^{p951} result given *settings object*, *destination*, and *visited set*.

Note

Generally, performing these steps will be beneficial for performance, as it allows pre-loading the modules that will invariably be requested later, via algorithms such as [fetch an external module script graph](#)^{p949} that fetch the entire graph. However, user agents might wish to skip them in bandwidth-constrained situations, or situations where the relevant fetches are already in flight.

To **fetch an inline module script graph** given a *source text*, *base URL*, *settings object*, and *options*, run these steps. The algorithm will asynchronously complete with either null (on failure) or a [module script](#)^{p946} (on success).

1. Let *script* be the result of [creating a JavaScript module script](#)^{p955} using *source text*, *settings object*, *base URL*, and *options*.
2. If *script* is null, asynchronously complete this algorithm with null, and return.
3. Let *visited set* be an empty [set](#).
4. [Fetch the descendants of and link](#)^{p951} *script*, given *settings object*, the destination "script", and *visited set*. When this asynchronously completes with *final result*, asynchronously complete this algorithm with *final result*.

To **fetch a module worker script graph** given a *url*, a *fetch client settings object*, a *destination*, a *credentials mode*, and a *module map settings object*, [fetch a worklet/module worker script graph](#)^{p951} given *url*, *fetch client settings object*, *destination*, *credentials mode*, and *module map settings object*, asynchronously completing with the asynchronous completion result of that algorithm.

To **fetch a worklet script graph** given a *url*, a *fetch client settings object*, a *destination*, a *credentials mode*, a *module map settings object*, and a *module responses map*, [fetch a worklet/module worker script graph](#)^{p951} given *url*, *fetch client settings object*, *destination*, *credentials mode*, and *module map settings object*, asynchronously completing with the asynchronous completion result of that algorithm. Use the following custom steps to [perform the fetch](#)^{p947} given *response*:

1. Let *requestURL* be *request*'s [URL](#).
2. If *moduleResponsesMap*[*requestURL*] is "fetching", wait [in parallel](#)^{p42} until that entry's value changes, then [queue a task](#)^{p970} on the [networking task source](#)^{p977} to proceed with running the following steps.
3. If *moduleResponsesMap*[*requestURL*] [exists](#), then asynchronously complete the [perform the fetch](#)^{p947} steps with *moduleResponsesMap*[*requestURL*].
4. [Set](#) *moduleResponsesMap*[*requestURL*] to "fetching".
5. [Fetch request](#), with [processResponseConsumeBody](#) set to the following steps given *response* *response*:
 1. Set *moduleResponsesMap*[*requestURL*] to *response*.
 2. Asynchronously complete the [perform the fetch](#)^{p947} steps with *response*.

The following algorithms are meant for internal use by this specification only as part of [fetching an external module script graph](#)^{p949} or other similar concepts above, and should not be used directly by other specifications.

This diagram illustrates how these algorithms relate to the ones above, as well as to each other:

To **fetch a worklet/module worker script graph** given a *url*, a *fetch client settings object*, a *destination*, a *credentials mode*, and a *module map settings object*, run these steps. The algorithm will asynchronously complete with either null (on failure) or a [module script^{p946}](#) (on success).

1. Let *options* be a [script fetch options^{p946}](#) whose [cryptographic nonce^{p946}](#) is the empty string, [integrity metadata^{p946}](#) is the empty string, [parser metadata^{p946}](#) is "not-parser-inserted", [credentials mode^{p946}](#) is *credentials mode*, and [referrer policy^{p946}](#) is the empty string.
2. [Fetch a single module script^{p952}](#) given *url*, *fetch client settings object*, *destination*, *options*, *module map settings object*, "client", and with the *top-level module fetch flag* set. If the caller of this algorithm specified custom [perform the fetch^{p947}](#) steps, pass those along as well. Wait until the algorithm asynchronously completes with *result*.
3. If *result* is null, asynchronously complete this algorithm with null, and return.
4. Let *visited set* be « (*url*, "javascript") ».
5. [Fetch the descendants of and link^{p951}](#) *result* given *fetch client settings object*, *destination*, and *visited set*. When this asynchronously completes with *final result*, asynchronously complete this algorithm with *final result*.

To **fetch the descendants of and link a module script** *module script*, given a *fetch client settings object*, a *destination*, and a *visited set*, run these steps. The algorithm will asynchronously complete with either null (on failure) or with *module script* (on success).

1. [Fetch the descendants of^{p951}](#) *module script*, given *fetch client settings object*, *destination*, and *visited set*.
2. Return from this algorithm, and run the following steps when [fetching the descendants of a module script^{p951}](#) asynchronously completes with *result*.
3. If *result* is null, then asynchronously complete this algorithm with *result*.

Note

In this case, there was an error fetching one or more of the descendants. We will not attempt to link.

4. Let *parse error* be the result of [finding the first parse error^{p953}](#) given *result*.
5. If *parse error* is null, then:
 1. Let *record* be *result*'s [record^{p945}](#).
 2. Perform *record*.[Link\(\)](#).

Note

This step will recursively call [Link](#) on all of the module's unlinked dependencies.

If this throws an exception, set *result*'s [error to rethrow^{p945}](#) to that exception.

6. Otherwise, set *result*'s [error to rethrow^{p945}](#) to *parse error*.
7. Asynchronously complete this algorithm with *result*.

To **fetch the descendants of a module script** *module script*, given a *fetch client settings object*, a *destination*, and a *visited set*, run these steps. The algorithm will asynchronously complete with either null (on failure) or with *module script* (on success).

1. If *module script*'s [record^{p945}](#) is null, then asynchronously complete this algorithm with *module script* and return.
2. Let *record* be *module script*'s [record^{p945}](#).

3. If *record* is not a [Cyclic Module Record](#), or if *record*.[[RequestedModules]] is [empty](#), asynchronously complete this algorithm with *module script*.
4. Let *moduleRequests* be a new empty [list](#).
5. [For each ModuleRequest Record](#) *requested* of *record*.[[RequestedModules]],
 1. Let *url* be the result of [resolving a module specifier](#)^{p966} given *module script*'s [base URL](#)^{p945} and *requested*.[[Specifier]].
 2. Assert: *url* is never failure, because [resolving a module specifier](#)^{p966} must have been [previously successful](#)^{p955} with these same two arguments.
 3. Let *moduleType* be the result of running the [module type from module request](#)^{p956} steps given *requested*.
 4. If *visited set* does not [contain](#) (*url*, *moduleType*), then:
 1. [Append](#) *requested* to *moduleRequests*.
 2. [Append](#) (*url*, *moduleType*) to *visited set*.
6. Let *options* be the [descendant script fetch options](#)^{p947} for *module script*'s [fetch options](#)^{p945}.
7. Assert: *options* is not null, as *module script* is a [JavaScript module script](#)^{p946}.
8. [For each](#) *moduleRequest* in *moduleRequests*, perform the [internal module script graph fetching procedure](#)^{p952} given *moduleRequest*, *fetch client settings object*, *destination*, *options*, *module script*'s [settings object](#)^{p945}, *visited set*, and *module script*'s [base URL](#)^{p945}. If the caller of this algorithm specified custom [perform the fetch](#)^{p947} steps, pass those along while performing the [internal module script graph fetching procedure](#)^{p952}.

These invocations of the [internal module script graph fetching procedure](#)^{p952} should be performed in parallel to each other.

If any of the invocations of the [internal module script graph fetching procedure](#)^{p952} asynchronously complete with null, asynchronously complete this algorithm with null, and return.

Otherwise, wait until all of the [internal module script graph fetching procedure](#)^{p952} invocations have asynchronously completed. Asynchronously complete this algorithm with *module script*.

To perform the **internal module script graph fetching procedure** given a *moduleRequest*, a *fetch client settings object*, a *destination*, some *options*, a *module map settings object*, a *visited set*, and a *referrer*, perform these steps. The algorithm will asynchronously complete with either null (on failure) or a [module script](#)^{p946} (on success).

1. Let *url* be the result of [resolving a module specifier](#)^{p966} given *referrer* and *moduleRequest*.[[Specifier]].
2. Assert: *url* is never failure, because [resolving a module specifier](#)^{p966} must have been [previously successful](#)^{p955} with these same two arguments.
3. Let *moduleType* be the result of running the [module type from module request](#)^{p956} steps given *moduleRequest*.
4. Assert: *visited set* [contains](#) (*url*, *moduleType*).
5. [Fetch a single module script](#)^{p952} given *url*, *fetch client settings object*, *destination*, *options*, *module map settings object*, *referrer*, *moduleRequest*, and with the *top-level module fetch flag* unset. If the caller of this algorithm specified custom [perform the fetch](#)^{p947} steps, pass those along while [fetching a single module script](#)^{p952}.
6. Return from this algorithm, and run the following steps when [fetching a single module script](#)^{p952} asynchronously completes with *result*:
7. If *result* is null, asynchronously complete this algorithm with null, and return.
8. [Fetch the descendants of](#)^{p951} *result* given *fetch client settings object*, *destination*, and *visited set*.
9. When the appropriate algorithm asynchronously completes with *final result*, asynchronously complete this algorithm with *final result*.

To **fetch a single module script**, given a *url*, a *fetch client settings object*, a *destination*, some *options*, a *module map settings object*, a *referrer*, an optional *moduleRequest*, and a *top-level module fetch* flag, run these steps. The algorithm will asynchronously complete with either null (on failure) or a [module script](#)^{p946} (on success).

1. Let *moduleType* be "javascript".

2. If *moduleRequest* was given, then set *moduleType* to the result of running the [module type from module request](#)^{p956} steps given *moduleRequest*.
3. Assert: the result of running the [module type allowed](#)^{p956} steps given *moduleType* and *module map settings object* is true. Otherwise we would not have reached this point because a failure would have been raised when inspecting *moduleRequest*.[[Assertions]] in [create a JavaScript module script](#)^{p955} or [fetch an import\(\) module script graph](#)^{p949}.
4. Let *moduleMap* be *module map settings object*'s [module map](#)^{p937}.
5. If *moduleMap*[(*url*, *moduleType*)] is "fetching", wait [in parallel](#)^{p42} until that entry's value changes, then [queue a task](#)^{p970} on the [networking task source](#)^{p977} to proceed with running the following steps.
6. If *moduleMap*[(*url*, *moduleType*)] [exists](#), asynchronously complete this algorithm with *moduleMap*[(*url* / *moduleType*)], and return.
7. [Set](#) *moduleMap*[(*url*, *moduleType*)] to "fetching".
8. Let *request* be a new [request](#) whose [URL](#) is *url*, [destination](#) is *destination*, [mode](#) is "cors", [referrer](#) is *referrer*, and [client](#) is *fetch client settings object*.
9. If *destination* is "worker", "sharedworker", or "serviceworker", and the *top-level module fetch* flag is set, then set *request*'s [mode](#) to "same-origin".
10. [Set up the module script request](#)^{p947} given *request* and *options*.
11. If the caller specified custom steps to [perform the fetch](#)^{p947}, perform them on *request*, setting the [is top-level](#)^{p947} flag if the *top-level module fetch* flag is set. Return from this algorithm, and when the custom [perform the fetch](#)^{p947} steps complete with [response](#) *response*, run the remaining steps.

Otherwise, [fetch](#) *request*. Return from this algorithm, and run the remaining steps as part of the fetch's [processResponseConsumeBody](#) given [response](#) *response*.

Note

response is always [CORS-same-origin](#)^{p92}.

12. [Finalize and report timing](#) with *response*, *fetch client settings object*'s [global object](#)^{p938}, and "other".
13. If either of the following conditions are met:
 - *response*'s [type](#) is "error"; or
 - *response*'s [status](#) is not an [ok status](#).
 then [set](#) *moduleMap*[(*url*, *moduleType*)] to null, asynchronously complete this algorithm with null, and return.
14. Let *source text* be the result of [UTF-8 decoding](#) *response*'s [body](#).
15. Let *MIME type* be the result of [extracting a MIME type](#) from *response*'s [header list](#).
16. Let *module script* be null.
17. If *MIME type* is a [JavaScript MIME type](#) and *moduleType* is "javascript", then set *module script* to the result of [creating a JavaScript module script](#)^{p955} given *source text*, *module map settings object*, *response*'s [url](#), and *options*.
18. If the [MIME type essence](#) of *MIME type* is "[text/css](#)^{p1303}" and *moduleType* is "css", then set *module script* to the result of [creating a CSS module script](#)^{p955} given *source text* and *module map settings object*.
19. If *MIME type essence* is a [JSON MIME type](#) and *moduleType* is "json", then set *module script* to the result of [creating a JSON module script](#)^{p956} given *source text* and *module map settings object*.
20. [Set](#) *moduleMap*[(*url*, *moduleType*)] to *module script*, and asynchronously complete this algorithm with *module script*.

Note

It is intentional that the [module map](#)^{p965} is keyed by the [request URL](#), whereas the [base URL](#)^{p945} for the [module script](#)^{p946} is set to the [response URL](#). The former is used to deduplicate fetches, while the latter is used for URL resolution.

To find the first parse error given a root *moduleScript* and an optional *discoveredSet*:

1. Let *moduleMap* be *moduleScript*'s [settings object](#)^{p945}'s [module map](#)^{p937}.

2. If *discoveredSet* was not given, let it be an empty [set](#).
3. [Append](#) *moduleScript* to *discoveredSet*.
4. If *moduleScript*'s [record](#)^{p945} is null, then return *moduleScript*'s [parse_error](#)^{p945}.
5. If *moduleScript*'s [record](#)^{p945} is not a [Cyclic Module Record](#), then return null.
6. Let *moduleRequests* be the value of *moduleScript*'s [record](#)^{p945}'s `[[RequestedModules]]` internal slot.
7. [For each](#) *moduleRequest* of *moduleRequests*:
 1. Let *childURL* be the result of [resolving a module specifier](#)^{p966} given *moduleScript*'s [base URL](#)^{p945} and *moduleRequest*.`[[Specifier]]`. (This will never fail, as otherwise *moduleScript* would have been [marked as itself having a parse error](#)^{p955}.)
 2. Let *moduleType* be the result of running the [module type from module request](#)^{p956} steps given *moduleRequest*.
 3. Let *childModule* be [moduleMap](#)`((childURL, moduleType))`.
 4. Assert: *childModule* is a [module script](#)^{p946} (i.e., it is not "fetching" or null); by now all [module scripts](#)^{p946} in the graph rooted at *moduleScript* will have successfully been fetched.
 5. If *discoveredSet* already [contains](#) *childModule*, [continue](#).
 6. Let *childParseError* be the result of [finding the first parse error](#)^{p953} given *childModule* and *discoveredSet*.
 7. If *childParseError* is not null, return *childParseError*.
8. Return null.

8.1.4.3 Creating scripts § p95 4

To **create a classic script**, given a [string](#) *source*, an [environment settings object](#)^{p937} *settings*, a [URL](#) *baseURL*, some [script fetch options](#)^{p946} *options*, and an optional *muted errors* boolean:

1. If *muted errors* was not provided, let it be false.
2. If *muted errors* is true, then set *baseURL* to [about:blank](#)^{p51}.

Note

When *muted errors* is true, *baseURL* is the script's [CORS-cross-origin](#)^{p92} *response*'s *url*, which shouldn't be exposed to JavaScript. Therefore, *baseURL* is sanitized here.

3. If [scripting is disabled](#)^{p944} for *settings*, then set *source* to the empty string.
4. Let *script* be a new [classic script](#)^{p945} that this algorithm will subsequently initialize.
5. Set *script*'s [settings object](#)^{p945} to *settings*.
6. Set *script*'s [base URL](#)^{p945} to *baseURL*.
7. Set *script*'s [fetch options](#)^{p945} to *options*.
8. Set *script*'s [muted errors](#)^{p945} to *muted errors*.
9. Set *script*'s [parse_error](#)^{p945} and [error to rethrow](#)^{p945} to null.
10. Let *result* be [ParseScript](#)`(source, settings's Realmp938, script)`.

Note

Passing *script* as the last parameter here ensures `result.[[HostDefined]]` will be *script*.

11. If *result* is a [list](#) of errors, then:
 1. Set *script*'s [parse_error](#)^{p945} and its [error to rethrow](#)^{p945} to `result[0]`.
 2. Return *script*.

12. Set *script*'s [record](#)^{p945} to *result*.
13. Return *script*.

To **create a JavaScript module script**, given a [string](#) *source*, an [environment settings object](#)^{p937} *settings*, a [URL](#) *baseURL*, and some [script fetch options](#)^{p946} *options*:

1. If [scripting is disabled](#)^{p944} for *settings*, then set *source* to the empty string.
2. Let *script* be a new [module script](#)^{p946} that this algorithm will subsequently initialize.
3. Set *script*'s [settings object](#)^{p945} to *settings*.
4. Set *script*'s [base URL](#)^{p945} to *baseURL*.
5. Set *script*'s [fetch options](#)^{p945} to *options*.
6. Set *script*'s [parse error](#)^{p945} and [error to rethrow](#)^{p945} to null.
7. Let *result* be [ParseModule](#)(*source*, *settings*'s [Realm](#)^{p938}, *script*).

Note

Passing script as the last parameter here ensures result.[[HostDefined]] will be script.

8. If *result* is a [list](#) of errors, then:
 1. Set *script*'s [parse error](#)^{p945} to *result*[0].
 2. Return *script*.
9. Assert: *requested*.[[Assertions]] does not contain any [Record](#) entry such that *entry*.[[Key]] is not "type", because we only asked for "type" assertions in [HostGetSupportedImportAssertions](#)^{p968}.
10. [For each ModuleRequest record](#) *requested* of *result*.[[RequestedModules]]:
 1. Let *url* be the result of [resolving a module specifier](#)^{p966} given *script*'s [base URL](#)^{p945} and *requested*.[[Specifier]].
 2. Let *moduleType* be the result of running the [module type from module request](#)^{p956} steps given *requested*.
 3. If *url* is failure, or if the result of running the [module type allowed](#)^{p956} steps given *moduleType* and *settings* is false, then:
 1. Let *error* be a new [TypeError](#) exception.
 2. Set *script*'s [parse error](#)^{p945} to *error*.
 3. Return *script*.

Note

This step is essentially validating all of the requested module specifiers and type assertions. We treat a module with unresolvable module specifiers or unsupported type assertions the same as one that cannot be parsed; in both cases, a syntactic issue makes it impossible to ever contemplate linking the module later.

11. Set *script*'s [record](#)^{p945} to *result*.
12. Return *script*.

To **create a CSS module script**, given a string *source* and an [environment settings object](#)^{p937} *settings*:

1. Let *script* be a new [module script](#)^{p946} that this algorithm will subsequently initialize.
2. Set *script*'s [settings object](#)^{p945} to *settings*.
3. Set *script*'s [base URL](#)^{p945} and [fetch options](#)^{p945} to null.
4. Set *script*'s [parse error](#)^{p945} and [error to rethrow](#)^{p945} to null.
5. Let *sheet* be the result of running the steps to [create a constructed CSSStyleSheet](#) with an empty dictionary as the argument.

6. Run the steps to [synchronously replace the rules of a CSSStyleSheet](#) on *sheet* given *source*.
If this throws an exception, set *script*'s [parse error](#)^{p945} to that exception, and return *script*.

Note

*The steps to [synchronously replace the rules of a CSSStyleSheet](#) will throw if *source* contains any `@import` rules. This is by-design for now because there is not yet an agreement on how to handle these for CSS module scripts; therefore they are blocked altogether until a consensus is reached.*

7. Set *script*'s [record](#)^{p945} to the result of `CreateDefaultExportSyntheticModule(sheet)`.
8. Return *script*.

To **create a JSON module script**, given a string *source* and an [environment settings object](#)^{p937} *settings*:

1. Let *script* be a new [module script](#)^{p946} that this algorithm will subsequently initialize.
2. Set *script*'s [settings object](#)^{p945} to *settings*.
3. Set *script*'s [base URL](#)^{p945} and [fetch options](#)^{p945} to null.
4. Set *script*'s [parse error](#)^{p945} and [error to rethrow](#)^{p945} to null.
5. Let *result* be `ParseJSONModule(source)`.

If this throws an exception, set *script*'s [parse error](#)^{p945} to that exception, and return *script*.

6. Set *script*'s [record](#)^{p945} to *result*.
7. Return *script*.

The **module type from module request** steps, given a [ModuleRequest Record](#) *moduleRequest*, are as follows:

1. Let *moduleType* be "javascript".
2. If *moduleRequest*.[[Assertions]] has a [Record](#) entry such that *entry*.[[Key]] is "type", then:
 1. If *entry*.[[Value]] is "javascript", then set *moduleType* to null.

Note

*This specification uses the "javascript" module type internally for [JavaScript module scripts](#)^{p946}, so this step is needed to prevent modules from being imported using a "javascript" type assertion (a null *moduleType* will cause the [module type allowed](#)^{p956} check to fail).*

2. Otherwise, set *moduleType* to *entry*.[[Value]].
3. Return *moduleType*.

The **module type allowed** steps, given a [string](#) *moduleType* and an [environment settings object](#)^{p937} *settings*, are as follows:

1. If *moduleType* is not "javascript", "css", or "json", then return false.
2. If *moduleType* is "css" and the [CSSStyleSheet](#) interface is not [exposed](#) in *settings*'s [Realm](#)^{p938}, then return false.
3. Return true.

8.1.4.4 Calling scripts §^{p95}₆

To **run a classic script** given a [classic script](#)^{p945} *script* and an optional boolean *rethrow errors* (default false):

1. Let *settings* be the [settings object](#)^{p945} of *script*.
2. [Check if we can run script](#)^{p957} with *settings*. If this returns "do not run" then return [NormalCompletion](#)(empty).
3. [Prepare to run script](#)^{p958} given *settings*.
4. Let *evaluationStatus* be null.

5. If *script*'s [error to rethrow](#)^{p945} is not null, then set *evaluationStatus* to Completion { [[Type]]: throw, [[Value]]: *script*'s [error to rethrow](#)^{p945}, [[Target]]: empty }.
 6. Otherwise, set *evaluationStatus* to [ScriptEvaluation](#)(*script*'s [record](#)^{p945}).
- If [ScriptEvaluation](#) does not complete because the user agent has [aborted the running script](#)^{p958}, leave *evaluationStatus* as null.
7. If *evaluationStatus* is an [abrupt completion](#), then:
 1. If *rethrow errors* is true and *script*'s [muted errors](#)^{p945} is false, then:
 1. [Clean up after running script](#)^{p958} with *settings*.
 2. Rethrow *evaluationStatus*.[[Value]].
 2. If *rethrow errors* is true and *script*'s [muted errors](#)^{p945} is true, then:
 1. [Clean up after running script](#)^{p958} with *settings*.
 2. Throw a ["NetworkError" DOMException](#).
 3. Otherwise, *rethrow errors* is false. Perform the following steps:
 1. [Report the exception](#)^{p959} given by *evaluationStatus*.[[Value]] for *script*.
 2. [Clean up after running script](#)^{p958} with *settings*.
 3. Return *evaluationStatus*.
 8. [Clean up after running script](#)^{p958} with *settings*.
 9. If *evaluationStatus* is a normal completion, then return *evaluationStatus*.
 10. If we've reached this point, *evaluationStatus* was left as null because the script was [aborted prematurely](#)^{p958} during evaluation. Return Completion { [[Type]]: throw, [[Value]]: a new ["QuotaExceededError" DOMException](#), [[Target]]: empty }.

To **run a module script** given a [module script](#)^{p946} *script* and an optional boolean *preventErrorReporting* (default false):

1. Let *settings* be the [settings object](#)^{p945} of *script*.
2. [Check if we can run script](#)^{p957} with *settings*. If this returns "do not run", then return a promise resolved with undefined.
3. [Prepare to run script](#)^{p958} given *settings*.
4. Let *evaluationPromise* be null.
5. If *script*'s [error to rethrow](#)^{p945} is not null, then set *evaluationPromise* to [a promise rejected with script's error to rethrow](#)^{p945}.
6. Otherwise:
 1. Let *record* be *script*'s [record](#)^{p945}.
 2. Set *evaluationPromise* to *record*.[Evaluate](#)().

Note

This step will recursively evaluate all of the module's dependencies.

If [Evaluate](#) fails to complete as a result of the user agent [aborting the running script](#)^{p958}, then set *evaluationPromise* to [a promise rejected with](#) a new ["QuotaExceededError" DOMException](#).

7. If *preventErrorReporting* is false, then [upon rejection](#) of *evaluationPromise* with reason, [report the exception](#)^{p959} given by reason for *script*.
8. [Clean up after running script](#)^{p958} with *settings*.
9. Return *evaluationPromise*.

The steps to **check if we can run script** with an [environment settings object](#)^{p937} *settings* are as follows. They return either "run" or "do not run".

1. If the [global object](#)^{p938} specified by *settings* is a [Window](#)^{p855} object whose [Document](#)^{p117} object is not [fully active](#)^{p844}, then return "do not run".
2. If [scripting is disabled](#)^{p944} for *settings*, then return "do not run".
3. Return "run".

The steps to **prepare to run script** with an [environment settings object](#)^{p937} *settings* are as follows:

1. Push *settings*'s [realm execution context](#)^{p937} onto the [JavaScript execution context stack](#); it is now the [running JavaScript execution context](#).
2. Add *settings* to the currently running [task](#)^{p969}'s [script evaluation environment settings object set](#)^{p969}.

The steps to **clean up after running script** with an [environment settings object](#)^{p937} *settings* are as follows:

1. Assert: *settings*'s [realm execution context](#)^{p937} is the [running JavaScript execution context](#).
2. Remove *settings*'s [realm execution context](#)^{p937} from the [JavaScript execution context stack](#).
3. If the [JavaScript execution context stack](#) is now empty, [perform a microtask checkpoint](#)^{p974}. (If this runs scripts, these algorithms will be invoked reentrantly.)

Note

These algorithms are not invoked by one script directly calling another, but they can be invoked reentrantly in an indirect manner, e.g. if a script dispatches an event which has event listeners registered.

The **running script** is the [script](#)^{p945} in the `[[HostDefined]]` field in the `ScriptOrModule` component of the [running JavaScript execution context](#).

8.1.4.5 Killing scripts §^{p95}₈

Although the JavaScript specification does not account for this possibility, it's sometimes necessary to **abort a running script**. This causes any [ScriptEvaluation](#) or [Source Text Module Record Evaluate](#) invocations to cease immediately, emptying the [JavaScript execution context stack](#) without triggering any of the normal mechanisms like `finally` blocks. [\[JAVASCRIPT\]](#)^{p1308}

User agents may impose resource limitations on scripts, for example CPU quotas, memory limits, total execution time limits, or bandwidth limitations. When a script exceeds a limit, the user agent may either throw a ["QuotaExceededError" DOMException](#), [abort the script](#)^{p958} without an exception, prompt the user, or throttle script execution.

Example

For example, the following script never terminates. A user agent could, after waiting for a few seconds, prompt the user to either terminate the script or let it continue.

```
<script>
  while (true) { /* loop */ }
</script>
```

User agents are encouraged to allow users to disable scripting whenever the user is prompted either by a script (e.g. using the [window.alert\(\)](#)^{p1004} API) or because of a script's actions (e.g. because it has exceeded a time limit).

If scripting is disabled while a script is executing, the script should be terminated immediately.

User agents may allow users to specifically disable scripts just for the purposes of closing a [browsing context](#)^{p840}.

Example

For example, the prompt mentioned in the example above could also offer the user with a mechanism to just close the page entirely, without running any [unload](#)^{p1302} event handlers.

8.1.4.6 Runtime script errors § 9^{p95}

For web developers (non-normative)

`self.reportErrorp959(e)`

Dispatches an `errorp1301` event at the global object for the given value `e`, in the same fashion as an unhandled exception.

When the user agent is required to **report an error** for a particular `scriptp945` with a particular position `line:col`, using a particular target `target`, it must run these steps, after which the error is either **handled** or **not handled**:

1. If `target` is `in error reporting modep959`, then return; the error is `not handledp959`.
2. Let `target` be **in error reporting mode**.
3. Let `message` be an `implementation-defined` string describing the error in a helpful manner.
4. Let `errorValue` be the value that represents the error: in the case of an uncaught exception, that would be the value that was thrown; in the case of a JavaScript error that would be an `Error` object. If there is no corresponding value, then the null value must be used instead.
5. Let `urlString` be the result of applying the `URL serializer` to the `URL record` that corresponds to the resource from which `script` was obtained.

Note

The resource containing the script will typically be the file from which the `Documentp117` was parsed, e.g. for inline `scriptp624` elements or `event handler content attributesp981`; or the JavaScript file that the script was in, for external scripts. Even for dynamically-generated scripts, user agents are strongly encouraged to attempt to keep track of the original source of a script. For example, if an external script uses the `document.write()p996` API to insert an inline `scriptp624` element during parsing, the URL of the resource containing the script would ideally be reported as being the external script, and the line number might ideally be reported as the line with the `document.write()p996` call or where the string passed to that call was first constructed. Naturally, implementing this can be somewhat non-trivial.

Note

User agents are similarly encouraged to keep careful track of the original line numbers, even in the face of `document.write()p996` calls mutating the document as it is parsed, or `event handler content attributesp981` spanning multiple lines.

6. If `script` is a `classic scriptp945` and `script's muted errorsp945` is true, then set `message` to "Script error.", `urlString` to the empty string, `line` and `col` to 0, and `errorValue` to null.
7. Let `notHandled` be true.
8. If `target` implements `EventTarget`, then set `notHandled` to the result of `firing an event` named `errorp1301` at `target`, using `ErrorEventp960`, with the `cancelable` attribute initialized to true, the `messagep960` attribute initialized to `message`, the `filenamep960` attribute initialized to `urlString`, the `linenop960` attribute initialized to `line`, the `colnop960` attribute initialized to `col`, and the `errorp960` attribute initialized to `errorValue`.
9. Let `target` no longer be `in error reporting modep959`.
10. If `notHandled` is false, then the error is `handledp959`. Otherwise, the error is `not handledp959`.

Note

Returning true in an event handler cancels the event per `the event handler processing algorithmp983`.

When the user agent is to **report an exception** `E`, the user agent must `report the errorp959` for the relevant `scriptp945`, with the problematic position (line number and column number) in the resource containing the script, using the `global objectp938` specified by the script's `settings objectp945` as the target. If the error is still `not handledp959` after this, then the error may be reported to a developer console.

The existence of both `report an errorp959` and `report an exceptionp959` is confusing, and both algorithms have known problems. You can track future cleanup in this area in [issue #958](#).

The `reportError(e)` method steps are to `report the exceptionp959` `e`.

The [ErrorEvent](#)^{p960} interface is defined as follows:

```
IDL [Exposed=*]
interface ErrorEvent : Event {
  constructor(DOMString type, optional ErrorEventInit eventInitDict = {});

  readonly attribute DOMString message;
  readonly attribute USVString filename;
  readonly attribute unsigned long lineno;
  readonly attribute unsigned long colno;
  readonly attribute any error;
};

dictionary ErrorEventInit : EventInit {
  DOMString message = "";
  USVString filename = "";
  unsigned long lineno = 0;
  unsigned long colno = 0;
  any error = null;
};
```

The **message** attribute must return the value it was initialized to. It represents the error message.

The **filename** attribute must return the value it was initialized to. It represents the [URL](#) of the script in which the error originally occurred.

The **lineno** attribute must return the value it was initialized to. It represents the line number where the error occurred in the script.

The **colno** attribute must return the value it was initialized to. It represents the column number where the error occurred in the script.

The **error** attribute must return the value it was initialized to. Where appropriate, it is set to the object representing the error (e.g., the exception object in the case of an uncaught DOM exception).

8.1.4.7 Unhandled promise rejections §^{p96}₀

In addition to synchronous [runtime script errors](#)^{p959}, scripts may experience asynchronous promise rejections, tracked via the [unhandledrejection](#)^{p1302} and [rejectionhandled](#)^{p1302} events. Tracking these rejections is done via the [HostPromiseRejectionTracker](#)^{p961} abstract operation, but reporting them is defined here.

To **notify about rejected promises** on a given [environment settings object](#)^{p937} *settings object*:

1. Let *list* be a copy of *settings object*'s [about-to-be-notified rejected promises list](#)^{p937}.
2. If *list* is empty, return.
3. Clear *settings object*'s [about-to-be-notified rejected promises list](#)^{p937}.
4. Let *global* be *settings object*'s [global object](#)^{p938}.
5. [Queue a global task](#)^{p970} on the [DOM manipulation task source](#)^{p977} given *global* to run the following substep:
 1. For each promise *p* in *list*:
 1. If *p*'s [\[\[PromisesHandled\]\]](#) internal slot is true, continue to the next iteration of the loop.
 2. Let *notHandled* be the result of [firing an event](#) named [unhandledrejection](#)^{p1302} at *global*, using [PromiseRejectionEvent](#)^{p961}, with the [cancelable](#) attribute initialized to true, the [promise](#)^{p961} attribute initialized to *p*, and the [reason](#)^{p961} attribute initialized to the value of *p*'s [\[\[PromiseResult\]\]](#) internal slot.
 3. If *notHandled* is false, then the promise rejection is [handled](#)^{p961}. Otherwise, the promise rejection is [not handled](#)^{p961}.
 4. If *p*'s [\[\[PromisesHandled\]\]](#) internal slot is false, add *p* to *settings object*'s [outstanding rejected promises weak set](#)^{p937}.

This algorithm results in promise rejections being marked as **handled** or **not handled**. These concepts parallel [handled^{p959}](#) and [not handled^{p959}](#) script errors. If a rejection is still [not handled^{p961}](#) after this, then the rejection may be reported to a developer console.

The [PromiseRejectionEvent^{p961}](#) interface is defined as follows:

```
IDL [Exposed=*]
interface PromiseRejectionEvent : Event {
  constructor(DOMString type, PromiseRejectionEventInit eventInitDict);

  readonly attribute Promise<any> promise;
  readonly attribute any reason;
};

dictionary PromiseRejectionEventInit : EventInit {
  required Promise<any> promise;
  any reason;
};
```

The **promise** attribute must return the value it was initialized to. It represents the promise which this notification is about.

The **reason** attribute must return the value it was initialized to. It represents the rejection reason for the promise.

8.1.5 JavaScript specification host hooks [§ p96](#)₁

The JavaScript specification contains a number of [implementation-defined](#) abstract operations, that vary depending on the host environment. This section defines them for user agent hosts.

8.1.5.1 HostEnsureCanCompileStrings(*callerRealm*, *calleeRealm*) [§ p96](#)₁

JavaScript contains an [implementation-defined](#) [HostEnsureCanCompileStrings](#)(*callerRealm*, *calleeRealm*) abstract operation. User agents must use the following implementation: [\[JAVASCRIPT\]^{p1308}](#)

1. Perform ? [EnsureCSPDoesNotBlockStringCompilation](#)(*callerRealm*, *calleeRealm*). [\[CSP\]^{p1305}](#)

8.1.5.2 HostPromiseRejectionTracker(*promise*, *operation*) [§ p96](#)₁

JavaScript contains an [implementation-defined](#) [HostPromiseRejectionTracker](#)(*promise*, *operation*) abstract operation. User agents must use the following implementation: [\[JAVASCRIPT\]^{p1308}](#)

1. Let *script* be the [running script^{p958}](#).
2. If *script* is a [classic script^{p945}](#) and *script*'s [muted errors^{p945}](#) is true, terminate these steps.
3. Let *settings object* be *script*'s [settings object^{p945}](#).
4. If *operation* is "reject",
 1. Add *promise* to *settings object*'s [about-to-be-notified rejected promises list^{p937}](#).
5. If *operation* is "handle",
 1. If *settings object*'s [about-to-be-notified rejected promises list^{p937}](#) contains *promise*, then remove *promise* from that list and return.
 2. If *settings object*'s [outstanding rejected promises weak set^{p937}](#) does not contain *promise*, then return.
 3. Remove *promise* from *settings object*'s [outstanding rejected promises weak set^{p937}](#).
 4. Let *global* be *settings object*'s [global object^{p938}](#).

5. [Queue a global task](#)^{p970} on the [DOM manipulation task source](#)^{p977} given *global* to [fire an event](#) named [rejectionhandled](#)^{p1302} at *global*, using [PromiseRejectionEvent](#)^{p961}, with the [promise](#)^{p961} attribute initialized to *promise*, and the [reason](#)^{p961} attribute initialized to the value of *promise*'s `[[PromiseResult]]` internal slot.

8.1.5.3 Job-related host hooks ^{§^{p96}₂}

The JavaScript specification defines Jobs to be scheduled and run later by the host, as well as [JobCallback Records](#) which encapsulate JavaScript functions that are called as part of jobs. The JavaScript specification contains a number of [implementation-defined](#) abstract operations that lets the host define how jobs are scheduled and how JobCallbacks are handled. HTML uses these abstract operations to track the [incumbent settings object](#)^{p941} in promises and [FinalizationRegistry](#) callbacks by saving and restoring the [incumbent settings object](#)^{p941} and a [JavaScript execution context](#) for the [active script](#)^{p946} in JobCallbacks. This section defines them for user agent hosts.

8.1.5.3.1 [HostCallJobCallback\(callback, V, argumentsList\)](#) ^{§^{p96}₂}

JavaScript contains an [implementation-defined](#) [HostCallJobCallback\(callback, V, argumentsList\)](#) abstract operation to let hosts restore state when invoking JavaScript callbacks from inside tasks. User agents must use the following implementation: [\[JAVASCRIPT\]](#)^{p1308}

1. Let *incumbent settings* be `callback.[[HostDefined]].[[IncumbentSettings]]`.
2. Let *script execution context* be `callback.[[HostDefined]].[[ActiveScriptContext]]`.
3. [Prepare to run a callback](#)^{p941} with *incumbent settings*.

Note

This affects the [incumbent](#)^{p939} concept while the callback runs.

4. If *script execution context* is not null, then [push](#) *script execution context* onto the [JavaScript execution context stack](#).

Note

This affects the [active script](#)^{p946} while the callback runs.

5. Let *result* be `Call(callback.[[Callback]], V, argumentsList)`.
6. If *script execution context* is not null, then [pop](#) *script execution context* from the [JavaScript execution context stack](#).
7. [Clean up after running a callback](#)^{p941} with *incumbent settings*.
8. Return *result*.

8.1.5.3.2 [HostEnqueueFinalizationRegistryCleanupJob\(finalizationRegistry\)](#) ^{§^{p96}₂}

JavaScript has the ability to register objects with [FinalizationRegistry](#) objects, in order to schedule a cleanup action if they are found to be garbage collected. The JavaScript specification contains an [implementation-defined](#) [HostEnqueueFinalizationRegistryCleanupJob\(finalizationRegistry\)](#) abstract operation to schedule the cleanup action.

Note

The timing and occurrence of cleanup work is [implementation-defined](#) in the JavaScript specification. User agents might differ in when and whether an object is garbage collected, affecting both whether the return value of the `WeakRef.prototype.deref()` method is undefined, and whether [FinalizationRegistry](#) cleanup callbacks occur. There are well-known cases in popular web browsers where objects are not accessible to JavaScript, but they remain retained by the garbage collector indefinitely. HTML clears kept-alive [WeakRef](#) objects in the [perform a microtask checkpoint](#)^{p974} algorithm. Authors would be best off not depending on the timing details of garbage collection implementations.

Cleanup actions do not take place interspersed with synchronous JavaScript execution, but rather happen in queued [tasks](#)^{p969}. User agents must use the following implementation: [\[JAVASCRIPT\]](#)^{p1308}

1. Let *global* be `finalizationRegistry.[[Realm]]`'s [global object](#)^{p938}.

2. [Queue a global task](#)^{p970} on the **JavaScript engine task source** given *global* to perform the following steps:
 1. Let *entry* be *finalizationRegistry*.[[CleanupCallback]].[[Callback]].[[Realm]]'s [environment settings object](#)^{p938}.
 2. [Check if we can run script](#)^{p957} with *entry*. If this returns "do not run", then return.
 3. [Prepare to run script](#)^{p958} with *entry*.

Note

This affects the [entry](#)^{p939} concept while the cleanup callback runs.

4. Let *result* be the result of performing [CleanupFinalizationRegistry](#)(*finalizationRegistry*).
5. [Clean up after running script](#)^{p958} with *entry*.
6. If *result* is an [abrupt completion](#), then [report the exception](#)^{p959} given by *result*.[[Value]].

8.1.5.3.3 [HostEnqueuePromiseJob](#)(*job*, *realm*) §^{p96}₃

JavaScript contains an [implementation-defined HostEnqueuePromiseJob](#)(*job*, *realm*) abstract operation to schedule Promise-related operations. HTML schedules these operations in the microtask queue. User agents must use the following implementation: [\[JAVASCRIPT\]](#)^{p1308}

1. If *realm* is not null, then let *job settings* be the [settings object](#)^{p938} for *realm*. Otherwise, let *job settings* be null.

Note

*If *realm* is not null, it is the [Realm](#) of the author code that will run. When *job* is returned by [NewPromiseReactionJob](#), it is the realm of the promise's handler function. When *job* is returned by [NewPromiseResolveThenableJob](#), it is the realm of the then function.*

*If *realm* is null, either no author code will run or author code is guaranteed to throw. For the former, the author may not have passed in code to run, such as in `promise.then(null, null)`. For the latter, it is because a revoked Proxy was passed. In both cases, all the steps below that would otherwise use *job settings* get skipped.*

2. [Queue a microtask](#)^{p970} on the [surrounding agent](#)'s [event loop](#)^{p968} to perform the following steps:
 1. If *job settings* is not null, then [check if we can run script](#)^{p957} with *job settings*. If this returns "do not run" then return.
 2. If *job settings* is not null, then [prepare to run script](#)^{p958} with *job settings*.

Note

This affects the [entry](#)^{p939} concept while the job runs.

3. Let *result* be *job*().

Note

**job* is an [abstract closure](#) returned by [NewPromiseReactionJob](#) or [NewPromiseResolveThenableJob](#). The promise's handler function when *job* is returned by [NewPromiseReactionJob](#), and the then function when *job* is returned by [NewPromiseResolveThenableJob](#), are wrapped in [JobCallback Records](#). HTML saves the [incumbent settings object](#)^{p941} and a [JavaScript execution context](#) for to the [active script](#)^{p946} in [HostMakeJobCallback](#)^{p963} and restores them in [HostCallJobCallback](#)^{p962}.*

4. If *job settings* is not null, then [clean up after running script](#)^{p958} with *job settings*.
5. If *result* is an [abrupt completion](#), then [report the exception](#)^{p959} given by *result*.[[Value]].

8.1.5.3.4 [HostMakeJobCallback](#)(*callable*) §^{p96}₃

JavaScript contains an [implementation-defined HostMakeJobCallback](#)(*callable*) abstract operation to let hosts attach state to JavaScript callbacks that are called from inside [task](#)^{p969}s. User agents must use the following implementation: [\[JAVASCRIPT\]](#)^{p1308}

1. Let *incumbent settings* be the [incumbent settings object](#)^{p941}.
2. Let *active script* be the [active script](#)^{p946}.
3. Let *script execution context* be null.
4. If *active script* is not null, set *script execution context* to a new [JavaScript execution context](#), with its `Function` field set to null, its `Realm` field set to *active script*'s [settings object](#)^{p945}'s [Realm](#)^{p938}, and its `ScriptOrModule` set to *active script*'s [record](#)^{p945}.

Note

As seen below, this is used in order to propagate the current [active script](#)^{p946} forward to the time when the job callback is invoked.

Example

A case where *active script* is non-null, and saving it in this way is useful, is the following:

```
Promise.resolve('import(`./example.mjs`)').then(eval);
```

Without this step (and the steps that use it in [HostCallJobCallback](#)^{p962}), there would be no [active script](#)^{p946} when the `import()` expression is evaluated, since `eval()` is a built-in function that does not originate from any particular [script](#)^{p945}.

With this step in place, the active script is propagated from the above code into the job, allowing `import()` to use the original script's [base URL](#)^{p945} appropriately.

Example

active script can be null if the user clicks on the following button:

```
<button onclick="Promise.resolve('import(`./example.mjs`)').then(eval)">Click me</button>
```

In this case, the JavaScript function for the [event handler](#)^{p980} will be created by the [get the current value of the event handler](#)^{p985} algorithm, which creates a function with null `[[ScriptOrModule]]` value. Thus, when the promise machinery calls [HostMakeJobCallback](#)^{p963}, there will be no [active script](#)^{p946} to pass along.

As a consequence, this means that when the `import()` expression is evaluated, there will still be no [active script](#)^{p946}. Fortunately that is handled by our implementations of [HostResolveImportedModule](#)^{p967} and [HostImportModuleDynamically](#)^{p967}, by falling back to using the [current settings object](#)^{p944}'s [API base URL](#)^{p937}.

5. Return the [JobCallback Record](#) { `[[Callback]]`: *callable*, `[[HostDefined]]`: { `[[IncumbentSettings]]`: *incumbent settings*, `[[ActiveScriptContext]]`: *script execution context* } }.

8.1.5.4 Module-related host hooks § p96 4

The JavaScript specification defines a syntax for modules, as well as some host-agnostic parts of their processing model. This specification defines the rest of their processing model: how the module system is bootstrapped, via the [script](#)^{p624} element with [type](#)^{p625} attribute set to "module", and how modules are fetched, resolved, and executed. [\[JAVASCRIPT\]](#)^{p1308}

Note

Although the JavaScript specification speaks in terms of "scripts" versus "modules", in general this specification speaks in terms of [classic scripts](#)^{p945} versus [module scripts](#)^{p946}, since both of them use the [script](#)^{p624} element.

For web developers (non-normative)

`modulePromise = import(specifier)`

Returns a promise for the module namespace object for the [module script](#)^{p946} identified by *specifier*. This allows dynamic importing of module scripts at runtime, instead of statically using the `import` statement form. The specifier will be [resolved](#)^{p966} relative to the [active script](#)^{p946}'s [base URL](#)^{p945}.

The returned promise will be rejected if an invalid specifier is given, or if a failure is encountered while [fetching](#)^{p949} or [evaluating](#)^{p957} the resulting module graph.

This syntax can be used inside both [classic](#)^{p945} and [module scripts](#)^{p946}. It thus provides a bridge into the module-script world, from the classic-script world.

`url = import.meta.url`

Returns the [active module script](#)^{p946}'s [base URL](#)^{p945}.

This syntax can only be used inside [module scripts](#)^{p946}.

A **module map** is a [map](#) keyed by [tuples](#) consisting of a [URL record](#) and a [string](#). The [URL record](#) is the [request URL](#) at which the module was fetched, and the [string](#) indicates the type of the module (e.g. "javascript"). The [module map](#)^{p965}'s values are either a [module script](#)^{p946}, null (used to represent failed fetches), or a placeholder value "fetching". [Module maps](#)^{p965} are used to ensure that imported module scripts are only fetched, parsed, and evaluated once per [Document](#)^{p117} or [worker](#)^{p1046}.

Example

Since [module maps](#)^{p965} are keyed by (URL, module type), the following code will create three separate entries in the [module map](#)^{p965}, since it results in three different (URL, module type) [tuples](#) (all with "javascript" type):

```
import "https://example.com/module.mjs";
import "https://example.com/module.mjs#map-buster";
import "https://example.com/module.mjs?debug=true";
```

That is, URL [queries](#) and [fragments](#) can be varied to create distinct entries in the [module map](#)^{p965}; they are not ignored. Thus, three separate fetches and three separate module evaluations will be performed.

In contrast, the following code would only create a single entry in the [module map](#)^{p965}, since after applying the [URL parser](#) to these inputs, the resulting [URL records](#) are equal:

```
import "https://example.com/module2.mjs";
import "https:example.com/module2.mjs";
import "https://example.com/module2.mjs";
import "https://example.com/foo/./module2.mjs";
```

So in this second example, only one fetch and one module evaluation will occur.

Note that this behavior is the same as how [shared workers](#)^{p1072} are keyed by their parsed [constructor url](#)^{p1065}.

Example

Since module type is also part of the [module map](#)^{p965} key, the following code will create two separate entries in the [module map](#)^{p965} (the type is "javascript" for the first, and "css" for the second):

```
<script type=module>
  import "https://example.com/module";
</script>
<script type=module>
  import "https://example.com/module" assert { type: "css" };
</script>
```

This can result in two separate fetches and two separate module evaluations being performed. This is a [willful violation](#)^{p27} of a constraint recommended (but not required) by the import assertions specification stating that each call to [HostResolveImportedModule](#)^{p967} with the same (*referencingScriptOrModule*, *moduleRequest*.[[Specifier]]) pair must return the same [Module Record](#). [\[JSIMPORTASSERTIONS\]](#)^{p1309}

In practice, due to the as-yet-unspecified memory cache (see issue [#6110](#)) the resource may only be fetched once in WebKit and Blink-based browsers. Additionally, as long as all module types are mutually exclusive, the module type check in [fetch a single module script](#)^{p952} will fail for at least one of the imports, so at most one module evaluation will occur.

The purpose of including the type in the [module map](#)^{p965} key is so that an import with the wrong type assertion does not prevent a different import of the same specifier but with the correct type from succeeding.

Example

JavaScript module scripts are the default import type when importing from another JavaScript module; that is, when an `import` statement lacks a type import assertion the imported module script's type will be JavaScript. Attempting to import a JavaScript resource using an `import` statement with a type import assertion will fail:

```
<script type="module">
  // All of the following will fail, assuming that the imported .mjs files are served with a
  // JavaScript MIME type. JavaScript module scripts are the default and cannot be imported with
  // any import type assertion.
  import foo from "./foo.mjs" assert { type: "javascript" };
  import foo2 from "./foo2.mjs" assert { type: "js" };
  import foo3 from "./foo3.mjs" assert { type: "" };
  await import("./foo4.mjs", { assert: { type: null } });
  await import("./foo5.mjs", { assert: { type: undefined } });
</script>
```

To **resolve a module specifier** given a [URL base URL](#) and a [string specifier](#), perform the following steps. It will return either a [URL record](#) or failure.

1. Apply the [URL parser](#) to *specifier*. If the result is not failure, return the result.
2. If *specifier* does not start with the character U+002F SOLIDUS (/), the two-character sequence U+002E FULL STOP, U+002F SOLIDUS (./), or the three-character sequence U+002E FULL STOP, U+002E FULL STOP, U+002F SOLIDUS (./), return failure.

Note

This restriction is in place so that in the future we can allow custom module loaders to give special meaning to "bare" import specifiers, like `import "jquery"` or `import "web/crypto"`. For now any such imports will fail, instead of being treated as relative URLs.

3. Return the result of applying the [URL parser](#) to *specifier* with *base URL*.

Example

The following are valid module specifiers according to the above algorithm:

- `https://example.com/apples.mjs`
- `http:example.com\pears.js` (becomes `http://example.com/pears.js` as step 1 parses with no base URL)
- `//example.com/bananas`
- `./strawberries.mjs.cgi`
- `../lychees`
- `/limes.jsx`
- `data:text/javascript,export default 'grapes';`
- `blob:https://whatwg.org/d0360e2f-caee-469f-9a2f-87d5b0456f6f`

The following are valid module specifiers according to the above algorithm, but will invariably cause failures when they are [fetched](#)^{p952}:

- `javascript:export default 'artichokes';`
- `data:text/plain,export default 'kale';`
- `about:legumes`
- `wss://example.com/celery`

The following are not valid module specifiers according to the above algorithm:

- `https://eggplant:b/c`
- `pumpkins.js`
- `.tomato`
- `..zucchini.mjs`
- `.\yam.es`

8.1.5.4.1 *HostGetImportMetaProperties(moduleRecord)* §P96

JavaScript contains an [implementation-defined HostGetImportMetaProperties](#) abstract operation. User agents must use the following implementation: [\[JAVASCRIPT\]p1308](#)

1. Let *module script* be *moduleRecord*.[[HostDefined]].
2. Assert: *module script*'s [base URL](#)^{p945} is not null, as *module script* is a [JavaScript module script](#)^{p946}.
3. Let *urlString* be *module script*'s [base URL](#)^{p945}, [serialized](#).
4. Return « Record { [[Key]]: "url", [[Value]]: *urlString* } ».

8.1.5.4.2 *HostImportModuleDynamically*(*referencingScriptOrModule*, *moduleRequest*, *promiseCapability*) §^{p96}₇

JavaScript contains an [implementation-defined *HostImportModuleDynamically*](#) abstract operation. User agents must use the following implementation: [\[JAVASCRIPT\]](#)^{p1308}

1. Let *settings object* be the [current settings object](#)^{p944}.
2. If *settings object*'s [global object](#)^{p938} implements [WorkletGlobalScope](#)^{p1880} or [ServiceWorkerGlobalScope](#), then:
 1. Let *completion* be Completion { [[Type]]: throw, [[Value]]: a new [TypeError](#), [[Target]]: empty }.
 2. Perform [FinishDynamicImport](#)(*referencingScriptOrModule*, *moduleRequest*, *promiseCapability*, *completion*).
 3. Return.
3. Let *base URL* be *settings object*'s [API base URL](#)^{p937}.
4. Let *fetch options* be the [default classic script fetch options](#)^{p946}.
5. If *referencingScriptOrModule* is not null, then:
 1. Let *referencing script* be *referencingScriptOrModule*.[[HostDefined]].
 2. Set *settings object* to *referencing script*'s [settings object](#)^{p945}.
 3. Set *base URL* to *referencing script*'s [base URL](#)^{p945}.
 4. Set *fetch options* to the [descendant script fetch options](#)^{p947} for *referencing script*'s [fetch options](#)^{p945}.
 5. Assert: Neither *base URL* nor *fetch options* is null, as *referencing script* is a [classic script](#)^{p945} or a [JavaScript module script](#)^{p946}.

Note

As explained above for [HostResolveImportedModule](#)^{p967}, in the common case, *referencingScriptOrModule* is non-null.

6. [Fetch an import\(\) module script graph](#)^{p949} given *moduleRequest*, *base URL*, *settings object*, and *fetch options*. Wait until the algorithm asynchronously completes with *result*.
7. Let *promise* be null.
8. If *result* is null, then set *promise* to [a promise rejected with](#) a new [TypeError](#).
9. Otherwise, set *promise* to the result of [running a module script](#)^{p957} given *result* and true.
10. Perform [FinishDynamicImport](#)(*referencingScriptOrModule*, *moduleRequest*, *promiseCapability*, *promise*).
11. Return undefined.

8.1.5.4.3 *HostResolveImportedModule*(*referencingScriptOrModule*, *moduleRequest*) §^{p96}₇

JavaScript contains an [implementation-defined *HostResolveImportedModule*](#) abstract operation. User agents must use the following implementation: [\[JAVASCRIPT\]](#)^{p1308}

1. Let *settings object* be the [current settings object](#)^{p944}.
2. Let *base URL* be *settings object*'s [API base URL](#)^{p937}.
3. If *referencingScriptOrModule* is not null, then:

1. Let *referencing script* be *referencingScriptOrModule*.[[HostDefined]].
2. Set *settings object* to *referencing script*'s [settings object](#)^{p945}.
3. Set *base URL* to *referencing script*'s [base URL](#)^{p945}.
4. Assert: *base URL* is not null, as *referencing script* is a [classic script](#)^{p945} or a [JavaScript module script](#)^{p946}.

Example

referencingScriptOrModule is not usually null, but will be so for event handlers per the [get the current value of the event handler](#)^{p985} algorithm. For example, given:

```
<button onclick="import('./foo.mjs')">Click me</button>
```

If a [click](#) event occurs, then at the time the `import()` expression runs, `GetActiveScriptOrModule` will return null, which will be passed to this abstract operation when `HostResolveImportedModule` is called by `FinishDynamicImport`.

4. Let *moduleMap* be *settings object*'s [module map](#)^{p937}.
5. Let *url* be the result of [resolving a module specifier](#)^{p966} given *base URL* and *moduleRequest*.[[Specifier]].
6. Assert: *url* is never failure, because [resolving a module specifier](#)^{p966} must have been previously successful with these same two arguments (either [while creating the corresponding module script](#)^{p955}, or in [fetch an import\(\) module script graph](#)^{p949}).
7. Let *moduleType* be the result of running the [module type from module request](#)^{p956} steps given *moduleRequest*.
8. Let *resolved module script* be *moduleMap*[(*url*, *moduleType*)]. (This entry must [exist](#) for us to have gotten to this point.)
9. Assert: *resolved module script* is a [module script](#)^{p946} (i.e., is not null or "fetching").
10. Assert: *resolved module script*'s [record](#)^{p945} is not null.
11. Return *resolved module script*'s [record](#)^{p945}.

8.1.5.4.4 HostGetSupportedImportAssertions() ^{§ p96}₈

The *Import Assertions* proposal contains an [implementation-defined HostGetSupportedImportAssertions](#) abstract operation. User agents must use the following implementation: [\[JSIMPORTASSERTIONS\]](#)^{p1309}

1. Return « "type" ».

8.1.6 Event loops ^{§ p96}₈

8.1.6.1 Definitions ^{§ p96}₈

To coordinate events, user interaction, scripts, rendering, networking, and so forth, user agents must use **event loops** as described in this section. Each [agent](#) has an associated **event loop**, which is unique to that agent.

The [event loop](#)^{p968} of a [similar-origin window agent](#)^{p933} is known as a **window event loop**. The [event loop](#)^{p968} of a [dedicated worker agent](#)^{p933}, [shared worker agent](#)^{p933}, or [service worker agent](#)^{p933} is known as a **worker event loop**. And the [event loop](#)^{p968} of a [worklet agent](#)^{p933} is known as a **worklet event loop**.

Note

Event loops^{p968} do not necessarily correspond to implementation threads. For example, multiple [window event loops](#)^{p968} could be cooperatively scheduled in a single thread.

However, for the various worker [agents](#) that are allocated with `[[CanBlock]]` set to true, the JavaScript specification does place requirements on them regarding [forward progress](#), which effectively amount to requiring dedicated per-agent threads in those cases.

An [event loop](#)^{p968} has one or more **task queues**. A [task queue](#)^{p969} is a [set](#) of [tasks](#)^{p969}.

Note

Task queues^{p969} are sets, not queues, because [step one of the event loop processing model](#)^{p971} grabs the first [runnable](#)^{p969} task^{p969} from the chosen queue, instead of [dequeuing](#) the first task.

Note

The [microtask queue](#)^{p970} is not a [task queue](#)^{p969}.

Tasks encapsulate algorithms that are responsible for such work as:

Events

Dispatching an [Event](#) object at a particular [EventTarget](#) object is often done by a dedicated task.

Note

Not all events are dispatched using the [task queue](#)^{p969}; many are dispatched during other tasks.

Parsing

The [HTML parser](#)^{p1106} tokenizing one or more bytes, and then processing any resulting tokens, is typically a task.

Callbacks

Calling a callback is often done by a dedicated task.

Using a resource

When an algorithm [fetches](#) a resource, if the fetching occurs in a non-blocking fashion then the processing of the resource once some or all of the resource is available is performed by a task.

Reacting to DOM manipulation

Some elements have tasks that trigger in response to DOM manipulation, e.g. when that element is [inserted into the document](#)^{p44}.

Formally, a **task** is a [struct](#) which has:

Steps

A series of steps specifying the work to be done by the task.

A source

One of the [task sources](#)^{p969}, used to group and serialize related tasks.

A document

A [Document](#)^{p117} associated with the task, or null for tasks that are not in a [window event loop](#)^{p968}.

A script evaluation environment settings object set

A [set](#) of [environment settings objects](#)^{p937} used for tracking script evaluation during the task.

A [task](#)^{p969} is **runnable** if its [document](#)^{p969} is either null or [fully active](#)^{p844}.

Per its [source](#)^{p969} field, each [task](#)^{p969} is defined as coming from a specific **task source**. For each [event loop](#)^{p968}, every [task source](#)^{p969} must be associated with a specific [task queue](#)^{p969}.

Note

Essentially, [task sources](#)^{p969} are used within standards to separate logically-different types of tasks, which a user agent might wish to distinguish between. [Task queues](#)^{p969} are used by user agents to coalesce task sources within a given [event loop](#)^{p968}.

Example

For example, a user agent could have one [task queue](#)^{p969} for mouse and key events (to which the [user interaction task source](#)^{p977} is associated), and another to which all other [task sources](#)^{p969} are associated. Then, using the freedom granted in the initial step of the [event loop processing model](#)^{p971}, it could give keyboard and mouse events preference over other tasks three-quarters of the time, keeping the interface responsive but not starving other task queues. Note that in this setup, the processing model still enforces that the user agent would never process events from any one [task source](#)^{p969} out of order.

Each [event loop](#)^{p968} has a **currently running task**, which is either a [task](#)^{p969} or null. Initially, this is null. It is used to handle reentrancy.

Each [event loop](#)^{p968} has a **microtask queue**, which is a [queue](#) of [microtasks](#)^{p970}, initially empty. A **microtask** is a colloquial way of referring to a [task](#)^{p969} that was created via the [queue a microtask](#)^{p970} algorithm.

Each [event loop](#)^{p968} has a **performing a microtask checkpoint** boolean, which is initially false. It is used to prevent reentrant invocation of the [perform a microtask checkpoint](#)^{p974} algorithm.

Each [window event loop](#)^{p968} has a **DOMHighResTimeStamp last render opportunity time**, initially set to zero.

Each [window event loop](#)^{p968} has a **DOMHighResTimeStamp last idle period start time**, initially set to zero.

To get the **same-loop windows** for a [window event loop](#)^{p968} *loop*, return all [Window](#)^{p855} objects whose [relevant agent](#)^{p934}'s [event loop](#)^{p968} is *loop*.

8.1.6.2 Queuing tasks §^{p97}₀

To **queue a task** on a [task source](#)^{p969} *source*, which performs a series of steps *steps*, optionally given an event loop *event loop* and a document *document*:

1. If *event loop* was not given, set *event loop* to the [implied event loop](#)^{p971}.
2. If *document* was not given, set *document* to the [implied document](#)^{p971}.
3. Let *task* be a new [task](#)^{p969}.
4. Set *task*'s [steps](#)^{p969} to *steps*.
5. Set *task*'s [source](#)^{p969} to *source*.
6. Set *task*'s [document](#)^{p969} to the *document*.
7. Set *task*'s [script evaluation environment settings object set](#)^{p969} to an empty [set](#).
8. Let *queue* be the [task queue](#)^{p969} to which *source* is associated on *event loop*.
9. [Append](#) *task* to *queue*.

⚠Warning!

Failing to pass an event loop and document to [queue a task](#)^{p970} means relying on the ambiguous and poorly-specified [implied event loop](#)^{p971} and [implied document](#)^{p971} concepts. Specification authors should either always pass these values, or use the wrapper algorithms [queue a global task](#)^{p970} or [queue an element task](#)^{p970} instead. Using the wrapper algorithms is recommended.

To **queue a global task** on a [task source](#)^{p969} *source*, with a [global object](#)^{p938} *global* and a series of steps *steps*:

1. Let *event loop* be *global*'s [relevant agent](#)^{p934}'s [event loop](#)^{p968}.
2. Let *document* be *global*'s [associated Document](#)^{p856}, if *global* is a [Window](#)^{p855} object; otherwise null.
3. [Queue a task](#)^{p970} given *source*, *event loop*, *document*, and *steps*.

To **queue an element task** on a [task source](#)^{p969} *source*, with an element *element* and a series of steps *steps*:

1. Let *global* be *element*'s [relevant global object](#)^{p944}.
2. [Queue a global task](#)^{p970} given *source*, *global*, and *steps*.

To **queue a microtask** which performs a series of steps *steps*, optionally given an event loop *event loop* and a document *document*:

1. If *event loop* was not given, set *event loop* to the [implied event loop](#)^{p971}.
2. If *document* was not given, set *document* to the [implied document](#)^{p971}.

3. Let *microtask* be a new [task](#)^{p969}.
4. Set *microtask*'s [steps](#)^{p969} to *steps*.
5. Set *microtask*'s [source](#)^{p969} to the **microtask task source**.
6. Set *microtask*'s [document](#)^{p969} to *document*.
7. Set *microtask*'s [script evaluation environment settings object set](#)^{p969} to an empty [set](#).
8. [Enqueue](#) *microtask* on *event loop*'s [microtask queue](#)^{p970}.

Note

It is possible for a [microtask](#)^{p970} to be moved to a regular [task queue](#)^{p969}, if, during its initial execution, it [spins the event loop](#)^{p975}. This is the only case in which the [source](#)^{p969}, [document](#)^{p969}, and [script evaluation environment settings object set](#)^{p969} of the [microtask](#) are consulted; they are ignored by the [perform a microtask checkpoint](#)^{p974} algorithm.

The **implied event loop** when queuing a task is the one that can be deduced from the context of the calling algorithm. This is generally unambiguous, as most specification algorithms only ever involve a single [agent](#) (and thus a single [event loop](#)^{p968}). The exception is algorithms involving or specifying cross-agent communication (e.g., between a window and a worker); for those cases, the **implied event loop**^{p971} concept must not be relied upon and specifications must explicitly provide an [event loop](#)^{p968} when [queuing a task](#)^{p970} or [microtask](#)^{p970}.

The **implied document** when queuing a task on an [event loop](#)^{p968} *event loop* is determined as follows:

1. If *event loop* is not a [window event loop](#)^{p968}, then return null.
2. If the task is being queued in the context of an element, then return the element's [node document](#).
3. If the task is being queued in the context of a [browsing context](#)^{p840}, then return the browsing context's [active document](#)^{p840}.
4. If the task is being queued by or for a [script](#)^{p945}, then return the script's [settings object](#)^{p945}'s [responsible document](#)^{p937}.
5. Assert: this step is never reached, because one of the previous conditions must be true. Really?

Both [implied event loop](#)^{p971} and [implied document](#)^{p971} are vaguely-defined and have a lot of action-at-a-distance. The hope is to remove these, especially [implied document](#)^{p971}. See [issue #4980](#).

8.1.6.3 Processing model §^{p97}₁

An [event loop](#)^{p968} must continually run through the following steps for as long as it exists:

1. Let *taskQueue* be one of the [event loop](#)^{p968}'s [task queues](#)^{p969}, chosen in an [implementation-defined](#) manner, with the constraint that the chosen task queue must contain at least one [runnable](#)^{p969} [task](#)^{p969}. If there is no such task queue, then jump to the *microtasks* step below.

Note

Remember that the [microtask queue](#)^{p970} is not a [task queue](#)^{p969}, so it will not be chosen in this step. However, a [task queue](#)^{p969} to which the [microtask task source](#)^{p971} is associated might be chosen in this step. In that case, the [task](#)^{p969} chosen in the next step was originally a [microtask](#)^{p970}, but it got moved as part of [spinning the event loop](#)^{p975}.

2. Let *oldestTask* be the first [runnable](#)^{p969} [task](#)^{p969} in *taskQueue*, and [remove](#) it from *taskQueue*.
3. Set the [event loop](#)^{p968}'s [currently running task](#)^{p970} to *oldestTask*.
4. Let *taskStartTime* be the [current high resolution time](#).
5. Perform *oldestTask*'s [steps](#)^{p969}.
6. Set the [event loop](#)^{p968}'s [currently running task](#)^{p970} back to null.
7. *Microtasks*: [Perform a microtask checkpoint](#)^{p974}.
8. Let *hasARenderingOpportunity* be false.

9. Let *now* be the [current high resolution time](#). [HRT]^{p1308}
10. Report the [task](#)^{p969}'s duration by performing the following steps:
 1. Let *top-level browsing contexts* be an empty [set](#).
 2. For each [environment settings object](#)^{p937} *settings* of *oldestTask*'s [script evaluation environment settings object set](#)^{p969}, [append](#) *setting*'s [top-level browsing context](#)^{p844} to *top-level browsing contexts*.
 3. [Report long tasks](#), passing in *taskStartTime*, *now* (the end time of the task), *top-level browsing contexts*, and *oldestTask*.
11. **Update the rendering:** if this is a [window event loop](#)^{p968}, then:
 1. Let *docs* be all [Document](#)^{p117} objects whose [relevant agent](#)^{p934}'s [event loop](#)^{p968} is this event loop, sorted arbitrarily except that the following conditions must be met:
 - Any [Document](#)^{p117} *B* whose [browsing context](#)^{p840}'s [container document](#)^{p843} is *A* must be listed after *A* in the list.
 - If there are two documents *A* and *B* whose [browsing contexts](#)^{p840} are both [child browsing contexts](#)^{p843} whose [container documents](#)^{p843} are another [Document](#)^{p117} *C*, then the order of *A* and *B* in the list must match the [shadow-including tree order](#) of their respective [browsing context containers](#)^{p843} in *C*'s [node tree](#).

In the steps below that iterate over *docs*, each [Document](#)^{p117} must be processed in the order it is found in the list.

2. *Rendering opportunities:* Remove from *docs* all [Document](#)^{p117} objects whose [browsing context](#)^{p840} do not have a [rendering opportunity](#)^{p972}.

A [browsing context](#)^{p840} has a **rendering opportunity** if the user agent is currently able to present the contents of the [browsing context](#)^{p840} to the user, accounting for hardware refresh rate constraints and user agent throttling for performance reasons, but considering content presentable even if it's outside the viewport.

A [browsing context](#)^{p840} has no [rendering opportunities](#)^{p972} if its [active document](#)^{p840} is [render-blocked](#)^{p121}; otherwise, [rendering opportunities](#)^{p972} are determined based on hardware constraints such as display refresh rates and other factors such as page performance or whether the document's [visibility state](#)^{p793} is "visible". Rendering opportunities typically occur at regular intervals.

Note

This specification does not mandate any particular model for selecting rendering opportunities. But for example, if the browser is attempting to achieve a 60Hz refresh rate, then rendering opportunities occur at a maximum of every 60th of a second (about 16.7ms). If the browser finds that a [browsing context](#)^{p840} is not able to sustain this rate, it might drop to a more sustainable 30 rendering opportunities per second for that [browsing context](#)^{p840}, rather than occasionally dropping frames. Similarly, if a [browsing context](#)^{p840} is not visible, the user agent might decide to drop that page to a much slower 4 rendering opportunities per second, or even less.

3. If *docs* is not empty, then set *hasARenderingOpportunity* to true and set this [event loop](#)^{p968}'s [last render opportunity time](#)^{p970} to *taskStartTime*.
4. *Unnecessary rendering:* Remove from *docs* all [Document](#)^{p117} objects which meet both of the following conditions:
 - The user agent believes that updating the rendering of the [Document](#)^{p117}'s [browsing context](#)^{p840} would have no visible effect, and
 - The [Document](#)^{p117}'s [map of animation frame callbacks](#)^{p1022} is empty.
5. Remove from *docs* all [Document](#)^{p117} objects for which the user agent believes that it's preferable to skip updating the rendering for other reasons.

Note

The step labeled Rendering opportunities prevents the user agent from updating the rendering when it is unable to present new content to the user (there's no [rendering opportunity](#)^{p972}).

The step labeled Unnecessary rendering prevents the user agent from updating the rendering when there's no new content to draw.

This step enables the user agent to prevent the steps below from running for other reasons, for example, to ensure certain [tasks](#)^{p969} are executed immediately after each other, with only [microtask checkpoints](#)^{p974} interleaved (and without, e.g., [animation frame callbacks](#)^{p1022} interleaved). Concretely, a user agent might wish to coalesce timer callbacks together, with no intermediate rendering updates.

6. For each [fully active](#)^{p844} [Document](#)^{p117} in *docs*, [flush autofocus candidates](#)^{p811} for that [Document](#)^{p117} if its [browsing context](#)^{p840} is a [top-level browsing context](#)^{p844}.
 7. For each [fully active](#)^{p844} [Document](#)^{p117} in *docs*, [run the resize steps](#) for that [Document](#)^{p117}, passing in *now* as the timestamp. [\[CSSOMVIEW\]](#)^{p1307}
 8. For each [fully active](#)^{p844} [Document](#)^{p117} in *docs*, [run the scroll steps](#) for that [Document](#)^{p117}, passing in *now* as the timestamp. [\[CSSOMVIEW\]](#)^{p1307}
 9. For each [fully active](#)^{p844} [Document](#)^{p117} in *docs*, [evaluate media queries and report changes](#) for that [Document](#)^{p117}, passing in *now* as the timestamp. [\[CSSOMVIEW\]](#)^{p1307}
 10. For each [fully active](#)^{p844} [Document](#)^{p117} in *docs*, [update animations and send events](#) for that [Document](#)^{p117}, passing in *now* as the timestamp. [\[WEBANIMATIONS\]](#)^{p1312}
 11. For each [fully active](#)^{p844} [Document](#)^{p117} in *docs*, [run the fullscreen steps](#) for that [Document](#)^{p117}, passing in *now* as the timestamp. [\[FULLSCREEN\]](#)^{p1308}
 12. For each [fully active](#)^{p844} [Document](#)^{p117} in *docs*, if the user agent detects that the backing storage associated with a [CanvasRenderingContext2D](#)^{p650} or an [OffscreenCanvasRenderingContext2D](#)^{p716}, *context*, has been lost, then it must run the **context lost steps** for each such *context*:
 1. Let *canvas* be the value of *context*'s [canvas](#)^{p657} attribute, if *context* is a [CanvasRenderingContext2D](#)^{p650}, or the [associated OffscreenCanvas object](#)^{p716} for *context* otherwise.
 2. Set *context*'s [context lost](#)^{p659} to true.
 3. [Reset the rendering context to its default state](#)^{p659} given *context*.
 4. Let *shouldRestore* be the result of [firing an event](#) named [contextlost](#)^{p1301} at *canvas*, with the [cancelable](#) attribute initialized to true.
 5. If *shouldRestore* is false, then abort these steps.
 6. Attempt to restore *context* by creating a backing storage using *context*'s attributes and associating them with *context*. If this fails, then abort these steps.
 7. Set *context*'s [context lost](#)^{p659} to false.
 8. [Fire an event](#) named [contextrestored](#)^{p1301} at *canvas*.
 13. For each [fully active](#)^{p844} [Document](#)^{p117} in *docs*, [run the animation frame callbacks](#)^{p1022} for that [Document](#)^{p117}, passing in *now* as the timestamp.
 14. For each [fully active](#)^{p844} [Document](#)^{p117} in *docs*, [run the update intersection observations steps](#) for that [Document](#)^{p117}, passing in *now* as the timestamp. [\[INTERSECTIONOBSERVER\]](#)^{p1308}
 15. Invoke the [mark paint timing](#) algorithm for each [Document](#)^{p117} object in *docs*.
 16. For each [fully active](#)^{p844} [Document](#)^{p117} in *docs*, update the rendering or user interface of that [Document](#)^{p117} and its [browsing context](#)^{p840} to reflect the current state.
12. If all of the following are true
- this is a [window event loop](#)^{p968}
 - there is no [task](#)^{p969} in this [event loop](#)^{p968}'s [task queues](#)^{p969} whose [document](#)^{p969} is [fully active](#)^{p844}
 - this [event loop](#)^{p968}'s [microtask queue](#)^{p970} is [empty](#)
 - *hasARenderingOpportunity* is false

then:

1. Let *computeDeadline* be the following steps:

1. Let *deadline* be this [event loop](#)^{p968}'s [last idle period start time](#)^{p970} plus 50.

Note

The cap of 50ms in the future is to ensure responsiveness to new user input within the threshold of human perception.

2. Let *hasPendingRenders* be false.
 3. For each *windowInSameLoop* of the [same-loop windows](#)^{p970} for this [event loop](#)^{p968}:
 1. If *windowInSameLoop*'s [map of animation frame callbacks](#)^{p1022} is not [empty](#), or if the user agent believes that the *windowInSameLoop* might have pending rendering updates, set *hasPendingRenders* to true.
 2. Let *timerCallbackEstimates* be the result of [getting the values](#) of *windowInSameLoop*'s [map of active timers](#)^{p999}.
 3. For each *timeoutDeadline* of *timerCallbackEstimates*, if *timeoutDeadline* is less than *deadline*, set *deadline* to *timeoutDeadline*.
 4. If *hasPendingRenders* is true, then:
 1. Let *nextRenderDeadline* be this [event loop](#)^{p968}'s [last render opportunity time](#)^{p970} plus (1000 divided by the current refresh rate).

The refresh rate can be hardware- or implementation-specific. For a refresh rate of 60Hz, the *nextRenderDeadline* would be about 16.67ms after the [last render opportunity time](#)^{p970}.
 2. If *nextRenderDeadline* is less than *deadline*, then return *nextRenderDeadline*.
 5. Return *deadline*.
2. For each *win* of the [same-loop windows](#)^{p970} for this [event loop](#)^{p968}, perform the [start an idle period algorithm](#) for *win* with *computeDeadline*. [\[REQUESTIDLECALLBACK\]](#)^{p1310}
13. If this is a [worker event loop](#)^{p968}, then:
 1. If this [event loop](#)^{p968}'s [agent](#)'s single [realm](#)'s [global object](#)^{p938} is a [supported](#)^{p1022} [DedicatedWorkerGlobalScope](#)^{p1064} and the user agent believes that it would benefit from having its rendering updated at this time, then:
 1. Let *now* be the [current high resolution time](#). [\[HRT\]](#)^{p1308}
 2. [Run the animation frame callbacks](#)^{p1022} for that [DedicatedWorkerGlobalScope](#)^{p1064}, passing in *now* as the timestamp.
 3. Update the rendering of that dedicated worker to reflect the current state.

Note

Similar to the notes for [updating the rendering](#)^{p972} in a [window event loop](#)^{p968}, a user agent can determine the rate of rendering in the dedicated worker.

2. If there are no [tasks](#)^{p969} in the [event loop](#)^{p968}'s [task queues](#)^{p969} and the [WorkerGlobalScope](#)^{p1062} object's [closing](#)^{p1065} flag is true, then destroy the [event loop](#)^{p968}, aborting these steps, resuming the [run a worker](#)^{p1066} steps described in the [Web workers](#)^{p1046} section below.

When a user agent is to **perform a microtask checkpoint**:

1. If the [event loop](#)^{p968}'s [performing a microtask checkpoint](#)^{p970} is true, then return.
2. Set the [event loop](#)^{p968}'s [performing a microtask checkpoint](#)^{p970} to true.
3. While the [event loop](#)^{p968}'s [microtask queue](#)^{p970} is not [empty](#):
 1. Let *oldestMicrotask* be the result of [dequeuing](#) from the [event loop](#)^{p968}'s [microtask queue](#)^{p970}.
 2. Set the [event loop](#)^{p968}'s [currently running task](#)^{p970} to *oldestMicrotask*.

3. Run *oldestMicrotask*.

Note

This might involve invoking scripted callbacks, which eventually calls the [clean up after running script](#)^{p958} steps, which call this [perform a microtask checkpoint](#)^{p974} algorithm again, which is why we use the [performing a microtask checkpoint](#)^{p970} flag to avoid reentrancy.

4. Set the [event loop](#)^{p968}'s [currently running task](#)^{p970} back to null.
4. For each [environment settings object](#)^{p937} whose [responsible event loop](#)^{p938} is this [event loop](#)^{p968}, [notify about rejected promises](#)^{p960} on that [environment settings object](#)^{p937}.
5. [Cleanup Indexed Database transactions](#).
6. Perform [ClearKeptObjects\(\)](#).

Note

When [WeakRef.prototype.deref\(\)](#) returns an object, that object is kept alive until the next invocation of [ClearKeptObjects\(\)](#), after which it is again subject to garbage collection.

7. Set the [event loop](#)^{p968}'s [performing a microtask checkpoint](#)^{p970} to false.

When an algorithm running [in parallel](#)^{p42} is to **await a stable state**, the user agent must [queue a microtask](#)^{p970} that runs the following steps, and must then stop executing (execution of the algorithm resumes when the microtask is run, as described in the following steps):

1. Run the algorithm's **synchronous section**.
2. Resumes execution of the algorithm [in parallel](#)^{p42}, if appropriate, as described in the algorithm's steps.

Note

Steps in [synchronous sections](#)^{p975} are marked with .

Algorithm steps that say to **spin the event loop** until a condition *goal* is met are equivalent to substituting in the following algorithm steps:

1. Let *task* be the [event loop](#)^{p968}'s [currently running task](#)^{p970}.

Note

**task* could be a [microtask](#)^{p970}.*

2. Let *task source* be *task*'s [source](#)^{p969}.
3. Let *old stack* be a copy of the [JavaScript execution context stack](#).
4. Empty the [JavaScript execution context stack](#).
5. [Perform a microtask checkpoint](#)^{p974}.

Note

*If *task* is a [microtask](#)^{p970} this step will be a no-op due to [performing a microtask checkpoint](#)^{p970} being true.*

6. [In parallel](#)^{p42}:
 1. Wait until the condition *goal* is met.
 2. [Queue a task](#)^{p970} on *task source* to:
 1. Replace the [JavaScript execution context stack](#) with *old stack*.
 2. Perform any steps that appear after this [spin the event loop](#)^{p975} instance in the original algorithm.

Note

This resumes task.

7. Stop task, allowing whatever algorithm that invoked it to resume.

Note

This causes the [event loop^{p968}](#)'s main set of steps or the [perform a microtask checkpoint^{p974}](#) algorithm to continue.

Note

Unlike other algorithms in this and other specifications, which behave similar to programming-language function calls, [spin the event loop^{p975}](#) is more like a macro, which saves typing and indentation at the usage site by expanding into a series of steps and operations.

Example

An algorithm whose steps are:

1. Do something.
2. [Spin the event loop^{p975}](#) until awesomeness happens.
3. Do something else.

is a shorthand which, after "macro expansion", becomes

1. Do something.
2. Let *old stack* be a copy of the [JavaScript execution context stack](#).
3. Empty the [JavaScript execution context stack](#).
4. [Perform a microtask checkpoint^{p974}](#).
5. [In parallel^{p42}](#):
 1. Wait until awesomeness happens.
 2. [Queue a task^{p970}](#) on the task source in which "do something" was done to:
 1. Replace the [JavaScript execution context stack](#) with *old stack*.
 2. Do something else.

Example

Here is a more full example of the substitution, where the event loop is spun from inside a task that is queued from work in parallel. The version using [spin the event loop^{p975}](#):

1. [In parallel^{p42}](#):
 1. Do parallel thing 1.
 2. [Queue a task^{p970}](#) on the [DOM manipulation task source^{p977}](#) to:
 1. Do task thing 1.
 2. [Spin the event loop^{p975}](#) until awesomeness happens.
 3. Do task thing 2.
 3. Do parallel thing 2.

The fully expanded version:

1. [In parallel^{p42}](#):
 1. Do parallel thing 1.

2. Let *old stack* be null.
3. [Queue a task](#)^{p970} on the [DOM manipulation task source](#)^{p977} to:
 1. Do task thing 1.
 2. Set *old stack* to a copy of the [JavaScript execution context stack](#).
 3. Empty the [JavaScript execution context stack](#).
 4. [Perform a microtask checkpoint](#)^{p974}.
4. Wait until awesomeness happens.
5. [Queue a task](#)^{p970} on the [DOM manipulation task source](#)^{p977} to:
 1. Replace the [JavaScript execution context stack](#) with *old stack*.
 2. Do task thing 2.
6. Do parallel thing 2.

Some of the algorithms in this specification, for historical reasons, require the user agent to **pause** while running a [task](#)^{p969} until a condition *goal* is met. This means running the following steps:

1. If necessary, update the rendering or user interface of any [Document](#)^{p117} or [browsing context](#)^{p840} to reflect the current state.
2. Wait until the condition *goal* is met. While a user agent has a paused [task](#)^{p969}, the corresponding [event loop](#)^{p968} must not run further [tasks](#)^{p969}, and any script in the currently running [task](#)^{p969} must block. User agents should remain responsive to user input while paused, however, albeit in a reduced capacity since the [event loop](#)^{p968} will not be doing anything.

⚠Warning!

[Pausing](#)^{p977} is highly detrimental to the user experience, especially in scenarios where a single [event loop](#)^{p968} is shared among multiple documents. User agents are encouraged to experiment with alternatives to [pausing](#)^{p977}, such as [spinning the event loop](#)^{p975} or even simply proceeding without any kind of suspended execution at all, insofar as it is possible to do so while preserving compatibility with existing content. This specification will happily change if a less-drastic alternative is discovered to be web-compatible.

In the interim, implementers should be aware that the variety of alternatives that user agents might experiment with can change subtle aspects of [event loop](#)^{p968} behavior, including [task](#)^{p969} and [microtask](#)^{p970} timing. Implementations should continue experimenting even if doing so causes them to violate the exact semantics implied by the [pause](#)^{p977} operation.

8.1.6.4 Generic task sources §^{p97} 7

The following [task sources](#)^{p969} are used by a number of mostly unrelated features in this and other specifications.

The DOM manipulation task source

This [task source](#)^{p969} is used for features that react to DOM manipulations, such as things that happen in a non-blocking fashion when an element is [inserted into the document](#)^{p44}.

The user interaction task source

This [task source](#)^{p969} is used for features that react to user interaction, for example keyboard or mouse input.

Events sent in response to user input (e.g. [click](#) events) must be fired using [tasks](#)^{p969} [queued](#)^{p970} with the [user interaction task source](#)^{p977}. [\[UIEVENTS\]](#)^{p1312}

The networking task source

This [task source](#)^{p969} is used for features that trigger in response to network activity.

The history traversal task source

This [task source](#)^{p969} is used to queue calls to [history.back\(\)](#)^{p892} and similar APIs.

8.1.6.5 Dealing with the event loop from other specifications ^{§_ap97}

Writing specifications that correctly interact with the [event loop](#)^{p968} can be tricky. This is compounded by how this specification uses concurrency-model-independent terminology, so we say things like "[event loop](#)^{p968}" and "[in parallel](#)^{p42}" instead of using more familiar model-specific terms like "main thread" or "on a background thread".

By default, specification text generally runs on the [event loop](#)^{p968}. This falls out from the formal [event loop processing model](#)^{p971}, in that you can eventually trace most algorithms back to a [task](#)^{p969} [queued](#)^{p970} there.

Example

The algorithm steps for any JavaScript method will be invoked by author code calling that method. And author code can only be run via queued tasks, usually originating somewhere in the [script processing model](#)^{p630}.

From this starting point, the overriding guideline is that any work a specification needs to perform that would otherwise block the [event loop](#)^{p968} must instead be performed [in parallel](#)^{p42} with it. This includes (but is not limited to):

- performing heavy computation;
- displaying a user-facing prompt;
- performing operations which could require involving outside systems (i.e. "going out of process").

The next complication is that, in algorithm sections that are [in parallel](#)^{p42}, you must not create or manipulate objects associated to a specific [JavaScript realm](#), [global](#)^{p938}, or [environment settings object](#)^{p937}. (Stated in more familiar terms, you must not directly access main-thread artifacts from a background thread.) Doing so would create data races observable to JavaScript code, since after all, your algorithm steps are running [in parallel](#)^{p42} to the JavaScript code.

You can, however, manipulate specification-level data structures and values from *Infra*, as those are realm-agnostic. They are never directly exposed to JavaScript without a specific conversion taking place (often [via Web IDL](#)). [[INFRA](#)]^{p1308} [[WEBIDL](#)]^{p1313}

To affect the world of observable JavaScript objects, then, you must [queue a global task](#)^{p970} to perform any such manipulations. This ensures your steps are properly interleaved with respect to other things happening on the [event loop](#)^{p968}. Furthermore, you must choose a [task source](#)^{p969} when [queuing a global task](#)^{p970}; this governs the relative order of your steps versus others. If you are unsure which [task source](#)^{p969} to use, pick one of the [generic task sources](#)^{p977} that sounds most applicable. Finally, you must indicate which [global object](#)^{p938} your queued task is associated with; this ensures that if that global object is inactive, the task does not run.

Note

The base primitive, on which [queue a global task](#)^{p970} builds, is the [queue a task](#)^{p970} algorithm. In general, [queue a global task](#)^{p970} is better because it automatically picks the right [event loop](#)^{p968} and, where appropriate, [document](#)^{p969}. Older specifications often use [queue a task](#)^{p970} combined with the [implied event loop](#)^{p971} and [implied document](#)^{p971} concepts, but this is discouraged.

Putting this all together, we can provide a template for a typical algorithm that needs to do work asynchronously:

1. Do any synchronous setup work, while still on the [event loop](#)^{p968}. This may include converting [realm](#)-specific JavaScript values into realm-agnostic specification-level values.
2. Perform a set of potentially-expensive steps [in parallel](#)^{p42}, operating entirely on realm-agnostic values, and producing a realm-agnostic result.
3. [Queue a global task](#)^{p970}, on a specified [task source](#)^{p969} and given an appropriate [global object](#)^{p938}, to convert the realm-agnostic result back into observable effects on the observable world of JavaScript objects on the [event loop](#)^{p968}.

Example

The following is an algorithm that "encrypts" a passed-in [list of scalar value strings](#) *input*, after parsing them as URLs:

1. Let *urls* be an empty [list](#).

2. [For each](#) *string* of *input*:
 1. Let *parsed* be the result of [parsing](#)^{p91} *string* relative to the [current settings object](#)^{p944}.
 2. If *parsed* is failure, return a promise rejected with a `"SyntaxError"` `DOMException`.
 3. Let *serialized* be the result of applying the [URL serializer](#) to *parsed*.
 4. [Append](#) *serialized* to *urls*.
3. Let *realm* be the [current Realm Record](#).
4. Let *p* be a new promise.
5. Run the following steps [in parallel](#)^{p42}:
 1. Let *encryptedURLs* be an empty [list](#).
 2. [For each](#) *url* of *urls*:
 1. Wait 100 milliseconds, so that people think we're doing heavy-duty encryption.
 2. Let *encrypted* be a new [string](#) derived from *url*, whose *n*th [code unit](#) is equal to *url*'s *n*th [code unit](#) plus 13.
 3. [Append](#) *encrypted* to *encryptedURLs*.
 3. [Queue a global task](#)^{p970} on the [networking task source](#)^{p977}, given *realm*'s [global object](#)^{p938}, to perform the following steps:
 1. Let *array* be the result of [converting](#) *encryptedURLs* to a JavaScript array, in *realm*.
 2. Resolve *p* with *array*.
6. Return *p*.

Here are several things to notice about this algorithm:

- It does its URL parsing up front, on the [event loop](#)^{p968}, before going to the [in parallel](#)^{p42} steps. This is necessary, since parsing depends on the [current settings object](#)^{p944}, which would no longer be current after going [in parallel](#)^{p42}.
- Alternately, it could have saved a reference to the [current settings object](#)^{p944}'s [API base URL](#)^{p937} and used it during the [in parallel](#)^{p42} steps; that would have been equivalent. However, we recommend instead doing as much work as possible up front, as this example does. Attempting to save the correct values can be error prone; for example, if we'd saved just the [current settings object](#)^{p944}, instead of its [API base URL](#)^{p937}, there would have been a potential race.
- It implicitly passes a [list](#) of [strings](#) from the initial steps to the [in parallel](#)^{p42} steps. This is OK, as both [lists](#) and [strings](#) are [realm](#)-agnostic.
- It performs "expensive computation" (waiting for 100 milliseconds per input URL) during the [in parallel](#)^{p42} steps, thus not blocking the main [event loop](#)^{p968}.
- Promises, as observable JavaScript objects, are never created and manipulated during the [in parallel](#)^{p42} steps. *p* is created before entering those steps, and then is manipulated during a [task](#)^{p969} that is [queued](#)^{p970} specifically for that purpose.
- The creation of a JavaScript array object also happens during the queued task, and is careful to specify which realm it creates the array in since that is no longer obvious from context.

(On these last two points, see also [whatwg/webidl issue #135](#) and [whatwg/webidl issue #371](#), where we are still mulling over the subtleties of the above promise-resolution pattern.)

Another thing to note is that, in the event this algorithm was called from a Web IDL-specified operation taking a `sequence<USVString>`, there was an automatic conversion from [realm](#)-specific JavaScript objects provided by the author as input, into the [realm](#)-agnostic `sequence<USVString>` Web IDL type, which we then treat as a [list](#) of [scalar value strings](#). So depending on how your specification is structured, there may be other implicit steps happening on the main [event loop](#)^{p968} that play a part in this whole process of getting you ready to go [in parallel](#)^{p42}.

8.1.7 Events §^{p98}₀

8.1.7.1 Event handlers §^{p98}₀

Many objects can have **event handlers** specified. These act as non-capture [event listeners](#) for the object on which they are specified. [\[DOM\]](#)^{p1307}

An [event handler](#)^{p980} is a [struct](#) with two [items](#):

- a **value**, which is either null, a callback object, or an [internal raw uncompiled handler](#)^{p985}. The [EventHandler](#)^{p984} callback function type describes how this is exposed to scripts. Initially, an [event handler](#)^{p980}'s [value](#)^{p980} must be set to null.
- a **listener**, which is either null or an [event listener](#) responsible for running [the event handler processing algorithm](#)^{p983}. Initially, an [event handler](#)^{p980}'s [listener](#)^{p980} must be set to null.

Event handlers are exposed in two ways.

The first way, common to all event handlers, is as an [event handler IDL attribute](#)^{p981}.

The second way is as an [event handler content attribute](#)^{p981}. Event handlers on [HTML elements](#)^{p44} and some of the event handlers on [Window](#)^{p855} objects are exposed in this way.

For both of these two ways, the [event handler](#)^{p980} is exposed through a **name**, which is a string that always starts with "on" and is followed by the name of the event for which the handler is intended.

Most of the time, the object that exposes an [event handler](#)^{p980} is the same as the object on which the corresponding [event listener](#) is added. However, the [body](#)^{p184} and [frameset](#)^{p1264} elements expose several [event handlers](#)^{p980} that act upon the element's [Window](#)^{p855} object, if one exists. In either case, we call the object an [event handler](#)^{p980} acts upon the **target** of that [event handler](#)^{p980}.

To **determine the target of an event handler**, given an [EventTarget](#) object *eventTarget* on which the [event handler](#)^{p980} is exposed, and an [event handler name](#)^{p980} *name*, the following steps are taken:

1. If *eventTarget* is not a [body](#)^{p184} element or a [frameset](#)^{p1264} element, then return *eventTarget*.
2. If *name* is not the name of an attribute member of the [WindowEventHandlers](#)^{p990} interface mixin and the [Window-reflecting body element event handler set](#)^{p988} does not [contain](#) *name*, then return *eventTarget*.
3. If *eventTarget*'s [node document](#) is not an [active document](#)^{p840}, then return null.

Note

This could happen if this object is a [body](#)^{p184} element without a corresponding [Window](#)^{p855} object, for example.

Note

This check does not necessarily prevent [body](#)^{p184} and [frameset](#)^{p1264} elements that are not [the body element](#)^{p123} of their [node document](#) from reaching the next step. In particular, a [body](#)^{p184} element created in an [active document](#)^{p840} (perhaps with [document.createElement\(\)](#)) but not [connected](#) will also have its corresponding [Window](#)^{p855} object as the [target](#)^{p980} of several [event handlers](#)^{p980} exposed through it.

4. Return *eventTarget*'s [node document](#)'s [relevant global object](#)^{p944}.

Each [EventTarget](#) object that has one or more [event handlers](#)^{p980} specified has an associated **event handler map**, which is a [map](#) of strings representing [names](#)^{p980} of [event handlers](#)^{p980} to [event handlers](#)^{p980}.

When an [EventTarget](#) object that has one or more [event handlers](#)^{p980} specified is created, its [event handler map](#)^{p980} must be initialized such that it contains an [entry](#) for each [event handler](#)^{p980} that has that object as [target](#)^{p980}, with [items](#) in those [event handlers](#)^{p980} set to their initial values.

Note

The order of the [entries](#) of [event handler map](#)^{p980} could be arbitrary. It is not observable through any algorithms that operate on the map.

Note

Entries are not created in the [event handler map](#)^{p980} of an object for [event handlers](#)^{p980} that are merely exposed on that object, but have some other object as their [targets](#)^{p980}.

An **event handler IDL attribute** is an IDL attribute for a specific [event handler](#)^{p980}. The name of the IDL attribute is the same as the [name](#)^{p980} of the [event handler](#)^{p980}.

The getter of an [event handler IDL attribute](#)^{p981} with name *name*, when called, must run these steps:

1. Let *eventTarget* be the result of [determining the target of an event handler](#)^{p980} given this object and *name*.
2. If *eventTarget* is null, then return null.
3. Return the result of [getting the current value of the event handler](#)^{p985} given *eventTarget* and *name*.

The setter of an [event handler IDL attribute](#)^{p981} with name *name*, when called, must run these steps:

1. Let *eventTarget* be the result of [determining the target of an event handler](#)^{p980} given this object and *name*.
2. If *eventTarget* is null, then return.
3. If the given value is null, then [deactivate an event handler](#)^{p982} given *eventTarget* and *name*.
4. Otherwise:
 1. Let *handlerMap* be *eventTarget*'s [event handler map](#)^{p980}.
 2. Let *eventHandler* be *handlerMap*[*name*].
 3. Set *eventHandler*'s [value](#)^{p980} to the given value.
 4. [Activate an event handler](#)^{p982} given *eventTarget* and *name*.

Note

Certain [event handler IDL attributes](#)^{p981} have additional requirements, in particular the [onmessage](#)^{p1642} attribute of [MessagePort](#)^{p1646} objects.

An **event handler content attribute** is a content attribute for a specific [event handler](#)^{p980}. The name of the content attribute is the same as the [name](#)^{p980} of the [event handler](#)^{p980}.

[Event handler content attributes](#)^{p981}, when specified, must contain valid JavaScript code which, when parsed, would match the [FunctionBody](#) production after [automatic semicolon insertion](#).

The following [attribute change steps](#) are used to synchronize between [event handler content attributes](#)^{p981} and [event handlers](#)^{p980}: [\[DOM\]](#)^{p1307}

1. If *namespace* is not null, or *localName* is not the name of an [event handler content attribute](#)^{p981} on *element*, then return.
2. Let *eventTarget* be the result of [determining the target of an event handler](#)^{p980} given *element* and *localName*.
3. If *eventTarget* is null, then return.
4. If *value* is null, then [deactivate an event handler](#)^{p982} given *eventTarget* and *localName*.
5. Otherwise:
 1. If the [Should element's inline behavior be blocked by Content Security Policy?](#) algorithm returns "Blocked" when executed upon *element*, "script attribute", and *value*, then return. [\[CSP\]](#)^{p1305}
 2. Let *handlerMap* be *eventTarget*'s [event handler map](#)^{p980}.
 3. Let *eventHandler* be *handlerMap*[*localName*].
 4. Let *location* be the script location that triggered the execution of these steps.
 5. Set *eventHandler*'s [value](#)^{p980} to the [internal raw uncompiled handler](#)^{p985} *value/location*.

6. [Activate an event handler](#)^{p982} given `eventTarget` and `localName`.

Note

Per the DOM Standard, these steps are run even if `oldValue` and `value` are identical (setting an attribute to its current value), but not if `oldValue` and `value` are both null (removing an attribute that doesn't currently exist). [DOM]^{p1307}

To **deactivate an event handler** given an `EventTarget` object `eventTarget` and a string `name` that is the `name`^{p980} of an `event handler`^{p980}, run these steps:

1. Let `handlerMap` be `eventTarget`'s `event handler map`^{p980}.
2. Let `eventHandler` be `handlerMap[name]`.
3. Set `eventHandler`'s `value`^{p980} to null.
4. Let `listener` be `eventHandler`'s `listener`^{p980}.
5. If `listener` is not null, then [remove an event listener](#) with `eventTarget` and `listener`.
6. Set `eventHandler`'s `listener`^{p980} to null.

To **erase all event listeners and handlers** given an `EventTarget` object `eventTarget`, run these steps:

1. If `eventTarget` has an associated `event handler map`^{p980}, then for each `name` → `eventHandler` of `eventTarget`'s associated `event handler map`^{p980}, [deactivate an event handler](#)^{p982} given `eventTarget` and `name`.
2. [Remove all event listeners](#) given `eventTarget`.

Note

This algorithm is used to define `document.open()`^{p995}.

To **activate an event handler** given an `EventTarget` object `eventTarget` and a string `name` that is the `name`^{p980} of an `event handler`^{p980}, run these steps:

1. Let `handlerMap` be `eventTarget`'s `event handler map`^{p980}.
2. Let `eventHandler` be `handlerMap[name]`.
3. If `eventHandler`'s `listener`^{p980} is not null, then return.
4. Let `callback` be the result of creating a Web IDL `EventListener` instance representing a reference to a function of one argument that executes the steps of [the event handler processing algorithm](#)^{p983}, given `eventTarget`, `name`, and its argument.

The `EventListener`'s `callback context` can be arbitrary; it does not impact the steps of [the event handler processing algorithm](#)^{p983}. [DOM]^{p1307}

Note

The `callback` is emphatically not the `event handler`^{p980} itself. Every event handler ends up registering the same `callback`, the algorithm defined below, which takes care of invoking the right code, and processing the code's return value.

5. Let `listener` be a new `event listener` whose `type` is the **event handler event type** corresponding to `eventHandler` and `callback` is `callback`.

Note

To be clear, an `event listener` is different from an `EventListener`.

6. [Add an event listener](#) with `eventTarget` and `listener`.
7. Set `eventHandler`'s `listener`^{p980} to `listener`.

Note

The event listener registration happens only if the `event handler`^{p980}'s `value`^{p980} is being set to non-null, and the `event handler`^{p980} is

not already activated. Since listeners are called in the order they were registered, assuming no [deactivation](#)^{p982} occurred, the order of event listeners for a particular event type will always be:

1. the event listeners registered with `addEventListener()` before the first time the [event handler](#)^{p980}'s [value](#)^{p980} was set to non-null
2. then the callback to which it is currently set, if any
3. and finally the event listeners registered with `addEventListener()` after the first time the [event handler](#)^{p980}'s [value](#)^{p980} was set to non-null.

Example

This example demonstrates the order in which event listeners are invoked. If the button in this example is clicked by the user, the page will show four alerts, with the text "ONE", "TWO", "THREE", and "FOUR" respectively.

```
<button id="test">Start Demo</button>
<script>
  var button = document.getElementById('test');
  button.addEventListener('click', function () { alert('ONE') }, false);
  button.setAttribute('onclick', "alert('NOT CALLED')"); // event handler listener is registered
  here
  button.addEventListener('click', function () { alert('THREE') }, false);
  button.onclick = function () { alert('TWO') };
  button.addEventListener('click', function () { alert('FOUR') }, false);
</script>
```

However, in the following example, the event handler is [deactivated](#)^{p982} after its initial activation (and its event listener is removed), before being reactivated at a later time. The page will show five alerts with "ONE", "TWO", "THREE", "FOUR", and "FIVE" respectively, in order.

```
<button id="test">Start Demo</button>
<script>
  var button = document.getElementById('test');
  button.addEventListener('click', function () { alert('ONE') }, false);
  button.setAttribute('onclick', "alert('NOT CALLED')"); // event handler is activated here
  button.addEventListener('click', function () { alert('TWO') }, false);
  button.onclick = null; // but deactivated here
  button.addEventListener('click', function () { alert('THREE') }, false);
  button.onclick = function () { alert('FOUR') }; // and re-activated here
  button.addEventListener('click', function () { alert('FIVE') }, false);
</script>
```

Note

The interfaces implemented by the event object do not influence whether an [event handler](#)^{p980} is triggered or not.

The event handler processing algorithm for an [EventTarget](#) object `eventTarget`, a string `name` representing the [name](#)^{p980} of an [event handler](#)^{p980}, and an [Event](#) object `event` is as follows:

1. Let `callback` be the result of [getting the current value of the event handler](#)^{p985} given `eventTarget` and `name`.
2. If `callback` is null, then return.
3. Let `special error event handling` be true if `event` is an [ErrorEvent](#)^{p960} object, `event`'s `type` is [error](#)^{p1301}, and `event`'s `currentTarget` implements the [WindowOrWorkerGlobalScope](#)^{p991} mixin. Otherwise, let `special error event handling` be false.
4. Process the [Event](#) object `event` as follows:
 - ↳ **If `special error event handling` is true**
[Invoke](#) `callback` with five arguments, the first one having the value of `event`'s `message`^{p960} attribute, the second having the value of `event`'s `filename`^{p960} attribute, the third having the value of `event`'s `lineno`^{p960} attribute, the fourth

having the value of event's `colno`^{p960} attribute, the fifth having the value of event's `error`^{p960} attribute, and with the `callback this value` set to event's `currentTarget`. Let `return value` be the callback's return value. [WEBIDL]^{p1313}

↪ **Otherwise**

`Invoke` `callback` with one argument, the value of which is the `Event` object `event`, with the `callback this value` set to event's `currentTarget`. Let `return value` be the callback's return value. [WEBIDL]^{p1313}

If an exception gets thrown by the callback, end these steps and allow the exception to propagate. (It will propagate to the `DOM event dispatch logic`, which will then `report the exception`^{p959}.)

5. Process `return value` as follows:

↪ **If event is a `BeforeUnloadEvent`^{p930} object and event's `type` is `beforeunload`^{p1300}**

Note

In this case, the `event handler IDL attribute`^{p981}'s type will be `OnBeforeUnloadEventHandler`^{p985}, so `return value` will have been coerced into either `null` or a `DOMString`.

If `return value` is not null, then:

1. Set event's `canceled flag`.
2. If event's `returnValue`^{p930} attribute's value is the empty string, then set event's `returnValue`^{p930} attribute's value to `return value`.

↪ **If special error event handling is true**

If `return value` is true, then set event's `canceled flag`.

↪ **Otherwise**

If `return value` is false, then set event's `canceled flag`.

Note

If we've gotten to this "Otherwise" clause because event's `type` is `beforeunload`^{p1300} but event is not a `BeforeUnloadEvent`^{p930} object, then `return value` will never be false, since in such cases `return value` will have been coerced into either `null` or a `DOMString`.

The `EventHandler`^{p984} callback function type represents a callback used for event handlers. It is represented in Web IDL as follows:

```
IDL [LegacyTreatNonObjectAsNull]
callback EventHandlerNonNull = any (Event event);
typedef EventHandlerNonNull? EventHandler;
```

Note

In JavaScript, any `Function` object implements this interface.

Example

For example, the following document fragment:

```
<body onload="alert(this)" onclick="alert(this)">
```

...leads to an alert saying "[object Window]" when the document is loaded, and an alert saying "[object HTMLBodyElement]" whenever the user clicks something in the page.

Note

The `return value` of the function affects whether the event is canceled or not: as described above, if the `return value` is false, the event is canceled.

There are two exceptions in the platform, for historical reasons:

- The [onerror](#)^{p988} handlers on global objects, where returning true cancels the event.
- The [onbeforeunload](#)^{p988} handler, where returning any non-null and non-undefined value will cancel the event.

For historical reasons, the [onerror](#)^{p988} handler has different arguments:

```
IDL [LegacyTreatNonObjectAsNull]
callback OnErrorHandlerNonNull = any ((Event or DOMString) event, optional DOMString source,
optional unsigned long lineno, optional unsigned long colno, optional any error);
typedef OnErrorHandlerNonNull? OnErrorHandler;
```

Example

```
window.onerror = (message, source, lineno, colno, error) => { ... };
```

Similarly, the [onbeforeunload](#)^{p988} handler has a different return value:

```
IDL [LegacyTreatNonObjectAsNull]
callback OnBeforeUnloadEventHandlerNonNull = DOMString? (Event event);
typedef OnBeforeUnloadEventHandlerNonNull? OnBeforeUnloadEventHandler;
```

An **internal raw uncompiled handler** is a tuple with the following information:

- An uncompiled script body
- A location where the script body originated, in case an error needs to be reported

When the user agent is to **get the current value of the event handler** given an [EventTarget](#) object *eventTarget* and a string *name* that is the [name](#)^{p980} of an [event handler](#)^{p980}, it must run these steps:

1. Let *handlerMap* be *eventTarget*'s [event handler map](#)^{p980}.
2. Let *eventHandler* be *handlerMap*[*name*].
3. If *eventHandler*'s [value](#)^{p980} is an [internal raw uncompiled handler](#)^{p985}, then:
 1. If *eventTarget* is an element, then let *element* be *eventTarget*, and *document* be *element*'s [node document](#). Otherwise, *eventTarget* is a [Window](#)^{p855} object, let *element* be null, and *document* be *eventTarget*'s [associated Document](#)^{p856}.
 2. If [scripting is disabled](#)^{p944} for *document*, then return null.
 3. Let *body* be the uncompiled script body in *eventHandler*'s [value](#)^{p980}.
 4. Let *location* be the location where the script body originated, as given by *eventHandler*'s [value](#)^{p980}.
 5. If *element* is not null and *element* has a [form owner](#)^{p576}, let *form owner* be that [form owner](#)^{p576}. Otherwise, let *form owner* be null.
 6. Let *settings object* be the [relevant settings object](#)^{p944} of *document*.
 7. If *body* is not parsable as [FunctionBody](#) or if parsing detects an [early error](#), then follow these substeps:
 1. Set *eventHandler*'s [value](#)^{p980} to null.

Note

This does not [deactivate](#)^{p982} the event handler, which additionally [removes](#) the event handler's [listener](#)^{p980} (if present).

2. [Report the error](#)^{p959} for the appropriate [script](#)^{p945} and with the appropriate position (line number and

column number) given by *location*, using *settings object*'s [global object](#)^{p938}. If the error is still *not handled*^{p959} after this, then the error may be reported to a developer console.

3. Return null.

8. Push *settings object*'s [realm execution context](#)^{p937} onto the [JavaScript execution context stack](#); it is now the [running JavaScript execution context](#).

Note

This is necessary so the subsequent invocation of [OrdinaryFunctionCreate](#) takes place in the correct [JavaScript Realm](#).

9. Let *function* be the result of calling [OrdinaryFunctionCreate](#), with arguments:

functionPrototype

[%Function.prototype%](#)

sourceText

↪ If *name* is [onerror](#)^{p988} and *eventTarget* is a [Window](#)^{p855} object

The string formed by concatenating "function ", *name*, "(event, source, lineno, colno, error) {" , U+000A LF, *body*, U+000A LF, and " }".

↪ Otherwise

The string formed by concatenating "function ", *name*, "(event) {" , U+000A LF, *body*, U+000A LF, and " }".

ParameterList

↪ If *name* is [onerror](#)^{p988} and *eventTarget* is a [Window](#)^{p855} object

Let the function have five arguments, named event, source, lineno, colno, and error.

↪ Otherwise

Let the function have a single argument called event.

body

The result of parsing *body* above.

thisMode

non-lexical-this

scope

1. Let *realm* be *settings object*'s [Realm](#)^{p938}.
 2. Let *scope* be *realm*.[[GlobalEnv]].
 3. If *eventHandler* is an element's [event handler](#)^{p980}, then set *scope* to [NewObjectEnvironment](#)(*document*, true, *scope*).
(Otherwise, *eventHandler* is a [Window](#)^{p855} object's [event handler](#)^{p980}.)
 4. If *form owner* is not null, then set *scope* to [NewObjectEnvironment](#)(*form owner*, true, *scope*).
 5. If *element* is not null, then set *scope* to [NewObjectEnvironment](#)(*element*, true, *scope*).
 6. Return *scope*.
10. Remove *settings object*'s [realm execution context](#)^{p937} from the [JavaScript execution context stack](#).
11. Set *function*.[[ScriptOrModule]] to null.

Note

This is done because the default behavior, of associating the created function with the nearest [script](#)^{p945} on the stack, can lead to path-dependent results. For example, an event handler which is first invoked by user interaction would end up with null [[ScriptOrModule]] (since then this algorithm would be first invoked when the [active script](#)^{p946} is null), whereas one that is first invoked by dispatching an event from script would have its [[ScriptOrModule]] set to that script.

Instead, we just always set [[ScriptOrModule]] to null. This is more intuitive anyway; the idea that the first

script which dispatches an event is somehow responsible for the event handler code is dubious.

In practice, this only affects the resolution of relative URLs via `import()`, which consult the [base URL](#)^{p945} of the associated script. Nulling out `[[ScriptOrModule]]` means that [HostResolveImportedModule](#)^{p967} and [HostImportModuleDynamically](#)^{p967} will fall back to the [current settings object](#)^{p944}'s [API base URL](#)^{p937}.

12. Set `eventHandler`'s [value](#)^{p980} to the result of creating a Web IDL [EventHandler](#)^{p984} callback function object whose object reference is `function` and whose [callback context](#) is `settings object`.

4. Return `eventHandler`'s [value](#)^{p980}.

8.1.7.2 Event handlers on elements, [Document](#)^{p117} objects, and [Window](#)^{p855} objects §^{p98} 7

The following are the [event handlers](#)^{p980} (and their corresponding [event handler event types](#)^{p982}) that must be supported by all [HTML elements](#)^{p44}, as both [event handler content attributes](#)^{p981} and [event handler IDL attributes](#)^{p981}; and that must be supported by all [Document](#)^{p117} and [Window](#)^{p855} objects, as [event handler IDL attributes](#)^{p981}:

Event handler ^{p980}	Event handler event type ^{p982}	
onabort	abort	<input checked="" type="checkbox"/> MDN
onauxclick	auxclick	
oncancel	cancel ^{p1301}	<input type="checkbox"/> MDN

8.1.7.3 Event firing ^{§ p99}₁

Certain operations and methods are defined as firing events on elements. For example, the `click()`^{p796} method on the `HTMLElement`^{p128} interface is defined as firing a `click` event on the element. [UIEVENTS]^{p1312}

Firing a synthetic pointer event named *e* at *target*, with an optional *not trusted flag*, means running these steps:

1. Let *event* be the result of [creating an event](#) using `PointerEvent`.
2. Initialize *event*'s `type` attribute to *e*.
3. Initialize *event*'s `bubbles` and `cancelable` attributes to true.
4. Set *event*'s `composed flag`.
5. If the *not trusted flag* is set, initialize *event*'s `isTrusted` attribute to false.
6. Initialize *event*'s `ctrlKey`, `shiftKey`, `altKey`, and `metaKey` attributes according to the current state of the key input device, if any (false for any keys that are not available).
7. Initialize *event*'s `view` attribute to *target*'s `node document`'s `Window`^{p855} object, if any, and null otherwise.
8. *event*'s `getModifierState()` method is to return values appropriately describing the current state of the key input device.
9. Return the result of [dispatching](#) *event* at *target*.

Firing a `click` event at *target* means [firing a synthetic pointer event named `click`](#)^{p991} at *target*.

8.2 The `WindowOrWorkerGlobalScope`^{p991} **mixin** ^{§ p99}₁

The `WindowOrWorkerGlobalScope`^{p991} mixin is for use of APIs that are to be exposed on `Window`^{p855} and `WorkerGlobalScope`^{p1062} objects.

Note

Other standards are encouraged to further extend it using partial interface mixin `WindowOrWorkerGlobalScope`^{p991} { ... }; along with an appropriate reference.

```

IDL typedef (DOMString or Function) TimerHandler;

interface mixin WindowOrWorkerGlobalScope {
  [Replaceable] readonly attribute USVString origin;
};

```

```

readonly attribute boolean isSecureContext;
readonly attribute boolean crossOriginIsolated;

undefined reportError(any e);

// base64 utility methods
DOMString btoa(DOMString data);
ByteString atob(DOMString data);

// timers
long setTimeout(TimerHandler handler, optional long timeout = 0, any... arguments);
undefined clearTimeout(optional long id = 0);
long setInterval(TimerHandler handler, optional long timeout = 0, any... arguments);
undefined clearInterval(optional long id = 0);

// microtask queuing
undefined queueMicrotask(VoidFunction callback);

// ImageBitmap
Promise<ImageBitmap> createImageBitmap(ImageBitmapSource image, optional ImageBitmapOptions options = {});
Promise<ImageBitmap> createImageBitmap(ImageBitmapSource image, long sx, long sy, long sw, long sh, optional ImageBitmapOptions options = {});

// structured cloning
any structuredClone(any value, optional StructuredSerializeOptions options = {});
};
Window includes WindowOrWorkerGlobalScope;
WorkerGlobalScope includes WindowOrWorkerGlobalScope;

```

For web developers (non-normative)

`self.isSecureContext`^{p992}

Returns whether or not this global object represents a [secure context](#)^{p944}. [\[SECURE-CONTEXTS\]](#)^{p1311}

`self.origin`^{p992}

Returns the global object's [origin](#)^{p868}, serialized as string.

`self.crossOriginIsolated`^{p993}

Returns whether scripts running in this global are allowed to use APIs that require cross-origin isolation. This depends on the ``Cross-Origin-Opener-Policy`p877` and ``Cross-Origin-Embedder-Policy`p885` HTTP response headers and the `"cross-origin-isolated"`^{p68} feature.

Example

Developers are strongly encouraged to use `self.origin` over `location.origin`. The former returns the [origin](#)^{p868} of the environment, the latter of the URL of the environment. Imagine the following script executing in a document on `https://stargate.example/`:

```

var frame = document.createElement("iframe")
frame.onload = function() {
  var frameWin = frame.contentWindow
  console.log(frameWin.location.origin) // "null"
  console.log(frameWin.origin) // "https://stargate.example"
}
document.body.appendChild(frame)

```

`self.origin` is a more reliable security indicator.

The `isSecureContext` getter steps are to return true if [this's relevant settings object](#)^{p944} is a [secure context](#)^{p944}, or false otherwise.

The `origin` getter steps are to return [this's relevant settings object](#)^{p944}'s [origin](#)^{p937}, [serialized](#)^{p869}.

The `crossOriginIsolated` getter steps are to return [this's relevant settings object](#)^{p944}'s [cross-origin isolated capability](#)^{p937}.

8.3 Base64 utility methods §^{p99}₃

The [atob\(\)](#)^{p993} and [btoa\(\)](#)^{p993} methods allow developers to transform content to and from the base64 encoding.

Note

In these APIs, for mnemonic purposes, the "b" can be considered to stand for "binary", and the "a" for "ASCII". In practice, though, for primarily historical reasons, both the input and output of these functions are Unicode strings.

For web developers (non-normative)

result = self.btoa^{p993}(data)

Takes the input data, in the form of a Unicode string containing only characters in the range U+0000 to U+00FF, each representing a binary byte with values 0x00 to 0xFF respectively, and converts it to its base64 representation, which it returns.

Throws an ["InvalidCharacterError" DOMException](#) exception if the input string contains any out-of-range characters.

result = self.atob^{p993}(data)

Takes the input data, in the form of a Unicode string containing base64-encoded binary data, decodes it, and returns a string consisting of characters in the range U+0000 to U+00FF, each representing a binary byte with values 0x00 to 0xFF respectively, corresponding to that binary data.

Throws an ["InvalidCharacterError" DOMException](#) if the input string is not valid base64 data.

The [btoa\(data\)](#) method must throw an ["InvalidCharacterError" DOMException](#) if *data* contains any character whose code point is greater than U+00FF. Otherwise, the user agent must convert *data* to a byte sequence whose *n*th byte is the eight-bit representation of the *n*th code point of *data*, and then must apply [forgiving-base64 encode](#) to that byte sequence and return the result.

The [atob\(data\)](#) method steps are:

1. Let *decodedData* be the result of running [forgiving-base64 decode](#) on *data*.
2. If *decodedData* is failure, then throw an ["InvalidCharacterError" DOMException](#).
3. Return *decodedData*.

8.4 Dynamic markup insertion §^{p99}₃

Note

APIs for dynamically inserting markup into the document interact with the parser, and thus their behavior varies depending on whether they are used with [HTML documents](#) (and the [HTML parser](#)^{p1106}) or [XML documents](#) (and the [XML parser](#)^{p1217}).

[Document](#)^{p117} objects have a **throw-on-dynamic-markup-insertion counter**, which is used in conjunction with the [create an element for the token](#)^{p1154} algorithm to prevent [custom element constructors](#)^{p728} from being able to use [document.open\(\)](#)^{p995}, [document.close\(\)](#)^{p995}, and [document.write\(\)](#)^{p996} when they are invoked by the parser. Initially, the counter must be set to zero.

8.4.1 Opening the input stream §^{p99}₃

For web developers (non-normative)

document = document.open^{p995}()

Causes the [Document](#)^{p117} to be replaced in-place, as if it was a new [Document](#)^{p117} object, but reusing the previous object, which is then returned.

The resulting [Document](#)^{p117} has an HTML parser associated with it, which can be given data to parse using

`document.write()`^{p996}.

The method has no effect if the `Document`^{p117} is still being parsed.

Throws an `"InvalidStateError"` `DOMException` if the `Document`^{p117} is an `XML document`.

Throws an `"InvalidStateError"` `DOMException` if the parser is currently executing a `custom element constructor`^{p728}.

`window = document.open`^{p995}(`url`, `name`, `features`)

Works like the `window.open()`^{p858} method.

`Document`^{p117} objects have an `active parser was aborted` boolean, which is used to prevent scripts from invoking the `document.open()`^{p995} and `document.write()`^{p996} methods (directly or indirectly) after the document's `active parser`^{p121} has been aborted. It is initially false.

The **document open steps**, given a `document`, are as follows:

1. If `document` is an `XML document`, then throw an `"InvalidStateError"` `DOMException` exception.
2. If `document`'s `throw-on-dynamic-markup-insertion counter`^{p993} is greater than 0, then throw an `"InvalidStateError"` `DOMException`.
3. Let `entryDocument` be the `entry global object`^{p941}'s `associated Document`^{p856}.
4. If `document`'s `origin` is not `same origin`^{p869} to `entryDocument`'s `origin`, then throw a `"SecurityError"` `DOMException`.
5. If `document` has an `active parser`^{p121} whose `script nesting level`^{p1108} is greater than 0, then return `document`.

Note

This basically causes `document.open()`^{p995} to be ignored when it's called in an inline script found during parsing, while still letting it have an effect when called from a non-parser task such as a timer callback or event handler.

6. Similarly, if `document`'s `unload counter`^{p928} is greater than 0, then return `document`.

Note

This basically causes `document.open()`^{p995} to be ignored when it's called from a `beforeunload`^{p1300}, `pagehide`^{p1301}, or `unload`^{p1302} event handler while the `Document`^{p117} is being unloaded.

7. If `document`'s `active parser was aborted`^{p994} is true, then return `document`.

Note

This notably causes `document.open()`^{p995} to be ignored if it is called after a `navigation`^{p906} has started, but only during the initial parse. See [issue #4723](#) for more background.

8. If `document`'s `browsing context`^{p840} is non-null and there is an existing attempt to `navigate`^{p906} `document`'s `browsing context`^{p840}, then `stop document loading`^{p930} given `document`.

Issue #3447 looks into the distinction between an ongoing instance of the `navigate`^{p906} algorithm versus tasks to `navigate`^{p906} that are still queued. For the purpose of implementing this step, both an ongoing instance of the `navigate`^{p906} algorithm and tasks queued to `navigate`^{p906} should be counted towards "an existing attempt to `navigate`^{p906}," at least until that issue is resolved.

9. For each `shadow-including inclusive descendant node` of `document`, `erase all event listeners and handlers`^{p982} given `node`.
10. If `document` is the `associated Document`^{p856} of `document`'s `relevant global object`^{p944}, then `erase all event listeners and handlers`^{p982} given `document`'s `relevant global object`^{p944}.
11. `Replace all` with null within `document`, without firing any mutation events.
12. If `document` is `fully active`^{p844}, then:
 1. Let `newURL` be a copy of `entryDocument`'s `URL`.
 2. If `entryDocument` is not `document`, then set `newURL`'s `fragment` to null.

3. Run the [URL and history update steps](#)^{p893} with *document* and *newURL*.
13. Set *document*'s [is initial about:blank](#)^{p118} to false.
14. If *document*'s [iframe load in progress](#)^{p373} flag is set, then set *document*'s [mute iframe load](#)^{p373} flag.
15. Set *document* to [no-quirks mode](#).
16. Create a new [HTML parser](#)^{p1106} and associate it with *document*. This is a **script-created parser** (meaning that it can be closed by the [document.open\(\)](#)^{p995} and [document.close\(\)](#)^{p995} methods, and that the tokenizer will wait for an explicit call to [document.close\(\)](#)^{p995} before emitting an end-of-file token). The encoding [confidence](#)^{p1113} is *irrelevant*.
17. Set the [insertion point](#)^{p1120} to point at just before the end of the [input stream](#)^{p1119} (which at this point will be empty).
18. [Update the current document readiness](#)^{p120} of *document* to "loading".

Note

This causes a [readystatechange](#)^{p1302} event to fire, but the event is actually unobservable to author code, because of the previous step which [erased all event listeners and handlers](#)^{p982} that could observe it.

19. Return *document*.

Note

The [document open steps](#)^{p994} do not affect whether a [Document](#)^{p117} is [ready for post-load tasks](#)^{p1193} or [completely loaded](#)^{p927}.

The [open\(*unused1*, *unused2*\)](#) method must return the result of running the [document open steps](#)^{p994} with [this](#).

Note

The *unused1* and *unused2* arguments are ignored, but kept in the IDL to allow code that calls the function with one or two arguments to continue working. They are necessary due to Web IDL [overload resolution algorithm](#) rules, which would throw a [TypeError](#) exception for such calls had the arguments not been there. [whatwg/webidl issue #581](#) investigates changing the algorithm to allow for their removal. [\[WEBIDL\]](#)^{p1313}

The [open\(*url*, *name*, *features*\)](#) method must run these steps:

1. If [this](#) is not an [active document](#)^{p840}, then throw an ["InvalidAccessError" DOMException](#) exception.
2. Return the result of running the [window open steps](#)^{p857} with *url*, *name*, and *features*.

8.4.2 Closing the input stream §^{p99} 5

For web developers (non-normative)

[document.close](#)^{p995} ()

Closes the input stream that was opened by the [document.open\(\)](#)^{p995} method.

Throws an ["InvalidStateError" DOMException](#) if the [Document](#)^{p117} is an [XML document](#).

Throws an ["InvalidStateError" DOMException](#) if the parser is currently executing a [custom element constructor](#)^{p728}.

The [close\(\)](#) method must run the following steps:

1. If the [Document](#)^{p117} object is an [XML document](#), then throw an ["InvalidStateError" DOMException](#).
2. If the [Document](#)^{p117} object's [throw-on-dynamic-markup-insertion counter](#)^{p993} is greater than zero, then throw an ["InvalidStateError" DOMException](#).
3. If there is no [script-created parser](#)^{p995} associated with the document, then return.
4. Insert an [explicit "EOF" character](#)^{p1120} at the end of the parser's [input stream](#)^{p1119}.
5. If there is a [pending parsing-blocking script](#)^{p634}, then return.
6. Run the tokenizer, processing resulting tokens as they are emitted, and stopping when the tokenizer reaches the [explicit](#)

"EOF" character^{p1120} or spins the event loop^{p975}.

8.4.3 `document.write()`^{p996} §^{p99}₆

For web developers (non-normative)

`document.write`^{p996} (...text)

In general, adds the given string(s) to the `Document`^{p117}'s input stream.

⚠Warning!

*This method has very idiosyncratic behavior. In some cases, this method can affect the state of the **HTML parser**^{p1106} while the parser is running, resulting in a DOM that does not correspond to the source of the document (e.g. if the string written is the string "`<plaintext>`" or "`<!--`"). In other cases, the call can clear the current page first, as if `document.open()`^{p995} had been called. In yet more cases, the method is simply ignored, or throws an exception. Users agents are explicitly allowed to avoid executing script elements inserted via this method^{p1163}. And to make matters even worse, the exact behavior of this method can in some cases be dependent on network latency, which can lead to failures that are very hard to debug. For all these reasons, use of this method is strongly discouraged.*

Throws an "`InvalidStateError`" `DOMException` when invoked on `XML documents`.

Throws an "`InvalidStateError`" `DOMException` if the parser is currently executing a `custom element constructor`^{p728}.

`Document`^{p117} objects have an **ignore-destructive-writes counter**, which is used in conjunction with the processing of `script`^{p624} elements to prevent external scripts from being able to use `document.write()`^{p996} to blow away the document by implicitly calling `document.open()`^{p995}. Initially, the counter must be set to zero.

The **document write steps**, given a `Document`^{p117} object `document` and a string `input`, are as follows:

1. If `document` is an `XML document`, then throw an "`InvalidStateError`" `DOMException`.
2. If `document`'s `throw-on-dynamic-markup-insertion counter`^{p993} is greater than 0, then throw an "`InvalidStateError`" `DOMException`.
3. If `document`'s `active parser was aborted`^{p994} is true, then return.
4. If the `insertion point`^{p1120} is undefined, then:
 1. If `document`'s `unload counter`^{p928} is greater than 0 or `document`'s `ignore-destructive-writes counter`^{p996} is greater than 0, then return.
 2. Run the `document open steps`^{p994} with `document`.
5. Insert `input` into the `input stream`^{p1119} just before the `insertion point`^{p1120}.
6. If there is no `pending parsing-blocking script`^{p634}, have the `HTML parser`^{p1106} process `input`, one code point at a time, processing resulting tokens as they are emitted, and stopping when the tokenizer reaches the insertion point or when the processing of the tokenizer is aborted by the tree construction stage (this can happen if a `script`^{p624} end tag token is emitted by the tokenizer).

Note

*If the `document.write()`^{p996} method was called from script executing inline (i.e. executing because the parser parsed a set of `script`^{p624} tags), then this is a **reentrant invocation of the parser**^{p1107}. If the `parser pause flag`^{p1108} is set, the tokenizer will abort immediately and no HTML will be parsed, per the tokenizer's `parser pause flag check`^{p1125}.*

The `document.write(...)` method steps are to run the `document write steps`^{p996} with `this` and a string that is the concatenation of all arguments passed.

8.4.4 `document.writeln()`^{p997} §^{p99}₆

For web developers (non-normative)

`document.writeln`^{p997}(...text)

Adds the given string(s) to the `Document`^{p117}'s input stream, followed by a newline character. If necessary, calls the `open()`^{p995} method implicitly first.

Throws an `"InvalidStateError"` `DOMException` when invoked on [XML documents](#).

Throws an `"InvalidStateError"` `DOMException` if the parser is currently executing a [custom element constructor](#)^{p728}.

The `document.writeln(...)` method steps are to run the [document write steps](#)^{p996} with [this](#) and a string that is the concatenation of all arguments passed and U+000A LINE FEED.

8.5 DOM parsing ^{p99}₇

The `DOMParser`^{p997} interface allows authors to create new `Document`^{p117} objects by parsing strings, as either HTML or XML.

For web developers (non-normative)

`parser = new DOMParser`^{p997}()

Constructs a new `DOMParser`^{p997} object.

`document = parser.parseFromString`^{p997}(string, type)

Parses *string* using either the HTML or XML parser, according to *type*, and returns the resulting `Document`^{p117}. *type* can be `"text/html"`^{p1275} (which will invoke the HTML parser), or any of `"text/xml"`^{p1304}, `"application/xml"`^{p1303}, `"application/xhtml+xml"`^{p1277}, or `"image/svg+xml"`^{p1303} (which will invoke the XML parser).

For the XML parser, if *string* cannot be parsed, then the returned `Document`^{p117} will contain elements describing the resulting error.

Note that `script`^{p624} elements are not evaluated during parsing, and the resulting document's [encoding](#) will always be [UTF-8](#).

Values other than the above for *type* will cause a `TypeError` exception to be thrown.

Note

The design of `DOMParser`^{p997}, as a class that needs to be constructed and then have its `parseFromString()`^{p997} method called, is an unfortunate historical artifact. If we were designing this functionality today it would be a standalone function.

```
IDL [Exposed=Window]
interface DOMParser {
  constructor();

  [NewObject] Document parseFromString(DOMString string, DOMParserSupportedType type);
};

enum DOMParserSupportedType {
  "text/html",
  "text/xml",
  "application/xml",
  "application/xhtml+xml",
  "image/svg+xml"
};
```

The new `DOMParser()` constructor steps are to do nothing.

The `parseFromString(string, type)` method steps are:

1. Let *document* be a new `Document`^{p117}, whose [content type](#) is *type* and [url](#) is this's [relevant global object](#)^{p944}'s [associated Document](#)^{p856}'s [URL](#).

Note

The document's [encoding](#) will be left as its default, of [UTF-8](#). In particular, any XML declarations or `meta`^{p170} elements

found while parsing string will have no effect.

2. Switch on type:

↳ "text/html"

1. Set *document*'s [type](#) to "html".
2. Create an [HTML_parser^{p1106}](#) parser, associated with *document*.
3. Place *string* into the [input_stream^{p1119}](#) for parser. The encoding [confidence^{p1113}](#) is *irrelevant*.
4. Start *parser* and let it run until it has consumed all the characters just inserted into the input stream.

Note

This might mutate the document's [mode](#).

Note

Since document does not have a [browsing_context^{p840}](#), [scripting is disabled^{p944}](#).

↳ **Otherwise**

1. Create an [XML_parser^{p1217}](#) parse, associated with *document*, and with [XML_scripting_support_disabled^{p1218}](#).
2. Parse *string* using *parser*.
3. If the previous step resulted in an XML well-formedness or XML namespace well-formedness error, then:
 1. Assert: *document* has no child nodes.
 2. Let *root* be the result of [creating an element](#) given *document*, "parsererror", and "http://www.mozilla.org/newlayout/xml/parsererror.xml".
 3. Optionally, add attributes or children to *root* to describe the nature of the parsing error.
 4. [Append](#) *root* to *document*.

3. Return *document*.

8.6 Timers §^{p99} 8

The [setTimeout\(\)^{p999}](#) and [setInterval\(\)^{p999}](#) methods allow authors to schedule timer-based callbacks.

For web developers (non-normative)

```
id = self.setTimeoutp999(handler [, timeout [, ...arguments ] ])
```

Schedules a timeout to run *handler* after *timeout* milliseconds. Any *arguments* are passed straight through to the *handler*.

```
id = self.setTimeoutp999(code [, timeout ])
```

Schedules a timeout to compile and run *code* after *timeout* milliseconds.

```
self.clearTimeoutp999(id)
```

Cancels the timeout set with [setTimeout\(\)^{p999}](#) or [setInterval\(\)^{p999}](#) identified by *id*.

```
id = self.setIntervalp999(handler [, timeout [, ...arguments ] ])
```

Schedules a timeout to run *handler* every *timeout* milliseconds. Any *arguments* are passed straight through to the *handler*.

```
id = self.setIntervalp999(code [, timeout ])
```

Schedules a timeout to compile and run *code* every *timeout* milliseconds.

```
self.clearIntervalp999(id)
```

Cancels the timeout set with [setInterval\(\)^{p999}](#) or [setTimeout\(\)^{p999}](#) identified by *id*.

Note

Timers can be nested; after five such nested timers, however, the interval is forced to be at least four milliseconds.

Note

This API does not guarantee that timers will run exactly on schedule. Delays due to CPU load, other tasks, etc, are to be expected.

Objects that implement the [WindowOrWorkerGlobalScope](#)^{p991} mixin have a **map of active timers**, which is a [map](#)^{p450}, initially empty. Each [key](#) in this map is an identifier for a timer, and each [value](#) is a [DOMHighResTimeStamp](#), representing the expiry time for that timer.

Note

For entries put in the [map of active timers](#)^{p999} by the [timer initialization steps](#)^{p999}, i.e., by [setTimeout\(\)](#)^{p999} and [setInterval\(\)](#)^{p999}, the keys are numbers. For other specifications that use the [run steps after a timeout](#)^{p1001} algorithm, the identifier is a unique non-numeric value. Only the numeric-keyed timers are affected by [clearTimeout\(\)](#)^{p999} and [clearInterval\(\)](#)^{p999}, but all timers contribute to [idle deadline computation](#)^{p973}, and are cleared when the relevant global is destroyed.

The [setTimeout\(handler, timeout, ...arguments\)](#) method steps are to return the result of running the [timer initialization steps](#)^{p999} given [this](#), [handler](#), [timeout](#), [arguments](#), and false.

The [setInterval\(handler, timeout, ...arguments\)](#) method steps are to return the result of running the [timer initialization steps](#)^{p999} given [this](#), [handler](#), [timeout](#), [arguments](#), and true.

The [clearTimeout\(id\)](#) and [clearInterval\(id\)](#) method steps are to [remove this's map of active timers](#)^{p999}[[id](#)].

Note

Because [clearTimeout\(\)](#)^{p999} and [clearInterval\(\)](#)^{p999} clear entries from the same map, either method can be used to clear timers created by [setTimeout\(\)](#)^{p999} or [setInterval\(\)](#)^{p999}.

The **timer initialization steps**, given a [WindowOrWorkerGlobalScope](#)^{p991} [global](#), a string or [Function](#) [handler](#), a number [timeout](#), a list [arguments](#), a boolean [repeat](#), and optionally (and only if [repeat](#) is true) a number [previousId](#), are:

1. Let [thisArg](#) be [global](#) if that is a [WorkerGlobalScope](#)^{p1062} object; otherwise let [thisArg](#) be the [WindowProxy](#)^{p865} that corresponds to [global](#).
2. If [previousId](#) was given, let [id](#) be [previousId](#); otherwise, let [id](#) be an [implementation-defined](#) integer that is greater than zero and does not already [exist](#) in [global's map of active timers](#)^{p999}.
3. If the [surrounding agent's event loop](#)^{p968}'s [currently running task](#)^{p970} is a task that was created by this algorithm, then let [nesting level](#) be the [task](#)^{p969}'s [timer nesting level](#)^{p1000}. Otherwise, let [nesting level](#) be zero.

Note

The task's [timer nesting level](#)^{p1000} is used both for nested calls to [setTimeout\(\)](#)^{p999}, and for the repeating timers created by [setInterval\(\)](#)^{p999}. (Or, indeed, for any combination of the two.) In other words, it represents nested invocations of this algorithm, not of a particular method.

4. If [timeout](#) is less than 0, then set [timeout](#) to 0.
5. If [nesting level](#) is greater than 5, and [timeout](#) is less than 4, then set [timeout](#) to 4.
6. Let [callerRealm](#) be the [current Realm Record](#), and [calleeRealm](#) be [global's relevant Realm](#)^{p944}.
7. Let [initiating script](#) be the [active script](#)^{p946}.
8. Assert: [initiating script](#) is not null, since this algorithm is always called from some script.
9. Let [task](#) be a [task](#)^{p969} that runs the following substeps:
 1. If [id](#) does not [exist](#) in [global's map of active timers](#)^{p999}, then abort these steps.
 2. If [handler](#) is a [Function](#), then [invoke handler](#) given [arguments](#) with the [callback this value](#) set to [thisArg](#). If this throws an exception, catch it, and [report the exception](#)^{p959}.

3. Otherwise:

1. Assert: *handler* is a string.
2. Perform [HostEnsureCanCompileStrings](#)^{p961}(*callerRealm*, *calleeRealm*). If this throws an exception, catch it, [report the exception](#)^{p959}, and abort these steps.
3. Let *settings object* be *global*'s [relevant settings object](#)^{p944}.
4. Let *base URL* be *initiating script*'s [base URL](#)^{p945}.
5. Assert: *base URL* is not null, as *initiating script* is a [classic script](#)^{p945} or a [JavaScript module script](#)^{p946}.
6. Let *fetch options* be a [script fetch options](#)^{p946} whose [cryptographic nonce](#)^{p946} is *initiating script*'s [fetch options](#)^{p945}'s [cryptographic nonce](#)^{p946}, [integrity metadata](#)^{p946} is the empty string, [parser metadata](#)^{p946} is "not-parser-inserted", [credentials mode](#)^{p946} is *initiating script*'s [fetch options](#)^{p945}'s [credentials mode](#)^{p946}, and [referrer policy](#)^{p946} is *initiating script*'s [fetch options](#)^{p945}'s [referrer policy](#)^{p946}.

Note

The effect of these options ensures that the string compilation done by [setTimeout\(\)](#)^{p999} and [setInterval\(\)](#)^{p999} behaves equivalently to that done by [eval\(\)](#). That is, [module script](#)^{p946} fetches via [import\(\)](#) will behave the same in both contexts.

7. Let *script* be the result of [creating a classic script](#)^{p954} given *handler*, *settings object*, *base URL*, and *fetch options*.
 8. [Run the classic script](#)^{p956} *script*.
4. If *id* does not [exist](#) in *global*'s [map of active timers](#)^{p999}, then abort these steps.

Note

It might have been removed via the author code in handler calling [clearTimeout\(\)](#)^{p999} or [clearInterval\(\)](#)^{p999}.

5. If *repeat* is true, then perform the [timer initialization steps](#)^{p999} again, given *global*, *handler*, *timeout*, *arguments*, true, and *id*.
 6. Otherwise, [remove](#) *global*'s [map of active timers](#)^{p999}[*id*].
10. Increment *nesting level* by one.
 11. Set *task*'s **timer nesting level** to *nesting level*.
 12. Let *completionStep* be an algorithm step which [queues a global task](#)^{p970} on the **timer task source** given *global* to run *task*.
 13. [Run steps after a timeout](#)^{p1001} given *global*, "setTimeout/setInterval", *timeout*, *completionStep*, and *id*.
 14. Return *id*.

Note

Argument conversion as defined by Web IDL (for example, invoking [toString\(\)](#) methods on objects passed as the first argument) happens in the algorithms defined in Web IDL, before this algorithm is invoked.

Example

So for example, the following rather silly code will result in the log containing "ONE TWO ":

```
var log = '';
function logger(s) { log += s + ' '; }

setTimeout({ toString: function () {
  setTimeout("logger('ONE')", 100);
  return "logger('TWO')";
} }, 100);
```

Example

To run tasks of several milliseconds back to back without any delay, while still yielding back to the browser to avoid starving the user interface (and to avoid the browser killing the script for hogging the CPU), simply queue the next timer before performing work:

```
function doExpensiveWork() {
  var done = false;
  // ...
  // this part of the function takes up to five milliseconds
  // set done to true if we're done
  // ...
  return done;
}

function rescheduleWork() {
  var id = setTimeout(rescheduleWork, 0); // preschedule next iteration
  if (doExpensiveWork())
    clearTimeout(id); // clear the timeout if we don't need it
}

function scheduleWork() {
  setTimeout(rescheduleWork, 0);
}

scheduleWork(); // queues a task to do lots of work
```

To **run steps after a timeout**, given a [WindowOrWorkerGlobalScope](#)^{p991} *global*, a string *orderingIdentifier*, a number *milliseconds*, a set of steps *completionSteps*, and an optional value *timerKey*:

1. Assert: if *timerKey* is given, then the caller of this algorithm is the [timer initialization steps](#)^{p999}. (Other specifications must not pass *timerKey*.)
2. If *timerKey* is not given, then set it to a new unique non-numeric value.
3. Let *startTime* be the [current high resolution time](#).
4. Set *global*'s [map of active timers](#)^{p999}[*timerKey*] to *startTime* plus *milliseconds*.
5. Run the following steps [in parallel](#)^{p42}:
 1. If *global* is a [Window](#)^{p855} object, wait until *global*'s [associated Document](#)^{p856} has been [fully active](#)^{p844} for a further *milliseconds* milliseconds (not necessarily consecutively).
Otherwise, *global* is a [WorkerGlobalScope](#)^{p1062} object; wait until *milliseconds* milliseconds have passed with the worker not suspended (not necessarily consecutively).
 2. Wait until any invocations of this algorithm that had the same *global* and *orderingIdentifier*, that started before this one, and whose *milliseconds* is equal to or less than this one's, have completed.
 3. Optionally, wait a further [implementation-defined](#) length of time.

Note

This is intended to allow user agents to pad timeouts as needed to optimize the power usage of the device. For example, some processors have a low-power mode where the granularity of timers is reduced; on such platforms, user agents can slow timers down to fit this schedule instead of requiring the processor to use the more accurate mode with its associated higher power usage.

4. Perform *completionSteps*.
5. If *timerKey* is a non-numeric value, [remove](#) *global*'s [map of active timers](#)^{p999}[*timerKey*].

Note

Run steps after a timeout^{p1001} is meant to be used by other specifications that want to execute developer-supplied code after a developer-supplied timeout, in a similar manner to [setTimeout\(\)](#)^{p999}. (Note, however, it does not have the nesting and clamping

behavior of [setTimeout\(\)](#)^{p999}.) Such specifications can choose an ordering identifier to ensure ordering within their specification's timeouts, while not constraining ordering with respect to other specification's timeouts.

8.7 Microtask queuing ^{§ p1002}

For web developers (non-normative)

`self.queueMicrotask`^{p1002} (*callback*)

Queues [a microtask](#)^{p970} to run the given *callback*.

The `queueMicrotask(callback)` method must [queue a microtask](#)^{p970} to *invoke* *callback*, and if *callback* throws an exception, [report the exception](#)^{p959}.

The `queueMicrotask()`^{p1002} method allows authors to schedule a callback on the [microtask queue](#)^{p970}. This allows their code to run once the [JavaScript execution context stack](#) is next empty, which happens once all currently executing synchronous JavaScript has run to completion. This doesn't yield control back to the [event loop](#)^{p968}, as would be the case when using, for example, `setTimeout(f, 0)`^{p999}.

Authors ought to be aware that scheduling a lot of microtasks has the same performance downsides as running a lot of synchronous code. Both will prevent the browser from doing its own work, such as rendering. In many cases, [requestAnimationFrame\(\)](#)^{p1022} or [requestIdleCallback\(\)](#) is a better choice. In particular, if the goal is to run code before the next rendering cycle, that is the purpose of [requestAnimationFrame\(\)](#)^{p1022}.

As can be seen from the following examples, the best way of thinking about `queueMicrotask()`^{p1002} is as a mechanism for rearranging synchronous code, effectively placing the queued code immediately after the currently executing synchronous JavaScript has run to completion.

Example

The most common reason for using `queueMicrotask()`^{p1002} is to create consistent ordering, even in the cases where information is available synchronously, without introducing undue delay.

For example, consider a custom element firing a `load` event, that also maintains an internal cache of previously-loaded data. A naïve implementation might look like:

```
MyElement.prototype.loadData = function (url) {
  if (this._cache[url]) {
    this._setData(this._cache[url]);
    this.dispatchEvent(new Event("load"));
  } else {
    fetch(url).then(res => res.arrayBuffer()).then(data => {
      this._cache[url] = data;
      this._setData(data);
      this.dispatchEvent(new Event("load"));
    });
  }
};
```

This naïve implementation is problematic, however, in that it causes its users to experience inconsistent behavior. For example, code such as

```
element.addEventListener("load", () => console.log("loaded"));
console.log("1");
element.loadData();
console.log("2");
```

will sometimes log "1, 2, loaded" (if the data needs to be fetched), and sometimes log "1, loaded, 2" (if the data is already cached).

Similarly, after the call to `loadData()`, it will be inconsistent whether or not the data is set on the element.

To get a consistent ordering, [`queueMicrotask\(\)`](#)^{p1002} can be used:

```
MyElement.prototype.loadData = function (url) {
  if (this._cache[url]) {
    queueMicrotask(() => {
      this._setData(this._cache[url]);
      this.dispatchEvent(new Event("load"));
    });
  } else {
    fetch(url).then(res => res.arrayBuffer()).then(data => {
      this._cache[url] = data;
      this._setData(data);
      this.dispatchEvent(new Event("load"));
    });
  }
};
```

By essentially rearranging the queued code to be after the [JavaScript execution context stack](#) empties, this ensures a consistent ordering and update of the element's state.

Example

Another interesting use of [`queueMicrotask\(\)`](#)^{p1002} is to allow uncoordinated "batching" of work by multiple callers. For example, consider a library function that wants to send data somewhere as soon as possible, but doesn't want to make multiple network requests if doing so is easily avoidable. One way to balance this would be like so:

```
const queuedToSend = [];

function sendData(data) {
  queuedToSend.push(data);

  if (queuedToSend.length === 1) {
    queueMicrotask(() => {
      const stringToSend = JSON.stringify(queuedToSend);
      queuedToSend.length = 0;

      fetch("/endpoint", stringToSend);
    });
  }
}
```

With this architecture, multiple subsequent calls to `sendData()` within the currently executing synchronous JavaScript will be batched together into one [`fetch\(\)`](#) call, but with no intervening event loop tasks preempting the fetch (as would have happened with similar code that instead used [`setTimeout\(\)`](#)^{p999}).

8.8 User prompts § p1003

8.8.1 Simple dialogs § p1003

For web developers (non-normative)

`window.alert`^{p1004}(*message*)

Displays a modal alert with the given message, and waits for the user to dismiss it.

`result = window.confirm`^{p1004}(*message*)

Displays a modal OK/Cancel prompt with the given message, waits for the user to dismiss it, and returns true if the user clicks

OK and false if the user clicks Cancel.

result = window.prompt^{p1004}(message [, default])

Displays a modal text control prompt with the given message, waits for the user to dismiss it, and returns the value that the user entered. If the user cancels the prompt, then returns null instead. If the second argument is present, then the given value is used as a default.

Note

Logic that depends on [tasks^{p969}](#) or [microtasks^{p970}](#), such as [media elements^{p396}](#) loading their [media data^{p397}](#), are stalled when these methods are invoked.

The **alert()** and **alert(message)** method steps are:

1. If we [cannot show simple dialogs^{p1005}](#) for [this](#), then return.
2. If the method was invoked with no arguments, then let *message* be the empty string; otherwise, let *message* be the method's first argument.
3. Set *message* to the result of [normalizing newlines](#) given *message*.
4. Set *message* to the result of [optionally truncating^{p1004}](#) *message*.
5. Show *message* to the user, treating U+000A LF as a line break.
6. Optionally, [pause^{p977}](#) while waiting for the user to acknowledge the message.

Note

This method is defined using two overloads, instead of using an optional argument, for historical reasons. The practical impact of this is that `alert(undefined)` is treated as `alert("undefined")`, but `alert()` is treated as `alert("")`.

The **confirm(message)** method steps are:

1. If we [cannot show simple dialogs^{p1005}](#) for [this](#), then return false.
2. Set *message* to the result of [normalizing newlines](#) given *message*.
3. Set *message* to the result of [optionally truncating^{p1004}](#) *message*.
4. Show *message* to the user, treating U+000A LF as a line break, and ask the user to respond with a positive or negative response.
5. [Pause^{p977}](#) until the user responds either positively or negatively.
6. If the user responded positively, return true; otherwise, the user responded negatively: return false.

The **prompt(message, default)** method steps are:

1. If we [cannot show simple dialogs^{p1005}](#) for [this](#), then return null.
2. Set *message* to the result of [normalizing newlines](#) given *message*.
3. Set *message* to the result of [optionally truncating^{p1004}](#) *message*.
4. Set *default* to the result of [optionally truncating^{p1004}](#) *default*.
5. Show *message* to the user, treating U+000A LF as a line break, and ask the user to either respond with a string value or abort. The response must be defaulted to the value given by *default*.
6. [Pause^{p977}](#) while waiting for the user's response.
7. If the user aborts, then return null; otherwise, return the string that the user responded with.

To **optionally truncate a simple dialog string** *s*, return either *s* itself or some string derived from *s* that is shorter. User agents should not provide UI for displaying the elided portion of *s*, as this makes it too easy for abusers to create dialogs of the form "Important security alert! Click 'Show More' for full details!".

Note

For example, a user agent might want to only display the first 100 characters of a message. Or, a user agent might replace the middle of the string with "...". These types of modifications can be useful in limiting the abuse potential of unnaturally large, trustworthy-looking system dialogs.

We **cannot show simple dialogs** for a [Window](#)^{p855} window when the following algorithm returns true:

1. If the [active sandboxing flag set](#)^{p875} of window's [associated Document](#)^{p856} has the [sandboxed modals flag](#)^{p874} set, then return true.
2. If window's [relevant settings object](#)^{p944}'s [origin](#)^{p937} and window's [relevant settings object](#)^{p944}'s [top-level origin](#)^{p936} are not [same origin-domain](#)^{p869}, then return true.
3. If window's [relevant agent](#)^{p934}'s [event loop](#)^{p968}'s [termination nesting level](#)^{p928} is nonzero, then optionally return true.
4. Optionally, return true. (For example, the user agent might give the user the option to ignore all modal dialogs, and would thus abort at this step whenever the method was invoked.)
5. Return false.

8.8.2 Printing §^{p10}₀₅

For web developers (non-normative)

`window.print`^{p1005} ()

Prompts the user to print the page.

The **`print()`** method steps are:

1. Let *document* be *this*'s [associated Document](#)^{p856}.
2. If *document* is not [fully active](#)^{p844}, then return.
3. If *document*'s [unload counter](#)^{p928} is greater than 0, then return.
4. If *document* is [ready for post-load tasks](#)^{p1193}, then run the [printing steps](#)^{p1005} for *document*.
5. Otherwise, set *document*'s **print when loaded** flag.

User agents should also run the [printing steps](#)^{p1005} whenever the user asks for the opportunity to [obtain a physical form](#)^{p1254} (e.g. printed copy), or the representation of a physical form (e.g. PDF copy), of a document.

The **printing steps** for a [Document](#)^{p117} *document* are:

1. The user agent may display a message to the user or return (or both).

Example

For instance, a kiosk browser could silently ignore any invocations of the `print()`^{p1005} method.

Example

For instance, a browser on a mobile device could detect that there are no printers in the vicinity and display a message saying so before continuing to offer a "save to PDF" option.

2. If the [active sandboxing flag set](#)^{p875} of *document* has the [sandboxed modals flag](#)^{p874} set, then return.

Note

If the printing dialog is blocked by a [Document](#)^{p117}'s sandbox, then neither the [beforeprint](#)^{p1300} nor [afterprint](#)^{p1300} events will be fired.

3. The user agent must **fire an event** named [beforeprint](#)^{p1300} at the [relevant global object](#)^{p944} of *document*, as well as any [child browsing contexts](#)^{p843} in it.

Example

The [beforeprint^{p1300}](#) event can be used to annotate the printed copy, for instance adding the time at which the document was printed.

- The user agent should offer the user the opportunity to [obtain a physical form^{p1254}](#) (or the representation of a physical form) of *document*. The user agent may wait for the user to either accept or decline before returning; if so, the user agent must [pause^{p977}](#) while the method is waiting. Even if the user agent doesn't wait at this point, the user agent must use the state of the relevant documents as they are at this point in the algorithm if and when it eventually creates the alternate form.
- The user agent must [fire an event](#) named [afterprint^{p1300}](#) at the [relevant global object^{p944}](#) of *document*, as well as any [child browsing contexts^{p843}](#) in it.

Example

The [afterprint^{p1300}](#) event can be used to revert annotations added in the earlier event, as well as showing post-printing UI. For instance, if a page is walking the user through the steps of applying for a home loan, the script could automatically advance to the next step after having printed a form or other.

8.9 System state and capabilities §^{p10}₀₆

8.9.1 The [Navigator^{p1006}](#) object §^{p10}₀₆

Instances of [Navigator^{p1006}](#) represent the identity and state of the user agent (the client). They also serve as a generic global under which various APIs are located in this and other specifications.

```
IDL [Exposed=Window]
interface Navigator {
  // objects implementing this interface also implement the interfaces given below
};
Navigator includes NavigatorID;
Navigator includes NavigatorLanguage;
Navigator includes NavigatorOnLine;
Navigator includes NavigatorContentUtils;
Navigator includes NavigatorCookies;
Navigator includes NavigatorPlugins;
Navigator includes NavigatorConcurrentHardware;
```

Note

These interface mixins are defined separately so that [WorkerNavigator^{p1075}](#) can reuse parts of the [Navigator^{p1006}](#) interface.

Each [Window^{p855}](#) has an **associated Navigator**, which is a [Navigator^{p1006}](#) object. Upon creation of the [Window^{p855}](#) object, its **associated Navigator^{p1006}** must be set to a **new Navigator^{p1006}** object created in the [Window^{p855}](#) object's **relevant Realm^{p944}**.

The **navigator** and **clientInformation** getter steps are to return **this's associated Navigator^{p1006}**.

8.9.1.1 Client identification §^{p10}₀₆

```
IDL interface mixin NavigatorID {
  readonly attribute DOMString appCodeName; // constant "Mozilla"
  readonly attribute DOMString appName; // constant "Netscape"
  readonly attribute DOMString appVersion;
  readonly attribute DOMString platform;
  readonly attribute DOMString product; // constant "Gecko"
  [Exposed=Window] readonly attribute DOMString productSub;
  readonly attribute DOMString userAgent;
  [Exposed=Window] readonly attribute DOMString vendor;
  [Exposed=Window] readonly attribute DOMString vendorSub; // constant ""
```

```
};
```

In certain cases, despite the best efforts of the entire industry, web browsers have bugs and limitations that web authors are forced to work around.

This section defines a collection of attributes that can be used to determine, from script, the kind of user agent in use, in order to work around these issues.

The user agent has a **navigator compatibility mode**, which is either *Chrome*, *Gecko*, or *WebKit*.

Note

The [navigator compatibility mode](#)^{p1007} constrains the [NavigatorID](#)^{p1006} mixin to the combinations of attribute values and presence of [taintEnabled\(\)](#)^{p1008} and [oscpu](#)^{p1008} that are known to be compatible with existing web content.

Client detection should always be limited to detecting known current versions; future versions and unknown versions should always be assumed to be fully compliant.

For web developers (non-normative)

[self.navigator](#)^{p1006}.[appCodeName](#)^{p1007}

Returns the string "Mozilla".

[self.navigator](#)^{p1006}.[appName](#)^{p1007}

Returns the string "Netscape".

[self.navigator](#)^{p1006}.[appVersion](#)^{p1007}

Returns the version of the browser.

[self.navigator](#)^{p1006}.[platform](#)^{p1007}

Returns the name of the platform.

[self.navigator](#)^{p1006}.[product](#)^{p1007}

Returns the string "Gecko".

[window.navigator](#)^{p1006}.[productSub](#)^{p1008}

Returns either the string "20030107", or the string "20100101".

[self.navigator](#)^{p1006}.[userAgent](#)^{p1008}

Returns the complete `User-Agent` header.

[window.navigator](#)^{p1006}.[vendor](#)^{p1008}

Returns either the empty string, the string "Apple Computer, Inc.", or the string "Google Inc.".

[window.navigator](#)^{p1006}.[vendorSub](#)^{p1008}

Returns the empty string.

appCodeName

Must return the string "Mozilla".

appName

Must return the string "Netscape".

appVersion

Must return either the string "4.0" or a string representing the version of the browser in detail, e.g. "1.0 (VMS; en-US) Mellblomenator/9000".

platform

Must return either the empty string or a string representing the platform on which the browser is executing, e.g. "MacIntel", "Win32", "FreeBSD i386", "WebTV OS".

product

Must return the string "Gecko".

productSub

Must return the appropriate string from the following list:

- ↪ If the [navigator compatibility mode](#)^{p1007} is **Chrome** or **WebKit**
The string "20030107".
- ↪ If the [navigator compatibility mode](#)^{p1007} is **Gecko**
The string "20100101".

userAgent

Must return the [default `User-Agent` value](#).

vendor

Must return the appropriate string from the following list:

- ↪ If the [navigator compatibility mode](#)^{p1007} is **Chrome**
The string "Google Inc.".
- ↪ If the [navigator compatibility mode](#)^{p1007} is **Gecko**
The empty string.
- ↪ If the [navigator compatibility mode](#)^{p1007} is **WebKit**
The string "Apple Computer, Inc.".

vendorSub

Must return the empty string.

If the [navigator compatibility mode](#)^{p1007} is *Gecko*, then the user agent must also support the following partial interface:

```
IDL partial interface mixin NavigatorID {  
  [Exposed=Window] boolean taintEnabled(); // constant false  
  [Exposed=Window] readonly attribute DOMString oscpu;  
};
```

The `taintEnabled()` method must return false.

The `oscpu` attribute's getter must return either the empty string or a string representing the platform on which the browser is executing, e.g. "Windows NT 10.0; Win64; x64", "Linux x86_64".

⚠Warning!

Any information in this API that varies from user to user can be used to profile the user. In fact, if enough such information is available, a user can actually be uniquely identified. For this reason, user agent implementers are strongly urged to include as little information in this API as possible.

8.9.1.2 Language preferences §^{p10}₀₈

```
IDL interface mixin NavigatorLanguage {  
  readonly attribute DOMString language;  
  readonly attribute FrozenArray<DOMString> languages;  
};
```

For web developers (non-normative)

`self.navigatorp1006.languagep1009`

Returns a language tag representing the user's preferred language.

`self.navigatorp1006.languagesp1009`

Returns an array of language tags representing the user's preferred languages, with the most preferred language first.

The most preferred language is the one returned by `navigator.languagep1009`.

Note

A [languagechange](#)^{p1301} event is fired at the [Window](#)^{p855} or [WorkerGlobalScope](#)^{p1062} object when the user agent's understanding of what the user's preferred languages are changes.

Language

Must return a valid BCP 47 language tag representing either a [plausible language](#)^{p1009} or the user's most preferred language. [\[BCP47\]](#)^{p1305}

Languages

Must return a [frozen array](#) of valid BCP 47 language tags representing either one or more [plausible languages](#)^{p1009}, or the user's preferred languages, ordered by preference with the most preferred language first. The same object must be returned until the user agent needs to return different values, or values in a different order. [\[BCP47\]](#)^{p1305}

Whenever the user agent needs to make the [navigator.languages](#)^{p1009} attribute of a [Window](#)^{p855} or [WorkerGlobalScope](#)^{p1062} object *global* return a new set of language tags, the user agent must [queue a global task](#)^{p970} on the [DOM manipulation task source](#)^{p977} given *global* to [fire an event](#) named [languagechange](#)^{p1301} at *global*, and wait until that task begins to be executed before actually returning a new value.

To determine a **plausible language**, the user agent should bear in mind the following:

- Any information in this API that varies from user to user can be used to profile or identify the user.
- If the user is not using a service that obfuscates the user's point of origin (e.g. the Tor anonymity network), then the value that is least likely to distinguish the user from other users with similar origins (e.g. from the same IP address block) is the language used by the majority of such users. [\[TOR\]](#)^{p1312}
- If the user is using an anonymizing service, then the value "en-US" is suggested; if all users of the service use that same value, that reduces the possibility of distinguishing the users from each other.

To avoid introducing any more fingerprinting vectors, user agents should use the same list for the APIs defined in this function as for the HTTP `Accept-Language` header.

8.9.1.3 Browser state ^{§^{p10}₀₉}

```
IDL interface mixin NavigatorOnline {  
  readonly attribute boolean online;  
};
```

For web developers (non-normative)

`self.navigator`^{p1006}.`online`^{p1009}

Returns false if the user agent is definitely offline (disconnected from the network). Returns true if the user agent might be online.

The events [online](#)^{p1301} and [offline](#)^{p1301} are fired when the value of this attribute changes.

The `online` attribute must return false if the user agent will not contact the network when the user follows links or when a script requests a remote page (or knows that such an attempt would fail), and must return true otherwise.

When the value that would be returned by the [navigator.online](#)^{p1009} attribute of a [Window](#)^{p855} or [WorkerGlobalScope](#)^{p1062} *global* changes from true to false, the user agent must [queue a global task](#)^{p970} on the [networking task source](#)^{p977} given *global* to [fire an event](#) named [offline](#)^{p1301} at *global*.

On the other hand, when the value that would be returned by the [navigator.online](#)^{p1009} attribute of a [Window](#)^{p855} or [WorkerGlobalScope](#)^{p1062} *global* changes from false to true, the user agent must [queue a global task](#)^{p970} on the [networking task source](#)^{p977} given *global* to [fire an event](#) named [online](#)^{p1301} at the [Window](#)^{p855} or [WorkerGlobalScope](#)^{p1062} object.

Note

This attribute is inherently unreliable. A computer can be connected to a network without having Internet access.

Example

In this example, an indicator is updated as the browser goes online and offline.

```
<!DOCTYPE HTML>
<html lang="en">
  <head>
    <title>Online status</title>
    <script>
      function updateIndicator() {
        document.getElementById('indicator').textContent = navigator.onLine ? 'online' : 'offline';
      }
    </script>
  </head>
  <body onload="updateIndicator()" ononline="updateIndicator()" onoffline="updateIndicator()">
    <p>The network is: <span id="indicator">(state unknown)</span>
  </body>
</html>
```

MDN

8.9.1.4 Custom scheme handlers: the `registerProtocolHandler()` ^{p1010} method ^{§p10}₁₀

```
IDL interface mixin NavigatorContentUtils {
  [SecureContext] undefined registerProtocolHandler(DOMString scheme, USVString url);
  [SecureContext] undefined unregisterProtocolHandler(DOMString scheme, USVString url);
};
```

For web developers (non-normative)

`window.navigator` ^{p1006}.`registerProtocolHandler` ^{p1010}(*scheme*, *url*)

Registers a handler for *scheme* at *url*. For example, an online telephone messaging service could register itself as a handler of the `sms:` scheme, so that if the user clicks on such a link, they are given the opportunity to use that web site. [\[SMS\]](#) ^{p1311}

The string "%s" in *url* is used as a placeholder for where to put the URL of the content to be handled.

Throws a `"SecurityError" DOMException` if the user agent blocks the registration (this might happen if trying to register as a handler for "http", for instance).

Throws a `"SyntaxError" DOMException` if the "%s" string is missing in *url*.

`window.navigator` ^{p1006}.`unregisterProtocolHandler` ^{p1011}(*scheme*, *url*)

Unregisters the handler given by the arguments.

Throws a `"SecurityError" DOMException` if the user agent blocks the deregistration (this might happen if with invalid schemes, for instance).

Throws a `"SyntaxError" DOMException` if the "%s" string is missing in *url*.

The `registerProtocolHandler(scheme, url)` method steps are:

1. Let (*normalizedScheme*, *normalizedURLString*) be the result of running [normalize protocol handler parameters](#) ^{p1011} with *scheme*, *url*, and [this's relevant settings object](#) ^{p944}.
2. [In parallel](#) ^{p42}: **register a protocol handler** for *normalizedScheme* and *normalizedURLString*. User agents may, within the constraints described, do whatever they like. A user agent could, for instance, prompt the user and offer the user the opportunity to add the site to a shortlist of handlers, or make the handlers their default, or cancel the request. User agents could also silently collect the information, providing it only when relevant to the user.

User agents should keep track of which sites have registered handlers (even if the user has declined such registrations) so that the user is not repeatedly prompted with the same request.

When the **user agent uses this handler** for a [URL](#) *inputURL*:

1. Assert: *inputURL*'s `scheme` is *normalizedScheme*.
2. [Set the username](#) given *inputURL* and the empty string.

3. [Set the password](#) given *inputURL* and the empty string.
4. Let *inputURLString* be the [serialization](#) of *inputURL*.
5. Let *encodedURL* be the result of running [UTF-8 percent-encode](#) on *inputURLString* using the [component percent-encode set](#).
6. Let *handlerURLString* be [normalizedURLString](#).
7. Replace the first instance of "%s" in *handlerURLString* with *encodedURL*.
8. Let *resultURL* be the result of [parsing](#) *handlerURLString*.
9. [Navigate](#)^{p906} an appropriate [browsing context](#)^{p840} to *resultURL*.

Example

If the user had visited a site at `https://example.com/` that made the following call:

```
navigator.registerProtocolHandler('web+soup', 'soup?url=%s')
```

...and then, much later, while visiting `https://www.example.net/`, clicked on a link such as:

```
<a href="web+soup:chicken-kīwi">Download our Chicken Kīwi soup!</a>
```

...then the UA might navigate to the following URL:

```
https://example.com/soup?url=web+soup:chicken-k%C3%AFwi
```

This site could then do whatever it is that it does with soup (synthesize it and ship it to the user, or whatever).

This does not define when the handler is used. To some extent, the [processing model for navigating across documents](#)^{p906} defines some cases where it is relevant, but in general user agents may use this information wherever they would otherwise consider handing schemes to native plugins or helper applications.

The `unregisterProtocolHandler(scheme, url)` method steps are:

1. Let (*normalizedScheme*, *normalizedURLString*) be the result of running [normalize protocol handler parameters](#)^{p1011} with *scheme*, *url*, and [this's relevant settings object](#)^{p944}.
2. [In parallel](#)^{p42}: unregister the handler described by *normalizedScheme* and *normalizedURLString*.

To **normalize protocol handler parameters**, given a string *scheme*, a string *url*, and an [environment settings object](#)^{p937} *environment*, run these steps:

1. Set *scheme* to *scheme*, [converted to ASCII lowercase](#).
2. If *scheme* is neither a [safelisted scheme](#)^{p1011} nor a string starting with "web+" followed by one or more [ASCII lower alphas](#), then throw a `"SecurityError" DOMException`.

Note

This means that including a colon in scheme (as in "mailto:") will throw.

The following schemes are the **safelisted schemes**:

- bitcoin
- ftp
- ftps
- geo
- im
- irc
- ircs
- magnet
- mailto
- matrix
- mms
- news
- nntp

- openpgp4fpr
- sftp
- sip
- sms
- smsto
- ssh
- tel
- urn
- webcal
- wtai
- xmpp

Note

This list can be changed. If there are schemes that ought to be added, please send feedback.

3. If *url* does not contain "%s", then throw a `"SyntaxError" DOMException`.
4. `Parsep91` *url* relative to *environment*.
5. If that fails, then throw a `"SyntaxError" DOMException`.

Note

This is forcibly the case if the %s placeholder is in the host or port of the URL.

6. If the `resulting URL recordp91`'s `scheme` is not an `HTTP(S) scheme` or the `resulting URL recordp91`'s `origin` is not `same originp869` with *environment*'s `originp937`, then throw a `"SecurityError" DOMException`.
7. Assert: the result of `is url potentially trustworthy?` given the `resulting URL recordp91` is "Potentially Trustworthy".

Note

Because `normalize_protocol_handler_parametersp1011` is run within a `secure contextp944`, this is implied by the `same originp869` condition.

8. Return (`scheme`, `resulting URL stringp91`).

Note

The `resulting URL stringp91` will by definition not be a `valid URL string` as it includes the string "%s" which is not a valid component in a URL.

8.9.1.4.1 Security and privacy §^{p10}₁₂

Custom scheme handlers can introduce a number of concerns, in particular privacy concerns.

Hijacking all web usage. User agents should not allow schemes that are key to its normal operation, such as an `HTTP(S) scheme`, to be rerouted through third-party sites. This would allow a user's activities to be trivially tracked, and would allow user information, even in secure connections, to be collected.

Hijacking defaults. User agents are strongly urged to not automatically change any defaults, as this could lead the user to send data to remote hosts that the user is not expecting. New handlers registering themselves should never automatically cause those sites to be used.

Registration spamming. User agents should consider the possibility that a site will attempt to register a large number of handlers, possibly from multiple domains (e.g., by redirecting through a series of pages each on a different domain, and each registering a handler for `web+spam`: — analogous practices abusing other web browser features have been used by pornography web sites for many years). User agents should gracefully handle such hostile attempts, protecting the user.

Hostile handler metadata. User agents should protect against typical attacks against strings embedded in their interface, for example ensuring that markup or escape characters in such strings are not executed, that null bytes are properly handled, that over-long strings do not cause crashes or buffer overruns, and so forth.

Leaking private data. Web page authors may reference a custom scheme handler using URL data considered private. They might do so with the expectation that the user's choice of handler points to a page inside the organization, ensuring that sensitive data will not be exposed to third parties. However, a user may have registered a handler pointing to an external site, resulting in a data leak to that third party. Implementers might wish to consider allowing administrators to disable custom handlers on certain subdomains, content

types, or schemes.

Interface interference. User agents should be prepared to handle intentionally long arguments to the methods. For example, if the user interface exposed consists of an "accept" button and a "deny" button, with the "accept" binding containing the name of the handler, it's important that a long name not cause the "deny" button to be pushed off the screen.

8.9.1.5 Cookies § p10 13

```
IDL interface mixin NavigatorCookies {
  readonly attribute boolean cookieEnabled;
};
```

For web developers (non-normative)

`window.navigatorp1006.cookieEnabledp1013`

Returns false if setting a cookie will be ignored, and true otherwise.

The `cookieEnabled` attribute must return true if the user agent attempts to handle cookies according to *HTTP State Management Mechanism*, and false if it ignores cookie change requests. [\[COOKIES\]^{p1305}](#)

8.9.1.6 PDF viewing support § p10 13

For web developers (non-normative)

`window.navigatorp1006.pdfViewerEnabledp1014`

Returns true if the user agent supports inline viewing of PDF files when [navigating^{p906}](#) to them, or false otherwise. In the latter case, PDF files will be handled by [external software^{p913}](#).

```
IDL interface mixin NavigatorPlugins {
  [SameObject] readonly attribute PluginArray plugins;
  [SameObject] readonly attribute MimeTypeArray mimeTypes;
  boolean javaEnabled();
  readonly attribute boolean pdfViewerEnabled;
};

[Exposed=Window,
 LegacyUnenumerableNamedProperties]
interface PluginArray {
  undefined refresh();
  readonly attribute unsigned long length;
  getter Plugin? item(unsigned long index);
  getter Plugin? namedItem(DOMString name);
};

[Exposed=Window,
 LegacyUnenumerableNamedProperties]
interface MimeTypeArray {
  readonly attribute unsigned long length;
  getter MimeType? item(unsigned long index);
  getter MimeType? namedItem(DOMString name);
};

[Exposed=Window,
 LegacyUnenumerableNamedProperties]
interface Plugin {
  readonly attribute DOMString name;
  readonly attribute DOMString description;
  readonly attribute DOMString filename;
```

```

readonly attribute unsigned long length;
getter MimeType? item(unsigned long index);
getter MimeType? namedItem(DOMString name);
};

[Exposed=Window]
interface MimeType {
  readonly attribute DOMString type;
  readonly attribute DOMString description;
  readonly attribute DOMString suffixes;
  readonly attribute Plugin enabledPlugin;
};

```

Although these days detecting PDF viewer support can be done via [navigator.pdfViewerEnabled](#)^{p1014}, for historical reasons, there are a number of complex and intertwined interfaces that provide the same capability, which legacy code relies on. This section specifies both the simple modern variant and the complicated historical one.

Each user agent has a **PDF viewer supported** boolean, whose value is [implementation-defined](#) (and might vary according to user preferences).

Note

This value also impacts the [navigation](#)^{p906} processing model.

Each [Window](#)^{p855} object has a **PDF viewer plugin objects** list. If the user agent's [PDF viewer supported](#)^{p1014} is false, then it is the empty list. Otherwise, it is a list containing five [Plugin](#)^{p1013} objects, whose [names](#)^{p1015} are, respectively:

0. "PDF Viewer"
1. "Chrome PDF Viewer"
2. "Chromium PDF Viewer"
3. "Microsoft Edge PDF Viewer"
4. "WebKit built-in PDF"

The values of the above list form the **PDF viewer plugin names** list.

Note

These names were chosen based on evidence of what websites historically search for, and thus what is necessary for user agents to expose in order to maintain compatibility with existing content. They are ordered alphabetically. The "PDF Viewer" name was then inserted in the 0th position so that the [enabledPlugin](#)^{p1016} getter could point to a generic plugin name.

Each [Window](#)^{p855} object has a **PDF viewer mime type objects** list. If the user agent's [PDF viewer supported](#)^{p1014} is false, then it is the empty list. Otherwise, it is a list containing two [MimeType](#)^{p1014} objects, whose [types](#)^{p1016} are, respectively:

0. "application/pdf"
1. "text/pdf"

The values of the above list form the **PDF viewer mime types** list.

Each [NavigatorPlugins](#)^{p1013} object has a **plugins array**, which is a new [PluginArray](#)^{p1013}, and a **mime types array**, which is a new [MimeTypeArray](#)^{p1013}.

The [NavigatorPlugins](#)^{p1013} mixin's **plugins** getter steps are to return [this's plugins array](#)^{p1014}.

The [NavigatorPlugins](#)^{p1013} mixin's **mimeTypes** getter steps are to return [this's mime types array](#)^{p1014}.

The [NavigatorPlugins](#)^{p1013} mixin's **javaEnabled()** method steps are to return false.

The [NavigatorPlugins](#)^{p1013} mixin's **pdfViewerEnabled** getter steps are to return the user agent's [PDF viewer supported](#)^{p1014}.

The [PluginArray](#)^{p1013} interface [supports named properties](#). If the user agent's [PDF viewer supported](#)^{p1014} is true, then they are the [PDF viewer plugin names](#)^{p1014}. Otherwise, they are the empty list.

The [PluginArray^{p1013}](#) interface's **namedItem(*name*)** method steps are:

1. For each [Plugin^{p1013}](#) *plugin* of this's [relevant global object^{p944}](#)'s [PDF viewer plugin objects^{p1014}](#): if *plugin*'s [name^{p1015}](#) is *name*, then return *plugin*.
2. Return null.

The [PluginArray^{p1013}](#) interface [supports indexed properties](#). The [supported property indices](#) are the [indices](#) of this's [relevant global object^{p944}](#)'s [PDF viewer plugin objects^{p1014}](#).

The [PluginArray^{p1013}](#) interface's **item(*index*)** method steps are:

1. Let *plugins* be this's [relevant global object^{p944}](#)'s [PDF viewer plugin objects^{p1014}](#).
2. If *index* < *plugins*'s [size](#), then return *plugins*[*index*].
3. Return null.

The [PluginArray^{p1013}](#) interface's **length** getter steps are to return this's [relevant global object^{p944}](#)'s [PDF viewer plugin objects^{p1014}](#)'s [size](#).

The [PluginArray^{p1013}](#) interface's **refresh()** method steps are to do nothing.

The [MimeTypeArray^{p1013}](#) interface [supports named properties](#). If the user agent's [PDF viewer supported^{p1014}](#) is true, then they are the [PDF viewer mime types^{p1014}](#). Otherwise, they are the empty list.

The [MimeTypeArray^{p1013}](#) interface's **namedItem(*name*)** method steps are:

1. For each [MimeType^{p1014}](#) *mimeType* of this's [relevant global object^{p944}](#)'s [PDF viewer mime type objects^{p1014}](#): if *mimeType*'s [type^{p1016}](#) is *name*, then return *mimeType*.
2. Return null.

The [MimeTypeArray^{p1013}](#) interface [supports indexed properties](#). The [supported property indices](#) are the [indices](#) of this's [relevant global object^{p944}](#)'s [PDF viewer mime type objects^{p1014}](#).

The [MimeTypeArray^{p1013}](#) interface's **item(*index*)** method steps are:

1. Let *mimeTypes* be this's [relevant global object^{p944}](#)'s [PDF viewer mime type objects^{p1014}](#).
2. If *index* < *mimeTypes*'s [size](#), then return *mimeTypes*[*index*].
3. Return null.

The [MimeTypeArray^{p1013}](#) interface's **length** getter steps are to return this's [relevant global object^{p944}](#)'s [PDF viewer mime type objects^{p1014}](#)'s [size](#).

Each [Plugin^{p1013}](#) object has a **name**, which is set when the object is created.

The [Plugin^{p1013}](#) interface's **name** getter steps are to return this's [name^{p1015}](#).

The [Plugin^{p1013}](#) interface's **description** getter steps are to return "Portable Document Format".

The [Plugin^{p1013}](#) interface's **filename** getter steps are to return "internal-pdf-viewer".

The [Plugin^{p1013}](#) interface [supports named properties](#). If the user agent's [PDF viewer supported^{p1014}](#) is true, then they are the [PDF viewer mime types^{p1014}](#). Otherwise, they are the empty list.

The [Plugin^{p1013}](#) interface's **namedItem(*name*)** method steps are:

1. For each [MimeType^{p1014}](#) *mimeType* of this's [relevant global object^{p944}](#)'s [PDF viewer mime type objects^{p1014}](#): if *mimeType*'s [type^{p1016}](#) is *name*, then return *mimeType*.
2. Return null.

The [Plugin^{p1013}](#) interface [supports indexed properties](#). The [supported property indices](#) are the [indices](#) of [this's relevant global object^{p944}'s PDF viewer mime type objects^{p1014}](#).

The [Plugin^{p1013}](#) interface's [item\(index\)](#) method steps are:

1. Let *mimeTypes* be [this's relevant global object^{p944}'s PDF viewer mime type objects^{p1014}](#).
2. If *index* < *mimeType*'s [size](#), then return *mimeTypes*[*index*].
3. Return null.

The [Plugin^{p1013}](#) interface's [length](#) getter steps are to return [this's relevant global object^{p944}'s PDF viewer mime type objects^{p1014}'s size](#).

Each [MimeType^{p1014}](#) object has a [type](#), which is set when the object is created.

The [MimeType^{p1014}](#) interface's [type](#) getter steps are to return [this's type^{p1016}](#).

The [MimeType^{p1014}](#) interface's [description](#) getter steps are to return "Portable Document Format".

The [MimeType^{p1014}](#) interface's [suffixes](#) getter steps are to return "pdf".

The [MimeType^{p1014}](#) interface's [enabledPlugin](#) getter steps are to return [this's relevant global object^{p944}'s PDF viewer plugin objects^{p1014}](#)[0] (i.e., the generic "PDF Viewer" one).

8.10 Images §p10 16

```
IDL [Exposed=(Window,Worker), Serializable, Transferable]
interface ImageBitmap {
  readonly attribute unsigned long width;
  readonly attribute unsigned long height;
  undefined close();
};

typedef (CanvasImageSource or
        Blob or
        ImageData) ImageBitmapSource;

enum ImageOrientation { "none", "flipY" };
enum PremultiplyAlpha { "none", "premultiply", "default" };
enum ColorSpaceConversion { "none", "default" };
enum ResizeQuality { "pixelated", "low", "medium", "high" };

dictionary ImageBitmapOptions {
  ImageOrientation imageOrientation = "none";
  PremultiplyAlpha premultiplyAlpha = "default";
  ColorSpaceConversion colorSpaceConversion = "default";
  [EnforceRange] unsigned long resizeWidth;
  [EnforceRange] unsigned long resizeHeight;
  ResizeQuality resizeQuality = "low";
};
```

An [ImageBitmap^{p1016}](#) object represents a bitmap image that can be painted to a canvas without undue latency.

Note

The exact judgement of what is undue latency of this is left up to the implementer, but in general if making use of the bitmap requires network I/O, or even local disk I/O, then the latency is probably undue; whereas if it only requires a blocking read from a GPU or system RAM, the latency is probably acceptable.

For web developers (non-normative)

`promise = self.createImageBitmapp1018(image [, options])`

`promise = self.createImageBitmapp1018(image, sx, sy, sw, sh [, options])`

Takes *image*, which can be an [img^{p327}](#) element, an [SVG image](#) element, a [video^{p388}](#) element, a [canvas^{p645}](#) element, a [Blob](#) object, an [ImageData^{p655}](#) object, or another [ImageBitmap^{p1016}](#) object, and returns a promise that is resolved when a new [ImageBitmap^{p1016}](#) is created.

If no [ImageBitmap^{p1016}](#) object can be constructed, for example because the provided *image* data is not actually an image, then the promise is rejected instead.

If *sx*, *sy*, *sw*, and *sh* arguments are provided, the source image is cropped to the given pixels, with any pixels missing in the original replaced by [transparent black](#). These coordinates are in the source image's pixel coordinate space, *not* in [CSS pixels](#).

If *options* is provided, the [ImageBitmap^{p1016}](#) object's bitmap data is modified according to *options*. For example, if the [premultiplyAlpha^{p1020}](#) option is set to "[premultiply^{p1020}](#)", the [bitmap_data^{p1017}](#)'s color channels are [premultiplied by its alpha channel^{p719}](#).

Rejects the promise with an ["InvalidStateError" DOMException](#) if the source image is not in a valid state (e.g., an [img^{p327}](#) element that hasn't loaded successfully, an [ImageBitmap^{p1016}](#) object whose [\[\[Detached\]\]^{p107}](#) internal slot value is true, an [ImageData^{p655}](#) object whose [data^{p696}](#) attribute value's [\[\[ViewedArrayBuffer\]\]](#) internal slot is detached, or a [Blob](#) whose data cannot be interpreted as a bitmap image).

Rejects the promise with a ["SecurityError" DOMException](#) if the script is not allowed to access the image data of the source image (e.g. a [video^{p388}](#) that is [CORS-cross-origin^{p92}](#), or a [canvas^{p645}](#) being drawn on by a script in a worker from another [origin^{p868}](#)).

`imageBitmap.closep1020()`

Releases *imageBitmap*'s underlying [bitmap_data^{p1017}](#).

`imageBitmap.widthp1020`

Returns the [intrinsic width](#) of the image, in [CSS pixels](#).

`imageBitmap.heightp1021`

Returns the [intrinsic height](#) of the image, in [CSS pixels](#).

An [ImageBitmap^{p1016}](#) object whose [\[\[Detached\]\]^{p107}](#) internal slot value is false always has associated **bitmap data**, with a width and a height. However, it is possible for this data to be corrupted. If an [ImageBitmap^{p1016}](#) object's media data can be decoded without errors, it is said to be **fully decodable**.

An [ImageBitmap^{p1016}](#) object's bitmap has an [origin-clean^{p647}](#) flag, which indicates whether the bitmap is tainted by content from a different [origin^{p868}](#). The flag is initially set to true and may be changed to false by the steps of [createImageBitmap\(\)^{p1018}](#).

[ImageBitmap^{p1016}](#) objects are [serializable objects^{p105}](#) and [transferable objects^{p106}](#).

Their [serialization steps^{p105}](#), given *value* and *serialized*, are:

1. If *value*'s [origin-clean^{p647}](#) flag is not set, then throw a ["DataCloneError" DOMException](#).
2. Set *serialized*.[\[\[BitmapData\]\]](#) to a copy of *value*'s [bitmap_data^{p1017}](#).

Their [deserialization steps^{p105}](#), given *serialized* and *value*, are:

1. Set *value*'s [bitmap_data^{p1017}](#) to *serialized*.[\[\[BitmapData\]\]](#).

Their [transfer steps^{p106}](#), given *value* and *dataHolder*, are:

1. If *value*'s [origin-clean^{p647}](#) flag is not set, then throw a ["DataCloneError" DOMException](#).
2. Set *dataHolder*.[\[\[BitmapData\]\]](#) to *value*'s [bitmap_data^{p1017}](#).
3. Unset *value*'s [bitmap_data^{p1017}](#).

Their [transfer-receiving steps^{p106}](#), given *dataHolder* and *value*, are:

1. Set *value*'s [bitmap_data^{p1017}](#) to *dataHolder*.[\[\[BitmapData\]\]](#).

The `createImageBitmap(image, options)` and `createImageBitmap(image sx, sy, sw, sh, options)` methods, when invoked, must run these steps:

1. Let *p* be a new promise.
2. If either *sw* or *sh* is given and is 0, then return *p* rejected with a `RangeError`.
3. If either *options*'s `resizeWidth` or *options*'s `resizeHeight` is present and is 0, then return *p* rejected with an `"InvalidStateError" DOMException`.
4. [Check the usability of the *image* argument](#)^{p679}. If this throws an exception or returns *bad*, then return *p* rejected with an `"InvalidStateError" DOMException`.
5. Let *imageBitmap* be a new `ImageBitmap`^{p1016} object.
6. Switch on *image*:

↳ [img](#)^{p327}

↳ [SVG image](#)

1. If *image*'s media data has no [intrinsic dimensions](#) (e.g., it's a vector graphic with no specified content size) and either *options*'s `resizeWidth`^{p1018} or *options*'s `resizeHeight`^{p1018} is not present, then return *p* rejected with an `"InvalidStateError" DOMException`.
2. If *image*'s media data has no [intrinsic dimensions](#) (e.g., it's a vector graphics with no specified content size), it should be rendered to a bitmap of the size specified by the `resizeWidth`^{p1018} and the `resizeHeight`^{p1018} options.
3. Set *imageBitmap*'s `bitmap data`^{p1017} to a copy of *image*'s media data, [cropped to the source rectangle with formatting](#)^{p1019}. If this is an animated image, *imageBitmap*'s `bitmap data`^{p1017} must only be taken from the default image of the animation (the one that the format defines is to be used when animation is not supported or is disabled), or, if there is no such image, the first frame of the animation.
4. If *image* is not origin-clean^{p680}, then set the `origin-clean`^{p647} flag of *imageBitmap*'s bitmap to false.
5. Run this step [in parallel](#)^{p42}:

1. Resolve *p* with *imageBitmap*.

↳ [video](#)^{p388}

1. If *image*'s `networkState`^{p400} attribute is `NETWORK_EMPTY`^{p400}, then return *p* rejected with an `"InvalidStateError" DOMException`.
2. Set *imageBitmap*'s `bitmap data`^{p1017} to a copy of the frame at the [current playback position](#)^{p412}, at the [media resource](#)^{p397}'s `intrinsic width`^{p390} and `intrinsic height`^{p390} (i.e., after any aspect-ratio correction has been applied), [cropped to the source rectangle with formatting](#)^{p1019}.
3. If *image* is not origin-clean^{p680}, then set the `origin-clean`^{p647} flag of *imageBitmap*'s bitmap to false.
4. Run this step [in parallel](#)^{p42}:

1. Resolve *p* with *imageBitmap*.

↳ [canvas](#)^{p645}

1. Set *imageBitmap*'s `bitmap data`^{p1017} to a copy of *image*'s `bitmap data`^{p1017}, [cropped to the source rectangle with formatting](#)^{p1019}.
2. Set the `origin-clean`^{p647} flag of the *imageBitmap*'s bitmap to the same value as the `origin-clean`^{p647} flag of *image*'s bitmap.
3. Run this step [in parallel](#)^{p42}:

1. Resolve *p* with *imageBitmap*.

↳ [Blob](#)

Run these step [in parallel](#)^{p42}:

1. Let *imageData* be the result of reading *image*'s data. If an [error occurs during reading of the object](#)^{p58}, then

reject p with an ["InvalidStateError" DOMException](#) and abort these steps.

2. Apply the [image sniffing rules](#) to determine the file format of $imageData$, with MIME type of $image$ (as given by $image$'s `type` attribute) giving the official type.
3. If $imageData$ is not in a supported image file format (e.g., it's not an image at all), or if $imageData$ is corrupted in some fatal way such that the image dimensions cannot be obtained (e.g., a vector graphic with no intrinsic size), then reject p with an ["InvalidStateError" DOMException](#) and abort these steps.
4. Set $imageBitmap$'s [bitmap data](#)^{p1017} to $imageData$, [cropped to the source rectangle with formatting](#)^{p1019}. If this is an animated image, $imageBitmap$'s [bitmap data](#)^{p1017} must only be taken from the default image of the animation (the one that the format defines is to be used when animation is not supported or is disabled), or, if there is no such image, the first frame of the animation.
5. Resolve p with $imageBitmap$.

↪ [ImageData](#)^{p655}

1. Let $buffer$ be $image$'s [data](#)^{p696} attribute value's `[[ViewedArrayBuffer]]` internal slot.
2. If `IsDetachedBuffer(buffer)` is true, then return p rejected with an ["InvalidStateError" DOMException](#).
3. Set $imageBitmap$'s [bitmap data](#)^{p1017} to $image$'s image data, [cropped to the source rectangle with formatting](#)^{p1019}.
4. Run this step [in parallel](#)^{p42}:
 1. Resolve p with $imageBitmap$.

↪ [ImageBitmap](#)^{p1016}

1. Set $imageBitmap$'s [bitmap data](#)^{p1017} to a copy of $image$'s [bitmap data](#)^{p1017}, [cropped to the source rectangle with formatting](#)^{p1019}.
2. Set the [origin-clean](#)^{p647} flag of $imageBitmap$'s bitmap to the same value as the [origin-clean](#)^{p647} flag of $image$'s bitmap.
3. Run this step [in parallel](#)^{p42}:
 1. Resolve p with $imageBitmap$.

↪ [VideoFrame](#)

1. Set $imageBitmap$'s [bitmap data](#)^{p1017} to a copy of $image$'s visible pixel data, [cropped to the source rectangle with formatting](#)^{p1019}.
2. Run this step [in parallel](#)^{p42}:
 1. Resolve p with $imageBitmap$.

7. Return p .

When the steps above require that the user agent **crop bitmap data to the source rectangle with formatting**, the user agent must run the following steps:

1. Let $input$ be the [bitmap data](#)^{p1017} being transformed.
2. If sx , sy , sw and sh are specified, let $sourceRectangle$ be a rectangle whose corners are the four points (sx, sy) , $(sx+sw, sy)$, $(sx+sw, sy+sh)$, $(sx, sy+sh)$. Otherwise let $sourceRectangle$ be a rectangle whose corners are the four points $(0,0)$, $(width\ of\ input, 0)$, $(width\ of\ input, height\ of\ input)$, $(0, height\ of\ input)$.

Note

If either sw or sh are negative, then the top-left corner of this rectangle will be to the left or above the (sx, sy) point.

3. Let $outputWidth$ be determined as follows:

- ↪ If the [resizeWidth](#)^{p1018} member of `options` is specified
the value of the [resizeWidth](#)^{p1018} member of `options`

- ↪ If the `resizeWidthp1018` member of `options` is not specified, but the `resizeHeightp1018` member is specified the width of `sourceRectangle`, times the value of the `resizeHeightp1018` member of `options`, divided by the height of `sourceRectangle`, rounded up to the nearest integer
- ↪ If neither `resizeWidthp1018` nor `resizeHeightp1018` are specified the width of `sourceRectangle`

4. Let `outputHeight` be determined as follows:

- ↪ If the `resizeHeightp1018` member of `options` is specified the value of the `resizeHeightp1018` member of `options`
- ↪ If the `resizeHeightp1018` member of `options` is not specified, but the `resizeWidthp1018` member is specified the height of `sourceRectangle`, times the value of the `resizeWidthp1018` member of `options`, divided by the width of `sourceRectangle`, rounded up to the nearest integer
- ↪ If neither `resizeWidthp1018` nor `resizeHeightp1018` are specified the height of `sourceRectangle`

5. Place `input` on an infinite `transparent black` grid plane, positioned so that its top left corner is at the origin of the plane, with the x-coordinate increasing to the right, and the y-coordinate increasing down, and with each pixel in the `input` image data occupying a cell on the plane's grid.
6. Let `output` be the rectangle on the plane denoted by `sourceRectangle`.
7. Scale `output` to the size specified by `outputWidth` and `outputHeight`. The user agent should use the value of the `resizeQuality` option to guide the choice of scaling algorithm.
8. If the value of the `imageOrientation` member of `options` is `"flipY"`, `output` must be flipped vertically, disregarding any image orientation metadata of the source (such as EXIF metadata), if any. [\[EXIF\]^{p1308}](#)

Note

If the value is `"none"`, no extra step is required.

9. If `image` is an `imgp327` element or a `Blob` object, let `val` be the value of the `colorSpaceConversion` member of `options`, and then run these substeps:
 1. If `val` is `"default"`, the color space conversion behavior is implementation-specific, and should be chosen according to the default color space that the implementation uses for drawing images onto the canvas.
 2. If `val` is `"none"`, `output` must be decoded without performing any color space conversions. This means that the image decoding algorithm must ignore color profile metadata embedded in the source data as well as the display device color profile.
10. Let `val` be the value of `premultiplyAlpha` member of `options`, and then run these substeps:
 1. If `val` is `"default"`, the alpha premultiplication behavior is implementation-specific, and should be chosen according to implementation deems optimal for drawing images onto the canvas.
 2. If `val` is `"premultiply"`, the `output` that is not premultiplied by alpha must have its color components [multiplied by alpha^{p720}](#) and that is premultiplied by alpha must be left untouched.
 3. If `val` is `"none"`, the `output` that is not premultiplied by alpha must be left untouched and that is premultiplied by alpha must have its color components [divided by alpha^{p720}](#).
11. Return `output`.

The `close()` method steps are:

1. Set `this`'s [\[\[Detached\]\]^{p107}](#) internal slot value to true.
2. Unset `this`'s [bitmap data^{p1017}](#).

The `width` getter steps are:

1. If `this`'s [\[\[Detached\]\]^{p107}](#) internal slot's value is true, then return 0.
2. Return `this`'s width, in [CSS pixels](#).

The **height** getter steps are:

1. If [this's `\[\[Detached\]\]`](#)^{p107} internal slot's value is true, then return 0.
2. Return [this's height](#), in [CSS pixels](#).

The [ResizeQuality](#)^{p1016} enumeration is used to express a preference for the interpolation quality to use when scaling images.

The **"pixelated"** value indicates a preference to scale the image that maximizes the appearance. Scaling algorithms that "smooth" colors are acceptable, such as bilinear interpolation.

The **"low"** value indicates a preference for a low level of image interpolation quality. Low-quality image interpolation may be more computationally efficient than higher settings.

The **"medium"** value indicates a preference for a medium level of image interpolation quality.

The **"high"** value indicates a preference for a high level of image interpolation quality. High-quality image interpolation may be more computationally expensive than lower settings.

Note
Bilinear scaling is an example of a relatively fast, lower-quality image-smoothing algorithm. Bicubic or Lanczos scaling are examples of image-scaling algorithms that produce higher-quality output. This specification does not mandate that specific interpolation algorithms be used unless the value is ["pixelated"](#)^{p1021}.

Example
Using this API, a sprite sheet can be precut and prepared:

```
var sprites = {};  
function loadMySprites() {  
  var image = new Image();  
  image.src = 'mysprites.png';  
  var resolver;  
  var promise = new Promise(function (arg) { resolver = arg });  
  image.onload = function () {  
    resolver(Promise.all([  
      createImageBitmap(image, 0, 0, 40, 40).then(function (image) { sprites.person = image }),  
      createImageBitmap(image, 40, 0, 40, 40).then(function (image) { sprites.grass = image }),  
      createImageBitmap(image, 80, 0, 40, 40).then(function (image) { sprites.tree = image }),  
      createImageBitmap(image, 0, 40, 40, 40).then(function (image) { sprites.hut = image }),  
      createImageBitmap(image, 40, 40, 40, 40).then(function (image) { sprites.apple = image }),  
      createImageBitmap(image, 80, 40, 40, 40).then(function (image) { sprites.snake = image })  
    ]));  
  };  
  return promise;  
}  
  
function runDemo() {  
  var canvas = document.querySelector('canvas#demo');  
  var context = canvas.getContext('2d');  
  context.drawImage(sprites.tree, 30, 10);  
  context.drawImage(sprites.snake, 70, 10);  
}  
  
loadMySprites().then(runDemo);
```

8.11 Animation frames ^{p10}

21

Some objects include the [AnimationFrameProvider](#)^{p1022} interface mixin.

```

IDL callback FrameRequestCallback = undefined (DOMHighResTimeStamp time);

interface mixin AnimationFrameProvider {
  unsigned long requestAnimationFrame(FrameRequestCallback callback);
  undefined cancelAnimationFrame(unsigned long handle);
};
Window includes AnimationFrameProvider;
DedicatedWorkerGlobalScope includes AnimationFrameProvider;

```

Each [AnimationFrameProvider](#)^{p1022} object also has a **target object** that stores the provider's internal state. It is defined as follows:

If the [AnimationFrameProvider](#)^{p1022} is a [Window](#)^{p855}

The [Window](#)^{p855}'s [associated Document](#)^{p856}

If the [AnimationFrameProvider](#)^{p1022} is a [DedicatedWorkerGlobalScope](#)^{p1064}

The [DedicatedWorkerGlobalScope](#)^{p1064}

Each [target object](#)^{p1022} has a **map of animation frame callbacks**, which is an [ordered map](#) that must be initially empty, and an **animation frame callback identifier**, which is a number that must initially be zero.

An [AnimationFrameProvider](#)^{p1022} *provider* is considered **supported** if any of the following hold:

- *provider* is a [Window](#)^{p855}.
- *provider*'s [owner set](#)^{p1062} contains a [Document](#)^{p117} object.
- Any of the [DedicatedWorkerGlobalScope](#)^{p1064} objects in *provider*'s [owner set](#)^{p1062} are [supported](#)^{p1022}.

The [requestAnimationFrame\(*callback*\)](#) method steps are:

1. If [this](#) is not [supported](#)^{p1022}, then throw a ["NotSupportedError"](#) [DOMException](#).
2. Let *target* be [this](#)'s [target object](#)^{p1022}.
3. Increment *target*'s [animation frame callback identifier](#)^{p1022} by one, and let *handle* be the result.
4. Let *callbacks* be *target*'s [map of animation frame callbacks](#)^{p1022}.
5. [Set](#) *callbacks*[*handle*] to *callback*.
6. Return *handle*.

The [cancelAnimationFrame\(*handle*\)](#) method steps are:

1. If [this](#) is not [supported](#)^{p1022}, then throw a ["NotSupportedError"](#) [DOMException](#).
2. Let *callbacks* be [this](#)'s [target object](#)^{p1022}'s [map of animation frame callbacks](#)^{p1022}.
3. [Remove](#) *callbacks*[*handle*].

To **run the animation frame callbacks** for a [target object](#)^{p1022} *target* with a timestamp *now*:

1. Let *callbacks* be *target*'s [map of animation frame callbacks](#)^{p1022}.
2. Let *callbackHandles* be the result of [getting the keys](#) of *callbacks*.
3. [For each](#) *handle* in *callbackHandles*, if *handle* [exists](#) in *callbacks*:
 1. Let *callback* be *callbacks*[*handle*].
 2. [Remove](#) *callbacks*[*handle*].
 3. [Invoke](#) *callback*, passing *now* as the only argument, and if an exception is thrown, [report the exception](#)^{p959}.

Example

Inside workers, [requestAnimationFrame\(\)](#)^{p1022} can be used together with an [OffscreenCanvas](#)^{p712} transferred from a [canvas](#)^{p645} element. First, in the document, transfer control to the worker:

```
const offscreenCanvas = document.getElementById("c").transferControlToOffscreen();
worker.postMessage(offscreenCanvas, [offscreenCanvas]);
```

Then, in the worker, the following code will draw a rectangle moving from left to right:

```
let ctx, pos = 0;
function draw(dt) {
  ctx.clearRect(0, 0, 100, 100);
  ctx.fillRect(pos, 0, 10, 10);
  pos += 10 * dt;
  requestAnimationFrame(draw);
}

self.onmessage = function(ev) {
  const transferredCanvas = ev.data;
  ctx = transferredCanvas.getContext("2d");
  draw();
};
```

9 Communication § p10 24

Note

The `WebSocket` interface used to be defined here. It is now defined in `WebSockets`. [\[WEBSOCKETS\]](#)^{p1313}

9.1 The `MessageEvent`^{p1024} interface § p10 24

Messages in [server-sent events](#)^{p1025}, [cross-document messaging](#)^{p1034}, [channel messaging](#)^{p1037}, [broadcast channels](#)^{p1043}, and `WebSockets` use the `MessageEvent`^{p1024} interface for their `message`^{p1301} events: [\[WEBSOCKETS\]](#)^{p1313}

```
IDL [Exposed=(Window,Worker,AudioWorklet)]
interface MessageEvent : Event {
  constructor(DOMString type, optional MessageEventInit eventInitDict = {});

  readonly attribute any data;
  readonly attribute USVString origin;
  readonly attribute DOMString lastEventId;
  readonly attribute MessageEventSource? source;
  readonly attribute FrozenArray<MessagePort> ports;

  undefined initMessageEvent(DOMString type, optional boolean bubbles = false, optional boolean
cancelable = false, optional any data = null, optional USVString origin = "", optional DOMString
lastEventId = "", optional MessageEventSource? source = null, optional sequence<MessagePort> ports =
[]);
};

dictionary MessageEventInit : EventInit {
  any data = null;
  USVString origin = "";
  DOMString lastEventId = "";
  MessageEventSource? source = null;
  sequence<MessagePort> ports = [];
};

typedef (WindowProxy or MessagePort or ServiceWorker) MessageEventSource;
```

For web developers (non-normative)

`event.data`^{p1024}

Returns the data of the message.

`event.origin`^{p1025}

Returns the origin of the message, for [server-sent events](#)^{p1025} and [cross-document messaging](#)^{p1034}.

`event.lastEventId`^{p1025}

Returns the [last event ID string](#)^{p1026}, for [server-sent events](#)^{p1025}.

`event.source`^{p1025}

Returns the [WindowProxy](#)^{p865} of the source window, for [cross-document messaging](#)^{p1034}, and the [MessagePort](#)^{p1040} being attached, in the [connect](#)^{p1301} event fired at [SharedWorkerGlobalScope](#)^{p1064} objects.

`event.ports`^{p1025}

Returns the [MessagePort](#)^{p1040} array sent with the message, for [cross-document messaging](#)^{p1034} and [channel messaging](#)^{p1037}.

The `data` attribute must return the value it was initialized to. It represents the message being sent.

The **origin** attribute must return the value it was initialized to. It represents, in [server-sent events](#)^{p1025} and [cross-document messaging](#)^{p1034}, the **origin** of the document that sent the message (typically the scheme, hostname, and port of the document, but not its path or [fragment](#)).

The **lastEventId** attribute must return the value it was initialized to. It represents, in [server-sent events](#)^{p1025}, the **last event ID string**^{p1026} of the event source.

The **source** attribute must return the value it was initialized to. It represents, in [cross-document messaging](#)^{p1034}, the [WindowProxy](#)^{p865} of the [browsing context](#)^{p840} of the [Window](#)^{p855} object from which the message came; and in the [connect](#)^{p1301} events used by [shared workers](#)^{p1064}, the newly connecting [MessagePort](#)^{p1040}.

The **ports** attribute must return the value it was initialized to. It represents, in [cross-document messaging](#)^{p1034} and [channel messaging](#)^{p1037}, the [MessagePort](#)^{p1040} array being sent.

The **initMessageEvent(*type, bubbles, cancelable, data, origin, lastEventId, source, ports*)** method must initialize the event in a manner analogous to the similarly-named **initEvent()** method. [\[DOM\]](#)^{p1307}

Note

Various APIs (e.g., [WebSocket](#), [EventSource](#)^{p1026}) use the [MessageEvent](#)^{p1024} interface for their [message](#)^{p1301} event without using the [MessagePort](#)^{p1040} API.

9.2 Server-sent events § p1025

9.2.1 Introduction § p1025

This section is non-normative.

To enable servers to push data to web pages over HTTP or using dedicated server-push protocols, this specification introduces the [EventSource](#)^{p1026} interface.

Using this API consists of creating an [EventSource](#)^{p1026} object and registering an event listener.

```
var source = new EventSource('updates.cgi');
source.onmessage = function (event) {
  alert(event.data);
};
```

On the server-side, the script ("updates.cgi" in this case) sends messages in the following form, with the [text/event-stream](#)^{p1280} MIME type:

```
data: This is the first message.

data: This is the second message, it
data: has two lines.

data: This is the third message.
```

Authors can separate events by using different event types. Here is a stream that has two event types, "add" and "remove":

```
event: add
data: 73857293

event: remove
data: 2153

event: add
```

data: 113411

The script to handle such a stream would look like this (where `addHandler` and `removeHandler` are functions that take one argument, the event):

```
var source = new EventSource('updates.cgi');
source.addEventListener('add', addHandler, false);
source.addEventListener('remove', removeHandler, false);
```

The default event type is "message".

Event streams are always decoded as UTF-8. There is no way to specify another character encoding.

Event stream requests can be redirected using HTTP 301 and 307 redirects as with normal HTTP requests. Clients will reconnect if the connection is closed; a client can be told to stop reconnecting using the HTTP 204 No Content response code.

Using this API rather than emulating it using [XMLHttpRequest](#) or an [iframe](#)^{p369} allows the user agent to make better use of network resources in cases where the user agent implementer and the network operator are able to coordinate in advance. Amongst other benefits, this can result in significant savings in battery life on portable devices. This is discussed further in the section below on [connectionless push](#)^{p1032}.

9.2.2 The [EventSource](#)^{p1026} interface §^{p10}₂₆

```
IDL [Exposed=(Window,Worker)]
interface EventSource : EventTarget {
  constructor(USVString url, optional EventSourceInit eventSourceInitDict = {});

  readonly attribute USVString url;
  readonly attribute boolean withCredentials;

  // ready state
  const unsigned short CONNECTING = 0;
  const unsigned short OPEN = 1;
  const unsigned short CLOSED = 2;
  readonly attribute unsigned short readyState;

  // networking
  attribute EventHandler onopen;
  attribute EventHandler onmessage;
  attribute EventHandler onerror;
  undefined close();
};

dictionary EventSourceInit {
  boolean withCredentials = false;
};
```

Each [EventSource](#)^{p1026} object has the following associated with it:

- A **url** (a [URL record](#)). Set during construction.
- A **request**. This must initially be null.
- A **reconnection time**, in milliseconds. This must initially be an [implementation-defined](#) value, probably in the region of a few seconds.
- A **last event ID string**. This must initially be the empty string.

Apart from [url](#)^{p1026} these are not currently exposed on the [EventSource](#)^{p1026} object.

For web developers (non-normative)

source = new **EventSource**^{p1027}(*url* [, { **withCredentials**^{p1026}: true }])

Creates a new **EventSource**^{p1026} object.

url is a string giving the **URL** that will provide the event stream.

Setting **withCredentials**^{p1026} to true will set the **credentials mode** for connection requests to *url* to "include".

source.close^{p1028} ()

Aborts any instances of the **fetch** algorithm started for this **EventSource**^{p1026} object, and sets the **readyState**^{p1028} attribute to **CLOSED**^{p1028}.

source.url^{p1028}

Returns the **URL providing the event stream**^{p1026}.

source.withCredentials^{p1028}

Returns true if the **credentials mode** for connection requests to the **URL providing the event stream**^{p1026} is set to "include", and false otherwise.

source.readyState^{p1028}

Returns the state of this **EventSource**^{p1026} object's connection. It can have the values described below.

The **EventSource**(*url*, *eventSourceInitDict*) constructor, when invoked, must run these steps:

1. Let *ev* be a new **EventSource**^{p1026} object.
2. Let *settings* be *ev*'s **relevant settings object**^{p944}.
3. Let *urlRecord* be the result of **parsing** *url* with *settings*'s **API base URL**^{p937} and *settings*'s **API URL character encoding**^{p937}.
4. If *urlRecord* is failure, then throw a **"SyntaxError" DOMException**.
5. Set *ev*'s **url**^{p1026} to *urlRecord*.
6. Let *corsAttributeState* be **Anonymous**^{p93}.
7. If the value of *eventSourceInitDict*'s **withCredentials**^{p1026} member is true, then set *corsAttributeState* to **Use Credentials**^{p93} and set *ev*'s **withCredentials**^{p1028} attribute to true.
8. Let *request* be the result of **creating a potential-CORS request**^{p92} given *urlRecord*, the empty string, and *corsAttributeState*.
9. Set *request*'s **client** to *settings*.
10. User agents may **set** (**Accept**, **text/event-stream**^{p1280}) in *request*'s **header list**.
11. Set *request*'s **cache mode** to "no-store".
12. Set *ev*'s **request**^{p1026} to *request*.
13. Let *finalizeEventSourceFetch* given **response** *res* be to **finalize and report timing** with *res*, *settings*'s **global object**^{p938}, and "other".
14. Let *processEventSourceEndOfBody* given **response** *res* be the following step: if *res* is not a **network error**, then **finalizeEventSourceFetch** with *res*, and **reestablish the connection**^{p1028}.
15. **Fetch** *request* with **processResponseEndOfBody** set to *processEventSourceEndOfBody* and **processResponse** set to the following steps given **response** *res*:
 1. If *res* is an **aborted network error**, then **fail the connection**^{p1029}.
 2. Otherwise, if *res* is a **network error**, then call **finalizeEventSourceFetch** given *res*, and **reestablish the connection**^{p1028}, unless the user agent knows that to be futile, in which case the user agent may **fail the connection**^{p1029}.
 3. Otherwise, if *res*'s **status** is not 200, or if *res*'s **Content-Type**^{p92} is not **text/event-stream**^{p1280}, then **fail the connection**^{p1029}.
 4. Otherwise, **announce the connection**^{p1028} and **interpret**^{p1030} *res*'s **body** line by line.
16. Return *ev*.

The `url` attribute's getter must return the [serialization](#) of this [EventSource](#)^{p1026} object's [url](#)^{p1026}.

The `withCredentials` attribute must return the value to which it was last initialized. When the object is created, it must be initialized to false.

The `readyState` attribute represents the state of the connection. It can have the following values:

CONNECTING (numeric value 0)

The connection has not yet been established, or it was closed and the user agent is reconnecting.

OPEN (numeric value 1)

The user agent has an open connection and is dispatching events as it receives them.

CLOSED (numeric value 2)

The connection is not open, and the user agent is not trying to reconnect. Either there was a fatal error or the `close()`^{p1028} method was invoked.

When the object is created its `readyState`^{p1028} must be set to `CONNECTING`^{p1028} (0). The rules given below for handling the connection define when the value changes.

The `close()` method must abort any instances of the `fetch` algorithm started for this [EventSource](#)^{p1026} object, and must set the `readyState`^{p1028} attribute to `CLOSED`^{p1028}.

The following are the [event handlers](#)^{p980} (and their corresponding [event handler event types](#)^{p982}) that must be supported, as [event handler IDL attributes](#)^{p981}, by all objects implementing the [EventSource](#)^{p1026} interface:

Event handler ^{p980}	Event handler event type ^{p982}
<code>onopen</code>	<code>open</code> ^{p1301}
<code>onmessage</code>	<code>message</code> ^{p1301}
<code>onerror</code>	<code>error</code> ^{p1301}

9.2.3 Processing model § p10 28

When a user agent is to **announce the connection**, the user agent must [queue a task](#)^{p970} which, if the `readyState`^{p1028} attribute is set to a value other than `CLOSED`^{p1028}, sets the `readyState`^{p1028} attribute to `OPEN`^{p1028} and [fires an event](#) named `open`^{p1301} at the [EventSource](#)^{p1026} object.

When a user agent is to **reestablish the connection**, the user agent must run the following steps. These steps are run [in parallel](#)^{p42}, not as part of a [task](#)^{p969}. (The tasks that it queues, of course, are run like normal tasks and not themselves [in parallel](#)^{p42}.)

1. [Queue a task](#)^{p970} to run the following steps:
 1. If the `readyState`^{p1028} attribute is set to `CLOSED`^{p1028}, abort the task.
 2. Set the `readyState`^{p1028} attribute to `CONNECTING`^{p1028}.
 3. [Fire an event](#) named `error`^{p1301} at the [EventSource](#)^{p1026} object.
2. Wait a delay equal to the reconnection time of the event source.
3. Optionally, wait some more. In particular, if the previous attempt failed, then user agents might introduce an exponential backoff delay to avoid overloading a potentially already overloaded server. Alternatively, if the operating system has reported that there is no network connectivity, user agents might wait for the operating system to announce that the network connection has returned before retrying.
4. Wait until the aforementioned task has run, if it has not yet run.
5. [Queue a task](#)^{p970} to run the following steps:
 1. If the [EventSource](#)^{p1026} object's `readyState`^{p1028} attribute is not set to `CONNECTING`^{p1028}, then return.
 2. Let `request` be the [EventSource](#)^{p1026} object's [request](#)^{p1026}.
 3. If the [EventSource](#)^{p1026} object's [last event ID string](#)^{p1026} is not the empty string, then:

1. Let *lastEventIDValue* be the [EventSource^{p1026}](#) object's [last event ID string^{p1026}](#), [encoded as UTF-8](#).
2. [Set](#) (`Last-Event-IDp1029`, *lastEventIDValue*) in *request*'s [header list](#).
4. [Fetch request](#) and process the response obtained in this fashion, if any, as described earlier in this section.

When a user agent is to **fail the connection**, the user agent must [queue a task^{p970}](#) which, if the [readyState^{p1028}](#) attribute is set to a value other than [CLOSED^{p1028}](#), sets the [readyState^{p1028}](#) attribute to [CLOSED^{p1028}](#) and [fires an event](#) named [error^{p1301}](#) at the [EventSource^{p1026}](#) object. **Once the user agent has failed the connection^{p1029}, it does not attempt to reconnect.**

The [task source^{p969}](#) for any [tasks^{p969}](#) that are [queued^{p970}](#) by [EventSource^{p1026}](#) objects is the **remote event task source**.

9.2.4 The `Last-Event-IDp1029` header §^{p10}₂₉

The `Last-Event-ID` HTTP request header reports an [EventSource^{p1026}](#) object's [last event ID string^{p1026}](#) to the server when the user agent is to [reestablish the connection^{p1028}](#).

See [whatwg/html issue #7363](#) to define the value space better. It is essentially any UTF-8 encoded string, that does not contain U+0000 NULL, U+000A LF, or U+000D CR.

9.2.5 Parsing an event stream §^{p10}₂₉

This event stream format's [MIME type](#) is [text/event-stream^{p1280}](#).

The event stream format is as described by the `stream` production of the following ABNF, the character set for which is Unicode. [\[ABNF\]^{p1305}](#)

```
stream      = [ bom ] *event
event       = *( comment / field ) end-of-line
comment     = colon *any-char end-of-line
field       = 1*name-char [ colon [ space ] *any-char ] end-of-line
end-of-line = ( cr lf / cr / lf )

; characters
lf          = %x000A ; U+000A LINE FEED (LF)
cr          = %x000D ; U+000D CARRIAGE RETURN (CR)
space       = %x0020 ; U+0020 SPACE
colon       = %x003A ; U+003A COLON (:)
bom         = %xFEFF ; U+FEFF BYTE ORDER MARK
name-char   = %x0000-0009 / %x000B-000C / %x000E-0039 / %x003B-10FFFF
             ; a scalar_value other than U+000A LINE FEED (LF), U+000D CARRIAGE RETURN (CR), or
             U+003A COLON (:)
any-char    = %x0000-0009 / %x000B-000C / %x000E-10FFFF
             ; a scalar_value other than U+000A LINE FEED (LF) or U+000D CARRIAGE RETURN (CR)
```

Event streams in this format must always be encoded as UTF-8. [\[ENCODING\]^{p1307}](#)

Lines must be separated by either a U+000D CARRIAGE RETURN U+000A LINE FEED (CRLF) character pair, a single U+000A LINE FEED (LF) character, or a single U+000D CARRIAGE RETURN (CR) character.

Since connections established to remote servers for such resources are expected to be long-lived, UAs should ensure that appropriate buffering is used. In particular, while line buffering with lines are defined to end with a single U+000A LINE FEED (LF) character is safe, block buffering or line buffering with different expected line endings can cause delays in event dispatch.

9.2.6 Interpreting an event stream ^{§^{p10}}₃₀

Streams must be decoded using the [UTF-8 decode](#) algorithm.

Note

The [UTF-8 decode](#) algorithm strips one leading UTF-8 Byte Order Mark (BOM), if any.

The stream must then be parsed by reading everything line by line, with a U+000D CARRIAGE RETURN U+000A LINE FEED (CRLF) character pair, a single U+000A LINE FEED (LF) character not preceded by a U+000D CARRIAGE RETURN (CR) character, and a single U+000D CARRIAGE RETURN (CR) character not followed by a U+000A LINE FEED (LF) character being the ways in which a line can end.

When a stream is parsed, a *data* buffer, an *event type* buffer, and a *last event ID* buffer must be associated with it. They must be initialized to the empty string.

Lines must be processed, in the order they are received, as follows:

↪ **If the line is empty (a blank line)**

[Dispatch the event](#)^{p1030}, as defined below.

↪ **If the line starts with a U+003A COLON character (:)**

Ignore the line.

↪ **If the line contains a U+003A COLON character (:)**

Collect the characters on the line before the first U+003A COLON character (:), and let *field* be that string.

Collect the characters on the line after the first U+003A COLON character (:), and let *value* be that string. If *value* starts with a U+0020 SPACE character, remove it from *value*.

[Process the field](#)^{p1030} using the steps described below, using *field* as the field name and *value* as the field value.

↪ **Otherwise, the string is not empty but does not contain a U+003A COLON character (:)**

[Process the field](#)^{p1030} using the steps described below, using the whole line as the field name, and the empty string as the field value.

Once the end of the file is reached, any pending data must be discarded. (If the file ends in the middle of an event, before the final empty line, the incomplete event is not dispatched.)

The steps to **process the field** given a field name and a field value depend on the field name, as given in the following list. Field names must be compared literally, with no case folding performed.

↪ **If the field name is "event"**

Set the *event type* buffer to field value.

↪ **If the field name is "data"**

Append the field value to the *data* buffer, then append a single U+000A LINE FEED (LF) character to the *data* buffer.

↪ **If the field name is "id"**

If the field value does not contain U+0000 NULL, then set the *last event ID* buffer to the field value. Otherwise, ignore the field.

↪ **If the field name is "retry"**

If the field value consists of only [ASCII digits](#), then interpret the field value as an integer in base ten, and set the event stream's [reconnection time](#)^{p1026} to that integer. Otherwise, ignore the field.

↪ **Otherwise**

The field is ignored.

When the user agent is required to **dispatch the event**, the user agent must process the *data* buffer, the *event type* buffer, and the *last event ID* buffer using steps appropriate for the user agent.

For web browsers, the appropriate steps to [dispatch the event](#)^{p1030} are as follows:

1. Set the [last event ID string](#)^{p1026} of the event source to the value of the *last event ID* buffer. The buffer does not get reset, so

the [last_event_ID_string^{p1026}](#) of the event source remains set to this value until the next time it is set by the server.

2. If the *data* buffer is an empty string, set the *data* buffer and the *event type* buffer to the empty string and return.
3. If the *data* buffer's last character is a U+000A LINE FEED (LF) character, then remove the last character from the *data* buffer.
4. Let *event* be the result of [creating an event](#) using [MessageEvent^{p1024}](#), in the [relevant Realm^{p944}](#) of the [EventSource^{p1026}](#) object.
5. Initialize *event*'s *type* attribute to [message^{p1301}](#), its *data^{p1024}* attribute to *data*, its *origin^{p1025}* attribute to the [serialization^{p869}](#) of the *origin* of the event stream's final URL (i.e., the URL after redirects), and its *LastEventId^{p1025}* attribute to the [last event ID string^{p1026}](#) of the event source.
6. If the *event type* buffer has a value other than the empty string, change the *type* of the newly created event to equal the value of the *event type* buffer.
7. Set the *data* buffer and the *event type* buffer to the empty string.
8. [Queue a task^{p970}](#) which, if the *readyState^{p1028}* attribute is set to a value other than [CLOSED^{p1028}](#), [dispatches](#) the newly created event at the [EventSource^{p1026}](#) object.

Note

If an event doesn't have an "id" field, but an earlier event did set the event source's [last event ID string^{p1026}](#), then the event's [lastEventId^{p1025}](#) field will be set to the value of whatever the last seen "id" field was.

For other user agents, the appropriate steps to [dispatch the event^{p1030}](#) are implementation dependent, but at a minimum they must set the *data* and *event type* buffers to the empty string before returning.

Example

The following event stream, once followed by a blank line:

```
data: YH00
data: +2
data: 10
```

...would cause an event [message^{p1301}](#) with the interface [MessageEvent^{p1024}](#) to be dispatched on the [EventSource^{p1026}](#) object. The event's *data^{p1024}* attribute would contain the string "YH00\n+2\n10" (where "\n" represents a newline).

This could be used as follows:

```
var stocks = new EventSource("https://stocks.example.com/ticker.php");
stocks.onmessage = function (event) {
  var data = event.data.split('\n');
  updateStocks(data[0], data[1], data[2]);
};
```

...where `updateStocks()` is a function defined as:

```
function updateStocks(symbol, delta, value) { ... }
```

...or some such.

Example

The following stream contains four blocks. The first block has just a comment, and will fire nothing. The second block has two fields with names "data" and "id" respectively; an event will be fired for this block, with the data "first event", and will then set the last event ID to "1" so that if the connection died between this block and the next, the server would be sent a [Last-Event-ID^{p1029}](#) header with the value `1`. The third block fires an event with data "second event", and also has an "id" field, this time with no value, which resets the last event ID to the empty string (meaning no [Last-Event-ID^{p1029}](#) header will now be sent in the event of a reconnection being attempted). Finally, the last block just fires an event with the data " third event" (with a single leading space character). Note that the last still has to end with a blank line, the end of the stream is not enough to trigger the dispatch of the last event.

```
: test stream

data: first event
id: 1

data:second event
id

data:  third event
```

Example

The following stream fires two events:

```
data

data
data

data:
```

The first block fires events with the data set to the empty string, as would the last block if it was followed by a blank line. The middle block fires an event with the data set to a single newline character. The last block is discarded because it is not followed by a blank line.

Example

The following stream fires two identical events:

```
data: test

data: test
```

This is because the space after the colon is ignored if present.

9.2.7 Authoring notes §^{p10}₃₂

Legacy proxy servers are known to, in certain cases, drop HTTP connections after a short timeout. To protect against such proxy servers, authors can include a comment line (one starting with a ':' character) every 15 seconds or so.

Authors wishing to relate event source connections to each other or to specific documents previously served might find that relying on IP addresses doesn't work, as individual clients can have multiple IP addresses (due to having multiple proxy servers) and individual IP addresses can have multiple clients (due to sharing a proxy server). It is better to include a unique identifier in the document when it is served and then pass that identifier as part of the URL when the connection is established.

Authors are also cautioned that HTTP chunking can have unexpected negative effects on the reliability of this protocol, in particular if the chunking is done by a different layer unaware of the timing requirements. If this is a problem, chunking can be disabled for serving event streams.

Clients that support HTTP's per-server connection limitation might run into trouble when opening multiple pages from a site if each page has an [EventSource^{p1026}](#) to the same domain. Authors can avoid this using the relatively complex mechanism of using unique domain names per connection, or by allowing the user to enable or disable the [EventSource^{p1026}](#) functionality on a per-page basis, or by sharing a single [EventSource^{p1026}](#) object using a [shared worker^{p1064}](#).

9.2.8 Connectionless push and other features §^{p10}₃₂

User agents running in controlled environments, e.g. browsers on mobile handsets tied to specific carriers, may offload the management of the connection to a proxy on the network. In such a situation, the user agent for the purposes of conformance is

considered to include both the handset software and the network proxy.

Example

For example, a browser on a mobile device, after having established a connection, might detect that it is on a supporting network and request that a proxy server on the network take over the management of the connection. The timeline for such a situation might be as follows:

1. Browser connects to a remote HTTP server and requests the resource specified by the author in the [EventSource^{p1027}](#) constructor.
2. The server sends occasional messages.
3. In between two messages, the browser detects that it is idle except for the network activity involved in keeping the TCP connection alive, and decides to switch to sleep mode to save power.
4. The browser disconnects from the server.
5. The browser contacts a service on the network, and requests that the service, a "push proxy", maintain the connection instead.
6. The "push proxy" service contacts the remote HTTP server and requests the resource specified by the author in the [EventSource^{p1027}](#) constructor (possibly including a ``Last-Event-IDp1029`` HTTP header, etc.).
7. The browser allows the mobile device to go to sleep.
8. The server sends another message.
9. The "push proxy" service uses a technology such as OMA push to convey the event to the mobile device, which wakes only enough to process the event and then returns to sleep.

This can reduce the total data usage, and can therefore result in considerable power savings.

As well as implementing the existing API and [text/event-stream^{p1280}](#) wire format as defined by this specification and in more distributed ways as described above, formats of event framing defined by [other applicable specifications^{p67}](#) may be supported. This specification does not define how they are to be parsed or processed.

9.2.9 Garbage collection §^{p10} 33

While an [EventSource^{p1026}](#) object's [readyState^{p1028}](#) is [CONNECTING^{p1028}](#), and the object has one or more event listeners registered for [open^{p1301}](#), [message^{p1301}](#) or [error^{p1301}](#) events, there must be a strong reference from the [Window^{p855}](#) or [WorkerGlobalScope^{p1062}](#) object that the [EventSource^{p1026}](#) object's constructor was invoked from to the [EventSource^{p1026}](#) object itself.

While an [EventSource^{p1026}](#) object's [readyState^{p1028}](#) is [OPEN^{p1028}](#), and the object has one or more event listeners registered for [message^{p1301}](#) or [error^{p1301}](#) events, there must be a strong reference from the [Window^{p855}](#) or [WorkerGlobalScope^{p1062}](#) object that the [EventSource^{p1026}](#) object's constructor was invoked from to the [EventSource^{p1026}](#) object itself.

While there is a task queued by an [EventSource^{p1026}](#) object on the [remote event task source^{p1029}](#), there must be a strong reference from the [Window^{p855}](#) or [WorkerGlobalScope^{p1062}](#) object that the [EventSource^{p1026}](#) object's constructor was invoked from to that [EventSource^{p1026}](#) object.

If a user agent is to **forcibly close** an [EventSource^{p1026}](#) object (this happens when a [Document^{p117}](#) object goes away permanently), the user agent must abort any instances of the [fetch](#) algorithm started for this [EventSource^{p1026}](#) object, and must set the [readyState^{p1028}](#) attribute to [CLOSED^{p1028}](#).

If an [EventSource^{p1026}](#) object is garbage collected while its connection is still open, the user agent must abort any instance of the [fetch](#) algorithm opened by this [EventSource^{p1026}](#).

9.2.10 Implementation advice §^{p10} 33

This section is non-normative.

User agents are strongly urged to provide detailed diagnostic information about [EventSource^{p1026}](#) objects and their related network connections in their development consoles, to aid authors in debugging code using this API.

For example, a user agent could have a panel displaying all the [EventSource^{p1026}](#) objects a page has created, each listing the constructor's arguments, whether there was a network error, what the CORS status of the connection is and what headers were sent by the client and received from the server to lead to that status, the messages that were received and how they were parsed, and so forth.

Implementations are especially encouraged to report detailed information to their development consoles whenever an [error^{p1301}](#) event is fired, since little to no information can be made available in the events themselves.

9.3 Cross-document messaging §^{p10} 34

Web browsers, for security and privacy reasons, prevent documents in different domains from affecting each other; that is, cross-site scripting is disallowed.

While this is an important security feature, it prevents pages from different domains from communicating even when those pages are not hostile. This section introduces a messaging system that allows documents to communicate with each other regardless of their source domain, in a way designed to not enable cross-site scripting attacks.

Note

The [postMessage\(\)^{p1036}](#) API can be used as a [tracking vector](#).

9.3.1 Introduction §^{p10} 34

This section is non-normative.

Example

For example, if document A contains an [iframe^{p369}](#) element that contains document B, and script in document A calls [postMessage\(\)^{p1036}](#) on the [Window^{p855}](#) object of document B, then a message event will be fired on that object, marked as originating from the [Window^{p855}](#) of document A. The script in document A might look like:

```
var o = document.getElementsByTagName('iframe')[0];
o.contentWindow.postMessage('Hello world', 'https://b.example.org/');
```

To register an event handler for incoming events, the script would use `addEventListener()` (or similar mechanisms). For example, the script in document B might look like:

```
window.addEventListener('message', receiver, false);
function receiver(e) {
  if (e.origin == 'https://example.com') {
    if (e.data == 'Hello world') {
      e.source.postMessage('Hello', e.origin);
    } else {
      alert(e.data);
    }
  }
}
```

This script first checks the domain is the expected domain, and then looks at the message, which it either displays to the user, or responds to by sending a message back to the document which sent the message in the first place.

9.3.2 Security § p10

35

9.3.2.1 Authors § p10

35

⚠Warning!

Use of this API requires extra care to protect users from hostile entities abusing a site for their own purposes.

Authors should check the [origin^{p1025}](#) attribute to ensure that messages are only accepted from domains that they expect to receive messages from. Otherwise, bugs in the author's message handling code could be exploited by hostile sites.

Furthermore, even after checking the [origin^{p1025}](#) attribute, authors should also check that the data in question is of the expected format. Otherwise, if the source of the event has been attacked using a cross-site scripting flaw, further unchecked processing of information sent using the [postMessage\(\)^{p1036}](#) method could result in the attack being propagated into the receiver.

Authors should not use the wildcard keyword (*) in the *targetOrigin* argument in messages that contain any confidential information, as otherwise there is no way to guarantee that the message is only delivered to the recipient to which it was intended.

Authors who accept messages from any origin are encouraged to consider the risks of a denial-of-service attack. An attacker could send a high volume of messages; if the receiving page performs expensive computation or causes network traffic to be sent for each such message, the attacker's message could be multiplied into a denial-of-service attack. Authors are encouraged to employ rate limiting (only accepting a certain number of messages per minute) to make such attacks impractical.

9.3.2.2 User agents § p10

35

The integrity of this API is based on the inability for scripts of one [origin^{p868}](#) to post arbitrary events (using `dispatchEvent()` or otherwise) to objects in other origins (those that are not the [same^{p869}](#)).

Note

Implementers are urged to take extra care in the implementation of this feature. It allows authors to transmit information from one domain to another domain, which is normally disallowed for security reasons. It also requires that UAs be careful to allow access to certain properties but not others.

User agents are also encouraged to consider rate-limiting message traffic between different [origins^{p868}](#), to protect naïve sites from denial-of-service attacks.

9.3.3 Posting messages § p10

35

For web developers (non-normative)

`window.postMessagep1036(message [, options])`

Posts a message to the given window. Messages can be structured objects, e.g. nested objects and arrays, can contain JavaScript values (strings, numbers, `Date` objects, etc.), and can contain certain data objects such as `File Blob`, `FileList`, and `ArrayBuffer` objects.

Objects listed in the [transfer^{p1040}](#) member of *options* are transferred, not just cloned, meaning that they are no longer usable on the sending side.

A target origin can be specified using the [targetOrigin^{p855}](#) member of *options*. If not provided, it defaults to `"/`". This default restricts the message to same-origin targets only.

If the origin of the target window doesn't match the given target origin, the message is discarded, to avoid information leakage. To send the message to the target regardless of origin, set the target origin to `"*"`.

Throws a `"DataCloneError"` `DOMException` if *transfer* array contains duplicate objects or if *message* could not be cloned.

`window.postMessagep1036(message, targetOrigin [, transfer])`

This is an alternate version of [postMessage\(\)^{p1036}](#) where the target origin is specified as a parameter. Calling `window.postMessage(message, target, transfer)` is equivalent to `window.postMessage(message, {targetOrigin, transfer})`.

Note

When posting a message to a [Window^{p855}](#) of a [browsing context^{p840}](#) that has just been navigated to a new [Document^{p117}](#) is likely to result in the message not receiving its intended recipient: the scripts in the target [browsing context^{p840}](#) have to have had time to set up listeners for the messages. Thus, for instance, in situations where a message is to be sent to the [Window^{p855}](#) of newly created child [iframe^{p369}](#), authors are advised to have the child [Document^{p117}](#) post a message to their parent announcing their readiness to receive messages, and for the parent to wait for this message before beginning posting messages.

The **window post message steps**, given a *targetWindow*, *message*, and *options*, are as follows:

1. Let *targetRealm* be *targetWindow*'s [Realm^{p938}](#).
2. Let *incumbentSettings* be the [incumbent settings object^{p941}](#).
3. Let *targetOrigin* be *options*["[targetOrigin^{p855}](#)"].
4. If *targetOrigin* is a single U+002F SOLIDUS character (/), then set *targetOrigin* to *incumbentSettings*'s [origin^{p937}](#).
5. Otherwise, if *targetOrigin* is not a single U+002A ASTERISK character (*), then:
 1. Let *parsedURL* be the result of running the [URL parser](#) on *targetOrigin*.
 2. If *parsedURL* is failure, then throw a ["SyntaxError" DOMException](#).
 3. Set *targetOrigin* to *parsedURL*'s [origin](#).
6. Let *transfer* be *options*["[transfer^{p1040}](#)"].
7. Let *serializeWithTransferResult* be [StructuredSerializeWithTransfer^{p113}](#)(*message*, *transfer*). Rethrow any exceptions.
8. [Queue a global task^{p970}](#) on the **posted message task source** given *targetWindow* to run the following steps:
 1. If the *targetOrigin* argument is not a single literal U+002A ASTERISK character (*) and *targetWindow*'s [associated Document^{p856}](#)'s [origin](#) is not [same origin^{p869}](#) with *targetOrigin*, then return.
 2. Let *origin* be the [serialization^{p869}](#) of *incumbentSettings*'s [origin^{p937}](#).
 3. Let *source* be the [WindowProxy^{p865}](#) object corresponding to *incumbentSettings*'s [global object^{p938}](#) (a [Window^{p855}](#) object).
 4. Let *deserializeRecord* be [StructuredDeserializeWithTransfer^{p114}](#)(*serializeWithTransferResult*, *targetRealm*).
If this throws an exception, catch it, [fire an event](#) named [messageerror^{p1301}](#) at *targetWindow*, using [MessageEvent^{p1024}](#), with the [origin^{p1025}](#) attribute initialized to *origin* and the [source^{p1025}](#) attribute initialized to *source*, and then return.
 5. Let *messageClone* be *deserializeRecord*.[[Deserialized]].
 6. Let *newPorts* be a new [frozen array](#) consisting of all [MessagePort^{p1040}](#) objects in *deserializeRecord*.[[TransferredValues]], if any, maintaining their relative order.
 7. [Fire an event](#) named [message^{p1301}](#) at *targetWindow*, using [MessageEvent^{p1024}](#), with the [origin^{p1025}](#) attribute initialized to *origin*, the [source^{p1025}](#) attribute initialized to *source*, the [data^{p1024}](#) attribute initialized to *messageClone*, and the [ports^{p1025}](#) attribute initialized to *newPorts*.

The [Window^{p855}](#) interface's **postMessage(*message*, *options*)** method steps are to run the [window post message steps^{p1036}](#) given *this*, *message*, and *options*.

The [Window^{p855}](#) interface's **postMessage(*message*, *targetOrigin*, *transfer*)** method steps are to run the [window post message steps^{p1036}](#) given *this*, *message*, and «["[targetOrigin^{p855}](#)" → *targetOrigin*, "[transfer^{p1040}](#)" → *transfer*]».

9.4 Channel messaging § p10 37

9.4.1 Introduction § p10 37

This section is non-normative.

To enable independent pieces of code (e.g. running in different [browsing contexts](#)^{p840}) to communicate directly, authors can use [channel messaging](#)^{p1037}.

Communication channels in this mechanism are implemented as two-ways pipes, with a port at each end. Messages sent in one port are delivered at the other port, and vice-versa. Messages are delivered as DOM events, without interrupting or blocking running [tasks](#)^{p969}.

To create a connection (two "entangled" ports), the `MessageChannel()` constructor is called:

```
var channel = new MessageChannel();
```

One of the ports is kept as the local port, and the other port is sent to the remote code, e.g. using [postMessage\(\)](#)^{p1036}:

```
otherWindow.postMessage('hello', 'https://example.com', [channel.port2]);
```

To send messages, the [postMessage\(\)](#)^{p1042} method on the port is used:

```
channel.port1.postMessage('hello');
```

To receive messages, one listens to [message](#)^{p1301} events:

```
channel.port1.onmessage = handleMessage;
function handleMessage(event) {
  // message is in event.data
  // ...
}
```

Data sent on a port can be structured data; for example here an array of strings is passed on a [MessagePort](#)^{p1040}:

```
port1.postMessage(['hello', 'world']);
```

9.4.1.1 Examples § p10 37

This section is non-normative.

Example

In this example, two JavaScript libraries are connected to each other using [MessagePort](#)^{p1040}s. This allows the libraries to later be hosted in different frames, or in [Worker](#)^{p1070} objects, without any change to the APIs.

```
<script src="contacts.js"></script> <!-- exposes a contacts object -->
<script src="compose-mail.js"></script> <!-- exposes a composer object -->
<script>
  var channel = new MessageChannel();
  composer.addContactsProvider(channel.port1);
  contacts.registerConsumer(channel.port2);
</script>
```

Here's what the "addContactsProvider()" function's implementation could look like:

```
function addContactsProvider(port) {
  port.onmessage = function (event) {
    switch (event.data.messageType) {
      case 'search-result': handleSearchResult(event.data.results); break;
      case 'search-done': handleSearchDone(); break;
      case 'search-error': handleSearchError(event.data.message); break;
      // ...
    }
  };
};
```

Alternatively, it could be implemented as follows:

```
function addContactsProvider(port) {
  port.addEventListener('message', function (event) {
    if (event.data.messageType == 'search-result')
      handleSearchResult(event.data.results);
  });
  port.addEventListener('message', function (event) {
    if (event.data.messageType == 'search-done')
      handleSearchDone();
  });
  port.addEventListener('message', function (event) {
    if (event.data.messageType == 'search-error')
      handleSearchError(event.data.message);
  });
  // ...
  port.start();
};
```

The key difference is that when using `addEventListener()`, the `start()`^{p1042} method must also be invoked. When using `onmessage`^{p1042}, the call to `start()`^{p1042} is implied.

The `start()`^{p1042} method, whether called explicitly or implicitly (by setting `onmessage`^{p1042}), starts the flow of messages: messages posted on message ports are initially paused, so that they don't get dropped on the floor before the script has had a chance to set up its handlers.

9.4.1.2 Ports as the basis of an object-capability model on the web §^{p10}₃₈

This section is non-normative.

Ports can be viewed as a way to expose limited capabilities (in the object-capability model sense) to other actors in the system. This can either be a weak capability system, where the ports are merely used as a convenient model within a particular origin, or as a strong capability model, where they are provided by one origin *provider* as the only mechanism by which another origin *consumer* can effect change in or obtain information from *provider*.

For example, consider a situation in which a social web site embeds in one `iframe`^{p369} the user's email contacts provider (an address book site, from a second origin), and in a second `iframe`^{p369} a game (from a third origin). The outer social site and the game in the second `iframe`^{p369} cannot access anything inside the first `iframe`^{p369}; together they can only:

- `Navigate`^{p906} the `iframe`^{p369} to a new `URL`, such as the same `URL` but with a different `fragment`, causing the `Window`^{p855} in the `iframe`^{p369} to receive a `hashchange`^{p1301} event.
- Resize the `iframe`^{p369}, causing the `Window`^{p855} in the `iframe`^{p369} to receive a `resize` event.
- Send a `message`^{p1301} event to the `Window`^{p855} in the `iframe`^{p369} using the `window.postMessage()`^{p1036} API.

The contacts provider can use these methods, most particularly the third one, to provide an API that can be accessed by other origins to manipulate the user's address book. For example, it could respond to a message "add-contact Guillaume Tell <tell@pomme.example.net>" by adding the given person and email address to the user's address book.

To avoid any site on the web being able to manipulate the user's contacts, the contacts provider might only allow certain trusted sites,

such as the social site, to do this.

Now suppose the game wanted to add a contact to the user's address book, and that the social site was willing to allow it to do so on its behalf, essentially "sharing" the trust that the contacts provider had with the social site. There are several ways it could do this; most simply, it could just proxy messages between the game site and the contacts site. However, this solution has a number of difficulties: it requires the social site to either completely trust the game site not to abuse the privilege, or it requires that the social site verify each request to make sure it's not a request that it doesn't want to allow (such as adding multiple contacts, reading the contacts, or deleting them); it also requires some additional complexity if there's ever the possibility of multiple games simultaneously trying to interact with the contacts provider.

Using message channels and [MessagePort](#)^{p1040} objects, however, all of these problems can go away. When the game tells the social site that it wants to add a contact, the social site can ask the contacts provider not for it to add a contact, but for the *capability* to add a single contact. The contacts provider then creates a pair of [MessagePort](#)^{p1040} objects, and sends one of them back to the social site, who forwards it on to the game. The game and the contacts provider then have a direct connection, and the contacts provider knows to only honor a single "add contact" request, nothing else. In other words, the game has been granted the capability to add a single contact.

9.4.1.3 Ports as the basis of abstracting out service implementations § p1039

This section is non-normative.

Continuing the example from the previous section, consider the contacts provider in particular. While an initial implementation might have simply used [XMLHttpRequest](#) objects in the service's [iframe](#)^{p369}, an evolution of the service might instead want to use a [shared worker](#)^{p1072} with a single [WebSocket](#) connection.

If the initial design used [MessagePort](#)^{p1040} objects to grant capabilities, or even just to allow multiple simultaneous independent sessions, the service implementation can switch from the [XMLHttpRequests-in-each-iframe](#)^{p369} model to the shared-[WebSocket](#) model without changing the API at all: the ports on the service provider side can all be forwarded to the shared worker without it affecting the users of the API in the slightest.

9.4.2 Message channels § p1039

```
IDL [Exposed=(Window,Worker)]
interface MessageChannel {
  constructor();

  readonly attribute MessagePort port1;
  readonly attribute MessagePort port2;
};
```

For web developers (non-normative)

channel = new [MessageChannel](#)^{p1039} ()

Returns a new [MessageChannel](#)^{p1039} object with two new [MessagePort](#)^{p1040} objects.

channel.port1^{p1040}

Returns the first [MessagePort](#)^{p1040} object.

channel.port2^{p1040}

Returns the second [MessagePort](#)^{p1040} object.

A [MessageChannel](#)^{p1039} object has an associated **port 1** and an associated **port 2**, both [MessagePort](#)^{p1040} objects.

The new [MessageChannel](#)() constructor steps are:

1. Set **this**'s [port 1](#)^{p1039} to a new [MessagePort](#)^{p1040} in **this**'s [relevant Realm](#)^{p944}.
2. Set **this**'s [port 2](#)^{p1039} to a new [MessagePort](#)^{p1040} in **this**'s [relevant Realm](#)^{p944}.
3. [Entangle](#)^{p1041} **this**'s [port 1](#)^{p1039} and **this**'s [port 2](#)^{p1039}.

The `port1` getter steps are to return [this's port 1](#)^{p1039}.

The `port2` getter steps are to return [this's port 2](#)^{p1039}.

9.4.3 Message ports § p1040

Each channel has two message ports. Data sent through one port is received by the other port, and vice versa.

```
IDL [Exposed=(Window,Worker,AudioWorklet), Transferable]
interface MessagePort : EventTarget {
  undefined postMessage(any message, sequence<object> transfer);
  undefined postMessage(any message, optional StructuredSerializeOptions options = {});
  undefined start();
  undefined close();

  // event handlers
  attribute EventHandler onmessage;
  attribute EventHandler onmessageerror;
};

dictionary StructuredSerializeOptions {
  sequence<object> transfer = [];
};
```

For web developers (non-normative)

`port.postMessage`^{p1042}(*message* [, *transfer*])

`port.postMessage`^{p1042}(*message* [, { *transfer* }])

Posts a message through the channel. Objects listed in *transfer* are transferred, not just cloned, meaning that they are no longer usable on the sending side.

Throws a `"DataCloneError"` `DOMException` if *transfer* contains duplicate objects or *port*, or if *message* could not be cloned.

`port.start`^{p1042}()

Begins dispatching messages received on the port.

`port.close`^{p1042}()

Disconnects the port, so that it is no longer active.

Each `MessagePort`^{p1040} object can be entangled with another (a symmetric relationship). Each `MessagePort`^{p1040} object also has a `task source`^{p969} called the **port message queue**, initially empty. A `port message queue`^{p1040} can be enabled or disabled, and is initially disabled. Once enabled, a port can never be disabled again (though messages in the queue can get moved to another queue or removed altogether, which has much the same effect). A `MessagePort`^{p1040} also has a **has been shipped** flag, which must initially be false.

When a port's `port message queue`^{p1040} is enabled, the `event loop`^{p968} must use it as one of its `task sources`^{p969}. When a port's `relevant global object`^{p944} is a `Window`^{p855}, all `tasks`^{p969} `queued`^{p970} on its `port message queue`^{p1040} must be associated with the port's `relevant global object`^{p944}'s `associated Document`^{p856}.

Note

If the document is `fully active`^{p844}, but the event listeners all have scripts whose `settings objects`^{p945} specify `responsible documents`^{p937} that are not `fully active`^{p844}, then the messages will not be received unless and until the documents become `fully active`^{p844} again.

Each `event loop`^{p968} has a `task source`^{p969} called the **unshipped port message queue**. This is a virtual `task source`^{p969}: it must act as if it contained the `tasks`^{p969} of each `port message queue`^{p1040} of each `MessagePort`^{p1040} whose `has been shipped`^{p1040} flag is false, whose `port message queue`^{p1040} is enabled, and whose `relevant agent`^{p934}'s `event loop`^{p968} is that `event loop`^{p968}, in the order in which they were added to their respective `task source`^{p969}. When a `task`^{p969} would be removed from the `unshipped port message queue`^{p1040}, it must instead be removed from its `port message queue`^{p1040}.

When a [MessagePort](#)^{p1040}'s [has been shipped](#)^{p1040} flag is false, its [port message queue](#)^{p1040} must be ignored for the purposes of the [event loop](#)^{p968}. (The [unshipped port message queue](#)^{p1040} is used instead.)

Note

The [has been shipped](#)^{p1040} flag is set to true when a port, its twin, or the object it was cloned from, is or has been transferred. When a [MessagePort](#)^{p1040}'s [has been shipped](#)^{p1040} flag is true, its [port message queue](#)^{p1040} acts as a first-class [task source](#)^{p969}, unaffected to any [unshipped port message queue](#)^{p1040}.

When the user agent is to **entangle** two [MessagePort](#)^{p1040} objects, it must run the following steps:

1. If one of the ports is already entangled, then disentangle it and the port that it was entangled with.

Note

If those two previously entangled ports were the two ports of a [MessageChannel](#)^{p1039} object, then that [MessageChannel](#)^{p1039} object no longer represents an actual channel: the two ports in that object are no longer entangled.

2. Associate the two ports to be entangled, so that they form the two parts of a new channel. (There is no [MessageChannel](#)^{p1039} object that represents this channel.)

Two ports A and B that have gone through this step are now said to be entangled; one is entangled to the other, and vice versa.

Note

While this specification describes this process as instantaneous, implementations are more likely to implement it via message passing. As with all algorithms, the key is "merely" that the end result be indistinguishable, in a black-box sense, from the specification.

[MessagePort](#)^{p1040} objects are [transferable objects](#)^{p106}. Their [transfer steps](#)^{p106}, given *value* and *dataHolder*, are:

1. Set *value*'s [has been shipped](#)^{p1040} flag to true.
2. Set *dataHolder*.[[PortMessageQueue]] to *value*'s [port message queue](#)^{p1040}.
3. If *value* is entangled with another port *remotePort*, then:
 1. Set *remotePort*'s [has been shipped](#)^{p1040} flag to true.
 2. Set *dataHolder*.[[RemotePort]] to *remotePort*.
4. Otherwise, set *dataHolder*.[[RemotePort]] to null.

Their [transfer-receiving steps](#)^{p106}, given *dataHolder* and *value*, are:

1. Set *value*'s [has been shipped](#)^{p1040} flag to true.
2. Move all the [tasks](#)^{p969} that are to fire [message](#)^{p1301} events in *dataHolder*.[[PortMessageQueue]] to the [port message queue](#)^{p1040} of *value*, if any, leaving *value*'s [port message queue](#)^{p1040} in its initial disabled state, and, if *value*'s [relevant global object](#)^{p944} is a [Window](#)^{p855}, associating the moved [tasks](#)^{p969} with *value*'s [relevant global object](#)^{p944}'s [associated Document](#)^{p856}.
3. If *dataHolder*.[[RemotePort]] is not null, then [entangle](#)^{p1041} *dataHolder*.[[RemotePort]] and *value*. (This will disentangle *dataHolder*.[[RemotePort]] from the original port that was transferred.)

The **message port post message steps**, given *sourcePart*, *targetPort*, *message* and *options* are as follows:

1. Let *transfer* be *options*["[transfer](#)^{p1040}"].
2. If *transfer* [contains](#) *sourcePort*, then throw a "[DataCloneError](#)" [DOMException](#).
3. Let *doomed* be false.
4. If *targetPort* is not null and *transfer* [contains](#) *targetPort*, then set *doomed* to true and optionally report to a developer console that the target port was posted to itself, causing the communication channel to be lost.

5. Let `serializeWithTransferResult` be [StructuredSerializeWithTransfer](#)^{p113}(`message`, `transfer`). Rethrow any exceptions.
6. If `targetPort` is null, or if `doomed` is true, then return.
7. Add a [task](#)^{p969} that runs the following steps to the [port message queue](#)^{p1040} of `targetPort`:
 1. Let `finalTargetPort` be the [MessagePort](#)^{p1040} in whose [port message queue](#)^{p1040} the task now finds itself.

Note

This can be different from `targetPort`, if `targetPort` itself was transferred and thus all its tasks moved along with it.

2. Let `targetRealm` be `finalTargetPort`'s [relevant Realm](#)^{p944}.
3. Let `deserializeRecord` be [StructuredDeserializeWithTransfer](#)^{p114}(`serializeWithTransferResult`, `targetRealm`).
If this throws an exception, catch it, [fire an event](#) named [messageerror](#)^{p1301} at `finalTargetPort`, using [MessageEvent](#)^{p1024}, and then return.
4. Let `messageClone` be `deserializeRecord`.[[Deserialized]].
5. Let `newPorts` be a new [frozen array](#) consisting of all [MessagePort](#)^{p1040} objects in `deserializeRecord`.[[TransferredValues]], if any, maintaining their relative order.
6. [Fire an event](#) named [message](#)^{p1301} at `finalTargetPort`, using [MessageEvent](#)^{p1024}, with the [data](#)^{p1024} attribute initialized to `messageClone` and the [ports](#)^{p1025} attribute initialized to `newPorts`.

The [postMessage\(`message`, `options`\)](#) method steps are:

1. Let `targetPort` be the port with which [this](#) is entangled, if any; otherwise let it be null.
2. Run the [message port post message steps](#)^{p1041} providing [this](#), `targetPort`, `message` and `options`.

The [postMessage\(`message`, `transfer`\)](#) method steps are:

1. Let `targetPort` be the port with which [this](#) is entangled, if any; otherwise let it be null.
2. Let `options` be «["[transfer](#)^{p1040}" → `transfer`]».
3. Run the [message port post message steps](#)^{p1041} providing [this](#), `targetPort`, `message` and `options`.

The [start\(\)](#) method steps are to enable [this](#)'s [port message queue](#)^{p1040}, if it is not already enabled.

The [close\(\)](#) method steps are:

1. Set [this](#)'s [\[\[Detached\]\]](#)^{p107} internal slot value to true.
2. If [this](#) is entangled, disentangle it.

The following are the [event handlers](#)^{p980} (and their corresponding [event handler event types](#)^{p982}) that must be supported, as [event handler IDL attributes](#)^{p981}, by all objects implementing the [MessagePort](#)^{p1040} interface:

Event handler ^{p980}	Event handler event type ^{p982}
onmessage	message ^{p1301}
onmessageerror	messageerror ^{p1301}

The first time a [MessagePort](#)^{p1040} object's [onmessage](#)^{p1042} IDL attribute is set, the port's [port message queue](#)^{p1040} must be enabled, as if the [start\(\)](#)^{p1042} method had been called.

9.4.4 Broadcasting to many ports § p10 43

This section is non-normative.

Broadcasting to many ports is in principle relatively simple: keep an array of [MessagePort](#)^{p1040} objects to send messages to, and iterate through the array to send a message. However, this has one rather unfortunate effect: it prevents the ports from being garbage collected, even if the other side has gone away. To avoid this problem, implement a simple protocol whereby the other side acknowledges it still exists. If it doesn't do so after a certain amount of time, assume it's gone, close the [MessagePort](#)^{p1040} object, and let it be garbage collected.

9.4.5 Ports and garbage collection § p10 43

When a [MessagePort](#)^{p1040} object *o* is entangled, user agents must either act as if *o*'s entangled [MessagePort](#)^{p1040} object has a strong reference to *o*, or as if *o*'s [relevant global object](#)^{p944} has a strong reference to *o*.

Note

Thus, a message port can be received, given an event listener, and then forgotten, and so long as that event listener could receive a message, the channel will be maintained.

Of course, if this was to occur on both sides of the channel, then both ports could be garbage collected, since they would not be reachable from live code, despite having a strong reference to each other.

Furthermore, a [MessagePort](#)^{p1040} object must not be garbage collected while there exists an event referenced by a [task](#)^{p969} in a [task queue](#)^{p969} that is to be dispatched on that [MessagePort](#)^{p1040} object, or while the [MessagePort](#)^{p1040} object's [port message queue](#)^{p1040} is enabled and not empty.

Note

Authors are strongly encouraged to explicitly close [MessagePort](#)^{p1040} objects to disentangle them, so that their resources can be reclaimed. Creating many [MessagePort](#)^{p1040} objects and discarding them without closing them can lead to high transient memory usage since garbage collection is not necessarily performed promptly, especially for [MessagePort](#)^{p1040}s where garbage collection can involve cross-process coordination.

9.5 Broadcasting to other browsing contexts § p10 43

Pages on a single [origin](#)^{p868} opened by the same user in the same user agent but in different unrelated [browsing contexts](#)^{p840} sometimes need to send notifications to each other, for example "hey, the user logged in over here, check your credentials again".

For elaborate cases, e.g. to manage locking of shared state, to manage synchronization of resources between a server and multiple local clients, to share a [WebSocket](#) connection with a remote host, and so forth, [shared workers](#)^{p1072} are the most appropriate solution.

For simple cases, though, where a shared worker would be an unreasonable overhead, authors can use the simple channel-based broadcast mechanism described in this section.

```
IDL [Exposed=(Window,Worker)]
interface BroadcastChannel : EventTarget {
  constructor(DOMString name);

  readonly attribute DOMString name;
  undefined postMessage(any message);
  undefined close();
  attribute EventHandler onmessage;
  attribute EventHandler onmessageerror;
};
```

For web developers (non-normative)

`broadcastChannel` = new **`BroadcastChannel`**^{p1044} (*name*)

Returns a new **`BroadcastChannel`**^{p1043} object via which messages for the given channel name can be sent and received.

`broadcastChannel.name`^{p1044}

Returns the channel name (as passed to the constructor).

`broadcastChannel.postMessage`^{p1044} (*message*)

Sends the given message to other **`BroadcastChannel`**^{p1043} objects set up for this channel. Messages can be structured objects, e.g. nested objects and arrays.

`broadcastChannel.close`^{p1045} ()

Closes the **`BroadcastChannel`**^{p1043} object, opening it up to garbage collection.

A **`BroadcastChannel`**^{p1043} object has a **channel name** and a **closed flag**.

The **new `BroadcastChannel(name)`** constructor steps are:

1. Set **this's channel name**^{p1044} to *name*.
2. Set **this's closed flag**^{p1044} to false.

The **name** getter steps are to return **this's channel name**^{p1044}.

A **`BroadcastChannel`**^{p1043} object is said to be **eligible for messaging** when its **relevant global object**^{p944} is either:

- a **`Window`**^{p855} object whose **associated Document**^{p856} is **fully active**^{p844}, or
- a **`WorkerGlobalScope`**^{p1062} object whose **closing**^{p1065} flag is false and whose **worker**^{p1070} is not a **suspendable worker**^{p1066}.

The **`postMessage(message)`** method steps are:

1. If **this** is not **eligible for messaging**^{p1044}, then return.
2. If **this's closed flag**^{p1044} is true, then throw an **"InvalidStateError" DOMException**.
3. Let *serialized* be **StructuredSerialize**^{p110}(*message*). Rethrow any exceptions.
4. Let *sourceOrigin* be **this's relevant settings object**^{p944}'s **origin**^{p937}.
5. Let *sourceStorageKey* be the result of running **obtain a storage key for non-storage purposes** with **this's relevant settings object**^{p944}.
6. Let *destinations* be a list of **`BroadcastChannel`**^{p1043} objects that match the following criteria:
 - They are **eligible for messaging**^{p1044}.
 - The result of running **obtain a storage key for non-storage purposes** with their **relevant settings object**^{p944} **equals** *sourceStorageKey*.
 - Their **channel name**^{p1044} **is this's channel name**^{p1044}.
7. Remove *source* from *destinations*.
8. Sort *destinations* such that all **`BroadcastChannel`**^{p1043} objects whose **relevant agents**^{p934} are the same are sorted in creation order, oldest first. (This does not define a complete ordering. Within this constraint, user agents may sort the list in any **implementation-defined** manner.)
9. For each *destination* in *destinations*, **queue a global task**^{p970} on the **DOM manipulation task source**^{p977} given *destination's relevant global object*^{p944} to perform the following steps:
 1. If *destination's closed flag*^{p1044} is true, then abort these steps.
 2. Let *targetRealm* be *destination's relevant Realm*^{p944}.
 3. Let *data* be **StructuredDeserialize**^{p110}(*serialized*, *targetRealm*).

If this throws an exception, catch it, **fire an event** named **messageerror**^{p1301} at *destination*, using **MessageEvent**^{p1024}, with the **origin**^{p1025} attribute initialized to the **serialization**^{p869} of *sourceOrigin*, and then abort

these steps.

4. [Fire an event](#) named [message](#)^{p1301} at *destination*, using [MessageEvent](#)^{p1024}, with the [data](#)^{p1024} attribute initialized to *data* and the [origin](#)^{p1025} attribute initialized to the [serialization](#)^{p869} of *sourceOrigin*.

While a [BroadcastChannel](#)^{p1043} object whose [closed flag](#)^{p1044} is false has an event listener registered for [message](#)^{p1301} or [messageerror](#)^{p1301} events, there must be a strong reference from the [BroadcastChannel](#)^{p1043} object's [relevant global object](#)^{p944} to the [BroadcastChannel](#)^{p1043} object itself.

The [close\(\)](#) method steps are to set [this](#)'s [closed flag](#)^{p1044} to true.

Note

Authors are strongly encouraged to explicitly close [BroadcastChannel](#)^{p1043} objects when they are no longer needed, so that they can be garbage collected. Creating many [BroadcastChannel](#)^{p1043} objects and discarding them while leaving them with an event listener and without closing them can lead to an apparent memory leak, since the objects will continue to live for as long as they have an event listener (or until their page or worker is closed).

The following are the [event handlers](#)^{p980} (and their corresponding [event handler event types](#)^{p982}) that must be supported, as [event handler IDL attributes](#)^{p981}, by all objects implementing the [BroadcastChannel](#)^{p1043} interface:

Event handler ^{p980}	Event handler event type ^{p982}
onmessage	message ^{p1301}
onmessageerror	messageerror ^{p1301}

Example

Suppose a page wants to know when the user logs out, even when the user does so from another tab at the same site:

```
var authChannel = new BroadcastChannel('auth');
authChannel.onmessage = function (event) {
  if (event.data == 'logout')
    showLogout();
}

function logoutRequested() {
  // called when the user asks us to log them out
  doLogout();
  showLogout();
  authChannel.postMessage('logout');
}

function doLogout() {
  // actually log the user out (e.g. clearing cookies)
  // ...
}

function showLogout() {
  // update the UI to indicate we're logged out
  // ...
}
```

10 Web workers §^{p10} 46

10.1 Introduction §^{p10} 46

10.1.1 Scope §^{p10} 46

This section is non-normative.

This specification defines an API for running scripts in the background independently of any user interface scripts.

This allows for long-running scripts that are not interrupted by scripts that respond to clicks or other user interactions, and allows long tasks to be executed without yielding to keep the page responsive.

Workers (as these background scripts are called herein) are relatively heavy-weight, and are not intended to be used in large numbers. For example, it would be inappropriate to launch one worker for each pixel of a four megapixel image. The examples below show some appropriate uses of workers.

Generally, workers are expected to be long-lived, have a high start-up performance cost, and a high per-instance memory cost.

10.1.2 Examples §^{p10} 46

This section is non-normative.

There are a variety of uses that workers can be put to. The following subsections show various examples of this use.

10.1.2.1 A background number-crunching worker §^{p10} 46

This section is non-normative.

The simplest use of workers is for performing a computationally expensive task without interrupting the user interface.

In this example, the main document spawns a worker to (naïvely) compute prime numbers, and progressively displays the most recently found prime number.

The main page is as follows:

```
<!DOCTYPE HTML>
<html lang="en">
  <head>
    <meta charset="utf-8">
    <title>Worker example: One-core computation</title>
  </head>
  <body>
    <p>The highest prime number discovered so far is: <output id="result"></output></p>
    <script>
      var worker = new Worker('worker.js');
      worker.onmessage = function (event) {
        document.getElementById('result').textContent = event.data;
      };
    </script>
  </body>
</html>
```

communicate with the worker. That object's [onmessage](#)^{p1071} event handler allows the code to receive messages from the worker.

The worker itself is as follows:

```
var n = 1;
search: while (true) {
  n += 1;
  for (var i = 2; i <= Math.sqrt(n); i += 1)
    if (n % i == 0)
      continue search;
  // found a prime!
  postMessage(n);
}
```

The bulk of this code is simply an unoptimized search for a prime number. The [postMessage\(\)](#)^{p1064} method is used to send a message back to the page when a prime is found.

[View this example online.](#)

10.1.2.2 Using a JavaScript module as a worker ^{p10}₄₇

This section is non-normative.

All of our examples so far show workers that run [classic scripts](#)^{p945}. Workers can instead be instantiated using [module scripts](#)^{p946}, which have the usual benefits: the ability to use the JavaScript `import` statement to import other modules; strict mode by default; and top-level declarations not polluting the worker's global scope.

As the `import` statement is available, the [importScripts\(\)](#)^{p1074} method will automatically fail inside module workers.

In this example, the main document uses a worker to do off-main-thread image manipulation. It imports the filters used from another module.

The main page is as follows:

```
<!DOCTYPE html>
<html lang="en">
<meta charset="utf-8">
<title>Worker example: image decoding</title>

<p>
  <label>
    Type an image URL to decode
    <input type="url" id="image-url" list="image-list">
    <datalist id="image-list">
      <option value="https://html.spec.whatwg.org/images/drawImage.png">
      <option value="https://html.spec.whatwg.org/images/robots.jpeg">
      <option value="https://html.spec.whatwg.org/images/arcTo2.png">
    </datalist>
  </label>
</p>

<p>
  <label>
    Choose a filter to apply
    <select id="filter">
      <option value="none">none</option>
      <option value="grayscale">grayscale</option>
      <option value="brighten">brighten by 20%</option>
    </select>
  </label>
</p>
```

```

<div id="output"></div>

<script type="module">
  const worker = new Worker("worker.js", { type: "module" });
  worker.onmessage = receiveFromWorker;

  const url = document.querySelector("#image-url");
  const filter = document.querySelector("#filter");
  const output = document.querySelector("#output");

  url.oninput = updateImage;
  filter.oninput = sendToWorker;

  let imageData, context;

  function updateImage() {
    const img = new Image();
    img.src = url.value;

    img.onload = () => {
      const canvas = document.createElement("canvas");
      canvas.width = img.width;
      canvas.height = img.height;

      context = canvas.getContext("2d");
      context.drawImage(img, 0, 0);
      imageData = context.getImageData(0, 0, canvas.width, canvas.height);

      sendToWorker();
      output.replaceChildren(canvas);
    };
  }

  function sendToWorker() {
    worker.postMessage({ imageData, filter: filter.value });
  }

  function receiveFromWorker(e) {
    context.putImageData(e.data, 0, 0);
  }
</script>

```

The worker file is then:

```

import * as filters from "./filters.js";

self.onmessage = e => {
  const { imageData, filter } = e.data;
  filters[filter](imageData);
  self.postMessage(imageData, [imageData.data.buffer]);
};

```

Which imports the file filters.js:

```

export function none() {}

export function grayscale({ data: d }) {
  for (let i = 0; i < d.length; i += 4) {
    const [r, g, b] = [d[i], d[i + 1], d[i + 2]];

```

```

// CIE luminance for the RGB
// The human eye is bad at seeing red and blue, so we de-emphasize them.
d[i] = d[i + 1] = d[i + 2] = 0.2126 * r + 0.7152 * g + 0.0722 * b;
}
};

export function brighten({ data: d }) {
  for (let i = 0; i < d.length; ++i) {
    d[i] *= 1.2;
  }
};

```

[View this example online.](#)

10.1.2.3 Shared workers introduction §P10 49

MDN

This section is non-normative.

This section introduces shared workers using a Hello World example. Shared workers use slightly different APIs, since each worker can have multiple connections.

This first example shows how you connect to a worker and how a worker can send a message back to the page when it connects to it. Received messages are displayed in a log.

Here is the HTML page:

```

<!DOCTYPE HTML>
<html lang="en">
<meta charset="utf-8">
<title>Shared workers: demo 1</title>
<pre id="log">Log:</pre>
<script>
  var worker = new SharedWorker('test.js');
  var log = document.getElementById('log');
  worker.port.onmessage = function(e) { // note: not worker.onmessage!
    log.textContent += '\n' + e.data;
  }
</script>

```

Here is the JavaScript worker:

```

onconnect = function(e) {
  var port = e.ports[0];
  port.postMessage('Hello World!');
}

```

[View this example online.](#)

This second example extends the first one by changing two things: first, messages are received using `addEventListener()` instead of an [event handler IDL attribute](#)^{P981}, and second, a message is sent to the worker, causing the worker to send another message in return. Received messages are again displayed in a log.

Here is the HTML page:

```

<!DOCTYPE HTML>
<html lang="en">
<meta charset="utf-8">
<title>Shared workers: demo 2</title>
<pre id="log">Log:</pre>

```

```

<script>
  var worker = new SharedWorker('test.js');
  var log = document.getElementById('log');
  worker.port.addEventListener('message', function(e) {
    log.textContent += '\n' + e.data;
  }, false);
  worker.port.start(); // note: need this when using addEventListener
  worker.port.postMessage('ping');
</script>

```

Here is the JavaScript worker:

```

onconnect = function(e) {
  var port = e.ports[0];
  port.postMessage('Hello World!');
  port.onmessage = function(e) {
    port.postMessage('pong'); // not e.ports[0].postMessage!
    // e.target.postMessage('pong'); would work also
  }
}

```

[View this example online.](#)

Finally, the example is extended to show how two pages can connect to the same worker; in this case, the second page is merely in an [iframe^{P369}](#) on the first page, but the same principle would apply to an entirely separate page in a separate [top-level browsing context^{B844}](#).

Here is the outer HTML page:

```

<!DOCTYPE HTML>
<html lang="en">
<meta charset="utf-8">
<title>Shared workers: demo 3</title>
<pre id="log">Log:</pre>
<script>
  var worker = new SharedWorker('test.js');
  var log = document.getElementById('log');
  worker.port.addEventListener('message', function(e) {
    log.textContent += '\n' + e.data;
  }, false);
  worker.port.start();
  worker.port.postMessage('ping');
</script>
<iframe src="inner.html"></iframe>

```

Here is the inner HTML page:

```

<!DOCTYPE HTML>
<html lang="en">
<meta charset="utf-8">
<title>Shared workers: demo 3 inner frame</title>
<pre id=log>Inner log:</pre>
<script>
  var worker = new SharedWorker('test.js');
  var log = document.getElementById('log');
  worker.port.onmessage = function(e) {
    log.textContent += '\n' + e.data;
  }
</script>

```

Here is the JavaScript worker:

```
var count = 0;
onconnect = function(e) {
  count += 1;
  var port = e.ports[0];
  port.postMessage('Hello World! You are connection #' + count);
  port.onmessage = function(e) {
    port.postMessage('pong');
  }
}
```

[View this example online.](#)

10.1.2.4 Shared state using a shared worker §p10 51

This section is non-normative.

In this example, multiple windows (viewers) can be opened that are all viewing the same map. All the windows share the same map information, with a single worker coordinating all the viewers. Each viewer can move around independently, but if they set any data on the map, all the viewers are updated.

The main page isn't interesting, it merely provides a way to open the viewers:

```
<!DOCTYPE HTML>
<html lang="en">
<head>
  <meta charset="utf-8">
  <title>Workers example: Multiviewer</title>
  <script>
    function openViewer() {
      window.open('viewer.html');
    }
  </script>
</head>
<body>
  <p><button type="button" onclick="openViewer()">Open a new
  viewer</button></p>
  <p>Each viewer opens in a new window. You can have as many viewers
  as you like, they all view the same data.</p>
</body>
</html>
```

The viewer is more involved:

```
<!DOCTYPE HTML>
<html lang="en">
<head>
  <meta charset="utf-8">
  <title>Workers example: Multiviewer viewer</title>
  <script>
    var worker = new SharedWorker('worker.js', 'core');

    // CONFIGURATION
    function configure(event) {
      if (event.data.substr(0, 4) != 'cfg ') return;
      var name = event.data.substr(4).split(' ', 1)[0];
      // update display to mention our name is name
      document.getElementsByTagName('h1')[0].textContent += ' ' + name;
      // no longer need this listener
```

```

    worker.port.removeEventListener('message', configure, false);
}
worker.port.addEventListener('message', configure, false);

// MAP
function paintMap(event) {
    if (event.data.substr(0, 4) !== 'map ') return;
    var data = event.data.substr(4).split(',');
    // display tiles data[0] .. data[8]
    var canvas = document.getElementById('map');
    var context = canvas.getContext('2d');
    for (var y = 0; y < 3; y += 1) {
        for (var x = 0; x < 3; x += 1) {
            var tile = data[y * 3 + x];
            if (tile === '0')
                context.fillStyle = 'green';
            else
                context.fillStyle = 'maroon';
            context.fillRect(x * 50, y * 50, 50, 50);
        }
    }
}
worker.port.addEventListener('message', paintMap, false);

// PUBLIC CHAT
function updatePublicChat(event) {
    if (event.data.substr(0, 4) !== 'txt ') return;
    var name = event.data.substr(4).split(' ', 1)[0];
    var message = event.data.substr(4 + name.length + 1);
    // display "<name> message" in public chat
    var public = document.getElementById('public');
    var p = document.createElement('p');
    var n = document.createElement('button');
    n.textContent = '<' + name + '> ';

  </p>
</form>
<h2>Private Chat</h2>
<ul id="private"></ul>
</body>
</html>

```

There are several key things worth noting about the way the viewer is written.

Multiple listeners. Instead of a single message processing function, the code here attaches multiple event listeners, each one performing a quick check to see if it is relevant for the message. In this example it doesn't make much difference, but if multiple authors wanted to collaborate using a single port to communicate with a worker, it would allow for independent code instead of changes having to all be made to a single event handling function.

Registering event listeners in this way also allows you to unregister specific listeners when you are done with them, as is done with the `configure()` method in this example.

Finally, the worker:

```
var nextName = 0;
function getNextName() {
  // this could use more friendly names
  // but for now just return a number
  return nextName++;
}

var map = [
  [0, 0, 0, 0, 0, 0, 0],
  [1, 1, 0, 1, 0, 1, 1],
  [0, 1, 0, 1, 0, 0, 0],
  [0, 1, 0, 1, 0, 1, 1],
  [0, 0, 0, 1, 0, 0, 0],
  [1, 0, 0, 1, 1, 1, 1],
  [1, 1, 0, 1, 1, 0, 1],
];

function wrapX(x) {
  if (x < 0) return wrapX(x + map[0].length);
  if (x >= map[0].length) return wrapX(x - map[0].length);
  return x;
}

function wrapY(y) {
  if (y < 0) return wrapY(y + map.length);
  if (y >= map[0].length) return wrapY(y - map.length);
  return y;
}

function wrap(val, min, max) {
  if (val < min)
    return val + (max-min)+1;
  if (val > max)
    return val - (max-min)-1;
  return val;
}

function sendMapData(viewer) {
  var data = '';
  for (var y = viewer.y-1; y <= viewer.y+1; y += 1) {
    for (var x = viewer.x-1; x <= viewer.x+1; x += 1) {
      if (data != '')
        data += ',';
      data += map[wrap(y, 0, map[0].length-1)][wrap(x, 0, map.length-1)];
    }
  }
  viewer.port.postMessage('map ' + data);
}

var viewers = {};
onconnect = function (event) {
  var name = getNextName();
  event.ports[0]._data = { port: event.ports[0], name: name, x: 0, y: 0, };
  viewers[name] = event.ports[0]._data;
  event.ports[0].postMessage('cfg ' + name);
  event.ports[0].onmessage = getMessage;
  sendMapData(event.ports[0]._data);
}
```

```

};

function getMessage(event) {
  switch (event.data.substr(0, 4)) {
    case 'mov ':
      var direction = event.data.substr(4);
      var dx = 0;
      var dy = 0;
      switch (direction) {
        case 'up': dy = -1; break;
        case 'down': dy = 1; break;
        case 'left': dx = -1; break;
        case 'right': dx = 1; break;
      }
      event.target._data.x = wrapX(event.target._data.x + dx);
      event.target._data.y = wrapY(event.target._data.y + dy);
      sendMapData(event.target._data);
      break;
    case 'set ':
      var value = event.data.substr(4);
      map[event.target._data.y][event.target._data.x] = value;
      for (var viewer in viewers)
        sendMapData(viewers[viewer]);
      break;
    case 'txt ':
      var name = event.target._data.name;
      var message = event.data.substr(4);
      for (var viewer in viewers)
        viewers[viewer].port.postMessage('txt ' + name + ' ' + message);
      break;
    case 'msg ':
      var party1 = event.target._data;
      var party2 = viewers[event.data.substr(4).split(' ', 1)[0]];
      if (party2) {
        var channel = new MessageChannel();
        party1.port.postMessage('msg ' + party2.name, [channel.port1]);
        party2.port.postMessage('msg ' + party1.name, [channel.port2]);
      }
      break;
  }
}
}

```

Connecting to multiple pages. The script uses the [onconnect^{p1065}](#) event listener to listen for multiple connections.

Direct channels. When the worker receives a "msg" message from one viewer naming another viewer, it sets up a direct connection between the two, so that the two viewers can communicate directly without the worker having to proxy all the messages.

[View this example online.](#)

10.1.2.5 Delegation §^{p10}₅₅

This section is non-normative.

With multicore CPUs becoming prevalent, one way to obtain better performance is to split computationally expensive tasks amongst multiple workers. In this example, a computationally expensive task that is to be performed for every number from 1 to 10,000,000 is farmed out to ten subworkers.

The main page is as follows, it just reports the result:

```

<!DOCTYPE HTML>
<html lang="en">

```

```

<head>
  <meta charset="utf-8">
  <title>Worker example: Multicore computation</title>
</head>
<body>
  <p>Result: <output id="result"></output></p>
  <script>
    var worker = new Worker('worker.js');
    worker.onmessage = function (event) {
      document.getElementById('result').textContent = event.data;
    };
  </script>
</body>
</html>

```

The worker itself is as follows:

```

// settings
var num_workers = 10;
var items_per_worker = 1000000;

// start the workers
var result = 0;
var pending_workers = num_workers;
for (var i = 0; i < num_workers; i += 1) {
  var worker = new Worker('core.js');
  worker.postMessage(i * items_per_worker);
  worker.postMessage((i+1) * items_per_worker);
  worker.onmessage = storeResult;
}

// handle the results
function storeResult(event) {
  result += 1*event.data;
  pending_workers -= 1;
  if (pending_workers <= 0)
    postMessage(result); // finished!
}

```

It consists of a loop to start the subworkers, and then a handler that waits for all the subworkers to respond.

The subworkers are implemented as follows:

```

var start;
onmessage = getStart;
function getStart(event) {
  start = 1*event.data;
  onmessage = getEnd;
}

var end;
function getEnd(event) {
  end = 1*event.data;
  onmessage = null;
  work();
}

function work() {
  var result = 0;
  for (var i = start; i < end; i += 1) {
    // perform some complex calculation here
    result += 1;
  }
}

```

```

}
postMessage(result);
close();
}

```

They receive two numbers in two events, perform the computation for the range of numbers thus specified, and then report the result back to the parent.

[View this example online.](#)

10.1.2.6 Providing libraries § p10 57

This section is non-normative.

Suppose that a cryptography library is made available that provides three tasks:

Generate a public/private key pair

Takes a port, on which it will send two messages, first the public key and then the private key.

Given a plaintext and a public key, return the corresponding ciphertext

Takes a port, to which any number of messages can be sent, the first giving the public key, and the remainder giving the plaintext, each of which is encrypted and then sent on that same channel as the ciphertext. The user can close the port when it is done encrypting content.

Given a ciphertext and a private key, return the corresponding plaintext

Takes a port, to which any number of messages can be sent, the first giving the private key, and the remainder giving the ciphertext, each of which is decrypted and then sent on that same channel as the plaintext. The user can close the port when it is done decrypting content.

The library itself is as follows:

```

function handleMessage(e) {
  if (e.data == "genkeys")
    genkeys(e.ports[0]);
  else if (e.data == "encrypt")
    encrypt(e.ports[0]);
  else if (e.data == "decrypt")
    decrypt(e.ports[0]);
}

function genkeys(p) {
  var keys = _generateKeyPair();
  p.postMessage(keys[0]);
  p.postMessage(keys[1]);
}

function encrypt(p) {
  var key, state = 0;
  p.onmessage = function (e) {
    if (state == 0) {
      key = e.data;
      state = 1;
    } else {
      p.postMessage(_encrypt(key, e.data));
    }
  };
}

function decrypt(p) {
  var key, state = 0;
  p.onmessage = function (e) {

```

```

    if (state == 0) {
      key = e.data;
      state = 1;
    } else {
      p.postMessage(_decrypt(key, e.data));
    }
  };
}

// support being used as a shared worker as well as a dedicated worker
if ('onmessage' in this) // dedicated worker
  onmessage = handleMessage;
else // shared worker
  onconnect = function (e) { e.port.onmessage = handleMessage; }

// the "crypto" functions:

function _generateKeyPair() {
  return [Math.random(), Math.random()];
}

function _encrypt(k, s) {
  return 'encrypted-' + k + ' ' + s;
}

function _decrypt(k, s) {
  return s.substr(s.indexOf(' ') + 1);
}

```

Note that the crypto functions here are just stubs and don't do real cryptography.

This library could be used as follows:

```

<!DOCTYPE HTML>
<html lang="en">
<head>
<meta charset="utf-8">
<title>Worker example: Crypto library</title>
<script>
const cryptoLib = new Worker('libcrypto-v1.js'); // or could use 'libcrypto-v2.js'
function startConversation(source, message) {
  const messageChannel = new MessageChannel();
  source.postMessage(message, [messageChannel.port2]);
  return messageChannel.port1;
}
function getKeys() {
  let state = 0;
  startConversation(cryptoLib, "genkeys").onmessage = function (e) {
    if (state === 0)
      document.getElementById('public').value = e.data;
    else if (state === 1)
      document.getElementById('private').value = e.data;
    state += 1;
  };
}
function enc() {
  const port = startConversation(cryptoLib, "encrypt");
  port.postMessage(document.getElementById('public').value);
  port.postMessage(document.getElementById('input').value);
  port.onmessage = function (e) {
    document.getElementById('input').value = e.data;
  };
}

```

```

    port.close();
  };
}
function dec() {
  const port = startConversation(cryptoLib, "decrypt");
  port.postMessage(document.getElementById('private').value);
  port.postMessage(document.getElementById('input').value);
  port.onmessage = function (e) {
    document.getElementById('input').value = e.data;
    port.close();
  };
}
</script>
<style>
  textarea { display: block; }
</style>
</head>
<body onload="getKeys()">
  <fieldset>
    <legend>Keys</legend>
    <p><label>Public Key: <textarea id="public"></textarea></label></p>
    <p><label>Private Key: <textarea id="private"></textarea></label></p>
  </fieldset>
  <p><label>Input: <textarea id="input"></textarea></label></p>
  <p><button onclick="enc()">Encrypt</button> <button onclick="dec()">Decrypt</button></p>
</body>
</html>

```

A later version of the API, though, might want to offload all the crypto work onto subworkers. This could be done as follows:

```

function handleMessage(e) {
  if (e.data == "genkeys")
    genkeys(e.ports[0]);
  else if (e.data == "encrypt")
    encrypt(e.ports[0]);
  else if (e.data == "decrypt")
    decrypt(e.ports[0]);
}

function genkeys(p) {
  var generator = new Worker('libcrypto-v2-generator.js');
  generator.postMessage('', [p]);
}

function encrypt(p) {
  p.onmessage = function (e) {
    var key = e.data;
    var encryptor = new Worker('libcrypto-v2-encryptor.js');
    encryptor.postMessage(key, [p]);
  };
}

function decrypt(p) {
  p.onmessage = function (e) {
    var key = e.data;
    var decryptor = new Worker('libcrypto-v2-decryptor.js');
    decryptor.postMessage(key, [p]);
  };
}

// support being used as a shared worker as well as a dedicated worker
if ('onmessage' in this) // dedicated worker

```

```

onmessage = handleMessage;
else // shared worker
onconnect = function (e) { e.ports[0].onmessage = handleMessage };

```

The little subworkers would then be as follows.

For generating key pairs:

```

onmessage = function (e) {
  var k = _generateKeyPair();
  e.ports[0].postMessage(k[0]);
  e.ports[0].postMessage(k[1]);
  close();
}

function _generateKeyPair() {
  return [Math.random(), Math.random()];
}

```

For encrypting:

```

onmessage = function (e) {
  var key = e.data;
  e.ports[0].onmessage = function (e) {
    var s = e.data;
    postMessage(_encrypt(key, s));
  }
}

function _encrypt(k, s) {
  return 'encrypted-' + k + ' ' + s;
}

```

For decrypting:

```

onmessage = function (e) {
  var key = e.data;
  e.ports[0].onmessage = function (e) {
    var s = e.data;
    postMessage(_decrypt(key, s));
  }
}

function _decrypt(k, s) {
  return s.substr(s.indexOf(' ')+1);
}

```

Notice how the users of the API don't have to even know that this is happening — the API hasn't changed; the library can delegate to subworkers without changing its API, even though it is accepting data using message channels.

[View this example online.](#)

10.1.3 Tutorials §^{p10}₆₀

10.1.3.1 Creating a dedicated worker §^{p10}₆₀

This section is non-normative.

Creating a worker requires a URL to a JavaScript file. The `Worker()` p1071 constructor is invoked with the URL to that file as its only argument; a worker is then created and returned:

```
var worker = new Worker('helper.js');
```

If you want your worker script to be interpreted as a [module script](#)^{p946} instead of the default [classic script](#)^{p945}, you need to use a slightly different signature:

```
var worker = new Worker('helper.mjs', { type: "module" });
```

10.1.3.2 Communicating with a dedicated worker § p1061

This section is non-normative.

Dedicated workers use [MessagePort](#)^{p1040} objects behind the scenes, and thus support all the same features, such as sending structured data, transferring binary data, and transferring other ports.

To receive messages from a dedicated worker, use the [onmessage](#)^{p1071} [event handler IDL attribute](#)^{p981} on the [Worker](#)^{p1070} object:

```
worker.onmessage = function (event) { ... };
```

You can also use the [addEventListener\(\)](#) method.

Note

The implicit [MessagePort](#)^{p1040} used by dedicated workers has its [port message queue](#)^{p1040} implicitly enabled when it is created, so there is no equivalent to the [MessagePort](#)^{p1040} interface's [start\(\)](#)^{p1042} method on the [Worker](#)^{p1070} interface.

To send data to a worker, use the [postMessage\(\)](#)^{p1071} method. Structured data can be sent over this communication channel. To send [ArrayBuffer](#) objects efficiently (by transferring them rather than cloning them), list them in an array in the second argument.

```
worker.postMessage({
  operation: 'find-edges',
  input: buffer, // an ArrayBuffer object
  threshold: 0.6,
}, [buffer]);
```

To receive a message inside the worker, the [onmessage](#)^{p1064} [event handler IDL attribute](#)^{p981} is used.

```
onmessage = function (event) { ... };
```

You can again also use the [addEventListener\(\)](#) method.

In either case, the data is provided in the event object's [data](#)^{p1024} attribute.

To send messages back, you again use [postMessage\(\)](#)^{p1064}. It supports the structured data in the same manner.

```
postMessage(event.data.input, [event.data.input]); // transfer the buffer back
```

10.1.3.3 Shared workers § p1061

This section is non-normative.

Shared workers are identified by the URL of the script used to create it, optionally with an explicit name. The name allows multiple instances of a particular shared worker to be started.

Shared workers are scoped by [origin](#)^{p868}. Two different sites using the same names will not collide. However, if a page tries to use the same shared worker name as another page on the same site, but with a different script URL, it will fail.

Creating shared workers is done using the [SharedWorker\(\)](#)^{p1072} constructor. This constructor takes the URL to the script to use for its

first argument, and the name of the worker, if any, as the second argument.

```
var worker = new SharedWorker('service.js');
```

Communicating with shared workers is done with explicit [MessagePort](#)^{p1040} objects. The object returned by the [SharedWorker\(\)](#)^{p1072} constructor holds a reference to the port on its [port](#)^{p1072} attribute.

```
worker.port.onmessage = function (event) { ... };  
worker.port.postMessage('some message');  
worker.port.postMessage({ foo: 'structured', bar: ['data', 'also', 'possible']});
```

Inside the shared worker, new clients of the worker are announced using the [connect](#)^{p1301} event. The port for the new client is given by the event object's [source](#)^{p1025} attribute.

```
onconnect = function (event) {  
  var newPort = event.source;  
  // set up a listener  
  newPort.onmessage = function (event) { ... };  
  // send a message back to the port  
  newPort.postMessage('ready!'); // can also send structured data, of course  
};
```

10.2 Infrastructure §^{p10}₆₂

This standard defines two kinds of workers: dedicated workers, and shared workers. Dedicated workers, once created, are linked to their creator, but message ports can be used to communicate from a dedicated worker to multiple other browsing contexts or workers. Shared workers, on the other hand, are named, and once created any script running in the same [origin](#)^{p868} can obtain a reference to that worker and communicate with it. *Service Workers* defines a third kind. [\[SW\]](#)^{p1312}

10.2.1 The global scope §^{p10}₆₂

The global scope is the "inside" of a worker.

10.2.1.1 The [WorkerGlobalScope](#)^{p1062} common interface §^{p10}₆₂

```
IDL [Exposed=Worker]  
interface WorkerGlobalScope : EventTarget {  
  readonly attribute WorkerGlobalScope self;  
  readonly attribute WorkerLocation location;  
  readonly attribute WorkerNavigator navigator;  
  undefined importScripts(USVString... urls);  
  
  attribute OnErrorHandler onerror;  
  attribute EventHandler onlanguagechange;  
  attribute EventHandler onoffline;  
  attribute EventHandler ononline;  
  attribute EventHandler onrejectionhandled;  
  attribute EventHandler onunhandledrejection;  
};
```

[WorkerGlobalScope](#)^{p1062} serves as the base class for specific types of worker global scope objects, including [DedicatedWorkerGlobalScope](#)^{p1064}, [SharedWorkerGlobalScope](#)^{p1064}, and [ServiceWorkerGlobalScope](#).

A [WorkerGlobalScope](#)^{p1062} object has an associated **owner set** (a **set** of [Document](#)^{p117} and [WorkerGlobalScope](#)^{p1062} objects). It is

initially empty and populated when the worker is created or obtained.

Note

It is a [set](#), instead of a single owner, to accommodate [SharedWorkerGlobalScope](#)^{p1064} objects.

A [WorkerGlobalScope](#)^{p1062} object has an associated **type** ("classic" or "module"). It is set during creation.

A [WorkerGlobalScope](#)^{p1062} object has an associated **url** (null or a [URL](#)). It is initially null.

A [WorkerGlobalScope](#)^{p1062} object has an associated **name** (a string). It is set during creation.

Note

The [name](#)^{p1063} can have different semantics for each subclass of [WorkerGlobalScope](#)^{p1062}. For [DedicatedWorkerGlobalScope](#)^{p1064} instances, it is simply a developer-supplied name, useful mostly for debugging purposes. For [SharedWorkerGlobalScope](#)^{p1064} instances, it allows obtaining a reference to a common shared worker via the [SharedWorker\(\)](#)^{p1072} constructor. For [ServiceWorkerGlobalScope](#) objects, it doesn't make sense (and as such isn't exposed through the JavaScript API at all).

A [WorkerGlobalScope](#)^{p1062} object has an associated **policy container** (a [policy container](#)^{p886}). It is initially a new [policy container](#)^{p886}.

A [WorkerGlobalScope](#)^{p1062} object has an associated **embedder policy** (an [embedder policy](#)^{p884}).

A [WorkerGlobalScope](#)^{p1062} object has an associated **module map**. It is a [module map](#)^{p965}, initially empty.

A [WorkerGlobalScope](#)^{p1062} object has an associated **cross-origin isolated capability** boolean. It is initially false.

For web developers (non-normative)

[workerGlobal.self](#)^{p1063}

Returns [workerGlobal](#).

[workerGlobal.location](#)^{p1063}

Returns [workerGlobal](#)'s [WorkerLocation](#)^{p1075} object.

[workerGlobal.navigator](#)^{p1074}

Returns [workerGlobal](#)'s [WorkerNavigator](#)^{p1075} object.

[workerGlobal.importScripts](#)^{p1074} (...urls)

Fetches each [URL](#) in [urls](#), executes them one-by-one in the order they are passed, and then returns (or throws if something went amiss).

The **self** attribute must return the [WorkerGlobalScope](#)^{p1062} object itself.

The **location** attribute must return the [WorkerLocation](#)^{p1075} object whose associated [WorkerGlobalScope object](#)^{p1075} is the [WorkerGlobalScope](#)^{p1062} object.

Note

While the [WorkerLocation](#)^{p1075} object is created after the [WorkerGlobalScope](#)^{p1062} object, this is not problematic as it cannot be observed from script.

The following are the [event handlers](#)^{p980} (and their corresponding [event handler event types](#)^{p982}) that must be supported, as [event handler IDL attributes](#)^{p981}, by objects implementing the [WorkerGlobalScope](#)^{p1062} interface:

Event handler ^{p980}	Event handler event type ^{p982}
onerror	error ^{p1301}
onlanguagechange	languagechange ^{p1301}
onoffline	offline ^{p1301}
ononline	online ^{p1301}
onrejectionhandled	rejectionhandled ^{p1302}
onunhandledrejection	unhandledrejection ^{p1302}

10.2.1.2 Dedicated workers and the [DedicatedWorkerGlobalScope](#)^{p1064} interface §^{p10} 64

```
IDL [Global=(Worker,DedicatedWorker),Exposed=DedicatedWorker]
interface DedicatedWorkerGlobalScope : WorkerGlobalScope {
  [Replaceable] readonly attribute DOMString name;

  undefined postMessage(any message, sequence<object> transfer);
  undefined postMessage(any message, optional StructuredSerializeOptions options = {});

  undefined close();

  attribute EventHandler onmessage;
  attribute EventHandler onmessageerror;
};
```

[DedicatedWorkerGlobalScope](#)^{p1064} objects act as if they had an implicit [MessagePort](#)^{p1040} associated with them. This port is part of a channel that is set up when the worker is created, but it is not exposed. This object must never be garbage collected before the [DedicatedWorkerGlobalScope](#)^{p1064} object.

All messages received by that port must immediately be retargeted at the [DedicatedWorkerGlobalScope](#)^{p1064} object.

For web developers (non-normative)

[dedicatedWorkerGlobal.name](#)^{p1064}

Returns [dedicatedWorkerGlobal](#)'s [name](#)^{p1063}, i.e. the value given to the [Worker](#)^{p1070} constructor. Primarily useful for debugging.

[dedicatedWorkerGlobal.postMessage](#)^{p1064}(message [, transfer])

[dedicatedWorkerGlobal.postMessage](#)^{p1064}(message [, { transfer^{p1040} }])

Clones *message* and transmits it to the [Worker](#)^{p1070} object associated with [dedicatedWorkerGlobal](#). *transfer* can be passed as a list of objects that are to be transferred rather than cloned.

[dedicatedWorkerGlobal.close](#)^{p1064}()

Aborts [dedicatedWorkerGlobal](#).

The [name](#) getter steps are to return [this](#)'s [name](#)^{p1063}. Its value represents the name given to the worker using the [Worker](#)^{p1070} constructor, used primarily for debugging purposes.

The [postMessage\(message, transfer\)](#) and [postMessage\(message, options\)](#) methods on [DedicatedWorkerGlobalScope](#)^{p1064} objects act as if, when invoked, it immediately invoked the respective [postMessage\(message, transfer\)](#)^{p1042} and [postMessage\(message, options\)](#)^{p1042} on the port, with the same arguments, and returned the same return value.

To **close a worker**, given a *workerGlobal*, run these steps:

1. Discard any [tasks](#)^{p969} that have been added to *workerGlobal*'s [relevant agent](#)^{p934}'s [event loop](#)^{p968}'s [task queues](#)^{p969}.
2. Set *workerGlobal*'s [closing](#)^{p1065} flag to true. (This prevents any further tasks from being queued.)

The [close\(\)](#) method steps are to [close a worker](#)^{p1064} given [this](#).

The following are the [event handlers](#)^{p980} (and their corresponding [event handler event types](#)^{p982}) that must be supported, as [event handler IDL attributes](#)^{p981}, by objects implementing the [DedicatedWorkerGlobalScope](#)^{p1064} interface:

Event handler ^{p980}	Event handler event type ^{p982}
onmessage	message ^{p1301}
onmessageerror	messageerror ^{p1301}

10.2.1.3 Shared workers and the [SharedWorkerGlobalScope](#)^{p1064} interface §^{p10} 64

```
IDL [Global=(Worker,SharedWorker),Exposed=SharedWorker]
interface SharedWorkerGlobalScope : WorkerGlobalScope {
```

```
[Replaceable] readonly attribute DOMString name;

undefined close();

attribute EventHandler onconnect;
};
```

A [SharedWorkerGlobalScope](#)^{p1064} object has an associated **constructor origin**, **constructor url**, and **credentials**. They are initialized when the [SharedWorkerGlobalScope](#)^{p1064} object is created, in the [run a worker](#)^{p1066} algorithm.

Shared workers receive message ports through [connect](#)^{p1301} events on their [SharedWorkerGlobalScope](#)^{p1064} object for each connection.

For web developers (non-normative)

[sharedWorkerGlobal.name](#)^{p1065}

Returns *sharedWorkerGlobal*'s [name](#)^{p1063}, i.e. the value given to the [SharedWorker](#)^{p1072} constructor. Multiple [SharedWorker](#)^{p1072} objects can correspond to the same shared worker (and [SharedWorkerGlobalScope](#)^{p1064}), by reusing the same name.

[sharedWorkerGlobal.close](#)^{p1065} ()

Aborts *sharedWorkerGlobal*.

The **name** getter steps are to return [this's name](#)^{p1063}. Its value represents the name that can be used to obtain a reference to the worker using the [SharedWorker](#)^{p1072} constructor.

The **close()** method steps are to [close a worker](#)^{p1064} given [this](#).

The following are the [event handlers](#)^{p980} (and their corresponding [event handler event types](#)^{p982}) that must be supported, as [event handler IDL attributes](#)^{p981}, by objects implementing the [SharedWorkerGlobalScope](#)^{p1064} interface:

Event handler ^{p980}	Event handler event type ^{p982}
onconnect	connect ^{p1301}

MDN

10.2.2 The event loop §^{p10}₆₅

A [worker event loop](#)^{p968}'s [task queues](#)^{p969} only have events, callbacks, and networking activity as [tasks](#)^{p969}. These [worker event loops](#)^{p968} are created by the [run a worker](#)^{p1066} algorithm.

Each [WorkerGlobalScope](#)^{p1062} object has a **closing** flag, which must be initially false, but which can get set to true by the algorithms in the processing model section below.

Once the [WorkerGlobalScope](#)^{p1062}'s [closing](#)^{p1065} flag is set to true, the [event loop](#)^{p968}'s [task queues](#)^{p969} must discard any further [tasks](#)^{p969} that would be added to them (tasks already on the queue are unaffected except where otherwise specified). Effectively, once the [closing](#)^{p1065} flag is true, timers stop firing, notifications for all pending background operations are dropped, etc.

10.2.3 The worker's lifetime §^{p10}₆₅

Workers communicate with other workers and with [browsing contexts](#)^{p840} through [message channels](#)^{p1037} and their [MessagePort](#)^{p1040} objects.

Each [WorkerGlobalScope](#)^{p1062} object *worker global scope* has a list of **the worker's ports**, which consists of all the [MessagePort](#)^{p1040} objects that are entangled with another port and that have one (but only one) port owned by *worker global scope*. This list includes the implicit [MessagePort](#)^{p1040} in the case of [dedicated workers](#)^{p1064}.

Given an [environment settings object](#)^{p937} *o* when creating or obtaining a worker, the **relevant owner to add** depends on the type of [global object](#)^{p938} specified by *o*. If *o* specifies a [global object](#)^{p938} that is a [WorkerGlobalScope](#)^{p1062} object (i.e., if we are creating a nested dedicated worker), then the relevant owner is that global object. Otherwise, *o* specifies a [global object](#)^{p938} that is a [Window](#)^{p855}

object, and the relevant owner is the [responsible document](#)^{p937} specified by *o*.

A worker is said to be a **permissible worker** if its [WorkerGlobalScope](#)^{p1062}'s [owner set](#)^{p1062} is not [empty](#) or:

- its [owner set](#)^{p1062} has been [empty](#) for no more than a short [implementation-defined](#) timeout value,
- its [WorkerGlobalScope](#)^{p1062} object is a [SharedWorkerGlobalScope](#)^{p1064} object (i.e., the worker is a shared worker), and
- the user agent has a [browsing context](#)^{p840} whose [Document](#)^{p117} object is not [completely loaded](#)^{p927}.

Note

The second part of this definition allows a shared worker to survive for a short time while a page is loading, in case that page is going to contact the shared worker again. This can be used by user agents as a way to avoid the cost of restarting a shared worker used by a site when the user is navigating from page to page within that site.

A worker is said to be an **active needed worker** if any its [owners](#)^{p1062} are either [Document](#)^{p117} objects that are [fully active](#)^{p844} or [active needed workers](#)^{p1066}.

A worker is said to be a **protected worker** if it is an [active needed worker](#)^{p1066} and either it has outstanding timers, database transactions, or network connections, or its list of [the worker's ports](#)^{p1065} is not empty, or its [WorkerGlobalScope](#)^{p1062} is actually a [SharedWorkerGlobalScope](#)^{p1064} object (i.e., the worker is a shared worker).

A worker is said to be a **suspendable worker** if it is not an [active needed worker](#)^{p1066} but it is a [permissible worker](#)^{p1066}.

10.2.4 Processing model ^{p10}₆₆

When a user agent is to **run a worker** for a script with [Worker](#)^{p1070} or [SharedWorker](#)^{p1072} object *worker*, [URL](#) *url*, [environment settings object](#)^{p937} *outside settings*, [MessagePort](#)^{p1040} *outside port*, and a [WorkerOptions](#)^{p1070} dictionary *options*, it must run the following steps.

1. Let *is shared* be true if *worker* is a [SharedWorker](#)^{p1072} object, and false otherwise.
2. Let *owner* be the [relevant owner to add](#)^{p1065} given *outside settings*.
3. Let *parent worker global scope* be null.
4. If *owner* is a [WorkerGlobalScope](#)^{p1062} object (i.e., we are creating a nested dedicated worker), then set *parent worker global scope* to *owner*.
5. Let *unsafeWorkerCreationTime* be the [unsafe shared current time](#).
6. Let *agent* be the result of [obtaining a dedicated/shared worker agent](#)^{p935} given *outside settings* and *is shared*. Run the rest of these steps in that agent.
7. Let *realm execution context* be the result of [creating a new JavaScript realm](#)^{p938} given *agent* and the following customizations:
 - For the global object, if *is shared* is true, create a new [SharedWorkerGlobalScope](#)^{p1064} object. Otherwise, create a new [DedicatedWorkerGlobalScope](#)^{p1064} object.
8. Let *worker global scope* be the [global object](#)^{p938} of *realm execution context*'s Realm component.

Note

This is the [DedicatedWorkerGlobalScope](#)^{p1064} or [SharedWorkerGlobalScope](#)^{p1064} object created in the previous step.

9. [Set up a worker environment settings object](#)^{p1069} with *realm execution context*, *outside settings*, and *unsafeWorkerCreationTime*, and let *inside settings* be the result.
10. Set *worker global scope*'s [name](#)^{p1063} to the value of *options*'s *name* member.
11. [Append](#) *owner* to *worker global scope*'s [owner set](#)^{p1062}.
12. If *is shared* is true, then:
 1. Set *worker global scope*'s [constructor origin](#)^{p1065} to *outside settings*'s [origin](#)^{p937}.

2. Set *worker global scope*'s [constructor url](#)^{p1065} to *url*.
 3. Set *worker global scope*'s [type](#)^{p1063} to the value of *options*'s *type* member.
 4. Set *worker global scope*'s [credentials](#)^{p1065} to the value of *options*'s *credentials* member.
13. Let *destination* be "sharedworker" if *is shared* is true, and "worker" otherwise.
14. Obtain *script* by switching on the value of *options*'s *type* member:
- ↳ "classic"
 - [Fetch a classic worker script](#)^{p948} given *url*, *outside settings*, *destination*, and *inside settings*.
 - ↳ "module"
 - [Fetch a module worker script graph](#)^{p950} given *url*, *outside settings*, *destination*, the value of the *credentials* member of *options*, and *inside settings*.

In both cases, to [perform the fetch](#)^{p947} given *request*, perform the following steps if the [is top-level](#)^{p947} flag is set:

1. Set *request*'s [reserved client](#) to *inside settings*.
2. [Fetch](#) *request*, and asynchronously wait to run the remaining steps as part of *fetch*'s [process response](#) for the [response](#) *response*.
3. Set *worker global scope*'s [url](#)^{p1063} to *response*'s *url*.
4. [Initialize worker global scope's policy container](#)^{p887} given *worker global scope*, *response*, and *inside settings*.
5. If the [Run CSP initialization for a global object](#) algorithm returns "Blocked" when executed upon *worker global scope*, set *response* to a [network error](#). [[CSP](#)]^{p1305}
6. If *worker global scope*'s [embedder policy](#)^{p1063}'s [value](#)^{p885} is [compatible with cross-origin isolation](#)^{p884} and *is shared* is true, then set *agent*'s [agent cluster](#)'s [cross-origin isolation mode](#)^{p934} to "[logical](#)^{p848}" or "[concrete](#)^{p848}". The one chosen is [implementation-defined](#).

This really ought to be set when the agent cluster is created, which requires a redesign of this section.

7. If the result of [checking a global object's embedder policy](#)^{p886} with *worker global scope*, *outside settings*, and *response* is false, then set *response* to a [network error](#).
8. Set *worker global scope*'s [cross-origin isolated capability](#)^{p1063} to true if *agent*'s [agent cluster](#)'s [cross-origin isolation mode](#)^{p934} is "[concrete](#)^{p848}".
9. If *is shared* is false and *owner*'s [cross-origin isolated capability](#)^{p937} is false, then set *worker global scope*'s [cross-origin isolated capability](#)^{p1063} to false.
10. If *is shared* is false and *response*'s *url*'s [scheme](#) is "data", then set *worker global scope*'s [cross-origin isolated capability](#)^{p1063} to false.

Note

This is a conservative default for now, while we figure out how workers in general, and [data:](#) URL workers in particular (which are cross-origin from their owner), will be treated in the context of permissions policies. See [w3c/webappsec-permissions-policy issue #207](#) for more details.

11. Asynchronously complete the [perform the fetch](#)^{p947} steps with *response*.

If the algorithm asynchronously completes with null or with a *script* whose [error to rethrow](#)^{p945} is non-null, then:

1. [Queue a global task](#)^{p970} on the [DOM manipulation task source](#)^{p977} given *worker*'s [relevant global object](#)^{p944} to [fire an event](#) named [error](#)^{p1301} at *worker*.
2. Run the [environment discarding steps](#)^{p937} for *inside settings*.
3. Return.

Otherwise, continue the rest of these steps after the algorithm's asynchronous completion, with *script* being the asynchronous completion value.

15. Associate *worker* with *worker global scope*.

16. Let *inside port* be a [new MessagePort^{p1049}](#) object in *inside settings*'s [Realm^{p938}](#).
17. Associate *inside port* with *worker global scope*.
18. [Entangle^{p1041}](#) *outside port* and *inside port*.
19. Create a new [WorkerLocation^{p1075}](#) object and associate it with *worker global scope*.
20. **Closing orphan workers:** Start monitoring the worker such that no sooner than it stops being a [protected worker^{p1066}](#), and no later than it stops being a [permissible worker^{p1066}](#), *worker global scope*'s [closing^{p1065}](#) flag is set to true.
21. **Suspending workers:** Start monitoring the worker, such that whenever *worker global scope*'s [closing^{p1065}](#) flag is false and the worker is a [suspendable worker^{p1066}](#), the user agent suspends execution of script in that worker until such time as either the [closing^{p1065}](#) flag switches to true or the worker stops being a [suspendable worker^{p1066}](#).
22. Set *inside settings*'s [execution ready flag^{p937}](#).
23. If *script* is a [classic script^{p945}](#), then [run the classic script^{p956}](#) *script*. Otherwise, it is a [module script^{p946}](#); [run the module script^{p957}](#) *script*.

Note

In addition to the usual possibilities of returning a value or failing due to an exception, this could be [prematurely aborted^{p958}](#) by the [terminate a worker^{p1068}](#) algorithm defined below.

24. Enable *outside port*'s [port message queue^{p1040}](#).
25. If *is shared* is false, enable the [port message queue^{p1040}](#) of the worker's implicit port.
26. If *is shared* is true, then [queue a global task^{p970}](#) on [DOM manipulation task source^{p977}](#) given *worker global scope* to [fire an event](#) named [connect^{p1301}](#) at *worker global scope*, using [MessageEvent^{p1024}](#), with the [data^{p1024}](#) attribute initialized to the empty string, the [ports^{p1025}](#) attribute initialized to a new [frozen array](#) containing *inside port*, and the [source^{p1025}](#) attribute initialized to *inside port*.
27. Enable the [client message queue](#) of the [ServiceWorkerContainer](#) object whose associated [service worker client](#) is *worker global scope*'s [relevant settings object^{p944}](#).
28. **Event loop:** Run the [responsible event loop^{p938}](#) specified by *inside settings* until it is destroyed.

Note

The handling of events or the execution of callbacks by [tasks^{p969}](#) run by the [event loop^{p968}](#) might get [prematurely aborted^{p958}](#) by the [terminate a worker^{p1068}](#) algorithm defined below.

Note

The worker processing model remains on this step until the event loop is destroyed, which happens after the [closing^{p1065}](#) flag is set to true, as described in the [event loop^{p968}](#) processing model.

29. [Clear](#) the *worker global scope*'s [map of active timers^{p999}](#).
30. Disentangle all the ports in the list of [the worker's ports^{p1065}](#).
31. [Empty](#) *worker global scope*'s [owner set^{p1062}](#).

When a user agent is to **terminate a worker** it must run the following steps [in parallel^{p42}](#) with the worker's main loop (the "[run a worker^{p1066}](#)" processing model defined above):

1. Set the worker's [WorkerGlobalScope^{p1062}](#) object's [closing^{p1065}](#) flag to true.
2. If there are any [tasks^{p969}](#) queued in the [WorkerGlobalScope^{p1062}](#) object's [relevant agent^{p934}](#)'s [event loop^{p968}](#)'s [task queues^{p969}](#), discard them without processing them.
3. [Abort the script^{p958}](#) currently running in the worker.
4. If the worker's [WorkerGlobalScope^{p1062}](#) object is actually a [DedicatedWorkerGlobalScope^{p1064}](#) object (i.e. the worker is a dedicated worker), then empty the [port message queue^{p1040}](#) of the port that the worker's implicit port is entangled with.

User agents may invoke the [terminate a worker^{p1068}](#) algorithm when a worker stops being an [active needed worker^{p1066}](#) and the worker

continues executing even after its [closing](#)^{p1065} flag was set to true.

10.2.5 Runtime script errors § p10 69

Whenever an uncaught runtime script error occurs in one of the worker's scripts, if the error did not occur while handling a previous script error, the user agent must [report the error](#)^{p959} for that [script](#)^{p945}, with the position (line number and column number) where the error occurred, using the [WorkerGlobalScope](#)^{p1062} object as the target.

For shared workers, if the error is still [not handled](#)^{p959} afterwards, the error may be reported to a developer console.

For dedicated workers, if the error is still [not handled](#)^{p959} afterwards, the user agent must [queue a task](#)^{p970} to run these steps:

1. Let *notHandled* be the result of [firing an event](#) named [error](#)^{p1301} at the [Worker](#)^{p1070} object associated with the worker, using [ErrorEvent](#)^{p960}, with the [cancelable](#) attribute initialized to true, the [message](#)^{p960}, [filename](#)^{p960}, [lineno](#)^{p960}, and [colno](#)^{p960} attributes initialized appropriately, and the [error](#)^{p960} attribute initialized to null.
2. If *notHandled* is true, then the user agent must act as if the uncaught runtime script error had occurred in the global scope that the [Worker](#)^{p1070} object is in, thus repeating the entire runtime script error reporting process one level up.

If the implicit port connecting the worker to its [Worker](#)^{p1070} object has been disentangled (i.e. if the parent worker has been terminated), then the user agent must act as if the [Worker](#)^{p1070} object had no [error](#)^{p1301} event handler and as if that worker's [onerror](#)^{p1063} attribute was null, but must otherwise act as described above.

Note

Thus, error reports propagate up to the chain of dedicated workers up to the original [Document](#)^{p117}, even if some of the workers along this chain have been terminated and garbage collected.

The [task source](#)^{p969} for the task mentioned above is the [DOM manipulation task source](#)^{p977}.

10.2.6 Creating workers § p10 69

10.2.6.1 The [AbstractWorker](#)^{p1069} mixin § p10 69

```
IDL interface mixin AbstractWorker {  
  attribute EventHandler onerror;  
};
```

The following are the [event handlers](#)^{p980} (and their corresponding [event handler event types](#)^{p982}) that must be supported, as [event handler IDL attributes](#)^{p981}, by objects implementing the [AbstractWorker](#)^{p1069} interface:

Event handler ^{p980}	Event handler event type ^{p982}
onerror	error ^{p1301}

10.2.6.2 Script settings for workers § p10 69

To **set up a worker environment settings object**, given a [JavaScript execution context](#) *execution context*, an [environment settings object](#)^{p937} *outside settings*, and a number *unsafeWorkerCreationTime*:

1. Let *inherited origin* be *outside settings*'s [origin](#)^{p937}.
2. Let *realm* be the value of *execution context*'s Realm component.
3. Let *worker global scope* be *realm*'s [global object](#)^{p938}.
4. Let *settings object* be a new [environment settings object](#)^{p937} whose algorithms are defined as follows:

The [realm execution context](#)^{p937}

Return *execution context*.

The [module map](#)^{p937}

Return *worker global scope's* [module map](#)^{p1063}.

The [responsible document](#)^{p937}

Not applicable (the [responsible event loop](#)^{p938} is not a [window event loop](#)^{p968}).

The [API URL character encoding](#)^{p937}

Return [UTF-8](#).

The [API base URL](#)^{p937}

Return *worker global scope's* [url](#)^{p1063}.

The [origin](#)^{p937}

Return a unique [opaque origin](#)^{p868} if *worker global scope's* [url](#)^{p1063}'s [scheme](#) is "data", and *inherited origin* otherwise.

The [policy container](#)^{p937}

Return *worker global scope's* [policy container](#)^{p1063}.

The [cross-origin isolated capability](#)^{p937}

Return *worker global scope's* [cross-origin isolated capability](#)^{p1063}.

The [time origin](#)^{p937}

Return the result of [coarsening](#) *unsafeWorkerCreationTime* with *worker global scope's* [cross-origin isolated capability](#)^{p1063}.

5. Set *settings object's* [id](#)^{p936} to a new unique opaque string, [creation URL](#)^{p936} to *worker global scope's* [url](#), [top-level creation URL](#)^{p936} to null, [target browsing context](#)^{p937} to null, and [active service worker](#)^{p937} to null.
6. If *worker global scope* is a [DedicatedWorkerGlobalScope](#)^{p1064} object, then set *settings object's* [top-level origin](#)^{p936} to *outside settings's* [top-level origin](#)^{p936}.
7. Otherwise, set *settings object's* [top-level origin](#)^{p936} to an [implementation-defined](#) value.

See [Client-Side Storage Partitioning](#) for the latest on properly defining this.

8. Set *realm's* `[[HostDefined]]` field to *settings object*.
9. Return *settings object*.

**10.2.6.3 Dedicated workers and the [Worker](#)^{p1070} interface** §^{p10}
70

```
IDL [Exposed=(Window,DedicatedWorker,SharedWorker)]
interface Worker : EventTarget {
  constructor(USVString scriptURL, optional WorkerOptions options = {});

  undefined terminate();

  undefined postMessage(any message, sequence<object> transfer);
  undefined postMessage(any message, optional StructuredSerializeOptions options = {});
  attribute EventHandler onmessage;
  attribute EventHandler onmessageerror;
};

dictionary WorkerOptions {
  WorkerType type = "classic";
  RequestCredentials credentials = "same-origin"; // credentials is only used if type is "module"
  DOMString name = "";
};
```

```
enum WorkerType { "classic", "module" };

Worker includes AbstractWorker;
```

For web developers (non-normative)

worker = new **Worker**^{p1071}(*scriptURL* [, *options*])

Returns a new **Worker**^{p1070} object. *scriptURL* will be fetched and executed in the background, creating a new global environment for which *worker* represents the communication channel. *options* can be used to define the **name**^{p1063} of that global environment via the *name* option, primarily for debugging purposes. It can also ensure this new global environment supports JavaScript modules (specify *type*: "module"), and if that is specified, can also be used to specify how *scriptURL* is fetched through the *credentials* option.

worker.terminate^{p1071}()

Aborts *worker's* associated global environment.

worker.postMessage^{p1071}(*message* [, *transfer*])

worker.postMessage^{p1071}(*message* [, { **transfer**^{p1040} }])

Clones *message* and transmits it to *worker's* global environment. *transfer* can be passed as a list of objects that are to be transferred rather than cloned.

The **terminate()** method, when invoked, must cause the **terminate a worker**^{p1068} algorithm to be run on the worker with which the object is associated.

Worker^{p1070} objects act as if they had an implicit **MessagePort**^{p1040} associated with them. This port is part of a channel that is set up when the worker is created, but it is not exposed. This object must never be garbage collected before the **Worker**^{p1070} object.

All messages received by that port must immediately be retargeted at the **Worker**^{p1070} object.

The **postMessage(message, transfer)** and **postMessage(message, options)** methods on **Worker**^{p1070} objects act as if, when invoked, they immediately invoked the respective **postMessage(message, transfer)**^{p1042} and **postMessage(message, options)**^{p1042} on the port, with the same arguments, and returned the same return value.

Example

The **postMessage()**^{p1071} method's first argument can be structured data:

```
worker.postMessage({opcode: 'activate', device: 1938, parameters: [23, 102]});
```

The following are the **event handlers**^{p980} (and their corresponding **event handler event types**^{p982}) that must be supported, as **event handler IDL attributes**^{p981}, by objects implementing the **Worker**^{p1070} interface:

Event handler ^{p980}	Event handler event type ^{p982}
onmessage	message ^{p1301}
onmessageerror	messageerror ^{p1301}

When the **Worker(scriptURL, options)** constructor is invoked, the user agent must run the following steps:

1. The user agent may throw a **"SecurityError" DOMException** if the request violates a policy decision (e.g. if the user agent is configured to not allow the page to start dedicated workers).
2. Let *outside settings* be the **current settings object**^{p944}.
3. **Parse**^{p91} the *scriptURL* argument relative to *outside settings*.
4. If this fails, throw a **"SyntaxError" DOMException**.
5. Let *worker URL* be the **resulting URL record**^{p91}.

Note

Any **same-origin**^{p869} URL (including **blob:** URLs) can be used. **data:** URLs can also be used, but they create a worker with

an [opaque origin](#)^{p868}.

- Let *worker* be a new [Worker](#)^{p1070} object.
- Let *outside port* be a new [MessagePort](#)^{p1040} in *outside settings*'s [Realm](#)^{p938}.
- Associate the *outside port* with *worker*.
- Run this step [in parallel](#)^{p42}:
 - [Run a worker](#)^{p1066} given *worker*, *worker URL*, *outside settings*, *outside port*, and *options*.
- Return *worker*.

10.2.6.4 Shared workers and the [SharedWorker](#)^{p1072} interface §^{p10}₇₂

MDN

```
IDL [Exposed=Window]
interface SharedWorker : EventTarget {
  constructor(USVString scriptURL, optional (DOMString or WorkerOptions) options = {});

  readonly attribute MessagePort port;
};
SharedWorker includes AbstractWorker;
```

For web developers (non-normative)

***sharedWorker* = new SharedWorker^{p1072}(*scriptURL* [, *name*])**

Returns a new [SharedWorker](#)^{p1072} object. *scriptURL* will be fetched and executed in the background, creating a new global environment for which *sharedWorker* represents the communication channel. *name* can be used to define the [name](#)^{p1063} of that global environment.

***sharedWorker* = new SharedWorker^{p1072}(*scriptURL* [, *options*])**

Returns a new [SharedWorker](#)^{p1072} object. *scriptURL* will be fetched and executed in the background, creating a new global environment for which *sharedWorker* represents the communication channel. *options* can be used to define the [name](#)^{p1063} of that global environment via the *name* option. It can also ensure this new global environment supports JavaScript modules (specify *type*: "module"), and if that is specified, can also be used to specify how *scriptURL* is fetched through the *credentials* option. Note that attempting to construct a shared worker with *options* whose *type* or *credentials* values mismatch an existing shared worker will cause the returned *sharedWorker* to fire an error event and not connect to the existing shared worker.

***sharedWorker*.port^{p1072}**

Returns *sharedWorker*'s [MessagePort](#)^{p1040} object which can be used to communicate with the global environment.

The **port** attribute must return the value it was assigned by the object's constructor. It represents the [MessagePort](#)^{p1040} for communicating with the shared worker.

A user agent has an associated **shared worker manager** which is the result of [starting a new parallel queue](#)^{p42}.

Note

Each user agent has a single [shared worker manager](#)^{p1072} for simplicity. Implementations could use one per [origin](#)^{p868}; that would not be observably different and enables more concurrency.

When the [SharedWorker](#)(*scriptURL*, *options*) constructor is invoked:

- Optionally, throw a ["SecurityError" DOMException](#) if the request violates a policy decision (e.g. if the user agent is configured to not allow the page to start shared workers).
- If *options* is a [DOMString](#), set *options* to a new [WorkerOptions](#)^{p1070} dictionary whose *name* member is set to the value of *options* and whose other members are set to their default values.
- Let *outside settings* be the [current settings object](#)^{p944}.

4. [Parse](#)^{p91} `scriptURL` relative to `outside settings`.
5. If this fails, throw a `"SyntaxError" DOMException`.
6. Otherwise, let `urlRecord` be the [resulting URL record](#)^{p91}.

Note

Any [same-origin](#)^{p869} URL (including `blob:` URLs) can be used. `data:` URLs can also be used, but they create a worker with an [opaque origin](#)^{p868}.

7. Let `worker` be a new [SharedWorker](#)^{p1072} object.
8. Let `outside port` be a new [MessagePort](#)^{p1040} in `outside settings`'s [Realm](#)^{p938}.
9. Assign `outside port` to the `port`^{p1072} attribute of `worker`.
10. Let `callerIsSecureContext` be true if `outside settings` is a [secure context](#)^{p944}; otherwise, false.
11. [Enqueue the following steps](#)^{p42} to the [shared worker manager](#)^{p1072}:
 1. Let `worker global scope` be null.
 2. If there exists a [SharedWorkerGlobalScope](#)^{p1064} object whose `closing`^{p1065} flag is false, `constructor origin`^{p1065} is [same origin](#)^{p869} with `outside settings`'s `origin`^{p937}, `constructor url`^{p1065} equals `urlRecord`, and `name`^{p1063} equals the value of `options`'s `name` member, then set `worker global scope` to that [SharedWorkerGlobalScope](#)^{p1064} object.

Note

`data:` URLs create a worker with an [opaque origin](#)^{p868}. Both the `constructor origin`^{p1065} and `constructor url`^{p1065} are compared so the same `data:` URL can be used within an `origin`^{p868} to get to the same [SharedWorkerGlobalScope](#)^{p1064} object, but cannot be used to bypass the [same origin](#)^{p869} restriction.

3. If `worker global scope` is not null, but the user agent has been configured to disallow communication between the worker represented by the `worker global scope` and the [scripts](#)^{p945} whose `settings object`^{p945} is `outside settings`, then set `worker global scope` to null.

Note

For example, a user agent could have a development mode that isolates a particular [top-level browsing context](#)^{p844} from all other pages, and scripts in that development mode could be blocked from connecting to shared workers running in the normal browser mode.

4. If `worker global scope` is not null, then check if `worker global scope`'s `type`^{p1063} and `credentials`^{p1065} match the `options` values. If not, [queue a task](#)^{p970} to [fire an event](#) named `error`^{p1301} and abort these steps.
 5. If `worker global scope` is not null, then run these subsubsteps:
 1. Let `settings object` be the [relevant settings object](#)^{p944} for `worker global scope`.
 2. Let `workerIsSecureContext` be true if `settings object` is a [secure context](#)^{p944}; otherwise, false.
 3. If `workerIsSecureContext` is not `callerIsSecureContext`, then [queue a task](#)^{p970} to [fire an event](#) named `error`^{p1301} at `worker` and abort these steps. [\[SECURE-CONTEXTS\]](#)^{p1311}
 4. Associate `worker` with `worker global scope`.
 5. Let `inside port` be a new [MessagePort](#)^{p1040} in `settings object`'s [Realm](#)^{p938}.
 6. [Entangle](#)^{p1041} `outside port` and `inside port`.
 7. [Queue a task](#)^{p970}, using the [DOM manipulation task source](#)^{p977}, to [fire an event](#) named `connect`^{p1301} at `worker global scope`, using [MessageEvent](#)^{p1024}, with the `data`^{p1024} attribute initialized to the empty string, the `ports`^{p1025} attribute initialized to a new [frozen array](#) containing only `inside port`, and the `source`^{p1025} attribute initialized to `inside port`.
 8. [Append](#) the [relevant owner to add](#)^{p1065} given `outside settings` to `worker global scope`'s `owner set`^{p1062}.
 6. Otherwise, [in parallel](#)^{p42}, [run a worker](#)^{p1066} given `worker`, `urlRecord`, `outside settings`, `outside port`, and `options`.
12. Return `worker`.

10.2.7 Concurrent hardware capabilities § p10 74

```
IDL interface mixin NavigatorConcurrentHardware {  
  readonly attribute unsigned long long hardwareConcurrency;  
};
```

For web developers (non-normative)

`self.navigatorp1806.hardwareConcurrencyp1074`

Returns the number of logical processors potentially available to the user agent.

The `navigator.hardwareConcurrency` attribute's getter must return a number between 1 and the number of logical processors potentially available to the user agent. If this cannot be determined, the getter must return 1.

User agents should err toward exposing the number of logical processors available, using lower values only in cases where there are user-agent specific limits in place (such as a limitation on the number of [workers^{p1070}](#) that can be created) or when the user agent desires to limit fingerprinting possibilities.

10.3 APIs available to workers § p10 74

10.3.1 Importing scripts and libraries § p10 74

The `importScripts(...urls)` method steps are to [import scripts into worker global scope^{p1074}](#) given `this` and `urls`.

To [import scripts into worker global scope](#), given a [WorkerGlobalScope^{p1062}](#) object *worker global scope* and a sequence<DOMString> `urls`, run these steps. The algorithm may optionally be customized by supplying custom [perform the fetch^{p947}](#) hooks, which if provided will be used when invoking [fetch a classic worker-imported script^{p948}](#).

1. If *worker global scope*'s [type^{p1063}](#) is "module", throw a `TypeError` exception.
2. Let *settings object* be the [current settings object^{p944}](#).
3. If `urls` is empty, return.
4. [Parse^{p91}](#) each value in `urls` relative to *settings object*. If any fail, throw a `"SyntaxError" DOMException`.
5. For each `url` in the [resulting URL records^{p91}](#), run these substeps:
 1. [Fetch a classic worker-imported script^{p948}](#) given `url` and *settings object*, passing along any custom [perform the fetch^{p947}](#) steps provided. If this succeeds, let *script* be the result. Otherwise, rethrow the exception.
 2. [Run the classic script^{p956}](#) *script*, with the rethrow errors argument set to true.

Note

script will run until it either returns, fails to parse, fails to catch an exception, or gets [prematurely aborted^{p958}](#) by the [terminate a worker^{p1068}](#) algorithm defined above.

If an exception was thrown or if the script was [prematurely aborted^{p958}](#), then abort all these steps, letting the exception or aborting continue to be processed by the calling [script^{p945}](#).

Note

Service Workers is an example of a specification that runs this algorithm with its own options for the [perform the fetch^{p947}](#) hook. [\[SW\]^{p1312}](#)

10.3.2 The `WorkerNavigatorp1075` interface § p10 74

The `navigator` attribute of the [WorkerGlobalScope^{p1062}](#) interface must return an instance of the [WorkerNavigator^{p1075}](#) interface, which represents the identity and state of the user agent (the client):

```
IDL [Exposed=Worker]
interface WorkerNavigator {};
WorkerNavigator includes NavigatorID;
WorkerNavigator includes NavigatorLanguage;
WorkerNavigator includes NavigatorOnLine;
WorkerNavigator includes NavigatorConcurrentHardware;
```

10.3.3 The [WorkerLocation](#)^{p1075} interface §^{p10} 75

```
IDL [Exposed=Worker]
interface WorkerLocation {
  stringifier readonly attribute USVString href;
  readonly attribute USVString origin;
  readonly attribute USVString protocol;
  readonly attribute USVString host;
  readonly attribute USVString hostname;
  readonly attribute USVString port;
  readonly attribute USVString pathname;
  readonly attribute USVString search;
  readonly attribute USVString hash;
};
```

A [WorkerLocation](#)^{p1075} object has an associated [WorkerGlobalScope](#) object (a [WorkerGlobalScope](#)^{p1062} object).

The **href** getter steps are to return [this's WorkerGlobalScope object](#)^{p1075}'s [url](#)^{p1063}, [serialized](#).

The **origin** getter steps are to return the [serialization](#)^{p869} of [this's WorkerGlobalScope object](#)^{p1075}'s [url](#)^{p1063}'s [origin](#).

The **protocol** getter steps are to return [this's WorkerGlobalScope object](#)^{p1075}'s [url](#)^{p1063}'s [scheme](#), followed by ":".

The **host** getter steps are:

1. Let *url* be [this's WorkerGlobalScope object](#)^{p1075}'s [url](#)^{p1063}.
2. If *url*'s [host](#) is null, return the empty string.
3. If *url*'s [port](#) is null, return *url*'s [host](#), [serialized](#).
4. Return *url*'s [host](#), [serialized](#), followed by ":" and *url*'s [port](#), [serialized](#).

The **hostname** getter steps are:

1. Let *host* be [this's WorkerGlobalScope object](#)^{p1075}'s [url](#)^{p1063}'s [host](#).
2. If *host* is null, return the empty string.
3. Return *host*, [serialized](#).

The **port** getter steps are:

1. Let *port* be [this's WorkerGlobalScope object](#)^{p1075}'s [url](#)^{p1063}'s [port](#).
2. If *port* is null, return the empty string.
3. Return *port*, [serialized](#).

The **pathname** getter steps are to return the result of [URL path serializing](#) [this's WorkerGlobalScope object](#)^{p1075}'s [url](#)^{p1063}.

The **search** getter steps are:

1. Let *query* be [this's WorkerGlobalScope object](#)^{p1075}'s [url](#)^{p1063}'s [query](#).
2. If *query* is either null or the empty string, return the empty string.

MDN

MDN

MDN

MDN

MDN

MDN

MDN

MDN

MDN

MDN

3. Return "?", followed by *query*.

The **hash** getter steps are:

1. Let *fragment* be [this's WorkerGlobalScope object](#)^{p1075}'s [url](#)^{p1063}'s [fragment](#).
2. If *fragment* is either null or the empty string, return the empty string.
3. Return "#", followed by *fragment*.

11 Worklets § p10 77

11.1 Introduction § p10 77

This section is non-normative.

Worklets are a piece of specification infrastructure which can be used for running scripts independent of the main JavaScript execution environment, while not requiring any particular implementation model.

The worklet infrastructure specified here cannot be used directly by web developers. Instead, other specifications build upon it to create directly-usable worklet types, specialized for running in particular parts of the browser implementation pipeline.

11.1.1 Motivations § p10 77

This section is non-normative.

Allowing extension points to rendering, or other sensitive parts of the implementation pipeline such as audio output, is difficult. If extension points were done with full access to the APIs available on [Window](#)^{p855}, engines would need to abandon previously-held assumptions for what could happen in the middle of those phases. For example, during the layout phase, rendering engines assume that no DOM will be modified.

Additionally, defining extension points in the [Window](#)^{p855} environment would restrict user agents to performing work in the same thread as the [Window](#)^{p855} object. (Unless implementations added complex, high-overhead infrastructure to allow thread-safe APIs, as well as thread-joining guarantees.)

Worklets are designed to allow extension points, while keeping guarantees that user agents currently rely on. This is done through new global environments, based on subclasses of [WorkletGlobalScope](#)^{p1080}.

Worklets are similar to web workers. However, they:

- Are thread-agnostic. That is, they are not designed to run on a dedicated separate thread, like each worker is. Implementations can run worklets wherever they choose (including on the main thread).
- Are able to have multiple duplicate instances of the global scope created, for the purpose of parallelism.
- Do not use an event-based API. Instead, classes are registered on the global scope, whose methods are invoked by the user agent.
- Have a reduced API surface on the global scope.
- Have a lifetime for their [global object](#)^{p938} which is defined by other specifications, often in an [implementation-defined](#) manner.

As worklets have relatively high overhead, they are best used sparingly. Due to this, a given [WorkletGlobalScope](#)^{p1080} is expected to be shared between multiple separate scripts. (This is similar to how a single [Window](#)^{p855} is shared between multiple separate scripts.)

Worklets are a general technology that serve different use cases. Some worklets, such as those defined in *CSS Painting API*, provide extension points intended for stateless, idempotent, and short-running computations, which have special considerations as described in the next couple of sections. Others, such as those defined in *Web Audio API*, are used for stateful, long-running operations. [\[CSSPAINT\]](#)^{p1307} [\[WEBAUDIO\]](#)^{p1312}

11.1.2 Code idempotence § p10 77

Some specifications which use worklets are intended to allow user agents to parallelize work over multiple threads, or to move work between threads as required. In these specifications, user agents might invoke methods on a web-developer-provided class in an [implementation-defined](#) order.

As a result of this, to prevent interoperability issues, authors who register classes on such [WorkletGlobalScope](#)^{p1080}s should make their

code idempotent. That is, a method or set of methods on the class should produce the same output given a particular input.

This specification uses the following techniques in order to encourage authors to write code in an idempotent way:

- No reference to the global object is available (i.e., there is no counterpart to `self` on `WorkletGlobalScope`).

Although this was the intention when worklets were first specified, the introduction of `globalThis` has made it no longer true. See [issue #6059](#) for more discussion.

- Code is loaded as a `module script`, which results in the code being executed in strict mode and with no shared `this` referencing the global proxy.

Together, these restrictions help prevent two different scripts from sharing state using properties of the `global object`.

Additionally, specifications which use worklets and intend to allow `implementation-defined` behavior must obey the following:

- They must require user agents to always have at least two `WorkletGlobalScope` instances per `Worklet`, and randomly assign a method or set of methods on a class to a particular `WorkletGlobalScope` instance. These specifications may provide an opt-out under memory constraints.
- These specifications must allow user agents to create and destroy instances of their `WorkletGlobalScope` subclasses at any time.

11.1.3 Speculative evaluation §^{p10}₇₈

Some specifications which use worklets can invoke methods on a web-developer-provided class based on the state of the user agent. To increase concurrency between threads, a user agent may invoke a method speculatively, based on potential future states.

In these specifications, user agents might invoke such methods at any time, and with any arguments, not just ones corresponding to the current state of the user agent. The results of such speculative evaluations are not displayed immediately, but can be cached for use if the user agent state matches the speculated state. This can increase the concurrency between the user agent and worklet threads.

As a result of this, to prevent interoperability risks between user agents, authors who register classes on such `WorkletGlobalScope`s should make their code stateless. That is, the only effect of invoking a method should be its result, and not any side effects such as updating mutable state.

The same techniques which encourage `code idempotence` also encourage authors to write stateless code.

11.2 Examples §^{p10}₇₈

This section is non-normative.

For these examples, we'll use a fake worklet. The `Window` object provides two `Worklet` instances, which each run code in their own collection of `FakeWorkletGlobalScope`s:

```
IDL partial interface Window {
  [SameObject, SecureContext] readonly attribute Worklet fakeWorklet1;
  [SameObject, SecureContext] readonly attribute Worklet fakeWorklet2;
};
```

Each `Window` has two `Worklet` instances, **fake worklet 1** and **fake worklet 2**. Both of these have their `worklet global scope type` set to `FakeWorkletGlobalScope`, and their `worklet destination type` set to "fakeworklet". User agents should create at least two `FakeWorkletGlobalScope` instances per worklet.

Note

"fakeworklet" is not actually a valid `destination` per Fetch. But this illustrates how real worklets would generally have their own worklet-type-specific destination. [\[FETCH\]^{p1308}](#)

The `fakeWorklet1` getter steps are to return [this's `fake worklet 1`](#)^{p1078}.

The `fakeWorklet2` getter steps are to return [this's `fake worklet 2`](#)^{p1078}.

```
IDL [Global=(Worklet,FakeWorklet),
     Exposed=FakeWorklet,
     SecureContext]
interface FakeWorkletGlobalScope : WorkletGlobalScope {
  undefined registerFake(DOMString type, Function classConstructor);
};
```

Each [FakeWorkletGlobalScope](#)^{p1079} has a **registered class constructors map**, which is an [ordered map](#), initially empty.

The `registerFake(type, classConstructor)` method steps are to set [this's `registered class constructors map`](#)^{p1079}[*type*] to *classConstructor*.

11.2.1 Loading scripts §^{p10}₇₉

This section is non-normative.

To load scripts into [fake worklet 1](#)^{p1078}, a web developer would write:

```
window.fakeWorklet1.addModule('script1.mjs');
window.fakeWorklet1.addModule('script2.mjs');
```

Note that which script finishes fetching and runs first is dependent on network timing: it could be either `script1.mjs` or `script2.mjs`. This generally won't matter for well-written scripts intended to be loaded in worklets, if they follow the suggestions about preparing for [speculative evaluation](#)^{p1078}.

If a web developer wants to perform a task only after the scripts have successfully run and loaded into some worklets, they could write:

```
Promise.all([
  window.fakeWorklet1.addModule('script1.mjs'),
  window.fakeWorklet2.addModule('script2.mjs')
]).then(() => {
  // Do something which relies on those scripts being loaded.
});
```

Another important point about script-loading is that loaded scripts can be run in multiple [WorkletGlobalScope](#)^{p1080}s per [Worklet](#)^{p1083}, as discussed in the section on [code idempotence](#)^{p1077}. In particular, the specification above for [fake worklet 1](#)^{p1078} and [fake worklet 2](#)^{p1078} require this. So, consider a scenario such as the following:

```
// script.mjs
console.log("Hello from a FakeWorkletGlobalScope!");
```

```
// app.mjs
window.fakeWorklet1.addModule("script.mjs");
```

This could result in output such as the following from a user agent's console:

```
[fakeWorklet1#1] Hello from a FakeWorkletGlobalScope!
[fakeWorklet1#4] Hello from a FakeWorkletGlobalScope!
[fakeWorklet1#2] Hello from a FakeWorkletGlobalScope!
[fakeWorklet1#3] Hello from a FakeWorkletGlobalScope!
```

If the user agent at some point decided to kill and restart the third instance of [FakeWorkletGlobalScope](#)^{p1079}, the console would again print `[fakeWorklet1#3] Hello from a FakeWorkletGlobalScope!` when this occurs.

11.2.2 Registering a class and invoking its methods § p1080

This section is non-normative.

Let's say that one of the intended usages of our fake worklet by web developers is to allow them to customize the highly-complex process of boolean negation. They might register their customization as follows:

```
// script.mjs
registerFake('negation-processor', class {
  process(arg) {
    return !arg;
  }
});
```

```
// app.mjs
window.fakeWorklet1.addModule("script.mjs");
```

To make use of such registered classes, the specification for fake worklets could define a **find the opposite of true** algorithm, given a [Worklet](#)^{p1083} *worklet*:

1. Optionally, [create a worklet global scope](#)^{p1081} for *worklet*.
2. Let *workletGlobalScope* be one of *worklet*'s [global scopes](#)^{p1083}, chosen in an [implementation-defined](#) manner.
3. Let *classConstructor* be *workletGlobalScope*'s [registered class constructors map](#)^{p1079}["negation-processor"].
4. Let *classInstance* be the result of [constructing](#) *classConstructor*, with no arguments.
5. Let *function* be [Get](#)(*classInstance*, "process"). Rethrow any exceptions.
6. Let *callback* be the result of [converting](#) *function* to a Web IDL [Function](#) instance.
7. Return the result of [invoking](#) *callback* with the arguments « true » and with *classInstance* as the [callback this value](#).

Note

Another, perhaps better, specification architecture would be to extract the "process" property and convert it into a [Function](#) at registration time, as part of the [registerFake\(\)](#)^{p1079} method steps.

11.3 Infrastructure § p1080

11.3.1 The global scope § p1080

Subclasses of [WorkletGlobalScope](#)^{p1080} are used to create [global objects](#)^{p938} wherein code loaded into a particular [Worklet](#)^{p1083} can execute.

```
IDL [Exposed=Worklet, SecureContext]
interface WorkletGlobalScope {};
```

Note

Other specifications are intended to subclass [WorkletGlobalScope](#)^{p1080}, adding APIs to register a class, as well as other APIs specific for their worklet type.

Each [WorkletGlobalScope](#)^{p1080} has an associated **module map**. It is a [module map](#)^{p965}, initially empty.

11.3.1.1 Agents and event loops § p10 81

This section is non-normative.

Each [WorkletGlobalScope](#)^{p1080} is contained in its own [worklet agent](#)^{p933}, which has its corresponding [event loop](#)^{p968}. However, in practice, implementation of these agents and event loops is expected to be different from most others.

A [worklet agent](#)^{p933} exists for each [WorkletGlobalScope](#)^{p1080} since, in theory, an implementation could use a separate thread for each [WorkletGlobalScope](#)^{p1080} instance, and allowing this level of parallelism is best done using agents. However, because their `[[CanBlock]]` value is false, there is no requirement that agents and threads are one-to-one. This allows implementations the freedom to execute scripts loaded into a worklet on any thread, including one running code from other agents with `[[CanBlock]]` of false, such as the thread of a [similar-origin window agent](#)^{p933} ("the main thread"). Contrast this with [dedicated worker agents](#)^{p933}, whose true value for `[[CanBlock]]` effectively requires them to get a dedicated operating system thread.

Worklet [event loops](#)^{p968} are also somewhat special. They are only used for [tasks](#)^{p969} associated with [addModule\(\)](#)^{p1084}, tasks wherein the user agent invokes author-defined methods, and [microtasks](#)^{p970}. Thus, even though the [event loop processing model](#)^{p971} specifies that all event loops run continuously, implementations can achieve observably-equivalent results using a simpler strategy, which just [invokes](#) author-provided methods and then relies on that process to [perform a microtask checkpoint](#)^{p974}.

11.3.1.2 Creation and termination § p10 81

To create a worklet global scope for a [Worklet](#)^{p1083} *worklet*:

1. Let *outsideSettings* be *worklet*'s [relevant settings object](#)^{p944}.
2. Let *agent* be the result of [obtaining a worklet agent](#)^{p935} given *outsideSettings*. Run the rest of these steps in that agent.
3. Let *realmExecutionContext* be the result of [creating a new JavaScript realm](#)^{p938} given *agent* and the following customizations:
 - For the global object, create a new object of the type given by *worklet*'s [worklet global scope type](#)^{p1083}.
4. Let *workletGlobalScope* be the [global object](#)^{p938} of *realmExecutionContext*'s Realm component.
5. Let *insideSettings* be the result of [setting up a worklet environment settings object](#)^{p1082} given *realmExecutionContext* and *outsideSettings*.
6. [For each](#) *moduleURL* of *worklet*'s [added modules list](#)^{p1083}:
 1. [Fetch a worklet script graph](#)^{p950} given *moduleURL*, *insideSettings*, *worklet*'s [worklet destination type](#)^{p1083}, what credentials mode?, *insideSettings*, and *worklet*'s [module responses map](#)^{p1083}. Wait until the algorithm asynchronously completes with *script*.

Note

This will not actually perform a network request, as it will just reuse [responses](#) from *worklet*'s [module responses map](#)^{p1083}. The main purpose of this step is to create a new *workletGlobalScope*-specific [module script](#)^{p946} from the [response](#).

2. Assert: *script* is not null, since the fetch succeeded and the source text was successfully parsed when *worklet*'s [module responses map](#)^{p1083} was initially populated with *moduleURL*.
3. [Run a module script](#)^{p957} given *script*.
7. [Append](#) *workletGlobalScope* to *outsideSettings*'s [global object](#)^{p938}'s [associated Document](#)^{p856}'s [worklet global scopes](#)^{p1085}.
8. [Append](#) *workletGlobalScope* to *worklet*'s [global scopes](#)^{p1083}.
9. Run the [responsible event loop](#)^{p938} specified by *insideSettings*.

To terminate a worklet global scope given a [WorkletGlobalScope](#)^{p1080} *workletGlobalScope*:

1. Let *eventLoop* be *workletGlobalScope*'s [relevant agent](#)^{p934}'s [event loop](#)^{p968}.
2. If there are any [tasks](#)^{p969} queued in *eventLoop*'s [task queues](#)^{p969}, discard them without processing them.
3. Wait for *eventLoop* to complete the [currently running task](#)^{p970}.

4. If the previous step doesn't complete within an [implementation-defined](#) period of time, then [abort the script](#)^{p958} currently running in the worklet.
5. Destroy `eventLoop`.
6. [Remove](#) `workletGlobalScope` from the [global scopes](#)^{p1083} of the [Worklet](#)^{p1083} whose [global scopes](#)^{p1083} contains `workletGlobalScope`.
7. [Remove](#) `workletGlobalScope` from the [worklet global scopes](#)^{p1085} of the [Document](#)^{p117} whose [worklet global scopes](#)^{p1085} contains `workletGlobalScope`.

11.3.1.3 Script settings for worklets §^{p10}₈₂

To **set up a worklet environment settings object**, given a [JavaScript execution context](#) `executionContext` and an [environment settings object](#)^{p937} `outsideSettings`:

1. Let `origin` be a unique [opaque origin](#)^{p868}.
2. Let `inheritedAPIBaseURL` be `outsideSettings`'s [API base URL](#)^{p937}.
3. Let `inheritedPolicyContainer` be a [clone](#)^{p887} of `outsideSettings`'s [policy container](#)^{p937}.
4. Let `realm` be the value of `executionContext`'s Realm component.
5. Let `workletGlobalScope` be `realm`'s [global object](#)^{p938}.
6. Let `settingsObject` be a new [environment settings object](#)^{p937} whose algorithms are defined as follows:

The [realm execution context](#)^{p937}

Return `executionContext`.

The [module map](#)^{p937}

Return `workletGlobalScope`'s [module map](#)^{p1080}.

The [responsible document](#)^{p937}

Not applicable (the [responsible event loop](#)^{p938} is not a [window event loop](#)^{p968}).

The [API URL character encoding](#)^{p937}

Return [UTF-8](#).

The [API base URL](#)^{p937}

Return `inheritedAPIBaseURL`.

Note

Unlike workers or other globals derived from a single resource, worklets have no primary resource; instead, multiple scripts, each with their own URL, are loaded into the global scope via `worklet.addModule()`^{p1084}. So this [API base URL](#)^{p937} is rather unlike that of other globals. However, so far this doesn't matter, as no APIs available to worklet code make use of the [API base URL](#)^{p937}.

The [origin](#)^{p937}

Return `origin`.

The [policy container](#)^{p937}

Return `inheritedPolicyContainer`.

The [cross-origin isolated capability](#)^{p937}

Return TODO.

The [time origin](#)^{p937}

Assert: this algorithm is never called, because the [time origin](#)^{p937} is not available in a worklet context.

7. Set `settingsObject`'s [id](#)^{p936} to a new unique opaque string, [creation URL](#)^{p936} to `inheritedAPIBaseURL`, [top-level creation URL](#)^{p936}

to null, [top-level origin](#)^{p936} to *outsideSettings*'s [top-level origin](#)^{p936}, [target browsing context](#)^{p937} to null, and [active service worker](#)^{p937} to null.

8. Set *realm*'s `[[HostDefined]]` field to *settingsObject*.
9. Return *settingsObject*.

11.3.2 The [Worklet](#)^{p1083} class §^{p10}₈₃

The [Worklet](#)^{p1083} class provides the capability to add module scripts into its associated [WorkletGlobalScope](#)^{p1080}s. The user agent can then create classes registered on the [WorkletGlobalScope](#)^{p1080}s and invoke their methods.

```
IDL [Exposed=Window, SecureContext]
interface Worklet {
  [NewObject] Promise<undefined> addModule(USVString moduleURL, optional WorkletOptions options = {});
};

dictionary WorkletOptions {
  RequestCredentials credentials = "same-origin";
};
```

Specifications that create [Worklet](#)^{p1083} instances must specify the following for a given instance:

- its **worklet global scope type**, which must be a Web IDL type that [inherits](#) from [WorkletGlobalScope](#)^{p1080}; and
- its **worklet destination type**, which must be a [destination](#), and is used when fetching scripts.

For web developers (non-normative)

```
await worklet.addModulep1084(moduleURL[, { credentialsp1083 }])
```

Loads and executes the [module script](#)^{p946} given by *moduleURL* into all of *worklet*'s [global scopes](#)^{p1083}. It can also create additional global scopes as part of this process, depending on the worklet type. The returned promise will fulfill once the script has been successfully loaded and run in all global scopes.

The [credentials](#)^{p1083} option can be set to a [credentials mode](#) to modify the script-fetching process. It defaults to "same-origin".

Any failures in [fetching](#)^{p950} the script or its dependencies will cause the returned promise to be rejected with an ["AbortError" DOMException](#). Any errors in parsing the script or its dependencies will cause the returned promise to be rejected with the exception generated during parsing.

A [Worklet](#)^{p1083} has a [list of global scopes](#), which contains instances of the [Worklet](#)^{p1083}'s [worklet global scope type](#)^{p1083}. It is initially empty.

A [Worklet](#)^{p1083} has an **added modules list**, which is a [list of URLs](#), initially empty. Access to this list should be thread-safe.

A [Worklet](#)^{p1083} has a **module responses map**, which is an [ordered map](#) from [URLs](#) to [responses](#), initially empty. Access to this map should be thread-safe.

Note

The [added modules list](#)^{p1083} and [module responses map](#)^{p1083} exist to ensure that [WorkletGlobalScope](#)^{p1080}s created at different times get equivalent [module scripts](#)^{p946} run in them, based on the same source text. This allows the creation of additional [WorkletGlobalScope](#)^{p1080}s to be transparent to the author.

In practice, user agents are not expected to implement these data structures, and the algorithms that consult them, using thread-safe programming techniques. Instead, when `addModule()`^{p1084} is called, user agents can fetch the module graph on the main thread, and send the fetched source text (i.e., the important data contained in the [module responses map](#)^{p1083}) to each thread which has a [WorkletGlobalScope](#)^{p1080}.

Then, when a user agent [creates](#)^{p1081} a new [WorkletGlobalScope](#)^{p1080} for a given [Worklet](#)^{p1083}, it can simply send the map of fetched source text and the list of entry points from the main thread to the thread containing the new [WorkletGlobalScope](#)^{p1080}.

The `addModule(moduleURL, options)` method steps are:

1. Let *outsideSettings* be the [relevant settings object](#)^{p944} of *this*.
2. [Parse](#)^{p91} *moduleURL* relative to *outsideSettings*.
3. If this fails, then return a promise rejected with a `"SyntaxError" DOMException`.
4. Let *moduleURLRecord* be the [resulting URL record](#)^{p91}.
5. Let *promise* be a new promise.
6. Run the following steps [in parallel](#)^{p42}:
 1. If *this*'s [global scopes](#)^{p1083} is empty, then:
 1. [Create a worklet global scope](#)^{p1081} given *this*.
 2. Optionally, [create](#)^{p1081} additional global scope instances given *this*, depending on the specific worklet in question and its specification.
 3. Wait for all steps of the [creation](#)^{p1081} process(es) — including those taking place within the [worklet agents](#)^{p933} — to complete, before moving on.
 2. Let *pendingTasks* be *this*'s [global scopes](#)^{p1083}'s [size](#).
 3. Let *addedSuccessfully* be false.
 4. [For each](#) *workletGlobalScope* of *this*'s [global scopes](#)^{p1083}, [queue a global task](#)^{p970} on the [networking task source](#)^{p977} given *workletGlobalScope* to perform the following steps:
 1. [Fetch a worklet script graph](#)^{p950} given *moduleURLRecord*, *outsideSettings*, *this*'s [worklet destination type](#)^{p1083}, *options*["[credentials](#)^{p1083}"], *workletGlobalScope*'s [relevant settings object](#)^{p944}, and *this*'s [module responses map](#)^{p1083}. Wait until the algorithm asynchronously completes with *script*.

Note

Only the first of these fetches will actually perform a network request; the ones for other [WorkletGlobalScope](#)^{p1080}s will reuse responses from *this*'s [module responses map](#)^{p1083}.

2. If *script* is null, then:
 1. [Queue a global task](#)^{p970} on the [networking task source](#)^{p977} given *this*'s [relevant global object](#)^{p944} to perform the following steps:
 1. If *pendingTasks* is not -1 , then:
 1. Set *pendingTasks* to -1 .
 2. Reject *promise* with an `"AbortError" DOMException`.
 2. Abort these steps.
 3. If *script*'s [error to rethrow](#)^{p945} is not null, then:
 1. [Queue a global task](#)^{p970} on the [networking task source](#)^{p977} given *this*'s [relevant global object](#)^{p944} to perform the following steps:
 1. If *pendingTasks* is not -1 , then:
 1. Set *pendingTasks* to -1 .
 2. Reject *promise* with *script*'s [error to rethrow](#)^{p945}.
 2. Abort these steps.
 4. If *addedSuccessfully* is false, then:
 1. [Append](#) *moduleURLRecord* to *this*'s [added modules list](#)^{p1083}.
 2. Set *addedSuccessfully* to true.

5. [Run a module script](#)^{p957} given *script*.
6. [Queue a global task](#)^{p970} on the [networking task source](#)^{p977} given [this's relevant global object](#)^{p944} to perform the following steps:
 1. If *pendingTasks* is not -1 , then:
 1. Set *pendingTasks* to *pendingTasks* $- 1$.
 2. If *pendingTasks* is 0, then resolve *promise*.
7. Return *promise*.

11.3.3 The worklet's lifetime §^{p10} 85

The lifetime of a [Worklet](#)^{p1083} has no special considerations; it is tied to the object it belongs to, such as the [Window](#)^{p855}.

Each [Document](#)^{p117} has a **worklet global scopes**, which is a [set](#) of [WorkletGlobalScope](#)^{p1080}s, initially empty.

The lifetime of a [WorkletGlobalScope](#)^{p1080} is, at a minimum, tied to the [Document](#)^{p117} whose [worklet global scopes](#)^{p1085} contain it. In particular, [discarding](#)^{p862} the [Document](#)^{p117} will [terminate](#)^{p1081} the corresponding [WorkletGlobalScope](#)^{p1080} and allow it to be garbage-collected.

Additionally, user agents may, at any time, [terminate](#)^{p1081} a given [WorkletGlobalScope](#)^{p1080}, unless the specification defining the corresponding worklet type says otherwise. For example, they might terminate them if the [worklet agent](#)^{p933}'s [event loop](#)^{p968} has no [tasks](#)^{p969} queued, or if the user agent has no pending operations planning to make use of the worklet, or if the user agent detects abnormal operations such as infinite loops or callbacks exceeding imposed time limits.

Finally, specifications for specific worklet types can give more specific details on when to [create](#)^{p1081} [WorkletGlobalScope](#)^{p1080}s for a given worklet type. For example, they might create them during specific processes that call upon worklet code, as in the [example](#)^{p1080}.

12 Web storage §^{p10}₈₆

12.1 Introduction §^{p10}₈₆

This section is non-normative.

This specification introduces two related mechanisms, similar to HTTP session cookies, for storing name-value pairs on the client side. [\[COOKIES\]](#)^{p1305}

The first is designed for scenarios where the user is carrying out a single transaction, but could be carrying out multiple transactions in different windows at the same time.

Cookies don't really handle this case well. For example, a user could be buying plane tickets in two different windows, using the same site. If the site used cookies to keep track of which ticket the user was buying, then as the user clicked from page to page in both windows, the ticket currently being purchased would "leak" from one window to the other, potentially causing the user to buy two tickets for the same flight without noticing.

To address this, this specification introduces the [sessionStorage](#)^{p1089} getter. Sites can add data to the session storage, and it will be accessible to any page from the same site opened in that window.

Example

For example, a page could have a checkbox that the user ticks to indicate that they want insurance:

```
<label>
  <input type="checkbox" onchange="sessionStorage.insurance = checked ? 'true' : ''>
  I want insurance on this trip.
</label>
```

A later page could then check, from script, whether the user had checked the checkbox or not:

```
if (sessionStorage.insurance) { ... }
```

If the user had multiple windows opened on the site, each one would have its own individual copy of the session storage object.

The second storage mechanism is designed for storage that spans multiple windows, and lasts beyond the current session. In particular, web applications might wish to store megabytes of user data, such as entire user-authored documents or a user's mailbox, on the client side for performance reasons.

Again, cookies do not handle this case well, because they are transmitted with every request.

The [localStorage](#)^{p1090} getter is used to access a page's local storage area.

Example

The site at example.com can display a count of how many times the user has loaded its page by putting the following at the bottom of its page:

```
<p>
  You have viewed this page
  <span id="count">an untold number of</span>
  time(s).
</p>
<script>
  if (!localStorage.pageLoadCount)
    localStorage.pageLoadCount = 0;
```

```
localStorage.pageLoadCount = parseInt(localStorage.pageLoadCount) + 1;
document.getElementById('count').textContent = localStorage.pageLoadCount;
</script>
```

Each site has its own separate storage area.

⚠ Warning!

The `localStorage` ^{p1090} getter provides access to shared state. This specification does not define the interaction with other browsing contexts in a multiprocess user agent, and authors are encouraged to assume that there is no locking mechanism. A site could, for instance, try to read the value of a key, increment its value, then write it back out, using the new value as a unique identifier for the session; if the site does this twice in two different browser windows at the same time, it might end up using the same "unique" identifier for both sessions, with potentially disastrous effects.

12.2 The API ^{p10}₈₇

12.2.1 The `Storage` ^{p1087} interface ^{p10}₈₇

```
IDL [Exposed=Window]
interface Storage {
  readonly attribute unsigned long length;
  DOMString? key(unsigned long index);
  getter DOMString? getItem(DOMString key);
  setter undefined setItem(DOMString key, DOMString value);
  deleter undefined removeItem(DOMString key);
  undefined clear();
};
```

For web developers (non-normative)

`storage.length` ^{p1088}

Returns the number of key/value pairs.

`storage.key` ^{p1088} (*n*)

Returns the name of the *n*th key, or null if *n* is greater than or equal to the number of key/value pairs.

`value = storage.getItem` ^{p1088} (*key*)

`value = storage[key]`

Returns the current value associated with the given *key*, or null if the given *key* does not exist.

`storage.setItem` ^{p1088} (*key*, *value*)

`storage[key] = value`

Sets the value of the pair identified by *key* to *value*, creating a new key/value pair if none existed for *key* previously.

Throws a `"QuotaExceededError"` `DOMException` exception if the new value couldn't be set. (Setting could fail if, e.g., the user has disabled storage for the site, or if the quota has been exceeded.)

Dispatches a `storage` ^{p1302} event on `Window` ^{p855} objects holding an equivalent `Storage` ^{p1087} object.

`storage.removeItem` ^{p1089} (*key*)

`delete storage[key]`

Removes the key/value pair with the given *key*, if a key/value pair with the given *key* exists.

Dispatches a `storage` ^{p1302} event on `Window` ^{p855} objects holding an equivalent `Storage` ^{p1087} object.

`storage.clear`^{p1089} ()

Removes all key/value pairs, if there are any.

Dispatches a `storage`^{p1302} event on `Window`^{p855} objects holding an equivalent `Storage`^{p1087} object.

A `Storage`^{p1087} object has an associated:

map

A [storage proxy map](#).

type

"local" or "session".

To **reorder** a `Storage`^{p1087} object `storage`, reorder `storage`'s `map`^{p1088}'s [entries](#) in an [implementation-defined](#) manner.

Note

Unfortunate as it is, iteration order is not defined and can change upon most mutations.

To **broadcast** a `Storage`^{p1087} object `storage`, given a `key`, `oldValue`, and `newValue`, run these steps:

1. Let `url` be `storage`'s [relevant global object](#)^{p944}'s [associated Document](#)^{p856}'s [URL](#).
2. Let `remoteStorages` be all `Storage`^{p1087} objects excluding `storage` whose:
 - [type](#)^{p1088} is `storage`'s [type](#)^{p1088}
 - [relevant settings object](#)^{p944}'s [origin](#)^{p868} is [same origin](#)^{p869} with `storage`'s [relevant settings object](#)^{p944}'s [origin](#)^{p868}.

and, if [type](#)^{p1088} is "session", whose [relevant settings object](#)^{p944}'s [browsing session](#)^{p888} is `storage`'s [relevant settings object](#)^{p944}'s [browsing session](#)^{p888}.

3. **For each** `remoteStorage` of `remoteStorages`: [queue a global task](#)^{p970} on the [DOM manipulation task source](#)^{p977} given `remoteStorage`'s [relevant global object](#)^{p944} to [fire an event](#) named `storage`^{p1302} at `remoteStorage`'s [relevant global object](#)^{p944}, using [StorageEvent](#)^{p1090}, with [key](#)^{p1091} initialized to `key`, [oldValue](#)^{p1091} initialized to `oldValue`, [newValue](#)^{p1091} initialized to `newValue`, [url](#)^{p1091} initialized to `url`, and [storageArea](#)^{p1091} initialized to `remoteStorage`.

Note

The [Document](#)^{p117} object associated with the resulting [task](#)^{p969} is not necessarily [fully active](#)^{p844}, but events fired on such objects are ignored by the [event loop](#)^{p968} until the [Document](#)^{p117} becomes [fully active](#)^{p844} again.

The **length** getter steps are to return `this`'s `map`^{p1088}'s [size](#).

The **key**(`index`) method steps are:

1. If `index` is greater than or equal to `this`'s `map`^{p1088}'s [size](#), then return null.
2. Let `keys` be the result of running [get the keys](#) on `this`'s `map`^{p1088}.
3. Return `keys[index]`.

The [supported property names](#) on a `Storage`^{p1087} object `storage` are the result of running [get the keys](#) on `storage`'s `map`^{p1088}.

The **getItem**(`key`) method steps are:

1. If `this`'s `map`^{p1088}[`key`] does not [exist](#), then return null.
2. Return `this`'s `map`^{p1088}[`key`].

The **setItem**(`key`, `value`) method are:

1. Let `oldValue` be null.
2. Let `reorder` be true.

3. If [this's map^{p1088}\[key\]](#) exists:
 1. Set *oldValue* to [this's map^{p1088}\[key\]](#).
 2. If *oldValue* is *value*, then return.
 3. Set *reorder* to false.
4. If *value* cannot be stored, then throw a ["QuotaExceededError" DOMException](#) exception.
5. [Set this's map^{p1088}\[key\]](#) to *value*.
6. If *reorder* is true, then [reorder^{p1088} this](#).
7. [Broadcast^{p1088} this](#) with *key*, *oldValue*, and *value*.

The [removeItem\(key\)](#) method steps are:

1. If [this's map^{p1088}\[key\]](#) does not exist, then return null.
2. Set *oldValue* to [this's map^{p1088}\[key\]](#).
3. [Remove this's map^{p1088}\[key\]](#).
4. [Reorder^{p1088} this](#).
5. [Broadcast^{p1088} this](#) with *key*, *oldValue*, and null.

The [clear\(\)](#) method steps are:

1. [Clear this's map^{p1088}](#).
2. [Broadcast^{p1088} this](#) with null, null, and null.

12.2.2 The [sessionStorage^{p1089}](#) getter §^{p10}₈₉

```
IDL
interface mixin WindowSessionStorage {
  readonly attribute Storage sessionStorage;
};
Window includes WindowSessionStorage;
```

For web developers (non-normative)

[window.sessionStorage^{p1089}](#)

Returns the [Storage^{p1087}](#) object associated with that *window*'s origin's session storage area.

Throws a ["SecurityError" DOMException](#) if the [Document^{p117}](#)'s [origin](#) is an [opaque origin^{p868}](#) or if the request violates a policy decision (e.g., if the user agent is configured to not allow the page to persist data).

A [Document^{p117}](#) object has an associated **session storage holder**, which is null or a [Storage^{p1087}](#) object. It is initially null.

The [sessionStorage](#) getter steps are:

1. If [this's associated Document^{p856}'s session storage holder^{p1089}](#) is non-null, then return [this's associated Document^{p856}'s session storage holder^{p1089}](#).
2. Let *map* be the result of running [obtain a session storage bottle map](#) with [this's relevant settings object^{p944}](#) and "sessionStorage".
3. If *map* is failure, then throw a ["SecurityError" DOMException](#).
4. Let *storage* be a new [Storage^{p1087}](#) object whose [map^{p1088}](#) is *map*.
5. Set [this's associated Document^{p856}'s session storage holder^{p1089}](#) to *storage*.
6. Return *storage*.

Note

While [creating a new auxiliary browsing context](#)^{p842}, the session storage [is copied](#)^{p843} over.

12.2.3 The [localStorage](#)^{p1090} getter § p1090

```
IDL interface mixin WindowLocalStorage {
  readonly attribute Storage localStorage;
};
Window includes WindowLocalStorage;
```

For web developers (non-normative)

[window.localStorage](#)^{p1090}

Returns the [Storage](#)^{p1087} object associated with *window*'s origin's local storage area.

Throws a ["SecurityError" DOMException](#) if the [Document](#)^{p117}'s [origin](#) is an [opaque origin](#)^{p868} or if the request violates a policy decision (e.g., if the user agent is configured to not allow the page to persist data).

A [Document](#)^{p117} object has an associated **local storage holder**, which is null or a [Storage](#)^{p1087} object. It is initially null.

The [localStorage](#) getter steps are:

1. If *this*'s [associated Document](#)^{p856}'s [local storage holder](#)^{p1090} is non-null, then return *this*'s [associated Document](#)^{p856}'s [local storage holder](#)^{p1090}.
2. Let *map* be the result of running [obtain a local storage bottle map](#) with *this*'s [relevant settings object](#)^{p944} and "localStorage".
3. If *map* is failure, then throw a ["SecurityError" DOMException](#).
4. Let *storage* be a new [Storage](#)^{p1087} object whose [map](#)^{p1088} is *map*.
5. Set *this*'s [associated Document](#)^{p856}'s [local storage holder](#)^{p1090} to *storage*.
6. Return *storage*.

12.2.4 The [StorageEvent](#)^{p1090} interface § p1090

```
IDL [Exposed=Window]
interface StorageEvent : Event {
  constructor(DOMString type, optional StorageEventInit eventInitDict = {});

  readonly attribute DOMString? key;
  readonly attribute DOMString? oldValue;
  readonly attribute DOMString? newValue;
  readonly attribute USVString url;
  readonly attribute Storage? storageArea;

  undefined initStorageEvent(DOMString type, optional boolean bubbles = false, optional boolean cancelable = false, optional DOMString? key = null, optional DOMString? oldValue = null, optional DOMString? newValue = null, optional USVString url = "", optional Storage? storageArea = null);
};

dictionary StorageEventInit : EventInit {
  DOMString? key = null;
  DOMString? oldValue = null;
  DOMString? newValue = null;
  USVString url = "";
  Storage? storageArea = null;
};
```

```
};
```

For web developers (non-normative)

event.key^{p1091}

Returns the key of the storage item being changed.

event.oldValue^{p1091}

Returns the old value of the key of the storage item whose value is being changed.

event.newValue^{p1091}

Returns the new value of the key of the storage item whose value is being changed.

event.url^{p1091}

Returns the [URL](#) of the document whose storage item changed.

event.storageArea^{p1091}

Returns the [Storage](#)^{p1087} object that was affected.

MDN

The **key**, **oldValue**, **newValue**, **url**, and **storageArea** attributes must return the values they were initialized to.

The **initStorageEvent**(*type*, *bubbles*, *cancelable*, *key*, *oldValue*, *newValue*, *url*, *storageArea*) method must initialize the event in a manner analogous to the similarly-named **initEvent**() method. [\[DOM\]](#)^{p1307}

12.3 Privacy ^{§ p1091}

12.3.1 User tracking ^{§ p1091}

A third-party advertiser (or any entity capable of getting content distributed to multiple sites) could use a unique identifier stored in its local storage area to track a user across multiple sessions, building a profile of the user's interests to allow for highly targeted advertising. In conjunction with a site that is aware of the user's real identity (for example an e-commerce site that requires authenticated credentials), this could allow oppressive groups to target individuals with greater accuracy than in a world with purely anonymous web usage.

There are a number of techniques that can be used to mitigate the risk of user tracking:

Blocking third-party storage

User agents may restrict access to the [localStorage](#)^{p1090} objects to scripts originating at the domain of the [active document](#)^{p840} of the [top-level browsing context](#)^{p844}, for instance denying access to the API for pages from other domains running in [iframe](#)^{p369}s.

Expiring stored data

User agents may, possibly in a manner configured by the user, automatically delete stored data after a period of time.

For example, a user agent could be configured to treat third-party local storage areas as session-only storage, deleting the data once the user had closed all the [browsing contexts](#)^{p840} that could access it.

This can restrict the ability of a site to track a user, as the site would then only be able to track the user across multiple sessions when they authenticate with the site itself (e.g. by making a purchase or logging in to a service).

However, this also reduces the usefulness of the API as a long-term storage mechanism. It can also put the user's data at risk, if the user does not fully understand the implications of data expiration.

Treating persistent storage as cookies

If users attempt to protect their privacy by clearing cookies without also clearing data stored in the local storage area, sites can defeat those attempts by using the two features as redundant backup for each other. User agents should present the interfaces for clearing these in a way that helps users to understand this possibility and enables them to delete data in all persistent storage features simultaneously. [\[COOKIES\]](#)^{p1305}

Site-specific safelisting of access to local storage areas

User agents may allow sites to access session storage areas in an unrestricted manner, but require the user to authorize access to local storage areas.

Origin-tracking of stored data

User agents may record the [origins^{p868}](#) of sites that contained content from third-party origins that caused data to be stored.

If this information is then used to present the view of data currently in persistent storage, it would allow the user to make informed decisions about which parts of the persistent storage to prune. Combined with a blocklist ("delete this data and prevent this domain from ever storing data again"), the user can restrict the use of persistent storage to sites that they trust.

Shared blocklists

User agents may allow users to share their persistent storage domain blocklists.

This would allow communities to act together to protect their privacy.

While these suggestions prevent trivial use of this API for user tracking, they do not block it altogether. Within a single domain, a site can continue to track the user during a session, and can then pass all this information to the third party along with any identifying information (names, credit card numbers, addresses) obtained by the site. If a third party cooperates with multiple sites to obtain such information, a profile can still be created.

However, user tracking is to some extent possible even with no cooperation from the user agent whatsoever, for instance by using session identifiers in URLs, a technique already commonly used for innocuous purposes but easily repurposed for user tracking (even retroactively). This information can then be shared with other sites, using visitors' IP addresses and other user-specific data (e.g. user-agent headers and configuration settings) to combine separate sessions into coherent user profiles.

12.3.2 Sensitivity of data §^{p10}₉₂

User agents should treat persistently stored data as potentially sensitive; it's quite possible for emails, calendar appointments, health records, or other confidential documents to be stored in this mechanism.

To this end, user agents should ensure that when deleting data, it is promptly deleted from the underlying storage.

12.4 Security §^{p10}₉₂

12.4.1 DNS spoofing attacks §^{p10}₉₂

Because of the potential for DNS spoofing attacks, one cannot guarantee that a host claiming to be in a certain domain really is from that domain. To mitigate this, pages can use TLS. Pages using TLS can be sure that only the user, software working on behalf of the user, and other pages using TLS that have certificates identifying them as being from the same domain, can access their storage areas.

12.4.2 Cross-directory attacks §^{p10}₉₂

Different authors sharing one host name, for example users hosting content on the now defunct [geocities.com](#), all share one local storage object. There is no feature to restrict the access by pathname. Authors on shared hosts are therefore urged to avoid using these features, as it would be trivial for other authors to read the data and overwrite it.

Note

Even if a path-restriction feature was made available, the usual DOM scripting security model would make it trivial to bypass this protection and access the data from any path.

12.4.3 Implementation risks §^{p10}₉₂

The two primary risks when implementing these persistent storage features are letting hostile sites read information from other domains, and letting hostile sites write information that is then read from other domains.

Letting third-party sites read data that is not supposed to be read from their domain causes *information leakage*. For example, a user's

shopping wishlist on one domain could be used by another domain for targeted advertising; or a user's work-in-progress confidential documents stored by a word-processing site could be examined by the site of a competing company.

Letting third-party sites write data to the persistent storage of other domains can result in *information spoofing*, which is equally dangerous. For example, a hostile site could add items to a user's wishlist; or a hostile site could set a user's session identifier to a known ID that the hostile site can then use to track the user's actions on the victim site.

Thus, strictly following the [origin^{p868}](#) model described in this specification is important for user security.

13 The HTML syntax §^{p10}

94

Note

This section only describes the rules for resources labeled with an [HTML MIME type](#). Rules for XML resources are discussed in the section below entitled "[The XML syntax](#)^{p1217}".

13.1 Writing HTML documents §^{p10}

94

This section only applies to documents, authoring tools, and markup generators. In particular, it does not apply to conformance checkers; conformance checkers must use the requirements given in the next section ("parsing HTML documents").

Documents must consist of the following parts, in the given order:

1. Optionally, a single U+FEFF BYTE ORDER MARK (BOM) character.
2. Any number of [comments](#)^{p1105} and [ASCII whitespace](#).
3. A [DOCTYPE](#)^{p1094}.
4. Any number of [comments](#)^{p1105} and [ASCII whitespace](#).
5. The [document element](#), in the form of an [html](#)^{p157} [element](#)^{p1095}.
6. Any number of [comments](#)^{p1105} and [ASCII whitespace](#).

The various types of content mentioned above are described in the next few sections.

In addition, there are some restrictions on how [character encoding declarations](#)^{p179} are to be serialized, as discussed in the section on that topic.

Note

[ASCII whitespace](#) before the [html](#)^{p157} [element](#), at the start of the [html](#)^{p157} [element](#) and before the [head](#)^{p158} [element](#), will be dropped when the document is parsed; [ASCII whitespace](#) after the [html](#)^{p157} [element](#) will be parsed as if it were at the end of the [body](#)^{p184} [element](#). Thus, [ASCII whitespace](#) around the [document element](#) does not round-trip.

It is suggested that newlines be inserted after the DOCTYPE, after any comments that are before the document element, after the [html](#)^{p157} [element's](#) start tag (if it is not [omitted](#)^{p1098}), and after any comments that are inside the [html](#)^{p157} [element](#) but before the [head](#)^{p158} [element](#).

Many strings in the HTML syntax (e.g. the names of elements and their attributes) are case-insensitive, but only for [ASCII upper alphas](#) and [ASCII lower alphas](#). For convenience, in this section this is just referred to as "case-insensitive".

13.1.1 The DOCTYPE §^{p10}

94

A **DOCTYPE** is a required preamble.

Note

DOCTYPEs are required for legacy reasons. When omitted, browsers tend to use a different rendering mode that is incompatible with some specifications. Including the DOCTYPE in a document ensures that the browser makes a best-effort attempt at following the relevant specifications.

A DOCTYPE must consist of the following components, in this order:

1. A string that is an [ASCII case-insensitive](#) match for the string "<!DOCTYPE".
2. One or more [ASCII whitespace](#).

3. A string that is an [ASCII case-insensitive](#) match for the string "html".
4. Optionally, a [DOCTYPE legacy string](#)^{p1095}.
5. Zero or more [ASCII whitespace](#).
6. A U+003E GREATER-THAN SIGN character (>).

Note

In other words, <!DOCTYPE html>, case-insensitively.

For the purposes of HTML generators that cannot output HTML markup with the short DOCTYPE "<!DOCTYPE html>", a **DOCTYPE legacy string** may be inserted into the DOCTYPE (in the position defined above). This string must consist of:

1. One or more [ASCII whitespace](#).
2. A string that is an [ASCII case-insensitive](#) match for the string "SYSTEM".
3. One or more [ASCII whitespace](#).
4. A U+0022 QUOTATION MARK or U+0027 APOSTROPHE character (the *quote mark*).
5. The literal string "[about:legacy-compat](#)^{p98}".
6. A matching U+0022 QUOTATION MARK or U+0027 APOSTROPHE character (i.e. the same character as in the earlier step labeled *quote mark*).

Note

In other words, <!DOCTYPE html SYSTEM "about:legacy-compat"> or <!DOCTYPE html SYSTEM 'about:legacy-compat'>, case-insensitively except for the part in single or double quotes.

The [DOCTYPE legacy string](#)^{p1095} should not be used unless the document is generated from a system that cannot output the shorter string.

13.1.2 Elements § p10 95

There are six different kinds of **elements**: [void elements](#)^{p1095}, [the template element](#)^{p1095}, [raw text elements](#)^{p1095}, [escapable raw text elements](#)^{p1095}, [foreign elements](#)^{p1095}, and [normal elements](#)^{p1095}.

Void elements

[area](#)^{p452}, [base](#)^{p160}, [br](#)^{p286}, [col](#)^{p468}, [embed](#)^{p378}, [hr](#)^{p220}, [img](#)^{p327}, [input](#)^{p501}, [link](#)^{p162}, [meta](#)^{p170}, [param](#)^{p387}, [source](#)^{p324}, [track](#)^{p393}, [wbr](#)^{p287}

The **template element**

[template](#)^{p640}

Raw text elements

[script](#)^{p624}, [style](#)^{p180}

Escapable raw text elements

[textarea](#)^{p558}, [title](#)^{p159}

Foreign elements

Elements from the [MathML namespace](#) and the [SVG namespace](#).

Normal elements

All other allowed [HTML elements](#)^{p44} are normal elements.

Tags are used to delimit the start and end of elements in the markup. [Raw text](#)^{p1095}, [escapable raw text](#)^{p1095}, and [normal](#)^{p1095} elements have a [start tag](#)^{p1096} to indicate where they begin, and an [end tag](#)^{p1097} to indicate where they end. The start and end tags of certain [normal elements](#)^{p1095} can be [omitted](#)^{p1098}, as described below in the section on [optional tags](#)^{p1098}. Those that cannot be omitted must not be omitted. [Void elements](#)^{p1095} only have a start tag; end tags must not be specified for [void elements](#)^{p1095}. [Foreign elements](#)^{p1095} must either have a start tag and an end tag, or a start tag that is marked as self-closing, in which case they must not have an end tag.

The [contents](#)^{p133} of the element must be placed between just after the start tag (which [might be implied, in certain cases](#)^{p1098}) and just before the end tag (which again, [might be implied in certain cases](#)^{p1098}). The exact allowed contents of each individual element depend on the [content model](#)^{p133} of that element, as described earlier in this specification. Elements must not contain content that their content model disallows. In addition to the restrictions placed on the contents by those content models, however, the five types of elements have additional *syntactic* requirements.

[Void elements](#)^{p1095} can't have any contents (since there's no end tag, no content can be put between the start tag and the end tag).

The [template element](#)^{p1095} can have [template contents](#)^{p642}, but such [template contents](#)^{p642} are not children of the [template](#)^{p640} element itself. Instead, they are stored in a [DocumentFragment](#) associated with a different [Document](#)^{p117} — without a [browsing context](#)^{p840} — so as to avoid the [template](#)^{p640} contents interfering with the main [Document](#)^{p117}. The markup for the [template contents](#)^{p642} of a [template](#)^{p640} element is placed just after the [template](#)^{p640} element's start tag and just before [template](#)^{p640} element's end tag (as with other elements), and may consist of any [text](#)^{p1104}, [character references](#)^{p1104}, [elements](#)^{p1095}, and [comments](#)^{p1105}, but the text must not contain the character U+003C LESS-THAN SIGN (<) or an [ambiguous ampersand](#)^{p1105}.

[Raw text elements](#)^{p1095} can have [text](#)^{p1104}, though it has [restrictions](#)^{p1104} described below.

[Escapable raw text elements](#)^{p1095} can have [text](#)^{p1104} and [character references](#)^{p1104}, but the text must not contain an [ambiguous ampersand](#)^{p1105}. There are also [further restrictions](#)^{p1104} described below.

[Foreign elements](#)^{p1095} whose start tag is marked as self-closing can't have any contents (since, again, as there's no end tag, no content can be put between the start tag and the end tag). [Foreign elements](#)^{p1095} whose start tag is *not* marked as self-closing can have [text](#)^{p1104}, [character references](#)^{p1104}, [CDATA sections](#)^{p1105}, other [elements](#)^{p1095}, and [comments](#)^{p1105}, but the text must not contain the character U+003C LESS-THAN SIGN (<) or an [ambiguous ampersand](#)^{p1105}.

Note

The HTML syntax does not support namespace declarations, even in [foreign elements](#)^{p1095}.

For instance, consider the following HTML fragment:

```
<p>
  <svg>
    <metadata>
      <!-- this is invalid -->
      <cdr:license xmlns:cdr="https://www.example.com/cdr/metadata" name="MIT"/>
    </metadata>
  </svg>
</p>
```

The innermost element, `cdr:license`, is actually in the SVG namespace, as the `xmlns:cdr` attribute has no effect (unlike in XML). In fact, as the comment in the fragment above says, the fragment is actually non-conforming. This is because SVG 2 does not define any elements called `cdr:license` in the SVG namespace.

[Normal elements](#)^{p1095} can have [text](#)^{p1104}, [character references](#)^{p1104}, other [elements](#)^{p1095}, and [comments](#)^{p1105}, but the text must not contain the character U+003C LESS-THAN SIGN (<) or an [ambiguous ampersand](#)^{p1105}. Some [normal elements](#)^{p1095} also have [yet more restrictions](#)^{p1104} on what content they are allowed to hold, beyond the restrictions imposed by the content model and those described in this paragraph. Those restrictions are described below.

Tags contain a **tag name**, giving the element's name. HTML elements all have names that only use [ASCII alphanumerics](#). In the HTML syntax, tag names, even those for [foreign elements](#)^{p1095}, may be written with any mix of lower- and uppercase letters that, when converted to all-lowercase, matches the element's tag name; tag names are case-insensitive.

13.1.2.1 Start tags §^{p10}₉₆

Start tags must have the following format:

1. The first character of a start tag must be a U+003C LESS-THAN SIGN character (<).
2. The next few characters of a start tag must be the element's [tag name](#)^{p1096}.
3. If there are to be any attributes in the next step, there must first be one or more [ASCII whitespace](#).
4. Then, the start tag may have a number of attributes, the [syntax for which](#)^{p1097} is described below. Attributes must be separated from each other by one or more [ASCII whitespace](#).
5. After the attributes, or after the [tag name](#)^{p1096} if there are no attributes, there may be one or more [ASCII whitespace](#). (Some attributes are required to be followed by a space. See the [attributes section](#)^{p1097} below.)
6. Then, if the element is one of the [void elements](#)^{p1095}, or if the element is a [foreign element](#)^{p1095}, then there may be a single U+002F SOLIDUS character (/). This character has no effect on [void elements](#)^{p1095}, but on [foreign elements](#)^{p1095} it marks the

start tag as self-closing.

7. Finally, start tags must be closed by a U+003E GREATER-THAN SIGN character (>).

13.1.2.2 End tags §^{p10}₉₇

End tags must have the following format:

1. The first character of an end tag must be a U+003C LESS-THAN SIGN character (<).
2. The second character of an end tag must be a U+002F SOLIDUS character (/).
3. The next few characters of an end tag must be the element's [tag name](#)^{p1096}.
4. After the tag name, there may be one or more [ASCII whitespace](#).
5. Finally, end tags must be closed by a U+003E GREATER-THAN SIGN character (>).

13.1.2.3 Attributes §^{p10}₉₇

Attributes for an element are expressed inside the element's start tag.

Attributes have a name and a value. **Attribute names** must consist of one or more characters other than [controls](#), U+0020 SPACE, U+0022 ("), U+0027 ('), U+003E (>), U+002F (/), U+003D (=), and [noncharacters](#). In the HTML syntax, attribute names, even those for [foreign elements](#)^{p1095}, may be written with any mix of [ASCII lower](#) and [ASCII upper alphas](#).

Attribute values are a mixture of [text](#)^{p1104} and [character references](#)^{p1104}, except with the additional restriction that the text cannot contain an [ambiguous ampersand](#)^{p1105}.

Attributes can be specified in four different ways:

Empty attribute syntax

Just the [attribute name](#)^{p1097}. The value is implicitly the empty string.

Example

In the following example, the [disabled](#)^{p580} attribute is given with the empty attribute syntax:

```
<input disabled>
```

If an attribute using the empty attribute syntax is to be followed by another attribute, then there must be [ASCII whitespace](#) separating the two.

Unquoted attribute value syntax

The [attribute name](#)^{p1097}, followed by zero or more [ASCII whitespace](#), followed by a single U+003D EQUALS SIGN character, followed by zero or more [ASCII whitespace](#), followed by the [attribute value](#)^{p1097}, which, in addition to the requirements given above for attribute values, must not contain any literal [ASCII whitespace](#), any U+0022 QUOTATION MARK characters ("), U+0027 APOSTROPHE characters ('), U+003D EQUALS SIGN characters (=), U+003C LESS-THAN SIGN characters (<), U+003E GREATER-THAN SIGN characters (>), or U+0060 GRAVE ACCENT characters (`), and must not be the empty string.

Example

In the following example, the [value](#)^{p505} attribute is given with the unquoted attribute value syntax:

```
<input value=yes>
```

If an attribute using the unquoted attribute syntax is to be followed by another attribute or by the optional U+002F SOLIDUS character (/) allowed in step 6 of the [start tag](#)^{p1096} syntax above, then there must be [ASCII whitespace](#) separating the two.

Single-quoted attribute value syntax

The [attribute name](#)^{p1097}, followed by zero or more [ASCII whitespace](#), followed by a single U+003D EQUALS SIGN character, followed by zero or more [ASCII whitespace](#), followed by a single U+0027 APOSTROPHE character ('), followed by the [attribute value](#)^{p1097}, which, in addition to the requirements given above for attribute values, must not contain any literal U+0027 APOSTROPHE characters ('), and finally followed by a second single U+0027 APOSTROPHE character (').

Example

In the following example, the [type](#)^{p503} attribute is given with the single-quoted attribute value syntax:

```
<input type='checkbox'>
```

If an attribute using the single-quoted attribute syntax is to be followed by another attribute, then there must be [ASCII whitespace](#) separating the two.

Double-quoted attribute value syntax

The [attribute name](#)^{p1097}, followed by zero or more [ASCII whitespace](#), followed by a single U+003D EQUALS SIGN character, followed by zero or more [ASCII whitespace](#), followed by a single U+0022 QUOTATION MARK character ("), followed by the [attribute value](#)^{p1097}, which, in addition to the requirements given above for attribute values, must not contain any literal U+0022 QUOTATION MARK characters ("), and finally followed by a second single U+0022 QUOTATION MARK character (").

Example

In the following example, the [name](#)^{p577} attribute is given with the double-quoted attribute value syntax:

```
<input name="be evil">
```

If an attribute using the double-quoted attribute syntax is to be followed by another attribute, then there must be [ASCII whitespace](#) separating the two.

There must never be two or more attributes on the same start tag whose names are an [ASCII case-insensitive](#) match for each other.

When a [foreign element](#)^{p1095} has one of the namespaced attributes given by the local name and namespace of the first and second cells of a row from the following table, it must be written using the name given by the third cell from the same row.

Local name	Namespace	Attribute name
actuate	XLink namespace	xlink:actuate
arcrole	XLink namespace	xlink:arcrole
href	XLink namespace	xlink:href
role	XLink namespace	xlink:role
show	XLink namespace	xlink:show
title	XLink namespace	xlink:title
type	XLink namespace	xlink:type
lang	XML namespace	xml:lang
space	XML namespace	xml:space
xmlns	XMLNS namespace	xmlns
xlink	XMLNS namespace	xmlns:xlink

No other namespaced attribute can be expressed in [the HTML syntax](#)^{p1094}.

Note

Whether the attributes in the table above are conforming or not is defined by other specifications (e.g. SVG 2 and MathML); this section only describes the syntax rules if the attributes are serialized using the HTML syntax.

13.1.2.4 Optional tags ^{p110}₉₈

Certain tags can be **omitted**.

Note

Omitting an element's [start tag](#)^{p1096} in the situations described below does not mean the element is not present; it is implied, but it is still there. For example, an HTML document always has a root [html](#)^{p157} element, even if the string `<html>` doesn't appear anywhere in the markup.

An [html](#)^{p157} element's [start tag](#)^{p1096} may be omitted if the first thing inside the [html](#)^{p157} element is not a [comment](#)^{p1105}.

Example

For example, in the following case it's ok to remove the "`<html>`" tag:

```
<!DOCTYPE HTML>
<html>
  <head>
    <title>Hello</title>
  </head>
  <body>
    <p>Welcome to this example.</p>
  </body>
</html>
```

Doing so would make the document look like this:

```
<!DOCTYPE HTML>

  <head>
    <title>Hello</title>
  </head>
  <body>
    <p>Welcome to this example.</p>
  </body>
</html>
```

This has the exact same DOM. In particular, note that whitespace around the [document element](#) is ignored by the parser. The following example would also have the exact same DOM:

```
<!DOCTYPE HTML><head>
  <title>Hello</title>
</head>
<body>
  <p>Welcome to this example.</p>
</body>
</html>
```

However, in the following example, removing the start tag moves the comment to before the [html](#)^{p157} element:

```
<!DOCTYPE HTML>
<html>
  <!-- where is this comment in the DOM? -->
  <head>
    <title>Hello</title>
  </head>
  <body>
    <p>Welcome to this example.</p>
  </body>
</html>
```

With the tag removed, the document actually turns into the same as this:

```
<!DOCTYPE HTML>
```

```

<!-- where is this comment in the DOM? -->
<html>
  <head>
    <title>Hello</title>
  </head>
  <body>
    <p>Welcome to this example.</p>
  </body>
</html>

```

This is why the tag can only be removed if it is not followed by a comment: removing the tag when there is a comment there changes the document's resulting parse tree. Of course, if the position of the comment does not matter, then the tag can be omitted, as if the comment had been moved to before the start tag in the first place.

An [html^{p157}](#) element's [end tag^{p1097}](#) may be omitted if the [html^{p157}](#) element is not immediately followed by a [comment^{p1105}](#).

A [head^{p158}](#) element's [start tag^{p1096}](#) may be omitted if the element is empty, or if the first thing inside the [head^{p158}](#) element is an element.

A [head^{p158}](#) element's [end tag^{p1097}](#) may be omitted if the [head^{p158}](#) element is not immediately followed by [ASCII whitespace](#) or a [comment^{p1105}](#).

A [body^{p184}](#) element's [start tag^{p1096}](#) may be omitted if the element is empty, or if the first thing inside the [body^{p184}](#) element is not [ASCII whitespace](#) or a [comment^{p1105}](#), except if the first thing inside the [body^{p184}](#) element is a [meta^{p170}](#), [link^{p162}](#), [script^{p624}](#), [style^{p180}](#), or [template^{p640}](#) element.

A [body^{p184}](#) element's [end tag^{p1097}](#) may be omitted if the [body^{p184}](#) element is not immediately followed by a [comment^{p1105}](#).

Example

Note that in the example above, the [head^{p158}](#) element start and end tags, and the [body^{p184}](#) element start tag, can't be omitted, because they are surrounded by whitespace:

```

<!DOCTYPE HTML>
<html>
  <head>
    <title>Hello</title>
  </head>
  <body>
    <p>Welcome to this example.</p>
  </body>
</html>

```

(The [body^{p184}](#) and [html^{p157}](#) element end tags could be omitted without trouble; any spaces after those get parsed into the [body^{p184}](#) element anyway.)

Usually, however, whitespace isn't an issue. If we first remove the whitespace we don't care about:

```

<!DOCTYPE HTML><html><head><title>Hello</title></head><body><p>Welcome to this
example.</p></body></html>

```

Then we can omit a number of tags without affecting the DOM:

```

<!DOCTYPE HTML><title>Hello</title><p>Welcome to this example.</p>

```

At that point, we can also add some whitespace back:

```

<!DOCTYPE HTML>
<title>Hello</title>

```

```
<p>Welcome to this example.</p>
```

This would be equivalent to this document, with the omitted tags shown in their parser-implied positions; the only whitespace text node that results from this is the newline at the end of the [head^{p158}](#) element:

```
<!DOCTYPE HTML>
<html><head><title>Hello</title>
</head><body><p>Welcome to this example.</p></body></html>
```

An [li^{p230}](#) element's [end tag^{p1097}](#) may be omitted if the [li^{p230}](#) element is immediately followed by another [li^{p230}](#) element or if there is no more content in the parent element.

A [dt^{p236}](#) element's [end tag^{p1097}](#) may be omitted if the [dt^{p236}](#) element is immediately followed by another [dt^{p236}](#) element or a [dd^{p237}](#) element.

A [dd^{p237}](#) element's [end tag^{p1097}](#) may be omitted if the [dd^{p237}](#) element is immediately followed by another [dd^{p237}](#) element or a [dt^{p236}](#) element, or if there is no more content in the parent element.

A [p^{p218}](#) element's [end tag^{p1097}](#) may be omitted if the [p^{p218}](#) element is immediately followed by an [address^{p204}](#), [article^{p186}](#), [aside^{p194}](#), [blockquote^{p224}](#), [details^{p614}](#), [div^{p243}](#), [dl^{p233}](#), [fieldset^{p572}](#), [figcaption^{p241}](#), [figure^{p238}](#), [footer^{p201}](#), [form^{p494}](#), [h1^{p196}](#), [h2^{p196}](#), [h3^{p196}](#), [h4^{p196}](#), [h5^{p196}](#), [h6^{p196}](#), [header^{p200}](#), [hgroup^{p197}](#), [hr^{p220}](#), [main^{p242}](#), [menu^{p229}](#), [nav^{p191}](#), [ol^{p226}](#), [p^{p218}](#), [pre^{p222}](#), [section^{p188}](#), [table^{p458}](#), or [ul^{p228}](#) element, or if there is no more content in the parent element and the parent element is an [HTML element^{p44}](#) that is not an [a^{p244}](#), [audio^{p392}](#), [del^{p320}](#), [ins^{p319}](#), [map^{p450}](#), [noscript^{p638}](#), or [video^{p388}](#) element, or an [autonomous custom element^{p728}](#).

Example

We can thus simplify the earlier example further:

```
<!DOCTYPE HTML><title>Hello</title><p>Welcome to this example.
```

An [rt^{p264}](#) element's [end tag^{p1097}](#) may be omitted if the [rt^{p264}](#) element is immediately followed by an [rt^{p264}](#) or [rp^{p264}](#) element, or if there is no more content in the parent element.

An [rp^{p264}](#) element's [end tag^{p1097}](#) may be omitted if the [rp^{p264}](#) element is immediately followed by an [rt^{p264}](#) or [rp^{p264}](#) element, or if there is no more content in the parent element.

An [optgroup^{p554}](#) element's [end tag^{p1097}](#) may be omitted if the [optgroup^{p554}](#) element is immediately followed by another [optgroup^{p554}](#) element, or if there is no more content in the parent element.

An [option^{p555}](#) element's [end tag^{p1097}](#) may be omitted if the [option^{p555}](#) element is immediately followed by another [option^{p555}](#) element, or if it is immediately followed by an [optgroup^{p554}](#) element, or if there is no more content in the parent element.

A [colgroup^{p467}](#) element's [start tag^{p1096}](#) may be omitted if the first thing inside the [colgroup^{p467}](#) element is a [col^{p468}](#) element, and if the element is not immediately preceded by another [colgroup^{p467}](#) element whose [end tag^{p1097}](#) has been omitted. (It can't be omitted if the element is empty.)

A [colgroup^{p467}](#) element's [end tag^{p1097}](#) may be omitted if the [colgroup^{p467}](#) element is not immediately followed by [ASCII whitespace](#) or a [comment^{p1105}](#).

A [caption^{p466}](#) element's [end tag^{p1097}](#) may be omitted if the [caption^{p466}](#) element is not immediately followed by [ASCII whitespace](#) or a [comment^{p1105}](#).

A [thead^{p470}](#) element's [end tag^{p1097}](#) may be omitted if the [thead^{p470}](#) element is immediately followed by a [tbody^{p469}](#) or [tfoot^{p471}](#) element.

A [tbody^{p469}](#) element's [start tag^{p1096}](#) may be omitted if the first thing inside the [tbody^{p469}](#) element is a [tr^{p472}](#) element, and if the element is not immediately preceded by a [tbody^{p469}](#), [thead^{p470}](#), or [tfoot^{p471}](#) element whose [end tag^{p1097}](#) has been omitted. (It can't be omitted if the element is empty.)

A [tbody^{p469}](#) element's [end tag^{p1097}](#) may be omitted if the [tbody^{p469}](#) element is immediately followed by a [tbody^{p469}](#) or [tfoot^{p471}](#) element, or if there is no more content in the parent element.

A `tfoot`^{p471} element's `end tag`^{p1097} may be omitted if there is no more content in the parent element.

A `tr`^{p472} element's `end tag`^{p1097} may be omitted if the `tr`^{p472} element is immediately followed by another `tr`^{p472} element, or if there is no more content in the parent element.

A `td`^{p474} element's `end tag`^{p1097} may be omitted if the `td`^{p474} element is immediately followed by a `td`^{p474} or `th`^{p475} element, or if there is no more content in the parent element.

A `th`^{p475} element's `end tag`^{p1097} may be omitted if the `th`^{p475} element is immediately followed by a `td`^{p474} or `th`^{p475} element, or if there is no more content in the parent element.

Example

The ability to omit all these table-related tags makes table markup much terser.

Take this example:

```
<table>
  <caption>37547 TEE Electric Powered Rail Car Train Functions (Abbreviated)</caption>
  <colgroup><col><col><col></colgroup>
  <thead>
    <tr>
      <th>Function</th>
      <th>Control Unit</th>
      <th>Central Station</th>
    </tr>
  </thead>
  <tbody>
    <tr>
      <td>Headlights</td>
      <td>✓</td>
      <td>✓</td>
    </tr>
    <tr>
      <td>Interior Lights</td>
      <td>✓</td>
      <td>✓</td>
    </tr>
    <tr>
      <td>Electric locomotive operating sounds</td>
      <td>✓</td>
      <td>✓</td>
    </tr>
    <tr>
      <td>Engineer's cab lighting</td>
      <td></td>
      <td>✓</td>
    </tr>
    <tr>
      <td>Station Announcements - Swiss</td>
      <td></td>
      <td>✓</td>
    </tr>
  </tbody>
</table>
```

The exact same table, modulo some whitespace differences, could be marked up as follows:

```
<table>
  <caption>37547 TEE Electric Powered Rail Car Train Functions (Abbreviated)
  <colgroup><col><col><col>
  <thead>
```

```

<tr>
  <th>Function
  <th>Control Unit
  <th>Central Station
</thead>
<tbody>
<tr>
  <td>Headlights
  <td>✓
  <td>✓
</tr>
<tr>
  <td>Interior Lights
  <td>✓
  <td>✓
</tr>
<tr>
  <td>Electric locomotive operating sounds
  <td>✓
  <td>✓
</tr>
<tr>
  <td>Engineer's cab lighting
  <td>
  <td>✓
</tr>
<tr>
  <td>Station Announcements - Swiss
  <td>
  <td>✓
</tr>
</tbody>
</table>

```

Since the cells take up much less room this way, this can be made even terser by having each row on one line:

```

<table>
  <caption>37547 TEE Electric Powered Rail Car Train Functions (Abbreviated)
  <colgroup><col><col><col>
  <thead>
    <tr> <th>Function           <th>Control Unit   <th>Central Station
  </thead>
  <tbody>
    <tr> <td>Headlights         <td>✓             <td>✓
    <tr> <td>Interior Lights    <td>✓             <td>✓
    <tr> <td>Electric locomotive operating sounds <td>✓             <td>✓
    <tr> <td>Engineer's cab lighting <td>              <td>✓
    <tr> <td>Station Announcements - Swiss <td>              <td>✓
  </tbody>
</table>

```

The only differences between these tables, at the DOM level, is with the precise position of the (in any case semantically-neutral) whitespace.

However, a [start tag](#)^{p1096} must never be omitted if it has any attributes.

Example

Returning to the earlier example with all the whitespace removed and then all the optional tags removed:

```
<!DOCTYPE HTML><title>Hello</title><p>Welcome to this example.
```

If the [body](#)^{p184} element in this example had to have a [class](#)^{p141} attribute and the [html](#)^{p157} element had to have a [lang](#)^{p144} attribute, the markup would have to become:

```
<!DOCTYPE HTML><html lang="en"><title>Hello</title><body class="demo"><p>Welcome to this example.
```

Note

This section assumes that the document is conforming, in particular, that there are no [content model](#)^{p133} violations. Omitting tags in the fashion described in this section in a document that does not conform to the [content models](#)^{p133} described in this specification is likely to result in unexpected DOM differences (this is, in part, what the content models are designed to avoid).

13.1.2.5 Restrictions on content models § p11 04

For historical reasons, certain elements have extra restrictions beyond even the restrictions given by their content model.

A [table](#)^{p458} element must not contain [tr](#)^{p472} elements, even though these elements are technically allowed inside [table](#)^{p458} elements according to the content models described in this specification. (If a [tr](#)^{p472} element is put inside a [table](#)^{p458} in the markup, it will in fact imply a [tbody](#)^{p469} start tag before it.)

A single [newline](#)^{p1104} may be placed immediately after the [start tag](#)^{p1096} of [pre](#)^{p222} and [textarea](#)^{p558} elements. This does not affect the processing of the element. The otherwise optional [newline](#)^{p1104} *must* be included if the element's contents themselves start with a [newline](#)^{p1104} (because otherwise the leading newline in the contents would be treated like the optional newline, and ignored).

Example

The following two [pre](#)^{p222} blocks are equivalent:

```
<pre>Hello</pre>
```

```
<pre>  
Hello</pre>
```

13.1.2.6 Restrictions on the contents of raw text and escapable raw text elements § p11 04

The text in [raw text](#)^{p1095} and [escapable raw text elements](#)^{p1095} must not contain any occurrences of the string "</" (U+003C LESS-THAN SIGN, U+002F SOLIDUS) followed by characters that case-insensitively match the tag name of the element followed by one of U+0009 CHARACTER TABULATION (tab), U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), U+0020 SPACE, U+003E GREATER-THAN SIGN (>), or U+002F SOLIDUS (/).

13.1.3 Text § p11 04

Text is allowed inside elements, attribute values, and comments. Extra constraints are placed on what is and what is not allowed in text based on where the text is to be put, as described in the other sections.

13.1.3.1 Newlines § p11 04

Newlines in HTML may be represented either as U+000D CARRIAGE RETURN (CR) characters, U+000A LINE FEED (LF) characters, or pairs of U+000D CARRIAGE RETURN (CR), U+000A LINE FEED (LF) characters in that order.

Where [character references](#)^{p1104} are allowed, a character reference of a U+000A LINE FEED (LF) character (but not a U+000D CARRIAGE RETURN (CR) character) also represents a [newline](#)^{p1104}.

13.1.4 Character references § p11 04

In certain cases described in other sections, [text](#)^{p1104} may be mixed with **character references**. These can be used to escape characters that couldn't otherwise legally be included in [text](#)^{p1104}.

Character references must start with a U+0026 AMPERSAND character (&). Following this, there are three possible kinds of character references:

Named character references

The ampersand must be followed by one of the names given in the [named character references^{p1207}](#) section, using the same case. The name must be one that is terminated by a U+003B SEMICOLON character (;).

Decimal numeric character reference

The ampersand must be followed by a U+0023 NUMBER SIGN character (#), followed by one or more [ASCII digits](#), representing a base-ten integer that corresponds to a code point that is allowed according to the definition below. The digits must then be followed by a U+003B SEMICOLON character (;).

Hexadecimal numeric character reference

The ampersand must be followed by a U+0023 NUMBER SIGN character (#), which must be followed by either a U+0078 LATIN SMALL LETTER X character (x) or a U+0058 LATIN CAPITAL LETTER X character (X), which must then be followed by one or more [ASCII hex digits](#), representing a hexadecimal integer that corresponds to a code point that is allowed according to the definition below. The digits must then be followed by a U+003B SEMICOLON character (;).

The numeric character reference forms described above are allowed to reference any code point excluding U+000D CR, [noncharacters](#), and [controls](#) other than [ASCII whitespace](#).

An **ambiguous ampersand** is a U+0026 AMPERSAND character (&) that is followed by one or more [ASCII alphanumerics](#), followed by a U+003B SEMICOLON character (;), where these characters do not match any of the names given in the [named character references^{p1207}](#) section.

13.1.5 CDATA sections §^{p11}₀₅

CDATA sections must consist of the following components, in this order:

1. The string "<![CDATA[".
2. Optionally, [text^{p1104}](#), with the additional restriction that the text must not contain the string "]]>".
3. The string "]]>".

Example

CDATA sections can only be used in foreign content (MathML or SVG). In this example, a CDATA section is used to escape the contents of a [MathML `ms`](#) element:

```
<p>You can add a string to a number, but this stringifies the number:</p>
<math>
  <ms><![CDATA[x<y]]></ms>
  <mo>+</mo>
  <mn>3</mn>
  <mo>=</mo>
  <ms><![CDATA[x<y3]]></ms>
</math>
```

13.1.6 Comments §^{p11}₀₅

Comments must have the following format:

1. The string "<!--".
2. Optionally, [text^{p1104}](#), with the additional restriction that the text must not start with the string ">", nor start with the string "->", nor contain the strings "<!--", "-->", or "--!>", nor end with the string "<!--".
3. The string "-->".

Note

The [text^{p1104}](#) is allowed to end with the string "<!", as in <!--My favorite operators are > and <!-->.

13.2 Parsing HTML documents ^{§[p11](#)} ₀₆

This section only applies to user agents, data mining tools, and conformance checkers.

Note

The rules for parsing XML documents into DOM trees are covered by the next section, entitled "[The XML syntax](#)^{[p1217](#)}".

User agents must use the parsing rules described in this section to generate the DOM trees from [text/html](#)^{[p1275](#)} resources. Together, these rules define what is referred to as the **HTML parser**.

Note

While the HTML syntax described in this specification bears a close resemblance to SGML and XML, it is a separate language with its own parsing rules.

Some earlier versions of HTML (in particular from HTML2 to HTML4) were based on SGML and used SGML parsing rules. However, few (if any) web browsers ever implemented true SGML parsing for HTML documents; the only user agents to strictly handle HTML as an SGML application have historically been validators. The resulting confusion — with validators claiming documents to have one representation while widely deployed web browsers interoperably implemented a different representation — has wasted decades of productivity. This version of HTML thus returns to a non-SGML basis.

Authors interested in using SGML tools in their authoring pipeline are encouraged to use XML tools and the XML serialization of HTML.

For the purposes of conformance checkers, if a resource is determined to be in [the HTML syntax](#)^{[p1094](#)}, then it is an [HTML document](#).

Note

As stated [in the terminology section](#)^{[p44](#)}, references to [element types](#)^{[p44](#)} that do not explicitly specify a namespace always refer to elements in the [HTML namespace](#). For example, if the spec talks about "a [menu](#)^{[p229](#)} element", then that is an element with the local name "menu", the namespace "[http://www.w3.org/1999/xhtml](#)", and the interface [HTMLMenuElement](#)^{[p230](#)}. Where possible, references to such elements are hyperlinked to their definition.

13.2.1 Overview of the parsing model § p1107

The input to the HTML parsing process consists of a stream of [code points](#), which is passed through a [tokenization](#) stage followed by a [tree construction](#) stage. The output is a [Document](#) object.

Note

Implementations that [do not support scripting](#) do not have to actually create a [DOM Document](#) object, but the DOM tree in such cases is still used as the model for the rest of the specification.

In the common case, the data handled by the tokenization stage comes from the network, but [it can also come from script](#) running in the user agent, e.g. using the [document.write\(\)](#) API.

There is only one set of states for the tokenizer stage and the tree construction stage, but the tree construction stage is reentrant, meaning that while the tree construction stage is handling one token, the tokenizer might be resumed, causing further tokens to be emitted and processed before the first token's processing is complete.

Example

In the following example, the tree construction stage will be called upon to handle a "p" start tag token while handling the "script" end tag token:

```
...
<script>
  document.write('<p>');
</script>
...
```

To handle these cases, parsers have a **script nesting level**, which must be initially set to zero, and a **parser pause flag**, which must be initially set to false.

13.2.2 Parse errors ^{§p11}₀₈

This specification defines the parsing rules for HTML documents, whether they are syntactically correct or not. Certain points in the parsing algorithm are said to be [parse errors](#)^{p1108}. The error handling for parse errors is well-defined (that's the processing rules described throughout this specification), but user agents, while parsing an HTML document, may [abort the parser](#)^{p1193} at the first [parse error](#)^{p1108} that they encounter for which they do not wish to apply the rules described in this specification.

Conformance checkers must report at least one parse error condition to the user if one or more parse error conditions exist in the document and must not report parse error conditions if none exist in the document. Conformance checkers may report more than one parse error condition if more than one parse error condition exists in the document.

Note

Parse errors are only errors with the syntax of HTML. In addition to checking for parse errors, conformance checkers will also verify that the document obeys all the other conformance requirements described in this specification.

Some parse errors have dedicated codes outlined in the table below that should be used by conformance checkers in reports.

Error descriptions in the table below are non-normative.

Code	Description
abrupt-closing-of-empty-comment	This error occurs if the parser encounters an empty comment ^{p1105} that is abruptly closed by a U+003E (>) code point (i.e., <!--> or <!-->). The parser behaves as if the comment is closed correctly.
abrupt-doctype-public-identifier	This error occurs if the parser encounters a U+003E (>) code point in the DOCTYPE ^{p1094} public identifier (e.g., <!DOCTYPE html PUBLIC "foo>). In such a case, if the DOCTYPE is correctly placed as a document preamble, the parser sets the Document ^{p117} to quirks mode .
abrupt-doctype-system-identifier	This error occurs if the parser encounters a U+003E (>) code point in the DOCTYPE ^{p1094} system identifier (e.g., <!DOCTYPE html PUBLIC "-//W3C//DTD HTML 4.01//EN" "foo>). In such a case, if the DOCTYPE is correctly placed as a document preamble, the parser sets the Document ^{p117} to quirks mode .
absence-of-digits-in-numeric-character-reference	This error occurs if the parser encounters a numeric character reference ^{p1104} that doesn't contain any digits (e.g., &#qux;). In this case the parser doesn't resolve the character reference.
cdata-in-html-content	This error occurs if the parser encounters a CDATA section ^{p1105} outside of foreign content (SVG or MathML). The parser treats such CDATA sections (including leading "[CDATA[" and trailing "]" strings) as comments.
character-reference-outside-unicode-range	This error occurs if the parser encounters a numeric character reference ^{p1104} that references a code point that is greater than the valid Unicode range. The parser resolves such a character reference to a U+FFFD REPLACEMENT CHARACTER.
control-character-in-input-stream	This error occurs if the input stream ^{p1119} contains a control code point that is not ASCII whitespace or U+0000 NULL. Such code points are parsed as-is and usually, where parsing rules don't apply any additional restrictions, make their way into the DOM.
control-character-reference	This error occurs if the parser encounters a numeric character reference ^{p1104} that references a control code point that is not ASCII whitespace or is a U+000D CARRIAGE RETURN. The parser resolves such character references as-is except C1 control references that are replaced according to the numeric character reference end state ^{p1152} .
end-tag-with-attributes	This error occurs if the parser encounters an end tag ^{p1097} with attributes ^{p1097} . Attributes in end tags are ignored and do not make their way into the DOM.
duplicate-attribute	This error occurs if the parser encounters an attribute ^{p1097} in a tag that already has an attribute with the same name. The parser ignores all such duplicate occurrences of the attribute.
end-tag-with-trailing-solidus	This error occurs if the parser encounters an end tag ^{p1097} that has a U+002F (/) code point right before the closing U+003E (>) code point (e.g., </div/>). Such a tag is treated as a regular end tag.
eof-before-tag-name	This error occurs if the parser encounters the end of the input stream ^{p1119} where a tag name is expected. In this case the parser treats the beginning of a start tag ^{p1096} (i.e., <) or an end tag ^{p1097} (i.e., </) as text content.

Code	Description
eof-in-cdata	This error occurs if the parser encounters the end of the input stream ^{p1119} in a CDATA section ^{p1105} . The parser treats such CDATA sections as if they are closed immediately before the end of the input stream.
eof-in-comment	This error occurs if the parser encounters the end of the input stream ^{p1119} in a comment ^{p1105} . The parser treats such comments as if they are closed immediately before the end of the input stream.
eof-in-doctype	This error occurs if the parser encounters the end of the input stream in a DOCTYPE ^{p1094} . In such a case, if the DOCTYPE is correctly placed as a document preamble, the parser sets the Document ^{p117} to quirks mode .
eof-in-script-html-comment-like-text	This error occurs if the parser encounters the end of the input stream ^{p1119} in text that resembles an HTML comment ^{p1105} inside script ^{p624} element content (e.g., <code><script><!-- foo</code>). <p>Note</p> <p><i>Syntactic structures that resemble HTML comments in script^{p624} elements are parsed as text content. They can be a part of a scripting language-specific syntactic structure or be treated as an HTML-like comment, if the scripting language supports them (e.g., parsing rules for HTML-like comments can be found in Annex B of the JavaScript specification). The common reason for this error is a violation of the restrictions for contents of script elements^{p635}. [JAVASCRIPT]^{p1308}</i></p>
eof-in-tag	This error occurs if the parser encounters the end of the input stream ^{p1119} in a start tag ^{p1096} or an end tag ^{p1097} (e.g., <code><div id=</code>). Such a tag is ignored.
incorrectly-closed-comment	This error occurs if the parser encounters a comment ^{p1105} that is closed by the <code>"-!>"</code> code point sequence. The parser treats such comments as if they are correctly closed by the <code>"->"</code> code point sequence.
incorrectly-opened-comment	This error occurs if the parser encounters the <code>"<!"</code> code point sequence that is not immediately followed by two U+002D (-) code points and that is not the start of a DOCTYPE ^{p1094} or a CDATA section ^{p1105} . All content that follows the <code>"<!"</code> code point sequence up to a U+003E (>) code point (if present) or to the end of the input stream ^{p1119} is treated as a comment. <p>Note</p> <p><i>One possible cause of this error is using an XML markup declaration (e.g., <code><!ELEMENT br EMPTY></code>) in HTML.</i></p>
invalid-character-sequence-after-doctype-name	This error occurs if the parser encounters any code point sequence other than "PUBLIC" and "SYSTEM" keywords after a DOCTYPE ^{p1094} name. In such a case, the parser ignores any following public or system identifiers, and if the DOCTYPE is correctly placed as a document preamble, and if the parser cannot change the mode flag ^{p1159} is false, sets the Document ^{p117} to quirks mode .
invalid-first-character-of-tag-name	This error occurs if the parser encounters a code point that is not an ASCII alpha where first code point of a start tag ^{p1096} name or an end tag ^{p1097} name is expected. If a start tag was expected such code point and a preceding U+003C (<) is treated as text content, and all content that follows is treated as markup. Whereas, if an end tag was expected, such code point and all content that follows up to a U+003E (>) code point (if present) or to the end of the input stream ^{p1119} is treated as a comment. <p>Example</p> <p>For example, consider the following markup:</p> <pre><42></42></pre> <p>This will be parsed into:</p> <pre> L html^{p157} ├ head^{p158} │ └ body^{p184} │ └ #text: <42> └ #comment: 42 </pre> <p>Note</p> <p><i>While the first code point of a tag name is limited to an ASCII alpha, a wide range of code points (including ASCII digits) is allowed in subsequent positions.</i></p>
missing-attribute-value	This error occurs if the parser encounters a U+003E (>) code point where an attribute ^{p1097} value is expected (e.g., <code><div id=></code>). The parser treats the attribute as having an empty value.
missing-doctype-name	This error occurs if the parser encounters a DOCTYPE ^{p1094} that is missing a name (e.g., <code><!DOCTYPE></code>). In such a case, if the DOCTYPE is correctly placed as a document preamble, the parser sets the Document ^{p117} to quirks mode .
missing-doctype-public-identifier	This error occurs if the parser encounters a U+003E (>) code point where start of the DOCTYPE ^{p1094} public identifier is expected (e.g., <code><!DOCTYPE html PUBLIC ></code>). In such a case, if the DOCTYPE is correctly placed as a document preamble, the parser sets the Document ^{p117} to quirks mode .

Code	Description
missing-doctype-system-identifier	This error occurs if the parser encounters a U+003E (>) code point where start of the DOCTYPE^{p1094} system identifier is expected (e.g., <!DOCTYPE html SYSTEM >). In such a case, if the DOCTYPE is correctly placed as a document preamble, the parser sets the Document^{p117} to quirks mode .
missing-end-tag-name	This error occurs if the parser encounters a U+003E (>) code point where an end tag^{p1097} name is expected, i.e., </>. The parser ignores the whole "</>" code point sequence.
missing-quote-before-doctype-public-identifier	This error occurs if the parser encounters the DOCTYPE^{p1094} public identifier that is not preceded by a quote (e.g., <!DOCTYPE html PUBLIC -//W3C//DTD HTML 4.01//EN">). In such a case, the parser ignores the public identifier, and if the DOCTYPE is correctly placed as a document preamble, sets the Document^{p117} to quirks mode .
missing-quote-before-doctype-system-identifier	This error occurs if the parser encounters the DOCTYPE^{p1094} system identifier that is not preceded by a quote (e.g., <!DOCTYPE html SYSTEM http://www.w3.org/TR/xhtml1/DTD/xhtml1-transitional.dtd">). In such a case, the parser ignores the system identifier, and if the DOCTYPE is correctly placed as a document preamble, sets the Document^{p117} to quirks mode .
missing-semicolon-after-character-reference	This error occurs if the parser encounters a character reference^{p1104} that is not terminated by a U+003B (;) code point . Usually the parser behaves as if character reference is terminated by the U+003B (;) code point; however, there are some ambiguous cases in which the parser includes subsequent code points in the character reference. Example For example, ¬in will be parsed as "-in" whereas ¬in will be parsed as "¢".
missing-whitespace-after-doctype-public-keyword	This error occurs if the parser encounters a DOCTYPE^{p1094} whose "PUBLIC" keyword and public identifier are not separated by ASCII whitespace . In this case the parser behaves as if ASCII whitespace is present.
missing-whitespace-after-doctype-system-keyword	This error occurs if the parser encounters a DOCTYPE^{p1094} whose "SYSTEM" keyword and system identifier are not separated by ASCII whitespace . In this case the parser behaves as if ASCII whitespace is present.
missing-whitespace-before-doctype-name	This error occurs if the parser encounters a DOCTYPE^{p1094} whose "DOCTYPE" keyword and name are not separated by ASCII whitespace . In this case the parser behaves as if ASCII whitespace is present.
missing-whitespace-between-attributes	This error occurs if the parser encounters attributes^{p1097} that are not separated by ASCII whitespace (e.g., <div id="foo" class="bar">). In this case the parser behaves as if ASCII whitespace is present.
missing-whitespace-between-doctype-public-and-system-identifiers	This error occurs if the parser encounters a DOCTYPE^{p1094} whose public and system identifiers are not separated by ASCII whitespace . In this case the parser behaves as if ASCII whitespace is present.
nested-comment	This error occurs if the parser encounters a nested comment^{p1105} (e.g., <!-- <!-- nested --> -->). Such a comment will be closed by the first occurring "-->" code point sequence and everything that follows will be treated as markup.
noncharacter-character-reference	This error occurs if the parser encounters a numeric character reference^{p1104} that references a noncharacter . The parser resolves such character references as-is.
noncharacter-in-input-stream	This error occurs if the input stream^{p1119} contains a noncharacter . Such code points are parsed as-is and usually, where parsing rules don't apply any additional restrictions, make their way into the DOM.
non-void-html-element-start-tag-with-trailing-solidus	This error occurs if the parser encounters a start tag^{p1096} for an element that is not in the list of void elements^{p1095} or is not a part of foreign content (i.e., not an SVG or MathML element) that has a U+002F (/) code point right before the closing U+003E (>) code point. The parser behaves as if the U+002F (/) is not present. Example For example, consider the following markup: <pre><div></pre> This will be parsed into: <pre>L html^{p157} L head^{p158} L body^{p184} L div^{p243}</pre>

Code	Description
	<div data-bbox="354 176 446 226" style="border: 1px solid black; padding: 2px; display: inline-block;"> ^{p285} ^{p285} </div> <p>Note <i>The trailing U+002F (/) in a start tag name can be used only in foreign content to specify self-closing tags. (Self-closing tags don't exist in HTML.) It is also allowed for void elements, but doesn't have any effect in this case.</i></p>
null-character-reference	<p>This error occurs if the parser encounters a numeric character reference^{p1104} that references a U+0000 NULL code point. The parser resolves such character references to a U+FFFD REPLACEMENT CHARACTER.</p>
surrogate-character-reference	<p>This error occurs if the parser encounters a numeric character reference^{p1104} that references a surrogate. The parser resolves such character references to a U+FFFD REPLACEMENT CHARACTER.</p>
surrogate-in-input-stream	<p>This error occurs if the input stream^{p1119} contains a surrogate. Such code points are parsed as-is and usually, where parsing rules don't apply any additional restrictions, make their way into the DOM.</p> <p>Note <i>Surrogates can only find their way into the input stream via script APIs such as <code>document.write()</code>^{p996}.</i></p>
unexpected-character-after-doctype-system-identifier	<p>This error occurs if the parser encounters any code points other than ASCII whitespace or closing U+003E (>) after the DOCTYPE^{p1094} system identifier. The parser ignores these code points.</p>
unexpected-character-in-attribute-name	<p>This error occurs if the parser encounters a U+0022 ("), U+0027 ('), or U+003C (<) code point in an attribute name^{p1097}. The parser includes such code points in the attribute name.</p> <p>Note <i>Code points that trigger this error are usually a part of another syntactic construct and can be a sign of a typo around the attribute name.</i></p> <p>Example</p> <p>For example, consider the following markup:</p> <pre data-bbox="354 1150 496 1176"><div foo<div></pre> <p>Due to a forgotten U+003E (>) code point after <code>foo</code> the parser treats this markup as a single div^{p243} element with a "foo<div" attribute.</p> <p>As another example of this error, consider the following markup:</p> <pre data-bbox="354 1339 496 1365"><div id'bar'></pre> <p>Due to a forgotten U+003D (=) code point between an attribute name and value the parser treats this markup as a div^{p243} element with the attribute "id'bar'" that has an empty value.</p>
unexpected-character-in-unquoted-attribute-value	<p>This error occurs if the parser encounters a U+0022 ("), U+0027 ('), U+003C (<), U+003D (=), or U+0060 (`) code point in an unquoted attribute value^{p1097}. The parser includes such code points in the attribute value.</p> <p>Note <i>Code points that trigger this error are usually a part of another syntactic construct and can be a sign of a typo around the attribute value.</i></p> <p>Note <i>U+0060 (`) is in the list of code points that trigger this error because certain legacy user agents treat it as a quote.</i></p> <p>Example</p> <p>For example, consider the following markup:</p> <pre data-bbox="354 1885 516 1911"><div foo=b'ar'></pre> <p>Due to a misplaced U+0027 (') code point the parser sets the value of the "foo" attribute to "b'ar'".</p>

Code	Description
unexpected-equals-sign-before-attribute-name	<p>This error occurs if the parser encounters a U+003D (=) code point before an attribute name. In this case the parser treats U+003D (=) as the first code point of the attribute name.</p> <p>Note</p> <p><i>The common reason for this error is a forgotten attribute name.</i></p> <p>Example</p> <p>For example, consider the following markup:</p> <pre><div foo="bar" ="baz"></pre> <p>Due to a forgotten attribute name the parser treats this markup as a div^{p243} element with two attributes: a "foo" attribute with a "bar" value and a "="baz"" attribute with an empty value.</p>
unexpected-null-character	<p>This error occurs if the parser encounters a U+0000 NULL code point in the input stream^{p119} in certain positions. In general, such code points are either ignored or, for security reasons, replaced with a U+FFFD REPLACEMENT CHARACTER.</p>
unexpected-question-mark-instead-of-tag-name	<p>This error occurs if the parser encounters a U+003F (?) code point where first code point of a start tag^{p106} name is expected. The U+003F (?) and all content that follows up to a U+003E (>) code point (if present) or to the end of the input stream^{p119} is treated as a comment.</p> <p>Example</p> <p>For example, consider the following markup:</p> <pre><?xml-stylesheet type="text/css" href="style.css"?)></pre> <p>This will be parsed into:</p> <pre>#comment: ?xml-stylesheet type="text/css" href="style.css"? html^{p157} ├ head^{p158} └ body^{p184}</pre> <p>Note</p> <p><i>The common reason for this error is an XML processing instruction (e.g., <?xml-stylesheet type="text/css" href="style.css"?) or an XML declaration (e.g., <?xml version="1.0" encoding="UTF-8"?) being used in HTML.</i></p>
unexpected-solidus-in-tag	<p>This error occurs if the parser encounters a U+002F (/) code point that is not a part of a quoted attribute^{p107} value and not immediately followed by a U+003E (>) code point in a tag (e.g., <div / id="foo">). In this case the parser behaves as if it encountered ASCII whitespace.</p>
unknown-named-character-reference	<p>This error occurs if the parser encounters an ambiguous ampersand^{p105}. In this case the parser doesn't resolve the character reference^{p104}.</p>

13.2.3 The input byte stream ^{p11}₁₂

The stream of code points that comprises the input to the tokenization stage will be initially seen by the user agent as a stream of bytes (typically coming over the network or from the local file system). The bytes encode the actual characters according to a particular *character encoding*, which the user agent uses to decode the bytes into characters.

Note

For XML documents, the algorithm user agents are required to use to determine the character encoding is given by XML. This section does not apply to XML documents. [\[XML\]^{p1313}](#)

Usually, the [encoding sniffing algorithm^{p113}](#) defined below is used to determine the character encoding.

Given a character encoding, the bytes in the [input byte stream^{p112}](#) must be converted to characters for the tokenizer's [input stream^{p119}](#), by passing the [input byte stream^{p112}](#) and character encoding to [decode](#).

Note

A leading Byte Order Mark (BOM) causes the character encoding argument to be ignored and will itself be skipped.

Note

Bytes or sequences of bytes in the original byte stream that did not conform to the Encoding standard (e.g. invalid UTF-8 byte sequences in a UTF-8 input byte stream) are errors that conformance checkers are expected to report. [ENCODING]^{p1307}

Warning!

The decoder algorithms describe how to handle invalid input; for security reasons, it is imperative that those rules be followed precisely. Differences in how invalid byte sequences are handled can result in, amongst other problems, script injection vulnerabilities ("XSS").

When the HTML parser is decoding an input byte stream, it uses a character encoding and a **confidence**. The confidence is either *tentative*, *certain*, or *irrelevant*. The encoding used, and whether the confidence in that encoding is *tentative* or *certain*, is [used during the parsing](#)^{p1162} to determine whether to [change the encoding](#)^{p1119}. If no encoding is necessary, e.g. because the parser is operating on a Unicode stream and doesn't have to use a character encoding at all, then the [confidence](#)^{p1113} is *irrelevant*.

Note

Some algorithms feed the parser by directly adding characters to the [input stream](#)^{p1119} rather than adding bytes to the [input byte stream](#)^{p1112}.

13.2.3.1 Parsing with a known character encoding §^{p11}₁₃

When the HTML parser is to operate on an input byte stream that has a **known definite encoding**, then the character encoding is that encoding and the [confidence](#)^{p1113} is *certain*.

13.2.3.2 Determining the character encoding §^{p11}₁₃

In some cases, it might be impractical to unambiguously determine the encoding before parsing the document. Because of this, this specification provides for a two-pass mechanism with an optional pre-scan. Implementations are allowed, as described below, to apply a simplified parsing algorithm to whatever bytes they have available before beginning to parse the document. Then, the real parser is started, using a tentative encoding derived from this pre-parse and other out-of-band metadata. If, while the document is being loaded, the user agent discovers a character encoding declaration that conflicts with this information, then the parser can get reinvoked to perform a parse of the document with the real encoding.

User agents must use the following algorithm, called the **encoding sniffing algorithm**, to determine the character encoding to use when decoding a document in the first pass. This algorithm takes as input any out-of-band metadata available to the user agent (e.g. the [Content-Type metadata](#)^{p92} of the document) and all the bytes available so far, and returns a character encoding and a [confidence](#)^{p1113} that is either *tentative* or *certain*.

1. If the result of [BOM sniffing](#) is an encoding, return that encoding with [confidence](#)^{p1113} *certain*.

Note

Although the [decode](#) algorithm will itself change the encoding to use based on the presence of a byte order mark, this algorithm sniffs the BOM as well in order to set the correct [document's character encoding](#) and [confidence](#)^{p1113}.

2. If the user has explicitly instructed the user agent to override the document's character encoding with a specific encoding, optionally return that encoding with the [confidence](#)^{p1113} *certain*.

Note

Typically, user agents remember such user requests across sessions, and in some cases apply them to documents in [iframe](#)^{p369}s as well.

3. The user agent may wait for more bytes of the resource to be available, either in this step or at any later step in this algorithm. For instance, a user agent might wait 500ms or 1024 bytes, whichever came first. In general preparing the source to find the encoding improves performance, as it reduces the need to throw away the data structures used when parsing upon finding the encoding information. However, if the user agent delays too long to obtain data to determine the encoding, then the cost of the delay could outweigh any performance improvements from the preparse.

Note

The authoring conformance requirements for character encoding declarations limit them to only appearing [in the first 1024 bytes^{p180}](#). User agents are therefore encouraged to use the prescan algorithm below (as invoked by these steps) on the first 1024 bytes, but not to stall beyond that.

4. If the transport layer specifies a character encoding, and it is supported, return that encoding with the [confidence^{p1113}](#) *certain*.
5. Optionally [prescan the byte stream to determine its encoding^{p1115}](#), with the [end condition^{p1115}](#) being when the user agent decides that scanning further bytes would not be efficient. User agents are encouraged to only prescan the first 1024 bytes. User agents may decide that scanning *any* bytes is not efficient, in which case these substeps are entirely skipped.

The aforementioned algorithm returns either a character encoding or failure. If it returns a character encoding, then return the same encoding, with [confidence^{p1113}](#) *tentative*.

6. If the [HTML parser^{p1106}](#) for which this algorithm is being run is associated with a [Document^{p117}](#) *d* whose [browsing context^{p840}](#) is non-null and a [child browsing context^{p843}](#), then:
 1. Let *parentDocument* be *d*'s [browsing context^{p840}](#)'s [container document^{p843}](#).
 2. If *parentDocument*'s [origin](#) is [same origin^{p869}](#) with *d*'s [origin](#) and *parentDocument*'s [character encoding](#) is not [UTF-16BE/LE](#), then return *parentDocument*'s [character encoding](#), with the [confidence^{p1113}](#) *tentative*.
7. Otherwise, if the user agent has information on the likely encoding for this page, e.g. based on the encoding of the page when it was last visited, then return that encoding, with the [confidence^{p1113}](#) *tentative*.
8. The user agent may attempt to autodetect the character encoding from applying frequency analysis or other algorithms to the data stream. Such algorithms may use information about the resource other than the resource's contents, including the address of the resource. If autodetection succeeds in determining a character encoding, and that encoding is a supported encoding, then return that encoding, with the [confidence^{p1113}](#) *tentative*. [\[UNIVCHARDET\]^{p1312}](#)

Note

User agents are generally discouraged from attempting to autodetect encodings for resources obtained over the network, since doing so involves inherently non-interoperable heuristics. Attempting to detect encodings based on an HTML document's preamble is especially tricky since HTML markup typically uses only ASCII characters, and HTML documents tend to begin with a lot of markup rather than with text content.

Note

The UTF-8 encoding has a highly detectable bit pattern. Files from the local file system that contain bytes with values greater than 0x7F which match the UTF-8 pattern are very likely to be UTF-8, while documents with byte sequences that do not match it are very likely not. When a user agent can examine the whole file, rather than just the preamble, detecting for UTF-8 specifically can be especially effective. [\[PPUTF8\]^{p1310}](#) [\[UTF8DET\]^{p1312}](#)

9. Otherwise, return an [implementation-defined](#) or user-specified default character encoding, with the [confidence^{p1113}](#) *tentative*.

In controlled environments or in environments where the encoding of documents can be prescribed (for example, for user agents intended for dedicated use in new networks), the comprehensive UTF-8 encoding is suggested.

In other environments, the default encoding is typically dependent on the user's locale (an approximation of the languages, and thus often encodings, of the pages that the user is likely to frequent). The following table gives suggested defaults based on the user's locale, for compatibility with legacy content. Locales are identified by BCP 47 language tags. [\[BCP47\]^{p1305}](#) [\[ENCODING\]^{p1307}](#)

Locale language		Suggested default encoding
ar	Arabic	windows-1256
az	Azeri	windows-1254
ba	Bashkir	windows-1251
be	Belarusian	windows-1251
bg	Bulgarian	windows-1251
cs	Czech	windows-1250
el	Greek	ISO-8859-7
et	Estonian	windows-1257
fa	Persian	windows-1256
he	Hebrew	windows-1255

Locale language		Suggested default encoding
hr	Croatian	windows-1250
hu	Hungarian	ISO-8859-2
ja	Japanese	Shift_JIS
kk	Kazakh	windows-1251
ko	Korean	EUC-KR
ku	Kurdish	windows-1254
ky	Kyrgyz	windows-1251
lt	Lithuanian	windows-1257
lv	Latvian	windows-1257
mk	Macedonian	windows-1251
pl	Polish	ISO-8859-2
ru	Russian	windows-1251
sah	Yakut	windows-1251
sk	Slovak	windows-1250
sl	Slovenian	ISO-8859-2
sr	Serbian	windows-1251
tg	Tajik	windows-1251
th	Thai	windows-874
tr	Turkish	windows-1254
tt	Tatar	windows-1251
uk	Ukrainian	windows-1251
vi	Vietnamese	windows-1258
zh-Hans, zh-CN, zh-SG	Chinese, Simplified	GBK
zh-Hant, zh-HK, zh-MO, zh-TW	Chinese, Traditional	Big5
All other locales		windows-1252

The contents of this table are derived from the intersection of Windows, Chrome, and Firefox defaults.

The [document's character encoding](#) must immediately be set to the value returned from this algorithm, at the same time as the user agent uses the returned value to select the decoder to use for the input byte stream.

When an algorithm requires a user agent to **prescan a byte stream to determine its encoding**, given some defined *end condition*, then it must run the following steps. If at any point during these steps (including during instances of the [get an attribute](#)^{p1117} algorithm invoked by this one) the user agent either runs out of bytes (meaning the *position* pointer created in the first step below goes beyond the end of the byte stream obtained so far) or reaches its *end condition*, then abort the [prescan a byte stream to determine its encoding](#)^{p1115} algorithm and return the result [get an XML encoding](#)^{p1118} applied to the same bytes that the [prescan a byte stream to determine its encoding](#)^{p1115} algorithm was applied to. Otherwise, these steps will return a character encoding.

1. Let *fallback encoding* be null.
2. Let *position* be a pointer to a byte in the input byte stream, initially pointing at the first byte.
3. Prescan for UTF-16 XML declarations: If *position* points to:
 - ↪ **A sequence of bytes starting with: 0x3C, 0x0, 0x3F, 0x0, 0x78, 0x0 (case-sensitive UTF-16 little-endian '<?x')**
Return [UTF-16LE](#).
 - ↪ **A sequence of bytes starting with: 0x0, 0x3C, 0x0, 0x3F, 0x0, 0x78 (case-sensitive UTF-16 big-endian '<?x')**
Return [UTF-16BE](#).

Note

For historical reasons, the prefix is two bytes longer than in [Appendix F](#) of XML and the encoding name is not checked.

4. Loop: If *position* points to:
 - ↪ **A sequence of bytes starting with: 0x3C 0x21 0x2D 0x2D ('<!--')**
Advance the *position* pointer so that it points at the first 0x3E byte which is preceded by two 0x2D bytes (i.e. at the end of an ASCII '-->' sequence) and comes after the 0x3C byte that was found. (The two 0x2D bytes can be the same as those in the '<!--' sequence.)

↪ **A sequence of bytes starting with: 0x3C, 0x4D or 0x6D, 0x45 or 0x65, 0x54 or 0x74, 0x41 or 0x61, and one of 0x09, 0x0A, 0x0C, 0x0D, 0x20, 0x2F (case-insensitive ASCII '<meta' followed by a space or slash)**

1. Advance the *position* pointer so that it points at the next 0x09, 0x0A, 0x0C, 0x0D, 0x20, or 0x2F byte (the one in sequence of characters matched above).
2. Let *attribute list* be an empty list of strings.
3. Let *got pragma* be false.
4. Let *need pragma* be null.
5. Let *charset* be the null value (which, for the purposes of this algorithm, is distinct from an unrecognized encoding or the empty string).
6. *Attributes*: [Get an attribute^{p1117}](#) and its value. If no attribute was sniffed, then jump to the *processing* step below.
7. If the attribute's name is already in *attribute list*, then return to the step labeled *attributes*.
8. Add the attribute's name to *attribute list*.
9. Run the appropriate step from the following list, if one applies:
 - ↪ **If the attribute's name is "http-equiv"**
If the attribute's value is "content-type", then set *got pragma* to true.
 - ↪ **If the attribute's name is "content"**
Apply the [algorithm for extracting a character encoding from a meta element^{p92}](#), giving the attribute's value as the string to parse. If a character encoding is returned, and if *charset* is still set to null, let *charset* be the encoding returned, and set *need pragma* to true.
 - ↪ **If the attribute's name is "charset"**
Let *charset* be the result of [getting an encoding](#) from the attribute's value, and set *need pragma* to false.
10. Return to the step labeled *attributes*.
11. *Processing*: If *need pragma* is null, then jump to the step below labeled *next byte*.
12. If *need pragma* is true but *got pragma* is false, then jump to the step below labeled *next byte*.
13. If *charset* is failure, then jump to the step below labeled *next byte*.
14. If *charset* is [UTF-16BE/LE](#), then set *charset* to [UTF-8](#).
15. If *charset* is [x-user-defined](#), then set *charset* to [windows-1252](#).
16. Return *charset*.

↪ **A sequence of bytes starting with a 0x3C byte (<), optionally a 0x2F byte (/), and finally a byte in the range 0x41-0x5A or 0x61-0x7A (A-Z or a-z)**

1. Advance the *position* pointer so that it points at the next 0x09 (HT), 0x0A (LF), 0x0C (FF), 0x0D (CR), 0x20 (SP), or 0x3E (>) byte.
2. Repeatedly [get an attribute^{p1117}](#) until no further attributes can be found, then jump to the step below labeled *next byte*.

↪ **A sequence of bytes starting with: 0x3C 0x21 (`<!`)**

↪ **A sequence of bytes starting with: 0x3C 0x2F (`</`)**

↪ **A sequence of bytes starting with: 0x3C 0x3F (`<?`)**

Advance the *position* pointer so that it points at the first 0x3E byte (>) that comes after the 0x3C byte that was found.

↪ **Any other byte**

Do nothing with that byte.

5. *Next byte*: Move *position* so it points at the next byte in the input byte stream, and return to the step above labeled *loop*.

When the [prescan a byte stream to determine its encoding^{p1115}](#) algorithm says to **get an attribute**, it means doing this:

1. If the byte at *position* is one of 0x09 (HT), 0x0A (LF), 0x0C (FF), 0x0D (CR), 0x20 (SP), or 0x2F (/) then advance *position* to the next byte and redo this step.
2. If the byte at *position* is 0x3E (>), then abort the [get an attribute^{p1117}](#) algorithm. There isn't one.
3. Otherwise, the byte at *position* is the start of the attribute name. Let *attribute name* and *attribute value* be the empty string.
4. Process the byte at *position* as follows:
 - ↪ **If it is 0x3D (=), and the attribute name is longer than the empty string**
Advance *position* to the next byte and jump to the step below labeled *value*.
 - ↪ **If it is 0x09 (HT), 0x0A (LF), 0x0C (FF), 0x0D (CR), or 0x20 (SP)**
Jump to the step below labeled *spaces*.
 - ↪ **If it is 0x2F (/) or 0x3E (>)**
Abort the [get an attribute^{p1117}](#) algorithm. The attribute's name is the value of *attribute name*, its value is the empty string.
 - ↪ **If it is in the range 0x41 (A) to 0x5A (Z)**
Append the code point $b+0x20$ to *attribute name* (where b is the value of the byte at *position*). (This converts the input to lowercase.)
 - ↪ **Anything else**
Append the code point with the same value as the byte at *position* to *attribute name*. (It doesn't actually matter how bytes outside the ASCII range are handled here, since only ASCII bytes can contribute to the detection of a character encoding.)
5. Advance *position* to the next byte and return to the previous step.
6. *Spaces*: If the byte at *position* is one of 0x09 (HT), 0x0A (LF), 0x0C (FF), 0x0D (CR), or 0x20 (SP) then advance *position* to the next byte, then, repeat this step.
7. If the byte at *position* is *not* 0x3D (=), abort the [get an attribute^{p1117}](#) algorithm. The attribute's name is the value of *attribute name*, its value is the empty string.
8. Advance *position* past the 0x3D (=) byte.
9. *Value*: If the byte at *position* is one of 0x09 (HT), 0x0A (LF), 0x0C (FF), 0x0D (CR), or 0x20 (SP) then advance *position* to the next byte, then, repeat this step.
10. Process the byte at *position* as follows:
 - ↪ **If it is 0x22 (") or 0x27 (')**
 1. Let b be the value of the byte at *position*.
 2. *Quote loop*: Advance *position* to the next byte.
 3. If the value of the byte at *position* is the value of b , then advance *position* to the next byte and abort the "get an attribute" algorithm. The attribute's name is the value of *attribute name*, and its value is the value of *attribute value*.
 4. Otherwise, if the value of the byte at *position* is in the range 0x41 (A) to 0x5A (Z), then append a code point to *attribute value* whose value is $0x20$ more than the value of the byte at *position*.
 5. Otherwise, append a code point to *attribute value* whose value is the same as the value of the byte at *position*.
 6. Return to the step above labeled *quote loop*.
 - ↪ **If it is 0x3E (>)**
Abort the [get an attribute^{p1117}](#) algorithm. The attribute's name is the value of *attribute name*, its value is the empty string.
 - ↪ **If it is in the range 0x41 (A) to 0x5A (Z)**
Append a code point $b+0x20$ to *attribute value* (where b is the value of the byte at *position*). Advance *position* to the next byte.

↪ **Anything else**

Append a code point with the same value as the byte at *position* to *attribute value*. Advance *position* to the next byte.

11. Process the byte at *position* as follows:

↪ **If it is 0x09 (HT), 0x0A (LF), 0x0C (FF), 0x0D (CR), 0x20 (SP), or 0x3E (>)**

Abort the [get an attribute](#)^{p1117} algorithm. The attribute's name is the value of *attribute name* and its value is the value of *attribute value*.

↪ **If it is in the range 0x41 (A) to 0x5A (Z)**

Append a code point $b+0x20$ to *attribute value* (where b is the value of the byte at *position*).

↪ **Anything else**

Append a code point with the same value as the byte at *position* to *attribute value*.

12. Advance *position* to the next byte and return to the previous step.

When the [prescan a byte stream to determine its encoding](#)^{p1115} algorithm is aborted without returning an encoding, **get an XML encoding** means doing this.

Note

Looking for syntax resembling an XML declaration, even in [text/html](#)^{p1275}, is necessary for compatibility with existing content.

1. Let *encodingPosition* be a pointer to the start of the stream.
2. If *encodingPosition* does not point to the start of a byte sequence 0x3C, 0x3F, 0x78, 0x6D, 0x6C (``<?xml``), then return failure.
3. Let *xmlDeclarationEnd* be a pointer to the next byte in the input byte stream which is 0x3E (>). If there is no such byte, then return failure.
4. Set *encodingPosition* to the position of the first occurrence of the subsequence of bytes 0x65, 0x6E, 0x63, 0x6F, 0x64, 0x69, 0x6E, 0x67 (``encoding``) at or after the current *encodingPosition*. If there is no such sequence, then return failure.
5. Advance *encodingPosition* past the 0x67 (g) byte.
6. While the byte at *encodingPosition* is less than or equal to 0x20 (i.e., it is either an ASCII space or control character), advance *encodingPosition* to the next byte.
7. If the byte at *encodingPosition* is not 0x3D (=), then return failure.
8. Advance *encodingPosition* to the next byte.
9. While the byte at *encodingPosition* is less than or equal to 0x20 (i.e., it is either an ASCII space or control character), advance *encodingPosition* to the next byte.
10. Let *quoteMark* be the byte at *encodingPosition*.
11. If *quoteMark* is not either 0x22 (") or 0x27 ('), then return failure.
12. Advance *encodingPosition* to the next byte.
13. Let *encodingEndPosition* be the position of the next occurrence of *quoteMark* at or after *encodingPosition*. If *quoteMark* does not occur again, then return failure.
14. Let *potentialEncoding* be the sequence of the bytes between *encodingPosition* (inclusive) and *encodingEndPosition* (exclusive).
15. If *potentialEncoding* contains one or more bytes whose byte value is 0x20 or below, then return failure.
16. Let *encoding* be the result of [getting an encoding](#) given *potentialEncoding* [isomorphic decoded](#).
17. If the *encoding* is [UTF-16BE/LE](#), then change it to [UTF-8](#).
18. Return *encoding*.

For the sake of interoperability, user agents should not use a pre-scan algorithm that returns different results than the one described above. (But, if you do, please at least let us know, so that we can improve this algorithm and benefit everyone...)

13.2.3.3 Character encodings ^{§ p11}₁₉

User agents must support the encodings defined in *Encoding*, including, but not limited to, [UTF-8](#), [ISO-8859-2](#), [ISO-8859-7](#), [ISO-8859-8](#), [windows-874](#), [windows-1250](#), [windows-1251](#), [windows-1252](#), [windows-1254](#), [windows-1255](#), [windows-1256](#), [windows-1257](#), [windows-1258](#), [GBK](#), [Big5](#), [ISO-2022-JP](#), [Shift_JIS](#), [EUC-KR](#), [UTF-16BE](#), [UTF-16LE](#), [UTF-16BE/LE](#), and [x-user-defined](#). User agents must not support other encodings.

Note

The above prohibits supporting, for example, CESU-8, UTF-7, BOCU-1, SCSU, EBCDIC, and UTF-32. This specification does not make any attempt to support prohibited encodings in its algorithms; support and use of prohibited encodings would thus lead to unexpected behavior. [\[CESU8\]](#)^{p1305} [\[UTF7\]](#)^{p1312} [\[BOCU1\]](#)^{p1305} [\[SCSU\]](#)^{p1311}

13.2.3.4 Changing the encoding while parsing ^{§ p11}₁₉

When the parser requires the user agent to **change the encoding**, it must run the following steps. This might happen if the [encoding sniffing algorithm](#)^{p1113} described above failed to find a character encoding, or if it found a character encoding that was not the actual encoding of the file.

1. If the encoding that is already being used to interpret the input stream is [UTF-16BE/LE](#), then set the [confidence](#)^{p1113} to *certain* and return. The new encoding is ignored; if it was anything but the same encoding, then it would be clearly incorrect.
2. If the new encoding is [UTF-16BE/LE](#), then change it to [UTF-8](#).
3. If the new encoding is [x-user-defined](#), then change it to [windows-1252](#).
4. If the new encoding is identical or equivalent to the encoding that is already being used to interpret the input stream, then set the [confidence](#)^{p1113} to *certain* and return. This happens when the encoding information found in the file matches what the [encoding sniffing algorithm](#)^{p1113} determined to be the encoding, and in the second pass through the parser if the first pass found that the encoding sniffing algorithm described in the earlier section failed to find the right encoding.
5. If all the bytes up to the last byte converted by the current decoder have the same Unicode interpretations in both the current encoding and the new encoding, and if the user agent supports changing the converter on the fly, then the user agent may change to the new converter for the encoding on the fly. Set the [document's character encoding](#) and the encoding used to convert the input stream to the new encoding, set the [confidence](#)^{p1113} to *certain*, and return.
6. Otherwise, [navigate](#)^{p906} to the document again, with [historyHandling](#)^{p906} set to "[replace](#)^{p906}", and using the same [source browsing context](#)^{p906}, but this time skip the [encoding sniffing algorithm](#)^{p1113} and instead just set the encoding to the new encoding and the [confidence](#)^{p1113} to *certain*. Whenever possible, this should be done without actually contacting the network layer (the bytes should be re-parsed from memory), even if, e.g., the document is marked as not being cacheable. If this is not possible and contacting the network layer would involve repeating a request that uses a method other than `GET`, then instead set the [confidence](#)^{p1113} to *certain* and ignore the new encoding. The resource will be misinterpreted. User agents may notify the user of the situation, to aid in application development.

Note

This algorithm is only invoked when a new encoding is found declared on a [meta](#)^{p170} element.

13.2.3.5 Preprocessing the input stream ^{§ p11}₁₉

The **input stream** consists of the characters pushed into it as the [input byte stream](#)^{p1112} is decoded or from the various APIs that directly manipulate the input stream.

Any occurrences of [surrogates](#) are [surrogate-in-input-stream](#)^{p1111} [parse errors](#)^{p1108}. Any occurrences of [noncharacters](#) are [noncharacter-in-input-stream](#)^{p1110} [parse errors](#)^{p1108} and any occurrences of [controls](#) other than [ASCII whitespace](#) and U+0000 NULL characters are [control-character-in-input-stream](#)^{p1108} [parse errors](#)^{p1108}.

Note

The handling of U+0000 NULL characters varies based on where the characters are found and happens at the later stages of the parsing. They are either ignored or, for security reasons, replaced with a U+FFFD REPLACEMENT CHARACTER. This handling is, by necessity, spread across both the tokenization stage and the tree construction stage.

Before the [tokenization^{p1124}](#) stage, the input stream must be preprocessed by [normalizing newlines](#). Thus, newlines in HTML DOMs are represented by U+000A LF characters, and there are never any U+000D CR characters in the input to the [tokenization^{p1124}](#) stage.

The **next input character** is the first character in the [input stream^{p1119}](#) that has not yet been **consumed** or explicitly ignored by the requirements in this section. Initially, the [next input character^{p1120}](#) is the first character in the input. The **current input character** is the last character to have been *consumed*.

The **insertion point** is the position (just before a character or just before the end of the input stream) where content inserted using [document.write\(\)^{p996}](#) is actually inserted. The insertion point is relative to the position of the character immediately after it, it is not an absolute offset into the input stream. Initially, the insertion point is undefined.

The "EOF" character in the tables below is a conceptual character representing the end of the [input stream^{p1119}](#). If the parser is a [script-created parser^{p995}](#), then the end of the [input stream^{p1119}](#) is reached when an **explicit "EOF" character** (inserted by the [document.close\(\)^{p995}](#) method) is consumed. Otherwise, the "EOF" character is not a real character in the stream, but rather the lack of any further characters.

13.2.4 Parse state §^{p11}₂₀

13.2.4.1 The insertion mode §^{p11}₂₀

The **insertion mode** is a state variable that controls the primary operation of the tree construction stage.

Initially, the [insertion mode^{p1120}](#) is "[initial^{p1159}](#)". It can change to "[before html^{p1161}](#)", "[before head^{p1161}](#)", "[in head^{p1162}](#)", "[in head noscript^{p1164}](#)", "[after head^{p1165}](#)", "[in body^{p1166}](#)", "[text^{p1176}](#)", "[in table^{p1177}](#)", "[in table text^{p1179}](#)", "[in caption^{p1179}](#)", "[in column group^{p1180}](#)", "[in table body^{p1181}](#)", "[in row^{p1182}](#)", "[in cell^{p1183}](#)", "[in select^{p1184}](#)", "[in select in table^{p1185}](#)", "[in template^{p1186}](#)", "[after body^{p1187}](#)", "[in frameset^{p1187}](#)", "[after frameset^{p1188}](#)", "[after after body^{p1189}](#)", and "[after after frameset^{p1189}](#)" during the course of the parsing, as described in the [tree construction^{p1152}](#) stage. The insertion mode affects how tokens are processed and whether CDATA sections are supported.

Several of these modes, namely "[in head^{p1162}](#)", "[in body^{p1166}](#)", "[in table^{p1177}](#)", and "[in select^{p1184}](#)", are special, in that the other modes defer to them at various times. When the algorithm below says that the user agent is to do something "**using the rules for the *m* insertion mode**", where *m* is one of these modes, the user agent must use the rules described under the *m* [insertion mode^{p1120}](#)'s section, but must leave the [insertion mode^{p1120}](#) unchanged unless the rules in *m* themselves switch the [insertion mode^{p1120}](#) to a new value.

When the insertion mode is switched to "[text^{p1176}](#)" or "[in table text^{p1179}](#)", the **original insertion mode** is also set. This is the insertion mode to which the tree construction stage will return.

Similarly, to parse nested [template^{p640}](#) elements, a **stack of template insertion modes** is used. It is initially empty. The **current template insertion mode** is the insertion mode that was most recently added to the [stack of template insertion modes^{p1120}](#). The algorithms in the sections below will *push* insertion modes onto this stack, meaning that the specified insertion mode is to be added to the stack, and *pop* insertion modes from the stack, which means that the most recently added insertion mode must be removed from the stack.

When the steps below require the UA to **reset the insertion mode appropriately**, it means the UA must follow these steps:

1. Let *last* be false.
2. Let *node* be the last node in the [stack of open elements^{p1121}](#).
3. *Loop*: If *node* is the first node in the stack of open elements, then set *last* to true, and, if the parser was created as part of the [HTML fragment parsing algorithm^{p1206}](#) ([fragment case^{p1206}](#)), set *node* to the [context^{p1206}](#) element passed to that algorithm.
4. If *node* is a [select^{p547}](#) element, run these substeps:
 1. If *last* is true, jump to the step below labeled *done*.
 2. Let *ancestor* be *node*.
 3. *Loop*: If *ancestor* is the first node in the [stack of open elements^{p1121}](#), jump to the step below labeled *done*.
 4. Let *ancestor* be the node before *ancestor* in the [stack of open elements^{p1121}](#).

5. If *ancestor* is a [template](#)^{p640} node, jump to the step below labeled *done*.
6. If *ancestor* is a [table](#)^{p458} node, switch the [insertion mode](#)^{p1120} to "[in select in table](#)^{p1185}" and return.
7. Jump back to the step labeled *loop*.
8. *Done*: Switch the [insertion mode](#)^{p1120} to "[in select](#)^{p1184}" and return.
5. If *node* is a [td](#)^{p474} or [th](#)^{p475} element and *last* is false, then switch the [insertion mode](#)^{p1120} to "[in cell](#)^{p1183}" and return.
6. If *node* is a [tr](#)^{p472} element, then switch the [insertion mode](#)^{p1120} to "[in row](#)^{p1182}" and return.
7. If *node* is a [tbody](#)^{p469}, [thead](#)^{p470}, or [tfoot](#)^{p471} element, then switch the [insertion mode](#)^{p1120} to "[in table body](#)^{p1181}" and return.
8. If *node* is a [caption](#)^{p466} element, then switch the [insertion mode](#)^{p1120} to "[in caption](#)^{p1179}" and return.
9. If *node* is a [colgroup](#)^{p467} element, then switch the [insertion mode](#)^{p1120} to "[in column group](#)^{p1180}" and return.
10. If *node* is a [table](#)^{p458} element, then switch the [insertion mode](#)^{p1120} to "[in table](#)^{p1177}" and return.
11. If *node* is a [template](#)^{p640} element, then switch the [insertion mode](#)^{p1120} to the [current template insertion mode](#)^{p1120} and return.
12. If *node* is a [head](#)^{p158} element and *last* is false, then switch the [insertion mode](#)^{p1120} to "[in head](#)^{p1162}" and return.
13. If *node* is a [body](#)^{p184} element, then switch the [insertion mode](#)^{p1120} to "[in body](#)^{p1166}" and return.
14. If *node* is a [frameset](#)^{p1264} element, then switch the [insertion mode](#)^{p1120} to "[in frameset](#)^{p1187}" and return. ([fragment case](#)^{p1206})
15. If *node* is an [html](#)^{p157} element, run these substeps:
 1. If the [head element pointer](#)^{p1124} is null, switch the [insertion mode](#)^{p1120} to "[before head](#)^{p1161}" and return. ([fragment case](#)^{p1206})
 2. Otherwise, the [head element pointer](#)^{p1124} is not null, switch the [insertion mode](#)^{p1120} to "[after head](#)^{p1165}" and return.
16. If *last* is true, then switch the [insertion mode](#)^{p1120} to "[in body](#)^{p1166}" and return. ([fragment case](#)^{p1206})
17. Let *node* now be the node before *node* in the [stack of open elements](#)^{p1121}.
18. Return to the step labeled *loop*.

13.2.4.2 The stack of open elements §^{p11} 21

Initially, the **stack of open elements** is empty. The stack grows downwards; the topmost node on the stack is the first one added to the stack, and the bottommost node of the stack is the most recently added node in the stack (notwithstanding when the stack is manipulated in a random access fashion as part of [the handling for misnested tags](#)^{p1174}).

Note

The "[before html](#)^{p1161}" [insertion mode](#)^{p1120} creates the [html](#)^{p157} document element, which is then added to the stack.

Note

In the [fragment case](#)^{p1206}, the [stack of open elements](#)^{p1121} is initialized to contain an [html](#)^{p157} element that is created as part of [that algorithm](#)^{p1206}. (The [fragment case](#)^{p1206} skips the "[before html](#)^{p1161}" [insertion mode](#)^{p1120}.)

The [html](#)^{p157} node, however it is created, is the topmost node of the stack. It only gets popped off the stack when the parser [finishes](#)^{p1192}.

The **current node** is the bottommost node in this [stack of open elements](#)^{p1121}.

The **adjusted current node** is the [context](#)^{p1206} element if the parser was created as part of the [HTML fragment parsing algorithm](#)^{p1206} and the [stack of open elements](#)^{p1121} has only one element in it ([fragment case](#)^{p1206}); otherwise, the [adjusted current node](#)^{p1121} is the [current node](#)^{p1121}.

Elements in the [stack of open elements](#)^{p1121} fall into the following categories:

Special

The following elements have varying levels of special parsing rules: HTML's [address](#)^{p204}, [applet](#)^{p1257}, [area](#)^{p452}, [article](#)^{p186}, [aside](#)^{p194}, [base](#)^{p160}, [basefont](#)^{p1258}, [bgound](#)^{p1257}, [blockquote](#)^{p224}, [body](#)^{p184}, [br](#)^{p286}, [button](#)^{p545}, [caption](#)^{p466}, [center](#)^{p1258}, [col](#)^{p468}, [colgroup](#)^{p467}, [dd](#)^{p237}, [details](#)^{p614}, [dir](#)^{p1257}, [div](#)^{p243}, [dl](#)^{p233}, [dt](#)^{p236}, [embed](#)^{p378}, [fieldset](#)^{p572}, [figcaption](#)^{p241}, [figure](#)^{p238}, [footer](#)^{p201}, [form](#)^{p494}, [frame](#)^{p1264}, [frameset](#)^{p1264}, [h1](#)^{p196}, [h2](#)^{p196}, [h3](#)^{p196}, [h4](#)^{p196}, [h5](#)^{p196}, [h6](#)^{p196}, [head](#)^{p158}, [header](#)^{p200}, [hgroup](#)^{p197}, [hr](#)^{p220}, [html](#)^{p157}, [iframe](#)^{p369}, [img](#)^{p327}, [input](#)^{p501}, [keygen](#)^{p1257}, [li](#)^{p230}, [link](#)^{p162}, [listing](#)^{p1257}, [main](#)^{p242}, [marquee](#)^{p1262}, [menu](#)^{p229}, [meta](#)^{p170}, [nav](#)^{p191}, [noembed](#)^{p1257}, [noframes](#)^{p1257}, [noscript](#)^{p638}, [object](#)^{p381}, [ol](#)^{p226}, [p](#)^{p218}, [param](#)^{p387}, [plaintext](#)^{p1257}, [pre](#)^{p222}, [script](#)^{p624}, [section](#)^{p188}, [select](#)^{p547}, [source](#)^{p324}, [style](#)^{p180}, [summary](#)^{p617}, [table](#)^{p458}, [tbody](#)^{p469}, [td](#)^{p474}, [template](#)^{p640}, [textarea](#)^{p558}, [tfoot](#)^{p471}, [th](#)^{p475}, [thead](#)^{p470}, [title](#)^{p159}, [tr](#)^{p472}, [track](#)^{p393}, [ul](#)^{p228}, [wbr](#)^{p287}, [xmp](#)^{p1258}; [MathML mi](#), [MathML mo](#), [MathML mn](#), [MathML ms](#), [MathML mtext](#), and [MathML annotation-xml](#); and [SVG foreignObject](#), [SVG desc](#), and [SVG title](#).

Note

An image *start tag token* is handled by the tree builder, but it is not in this list because it is not an element; it gets turned into an [img](#)^{p327} element.

Formatting

The following HTML elements are those that end up in the [list of active formatting elements](#)^{p1123}: [a](#)^{p244}, [b](#)^{p279}, [big](#)^{p1258}, [code](#)^{p273}, [em](#)^{p247}, [font](#)^{p1258}, [i](#)^{p278}, [nobr](#)^{p1258}, [s](#)^{p251}, [small](#)^{p250}, [strike](#)^{p1258}, [strong](#)^{p249}, [tt](#)^{p1258}, and [u](#)^{p281}.

Ordinary

All other elements found while parsing an HTML document.

Note

Typically, the [special](#)^{p1122} elements have the start and end tag tokens handled specifically, while [ordinary](#)^{p1122} elements' tokens fall into "any other start tag" and "any other end tag" clauses, and some parts of the tree builder check if a particular element in the [stack of open elements](#)^{p1121} is in the [special](#)^{p1122} category. However, some elements (e.g., the [option](#)^{p555} element) have their start or end tag tokens handled specifically, but are still not in the [special](#)^{p1122} category, so that they get the [ordinary](#)^{p1122} handling elsewhere.

The [stack of open elements](#)^{p1121} is said to **have an element target node in a specific scope** consisting of a list of element types *list* when the following algorithm terminates in a match state:

1. Initialize *node* to be the [current node](#)^{p1121} (the bottommost node of the stack).
2. If *node* is the target node, terminate in a match state.
3. Otherwise, if *node* is one of the element types in *list*, terminate in a failure state.
4. Otherwise, set *node* to the previous entry in the [stack of open elements](#)^{p1121} and return to step 2. (This will never fail, since the loop will always terminate in the previous step if the top of the stack — an [html](#)^{p157} element — is reached.)

The [stack of open elements](#)^{p1121} is said to **have a particular element in scope** when it [has that element in the specific scope](#)^{p1122} consisting of the following element types:

- [applet](#)^{p1257}
- [caption](#)^{p466}
- [html](#)^{p157}
- [table](#)^{p458}
- [td](#)^{p474}
- [th](#)^{p475}
- [marquee](#)^{p1262}
- [object](#)^{p381}
- [template](#)^{p640}
- [MathML mi](#)
- [MathML mo](#)
- [MathML mn](#)
- [MathML ms](#)
- [MathML mtext](#)
- [MathML annotation-xml](#)
- [SVG foreignObject](#)
- [SVG desc](#)
- [SVG title](#)

The [stack of open elements](#)^{p1121} is said to **have a particular element in list item scope** when it [has that element in the specific scope](#)^{p1122} consisting of the following element types:

- All the element types listed above for the [has an element in scope](#)^{p1122} algorithm.
- [ol](#)^{p226} in the [HTML namespace](#)
- [ul](#)^{p228} in the [HTML namespace](#)

The [stack of open elements](#)^{p1121} is said to **have a particular element in button scope** when it [has that element in the specific scope](#)^{p1122} consisting of the following element types:

- All the element types listed above for the [has an element in scope](#)^{p1122} algorithm.
- [button](#)^{p545} in the [HTML namespace](#)

The [stack of open elements](#)^{p1121} is said to **have a particular element in table scope** when it [has that element in the specific scope](#)^{p1122} consisting of the following element types:

- [html](#)^{p157} in the [HTML namespace](#)
- [table](#)^{p458} in the [HTML namespace](#)
- [template](#)^{p640} in the [HTML namespace](#)

The [stack of open elements](#)^{p1121} is said to **have a particular element in select scope** when it [has that element in the specific scope](#)^{p1122} consisting of all element types except the following:

- [optgroup](#)^{p554} in the [HTML namespace](#)
- [option](#)^{p555} in the [HTML namespace](#)

Nothing happens if at any time any of the elements in the [stack of open elements](#)^{p1121} are moved to a new location in, or removed from, the [Document](#)^{p117} tree. In particular, the stack is not changed in this situation. This can cause, amongst other strange effects, content to be appended to nodes that are no longer in the DOM.

Note

In some cases (namely, when [closing misnested formatting elements](#)^{p1174}), the stack is manipulated in a random-access fashion.

13.2.4.3 The list of active formatting elements §^{p11}₂₃

Initially, the **list of active formatting elements** is empty. It is used to handle mis-nested [formatting element tags](#)^{p1122}.

The list contains elements in the [formatting](#)^{p1122} category, and [markers](#)^{p1123}. The **markers** are inserted when entering [applet](#)^{p1257}, [object](#)^{p381}, [marquee](#)^{p1262}, [template](#)^{p640}, [td](#)^{p474}, [th](#)^{p475}, and [caption](#)^{p466} elements, and are used to prevent formatting from "leaking" into [applet](#)^{p1257}, [object](#)^{p381}, [marquee](#)^{p1262}, [template](#)^{p640}, [td](#)^{p474}, [th](#)^{p475}, and [caption](#)^{p466} elements.

In addition, each element in the [list of active formatting elements](#)^{p1123} is associated with the token for which it was created, so that further elements can be created for that token if necessary.

When the steps below require the UA to **push onto the list of active formatting elements** an element *element*, the UA must perform the following steps:

1. If there are already three elements in the [list of active formatting elements](#)^{p1123} after the last [marker](#)^{p1123}, if any, or anywhere in the list if there are no [markers](#)^{p1123}, that have the same tag name, namespace, and attributes as *element*, then remove the earliest such element from the [list of active formatting elements](#)^{p1123}. For these purposes, the attributes must be compared as they were when the elements were created by the parser; two elements have the same attributes if all their parsed attributes can be paired such that the two attributes in each pair have identical names, namespaces, and values (the order of the attributes does not matter).

Note

This is the Noah's Ark clause. But with three per family instead of two.

2. Add *element* to the [list of active formatting elements](#)^{p1123}.

When the steps below require the UA to **reconstruct the active formatting elements**, the UA must perform the following steps:

1. If there are no entries in the [list of active formatting elements](#)^{p1123}, then there is nothing to reconstruct; stop this algorithm.
2. If the last (most recently added) entry in the [list of active formatting elements](#)^{p1123} is a [marker](#)^{p1123}, or if it is an element that is in the [stack of open elements](#)^{p1121}, then there is nothing to reconstruct; stop this algorithm.
3. Let *entry* be the last (most recently added) element in the [list of active formatting elements](#)^{p1123}.

4. *Rewind*: If there are no entries before *entry* in the [list of active formatting elements](#)^{p1123}, then jump to the step labeled *create*.
5. Let *entry* be the entry one earlier than *entry* in the [list of active formatting elements](#)^{p1123}.
6. If *entry* is neither a [marker](#)^{p1123} nor an element that is also in the [stack of open elements](#)^{p1121}, go to the step labeled *rewind*.
7. *Advance*: Let *entry* be the element one later than *entry* in the [list of active formatting elements](#)^{p1123}.
8. *Create*: [Insert an HTML element](#)^{p1156} for the token for which the element *entry* was created, to obtain *new element*.
9. Replace the entry for *entry* in the list with an entry for *new element*.
10. If the entry for *new element* in the [list of active formatting elements](#)^{p1123} is not the last entry in the list, return to the step labeled *advance*.

This has the effect of reopening all the formatting elements that were opened in the current body, cell, or caption (whichever is youngest) that haven't been explicitly closed.

Note

The way this specification is written, the [list of active formatting elements](#)^{p1123} always consists of elements in chronological order with the least recently added element first and the most recently added element last (except for while steps 7 to 10 of the above algorithm are being executed, of course).

When the steps below require the UA to **clear the list of active formatting elements up to the last marker**, the UA must perform the following steps:

1. Let *entry* be the last (most recently added) entry in the [list of active formatting elements](#)^{p1123}.
2. Remove *entry* from the [list of active formatting elements](#)^{p1123}.
3. If *entry* was a [marker](#)^{p1123}, then stop the algorithm at this point. The list has been cleared up to the last [marker](#)^{p1123}.
4. Go to step 1.

13.2.4.4 The element pointers § p11 24

Initially, the **head element pointer** and the **form element pointer** are both null.

Once a [head](#)^{p158} element has been parsed (whether implicitly or explicitly) the [head element pointer](#)^{p1124} gets set to point to this node.

The [form element pointer](#)^{p1124} points to the last [form](#)^{p494} element that was opened and whose end tag has not yet been seen. It is used to make form controls associate with forms in the face of dramatically bad markup, for historical reasons. It is ignored inside [template](#)^{p640} elements.

13.2.4.5 Other parsing state flags § p11 24

The **scripting flag** is set to "enabled" if [scripting was enabled](#)^{p944} for the [Document](#)^{p117} with which the parser is associated when the parser was created, and "disabled" otherwise.

Note

The [scripting flag](#)^{p1124} can be enabled even when the parser was created as part of the [HTML fragment parsing algorithm](#)^{p1206}, even though [script](#)^{p624} elements don't execute in that case.

The **frameset-ok flag** is set to "ok" when the parser is created. It is set to "not ok" after certain tokens are seen.

13.2.5 Tokenization § p11 24

Implementations must act as if they used the following state machine to tokenize HTML. The state machine must start in the [data](#)

[state](#)^{p1125}. Most states consume a single character, which may have various side-effects, and either switches the state machine to a new state to [reconsume](#)^{p1125} the [current input character](#)^{p1120}, or switches it to a new state to consume the [next character](#)^{p1120}, or stays in the same state to consume the next character. Some states have more complicated behavior and can consume several characters before switching to another state. In some cases, the tokenizer state is also changed by the tree construction stage.

When a state says to **reconsume** a matched character in a specified state, that means to switch to that state, but when it attempts to consume the [next input character](#)^{p1120}, provide it with the [current input character](#)^{p1120} instead.

The exact behavior of certain states depends on the [insertion mode](#)^{p1120} and the [stack of open elements](#)^{p1121}. Certain states also use a **temporary buffer** to track progress, and the [character reference state](#)^{p1149} uses a **return state** to return to the state it was invoked from.

The output of the tokenization step is a series of zero or more of the following tokens: DOCTYPE, start tag, end tag, comment, character, end-of-file. DOCTYPE tokens have a name, a public identifier, a system identifier, and a **force-quirks flag**. When a DOCTYPE token is created, its name, public identifier, and system identifier must be marked as missing (which is a distinct state from the empty string), and the [force-quirks flag](#)^{p1125} must be set to *off* (its other state is *on*). Start and end tag tokens have a tag name, a **self-closing flag**, and a list of attributes, each of which has a name and a value. When a start or end tag token is created, its [self-closing flag](#)^{p1125} must be unset (its other state is that it be set), and its attributes list must be empty. Comment and character tokens have data.

When a token is emitted, it must immediately be handled by the [tree construction](#)^{p1152} stage. The tree construction stage can affect the state of the tokenization stage, and can insert additional characters into the stream. (For example, the [script](#)^{p624} element can result in scripts executing and using the [dynamic markup insertion](#)^{p993} APIs to insert characters into the stream being tokenized.)

Note
Creating a token and emitting it are distinct actions. It is possible for a token to be created but implicitly abandoned (never emitted), e.g. if the file ends unexpectedly while processing the characters that are being parsed into a start tag token.

When a start tag token is emitted with its [self-closing flag](#)^{p1125} set, if the flag is not **acknowledged** when it is processed by the tree construction stage, that is a [non-void-html-element-start-tag-with-trailing-solidus](#)^{p1110} [parse error](#)^{p1108}.

When an end tag token is emitted with attributes, that is an [end-tag-with-attributes](#)^{p1108} [parse error](#)^{p1108}.

When an end tag token is emitted with its [self-closing flag](#)^{p1125} set, that is an [end-tag-with-trailing-solidus](#)^{p1108} [parse error](#)^{p1108}.

An **appropriate end tag token** is an end tag token whose tag name matches the tag name of the last start tag to have been emitted from this tokenizer, if any. If no start tag has been emitted from this tokenizer, then no end tag token is appropriate.

A [character reference](#)^{p1104} is said to be **consumed as part of an attribute** if the [return state](#)^{p1125} is either [attribute value \(double-quoted\) state](#)^{p1137}, [attribute value \(single-quoted\) state](#)^{p1137} or [attribute value \(unquoted\) state](#)^{p1138}.

When a state says to **flush code points consumed as a character reference**, it means that for each [code point](#) in the [temporary buffer](#)^{p1125} (in the order they were added to the buffer) user agent must append the code point from the buffer to the current attribute's value if the character reference was [consumed as part of an attribute](#)^{p1125}, or emit the code point as a character token otherwise.

Before each step of the tokenizer, the user agent must first check the [parser pause flag](#)^{p1108}. If it is true, then the tokenizer must abort the processing of any nested invocations of the tokenizer, yielding control back to the caller.

The tokenizer state machine consists of the states defined in the following subsections.

13.2.5.1 Data state §^{p11}₂₅

Consume the [next input character](#)^{p1120}:

↪ **U+0026 AMPERSAND (&)**

Set the [return state](#)^{p1125} to the [data state](#)^{p1125}. Switch to the [character reference state](#)^{p1149}.

↪ **U+003C LESS-THAN SIGN (<)**

Switch to the [tag open state](#)^{p1127}.

↳ **U+0000 NULL**

This is an [unexpected-null-character^{p1112}](#) [parse error^{p1108}](#). Emit the [current input character^{p1120}](#) as a character token.

↳ **EOF**

Emit an end-of-file token.

↳ **Anything else**

Emit the [current input character^{p1120}](#) as a character token.

13.2.5.2 RCDATA state §^{p11}₂₆

Consume the [next input character^{p1120}](#):

↳ **U+0026 AMPERSAND (&)**

Set the [return state^{p1125}](#) to the [RCDATA state^{p1126}](#). Switch to the [character reference state^{p1149}](#).

↳ **U+003C LESS-THAN SIGN (<)**

Switch to the [RCDATA less-than sign state^{p1128}](#).

↳ **U+0000 NULL**

This is an [unexpected-null-character^{p1112}](#) [parse error^{p1108}](#). Emit a U+FFFD REPLACEMENT CHARACTER character token.

↳ **EOF**

Emit an end-of-file token.

↳ **Anything else**

Emit the [current input character^{p1120}](#) as a character token.

13.2.5.3 RAWTEXT state §^{p11}₂₆

Consume the [next input character^{p1120}](#):

↳ **U+003C LESS-THAN SIGN (<)**

Switch to the [RAWTEXT less-than sign state^{p1129}](#).

↳ **U+0000 NULL**

This is an [unexpected-null-character^{p1112}](#) [parse error^{p1108}](#). Emit a U+FFFD REPLACEMENT CHARACTER character token.

↳ **EOF**

Emit an end-of-file token.

↳ **Anything else**

Emit the [current input character^{p1120}](#) as a character token.

13.2.5.4 Script data state §^{p11}₂₆

Consume the [next input character^{p1120}](#):

↳ **U+003C LESS-THAN SIGN (<)**

Switch to the [script data less-than sign state^{p1130}](#).

↳ **U+0000 NULL**

This is an [unexpected-null-character^{p1112}](#) [parse error^{p1108}](#). Emit a U+FFFD REPLACEMENT CHARACTER character token.

↳ **EOF**

Emit an end-of-file token.

↳ **Anything else**

Emit the [current input character^{p1120}](#) as a character token.

13.2.5.5 PLAINTEXT state §^{p11}₂₇

Consume the [next input character^{p1120}](#):

↪ **U+0000 NULL**

This is an [unexpected-null-character^{p1112}](#) [parse error^{p1108}](#). Emit a U+FFFD REPLACEMENT CHARACTER character token.

↪ **EOF**

Emit an end-of-file token.

↪ **Anything else**

Emit the [current input character^{p1120}](#) as a character token.

13.2.5.6 Tag open state §^{p11}₂₇

Consume the [next input character^{p1120}](#):

↪ **U+0021 EXCLAMATION MARK (!)**

Switch to the [markup declaration open state^{p1139}](#).

↪ **U+002F SOLIDUS (/)**

Switch to the [end tag open state^{p1127}](#).

↪ **ASCII alpha**

Create a new start tag token, set its tag name to the empty string. [Reconsume^{p1125}](#) in the [tag name state^{p1127}](#).

↪ **U+003F QUESTION MARK (?)**

This is an [unexpected-question-mark-instead-of-tag-name^{p1112}](#) [parse error^{p1108}](#). Create a comment token whose data is the empty string. [Reconsume^{p1125}](#) in the [bogus comment state^{p1139}](#).

↪ **EOF**

This is an [eof-before-tag-name^{p1108}](#) [parse error^{p1108}](#). Emit a U+003C LESS-THAN SIGN character token and an end-of-file token.

↪ **Anything else**

This is an [invalid-first-character-of-tag-name^{p1109}](#) [parse error^{p1108}](#). Emit a U+003C LESS-THAN SIGN character token. [Reconsume^{p1125}](#) in the [data state^{p1125}](#).

13.2.5.7 End tag open state §^{p11}₂₇

Consume the [next input character^{p1120}](#):

↪ **ASCII alpha**

Create a new end tag token, set its tag name to the empty string. [Reconsume^{p1125}](#) in the [tag name state^{p1127}](#).

↪ **U+003E GREATER-THAN SIGN (>)**

This is a [missing-end-tag-name^{p1110}](#) [parse error^{p1108}](#). Switch to the [data state^{p1125}](#).

↪ **EOF**

This is an [eof-before-tag-name^{p1108}](#) [parse error^{p1108}](#). Emit a U+003C LESS-THAN SIGN character token, a U+002F SOLIDUS character token and an end-of-file token.

↪ **Anything else**

This is an [invalid-first-character-of-tag-name^{p1109}](#) [parse error^{p1108}](#). Create a comment token whose data is the empty string. [Reconsume^{p1125}](#) in the [bogus comment state^{p1139}](#).

13.2.5.8 Tag name state §^{p11}₂₇

Consume the [next input character^{p1120}](#):

↪ **U+0009 CHARACTER TABULATION (tab)**

↪ **U+000A LINE FEED (LF)**

↪ **U+000C FORM FEED (FF)**

↪ **U+0020 SPACE**

Switch to the [before attribute name state](#)^{p1135}.

↪ **U+002F SOLIDUS (/)**

Switch to the [self-closing start tag state](#)^{p1139}.

↪ **U+003E GREATER-THAN SIGN (>)**

Switch to the [data state](#)^{p1125}. Emit the current tag token.

↪ **ASCII upper alpha**

Append the lowercase version of the [current input character](#)^{p1120} (add 0x0020 to the character's code point) to the current tag token's tag name.

↪ **U+0000 NULL**

This is an [unexpected-null-character](#)^{p1112} [parse error](#)^{p1108}. Append a U+FFFD REPLACEMENT CHARACTER character to the current tag token's tag name.

↪ **EOF**

This is an [eof-in-tag](#)^{p1109} [parse error](#)^{p1108}. Emit an end-of-file token.

↪ **Anything else**

Append the [current input character](#)^{p1120} to the current tag token's tag name.

13.2.5.9 RCDATA less-than sign state §^{p11}₂₈

Consume the [next input character](#)^{p1120}:

↪ **U+002F SOLIDUS (/)**

Set the [temporary buffer](#)^{p1125} to the empty string. Switch to the [RCDATA end tag open state](#)^{p1128}.

↪ **Anything else**

Emit a U+003C LESS-THAN SIGN character token. [Reconsume](#)^{p1125} in the [RCDATA state](#)^{p1126}.

13.2.5.10 RCDATA end tag open state §^{p11}₂₈

Consume the [next input character](#)^{p1120}:

↪ **ASCII alpha**

Create a new end tag token, set its tag name to the empty string. [Reconsume](#)^{p1125} in the [RCDATA end tag name state](#)^{p1128}.

↪ **Anything else**

Emit a U+003C LESS-THAN SIGN character token and a U+002F SOLIDUS character token. [Reconsume](#)^{p1125} in the [RCDATA state](#)^{p1126}.

13.2.5.11 RCDATA end tag name state §^{p11}₂₈

Consume the [next input character](#)^{p1120}:

↪ **U+0009 CHARACTER TABULATION (tab)**

↪ **U+000A LINE FEED (LF)**

↪ **U+000C FORM FEED (FF)**

↪ **U+0020 SPACE**

If the current end tag token is an [appropriate end tag token](#)^{p1125}, then switch to the [before attribute name state](#)^{p1135}. Otherwise, treat it as per the "anything else" entry below.

↪ **U+002F SOLIDUS (/)**

If the current end tag token is an [appropriate end tag token](#)^{p1125}, then switch to the [self-closing start tag state](#)^{p1139}. Otherwise, treat it as per the "anything else" entry below.

↪ **U+003E GREATER-THAN SIGN (>)**

If the current end tag token is an [appropriate end tag token](#)^{p1125}, then switch to the [data state](#)^{p1125} and emit the current tag token. Otherwise, treat it as per the "anything else" entry below.

↪ **ASCII upper alpha**

Append the lowercase version of the [current input character](#)^{p1120} (add 0x0020 to the character's code point) to the current tag token's tag name. Append the [current input character](#)^{p1120} to the [temporary buffer](#)^{p1125}.

↪ **ASCII lower alpha**

Append the [current input character](#)^{p1120} to the current tag token's tag name. Append the [current input character](#)^{p1120} to the [temporary buffer](#)^{p1125}.

↪ **Anything else**

Emit a U+003C LESS-THAN SIGN character token, a U+002F SOLIDUS character token, and a character token for each of the characters in the [temporary buffer](#)^{p1125} (in the order they were added to the buffer). [Reconsume](#)^{p1125} in the [RCDATA state](#)^{p1126}.

13.2.5.12 RAWTEXT less-than sign state §^{p11}₂₉

Consume the [next input character](#)^{p1120}:

↪ **U+002F SOLIDUS (/)**

Set the [temporary buffer](#)^{p1125} to the empty string. Switch to the [RAWTEXT end tag open state](#)^{p1129}.

↪ **Anything else**

Emit a U+003C LESS-THAN SIGN character token. [Reconsume](#)^{p1125} in the [RAWTEXT state](#)^{p1126}.

13.2.5.13 RAWTEXT end tag open state §^{p11}₂₉

Consume the [next input character](#)^{p1120}:

↪ **ASCII alpha**

Create a new end tag token, set its tag name to the empty string. [Reconsume](#)^{p1125} in the [RAWTEXT end tag name state](#)^{p1129}.

↪ **Anything else**

Emit a U+003C LESS-THAN SIGN character token and a U+002F SOLIDUS character token. [Reconsume](#)^{p1125} in the [RAWTEXT state](#)^{p1126}.

13.2.5.14 RAWTEXT end tag name state §^{p11}₂₉

Consume the [next input character](#)^{p1120}:

↪ **U+0009 CHARACTER TABULATION (tab)**

↪ **U+000A LINE FEED (LF)**

↪ **U+000C FORM FEED (FF)**

↪ **U+0020 SPACE**

If the current end tag token is an [appropriate end tag token](#)^{p1125}, then switch to the [before attribute name state](#)^{p1135}. Otherwise, treat it as per the "anything else" entry below.

↪ **U+002F SOLIDUS (/)**

If the current end tag token is an [appropriate end tag token](#)^{p1125}, then switch to the [self-closing start tag state](#)^{p1139}. Otherwise, treat it as per the "anything else" entry below.

↪ **U+003E GREATER-THAN SIGN (>)**

If the current end tag token is an [appropriate end tag token](#)^{p1125}, then switch to the [data state](#)^{p1125} and emit the current tag token. Otherwise, treat it as per the "anything else" entry below.

↪ **ASCII upper alpha**

Append the lowercase version of the [current input character^{p1120}](#) (add 0x0020 to the character's code point) to the current tag token's tag name. Append the [current input character^{p1120}](#) to the [temporary buffer^{p1125}](#).

↪ **ASCII lower alpha**

Append the [current input character^{p1120}](#) to the current tag token's tag name. Append the [current input character^{p1120}](#) to the [temporary buffer^{p1125}](#).

↪ **Anything else**

Emit a U+003C LESS-THAN SIGN character token, a U+002F SOLIDUS character token, and a character token for each of the characters in the [temporary buffer^{p1125}](#) (in the order they were added to the buffer). [Reconsume^{p1125}](#) in the [RAWTEXT state^{p1126}](#).

13.2.5.15 Script data less-than sign state §^{p11}₃₀

Consume the [next input character^{p1120}](#):

↪ **U+002F SOLIDUS (/)**

Set the [temporary buffer^{p1125}](#) to the empty string. Switch to the [script data end tag open state^{p1130}](#).

↪ **U+0021 EXCLAMATION MARK (!)**

Switch to the [script data escape start state^{p1131}](#). Emit a U+003C LESS-THAN SIGN character token and a U+0021 EXCLAMATION MARK character token.

↪ **Anything else**

Emit a U+003C LESS-THAN SIGN character token. [Reconsume^{p1125}](#) in the [script data state^{p1126}](#).

13.2.5.16 Script data end tag open state §^{p11}₃₀

Consume the [next input character^{p1120}](#):

↪ **ASCII alpha**

Create a new end tag token, set its tag name to the empty string. [Reconsume^{p1125}](#) in the [script data end tag name state^{p1130}](#).

↪ **Anything else**

Emit a U+003C LESS-THAN SIGN character token and a U+002F SOLIDUS character token. [Reconsume^{p1125}](#) in the [script data state^{p1126}](#).

13.2.5.17 Script data end tag name state §^{p11}₃₀

Consume the [next input character^{p1120}](#):

↪ **U+0009 CHARACTER TABULATION (tab)**

↪ **U+000A LINE FEED (LF)**

↪ **U+000C FORM FEED (FF)**

↪ **U+0020 SPACE**

If the current end tag token is an [appropriate end tag token^{p1125}](#), then switch to the [before attribute name state^{p1135}](#). Otherwise, treat it as per the "anything else" entry below.

↪ **U+002F SOLIDUS (/)**

If the current end tag token is an [appropriate end tag token^{p1125}](#), then switch to the [self-closing start tag state^{p1139}](#). Otherwise, treat it as per the "anything else" entry below.

↪ **U+003E GREATER-THAN SIGN (>)**

If the current end tag token is an [appropriate end tag token^{p1125}](#), then switch to the [data state^{p1125}](#) and emit the current tag token. Otherwise, treat it as per the "anything else" entry below.

↪ **ASCII upper alpha**

Append the lowercase version of the [current input character^{p1120}](#) (add 0x0020 to the character's code point) to the current tag token's tag name. Append the [current input character^{p1120}](#) to the [temporary buffer^{p1125}](#).

↪ **ASCII lower alpha**

Append the [current input character^{p1120}](#) to the current tag token's tag name. Append the [current input character^{p1120}](#) to the [temporary buffer^{p1125}](#).

↪ **Anything else**

Emit a U+003C LESS-THAN SIGN character token, a U+002F SOLIDUS character token, and a character token for each of the characters in the [temporary buffer^{p1125}](#) (in the order they were added to the buffer). [Reconsume^{p1125}](#) in the [script data state^{p1126}](#).

13.2.5.18 Script data escape start state §^{p11}₃₁

Consume the [next input character^{p1120}](#):

↪ **U+002D HYPHEN-MINUS (-)**

Switch to the [script data escape start dash state^{p1131}](#). Emit a U+002D HYPHEN-MINUS character token.

↪ **Anything else**

[Reconsume^{p1125}](#) in the [script data state^{p1126}](#).

13.2.5.19 Script data escape start dash state §^{p11}₃₁

Consume the [next input character^{p1120}](#):

↪ **U+002D HYPHEN-MINUS (-)**

Switch to the [script data escaped dash dash state^{p1132}](#). Emit a U+002D HYPHEN-MINUS character token.

↪ **Anything else**

[Reconsume^{p1125}](#) in the [script data state^{p1126}](#).

13.2.5.20 Script data escaped state §^{p11}₃₁

Consume the [next input character^{p1120}](#):

↪ **U+002D HYPHEN-MINUS (-)**

Switch to the [script data escaped dash state^{p1131}](#). Emit a U+002D HYPHEN-MINUS character token.

↪ **U+003C LESS-THAN SIGN (<)**

Switch to the [script data escaped less-than sign state^{p1132}](#).

↪ **U+0000 NULL**

This is an [unexpected-null-character^{p1112}](#) [parse error^{p1108}](#). Emit a U+FFFD REPLACEMENT CHARACTER character token.

↪ **EOF**

This is an [eof-in-script-html-comment-like-text^{p1109}](#) [parse error^{p1108}](#). Emit an end-of-file token.

↪ **Anything else**

Emit the [current input character^{p1120}](#) as a character token.

13.2.5.21 Script data escaped dash state §^{p11}₃₁

Consume the [next input character^{p1120}](#):

↪ **U+002D HYPHEN-MINUS (-)**

Switch to the [script data escaped dash dash state^{p1132}](#). Emit a U+002D HYPHEN-MINUS character token.

↪ **U+003C LESS-THAN SIGN (<)**

Switch to the [script data escaped less-than sign state^{p1132}](#).

↪ **U+0000 NULL**

This is an [unexpected-null-character^{p1112}](#) [parse error^{p1108}](#). Switch to the [script data escaped state^{p1131}](#). Emit a U+FFFD REPLACEMENT CHARACTER character token.

↪ **EOF**

This is an [eof-in-script-html-comment-like-text^{p1109}](#) [parse error^{p1108}](#). Emit an end-of-file token.

↪ **Anything else**

Switch to the [script data escaped state^{p1131}](#). Emit the [current input character^{p1120}](#) as a character token.

13.2.5.22 Script data escaped dash dash state §^{p11}₃₂

Consume the [next input character^{p1120}](#):

↪ **U+002D HYPHEN-MINUS (-)**

Emit a U+002D HYPHEN-MINUS character token.

↪ **U+003C LESS-THAN SIGN (<)**

Switch to the [script data escaped less-than sign state^{p1132}](#).

↪ **U+003E GREATER-THAN SIGN (>)**

Switch to the [script data state^{p1126}](#). Emit a U+003E GREATER-THAN SIGN character token.

↪ **U+0000 NULL**

This is an [unexpected-null-character^{p1112}](#) [parse error^{p1108}](#). Switch to the [script data escaped state^{p1131}](#). Emit a U+FFFD REPLACEMENT CHARACTER character token.

↪ **EOF**

This is an [eof-in-script-html-comment-like-text^{p1109}](#) [parse error^{p1108}](#). Emit an end-of-file token.

↪ **Anything else**

Switch to the [script data escaped state^{p1131}](#). Emit the [current input character^{p1120}](#) as a character token.

13.2.5.23 Script data escaped less-than sign state §^{p11}₃₂

Consume the [next input character^{p1120}](#):

↪ **U+002F SOLIDUS (/)**

Set the [temporary buffer^{p1125}](#) to the empty string. Switch to the [script data escaped end tag open state^{p1132}](#).

↪ **ASCII alpha**

Set the [temporary buffer^{p1125}](#) to the empty string. Emit a U+003C LESS-THAN SIGN character token. [Reconsume^{p1125}](#) in the [script data double escape start state^{p1133}](#).

↪ **Anything else**

Emit a U+003C LESS-THAN SIGN character token. [Reconsume^{p1125}](#) in the [script data escaped state^{p1131}](#).

13.2.5.24 Script data escaped end tag open state §^{p11}₃₂

Consume the [next input character^{p1120}](#):

↪ **ASCII alpha**

Create a new end tag token, set its tag name to the empty string. [Reconsume^{p1125}](#) in the [script data escaped end tag name state^{p1133}](#).

↪ **Anything else**

Emit a U+003C LESS-THAN SIGN character token and a U+002F SOLIDUS character token. [Reconsume^{p1125}](#) in the [script data escaped state^{p1131}](#).

13.2.5.25 Script data escaped end tag name state §^{p11}₃₃

Consume the [next input character^{p1120}](#):

↪ **U+0009 CHARACTER TABULATION (tab)**

↪ **U+000A LINE FEED (LF)**

↪ **U+000C FORM FEED (FF)**

↪ **U+0020 SPACE**

If the current end tag token is an [appropriate end tag token^{p1125}](#), then switch to the [before attribute name state^{p1135}](#). Otherwise, treat it as per the "anything else" entry below.

↪ **U+002F SOLIDUS (/)**

If the current end tag token is an [appropriate end tag token^{p1125}](#), then switch to the [self-closing start tag state^{p1139}](#). Otherwise, treat it as per the "anything else" entry below.

↪ **U+003E GREATER-THAN SIGN (>)**

If the current end tag token is an [appropriate end tag token^{p1125}](#), then switch to the [data state^{p1125}](#) and emit the current tag token. Otherwise, treat it as per the "anything else" entry below.

↪ **ASCII upper alpha**

Append the lowercase version of the [current input character^{p1120}](#) (add 0x0020 to the character's code point) to the current tag token's tag name. Append the [current input character^{p1120}](#) to the [temporary buffer^{p1125}](#).

↪ **ASCII lower alpha**

Append the [current input character^{p1120}](#) to the current tag token's tag name. Append the [current input character^{p1120}](#) to the [temporary buffer^{p1125}](#).

↪ **Anything else**

Emit a U+003C LESS-THAN SIGN character token, a U+002F SOLIDUS character token, and a character token for each of the characters in the [temporary buffer^{p1125}](#) (in the order they were added to the buffer). [Reconsume^{p1125}](#) in the [script data escaped state^{p1131}](#).

13.2.5.26 Script data double escape start state §^{p11}₃₃

Consume the [next input character^{p1120}](#):

↪ **U+0009 CHARACTER TABULATION (tab)**

↪ **U+000A LINE FEED (LF)**

↪ **U+000C FORM FEED (FF)**

↪ **U+0020 SPACE**

↪ **U+002F SOLIDUS (/)**

↪ **U+003E GREATER-THAN SIGN (>)**

If the [temporary buffer^{p1125}](#) is the string "script", then switch to the [script data double escaped state^{p1133}](#). Otherwise, switch to the [script data escaped state^{p1131}](#). Emit the [current input character^{p1120}](#) as a character token.

↪ **ASCII upper alpha**

Append the lowercase version of the [current input character^{p1120}](#) (add 0x0020 to the character's code point) to the [temporary buffer^{p1125}](#). Emit the [current input character^{p1120}](#) as a character token.

↪ **ASCII lower alpha**

Append the [current input character^{p1120}](#) to the [temporary buffer^{p1125}](#). Emit the [current input character^{p1120}](#) as a character token.

↪ **Anything else**

[Reconsume^{p1125}](#) in the [script data escaped state^{p1131}](#).

13.2.5.27 Script data double escaped state §^{p11}₃₃

Consume the [next input character^{p1120}](#):

↪ **U+002D HYPHEN-MINUS (-)**

Switch to the [script data double escaped dash state^{p1134}](#). Emit a U+002D HYPHEN-MINUS character token.

↪ **U+003C LESS-THAN SIGN (<)**

Switch to the [script data double escaped less-than sign state^{p1134}](#). Emit a U+003C LESS-THAN SIGN character token.

↪ **U+0000 NULL**

This is an [unexpected-null-character^{p1112}](#) [parse error^{p1108}](#). Emit a U+FFFD REPLACEMENT CHARACTER character token.

↪ **EOF**

This is an [eof-in-script-html-comment-like-text^{p1109}](#) [parse error^{p1108}](#). Emit an end-of-file token.

↪ **Anything else**

Emit the [current input character^{p1120}](#) as a character token.

13.2.5.28 Script data double escaped dash state §^{p11}₃₄

Consume the [next input character^{p1120}](#):

↪ **U+002D HYPHEN-MINUS (-)**

Switch to the [script data double escaped dash dash state^{p1134}](#). Emit a U+002D HYPHEN-MINUS character token.

↪ **U+003C LESS-THAN SIGN (<)**

Switch to the [script data double escaped less-than sign state^{p1134}](#). Emit a U+003C LESS-THAN SIGN character token.

↪ **U+0000 NULL**

This is an [unexpected-null-character^{p1112}](#) [parse error^{p1108}](#). Switch to the [script data double escaped state^{p1133}](#). Emit a U+FFFD REPLACEMENT CHARACTER character token.

↪ **EOF**

This is an [eof-in-script-html-comment-like-text^{p1109}](#) [parse error^{p1108}](#). Emit an end-of-file token.

↪ **Anything else**

Switch to the [script data double escaped state^{p1133}](#). Emit the [current input character^{p1120}](#) as a character token.

13.2.5.29 Script data double escaped dash dash state §^{p11}₃₄

Consume the [next input character^{p1120}](#):

↪ **U+002D HYPHEN-MINUS (-)**

Emit a U+002D HYPHEN-MINUS character token.

↪ **U+003C LESS-THAN SIGN (<)**

Switch to the [script data double escaped less-than sign state^{p1134}](#). Emit a U+003C LESS-THAN SIGN character token.

↪ **U+003E GREATER-THAN SIGN (>)**

Switch to the [script data state^{p1126}](#). Emit a U+003E GREATER-THAN SIGN character token.

↪ **U+0000 NULL**

This is an [unexpected-null-character^{p1112}](#) [parse error^{p1108}](#). Switch to the [script data double escaped state^{p1133}](#). Emit a U+FFFD REPLACEMENT CHARACTER character token.

↪ **EOF**

This is an [eof-in-script-html-comment-like-text^{p1109}](#) [parse error^{p1108}](#). Emit an end-of-file token.

↪ **Anything else**

Switch to the [script data double escaped state^{p1133}](#). Emit the [current input character^{p1120}](#) as a character token.

13.2.5.30 Script data double escaped less-than sign state §^{p11}₃₄

Consume the [next input character^{p1120}](#):

↪ **U+002F SOLIDUS (/)**

Set the [temporary buffer^{p1125}](#) to the empty string. Switch to the [script data double escape end state^{p1135}](#). Emit a U+002F SOLIDUS character token.

↪ **Anything else**

[Reconsume^{p1125}](#) in the [script data double escaped state^{p1133}](#).

13.2.5.31 Script data double escape end state §^{p11}₃₅

Consume the [next input character^{p1120}](#):

↪ **U+0009 CHARACTER TABULATION (tab)**

↪ **U+000A LINE FEED (LF)**

↪ **U+000C FORM FEED (FF)**

↪ **U+0020 SPACE**

↪ **U+002F SOLIDUS (/)**

↪ **U+003E GREATER-THAN SIGN (>)**

If the [temporary buffer^{p1125}](#) is the string "script", then switch to the [script data escaped state^{p1131}](#). Otherwise, switch to the [script data double escaped state^{p1133}](#). Emit the [current input character^{p1120}](#) as a character token.

↪ **ASCII upper alpha**

Append the lowercase version of the [current input character^{p1120}](#) (add 0x0020 to the character's code point) to the [temporary buffer^{p1125}](#). Emit the [current input character^{p1120}](#) as a character token.

↪ **ASCII lower alpha**

Append the [current input character^{p1120}](#) to the [temporary buffer^{p1125}](#). Emit the [current input character^{p1120}](#) as a character token.

↪ **Anything else**

[Reconsume^{p1125}](#) in the [script data double escaped state^{p1133}](#).

13.2.5.32 Before attribute name state §^{p11}₃₅

Consume the [next input character^{p1120}](#):

↪ **U+0009 CHARACTER TABULATION (tab)**

↪ **U+000A LINE FEED (LF)**

↪ **U+000C FORM FEED (FF)**

↪ **U+0020 SPACE**

Ignore the character.

↪ **U+002F SOLIDUS (/)**

↪ **U+003E GREATER-THAN SIGN (>)**

↪ **EOF**

[Reconsume^{p1125}](#) in the [after attribute name state^{p1136}](#).

↪ **U+003D EQUALS SIGN (=)**

This is an [unexpected-equals-sign-before-attribute-name^{p1112}](#) [parse error^{p1108}](#). Start a new attribute in the current tag token. Set that attribute's name to the [current input character^{p1120}](#), and its value to the empty string. Switch to the [attribute name state^{p1135}](#).

↪ **Anything else**

Start a new attribute in the current tag token. Set that attribute name and value to the empty string. [Reconsume^{p1125}](#) in the [attribute name state^{p1135}](#).

13.2.5.33 Attribute name state §^{p11}₃₅

Consume the [next input character^{p1120}](#):

- ↪ **U+0009 CHARACTER TABULATION (tab)**
- ↪ **U+000A LINE FEED (LF)**
- ↪ **U+000C FORM FEED (FF)**
- ↪ **U+0020 SPACE**
- ↪ **U+002F SOLIDUS (/)**
- ↪ **U+003E GREATER-THAN SIGN (>)**
- ↪ **EOF**
 - ↪ [Reconsume](#)^{p1125} in the [after attribute name state](#)^{p1136}.
- ↪ **U+003D EQUALS SIGN (=)**
 - ↪ Switch to the [before attribute value state](#)^{p1137}.
- ↪ **ASCII upper alpha**
 - ↪ Append the lowercase version of the [current input character](#)^{p1120} (add 0x0020 to the character's code point) to the current attribute's name.
- ↪ **U+0000 NULL**
 - ↪ This is an [unexpected-null-character](#)^{p1112} [parse error](#)^{p1108}. Append a U+FFFD REPLACEMENT CHARACTER character to the current attribute's name.
- ↪ **U+0022 QUOTATION MARK (")**
- ↪ **U+0027 APOSTROPHE (')**
- ↪ **U+003C LESS-THAN SIGN (<)**
 - ↪ This is an [unexpected-character-in-attribute-name](#)^{p1111} [parse error](#)^{p1108}. Treat it as per the "anything else" entry below.
- ↪ **Anything else**
 - ↪ Append the [current input character](#)^{p1120} to the current attribute's name.

When the user agent leaves the attribute name state (and before emitting the tag token, if appropriate), the complete attribute's name must be compared to the other attributes on the same token; if there is already an attribute on the token with the exact same name, then this is a [duplicate-attribute](#)^{p1108} [parse error](#)^{p1108} and the new attribute must be removed from the token.

Note
If an attribute is so removed from a token, it, and the value that gets associated with it, if any, are never subsequently used by the parser, and are therefore effectively discarded. Removing the attribute in this way does not change its status as the "current attribute" for the purposes of the tokenizer, however.

13.2.5.34 After attribute name state §^{p11}₃₆

Consume the [next input character](#)^{p1120}:

- ↪ **U+0009 CHARACTER TABULATION (tab)**
- ↪ **U+000A LINE FEED (LF)**
- ↪ **U+000C FORM FEED (FF)**
- ↪ **U+0020 SPACE**
 - ↪ Ignore the character.
- ↪ **U+002F SOLIDUS (/)**
 - ↪ Switch to the [self-closing start tag state](#)^{p1139}.
- ↪ **U+003D EQUALS SIGN (=)**
 - ↪ Switch to the [before attribute value state](#)^{p1137}.
- ↪ **U+003E GREATER-THAN SIGN (>)**
 - ↪ Switch to the [data state](#)^{p1125}. Emit the current tag token.
- ↪ **EOF**
 - ↪ This is an [eof-in-tag](#)^{p1109} [parse error](#)^{p1108}. Emit an end-of-file token.
- ↪ **Anything else**
 - ↪ Start a new attribute in the current tag token. Set that attribute name and value to the empty string. [Reconsume](#)^{p1125} in the

[attribute_name_state^{p1135}](#).

13.2.5.35 Before attribute value state §^{p11}₃₇

Consume the [next_input_character^{p1120}](#):

↪ **U+0009 CHARACTER TABULATION (tab)**

↪ **U+000A LINE FEED (LF)**

↪ **U+000C FORM FEED (FF)**

↪ **U+0020 SPACE**

Ignore the character.

↪ **U+0022 QUOTATION MARK (")**

Switch to the [attribute_value \(double-quoted\) state^{p1137}](#).

↪ **U+0027 APOSTROPHE (')**

Switch to the [attribute_value \(single-quoted\) state^{p1137}](#).

↪ **U+003E GREATER-THAN SIGN (>)**

This is a [missing-attribute-value^{p1109}](#) [parse_error^{p1108}](#). Switch to the [data_state^{p1125}](#). Emit the current tag token.

↪ **Anything else**

[Reconsume^{p1125}](#) in the [attribute_value \(unquoted\) state^{p1138}](#).

13.2.5.36 Attribute value (double-quoted) state §^{p11}₃₇

Consume the [next_input_character^{p1120}](#):

↪ **U+0022 QUOTATION MARK (")**

Switch to the [after_attribute_value \(quoted\) state^{p1138}](#).

↪ **U+0026 AMPERSAND (&)**

Set the [return_state^{p1125}](#) to the [attribute_value \(double-quoted\) state^{p1137}](#). Switch to the [character_reference_state^{p1149}](#).

↪ **U+0000 NULL**

This is an [unexpected-null-character^{p1112}](#) [parse_error^{p1108}](#). Append a U+FFFD REPLACEMENT CHARACTER character to the current attribute's value.

↪ **EOF**

This is an [eof-in-tag^{p1109}](#) [parse_error^{p1108}](#). Emit an end-of-file token.

↪ **Anything else**

Append the [current_input_character^{p1120}](#) to the current attribute's value.

13.2.5.37 Attribute value (single-quoted) state §^{p11}₃₇

Consume the [next_input_character^{p1120}](#):

↪ **U+0027 APOSTROPHE (')**

Switch to the [after_attribute_value \(quoted\) state^{p1138}](#).

↪ **U+0026 AMPERSAND (&)**

Set the [return_state^{p1125}](#) to the [attribute_value \(single-quoted\) state^{p1137}](#). Switch to the [character_reference_state^{p1149}](#).

↪ **U+0000 NULL**

This is an [unexpected-null-character^{p1112}](#) [parse_error^{p1108}](#). Append a U+FFFD REPLACEMENT CHARACTER character to the current attribute's value.

↪ **EOF**

This is an [eof-in-tag^{p1109}](#) [parse_error^{p1108}](#). Emit an end-of-file token.

↪ **Anything else**

Append the [current input character^{p1120}](#) to the current attribute's value.

13.2.5.38 Attribute value (unquoted) state §^{p11}₃₈

Consume the [next input character^{p1120}](#):

↪ **U+0009 CHARACTER TABULATION (tab)**

↪ **U+000A LINE FEED (LF)**

↪ **U+000C FORM FEED (FF)**

↪ **U+0020 SPACE**

Switch to the [before attribute name state^{p1135}](#).

↪ **U+0026 AMPERSAND (&)**

Set the [return state^{p1125}](#) to the [attribute value \(unquoted\) state^{p1138}](#). Switch to the [character reference state^{p1149}](#).

↪ **U+003E GREATER-THAN SIGN (>)**

Switch to the [data state^{p1125}](#). Emit the current tag token.

↪ **U+0000 NULL**

This is an [unexpected-null-character^{p1112}](#) [parse error^{p1108}](#). Append a U+FFFD REPLACEMENT CHARACTER character to the current attribute's value.

↪ **U+0022 QUOTATION MARK (")**

↪ **U+0027 APOSTROPHE (')**

↪ **U+003C LESS-THAN SIGN (<)**

↪ **U+003D EQUALS SIGN (=)**

↪ **U+0060 GRAVE ACCENT (`)**

This is an [unexpected-character-in-unquoted-attribute-value^{p1111}](#) [parse error^{p1108}](#). Treat it as per the "anything else" entry below.

↪ **EOF**

This is an [eof-in-tag^{p1109}](#) [parse error^{p1108}](#). Emit an end-of-file token.

↪ **Anything else**

Append the [current input character^{p1120}](#) to the current attribute's value.

13.2.5.39 After attribute value (quoted) state §^{p11}₃₈

Consume the [next input character^{p1120}](#):

↪ **U+0009 CHARACTER TABULATION (tab)**

↪ **U+000A LINE FEED (LF)**

↪ **U+000C FORM FEED (FF)**

↪ **U+0020 SPACE**

Switch to the [before attribute name state^{p1135}](#).

↪ **U+002F SOLIDUS (/)**

Switch to the [self-closing start tag state^{p1139}](#).

↪ **U+003E GREATER-THAN SIGN (>)**

Switch to the [data state^{p1125}](#). Emit the current tag token.

↪ **EOF**

This is an [eof-in-tag^{p1109}](#) [parse error^{p1108}](#). Emit an end-of-file token.

↪ **Anything else**

This is a [missing-whitespace-between-attributes^{p1110}](#) [parse error^{p1108}](#). [Reconsume^{p1125}](#) in the [before attribute name state^{p1135}](#).

13.2.5.40 Self-closing start tag state §^{p11}₃₉

Consume the [next input character^{p1120}](#):

↪ **U+003E GREATER-THAN SIGN (>)**

Set the [self-closing flag^{p1125}](#) of the current tag token. Switch to the [data state^{p1125}](#). Emit the current tag token.

↪ **EOF**

This is an [eof-in-tag^{p1109} parse error^{p1108}](#). Emit an end-of-file token.

↪ **Anything else**

This is an [unexpected-solidus-in-tag^{p1112} parse error^{p1108}](#). [Reconsume^{p1125}](#) in the [before attribute name state^{p1135}](#).

13.2.5.41 Bogus comment state §^{p11}₃₉

Consume the [next input character^{p1120}](#):

↪ **U+003E GREATER-THAN SIGN (>)**

Switch to the [data state^{p1125}](#). Emit the current comment token.

↪ **EOF**

Emit the comment. Emit an end-of-file token.

↪ **U+0000 NULL**

This is an [unexpected-null-character^{p1112} parse error^{p1108}](#). Append a U+FFFD REPLACEMENT CHARACTER character to the comment token's data.

↪ **Anything else**

Append the [current input character^{p1120}](#) to the comment token's data.

13.2.5.42 Markup declaration open state §^{p11}₃₉

If the next few characters are:

↪ **Two U+002D HYPHEN-MINUS characters (-)**

Consume those two characters, create a comment token whose data is the empty string, and switch to the [comment start state^{p1139}](#).

↪ **ASCII case-insensitive match for the word "DOCTYPE"**

Consume those characters and switch to the [DOCTYPE state^{p1142}](#).

↪ **The string "[CDATA[" (the five uppercase letters "CDATA" with a U+005B LEFT SQUARE BRACKET character before and after)**

Consume those characters. If there is an [adjusted current node^{p1121}](#) and it is not an element in the [HTML namespace](#), then switch to the [CDATA section state^{p1149}](#). Otherwise, this is a [CDATA-in-html-content^{p1108} parse error^{p1108}](#). Create a comment token whose data is the "[CDATA[" string. Switch to the [bogus comment state^{p1139}](#).

↪ **Anything else**

This is an [incorrectly-opened-comment^{p1109} parse error^{p1108}](#). Create a comment token whose data is the empty string. Switch to the [bogus comment state^{p1139}](#) (don't consume anything in the current state).

13.2.5.43 Comment start state §^{p11}₃₉

Consume the [next input character^{p1120}](#):

↪ **U+002D HYPHEN-MINUS (-)**

Switch to the [comment start dash state^{p1140}](#).

↪ **U+003E GREATER-THAN SIGN (>)**

This is an [abrupt-closing-of-empty-comment^{p1108} parse error^{p1108}](#). Switch to the [data state^{p1125}](#). Emit the current comment token.

↳ **Anything else**

[Reconsume^{p1125}](#) in the [comment state^{p1140}](#).

13.2.5.44 Comment start dash state \S^{p11}_{40}

Consume the [next input character^{p1120}](#):

↳ **U+002D HYPHEN-MINUS (-)**

Switch to the [comment end state^{p1141}](#).

↳ **U+003E GREATER-THAN SIGN (>)**

This is an [abrupt-closing-of-empty-comment^{p1108}](#) [parse error^{p1108}](#). Switch to the [data state^{p1125}](#). Emit the current comment token.

↳ **EOF**

This is an [eof-in-comment^{p1109}](#) [parse error^{p1108}](#). Emit the current comment token. Emit an end-of-file token.

↳ **Anything else**

Append a U+002D HYPHEN-MINUS character (-) to the comment token's data. [Reconsume^{p1125}](#) in the [comment state^{p1140}](#).

13.2.5.45 Comment state \S^{p11}_{40}

Consume the [next input character^{p1120}](#):

↳ **U+003C LESS-THAN SIGN (<)**

Append the [current input character^{p1120}](#) to the comment token's data. Switch to the [comment less-than sign state^{p1140}](#).

↳ **U+002D HYPHEN-MINUS (-)**

Switch to the [comment end dash state^{p1141}](#).

↳ **U+0000 NULL**

This is an [unexpected-null-character^{p1112}](#) [parse error^{p1108}](#). Append a U+FFFD REPLACEMENT CHARACTER character to the comment token's data.

↳ **EOF**

This is an [eof-in-comment^{p1109}](#) [parse error^{p1108}](#). Emit the current comment token. Emit an end-of-file token.

↳ **Anything else**

Append the [current input character^{p1120}](#) to the comment token's data.

13.2.5.46 Comment less-than sign state \S^{p11}_{40}

Consume the [next input character^{p1120}](#):

↳ **U+0021 EXCLAMATION MARK (!)**

Append the [current input character^{p1120}](#) to the comment token's data. Switch to the [comment less-than sign bang state^{p1140}](#).

↳ **U+003C LESS-THAN SIGN (<)**

Append the [current input character^{p1120}](#) to the comment token's data.

↳ **Anything else**

[Reconsume^{p1125}](#) in the [comment state^{p1140}](#).

13.2.5.47 Comment less-than sign bang state \S^{p11}_{40}

Consume the [next input character^{p1120}](#):

↳ **U+002D HYPHEN-MINUS (-)**

Switch to the [comment less-than sign bang dash state^{p1141}](#).

↳ **Anything else**

[Reconsume^{p1125}](#) in the [comment state^{p1140}](#).

13.2.5.48 Comment less-than sign bang dash state §^{p11} 41

Consume the [next input character^{p1120}](#):

↳ **U+002D HYPHEN-MINUS (-)**

Switch to the [comment less-than sign bang dash dash state^{p1141}](#).

↳ **Anything else**

[Reconsume^{p1125}](#) in the [comment end dash state^{p1141}](#).

This is an [unexpected-null-character^{p1112}](#) [parse error^{p1108}](#). Ignore the character.

↪ **EOF**

Emit the DOCTYPE token. Emit an end-of-file token.

↳ **Anything else**

Ignore the character.

13.2.5.69 CDATA section state §^{p11}₄₉

Consume the [next input character](#)^{p1120}:

↳ **U+005D RIGHT SQUARE BRACKET (])**

Switch to the [CDATA section bracket state](#)^{p1149}.

↳ **EOF**

This is an [eof-in-cdata](#)^{p1109} [parse error](#)^{p1108}. Emit an end-of-file token.

↳ **Anything else**

Emit the [current input character](#)^{p1120} as a character token.

Note

U+0000 NULL characters are handled in the tree construction stage, as part of the [in foreign content](#)^{p1189} insertion mode, which is the only place where CDATA sections can appear.

13.2.5.70 CDATA section bracket state §^{p11}₄₉

Consume the [next input character](#)^{p1120}:

↳ **U+005D RIGHT SQUARE BRACKET (])**

Switch to the [CDATA section end state](#)^{p1149}.

↳ **Anything else**

Emit a U+005D RIGHT SQUARE BRACKET character token. [Reconsume](#)^{p1125} in the [CDATA section state](#)^{p1149}.

13.2.5.71 CDATA section end state §^{p11}₄₉

Consume the [next input character](#)^{p1120}:

↳ **U+005D RIGHT SQUARE BRACKET (])**

Emit a U+005D RIGHT SQUARE BRACKET character token.

↳ **U+003E GREATER-THAN SIGN character**

Switch to the [data state](#)^{p1125}.

↳ **Anything else**

Emit two U+005D RIGHT SQUARE BRACKET character tokens. [Reconsume](#)^{p1125} in the [CDATA section state](#)^{p1149}.

13.2.5.72 Character reference state §^{p11}₄₉

Set the [temporary buffer](#)^{p1125} to the empty string. Append a U+0026 AMPERSAND (&) character to the [temporary buffer](#)^{p1125}. Consume the [next input character](#)^{p1120}:

↳ **ASCII alphanumeric**

[Reconsume](#)^{p1125} in the [named character reference state](#)^{p1150}.

↳ **U+0023 NUMBER SIGN (#)**

Append the [current input character](#)^{p1120} to the [temporary buffer](#)^{p1125}. Switch to the [numeric character reference state](#)^{p1150}.

↳ **Anything else**

[Flush code points consumed as a character reference](#)^{p1125}. [Reconsume](#)^{p1125} in the [return state](#)^{p1125}.

13.2.5.73 Named character reference state §^{p11}₅₀

Consume the maximum number of characters possible, where the consumed characters are one of the identifiers in the first column of the [named character references^{p1207}](#) table. Append each character to the [temporary buffer^{p1125}](#) when it's consumed.

↪ If there is a match

If the character reference was [consumed as part of an attribute^{p1125}](#), and the last character matched is not a U+003B SEMICOLON character (;), and the [next input character^{p1120}](#) is either a U+003D EQUALS SIGN character (=) or an [ASCII alphanumeric](#), then, for historical reasons, [flush code points consumed as a character reference^{p1125}](#) and switch to the [return state^{p1125}](#).

Otherwise:

1. If the last character matched is not a U+003B SEMICOLON character (;), then this is a [missing-semicolon-after-character-reference^{p1110}](#) [parse error^{p1108}](#).
2. Set the [temporary buffer^{p1125}](#) to the empty string. Append one or two characters corresponding to the character reference name (as given by the second column of the [named character references^{p1207}](#) table) to the [temporary buffer^{p1125}](#).
3. [Flush code points consumed as a character reference^{p1125}](#). Switch to the [return state^{p1125}](#).

↪ Otherwise

[Flush code points consumed as a character reference^{p1125}](#). Switch to the [ambiguous ampersand state^{p1150}](#).

Example

If the markup contains (not in an attribute) the string I'm ¬it; I tell you, the character reference is parsed as "not", as in, I'm ~it; I tell you (and this is a parse error). But if the markup was I'm ∉ I tell you, the character reference would be parsed as "notin;", resulting in I'm ∉ I tell you (and no parse error).

However, if the markup contains the string I'm ¬it; I tell you in an attribute, no character reference is parsed and string remains intact (and there is no parse error).

13.2.5.74 Ambiguous ampersand state §^{p11}₅₀

Consume the [next input character^{p1120}](#):

↪ ASCII alphanumeric

If the character reference was [consumed as part of an attribute^{p1125}](#), then append the [current input character^{p1120}](#) to the current attribute's value. Otherwise, emit the [current input character^{p1120}](#) as a character token.

↪ U+003B SEMICOLON (;)

This is an [unknown-named-character-reference^{p1112}](#) [parse error^{p1108}](#). [Reconsume^{p1125}](#) in the [return state^{p1125}](#).

↪ Anything else

[Reconsume^{p1125}](#) in the [return state^{p1125}](#).

13.2.5.75 Numeric character reference state §^{p11}₅₀

Set the *character reference code* to zero (0).

Consume the [next input character^{p1120}](#):

↪ U+0078 LATIN SMALL LETTER X

↪ U+0058 LATIN CAPITAL LETTER X

Append the [current input character^{p1120}](#) to the [temporary buffer^{p1125}](#). Switch to the [hexadecimal character reference start state^{p1151}](#).

↪ Anything else

[Reconsume^{p1125}](#) in the [decimal character reference start state^{p1151}](#).

13.2.5.76 Hexadecimal character reference start state \S^{p11}_{51}

Consume the [next input character](#)^{p1120}:

↪ **ASCII hex digit**

Reconsume^{p1125} in the [hexadecimal character reference state](#)^{p1151}.

↪ **Anything else**

This is an [absence-of-digits-in-numeric-character-reference](#)^{p1108} [parse error](#)^{p1108}. Flush code points consumed as a character reference^{p1125}. Recconsume^{p1125} in the [return state](#)^{p1125}.

13.2.5.77 Decimal character reference start state \S^{p11}_{51}

Consume the [next input character](#)^{p1120}:

↪ **ASCII digit**

Reconsume^{p1125} in the [decimal character reference state](#)^{p1151}.

↪ **Anything else**

This is an [absence-of-digits-in-numeric-character-reference](#)^{p1108} [parse error](#)^{p1108}. Flush code points consumed as a character reference^{p1125}. Recconsume^{p1125} in the [return state](#)^{p1125}.

13.2.5.78 Hexadecimal character reference state \S^{p11}_{51}

Consume the [next input character](#)^{p1120}:

↪ **ASCII digit**

Multiply the [character reference code](#)^{p1150} by 16. Add a numeric version of the [current input character](#)^{p1120} (subtract 0x0030 from the character's code point) to the [character reference code](#)^{p1150}.

↪ **ASCII upper hex digit**

Multiply the [character reference code](#)^{p1150} by 16. Add a numeric version of the [current input character](#)^{p1120} as a hexadecimal digit (subtract 0x0037 from the character's code point) to the [character reference code](#)^{p1150}.

↪ **ASCII lower hex digit**

Multiply the [character reference code](#)^{p1150} by 16. Add a numeric version of the [current input character](#)^{p1120} as a hexadecimal digit (subtract 0x0057 from the character's code point) to the [character reference code](#)^{p1150}.

↪ **U+003B SEMICOLON**

Switch to the [numeric character reference end state](#)^{p1152}.

↪ **Anything else**

This is a [missing-semicolon-after-character-reference](#)^{p1110} [parse error](#)^{p1108}. Recconsume^{p1125} in the [numeric character reference end state](#)^{p1152}.

13.2.5.79 Decimal character reference state \S^{p11}_{51}

Consume the [next input character](#)^{p1120}:

↪ **ASCII digit**

Multiply the [character reference code](#)^{p1150} by 10. Add a numeric version of the [current input character](#)^{p1120} (subtract 0x0030 from the character's code point) to the [character reference code](#)^{p1150}.

↪ **U+003B SEMICOLON**

Switch to the [numeric character reference end state](#)^{p1152}.

↪ **Anything else**

This is a [missing-semicolon-after-character-reference](#)^{p1110} [parse error](#)^{p1108}. Recconsume^{p1125} in the [numeric character reference end state](#)^{p1152}.

13.2.5.80 Numeric character reference end state § p11 52

Check the [character reference code^{p1150}](#):

- If the number is 0x00, then this is a [null-character-reference^{p1111} parse error^{p1108}](#). Set the [character reference code^{p1150}](#) to 0xFFFFD.
- If the number is greater than 0x10FFFF, then this is a [character-reference-outside-unicode-range^{p1108} parse error^{p1108}](#). Set the [character reference code^{p1150}](#) to 0xFFFFD.
- If the number is a [surrogate](#), then this is a [surrogate-character-reference^{p1111} parse error^{p1108}](#). Set the [character reference code^{p1150}](#) to 0xFFFFD.
- If the number is a [noncharacter](#), then this is a [noncharacter-character-reference^{p1110} parse error^{p1108}](#).
- If the number is 0x0D, or a [control](#) that's not [ASCII whitespace](#), then this is a [control-character-reference^{p1108} parse error^{p1108}](#). If the number is one of the numbers in the first column of the following table, then find the row with that number in the first column, and set the [character reference code^{p1150}](#) to the number in the second column of that row.

Number	Code point
0x80	0x20AC EURO SIGN (€)
0x82	0x201A SINGLE LOW-9 QUOTATION MARK (,)
0x83	0x0192 LATIN SMALL LETTER F WITH HOOK (f)
0x84	0x201E DOUBLE LOW-9 QUOTATION MARK (,,)
0x85	0x2026 HORIZONTAL ELLIPSIS (...)
0x86	0x2020 DAGGER (†)
0x87	0x2021 DOUBLE DAGGER (‡)
0x88	0x02C6 MODIFIER LETTER CIRCUMFLEX ACCENT (ˆ)
0x89	0x2030 PER MILLE SIGN (‰)
0x8A	0x0160 LATIN CAPITAL LETTER S WITH CARON (Š)
0x8B	0x2039 SINGLE LEFT-POINTING ANGLE QUOTATION MARK (‹)
0x8C	0x0152 LATIN CAPITAL LIGATURE OE (Œ)
0x8E	0x017D LATIN CAPITAL LETTER Z WITH CARON (Ž)
0x91	0x2018 LEFT SINGLE QUOTATION MARK (‘)
0x92	0x2019 RIGHT SINGLE QUOTATION MARK (’)
0x93	0x201C LEFT DOUBLE QUOTATION MARK (“)
0x94	0x201D RIGHT DOUBLE QUOTATION MARK (”)
0x95	0x2022 BULLET (•)
0x96	0x2013 EN DASH (-)
0x97	0x2014 EM DASH (—)

0x99	0x2122 TRADE MARK SIGN (™)
0x9A	0x0161 LATIN SMALL LETTER S WITH CARON (š)
0x9B	0x203A SINGLE RIGHT-POINTING ANGLE QUOTATION MARK (›)
0x9C	0x0153 LATIN SMALL LIGATURE OE (œ)
0x9E	0x017E LATIN SMALL LETTER Z WITH CARON (ž)
0x9F	0x0178 LATIN CAPITAL LETTER Y WITH DIAERESIS (ÿ)

Set the [temporary buffer^{p1125}](#) to the empty string. Append a code point equal to the [character reference code^{p1150}](#) to the [temporary buffer^{p1125}](#). [Flush code points consumed as a character reference^{p1125}](#). Switch to the [return state^{p1125}](#).

13.2.6 Tree construction § p11 52

The input to the tree construction stage is a sequence of tokens from the [tokenization^{p1124}](#) stage. The tree construction stage is associated with a DOM [Document^{p117}](#) object when a parser is created. The "output" of this stage consists of dynamically modifying or extending that document's DOM tree.

This specification does not define when an interactive user agent has to render the [Document^{p117}](#) so that it is available to the user, or when it has to begin accepting user input.

As each token is emitted from the tokenizer, the user agent must follow the appropriate steps from the following list, known as the **tree construction dispatcher**:

- ↪ If the [stack of open elements](#)^{p1121} is empty
- ↪ If the [adjusted current node](#)^{p1121} is an element in the [HTML namespace](#)
- ↪ If the [adjusted current node](#)^{p1121} is a [MathML text integration point](#)^{p1153} and the token is a start tag whose tag name is neither "mglyph" nor "malignmark"
- ↪ If the [adjusted current node](#)^{p1121} is a [MathML text integration point](#)^{p1153} and the token is a character token
- ↪ If the [adjusted current node](#)^{p1121} is a [MathML annotation-xml](#) element and the token is a start tag whose tag name is "svg"
- ↪ If the [adjusted current node](#)^{p1121} is an [HTML integration point](#)^{p1153} and the token is a start tag
- ↪ If the [adjusted current node](#)^{p1121} is an [HTML integration point](#)^{p1153} and the token is a character token
- ↪ If the token is an end-of-file token

Process the token according to the rules given in the section corresponding to the current [insertion mode](#)^{p1120} in HTML content.

↪ **Otherwise**

Process the token according to the rules given in the section for parsing tokens [in foreign content](#)^{p1189}.

The **next token** is the token that is about to be processed by the [tree construction dispatcher](#)^{p1153} (even if the token is subsequently just ignored).

A node is a **MathML text integration point** if it is one of the following elements:

- A [MathML mi](#) element
- A [MathML mo](#) element
- A [MathML mn](#) element
- A [MathML ms](#) element
- A [MathML mtext](#) element

A node is an **HTML integration point** if it is one of the following elements:

- A [MathML annotation-xml](#) element whose start tag token had an attribute with the name "encoding" whose value was an [ASCII case-insensitive](#) match for the string "text/html"
- A [MathML annotation-xml](#) element whose start tag token had an attribute with the name "encoding" whose value was an [ASCII case-insensitive](#) match for the string "application/xhtml+xml"
- An [SVG foreignObject](#) element
- An [SVG desc](#) element
- An [SVG title](#) element

Note

If the node in question is the [context](#)^{p1206} element passed to the [HTML fragment parsing algorithm](#)^{p1206}, then the start tag token for that element is the "fake" token created during by that [HTML fragment parsing algorithm](#)^{p1206}.

Note

Not all of the tag names mentioned below are conformant tag names in this specification; many are included to handle legacy content. They still form part of the algorithm that implementations are required to implement to claim conformance.

Note

The algorithm described below places no limit on the depth of the DOM tree generated, or on the length of tag names, attribute names, attribute values, [Text](#) nodes, etc. While implementers are encouraged to avoid arbitrary limits, it is recognized that [practical concerns](#)^{p48} will likely force user agents to impose nesting depth constraints.

13.2.6.1 Creating and inserting nodes §^{p11} 53

While the parser is processing a token, it can enable or disable **foster parenting**. This affects the following algorithm.

The **appropriate place for inserting a node**, optionally using a particular *override target*, is the position in an element returned by running the following steps:

1. If there was an *override target* specified, then let *target* be the *override target*.

Otherwise, let *target* be the [current node](#)^{p1121}.

2. Determine the *adjusted insertion location* using the first matching steps from the following list:

↪ If [foster parenting](#)^{p1153} is enabled and *target* is a [table](#)^{p458}, [tbody](#)^{p469}, [tfoot](#)^{p471}, [thead](#)^{p470}, or [tr](#)^{p472} element

Note

Foster parenting happens when content is misnested in tables.

Run these substeps:

1. Let *last template* be the last [template](#)^{p640} element in the [stack of open elements](#)^{p1121}, if any.
2. Let *last table* be the last [table](#)^{p458} element in the [stack of open elements](#)^{p1121}, if any.
3. If there is a *last template* and either there is no *last table*, or there is one, but *last template* is lower (more recently added) than *last table* in the [stack of open elements](#)^{p1121}, then: let *adjusted insertion location* be inside *last template*'s [template contents](#)^{p642}, after its last child (if any), and abort these steps.
4. If there is no *last table*, then let *adjusted insertion location* be inside the first element in the [stack of open elements](#)^{p1121} (the [html](#)^{p157} element), after its last child (if any), and abort these steps. ([fragment case](#)^{p1206})
5. If *last table* has a parent node, then let *adjusted insertion location* be inside *last table*'s parent node, immediately before *last table*, and abort these steps.
6. Let *previous element* be the element immediately above *last table* in the [stack of open elements](#)^{p1121}.
7. Let *adjusted insertion location* be inside *previous element*, after its last child (if any).

Note

These steps are involved in part because it's possible for elements, the [table](#)^{p458} element in this case in particular, to have been moved by a script around in the DOM, or indeed removed from the DOM entirely, after the element was inserted by the parser.

↪ **Otherwise**

Let *adjusted insertion location* be inside *target*, after its last child (if any).

3. If the *adjusted insertion location* is inside a [template](#)^{p640} element, let it instead be inside the [template](#)^{p640} element's [template contents](#)^{p642}, after its last child (if any).
4. Return the *adjusted insertion location*.

When the steps below require the UA to **create an element for a token** in a particular *given namespace* and with a particular *intended parent*, the UA must run the following steps:

1. If the [active speculative HTML parser](#)^{p1193} is not null, then return the result of [creating a speculative mock element](#)^{p1194} given *given namespace*, the tag name of the given token, and the attributes of the given token.
2. Otherwise, optionally [create a speculative mock element](#)^{p1194} given *given namespace*, the tag name of the given token, and the attributes of the given token.

Note

The result is not used. This step allows for a [speculative fetch](#)^{p1193} to be initiated from non-speculative parsing. The fetch is still speculative at this point, because, for example, by the time the element is inserted, intended parent might have been removed from the document.

3. Let *document* be *intended parent*'s [node document](#).
4. Let *local name* be the tag name of the token.
5. Let *is* be the value of the "[is](#)^{p728}" attribute in the given token, if such an attribute exists, or null otherwise.
6. Let *definition* be the result of [looking up a custom element definition](#)^{p730} given *document*, *given namespace*, *local name*, and *is*.

7. If *definition* is non-null and the parser was not created as part of the [HTML fragment parsing algorithm](#)^{p1206}, then let *will execute script* be true. Otherwise, let it be false.
8. If *will execute script* is true, then:
 1. Increment *document*'s [throw-on-dynamic-markup-insertion counter](#)^{p993}.
 2. If the [JavaScript execution context stack](#) is empty, then [perform a microtask checkpoint](#)^{p974}.
 3. Push a new [element queue](#)^{p737} onto *document*'s [relevant agent](#)^{p934}'s [custom element reactions stack](#)^{p737}.
9. Let *element* be the result of [creating an element](#) given *document*, *localName*, *given namespace*, null, and *is*. If *will execute script* is true, set the *synchronous custom elements flag*; otherwise, leave it unset.

Note

This will cause [custom element constructors](#)^{p728} to run, if *will execute script* is true. However, since we incremented the [throw-on-dynamic-markup-insertion counter](#)^{p993}, this cannot cause [new characters to be inserted into the tokenizer](#)^{p996}, or the document to be blown away^{p995}.

10. [Append](#) each attribute in the given token to *element*.

Note

This can [enqueue a custom element callback reaction](#)^{p738} for the `attributeChangedCallback`, which might run immediately (in the next step).

Note

Even though the `is`^{p728} attribute governs the [creation](#) of a [customized built-in element](#)^{p728}, it is not present during the execution of the relevant [custom element constructor](#)^{p728}; it is appended in this step, along with all other attributes.

11. If *will execute script* is true, then:
 1. Let *queue* be the result of popping from *document*'s [relevant agent](#)^{p934}'s [custom element reactions stack](#)^{p737}. (This will be the same [element queue](#)^{p737} as was pushed above.)
 2. [Invoke custom element reactions](#)^{p739} in *queue*.
 3. Decrement *document*'s [throw-on-dynamic-markup-insertion counter](#)^{p993}.
12. If *element* has an `xmlns` attribute in the [XMLNS namespace](#) whose value is not exactly the same as the element's namespace, that is a [parse error](#)^{p1108}. Similarly, if *element* has an `xmlns:xlink` attribute in the [XMLNS namespace](#) whose value is not the [XLink Namespace](#), that is a [parse error](#)^{p1108}.
13. If *element* is a [resettable element](#)^{p494}, invoke its [reset algorithm](#)^{p614}. (This initializes the element's [value](#)^{p575} and [checkedness](#)^{p575} based on the element's attributes.)
14. If *element* is a [form-associated element](#)^{p494} and not a [form-associated custom element](#)^{p729}, the [form element pointer](#)^{p1124} is not null, there is no [template](#)^{p649} element on the [stack of open elements](#)^{p1121}, *element* is either not [listed](#)^{p494} or doesn't have a [form](#)^{p576} attribute, and the *intended parent* is in the same [tree](#) as the element pointed to by the [form element pointer](#)^{p1124}, then [associate](#)^{p576} *element* with the [form](#)^{p494} element pointed to by the [form element pointer](#)^{p1124} and set *element*'s [parser inserted flag](#)^{p576}.
15. Return *element*.

When the steps below require the user agent to **insert a foreign element** for a token in a given namespace, the user agent must run these steps:

1. Let the *adjusted insertion location* be the [appropriate place for inserting a node](#)^{p1153}.
2. Let *element* be the result of [creating an element for the token](#)^{p1154} in the given namespace, with the intended parent being the element in which the *adjusted insertion location* finds itself.
3. If it is possible to insert *element* at the *adjusted insertion location*, then:
 1. If the parser was not created as part of the [HTML fragment parsing algorithm](#)^{p1206}, then push a new [element queue](#)^{p737} onto *element*'s [relevant agent](#)^{p934}'s [custom element reactions stack](#)^{p737}.

2. Insert *element* at the *adjusted insertion location*.
3. If the parser was not created as part of the [HTML fragment parsing algorithm](#)^{p1206}, then pop the [element queue](#)^{p737} from *element*'s [relevant agent](#)^{p934}'s [custom element reactions stack](#)^{p737}, and [invoke custom element reactions](#)^{p739} in that queue.

Note

If the adjusted insertion location cannot accept more elements, e.g. because it's a [Document](#)^{p117} that already has an element child, then element is dropped on the floor.

4. Push *element* onto the [stack of open elements](#)^{p1121} so that it is the new [current node](#)^{p1121}.
5. Return *element*.

When the steps below require the user agent to **insert an HTML element** for a token, the user agent must [insert a foreign element](#)^{p1155} for the token, in the [HTML namespace](#).

When the steps below require the user agent to **adjust MathML attributes** for a token, then, if the token has an attribute named `definitionurl`, change its name to `definitionURL` (note the case difference).

When the steps below require the user agent to **adjust SVG attributes** for a token, then, for each attribute on the token whose attribute name is one of the ones in the first column of the following table, change the attribute's name to the name given in the corresponding cell in the second column. (This fixes the case of SVG attributes that are not all lowercase.)

Attribute name on token	Attribute name on element
attributename	attributeName
attributetype	attributeType
basefrequency	baseFrequency
baseprofile	baseProfile
calcmode	calcMode
clippathunits	clipPathUnits
diffuseconstant	diffuseConstant
edgemode	edgeMode
filterunits	filterUnits
glyphref	glyphRef
gradienttransform	gradientTransform
gradientunits	gradientUnits
kernelmatrix	kernelMatrix
kernelunitlength	kernelUnitLength
keypoints	keyPoints
keysplines	keySplines
keytimes	keyTimes
lengthadjust	lengthAdjust
limitingconeangle	limitingConeAngle
markerheight	markerHeight
markerunits	markerUnits
markerwidth	markerWidth
maskcontentunits	maskContentUnits
maskunits	maskUnits
numoctaves	numOctaves
pathlength	pathLength
patterncontentunits	patternContentUnits
patterntransform	patternTransform
patternunits	patternUnits
pointsatx	pointsAtX
pointsaty	pointsAtY
pointsatz	pointsAtZ
preservealpha	preserveAlpha
preserveaspectratio	preserveAspectRatio

Attribute name on token	Attribute name on element
primitiveunits	primitiveUnits
refx	refX
refy	refY
repeatcount	repeatCount
repeatdur	repeatDur
requiredextensions	requiredExtensions
requiredfeatures	requiredFeatures
specularconstant	specularConstant
specularexponent	specularExponent
spreadmethod	spreadMethod
startoffset	startOffset
stddeviation	stdDeviation
stitchtiles	stitchTiles
surfacescale	surfaceScale
systemlanguage	systemLanguage
tablevalues	tableValues
targetx	targetX
targety	targetY
textlength	textLength
viewbox	viewBox
viewtarget	viewTarget
xchannelselector	xChannelSelector
ychannelselector	yChannelSelector
zoomandpan	zoomAndPan

When the steps below require the user agent to **adjust foreign attributes** for a token, then, if any of the attributes on the token match the strings given in the first column of the following table, let the attribute be a namespaced attribute, with the prefix being the string given in the corresponding cell in the second column, the local name being the string given in the corresponding cell in the third column, and the namespace being the namespace given in the corresponding cell in the fourth column. (This fixes the use of namespaced attributes, in particular [lang attributes in the XML namespace](#).)

Attribute name	Prefix	Local name	Namespace
xlink:actuate	xlink	actuate	XLink namespace
xlink:arcrole	xlink	arcrole	XLink namespace
xlink:href	xlink	href	XLink namespace
xlink:role	xlink	role	XLink namespace
xlink:show	xlink	show	XLink namespace
xlink:title	xlink	title	XLink namespace
xlink:type	xlink	type	XLink namespace
xml:lang	xml	lang	XML namespace
xml:space	xml	space	XML namespace
xmlns	(none)	xmlns	XMLNS namespace
xmlns:xlink	xmlns	xlink	XMLNS namespace

When the steps below require the user agent to **insert a character** while processing a token, the user agent must run the following steps:

1. Let *data* be the characters passed to the algorithm, or, if no characters were explicitly specified, the character of the character token being processed.
2. Let the *adjusted insertion location* be the [appropriate place for inserting a node](#)^{p1153}.
3. If the *adjusted insertion location* is in a [Document](#)^{p117} node, then return.

Note

The DOM will not let [Document](#)^{p117} nodes have [Text](#) node children, so they are dropped on the floor.

- If there is a **Text** node immediately before the *adjusted insertion location*, then append *data* to that **Text** node's *data*.

Otherwise, create a new **Text** node whose *data* is *data* and whose *node document* is the same as that of the element in which the *adjusted insertion location* finds itself, and insert the newly created node at the *adjusted insertion location*.

Example

Here are some sample inputs to the parser and the corresponding number of **Text** nodes that they result in, assuming a user agent that executes scripts.

Input	Number of Text nodes
<pre>A<script> var script = document.getElementsByTagName('script')[0]; document.body.removeChild(script); </script>B</pre>	One Text node in the document, containing "AB".
<pre>A<script> var text = document.createTextNode('B'); document.body.appendChild(text); </script>C</pre>	Three Text nodes; "A" before the script, the script's contents, and "BC" after the script (the parser appends to the Text node created by the script).
<pre>A<script> var text = document.getElementsByTagName('script')[0].firstChild; text.data = 'B'; document.body.appendChild(text); </script>C</pre>	Two adjacent Text nodes in the document, containing "A" and "BC".
<pre>A<table>B<tr>C</tr>D</table></pre>	One Text node before the table, containing "ABCD". (This is caused by foster parenting ^{p1153} .)
<pre>A<table><tr> B</tr> C</table></pre>	One Text node before the table, containing "A B C" (A-space-B-space-C). (This is caused by foster parenting ^{p1153} .)
<pre>A<table><tr> B</tr> C</table></pre>	One Text node before the table, containing "A BC" (A-space-B-C), and one Text node inside the table (as a child of a tbody ^{p469}) with a single space character. (Space characters separated from non-space characters by non-character tokens are not affected by foster parenting ^{p1153} , even if those other tokens then get ignored.)

When the steps below require the user agent to **insert a comment** while processing a comment token, optionally with an explicitly insertion position *position*, the user agent must run the following steps:

- Let *data* be the data given in the comment token being processed.
- If *position* was specified, then let the *adjusted insertion location* be *position*. Otherwise, let *adjusted insertion location* be the [appropriate place for inserting a node](#)^{p1153}.
- Create a **Comment** node whose *data* attribute is set to *data* and whose *node document* is the same as that of the node in which the *adjusted insertion location* finds itself.
- Insert the newly created node at the *adjusted insertion location*.

DOM mutation events must not fire for changes caused by the UA parsing the document. This includes the parsing of any content inserted using [document.write\(\)](#)^{p996} and [document.writeln\(\)](#)^{p997} calls. [\[UIEVENTS\]](#)^{p1312}

However, [mutation observers](#) do fire, as required by *DOM*.

13.2.6.2 Parsing elements that contain only text § p1158

The **generic raw text element parsing algorithm** and the **generic RCDATA element parsing algorithm** consist of the following steps. These algorithms are always invoked in response to a start tag token.

- [Insert an HTML element](#)^{p1156} for the token.

2. If the algorithm that was invoked is the [generic raw text element parsing algorithm](#)^{p1158}, switch the tokenizer to the [RAWTEXT state](#)^{p1126}; otherwise the algorithm invoked was the [generic RCDATA element parsing algorithm](#)^{p1158}, switch the tokenizer to the [RCDATA state](#)^{p1126}.
3. Let the [original insertion mode](#)^{p1120} be the current [insertion mode](#)^{p1120}.
4. Then, switch the [insertion mode](#)^{p1120} to "[text](#)^{p1176}".

13.2.6.3 Closing elements that have implied end tags §^{p11}₅₉

When the steps below require the UA to **generate implied end tags**, then, while the [current node](#)^{p1121} is a [dd](#)^{p237} element, a [dt](#)^{p236} element, an [li](#)^{p230} element, an [optgroup](#)^{p554} element, an [option](#)^{p555} element, a [p](#)^{p218} element, an [rb](#)^{p1257} element, an [rp](#)^{p264} element, an [rt](#)^{p264} element, or an [rtc](#)^{p1257} element, the UA must pop the [current node](#)^{p1121} off the [stack of open elements](#)^{p1121}.

If a step requires the UA to generate implied end tags but lists an element to exclude from the process, then the UA must perform the above steps as if that element was not in the above list.

When the steps below require the UA to **generate all implied end tags thoroughly**, then, while the [current node](#)^{p1121} is a [caption](#)^{p466} element, a [colgroup](#)^{p467} element, a [dd](#)^{p237} element, a [dt](#)^{p236} element, an [li](#)^{p230} element, an [optgroup](#)^{p554} element, an [option](#)^{p555} element, a [p](#)^{p218} element, an [rb](#)^{p1257} element, an [rp](#)^{p264} element, an [rt](#)^{p264} element, an [rtc](#)^{p1257} element, a [tbody](#)^{p469} element, a [td](#)^{p474} element, a [tfoot](#)^{p471} element, a [th](#)^{p475} element, a [thead](#)^{p470} element, or a [tr](#)^{p472} element, the UA must pop the [current node](#)^{p1121} off the [stack of open elements](#)^{p1121}.

13.2.6.4 The rules for parsing tokens in HTML content §^{p11}₅₉

13.2.6.4.1 The "initial" insertion mode §^{p11}₅₉

A [Document](#)^{p117} object has an associated **parser cannot change the mode flag** (a boolean). It is initially false.

When the user agent is to apply the rules for the "[initial](#)^{p1159}" [insertion mode](#)^{p1120}, the user agent must handle the token as follows:

↪ **A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE**

Ignore the token.

↪ **A comment token**

[Insert a comment](#)^{p1158} as the last child of the [Document](#)^{p117} object.

↪ **A DOCTYPE token**

If the DOCTYPE token's name is not "html", or the token's public identifier is not missing, or the token's system identifier is neither missing nor "[about:legacy-compat](#)^{p90}", then there is a [parse error](#)^{p1108}.

Append a [DocumentType](#) node to the [Document](#)^{p117} node, with its [name](#) set to the name given in the DOCTYPE token, or the empty string if the name was missing; its [public ID](#) set to the public identifier given in the DOCTYPE token, or the empty string if the public identifier was missing; and its [system ID](#) set to the system identifier given in the DOCTYPE token, or the empty string if the system identifier was missing.

Note

This also ensures that the [DocumentType](#) node is returned as the value of the [doctype](#) attribute of the [Document](#)^{p117} object.

Then, if the document is *not* an [iframe srcdoc document](#)^{p370}, and the [parser cannot change the mode flag](#)^{p1159} is false, and the DOCTYPE token matches one of the conditions in the following list, then set the [Document](#)^{p117} to [quirks mode](#):

- The [force-quirks flag](#)^{p1125} is set to *on*.
- The name is not "html".
- The public identifier is set to: "-//W30//DTD W3 HTML Strict 3.0//EN//"
- The public identifier is set to: "-//W3C//DTD HTML 4.0 Transitional//EN"
- The public identifier is set to: "HTML"
- The system identifier is set to: "http://www.ibm.com/data/dtd/v11/ibmhtml1-transitional.dtd"
- The public identifier starts with: "+//Silmaril//dtd html Pro v0r11 19970101//"
- The public identifier starts with: "-//AS//DTD HTML 3.0 asWedit + extensions//"
- The public identifier starts with: "-//AdvaSoft Ltd//DTD HTML 3.0 asWedit + extensions//"

- The public identifier starts with: "-//IETF//DTD HTML 2.0 Level 1//"
- The public identifier starts with: "-//IETF//DTD HTML 2.0 Level 2//"
- The public identifier starts with: "-//IETF//DTD HTML 2.0 Strict Level 1//"
- The public identifier starts with: "-//IETF//DTD HTML 2.0 Strict Level 2//"
- The public identifier starts with: "-//IETF//DTD HTML 2.0 Strict//"
- The public identifier starts with: "-//IETF//DTD HTML 2.0//"
- The public identifier starts with: "-//IETF//DTD HTML 2.1E//"
- The public identifier starts with: "-//IETF//DTD HTML 3.0//"
- The public identifier starts with: "-//IETF//DTD HTML 3.2 Final//"
- The public identifier starts with: "-//IETF//DTD HTML 3.2//"
- The public identifier starts with: "-//IETF//DTD HTML 3//"
- The public identifier starts with: "-//IETF//DTD HTML Level 0//"
- The public identifier starts with: "-//IETF//DTD HTML Level 1//"
- The public identifier starts with: "-//IETF//DTD HTML Level 2//"
- The public identifier starts with: "-//IETF//DTD HTML Level 3//"
- The public identifier starts with: "-//IETF//DTD HTML Strict Level 0//"
- The public identifier starts with: "-//IETF//DTD HTML Strict Level 1//"
- The public identifier starts with: "-//IETF//DTD HTML Strict Level 2//"
- The public identifier starts with: "-//IETF//DTD HTML Strict Level 3//"
- The public identifier starts with: "-//IETF//DTD HTML Strict//"
- The public identifier starts with: "-//IETF//DTD HTML//"
- The public identifier starts with: "-//Metrius//DTD Metrius Presentational//"
- The public identifier starts with: "-//Microsoft//DTD Internet Explorer 2.0 HTML Strict//"
- The public identifier starts with: "-//Microsoft//DTD Internet Explorer 2.0 HTML//"
- The public identifier starts with: "-//Microsoft//DTD Internet Explorer 2.0 Tables//"
- The public identifier starts with: "-//Microsoft//DTD Internet Explorer 3.0 HTML Strict//"
- The public identifier starts with: "-//Microsoft//DTD Internet Explorer 3.0 HTML//"
- The public identifier starts with: "-//Microsoft//DTD Internet Explorer 3.0 Tables//"
- The public identifier starts with: "-//Netscape Comm. Corp.//DTD HTML//"
- The public identifier starts with: "-//Netscape Comm. Corp.//DTD Strict HTML//"
- The public identifier starts with: "-//O'Reilly and Associates//DTD HTML 2.0//"
- The public identifier starts with: "-//O'Reilly and Associates//DTD HTML Extended 1.0//"
- The public identifier starts with: "-//O'Reilly and Associates//DTD HTML Extended Relaxed 1.0//"
- The public identifier starts with: "-//SQ//DTD HTML 2.0 HoTMetal + extensions//"
- The public identifier starts with: "-//SoftQuad Software//DTD HoTMetal PRO 6.0::19990601::extensions to HTML 4.0//"
- The public identifier starts with: "-//SoftQuad//DTD HoTMetal PRO 4.0::19971010::extensions to HTML 4.0//"
- The public identifier starts with: "-//Spyglass//DTD HTML 2.0 Extended//"
- The public identifier starts with: "-//Sun Microsystems Corp.//DTD HotJava HTML//"
- The public identifier starts with: "-//Sun Microsystems Corp.//DTD HotJava Strict HTML//"
- The public identifier starts with: "-//W3C//DTD HTML 3 1995-03-24//"
- The public identifier starts with: "-//W3C//DTD HTML 3.2 Draft//"
- The public identifier starts with: "-//W3C//DTD HTML 3.2 Final//"
- The public identifier starts with: "-//W3C//DTD HTML 3.2//"
- The public identifier starts with: "-//W3C//DTD HTML 3.2S Draft//"
- The public identifier starts with: "-//W3C//DTD HTML 4.0 Frameset//"
- The public identifier starts with: "-//W3C//DTD HTML 4.0 Transitional//"
- The public identifier starts with: "-//W3C//DTD HTML Experimental 19960712//"
- The public identifier starts with: "-//W3C//DTD HTML Experimental 970421//"
- The public identifier starts with: "-//W3C//DTD W3 HTML//"
- The public identifier starts with: "-//W30//DTD W3 HTML 3.0//"
- The public identifier starts with: "-//WebTechs//DTD Mozilla HTML 2.0//"
- The public identifier starts with: "-//WebTechs//DTD Mozilla HTML//"
- The system identifier is missing and the public identifier starts with: "-//W3C//DTD HTML 4.01 Frameset//"
- The system identifier is missing and the public identifier starts with: "-//W3C//DTD HTML 4.01 Transitional//"

Otherwise, if the document is *not* an [iframe srcdoc document](#)^{p370}, and the [parser cannot change the mode flag](#)^{p1159} is false, and the DOCTYPE token matches one of the conditions in the following list, then then set the [Document](#)^{p117} to [limited-quirks mode](#):

- The public identifier starts with: "-//W3C//DTD XHTML 1.0 Frameset//"
- The public identifier starts with: "-//W3C//DTD XHTML 1.0 Transitional//"
- The system identifier is not missing and the public identifier starts with: "-//W3C//DTD HTML 4.01 Frameset//"
- The system identifier is not missing and the public identifier starts with: "-//W3C//DTD HTML 4.01 Transitional//"

The system identifier and public identifier strings must be compared to the values given in the lists above in an [ASCII case-insensitive](#) manner. A system identifier whose value is the empty string is not considered missing for the purposes of the conditions above.

Then, switch the [insertion mode](#)^{p1120} to "[before html](#)^{p1161}".

↪ Anything else

If the document is *not* an [iframe srcdoc document](#)^{p370}, then this is a [parse error](#)^{p1108}; if the [parser cannot change the mode flag](#)^{p1159} is false, set the [Document](#)^{p117} to [quirks mode](#).

In any case, switch the [insertion mode](#)^{p1120} to "[before html](#)^{p1161}", then reprocess the token.

13.2.6.4.2 The "before html" insertion mode §^{p11}₆₁

When the user agent is to apply the rules for the "before html^{p1161}" insertion mode^{p1120}, the user agent must handle the token as follows:

↪ **A DOCTYPE token**

[Parse error^{p1108}](#). Ignore the token.

↪ **A comment token**

[Insert a comment^{p1158}](#) as the last child of the [Document^{p117}](#) object.

↪ **A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE**

Ignore the token.

↪ **A start tag whose tag name is "html"**

[Create an element for the token^{p1154}](#) in the [HTML namespace](#), with the [Document^{p117}](#) as the intended parent. Append it to the [Document^{p117}](#) object. Put this element in the [stack of open elements^{p1121}](#).

Switch the [insertion mode^{p1120}](#) to "[before head^{p1161}](#)".

↪ **An end tag whose tag name is one of: "head", "body", "html", "br"**

Act as described in the "anything else" entry below.

↪ **Any other end tag**

[Parse error^{p1108}](#). Ignore the token.

↪ **Anything else**

Create an [html^{p157}](#) element whose [node document](#) is the [Document^{p117}](#) object. Append it to the [Document^{p117}](#) object. Put this element in the [stack of open elements^{p1121}](#).

Switch the [insertion mode^{p1120}](#) to "[before head^{p1161}](#)", then reprocess the token.

The [document element](#) can end up being removed from the [Document^{p117}](#) object, e.g. by scripts; nothing in particular happens in such cases, content continues being appended to the nodes as described in the next section.

13.2.6.4.3 The "before head" insertion mode §^{p11}₆₁

When the user agent is to apply the rules for the "before head^{p1161}" insertion mode^{p1120}, the user agent must handle the token as follows:

↪ **A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE**

Ignore the token.

↪ **A comment token**

[Insert a comment^{p1158}](#).

↪ **A DOCTYPE token**

[Parse error^{p1108}](#). Ignore the token.

↪ **A start tag whose tag name is "html"**

Process the token [using the rules for^{p1120}](#) the "[in body^{p1166}](#)" [insertion mode^{p1120}](#).

↪ **A start tag whose tag name is "head"**

[Insert an HTML element^{p1156}](#) for the token.

Set the [head element pointer^{p1124}](#) to the newly created [head^{p158}](#) element.

Switch the [insertion mode^{p1120}](#) to "[in head^{p1162}](#)".

↪ **An end tag whose tag name is one of: "head", "body", "html", "br"**

Act as described in the "anything else" entry below.

↪ **Any other end tag**

[Parse error^{p1108}](#). Ignore the token.

↪ **Anything else**

[Insert an HTML element^{p1156}](#) for a "head" start tag token with no attributes.

Set the [head element pointer^{p1124}](#) to the newly created [head^{p158}](#) element.

Switch the [insertion mode^{p1120}](#) to "[in head^{p1162}](#)".

Reprocess the current token.

13.2.6.4.4 The "in head" insertion mode §^{p11} 62

When the user agent is to apply the rules for the "[in head^{p1162}](#)" [insertion mode^{p1120}](#), the user agent must handle the token as follows:

↪ **A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE**

[Insert the character^{p1157}](#).

↪ **A comment token**

[Insert a comment^{p1158}](#).

↪ **A DOCTYPE token**

[Parse error^{p1108}](#). Ignore the token.

↪ **A start tag whose tag name is "html"**

Process the token [using the rules for^{p1120}](#) the "[in body^{p1166}](#)" [insertion mode^{p1120}](#).

↪ **A start tag whose tag name is one of: "base", "basefont", "bgsound", "link"**

[Insert an HTML element^{p1156}](#) for the token. Immediately pop the [current node^{p1121}](#) off the [stack of open elements^{p1121}](#).

[Acknowledge the token's self-closing flag^{p1125}](#), if it is set.

↪ **A start tag whose tag name is "meta"**

[Insert an HTML element^{p1156}](#) for the token. Immediately pop the [current node^{p1121}](#) off the [stack of open elements^{p1121}](#).

[Acknowledge the token's self-closing flag^{p1125}](#), if it is set.

If the [active speculative HTML parser^{p1193}](#) is null, then:

1. If the element has a [charset^{p170}](#) attribute, and [getting an encoding](#) from its value results in an [encoding](#), and the [confidence^{p1113}](#) is currently *tentative*, then [change the encoding^{p1119}](#) to the resulting encoding.
2. Otherwise, if the element has an [http-equiv^{p176}](#) attribute whose value is an [ASCII case-insensitive](#) match for the string "Content-Type", and the element has a [content^{p171}](#) attribute, and applying the [algorithm for extracting a character encoding from a meta element^{p92}](#) to that attribute's value returns an [encoding](#), and the [confidence^{p1113}](#) is currently *tentative*, then [change the encoding^{p1119}](#) to the extracted encoding.

Note

The [speculative HTML parser^{p1193}](#) doesn't speculatively apply character encoding declarations in order to reduce implementation complexity.

↪ **A start tag whose tag name is "title"**

Follow the [generic RCDATA element parsing algorithm^{p1158}](#).

↪ **A start tag whose tag name is "noscript", if the [scripting flag](#)^{p1124} is enabled**

↪ **A start tag whose tag name is one of: "noframes", "style"**

Follow the [generic raw text element parsing algorithm](#)^{p1158}.

↪ **A start tag whose tag name is "noscript", if the [scripting flag](#)^{p1124} is disabled**

[Insert an HTML element](#)^{p1156} for the token.

Switch the [insertion mode](#)^{p1120} to "[in head noscript](#)^{p1164}".

↪ **A start tag whose tag name is "script"**

Run these steps:

1. Let the *adjusted insertion location* be the [appropriate place for inserting a node](#)^{p1153}.
2. [Create an element for the token](#)^{p1154} in the [HTML namespace](#), with the intended parent being the element in which the *adjusted insertion location* finds itself.
3. Set the element's [parser document](#)^{p630} to the [Document](#)^{p117}, and unset the element's "[non-blocking](#)"^{p630} flag.

Note

This ensures that, if the script is external, any [document.write\(\)](#)^{p996} calls in the script will execute in-line, instead of blowing the document away, as would happen in most other cases. It also prevents the script from executing until the end tag is seen.

4. If the parser was created as part of the [HTML fragment parsing algorithm](#)^{p1206}, then mark the [script](#)^{p624} element as "[already started](#)"^{p630}. ([fragment case](#)^{p1206})
5. If the parser was invoked via the [document.write\(\)](#)^{p996} or [document.writeln\(\)](#)^{p997} methods, then optionally mark the [script](#)^{p624} element as "[already started](#)"^{p630}. (For example, the user agent might use this clause to prevent execution of [cross-origin](#)^{p868} scripts inserted via [document.write\(\)](#)^{p996} under slow network conditions, or when the page has already taken a long time to load.)
6. Insert the newly created element at the *adjusted insertion location*.
7. Push the element onto the [stack of open elements](#)^{p1121} so that it is the new [current node](#)^{p1121}.
8. Switch the tokenizer to the [script data state](#)^{p1126}.
9. Let the [original insertion mode](#)^{p1120} be the current [insertion mode](#)^{p1120}.
10. Switch the [insertion mode](#)^{p1120} to "[text](#)^{p1176}".

↪ **An end tag whose tag name is "head"**

Pop the [current node](#)^{p1121} (which will be the [head](#)^{p158} element) off the [stack of open elements](#)^{p1121}.

Switch the [insertion mode](#)^{p1120} to "[after head](#)^{p1165}".

↪ **An end tag whose tag name is one of: "body", "html", "br"**

Act as described in the "anything else" entry below.

↪ **A start tag whose tag name is "template"**

[Insert an HTML element](#)^{p1156} for the token.

Insert a [marker](#)^{p1123} at the end of the [list of active formatting elements](#)^{p1123}.

Set the [frameset-ok flag](#)^{p1124} to "not ok".

Switch the [insertion mode](#)^{p1120} to "[in template](#)^{p1186}".

Push "[in template](#)^{p1186}" onto the [stack of template insertion modes](#)^{p1120} so that it is the new [current template insertion mode](#)^{p1120}.

↪ **An end tag whose tag name is "template"**

If there is no [template](#)^{p640} element on the [stack of open elements](#)^{p1121}, then this is a [parse error](#)^{p1108}; ignore the token.

Otherwise, run these steps:

1. [Generate all implied end tags thoroughly](#)^{p1159}.
2. If the [current node](#)^{p1121} is not a [template](#)^{p640} element, then this is a [parse error](#)^{p1108}.
3. Pop elements from the [stack of open elements](#)^{p1121} until a [template](#)^{p640} element has been popped from the stack.
4. [Clear the list of active formatting elements up to the last marker](#)^{p1124}.
5. Pop the [current template insertion mode](#)^{p1120} off the [stack of template insertion modes](#)^{p1120}.
6. [Reset the insertion mode appropriately](#)^{p1120}.

↪ **A start tag whose tag name is "head"**

↪ **Any other end tag**

[Parse error](#)^{p1108}. Ignore the token.

↪ **Anything else**

Pop the [current node](#)^{p1121} (which will be the [head](#)^{p158} element) off the [stack of open elements](#)^{p1121}.

Switch the [insertion mode](#)^{p1120} to "[after head](#)^{p1165}".

Reprocess the token.

13.2.6.4.5 The "in head noscript" insertion mode §^{p111} 64

When the user agent is to apply the rules for the "[in head noscript](#)^{p1164}" [insertion mode](#)^{p1120}, the user agent must handle the token as follows:

↪ **A DOCTYPE token**

[Parse error](#)^{p1108}. Ignore the token.

↪ **A start tag whose tag name is "html"**

Process the token [using the rules for](#)^{p1120} the "[in body](#)^{p1166}" [insertion mode](#)^{p1120}.

↪ **An end tag whose tag name is "noscript"**

Pop the [current node](#)^{p1121} (which will be a [noscript](#)^{p638} element) from the [stack of open elements](#)^{p1121}; the new [current node](#)^{p1121} will be a [head](#)^{p158} element.

Switch the [insertion mode](#)^{p1120} to "[in head](#)^{p1162}".

↪ **A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE**

↪ **A comment token**

↪ **A start tag whose tag name is one of: "basefont", "bgsound", "link", "meta", "noframes", "style"**

Process the token [using the rules for](#)^{p1120} the "[in head](#)^{p1162}" [insertion mode](#)^{p1120}.

↪ **An end tag whose tag name is "br"**

Act as described in the "anything else" entry below.

↪ **A start tag whose tag name is one of: "head", "noscript"**

↪ **Any other end tag**

[Parse error](#)^{p1108}. Ignore the token.

↪ **Anything else**

[Parse error](#)^{p1108}.

Pop the [current node](#)^{p1121} (which will be a [noscript](#)^{p638} element) from the [stack of open elements](#)^{p1121}; the new [current node](#)^{p1121} will be a [head](#)^{p158} element.

Switch the [insertion mode](#)^{p1120} to "[in head](#)^{p1162}".

Reprocess the token.

13.2.6.4.6 The "after head" insertion mode §^{p11}₆₅

When the user agent is to apply the rules for the "after head^{p1165}" [insertion mode^{p1120}](#), the user agent must handle the token as follows:

↪ **A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE**

[Insert the character^{p1157}](#).

↪ **A comment token**

[Insert a comment^{p1158}](#).

↪ **A DOCTYPE token**

[Parse error^{p1108}](#). Ignore the token.

↪ **A start tag whose tag name is "html"**

Process the token [using the rules for^{p1120}](#) the "in body^{p1166}" [insertion mode^{p1120}](#).

↪ **A start tag whose tag name is "body"**

[Insert an HTML element^{p1156}](#) for the token.

Set the [frameset-ok flag^{p1124}](#) to "not ok".

Switch the [insertion mode^{p1120}](#) to "in body^{p1166}".

↪ **A start tag whose tag name is "frameset"**

[Insert an HTML element^{p1156}](#) for the token.

Switch the [insertion mode^{p1120}](#) to "in frameset^{p1187}".

↪ **A start tag whose tag name is one of: "base", "basefont", "bgsound", "link", "meta", "noframes", "script", "style", "template", "title"**

[Parse error^{p1108}](#).

Push the node pointed to by the [head element pointer^{p1124}](#) onto the [stack of open elements^{p1121}](#).

Process the token [using the rules for^{p1120}](#) the "in head^{p1162}" [insertion mode^{p1120}](#).

Remove the node pointed to by the [head element pointer^{p1124}](#) from the [stack of open elements^{p1121}](#). (It might not be the [current node^{p1121}](#) at this point.)

Note

The [head element pointer^{p1124}](#) cannot be null at this point.

↪ **An end tag whose tag name is "template"**

Process the token [using the rules for^{p1120}](#) the "in head^{p1162}" [insertion mode^{p1120}](#).

↪ **An end tag whose tag name is one of: "body", "html", "br"**

Act as described in the "anything else" entry below.

↪ **A start tag whose tag name is "head"**

↪ **Any other end tag**

[Parse error^{p1108}](#). Ignore the token.

↪ **Anything else**

[Insert an HTML element^{p1156}](#) for a "body" start tag token with no attributes.

Switch the [insertion mode^{p1120}](#) to "in body^{p1166}".

Reprocess the current token.

13.2.6.4.7 The "in body" insertion mode §^{p11}₆₆

When the user agent is to apply the rules for the "[in body](#)^{p1166}" [insertion mode](#)^{p1120}, the user agent must handle the token as follows:

↪ **A character token that is U+0000 NULL**

[Parse error](#)^{p1108}. Ignore the token.

↪ **A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE**

[Reconstruct the active formatting elements](#)^{p1123}, if any.

[Insert the token's character](#)^{p1157}.

↪ **Any other character token**

[Reconstruct the active formatting elements](#)^{p1123}, if any.

[Insert the token's character](#)^{p1157}.

Set the [frameset-ok flag](#)^{p1124} to "not ok".

↪ **A comment token**

[Insert a comment](#)^{p1158}.

↪ **A DOCTYPE token**

[Parse error](#)^{p1108}. Ignore the token.

↪ **A start tag whose tag name is "html"**

[Parse error](#)^{p1108}.

If there is a [template](#)^{p640} element on the [stack of open elements](#)^{p1121}, then ignore the token.

Otherwise, for each attribute on the token, check to see if the attribute is already present on the top element of the [stack of open elements](#)^{p1121}. If it is not, add the attribute and its corresponding value to that element.

↪ **A start tag whose tag name is one of: "base", "basefont", "bgsound", "link", "meta", "noframes", "script", "style", "template", "title"**

↪ **An end tag whose tag name is "template"**

Process the token [using the rules for](#)^{p1120} the "[in head](#)^{p1162}" [insertion mode](#)^{p1120}.

↪ **A start tag whose tag name is "body"**

[Parse error](#)^{p1108}.

If the second element on the [stack of open elements](#)^{p1121} is not a [body](#)^{p184} element, if the [stack of open elements](#)^{p1121} has only one node on it, or if there is a [template](#)^{p640} element on the [stack of open elements](#)^{p1121}, then ignore the token. ([fragment case](#)^{p1206})

Otherwise, set the [frameset-ok flag](#)^{p1124} to "not ok"; then, for each attribute on the token, check to see if the attribute is already present on the [body](#)^{p184} element (the second element) on the [stack of open elements](#)^{p1121}, and if it is not, add the attribute and its corresponding value to that element.

↪ **A start tag whose tag name is "frameset"**

[Parse error](#)^{p1108}.

If the [stack of open elements](#)^{p1121} has only one node on it, or if the second element on the [stack of open elements](#)^{p1121} is not a [body](#)^{p184} element, then ignore the token. ([fragment case](#)^{p1206})

If the [frameset-ok flag](#)^{p1124} is set to "not ok", ignore the token.

Otherwise, run the following steps:

1. Remove the second element on the [stack of open elements](#)^{p1121} from its parent node, if it has one.
2. Pop all the nodes from the bottom of the [stack of open elements](#)^{p1121}, from the [current node](#)^{p1121} up to, but not including, the root [html](#)^{p157} element.
3. [Insert an HTML element](#)^{p1156} for the token.
4. Switch the [insertion mode](#)^{p1120} to "[in frameset](#)^{p1187}".

↪ An end-of-file token

If the [stack of template insertion modes](#)^{p1120} is not empty, then process the token [using the rules for](#)^{p1120} the "[in template](#)^{p1186}" [insertion mode](#)^{p1120}.

Otherwise, follow these steps:

1. If there is a node in the [stack of open elements](#)^{p1121} that is not either a [dd](#)^{p237} element, a [dt](#)^{p236} element, an [li](#)^{p230} element, an [optgroup](#)^{p554} element, an [option](#)^{p555} element, a [p](#)^{p218} element, an [rb](#)^{p1257} element, an [rp](#)^{p264} element, an [rt](#)^{p264} element, an [rtc](#)^{p1257} element, a [tbody](#)^{p469} element, a [td](#)^{p474} element, a [tfoot](#)^{p471} element, a [th](#)^{p475} element, a [thead](#)^{p470} element, a [tr](#)^{p472} element, the [body](#)^{p184} element, or the [html](#)^{p157} element, then this is a [parse error](#)^{p1108}.
2. [Stop parsing](#)^{p1192}.

↪ An end tag whose tag name is "body"

If the [stack of open elements](#)^{p1121} does not [have a body element in scope](#)^{p1122}, this is a [parse error](#)^{p1108}; ignore the token.

Otherwise, if there is a node in the [stack of open elements](#)^{p1121} that is not either a [dd](#)^{p237} element, a [dt](#)^{p236} element, an [li](#)^{p230} element, an [optgroup](#)^{p554} element, an [option](#)^{p555} element, a [p](#)^{p218} element, an [rb](#)^{p1257} element, an [rp](#)^{p264} element, an [rt](#)^{p264} element, an [rtc](#)^{p1257} element, a [tbody](#)^{p469} element, a [td](#)^{p474} element, a [tfoot](#)^{p471} element, a [th](#)^{p475} element, a [thead](#)^{p470} element, a [tr](#)^{p472} element, the [body](#)^{p184} element, or the [html](#)^{p157} element, then this is a [parse error](#)^{p1108}.

Switch the [insertion mode](#)^{p1120} to "[after body](#)^{p1187}".

↪ An end tag whose tag name is "html"

If the [stack of open elements](#)^{p1121} does not [have a body element in scope](#)^{p1122}, this is a [parse error](#)^{p1108}; ignore the token.

Otherwise, if there is a node in the [stack of open elements](#)^{p1121} that is not either a [dd](#)^{p237} element, a [dt](#)^{p236} element, an [li](#)^{p230} element, an [optgroup](#)^{p554} element, an [option](#)^{p555} element, a [p](#)^{p218} element, an [rb](#)^{p1257} element, an [rp](#)^{p264} element, an [rt](#)^{p264} element, an [rtc](#)^{p1257} element, a [tbody](#)^{p469} element, a [td](#)^{p474} element, a [tfoot](#)^{p471} element, a [th](#)^{p475} element, a [thead](#)^{p470} element, a [tr](#)^{p472} element, the [body](#)^{p184} element, or the [html](#)^{p157} element, then this is a [parse error](#)^{p1108}.

Switch the [insertion mode](#)^{p1120} to "[after body](#)^{p1187}".

Reprocess the token.

↪ A start tag whose tag name is one of: "address", "article", "aside", "blockquote", "center", "details", "dialog", "dir", "div", "dl", "fieldset", "figcaption", "figure", "footer", "header", "hgroup", "main", "menu", "nav", "ol", "p", "section", "summary", "ul"

If the [stack of open elements](#)^{p1121} [has a p element in button scope](#)^{p1123}, then [close a p element](#)^{p1174}.

[Insert an HTML element](#)^{p1156} for the token.

↪ A start tag whose tag name is one of: "h1", "h2", "h3", "h4", "h5", "h6"

If the [stack of open elements](#)^{p1121} [has a p element in button scope](#)^{p1123}, then [close a p element](#)^{p1174}.

If the [current node](#)^{p1121} is an [HTML element](#)^{p44} whose tag name is one of "h1", "h2", "h3", "h4", "h5", or "h6", then this is a [parse error](#)^{p1108}; pop the [current node](#)^{p1121} off the [stack of open elements](#)^{p1121}.

[Insert an HTML element](#)^{p1156} for the token.

↪ A start tag whose tag name is one of: "pre", "listing"

If the [stack of open elements](#)^{p1121} [has a p element in button scope](#)^{p1123}, then [close a p element](#)^{p1174}.

[Insert an HTML element](#)^{p1156} for the token.

If the [next token](#)^{p1153} is a U+000A LINE FEED (LF) character token, then ignore that token and move on to the next one.

(Newlines at the start of [pre](#)^{p222} blocks are ignored as an authoring convenience.)

Set the [frameset-ok flag](#)^{p1124} to "not ok".

↪ A start tag whose tag name is "form"

If the [form element pointer](#)^{p1124} is not null, and there is no [template](#)^{p640} element on the [stack of open elements](#)^{p1121}, then this is a [parse error](#)^{p1108}; ignore the token.

Otherwise:

If the [stack of open elements](#)^{p1121} has a [p element in button scope](#)^{p1123}, then [close a p element](#)^{p1174}.

[Insert an HTML element](#)^{p1156} for the token, and, if there is no [template](#)^{p640} element on the [stack of open elements](#)^{p1121}, set the [form element pointer](#)^{p1124} to point to the element created.

↪ A start tag whose tag name is "li"

Run these steps:

1. Set the [frameset-ok flag](#)^{p1124} to "not ok".
2. Initialize *node* to be the [current node](#)^{p1121} (the bottommost node of the stack).
3. *Loop*: If *node* is an [li](#)^{p230} element, then run these substeps:
 1. [Generate implied end tags](#)^{p1159}, except for [li](#)^{p230} elements.
 2. If the [current node](#)^{p1121} is not an [li](#)^{p230} element, then this is a [parse error](#)^{p1108}.
 3. Pop elements from the [stack of open elements](#)^{p1121} until an [li](#)^{p230} element has been popped from the stack.
 4. Jump to the step labeled *done* below.
4. If *node* is in the [special](#)^{p1122} category, but is not an [address](#)^{p204}, [div](#)^{p243}, or [p](#)^{p218} element, then jump to the step labeled *done* below.
5. Otherwise, set *node* to the previous entry in the [stack of open elements](#)^{p1121} and return to the step labeled *loop*.
6. *Done*: If the [stack of open elements](#)^{p1121} has a [p element in button scope](#)^{p1123}, then [close a p element](#)^{p1174}.
7. Finally, [insert an HTML element](#)^{p1156} for the token.

↪ A start tag whose tag name is one of: "dd", "dt"

Run these steps:

1. Set the [frameset-ok flag](#)^{p1124} to "not ok".
2. Initialize *node* to be the [current node](#)^{p1121} (the bottommost node of the stack).
3. *Loop*: If *node* is a [dd](#)^{p237} element, then run these substeps:
 1. [Generate implied end tags](#)^{p1159}, except for [dd](#)^{p237} elements.
 2. If the [current node](#)^{p1121} is not a [dd](#)^{p237} element, then this is a [parse error](#)^{p1108}.
 3. Pop elements from the [stack of open elements](#)^{p1121} until a [dd](#)^{p237} element has been popped from the stack.
 4. Jump to the step labeled *done* below.
4. If *node* is a [dt](#)^{p236} element, then run these substeps:
 1. [Generate implied end tags](#)^{p1159}, except for [dt](#)^{p236} elements.
 2. If the [current node](#)^{p1121} is not a [dt](#)^{p236} element, then this is a [parse error](#)^{p1108}.
 3. Pop elements from the [stack of open elements](#)^{p1121} until a [dt](#)^{p236} element has been popped from the stack.
 4. Jump to the step labeled *done* below.
5. If *node* is in the [special](#)^{p1122} category, but is not an [address](#)^{p204}, [div](#)^{p243}, or [p](#)^{p218} element, then jump to the step labeled *done* below.

6. Otherwise, set *node* to the previous entry in the [stack of open elements](#)^{p1121} and return to the step labeled *loop*.
7. *Done*: If the [stack of open elements](#)^{p1121} has a [p element in button scope](#)^{p1123}, then [close a p element](#)^{p1174}.
8. Finally, [insert an HTML element](#)^{p1156} for the token.

↪ **A start tag whose tag name is "plaintext"**

If the [stack of open elements](#)^{p1121} has a [p element in button scope](#)^{p1123}, then [close a p element](#)^{p1174}.

[Insert an HTML element](#)^{p1156} for the token.

Switch the tokenizer to the [PLAINTEXT state](#)^{p1127}.

Note

Once a start tag with the tag name "plaintext" has been seen, that will be the last token ever seen other than character tokens (and the end-of-file token), because there is no way to switch out of the [PLAINTEXT state](#)^{p1127}.

↪ **A start tag whose tag name is "button"**

1. If the [stack of open elements](#)^{p1121} has a [button element in scope](#)^{p1122}, then run these substeps:
 1. [Parse error](#)^{p1108}.
 2. [Generate implied end tags](#)^{p1159}.
 3. Pop elements from the [stack of open elements](#)^{p1121} until a [button](#)^{p545} element has been popped from the stack.
2. [Reconstruct the active formatting elements](#)^{p1123}, if any.
3. [Insert an HTML element](#)^{p1156} for the token.
4. Set the [frameset-ok flag](#)^{p1124} to "not ok".

↪ **An end tag whose tag name is one of: "address", "article", "aside", "blockquote", "button", "center", "details", "dialog", "dir", "div", "dl", "fieldset", "figcaption", "figure", "footer", "header", "hgroup", "listing", "main", "menu", "nav", "ol", "pre", "section", "summary", "ul"**

If the [stack of open elements](#)^{p1121} does not [have an element in scope](#)^{p1122} that is an [HTML element](#)^{p44} with the same tag name as that of the token, then this is a [parse error](#)^{p1108}; ignore the token.

Otherwise, run these steps:

1. [Generate implied end tags](#)^{p1159}.
2. If the [current node](#)^{p1121} is not an [HTML element](#)^{p44} with the same tag name as that of the token, then this is a [parse error](#)^{p1108}.
3. Pop elements from the [stack of open elements](#)^{p1121} until an [HTML element](#)^{p44} with the same tag name as the token has been popped from the stack.

↪ **An end tag whose tag name is "form"**

If there is no [template](#)^{p649} element on the [stack of open elements](#)^{p1121}, then run these substeps:

1. Let *node* be the element that the [form element pointer](#)^{p1124} is set to, or null if it is not set to an element.
2. Set the [form element pointer](#)^{p1124} to null.
3. If *node* is null or if the [stack of open elements](#)^{p1121} does not [have node in scope](#)^{p1122}, then this is a [parse error](#)^{p1108}; return and ignore the token.
4. [Generate implied end tags](#)^{p1159}.
5. If the [current node](#)^{p1121} is not *node*, then this is a [parse error](#)^{p1108}.
6. Remove *node* from the [stack of open elements](#)^{p1121}.

If there is a [template](#)^{p649} element on the [stack of open elements](#)^{p1121}, then run these substeps instead:

1. If the [stack of open elements](#)^{p1121} does not [have a form element in scope](#)^{p1122}, then this is a [parse error](#)^{p1108}; return and ignore the token.
2. [Generate implied end tags](#)^{p1159}.
3. If the [current node](#)^{p1121} is not a [form](#)^{p494} element, then this is a [parse error](#)^{p1108}.
4. Pop elements from the [stack of open elements](#)^{p1121} until a [form](#)^{p494} element has been popped from the stack.

↪ **An end tag whose tag name is "p"**

If the [stack of open elements](#)^{p1121} does not [have a p element in button scope](#)^{p1123}, then this is a [parse error](#)^{p1108}; [insert an HTML element](#)^{p1156} for a "p" start tag token with no attributes.

[Close a p element](#)^{p1174}.

↪ **An end tag whose tag name is "li"**

If the [stack of open elements](#)^{p1121} does not [have an li element in list item scope](#)^{p1122}, then this is a [parse error](#)^{p1108}; ignore the token.

Otherwise, run these steps:

1. [Generate implied end tags](#)^{p1159}, except for [li](#)^{p230} elements.
2. If the [current node](#)^{p1121} is not an [li](#)^{p230} element, then this is a [parse error](#)^{p1108}.
3. Pop elements from the [stack of open elements](#)^{p1121} until an [li](#)^{p230} element has been popped from the stack.

↪ **An end tag whose tag name is one of: "dd", "dt"**

If the [stack of open elements](#)^{p1121} does not [have an element in scope](#)^{p1122} that is an [HTML element](#)^{p44} with the same tag name as that of the token, then this is a [parse error](#)^{p1108}; ignore the token.

Otherwise, run these steps:

1. [Generate implied end tags](#)^{p1159}, except for [HTML elements](#)^{p44} with the same tag name as the token.
2. If the [current node](#)^{p1121} is not an [HTML element](#)^{p44} with the same tag name as that of the token, then this is a [parse error](#)^{p1108}.
3. Pop elements from the [stack of open elements](#)^{p1121} until an [HTML element](#)^{p44} with the same tag name as the token has been popped from the stack.

↪ **An end tag whose tag name is one of: "h1", "h2", "h3", "h4", "h5", "h6"**

If the [stack of open elements](#)^{p1121} does not [have an element in scope](#)^{p1122} that is an [HTML element](#)^{p44} and whose tag name is one of "h1", "h2", "h3", "h4", "h5", or "h6", then this is a [parse error](#)^{p1108}; ignore the token.

Otherwise, run these steps:

1. [Generate implied end tags](#)^{p1159}.
2. If the [current node](#)^{p1121} is not an [HTML element](#)^{p44} with the same tag name as that of the token, then this is a [parse error](#)^{p1108}.
3. Pop elements from the [stack of open elements](#)^{p1121} until an [HTML element](#)^{p44} whose tag name is one of "h1", "h2", "h3", "h4", "h5", or "h6" has been popped from the stack.

↪ **An end tag whose tag name is "sarcasm"**

Take a deep breath, then act as described in the "any other end tag" entry below.

↪ **A start tag whose tag name is "a"**

If the [list of active formatting elements](#)^{p1123} contains an [a](#)^{p244} element between the end of the list and the last [marker](#)^{p1123} on the list (or the start of the list if there is no [marker](#)^{p1123} on the list), then this is a [parse error](#)^{p1108}; run the [adoption agency algorithm](#)^{p1174} for the token, then remove that element from the [list of active formatting elements](#)^{p1123} and the [stack of open elements](#)^{p1121} if the [adoption agency algorithm](#)^{p1174} didn't already remove it (it might not have if the element is not [in table scope](#)^{p1123}).

Example

In the non-conforming stream `a<table>b</table>x`, the first [a^{p244}](#) element would be closed upon seeing the second one, and the "x" character would be inside a link to "b", not to "a". This is despite the fact that the outer [a^{p244}](#) element is not in table scope (meaning that a regular `` end tag at the start of the table wouldn't close the outer [a^{p244}](#) element). The result is that the two [a^{p244}](#) elements are indirectly nested inside each other — non-conforming markup will often result in non-conforming DOMs when parsed.

[Reconstruct the active formatting elements^{p1123}](#), if any.

[Insert an HTML element^{p1156}](#) for the token. [Push onto the list of active formatting elements^{p1123}](#) that element.

↪ **A start tag whose tag name is one of: "b", "big", "code", "em", "font", "i", "s", "small", "strike", "strong", "tt", "u"**

[Reconstruct the active formatting elements^{p1123}](#), if any.

[Insert an HTML element^{p1156}](#) for the token. [Push onto the list of active formatting elements^{p1123}](#) that element.

↪ **A start tag whose tag name is "nobr"**

[Reconstruct the active formatting elements^{p1123}](#), if any.

If the [stack of open elements^{p1121}](#) has a `no`br element in scope^{p1122}, then this is a [parse error^{p1108}](#); run the [adoption agency algorithm^{p1174}](#) for the token, then once again [reconstruct the active formatting elements^{p1123}](#), if any.

[Insert an HTML element^{p1156}](#) for the token. [Push onto the list of active formatting elements^{p1123}](#) that element.

↪ **An end tag whose tag name is one of: "a", "b", "big", "code", "em", "font", "i", "nobr", "s", "small", "strike", "strong", "tt", "u"**

Run the [adoption agency algorithm^{p1174}](#) for the token.

↪ **A start tag whose tag name is one of: "applet", "marquee", "object"**

[Reconstruct the active formatting elements^{p1123}](#), if any.

[Insert an HTML element^{p1156}](#) for the token.

Insert a [marker^{p1123}](#) at the end of the [list of active formatting elements^{p1123}](#).

Set the [frameset-ok flag^{p1124}](#) to "not ok".

↪ **An end tag token whose tag name is one of: "applet", "marquee", "object"**

If the [stack of open elements^{p1121}](#) does not [have an element in scope^{p1122}](#) that is an [HTML element^{p44}](#) with the same tag name as that of the token, then this is a [parse error^{p1108}](#); ignore the token.

Otherwise, run these steps:

1. [Generate implied end tags^{p1159}](#).
2. If the [current node^{p1121}](#) is not an [HTML element^{p44}](#) with the same tag name as that of the token, then this is a [parse error^{p1108}](#).
3. Pop elements from the [stack of open elements^{p1121}](#) until an [HTML element^{p44}](#) with the same tag name as the token has been popped from the stack.
4. [Clear the list of active formatting elements up to the last marker^{p1124}](#).

↪ **A start tag whose tag name is "table"**

If the [Document^{p117}](#) is not set to [quirks mode](#), and the [stack of open elements^{p1121}](#) has a `p` element in button scope^{p1123}, then [close a p element^{p1174}](#).

[Insert an HTML element^{p1156}](#) for the token.

Set the [frameset-ok flag^{p1124}](#) to "not ok".

Switch the [insertion mode^{p1120}](#) to "[in table^{p1177}](#)".

↪ **An end tag whose tag name is "br"**

[Parse error^{p1108}](#). Drop the attributes from the token, and act as described in the next entry; i.e. act as if this was a "br" start tag token with no attributes, rather than the end tag token that it actually is.

↪ **A start tag whose tag name is one of: "area", "br", "embed", "img", "keygen", "wbr"**

[Reconstruct the active formatting elements^{p1123}](#), if any.

[Insert an HTML element^{p1156}](#) for the token. Immediately pop the [current node^{p1121}](#) off the [stack of open elements^{p1121}](#).

[Acknowledge the token's self-closing flag^{p1125}](#), if it is set.

Set the [frameset-ok flag^{p1124}](#) to "not ok".

↪ **A start tag whose tag name is "input"**

[Reconstruct the active formatting elements^{p1123}](#), if any.

[Insert an HTML element^{p1156}](#) for the token. Immediately pop the [current node^{p1121}](#) off the [stack of open elements^{p1121}](#).

[Acknowledge the token's self-closing flag^{p1125}](#), if it is set.

If the token does not have an attribute with the name "type", or if it does, but that attribute's value is not an [ASCII case-insensitive](#) match for the string "hidden", then: set the [frameset-ok flag^{p1124}](#) to "not ok".

↪ **A start tag whose tag name is one of: "param", "source", "track"**

[Insert an HTML element^{p1156}](#) for the token. Immediately pop the [current node^{p1121}](#) off the [stack of open elements^{p1121}](#).

[Acknowledge the token's self-closing flag^{p1125}](#), if it is set.

↪ **A start tag whose tag name is "hr"**

If the [stack of open elements^{p1121}](#) has a [p element in button scope^{p1123}](#), then [close a p element^{p1174}](#).

[Insert an HTML element^{p1156}](#) for the token. Immediately pop the [current node^{p1121}](#) off the [stack of open elements^{p1121}](#).

[Acknowledge the token's self-closing flag^{p1125}](#), if it is set.

Set the [frameset-ok flag^{p1124}](#) to "not ok".

↪ **A start tag whose tag name is "image"**

[Parse error^{p1108}](#). Change the token's tag name to "img" and reprocess it. (Don't ask.)

↪ **A start tag whose tag name is "textarea"**

Run these steps:

1. [Insert an HTML element^{p1156}](#) for the token.
2. If the [next token^{p1153}](#) is a U+000A LINE FEED (LF) character token, then ignore that token and move on to the next one. (Newlines at the start of [textarea^{p558}](#) elements are ignored as an authoring convenience.)
3. Switch the tokenizer to the [RCDATA state^{p1126}](#).
4. Let the [original insertion mode^{p1120}](#) be the current [insertion mode^{p1120}](#).
5. Set the [frameset-ok flag^{p1124}](#) to "not ok".
6. Switch the [insertion mode^{p1120}](#) to "[text^{p1176}](#)".

↪ **A start tag whose tag name is "xmp"**

If the [stack of open elements^{p1121}](#) has a [p element in button scope^{p1123}](#), then [close a p element^{p1174}](#).

[Reconstruct the active formatting elements^{p1123}](#), if any.

Set the [frameset-ok flag^{p1124}](#) to "not ok".

Follow the [generic raw text element parsing algorithm^{p1158}](#).

- ↪ **A start tag whose tag name is "iframe"**
 - Set the [frameset-ok flag^{p1124}](#) to "not ok".
 - Follow the [generic raw text element parsing algorithm^{p1158}](#).
- ↪ **A start tag whose tag name is "noembed"**
- ↪ **A start tag whose tag name is "noscript", if the [scripting flag^{p1124}](#) is enabled**
 - Follow the [generic raw text element parsing algorithm^{p1158}](#).
- ↪ **A start tag whose tag name is "select"**
 - [Reconstruct the active formatting elements^{p1123}](#), if any.
 - [Insert an HTML element^{p1156}](#) for the token.
 - Set the [frameset-ok flag^{p1124}](#) to "not ok".
 - If the [insertion mode^{p1120}](#) is one of "[in table^{p1177}](#)", "[in caption^{p1179}](#)", "[in table body^{p1181}](#)", "[in row^{p1182}](#)", or "[in cell^{p1183}](#)", then switch the [insertion mode^{p1120}](#) to "[in select in table^{p1185}](#)". Otherwise, switch the [insertion mode^{p1120}](#) to "[in select^{p1184}](#)".
- ↪ **A start tag whose tag name is one of: "optgroup", "option"**
 - If the [current node^{p1121}](#) is an [option^{p555}](#) element, then pop the [current node^{p1121}](#) off the [stack of open elements^{p1121}](#).
 - [Reconstruct the active formatting elements^{p1123}](#), if any.
 - [Insert an HTML element^{p1156}](#) for the token.
- ↪ **A start tag whose tag name is one of: "rb", "rtc"**
 - If the [stack of open elements^{p1121}](#) has a [ruby element in scope^{p1122}](#), then [generate implied end tags^{p1159}](#). If the [current node^{p1121}](#) is not now a [ruby^{p258}](#) element, this is a [parse error^{p1108}](#).
 - [Insert an HTML element^{p1156}](#) for the token.
- ↪ **A start tag whose tag name is one of: "rp", "rt"**
 - If the [stack of open elements^{p1121}](#) has a [ruby element in scope^{p1122}](#), then [generate implied end tags^{p1159}](#), except for [rtc^{p1257}](#) elements. If the [current node^{p1121}](#) is not now a [rtc^{p1257}](#) element or a [ruby^{p258}](#) element, this is a [parse error^{p1108}](#).
 - [Insert an HTML element^{p1156}](#) for the token.
- ↪ **A start tag whose tag name is "math"**
 - [Reconstruct the active formatting elements^{p1123}](#), if any.
 - [Adjust MathML attributes^{p1156}](#) for the token. (This fixes the case of MathML attributes that are not all lowercase.)
 - [Adjust foreign attributes^{p1157}](#) for the token. (This fixes the use of namespaced attributes, in particular XLink.)
 - [Insert a foreign element^{p1155}](#) for the token, in the [MathML namespace](#).
 - If the token has its [self-closing flag^{p1125}](#) set, pop the [current node^{p1121}](#) off the [stack of open elements^{p1121}](#) and [acknowledge the token's self-closing flag^{p1125}](#).
- ↪ **A start tag whose tag name is "svg"**
 - [Reconstruct the active formatting elements^{p1123}](#), if any.
 - [Adjust SVG attributes^{p1156}](#) for the token. (This fixes the case of SVG attributes that are not all lowercase.)
 - [Adjust foreign attributes^{p1157}](#) for the token. (This fixes the use of namespaced attributes, in particular XLink in SVG.)
 - [Insert a foreign element^{p1155}](#) for the token, in the [SVG namespace](#).
 - If the token has its [self-closing flag^{p1125}](#) set, pop the [current node^{p1121}](#) off the [stack of open elements^{p1121}](#) and [acknowledge the token's self-closing flag^{p1125}](#).

↪ **A start tag whose tag name is one of:** "caption", "col", "colgroup", "frame", "head", "tbody", "td", "tfoot", "th", "thead", "tr"

[Parse error^{p1108}](#). Ignore the token.

↪ **Any other start tag**

[Reconstruct the active formatting elements^{p1123}](#), if any.

[Insert an HTML element^{p1156}](#) for the token.

Note

This element will be an [ordinary^{p1122}](#) element.

↪ **Any other end tag**

Run these steps:

1. Initialize *node* to be the [current node^{p1121}](#) (the bottommost node of the stack).
2. *Loop*: If *node* is an [HTML element^{p44}](#) with the same tag name as the token, then:
 1. [Generate implied end tags^{p1159}](#), except for [HTML elements^{p44}](#) with the same tag name as the token.
 2. If *node* is not the [current node^{p1121}](#), then this is a [parse error^{p1108}](#).
 3. Pop all the nodes from the [current node^{p1121}](#) up to *node*, including *node*, then stop these steps.
3. Otherwise, if *node* is in the [special^{p1122}](#) category, then this is a [parse error^{p1108}](#); ignore the token, and return.
4. Set *node* to the previous entry in the [stack of open elements^{p1121}](#).
5. Return to the step labeled *loop*.

When the steps above say the user agent is to **close a p element**, it means that the user agent must run the following steps:

1. [Generate implied end tags^{p1159}](#), except for [p^{p218}](#) elements.
2. If the [current node^{p1121}](#) is not a [p^{p218}](#) element, then this is a [parse error^{p1108}](#).
3. Pop elements from the [stack of open elements^{p1121}](#) until a [p^{p218}](#) element has been popped from the stack.

The **adoption agency algorithm**, which takes as its only argument a token *token* for which the algorithm is being run, consists of the following steps:

1. Let *subject* be *token*'s tag name.
2. If the [current node^{p1121}](#) is an [HTML element^{p44}](#) whose tag name is *subject*, and the [current node^{p1121}](#) is not in the [list of active formatting elements^{p1123}](#), then pop the [current node^{p1121}](#) off the [stack of open elements^{p1121}](#) and return.
3. Let *outer loop counter* be 0.
4. While true:
 1. If *outer loop counter* is greater than or equal to 8, then return.
 2. Increment *outer loop counter* by 1.
 3. Let *formatting element* be the last element in the [list of active formatting elements^{p1123}](#) that:
 - is between the end of the list and the last [marker^{p1123}](#) in the list, if any, or the start of the list otherwise, and
 - has the tag name *subject*.If there is no such element, then return and instead act as described in the "any other end tag" entry above.
5. If *formatting element* is not in the [stack of open elements^{p1121}](#), then this is a [parse error^{p1108}](#); remove the element from the list, and return.
5. If *formatting element* is in the [stack of open elements^{p1121}](#), but the element is not [in scope^{p1122}](#), then this is a [parse](#)

- [error^{p1108}](#); return.
6. If *formatting element* is not the [current node^{p1121}](#), this is a [parse error^{p1108}](#). (But do not return.)
 7. Let *furthest block* be the topmost node in the [stack of open elements^{p1121}](#) that is lower in the stack than *formatting element*, and is an element in the [special^{p1122}](#) category. There might not be one.
 8. If there is no *furthest block*, then the UA must first pop all the nodes from the bottom of the [stack of open elements^{p1121}](#), from the [current node^{p1121}](#) up to and including *formatting element*, then remove *formatting element* from the [list of active formatting elements^{p1123}](#), and finally return.
 9. Let *common ancestor* be the element immediately above *formatting element* in the [stack of open elements^{p1121}](#).
 10. Let a bookmark note the position of *formatting element* in the [list of active formatting elements^{p1123}](#) relative to the elements on either side of it in the list.
 11. Let *node* and *last node* be *furthest block*.
 12. Let *inner loop counter* be 0.
 13. While true:
 1. Increment *inner loop counter* by 1.
 2. Let *node* be the element immediately above *node* in the [stack of open elements^{p1121}](#), or if *node* is no longer in the [stack of open elements^{p1121}](#) (e.g. because it got removed by this algorithm), the element that was immediately above *node* in the [stack of open elements^{p1121}](#) before *node* was removed.
 3. If *node* is *formatting element*, then [break](#).
 4. If *inner loop counter* is greater than 3 and *node* is in the [list of active formatting elements^{p1123}](#), then remove *node* from the [list of active formatting elements^{p1123}](#).
 5. If *node* is not in the [list of active formatting elements^{p1123}](#), then remove *node* from the [stack of open elements^{p1121}](#) and [continue](#).
 6. [Create an element for the token^{p1154}](#) for which the element *node* was created, in the [HTML namespace](#), with *common ancestor* as the intended parent; replace the entry for *node* in the [list of active formatting elements^{p1123}](#) with an entry for the new element, replace the entry for *node* in the [stack of open elements^{p1121}](#) with an entry for the new element, and let *node* be the new element.
 7. If *last node* is *furthest block*, then move the aforementioned bookmark to be immediately after the new *node* in the [list of active formatting elements^{p1123}](#).
 8. [Append last node to node](#).
 9. Set *last node* to *node*.
 14. Insert whatever *last node* ended up being in the previous step at the [appropriate place for inserting a node^{p1153}](#), but using *common ancestor* as the *override target*.
 15. [Create an element for the token^{p1154}](#) for which *formatting element* was created, in the [HTML namespace](#), with *furthest block* as the intended parent.
 16. Take all of the child nodes of *furthest block* and append them to the element created in the last step.
 17. Append that new element to *furthest block*.
 18. Remove *formatting element* from the [list of active formatting elements^{p1123}](#), and insert the new element into the [list of active formatting elements^{p1123}](#) at the position of the aforementioned bookmark.
 19. Remove *formatting element* from the [stack of open elements^{p1121}](#), and insert the new element into the [stack of open elements^{p1121}](#) immediately below the position of *furthest block* in that stack.

Note

This algorithm's name, the "adoption agency algorithm", comes from the way it causes elements to change parents, and is in contrast with [other possible algorithms](#) for dealing with misnested content.

13.2.6.4.8 The "text" insertion mode §^{p11} 76

When the user agent is to apply the rules for the "text^{p1176}" [insertion mode^{p1120}](#), the user agent must handle the token as follows:

↪ A character token

[Insert the token's character^{p1157}](#).

Note

This can never be a U+0000 NULL character; the tokenizer converts those to U+FFFD REPLACEMENT CHARACTER characters.

↪ An end-of-file token

[Parse error^{p1108}](#).

If the [current node^{p1121}](#) is a [script^{p624}](#) element, mark the [script^{p624}](#) element as "[already started^{p630}](#)".

Pop the [current node^{p1121}](#) off the [stack of open elements^{p1121}](#).

Switch the [insertion mode^{p1120}](#) to the [original insertion mode^{p1120}](#) and reprocess the token.

↪ An end tag whose tag name is "script"

If the [active speculative HTML parser^{p1193}](#) is null and the [JavaScript execution context stack](#) is empty, then [perform a microtask checkpoint^{p974}](#).

Let *script* be the [current node^{p1121}](#) (which will be a [script^{p624}](#) element).

Pop the [current node^{p1121}](#) off the [stack of open elements^{p1121}](#).

Switch the [insertion mode^{p1120}](#) to the [original insertion mode^{p1120}](#).

Let the *old insertion point* have the same value as the current [insertion point^{p1120}](#). Let the [insertion point^{p1120}](#) be just before the [next input character^{p1120}](#).

Increment the parser's [script nesting level^{p1108}](#) by one.

If the [active speculative HTML parser^{p1193}](#) is null, then [prepare^{p630}](#) the *script*. This might cause some script to execute, which might cause [new characters to be inserted into the tokenizer^{p996}](#), and might cause the tokenizer to output more tokens, resulting in a [reentrant invocation of the parser^{p1107}](#).

Decrement the parser's [script nesting level^{p1108}](#) by one. If the parser's [script nesting level^{p1108}](#) is zero, then set the [parser pause flag^{p1108}](#) to false.

Let the [insertion point^{p1120}](#) have the value of the *old insertion point*. (In other words, restore the [insertion point^{p1120}](#) to its previous value. This value might be the "undefined" value.)

At this stage, if there is a [pending parsing-blocking script^{p634}](#), then:

↪ If the [script nesting level^{p1108}](#) is not zero:

Set the [parser pause flag^{p1108}](#) to true, and abort the processing of any nested invocations of the tokenizer, yielding control back to the caller. (Tokenization will resume when the caller returns to the "outer" tree construction stage.)

Note

The tree construction stage of this particular parser is [being called reentrantly^{p1107}](#), say from a call to [document.write\(\)^{p996}](#).

↪ Otherwise:

Run these steps:

1. Let *the script* be the [pending parsing-blocking script^{p634}](#). There is no longer a [pending parsing-blocking script^{p634}](#).
2. [Start the speculative HTML parser^{p1194}](#) for this instance of the HTML parser.

3. Block the [tokenizer^{p1124}](#) for this instance of the [HTML parser^{p1106}](#), such that the [event loop^{p968}](#) will not run [tasks^{p969}](#) that invoke the [tokenizer^{p1124}](#).
4. If the parser's [Document^{p117}](#) has a style sheet that is blocking scripts^{p184} or the script's "ready to be parser-executed"^{p630} flag is not set: [spin the event loop^{p975}](#) until the parser's [Document^{p117}](#) has no style sheet that is blocking scripts^{p184} and the script's "ready to be parser-executed"^{p630} flag is set.
5. If this [parser has been aborted^{p1193}](#) in the meantime, return.

Note

This could happen if, e.g., while the [spin the event loop^{p975}](#) algorithm is running, the [browsing context^{p840}](#) gets closed, or the [document.open\(\)^{p995}](#) method gets invoked on the [Document^{p117}](#).

6. [Stop the speculative HTML parser^{p1194}](#) for this instance of the HTML parser.
7. Unblock the [tokenizer^{p1124}](#) for this instance of the [HTML parser^{p1106}](#), such that [tasks^{p969}](#) that invoke the [tokenizer^{p1124}](#) can again be run.
8. Let the [insertion point^{p1120}](#) be just before the [next input character^{p1120}](#).
9. Increment the parser's [script nesting level^{p1108}](#) by one (it should be zero before this step, so this sets it to one).
10. [Execute^{p634}](#) the script.
11. Decrement the parser's [script nesting level^{p1108}](#) by one. If the parser's [script nesting level^{p1108}](#) is zero (which it always should be at this point), then set the [parser pause flag^{p1108}](#) to false.
12. Let the [insertion point^{p1120}](#) be undefined again.
13. If there is once again a [pending parsing-blocking script^{p634}](#), then repeat these steps from step 1.

↪ Any other end tag

Pop the [current node^{p1121}](#) off the [stack of open elements^{p1121}](#).

Switch the [insertion mode^{p1120}](#) to the [original insertion mode^{p1120}](#).

13.2.6.4.9 The "in table" insertion mode §^{p11}₇₇

When the user agent is to apply the rules for the "[in table^{p1177}](#)" [insertion mode^{p1120}](#), the user agent must handle the token as follows:

↪ A character token, if the [current node^{p1121}](#) is [table^{p458}](#), [tbody^{p469}](#), [tfoot^{p471}](#), [thead^{p478}](#), or [tr^{p472}](#) element

Let the **pending table character tokens** be an empty list of tokens.

Let the [original insertion mode^{p1120}](#) be the current [insertion mode^{p1120}](#).

Switch the [insertion mode^{p1120}](#) to "[in table text^{p1179}](#)" and reprocess the token.

↪ A comment token

[Insert a comment^{p1158}](#).

↪ A DOCTYPE token

[Parse error^{p1108}](#). Ignore the token.

↪ A start tag whose tag name is "caption"

[Clear the stack back to a table context^{p1179}](#). (See below.)

Insert a [marker^{p1123}](#) at the end of the [list of active formatting elements^{p1123}](#).

[Insert an HTML element^{p1156}](#) for the token, then switch the [insertion mode^{p1120}](#) to "[in caption^{p1179}](#)".

↪ A start tag whose tag name is "colgroup"

[Clear the stack back to a table context^{p1179}](#). (See below.)

[Insert an HTML element^{p1156}](#) for the token, then switch the [insertion mode^{p1120}](#) to "[in column group^{p1180}](#)".

↔ **A start tag whose tag name is "col"**

[Clear the stack back to a table context^{p1179}](#). (See below.)

[Insert an HTML element^{p1156}](#) for a "colgroup" start tag token with no attributes, then switch the [insertion mode^{p1120}](#) to "in column group^{p1180}".

Reprocess the current token.

↔ **A start tag whose tag name is one of: "tbody", "tfoot", "thead"**

[Clear the stack back to a table context^{p1179}](#). (See below.)

[Insert an HTML element^{p1156}](#) for the token, then switch the [insertion mode^{p1120}](#) to "in table body^{p1181}".

↔ **A start tag whose tag name is one of: "td", "th", "tr"**

[Clear the stack back to a table context^{p1179}](#). (See below.)

[Insert an HTML element^{p1156}](#) for a "tbody" start tag token with no attributes, then switch the [insertion mode^{p1120}](#) to "in table body^{p1181}".

Reprocess the current token.

↔ **A start tag whose tag name is "table"**

[Parse error^{p1108}](#).

If the [stack of open elements^{p1121}](#) does not [have a table element in table scope^{p1123}](#), ignore the token.

Otherwise:

Pop elements from this stack until a [table^{p458}](#) element has been popped from the stack.

[Reset the insertion mode appropriately^{p1120}](#).

Reprocess the token.

↔ **An end tag whose tag name is "table"**

If the [stack of open elements^{p1121}](#) does not [have a table element in table scope^{p1123}](#), this is a [parse error^{p1108}](#); ignore the token.

Otherwise:

Pop elements from this stack until a [table^{p458}](#) element has been popped from the stack.

[Reset the insertion mode appropriately^{p1120}](#).

↔ **An end tag whose tag name is one of: "body", "caption", "col", "colgroup", "html", "tbody", "td", "tfoot", "th", "thead", "tr"**

[Parse error^{p1108}](#). Ignore the token.

↔ **A start tag whose tag name is one of: "style", "script", "template"**

↔ **An end tag whose tag name is "template"**

Process the token [using the rules for^{p1120}](#) the "in head^{p1162}" [insertion mode^{p1120}](#).

↔ **A start tag whose tag name is "input"**

If the token does not have an attribute with the name "type", or if it does, but that attribute's value is not an [ASCII case-insensitive](#) match for the string "hidden", then: act as described in the "anything else" entry below.

Otherwise:

[Parse error^{p1108}](#).

[Insert an HTML element^{p1156}](#) for the token.

Pop that [input^{p501}](#) element off the [stack of open elements^{p1121}](#).

[Acknowledge the token's self-closing flag^{p1125}](#), if it is set.

↪ A start tag whose tag name is "form"

[Parse error^{p1108}](#).

If there is a [template^{p640}](#) element on the [stack of open elements^{p1121}](#), or if the [form element pointer^{p1124}](#) is not null, ignore the token.

Otherwise:

[Insert an HTML element^{p1156}](#) for the token, and set the [form element pointer^{p1124}](#) to point to the element created.

Pop that [form^{p494}](#) element off the [stack of open elements^{p1121}](#).

↪ An end-of-file token

Process the token [using the rules for^{p1120}](#) the "in body^{p1166}" [insertion mode^{p1120}](#).

↪ Anything else

[Parse error^{p1108}](#). Enable [foster parenting^{p1153}](#), process the token [using the rules for^{p1120}](#) the "in body^{p1166}" [insertion mode^{p1120}](#), and then disable [foster parenting^{p1153}](#).

When the steps above require the UA to **clear the stack back to a table context**, it means that the UA must, while the [current node^{p1121}](#) is not a [table^{p458}](#), [template^{p640}](#), or [html^{p157}](#) element, pop elements from the [stack of open elements^{p1121}](#).

Note

This is the same list of elements as used in the [has an element in table scope^{p1123}](#) steps.

Note

The [current node^{p1121}](#) being an [html^{p157}](#) element after this process is a [fragment case^{p1206}](#).

13.2.6.4.10 The "in table text" insertion mode §^{p11}₇₉

When the user agent is to apply the rules for the "in table text^{p1179}" [insertion mode^{p1120}](#), the user agent must handle the token as follows:

↪ A character token that is U+0000 NULL

[Parse error^{p1108}](#). Ignore the token.

↪ Any other character token

Append the character token to the [pending table character tokens^{p1177}](#) list.

↪ Anything else

If any of the tokens in the [pending table character tokens^{p1177}](#) list are character tokens that are not [ASCII whitespace](#), then this is a [parse error^{p1108}](#): reprocess the character tokens in the [pending table character tokens^{p1177}](#) list using the rules given in the "anything else" entry in the "in table^{p1177}" insertion mode.

Otherwise, [insert the characters^{p1157}](#) given by the [pending table character tokens^{p1177}](#) list.

Switch the [insertion mode^{p1120}](#) to the [original insertion mode^{p1120}](#) and reprocess the token.

13.2.6.4.11 The "in caption" insertion mode §^{p11}₇₉

When the user agent is to apply the rules for the "in caption^{p1179}" [insertion mode^{p1120}](#), the user agent must handle the token as follows:

↪ An end tag whose tag name is "caption"

If the [stack of open elements^{p1121}](#) does not [have a caption element in table scope^{p1123}](#), this is a [parse error^{p1108}](#); ignore the token. ([fragment case^{p1206}](#))

Otherwise:

[Generate implied end tags^{p1159}](#).

Now, if the [current node^{p1121}](#) is not a [caption^{p466}](#) element, then this is a [parse error^{p1108}](#).

Pop elements from this stack until a [caption^{p466}](#) element has been popped from the stack.

[Clear the list of active formatting elements up to the last marker^{p1124}](#).

Switch the [insertion mode^{p1120}](#) to "[in table^{p1177}](#)".

↪ **A start tag whose tag name is one of: "caption", "col", "colgroup", "tbody", "td", "tfoot", "th", "thead", "tr"**

↪ **An end tag whose tag name is "table"**

If the [stack of open elements^{p1121}](#) does not [have a caption element in table scope^{p1123}](#), this is a [parse error^{p1108}](#); ignore the token. ([fragment case^{p1206}](#))

Otherwise:

[Generate implied end tags^{p1159}](#).

Now, if the [current node^{p1121}](#) is not a [caption^{p466}](#) element, then this is a [parse error^{p1108}](#).

Pop elements from this stack until a [caption^{p466}](#) element has been popped from the stack.

[Clear the list of active formatting elements up to the last marker^{p1124}](#).

Switch the [insertion mode^{p1120}](#) to "[in table^{p1177}](#)".

Reprocess the token.

↪ **An end tag whose tag name is one of: "body", "col", "colgroup", "html", "tbody", "td", "tfoot", "th", "thead", "tr"**
[Parse error^{p1108}](#). Ignore the token.

↪ **Anything else**

Process the token [using the rules for^{p1120}](#) the "[in body^{p1166}](#)" [insertion mode^{p1120}](#).

13.2.6.4.12 The "in column group" insertion mode §^{p11}₈₀

When the user agent is to apply the rules for the "[in column group^{p1180}](#)" [insertion mode^{p1120}](#), the user agent must handle the token as follows:

↪ **A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE**
[Insert the character^{p1157}](#).

↪ **A comment token**
[Insert a comment^{p1158}](#).

↪ **A DOCTYPE token**
[Parse error^{p1108}](#). Ignore the token.

↪ **A start tag whose tag name is "html"**
Process the token [using the rules for^{p1120}](#) the "[in body^{p1166}](#)" [insertion mode^{p1120}](#).

↪ **A start tag whose tag name is "col"**
[Insert an HTML element^{p1156}](#) for the token. Immediately pop the [current node^{p1121}](#) off the [stack of open elements^{p1121}](#).
[Acknowledge the token's self-closing flag^{p1125}](#), if it is set.

↪ **An end tag whose tag name is "colgroup"**
If the [current node^{p1121}](#) is not a [colgroup^{p467}](#) element, then this is a [parse error^{p1108}](#); ignore the token.
Otherwise, pop the [current node^{p1121}](#) from the [stack of open elements^{p1121}](#). Switch the [insertion mode^{p1120}](#) to "[in table^{p1177}](#)".

↔ **An end tag whose tag name is "col"**

[Parse error^{p1108}](#). Ignore the token.

↔ **A start tag whose tag name is "template"**

↔ **An end tag whose tag name is "template"**

Process the token [using the rules for^{p1120}](#) the "in_head^{p1162}" [insertion mode^{p1120}](#).

↔ **An end-of-file token**

Process the token [using the rules for^{p1120}](#) the "in_body^{p1166}" [insertion mode^{p1120}](#).

↔ **Anything else**

If the [current node^{p1121}](#) is not a [colgroup^{p467}](#) element, then this is a [parse error^{p1108}](#); ignore the token.

Otherwise, pop the [current node^{p1121}](#) from the [stack of open elements^{p1121}](#).

Switch the [insertion mode^{p1120}](#) to "in_table^{p1177}".

Reprocess the token.

13.2.6.4.13 The "in table body" insertion mode §^{p11} 81

When the user agent is to apply the rules for the "in_table_body^{p1181}" [insertion mode^{p1120}](#), the user agent must handle the token as follows:

↔ **A start tag whose tag name is "tr"**

[Clear the stack back to a table body context^{p1182}](#). (See below.)

[Insert an HTML element^{p1156}](#) for the token, then switch the [insertion mode^{p1120}](#) to "in_row^{p1182}".

↔ **A start tag whose tag name is one of: "th", "td"**

[Parse error^{p1108}](#).

[Clear the stack back to a table body context^{p1182}](#). (See below.)

[Insert an HTML element^{p1156}](#) for a "tr" start tag token with no attributes, then switch the [insertion mode^{p1120}](#) to "in_row^{p1182}".

Reprocess the current token.

↔ **An end tag whose tag name is one of: "tbody", "tfoot", "thead"**

If the [stack of open elements^{p1121}](#) does not [have an element in table scope^{p1123}](#) that is an [HTML element^{p44}](#) with the same tag name as the token, this is a [parse error^{p1108}](#); ignore the token.

Otherwise:

[Clear the stack back to a table body context^{p1182}](#). (See below.)

Pop the [current node^{p1121}](#) from the [stack of open elements^{p1121}](#). Switch the [insertion mode^{p1120}](#) to "in_table^{p1177}".

↔ **A start tag whose tag name is one of: "caption", "col", "colgroup", "tbody", "tfoot", "thead"**

↔ **An end tag whose tag name is "table"**

If the [stack of open elements^{p1121}](#) does not [have a tbody, tthead, or ttfoot element in table scope^{p1123}](#), this is a [parse error^{p1108}](#); ignore the token.

Otherwise:

[Clear the stack back to a table body context^{p1182}](#). (See below.)

Pop the [current node^{p1121}](#) from the [stack of open elements^{p1121}](#). Switch the [insertion mode^{p1120}](#) to "in_table^{p1177}".

Reprocess the token.

↪ **An end tag whose tag name is one of: "body", "caption", "col", "colgroup", "html", "td", "th", "tr"**
[Parse error^{p1108}](#). Ignore the token.

↪ **Anything else**

Process the token [using the rules for^{p1120}](#) the "[in table^{p1177}](#)" [insertion mode^{p1120}](#).

When the steps above require the UA to **clear the stack back to a table body context**, it means that the UA must, while the [current node^{p1121}](#) is not a [tbody^{p469}](#), [tfoot^{p471}](#), [thead^{p470}](#), [template^{p640}](#), or [html^{p157}](#) element, pop elements from the [stack of open elements^{p1121}](#).

Note

The [current node^{p1121}](#) being an [html^{p157}](#) element after this process is a [fragment case^{p1206}](#).

13.2.6.4.14 The "in row" insertion mode §^{p11} 82

When the user agent is to apply the rules for the "[in row^{p1182}](#)" [insertion mode^{p1120}](#), the user agent must handle the token as follows:

↪ **A start tag whose tag name is one of: "th", "td"**

[Clear the stack back to a table row context^{p1183}](#). (See below.)

[Insert an HTML element^{p1156}](#) for the token, then switch the [insertion mode^{p1120}](#) to "[in cell^{p1183}](#)".

Insert a [marker^{p1123}](#) at the end of the [list of active formatting elements^{p1123}](#).

↪ **An end tag whose tag name is "tr"**

If the [stack of open elements^{p1121}](#) does not [have a tr element in table scope^{p1123}](#), this is a [parse error^{p1108}](#); ignore the token.

Otherwise:

[Clear the stack back to a table row context^{p1183}](#). (See below.)

Pop the [current node^{p1121}](#) (which will be a [tr^{p472}](#) element) from the [stack of open elements^{p1121}](#). Switch the [insertion mode^{p1120}](#) to "[in table body^{p1181}](#)".

↪ **A start tag whose tag name is one of: "caption", "col", "colgroup", "tbody", "tfoot", "thead", "tr"**

↪ **An end tag whose tag name is "table"**

If the [stack of open elements^{p1121}](#) does not [have a tr element in table scope^{p1123}](#), this is a [parse error^{p1108}](#); ignore the token.

Otherwise:

[Clear the stack back to a table row context^{p1183}](#). (See below.)

Pop the [current node^{p1121}](#) (which will be a [tr^{p472}](#) element) from the [stack of open elements^{p1121}](#). Switch the [insertion mode^{p1120}](#) to "[in table body^{p1181}](#)".

Reprocess the token.

↪ **An end tag whose tag name is one of: "tbody", "tfoot", "thead"**

If the [stack of open elements^{p1121}](#) does not [have an element in table scope^{p1123}](#) that is an [HTML element^{p44}](#) with the same tag name as the token, this is a [parse error^{p1108}](#); ignore the token.

If the [stack of open elements^{p1121}](#) does not [have a tr element in table scope^{p1123}](#), ignore the token.

Otherwise:

[Clear the stack back to a table row context^{p1183}](#). (See below.)

Pop the [current node^{p1121}](#) (which will be a [tr^{p472}](#) element) from the [stack of open elements^{p1121}](#). Switch the [insertion mode^{p1120}](#) to "[in table body^{p1181}](#)".

Reprocess the token.

↪ **An end tag whose tag name is one of: "body", "caption", "col", "colgroup", "html", "td", "th"**
[Parse error^{p1108}](#). Ignore the token.

↪ **Anything else**

Process the token [using the rules for^{p1120}](#) the "[in table^{p1177}](#)" [insertion mode^{p1120}](#).

When the steps above require the UA to **clear the stack back to a table row context**, it means that the UA must, while the [current node^{p1121}](#) is not a [tr^{p472}](#), [template^{p640}](#), or [html^{p157}](#) element, pop elements from the [stack of open elements^{p1121}](#).

Note

The [current node^{p1121}](#) being an [html^{p157}](#) element after this process is a [fragment case^{p1206}](#).

13.2.6.4.15 The "in cell" insertion mode §^{p11} 83

When the user agent is to apply the rules for the "[in cell^{p1183}](#)" [insertion mode^{p1120}](#), the user agent must handle the token as follows:

↪ **An end tag whose tag name is one of: "td", "th"**

If the [stack of open elements^{p1121}](#) does not [have an element in table scope^{p1123}](#) that is an [HTML element^{p44}](#) with the same tag name as that of the token, then this is a [parse error^{p1108}](#); ignore the token.

Otherwise:

[Generate implied end tags^{p1159}](#).

Now, if the [current node^{p1121}](#) is not an [HTML element^{p44}](#) with the same tag name as the token, then this is a [parse error^{p1108}](#).

Pop elements from the [stack of open elements^{p1121}](#) stack until an [HTML element^{p44}](#) with the same tag name as the token has been popped from the stack.

[Clear the list of active formatting elements up to the last marker^{p1124}](#).

Switch the [insertion mode^{p1120}](#) to "[in row^{p1182}](#)".

↪ **A start tag whose tag name is one of: "caption", "col", "colgroup", "tbody", "td", "tfoot", "th", "thead", "tr"**

If the [stack of open elements^{p1121}](#) does *not* [have a td or th element in table scope^{p1123}](#), then this is a [parse error^{p1108}](#); ignore the token. ([fragment case^{p1206}](#))

Otherwise, [close the cell^{p1183}](#) (see below) and reprocess the token.

↪ **An end tag whose tag name is one of: "body", "caption", "col", "colgroup", "html"**

[Parse error^{p1108}](#). Ignore the token.

↪ **An end tag whose tag name is one of: "table", "tbody", "tfoot", "thead", "tr"**

If the [stack of open elements^{p1121}](#) does not [have an element in table scope^{p1123}](#) that is an [HTML element^{p44}](#) with the same tag name as that of the token, then this is a [parse error^{p1108}](#); ignore the token.

Otherwise, [close the cell^{p1183}](#) (see below) and reprocess the token.

↪ **Anything else**

Process the token [using the rules for^{p1120}](#) the "[in body^{p1166}](#)" [insertion mode^{p1120}](#).

Where the steps above say to **close the cell**, they mean to run the following algorithm:

1. [Generate implied end tags^{p1159}](#).
2. If the [current node^{p1121}](#) is not now a [td^{p474}](#) element or a [th^{p475}](#) element, then this is a [parse error^{p1108}](#).
3. Pop elements from the [stack of open elements^{p1121}](#) stack until a [td^{p474}](#) element or a [th^{p475}](#) element has been popped from the stack.
4. [Clear the list of active formatting elements up to the last marker^{p1124}](#).

5. Switch the [insertion mode^{p1120}](#) to "[in_row^{p1182}](#)".

Note

The [stack of open elements^{p1121}](#) cannot have both a [td^{p474}](#) and a [th^{p475}](#) element [in table scope^{p1123}](#) at the same time, nor can it have neither when the [close the cell^{p1183}](#) algorithm is invoked.

13.2.6.4.16 The "in select" insertion mode §^{p11} 8.4

When the user agent is to apply the rules for the "[in_select^{p1184}](#)" [insertion mode^{p1120}](#), the user agent must handle the token as follows:

↪ **A character token that is U+0000 NULL**

[Parse error^{p1108}](#). Ignore the token.

↪ **Any other character token**

[Insert the token's character^{p1157}](#).

↪ **A comment token**

[Insert a comment^{p1158}](#).

↪ **A DOCTYPE token**

[Parse error^{p1108}](#). Ignore the token.

↪ **A start tag whose tag name is "html"**

Process the token [using the rules for^{p1120}](#) the "[in_body^{p1166}](#)" [insertion mode^{p1120}](#).

↪ **A start tag whose tag name is "option"**

If the [current node^{p1121}](#) is an [option^{p555}](#) element, pop that node from the [stack of open elements^{p1121}](#).

[Insert an HTML element^{p1156}](#) for the token.

↪ **A start tag whose tag name is "optgroup"**

If the [current node^{p1121}](#) is an [option^{p555}](#) element, pop that node from the [stack of open elements^{p1121}](#).

If the [current node^{p1121}](#) is an [optgroup^{p554}](#) element, pop that node from the [stack of open elements^{p1121}](#).

[Insert an HTML element^{p1156}](#) for the token.

↪ **An end tag whose tag name is "optgroup"**

First, if the [current node^{p1121}](#) is an [option^{p555}](#) element, and the node immediately before it in the [stack of open elements^{p1121}](#) is an [optgroup^{p554}](#) element, then pop the [current node^{p1121}](#) from the [stack of open elements^{p1121}](#).

If the [current node^{p1121}](#) is an [optgroup^{p554}](#) element, then pop that node from the [stack of open elements^{p1121}](#). Otherwise, this is a [parse error^{p1108}](#); ignore the token.

↪ **An end tag whose tag name is "option"**

If the [current node^{p1121}](#) is an [option^{p555}](#) element, then pop that node from the [stack of open elements^{p1121}](#). Otherwise, this is a [parse error^{p1108}](#); ignore the token.

↪ **An end tag whose tag name is "select"**

If the [stack of open elements^{p1121}](#) does not [have a select element in select scope^{p1123}](#), this is a [parse error^{p1108}](#); ignore the token. ([fragment case^{p1206}](#))

Otherwise:

Pop elements from the [stack of open elements^{p1121}](#) until a [select^{p547}](#) element has been popped from the stack.

[Reset the insertion mode appropriately^{p1120}](#).

↪ **A start tag whose tag name is "select"**

[Parse error^{p1108}](#).

If the [stack of open elements](#)^{p1121} does not [have a select element in select scope](#)^{p1123}, ignore the token. ([fragment case](#)^{p1206})

Otherwise:

Pop elements from the [stack of open elements](#)^{p1121} until a [select](#)^{p547} element has been popped from the stack.

[Reset the insertion mode appropriately](#)^{p1120}.

Note

It just gets treated like an end tag.

↪ **A start tag whose tag name is one of: "input", "keygen", "textarea"**

[Parse error](#)^{p1108}.

If the [stack of open elements](#)^{p1121} does not [have a select element in select scope](#)^{p1123}, ignore the token. ([fragment case](#)^{p1206})

Otherwise:

Pop elements from the [stack of open elements](#)^{p1121} until a [select](#)^{p547} element has been popped from the stack.

[Reset the insertion mode appropriately](#)^{p1120}.

Reprocess the token.

↪ **A start tag whose tag name is one of: "script", "template"**

↪ **An end tag whose tag name is "template"**

Process the token [using the rules for](#)^{p1120} the ["in head"](#)^{p1162} [insertion mode](#)^{p1120}.

↪ **An end-of-file token**

Process the token [using the rules for](#)^{p1120} the ["in body"](#)^{p1166} [insertion mode](#)^{p1120}.

↪ **Anything else**

[Parse error](#)^{p1108}. Ignore the token.

13.2.6.4.17 The "in select in table" insertion mode §^{p11}₈₅

When the user agent is to apply the rules for the ["in select in table"](#)^{p1185} [insertion mode](#)^{p1120}, the user agent must handle the token as follows:

↪ **A start tag whose tag name is one of: "caption", "table", "tbody", "tfoot", "thead", "tr", "td", "th"**

[Parse error](#)^{p1108}.

Pop elements from the [stack of open elements](#)^{p1121} until a [select](#)^{p547} element has been popped from the stack.

[Reset the insertion mode appropriately](#)^{p1120}.

Reprocess the token.

↪ **An end tag whose tag name is one of: "caption", "table", "tbody", "tfoot", "thead", "tr", "td", "th"**

[Parse error](#)^{p1108}.

If the [stack of open elements](#)^{p1121} does not [have an element in table scope](#)^{p1123} that is an [HTML element](#)^{p44} with the same tag name as that of the token, then ignore the token.

Otherwise:

Pop elements from the [stack of open elements](#)^{p1121} until a [select](#)^{p547} element has been popped from the stack.

[Reset the insertion mode appropriately](#)^{p1120}.

Reprocess the token.

↪ **Anything else**

Process the token [using the rules for](#)^{p1120} the "[in_select](#)^{p1184}" [insertion mode](#)^{p1120}.

13.2.6.4.18 The "in template" insertion mode §^{p11}₈₆

When the user agent is to apply the rules for the "[in_template](#)^{p1186}" [insertion mode](#)^{p1120}, the user agent must handle the token as follows:

↪ **A character token**

↪ **A comment token**

↪ **A DOCTYPE token**

Process the token [using the rules for](#)^{p1120} the "[in_body](#)^{p1166}" [insertion mode](#)^{p1120}.

↪ **A start tag whose tag name is one of: "base", "basefont", "bgsound", "link", "meta", "noframes", "script", "style", "template", "title"**

↪ **An end tag whose tag name is "template"**

Process the token [using the rules for](#)^{p1120} the "[in_head](#)^{p1162}" [insertion mode](#)^{p1120}.

↪ **A start tag whose tag name is one of: "caption", "colgroup", "tbody", "tfoot", "thead"**

Pop the [current template insertion mode](#)^{p1120} off the [stack of template insertion modes](#)^{p1120}.

Push "[in_table](#)^{p1177}" onto the [stack of template insertion modes](#)^{p1120} so that it is the new [current template insertion mode](#)^{p1120}.

Switch the [insertion mode](#)^{p1120} to "[in_table](#)^{p1177}", and reprocess the token.

↪ **A start tag whose tag name is "col"**

Pop the [current template insertion mode](#)^{p1120} off the [stack of template insertion modes](#)^{p1120}.

Push "[in_column_group](#)^{p1180}" onto the [stack of template insertion modes](#)^{p1120} so that it is the new [current template insertion mode](#)^{p1120}.

Switch the [insertion mode](#)^{p1120} to "[in_column_group](#)^{p1180}", and reprocess the token.

↪ **A start tag whose tag name is "tr"**

Pop the [current template insertion mode](#)^{p1120} off the [stack of template insertion modes](#)^{p1120}.

Push "[in_table body](#)^{p1181}" onto the [stack of template insertion modes](#)^{p1120} so that it is the new [current template insertion mode](#)^{p1120}.

Switch the [insertion mode](#)^{p1120} to "[in_table body](#)^{p1181}", and reprocess the token.

↪ **A start tag whose tag name is one of: "td", "th"**

Pop the [current template insertion mode](#)^{p1120} off the [stack of template insertion modes](#)^{p1120}.

Push "[in_row](#)^{p1182}" onto the [stack of template insertion modes](#)^{p1120} so that it is the new [current template insertion mode](#)^{p1120}.

Switch the [insertion mode](#)^{p1120} to "[in_row](#)^{p1182}", and reprocess the token.

↪ **Any other start tag**

Pop the [current template insertion mode](#)^{p1120} off the [stack of template insertion modes](#)^{p1120}.

Push "[in_body](#)^{p1166}" onto the [stack of template insertion modes](#)^{p1120} so that it is the new [current template insertion mode](#)^{p1120}.

Switch the [insertion mode](#)^{p1120} to "[in_body](#)^{p1166}", and reprocess the token.

↪ **Any other end tag**

[Parse error](#)^{p1108}. Ignore the token.

↪ **An end-of-file token**

If there is no [template](#)^{p640} element on the [stack of open elements](#)^{p1121}, then [stop parsing](#)^{p1192}. ([fragment case](#)^{p1206})

Otherwise, this is a [parse error](#)^{p1108}.

Pop elements from the [stack of open elements](#)^{p1121} until a [template](#)^{p640} element has been popped from the stack.

[Clear the list of active formatting elements up to the last marker](#)^{p1124}.

Pop the [current template insertion mode](#)^{p1120} off the [stack of template insertion modes](#)^{p1120}.

[Reset the insertion mode appropriately](#)^{p1120}.

Reprocess the token.

13.2.6.4.19 The "after body" insertion mode §^{p11}₈₇

When the user agent is to apply the rules for the "[after body](#)^{p1187}" [insertion mode](#)^{p1120}, the user agent must handle the token as follows:

↪ **A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE**

Process the token [using the rules for](#)^{p1120} the "[in body](#)^{p1166}" [insertion mode](#)^{p1120}.

↪ **A comment token**

[Insert a comment](#)^{p1158} as the last child of the first element in the [stack of open elements](#)^{p1121} (the [html](#)^{p157} element).

↪ **A DOCTYPE token**

[Parse error](#)^{p1108}. Ignore the token.

↪ **A start tag whose tag name is "html"**

Process the token [using the rules for](#)^{p1120} the "[in body](#)^{p1166}" [insertion mode](#)^{p1120}.

↪ **An end tag whose tag name is "html"**

If the parser was created as part of the [HTML fragment parsing algorithm](#)^{p1206}, this is a [parse error](#)^{p1108}; ignore the token. ([fragment case](#)^{p1206})

Otherwise, switch the [insertion mode](#)^{p1120} to "[after after body](#)^{p1189}".

↪ **An end-of-file token**

[Stop parsing](#)^{p1192}.

↪ **Anything else**

[Parse error](#)^{p1108}. Switch the [insertion mode](#)^{p1120} to "[in body](#)^{p1166}" and reprocess the token.

13.2.6.4.20 The "in frameset" insertion mode §^{p11}₈₇

When the user agent is to apply the rules for the "[in frameset](#)^{p1187}" [insertion mode](#)^{p1120}, the user agent must handle the token as follows:

↪ **A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE**

[Insert the character](#)^{p1157}.

↪ **A comment token**

[Insert a comment](#)^{p1158}.

↪ **A DOCTYPE token**

[Parse error](#)^{p1108}. Ignore the token.

↪ **A start tag whose tag name is "html"**

Process the token [using the rules for](#)^{p1120} the "[in body](#)^{p1166}" [insertion mode](#)^{p1120}.

↪ **A start tag whose tag name is "frameset"**

[Insert an HTML element^{p1156}](#) for the token.

↪ **An end tag whose tag name is "frameset"**

If the [current node^{p1121}](#) is the root [html^{p157}](#) element, then this is a [parse error^{p1108}](#); ignore the token. ([fragment case^{p1206}](#))

Otherwise, pop the [current node^{p1121}](#) from the [stack of open elements^{p1121}](#).

If the parser was not created as part of the [HTML fragment parsing algorithm^{p1206}](#) ([fragment case^{p1206}](#)), and the [current node^{p1121}](#) is no longer a [frameset^{p1264}](#) element, then switch the [insertion mode^{p1120}](#) to "[after frameset^{p1188}](#)".

↪ **A start tag whose tag name is "frame"**

[Insert an HTML element^{p1156}](#) for the token. Immediately pop the [current node^{p1121}](#) off the [stack of open elements^{p1121}](#).

[Acknowledge the token's self-closing flag^{p1125}](#), if it is set.

↪ **A start tag whose tag name is "noframes"**

Process the token [using the rules for^{p1120}](#) the "[in head^{p1162}](#)" [insertion mode^{p1120}](#).

↪ **An end-of-file token**

If the [current node^{p1121}](#) is not the root [html^{p157}](#) element, then this is a [parse error^{p1108}](#).

Note

The [current node^{p1121}](#) can only be the root [html^{p157}](#) element in the [fragment case^{p1206}](#).

[Stop parsing^{p1192}](#).

↪ **Anything else**

[Parse error^{p1108}](#). Ignore the token.

13.2.6.4.21 The "after frameset" insertion mode §^{p11} 88

When the user agent is to apply the rules for the "[after frameset^{p1188}](#)" [insertion mode^{p1120}](#), the user agent must handle the token as follows:

↪ **A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE**

[Insert the character^{p1157}](#).

↪ **A comment token**

[Insert a comment^{p1158}](#).

↪ **A DOCTYPE token**

[Parse error^{p1108}](#). Ignore the token.

↪ **A start tag whose tag name is "html"**

Process the token [using the rules for^{p1120}](#) the "[in body^{p1166}](#)" [insertion mode^{p1120}](#).

↪ **An end tag whose tag name is "html"**

Switch the [insertion mode^{p1120}](#) to "[after after frameset^{p1189}](#)".

↪ **A start tag whose tag name is "noframes"**

Process the token [using the rules for^{p1120}](#) the "[in head^{p1162}](#)" [insertion mode^{p1120}](#).

↪ **An end-of-file token**

[Stop parsing^{p1192}](#).

↪ **Anything else**

[Parse error^{p1108}](#). Ignore the token.

13.2.6.4.22 The "after after body" insertion mode §^{p11}₈₉

When the user agent is to apply the rules for the "after after body"^{p1189} insertion mode^{p1120}, the user agent must handle the token as follows:

↪ **A comment token**

[Insert a comment](#)^{p1158} as the last child of the [Document](#)^{p117} object.

↪ **A DOCTYPE token**

↪ **A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE**

↪ **A start tag whose tag name is "html"**

Process the token [using the rules for](#)^{p1120} the "in body"^{p1166} insertion mode^{p1120}.

↪ **An end-of-file token**

[Stop parsing](#)^{p1192}.

↪ **Anything else**

[Parse error](#)^{p1108}. Switch the [insertion mode](#)^{p1120} to "in body"^{p1166} and reprocess the token.

13.2.6.4.23 The "after after frameset" insertion mode §^{p11}₈₉

When the user agent is to apply the rules for the "after after frameset"^{p1189} insertion mode^{p1120}, the user agent must handle the token as follows:

↪ **A comment token**

[Insert a comment](#)^{p1158} as the last child of the [Document](#)^{p117} object.

↪ **A DOCTYPE token**

↪ **A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE**

↪ **A start tag whose tag name is "html"**

Process the token [using the rules for](#)^{p1120} the "in body"^{p1166} insertion mode^{p1120}.

↪ **An end-of-file token**

[Stop parsing](#)^{p1192}.

↪ **A start tag whose tag name is "noframes"**

Process the token [using the rules for](#)^{p1120} the "in head"^{p1162} insertion mode^{p1120}.

↪ **Anything else**

[Parse error](#)^{p1108}. Ignore the token.

13.2.6.5 The rules for parsing tokens in foreign content §^{p11}₈₉

When the user agent is to apply the rules for parsing tokens in foreign content, the user agent must handle the token as follows:

↪ **A character token that is U+0000 NULL**

[Parse error](#)^{p1108}. [Insert a U+FFFD REPLACEMENT CHARACTER character](#)^{p1157}.

↪ **A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE**

[Insert the token's character](#)^{p1157}.

↪ **Any other character token**

[Insert the token's character](#)^{p1157}.

Set the [frameset-ok flag](#)^{p1124} to "not ok".

↪ **A comment token**

[Insert a comment](#)^{p1158}.

↪ **A DOCTYPE token**

[Parse error](#)^{p1108}. Ignore the token.

↪ **A start tag whose tag name is one of: "b", "big", "blockquote", "body", "br", "center", "code", "dd", "div", "dl", "dt", "em", "embed", "h1", "h2", "h3", "h4", "h5", "h6", "head", "hr", "i", "img", "li", "listing", "menu", "meta", "nobr", "ol", "p", "pre", "ruby", "s", "small", "span", "strong", "strike", "sub", "sup", "table", "tt", "u", "ul", "var"**

↪ **A start tag whose tag name is "font", if the token has any attributes named "color", "face", or "size"**

↪ **An end tag whose tag name is "br", "p"**

[Parse error](#)^{p1108}.

While the [current node](#)^{p1121} is not a [MathML text integration point](#)^{p1153}, an [HTML integration point](#)^{p1153}, or an element in the [HTML namespace](#), pop elements from the [stack of open elements](#)^{p1121}.

Reprocess the token according to the rules given in the section corresponding to the current [insertion mode](#)^{p1120} in HTML content.

↪ **Any other start tag**

If the [adjusted current node](#)^{p1121} is an element in the [MathML namespace](#), [adjust MathML attributes](#)^{p1156} for the token. (This fixes the case of MathML attributes that are not all lowercase.)

If the [adjusted current node](#)^{p1121} is an element in the [SVG namespace](#), and the token's tag name is one of the ones in the first column of the following table, change the tag name to the name given in the corresponding cell in the second column. (This fixes the case of SVG elements that are not all lowercase.)

Tag name	Element name
altglyph	altGlyph
altglyphdef	altGlyphDef
altglyphitem	altGlyphItem
animatecolor	animateColor
animatemotion	animateMotion
animatetransform	animateTransform
clippath	clipPath
feblend	feBlend
fecolormatrix	feColorMatrix
fecomponenttransfer	feComponentTransfer
fecomposite	feComposite
feconvolvematrix	feConvolveMatrix
fediffuselighting	feDiffuseLighting
fedisplacementmap	feDisplacementMap
fedistantlight	feDistantLight
fedropshadow	feDropShadow
feflood	feFlood
fefunca	feFuncA
fefuncb	feFuncB
fefuncg	feFuncG
fefuncr	feFuncR
fegaussianblur	feGaussianBlur
feimage	feImage
femerge	feMerge
femergenode	feMergeNode
femorphology	feMorphology
feoffset	feOffset
fepointlight	fePointLight
fespecularlighting	feSpecularLighting
fespotlight	feSpotLight
fetile	feTile

Tag name	Element name
feturbulence	feTurbulence
foreignobject	foreignObject
glyphref	glyphRef
lineargradient	linearGradient
radialgradient	radialGradient
textpath	textPath

If the [adjusted current node](#)^{p1121} is an element in the [SVG namespace](#), [adjust SVG attributes](#)^{p1156} for the token. (This fixes the case of SVG attributes that are not all lowercase.)

[Adjust foreign attributes](#)^{p1157} for the token. (This fixes the use of namespaced attributes, in particular XLink in SVG.)

[Insert a foreign element](#)^{p1155} for the token, in the same namespace as the [adjusted current node](#)^{p1121}.

If the token has its [self-closing flag](#)^{p1125} set, then run the appropriate steps from the following list:

↪ **If the token's tag name is "script", and the new [current node](#)^{p1121} is in the [SVG namespace](#)**
[Acknowledge the token's self-closing flag](#)^{p1125}, and then act as described in the steps for a "script" end tag below.

↪ **Otherwise**

Pop the [current node](#)^{p1121} off the [stack of open elements](#)^{p1121} and [acknowledge the token's self-closing flag](#)^{p1125}.

↪ **An end tag whose tag name is "script", if the [current node](#)^{p1121} is an [SVG script element](#)**

Pop the [current node](#)^{p1121} off the [stack of open elements](#)^{p1121}.

Let the *old insertion point* have the same value as the current [insertion point](#)^{p1120}. Let the [insertion point](#)^{p1120} be just before the [next input character](#)^{p1120}.

Increment the parser's [script nesting level](#)^{p1108} by one. Set the [parser pause flag](#)^{p1108} to true.

If the [active speculative HTML parser](#)^{p1193} is null and the user agent supports SVG, then [Process the SVG script element](#) according to the SVG rules. [\[SVG\]](#)^{p1312}

Note

Even if this causes [new characters to be inserted into the tokenizer](#)^{p996}, the parser will not be executed reentrantly, since the [parser pause flag](#)^{p1108} is true.

Decrement the parser's [script nesting level](#)^{p1108} by one. If the parser's [script nesting level](#)^{p1108} is zero, then set the [parser pause flag](#)^{p1108} to false.

Let the [insertion point](#)^{p1120} have the value of the *old insertion point*. (In other words, restore the [insertion point](#)^{p1120} to its previous value. This value might be the "undefined" value.)

↪ **Any other end tag**

Run these steps:

1. Initialize *node* to be the [current node](#)^{p1121} (the bottommost node of the stack).
2. If *node*'s tag name, [converted to ASCII lowercase](#), is not the same as the tag name of the token, then this is a [parse error](#)^{p1108}.
3. *Loop*: If *node* is the topmost element in the [stack of open elements](#)^{p1121}, then return. ([fragment case](#)^{p1206})
4. If *node*'s tag name, [converted to ASCII lowercase](#), is the same as the tag name of the token, pop elements from the [stack of open elements](#)^{p1121} until *node* has been popped from the stack, and then return.
5. Set *node* to the previous entry in the [stack of open elements](#)^{p1121}.
6. If *node* is not an element in the [HTML namespace](#), return to the step labeled *loop*.
7. Otherwise, process the token according to the rules given in the section corresponding to the current [insertion mode](#)^{p1120} in HTML content.

13.2.7 The end ^{§ p11}₉₂

Once the user agent **stops parsing** the document, the user agent must run the following steps:

1. If the [active speculative HTML parser](#)^{p1193} is not null, then [stop the speculative HTML parser](#)^{p1194} and return.
2. Set the [insertion point](#)^{p1120} to undefined.
3. [Update the current document readiness](#)^{p120} to "interactive".
4. Pop *all* the nodes off the [stack of open elements](#)^{p1121}.
5. While the [list of scripts that will execute when the document has finished parsing](#)^{p633} is not empty:
 1. [Spin the event loop](#)^{p975} until the first [script](#)^{p624} in the [list of scripts that will execute when the document has finished parsing](#)^{p633} has its "ready to be parser-executed"^{p630} flag set *and* the parser's [Document](#)^{p117} has no style sheet that is blocking scripts^{p184}.
 2. [Execute](#)^{p634} the first [script](#)^{p624} in the [list of scripts that will execute when the document has finished parsing](#)^{p633}.
 3. Remove the first [script](#)^{p624} element from the [list of scripts that will execute when the document has finished parsing](#)^{p633} (i.e. shift out the first entry in the list).
6. [Queue a global task](#)^{p970} on the [DOM manipulation task source](#)^{p977} given the [Document](#)^{p117}'s [relevant global object](#)^{p944} to run the following substeps:
 1. Set the [Document](#)^{p117}'s [load timing info](#)^{p121}'s [DOM content loaded event start time](#)^{p121} to the [current high resolution time](#) given the [Document](#)^{p117}'s [relevant global object](#)^{p944}.
 2. [Fire an event](#) named [DOMContentLoaded](#)^{p1300} at the [Document](#)^{p117} object, with its [bubbles](#) attribute initialized to true.
 3. Set the [Document](#)^{p117}'s [load timing info](#)^{p121}'s [DOM content loaded event end time](#)^{p121} to the [current high resolution time](#) given the [Document](#)^{p117}'s [relevant global object](#)^{p944}.
 4. Enable the [client message queue](#) of the [ServiceWorkerContainer](#) object whose associated [service worker client](#) is the [Document](#)^{p117} object's [relevant settings object](#)^{p944}.
 5. Invoke [WebDriver BiDi DOM content loaded](#) with the [Document](#)^{p117}'s [browsing context](#)^{p840}, and a new [WebDriver BiDi navigation status](#) whose [id](#) is the [Document](#)^{p117} object's [navigation id](#)^{p118}, [status](#) is "pending", and [url](#) is the [Document](#)^{p117} object's [URL](#).
7. [Spin the event loop](#)^{p975} until the [set of scripts that will execute as soon as possible](#)^{p634} and the [list of scripts that will execute in order as soon as possible](#)^{p633} are empty.
8. [Spin the event loop](#)^{p975} until there is nothing that **delays the load event** in the [Document](#)^{p117}.
9. [Queue a global task](#)^{p970} on the [DOM manipulation task source](#)^{p977} given the [Document](#)^{p117}'s [relevant global object](#)^{p944} to run the following steps:
 1. [Update the current document readiness](#)^{p120} to "complete".
 2. If the [Document](#)^{p117} object's [browsing context](#)^{p840} is null, then abort these steps.
 3. Let *window* be the [Document](#)^{p117}'s [relevant global object](#)^{p944}.
 4. Set the [Document](#)^{p117}'s [load timing info](#)^{p121}'s [load event start time](#)^{p121} to the [current high resolution time](#) given *window*.
 5. [Fire an event](#) named [Load](#)^{p1301} at *window*, with *legacy target override flag* set.
 6. Invoke [WebDriver BiDi load complete](#) with the [Document](#)^{p117}'s [browsing context](#)^{p840}, and a new [WebDriver BiDi navigation status](#) whose [id](#) is the [Document](#)^{p117} object's [navigation id](#)^{p118}, [status](#) is "complete", and [url](#) is the [Document](#)^{p117} object's [URL](#).
 7. Set the [Document](#)^{p117} object's [navigation id](#)^{p118} to null.
 8. Set the [Document](#)^{p117}'s [load timing info](#)^{p121}'s [load event end time](#)^{p121} to the [current high resolution time](#) given

window.

9. Assert: [Document^{p117}](#)'s [page showing^{p928}](#) is false.
 10. Set the [Document^{p117}](#)'s [page showing^{p928}](#) flag to true.
 11. [Fire a page transition event^{p927}](#) named [pageshow^{p1301}](#) at *window* with false.
 12. [Completely finish loading^{p927}](#) the [Document^{p117}](#).
 13. [Queue the navigation timing entry](#) for the [Document^{p117}](#).
10. If the [Document^{p117}](#)'s [print when loaded^{p1005}](#) flag is set, then run the [printing steps^{p1005}](#).
 11. The [Document^{p117}](#) is now **ready for post-load tasks**.

When the user agent is to **abort a parser**, it must run the following steps:

1. Throw away any pending content in the [input stream^{p1119}](#), and discard any future content that would have been added to it.
2. [Stop the speculative HTML parser^{p1194}](#) for this HTML parser.
3. [Update the current document readiness^{p120}](#) to "interactive".
4. Pop *all* the nodes off the [stack of open elements^{p1121}](#).
5. [Update the current document readiness^{p120}](#) to "complete".

13.2.8 Speculative HTML parsing §^{p11} 93

User agents may implement an optimization, as described in this section, to speculatively fetch resources that are declared in the HTML markup while the HTML parser is waiting for a [pending parsing-blocking script^{p634}](#) to be fetched and executed, or during normal parsing, at the time [an element is created for a token^{p1154}](#). While this optimization is not defined in precise detail, there are some rules to consider for interoperability.

Each [HTML parser^{p1106}](#) can have an **active speculative HTML parser**. It is initially null.

The **speculative HTML parser** must act like the normal HTML parser (e.g., the tree builder rules apply), with some exceptions:

- The state of the normal HTML parser and the document itself must not be affected.

Example

For example, the [next input character^{p1120}](#) or the [stack of open elements^{p1121}](#) for the normal HTML parser is not affected by the [speculative HTML parser^{p1193}](#).

- Bytes pushed into the HTML parser's [input byte stream^{p1112}](#) must also be pushed into the speculative HTML parser's [input byte stream^{p1112}](#). Bytes read from the streams must be independent.
- The result of the speculative parsing is primarily a series of [speculative fetches^{p1193}](#). Which kinds of resources to speculatively fetch is [implementation-defined](#), but user agents must not speculatively fetch resources that would not be fetched with the normal HTML parser, under the assumption that the script that is blocking the HTML parser does nothing.

Note

It is possible that the same markup is seen multiple times from the [speculative HTML parser^{p1193}](#) and then the normal HTML parser. It is expected that duplicated fetches will be prevented by caching rules, which are not yet fully specified.

A **speculative fetch** for a [speculative mock element^{p1194}](#) *element* must follow these rules:

Should some of these things be applied to the document "for real", even though they are found speculatively?

- If the [speculative HTML parser^{p1193}](#) encounters one of the following elements, then act as if that element is processed for the purpose of its effect of subsequent speculative fetches.

- A [base^{p160}](#) element.
 - A [meta^{p170}](#) element whose [http-equiv^{p176}](#) attribute is in the [Content security policy^{p179}](#) state.
 - A [meta^{p170}](#) element whose [name^{p171}](#) attribute is an [ASCII case-insensitive](#) match for "[referrer^{p173}](#)".
 - A [meta^{p170}](#) element whose [name^{p171}](#) attribute is an [ASCII case-insensitive](#) match for "viewport". (This can affect whether a media query list [matches the environment^{p90}](#).) [[CSSDEVICEADAPT^{p1306}](#)]
- Let *url* be the [URL](#) that *element* would fetch if it was processed normally. If there is no such [URL](#) or if it is the empty string, then do nothing. Otherwise, if *url* is already in the [list of speculative fetch URLs^{p1194}](#), then do nothing. Otherwise, fetch *url* as if the element was processed normally, and add *url* to the [list of speculative fetch URLs^{p1194}](#).

Each [Document^{p117}](#) has a **list of speculative fetch URLs**, which is a [list](#) of [URLs](#), initially empty.

To **start the speculative HTML parser** for an instance of an HTML parser *parser*:

1. Optionally, return.

Note

This step allows user agents to opt out of speculative HTML parsing.

2. If *parser's* [active speculative HTML parser^{p1193}](#) is not null, then [stop the speculative HTML parser^{p1194}](#) for *parser*.

Note

This can happen when [document.write\(\)^{p996}](#) writes another parser-blocking script. For simplicity, this specification always restarts speculative parsing, but user agents can implement a more efficient strategy, so long as the end result is equivalent.

3. Let *speculativeParser* be a new [speculative HTML parser^{p1193}](#), with the same state as *parser*.
4. Let *speculativeDoc* be a new isomorphic representation of *parser's* [Document^{p117}](#), where all elements are instead [speculative mock elements^{p1194}](#). Let *speculativeParser* parse into *speculativeDoc*.
5. Set *parser's* [active speculative HTML parser^{p1193}](#) to *speculativeParser*.
6. [In parallel^{p42}](#), run *speculativeParser* until it is stopped or until it reaches the end of its [input stream^{p1119}](#).

To **stop the speculative HTML parser** for an instance of an HTML parser *parser*:

1. Let *speculativeParser* be *parser's* [active speculative HTML parser^{p1193}](#).
2. If *speculativeParser* is null, then return.
3. Throw away any pending content in *speculativeParser's* [input stream^{p1119}](#), and discard any future content that would have been added to it.
4. Set *parser's* [active speculative HTML parser^{p1193}](#) to null.

The [speculative HTML parser^{p1193}](#) will create [speculative mock elements^{p1194}](#) instead of normal elements. DOM operations that the tree builder normally does on elements are expected to work appropriately on speculative mock elements.

A **speculative mock element** is a [struct](#) with the following [items](#):

- A [string namespace](#), corresponding to an element's [namespace](#).
- A [string local name](#), corresponding to an element's [local name](#).
- A [list attribute list](#), corresponding to an element's [attribute list](#).
- A [list children](#), corresponding to an element's [children](#).

To **create a speculative mock element** given a *namespace*, *tagName*, and *attributes*:

1. Let *element* be a new [speculative mock element^{p1194}](#).
2. Set *element's* [namespace^{p1194}](#) to *namespace*.
3. Set *element's* [local name^{p1194}](#) to *tagName*.
4. Set *element's* [attribute list^{p1194}](#) to *attributes*.

5. Set *element*'s [children^{p1194}](#) to a new empty [list](#).
6. Optionally, perform a [speculative fetch^{p1193}](#) for *element*.
7. Return *element*.

When the tree builder says to insert an element into a [template^{p640}](#) element's [template contents^{p642}](#), if that is a [speculative mock element^{p1194}](#), instead do nothing. URLs found speculatively inside [template^{p640}](#) elements might themselves be templates, and must not be speculatively fetched.

13.2.9 Coercing an HTML DOM into an infoset §^{p11}₉₅

When an application uses an [HTML parser^{p1106}](#) in conjunction with an XML pipeline, it is possible that the constructed DOM is not compatible with the XML tool chain in certain subtle ways. For example, an XML toolchain might not be able to represent attributes with the name `xmlns`, since they conflict with the Namespaces in XML syntax. There is also some data that the [HTML parser^{p1106}](#) generates that isn't included in the DOM itself. This section specifies some rules for handling these issues.

If the XML API being used doesn't support DOCTYPEs, the tool may drop DOCTYPEs altogether.

If the XML API doesn't support attributes in no namespace that are named "xmlns", attributes whose names start with "xmlns:", or attributes in the [XMLNS namespace](#), then the tool may drop such attributes.

The tool may annotate the output with any namespace declarations required for proper operation.

If the XML API being used restricts the allowable characters in the local names of elements and attributes, then the tool may map all element and attribute local names that the API wouldn't support to a set of names that *are* allowed, by replacing any character that isn't supported with the uppercase letter U and the six digits of the character's code point when expressed in hexadecimal, using digits 0-9 and capital letters A-F as the symbols, in increasing numeric order.

Example

For example, the element name `foo<bar`, which can be output by the [HTML parser^{p1106}](#), though it is neither a legal HTML element name nor a well-formed XML element name, would be converted into `fooU000003Cbar`, which *is* a well-formed XML element name (though it's still not legal in HTML by any means).

Example

As another example, consider the attribute `xlink:href`. Used on a MathML element, it becomes, after being [adjusted^{p1157}](#), an attribute with a prefix "xlink" and a local name "href". However, used on an HTML element, it becomes an attribute with no prefix and the local name "xlink:href", which is not a valid NCName, and thus might not be accepted by an XML API. It could thus get converted, becoming "xlinkU000003Ahref".

Note

The resulting names from this conversion conveniently can't clash with any attribute generated by the [HTML parser^{p1106}](#), since those are all either lowercase or those listed in the [adjust foreign attributes^{p1157}](#) algorithm's table.

If the XML API restricts comments from having two consecutive U+002D HYPHEN-MINUS characters (--), the tool may insert a single U+0020 SPACE character between any such offending characters.

If the XML API restricts comments from ending in a U+002D HYPHEN-MINUS character (-), the tool may insert a single U+0020 SPACE character at the end of such comments.

If the XML API restricts allowed characters in character data, attribute values, or comments, the tool may replace any U+000C FORM FEED (FF) character with a U+0020 SPACE character, and any other literal non-XML character with a U+FFFD REPLACEMENT CHARACTER.

If the tool has no way to convey out-of-band information, then the tool may drop the following information:

- Whether the document is set to [no-quirks mode](#), [limited-quirks mode](#), or [quirks mode](#)
- The association between form controls and forms that aren't their nearest [form^{p494}](#) element ancestor (use of the [form element pointer^{p1124}](#) in the parser)

- The [template contents](#)^{p642} of any [template](#)^{p649} elements.

Note

The mutations allowed by this section apply after the [HTML parser](#)^{p1106}'s rules have been applied. For example, a `<a :>` start tag will be closed by a `</a :>` end tag, and never by a `</aU00003AU00003A>` end tag, even if the user agent is using the rules above to then generate an actual element in the DOM with the name `aU00003AU00003A` for that start tag.

13.2.10 An introduction to error handling and strange cases in the parser §^{p11}₉₆

This section is non-normative.

This section examines some erroneous markup and discusses how the [HTML parser](#)^{p1106} handles these cases.

13.2.10.1 Misnested tags: `<i></i>` §^{p11}₉₆

This section is non-normative.

The most-often discussed example of erroneous markup is as follows:

```
<p>1<b>2<i>3</b>4</i>5</p>
```

The parsing of this markup is straightforward up to the "3". At this point, the DOM looks like this:

Here, the [stack of open elements](#)^{p1121} has five elements on it: [html](#)^{p157}, [body](#)^{p184}, [p](#)^{p218}, [b](#)^{p279}, and [i](#)^{p278}. The [list of active formatting elements](#)^{p1123} just has two: [b](#)^{p279} and [i](#)^{p278}. The [insertion mode](#)^{p1120} is "[in body](#)^{p1166}".

Upon receiving the end tag token with the tag name "b", the [adoption agency algorithm](#)^{p1174} is invoked. This is a simple case, in that the *formatting element* is the [b](#)^{p279} element, and there is no *furthest block*. Thus, the [stack of open elements](#)^{p1121} ends up with just three elements: [html](#)^{p157}, [body](#)^{p184}, and [p](#)^{p218}, while the [list of active formatting elements](#)^{p1123} has just one: [i](#)^{p278}. The DOM tree is unmodified at this point.

The next token is a character ("4"), triggers the [reconstruction of the active formatting elements](#)^{p1123}, in this case just the [i](#)^{p278} element. A new [i](#)^{p278} element is thus created for the "4" [Text](#) node. After the end tag token for the "i" is also received, and the "5" [Text](#) node is inserted, the DOM looks as follows:

13.2.10.2 Misnested tags: `<p></p>` § p1197

This section is non-normative.

A case similar to the previous one is the following:

```
<b>1<p>2</b>3</p>
```

Up to the "2" the parsing here is straightforward:

The interesting part is when the end tag token with the tag name "b" is parsed.

Before that token is seen, the [stack of open elements](#) p1121 has four elements on it: [html](#) p157, [body](#) p184, [b](#) p279, and [p](#) p218. The [list of active formatting elements](#) p1123 just has the one: [b](#) p279. The [insertion mode](#) p1120 is "[in body](#) p1166".

Upon receiving the end tag token with the tag name "b", the "[adoption agency algorithm](#) p1174" is invoked, as in the previous example. However, in this case, there *is* a *furthest block*, namely the [p](#) p218 element. Thus, this time the adoption agency algorithm isn't skipped over.

The *common ancestor* is the [body](#) p184 element. A conceptual "bookmark" marks the position of the [b](#) p279 in the [list of active formatting elements](#) p1123, but since that list has only one element in it, the bookmark won't have much effect.

As the algorithm progresses, *node* ends up set to the formatting element ([b](#) p279), and *last node* ends up set to the *furthest block* ([p](#) p218).

The *last node* gets appended (moved) to the *common ancestor*, so that the DOM looks like:

A new [b](#) p279 element is created, and the children of the [p](#) p218 element are moved to it:

Finally, the new [b](#) p279 element is appended to the [p](#) p218 element, so that the DOM looks like:

The [b^{p279}](#) element is removed from the [list of active formatting elements^{p1123}](#) and the [stack of open elements^{p1121}](#), so that when the "3" is parsed, it is appended to the [p^{p218}](#) element:

13.2.10.3 Unexpected markup in tables §^{p11}₉₈

This section is non-normative.

Error handling in tables is, for historical reasons, especially strange. For example, consider the following markup:

```
<table><b><tr><td>aaa</td></tr>bbb</table>ccc
```

The highlighted [b^{p279}](#) element start tag is not allowed directly inside a table like that, and the parser handles this case by placing the element *before* the table. (This is called [foster parenting^{p1153}](#).) This can be seen by examining the DOM tree as it stands just after the [table^{p458}](#) element's start tag has been seen:

...and then immediately after the [b^{p279}](#) element start tag has been seen:

At this point, the [stack of open elements^{p1121}](#) has on it the elements [html^{p157}](#), [body^{p184}](#), [table^{p458}](#), and [b^{p279}](#) (in that order, despite the resulting DOM tree); the [list of active formatting elements^{p1123}](#) just has the [b^{p279}](#) element in it; and the [insertion mode^{p1120}](#) is "[in table^{p1177}](#)".

The [tr^{p472}](#) start tag causes the [b^{p279}](#) element to be popped off the stack and a [tbody^{p469}](#) start tag to be implied; the [tbody^{p469}](#) and [tr^{p472}](#) elements are then handled in a rather straight-forward manner, taking the parser through the "[in table body^{p1181}](#)" and "[in row^{p1182}](#)" insertion modes, after which the DOM looks as follows:

Here, the [stack of open elements^{p1121}](#) has on it the elements [html^{p157}](#), [body^{p184}](#), [table^{p458}](#), [tbody^{p469}](#), and [tr^{p472}](#); the [list of active formatting elements^{p1123}](#) still has the [b^{p279}](#) element in it; and the [insertion mode^{p1120}](#) is "[in row^{p1182}](#)".

The [td^{p474}](#) element start tag token, after putting a [td^{p474}](#) element on the tree, puts a [marker^{p1123}](#) on the [list of active formatting elements^{p1123}](#) (it also switches to the "[in cell^{p1183}](#)" [insertion mode^{p1120}](#)).

The [marker](#)^{p1123} means that when the "aaa" character tokens are seen, no [b](#)^{p279} element is created to hold the resulting [Text](#) node:

The end tags are handled in a straight-forward manner; after handling them, the [stack of open elements](#)^{p1121} has on it the elements [html](#)^{p157}, [body](#)^{p184}, [table](#)^{p458}, and [tbody](#)^{p469}; the [list of active formatting elements](#)^{p1123} still has the [b](#)^{p279} element in it (the [marker](#)^{p1123} having been removed by the "td" end tag token); and the [insertion mode](#)^{p1120} is "[in table body](#)^{p1181}".

Thus it is that the "bbb" character tokens are found. These trigger the "[in table text](#)^{p1179}" insertion mode to be used (with the [original insertion mode](#)^{p1120} set to "[in table body](#)^{p1181}"). The character tokens are collected, and when the next token (the [table](#)^{p458} element end tag) is seen, they are processed as a group. Since they are not all spaces, they are handled as per the "anything else" rules in the "[in table](#)^{p1177}" insertion mode, which defer to the "[in body](#)^{p1166}" insertion mode but with [foster parenting](#)^{p1153}.

When [the active formatting elements are reconstructed](#)^{p1123}, a [b](#)^{p279} element is created and [foster parented](#)^{p1153}, and then the "bbb" [Text](#) node is appended to it:

The [stack of open elements](#)^{p1121} has on it the elements [html](#)^{p157}, [body](#)^{p184}, [table](#)^{p458}, [tbody](#)^{p469}, and the new [b](#)^{p279} (again, note that this doesn't match the resulting tree!); the [list of active formatting elements](#)^{p1123} has the new [b](#)^{p279} element in it; and the [insertion mode](#)^{p1120} is still "[in table body](#)^{p1181}".

Had the character tokens been only [ASCII whitespace](#) instead of "bbb", then that [ASCII whitespace](#) would just be appended to the [tbody](#)^{p469} element.

Finally, the [table](#)^{p458} is closed by a "table" end tag. This pops all the nodes from the [stack of open elements](#)^{p1121} up to and including the [table](#)^{p458} element, but it doesn't affect the [list of active formatting elements](#)^{p1123}, so the "ccc" character tokens after the table result in yet another [b](#)^{p279} element being created, this time after the table:

```

└─┬─ trp472
  │ └─ tdp474
  │   └─ #text: aaa
└─ bp279
  └─ #text: ccc

```

13.2.10.4 Scripts that modify the page as it is being parsed §^{p12}₀₀

This section is non-normative.

Consider the following markup, which for this example we will assume is the document with [URL https://example.com/inner](https://example.com/inner), being rendered as the content of an [iframe^{p369}](https://example.com/outer) in another document with the [URL https://example.com/outer](https://example.com/outer):

```

<div id=a>
  <script>
    var div = document.getElementById('a');
    parent.document.body.appendChild(div);
  </script>
  <script>
    alert(document.URL);
  </script>
</div>
<script>
  alert(document.URL);
</script>

```

Up to the first "script" end tag, before the script is parsed, the result is relatively straightforward:

```

└─ htmlp157
  └─ headp158
  └─ bodyp184
    └─ divp243 idp141="a"
      └─ #text:
      └─ scriptp624
        └─ #text: var div = document.getElementById('a'); parent.document.body.appendChild(div);

```

After the script is parsed, though, the [div^{p243}](#) element and its child [script^{p624}](#) element are gone:

```

└─ htmlp157
  └─ headp158
  └─ bodyp184

```

They are, at this point, in the [Document^{p117}](#) of the aforementioned outer [browsing context^{p840}](#). However, the [stack of open elements^{p1121}](#) still contains the [div^{p243}](#) element.

Thus, when the second [script^{p624}](#) element is parsed, it is inserted *into the outer Document^{p117} object*.

Those parsed into different [Document^{p117}](#)s than the one the parser was created for do not execute, so the first alert does not show.

Once the [div^{p243}](#) element's end tag is parsed, the [div^{p243}](#) element is popped off the stack, and so the next [script^{p624}](#) element is in the inner [Document^{p117}](#):

```

└─ htmlp157
  └─ headp158
  └─ bodyp184
    └─ scriptp624
      └─ #text: alert(document.URL);

```

This script does execute, resulting in an alert that says "https://example.com/inner".

Note how the second [p^{p218}](#) element in the markup has no explicit [b^{p279}](#) elements, but in the resulting DOM, up to three of each kind of formatting element (in this case three [b^{p279}](#) elements with the class attribute, and two unadorned [b^{p279}](#) elements) get reconstructed before the element's "X".

Also note how this means that in the final paragraph only six [b^{p279}](#) end tags are needed to completely clear the [list of active formatting elements^{p1123}](#), even though nine [b^{p279}](#) start tags have been seen up to this point.

13.3 Serializing HTML fragments §^{p12}₀₂

For the purposes of the following algorithm, an element **serializes as void** if its element type is one of the [void elements^{p1095}](#), or is [basefont^{p1258}](#), [bgsound^{p1257}](#), [frame^{p1264}](#), or [keygen^{p1257}](#).

The following steps form the **HTML fragment serialization algorithm**. The algorithm takes as input a DOM [Element](#), [Document^{p117}](#), or [DocumentFragment](#) referred to as *the node*, and returns a string.

Note

This algorithm serializes the children of the node being serialized, not the node itself.

1. If *the node* [serializes as void^{p1202}](#), then return the empty string.
2. Let *s* be a string, and initialize it to the empty string.
3. If *the node* is a [template^{p640}](#) element, then let *the node* instead be the [template^{p640}](#) element's [template contents^{p642}](#) (a [DocumentFragment](#) node).
4. For each child node of *the node*, in [tree order](#), run the following steps:
 1. Let *current node* be the child node being processed.
 2. Append the appropriate string from the following list to *s*:
 - ↪ **If *current node* is an Element**

If *current node* is an element in the [HTML namespace](#), the [MathML namespace](#), or the [SVG namespace](#), then let *tagname* be *current node*'s local name. Otherwise, let *tagname* be *current node*'s qualified name.

Append a U+003C LESS-THAN SIGN character (<), followed by *tagname*.

Note

*For [HTML elements^{p44}](#) created by the [HTML parser^{p1106}](#) or [createElement\(\)](#), *tagname* will be lowercase.*

If *current node*'s [is_value](#) is not null, and the element does not have an [is^{p728}](#) attribute in its attribute list, then append the string " is=", followed by *current node*'s [is_value escaped as described below^{p1206}](#) in *attribute mode*, followed by a U+0022 QUOTATION MARK character (").

For each attribute that the element has, append a U+0020 SPACE character, the [attribute's serialized name as described below^{p1202}](#), a U+003D EQUALS SIGN character (=), a U+0022 QUOTATION MARK character ("), the attribute's value, [escaped as described below^{p1206}](#) in *attribute mode*, and a second U+0022 QUOTATION MARK character (").

An **attribute's serialized name** for the purposes of the previous paragraph must be determined as follows:

↪ If the attribute has no namespace

The attribute's serialized name is the attribute's local name.

Note

For attributes on [HTML elements^{p44}](#) set by the [HTML parser^{p1106}](#) or by [setAttribute\(\)](#), the local name will be lowercase.

- ↪ **If the attribute is in the [XML namespace](#)**
The attribute's serialized name is the string "xml:" followed by the attribute's local name.
- ↪ **If the attribute is in the [XMLNS namespace](#) and the attribute's local name is xmlns**
The attribute's serialized name is the string "xmlns".
- ↪ **If the attribute is in the [XMLNS namespace](#) and the attribute's local name is not xmlns**
The attribute's serialized name is the string "xmlns:" followed by the attribute's local name.
- ↪ **If the attribute is in the [XLink namespace](#)**
The attribute's serialized name is the string "xlink:" followed by the attribute's local name.
- ↪ **If the attribute is in some other namespace**
The attribute's serialized name is the attribute's qualified name.

While the exact order of attributes is [implementation-defined](#), and may depend on factors such as the order that the attributes were given in the original markup, the sort order must be stable, such that consecutive invocations of this algorithm serialize an element's attributes in the same order.

Append a U+003E GREATER-THAN SIGN character (>).

If *current node* [serializes as void](#)^{p1202}, then [continue](#) on to the next child node at this point.

Append the value of running the [HTML fragment serialization algorithm](#)^{p1202} on the *current node* element (thus recursing into this algorithm for that element), followed by a U+003C LESS-THAN SIGN character (<), a U+002F SOLIDUS character (/), *tagname* again, and finally a U+003E GREATER-THAN SIGN character (>).

↪ **If *current node* is a [Text node](#)**

If the parent of *current node* is a [style](#)^{p180}, [script](#)^{p624}, [xmp](#)^{p1258}, [iframe](#)^{p369}, [noembed](#)^{p1257}, [noframes](#)^{p1257}, or [plaintext](#)^{p1257} element, or if the parent of *current node* is a [noscript](#)^{p638} element and [scripting is enabled](#)^{p944} for the node, then append the value of *current node*'s [data](#) literally.

Otherwise, append the value of *current node*'s [data](#), [escaped as described below](#)^{p1206}.

↪ **If *current node* is a [Comment](#)**

Append the literal string "<!--" (U+003C LESS-THAN SIGN, U+0021 EXCLAMATION MARK, U+002D HYPHEN-MINUS, U+002D HYPHEN-MINUS), followed by the value of *current node*'s [data](#), followed by the literal string "-->" (U+002D HYPHEN-MINUS, U+002D HYPHEN-MINUS, U+003E GREATER-THAN SIGN).

↪ **If *current node* is a [ProcessingInstruction](#)**

Append the literal string "<?" (U+003C LESS-THAN SIGN, U+003F QUESTION MARK), followed by the value of *current node*'s [target](#) IDL attribute, followed by a single U+0020 SPACE character, followed by the value of *current node*'s [data](#), followed by a single U+003E GREATER-THAN SIGN character (>).

↪ **If *current node* is a [DocumentType](#)**

Append the literal string "<!DOCTYPE" (U+003C LESS-THAN SIGN, U+0021 EXCLAMATION MARK, U+0044 LATIN CAPITAL LETTER D, U+004F LATIN CAPITAL LETTER O, U+0043 LATIN CAPITAL LETTER C, U+0054 LATIN CAPITAL LETTER T, U+0059 LATIN CAPITAL LETTER Y, U+0050 LATIN CAPITAL LETTER P, U+0045 LATIN CAPITAL LETTER E), followed by a space (U+0020 SPACE), followed by the value of *current node*'s [name](#), followed by the literal string ">" (U+003E GREATER-THAN SIGN).

5. Return *s*.

⚠Warning!

It is possible that the output of this algorithm, if parsed with an [HTML parser](#)^{p1106}, will not return the original tree structure. Tree structures that do not roundtrip a serialize and reparse step can also be produced by the [HTML parser](#)^{p1106} itself, although such cases are typically non-conforming.

Example

For instance, if a [textarea](#)^{p558} element to which a [Comment](#) node has been appended is serialized and the output is then reparsed, the comment will end up being displayed in the text control. Similarly, if, as a result of DOM manipulation, an element contains a comment that contains the literal string "-->", then when the result of serializing the element is parsed, the comment will be

truncated at that point and the rest of the comment will be interpreted as markup. More examples would be making a [script](#)^{p624} element contain a [Text](#) node with the text string "</script>", or having a [p](#)^{p218} element that contains a [ul](#)^{p228} element (as the [ul](#)^{p228} element's [start tag](#)^{p1096} would imply the end tag for the [p](#)^{p218}).

This can enable cross-site scripting attacks. An example of this would be a page that lets the user enter some font family names that are then inserted into a CSS [style](#)^{p180} block via the DOM and which then uses the [innerHTML](#) IDL attribute to get the HTML serialization of that [style](#)^{p180} element: if the user enters "</style><script>attack</script>" as a font family name, [innerHTML](#) will return markup that, if parsed in a different context, would contain a [script](#)^{p624} node, even though no [script](#)^{p624} node existed in the original DOM.

Example

For example, consider the following markup:

```
<form id="outer"><div></form><form id="inner"><input>
```

This will be parsed into:

```
└─ htmlp157
  └─ headp158
  └─ bodyp184
    └─ formp494 idp141="outer"
      └─ divp243
        └─ formp494 idp141="inner"
          └─ inputp501
```

The [input](#)^{p501} element will be associated with the inner [form](#)^{p494} element. Now, if this tree structure is serialized and reparsed, the `<form id="inner">` start tag will be ignored, and so the [input](#)^{p501} element will be associated with the outer [form](#)^{p494} element instead.

```
<html><head></head><body><form id="outer"><div><form
id="inner"><input></form></div></form></body></html>
```

```
└─ htmlp157
  └─ headp158
  └─ bodyp184
    └─ formp494 idp141="outer"
      └─ divp243
        └─ inputp501
```

Example

As another example, consider the following markup:

```
<a><table><a>
```

This will be parsed into:

```
└─ htmlp157
  └─ headp158
  └─ bodyp184
    └─ ap244
      └─ ap244
        └─ tablep458
```

That is, the [a](#)^{p244} elements are nested, because the second [a](#)^{p244} element is [foster parented](#)^{p1153}. After a serialize-reparse roundtrip, the [a](#)^{p244} elements and the [table](#)^{p458} element would all be siblings, because the second `<a>` start tag implicitly closes the first [a](#)^{p244} element.

```
<html><head></head><body><a><a></a><table></table></a></body></html>
```

For historical reasons, this algorithm does not round-trip an initial U+000A LINE FEED (LF) character in [pre](#)^{p222}, [textarea](#)^{p558}, or [listing](#)^{p1257} elements, even though (in the first two cases) the markup being round-tripped can be conforming. The [HTML parser](#)^{p1106} will drop such a character during parsing, but this algorithm does *not* serialize an extra U+000A LINE FEED (LF) character.

Example

For example, consider the following markup:

```
<pre>
Hello.</pre>
```

When this document is first parsed, the [pre](#)^{p222} element's [child text content](#) starts with a single newline character. After a serialize-reparse roundtrip, the [pre](#)^{p222} element's [child text content](#) is simply "Hello.".

Because of the special role of the [is](#)^{p728} attribute in signaling the creation of [customized built-in elements](#)^{p728}, in that it provides a mechanism for parsed HTML to set the element's [is value](#), we special-case its handling during serialization. This ensures that an element's [is value](#) is preserved through serialize-parse roundtrips.

Example

When creating a [customized built-in element](#)^{p728} via the parser, a developer uses the [is](#)^{p728} attribute directly; in such cases serialize-parse roundtrips work fine.

```
<script>
window.SuperP = class extends HTMLParagraphElement {};
customElements.define("super-p", SuperP, { extends: "p" });
</script>

<div id="container"><p is="super-p">Superb!</p></div>

<script>
console.log(container.innerHTML); // <p is="super-p">
container.innerHTML = container.innerHTML;
console.log(container.innerHTML); // <p is="super-p">
console.assert(container.firstChild instanceof SuperP);
</script>
```

But when creating a customized built-in element via its [constructor](#)^{p728} or via [createElement\(\)](#), the [is](#)^{p728} attribute is not added. Instead, the [is value](#) (which is what the custom elements machinery uses) is set without intermediating through an attribute.

```
<script>
container.innerHTML = "";
const p = document.createElement("p", { is: "super-p" });
container.appendChild(p);

// The is attribute is not present in the DOM:
console.assert(!p.hasAttribute("is"));

// But the element is still a super-p:
console.assert(p instanceof SuperP);
</script>
```

To ensure that serialize-parse roundtrips still work, the serialization process explicitly writes out the element's `is_value` as an `is`^{p728} attribute:

```
<script>
console.log(container.innerHTML); // <p is="super-p">
container.innerHTML = container.innerHTML;
console.log(container.innerHTML); // <p is="super-p">
console.assert(container.firstChild instanceof SuperP);
</script>
```

Escaping a string (for the purposes of the algorithm above) consists of running the following steps:

1. Replace any occurrence of the "&" character by the string "&";
2. Replace any occurrences of the U+00A0 NO-BREAK SPACE character by the string " ";
3. If the algorithm was invoked in the *attribute mode*, replace any occurrences of the "\"" character by the string """;
4. If the algorithm was *not* invoked in the *attribute mode*, replace any occurrences of the "<" character by the string "<"; and any occurrences of the ">" character by the string ">";

13.4 Parsing HTML fragments §^{p12}₀₆

The following steps form the **HTML fragment parsing algorithm**. The algorithm takes as input an `Element` node, referred to as the **context** element, which gives the context for the parser, as well as *input*, a string to parse, and returns a list of zero or more nodes.

Note

*Parts marked **fragment case** in algorithms in the parser section are parts that only occur if the parser was created for the purposes of this algorithm. The algorithms have been annotated with such markings for informational purposes only; such markings have no normative weight. If it is possible for a condition described as a **fragment case**^{p1206} to occur even when the parser wasn't created for the purposes of handling this algorithm, then that is an error in the specification.*

1. Create a new `Document`^{p117} node, and mark it as being an `HTML document`.
2. If the `node document` of the `context`^{p1206} element is in `quirks mode`, then let the `Document`^{p117} be in `quirks mode`. Otherwise, the `node document` of the `context`^{p1206} element is in `limited-quirks mode`, then let the `Document`^{p117} be in `limited-quirks mode`. Otherwise, leave the `Document`^{p117} in `no-quirks mode`.
3. Create a new `HTML parser`^{p1106}, and associate it with the just created `Document`^{p117} node.
4. Set the state of the `HTML parser`^{p1106}'s `tokenization`^{p1124} stage as follows, switching on the `context`^{p1206} element:

↪ `title`^{p159}

↪ `textarea`^{p558}

Switch the tokenizer to the `RCDATA state`^{p1126}.

↪ `style`^{p180}

↪ `xmp`^{p1258}

↪ `iframe`^{p369}

↪ `noembed`^{p1257}

↪ `noframes`^{p1257}

Switch the tokenizer to the `RAWTEXT state`^{p1126}.

↪ `script`^{p624}

Switch the tokenizer to the `script data state`^{p1126}.

↪ `noscript`^{p638}

If the `scripting flag`^{p1124} is enabled, switch the tokenizer to the `RAWTEXT state`^{p1126}. Otherwise, leave the tokenizer in

the [data state](#)^{p1125}.

↳ [plaintext](#)^{p1257}

Switch the tokenizer to the [PLAINTEXT state](#)^{p1127}.

↳ **Any other element**

Leave the tokenizer in the [data state](#)^{p1125}.

Note

For performance reasons, an implementation that does not report errors and that uses the actual state machine described in this specification directly could use the PLAINTEXT state instead of the RAWTEXT and script data states where those are mentioned in the list above. Except for rules regarding parse errors, they are equivalent, since there is no [appropriate end tag token](#)^{p1125} in the fragment case, yet they involve far fewer state transitions.

- Let *root* be a new [html](#)^{p157} element with no attributes.
- Append the element *root* to the [Document](#)^{p117} node created above.
- Set up the parser's [stack of open elements](#)^{p1121} so that it contains just the single element *root*.
- If the [context](#)^{p1206} element is a [template](#)^{p640} element, push "[in template](#)^{p1186}" onto the [stack of template insertion modes](#)^{p1120} so that it is the new [current template insertion mode](#)^{p1120}.
- Create a start tag token whose name is the local name of [context](#)^{p1206} and whose attributes are the attributes of [context](#)^{p1206}.
Let this start tag token be the start tag token of the [context](#)^{p1206} node, e.g. for the purposes of determining if it is an [HTML integration point](#)^{p1153}.
- [Reset the parser's insertion mode appropriately](#)^{p1120}.

Note

The parser will reference the [context](#)^{p1206} element as part of that algorithm.

- Set the parser's [form element pointer](#)^{p1124} to the nearest node to the [context](#)^{p1206} element that is a [form](#)^{p494} element (going straight up the ancestor chain, and including the element itself, if it is a [form](#)^{p494} element), if any. (If there is no such [form](#)^{p494} element, the [form element pointer](#)^{p1124} keeps its initial value, null.)
- Place the *input* into the [input stream](#)^{p1119} for the [HTML parser](#)^{p1106} just created. The encoding [confidence](#)^{p1113} is *irrelevant*.
- Start the parser and let it run until it has consumed all the characters just inserted into the input stream.
- Return the child nodes of *root*, in [tree order](#).

13.5 Named character references §^{p12} 07

This table lists the character reference names that are supported by HTML, and the code points to which they refer. It is referenced by the previous sections.

Note

It is intentional, for legacy compatibility, that many code points have multiple character reference names. For example, some appear both with and without the trailing semicolon, or with different capitalizations.

This data is also available [as a JSON file](#).

The glyphs displayed above are non-normative. Refer to Unicode for formal definitions of the characters listed above.

Note

The character reference names originate from XML Entity Definitions for Characters, though only the above is considered normative. [\[XMLENTITY\]](#)^{p1313}

Note

*This list is static and **will not be expanded or changed in the future**.*

14 The XML syntax §^{p12} 17

Note

This section only describes the rules for XML resources. Rules for [text/html^{p1275}](#) resources are discussed in the section above entitled "[The HTML syntax^{p1094}](#)".

14.1 Writing documents in the XML syntax §^{p12} 17

Note

The XML syntax for HTML was formerly referred to as "XHTML", but this specification does not use that term (among other reasons, because no such term is used for the HTML syntaxes of MathML and SVG).

The syntax for XML is defined in *XML and Namespaces in XML*. [\[XML\]^{p1313}](#) [\[XMLNS\]^{p1313}](#)

This specification does not define any syntax-level requirements beyond those defined for XML proper.

XML documents may contain a DOCTYPE if desired, but this is not required to conform to this specification. This specification does not define a public or system identifier, nor provide a formal DTD.

Note

According to XML, XML processors are not guaranteed to process the external DTD subset referenced in the DOCTYPE. This means, for example, that using [entity references](#) for characters in XML documents is unsafe if they are defined in an external file (except for <, >, &, ", and ').

14.2 Parsing XML documents §^{p12} 17

This section describes the relationship between XML and the DOM, with a particular emphasis on how this interacts with HTML.

An **XML parser**, for the purposes of this specification, is a construct that follows the rules given in *XML* to map a string of bytes or characters into a [Document^{p117}](#) object.

Note

At the time of writing, no such rules actually exist.

An [XML parser^{p1217}](#) is either associated with a [Document^{p117}](#) object when it is created, or creates one implicitly.

This [Document^{p117}](#) must then be populated with DOM nodes that represent the tree structure of the input passed to the parser, as defined by *XML*, *Namespaces in XML*, and *DOM*. When creating DOM nodes representing elements, the [create an element for a token^{p1154}](#) algorithm or some equivalent that operates on appropriate XML data structures must be used, to ensure the proper [element interfaces](#) are created and that [custom elements^{p728}](#) are set up correctly.

DOM mutation events must not fire for the operations that the [XML parser^{p1217}](#) performs on the [Document^{p117}](#)'s tree, but the user agent must act as if elements and attributes were individually appended and set respectively so as to trigger rules in this specification regarding what happens when an element is inserted into a document or has its attributes set, and *DOM*'s requirements regarding [mutation observers](#) mean that mutation observers are fired (unlike mutation events). [\[XML\]^{p1313}](#) [\[XMLNS\]^{p1313}](#) [\[DOM\]^{p1307}](#) [\[UIEVENTS\]^{p1312}](#)

Between the time an element's start tag is parsed and the time either the element's end tag is parsed or the parser detects a well-formedness error, the user agent must act as if the element was in a [stack of open elements^{p1121}](#).

Note

This is used, e.g. by the [object^{p381}](#) element to avoid instantiating plugins before the [param^{p387}](#) element children have been parsed.

This specification provides the following additional information that user agents should use when retrieving an external entity: the public identifiers given in the following list all correspond to [the URL given by this link](#). (This URL is a DTD containing the [entity declarations](#) for the names listed in the [named character references^{p1207}](#) section.) [\[XML\]^{p1313}](#)

- `--W3C//DTD XHTML 1.0 Transitional//EN`
- `--W3C//DTD XHTML 1.1//EN`
- `--W3C//DTD XHTML 1.0 Strict//EN`
- `--W3C//DTD XHTML 1.0 Frameset//EN`
- `--W3C//DTD XHTML Basic 1.0//EN`
- `--W3C//DTD XHTML 1.1 plus MathML 2.0//EN`
- `--W3C//DTD XHTML 1.1 plus MathML 2.0 plus SVG 1.1//EN`
- `--W3C//DTD MathML 2.0//EN`
- `--WAPFORUM//DTD XHTML Mobile 1.0//EN`

Furthermore, user agents should attempt to retrieve the above external entity's content when one of the above public identifiers is used, and should not attempt to retrieve any other external entity's content.

Note

This is not strictly a [violation^{p27}](#) of XML, but it does contradict the spirit of XML's requirements. This is motivated by a desire for user agents to all handle entities in an interoperable fashion without requiring any network access for handling external subsets. [\[XML\]^{p1313}](#)

XML parsers can be invoked with **XML scripting support enabled** or **XML scripting support disabled**. Except where otherwise specified, XML parsers are invoked with [XML scripting support enabled^{p1218}](#).

When an [XML parser^{p1217}](#) with [XML scripting support enabled^{p1218}](#) creates a [script^{p624}](#) element, it must have its [parser document^{p630}](#) set and its `"non-blocking"p630` flag must be unset. If the parser was created as part of the [XML fragment parsing algorithm^{p1220}](#), then the element must be marked as `"already started"p630` also. When the element's end tag is subsequently parsed, the user agent must [perform a microtask checkpoint^{p974}](#), and then [prepare^{p630}](#) the [script^{p624}](#) element. If this causes there to be a [pending parsing-blocking script^{p634}](#), then the user agent must run the following steps:

1. Block this instance of the [XML parser^{p1217}](#), such that the [event loop^{p968}](#) will not run [tasks^{p969}](#) that invoke it.
2. [Spin the event loop^{p975}](#) until the parser's [Document^{p117}](#) [has no style sheet that is blocking scripts^{p184}](#) and the [pending parsing-blocking script^{p634}](#)'s `"ready to be parser-executed"p630` flag is set.
3. Unblock this instance of the [XML parser^{p1217}](#), such that [tasks^{p969}](#) that invoke it can again be run.
4. [Execute^{p634}](#) the [pending parsing-blocking script^{p634}](#).
5. There is no longer a [pending parsing-blocking script^{p634}](#).

Note

Since the [document.write\(\)^{p996}](#) API is not available for XML documents, much of the complexity in the [HTML parser^{p1106}](#) is not needed in the [XML parser^{p1217}](#).

Note

When the [XML parser^{p1217}](#) has [XML scripting support disabled^{p1218}](#), none of this happens.

When an [XML parser^{p1217}](#) would append a node to a [template^{p640}](#) element, it must instead append it to the [template^{p640}](#) element's [template contents^{p642}](#) (a `DocumentFragment` node).

Note

This is a [willful violation^{p27}](#) of XML; unfortunately, XML is not formally extensible in the manner that is needed for [template^{p640}](#) processing. [\[XML\]^{p1313}](#)

When an [XML parser^{p1217}](#) creates a `Node` object, its `node document` must be set to the `node document` of the node into which the newly created node is to be inserted.

Certain algorithms in this specification **spoon-feed the parser** characters one string at a time. In such cases, the [XML parser^{p1217}](#)

must act as it would have if faced with a single string consisting of the concatenation of all those characters.

When an [XML parser](#)^{p1217} reaches the end of its input, it must [stop parsing](#)^{p1192}, following the same rules as the [HTML parser](#)^{p1106}. An [XML parser](#)^{p1217} can also be [aborted](#)^{p1193}, which must again be done in the same way as for an [HTML parser](#)^{p1106}.

For the purposes of conformance checkers, if a resource is determined to be in [the XML syntax](#)^{p1217}, then it is an [XML document](#).

14.3 Serializing XML fragments §^{p12} 19

The **XML fragment serialization algorithm** for a [Document](#)^{p117} or [Element](#) node either returns a fragment of XML that represents that node or throws an exception.

For [Document](#)^{p117}s, the algorithm must return a string in the form of a [document entity](#), if none of the error cases below apply.

For [Element](#)s, the algorithm must return a string in the form of an [internal general parsed entity](#), if none of the error cases below apply.

In both cases, the string returned must be XML namespace-well-formed and must be an isomorphic serialization of all of that node's [relevant child nodes](#)^{p1219}, in [tree order](#). User agents may adjust prefixes and namespace declarations in the serialization (and indeed might be forced to do so in some cases to obtain namespace-well-formed XML). User agents may use a combination of regular text and character references to represent [Text](#) nodes in the DOM.

A node's **relevant child nodes** are those that apply given the following rules:

For [template](#)^{p640} elements

The [relevant child nodes](#)^{p1219} are the child nodes of the [template](#)^{p640} element's [template contents](#)^{p642}, if any.

For all other nodes

The [relevant child nodes](#)^{p1219} are the child nodes of node itself, if any.

For [Element](#)s, if any of the elements in the serialization are in no namespace, the default namespace in scope for those elements must be explicitly declared as the empty string. (This doesn't apply in the [Document](#)^{p117} case.) [\[XML\]](#)^{p1313} [\[XMLNS\]](#)^{p1313}

For the purposes of this section, an internal general parsed entity is considered XML namespace-well-formed if a document consisting of an element with no namespace declarations whose contents are the internal general parsed entity would itself be XML namespace-well-formed.

If any of the following error cases are found in the DOM subtree being serialized, then the algorithm must throw an ["InvalidStateError" DOMException](#) instead of returning a string:

- A [Document](#)^{p117} node with no child element nodes.
- A [DocumentType](#) node that has an external subset public identifier that contains characters that are not matched by the XML PubidChar production. [\[XML\]](#)^{p1313}
- A [DocumentType](#) node that has an external subset system identifier that contains both a U+0022 QUOTATION MARK (") and a U+0027 APOSTROPHE (') or that contains characters that are not matched by the XML Char production. [\[XML\]](#)^{p1313}
- A node with a local name containing a U+003A COLON (:).
- A node with a local name that does not match the XML [Name](#) production. [\[XML\]](#)^{p1313}
- An [Attr](#) node with no namespace whose local name is the lowercase string "xml:ns". [\[XMLNS\]](#)^{p1313}
- An [Element](#) node with two or more attributes with the same local name and namespace.
- An [Attr](#) node, [Text](#) node, [Comment](#) node, or [ProcessingInstruction](#) node whose data contains characters that are not matched by the XML Char production. [\[XML\]](#)^{p1313}
- A [Comment](#) node whose data contains two adjacent U+002D HYPHEN-MINUS characters (-) or ends with such a character.
- A [ProcessingInstruction](#) node whose target name is an [ASCII case-insensitive](#) match for the string "xml".
- A [ProcessingInstruction](#) node whose target name contains a U+003A COLON (:).
- A [ProcessingInstruction](#) node whose data contains the string ">".

Note

These are the only ways to make a DOM unserialisable. The DOM enforces all the other XML constraints; for example, trying to append two elements to a [Document^{p117}](#) node will throw a ["HierarchyRequestError" DOMException](#).

14.4 Parsing XML fragments §^{p12}₂₀

The **XML fragment parsing algorithm** either returns a [Document^{p117}](#) or throws a ["SyntaxError" DOMException](#). Given a string *input* and a context element [context^{p1206}](#), the algorithm is as follows:

1. Create a new [XML parser^{p1217}](#).
2. [Feed the parser^{p1218}](#) just created the string corresponding to the start tag of the [context^{p1206}](#) element, declaring all the namespace prefixes that are in scope on that element in the DOM, as well as declaring the default namespace (if any) that is in scope on that element in the DOM.

A namespace prefix is in scope if the DOM `lookupNamespaceURI()` method on the element would return a non-null value for that prefix.

The default namespace is the namespace for which the DOM `isDefaultNamespace()` method on the element would return true.

Note

No DOCTYPE is passed to the parser, and therefore no external subset is referenced, and therefore no entities will be recognized.

3. [Feed the parser^{p1218}](#) just created the string *input*.
4. [Feed the parser^{p1218}](#) just created the string corresponding to the end tag of the [context^{p1206}](#) element.
5. If there is an XML well-formedness or XML namespace well-formedness error, then throw a ["SyntaxError" DOMException](#).
6. If the [document element](#) of the resulting [Document^{p117}](#) has any sibling nodes, then throw a ["SyntaxError" DOMException](#).
7. Return the child nodes of the [document element](#) of the resulting [Document^{p117}](#), in [tree order](#).

15 Rendering §^{p12}₂₁

User agents are not required to present HTML documents in any particular way. However, this section provides a set of suggestions for rendering HTML documents that, if followed, are likely to lead to a user experience that closely resembles the experience intended by the documents' authors. So as to avoid confusion regarding the normativity of this section, "must" has not been used. Instead, the term "expected" is used to indicate behavior that will lead to this experience. For the purposes of conformance for user agents designated as [supporting the suggested default rendering](#)^{p47}, the term "expected" in this section has the same conformance implications as "must".

15.1 Introduction §^{p12}₂₁

The suggestions in this section are generally expressed in CSS terms. User agents are expected to either support CSS, or translate from the CSS rules given in this section to approximations for other presentation mechanisms.

In the absence of style-layer rules to the contrary (e.g. author style sheets), user agents are expected to render an element so that it conveys to the user the meaning that the element [represents](#)^{p128}, as described by this specification.

The suggestions in this section generally assume a visual output medium with a resolution of 96dpi or greater, but HTML is intended to apply to multiple media (it is a *media-independent* language). User agent implementers are encouraged to adapt the suggestions in this section to their target media.

An element is **being rendered** if it has any associated CSS layout boxes, SVG layout boxes, or some equivalent in other styling languages.

Note

Just being off-screen does not mean the element is not [being rendered](#)^{p1221}. The presence of the [hidden](#)^{p792} attribute normally means the element is not [being rendered](#)^{p1221}, though this might be overridden by the style sheets.

Note

The [fully active](#)^{p844} state does not affect whether an element is [being rendered](#)^{p1221} or not. Even if a document is not [fully active](#)^{p844} and not shown at all to the user, elements within it can still qualify as "being rendered".

An element is said to **intersect the viewport** when it is [being rendered](#)^{p1221} and its associated CSS layout box intersects the [viewport](#).

Note

Similar to the [being rendered](#)^{p1221} state, elements in non-[fully active](#)^{p844} documents can still [intersect the viewport](#)^{p1221}. The [viewport](#) is not shared between documents and might not always be shown to the user, so an element in a non-[fully active](#)^{p844} document can still intersect the [viewport](#) associated with its document.

Note

This specification does not define the precise timing for when the intersection is tested, but it is suggested that the timing match that of the Intersection Observer API. [\[INTERSECTIONOBSERVER\]](#)^{p1308}

User agents that do not honor author-level CSS style sheets are nonetheless expected to act as if they applied the CSS rules given in these sections in a manner consistent with this specification and the relevant CSS and Unicode specifications. [\[CSS\]](#)^{p1305} [\[UNICODE\]](#)^{p1312} [\[BIDI\]](#)^{p1305}

Note

This is especially important for issues relating to the ['display'](#), ['unicode-bidi'](#), and ['direction'](#) properties.

15.2 The CSS user agent style sheet and presentational hints § p12 22

The CSS rules given in these subsections are, except where otherwise specified, expected to be used as part of the user-agent level style sheet defaults for all documents that contain [HTML elements](#)^{p44}.

Some rules are intended for the author-level zero-specificity presentational hints part of the CSS cascade; these are explicitly called out as **presentational hints**.

When the text below says that an attribute *attribute* on an element *element* **maps to the pixel length property** (or properties) *properties*, it means that if *element* has an attribute *attribute* set, and parsing that attribute's value using the [rules for parsing non-negative integers](#)^{p70} doesn't generate an error, then the user agent is expected to use the parsed value as a pixel length for a [presentational hint](#)^{p1222} for *properties*.

When the text below says that an attribute *attribute* on an element *element* **maps to the dimension property** (or properties) *properties*, it means that if *element* has an attribute *attribute* set, and parsing that attribute's value using the [rules for parsing dimension values](#)^{p73} doesn't generate an error, then the user agent is expected to use the parsed dimension as the value for a [presentational hint](#)^{p1222} for *properties*, with the value given as a pixel length if the dimension was a length, and with the value given as a percentage if the dimension was a percentage.

When the text below says that an attribute *attribute* on an element *element* **maps to the dimension property (ignoring zero)** (or properties) *properties*, it means that if *element* has an attribute *attribute* set, and parsing that attribute's value using the [rules for parsing nonzero dimension values](#)^{p73} doesn't generate an error, then the user agent is expected to use the parsed dimension as the value for a [presentational hint](#)^{p1222} for *properties*, with the value given as a pixel length if the dimension was a length, and with the value given as a percentage if the dimension was a percentage.

When the text below says that a pair of attributes *w* and *h* on an element *element* **map to the aspect-ratio property**, it means that if *element* has both attributes *w* and *h*, and parsing those attributes' values using the [rules for parsing non-negative integers](#)^{p70} doesn't generate an error for either, then the user agent is expected to use the parsed integers as a [presentational hint](#)^{p1222} for the '[aspect-ratio](#)' property of the form `auto w / h`.

When the text below says that a pair of attributes *w* and *h* on an element *element* **map to the aspect-ratio property (using dimension rules)**, it means that if *element* has both attributes *w* and *h*, and parsing those attributes' values using the [rules for parsing dimension values](#)^{p73} doesn't generate an error or return a percentage for either, then the user agent is expected to use the parsed dimensions as a [presentational hint](#)^{p1222} for the '[aspect-ratio](#)' property of the form `auto w / h`.

When a user agent is to **align descendants** of a node, the user agent is expected to align only those descendants that have both their '[margin-inline-start](#)' and '[margin-inline-end](#)' properties computing to a value other than 'auto', that are over-constrained and that have one of those two margins with a [used value](#) forced to a greater value, and that do not themselves have an applicable `align` attribute. When multiple elements are to [align](#)^{p1222} a particular descendant, the most deeply nested such element is expected to override the others. Aligned elements are expected to be aligned by having the [used values](#) of their margins on the [line-left](#) and [line-right](#) sides be set accordingly. [\[CSSLOGICAL\]](#)^{p1306} [\[CSSWM\]](#)^{p1307}

15.3 Non-replaced elements § p12 22

15.3.1 Hidden elements § p12 22

```
CSS @namespace url(http://www.w3.org/1999/xhtml);

[hidden], area, base, basefont, datalist, head, link, meta, noembed,
noframes, param, rp, script, style, template, title {
  display: none;
}

embed[hidden] { display: inline; height: 0; width: 0; }

input[type=hidden i] { display: none !important; }

@media (scripting) {
  noscript { display: none !important; }
```

```
}
```

15.3.2 The page §^{p12}₂₃

```
CSS @namespace url(http://www.w3.org/1999/xhtml);
html, body { display: block; }
```

For each property in the table below, given a [body^{p184}](#) element, the first attribute that exists [maps to the pixel length property^{p1222}](#) on the [body^{p184}](#) element. If none of the attributes for a property are found, or if the value of the attribute that was found cannot be parsed successfully, then a default value of 8px is expected to be used for that property instead.

Property	Source
'margin-top'	The body^{p184} element's marginheight^{p1261} attribute
	The body^{p184} element's topmargin^{p1261} attribute
	The body^{p184} element's container frame element^{p1223} 's marginheight^{p1261} attribute
'margin-right'	The body^{p184} element's marginwidth^{p1261} attribute
	The body^{p184} element's rightmargin^{p1261} attribute
	The body^{p184} element's container frame element^{p1223} 's marginwidth^{p1261} attribute
'margin-bottom'	The body^{p184} element's marginheight^{p1261} attribute
	The body^{p184} element's bottommargin^{p1261} attribute
	The body^{p184} element's container frame element^{p1223} 's marginheight^{p1261} attribute
'margin-left'	The body^{p184} element's marginwidth^{p1261} attribute
	The body^{p184} element's leftmargin^{p1261} attribute
	The body^{p184} element's container frame element^{p1223} 's marginwidth^{p1261} attribute

If the [body^{p184}](#) element's [node document](#)'s [browsing context^{p840}](#) is a [child browsing context^{p843}](#), and the [container^{p843}](#) of that [browsing context^{p840}](#) is a [frame^{p1264}](#) or [iframe^{p369}](#) element, then the **container frame element** of the [body^{p184}](#) element is that [frame^{p1264}](#) or [iframe^{p369}](#) element. Otherwise, there is no [container frame element^{p1223}](#).

⚠Warning!

The above requirements imply that a page can change the margins of another page (including one from another origin^{p868}) using, for example, an [iframe^{p369}](#). This is potentially a security risk, as it might in some cases allow an attack to contrive a situation in which a page is rendered not as the author intended, possibly for the purposes of phishing or otherwise misleading the user.

If a [Document^{p117}](#)'s [browsing context^{p840}](#) is a [child browsing context^{p843}](#), then it is expected to be positioned and sized to fit inside the [content box](#) of the [container^{p843}](#) of that [browsing context^{p840}](#). If the [container^{p843}](#) is not [being rendered^{p1221}](#), the [browsing context^{p840}](#) is expected to have a [viewport](#) with zero width and zero height.

If a [Document^{p117}](#)'s [browsing context^{p840}](#) is a [child browsing context^{p843}](#), the [container^{p843}](#) of that [browsing context^{p840}](#) is a [frame^{p1264}](#) or [iframe^{p369}](#) element, that element has a `scrolling` attribute, and that attribute's value is an [ASCII case-insensitive](#) match for the string "off", "noscroll", or "no", then the user agent is expected to prevent any scrollbars from being shown for the [viewport](#) of the [Document^{p117}](#)'s [browsing context^{p840}](#), regardless of the `overflow` property that applies to that [viewport](#).

When a [body^{p184}](#) element has a [background^{p1262}](#) attribute set to a non-empty value, the new value is expected to be [parsed^{p91}](#) relative to the element's [node document](#), and if this is successful, the user agent is expected to treat the attribute as a [presentational hint^{p1222}](#) setting the element's `'background-image'` property to the [resulting URL string^{p91}](#).

When a [body^{p184}](#) element has a [bgcolor^{p1261}](#) attribute set, the new value is expected to be parsed using the [rules for parsing a legacy color value^{p88}](#), and if that does not return an error, the user agent is expected to treat the attribute as a [presentational hint^{p1222}](#) setting the element's `'background-color'` property to the resulting color.

When a [body^{p184}](#) element has a [text^{p1261}](#) attribute, its value is expected to be parsed using the [rules for parsing a legacy color value^{p88}](#), and if that does not return an error, the user agent is expected to treat the attribute as a [presentational hint^{p1222}](#) setting the element's

'color' property to the resulting color.

When a [body^{p184}](#) element has a [link^{p1261}](#) attribute, its value is expected to be parsed using the [rules for parsing a legacy color value^{p88}](#), and if that does not return an error, the user agent is expected to treat the attribute as a [presentational hint^{p1222}](#) setting the 'color' property of any element in the [Document^{p117}](#) matching the [:link^{p751}](#) pseudo-class to the resulting color.

When a [body^{p184}](#) element has a [vlink^{p1261}](#) attribute, its value is expected to be parsed using the [rules for parsing a legacy color value^{p88}](#), and if that does not return an error, the user agent is expected to treat the attribute as a [presentational hint^{p1222}](#) setting the 'color' property of any element in the [Document^{p117}](#) matching the [:visited^{p751}](#) pseudo-class to the resulting color.

When a [body^{p184}](#) element has an [alink^{p1261}](#) attribute, its value is expected to be parsed using the [rules for parsing a legacy color value^{p88}](#), and if that does not return an error, the user agent is expected to treat the attribute as a [presentational hint^{p1222}](#) setting the 'color' property of any element in the [Document^{p117}](#) matching the [:active^{p751}](#) pseudo-class and either the [:link^{p751}](#) pseudo-class or the [:visited^{p751}](#) pseudo-class to the resulting color.

15.3.3 Flow content §^{p12} 24

```
CSS @namespace url(http://www.w3.org/1999/xhtml);

address, blockquote, center, dialog, div, figure, figcaption, footer, form,
header, hr, legend, listing, main, p, plaintext, pre, xmp {
  display: block;
}

blockquote, figure, listing, p, plaintext, pre, xmp {
  margin-block-start: 1em; margin-block-end: 1em;
}

blockquote, figure { margin-inline-start: 40px; margin-inline-end: 40px; }

address { font-style: italic; }
listing, plaintext, pre, xmp {
  font-family: monospace; white-space: pre;
}

dialog:not([open]) { display: none; }
dialog {
  position: absolute;
  inset-inline-start: 0; inset-inline-end: 0;
  width: fit-content;
  height: fit-content;
  margin: auto;
  border: solid;
  padding: 1em;
  background: white;
  color: black;
}
dialog::backdrop {
  background: rgba(0,0,0,0.1);
}

slot {
  display: contents;
}
```

The following rules are also expected to apply, as [presentational hints^{p1222}](#):

```
CSS @namespace url(http://www.w3.org/1999/xhtml);

pre[wrap] { white-space: pre-wrap; }
```

In [quirks mode](#), the following rules are also expected to apply:

```
CSS @namespace url(http://www.w3.org/1999/xhtml);  
form { margin-block-end: 1em; }
```

The [center](#)^{p1258} element, and the [div](#)^{p243} element when it has an [align](#)^{p1261} attribute whose value is an [ASCII case-insensitive](#) match for either the string "center" or the string "middle", are expected to center text within themselves, as if they had their ['text-align'](#) property set to 'center' in a [presentational hint](#)^{p1222}, and to [align descendants](#)^{p1222} to the center.

The [div](#)^{p243} element, when it has an [align](#)^{p1261} attribute whose value is an [ASCII case-insensitive](#) match for the string "left", is expected to left-align text within itself, as if it had its ['text-align'](#) property set to 'left' in a [presentational hint](#)^{p1222}, and to [align descendants](#)^{p1222} to the left.

The [div](#)^{p243} element, when it has an [align](#)^{p1261} attribute whose value is an [ASCII case-insensitive](#) match for the string "right", is expected to right-align text within itself, as if it had its ['text-align'](#) property set to 'right' in a [presentational hint](#)^{p1222}, and to [align descendants](#)^{p1222} to the right.

The [div](#)^{p243} element, when it has an [align](#)^{p1261} attribute whose value is an [ASCII case-insensitive](#) match for the string "justify", is expected to full-justify text within itself, as if it had its ['text-align'](#) property set to 'justify' in a [presentational hint](#)^{p1222}, and to [align descendants](#)^{p1222} to the left.

The [dialog](#)^{p620} element, when its [is modal](#)^{p623} flag is true, is expected to act as if it had a user-agent-level style sheet rule setting the following properties:

- ['position'](#) property to 'fixed'
- ['overflow'](#) property to 'auto'
- ['inset-block-start'](#) property to '0'
- ['inset-block-end'](#) property to '0'
- ['max-width'](#) property to 'calc(100% - 6px - 2em)'
- ['max-height'](#) property to 'calc(100% - 6px - 2em)'

15.3.4 Phrasing content §^{p12}₂₅

```
CSS @namespace url(http://www.w3.org/1999/xhtml);  
  
cite, dfn, em, i, var { font-style: italic; }  
b, strong { font-weight: bolder; }  
code, kbd, samp, tt { font-family: monospace; }  
big { font-size: larger; }  
small { font-size: smaller; }  
  
sub { vertical-align: sub; }  
sup { vertical-align: super; }  
sub, sup { line-height: normal; font-size: smaller; }  
  
ruby { display: ruby; }  
rt { display: ruby-text; }

:visited { color: #551A8B; }  
:link:active, :visited:active { color: #FF0000; }  
:link, :visited { text-decoration: underline; cursor: pointer; }  
  
:focus-visible { outline: auto; }
```

```

mark { background: yellow; color: black; } /* this color is just a suggestion and can be changed based
on implementation feedback */

abbr[title], acronym[title] { text-decoration: dotted underline; }
ins, u { text-decoration: underline; }
del, s, strike { text-decoration: line-through; }

q::before { content: open-quote; }
q::after { content: close-quote; }

br { display-outside: newline; } /* this also has bidi implications */
noabr { white-space: nowrap; }
wbr { display-outside: break-opportunity; } /* this also has bidi implications */
noabr wbr { white-space: normal; }

```

The following rules are also expected to apply, as [presentational hints](#)^{p1222}:

```

CSS @namespace url(http://www.w3.org/1999/xhtml);

br[clear=left i] { clear: left; }
br[clear=right i] { clear: right; }
br[clear=all i], br[clear=both i] { clear: both; }

```

For the purposes of the CSS ruby model, runs of children of [ruby](#)^{p258} elements that are not [rt](#)^{p264} or [rp](#)^{p264} elements are expected to be wrapped in anonymous boxes whose `'display'` property has the value `'ruby-base'`. [\[CSSRUBY\]](#)^{p1307}

When a particular part of a ruby has more than one annotation, the annotations should be distributed on both sides of the base text so as to minimize the stacking of ruby annotations on one side.

Note

When it becomes possible to do so, the preceding requirement will be updated to be expressed in terms of CSS ruby. (Currently, CSS ruby does not handle nested [ruby](#)^{p258} elements or multiple sequential [rt](#)^{p264} elements, which is how this semantic is expressed.)

User agents that do not support correct ruby rendering are expected to render parentheses around the text of [rt](#)^{p264} elements in the absence of [rp](#)^{p264} elements.

User agents are expected to support the `'clear'` property on inline elements (in order to render [br](#)^{p286} elements with [clear](#)^{p1261} attributes) in the manner described in the non-normative note to this effect in CSS.

The initial value for the `'color'` property is expected to be black. The initial value for the `'background-color'` property is expected to be 'transparent'. The canvas's background is expected to be white.

When a [font](#)^{p1258} element has a `color` attribute, its value is expected to be parsed using the [rules for parsing a legacy color value](#)^{p88}, and if that does not return an error, the user agent is expected to treat the attribute as a [presentational hint](#)^{p1222} setting the element's `'color'` property to the resulting color.

The [font](#)^{p1258} element is expected to override the color of any text decoration that spans the text of the element to the [used value](#) of the element's `'color'` property.

When a [font](#)^{p1258} element has a `face` attribute, the user agent is expected to treat the attribute as a [presentational hint](#)^{p1222} setting the element's `'font-family'` property to the attribute's value.

When a [font](#)^{p1258} element has a `size` attribute, the user agent is expected to use the following steps, known as the **rules for parsing a legacy font size**, to treat the attribute as a [presentational hint](#)^{p1222} setting the element's `'font-size'` property:

1. Let *input* be the attribute's value.
2. Let *position* be a pointer into *input*, initially pointing at the start of the string.

3. [Skip ASCII whitespace](#) within *input* given *position*.
4. If *position* is past the end of *input*, there is no [presentational hint](#)^{p1222}. Return.
5. If the character at *position* is a U+002B PLUS SIGN character (+), then let *mode* be *relative-plus*, and advance *position* to the next character. Otherwise, if the character at *position* is a U+002D HYPHEN-MINUS character (-), then let *mode* be *relative-minus*, and advance *position* to the next character. Otherwise, let *mode* be *absolute*.
6. [Collect a sequence of code points](#) that are [ASCII digits](#) from *input* given *position*, and let the resulting sequence be *digits*.
7. If *digits* is the empty string, there is no [presentational hint](#)^{p1222}. Return.
8. Interpret *digits* as a base-ten integer. Let *value* be the resulting number.
9. If *mode* is *relative-plus*, then increment *value* by 3. If *mode* is *relative-minus*, then let *value* be the result of subtracting *value* from 3.
10. If *value* is greater than 7, let it be 7.
11. If *value* is less than 1, let it be 1.
12. Set `'font-size'` to the keyword corresponding to the value of *value* according to the following table:

value	'font-size' keyword
1	'x-small'
2	'small'
3	'medium'
4	'large'
5	'x-large'
6	'xx-large'
7	'xxx-large'

15.3.5 Bidirectional text §^{p12} 27

```

CSS @namespace url(http://www.w3.org/1999/xhtml);

[dir]:dir(ltr), bdi:dir(ltr), input[type=tel i]:dir(ltr) { direction: ltr; }
[dir]:dir rtl, bdi:dir rtl) { direction: rtl; }

address, blockquote, center, div, figure, figcaption, footer, form, header, hr,
legend, listing, main, p, plaintext, pre, summary, xmp, article, aside, h1, h2,
h3, h4, h5, h6, hgroup, nav, section, table, caption, colgroup, col, thead,
tbody, tfoot, tr, td, th, dir, dd, dl, dt, menu, ol, ul, li, bdi, output,
[dir=ltr i], [dir=rtl i], [dir=auto i] {
  unicode-bidi: isolate;
}

bdo, bdo[dir] { unicode-bidi: isolate-override; }

input[dir=auto i]:is([type=search i], [type=tel i], [type=url i],
[type=email i]), textarea[dir=auto i], pre[dir=auto i] {
  unicode-bidi: plaintext;
}
/* see prose for input elements whose type attribute is in the Text state */

/* the rules setting the 'content' property on br and wbr elements also has bidi implications */

```

When an [input](#)^{p501} element's [dir](#)^{p146} attribute is in the [auto](#)^{p146} state and its [type](#)^{p503} attribute is in the [Text](#)^{p508} state, then the user agent is expected to act as if it had a user-agent-level style sheet rule setting the `'unicode-bidi'` property to 'plaintext'.

Input fields (i.e. [textarea](#)^{p558} elements, and [input](#)^{p501} elements when their [type](#)^{p503} attribute is in the [Text](#)^{p508}, [Search](#)^{p508}, [Telephone](#)^{p508}, [URL](#)^{p509}, or [Email](#)^{p510} state) are expected to present an editing user interface with a directionality that matches the

element's `direction` property.

When the document's character encoding is [ISO-8859-8](#), the following rules are additionally expected to apply, following those above: [\[ENCODING\]](#)^{p1307}

```
CSS @namespace url(http://www.w3.org/1999/xhtml);

address, blockquote, center, div, figure, figcaption, footer, form, header, hr,

h3, h4, h5, h6, hgroup, nav, section, table, caption, colgroup, col, thead,
tbody, tfoot, tr, td, th, dir, dd, dl, dt, menu, ol, ul, li, [dir=ltr i],
[dir=rtl i], [dir=auto i], *|* {
  unicode-bidi: bidi-override;
}
input:not([type=submit i]):not([type=reset i]):not([type=button i]),
textarea {
  unicode-bidi: normal;
}
```

15.3.6 Sections and headings §^{p12}₂₈

```
CSS @namespace url(http://www.w3.org/1999/xhtml);

article, aside, h1, h2, h3, h4, h5, h6, hgroup, nav, section {
  display: block;
}

h1 { margin-block-start: 0.67em; margin-block-end: 0.67em; font-size: 2.00em; font-weight: bold; }
h2 { margin-block-start: 0.83em; margin-block-end: 0.83em; font-size: 1.50em; font-weight: bold; }
h3 { margin-block-start: 1.00em; margin-block-end: 1.00em; font-size: 1.17em; font-weight: bold; }
h4 { margin-block-start: 1.33em; margin-block-end: 1.33em; font-size: 1.00em; font-weight: bold; }
h5 { margin-block-start: 1.67em; margin-block-end: 1.67em; font-size: 0.83em; font-weight: bold; }
h6 { margin-block-start: 2.33em; margin-block-end: 2.33em; font-size: 0.67em; font-weight: bold; }
```

In the following CSS block, `x` is shorthand for the following selector: `:is(article, aside, nav, section)`

```
CSS @namespace url(http://www.w3.org/1999/xhtml);

x h1 { margin-block-start: 0.83em; margin-block-end: 0.83em; font-size: 1.50em; }
x x h1 { margin-block-start: 1.00em; margin-block-end: 1.00em; font-size: 1.17em; }
x x x h1 { margin-block-start: 1.33em; margin-block-end: 1.33em; font-size: 1.00em; }
x x x x h1 { margin-block-start: 1.67em; margin-block-end: 1.67em; font-size: 0.83em; }
x x x x x h1 { margin-block-start: 2.33em; margin-block-end: 2.33em; font-size: 0.67em; }

x hgroup > h1 ~ h2 { margin-block-start: 1.00em; margin-block-end: 1.00em; font-size: 1.17em; }
x x hgroup > h1 ~ h2 { margin-block-start: 1.33em; margin-block-end: 1.33em; font-size: 1.00em; }
x x x hgroup > h1 ~ h2 { margin-block-start: 1.67em; margin-block-end: 1.67em; font-size: 0.83em; }
x x x x hgroup > h1 ~ h2 { margin-block-start: 2.33em; margin-block-end: 2.33em; font-size: 0.67em; }

x hgroup > h1 ~ h3 { margin-block-start: 1.33em; margin-block-end: 1.33em; font-size: 1.00em; }
x x hgroup > h1 ~ h3 { margin-block-start: 1.67em; margin-block-end: 1.67em; font-size: 0.83em; }
x x x hgroup > h1 ~ h3 { margin-block-start: 2.33em; margin-block-end: 2.33em; font-size: 0.67em; }

x hgroup > h1 ~ h4 { margin-block-start: 1.67em; margin-block-end: 1.67em; font-size: 0.83em; }
x x hgroup > h1 ~ h4 { margin-block-start: 2.33em; margin-block-end: 2.33em; font-size: 0.67em; }

x hgroup > h1 ~ h5 { margin-block-start: 2.33em; margin-block-end: 2.33em; font-size: 0.67em; }
```

Note

The shorthand is used to keep this block at least mildly readable.

15.3.7 Lists ^{p12}₂₉

```

CSS @namespace url(http://www.w3.org/1999/xhtml);

dir, dd, dl, dt, menu, ol, ul { display: block; }
li { display: list-item; text-align: match-parent; }

dir, dl, menu, ol, ul { margin-block-start: 1em; margin-block-end: 1em; }

:is(dir, dl, menu, ol, ul) :is(dir, dl, menu, ol, ul) {
  margin-block-start: 0; margin-block-end: 0;
}

dd { margin-inline-start: 40px; }
dir, menu, ol, ul { padding-inline-start: 40px; }

ol, ul, menu { counter-reset: list-item; }
ol { list-style-type: decimal; }

dir, menu, ul {
  list-style-type: disc;
}
:is(dir, menu, ol, ul) :is(dir, menu, ul) {
  list-style-type: circle;
}
:is(dir, menu, ol, ul) :is(dir, menu, ol, ul) :is(dir, menu, ul) {
  list-style-type: square;
}

```

The following rules are also expected to apply, as [presentational hints](#)^{p1222}:

```

CSS @namespace url(http://www.w3.org/1999/xhtml);

ol[type="1"], li[type="1"] { list-style-type: decimal; }
ol[type=a s], li[type=a s] { list-style-type: lower-alpha; }
ol[type=A s], li[type=A s] { list-style-type: upper-alpha; }
ol[type=i s], li[type=i s] { list-style-type: lower-roman; }
ol[type=I s], li[type=I s] { list-style-type: upper-roman; }
ul[type=none i], li[type=none i] { list-style-type: none; }
ul[type=disc i], li[type=disc i] { list-style-type: disc; }
ul[type=circle i], li[type=circle i] { list-style-type: circle; }
ul[type=square i], li[type=square i] { list-style-type: square; }

```

When rendering [li](#)^{p230} elements, non-CSS user agents are expected to use the [ordinal value](#)^{p231} of the [li](#)^{p230} element to render the counter in the list item marker.

For CSS user agents, some aspects of rendering [list items](#) are defined by the *CSS Lists* specification. Additionally, the following attribute mappings are expected to apply: [\[CSSLISTS\]](#)^{p1306}

When an [li](#)^{p230} element has a [value](#)^{p231} attribute, and parsing that attribute's value using the [rules for parsing integers](#)^{p70} doesn't generate an error, the user agent is expected to use the parsed value *value* as a [presentational hint](#)^{p1222} for the `'counter-set'` property of the form `list-item value`.

When an [ol](#)^{p226} element has a [start](#)^{p227} attribute or a [reversed](#)^{p227} attribute, or both, the user agent is expected to use the following steps to treat the attributes as a [presentational hint](#)^{p1222} for the `'counter-reset'` property:

1. Let *value* be null.

2. If the element has a [start](#)^{p227} attribute, then set *value* to the result of parsing the attribute's value using the [rules for parsing integers](#)^{p70}.
3. If the element has a [reversed](#)^{p227} attribute, then:
 1. If *value* is an integer, then increment *value* by 1 and return `reversed(list-item) value`.
 2. Otherwise, return `reversed(list-item)`.

Note

Either the [start](#)^{p227} attribute was absent, or parsing its value resulted in an error.

4. Otherwise:
 1. If *value* is an integer, then decrement *value* by 1 and return `list-item value`.
 2. Otherwise, there is no [presentational hint](#)^{p1222}.

15.3.8 Tables §^{p12} 30

```

CSS @namespace url(http://www.w3.org/1999/xhtml);

table { display: table; }
caption { display: table-caption; }
colgroup, colgroup[hidden] { display: table-column-group; }
col, col[hidden] { display: table-column; }
thead, thead[hidden] { display: table-header-group; }
tbody, tbody[hidden] { display: table-row-group; }
tfoot, tfoot[hidden] { display: table-footer-group; }
tr, tr[hidden] { display: table-row; }
td, th { display: table-cell; }

colgroup[hidden], col[hidden], thead[hidden], tbody[hidden],
tfoot[hidden], tr[hidden] {
  visibility: collapse;
}

table {
  box-sizing: border-box;
  border-spacing: 2px;
  border-collapse: separate;
  text-indent: initial;
}

border-block-end-width: 1px;
border-block-end-style: solid;
}

table[rules=rows i] > tr, table[rules=rows i] > thead > tr,
table[rules=rows i] > tbody > tr, table[rules=rows i] > tfoot > tr {
border-block-start-width: 1px;
border-block-start-style: solid;
border-block-end-width: 1px;
border-block-end-style: solid;
}

```

In [quirks mode](#), the following rules are also expected to apply:

```

CSS @namespace url(http://www.w3.org/1999/xhtml);

table {
font-weight: initial;
font-style: initial;
font-variant: initial;
font-size: initial;
line-height: initial;
white-space: initial;
text-align: initial;
}

```

For the purposes of the CSS table model, the [col](#)^{p468} element is expected to be treated as if it was present as many times as its [span](#)^{p469} attribute [specifies](#)^{p70}.

For the purposes of the CSS table model, the [colgroup](#)^{p467} element, if it contains no [col](#)^{p468} element, is expected to be treated as if it had as many such children as its [span](#)^{p468} attribute [specifies](#)^{p70}.

For the purposes of the CSS table model, the [colspan](#)^{p477} and [rowspan](#)^{p477} attributes on [td](#)^{p474} and [th](#)^{p475} elements are expected to [provide](#)^{p70} the *special knowledge* regarding cells spanning rows and columns.

In [HTML documents](#), the following rules are also expected to apply:

```

CSS @namespace url(http://www.w3.org/1999/xhtml);

:is(table, thead, tbody, tfoot, tr) > form { display: none !important; }

```

The [table](#)^{p458} element's [cellspacing](#)^{p1262} attribute [maps to the pixel length property](#)^{p1222} ['border-spacing'](#) on the element.

The [table](#)^{p458} element's [cellpadding](#)^{p1262} attribute [maps to the pixel length properties](#)^{p1222} ['padding-top'](#), ['padding-right'](#), ['padding-bottom'](#), and ['padding-left'](#) of any [td](#)^{p474} and [th](#)^{p475} elements that have corresponding [cells](#)^{p478} in the [table](#)^{p478} corresponding to the [table](#)^{p458} element.

The [table](#)^{p458} element's [height](#)^{p1262} attribute [maps to the dimension property \(ignoring zero\)](#)^{p1222} ['height'](#) on the [table](#)^{p458} element.

The [table](#)^{p458} element's [width](#)^{p1262} attribute [maps to the dimension property \(ignoring zero\)](#)^{p1222} ['width'](#) on the [table](#)^{p458} element.

The `col`^{p468} element's `width`^{p1261} attribute [maps to the dimension property](#)^{p1222} `'width'` on the `col`^{p468} element.

The `thead`^{p470}, `tbody`^{p469}, and `tfoot`^{p471} elements' `height`^{p1262} attribute [maps to the dimension property](#)^{p1222} `'height'` on the element.

The `tr`^{p472} element's `height`^{p1262} attribute [maps to the dimension property](#)^{p1222} `'height'` on the `tr`^{p472} element.

The `td`^{p474} and `th`^{p475} elements' `height`^{p1262} attributes [map to the dimension property \(ignoring zero\)](#)^{p1222} `'height'` on the element.

The `td`^{p474} and `th`^{p475} elements' `width`^{p1262} attributes [map to the dimension property \(ignoring zero\)](#)^{p1222} `'width'` on the element.

The `thead`^{p470}, `tbody`^{p469}, `tfoot`^{p471}, `tr`^{p472}, `td`^{p474}, and `th`^{p475} elements, when they have an `align` attribute whose value is an [ASCII case-insensitive](#) match for either the string "center" or the string "middle", are expected to center text within themselves, as if they had their `'text-align'` property set to 'center' in a [presentational hint](#)^{p1222}, and to [align descendants](#)^{p1222} to the center.

The `thead`^{p470}, `tbody`^{p469}, `tfoot`^{p471}, `tr`^{p472}, `td`^{p474}, and `th`^{p475} elements, when they have an `align` attribute whose value is an [ASCII case-insensitive](#) match for the string "left", are expected to left-align text within themselves, as if they had their `'text-align'` property set to 'left' in a [presentational hint](#)^{p1222}, and to [align descendants](#)^{p1222} to the left.

The `thead`^{p470}, `tbody`^{p469}, `tfoot`^{p471}, `tr`^{p472}, `td`^{p474}, and `th`^{p475} elements, when they have an `align` attribute whose value is an [ASCII case-insensitive](#) match for the string "right", are expected to right-align text within themselves, as if they had their `'text-align'` property set to 'right' in a [presentational hint](#)^{p1222}, and to [align descendants](#)^{p1222} to the right.

The `thead`^{p470}, `tbody`^{p469}, `tfoot`^{p471}, `tr`^{p472}, `td`^{p474}, and `th`^{p475} elements, when they have an `align` attribute whose value is an [ASCII case-insensitive](#) match for the string "justify", are expected to full-justify text within themselves, as if they had their `'text-align'` property set to 'justify' in a [presentational hint](#)^{p1222}, and to [align descendants](#)^{p1222} to the left.

User agents are expected to have a rule in their user agent style sheet that matches `th`^{p475} elements that have a parent node whose [computed value](#) for the `'text-align'` property is its initial value, whose declaration block consists of just a single declaration that sets the `'text-align'` property to the value 'center'.

When a `table`^{p458}, `thead`^{p470}, `tbody`^{p469}, `tfoot`^{p471}, `tr`^{p472}, `td`^{p474}, or `th`^{p475} element has a `background`^{p1262} attribute set to a non-empty value, the new value is expected to be [parsed](#)^{p91} relative to the element's [node document](#), and if this is successful, the user agent is expected to treat the attribute as a [presentational hint](#)^{p1222} setting the element's `'background-image'` property to the [resulting URL string](#)^{p91}.

When a `table`^{p458}, `thead`^{p470}, `tbody`^{p469}, `tfoot`^{p471}, `tr`^{p472}, `td`^{p474}, or `th`^{p475} element has a `bgcolor` attribute set, the new value is expected to be [parsed using the rules for parsing a legacy color value](#)^{p88}, and if that does not return an error, the user agent is expected to treat the attribute as a [presentational hint](#)^{p1222} setting the element's `'background-color'` property to the resulting color.

When a `table`^{p458} element has a `bordercolor`^{p1262} attribute, its value is expected to be [parsed using the rules for parsing a legacy color value](#)^{p88}, and if that does not return an error, the user agent is expected to treat the attribute as a [presentational hint](#)^{p1222} setting the element's `'border-top-color'`, `'border-right-color'`, `'border-bottom-color'`, and `'border-left-color'` properties to the resulting color.

The `table`^{p458} element's `border`^{p1262} attribute [maps to the pixel length properties](#)^{p1222} `'border-top-width'`, `'border-right-width'`, `'border-bottom-width'`, `'border-left-width'` on the element. If the attribute is present but parsing the attribute's value using the [rules for parsing non-negative integers](#)^{p70} generates an error, a default value of 1px is expected to be used for that property instead.

Rules marked "**only if border is not equivalent to zero**" in the CSS block above is expected to only be applied if the `border`^{p1262} attribute mentioned in the selectors for the rule is not only present but, when parsed using the [rules for parsing non-negative integers](#)^{p70}, is also found to have a value other than zero or to generate an error.

In [quirks mode](#), a `td`^{p474} element or a `th`^{p475} element that has a `nowrap`^{p1262} attribute but also has a `width`^{p1262} attribute whose value, when parsed using the [rules for parsing nonzero dimension values](#)^{p73}, is found to be a length (not an error or a number classified as a percentage), is expected to have a [presentational hint](#)^{p1222} setting the element's `'white-space'` property to 'normal', overriding the rule in the CSS block above that sets it to 'nowrap'.

15.3.9 Margin collapsing quirks § p12 35

A node is **substantial** if it is a text node that is not [inter-element whitespace](#)^{p133}, or if it is an element node.

A node is **blank** if it is an element that contains no [substantial](#)^{p1235} nodes.

The **elements with default margins** are the following elements: [blockquote](#)^{p224}, [dir](#)^{p1257}, [dl](#)^{p233}, [h1](#)^{p196}, [h2](#)^{p196}, [h3](#)^{p196}, [h4](#)^{p196}, [h5](#)^{p196}, [h6](#)^{p196}, [listing](#)^{p1257}, [menu](#)^{p229}, [ol](#)^{p226}, [p](#)^{p218}, [plaintext](#)^{p1257}, [pre](#)^{p222}, [ul](#)^{p228}, [xmp](#)^{p1258}

In [quirks mode](#), any [element with default margins](#)^{p1235} that is the [child](#) of a [body](#)^{p184}, [td](#)^{p474}, or [th](#)^{p475} element and has no [substantial](#)^{p1235} previous siblings is expected to have a user-agent level style sheet rule that sets its ['margin-block-start'](#) property to zero.

In [quirks mode](#), any [element with default margins](#)^{p1235} that is the [child](#) of a [body](#)^{p184}, [td](#)^{p474}, or [th](#)^{p475} element, has no [substantial](#)^{p1235} previous siblings, and is [blank](#)^{p1235}, is expected to have a user-agent level style sheet rule that sets its ['margin-block-end'](#) property to zero also.

In [quirks mode](#), any [element with default margins](#)^{p1235} that is the [child](#) of a [td](#)^{p474} or [th](#)^{p475} element, has no [substantial](#)^{p1235} following siblings, and is [blank](#)^{p1235}, is expected to have a user-agent level style sheet rule that sets its ['margin-block-start'](#) property to zero.

In [quirks mode](#), any [p](#)^{p218} element that is the [child](#) of a [td](#)^{p474} or [th](#)^{p475} element and has no [substantial](#)^{p1235} following siblings, is expected to have a user-agent level style sheet rule that sets its ['margin-block-end'](#) property to zero.

15.3.10 Form controls § p12 35

```
CSS @namespace url(http://www.w3.org/1999/xhtml);

input, select, button, textarea {
  letter-spacing: initial;
  word-spacing: initial;
  line-height: initial;
  text-transform: initial;
  text-indent: initial;
  text-shadow: initial;
}

input, select, textarea {
  text-align: initial;
}

input:is([type=reset i], [type=button i], [type=submit i]), button {
  text-align: center;
}

input, button {
  display: inline-block;
}

input:is([type=radio i], [type=checkbox i], [type=reset i], [type=button i],
[type=submit i], [type=checkbox i], [type=search i]), select, button {
  box-sizing: border-box;
}

textarea { white-space: pre-wrap; }
```

In [quirks mode](#), the following rules are also expected to apply:

```
CSS @namespace url(http://www.w3.org/1999/xhtml);

input:not([type=image i]), textarea { box-sizing: border-box; }
```

Each kind of form control is also described in the [Widgets^{p1243}](#) section, which describes the look and feel of the control.

For [input^{p501}](#) elements where the [type^{p503}](#) attribute is not in the [Hidden^{p507}](#) state or the [Image Button^{p526}](#) state, and that are [being rendered^{p1221}](#), are expected to act as follows:

- The [inner display type](#) is always 'flow-root'.
- The ['overflow'](#) property is ignored, and always behaves as 'visible' for the purpose of interaction with other CSS features (in particular, the ['vertical-align'](#) property), but still clips any overflow at the border edge, and no scrolling mechanism is displayed.

15.3.11 The [hr^{p220}](#) element §^{p12} 36

```
CSS @namespace url(http://www.w3.org/1999/xhtml);

hr {
  color: gray;
  border-style: inset;
  border-width: 1px;
  margin-block-start: 0.5em;
  margin-inline-end: auto;
  margin-block-end: 0.5em;
  margin-inline-start: auto;
  overflow: hidden;
}
```

The following rules are also expected to apply, as [presentational hints^{p1222}](#):

```
CSS @namespace url(http://www.w3.org/1999/xhtml);

hr[align=left i] { margin-left: 0; margin-right: auto; }
hr[align=right i] { margin-left: auto; margin-right: 0; }
hr[align=center i] { margin-left: auto; margin-right: auto; }
hr[color], hr[noshade] { border-style: solid; }
```

If an [hr^{p220}](#) element has either a [color^{p1261}](#) attribute or a [noshade^{p1261}](#) attribute, and furthermore also has a [size^{p1261}](#) attribute, and parsing that attribute's value using the [rules for parsing non-negative integers^{p70}](#) doesn't generate an error, then the user agent is expected to use the parsed value divided by two as a pixel length for [presentational hints^{p1222}](#) for the properties ['border-top-width'](#), ['border-right-width'](#), ['border-bottom-width'](#), and ['border-left-width'](#) on the element.

Otherwise, if an [hr^{p220}](#) element has neither a [color^{p1261}](#) attribute nor a [noshade^{p1261}](#) attribute, but does have a [size^{p1261}](#) attribute, and parsing that attribute's value using the [rules for parsing non-negative integers^{p70}](#) doesn't generate an error, then: if the parsed value is one, then the user agent is expected to use the attribute as a [presentational hint^{p1222}](#) setting the element's ['border-bottom-width'](#) to 0; otherwise, if the parsed value is greater than one, then the user agent is expected to use the parsed value minus two as a pixel length for [presentational hints^{p1222}](#) for the ['height'](#) property on the element.

The [width^{p1261}](#) attribute on an [hr^{p220}](#) element [maps to the dimension property^{p1222}](#) ['width'](#) on the element.

When an [hr^{p220}](#) element has a [color^{p1261}](#) attribute, its value is expected to be parsed using the [rules for parsing a legacy color value^{p88}](#), and if that does not return an error, the user agent is expected to treat the attribute as a [presentational hint^{p1222}](#) setting the element's ['color'](#) property to the resulting color.

15.3.12 The [fieldset^{p572}](#) and [legend^{p574}](#) elements §^{p12} 36

```
CSS @namespace url(http://www.w3.org/1999/xhtml);

fieldset {
```

```

display: block;
margin-inline-start: 2px;
margin-inline-end: 2px;
border: groove 2px ThreeDFace;
padding-block-start: 0.35em;
padding-inline-end: 0.75em;
padding-block-end: 0.625em;
padding-inline-start: 0.75em;
min-inline-size: min-content;
}

legend {
padding-inline-start: 2px; padding-inline-end: 2px;
}

legend[align=left i] {
justify-self: left;
}

legend[align=center i] {
justify-self: center;
}

legend[align=right i] {
justify-self: right;
}

```

The [fieldset^{p572}](#) element, when it generates a [CSS box](#), is expected to act as follows:

- The element is expected to establish a new [block formatting context](#).
- The `'display'` property is expected to act as follows:
 - If the computed value of `'display'` is a value such that the [outer display type](#) is 'inline', then behave as 'inline-block'.
 - Otherwise, behave as 'flow-root'.

Note

This does not change the computed value.

- If the element's box has a child box that matches the conditions in the list below, then the first such child box is the 'fieldset' element's **rendered legend**:
 - The child is a [legend^{p574}](#) element.
 - The child's used value of `'float'` is 'none'.
 - The child's used value of `'position'` is not 'absolute' or 'fixed'.
- If the element has a [rendered legend^{p1237}](#), then the border is expected to not be painted behind the rectangle defined as follows, using the writing mode of the fieldset:
 1. The block-start edge of the rectangle is the smaller of the block-start edge of the [rendered legend^{p1237}](#)'s margin rectangle at its static position (ignoring transforms), and the block-start outer edge of the [fieldset^{p572}](#)'s border.
 2. The block-end edge of the rectangle is the larger of the block-end edge of the [rendered legend^{p1237}](#)'s margin rectangle at its static position (ignoring transforms), and the block-end outer edge of the [fieldset^{p572}](#)'s border.
 3. The inline-start edge of the rectangle is the smaller of the inline-start edge of the [rendered legend^{p1237}](#)'s border rectangle at its static position (ignoring transforms), and the inline-start outer edge of the [fieldset^{p572}](#)'s border.
 4. The inline-end edge of the rectangle is the larger of the inline-end edge of the [rendered legend^{p1237}](#)'s border rectangle at its static position (ignoring transforms), and the inline-end outer edge of the [fieldset^{p572}](#)'s border.
- The space allocated for the element's border on the block-start side is expected to be the element's `'border-block-start-width'` or the [rendered legend^{p1237}](#)'s margin box size in the [fieldset^{p572}](#)'s block-flow direction, whichever is greater.

- For the purpose of calculating the used `'block-size'`, if the computed `'block-size'` is not `'auto'`, the space allocated for the [rendered legend](#)^{p1237}'s margin box that spills out past the border, if any, is expected to be subtracted from the `'block-size'`. If the content box's block-size would be negative, then let the content box's block-size be zero instead.
- If the element has a [rendered legend](#)^{p1237}, then that element is expected to be the first child box.
- The [anonymous fieldset content box](#)^{p1238} is expected to appear after the [rendered legend](#)^{p1237} and is expected to contain the content (including the `::before` and `::after` pseudo-elements) of the [fieldset](#)^{p572} element except for the [rendered legend](#)^{p1237}, if there is one.
- The used value of the `'padding-top'`, `'padding-right'`, `'padding-bottom'`, and `'padding-left'` properties are expected to be zero.
- For the purpose of calculating the min-content inline size, use the greater of the min-content inline size of the [rendered legend](#)^{p1237} and the min-content inline size of the [anonymous fieldset content box](#)^{p1238}.
- For the purpose of calculating the max-content inline size, use the greater of the max-content inline size of the [rendered legend](#)^{p1237} and the max-content inline size of the [anonymous fieldset content box](#)^{p1238}.

A [fieldset](#)^{p572} element's [rendered legend](#)^{p1237}, if any, is expected to act as follows:

- The element is expected to establish a new [formatting context](#) for its contents. The type of this [formatting context](#) is determined by its `'display'` value, as usual.
- The `'display'` property is expected to behave as if its computed value was blockified.

Note

This does not change the computed value.

- If the [computed value](#) of `'inline-size'` is `'auto'`, then the [used value](#) is the [fit-content inline size](#).
- The element is expected to be positioned in the inline direction as is normal for blocks (e.g., taking into account margins and the `'justify-self'` property).
- The element's box is expected to be constrained in the inline direction by the inline content size of the [fieldset](#)^{p572} as if it had used its computed inline padding.

Example

For example, if the [fieldset](#)^{p572} has a specified padding of 50px, then the [rendered legend](#)^{p1237} will be positioned 50px in from the [fieldset](#)^{p572}'s border. The padding will further apply to the [anonymous fieldset content box](#)^{p1238} instead of the [fieldset](#)^{p572} element itself.

- The element is expected to be positioned in the block-flow direction such that its border box is centered over the border on the block-start side of the [fieldset](#)^{p572} element.

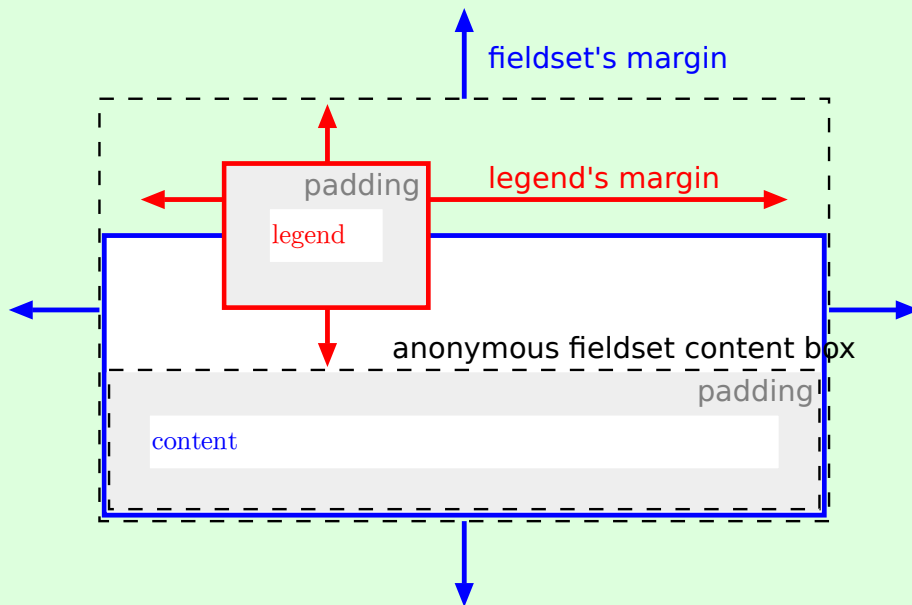

A [fieldset](#)^{p572} element's **anonymous fieldset content box** is expected to act as follows:

- The `'display'` property is expected to act as follows:
 - If the computed value of `'display'` on the [fieldset](#)^{p572} element is `'grid'` or `'inline-grid'`, then set the used value to `'grid'`.
 - If the computed value of `'display'` on the [fieldset](#)^{p572} element is `'flex'` or `'inline-flex'`, then set the used value to `'flex'`.
 - Otherwise, set the used value to `'flow-root'`.
- The following properties are expected to inherit from the [fieldset](#)^{p572} element:
 - `'align-content'`
 - `'align-items'`
 - `'border-radius'`
 - `'column-count'`
 - `'column-fill'`
 - `'column-gap'`
 - `'column-rule'`
 - `'column-width'`
 - `'flex-direction'`
 - `'flex-wrap'`
 - `'grid-auto-columns'`
 - `'grid-auto-flow'`

- ['grid-auto-rows'](#)
- ['grid-column-gap'](#)
- ['grid-row-gap'](#)
- ['grid-template-areas'](#)
- ['grid-template-columns'](#)
- ['grid-template-rows'](#)
- ['justify-content'](#)
- ['justify-items'](#)
- ['overflow'](#)
- ['padding-bottom'](#)
- ['padding-left'](#)
- ['padding-right'](#)
- ['padding-top'](#)
- ['text-overflow'](#)
- ['unicode-bidi'](#)

- The ['block-size'](#) property is expected to be set to '100%'.
- For the purpose of calculating percentage padding, act as if the padding was calculated for the [fieldset^{p572}](#) element.

Note

The legend is rendered over the top border, and the top border area reserves vertical space for the legend. The fieldset's top margin starts at the top margin edge of the legend. The legend's horizontal margins, or the ['justify-self'](#) property, gives its horizontal position. The [anonymous fieldset content box^{p1238}](#) appears below the legend.

15.4 Replaced elements §^{p12} 39

Note

The following elements can be [replaced elements](#): [audio^{p392}](#), [canvas^{p645}](#), [embed^{p378}](#), [iframe^{p369}](#), [img^{p327}](#), [input^{p501}](#), [object^{p381}](#), and [video^{p388}](#).

15.4.1 Embedded content §^{p12} 39

The [embed^{p378}](#), [iframe^{p369}](#), and [video^{p388}](#) elements are expected to be treated as [replaced elements](#).

A [canvas^{p645}](#) element that [represents^{p128} embedded content^{p137}](#) is expected to be treated as a [replaced element](#); the contents of such elements are the element's bitmap, if any, or else a [transparent black](#) bitmap with the same [intrinsic dimensions](#) as the element. Other [canvas^{p645}](#) elements are expected to be treated as ordinary elements in the rendering model.

An [object](#)^{p381} element that [represents](#)^{p128} an image, plugin, or its [nested browsing context](#)^{p843} is expected to be treated as a [replaced element](#). Other [object](#)^{p381} elements are expected to be treated as ordinary elements in the rendering model.

The [audio](#)^{p392} element, when it is [exposing a user interface](#)^{p444}, is expected to be treated as a [replaced element](#) about one line high, as wide as is necessary to expose the user agent's user interface features. When an [audio](#)^{p392} element is not [exposing a user interface](#)^{p444}, the user agent is expected to force its `'display'` property to compute to `'none'`, irrespective of CSS rules.

Whether a [video](#)^{p388} element is [exposing a user interface](#)^{p444} is not expected to affect the size of the rendering; controls are expected to be overlaid above the page content without causing any layout changes, and are expected to disappear when the user does not need them.

When a [video](#)^{p388} element represents a poster frame or frame of video, the poster frame or frame of video is expected to be rendered at the largest size that maintains the aspect ratio of that poster frame or frame of video without being taller or wider than the [video](#)^{p388} element itself, and is expected to be centered in the [video](#)^{p388} element.

Any subtitles or captions are expected to be overlaid directly on top of their [video](#)^{p388} element, as defined by the relevant rendering rules; for WebVTT, those are the [rules for updating the display of WebVTT text tracks](#). [[WEBVTT](#)]^{p1313}

When the user agent starts [exposing a user interface](#)^{p444} for a [video](#)^{p388} element, the user agent should run the [rules for updating the text track rendering](#)^{p431} of each of the [text tracks](#)^{p430} in the [video](#)^{p388} element's [list of text tracks](#)^{p430} that are [showing](#)^{p431} and whose [text track kind](#)^{p430} is one of [subtitles](#)^{p438} or [captions](#)^{p438} (e.g., for [text tracks](#)^{p430} based on WebVTT, the [rules for updating the display of WebVTT text tracks](#)). [[WEBVTT](#)]^{p1313}

Note

Resizing [video](#)^{p388} and [canvas](#)^{p645} elements does not interrupt video playback or clear the canvas.

The following CSS rules are expected to apply:

```
CSS @namespace url(http://www.w3.org/1999/xhtml);
iframe { border: 2px inset; }
video { object-fit: contain; }
```

15.4.2 Images §^{p12}₄₀

User agents are expected to render [img](#)^{p327} elements and [input](#)^{p501} elements whose [type](#)^{p503} attributes are in the [Image Button](#)^{p526} state, according to the first applicable rules from the following list:

↪ If the element [represents](#)^{p128} an image

The user agent is expected to treat the element as a [replaced element](#) and render the image according to the rules for doing so defined in CSS.

↪ If the element does not [represent](#)^{p128} an image and either:

- the user agent has reason to believe that the image will become [available](#)^{p344} and be rendered in due course, or
- the element has no `alt` attribute, or
- the [Document](#)^{p117} is in [quirks mode](#), and the element already has [intrinsic dimensions](#) (e.g., from the [dimension attributes](#)^{p458} or CSS rules)

The user agent is expected to treat the element as a [replaced element](#) whose content is the text that the element represents, if any, optionally alongside an icon indicating that the image is being obtained (if applicable). For [input](#)^{p501} elements, the element is expected to appear button-like to indicate that the element is a [button](#)^{p494}.

↪ If the element is an [img](#)^{p327} element that [represents](#)^{p128} some text and the user agent does not expect this to change

The user agent is expected to treat the element as a non-replaced phrasing element whose content is the text, optionally with an icon indicating that an image is missing, so that the user can request the image be displayed or investigate why it is not rendering. In non-graphical contexts, such an icon should be omitted.

↪ If the element is an [img](#)^{p327} element that [represents](#)^{p128} nothing and the user agent does not expect this to change

The user agent is expected to treat the element as a [replaced element](#) whose [intrinsic dimensions](#) are 0. (In the absence of further styles, this will cause the element to essentially not be rendered.)

↪ If the element is an [input^{p501}](#) element that does not [represent^{p128}](#) an image and the user agent does not expect this to change

The user agent is expected to treat the element as a [replaced element](#) consisting of a button whose content is the element's alternative text. The [intrinsic dimensions](#) of the button are expected to be about one line in height and whatever width is necessary to render the text on one line.

The icons mentioned above are expected to be relatively small so as not to disrupt most text but be easily clickable. In a visual environment, for instance, icons could be 16 pixels by 16 pixels square, or 1em by 1em if the images are scalable. In an audio environment, the icon could be a short bleep. The icons are intended to indicate to the user that they can be used to get to whatever options the UA provides for images, and, where appropriate, are expected to provide access to the context menu that would have come up if the user interacted with the actual image.

All animated images with the same [absolute URL](#) and the same image data are expected to be rendered synchronized to the same timeline as a group, with the timeline starting at the time of the least recent addition to the group.

Note

In other words, when a second image with the same [absolute URL](#) and animated image data is inserted into a document, it jumps to the point in the animation cycle that is currently being displayed by the first image.

When a user agent is to **restart the animation** for an [img^{p327}](#) element showing an animated image, all animated images with the same [absolute URL](#) and the same image data in that [img^{p327}](#) element's [node document](#) are expected to restart their animation from the beginning.

The following CSS rules are expected to apply when the [Document^{p117}](#) is in [quirks mode](#):

```
CSS @namespace url(http://www.w3.org/1999/xhtml);
img[align=left i] { margin-right: 3px; }
img[align=right i] { margin-left: 3px; }
```

15.4.3 Attributes for embedded content and images §^{p12}₄₁

The following CSS rules are expected to apply as [presentational hints^{p1222}](#):

```
CSS @namespace url(http://www.w3.org/1999/xhtml);
iframe[frameborder='0'], iframe[frameborder=no i] { border: none; }
embed[align=left i], iframe[align=left i], img[align=left i],
input[type=image i][align=left i], object[align=left i] {
  float: left;
}
embed[align=right i], iframe[align=right i], img[align=right i],
input[type=image i][align=right i], object[align=right i] {
  float: right;
}
embed[align=top i], iframe[align=top i], img[align=top i],
input[type=image i][align=top i], object[align=top i] {
  vertical-align: top;
}
embed[align=baseline i], iframe[align=baseline i], img[align=baseline i],
input[type=image i][align=baseline i], object[align=baseline i] {
  vertical-align: baseline;
}
```

```

}

embed[align=texttop i], iframe[align=texttop i], img[align=texttop i],
input[type=image i][align=texttop i], object[align=texttop i] {
  vertical-align: text-top;
}

embed[align=absmiddle i], iframe[align=absmiddle i], img[align=absmiddle i],
input[type=image i][align=absmiddle i], object[align=absmiddle i],
embed[align=abscenter i], iframe[align=abscenter i], img[align=abscenter i],
input[type=image i][align=abscenter i], object[align=abscenter i] {
  vertical-align: middle;
}

embed[align=bottom i], iframe[align=bottom i], img[align=bottom i],
input[type=image i][align=bottom i], object[align=bottom i] {
  vertical-align: bottom;
}

```

When an [embed^{p378}](#), [iframe^{p369}](#), [img^{p327}](#), or [object^{p381}](#) element, or an [input^{p501}](#) element whose [type^{p503}](#) attribute is in the [Image Button^{p526}](#) state, has an `align` attribute whose value is an [ASCII case-insensitive](#) match for the string "center" or the string "middle", the user agent is expected to act as if the element's `'vertical-align'` property was set to a value that aligns the vertical middle of the element with the parent element's baseline.

The `hspace` attribute of [embed^{p378}](#), [img^{p327}](#), or [object^{p381}](#) elements, and [input^{p501}](#) elements with a [type^{p503}](#) attribute in the [Image Button^{p526}](#) state, [maps to the dimension properties^{p1222}](#) `'margin-left'` and `'margin-right'` on the element.

The `vspace` attribute of [embed^{p378}](#), [img^{p327}](#), or [object^{p381}](#) elements, and [input^{p501}](#) elements with a [type^{p503}](#) attribute in the [Image Button^{p526}](#) state, [maps to the dimension properties^{p1222}](#) `'margin-top'` and `'margin-bottom'` on the element.

When an [img^{p327}](#) element, [object^{p381}](#) element, or [input^{p501}](#) element with a [type^{p503}](#) attribute in the [Image Button^{p526}](#) state has a `border` attribute whose value, when parsed using the [rules for parsing non-negative integers^{p70}](#), is found to be a number greater than zero, the user agent is expected to use the parsed value for eight [presentational hints^{p1222}](#): four setting the parsed value as a pixel length for the element's `'border-top-width'`, `'border-right-width'`, `'border-bottom-width'`, and `'border-left-width'` properties, and four setting the element's `'border-top-style'`, `'border-right-style'`, `'border-bottom-style'`, and `'border-left-style'` properties to the value 'solid'.

The [width^{p458}](#) and [height^{p458}](#) attributes on an [img^{p327}](#) element's [dimension attribute source^{p328}](#) [map to the dimension properties^{p1222}](#) `'width'` and `'height'` on the [img^{p327}](#) element respectively. They similarly [map to the aspect-ratio property \(using dimension rules\)^{p1222}](#) on the [img^{p327}](#) element.

The [width^{p458}](#) and [height^{p458}](#) attributes on [embed^{p378}](#), [iframe^{p369}](#), [object^{p381}](#), and [video^{p388}](#) elements, and [input^{p501}](#) elements with a [type^{p503}](#) attribute in the [Image Button^{p526}](#) state and that either represents an image or that the user expects will eventually represent an image, [map to the dimension properties^{p1222}](#) `'width'` and `'height'` on the element respectively.

The [width^{p458}](#) and [height^{p458}](#) attributes [map to the aspect-ratio property \(using dimension rules\)^{p1222}](#) on [img^{p327}](#) and [video^{p388}](#) elements, and [input^{p501}](#) elements with a [type^{p503}](#) attribute in the [Image Button^{p526}](#) state.

The [width^{p647}](#) and [height^{p647}](#) attributes [map to the aspect-ratio property^{p1222}](#) on [canvas^{p645}](#) elements.

15.4.4 Image maps §^{p12} 42

Shapes on an [image map^{p454}](#) are expected to act, for the purpose of the CSS cascade, as elements independent of the original [area^{p452}](#) element that happen to match the same style rules but inherit from the [img^{p327}](#) or [object^{p381}](#) element.

For the purposes of the rendering, only the `'cursor'` property is expected to have any effect on the shape.

Example

Thus, for example, if an [area^{p452}](#) element has a [style^{p149}](#) attribute that sets the `'cursor'` property to 'help', then when the user designates that shape, the cursor would change to a Help cursor.

Example

Similarly, if an [area^{p452}](#) element had a CSS rule that set its `'cursor'` property to 'inherit' (or if no rule setting the `'cursor'` property matched the element at all), the shape's cursor would be inherited from the [img^{p327}](#) or [object^{p381}](#) element of the [image map^{p454}](#), not from the parent of the [area^{p452}](#) element.

15.5 Widgets §^{p12} 43

15.5.1 Introduction §^{p12} 43

The elements defined in this section can be rendered in a variety of manners, within the guidelines provided below. User agents are encouraged to set the `'appearance'` CSS property appropriately to achieve platform-native appearances for widgets, and are expected to implement any relevant animations, etc, that are appropriate for the platform.

15.5.2 Button layout §^{p12} 43

Button layout is as follows:

- If the element is a [button^{p545}](#) element, then the `'display'` property is expected to act as follows:
 - If the computed value of `'display'` is 'inline-grid', 'grid', 'inline-flex', or 'flex', then behave as the computed value.
 - Otherwise, if the computed value of `'display'` is a value such that the [outer display type](#) is 'inline', then behave as 'inline-block'.
 - Otherwise, behave as 'flow-root'.
- The element is expected to establish a new [formatting context](#) for its contents. The type of this formatting context is determined by its `'display'` value, as usual.
- If the element is [absolutely-positioned](#), then for the purpose of the [CSS visual formatting model](#), act as if the element is a [replaced element](#). [\[CSS\]^{p1305}](#)
- If the [computed value](#) of `'inline-size'` is 'auto', then the [used value](#) is the [fit-content inline size](#).
- For the purpose of the 'normal' keyword of the `'align-self'` property, act as if the element is a replaced element.
- If the element is an [input^{p501}](#) element, or if it is a [button^{p545}](#) element and its computed value for `'display'` is not 'inline-grid', 'grid', 'inline-flex', or 'flex', then the element's box has a child **anonymous button content box** with the following behaviors:
 - The box is a [block-level block container](#) that establishes a new [block formatting context](#) (i.e., `'display'` is 'flow-root').
 - If the box does not overflow in the horizontal axis, then it is centered horizontally.
 - If the box does not overflow in the vertical axis, then it is centered vertically.

Otherwise, there is no [anonymous button content box^{p1243}](#).

15.5.3 The [button^{p545}](#) element §^{p12} 43

The [button^{p545}](#) element, when it generates a [CSS box](#), is expected to depict a button and to use [button layout^{p1243}](#) whose [anonymous button content box^{p1243}](#)'s contents (if there is an [anonymous button content box^{p1243}](#)) are the child boxes the element's box would otherwise have.

15.5.4 The [details](#)^{p614} and [summary](#)^{p617} elements §^{p12}₄₄

```
CSS @namespace url(http://www.w3.org/1999/xhtml);

summary {
  display: list-item;
  counter-increment: list-item 0;
  list-style: disclosure-closed inside;
}
details[open] > summary {
  list-style-type: disclosure-open;
}
```

The [details](#)^{p614} element is expected to render as a [block box](#). The element is also expected to have an internal [shadow tree](#) with two [slots](#). The first [slot](#) is expected to take the [details](#)^{p614} element's first [summary](#)^{p617} element child, if any. The second [slot](#) is expected to take the [details](#)^{p614} element's remaining descendants, if any.

The [details](#)^{p614} element's first [summary](#)^{p617} element child, if any, is expected to allow the user to request the details be shown or hidden.

The [details](#)^{p614} element's second [slot](#) is expected to have its [style](#)^{p149} attribute set to "display: block; content-visibility: hidden;" when the [details](#)^{p614} element does not have an [open](#)^{p615} attribute. When it does have the [open](#)^{p615} attribute, the [style](#)^{p149} attribute is expected to be removed from the second [slot](#).

Note

Because the slots are hidden inside a shadow tree, this [style](#)^{p149} attribute is not directly visible to author code. Its impacts, however, are visible. Notably, the choice of content-visibility: hidden instead of, e.g., display: none, impacts the results of various APIs that query layout information.

15.5.5 The [input](#)^{p501} element as a text entry widget §^{p12}₄₄

An [input](#)^{p501} element whose [type](#)^{p503} attribute is in the [Text](#)^{p508}, [Search](#)^{p508}, [Telephone](#)^{p508}, [URL](#)^{p509}, or [Email](#)^{p510} state, is expected to render as an ['inline-block'](#) box depicting a text control.

An [input](#)^{p501} element whose [type](#)^{p503} attribute is in the [Password](#)^{p512} state is expected to render as an ['inline-block'](#) box depicting a text control that obscures data entry.

For [input](#)^{p501} elements whose [type](#)^{p503} attribute is in one of the above states, the [used value](#) of the ['line-height'](#) property must be a length value that is no smaller than what the [used value](#) would be for ['line-height: normal'](#).

Note

The [used value](#) will not be the actual keyword 'normal'. Also, this rule does not affect the [computed value](#).

If these text controls provide a text selection, then, when the user changes the current selection, the user agent is expected to [queue an element task](#)^{p970} on the [user interaction task source](#)^{p977} given the [input](#)^{p501} element to [fire an event](#) named [select](#)^{p1302} at the element, with the [bubbles](#) attribute initialized to true.

If an [input](#)^{p501} element whose [type](#)^{p503} attribute is in one of the above states has a [size](#)^{p530} attribute, and parsing that attribute's value using the [rules for parsing non-negative integers](#)^{p70} doesn't generate an error, then the user agent is expected to use the attribute as a [presentational hint](#)^{p1222} for the ['width'](#) property on the element, with the value obtained from applying the [converting a character width to pixels](#)^{p1244} algorithm to the value of the attribute.

If an [input](#)^{p501} element whose [type](#)^{p503} attribute is in one of the above states does *not* have a [size](#)^{p530} attribute, then the user agent is expected to act as if it had a user-agent-level style sheet rule setting the ['width'](#) property on the element to the value obtained from applying the [converting a character width to pixels](#)^{p1244} algorithm to the number 20.

The **converting a character width to pixels** algorithm returns $(size-1) \times avg + max$, where *size* is the character width to convert, *avg* is the average character width of the primary font for the element for which the algorithm is being run, in pixels, and *max* is the maximum character width of that same font, also in pixels. (The element's ['letter-spacing'](#) property does not affect the result.)

These text controls are expected to be [scroll containers](#) and support scrolling in the [inline axis](#), but not the [block axis](#).

15.5.6 The [input^{p501}](#) element as domain-specific widgets §^{p12}₄₅

An [input^{p501}](#) element whose [type^{p503}](#) attribute is in the [Date^{p512}](#) state is expected to render as an ['inline-block'](#) box depicting a date control.

An [input^{p501}](#) element whose [type^{p503}](#) attribute is in the [Month^{p513}](#) state is expected to render as an ['inline-block'](#) box depicting a month control.

An [input^{p501}](#) element whose [type^{p503}](#) attribute is in the [Week^{p514}](#) state is expected to render as an ['inline-block'](#) box depicting a week control.

An [input^{p501}](#) element whose [type^{p503}](#) attribute is in the [Time^{p515}](#) state is expected to render as an ['inline-block'](#) box depicting a time control.

An [input^{p501}](#) element whose [type^{p503}](#) attribute is in the [Local Date and Time^{p516}](#) state is expected to render as an ['inline-block'](#) box depicting a local date and time control.

An [input^{p501}](#) element whose [type^{p503}](#) attribute is in the [Number^{p517}](#) state is expected to render as an ['inline-block'](#) box depicting a number control.

These controls are all expected to be about one line high, and about as wide as necessary to show the widest possible value.

15.5.7 The [input^{p501}](#) element as a range control §^{p12}₄₅

An [input^{p501}](#) element whose [type^{p503}](#) attribute is in the [Range^{p518}](#) state is expected to render as an ['inline-block'](#) box depicting a slider control.

When the control is wider than it is tall (or square), the control is expected to be a horizontal slider, with the lowest value on the right if the ['direction'](#) property on this element has a [computed value](#) of ['rtl'](#), and on the left otherwise. When the control is taller than it is wide, it is expected to be a vertical slider, with the lowest value on the bottom.

Predefined suggested values (provided by the [list^{p536}](#) attribute) are expected to be shown as tick marks on the slider, which the slider can snap to.

User agents are expected to use the [used value](#) of the ['direction'](#) property on the element to determine the direction in which the slider operates. Typically, a left-to-right (['ltr'](#)) horizontal control would have the lowest value on the left and the highest value on the right, and vice versa.

15.5.8 The [input^{p501}](#) element as a color well §^{p12}₄₅

An [input^{p501}](#) element whose [type^{p503}](#) attribute is in the [Color^{p521}](#) state is expected to depict a color well, which, when activated, provides the user with a color picker (e.g. a color wheel or color palette) from which the color can be changed. The element, when it generates a [CSS box](#), is expected to use [button layout^{p1243}](#), that has no child boxes of the [anonymous button content box^{p1243}](#). The [anonymous button content box^{p1243}](#) is expected to have a [presentational hint^{p1222}](#) setting the ['background-color'](#) property to the element's [value^{p575}](#).

Predefined suggested values (provided by the [list^{p536}](#) attribute) are expected to be shown in the color picker interface, not on the color well itself.

15.5.9 The [input^{p501}](#) element as a checkbox and radio button widgets §^{p12}₄₅

An [input^{p501}](#) element whose [type^{p503}](#) attribute is in the [Checkbox^{p521}](#) state is expected to render as an ['inline-block'](#) box containing a single checkbox control, with no label.

An [input^{p501}](#) element whose [type^{p503}](#) attribute is in the [Radio Button^{p522}](#) state is expected to render as an ['inline-block'](#) box containing a single radio button control, with no label.

15.5.10 The [input^{p501}](#) element as a file upload control §^{p12} 46

An [input^{p501}](#) element whose [type^{p503}](#) attribute is in the [File Upload^{p523}](#) state, when it generates a [CSS box](#), is expected to render as an ['inline-block'](#) box containing a span of text giving the filename(s) of the [selected files^{p523}](#), if any, followed by a button that, when activated, provides the user with a file picker from which the selection can be changed. The button is expected to use [button layout^{p1243}](#) and match the [':file-selector-button'](#) pseudo-element. The contents of its [anonymous button content box^{p1243}](#) are expected to be [implementation-defined](#) (and possibly locale-specific) text, for example "Choose file".

15.5.11 The [input^{p501}](#) element as a button §^{p12} 46

An [input^{p501}](#) element whose [type^{p503}](#) attribute is in the [Submit Button^{p526}](#), [Reset Button^{p529}](#), or [Button^{p529}](#) state, when it generates a [CSS box](#), is expected to depict a button and use [button layout^{p1243}](#) and the contents of the [anonymous button content box^{p1243}](#) are expected to be the text of the element's [value^{p505}](#) attribute, if any, or text derived from the element's [type^{p503}](#) attribute in an [implementation-defined](#) (and probably locale-specific) fashion, if not.

15.5.12 The [marquee^{p1262}](#) element §^{p12} 46

```
CSS @namespace url(http://www.w3.org/1999/xhtml);

marquee {
  display: inline-block;
  text-align: initial;
}
```

The [marquee^{p1262}](#) element, while [turned on^{p1263}](#), is expected to render in an animated fashion according to its attributes as follows:

If the element's [behavior^{p1263}](#) attribute is in the [scroll^{p1263}](#) state

Slide the contents of the element in the direction described by the [direction^{p1263}](#) attribute as defined below, such that it begins off the start side of the [marquee^{p1262}](#), and ends flush with the inner end side.

Example

For example, if the [direction^{p1263}](#) attribute is [left^{p1263}](#) (the default), then the contents would start such that their left edge are off the side of the right edge of the [marquee^{p1262}](#)'s [content area](#), and the contents would then slide up to the point where the left edge of the contents are flush with the left inner edge of the [marquee^{p1262}](#)'s [content area](#).

Once the animation has ended, the user agent is expected to [increment the marquee current loop index^{p1264}](#). If the element is still [turned on^{p1263}](#) after this, then the user agent is expected to restart the animation.

If the element's [behavior^{p1263}](#) attribute is in the [slide^{p1263}](#) state

Slide the contents of the element in the direction described by the [direction^{p1263}](#) attribute as defined below, such that it begins off the start side of the [marquee^{p1262}](#), and ends off the end side of the [marquee^{p1262}](#).

Example

For example, if the [direction^{p1263}](#) attribute is [left^{p1263}](#) (the default), then the contents would start such that their left edge are off the side of the right edge of the [marquee^{p1262}](#)'s [content area](#), and the contents would then slide up to the point where the *right* edge of the contents are flush with the left inner edge of the [marquee^{p1262}](#)'s [content area](#).

Once the animation has ended, the user agent is expected to [increment the marquee current loop index^{p1264}](#). If the element is still [turned on^{p1263}](#) after this, then the user agent is expected to restart the animation.

If the element's [behavior](#)^{p1263} attribute is in the [alternate](#)^{p1263} state

When the [marquee current loop index](#)^{p1264} is even (or zero), slide the contents of the element in the direction described by the [direction](#)^{p1263} attribute as defined below, such that it begins flush with the start side of the [marquee](#)^{p1262}, and ends flush with the end side of the [marquee](#)^{p1262}.

When the [marquee current loop index](#)^{p1264} is odd, slide the contents of the element in the opposite direction than that described by the [direction](#)^{p1263} attribute as defined below, such that it begins flush with the end side of the [marquee](#)^{p1262}, and ends flush with the start side of the [marquee](#)^{p1262}.

Example

For example, if the [direction](#)^{p1263} attribute is [left](#)^{p1263} (the default), then the contents would with their right edge flush with the right inner edge of the [marquee](#)^{p1262}'s [content area](#), and the contents would then slide up to the point where the *left* edge of the contents are flush with the left inner edge of the [marquee](#)^{p1262}'s [content area](#).

Once the animation has ended, the user agent is expected to [increment the marquee current loop index](#)^{p1264}. If the element is still [turned on](#)^{p1263} after this, then the user agent is expected to continue the animation.

The [direction](#)^{p1263} attribute has the meanings described in the following table:

direction ^{p1263} attribute state	Direction of animation	Start edge	End edge	Opposite direction
left ^{p1263}	← Right to left	Right	Left	→ Left to Right
right ^{p1263}	→ Left to Right	Left	Right	← Right to left
up ^{p1263}	↑ Up (Bottom to Top)	Bottom	Top	↓ Down (Top to Bottom)
down ^{p1263}	↓ Down (Top to Bottom)	Top	Bottom	↑ Up (Bottom to Top)

In any case, the animation should proceed such that there is a delay given by the [marquee scroll interval](#)^{p1263} between each frame, and such that the content moves at most the distance given by the [marquee scroll distance](#)^{p1263} with each frame.

When a [marquee](#)^{p1262} element has a [bgcolor](#) attribute set, the value is expected to be parsed using the [rules for parsing a legacy color value](#)^{p88}, and if that does not return an error, the user agent is expected to treat the attribute as a [presentational hint](#)^{p1222} setting the element's ['background-color'](#) property to the resulting color.

The width and height attributes on a [marquee](#)^{p1262} element [map to the dimension properties](#)^{p1222} ['width'](#) and ['height'](#) on the element respectively.

The [intrinsic height](#) of a [marquee](#)^{p1262} element with its [direction](#)^{p1263} attribute in the [up](#)^{p1263} or [down](#)^{p1263} states is 200 [CSS pixels](#).

The [vspace](#) attribute of a [marquee](#)^{p1262} element [maps to the dimension properties](#)^{p1222} ['margin-top'](#) and ['margin-bottom'](#) on the element. The [hspace](#) attribute of a [marquee](#)^{p1262} element [maps to the dimension properties](#)^{p1222} ['margin-left'](#) and ['margin-right'](#) on the element.

The ['overflow'](#) property on the [marquee](#)^{p1262} element is expected to be ignored; overflow is expected to always be hidden.

15.5.13 The [meter](#)^{p567} element §^{p12}₄₇

The [meter](#)^{p567} element is expected to render as an ['inline-block'](#) box with a ['height'](#) of '1em' and a ['width'](#) of '5em', a ['vertical-align'](#) of '-0.2em', and with its contents depicting a gauge.

When the element is wider than it is tall (or square), the depiction is expected to be of a horizontal gauge, with the minimum value on the right if the ['direction'](#) property on this element has a [computed value](#) of 'rtl', and on the left otherwise. When the element is taller than it is wide, it is expected to depict a vertical gauge, with the minimum value on the bottom.

User agents are expected to use a presentation consistent with platform conventions for gauges, if any.

Note

Requirements for what must be depicted in the gauge are included in the definition of the [meter](#)^{p567} element.

15.5.14 The `progress` element § p12 48

The `progress` element is expected to render as an `'inline-block'` box with a `'height'` of `'1em'` and a `'width'` of `'10em'`, and a `'vertical-align'` of `'-0.2em'`.

When the element is wider than it is tall, the element is expected to be depicted as a horizontal progress bar, with the start on the right and the end on the left if the `'direction'` property on this element has a `computed value` of `'rtl'`, and with the start on the left and the end on the right otherwise. When the element is taller than it is wide, it is expected to be depicted as a vertical progress bar, with the lowest value on the bottom. When the element is square, it is expected to be depicted as a direction-independent progress widget (e.g. a circular progress ring).

User agents are expected to use a presentation consistent with platform conventions for progress bars. In particular, user agents are expected to use different presentations for determinate and indeterminate progress bars. User agents are also expected to vary the presentation based on the dimensions of the element.

Example

For example, on some platforms for showing indeterminate progress there is a "spinner" progress indicator with square dimensions, which could be used when the element is square, and an indeterminate progress bar, which could be used when the element is wide.

Note

Requirements for how to determine if the progress bar is determinate or indeterminate, and what progress a determinate progress bar is to show, are included in the definition of the `progress` element.

15.5.15 The `select` element § p12 48

A `select` element is either a **list box** or a **drop-down box**, depending on its attributes.

A `select` element whose `multiple` attribute is present is expected to render as a multi-select **list box**.

A `select` element whose `multiple` attribute is absent, and whose `display size` is greater than 1, is expected to render as a single-select **list box**.

When the element renders as a **list box**, it is expected to render as an `'inline-block'` box whose `'height'` is the height necessary to contain as many rows for items as given by the element's `display size`, or four rows if the attribute is absent, and whose `'width'` is the **width of the select's labels** plus the width of a scrollbar.

A `select` element whose `multiple` attribute is absent, and whose `display size` is 1, is expected to render as an `'inline-block'` one-line **drop-down box** whose width is the **width of the select's labels**.

In either case (**list box** or **drop-down box**), the element's items are expected to be the element's **list of options**, with the element's `optgroup` element **children** providing headers for groups of options where applicable.

An `optgroup` element is expected to be rendered by displaying the element's `label` attribute.

An `option` element is expected to be rendered by displaying the element's `label`, indented under its `optgroup` element if it has one.

The **width of the select's labels** is the wider of the width necessary to render the widest `optgroup`, and the width necessary to render the widest `option` element in the element's **list of options** (including its indent, if any).

If a `select` element contains a **placeholder label option**, the user agent is expected to render that `option` in a manner that conveys that it is a label, rather than a valid option of the control. This can include preventing the **placeholder label option** from being explicitly selected by the user. When the **placeholder label option**'s `selectedness` is true, the control is expected to be

displayed in a fashion that indicates that no valid option is currently selected.

User agents are expected to render the labels in a [select^{p547}](#) in such a manner that any alignment remains consistent whether the label is being displayed as part of the page or in a menu control.

15.5.16 The [textarea^{p558}](#) element §^{p12} 49

The [textarea^{p558}](#) element is expected to render as an ['inline-block'](#) box depicting a multiline text control. If this multiline text control provides a selection, then, when the user changes the current selection, the user agent is expected to [queue an element task^{p970}](#) on the [user interaction task source^{p977}](#) given the [textarea^{p558}](#) element to [fire an event](#) named [select^{p1302}](#) at the element, with the [bubbles](#) attribute initialized to true.

If the element has a [cols^{p560}](#) attribute, and parsing that attribute's value using the [rules for parsing non-negative integers^{p70}](#) doesn't generate an error, then the user agent is expected to use the attribute as a [presentational hint^{p1222}](#) for the ['width'](#) property on the element, with the value being the [textarea effective width^{p1249}](#) (as defined below). Otherwise, the user agent is expected to act as if it had a user-agent-level style sheet rule setting the ['width'](#) property on the element to the [textarea effective width^{p1249}](#).

The **textarea effective width** of a [textarea^{p558}](#) element is $size \times avg + sbw$, where *size* is the element's [character width^{p560}](#), *avg* is the average character width of the primary font of the element, in [CSS pixels](#), and *sbw* is the width of a scrollbar, in [CSS pixels](#). (The element's ['letter-spacing'](#) property does not affect the result.)

If the element has a [rows^{p560}](#) attribute, and parsing that attribute's value using the [rules for parsing non-negative integers^{p70}](#) doesn't generate an error, then the user agent is expected to use the attribute as a [presentational hint^{p1222}](#) for the ['height'](#) property on the element, with the value being the [textarea effective height^{p1249}](#) (as defined below). Otherwise, the user agent is expected to act as if it had a user-agent-level style sheet rule setting the ['height'](#) property on the element to the [textarea effective height^{p1249}](#).

The **textarea effective height** of a [textarea^{p558}](#) element is the height in [CSS pixels](#) of the number of lines specified the element's [character height^{p560}](#), plus the height of a scrollbar in [CSS pixels](#).

User agents are expected to apply the ['white-space'](#) CSS property to [textarea^{p558}](#) elements. For historical reasons, if the element has a [wrap^{p560}](#) attribute whose value is an [ASCII case-insensitive](#) match for the string "off", then the user agent is expected to treat the attribute as a [presentational hint^{p1222}](#) setting the element's ['white-space'](#) property to 'pre'.

15.6 Frames and framesets §^{p12} 49

User agent are expected to render [frameset^{p1264}](#) elements as a box with the height and width of the [viewport](#), with a surface rendered according to the following layout algorithm:

1. The *cols* and *rows* variables are lists of zero or more pairs consisting of a number and a unit, the unit being one of *percentage*, *relative*, and *absolute*.

Use the [rules for parsing a list of dimensions^{p74}](#) to parse the value of the element's *cols* attribute, if there is one. Let *cols* be the result, or an empty list if there is no such attribute.

Use the [rules for parsing a list of dimensions^{p74}](#) to parse the value of the element's *rows* attribute, if there is one. Let *rows* be the result, or an empty list if there is no such attribute.

2. For any of the entries in *cols* or *rows* that have the number zero and the unit *relative*, change the entry's number to one.
3. If *cols* has no entries, then add a single entry consisting of the value 1 and the unit *relative* to *cols*.

If *rows* has no entries, then add a single entry consisting of the value 1 and the unit *relative* to *rows*.

4. Invoke the algorithm defined below to [convert a list of dimensions to a list of pixel values^{p1250}](#) using *cols* as the input list, and the width of the surface that the [frameset^{p1264}](#) is being rendered into, in [CSS pixels](#), as the input dimension. Let *sized cols* be the resulting list.

Invoke the algorithm defined below to [convert a list of dimensions to a list of pixel values^{p1250}](#) using *rows* as the input list, and the height of the surface that the [frameset^{p1264}](#) is being rendered into, in [CSS pixels](#), as the input dimension. Let *sized rows* be the resulting list.

5. Split the surface into a grid of $w \times h$ rectangles, where w is the number of entries in *sized cols* and h is the number of entries in *sized rows*.

Size the columns so that each column in the grid is as many [CSS pixels](#) wide as the corresponding entry in the *sized cols* list.

Size the rows so that each row in the grid is as many [CSS pixels](#) high as the corresponding entry in the *sized rows* list.

6. Let *children* be the list of [frame](#)^{p1264} and [frameset](#)^{p1264} elements that are [children](#) of the [frameset](#)^{p1264} element for which the algorithm was invoked.
7. For each row of the grid of rectangles created in the previous step, from top to bottom, run these substeps:
 1. For each rectangle in the row, from left to right, run these substeps:
 1. If there are any elements left in *children*, take the first element in the list, and assign it to the rectangle.

If this is a [frameset](#)^{p1264} element, then recurse the entire [frameset](#)^{p1264} layout algorithm for that [frameset](#)^{p1264} element, with the rectangle as the surface.

Otherwise, it is a [frame](#)^{p1264} element; render its [nested browsing context](#)^{p843}, positioned and sized to fit the rectangle.
 2. If there are any elements left in *children*, remove the first element from *children*.
8. If the [frameset](#)^{p1264} element [has a border](#)^{p1250}, draw an outer set of borders around the rectangles, using the element's [frame border color](#)^{p1250}.

For each rectangle, if there is an element assigned to that rectangle, and that element [has a border](#)^{p1250}, draw an inner set of borders around that rectangle, using the element's [frame border color](#)^{p1250}.

For each (visible) border that does not abut a rectangle that is assigned a [frame](#)^{p1264} element with a `noresize` attribute (including rectangles in further nested [frameset](#)^{p1264} elements), the user agent is expected to allow the user to move the border, resizing the rectangles within, keeping the proportions of any nested [frameset](#)^{p1264} grids.

A [frameset](#)^{p1264} or [frame](#)^{p1264} element **has a border** if the following algorithm returns true:

1. If the element has a `frameborder` attribute whose value is not the empty string and whose first character is either a U+0031 DIGIT ONE (1) character, a U+0079 LATIN SMALL LETTER Y character (y), or a U+0059 LATIN CAPITAL LETTER Y character (Y), then return true.
2. Otherwise, if the element has a `frameborder` attribute, return false.
3. Otherwise, if the element has a parent element that is a [frameset](#)^{p1264} element, then return true if *that* element [has a border](#)^{p1250}, and false if it does not.
4. Otherwise, return true.

The **frame border color** of a [frameset](#)^{p1264} or [frame](#)^{p1264} element is the color obtained from the following algorithm:

1. If the element has a `bordercolor` attribute, and applying the [rules for parsing a legacy color value](#)^{p88} to that attribute's value does not result in an error, then return the color so obtained.
2. Otherwise, if the element has a parent element that is a [frameset](#)^{p1264} element, then return the [frame border color](#)^{p1250} of that element.
3. Otherwise, return gray.

The algorithm to **convert a list of dimensions to a list of pixel values** consists of the following steps:

1. Let *input list* be the list of numbers and units passed to the algorithm.

Let *output list* be a list of numbers the same length as *input list*, all zero.

Entries in *output list* correspond to the entries in *input list* that have the same position.
2. Let *input dimension* be the size passed to the algorithm.
3. Let *count percentage* be the number of entries in *input list* whose unit is *percentage*.

Let *total percentage* be the sum of all the numbers in *input list* whose unit is *percentage*.

Let *count relative* be the number of entries in *input list* whose unit is *relative*.

Let *total relative* be the sum of all the numbers in *input list* whose unit is *relative*.

Let *count absolute* be the number of entries in *input list* whose unit is *absolute*.

Let *total absolute* be the sum of all the numbers in *input list* whose unit is *absolute*.

Let *remaining space* be the value of *input dimension*.

4. If *total absolute* is greater than *remaining space*, then for each entry in *input list* whose unit is *absolute*, set the corresponding value in *output list* to the number of the entry in *input list* multiplied by *remaining space* and divided by *total absolute*. Then, set *remaining space* to zero.

Otherwise, for each entry in *input list* whose unit is *absolute*, set the corresponding value in *output list* to the number of the entry in *input list*. Then, decrement *remaining space* by *total absolute*.

5. If *total percentage* multiplied by the *input dimension* and divided by 100 is greater than *remaining space*, then for each entry in *input list* whose unit is *percentage*, set the corresponding value in *output list* to the number of the entry in *input list* multiplied by *remaining space* and divided by *total percentage*. Then, set *remaining space* to zero.

Otherwise, for each entry in *input list* whose unit is *percentage*, set the corresponding value in *output list* to the number of the entry in *input list* multiplied by the *input dimension* and divided by 100. Then, decrement *remaining space* by *total percentage* multiplied by the *input dimension* and divided by 100.

6. For each entry in *input list* whose unit is *relative*, set the corresponding value in *output list* to the number of the entry in *input list* multiplied by *remaining space* and divided by *total relative*.

7. Return *output list*.

User agents working with integer values for frame widths (as opposed to user agents that can lay frames out with subpixel accuracy) are expected to distribute the remainder first to the last entry whose unit is *relative*, then equally (not proportionally) to each entry whose unit is *percentage*, then equally (not proportionally) to each entry whose unit is *absolute*, and finally, failing all else, to the last entry.

The contents of a [frame](#)^{p1264} element that does not have a [frameset](#)^{p1264} parent are expected to be rendered as [transparent black](#); the user agent is expected to not render its [nested browsing context](#)^{p843} in this case, and its [nested browsing context](#)^{p843} is expected to have a [viewport](#) with zero width and zero height.

15.7 Interactive media §^{p12} 51

15.7.1 Links, forms, and navigation §^{p12} 51

User agents are expected to allow the user to control aspects of [hyperlink](#)^{p289} activation and [form submission](#)^{p605}, such as which [browsing context](#)^{p840} is to be used for the subsequent [navigation](#)^{p906}.

User agents are expected to allow users to discover the destination of [hyperlinks](#)^{p289} and of [forms](#)^{p494} before triggering their [navigation](#)^{p906}.

User agents are expected to inform the user of whether a [hyperlink](#)^{p289} includes [hyperlink auditing](#)^{p299}, and to let them know at a minimum which domains will be contacted as part of such auditing.

User agents may allow users to [navigate](#)^{p906} [browsing contexts](#)^{p840} to the URLs [indicated](#)^{p91} by the `cite` attributes on [q](#)^{p254}, [blockquote](#)^{p224}, [ins](#)^{p319}, and [del](#)^{p320} elements.

User agents may surface [hyperlinks](#)^{p289} created by [link](#)^{p162} elements in their user interface, as discussed [previously](#)^{p169}.

15.7.2 The [title](#)^{p143} attribute §^{p12} 51

User agents are expected to expose the [advisory information](#)^{p144} of elements upon user request, and to make the user aware of the presence of such information.

On interactive graphical systems where the user can use a pointing device, this could take the form of a tooltip. When the user is unable to use a pointing device, then the user agent is expected to make the content available in some other fashion, e.g. by making the element a [focusable area](#)^{p798} and always displaying the [advisory information](#)^{p144} of the currently [focused](#)^{p799} element, or by showing the [advisory information](#)^{p144} of the elements under the user's finger on a touch device as the user pans around the screen.

U+000A LINE FEED (LF) characters are expected to cause line breaks in the tooltip; U+0009 CHARACTER TABULATION (tab) characters are expected to render as a nonzero horizontal shift that lines up the next glyph with the next tab stop, with tab stops occurring at points that are multiples of 8 times the width of a U+0020 SPACE character.

Example

For example, a visual user agent could make elements with a [title](#)^{p143} attribute [focusable](#)^{p800}, and could make any [focused](#)^{p799} element with a [title](#)^{p143} attribute show its tooltip under the element while the element has focus. This would allow a user to tab around the document to find all the advisory text.

Example

As another example, a screen reader could provide an audio cue when reading an element with a tooltip, with an associated key to read the last tooltip for which a cue was played.

15.7.3 Editing hosts § p12 52

The current text editing caret (i.e. the [active range](#), if it is empty and in an [editing host](#)^{p817}), if any, is expected to act like an inline [replaced element](#) with the vertical dimensions of the caret and with zero width for the purposes of the CSS rendering model.

Note

This means that even an empty block can have the caret inside it, and that when the caret is in such an element, it prevents margins from collapsing through the element.

15.7.4 Text rendered in native user interfaces § p12 52

User agents are expected to honor the Unicode semantics of text that is exposed in user interfaces, for example supporting the bidirectional algorithm in text shown in dialogs, title bars, popup menus, and tooltips. Text from the contents of elements is expected to be rendered in a manner that honors [the directionality](#)^{p146} of the element from which the text was obtained. Text from attributes is expected to be rendered in a manner that honours the [directionality of the attribute](#)^{p147}.

Example

Consider the following markup, which has Hebrew text asking for a programming language, the languages being text for which a left-to-right direction is important given the punctuation in some of their names:

```
<p dir="rtl" lang="he">
  <label>
    : בחר שפת תכנות:
  > <select>
    <option dir="ltr">C++</option>
    <option dir="ltr">C#</option>
    <option dir="ltr">FreePascal</option>
    <option dir="ltr">F#</option>
  </select>
</label>
</p>
```

If the [select](#)^{p547} element was rendered as a drop down box, a correct rendering would ensure that the punctuation was the same both in the drop down, and in the box showing the current selection.

Example

The directionality of attributes depends on the attribute and on the element's [dir](#)^{p146} attribute, as the following example demonstrates. Consider this markup:

```
<table>
<tr>
  <th abbr="(א" dir=ltr>A
  <th abbr="(א" dir=rtl>A
  <th abbr="(א" dir=auto>A
</table>
```

If the [abbr](#)^{p476} attributes are rendered, e.g. in a tooltip or other user interface, the first will have a left parenthesis (because the direction is 'ltr'), the second will have a right parenthesis (because the direction is 'rtl'), and the third will have a right parenthesis (because the direction is determined *from the attribute value* to be 'rtl').

However, if instead the attribute was not a [directionality-capable attribute](#)^{p148}, the results would be different:

```
<table>
<tr>
  <th data-abbr="(א" dir=ltr>A
  <th data-abbr="(א" dir=rtl>A
  <th data-abbr="(א" dir=auto>A
</table>
```

In this case, if the user agent were to expose the `data-abbr` attribute in the user interface (e.g. in a debugging environment), the last case would be rendered with a *left* parenthesis, because the direction would be determined from the element's contents.

A string provided by a script (e.g. the argument to [window.alert\(\)](#)^{p1004}) is expected to be treated as an independent set of one or more bidirectional algorithm paragraphs when displayed, as defined by the bidirectional algorithm, including, for instance, supporting the paragraph-breaking behavior of U+000A LINE FEED (LF) characters. For the purposes of determining the paragraph level of such text in the bidirectional algorithm, this specification does *not* provide a higher-level override of rules P2 and P3. [\[BIDI\]](#)^{p1305}

When necessary, authors can enforce a particular direction for a given paragraph by starting it with the Unicode U+200E LEFT-TO-RIGHT MARK or U+200F RIGHT-TO-LEFT MARK characters.

Example

Thus, the following script:

```
alert('\u05DC\u05DE\u05D3 HTML \u05D4\u05D9\u05D5\u05DD!')
```

...would always result in a message reading "HTML היום! למד" (not "HTML למד!"), regardless of the language of the user agent interface or the direction of the page or any of its elements.

Example

For a more complex example, consider the following script:

```
/* Warning: this script does not handle right-to-left scripts correctly */
var s;
```

```

if (s = prompt('What is your name?')) {
  alert(s + '! Ok, Fred, ' + s + ', and Wilma will get the car.');
```

When the user enters "Kitty", the user agent would alert "Kitty! Ok, Fred, Kitty, and Wilma will get the car.". However, if the user enters "لا أفهم", then the bidirectional algorithm will determine that the direction of the paragraph is right-to-left, and so the output will be the following unintended mess: ".and Wilma will get the car , لا أفهم ,Ok, Fred ! أفهم"

To force an alert that starts with user-provided text (or other text of unknown directionality) to render left-to-right, the string can be prefixed with a U+200E LEFT-TO-RIGHT MARK character:

```

var s;
if (s = prompt('What is your name?')) {
  alert('\u200E' + s + '! Ok, Fred, ' + s + ', and Wilma will get the car.');
```

15.8 Print media §^{p12} 54

User agents are expected to allow the user to request the opportunity to **obtain a physical form** (or a representation of a physical form) of a [Document^{p117}](#). For example, selecting the option to print a page or convert it to PDF format. [[PDF](#)]^{p1310}

When the user actually [obtains a physical form^{p1254}](#) (or a representation of a physical form) of a [Document^{p117}](#), the user agent is expected to create a new rendering of the [Document^{p117}](#) for the print media.

15.9 Unstyled XML documents §^{p12} 54

HTML user agents may, in certain circumstances, find themselves rendering non-HTML documents that use vocabularies for which they lack any built-in knowledge. This section provides for a way for user agents to handle such documents in a somewhat useful manner.

While a [Document^{p117}](#) is an [unstyled document^{p1254}](#), the user agent is expected to render an [unstyled document view^{p1254}](#).

A [Document^{p117}](#) is an **unstyled document** while it matches the following conditions:

- The [Document^{p117}](#) has no author style sheets (whether referenced by HTTP headers, processing instructions, elements like [link^{p162}](#), inline elements like [style^{p180}](#), or any other mechanism).
- None of the elements in the [Document^{p117}](#) have any [presentational hints^{p1222}](#).
- None of the elements in the [Document^{p117}](#) have any [style attributes](#).
- None of the elements in the [Document^{p117}](#) are in any of the following namespaces: [HTML namespace](#), [SVG namespace](#), [MathML namespace](#)
- The [Document^{p117}](#) has no [focusable area^{p798}](#) (e.g. from XLink) other than the [viewport](#).
- The [Document^{p117}](#) has no [hyperlinks^{p289}](#) (e.g. from XLink).
- There exists no [script^{p945}](#) whose [settings object^{p945}](#) specifies this [Document^{p117}](#) as the [responsible document^{p937}](#).
- None of the elements in the [Document^{p117}](#) have any registered event listeners.

An unstyled document view is one where the DOM is not rendered according to CSS (which would, since there are no applicable styles in this context, just result in a wall of text), but is instead rendered in a manner that is useful for a developer. This could consist of just showing the [Document^{p117}](#) object's source, maybe with syntax highlighting, or it could consist of displaying just the DOM tree, or simply a message saying that the page is not a styled document.

Note

If a [Document](#)^{p117} stops being an [unstyled document](#)^{p1254}, then the conditions above stop applying, and thus a user agent following these requirements will switch to using the regular CSS rendering.

16 Obsolete features § p12 56

16.1 Obsolete but conforming features § p12 56

Features listed in this section will trigger warnings in conformance checkers.

Authors should not specify a [border^{p1261}](#) attribute on an [img^{p327}](#) element. If the attribute is present, its value must be the string "0". CSS should be used instead.

Authors should not specify a [charset^{p1258}](#) attribute on a [script^{p624}](#) element. If the attribute is present, its value must be an [ASCII case-insensitive](#) match for "utf-8". (This has no effect in a document that conforms to the requirements elsewhere in this standard of being encoded as [UTF-8](#).)

Authors should not specify a [language^{p1260}](#) attribute on a [script^{p624}](#) element. If the attribute is present, its value must be an [ASCII case-insensitive](#) match for the string "JavaScript" and either the [type^{p625}](#) attribute must be omitted or its value must be an [ASCII case-insensitive](#) match for the string "text/javascript". The attribute should be entirely omitted instead (with the value "JavaScript", it has no effect), or replaced with use of the [type^{p625}](#) attribute.

Authors should not specify a value for the [type^{p625}](#) attribute on [script^{p624}](#) elements that is the empty string or a [JavaScript MIME type essence match](#). Instead, they should omit the attribute, which has the same effect.

Authors should not specify a [type^{p1260}](#) attribute on a [style^{p180}](#) element. If the attribute is present, its value must be an [ASCII case-insensitive](#) match for "[text/css^{p1303}](#)".

Authors should not specify the [name^{p1258}](#) attribute on [a^{p244}](#) elements. If the attribute is present, its value must not be the empty string and must neither be equal to the value of any of the [IDs](#) in the element's [tree](#) other than the element's own [ID](#), if any, nor be equal to the value of any of the other [name^{p1258}](#) attributes on [a^{p244}](#) elements in the element's [tree](#). If this attribute is present and the element has an [ID](#), then the attribute's value must be equal to the element's [ID](#). In earlier versions of the language, this attribute was intended as a way to specify possible targets for [fragments](#) in [URLs](#). The [id^{p141}](#) attribute should be used instead.

Authors should not, but may despite requirements to the contrary elsewhere in this specification, specify the [maxlength^{p530}](#) and [size^{p530}](#) attributes on [input^{p501}](#) elements whose [type^{p503}](#) attributes are in the [Number^{p517}](#) state. One valid reason for using these attributes regardless is to help legacy user agents that do not support [input^{p501}](#) elements with `type="number"` to still render the text control with a useful width.

16.1.1 Warnings for obsolete but conforming features § p12 56

To ease the transition from HTML4 Transitional documents to the language defined in *this* specification, and to discourage certain features that are only allowed in very few circumstances, conformance checkers must warn the user when the following features are used in a document. These are generally old obsolete features that have no effect, and are allowed only to distinguish between likely mistakes (regular conformance errors) and mere vestigial markup or unusual and discouraged practices (these warnings).

The following features must be categorized as described above:

- The presence of a [border^{p1261}](#) attribute on an [img^{p327}](#) element if its value is the string "0".
- The presence of a [charset^{p1258}](#) attribute on a [script^{p624}](#) element if its value is an [ASCII case-insensitive](#) match for "utf-8".
- The presence of a [language^{p1260}](#) attribute on a [script^{p624}](#) element if its value is an [ASCII case-insensitive](#) match for the string "JavaScript" and if there is no [type^{p625}](#) attribute or there is and its value is an [ASCII case-insensitive](#) match for the string "text/javascript".
- The presence of a [type^{p1260}](#) attribute on a [script^{p624}](#) element if its value is a [JavaScript MIME type essence match](#).
- The presence of a [type^{p1260}](#) attribute on a [style^{p180}](#) element if its value is an [ASCII case-insensitive](#) match for "[text/css^{p1303}](#)".
- The presence of a [name^{p1258}](#) attribute on an [a^{p244}](#) element, if its value is not the empty string.
- The presence of a [maxlength^{p530}](#) attribute on an [input^{p501}](#) element whose [type^{p503}](#) attribute is in the [Number^{p517}](#) state.

- The presence of a [size^{p530}](#) attribute on an [input^{p501}](#) element whose [type^{p503}](#) attribute is in the [Number^{p517}](#) state.

Conformance checkers must distinguish between pages that have no conformance errors and have none of these obsolete features, and pages that have no conformance errors but do have some of these obsolete features.

Example

For example, a validator could report some pages as "Valid HTML" and others as "Valid HTML with warnings".

16.2 Non-conforming features §^{p12} 57

Elements in the following list are entirely obsolete, and must not be used by authors:

applet

Use [embed^{p378}](#) or [object^{p381}](#) instead.

acronym

Use [abbr^{p256}](#) instead.

bgsound

Use [audio^{p392}](#) instead.

dir

Use [ul^{p228}](#) instead.

frame^{p1264}

frameset^{p1264}

noframes

Either use [iframe^{p369}](#) and CSS instead, or use server-side includes to generate complete pages with the various invariant parts merged in.

isindex

Use an explicit [form^{p494}](#) and [text control^{p508}](#) combination instead.

keygen

For enterprise device management use cases, use native on-device management capabilities.

For certificate enrollment use cases, use the Web Cryptography API to generate a keypair for the certificate, and then export the certificate and key to allow the user to install them manually. [\[WEBCRYPTO\]^{p1312}](#)

listing

Use [pre^{p222}](#) and [code^{p273}](#) instead.

menuitem

To implement a custom context menu, use script to handle the [contextmenu](#) event.

nextid

Use GUIDs instead.

noembed

Use [object^{p381}](#) instead of [embed^{p378}](#) when fallback is necessary.

plaintext

Use the "text/plain" [MIME type](#) instead.

rb

rtc

Providing the ruby base directly inside the [ruby^{p258}](#) element or using nested [ruby^{p258}](#) elements is sufficient.

strike

Use [del](#)^{p320} instead if the element is marking an edit, otherwise use [s](#)^{p251} instead.

xmp

Use [pre](#)^{p222} and [code](#)^{b273} instead, and escape "<" and "&" characters as "<" and "&" respectively.

basefont

big

blink

center

font

marquee

^{p1262}

multicol

nobr

spacer

tt

Use appropriate elements or CSS instead.

Where the [tt](#)^{p1258} element would have been used for marking up keyboard input, consider the [kbd](#)^{p276} element; for variables, consider the [var](#)^{p274} element; for computer code, consider the [code](#)^{b273} element; and for computer output, consider the [samp](#)^{p275} element.

Similarly, if the [big](#)^{p1258} element is being used to denote a heading, consider using the [h1](#)^{p196} element; if it is being used for marking up important passages, consider the [strong](#)^{p249} element; and if it is being used for highlighting text for reference purposes, consider the [mark](#)^{p281} element.

See also the [text-level semantics usage summary](#)^{p288} for more suggestions with examples.

The following attributes are obsolete (though the elements are still part of the language), and must not be used by authors:

charset on [a](#)^{p244} elements

charset on [link](#)^{p162} elements

Use an HTTP `Content-Type`^{p92} header on the linked resource instead.

charset on [script](#)^{p624} elements (except as noted in the previous section)

Omit the attribute. Both documents and scripts are required to use [UTF-8](#), so it is redundant to specify it on the [script](#)^{p624} element since it inherits from the document.

coords on [a](#)^{p244} elements

shape on [a](#)^{p244} elements

Use [area](#)^{p452} instead of [a](#)^{p244} for image maps.

methods on [a](#)^{p244} elements

methods on [link](#)^{p162} elements

Use the HTTP OPTIONS feature instead.

name on [a](#)^{p244} elements (except as noted in the previous section)

name on [embed](#)^{p378} elements

name on [img](#)^{p327} elements

name on [option](#)^{p555} elements

Use the [id](#)^{p141} attribute instead.

rev on [a](#)^{p244} elements

rev on [link](#)^{p162} elements

Use the [rel](#)^{p290} attribute instead, with an opposite term. (For example, instead of `rev="made"`, use `rel="author"`.)

urn on [a](#)^{p244} elements

urn on [link](#)^{p162} elements

Specify the preferred persistent identifier using the [href](#)^{p290} attribute instead.

accept on [form](#)^{p494} elements

Use the [accept](#)^{p524} attribute directly on the [input](#)^{p501} elements instead.

hreflang on [area](#)^{p452} elements

type on [area](#)^{p452} elements

These attributes do not do anything useful, and for historical reasons there are no corresponding IDL attributes on [area](#)^{p452} elements. Omit them altogether.

nohref on [area](#)^{p452} elements

Omitting the [href](#)^{p290} attribute is sufficient; the [nohref](#)^{p1259} attribute is unnecessary. Omit it altogether.

profile on [head](#)^{p158} elements

Unnecessary. Omit it altogether.

manifest on [html](#)^{p157} elements

Use service workers instead. [\[SW\]](#)^{p1312}

version on [html](#)^{p157} elements

Unnecessary. Omit it altogether.

ismap on [input](#)^{p501} elements

Unnecessary. Omit it altogether. All [input](#)^{p501} elements with a [type](#)^{p503} attribute in the [Image Button](#)^{p526} state are processed as server-side image maps.

usemap on [input](#)^{p501} elements

usemap on [object](#)^{p381} elements

Use the [img](#)^{p327} element for image maps.

longdesc on [iframe](#)^{p369} elements

longdesc on [img](#)^{p327} elements

Use a regular [a](#)^{p244} element to link to the description, or (in the case of images) use an [image map](#)^{p454} to provide a link from the image to the image's description.

lowsrc on [img](#)^{p327} elements

Use a progressive JPEG image (given in the [src](#)^{p328} attribute), instead of using two separate images.

target on [link](#)^{p162} elements

Unnecessary. Omit it altogether.

type on [menu](#)^{p229} elements

To implement a custom context menu, use script to handle the [contextmenu](#) event. For toolbar menus, omit the attribute.

label on [menu](#)^{p229} elements

contextmenu on all elements

onshow on all elements

To implement a custom context menu, use script to handle the [contextmenu](#) event.

scheme on [meta](#)^{p170} elements

Use only one scheme per field, or make the scheme declaration part of the value.

archive on [object](#)^{p381} elements

classid on [object](#)^{p381} elements

code on [object](#)^{p381} elements

codebase on [object](#)^{p381} elements

codetype on [object](#)^{p381} elements

Use the [data](#)^{p382} and [type](#)^{p382} attributes to invoke [plugins](#)^{p45}. To set parameters with these names in particular, the [param](#)^{p387}

element can be used.

declare on [object](#)^{p381} elements

Repeat the [object](#)^{p381} element completely each time the resource is to be reused.

standby on [object](#)^{p381} elements

Optimize the linked resource so that it loads quickly or, at least, incrementally.

typemustmatch on [object](#)^{p381} elements

Avoid using [object](#)^{p381} elements with untrusted resources.

type on [param](#)^{p387} elements

valuetype on [param](#)^{p387} elements

Use the [name](#)^{p387} and [value](#)^{p387} attributes without declaring value types.

language on [script](#)^{p624} elements (except as noted in the previous section)

Omit the attribute for JavaScript; for [data blocks](#)^{p625}, use the [type](#)^{p625} attribute instead.

event on [script](#)^{p624} elements

for on [script](#)^{p624} elements

Use DOM events mechanisms to register event listeners. [\[DOM\]](#)^{p1307}

type on [style](#)^{p180} elements (except as noted in the previous section)

Omit the attribute for CSS; for [data blocks](#)^{p625}, use [script](#)^{p624} as the container instead of [style](#)^{p180}.

datapagesize on [table](#)^{p458} elements

Unnecessary. Omit it altogether.

summary on [table](#)^{p458} elements

Use one of the [techniques for describing tables](#)^{p463} given in the [table](#)^{p458} section instead.

abbr on [td](#)^{p474} elements

Use text that begins in an unambiguous and terse manner, and include any more elaborate text after that. The [title](#)^{p143} attribute can also be useful in including more detailed text, so that the cell's contents can be made terse. If it's a heading, use [th](#)^{p475} (which has an [abbr](#)^{p476} attribute).

axis on [td](#)^{p474} and [th](#)^{p475} elements

Use the [scope](#)^{p475} attribute on the relevant [th](#)^{p475}.

scope on [td](#)^{p474} elements

Use [th](#)^{p475} elements for heading cells.

[datasrc](#) on [a](#)^{p244}, [button](#)^{p545}, [div](#)^{p243}, [frame](#)^{p1264}, [iframe](#)^{p369}, [img](#)^{p327}, [input](#)^{p501}, [label](#)^{p498}, [legend](#)^{p574}, [marquee](#)^{p1262}, [object](#)^{p381}, [option](#)^{p555}, [select](#)^{p547}, [span](#)^{p285}, [table](#)^{p458}, and [textarea](#)^{p558} elements

[datafld](#) on [a](#)^{p244}, [button](#)^{p545}, [div](#)^{p243}, [fieldset](#)^{p572}, [frame](#)^{p1264}, [iframe](#)^{p369}, [img](#)^{p327}, [input](#)^{p501}, [label](#)^{p498}, [legend](#)^{p574}, [marquee](#)^{p1262}, [object](#)^{p381}, [param](#)^{p387}, [select](#)^{p547}, [span](#)^{p285}, and [textarea](#)^{p558} elements

[dataformatas](#) on [button](#)^{p545}, [div](#)^{p243}, [input](#)^{p501}, [label](#)^{p498}, [legend](#)^{p574}, [marquee](#)^{p1262}, [object](#)^{p381}, [option](#)^{p555}, [select](#)^{p547}, [span](#)^{p285}, and [table](#)^{p458} elements

Use script and a mechanism such as [XMLHttpRequest](#) to populate the page dynamically. [\[XHR\]](#)^{p1313}

dropzone on all elements

Use script to handle the [dragenter](#)^{p838} and [dragover](#)^{p838} events instead.

Use CSS instead.

16.3 Requirements for implementations § p12

62

16.3.1 The `marquee` element § p12

62

The `marquee`^{p1262} element is a presentational element that animates content. CSS transitions and animations are a more appropriate mechanism. [\[CSSANIMATIONS\]](#)^{p1306} [\[CSSTRANSITIONS\]](#)^{p1307}

The `marquee`^{p1262} element must implement the `HTMLMarqueeElement`^{p1262} interface.

```

IDL [Exposed=Window]
interface HTMLMarqueeElement : HTMLElement {
  [HTMLConstructor] constructor();

  [CEReactions] attribute DOMString behavior;
  [CEReactions] attribute DOMString bgColor;
  [CEReactions] attribute DOMString direction;
  
```

```

[CEReactions] attribute DOMString height;
[CEReactions] attribute unsigned long hspace;
[CEReactions] attribute long loop;
[CEReactions] attribute unsigned long scrollAmount;
[CEReactions] attribute unsigned long scrollDelay;
[CEReactions] attribute boolean trueSpeed;
[CEReactions] attribute unsigned long vspace;
[CEReactions] attribute DOMString width;

undefined start();
undefined stop();
};

```

A [marquee^{p1262}](#) element can be **turned on** or **turned off**. When it is created, it is [turned on^{p1263}](#).

When the `start()` method is called, the [marquee^{p1262}](#) element must be [turned on^{p1263}](#).

When the `stop()` method is called, the [marquee^{p1262}](#) element must be [turned off^{p1263}](#).

The **behavior** content attribute on [marquee^{p1262}](#) elements is an [enumerated attribute^{p69}](#) with the following keywords (all non-conforming):

Keyword	State
scroll	scroll
slide	slide
alternate	alternate

The [missing value default^{p69}](#) and [invalid value default^{p69}](#) are the [scroll^{p1263}](#) state.

The **direction** content attribute on [marquee^{p1262}](#) elements is an [enumerated attribute^{p69}](#) with the following keywords (all non-conforming):

Keyword	State
left	left
right	right
up	up
down	down

The [missing value default^{p69}](#) and [invalid value default^{p69}](#) are the [left^{p1263}](#) state.

The **trueSpeed** content attribute on [marquee^{p1262}](#) elements is a [boolean attribute^{p69}](#).

A [marquee^{p1262}](#) element has a **marquee scroll interval**, which is obtained as follows:

1. If the element has a `scrollDelay` attribute, and parsing its value using the [rules for parsing non-negative integers^{p70}](#) does not return an error, then let *delay* be the parsed value. Otherwise, let *delay* be 85.
2. If the element does not have a [trueSpeed^{p1263}](#) attribute, and the *delay* value is less than 60, then let *delay* be 60 instead.
3. The [marquee scroll interval^{p1263}](#) is *delay*, interpreted in milliseconds.

A [marquee^{p1262}](#) element has a **marquee scroll distance**, which, if the element has a `scrollAmount` attribute, and parsing its value using the [rules for parsing non-negative integers^{p70}](#) does not return an error, is the parsed value interpreted in [CSS pixels](#), and otherwise is 6 [CSS pixels](#).

A [marquee^{p1262}](#) element has a **marquee loop count**, which, if the element has a **loop** attribute, and parsing its value using the [rules for parsing integers^{p70}](#) does not return an error or a number less than 1, is the parsed value, and otherwise is -1 .

The **loop** IDL attribute, on getting, must return the element's [marquee loop count^{p1264}](#); and on setting, if the new value is different than the element's [marquee loop count^{p1264}](#) and either greater than zero or equal to -1 , must set the element's [loop^{p1264}](#) content attribute (adding it if necessary) to the [valid integer^{p70}](#) that represents the new value. (Other values are ignored.)

A [marquee^{p1262}](#) element also has a **marquee current loop index**, which is zero when the element is created.

The rendering layer will occasionally **increment the marquee current loop index**, which must cause the following steps to be run:

1. If the [marquee loop count^{p1264}](#) is -1 , then return.
2. Increment the [marquee current loop index^{p1264}](#) by one.
3. If the [marquee current loop index^{p1264}](#) is now equal to or greater than the element's [marquee loop count^{p1264}](#), [turn off^{p1263}](#) the [marquee^{p1262}](#) element.

The **behavior**, **direction**, **height**, **hspace**, **vspace**, and **width** IDL attributes must [reflect^{p97}](#) the respective content attributes of the same name.

The **bgColor** IDL attribute must [reflect^{p97}](#) the `bgcolor` content attribute.

The **scrollAmount** IDL attribute must [reflect^{p97}](#) the `scrollamount` content attribute. The default value is 6.

The **scrollDelay** IDL attribute must [reflect^{p97}](#) the `scrolldelay` content attribute. The default value is 85.

The **trueSpeed** IDL attribute must [reflect^{p97}](#) the [truespeed^{p1263}](#) content attribute.

16.3.2 Frames §^{p12} 64

The **frameset** element acts as [the body element^{p123}](#) in documents that use frames.

The [frameset^{p1264}](#) element must implement the [HTMLFrameSetElement^{p1264}](#) interface.

```
IDL [Exposed=Window]
interface HTMLFrameSetElement : HTMLElement {
  [HTMLConstructor] constructor();

  [CEReactions] attribute DOMString cols;
  [CEReactions] attribute DOMString rows;
};
HTMLFrameSetElement includes WindowEventHandlers;
```

The **cols** and **rows** IDL attributes of the [frameset^{p1264}](#) element must [reflect^{p97}](#) the respective content attributes of the same name.

The [frameset^{p1264}](#) element exposes as [event handler content attributes^{p981}](#) a number of the [event handlers^{p980}](#) of the [Window^{p855}](#) object. It also mirrors their [event handler IDL attributes^{p981}](#).

The [event handlers^{p980}](#) of the [Window^{p855}](#) object named by the [Window-reflecting body element event handler set^{p988}](#), exposed on the [frameset^{p1264}](#) element, replace the generic [event handlers^{p980}](#) with the same names normally supported by [HTML elements^{p44}](#).

The **frame** element has a [nested browsing context^{p843}](#) similar to the [iframe^{p369}](#) element, but rendered within a [frameset^{p1264}](#) element.

A [frame^{p1264}](#) element is said to be an **active frame element** when it is [in a document](#).

When a [frame^{p1264}](#) element *element* is created as an [active frame element^{p1264}](#), or becomes an [active frame element^{p1264}](#) after not having been one, the user agent must run these steps:

1. [Create a new nested browsing context^{p843}](#) for *element*.

2. [Process the frame attributes](#)^{p1265} for *element*, with [initialInsertion](#)^{p1265} set to true.

When a [frame](#)^{p1264} element stops being an [active frame element](#)^{p1264}, the user agent must [discard](#)^{p862} the element's [nested browsing context](#)^{p843}, and then set the element's [nested browsing context](#)^{p843} to null.

Whenever a [frame](#)^{p1264} element with a non-null [nested browsing context](#)^{p843} has its `src` attribute set, changed, or removed, the user agent must [process the frame attributes](#)^{p1265}.

To **process the frame attributes** for an element *element*, with an optional boolean *initialInsertion*:

1. If *element* has a `src` attribute specified, or *initialInsertion* is false, then run the [shared attribute processing steps for iframe and frame elements](#)^{p372} given *element* and *initialInsertion*.

The [frame](#)^{p1264} element [potentially delays the load event](#)^{p373}.

The [frame](#)^{p1264} element must implement the [HTMLFrameElement](#)^{p1265} interface.

```
IDL [Exposed=Window]
interface HTMLFrameElement : HTMLElement {
  [HTMLConstructor] constructor();

  [CEReactions] attribute DOMString name;
  [CEReactions] attribute DOMString scrolling;
  [CEReactions] attribute USVString src;
  [CEReactions] attribute DOMString frameBorder;
  [CEReactions] attribute USVString longDesc;
  [CEReactions] attribute boolean noResize;
  readonly attribute Document? contentDocument;
  readonly attribute WindowProxy? contentWindow;

  [CEReactions] attribute [LegacyNullToEmptyString] DOMString marginHeight;
  [CEReactions] attribute [LegacyNullToEmptyString] DOMString marginWidth;
};
```

The **name**, **scrolling**, and **src** IDL attributes of the [frame](#)^{p1264} element must [reflect](#)^{p97} the respective content attributes of the same name. For the purposes of reflection, the [frame](#)^{p1264} element's `src` content attribute is defined as containing a [URL](#).

The **frameBorder** IDL attribute of the [frame](#)^{p1264} element must [reflect](#)^{p97} the element's `frameborder` content attribute.

The **longDesc** IDL attribute of the [frame](#)^{p1264} element must [reflect](#)^{p97} the element's `longdesc` content attribute, which for the purposes of reflection is defined as containing a [URL](#).

The **noResize** IDL attribute of the [frame](#)^{p1264} element must [reflect](#)^{p97} the element's `noresize` content attribute.

The **contentDocument** IDL attribute, on getting, must return the [frame](#)^{p1264} element's [content document](#)^{p845}.

The **contentWindow** IDL attribute must return the [WindowProxy](#)^{p865} object of the [frame](#)^{p1264} element's [nested browsing context](#)^{p843}, if the element's [nested browsing context](#)^{p843} is non-null, or return null otherwise.

The **marginHeight** IDL attribute of the [frame](#)^{p1264} element must [reflect](#)^{p97} the element's `marginheight` content attribute.

The **marginWidth** IDL attribute of the [frame](#)^{p1264} element must [reflect](#)^{p97} the element's `marginwidth` content attribute.

16.3.3 Other elements, attributes and APIs §^{p12}₆₅

User agents must treat [acronym](#)^{p1257} elements in a manner equivalent to [abbr](#)^{p256} elements in terms of semantics and for purposes of rendering.

```
IDL partial interface HTMLAnchorElement {
```

```

[CEReactions] attribute DOMString coords;
[CEReactions] attribute DOMString charset;
[CEReactions] attribute DOMString name;
[CEReactions] attribute DOMString rev;
[CEReactions] attribute DOMString shape;
};

```

The **coords**, **charset**, **name**, **rev**, and **shape** IDL attributes of the [a](#)^{p244} element must [reflect](#)^{p97} the respective content attributes of the same name.

```

IDL partial interface HTMLAreaElement {
  [CEReactions] attribute boolean noHref;
};

```

The **noHref** IDL attribute of the [area](#)^{p452} element must [reflect](#)^{p97} the element's [nohref](#)^{p1259} content attribute.

```

IDL partial interface HTMLBodyElement {
  [CEReactions] attribute [LegacyNullToEmptyString] DOMString text;
  [CEReactions] attribute [LegacyNullToEmptyString] DOMString link;
  [CEReactions] attribute [LegacyNullToEmptyString] DOMString vLink;
  [CEReactions] attribute [LegacyNullToEmptyString] DOMString aLink;
  [CEReactions] attribute [LegacyNullToEmptyString] DOMString bgColor;
  [CEReactions] attribute DOMString background;
};

```

The **text** IDL attribute of the [body](#)^{p184} element must [reflect](#)^{p97} the element's [text](#)^{p1261} content attribute.

The **link** IDL attribute of the [body](#)^{p184} element must [reflect](#)^{p97} the element's [link](#)^{p1261} content attribute.

The **aLink** IDL attribute of the [body](#)^{p184} element must [reflect](#)^{p97} the element's [alink](#)^{p1261} content attribute.

The **vLink** IDL attribute of the [body](#)^{p184} element must [reflect](#)^{p97} the element's [vlink](#)^{p1261} content attribute.

The **bgColor** IDL attribute of the [body](#)^{p184} element must [reflect](#)^{p97} the element's [bgcolor](#)^{p1261} content attribute.

The **background** IDL attribute of the [body](#)^{p184} element must [reflect](#)^{p97} the element's [background](#)^{p1262} content attribute. (The [background](#)^{p1262} content is *not* defined to contain a [URL](#), despite rules regarding its handling in the Rendering section above.)

```

IDL partial interface HTMLBRElement {
  [CEReactions] attribute DOMString clear;
};

```

The **clear** IDL attribute of the [br](#)^{p286} element must [reflect](#)^{p97} the content attribute of the same name.

```

IDL partial interface HTMLTableCaptionElement {
  [CEReactions] attribute DOMString align;
};

```

The **align** IDL attribute of the [caption](#)^{p466} element must [reflect](#)^{p97} the content attribute of the same name.

```

IDL partial interface HTMLTableColElement {
  [CEReactions] attribute DOMString align;
  [CEReactions] attribute DOMString ch;
};

```

```
[CEReactions] attribute DOMString chOff;
[CEReactions] attribute DOMString vAlign;
[CEReactions] attribute DOMString width;
};
```

The **align** and **width** IDL attributes of the **col**^{p468} element must **reflect**^{p97} the respective content attributes of the same name.

The **ch** IDL attribute of the **col**^{p468} element must **reflect**^{p97} the element's **char**^{p1261} content attribute.

The **chOff** IDL attribute of the **col**^{p468} element must **reflect**^{p97} the element's **charoff**^{p1261} content attribute.

The **vAlign** IDL attribute of the **col**^{p468} element must **reflect**^{p97} the element's **valign**^{p1261} content attribute.

User agents must treat **dir**^{p1257} elements in a manner equivalent to **ul**^{p228} elements in terms of semantics and for purposes of rendering.

The **dir**^{p1257} element must implement the **HTMLDirectoryElement**^{p1267} interface.

```
IDL [Exposed=Window]
interface HTMLDirectoryElement : HTMLElement {
  [HTMLConstructor] constructor();

  [CEReactions] attribute boolean compact;
};
```

The **compact** IDL attribute of the **dir**^{p1257} element must **reflect**^{p97} the content attribute of the same name.

```
IDL partial interface HTMLDivElement {
  [CEReactions] attribute DOMString align;
};
```

The **align** IDL attribute of the **div**^{p243} element must **reflect**^{p97} the content attribute of the same name.

```
IDL partial interface HTMLDListElement {
  [CEReactions] attribute boolean compact;
};
```

The **compact** IDL attribute of the **dl**^{p233} element must **reflect**^{p97} the content attribute of the same name.

```
IDL partial interface HTMLEmbedElement {
  [CEReactions] attribute DOMString align;
  [CEReactions] attribute DOMString name;
};
```

The **name** and **align** IDL attributes of the **embed**^{p378} element must **reflect**^{p97} the respective content attributes of the same name.

The **font**^{p1258} element must implement the **HTMLFontElement**^{p1267} interface.

```
IDL [Exposed=Window]
interface HTMLFontElement : HTMLElement {
  [HTMLConstructor] constructor();

  [CEReactions] attribute [LegacyNullToEmptyString] DOMString color;
  [CEReactions] attribute DOMString face;
};
```

```
[CEReactions] attribute DOMString size;
};
```

The **color**, **face**, and **size** IDL attributes of the `font`^{p1258} element must [reflect](#)^{p97} the respective content attributes of the same name.

```
IDL partial interface HTMLHeadingElement {
  [CEReactions] attribute DOMString align;
};
```

The **align** IDL attribute of the `h1`^{p196}–`h6`^{p196} elements must [reflect](#)^{p97} the content attribute of the same name.

Note

The **profile** IDL attribute on `head`^{p158} elements (with the `HTMLHeadElement`^{p158} interface) is intentionally omitted. Unless so required by [another applicable specification](#)^{p67}, implementations would therefore not support this attribute. (It is mentioned here as it was defined in a previous version of DOM.)

```
IDL partial interface HTMLHRElement {
  [CEReactions] attribute DOMString align;
  [CEReactions] attribute DOMString color;
  [CEReactions] attribute boolean noShade;
  [CEReactions] attribute DOMString size;
  [CEReactions] attribute DOMString width;
};
```

The **align**, **color**, **size**, and **width** IDL attributes of the `hr`^{p220} element must [reflect](#)^{p97} the respective content attributes of the same name.

The **noShade** IDL attribute of the `hr`^{p220} element must [reflect](#)^{p97} the element's `noshade`^{p1261} content attribute.

```
IDL partial interface HTMLHtmlElement {
  [CEReactions] attribute DOMString version;
};
```

The **version** IDL attribute of the `html`^{p157} element must [reflect](#)^{p97} the content attribute of the same name.

```
IDL partial interface HTMLIFrameElement {
  [CEReactions] attribute DOMString align;
  [CEReactions] attribute DOMString scrolling;
  [CEReactions] attribute DOMString frameBorder;
  [CEReactions] attribute USVString longDesc;

  [CEReactions] attribute [LegacyNullToEmptyString] DOMString marginHeight;
  [CEReactions] attribute [LegacyNullToEmptyString] DOMString marginWidth;
};
```

The **align** and **scrolling** IDL attributes of the `iframe`^{p369} element must [reflect](#)^{p97} the respective content attributes of the same name.

The **frameBorder** IDL attribute of the `iframe`^{p369} element must [reflect](#)^{p97} the element's `frameborder`^{p1261} content attribute.

The **longDesc** IDL attribute of the `iframe`^{p369} element must [reflect](#)^{p97} the element's `longdesc`^{p1259} content attribute, which for the purposes of reflection is defined as containing a [URL](#).

The **marginHeight** IDL attribute of the `iframe`^{p369} element must [reflect](#)^{p97} the element's `marginheight`^{p1261} content attribute.

The **marginWidth** IDL attribute of the **iframe**^{p369} element must **reflect**^{p97} the element's **marginwidth**^{p1261} content attribute.

```
IDL partial interface HTMLImageElement {
  [CEReactions] attribute DOMString name;
  [CEReactions] attribute USVString lowsrc;
  [CEReactions] attribute DOMString align;
  [CEReactions] attribute unsigned long hspace;
  [CEReactions] attribute unsigned long vspace;
  [CEReactions] attribute USVString longDesc;

  [CEReactions] attribute [LegacyNullToEmptyString] DOMString border;
};
```

The **name**, **align**, **border**, **hspace**, and **vspace** IDL attributes of the **img**^{p327} element must **reflect**^{p97} the respective content attributes of the same name.

The **longDesc** IDL attribute of the **img**^{p327} element must **reflect**^{p97} the element's **longdesc**^{p1259} content attribute, which for the purposes of reflection is defined as containing a **URL**.

The **lowsrc** IDL attribute of the **img**^{p327} element must **reflect**^{p97} the element's **lowsrc**^{p1259} content attribute, which for the purposes of reflection is defined as containing a **URL**.

```
IDL partial interface HTMLInputElement {
  [CEReactions] attribute DOMString align;
  [CEReactions] attribute DOMString useMap;
};
```

The **align** IDL attribute of the **input**^{p501} element must **reflect**^{p97} the content attribute of the same name.

The **useMap** IDL attribute of the **input**^{p501} element must **reflect**^{p97} the element's **usemap**^{p1259} content attribute.

```
IDL partial interface HTMLLegendElement {
  [CEReactions] attribute DOMString align;
};
```

The **align** IDL attribute of the **legend**^{p574} element must **reflect**^{p97} the content attribute of the same name.

```
IDL partial interface HTMLLIElement {
  [CEReactions] attribute DOMString type;
};
```

The **type** IDL attribute of the **li**^{p230} element must **reflect**^{p97} the content attribute of the same name.

```
IDL partial interface HTMLLinkElement {
  [CEReactions] attribute DOMString charset;
  [CEReactions] attribute DOMString rev;
  [CEReactions] attribute DOMString target;
};
```

The **charset**, **rev**, and **target** IDL attributes of the **link**^{p162} element must **reflect**^{p97} the respective content attributes of the same name.

User agents must treat **listing**^{p1257} elements in a manner equivalent to **pre**^{p222} elements in terms of semantics and for purposes of

rendering.

```
IDL partial interface HTMLMenuElement {
  [CEReactions] attribute boolean compact;
};
```

The **compact** IDL attribute of the **menu**^{p229} element must **reflect**^{p97} the content attribute of the same name.

```
IDL partial interface HTMLMetaElement {
  [CEReactions] attribute DOMString scheme;
};
```

User agents may treat the **scheme**^{p1259} content attribute on the **meta**^{p170} element as an extension of the element's **name**^{p171} content attribute when processing a **meta**^{p170} element with a **name**^{p171} attribute whose value is one that the user agent recognizes as supporting the **scheme**^{p1259} attribute.

User agents are encouraged to ignore the **scheme**^{p1259} attribute and instead process the value given to the metadata name as if it had been specified for each expected value of the **scheme**^{p1259} attribute.

Example

For example, if the user agent acts on **meta**^{p170} elements with **name**^{p171} attributes having the value "eGMS.subject.keyword", and knows that the **scheme**^{p1259} attribute is used with this metadata name, then it could take the **scheme**^{p1259} attribute into account, acting as if it was an extension of the **name**^{p171} attribute. Thus the following two **meta**^{p170} elements could be treated as two elements giving values for two different metadata names, one consisting of a combination of "eGMS.subject.keyword" and "LGCL", and the other consisting of a combination of "eGMS.subject.keyword" and "ORLY":

```
<!-- this markup is invalid -->
<meta name="eGMS.subject.keyword" scheme="LGCL" content="Abandoned vehicles">
<meta name="eGMS.subject.keyword" scheme="ORLY" content="Mah car: kthxbye">
```

The suggested processing of this markup, however, would be equivalent to the following:

```
<meta name="eGMS.subject.keyword" content="Abandoned vehicles">
<meta name="eGMS.subject.keyword" content="Mah car: kthxbye">
```

The **scheme** IDL attribute of the **meta**^{p170} element must **reflect**^{p97} the content attribute of the same name.

```
IDL partial interface HTMLObjectElement {
  [CEReactions] attribute DOMString align;
  [CEReactions] attribute DOMString archive;
  [CEReactions] attribute DOMString code;
  [CEReactions] attribute boolean declare;
  [CEReactions] attribute unsigned long hspace;
  [CEReactions] attribute DOMString standby;
  [CEReactions] attribute unsigned long vspace;
  [CEReactions] attribute DOMString codeBase;
  [CEReactions] attribute DOMString codeType;
  [CEReactions] attribute DOMString useMap;

  [CEReactions] attribute [LegacyNullToEmptyString] DOMString border;
};
```

The **align**, **archive**, **border**, **code**, **declare**, **hspace**, **standby**, and **vspace** IDL attributes of the **object**^{p381} element must **reflect**^{p97} the respective content attributes of the same name.

The **codeBase** IDL attribute of the **object**^{p381} element must **reflect**^{p97} the element's **codebase**^{p1259} content attribute, which for the

purposes of reflection is defined as containing a [URL](#).

The **codeType** IDL attribute of the [object](#)^{p381} element must [reflect](#)^{p97} the element's [codetype](#)^{p1259} content attribute.

The **useMap** IDL attribute must [reflect](#)^{p97} the [usemap](#)^{p454} content attribute.

```
IDL partial interface HTMLQListElement {
  [CEReactions] attribute boolean compact;
};
```

The **compact** IDL attribute of the [ol](#)^{p226} element must [reflect](#)^{p97} the content attribute of the same name.

```
IDL partial interface HTMLParagraphElement {
  [CEReactions] attribute DOMString align;
};
```

The **align** IDL attribute of the [p](#)^{p218} element must [reflect](#)^{p97} the content attribute of the same name.

```
IDL partial interface HTMLParamElement {
  [CEReactions] attribute DOMString type;
  [CEReactions] attribute DOMString valueType;
};
```

The **type** IDL attribute of the [param](#)^{p387} element must [reflect](#)^{p97} the content attribute of the same name.

The **valueType** IDL attribute of the [param](#)^{p387} element must [reflect](#)^{p97} the element's [valuetype](#)^{p1260} content attribute.

User agents must treat [plaintext](#)^{p1257} elements in a manner equivalent to [pre](#)^{p222} elements in terms of semantics and for purposes of rendering. (The parser has special behavior for this element, though.)

```
IDL partial interface HTMLPreElement {
  [CEReactions] attribute long width;
};
```

The **width** IDL attribute of the [pre](#)^{p222} element must [reflect](#)^{p97} the content attribute of the same name.

```
IDL partial interface HTMLStyleElement {
  [CEReactions] attribute DOMString type;
};
```

The **type** IDL attribute of the [style](#)^{p180} element must [reflect](#)^{p97} the element's [type](#)^{p1260} content attribute.

```
IDL partial interface HTMLScriptElement {
  [CEReactions] attribute DOMString charset;
  [CEReactions] attribute DOMString event;
  [CEReactions] attribute DOMString htmlFor;
};
```

The **charset** and **event** IDL attributes of the [script](#)^{p624} element must [reflect](#)^{p97} the respective content attributes of the same name.

The **htmlFor** IDL attribute of the [script](#)^{p624} element must [reflect](#)^{p97} the element's [for](#)^{p1260} content attribute.

```

IDL partial interface HTMLTableElement {
  [CEReactions] attribute DOMString align;
  [CEReactions] attribute DOMString border;
  [CEReactions] attribute DOMString frame;
  [CEReactions] attribute DOMString rules;
  [CEReactions] attribute DOMString summary;
  [CEReactions] attribute DOMString width;

  [CEReactions] attribute [LegacyNullToEmptyString] DOMString bgColor;
  [CEReactions] attribute [LegacyNullToEmptyString] DOMString cellPadding;
  [CEReactions] attribute [LegacyNullToEmptyString] DOMString cellSpacing;
};

```

The **align**, **border**, **frame**, **summary**, **rules**, and **width**, IDL attributes of the [table](#)^{p458} element must [reflect](#)^{p97} the respective content attributes of the same name.

The **bgColor** IDL attribute of the [table](#)^{p458} element must [reflect](#)^{p97} the element's [bgcolor](#)^{p1262} content attribute.

The **cellPadding** IDL attribute of the [table](#)^{p458} element must [reflect](#)^{p97} the element's [cellpadding](#)^{p1262} content attribute.

The **cellSpacing** IDL attribute of the [table](#)^{p458} element must [reflect](#)^{p97} the element's [cellspacing](#)^{p1262} content attribute.

```

IDL partial interface HTMLTableSectionElement {
  [CEReactions] attribute DOMString align;
  [CEReactions] attribute DOMString ch;
  [CEReactions] attribute DOMString chOff;
  [CEReactions] attribute DOMString vAlign;
};

```

The **align** IDL attribute of the [tbody](#)^{p469}, [thead](#)^{p470}, and [tfoot](#)^{p471} elements must [reflect](#)^{p97} the content attribute of the same name.

The **ch** IDL attribute of the [tbody](#)^{p469}, [thead](#)^{p470}, and [tfoot](#)^{p471} elements must [reflect](#)^{p97} the elements' [char](#)^{p1262} content attributes.

The **chOff** IDL attribute of the [tbody](#)^{p469}, [thead](#)^{p470}, and [tfoot](#)^{p471} elements must [reflect](#)^{p97} the elements' [charoff](#)^{p1262} content attributes.

The **vAlign** IDL attribute of the [tbody](#)^{p469}, [thead](#)^{p470}, and [tfoot](#)^{p471} element must [reflect](#)^{p97} the elements' [valign](#)^{p1262} content attributes.

```

IDL partial interface HTMLTableCellElement {
  [CEReactions] attribute DOMString align;
  [CEReactions] attribute DOMString axis;
  [CEReactions] attribute DOMString height;
  [CEReactions] attribute DOMString width;

  [CEReactions] attribute DOMString ch;
  [CEReactions] attribute DOMString chOff;
  [CEReactions] attribute boolean nowrap;
  [CEReactions] attribute DOMString vAlign;

  [CEReactions] attribute [LegacyNullToEmptyString] DOMString bgColor;
};

```

The **align**, **axis**, **height**, and **width** IDL attributes of the [td](#)^{p474} and [th](#)^{p475} elements must [reflect](#)^{p97} the respective content attributes of the same name.

The **ch** IDL attribute of the [td](#)^{p474} and [th](#)^{p475} elements must [reflect](#)^{p97} the elements' [char](#)^{p1262} content attributes.

The **chOff** IDL attribute of the [td](#)^{p474} and [th](#)^{p475} elements must [reflect](#)^{p97} the elements' [charoff](#)^{p1262} content attributes.

The **nowrap** IDL attribute of the [td](#)^{p474} and [th](#)^{p475} elements must [reflect](#)^{p97} the elements' [nowrap](#)^{p1262} content attributes.

The **vAlign** IDL attribute of the [td](#)^{p474} and [th](#)^{p475} elements must [reflect](#)^{p97} the elements' [vAlign](#)^{p1262} content attributes.

The **bgColor** IDL attribute of the [td](#)^{p474} and [th](#)^{p475} elements must [reflect](#)^{p97} the elements' [bgColor](#)^{p1262} content attributes.

```
IDL partial interface HTMLTableRowElement {
  [CEReactions] attribute DOMString align;
  [CEReactions] attribute DOMString ch;
  [CEReactions] attribute DOMString chOff;
  [CEReactions] attribute DOMString vAlign;

  [CEReactions] attribute [LegacyNullToEmptyString] DOMString bgColor;
};
```

The **align** IDL attribute of the [tr](#)^{p472} element must [reflect](#)^{p97} the content attribute of the same name.

The **ch** IDL attribute of the [tr](#)^{p472} element must [reflect](#)^{p97} the element's [char](#)^{p1262} content attribute.

The **chOff** IDL attribute of the [tr](#)^{p472} element must [reflect](#)^{p97} the element's [charoff](#)^{p1262} content attribute.

The **vAlign** IDL attribute of the [tr](#)^{p472} element must [reflect](#)^{p97} the element's [vAlign](#)^{p1262} content attribute.

The **bgColor** IDL attribute of the [tr](#)^{p472} element must [reflect](#)^{p97} the element's [bgColor](#)^{p1262} content attribute.

```
IDL partial interface HTMLULListElement {
  [CEReactions] attribute boolean compact;
  [CEReactions] attribute DOMString type;
};
```

The **compact** and **type** IDL attributes of the [ul](#)^{p228} element must [reflect](#)^{p97} the respective content attributes of the same name.

User agents must treat [xmp](#)^{p1258} elements in a manner equivalent to [pre](#)^{p222} elements in terms of semantics and for purposes of rendering. (The parser has special behavior for this element though.)

```
IDL partial interface Document {
  [CEReactions] attribute [LegacyNullToEmptyString] DOMString fgColor;
  [CEReactions] attribute [LegacyNullToEmptyString] DOMString linkColor;
  [CEReactions] attribute [LegacyNullToEmptyString] DOMString vlinkColor;
  [CEReactions] attribute [LegacyNullToEmptyString] DOMString alinkColor;
  [CEReactions] attribute [LegacyNullToEmptyString] DOMString bgColor;

  [SameObject] readonly attribute HTMLCollection anchors;
  [SameObject] readonly attribute HTMLCollection applets;

  undefined clear();
  undefined captureEvents();
  undefined releaseEvents();

  [SameObject] readonly attribute HTMLAllCollection all;
};
```

The attributes of the [Document](#)^{p117} object listed in the first column of the following table must [reflect](#)^{p97} the content attribute on [the body element](#)^{p123} with the name given in the corresponding cell in the second column on the same row, if [the body element](#)^{p123} is a [body](#)^{p184} element (as opposed to a [frameset](#)^{p1264} element). When there is no [body element](#)^{p123} or if it is a [frameset](#)^{p1264} element, the attributes must instead return the empty string on getting and do nothing on setting.

IDL attribute	Content attribute
<code>fgColor</code>	<code>text</code> ^{p1261}
<code>linkColor</code>	<code>link</code> ^{p1261}
<code>vlinkColor</code>	<code>vlink</code> ^{p1261}
<code>alinkColor</code>	<code>alink</code> ^{p1261}
<code>bgColor</code>	<code>bgcolor</code> ^{p1261}

The `anchors` attribute must return an `HTMLCollection` rooted at the `Document`^{p117} node, whose filter matches only `a`^{p244} elements with `name`^{p1258} attributes.

The `applets` attribute must return an `HTMLCollection` rooted at the `Document`^{p117} node, whose filter matches nothing. (It exists for historical reasons.)

The `clear()`, `captureEvents()`, and `releaseEvents()` methods must do nothing.

The `all` attribute must return an `HTMLAllCollection`^{p99} rooted at the `Document`^{p117} node, whose filter matches all elements.

```
IDL partial interface Window {
    undefined captureEvents();
    undefined releaseEvents();

    [Replaceable, SameObject] readonly attribute External external;
};
```

The `captureEvents()` and `releaseEvents()` methods must do nothing.

The `external` attribute of the `Window`^{p855} interface must return an instance of the `External`^{p1274} interface:

```
IDL [Exposed=Window]
interface External {
    undefined AddSearchProvider();
    undefined IsSearchProviderInstalled();
};
```

The `AddSearchProvider()` and `IsSearchProviderInstalled()` methods must do nothing.

17 IANA considerations ^{§ p12}

75

17.1 text/html ^{§ p12}

75

This registration is for community review and will be submitted to the IESG for review, approval, and registration with IANA.

Type name:

text

Subtype name:

html

Required parameters:

No required parameters

Optional parameters:

charset

The `charset` parameter may be provided to specify the [document's character encoding](#), overriding any [character encoding declarations](#)^{p179} in the document other than a Byte Order Mark (BOM). The parameter's value must be an [ASCII case-insensitive](#) match for the string "utf-8". [\[ENCODING\]](#)^{p1307}

Encoding considerations:

8bit (see the section on [character encoding declarations](#)^{p179})

Security considerations:

Entire novels have been written about the security considerations that apply to HTML documents. Many are listed in this document, to which the reader is referred for more details. Some general concerns bear mentioning here, however:

HTML is scripted language, and has a large number of APIs (some of which are described in this document). Script can expose the user to potential risks of information leakage, credential leakage, cross-site scripting attacks, cross-site request forgeries, and a host of other problems. While the designs in this specification are intended to be safe if implemented correctly, a full implementation is a massive undertaking and, as with any software, user agents are likely to have security bugs.

Even without scripting, there are specific features in HTML which, for historical reasons, are required for broad compatibility with legacy content but that expose the user to unfortunate security problems. In particular, the `img`^{p327} element can be used in conjunction with some other features as a way to effect a port scan from the user's location on the Internet. This can expose local network topologies that the attacker would otherwise not be able to determine.

HTML relies on a compartmentalization scheme sometimes known as the *same-origin policy*. An [origin](#)^{p868} in most cases consists of all the pages served from the same host, on the same port, using the same protocol.

It is critical, therefore, to ensure that any untrusted content that forms part of a site be hosted on a different [origin](#)^{p868} than any sensitive content on that site. Untrusted content can easily spoof any other page on the same origin, read data from that origin, cause scripts in that origin to execute, submit forms to and from that origin even if they are protected from cross-site request forgery attacks by unique tokens, and make use of any third-party resources exposed to or rights granted to that origin.

Interoperability considerations:

Rules for processing both conforming and non-conforming content are defined in this specification.

Published specification:

This document is the relevant specification. Labeling a resource with the `text/html`^{p1275} type asserts that the resource is an [HTML document](#) using [the HTML syntax](#)^{p1094}.

Applications that use this media type:

Web browsers, tools for processing web content, HTML authoring tools, search engines, validators.

Additional information:

Magic number(s):

No sequence of bytes can uniquely identify an HTML document. More information on detecting HTML documents is available in *MIME Sniffing*. [\[MIMESNIFF\]](#)^{p1309}

File extension(s):

"html" and ".html" are commonly, but certainly not exclusively, used as the extension for HTML documents.

Macintosh file type code(s):

[Fragments](#) used with [text/html^{p1275}](#) resources either refer to [the indicated part of the document^{p922}](#) or provide state information for in-page scripts.

17.2 multipart/x-mixed-replace §^{p12} 76

This registration is for community review and will be submitted to the IESG for review, approval, and registration with IANA.

Type name:

multipart

Subtype name:

x-mixed-replace

Required parameters:

- boundary (defined in RFC2046) [\[RFC2046\]^{p1310}](#)

Optional parameters:

No optional parameters.

Encoding considerations:

binary

Security considerations:

Subresources of a [multipart/x-mixed-replace^{p1276}](#) resource can be of any type, including types with non-trivial security implications such as [text/html^{p1275}](#).

Interoperability considerations:

None.

Published specification:

This specification describes processing rules for web browsers. Conformance requirements for generating resources with this type are the same as for [multipart/mixed^{p1303}](#). [\[RFC2046\]^{p1310}](#)

Applications that use this media type:

This type is intended to be used in resources generated by web servers, for consumption by web browsers.

Additional information:**Magic number(s):**

No sequence of bytes can uniquely identify a [multipart/x-mixed-replace^{p1276}](#) resource.

File extension(s):

No specific file extensions are recommended for this type.

Macintosh file type code(s):

No specific Macintosh file type codes are recommended for this type.

Person & email address to contact for further information:

[Fragments](#) used with [multipart/x-mixed-replace](#)^{p1276} resources apply to each body part as defined by the type used by that body part.

17.3 [application/xhtml+xml](#) §^{p12}₇₇

This registration is for community review and will be submitted to the IESG for review, approval, and registration with IANA.

Type name:

application

Subtype name:

xhtml+xml

Required parameters:

Same as for [application/xml](#)^{p1303} [[RFC7303](#)]^{p1311}

Optional parameters:

Same as for [application/xml](#)^{p1303} [[RFC7303](#)]^{p1311}

Encoding considerations:

Same as for [application/xml](#)^{p1303} [[RFC7303](#)]^{p1311}

Security considerations:

Same as for [application/xml](#)^{p1303} [[RFC7303](#)]^{p1311}

Interoperability considerations:

Same as for [application/xml](#)^{p1303} [[RFC7303](#)]^{p1311}

Published specification:

Labeling a resource with the [application/xhtml+xml](#)^{p1277} type asserts that the resource is an XML document that likely has a [document element](#) from the [HTML namespace](#). Thus, the relevant specifications are *XML*, *Namespaces in XML*, and this specification. [[XML](#)]^{p1313} [[XMLNS](#)]^{p1313}

Applications that use this media type:

Same as for [application/xml](#)^{p1303} [[RFC7303](#)]^{p1311}

Additional information:**Magic number(s):**

Same as for [application/xml](#)^{p1303} [[RFC7303](#)]^{p1311}

File extension(s):

"xhtml" and "xht" are sometimes used as extensions for XML resources that have a [document element](#) from the [HTML namespace](#).

Macintosh file type code(s):

[Fragments](#) used with [application/xhtml+xml](#)^{p1277} resources have the same semantics as with any [XML MIME type](#). [RFC7303]^{p1311}

17.4 text/ping §^{p12}₇₈

This registration is for community review and will be submitted to the IESG for review, approval, and registration with IANA.

Type name:

text

Subtype name:

ping

Required parameters:

No parameters

Optional parameters:

charset

The `charset` parameter may be provided. The parameter's value must be "utf-8". This parameter serves no purpose; it is only allowed for compatibility with legacy servers.

Encoding considerations:

Not applicable.

Security considerations:

If used exclusively in the fashion described in the context of [hyperlink auditing](#)^{p299}, this type introduces no new security concerns.

Interoperability considerations:

Rules applicable to this type are defined in this specification.

Published specification:

This document is the relevant specification.

Applications that use this media type:

Web browsers.

Additional information:**Magic number(s):**

[text/ping](#)^{p1278} resources always consist of the four bytes 0x50 0x49 0x4E 0x47 (`PING`).

File extension(s):

No specific file extension is recommended for this type.

Macintosh file type code(s):

No specific Macintosh file type codes are recommended for this type.

Person & email address to contact for further information:

Ian Hickson <ian@hixie.ch>

Intended usage:

Common

Restrictions on usage:

Only intended for use with HTTP POST requests generated as part of a web browser's processing of the [ping](#)^{p290} attribute.

Author:

Ian Hickson <ian@hixie.ch>

Change controller:

W3C

[Fragments](#) have no meaning with [text/ping](#)^{p1278} resources.

17.5 application/microdata+json §^{p12}₇₉

This registration is for community review and will be submitted to the IESG for review, approval, and registration with IANA.

Type name:

application

Subtype name:

microdata+json

Required parameters:

Same as for [application/json](#)^{p1303} [\[JSON\]](#)^{p1309}

Optional parameters:

Same as for [application/json](#)^{p1303} [\[JSON\]](#)^{p1309}

Encoding considerations:

8bit (always UTF-8)

Security considerations:

Same as for [application/json](#)^{p1303} [\[JSON\]](#)^{p1309}

Interoperability considerations:

Same as for [application/json](#)^{p1303} [\[JSON\]](#)^{p1309}

Published specification:

Labeling a resource with the [application/microdata+json](#)^{p1279} type asserts that the resource is a JSON text that consists of an object with a single entry called "items" consisting of an array of entries, each of which consists of an object with an entry called "id" whose value is a string, an entry called "type" whose value is another string, and an entry called "properties" whose value is an object whose entries each have a value consisting of an array of either objects or strings, the objects being of the same form as the objects in the aforementioned "items" entry. Thus, the relevant specifications are *JSON* and this specification. [\[JSON\]](#)^{p1309}

Applications that use this media type:

Applications that transfer data intended for use with HTML's microdata feature, especially in the context of drag-and-drop, are the primary application class for this type.

Additional information:**Magic number(s):**

Same as for [application/json](#)^{p1303} [\[JSON\]](#)^{p1309}

File extension(s):

Same as for [application/json](#)^{p1303} [\[JSON\]](#)^{p1309}

Macintosh file type code(s):

Same as for [application/json](#)^{p1303} [\[JSON\]](#)^{p1309}

Person & email address to contact for further information:

Ian Hickson <ian@hixie.ch>

Change controller:

W3C

[Fragments](#) used with [application/microdata+json](#)^{p1279} resources have the same semantics as when used with [application/json](#)^{p1363} (namely, at the time of writing, no semantics at all). [\[JSON\]](#)^{p1309}

17.6 text/event-stream §^{p12}₈₀

This registration is for community review and will be submitted to the IESG for review, approval, and registration with IANA.

Type name:

text

Subtype name:

event-stream

Required parameters:

No parameters

Optional parameters:

charset

The `charset` parameter may be provided. The parameter's value must be "utf-8". This parameter serves no purpose; it is only allowed for compatibility with legacy servers.

Encoding considerations:

8bit (always UTF-8)

Security considerations:

An event stream from an origin distinct from the origin of the content consuming the event stream can result in information leakage. To avoid this, user agents are required to apply CORS semantics. [\[FETCH\]](#)^{p1308}

Event streams can overwhelm a user agent; a user agent is expected to apply suitable restrictions to avoid depleting local resources because of an overabundance of information from an event stream.

Servers can be overwhelmed if a situation develops in which the server is causing clients to reconnect rapidly. Servers should use a 5xx status code to indicate capacity problems, as this will prevent conforming clients from reconnecting automatically.

Interoperability considerations:

Rules for processing both conforming and non-conforming content are defined in this specification.

Published specification:

This document is the relevant specification.

Applications that use this media type:

Web browsers and tools using web services.

Additional information:

Magic number(s):

No sequence of bytes can uniquely identify an event stream.

File extension(s):

No specific file extensions are recommended for this type.

Macintosh file type code(s):

No specific Macintosh file type codes are recommended for this type.

Person & email address to contact for further information:

Ian Hickson <ian@hixie.ch>

Intended usage:

Common

Restrictions on usage:

This format is only expected to be used by dynamic open-ended streams served using HTTP or a similar protocol. Finite resources are not expected to be labeled with this type.

Author:

Ian Hickson <ian@hixie.ch>

Change controller:

[Fragments](#) have no meaning with [text/event-stream](#)^{p1280} resources.

17.7 web+ scheme prefix §^{p12} 81

This section describes a convention for use with the IANA URI scheme registry. It does not itself register a specific scheme.

[\[RFC7595\]](#)^{p1311}

Scheme name:

Schemes starting with the four characters "web+" followed by one or more letters in the range a-z.

Status:

Permanent

Scheme syntax:

Scheme-specific.

Scheme semantics:

Scheme-specific.

Encoding considerations:

All "web+" schemes should use UTF-8 encodings where relevant.

Applications/protocols that use this scheme name:

Scheme-specific.

Interoperability considerations:

The scheme is expected to be used in the context of web applications.

Security considerations:

Any web page is able to register a handler for all "web+" schemes. As such, these schemes must not be used for features intended to be core platform features (e.g., HTTP). Similarly, such schemes must not store confidential information in their URLs, such as usernames, passwords, personal information, or confidential project names.

Contact:

Ian Hickson <ian@hixie.ch>

Change controller:

Ian Hickson <ian@hixie.ch>

An asterisk (*) in a cell indicates that the actual rules are more complicated than indicated in the table above.

† Categories in the "Parents" column refer to parents that list the given categories in their content model, not to elements that themselves are in those categories. For example, the [a](#)^{p244} element's "Parents" column says "phrasing", so any element whose content model contains the "phrasing" category could be a parent of an [a](#)^{p244} element. Since the "flow" category includes all the "phrasing" elements, that means the [th](#)^{p475} element could be a parent to an [a](#)^{p244} element.

Element content categories ^{§p12}

88

This section is non-normative.

List of element content categories

Category	Elements	Elements with exceptions
Metadata content ^{p135}	base ^{p160} ; link ^{p162} ; meta ^{p170} ; noscript ^{p638} ; script ^{p624} ; style ^{p180} ; template ^{p640} ; title ^{p159}	—

Phrasing content ^{p136}	a ^{p244} ; abbr ^{p256} ; audio ^{p392} ; b ^{p279} ; bdi ^{p284} ; bdo ^{p285} ; br ^{p286} ; button ^{p545} ; canvas ^{p645} ; cite ^{p252} ; code ^{p273} ; data ^{p265} ; datalist ^{p553} ; del ^{p320} ; dfn ^{p255} ; em ^{p247} ; embed ^{p378} ; i ^{p278} ; iframe ^{p369} ; img ^{p327} ; input ^{p501} ; ins ^{p319} ; kbd ^{p276} ; label ^{p498} ; map ^{p450} ; mark ^{p281} ; MathML math ; meter ^{p567} ; noscript ^{p638} ; object ^{p381} ; output ^{p563} ; picture ^{p324} ; progress ^{p565} ; q ^{p254} ; ruby ^{p258} ; s ^{p251} ; samp ^{p275} ; script ^{p624} ; select ^{p547} ; slot ^{p644} ; small ^{p250} ; span ^{p285} ; strong ^{p249} ; sub ^{p277} ; sup ^{p277} ; SVG svg ; template ^{p640} ; textarea ^{p558} ; time ^{p266} ; u ^{p281} ; var ^{p274} ; video ^{p388} ; wbr ^{p287} ; autonomous custom elements ^{p728} ; Text ^{p136}	area ^{p452} (if it is a descendant of a map ^{p450} element); link ^{p162} (if it is allowed in the body ^{p163}); meta ^{p170} (if the itemprop ^{p763} attribute is present)
Embedded content ^{p137}	audio ^{p392} ; canvas ^{p645} ; embed ^{p378} ; iframe ^{p369} ; img ^{p327} ; MathML math ; object ^{p381} ; picture ^{p324} ; SVG svg ; video ^{p388}	—
Interactive content ^{p137}	button ^{p545} ; details ^{p614} ; embed ^{p378} ; iframe ^{p369} ; label ^{p498} ; select ^{p547} ; textarea ^{p558}	a ^{p244} (if the href ^{p290} attribute is present); audio ^{p392} (if the controls ^{p444} attribute is present); img ^{p327} (if the usemap ^{p454} attribute is present); input ^{p501} (if the type ^{p503} attribute is <i>not</i> in the Hidden ^{p507} state); video ^{p388} (if the controls ^{p444} attribute is present)
Sectioning roots ^{p205}	blockquote ^{p224} ; body ^{p184} ; details ^{p614} ; dialog ^{p620} ; fieldset ^{p572} ; figure ^{p238} ; td ^{p474}	—
Form-associated elements ^{p494}	button ^{p545} ; fieldset ^{p572} ; input ^{p501} ; label ^{p498} ; object ^{p381} ; output ^{p563} ; select ^{p547} ; textarea ^{p558} ; img ^{p327} ; form-associated custom elements ^{p729}	—
Listed elements ^{p494}	button ^{p545} ; fieldset ^{p572} ; input ^{p501} ; object ^{p381} ; output ^{p563} ; select ^{p547} ; textarea ^{p558} ; form-associated custom elements ^{p729}	—
Submittable elements ^{p494}	button ^{p545} ; input ^{p501} ; select ^{p547} ; textarea ^{p558} ; form-associated custom elements ^{p729}	—
Resettable elements ^{p494}	input ^{p501} ; output ^{p563} ; select ^{p547} ; textarea ^{p558} ; form-associated custom elements ^{p729}	—
Autocapitalize-inheriting elements ^{p494}	button ^{p545} ; fieldset ^{p572} ; input ^{p501} ; output ^{p563} ; select ^{p547} ; textarea ^{p558}	—
Labelable elements ^{p494}	button ^{p545} ; input ^{p501} ; meter ^{p567} ; output ^{p563} ; progress ^{p565} ; select ^{p547} ; textarea ^{p558} ; form-associated custom elements ^{p729}	—
Palpable content ^{p137}	a ^{p244} ; abbr ^{p256} ; address ^{p204} ; article ^{p188} ; aside ^{p194} ; b ^{p279} ; bdi ^{p284} ; bdo ^{p285} ; blockquote ^{p224} ; button ^{p545} ; canvas ^{p645} ; cite ^{p252} ; code ^{p273} ; data ^{p265} ; details ^{p614} ; dfn ^{p255} ; div ^{p243} ; em ^{p247} ; embed ^{p378} ; fieldset ^{p572} ; figure ^{p238} ; footer ^{p201} ; form ^{p494} ; h1 ^{p196} ; h2 ^{p196} ; h3 ^{p196} ; h4 ^{p196} ; h5 ^{p196} ; h6 ^{p196} ; header ^{p200} ; hgroup ^{p197} ; i ^{p278} ; iframe ^{p369} ; img ^{p327} ; ins ^{p319} ; kbd ^{p276} ; label ^{p498} ; main ^{p242} ; map ^{p450} ; mark ^{p281} ; MathML math ; meter ^{p567} ; nav ^{p191} ; object ^{p381} ; output ^{p563} ; p ^{p218} ; pre ^{p222} ; progress ^{p565} ; q ^{p254} ; ruby ^{p258} ; s ^{p251} ; samp ^{p275} ; section ^{p188} ; select ^{p547} ; small ^{p250} ; span ^{p285} ; strong ^{p249} ; sub ^{p277} ; sup ^{p277} ; SVG svg ; table ^{p458} ; textarea ^{p558} ; time ^{p266} ; u ^{p281} ; var ^{p274} ; video ^{p388} ; autonomous custom elements ^{p728}	audio ^{p392} (if the controls ^{p444} attribute is present); dl ^{p233} (if the element's children include at least one name-value group); input ^{p501} (if the type ^{p503} attribute is <i>not</i> in the Hidden ^{p507} state); menu ^{p229} (if the element's children include at least one li ^{p230} element); ol ^{p226} (if the element's children include at least one li ^{p230} element); ul ^{p228} (if the element's children include at least one li ^{p230} element); Text ^{p136} that is not inter-element whitespace ^{p133}
Script-supporting elements ^{p137}	script ^{p624} ; template ^{p640}	—

Attributes ^{§ p12} ₈₉

This section is non-normative.

List of attributes (excluding event handler content attributes)

Attribute	Element(s)	Description	Value
abbr	th ^{p476}	Alternative label to use for the header cell when referencing the cell in other	Text ^{p133} *

Attribute	Element(s)	Description	Value
		contexts	
accept	input ^{p524}	Hint for expected file type in file upload controls ^{p523}	Set of comma-separated tokens ^{p89} * consisting of valid MIME type strings with no parameters or audio/*, video/*, or image/*
accept-charset	form ^{p495}	Character encodings to use for form submission ^{p605}	ASCII case-insensitive match for "UTF-8"
accesskey	HTML elements ^{p813}	Keyboard shortcut to activate or focus element	Ordered set of unique space-separated tokens ^{p89} , none of which are identical to another, each consisting of one code point in length
action	form ^{p580}	URL to use for form submission ^{p605}	Valid non-empty URL potentially surrounded by spaces ^{p90}
allow	iframe ^{p376}	Permissions policy to be applied to the iframe ^{p369} 's contents	Serialized permissions policy
allowfullscreen	iframe ^{p376}	Whether to allow the iframe ^{p369} 's contents to use requestFullscreen()	Boolean attribute ^{p69}
alt	area ^{p452} ; img ^{p328} ; input ^{p527}	Replacement text for use when images are not available	Text ^{p133} *
as	link ^{p165}	Potential destination for a preload request (for rel ^{p163} ="preload ^{p311} " and rel ^{p163} ="modulepreload ^{p307} ")	Potential destination , for rel ^{p163} ="preload ^{p311} "; script-like destination , for rel ^{p163} ="modulepreload ^{p307} "
async	script ^{p625}	Execute script when available, without blocking while fetching	Boolean attribute ^{p69}
autocapitalize	HTML elements ^{p820}	Recommended autocapitalization behavior (for supported input methods)	"on ^{p820} "; "off ^{p820} "; "none ^{p820} "; "sentences ^{p820} "; "words ^{p820} "; "characters ^{p820} "
autocomplete	form ^{p496}	Default setting for autofill feature for controls in the form	"on"; "off"
autocomplete	input ^{p582} ; select ^{p582} ; textarea ^{p582}	Hint for form autofill feature	Autofill field ^{p585} name and related tokens*
autofocus	HTML elements ^{p810}	Automatically focus the element when the page is loaded	Boolean attribute ^{p69}
autoplay	audio ^{p416} ; video ^{p416}	Hint that the media resource ^{p397} can be started automatically when the page is loaded	Boolean attribute ^{p69}
blocking	link ^{p166} ; script ^{p626} ; style ^{p181}	Whether the element is render-blocking ^{p97}	Unordered set of unique space-separated tokens ^{p89} *
charset	meta ^{p170}	Character encoding declaration ^{p179}	"utf-8"
checked	input ^{p505}	Whether the control is checked	Boolean attribute ^{p69}
cite	blockquote ^{p224} ; del ^{p321} ; ins ^{p321} ; q ^{p254}	Link to the source of the quotation or more information about the edit	Valid URL potentially surrounded by spaces ^{p90}
class	HTML elements ^{p141}	Classes to which the element belongs	Set of space-separated tokens ^{p89}
color	link ^{p166}	Color to use when customizing a site's icon (for rel ^{p163} ="mask-icon")	CSS <color>
cols	textarea ^{p560}	Maximum number of characters per line	Valid non-negative integer ^{p70} greater than zero
colspan	td ^{p477} ; th ^{p477}	Number of columns that the cell is to span	Valid non-negative integer ^{p70} greater than zero
content	meta ^{p171}	Value of the element	Text ^{p133} *
contenteditable	HTML elements ^{p815}	Whether the element is editable	"true"; "false"
controls	audio ^{p444} ; video ^{p444}	Show user agent controls	Boolean attribute ^{p69}
coords	area ^{p453}	Coordinates for the shape to be created in an image map ^{p454}	Valid list of floating-point numbers ^{p74} *
crossorigin	audio ^{p398} ; img ^{p329} ; link ^{p164} ; script ^{p626} ; video ^{p398}	How the element handles crossorigin requests	"anonymous ^{p93} "; "use-credentials ^{p93} "
data	object ^{p382}	Address of the resource	Valid non-empty URL potentially surrounded by spaces ^{p90}
datetime	del ^{p321} ; ins ^{p321}	Date and (optionally) time of the change	Valid date string with optional time ^{p86}
datetime	time ^{p267}	Machine-readable value	Valid month string ^{p75} , valid date string ^{p76} , valid yearless date string ^{p77} , valid time string ^{p78} , valid local date and time string ^{p79} , valid time-zone offset string ^{p79} , valid global date and time string ^{p81} , valid week string ^{p82} , valid non-negative integer ^{p70} , or valid duration string ^{p83}
decoding	img ^{p329}	Decoding hint to use when processing this image for presentation	"sync ^{p347} "; "async ^{p347} "; "auto ^{p347} "
default	track ^{p395}	Enable the track if no other text track ^{p430} is more suitable	Boolean attribute ^{p69}

Attribute	Element(s)	Description	Value
defer	script ^{p625}	Defer script execution	Boolean attribute ^{p69}
dir	HTML elements ^{p146}	The text directionality ^{p146} of the element	"ltr" ^{p146} ; "rtl" ^{p146} ; "auto" ^{p146}
dir	bdo ^{p285}	The text directionality ^{p146} of the element	"ltr" ^{p146} ; "rtl" ^{p146}
dirname	input ^{p578} ; textarea ^{p578}	Name of form control to use for sending the element's directionality ^{p146} in form submission ^{p605}	Text ^{p133} *
disabled	button ^{p580} ; input ^{p580} ; optgroup ^{p555} ; option ^{p556} ; select ^{p580} ; textarea ^{p580} ; form-associated custom elements ^{p580}	Whether the form control is disabled	Boolean attribute ^{p69}
disabled	fieldset ^{p573}	Whether the descendant form controls, except any inside legend ^{p574} , are disabled	Boolean attribute ^{p69}
disabled	link ^{p166}	Whether the link is disabled	Boolean attribute ^{p69}
download	a ^{p290} ; area ^{p290}	Whether to download the resource instead of navigating to it, and its filename if so	Text
draggable	HTML elements ^{p838}	Whether the element is draggable	"true"; "false"
enctype	form ^{p581}	Entry list ^{p609} encoding type to use for form submission ^{p605}	"application/x-www-form-urlencoded" ^{p581} ; "multipart/form-data" ^{p581} ; "text/plain" ^{p581}
enterkeyhint	HTML elements ^{p822}	Hint for selecting an enter key action	"enter" ^{p822} ; "done" ^{p822} ; "go" ^{p822} ; "next" ^{p822} ; "previous" ^{p822} ; "search" ^{p822} ; "send" ^{p822}
for	label ^{p499}	Associate the label with form control	ID*
for	output ^{p564}	Specifies controls from which the output was calculated	Unordered set of unique space-separated tokens ^{p89} consisting of IDs*
form	button ^{p576} ; fieldset ^{p576} ; input ^{p576} ; object ^{p576} ; output ^{p576} ; select ^{p576} ; textarea ^{p576} ; form-associated custom elements ^{p576}	Associates the element with a form ^{p494} element	ID*
formaction	button ^{p580} ; input ^{p580}	URL to use for form submission ^{p605}	Valid non-empty URL potentially surrounded by spaces ^{p90}
formenctype	button ^{p581} ; input ^{p581}	Entry list ^{p609} encoding type to use for form submission ^{p605}	"application/x-www-form-urlencoded" ^{p581} ; "multipart/form-data" ^{p581} ; "text/plain" ^{p581}
formmethod	button ^{p580} ; input ^{p580}	Variant to use for form submission ^{p605}	"GET"; "POST"; "dialog"
formnovalidate	button ^{p582} ; input ^{p582}	Bypass form control validation for form submission ^{p605}	Boolean attribute ^{p69}
formtarget	button ^{p581} ; input ^{p581}	Browsing context ^{p840} for form submission ^{p605}	Valid browsing context name or keyword ^{p849}
headers	td ^{p477} ; th ^{p477}	The header cells for this cell	Unordered set of unique space-separated tokens ^{p89} consisting of IDs*
height	canvas ^{p647} ; embed ^{p458} ; iframe ^{p458} ; img ^{p458} ; input ^{p458} ; object ^{p458} ; source ^{p458} (in picture ^{p324}); video ^{p458}	Vertical dimension	Valid non-negative integer ^{p70}
hidden	HTML elements ^{p792}	Whether the element is relevant	Boolean attribute ^{p69}
high	meter ^{p568}	Low limit of high range	Valid floating-point number ^{p71} *
href	a ^{p290} ; area ^{p290}	Address of the hyperlink ^{p289}	Valid URL potentially surrounded by spaces ^{p90}
href	link ^{p163}	Address of the hyperlink ^{p289}	Valid non-empty URL potentially surrounded by spaces ^{p90}
href	base ^{p161}	Document base URL ^{p90}	Valid URL potentially surrounded by spaces ^{p90}
hreflang	a ^{p290} ; link ^{p164}	Language of the linked resource	Valid BCP 47 language tag
http-equiv	meta ^{p176}	Pragma directive	"content-type" ^{p176} ; "default-style" ^{p176} ; "refresh" ^{p176} ; "x-ua-compatible" ^{p176} ; "content-security-policy" ^{p176}
id	HTML elements ^{p141}	The element's ID	Text ^{p133} *
imagesizes	link ^{p164}	Image sizes for different page layouts (for rel ^{p163} ="preload" ^{p311})	Valid source size list ^{p343}
imagesrcset	link ^{p164}	Images to use in different situations, e.g., high-resolution displays, small monitors, etc. (for rel ^{p163} ="preload" ^{p311})	Comma-separated list of image candidate strings ^{p343}
inert	HTML elements ^{p794}	Whether the element is inert ^{p793} .	Boolean attribute ^{p69}

Attribute	Element(s)	Description	Value
inputmode	HTML elements ^{p821}	Hint for selecting an input modality	"none" ^{p821} ; "text" ^{p821} ; "tel" ^{p821} ; "email" ^{p821} ; "url" ^{p821} ; "numeric" ^{p821} ; "decimal" ^{p821} ; "search" ^{p821}
integrity	link ^{p164} ; script ^{p626}	Integrity metadata used in <i>Subresource Integrity</i> checks [SRI] ^{p1311}	Text ^{p133}
is	HTML elements ^{p728}	Creates a customized built-in element ^{p728}	Valid custom element name ^{p729} of a defined customized built-in element ^{p728}
ismap	img ^{p331}	Whether the image is a server-side image map	Boolean attribute ^{p69}
itemid	HTML elements ^{p762}	Global identifier ^{p762} for a microdata item	Valid URL potentially surrounded by spaces ^{p90}
itemprop	HTML elements ^{p763}	Property names ^{p764} of a microdata item	Unordered set of unique space-separated tokens ^{p89} consisting of valid absolute URLs , defined property names ^{p764} , or text*
itemref	HTML elements ^{p762}	Referenced ^{p128} elements	Unordered set of unique space-separated tokens ^{p89} consisting of IDs*
itemscope	HTML elements ^{p761}	Introduces a microdata item	Boolean attribute ^{p69}
itemtype	HTML elements ^{p761}	Item types ^{p761} of a microdata item	Unordered set of unique space-separated tokens ^{p89} consisting of valid absolute URLs *
kind	track ^{p394}	The type of text track	"subtitles" ^{p394} ; "captions" ^{p394} ; "descriptions" ^{p394} ; "chapters" ^{p394} ; "metadata" ^{p394}
label	optgroup ^{p555} ; option ^{p556} ; track ^{p395}	User-visible label	Text ^{p133}
lang	HTML elements ^{p144}	Language ^{p144} of the element	Valid BCP 47 language tag or the empty string
list	input ^{p536}	List of autocomplete options	ID*
loading	img ^{p329} ; iframe ^{p377}	Used when determining loading deferral	"lazy" ^{p95} ; "eager" ^{p95}
loop	audio ^{p413} ; video ^{p413}	Whether to loop the media resource ^{p397}	Boolean attribute ^{p69}
low	meter ^{p568}	High limit of low range	Valid floating-point number ^{p71} *
max	input ^{p535}	Maximum value	Varies*
max	meter ^{p568} ; progress ^{p566}	Upper bound of range	Valid floating-point number ^{p71} *
maxlength	input ^{p530} ; textarea ^{p561}	Maximum length of value	Valid non-negative integer ^{p70}
media	link ^{p164} ; meta ^{p171} ; source ^{p325} (in picture ^{p324}); style ^{p181}	Applicable media	Valid media query list ^{p90}
method	form ^{p580}	Variant to use for form submission ^{p605}	"GET" ^{p580} ; "POST" ^{p580} ; "dialog" ^{p580}
min	input ^{p535}	Minimum value	Varies*
min	meter ^{p568}	Lower bound of range	Valid floating-point number ^{p71} *
minlength	input ^{p530} ; textarea ^{p561}	Minimum length of value	Valid non-negative integer ^{p70}
multiple	input ^{p532} ; select ^{p548}	Whether to allow multiple values	Boolean attribute ^{p69}
muted	audio ^{p446} ; video ^{p446}	Whether to mute the media resource ^{p397} by default	Boolean attribute ^{p69}
name	button ^{p577} ; fieldset ^{p577} ; input ^{p577} ; output ^{p577} ; select ^{p577} ; textarea ^{p577} ; form-associated custom elements ^{p577}	Name of the element to use for form submission ^{p605} and in the form.elements ^{p496} API	Text ^{p133} *
name	form ^{p495}	Name of form to use in the document.forms ^{p124} API	Text ^{p133} *
name	iframe ^{p374} ; object ^{p383}	Name of nested browsing context ^{p843}	Valid browsing context name or keyword ^{p849}
name	map ^{p451}	Name of image map ^{p454} to reference ^{p128} from the usemap ^{p454} attribute	Text ^{p133} *
name	meta ^{p171}	Metadata name	Text ^{p133} *
name	param ^{p387}	Name of parameter	Text ^{p133}
name	slot ^{p644}	Name of shadow tree slot	Text ^{p133}
nomodule	script ^{p625}	Prevents execution in user agents that support module scripts ^{p946}	Boolean attribute ^{p69}
nonce	HTML elements ^{p94}	Cryptographic nonce used in <i>Content Security Policy</i> checks [CSP] ^{p1305}	Text ^{p133}
novalidate	form ^{p582}	Bypass form control validation for form submission ^{p605}	Boolean attribute ^{p69}
open	details ^{p615}	Whether the details are visible	Boolean attribute ^{p69}
open	dialog ^{p621}	Whether the dialog box is showing	Boolean attribute ^{p69}

Attribute	Element(s)	Description	Value
optimum	meter ^{p568}	Optimum value in gauge	Valid floating-point number ^{p71} *
pattern	input ^{p533}	Pattern to be matched by the form control's value	Regular expression matching the JavaScript Pattern production
ping	a ^{p290} ; area ^{p290}	URLs to ping	Set of space-separated tokens ^{p89} consisting of valid non-empty URLs ^{p90}
placeholder	input ^{p539} ; textarea ^{p561}	User-visible label to be placed within the form control	Text ^{p133} *
playsinline	video ^{p389}	Encourage the user agent to display video content within the element's playback area	Boolean attribute ^{p69}
poster	video ^{p389}	Poster frame to show prior to video playback	Valid non-empty URL potentially surrounded by spaces ^{p90}
preload	audio ^{p410} ; video ^{p410}	Hints how much buffering the media resource ^{p397} will likely need	"none" ^{p410} ; "metadata" ^{p410} ; "auto" ^{p410}
readonly	input ^{p531} ; textarea ^{p559}	Whether to allow the value to be edited by the user	Boolean attribute ^{p69}
readonly	form-associated custom elements ^{p729}	Affects willValidate ^{p602} , plus any behavior added by the custom element author	Boolean attribute ^{p69}
referrerpolicy	a ^{p290} ; area ^{p290} ; iframe ^{p377} ; img ^{p329} ; link ^{p164} ; script ^{p626}	Referrer policy for fetches initiated by the element	Referrer policy
rel	a ^{p290} ; area ^{p290}	Relationship between the location in the document containing the hyperlink ^{p289} and the destination resource	Unordered set of unique space-separated tokens ^{p89} *
rel	link ^{p163}	Relationship between the document containing the hyperlink ^{p289} and the destination resource	Unordered set of unique space-separated tokens ^{p89} *
required	input ^{p531} ; select ^{p549} ; textarea ^{p561}	Whether the control is required for form submission ^{p605}	Boolean attribute ^{p69}
reversed	ol ^{p227}	Number the list backwards	Boolean attribute ^{p69}
rows	textarea ^{p560}	Number of lines to show	Valid non-negative integer ^{p70} greater than zero
rowspan	td ^{p477} ; th ^{p477}	Number of rows that the cell is to span	Valid non-negative integer ^{p70}
sandbox	iframe ^{p374}	Security rules for nested content	Unordered set of unique space-separated tokens ^{p89} , ASCII case-insensitive , consisting of <ul style="list-style-type: none"> "allow-downloads"^{p875} "allow-forms"^{p875} "allow-modals"^{p875} "allow-orientation-lock"^{p875} "allow-pointer-lock"^{p875} "allow-popups"^{p874} "allow-popups-to-escape-sandbox"^{p875} "allow-presentation"^{p875} "allow-same-origin"^{p875} "allow-scripts"^{p875} "allow-top-navigation"^{p874} "allow-top-navigation-by-user-activation"^{p875} "allow-top-navigation-to-custom-protocols"^{p875}
scope	th ^{p475}	Specifies which cells the header cell applies to	"row" ^{p476} ; "col" ^{p476} ; "rowgroup" ^{p476} ; "colgroup" ^{p476}
selected	option ^{p556}	Whether the option is selected by default	Boolean attribute ^{p69}
shape	area ^{p453}	The kind of shape to be created in an image map ^{p454}	"circle" ^{p453} ; "default" ^{p453} ; "poly" ^{p453} ; "rect" ^{p453}
size	input ^{p530} ; select ^{p549}	Size of the control	Valid non-negative integer ^{p70} greater than zero
sizes	link ^{p165}	Sizes of the icons (for rel ^{p163} = "icon" ^{p304})	Unordered set of unique space-separated tokens ^{p89} , ASCII case-insensitive , consisting of sizes*
sizes	img ^{p329} ; source ^{p325}	Image sizes for different page layouts	Valid source size list ^{p343}
slot	HTML elements ^{p141}	The element's desired slot	Text ^{p133}
span	col ^{p469} ; colgroup ^{p468}	Number of columns spanned by the element	Valid non-negative integer ^{p70} greater than zero
spellcheck	HTML elements ^{p818}	Whether the element is to have its spelling and grammar checked	"true"; "false"
src	audio ^{p398} ; embed ^{p378} ; iframe ^{p370} ; img ^{p328} ; input ^{p526} ;	Address of the resource	Valid non-empty URL potentially surrounded by spaces ^{p90}

Attribute	Element(s)	Description	Value
	script ^{p625} ; source ^{p326} (in video ^{p388} or audio ^{p392}); track ^{p394} ; video ^{p398}		
srcdoc	iframe ^{p370}	A document to render in the iframe ^{p369}	The source of an iframe srcdoc document ^{p370} *
srclang	track ^{p394}	Language of the text track	Valid BCP 47 language tag
srcset	img ^{p328} ; source ^{p325}	Images to use in different situations, e.g., high-resolution displays, small monitors, etc.	Comma-separated list of image candidate strings ^{p343}
start	ol ^{p227}	Starting value ^{p227} of the list	Valid integer ^{p70}
step	input ^{p536}	Granularity to be matched by the form control's value	Valid floating-point number ^{p71} greater than zero, or "any"
style	HTML elements ^{p149}	Presentational and formatting instructions	CSS declarations*
tabindex	HTML elements ^{p801}	Whether the element is focusable ^{p800} and sequentially focusable ^{p800} , and the relative order of the element for the purposes of sequential focus navigation ^{p807}	Valid integer ^{p70}
target	a ^{p290} ; area ^{p290}	Browsing context ^{p840} for hyperlink ^{p289} navigation ^{p906}	Valid browsing context name or keyword ^{p849}
target	base ^{p161}	Default browsing context ^{p840} for hyperlink ^{p289} navigation ^{p906} and form submission ^{p605}	Valid browsing context name or keyword ^{p849}
target	form ^{p581}	Browsing context ^{p840} for form submission ^{p605}	Valid browsing context name or keyword ^{p849}
title	HTML elements ^{p143}	Advisory information for the element	Text ^{p133}
title	abbr ^{p256} ; dfn ^{p255}	Full term or expansion of abbreviation	Text ^{p133}
title	input ^{p534}	Description of pattern (when used with pattern ^{p533} attribute)	Text ^{p133}
title	link ^{p164}	Title of the link	Text ^{p133}
title	link ^{p164} ; style ^{p181}	CSS style sheet set name	Text ^{p133}
translate	HTML elements ^{p145}	Whether the element is to be translated when the page is localized	"yes"; "no"
type	a ^{p290} ; link ^{p164}	Hint for the type of the referenced resource	Valid MIME type string
type	button ^{p546}	Type of button	" submit ^{p546} ", " reset ^{p546} ", " button ^{p546} "
type	embed ^{p378} ; object ^{p382} ; source ^{p325}	Type of embedded resource	Valid MIME type string
type	input ^{p503}	Type of form control	input type keyword ^{p503}
type	ol ^{p227}	Kind of list marker	" 1 ^{p227} ", " a ^{p227} ", " A ^{p228} ", " i ^{p228} ", " I ^{p228} "
type	script ^{p625}	Type of script	"module"; a valid MIME type string that is not a JavaScript MIME type essence match
usemap	img ^{p454}	Name of image map ^{p454} to use	Valid hash-name reference ^{p89} *
value	button ^{p547} ; option ^{p556}	Value to be used for form submission ^{p605}	Text ^{p133}
value	data ^{p266}	Machine-readable value	Text ^{p133} *
value	input ^{p505}	Value of the form control	Varies*
value	li ^{p231}	Ordinal value ^{p231} of the list item	Valid integer ^{p70}
value	meter ^{p568} ; progress ^{p566}	Current value of the element	Valid floating-point number ^{p71}
value	param ^{p387}	Value of parameter	Text ^{p133}
width	canvas ^{p647} ; embed ^{p458} ; iframe ^{p458} ; img ^{p458} ; input ^{p458} ; object ^{p458} ; source ^{p458} (in picture ^{p324}); video ^{p458}	Horizontal dimension	Valid non-negative integer ^{p70}
wrap	textarea ^{p560}	How the value of the form control is to be wrapped for form submission ^{p605}	" soft ^{p560} ", " hard ^{p560} "

An asterisk (*) in a cell indicates that the actual rules are more complicated than indicated in the table above.

List of event handler content attributes

Attribute	Element(s)	Description	Value
onauxclick	HTML elements ^{p987}	auxclick event handler	Event handler content attribute ^{p981}
onafterprint	body ^{p988}	afterprint ^{p1300} event handler for Window ^{p855} object	Event handler content attribute ^{p981}
onbeforeprint	body ^{p988}	beforeprint ^{p1300} event handler for Window ^{p855} object	Event handler content attribute ^{p981}
onbeforeunload	body ^{p988}	beforeunload ^{p1300} event handler for Window ^{p855} object	Event handler content attribute ^{p981}
onblur	HTML elements ^{p988}	blur ^{p1301} event handler	Event handler content attribute ^{p981}
oncancel	HTML elements ^{p987}	cancel ^{p1301} event handler	Event handler content attribute ^{p981}
oncanplay	HTML elements ^{p987}	canplay ^{p448} event handler	Event handler content attribute ^{p981}
oncanplaythrough	HTML elements ^{p987}	canplaythrough ^{p448} event handler	Event handler content attribute ^{p981}
onchange	HTML elements ^{p987}	change ^{p1301} event handler	Event handler content attribute ^{p981}
onclick	HTML elements ^{p987}	click event handler	Event handler content attribute ^{p981}
onclose	HTML elements ^{p987}	close ^{p1301} event handler	Event handler content attribute ^{p981}
oncontextlost	HTML elements ^{p987}	contextlost ^{p1301} event handler	Event handler content attribute ^{p981}
oncontextmenu	HTML elements ^{p987}	contextmenu event handler	Event handler content attribute ^{p981}
oncontextrestored	HTML elements ^{p987}	contextrestored ^{p1301} event handler	Event handler content attribute ^{p981}
oncopy	HTML elements ^{p989}	copy ^{p1301} event handler	Event handler content attribute ^{p981}
oncuechange	HTML elements ^{p987}	cuechange ^{p449} event handler	Event handler content attribute ^{p981}
oncut	HTML elements ^{p989}	cut ^{p1301} event handler	Event handler content attribute ^{p981}
ondblclick	HTML elements ^{p987}	dblclick event handler	Event handler content attribute ^{p981}
ondrag	HTML elements ^{p987}	drag ^{p838} event handler	Event handler content attribute ^{p981}
ondragend	HTML elements ^{p987}	dragend ^{p838} event handler	Event handler content attribute ^{p981}
ondragenter	HTML elements ^{p987}	dragenter ^{p838} event handler	Event handler content attribute ^{p981}
ondragleave	HTML elements ^{p987}	dragleave ^{p838} event handler	Event handler content attribute ^{p981}
ondragover	HTML elements ^{p987}	dragover ^{p838} event handler	Event handler content attribute ^{p981}
ondragstart	HTML elements ^{p987}	dragstart ^{p838} event handler	Event handler content attribute ^{p981}
ondrop	HTML elements ^{p987}	drop ^{p838} event handler	Event handler content attribute ^{p981}
ondurationchange	HTML elements ^{p987}	durationchange ^{p448} event handler	Event handler content attribute ^{p981}
onemptied	HTML elements ^{p987}	emptied ^{p447} event handler	Event handler content attribute ^{p981}
onended	HTML elements ^{p987}	ended ^{p448} event handler	Event handler content attribute ^{p981}
onerror	HTML elements ^{p988}	error ^{p1301} event handler	Event handler content attribute ^{p981}
onfocus	HTML elements ^{p988}	focus ^{p1301} event handler	Event handler content attribute ^{p981}
onformdata	HTML elements ^{p987}	formdata ^{p1301} event handler	Event handler content attribute ^{p981}
onhashchange	body ^{p988}	hashchange ^{p1301} event handler for Window ^{p855} object	Event handler content attribute ^{p981}
oninput	HTML elements ^{p987}	input ^{p1301} event handler	Event handler content attribute ^{p981}
oninvalid	HTML elements ^{p987}	invalid ^{p1301} event handler	Event handler content attribute ^{p981}
onkeydown	HTML elements ^{p987}	keydown event handler	Event handler content attribute ^{p981}
onkeypress	HTML elements ^{p987}	keypress event handler	Event handler content attribute ^{p981}
onkeyup	HTML elements ^{p987}	keyup event handler	Event handler content attribute ^{p981}
onlanguagechange	body ^{p989}	languagechange ^{p1301} event handler for Window ^{p855} object	Event handler content attribute ^{p981}
onload	HTML elements ^{p988}	load ^{p1301} event handler	Event handler content attribute ^{p981}
onloadeddata	HTML elements ^{p987}	loadeddata ^{p448} event handler	Event handler content attribute ^{p981}
onloadedmetadata	HTML elements ^{p987}	loadedmetadata ^{p448} event handler	Event handler content attribute ^{p981}
onloadstart	HTML elements ^{p987}	loadstart ^{p447} event handler	Event handler content attribute ^{p981}
onmessage	body ^{p989}	message ^{p1301} event handler for Window ^{p855} object	Event handler content attribute ^{p981}
onmessageerror	body ^{p989}	messageerror ^{p1301} event handler for Window ^{p855} object	Event handler content attribute ^{p981}
onmousedown	HTML elements ^{p987}	mousedown event handler	Event handler content attribute ^{p981}
onmouseenter	HTML elements ^{p987}	mouseenter event handler	Event handler content attribute ^{p981}
onmouseleave	HTML elements ^{p987}	mouseleave event handler	Event handler content attribute ^{p981}
onmousemove	HTML elements ^{p987}	mousemove event handler	Event handler content attribute ^{p981}
onmouseout	HTML elements ^{p987}	mouseout event handler	Event handler content attribute ^{p981}
onmouseover	HTML elements ^{p988}	mouseover event handler	Event handler content attribute ^{p981}
onmouseup	HTML elements ^{p988}	mouseup event handler	Event handler content attribute ^{p981}
onoffline	body ^{p989}	offline ^{p1301} event handler for Window ^{p855} object	Event handler content attribute ^{p981}
ononline	body ^{p989}	online ^{p1301} event handler for Window ^{p855} object	Event handler content attribute ^{p981}
onpagehide	body ^{p989}	pagehide ^{p1301} event handler for Window ^{p855} object	Event handler content attribute ^{p981}

Attribute	Element(s)	Description	Value
onpageshow	body ^{p989}	pageshow ^{p1301} event handler for Window ^{p855} object	Event handler content attribute ^{p981}
onpaste	HTML elements ^{p989}	paste ^{p1301} event handler	Event handler content attribute ^{p981}
onpause	HTML elements ^{p988}	pause ^{p448} event handler	Event handler content attribute ^{p981}
onplay	HTML elements ^{p988}	play ^{p448} event handler	Event handler content attribute ^{p981}
onplaying	HTML elements ^{p988}	playing ^{p448} event handler	Event handler content attribute ^{p981}
onpopstate	body ^{p989}	popstate ^{p1302} event handler for Window ^{p855} object	Event handler content attribute ^{p981}
onprogress	HTML elements ^{p988}	progress ^{p447} event handler	Event handler content attribute ^{p981}
onratechange	HTML elements ^{p988}	ratechange ^{p448} event handler	Event handler content attribute ^{p981}
onreset	HTML elements ^{p988}	reset ^{p1302} event handler	Event handler content attribute ^{p981}
onresize	HTML elements ^{p988}	resize event handler	Event handler content attribute ^{p981}
onrejectionhandled	body ^{p989}	rejectionhandled ^{p1302} event handler for Window ^{p855} object	Event handler content attribute ^{p981}
onscroll	HTML elements ^{p988}	scroll event handler	Event handler content attribute ^{p981}
onsecuritypolicyviolation	HTML elements ^{p988}	securitypolicyviolation ^{p1302} event handler	Event handler content attribute ^{p981}
onseeked	HTML elements ^{p988}	seeked ^{p448} event handler	Event handler content attribute ^{p981}
onseeking	HTML elements ^{p988}	seeking ^{p448} event handler	Event handler content attribute ^{p981}
onselect	HTML elements ^{p988}	select ^{p1302} event handler	Event handler content attribute ^{p981}
onslotchange	HTML elements ^{p988}	slotchange ^{p1302} event handler	Event handler content attribute ^{p981}
onstalled	HTML elements ^{p988}	stalled ^{p448} event handler	Event handler content attribute ^{p981}
onstorage	body ^{p989}	storage ^{p1302} event handler for Window ^{p855} object	Event handler content attribute ^{p981}
onsubmit	HTML elements ^{p988}	submit ^{p1302} event handler	Event handler content attribute ^{p981}
onsuspend	HTML elements ^{p988}	suspend ^{p447} event handler	Event handler content attribute ^{p981}
ontimeupdate	HTML elements ^{p988}	timeupdate ^{p448} event handler	Event handler content attribute ^{p981}
ontoggle	HTML elements ^{p988}	toggle ^{p1302} event handler	Event handler content attribute ^{p981}
onunhandledrejection	body ^{p989}	unhandledrejection ^{p1302} event handler for Window ^{p855} object	Event handler content attribute ^{p981}
onunload	body ^{p989}	unload ^{p1302} event handler for Window ^{p855} object	Event handler content attribute ^{p981}
onvolumechange	HTML elements ^{p988}	volumechange ^{p448} event handler	Event handler content attribute ^{p981}
onwaiting	HTML elements ^{p988}	waiting ^{p448} event handler	Event handler content attribute ^{p981}
onwheel	HTML elements ^{p988}	wheel event handler	Event handler content attribute ^{p981}

Element interfaces §^{p12}₉₆

This section is non-normative.

List of interfaces for elements

Element(s)	Interface(s)
a ^{p244}	HTMLAnchorElement ^{p245} : HTMLElement ^{p128}
abbr ^{p256}	HTMLElement ^{p128}
address ^{p204}	HTMLElement ^{p128}
area ^{p452}	HTMLAreaElement ^{p452} : HTMLElement ^{p128}
article ^{p186}	HTMLElement ^{p128}
aside ^{p194}	HTMLElement ^{p128}
audio ^{p392}	HTMLAudioElement ^{p392} : HTMLMediaElement ^{p396} : HTMLElement ^{p128}
b ^{p279}	HTMLElement ^{p128}
base ^{p160}	HTMLBaseElement ^{p160} : HTMLElement ^{p128}
bdi ^{p284}	HTMLElement ^{p128}
bdo ^{p285}	HTMLElement ^{p128}
blockquote ^{p224}	HTMLQuoteElement ^{p224} : HTMLElement ^{p128}
body ^{p184}	HTMLBodyElement ^{p185} : HTMLElement ^{p128}
br ^{p286}	HTMLBRElement ^{p286} : HTMLElement ^{p128}
button ^{p545}	HTMLButtonElement ^{p546} : HTMLElement ^{p128}
canvas ^{p645}	HTMLCanvasElement ^{p646} : HTMLElement ^{p128}
caption ^{p466}	HTMLTableCaptionElement ^{p467} : HTMLElement ^{p128}
cite ^{p252}	HTMLElement ^{p128}

Element(s)	Interface(s)
code ^{p273}	HTMLInputElement ^{p128}
col ^{p468}	HTMLTableColElement ^{p468} : HTMLInputElement ^{p128}
colgroup ^{p467}	HTMLTableColElement ^{p468} : HTMLInputElement ^{p128}
data ^{p265}	HTMLDataElement ^{p266} : HTMLInputElement ^{p128}
datalist ^{p553}	HTMLDataListElement ^{p553} : HTMLInputElement ^{p128}
dd ^{p237}	HTMLInputElement ^{p128}
del ^{p320}	HTMLModElement ^{p321} : HTMLInputElement ^{p128}
details ^{p614}	HTMLDetailsElement ^{p614} : HTMLInputElement ^{p128}
dfn ^{p255}	HTMLInputElement ^{p128}
dialog ^{p620}	HTMLDialogElement ^{p621} : HTMLInputElement ^{p128}
div ^{p243}	HTMLDivElement ^{p244} : HTMLInputElement ^{p128}
dl ^{p233}	HTMLDListElement ^{p233} : HTMLInputElement ^{p128}
dt ^{p236}	HTMLInputElement ^{p128}
em ^{p247}	HTMLInputElement ^{p128}
embed ^{p378}	HTMLEmbedElement ^{p378} : HTMLInputElement ^{p128}
fieldset ^{p572}	HTMLFieldSetElement ^{p572} : HTMLInputElement ^{p128}
figcaption ^{p241}	HTMLInputElement ^{p128}
figure ^{p238}	HTMLInputElement ^{p128}
footer ^{p201}	HTMLInputElement ^{p128}
form ^{p494}	HTMLFormElement ^{p495} : HTMLInputElement ^{p128}
h1 ^{p196}	HTMLHeadingElement ^{p196} : HTMLInputElement ^{p128}
h2 ^{p196}	HTMLHeadingElement ^{p196} : HTMLInputElement ^{p128}
h3 ^{p196}	HTMLHeadingElement ^{p196} : HTMLInputElement ^{p128}
h4 ^{p196}	HTMLHeadingElement ^{p196} : HTMLInputElement ^{p128}
h5 ^{p196}	HTMLHeadingElement ^{p196} : HTMLInputElement ^{p128}
h6 ^{p196}	HTMLHeadingElement ^{p196} : HTMLInputElement ^{p128}
head ^{p158}	HTMLHeadElement ^{p158} : HTMLInputElement ^{p128}
header ^{p200}	HTMLInputElement ^{p128}
hgroup ^{p197}	HTMLInputElement ^{p128}
hr ^{p220}	HTMLHRElement ^{p221} : HTMLInputElement ^{p128}
html ^{p157}	HTMLHtmlElement ^{p157} : HTMLInputElement ^{p128}
i ^{p278}	HTMLInputElement ^{p128}
iframe ^{p369}	HTMLIFrameElement ^{p370} : HTMLInputElement ^{p128}
img ^{p327}	HTMLImageElement ^{p328} : HTMLInputElement ^{p128}
input ^{p501}	HTMLInputElement ^{p502} : HTMLInputElement ^{p128}
ins ^{p319}	HTMLModElement ^{p321} : HTMLInputElement ^{p128}
kbd ^{p276}	HTMLInputElement ^{p128}
label ^{p498}	HTMLLabelElement ^{p499} : HTMLInputElement ^{p128}
legend ^{p574}	HTMLLegendElement ^{p575} : HTMLInputElement ^{p128}
li ^{p230}	HTMLLIElement ^{p231} : HTMLInputElement ^{p128}
link ^{p162}	HTMLLinkElement ^{p162} : HTMLInputElement ^{p128}
main ^{p242}	HTMLInputElement ^{p128}
map ^{p450}	HTMLMapElement ^{p451} : HTMLInputElement ^{p128}
mark ^{p281}	HTMLInputElement ^{p128}
menu ^{p229}	HTMLMenuElement ^{p230} : HTMLInputElement ^{p128}
meta ^{p170}	HTMLMetaElement ^{p170} : HTMLInputElement ^{p128}
meter ^{p567}	HTMLMeterElement ^{p568} : HTMLInputElement ^{p128}
nav ^{p191}	HTMLInputElement ^{p128}
noscript ^{p638}	HTMLInputElement ^{p128}
object ^{p381}	HTMLObjectElement ^{p382} : HTMLInputElement ^{p128}
ol ^{p226}	HTMLListElement ^{p227} : HTMLInputElement ^{p128}
optgroup ^{p554}	HTMLOptGroupElement ^{p554} : HTMLInputElement ^{p128}
option ^{p555}	HTMLOptionElement ^{p556} : HTMLInputElement ^{p128}
output ^{p563}	HTMLOutputElement ^{p563} : HTMLInputElement ^{p128}

Element(s)	Interface(s)
p ^{p218}	HTMLParagraphElement ^{p218} : HTMLElement ^{p128}
param ^{p387}	HTMLParamElement ^{p387} : HTMLElement ^{p128}
picture ^{p324}	HTMLPictureElement ^{p324} : HTMLElement ^{p128}
pre ^{p222}	HTMLPreElement ^{p222} : HTMLElement ^{p128}
progress ^{p565}	HTMLProgressElement ^{p565} : HTMLElement ^{p128}
q ^{p254}	HTMLQuoteElement ^{p224} : HTMLElement ^{p128}
rp ^{p264}	HTMLElement ^{p128}
rt ^{p264}	HTMLElement ^{p128}
ruby ^{p258}	HTMLElement ^{p128}
s ^{p251}	HTMLElement ^{p128}
samp ^{p275}	HTMLElement ^{p128}
script ^{p624}	HTMLScriptElement ^{p524} : HTMLElement ^{p128}
section ^{p188}	HTMLElement ^{p128}
select ^{p547}	HTMLSelectElement ^{p548} : HTMLElement ^{p128}
slot ^{p644}	HTMLSlotElement ^{p644} : HTMLElement ^{p128}
small ^{p250}	HTMLElement ^{p128}
source ^{p324}	HTMLSourceElement ^{p325} : HTMLElement ^{p128}
span ^{p285}	HTMLSpanElement ^{p286} : HTMLElement ^{p128}
strong ^{p249}	HTMLElement ^{p128}
style ^{p180}	HTMLStyleElement ^{p181} : HTMLElement ^{p128}
sub ^{p277}	HTMLElement ^{p128}
summary ^{p617}	HTMLElement ^{p128}
sup ^{p277}	HTMLElement ^{p128}
table ^{p458}	HTMLTableElement ^{p459} : HTMLElement ^{p128}
tbody ^{p469}	HTMLTableSectionElement ^{p469} : HTMLElement ^{p128}
td ^{p474}	HTMLTableCellElement ^{p474} : HTMLElement ^{p128}
template ^{p640}	HTMLTemplateElement ^{p641} : HTMLElement ^{p128}
textarea ^{p558}	HTMLTextAreaElement ^{p558} : HTMLElement ^{p128}
tfoot ^{p471}	HTMLTableSectionElement ^{p469} : HTMLElement ^{p128}
th ^{p475}	HTMLTableCellElement ^{p474} : HTMLElement ^{p128}
thead ^{p470}	HTMLTableSectionElement ^{p469} : HTMLElement ^{p128}
time ^{p266}	HTMLTimeElement ^{p267} : HTMLElement ^{p128}
title ^{p159}	HTMLTitleElement ^{p159} : HTMLElement ^{p128}
tr ^{p472}	HTMLTableRowElement ^{p472} : HTMLElement ^{p128}
track ^{p393}	HTMLTrackElement ^{p394} : HTMLElement ^{p128}
u ^{p281}	HTMLElement ^{p128}
ul ^{p228}	HTMLUListElement ^{p229} : HTMLElement ^{p128}
var ^{p274}	HTMLElement ^{p128}
video ^{p388}	HTMLVideoElement ^{p389} : HTMLMediaElement ^{p396} : HTMLElement ^{p128}
wbr ^{p287}	HTMLElement ^{p128}
custom elements ^{p728}	supplied by the element's author (inherits from HTMLElement ^{p128})

Events §^{p13}₀₀

This section is non-normative.

List of events

Event	Interface	Interesting targets	Description
DOMContentLoaded	Event	Document ^{p117}	Fired at the Document ^{p117} once the parser has finished
afterprint	Event	Window ^{p855}	Fired at the Window ^{p855} after printing
beforeprint	Event	Window ^{p855}	Fired at the Window ^{p855} before printing
beforeunload	BeforeUnloadEvent ^{p930}	Window ^{p855}	Fired at the Window ^{p855} when the page is about to be unloaded, in case the page would like to show a warning prompt

Event	Interface	Interesting targets	Description
blur	Event	Window ^{p855} , elements	Fired at nodes when they stop being focused ^{p799}
cancel	Event	dialog ^{p620} elements, input ^{p501} elements	Fired at dialog ^{p620} elements when they are canceled by the user (e.g., by pressing the Escape key), or at input ^{p501} elements in the File ^{p523} state when the user does not change their selection
change	Event	Form controls	Fired at controls when the user commits a value change (see also the input ^{p1301} event)
click	PointerEvent	Elements	Normally a mouse event; also synthetically fired at an element before its activation behavior is run, when an element is activated from a non-pointer input device (e.g. a keyboard)
close	Event	dialog ^{p620} elements	Fired at dialog ^{p620} elements when they are closed
connect	MessageEvent ^{p1024}	SharedWorkerGlobalScope ^{p1064}	Fired at a shared worker's global scope when a new client connects
contextlost	Event	canvas ^{p645} elements, OffscreenCanvas ^{p712} objects	Fired when the corresponding CanvasRenderingContext2D ^{p650} or OffscreenCanvasRenderingContext2D ^{p716} is lost
contextmenu	PointerEvent	Elements	Fired at elements when the user requests their context menu
contextrestored	Event	canvas ^{p645} elements, OffscreenCanvas ^{p712} objects	Fired when the corresponding CanvasRenderingContext2D ^{p650} or OffscreenCanvasRenderingContext2D ^{p716} is restored after being lost
copy	Event	Elements	Fired at elements when the user copies data to the clipboard
cut	Event	Elements	Fired at elements when the user copies the selected data on the clipboard and removes the selection from the document
error	Event or ErrorEvent ^{p960}	Global scope objects, Worker ^{p1070} objects, elements, networking-related objects	Fired when unexpected errors occur (e.g. networking errors, script errors, decoding errors)
focus	Event	Window ^{p855} , elements	Fired at nodes gaining focus ^{p799}
formdata	FormDataEvent ^{p613}	form ^{p494} elements	Fired at a form ^{p494} element when it is constructing the entry list ^{p610}
hashchange	HashChangeEvent ^{p926}	Window ^{p855}	Fired at the Window ^{p855} when the fragment part of the document's URL changes
input	Event	Form controls	Fired at controls when the user changes the value (see also the change ^{p1301} event)
invalid	Event	Form controls	Fired at controls during form validation if they do not satisfy their constraints
languagechange	Event	Global scope objects	Fired at the global scope object when the user's preferred languages change
load	Event	Window ^{p855} , elements	Fired at the Window ^{p855} when the document has finished loading; fired at an element containing a resource (e.g. img ^{p327} , embed ^{p378}) when its resource has finished loading
message	MessageEvent ^{p1024}	Window ^{p855} , EventSource ^{p1026} , MessagePort ^{p1040} , BroadcastChannel ^{p1043} , DedicatedWorkerGlobalScope ^{p1064} , Worker ^{p1070} , ServiceWorkerContainer	Fired at an object when it receives a message
messageerror	MessageEvent ^{p1024}	Window ^{p855} , MessagePort ^{p1040} , BroadcastChannel ^{p1043} , DedicatedWorkerGlobalScope ^{p1064} , Worker ^{p1070} , ServiceWorkerContainer	Fired at an object when it receives a message that cannot be deserialized
offline	Event	Global scope objects	Fired at the global scope object when the network connections fails
online	Event	Global scope objects	Fired at the global scope object when the network connections returns
open	Event	EventSource ^{p1026}	Fired at EventSource ^{p1026} objects when a connection is established
pagehide	PageTransitionEvent ^{p926}	Window ^{p855}	Fired at the Window ^{p855} when the page's entry in the session history ^{p888} stops being the current entry ^{p890}
pageshow	PageTransitionEvent ^{p926}	Window ^{p855}	Fired at the Window ^{p855} when the page's entry in the session history ^{p888} becomes the current entry ^{p890}
paste	Event	Elements	Fired at elements when the user will insert the clipboard data in the most suitable format (if any) supported for

Event	Interface	Interesting targets	Description
			the given context
popstate	PopStateEvent ^{p926}	Window ^{p855}	Fired at the Window ^{p855} when the user navigates the session history ^{p888}
readystatechange	Event	Document ^{p117}	Fired at the Document ^{p117} when it finishes parsing and again when all its subresources have finished loading
rejectionhandled	PromiseRejectionEvent ^{p961}	Global scope objects	Fired at global scope objects when a previously-unhandled promise rejection becomes handled
reset	Event	form ^{p494} elements	Fired at a form ^{p494} element when it is reset ^{p614}
securitypolicyviolation	Event	Elements	Fired at elements when a Content Security Policy violation is generated [CSP] ^{p1305}
select	Event	Form controls	Fired at form controls when their text selection is adjusted (whether by an API or by the user)
slotchange	Event	slot ^{p644} elements	Fired at slot ^{p644} elements when their assigned nodes change
storage	StorageEvent ^{p1090}	Window ^{p855}	Fired at Window ^{p855} event when the corresponding localStorage ^{p1090} or sessionStorage ^{p1089} storage areas change
submit	SubmitEvent ^{p613}	form ^{p494} elements	Fired at a form ^{p494} element when it is submitted ^{p606}
toggle	Event	details ^{p614} element	Fired at details ^{p614} elements when they open or close
unhandledrejection	PromiseRejectionEvent ^{p961}	Global scope objects	Fired at global scope objects when a promise rejection goes unhandled
unload	Event	Window ^{p855}	Fired at the Window ^{p855} object when the page is going away
visibilitychange	Event	Document ^{p117}	Fired at the Document ^{p117} object when the page becomes visible or hidden to the user. [PAGEVIS] ^{p1310}

Note

See also [media element events](#)^{p447} and [drag-and-drop events](#)^{p838}.

HTTP headers §^{p13} 02

This section is non-normative.

The following HTTP request headers are defined by this specification:

- [`Last-Event-ID`](#)^{p1029}
- [`Ping-From`](#)^{p300}
- [`Ping-To`](#)^{p300}

The following HTTP response headers are defined by this specification:

- [`Cross-Origin-Embedder-Policy`](#)^{p885}
- [`Cross-Origin-Embedder-Policy-Report-Only`](#)^{p885}
- [`Cross-Origin-Opener-Policy`](#)^{p877}
- [`Cross-Origin-Opener-Policy-Report-Only`](#)^{p877}
- [`Origin-Agent-Cluster`](#)^{p872}
- [`Refresh`](#)^{p932}
- [`X-Frame-Options`](#)^{p931}

MIME types ^{§[p13](#)}₀₃

This section is non-normative.

The following MIME types are mentioned in this specification:

application/atom+xml

Atom [[ATOM](#)]^{[p1305](#)}

application/ecmascript

JavaScript (legacy type) [[JAVASCRIPT](#)]^{[p1308](#)}

application/javascript

JavaScript (legacy type) [[JAVASCRIPT](#)]^{[p1308](#)}

application/json

JSON [[JSON](#)]^{[p1309](#)}

application/x-ecmascript

JavaScript (legacy type) [[JAVASCRIPT](#)]^{[p1308](#)}

application/x-javascript

JavaScript (legacy type) [[JAVASCRIPT](#)]^{[p1308](#)}

application/octet-stream

Generic binary data [[RFC2046](#)]^{[p1310](#)}

application/microdata+json^{[p1279](#)}

Microdata as JSON

application/rss+xml

RSS

application/x-www-form-urlencoded

Form submission

application/xhtml+xml^{[p1277](#)}

HTML

application/xml

XML [[XML](#)]^{[p1313](#)} [[RFC7303](#)]^{[p1311](#)}

image/gif

GIF images [[GIF](#)]^{[p1308](#)}

image/jpeg

JPEG images [[JPEG](#)]^{[p1309](#)}

image/png

PNG images [[PNG](#)]^{[p1310](#)}

image/svg+xml

SVG images [[SVG](#)]^{[p1312](#)}

multipart/form-data

Form submission [[RFC7578](#)]^{[p1311](#)}

multipart/mixed

Generic mixed content [[RFC2046](#)]^{[p1310](#)}

multipart/x-mixed-replace^{[p1276](#)}

Streaming server push

text/css

CSS [[CSS](#)]^{[p1305](#)}

text/ecmascript

JavaScript (legacy type) [[JAVASCRIPT](#)]^{[p1308](#)}

[text/event-stream](#)^{p1288}

Server-sent event streams

[text/javascript](#)

JavaScript [[JAVASCRIPT](#)]^{p1308}

[text/javascript1.0](#)

JavaScript (legacy type) [[JAVASCRIPT](#)]^{p1308}

[text/javascript1.1](#)

JavaScript (legacy type) [[JAVASCRIPT](#)]^{p1308}

[text/javascript1.2](#)

JavaScript (legacy type) [[JAVASCRIPT](#)]^{p1308}

[text/javascript1.3](#)

JavaScript (legacy type) [[JAVASCRIPT](#)]^{p1308}

[text/javascript1.4](#)

JavaScript (legacy type) [[JAVASCRIPT](#)]^{p1308}

[text/javascript1.5](#)

JavaScript (legacy type) [[JAVASCRIPT](#)]^{p1308}

[text/jscript](#)

JavaScript (legacy type) [[JAVASCRIPT](#)]^{p1308}

[text/json](#)

JSON (legacy type)

[text/livescript](#)

JavaScript (legacy type) [[JAVASCRIPT](#)]^{p1308}

[text/plain](#)

Generic plain text [[RFC2046](#)]^{p1310} [[RFC3676](#)]^{p1311}

[text/html](#)^{p1275}

HTML

[text/ping](#)^{p1278}

Hyperlink auditing

[text/uri-list](#)

List of URLs [[RFC2483](#)]^{p1311}

[text/vcard](#)

vCard [[RFC6350](#)]^{p1311}

[text/vtt](#)

WebVTT [[WEBVTT](#)]^{p1313}

[text/x-ecmascript](#)

JavaScript (legacy type) [[JAVASCRIPT](#)]^{p1308}

[text/x-javascript](#)

JavaScript (legacy type) [[JAVASCRIPT](#)]^{p1308}

[text/xml](#)

XML [[XML](#)]^{p1313} [[RFC7303](#)]^{p1311}

[video/mp4](#)

MPEG-4 video [[RFC4337](#)]^{p1311}

[video/mpeg](#)

MPEG video [[RFC2046](#)]^{p1310}

Andersen, for their useful comments, both large and small, that have led to changes to this specification over the years.

Thanks also to everyone who has ever posted about HTML to their blogs, public mailing lists, or forums, including all the contributors to the [various W3C HTML WG lists](#) and the [various WHATWG lists](#).

Special thanks to Richard Williamson for creating the first implementation of [canvas^{p645}](#) in Safari, from which the canvas feature was designed.

Special thanks also to the Microsoft employees who first implemented the event-based drag-and-drop mechanism, [contenteditable^{p815}](#), and other features first widely deployed by the Windows Internet Explorer browser.

Special thanks and \$10,000 to David Hyatt who came up with a broken implementation of the [adoption agency algorithm^{p1174}](#) that the editor had to reverse engineer and fix before using it in the parsing section.

Thanks to the participants of the microdata usability study for allowing us to use their mistakes as a guide for designing the microdata feature.

Thanks to the many sources that provided inspiration for the examples used in the specification.

Thanks also to the Microsoft blogging community for some ideas, to the attendees of the W3C Workshop on Web Applications and Compound Documents for inspiration, to the #mrt crew, the #mrt.no crew, and the #whatwg crew, and to Pillar and Hedral for their ideas and support.

Thanks to Igor Zhanov for generating PDF versions of the specification.

Special thanks to the [RIGG](#) for developing the [picture^{p324}](#) element and related features; in particular thanks to Adrian Bateman, Bruce Lawson, David Newton, Ilya Grigorik, John Schoenick, Leon de Rijke, Mat Marquis, Marcos Cáceres, Tab Atkins, Theresa O'Connor, and Yoav Weiss for their contributions.

Special thanks to the [WPWG](#) for incubating the [custom elements^{p720}](#) feature. In particular, thanks to David Hyatt and Ian Hickson for their influence through the XBL specifications, Dimitri Glazkov for the first draft of the custom elements specification, and to Alex Komoroske, Alex Russell, Andres Rios, Boris Zbarsky, Brian Kardell, Daniel Buchner, Dominic Cooney, Erik Arvidsson, Elliott Sprehn, Hajime Morrita, Hayato Ito, Jan Miksovsky, Jonas Sicking, Olli Pettay, Rafael Weinstein, Roland Steiner, Ryosuke Niwa, Scott Miles, Steve Faulkner, Steve Orvell, Tab Atkins, Theresa O'Connor, Tim Perry, and William Chen for their contributions.

Special thanks to the [CSSWG](#) for developing the [worklets^{p1077}](#). In particular, thanks to Ian Kilpatrick for his work as editor of the original worklets specification.

For about ten years starting in 2003, this standard was almost entirely written by Ian Hickson ([Google](#), ian@hixie.ch). More recently, Simon Pieters ([Bocoup](#), zcorpan@gmail.com), [Anne van Kesteren](#) ([Mozilla](#), annevk@annevk.nl), [Philip Jägenstedt](#) ([Google](#), philip@foolip.org), and [Domenic Denicola](#) ([Google](#), d@domenic.me), all previously long-time contributors, have joined Ian in editing the text directly.
