Impacts of the Adjacent Levee Alternative (Proposed Action) and Fix-in-Place Alternative on recreational uses would be limited to potential temporary disturbance of access to facilities on the western, eastern, and southern perimeter of the Natomas Basin during construction; potential temporary degradation in the quality of recreational experiences as a result of construction activity and noise; and damage to recreational facilities on and adjacent to the Sacramento River east levee (Reach A:19A–20) and the NEMDC, including the Ueda Parkway Bike Trail, Shorebird Park, Costa Park Site, Natomas Oaks Preserve, Bannon Creek Preserve, and Niños Parkway. Because of the temporary nature of the construction impacts and the likelihood that any access restrictions or degradation of the quality of recreational experiences would last for less than one construction season in any location, these impacts are not considered substantial enough to make a cumulatively considerable incremental contribution to a significant cumulative impact. Reconstruction and restoration of damaged park facilities would be required (Mitigation Measure 4.15-a). Recreation impacts would occur on a temporary project-specific basis rather than a cumulative basis, and any such incidents would be isolated. Therefore, the Phase 4b Project and related projects **would *not* result in a cumulatively considerable incremental contribution** to a cumulatively significant impact.

5.1.5.15 VISUAL RESOURCES

Phase 1–4a Projects

The Phase 1–4a Projects would include the removal of trees, other vegetation, and structures from the landside and/or waterside of the Sacramento River east levee within the footprint of the adjacent setback levee and berms.

These projects also include the removal of some vegetation and structural encroachments from the waterside of the Sacramento River east levee as part of encroachment removal actions, and would include the removal of trees from areas along the waterside of the NCC south levee. SAFCA's proposed levee integrity program would also require the removal of vegetation and other features that currently add to the rural and riverine character of views in the area. These changes would contribute to the substantial degradation of scenic resources in the Natomas Basin that are expected to result from various development projects and expansion of Airport facilities, as the area's visual character changes from rural agricultural landscape to urban/suburban setting. The Phase 1–4a Projects include the establishment of a substantial acreage of woodland plantings around the Basin to offset the projects' significant effects on scenic resources (oak and other native trees). The plantings, however, would require several years to become well established and several decades to achieve the same size and aesthetic value as the existing mature vegetation that would be removed, which in some cases such as Heritage oaks is likely 100 years old or older. Additionally, the Levee Raise-in-Place (Phase 3 Project) and RSLIP (Phase 4a Project) Alternatives would result in the loss of high-aesthetic-value woodlands along the waterside of the levee.

Furthermore, the construction of an adjacent setback levee along the Sacramento River east levee in Reaches C:1 to B:13 would reduce views for motorists and other viewers along Garden Highway of the Natomas Basin and Central Valley. Generally, the height of the new adjacent setback levee would be 1–3 feet higher in elevation than the waterside hinge point of the existing Garden Highway, with the greatest elevations starting in the north and declining toward the south. However, the levee would be an additional 2–4 feet higher in up to 15 locations to accommodate other project features, such as pipeline crossings and roadway intersections. For example, where Sankey Road intersects Garden Highway in Reach C:1, the adjacent levee, which was constructed in 2009 as part of the Phase 2 Project, is an additional 3–4 feet higher for a length of approximately 40 feet, with 100–150-foot-long transitions on both sides back to the typical adjacent levee profile. These raised levee sections would further decrease views of the Basin from the Garden Highway, although their relatively short length and the fact that they would be widely spaced over 12 miles of highway would tend to minimize the effect somewhat. For these reasons, USACE determined that the Phase 1–4a Projects **would result in a cumulatively considerable incremental contribution** to a cumulatively significant impact on visual resources, primarily from removal of vegetation (mature oak and other native trees) and the long time period for replanted vegetation to reach similar sizes.

Phase 4b Project

The Phase 4b Project (Adjacent Levee Alternative [Proposed Action] and Fix-in-Place Alternative) would involve nighttime construction lighting that would be clearly visible from nearby residences. Nighttime lighting related to 24/7 construction of cutoff walls along the PGCC and NEMDC and potentially in Sacramento River east levee Reach A:16–19A (west of the I-80 overcrossing) in particular could create a new source of substantial light or glare that would adversely affect nighttime views in the area. In addition, nighttime lighting would also be used for drilling and testing of groundwater replacements wells. Construction-related nighttime lighting, however, would be localized and temporary and there are no other projects in the area that would contribute to a cumulative increase in light and glare. Therefore, the Phase 4b Project **would *not* result in a cumulatively considerable incremental contribution** to a significant cumulative impact.

For the Phase 4b Project, the Adjacent Levee Alternative (Proposed Action) would include the removal of trees, including Heritage oaks, other vegetation, and structures from the landside of the Sacramento River east levee within the footprint of the adjacent levee and berms, and may include the removal of some vegetation from the waterside of the Sacramento River east levee. These changes would contribute to the substantial degradation of scenic resources in the Natomas Basin that are expected to result with various development projects and expansion of Airport facilities, as the area's visual character changes from rural agricultural landscape to urban/suburban setting. Although the Phase 4b Project includes the establishment of a substantial acreage of woodland plantings around the Basin to offset the significant effect of the project on scenic resources (oak and other native trees), the plantings would require decades to become well established and up to 100 years to replace

Heritage oaks. Furthermore, construction of an adjacent levee, in combination with removal of woodlands along the landside of the Sacramento River east levee would substantially alter the existing visual character of the Natomas Basin and surrounding areas. Not only would the setback levee result in a physical barrier to the existing viewshed in some locations, tree removal would degrade the visual coherence of the project area.

The Fix-in-Place Alternative would result in similar impacts to visual resources as the Adjacent Levee Alternative (Proposed Action) except that the Sacramento River east levee would be widened in place, requiring greater removal of riparian woodlands on the waterside of these levee reaches to conform with USACE guidance regarding levee encroachments. Therefore, the Fix-in-Place Alternative would result in the loss of high-aesthetic-value woodlands along the waterside of the levee. Widening of the existing levee would add an additional obstruction of views toward the east, although less than under the Adjacent Levee Alternative (Proposed Action).

Because the replacement plantings that are part of the Phase 4b Project would be planted along the landside of the levee, and mitigation is not available to fully compensate for the loss of waterside vegetation (including SRA habitat), the Adjacent Levee Alternative (Proposed Action) and Fix-in-Place Alternative **would result in a cumulatively considerable incremental contribution** to a cumulatively significant impact on visual resources, primarily from removal of vegetation (mature oak and other native trees) and the long time period for replanted vegetation to reach similar sizes.

5.1.5.16 Utilities and Service Systems

Phase 1–4a Projects

Construction of the Phase 1–4a Projects may damage irrigation systems and public utility infrastructure, resulting in temporary disruptions to service. Coordination with irrigation system users, consultation with service providers, and implementation of appropriate protection measures would minimize the possibility of any significant effects. Because utility and service system impacts would be isolated, temporary, and fully mitigated on a project-by-project basis, USACE and SAFCA determined that the Phase 1–4a Projects **would *not* result in a cumulatively considerable incremental contribution** to a cumulatively significant impact.

Phase 4b Project

Construction of the Phase 4b Project (Adjacent Levee Alternative [Proposed Action] and Fix-in-Place Alternative) may damage irrigation systems and public utility infrastructure, resulting in temporary disruptions to service. Coordination with irrigation system users, consultation with service providers, and implementation of Mitigation Measures 4.14-a and 4.14-b would minimize the possibility that any significant effect would occur. Because utility and service system impacts would be isolated, temporary, and fully mitigated on a project-by-project basis, the Phase 4b Project **would *not* result in a cumulatively considerable incremental contribution** to a cumulatively significant impact.

5.1.5.17 Hazards and Hazardous Materials

Phase 1–4a Projects

For the Phase 1–4a Projects, mitigation would be implemented to minimize the potential for exposure of people or the environment to hazardous materials encountered during construction activity. If hazardous materials are encountered, the impacts would be localized and would not be expected to combine with the impacts of related projects. Because hazards and hazardous materials impacts would occur on a project-specific basis rather than a cumulative basis, USACE and SAFCA determined that the Phase 1–4a Projects **would *not* result in a cumulatively considerable incremental contribution** to a cumulatively significant impact.

Phase 4b Project

Mitigation would be implemented to minimize the Phase 4b Project's potential for exposure of people or the environment to hazardous materials encountered during construction activity (Mitigation Measure 4.15-b). If hazardous materials are encountered, impacts would be localized and would not be expected to combine with the impacts of other projects. Because hazards and hazardous materials impacts would occur on a project-specific basis rather than a cumulative basis, implementation of either the Adjacent Levee Alternative (Proposed Action) or Fix-in-Place Alternative along with other related projects **would *not* result in a cumulatively considerable incremental contribution** to a cumulatively significant impact.

5.1.5.18 AIRPORT SAFETY

Phase 1–4a Projects

The potential for night lighting of project areas to affect aircraft operations is a function of the location of construction areas in relation to Airport Perimeter B and the runway approaches. Potential impacts of the Phase 1–4a Projects would be reduced through lighting restrictions and coordination with SCAS. The Phase 1–4a Projects' potential to increase the possibility of collisions between aircraft and wildlife is a result of the location of construction areas in relation to the Airport Perimeter B and the runway approaches, and broad changes to managed land cover types in or near Airport Perimeter B. There are no other known projects that would affect lands within Airport Perimeter B; therefore, USACE and SAFCA determined that the Phase 1–4a Projects **would *not* result in a cumulatively considerable incremental contribution** to a cumulatively significant impact.

Phase 4b Project

The Phase 4b Project would include night lighting in areas that could affect aircraft operations, depending on the location of construction areas in relation to Airport Perimeter B and the runway approaches. Potential impacts would be reduced through lighting restrictions and coordination with SCAS. The Phase 4b Project could potentially increase the possibility of collisions between aircraft and wildlife due to the proposed broad changes to managed land cover types in or near the Airport Perimeter B. There are no other known projects that would affect lands within the Airport Perimeter B, therefore the Phase 4b Project and related projects **would *not* result in a cumulatively considerable incremental contribution** to a cumulatively significant impact.

5.1.5.19 WILDFIRE HAZARDS

Phase 1–4a Projects

For the Phase 1–4a Projects, mitigation would be implemented to minimize the potential for wildland fires. If a wildland fire outbreak occurs, the impacts would be localized and would not be expected to combine with the impacts of related projects. Wildfire hazard impacts would occur on a project-specific basis rather than a cumulative basis, and any such incidents would be isolated. Therefore, USACE and SAFCA determined that the Phase 1–4a Projects **would *not* result in a cumulatively considerable incremental contribution** to a cumulatively significant impact.

Phase 4b Project

Mitigation would be implemented to minimize the Phase 4b Project's potential for wildland fires (Mitigation Measures 4.16-h). If a wildland fire outbreak occurs, the impacts would be localized and would not be expected to combine with the impacts of other projects. Because wildfire hazard impacts would occur on a project-specific basis rather than a cumulative basis, and any such incidents would be isolated, implementation of either the Adjacent Levee Alternative (Proposed Action) or Fix-in-Place Alternative along with other related projects **would *not* result in a cumulatively considerable incremental contribution** to a cumulatively significant impact.

5.2 GROWTH INDUCEMENT

Both NEPA (40 CFR Sections 1508[a] and [b]) and CEQA (State CEQA Guidelines [CCR Section 15126.2(d)] require an examination of the direct and indirect impacts of the proposed project, including the potential of the project to induce growth leading to changes in land use patterns and population densities and related impacts on environmental resources. Specifically, CEQA states that the EIR shall:

> Discuss the ways in which the proposed project could foster economic or population growth, or the construction of additional housing, either directly or indirectly, in the surrounding environment. Included in this are projects which would remove obstacles to population growth (a major expansion of a wastewater treatment plant might, for example, allow for more construction in service areas). Increases in the population may tax existing community service facilities, requiring construction of new facilities that could cause significant environmental effects. Also, discuss the characteristics of some projects which may encourage and facilitate other activities that could significantly affect the environment, either individually or cumulatively. It must not be assumed that growth in any area is necessarily beneficial, detrimental, or of little significance to the environment.

Direct growth inducement would result if a project involved construction of new housing. Indirect growth inducement would result, for instance, if implementing a project resulted in any of the following:

- substantial new permanent employment opportunities (e.g., commercial, industrial, or governmental enterprises);
- substantial short-term employment opportunities (e.g., construction employment) that indirectly stimulates the need for additional housing and services to support the new temporary employment demand; and/or
- removal of an obstacle to additional growth and development, such as removing a constraint on a required public utility or service (e.g., construction of a major sewer line with excess capacity through an undeveloped area).

Growth inducement itself is not an environmental effect, but it may foreseeably lead to changes in land use patterns and population densities and related impacts on environmental resources.

It is important to note that the project proponent(s) is not charged with the responsibility of weighing and balancing the benefits and burdens of growth in the Natomas Basin. Neither USACE nor SAFCA have authority to permit development in the Basin or to impose conditions on the development that is permitted. SAFCA is made up of five agencies, some of which have land use authority (City of Sacramento, Sacramento County, and Sutter County) and some of which do not (American River Flood Control District and Reclamation District 1000). However, SAFCA's authority extends only to regional flood control matters because SAFCA is a joint powers agency and is limited to exercising powers common to all of its constituent members.

Local land use decisions are within the jurisdiction of the cities and counties within the project area: the City of Sacramento and Sacramento and Sutter Counties. Each of these agencies has adopted a general plan consistent with state law. These general plans provide an overall framework for growth and development within the jurisdiction of each agency, including the project area. Within the Natomas Basin, as elsewhere, population growth and urban development are also influenced by local, regional, and national economic conditions.

Because the Phase 4b Project would not involve the construction of housing, it would not be directly growth-inducing. Construction activities would generate short-term employment, but it is anticipated that the construction jobs would be filled using the existing local employment pool and project implementation would not directly

result in a population increase. The Phase 4b Project would accommodate growth currently planned for undeveloped lands in the Natomas Basin. These lands have been identified in the general plans and additional planning policy documents of the City of Sacramento and Sacramento and Sutter Counties as the areas most suitable for urban growth.

The approximately 9,038-acre North Natomas Community Plan (NNCP) area is designated in the City of Sacramento's general plan as the city's major growth area for new housing and employment opportunities (City of Sacramento 2009b). In 2000, the estimated population of the North Natomas area of Sacramento County was 1,082 people occupying 416 housing units (SACOG 2001). At buildout (year 2016), the NNCP estimates a population of 66,495 in the NNCP area occupying approximately 9,038 acres (City of Sacramento 2009a). As of September 14, 2005, the City of Sacramento had approved 12,162 lots for development of residential, commercial, and industrial land uses; 10,801 building permits; 11,599 single-family residential special permits; and 6,003 multifamily residential special permits for this area (City of Sacramento 2009a). SACOG estimates there were 14,865 persons living in the NNCP area and 5,368 housing units in the area in 2005, and projects that 45,040 persons will occupy 17,230 housing units in the NCCP area in 2025 (SACOG 2005).

The environmental consequences of buildout of the NNCP were addressed in the 1986 NNCP EIR (certified by the Sacramento City Council in May 1986), as well as in the 1993 Supplement to the 1986 NNCP EIR. Development within the NNCP started in 1999. More than 9,000 acres of the NNCP area were historically used for agriculture. While other long-term consequences of NNCP buildout would be mitigated by measures incorporated into the individual NCCP area projects, including measures to ensure consistency of development with the Natomas Basin Habitat Conservation Plan, loss of important farmland will remain a significant and unavoidable environmental impact of this growth. In addition, the 1986 NNCP EIR and the 1993 NNCP EIR Supplement found that the development of the NNCP area would itself have growth-inducing effects on the adjacent areas surrounding the NNCP area, likely leading to the conversion of additional agricultural land to urban uses (City of Sacramento 1993).

Another indicator of anticipated future growth of the Natomas area is the City/County North Natomas Joint Vision Plan (Joint Vision). The Joint Vision is a long-term agreement between the City and County of Sacramento to collaboratively manage growth and preservation of open space and habitat in the 10,000-acre portion of unincorporated Natomas in Sacramento County. The Joint Vision anticipates that a substantial portion of the Natomas area will become urbanized. Both jurisdictions determined that it would be mutually beneficial to cooperatively plan for the urbanization of the area in accordance with smart growth principles. Concepts for development include a mixture of residential densities, an industrial park, and open spaces throughout, particularly in the northern part of Natomas to separate development from the Sutter County boundary. To date, no land use plans have been adopted.

Finally, in addition to the NNCP and the Joint Vision, Sutter County voters in 2004 passed Measure M, an advisory measure intended to provide the Sutter County Board of Supervisors with an indication of public sentiment regarding the types and level of development in the 7,500-acre area of the South Sutter County Industrial/Commercial Reserve in the northern part of Natomas. The southern boundary of the Measure M area forms the Sutter/Sacramento county line. Measure M did not approve any specific development proposals, but provides guidance for future development in the form of the following parameters for the South Sutter area:

- at least 3,600 acres for commercial/industrial development;
- at least 1,000 acres for schools, parks, other public uses, and retail; and
- no more than 2,900 acres for residential development, with a population cap of 39,000.

Regional infrastructure planning reflects these growth plans. In December 2004, SACOG, representing the Counties of El Dorado, Placer, Sacramento, Sutter, Yolo, and Yuba and their 22 constituent cities, adopted the "Preferred Blueprint Scenario" to guide land use and transportation choices over the next 50 years as the region's population grows from its current population of 2 million to include more than 3.8 million people. The Blueprint

project was initiated in 2002 to study future land use patterns and their potential effects on the region's transportation system, air quality, housing, open space, and other resources.

The study found that continuing the recent practice of building large-lot, low-density housing would consume another 660 square miles of undeveloped land. Residents would face longer commutes, more vehicle trips, dirtier air, and a growing disconnect between where they live and where they work.

Through a series of Blueprint workshops at the neighborhood, city, county, and regional level, more than 5,000 residents, elected officials, business leaders, and environmental interests helped craft an alternative vision that integrates smart growth concepts such as higher-density, mixed-use developments and reinvestment in existing developed areas. The Preferred Blueprint Scenario assumes certain levels and locations of both "reinvestment" (i.e., additional development on already-built parcels) and greenfield development (i.e., large-scale development on vacant land), including development on the land in the Natomas area that would be protected by the Phase 4b Project (**Plate 2-5**). An analysis of this scenario showed that following smart growth principles would shorten future commute times, reduce traffic congestion, lessen dependence on automobiles, and provide for housing choices that more closely align with the needs of an aging population.

The Preferred Blueprint Scenario will become part of SACOG's long-range transportation plan for the six-county region. It also will serve as a framework to guide local government in growth and transportation planning through 2050.

Using the above information, combined with an evaluation of residual flood damage, USACE and SAFCA have concluded that there is substantial evidence that the NLIP as a whole would accommodate anticipated growth in the project area in a manner that would be consistent with adopted local and regional growth management plans and with an the state's emerging State Plan of Flood Control. The growth-inducing effects of the NBHCP were completely analyzed in the adopted and approved HCP EIR, which identified no growth-inducing effects associated with the creation and ongoing operation of the HCP (City of Sacramento 2002).

Based on the information presented above, there is substantial evidence that the Phase 4b Project would accommodate planned regional growth. Thus, the Phase 4b Project, while accommodating planned regional growth, is not growth inducing itself.

5.3 RELATIONSHIP BETWEEN SHORT-TERM USES OF THE ENVIRONMENT AND LONG-TERM PRODUCTIVITY

NEPA requires that an EIS include a discussion of the relationship between short-term uses of the environment and long-term productivity. Within the context of this EIS/EIR, "short-term" refers to the construction period, while "long-term" refers to the operational life of the project and beyond.

Project construction would result in short-term construction-related effects such as interference with local traffic and circulation, and increased air emissions, ambient noise levels, dust generation, and disturbance of wildlife. These effects would be temporary, occurring only during construction, and are not expected to alter the long-term productivity of the natural environment. Project implementation would also result in long-term effects, including permanent loss of farmland, changes in visual resources, and adverse effects on existing waters, wetlands, and woodland habitat.

Project implementation would also assist in the long-term productivity of the environment by improving the levee system that protects the Natomas Basin by reducing the Basin's overall flood risk. In addition, it would also preserve and improve, over the long term, important habitat upon which the Natomas Basin species of concern to USFWS and DFG depend, by increasing acreages, connectivity, and habitat quality of wetlands and other waters of the United States in the Basin.

These long-term beneficial effects of the Phase 4b Project would outweigh its potentially significant short-term impacts to the environment.

5.4 SIGNIFICANT AND UNAVOIDABLE ENVIRONMENTAL IMPACTS

State CEQA Guidelines CCR Section 21100(b)(2)(A) provides that an EIR shall include a detailed statement setting forth "any significant effect on the environment that cannot be avoided if the project is implemented." Chapter 4, "Environmental Consequences and Mitigation Measures," provides a detailed analysis of all potentially significant, direct and indirect, environmental impacts of the Phase 4b Project, feasible mitigation measures that could reduce or avoid the project's significant impacts, and whether these mitigation measures would reduce these impacts to less-than-significant levels. The Phase 4b Project's significant cumulative impacts are discussed in Section 5.1, "Cumulative Impacts," above. If a specific impact cannot be reduced to a less-than-significant level, it is considered a significant and unavoidable impact.

The Adjacent Levee Alternative (Proposed Action) would have the following significant and unavoidable environmental impacts (direct, indirect, and/or cumulative), which are presented in the order they appear in Chapter 4, "Environmental Consequences and Mitigation Measures":

- conversion of Important Farmland to nonagricultural uses;
- conflicts with lands under Williamson Act[1] contracts;
- inconsistency with Airport Master Plan, Airport Comprehensive Land Use Plan, and Airport Wildlife Hazard Management Plans;
- inconsistency with the American River Parkway Plan and Wild and Scenic Rivers Act;
- potential to physically divide or disrupt an established community;
- loss of landside and waterside woodland and SRA habitats;
- disruption to and loss of existing wildlife corridors;
- impacts on Swainson's hawk and other special-status birds;
- potential damage or disturbance to known archaeological or architectural resources from ground-disturbance or other construction-related activities;
- potential damage to or destruction of previously unidentified or undiscovered cultural resources from ground-disturbance or other construction-related activities;
- potential discovery of human remains during construction;
- temporary and short-term increases in traffic on local roadways;
- temporary and short-term increases in traffic hazards on local roadways;
- generation of temporary and short-term construction noise;

[1] The California Land Conservation Act of 1965 is commonly known as the Williamson Act (California Government Code Section 51200 et seq.).

- temporary and short-term exposure of residents to increased traffic noise levels from truck hauling associated with borrow activity;
- effects related to the proposed Natomas Levee Class 1 Bike Trail Project (short-term: significant and unavoidable; long-term: less than significant [beneficial]);
- permanent disruption of recreational activities and facilities;
- alteration of scenic vistas, scenic resources, and existing visual character of the project area;
- new sources of light and glare that adversely affect views; and
- aircraft safety hazards resulting from project implementation.

Significant and unavoidable impacts associated with the Fix-in-Place Alternative would be the same as those for the Adjacent Levee Alternative (Proposed Action) with the following additional significant and unavoidable impacts:

- inconsistency with the Natomas Basin Habitat Conservation Plan;
- impacts on Successful Implementation of Habitat Conservation Plans; and
- temporary and short-term exposure of sensitive receptors to, or temporary and short-term generation of, excessive groundborne vibration.

Where feasible mitigation exists, it has been included to reduce these impacts; however, the mitigation would not be sufficient to reduce the impacts to a less-than-significant level.

5.5 IRREVERSIBLE AND IRRETRIEVABLE COMMITMENT OF RESOURCES AND ENERGY CONSERVATION

NEPA requires that an EIS include a discussion of the irreversible and irretrievable commitments of resources which may be involved should the project be implemented. Similarly, the State CEQA Guidelines require a discussion of the significant irreversible environmental changes that would be caused by the project should it be implemented.

The irreversible and irretrievable commitment of resources is the permanent loss of resources for future or alternative purposes. Irreversible and irretrievable resources are those that cannot be recovered or recycled, or those that are consumed or reduced to unrecoverable forms. Project implementation would result in the irreversible and irretrievable commitment of energy and material resources during project construction and maintenance, including the following:

- construction materials, including such resources as soil and rocks;
- land and water area committed to new/expanded project facilities; and
- energy expended in the form of electricity, gasoline, diesel fuel, and oil for equipment and transportation vehicles that would be needed for project construction, operation, and maintenance.

The use of these nonrenewable resources is expected to account for only a small portion of the region's resources and would not affect the availability of these resources for other needs within the region. Construction activities would not result in inefficient use of energy or natural resources.

CEQA further requires consideration of potential energy impacts of a proposed project (California Public Resources Code Section 21100[b][3]). Appendix F of the State CEQA Guidelines outlines issues related to energy conservation, and includes potential project description considerations, types of impacts applicable to energy use, and potential mitigation measures to reduce wasteful, inefficient, and unnecessary consumption of energy. According to CEQA, the goal of energy conservation implies wise and efficient use of energy, which can be accomplished by reducing energy consumption (e.g., natural gas and oil) and increasing reliance on renewable energy sources.

Energy used during project construction and operation would be expended in the form of electricity, gasoline, and diesel fuel, which would be used primarily by construction equipment and haul trucks during project construction and operation and maintenance activities (e.g., levee patrolling and flood fighting). As a result, ROG, NO_X, and PM_{10} emissions associated with the use of fuels are directly related to energy consumption. While there are no significance thresholds available for analysis of energy consumption, as shown in Impact 4.11-a, "Temporary and Short-Term Emissions of ROG, NO_X, and PM_{10}," and Impact 4.11-c, "Long-Term Changes in Emissions of ROG, NO_X, and PM_{10} Associated with Project Implementation," it is reasonable to conclude that energy use during construction would be considerable. Energy use for operations and maintenance activities would be similar compared to existing conditions. Mitigation Measure 4.11-a, "Implement Applicable District-Recommended Control Measures to Minimize Temporary and Short-Term Emissions of ROG, NO_X, and PM_{10} during Construction," includes reducing traffic speeds to 15 miles per hour on unpaved roads, and ensuring that equipment is properly tuned and maintained before and during on-site operation. Energy would be used wisely and efficiently during project construction and operation because air quality impacts would be mitigated to the extent feasible. Furthermore, the selected construction contractors would use the best available engineering techniques, construction and design practices, and equipment operating procedures. Finally, borrow sites have been selected to be located as close to levee construction as is feasible, which would reduce haul truck trip distances and, therefore, fuel consumption.

As described throughout this EIS/EIR, without implementation of the Phase 4b Project, the risk of levee failure would remain high. While a precise quantification of environmental impacts associated with potential levee failure is not possible, there is a potential for a variety of significant environmental impacts (see **Table ES-1** for a summary of potential impacts). Levee failure and the resulting emergency and reconstruction efforts could expend more energy, overall, than construction of the Phase 4b Project. Thus, project implementation preempts potentially substantial future energy consumption, and is likely to result in long-term energy conservation.

6 COMPLIANCE WITH FEDERAL ENVIRONMENTAL LAWS AND REGULATIONS

This chapter summarizes the Federal environmental laws and regulations that apply to the Phase 4b Project, aside from NEPA, and describes the Phase 4b Project's compliance with those laws and regulations. USACE, as the project proponent would not only comply with the Federal environmental laws and regulations, but would comply with all state, regional, and local laws, regulations, and ordinances, which are described in the "Regulatory Setting," of each individual issue area in Chapter 3, "Affected Environment."

If SAFCA chooses to implement the Phase 4b Project without Federal participation, SAFCA would comply with all Federal, state, regional, and local laws, regulations, and ordinances, despite the fact that SAFCA is a joint-powers authority and is not subject to regional and local plans, policies, and ordinances.

Although the Federal laws and regulations described in this chapter apply to the NLIP, this chapter focuses on the status of compliance with the Federal environmental laws and regulations that pertain to the Phase 4b Project.

6.1 CLEAN WATER ACT (SECTION 404)

The U.S. Environmental Protection Agency (EPA) is the lead Federal agency responsible for water quality management. The Clean Water Act of 1972 (CWA) is the primary Federal law that governs and authorizes water-quality control activities by EPA as well as the states. Various elements of the CWA address water quality, as discussed below.

CWA Section 404 establishes a requirement for a project proponent to obtain a permit from USACE before engaging in any activity that involves discharge of dredged or fill material into "waters of the United States," including wetlands. Fill material means material placed in waters of the United States where the material has the effect of replacing any portion of a water of the United States with dry land, or changing the bottom elevation of any portion of a water of the United States. Examples of fill material include but are not limited to rock, sand, soil, clay, plastics, construction debris, wood chips, overburden from mining or other excavation activities, and material used to create any structure or infrastructure in waters of the United States. Waters of the United States include navigable waters of the United States; interstate waters; all other waters where the use, degradation, or destruction of the waters could affect interstate or foreign commerce; tributaries to any of these waters; and wetlands that meet any of these criteria or that are adjacent to any of these waters. Wetlands are defined as those areas that are inundated or saturated by surface water or groundwater at a frequency and duration sufficient to support, and that under normal circumstances do support, a prevalence of vegetation typically adapted for life in saturated soil conditions. Jurisdictional wetlands must meet three criteria: hydrophytic vegetation, hydric soil, and wetland hydrology. In addition, under Section 404, jurisdictional wetlands must: be adjacent to traditional navigable waters; directly about relatively permanent waters; or have a significant nexus with a traditional navigable water.

Before USACE can issue a permit under CWA Section 404, it must determine that the project is in compliance with the CWA Section 404(b)(1) Guidelines. The Section 404(b)(1) Guidelines specifically require that "no discharge of dredged or fill material shall be permitted if there is a practicable alternative to the proposed discharge which would have less adverse impact on the aquatic ecosystem, so long as the alternative does not have other significant adverse environmental consequences" (40 Code of Federal Regulations [CFR] Section 230.10[a]). To comply with this provision, the applicant is required to evaluate opportunities that would result in less adverse impact on the aquatic ecosystem. A permit cannot be issued for a project, therefore, in circumstances where a less environmentally damaging practicable alternative exists that would fulfill the project purpose. An alternative is practicable if it is available and capable of being done after cost, existing technology, and logistics are taken into consideration in light of the overall project purpose as determined by USACE. If it is

otherwise a practicable alternative, an area not presently owned by the project applicant(s) that could reasonably be obtained, used, expanded, or managed to fulfill the purpose of the proposed activity may be considered.

As described in Chapter 1, "Introduction and Statement of Purpose and Need," if Congress authorizes the Common Features GRR and Common Features/Natomas PACR, and USACE implements the Phase 4b Project (as is the preferred plan), a Section 404 permit would not be required because USACE would be the project proponent and USACE does not issue permits for USACE projects. However, if Congress does not provide authorization and SAFCA chooses to proceed with implementation of the Phase 4b Project without Federal participation, implementation of either the Adjacent Levee Alternative (Proposed Action) or Fix-in-Place Alternative would require an individual permit from USACE under Section 404 of the CWA for the discharge of fill into waters of the United States, including wetlands. This EIS/EIR will be used to support USACE's decision whether to grant SAFCA an individual permit for the Adjacent Levee Alternative (Proposed Action) or Fix-in-Place Alternative.

Appendix D3 contains the Section 404(b)(1) evaluation.

6.2 RIVERS AND HARBORS ACT OF 1899, AS AMENDED

6.2.1 SECTION 14

Under Section 14 of the Rivers and Harbors Act of 1899 (33 United States Code [USC] Section 408), referred to as "Section 408," the Secretary of the Army, on the recommendation of the Chief of Engineers, may grant permission for the alteration of a Federal project levee by a non-Federal entity if the alteration is not injurious to the public interest and does not impair the usefulness of the project.

Similar to a Section 404 permit, if Congress authorizes the Common Features GRR and Common Features/Natomas PACR, and USACE implements the Phase 4b Project (as is the preferred plan), Section 408 permission would not be required because USACE would be the project proponent and USACE does not issue permits for USACE projects. However, if Congress does not provide authorization and SAFCA chooses to proceed with implementation of the Phase 4b Project without Federal participation, implementation of either the Adjacent Levee Alternative (Proposed Action) or Fix-in-Place Alternative would require Section 408 permission. This EIS/EIR will be used to support USACE's decision whether to grant SAFCA permission for the Phase 4b Project pursuant to Section 408.

6.2.2 SECTION 10

Under Section 10 of the Rivers and Harbors Act of 1899, work in, over, or under navigable waters of the United States is regulated by USACE. Navigable waters of the United States are defined as those waters subject to the ebb and flow of the tide shoreward to the mean high-water mark and those that are currently used, have been used in the past, or may be susceptible to use to transport interstate or foreign commerce. The jurisdiction of USACE under CWA overlaps and extends beyond the geographic scope of its jurisdiction under the Rivers and Harbors Act. USACE permitting authority under the Rivers and Harbors Act is not subject to EPA oversight or any other restrictions specific to the CWA, and, in some cases the Rivers and Harbors Act alone will apply to waters. A permit from USACE is required prior to any work in, over, or under navigable waters of the United States.

As part of the Phase 4b Project, modifications to Sacramento City Sump Pump 160 and Reclamation District (RD) 1000 Pumping Plants Nos. 1A and 1B involve raising and extending discharge pipes, replacing or modifying pumps and motors, and performing other seepage remediation, including relocation of the stations away from the levee to accommodate raising the discharge pipes. These Phase 4b Project elements would be subject to permission from USACE under Section 10.

Similar to a Section 404 permit and Section 408 permission, if Congress authorizes the Common Features GRR and Common Features/Natomas PACR, and USACE implements the Phase 4b Project (as is the preferred plan), a Section 10 permit would not be required because USACE would be the project proponent and USACE does not issue permits for USACE projects. However, if Congress does not provide authorization and SAFCA chooses to proceed with implementation of the Phase 4b Project without Federal participation, implementation of either the Adjacent Levee Alternative (Proposed Action) or Fix-in-Place Alternative would require a Section 10 permit. This EIS/EIR will be used to support USACE's decision whether to grant SAFCA a Section 10 permit for the Adjacent Levee Alternative (Proposed Action) or Fix-in-Place Alternative.

6.3 FISH AND WILDLIFE COORDINATION ACT OF 1934, AS AMENDED

The Fish and Wildlife Coordination Act (FWCA) ensures that fish and wildlife receive consideration equal to that of other project features for projects that are constructed, licensed, or permitted by Federal agencies. The FWCA requires that the views of the U.S. Fish and Wildlife Service (USFWS), National Marine Fisheries Service (NMFS), and the applicable state fish and wildlife agency (in this case, the California Department of Fish and Game [DFG]) be considered when impacts are evaluated and mitigation needs determined.

USACE is coordinating with USFWS, NMFS, and DFG to determine the effects of the Adjacent Levee Alternative (Proposed Action) on fish and wildlife in the project area. USFWS provided a FWCA report for the Phase 4b Project (see **Appendix D5**). USACE and SAFCA are providing USFWS, NMFS, and DFG with copies of this EIS/EIR for review and comment.

6.4 ENDANGERED SPECIES ACT OF 1973, AS AMENDED

Pursuant to the Federal Endangered Species Act (ESA), USFWS and NMFS have regulatory authority over Federally listed species. Under ESA, a permit to "take" a listed species is required for any Federal action that may harm an individual of that species. Take is defined under ESA Section 9 as "to harass, harm, pursue, hunt, shoot, wound, kill, trap, capture, or collect, or to attempt to engage in any such conduct." Under Federal regulation, take is further defined to include habitat modification or degradation where it would be expected to result in death or injury to listed wildlife by significantly impairing essential behavioral patterns, including breeding, feeding, or sheltering. ESA Section 7 outlines procedures for Federal interagency cooperation to conserve Federally listed species and designated critical habitat. Section 7(a)(2) requires Federal agencies to consult with USFWS and/or NMFS to ensure that they are not undertaking, funding, permitting, or authorizing actions likely to jeopardize the continued existence of listed species.

SAFCA held meetings to discuss project features with USFWS during the NLIP alternatives formulation and CEQA compliance process (see Section 7.3, "Coordination with Other Federal, State, and Local Agencies"). USACE and SAFCA subsequently held informal consultation meetings in January through September 2008 to clarify project details and discuss information needs for ESA permitting.

In October 2008, a programmatic Biological Opinion (BO) was issued by USFWS for the NLIP with incidental take authorization for the Phase 2 Project; an amended BO was issued in May 2009 and appendages were issued in September 2009 and May 2010. These are included in **Appendix D1**. A Biological Assessment (BA) for the Phase 4b Project has been submitted; it requests incidental take authorization and will be appended to the programmatic BO. USFWS issued a BO for the Phase 4b Project (see **Appendix D1**). NMFS is expected to issue a Letter of Concurrence of Determination of Not Likely to Adversely Affect for the Phase 4b Project.

USACE and SAFCA are providing USFWS and NMFS with copies of this EIS/EIR for review and comment.

6.5 MIGRATORY BIRD TREATY ACT OF 1918

The Migratory Bird Treaty Act (MBTA) implements a series of international treaties that provide for migratory bird protection. The MBTA authorizes the Secretary of the Interior to regulate the taking of migratory birds; the act provides that it shall be unlawful, except as permitted by regulations, "to pursue, take, or kill any migratory bird, or any part, nest or egg of any such bird…" (16 USC Section 703). This prohibition includes both direct and indirect acts, although harassment and habitat modification are not included unless they result in direct loss of birds, nests, or eggs. The current list of species protected by the MBTA includes several hundred species and essentially includes all native birds. Permits for take of nongame migratory birds can be issued only for specific activities, such as scientific collecting, rehabilitation, propagation, education, taxidermy, and protection of human health and safety and personal property.

Compliance with the MBTA is being addressed through compliance with the ESA and the California Endangered Species Act (CESA). The Phase 4b Project incorporates mitigation measures that would help ensure that construction activities do not result in the take of migratory birds, as discussed in Section 4.7, "Biological Resources."

6.6 BALD AND GOLDEN EAGLE PROTECTION ACT OF 1940

The Bald and Golden Eagle Protection Act provides for the protection of the bald eagle and the golden eagle by prohibiting, except under certain specified conditions, the taking, possession, and commerce of such birds.

The Phase 4b Project area does not contain bald eagle or golden eagle nesting habitat, and the Phase 4b Project would not result in the take of bald or golden eagles. The Phase 4b Project incorporates mitigation measures that would ensure that construction activities do not result in the take of any raptors, as discussed in Section 4.7, "Biological Resources."

6.7 CLEAN AIR ACT OF 1963, AS AMENDED

The Federal Clean Air Act (CAA) required EPA to establish national ambient air quality standards (NAAQS). EPA has established primary and secondary NAAQS for the following criteria air pollutants: ozone, respirable particulate matter with an aerodynamic diameter of 10 micrometers or less (PM_{10}), fine particulate matter with an aerodynamic diameter of 2.5 micrometers or less ($PM_{2.5}$), carbon monoxide (CO), nitrogen dioxide (NO_2), sulfur dioxide (SO_2), and lead. The primary standards protect the public health and the secondary standards protect public welfare. The CAA also required each state to prepare an air quality control plan referred to as a State Implementation Plan (SIP).

Under the CAA, the primary responsibility for planning for attainment and maintenance of the NAAQS rests with the state and local agencies. Accordingly, state and local air quality agencies are also designated as the primary permitting and enforcement authorities for most CAA requirements. During preparation of the Phase 2 EIR, the air management districts with jurisdiction over the project area, the Feather River Air Quality Management District (FRAQMD) and the Sacramento Metropolitan Air Quality Management District (SMAQMD), were given the opportunity to comment on the NLIP with regard to the scope and content of the Phase 2 EIR in relation to each agency's statutory responsibilities and regulatory oversight of the project. In addition, FRAQMD was consulted through several written and verbal exchanges regarding its air emissions regulations. SMAQMD provided written comments on the Phase 2 EIR, and revisions to the air quality information were incorporated into the Phase 2 Final EIR based on this input.

The air quality effects analysis and associated mitigation measures in this EIS/EIR are consistent with the approach that was used in the Phase 2 EIS and EIR, Phase 3 EIS and EIR, and Phase 4a EIS and EIR. However, it is important to note that, for the Phase 4a Project, a conformity determination was not required for CEQA compliance and thus was not addressed in the FEIR. Under NEPA, however, the requirement for a conformity

determination was triggered due to the magnitude of construction-related activities and their potential to overlap. Thus, a conformity determination was prepared for the Phase 4a Project. Mitigation Measure 4.11-a in this EIS/EIR directs the project proponent(s) to implement control measures recommended by FRAQMD and SMAQMD to minimize temporary emissions of reactive organic gases (ROG), oxides of nitrogen (NO_X), and PM_{10} during project construction, and comply with all applicable rules and regulations of FRAQMD and SMAQMD. As described under Impact 4.11-b, the Proposed Action (including implementation of proposed mitigation measures) would not exceed the EPA's General Conformity *de minimis* thresholds or hinder the attainment of air quality objectives in the local air basin with mitigation implementation.

USACE and SAFCA are providing FRAQMD and SMAQMD with copies of this EIS/EIR for review and comment.

6.8 NATIONAL HISTORIC PRESERVATION ACT OF 1966, AS AMENDED

Section 106 of the National Historic Preservation Act (NHPA) and its implementing regulations (36 CFR Part 800, as amended in 2004) require Federal agencies to consider the potential effects of their proposed undertakings on historic properties. Historic properties are cultural resources that are listed on, or are eligible for listing on, the National Register of Historic Places (NRHP) (36 CFR Section 800.16[l]). Undertakings include activities directly carried out, funded, or permitted by Federal agencies. Federal agencies must also allow the State Historic Preservation Officer (SHPO) and the Advisory Council on Historic Preservation (ACHP) an opportunity to comment on the proposed undertaking and its potential effects on historic properties.

As noted in Section 2.8, "Cultural Resources," inventories of all Phase 4b Project features that involve ground-disturbing work in native soils, including borrow locations, are ongoing; USACE and SAFCA will also complete evaluations, findings of effect, and treatment of identified resources where required. The project incorporates treatment measures to protect resources listed on or eligible for listing on the NRHP, as discussed in Section 4.8, "Cultural Resources." Determinations of the specific mitigation measures to be implemented will be made by USACE and SAFCA in consultation with the SHPO as part of the determination and eligibility and effect process, as required by NHPA Section 106. Implementation of the selected mitigation measures will be ensured through the execution of a Programmatic Agreement (PA). Signatories to the PA are USACE, SAFCA, and the SHPO. The ACHP has been consulted and waived participation as a signatory to the PA.

The PA addresses the scope of the Area of Potential Effect (APE) and provides that the APE will be defined for each project phase. The APE for each phase will be submitted with the cultural resources inventory reports, and will be consulted upon by SHPO. If areas are added to the project development activities subsequent to the SHPO concurrence on the map of the APE for a specific phase, USACE and SAFCA will complete an inventory of historic properties within the expanded APE. If historic properties that would be adversely affected by the project are identified in cultural resources inventories, USACE and SAFCA will prepare a Historic Properties Treatment Plan (HPTP) for review and written approval by the SHPO for those specific properties. Areas of archaeological sensitivity will be monitored in accordance with the HPTPs. A final report documenting the results of work prepared under the HPTPs will be submitted to the SHPO. The PA provides for public notice and consultation with Native Americans and the public. The signed and executed PA is included in **Appendix E1**.

The regulations implementing Section 106 state that:

> Compliance with the procedures established by an approved programmatic agreement satisfies the agency's section 106 responsibilities for all individual undertakings of the program covered by the agreement until it expires or is terminated by the agency, the president of NCSHPO when a signatory, or the Council (36 CFR Section 800.14[b][2][iii]).

The regulations further clarify that execution of agreement documents under 36 CFR Section 800.6, *Resolution of Adverse Effects* (including programmatic agreements adopted under that section per 36 CFR Section 800.14[b][3]) evidence satisfaction of Section 106 (36 CFR Section 800.6[b][3]):

> A memorandum of agreement executed and implemented pursuant to this section evidences the agency official's compliance with section 106 and this part and shall govern the undertaking and all of its parts. The agency official shall ensure that the undertaking is carried out in accordance with the memorandum of agreement.

Thus, execution of the PA, which was prepared through the process provided in 36 CFR Section 800.6, evidences USACE's compliance with Section 106. This does not mean that technical management activities under the PA are complete; they in fact are ongoing, as described above.

Appendix E2 contains a number of documents that are part of the record demonstrating Section 106 compliance. These include the following:

- June 7, 2007, letter from SAFCA's project archaeologist to the Native American Heritage Commission (NAHC) requesting a list of Native American individuals and organizations to contact regarding the project;
- June 19, 2007, response letter from the NAHC to SAFCA's project archaeologist supplying a list of the requested individuals and organizations;
- June 21, 2007, letters from SAFCA's project archaeologist to Native American individuals and organizations soliciting concerns and any information about cultural resources in the project area;
- July 9, 2007, telephone record of conversation between SAFCA's project archaeologist and Rose Enos (referred to by the NAHC as "Miwok/Maidu") regarding Ms. Enos' general concern regarding avoidance of burial sites and request to be contacted if work is conducted on such sites;
- January 2008 letter (and enclosures) from USACE to the SHPO initiating Section 106 consultation;
- February 1, 2008, letter from USACE to the United Auburn Indian Community of Auburn regarding an invitation to participate as a concurring party in the PA (Note: this is an example of about 20 letters that were sent to tribal entities inviting them to participate in the PA);
- May 8, 2008, letter from Shingle Springs Rancheria to the SHPO, USACE, and SAFCA regarding comments on the Draft PA and a request for formal consultation;
- June 11, 2008, response letter from USACE to Shingle Springs Rancheria regarding May 8, 2008 letter;
- June 12, 2008, response letter from SAFCA to Shingle Springs Rancheria regarding May 8, 2008 letter and the June 4, 2008, meeting; and
- July 23, 2008, letter from SAFCA to the California Department of Water Resources (DWR) providing further agency and public notice of the PA, per Stipulation VI of the PA, Native American and Other Consultation and Public Notice. (Note: This is an example of letters that were sent to local municipalities, relevant state agencies, Native American individuals and organizations, and local preservation societies.)

While this record is not necessarily exhaustive, it documents the critical steps for Section 106 compliance completed by USACE.

6.9 AMERICAN INDIAN RELIGIOUS FREEDOM ACT

The American Indian Religious Freedom Act of 1978 is also applicable to Federal undertakings. This act established "the policy of the United States to protect and preserve for American Indians their inherent right of freedom to believe, express, and exercise the traditional religions…including but not limited to access to sites, use and possession of sacred objects, and the freedom to worship through ceremonial and traditional rites" (Public Law 95-431). Consultations with Native Americans to determine concerns regarding the Phase 4b Project are discussed in Section 7.2, "Native American Consultation."

6.10 WILD AND SCENIC RIVERS ACT

The Wild and Scenic Rivers Act (16 USC Section 1271 et seq.) establishes a National Wild and Scenic Rivers System for the protection of rivers with important scenic, recreational, fish and wildlife, and other values. Rivers are classified as wild, scenic, or recreational. The act designates specific rivers for inclusion in the System and prescribes the methods and standards by which additional rivers may be added. The lower American River is included in the System and is designated as "Recreational."

The Phase 4b Project area includes a portion of the American River north levee, which is considered to be part of the Lower American River. Consistency of the Phase 4b Project with the Wild and Scenic Rivers Act is analyzed in Section 4.3, "Land Use, Socioeconomics, and Population and Housing." The Phase 4b Project's potential impacts to recreation uses of this portion of the river are discussed in Section 4.13, "Recreation." The values for which the Lower American River was included in the System would not be adversely affected by the Adjacent Levee Alternative (Proposed Action) or Fix-in-Place Alternative.

6.11 EXECUTIVE ORDER 11988, FLOODPLAIN MANAGEMENT

Executive Order (EO) 11988, Floodplain Management (May 24, 1977), directs Federal agencies to issue or amend existing regulations and procedures to ensure that the potential effects of any action it may take in a floodplain are evaluated and that its planning programs and budget requests reflect consideration of flood hazards and floodplain management. The purpose of this directive is "to avoid to the extent possible the long and short term adverse impacts associated with the occupancy and modification of floodplains and to avoid direct or indirect support of floodplain development wherever there is a practicable alternative." Guidance for implementation of EO 11988 is provided in the floodplain management guidelines of the U.S. Water Resources Council (40 CFR Part 6030; February 10, 1978) and in *A Unified National Program for Floodplain Management*, prepared by the Federal Interagency Task Force on Floodplain Management (1982).

Recognizing that improving the Natomas Basin perimeter levee system would indirectly support population growth within the Basin, USACE in 1991 conducted extensive studies of the feasibility of constructing a cross-levee spanning the Basin from east to west to limit the extent of flood damage reduction improvements and associated floodplain development to the southern one-half to two-thirds of the Basin. The present study reconsidered a cross-levee measure. For the reasons described in Section 2.1.5, "Alternatives Considered, But Eliminated from Further Consideration," this flood damage reduction alternative has been determined to be impracticable and unlikely to prevent the urbanization of the northern portion of the Basin without a very costly program for acquiring flowage easements and retiring development rights on the lands north of the cross levee. Consequently, improvements to the Natomas Basin perimeter levee system have been determined by USACE, the State, and SAFCA to be the feasible method of providing adequate flood damage reduction to existing development within the Basin and to the planned development. Although improving the perimeter levee system would fail to discourage further development within the Basin, this action is consistent with efforts by the State of California to comprehensively address floodplain development and flood risk on a regional scale. This comprehensive approach differentiates between flood damage reduction requirements for urbanized and nonurbanized floodplain areas, and will direct urban development away from those floodplains where a 200-year

level of flood risk reduction (0.005 annual exceedance probability [AEP]) cannot be achieved, while ensuring that this level of flood damage reduction is provided for already heavily populated areas such as the Natomas Basin.

The Phase 4b Project would reduce the risk of flood damage and minimize the impact of floods on human health, safety, and welfare by strengthening existing flood damage reduction infrastructure (see Section 4.5, "Hydrology and Hydraulics," for a discussion of the methodology and analysis of the Phase 4b Project's potential flood-related impacts). As noted in Section 2.7, "Residual Risk of Flooding," implementation of the Phase 4b Project would substantially lessen the probability of a flood in the Basin due to levee failure; however, the Natomas Basin would remain subject to a residual risk of flooding under both of the action alternatives. USACE and SAFCA would be required to maintain an ongoing residual risk management program, as described in Section 2.7. The Phase 4b Project would also create natural habitat that would serve ecological functions associated with natural floodplains (see Section 2.3.4, "Habitat Creation"). Because there is no practicable, feasible alternative to the urban floodplain development indirectly associated with the project, USACE and SAFCA would maintain an ongoing residual risk management program and satisfy EO 11988, as described below.

In 1982, the Interagency Task Force on Floodplain Management published additional guidance on the implementation of EO 11988. Additional standards were developed to protect human safety, health, and welfare. These standards apply to "critical actions," which are defined by the Water Resources Council Floodplain Management Guidelines as "any activity for which even a slight chance of flooding would be too great. The critical action floodplain is defined as the 500-year floodplain."

To assist in determining whether a proposed action is a "critical action," the following questions must be answered. If any answer is in the affirmative, a proposed action is considered a "critical action" and, therefore, subject to a higher standard.

- If flooded, would the proposed action create an added dimension to the disaster, as could be the case for liquefied natural gas terminals and facilities producing and storing highly volatile, toxic, or water-reactive materials?

- Given the flood warning lead-time available, would the occupants of buildings such as hospitals, schools, and nursing homes be insufficiently mobile to avoid loss of life and injury?

- Would essential and irreplaceable records, utilities, and/or emergency services be lost or become inoperative if flooded? (Interagency Task Force on Floodplain Management 1982.)

The NLIP is a program of levee improvements; it would not place sensitive land uses (e.g., hazardous materials storage facilities, senior care facilities, hospitals, schools, etc.) within a floodplain. Further, as described in Section 5.2, "Growth Inducement," and elsewhere in this EIS/EIR, neither USACE nor SAFCA have any authority over what types of land uses would be placed in the Natomas Basin, with or without implementation of the NLIP. Therefore, USACE and SAFCA have concluded that the NLIP is not a "critical action."

Notwithstanding USACE's and SAFCA's determination that the NLIP is not a "critical action" pursuant to EO 11988, the following eight-step process was followed as directed in the Water Resources Council Floodplain Management Guidelines for implementation of EO 11988 (these procedures are excerpted from USACE's ER 1165-2-26). Responses follow in italics.

a) Determine if the proposed action is in the base flood plain.

   Yes, the NLIP, of which the Phase 4b Project is a component, is a program of levee improvements in the Natomas Basin, which is in the 100-year floodplain.

b) If the action is in the base flood plain, identify and evaluate practicable alternatives to the action or to location of the action in the base flood plain as outlined in paragraph 7 above.

See Chapter 2, "Alternatives," of this EIS/EIR. Also, see Appendix B1, "Alternatives Formulation and Screening Details."

c) If the action must be in the flood plain, advise the general public in the affected area and obtain their views and comments.

Public involvement activities undertaken for the Phase 4b Project are described in Chapter 7, "Consultation and Coordination," of this EIS/EIR. NEPA- and CEQA-required notices have been mailed to affected property owners throughout the NLIP environmental review process, soliciting input on the content of the environmental documents and noticing various public meetings. Additionally, notices have also been posted in the largest local newspaper, The Sacramento Bee*, announcing various public meetings. USACE and SAFCA have also participated in numerous meetings and calls with affected property owners on an individual basis to discuss project-related concerns. Public comments received on the NOI/NOP are considered and addressed, where appropriate in the DEIS/DEIR; public comments received on the DEIS/DEIR are addressed in the FEIS/FEIR; and public comments received on the FEIS/FEIR will be addressed in the record of decision (ROD).*

d) Identify beneficial and adverse impacts due to the action and any expected losses of natural and beneficial flood plain values. Where actions proposed to be located outside the base flood plain will affect the base flood plain, impacts resulting from these actions should also be identified.

Potential impacts associated with the Phase 4b Project are identified in Chapter 4, "Environmental Consequences and Mitigation Measures," of this EIS/EIR. The Phase 4b Project also includes the creation of natural habitat that would serve ecological functions associated with natural floodplains (see Section 2.3.4, "Habitat Creation," of the EIS/EIR). As stated above, the Phase 4b Project would be located within the Natomas Basin; no project components would be located outside of the Natomas Basin, with the exception of the Triangle Properties Borrow Area, which is located outside of but directly adjacent to the Basin because of its proximity to the NCC, PGCC, and NEMDC.

e) If the action is likely to induce development in the base flood plain, determine if a practicable non-flood plain alternative for the development exists, as outlined in paragraph 7, above.

See Chapter 5.2, "Growth Inducement," of this EIS/EIR. The NLIP, including the Phase 4b Project, while accommodating planned regional growth, is not growth-inducing itself.

f) As part of the planning process under the Principles and Guidelines, determine viable methods to minimize any adverse impacts of the action including any likely induced development for which there is no practicable alternative and methods to restore and preserve the natural and beneficial flood plain values. This should include reevaluation of the "no action" alternative.

Mitigation measures are identified throughout this EIS/EIR and will be implemented as part of the Phase 4b Project to minimize the project's potentially adverse impacts (see Chapter 4, "Environmental Consequences and Mitigation Measures," of this EIS/EIR). As noted above, the Phase 4b Project includes the creation of natural habitat that would serve ecological functions associated with natural floodplains (see Section 2.3.4, "Habitat Creation," of this EIS/EIR). The No-Action Alternative is described in Section 2.2, "No-Action Alternative," of this EIS/EIR. Impacts of the No-Action Alternative are identified throughout Chapter 4, "Environmental Consequences and Mitigation Measures," of this EIS/EIR.

g) If the final determination is made that no practicable alternative exists to locating the action in the flood plain, advise the general public in the affected area of the findings.

See response to Item c, above.

h) Recommend the plan most responsive to the planning objectives established by the study and consistent with the requirements of the Executive Order stated in paragraph 6 above.

The objectives of the NLIP are to: (1) provide at least a 100-year level of flood risk reduction (0.01 AEP) to the Natomas Basin as quickly as possible, (2) provide 200-year flood risk reduction (0.005 AEP) to the Basin over time, and (3) avoid any substantial increase in expected annual damages as new development occurs in the Basin. The NLIP, including the Phase 4b Project, is responsive to the EO 11988 objective of "avoidance, to the extent possible, of long- and short-term adverse impacts associated with the occupancy and modification of the base flood plain and the avoidance of direct and indirect support of development in the base flood plain wherever there is a practicable alternative" because it would not induce development in the floodplain (objective a); would reduce the hazard and risk associated with floods (objective b) thereby minimizing the impacts of floods on human safety, health, and welfare (objective c); and would restore and preserve the natural and beneficial values of the base floodplain (objective d).

6.12 EXECUTIVE ORDER 11990, PROTECTION OF WETLANDS

The purpose of EO 11990 is to "minimize the destruction, loss or degradation of wetlands and to preserve and enhance the natural and beneficial values of wetlands." To meet these objectives, EO 11990 requires Federal agencies, in planning their actions, to consider alternatives to wetland sites and limit potential damage if an activity affecting a wetland cannot be avoided. EO 11990 applies to: acquisition, management, and disposition of Federal lands and facilities construction and improvement projects which are undertaken, financed, or assisted by Federal agencies; and Federal activities and programs affecting land use, including but not limited to water and related land resources planning, regulation, and licensing activities. USACE and SAFCA have taken actions to minimize project effects on wetlands where feasible and to create new wetlands as part of the project.

Implementation of the Phase 4b Project as proposed would ensure no-net-loss of aquatic resource function and services through SAFCA's proposed compensatory mitigation, proposed in consultation and coordination with USACE. Wetlands and other waters of the United States that would be created as part of the project are described in Section 2.3.4, "Habitat Creation." Wetlands that would be created as part of the project include marsh habitat in a portion of the Fisherman's Lake Borrow Area after being reclaimed, for which USACE and SAFCA have developed a preliminary design.

6.13 EXECUTIVE ORDER 12898, FEDERAL ACTIONS TO ADDRESS ENVIRONMENTAL JUSTICE IN MINORITY POPULATIONS AND LOW-INCOME POPULATIONS

EO 12898 "Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations" (59 Federal Register 7629 [1994]) requires Federal agencies to identify and address disproportionately high and adverse health or environmental effects on minority populations, low-income populations, and Native Americans that may result from any proposed action. The Council on Environmental Quality (CEQ) has oversight of the Federal government's compliance with the EO. To facilitate compliance, CEQ prepared and issued, in association with EPA, "Environmental Justice Guidance under the National Environmental Policy Act" (CEQ December 1997). The Environmental Justice Guidance provides six principles by which environmental justice issues should be identified and addressed (CEQ 1997:9):

1. Consider the composition of the affected area to determine whether minority populations, low-income populations, or Indian tribes are present in the area affected by the proposed action, and if so, determine if human health or environmental affects would be disproportionately high on those populations.

2. Consider relevant public health data and industry data concerning the potential for multiple or cumulative exposure to human health or environmental hazards including historical patterns of exposure to hazards.

3. Recognize the interrelated cultural, social, occupational, historical, or economic factors that may amplify the natural and physical environmental effects of the action.

4. Develop effective public participation strategies.

5. Assure meaningful community representation in the process.

6. See tribal representation in the process.

See Section 3.17 and 4.17, "Environmental Justice," for more information on project effects on minority and low-income populations, as well as on Native American tribes.

6.14 FARMLAND PROTECTION POLICY ACT

The Natural Resources Conservation Service (NRCS) is the agency primarily responsible for implementing the Federal Farmland Protection Policy Act (FPPA). The purpose of the FPPA is to minimize Federal contributions to the conversion of farmland to nonagricultural uses by ensuring that Federal programs are administered in a manner compatible with state government, local government, and private programs designed to protect farmland.

NRCS administers the FPPA, which is a voluntary program that provides funds to help purchase development rights to keep productive farmland in agricultural uses. The program provides matching funds to state, local, or tribal government entities and nongovernmental organizations with existing farmland protection programs to purchase conservation easements. Participating landowners agree not to convert the land to nonagricultural uses and retain all rights to the property for future agriculture. A minimum 30-year term is required for conservation easements, and priority is given to applications with perpetual easements. NRCS provides up to 50% of the fair market value of the easement (NRCS 2004).

Implementation of the Adjacent Levee Alternative (Proposed Action) or Fix-in-Place Alternative would require converting areas of farmland along the Natomas Basin perimeter levee system to non-agricultural uses. Additional areas of farmland would be used as sources of soil borrow material. The topsoil on these lands would be retained and replaced after several feet of underlying soil is removed, and most of these lands would continue to be farmable, although some would be converted to marsh habitat. Mitigation intended to reduce project effects on farmland is included in this EIS/EIR. Also, the proposed modifications of the agricultural irrigation and drainage infrastructure included in the action alternatives would support the maintenance of agricultural practices on the west side of the Natomas Basin.

The project complies with the FPPA because it provides for mitigation of unavoidable direct conversion of agricultural land to nonagricultural uses, would provide infrastructure that would support the continuation of agricultural uses on the west side of the Natomas Basin, and is consistent with state and regional planning efforts that will protect farmland on a regional scale from development. Consultation with the NRCS (including submittal of the Farmland Conservation Impact Rating form) does not apply to Federal activities involving permitting and licensing (see 7 CFR Part 658) and therefore is not required for the project.

6.15 WILDLIFE HAZARDS ON OR NEAR AIRPORTS

The Federal Aviation Administration (FAA) addresses control of hazardous wildlife in Advisory Circular (AC) 150/5200-33B, *Hazardous Wildlife Attractants on or Near Airports* (FAA 2007). The FAA provides direction on where public-use airports should restrict land uses that have the potential to attract hazardous wildlife. FAA recommends a distance of 10,000 feet separating wildlife attractants and aircraft movement areas. The area within

a 10,000-foot radius of the Airport Operations Area is designated as the Airport Perimeter B. The FAA definition of wildlife attractants in AC 150/5200-33B includes human-made or natural areas, such as poorly drained areas, retention ponds, agricultural activities, and wetlands. AC 150/5200-33B recommends against the use of Airport property for agricultural production within a 5-mile radius of the Airport Operations Area unless the income from the agricultural crops is necessary for the economic viability of the Airport.

Section 2.3.4.6, "Aviation Safety Components," describes FAA's regulatory interest in managing wildlife attractants within 5 miles of the edge of the Airport's Area of Operations. Potential borrow sites within this area have been identified based on balancing multiple management priorities (including flood risk reduction, aviation safety, and habitat conservation) and minimizing the cost and environmental effects of borrow haulage activities. Within the Airport Perimeter B, management of the grasslands created by borrow operations would also be consistent with the Airport's *Wildlife Hazard Management Plan* (Sacramento County Airport System 2007).

6.16 OBSTRUCTIONS AND AIRPORT LAND USE COMPATIBILITY

Part 77 of the Federal Aviation Regulations (FAR), "Objects Affecting Navigable Airspace," has been adopted as a means of monitoring and protecting the airspace required for safe operation of aircraft and airports. Objects that exceed certain specified height limits constitute airspace obstructions. FAR Section 77.13 requires that the FAA be notified of proposed construction or alteration of certain objects within a specified vicinity of an airport, among them the following:

1. Any construction or alteration of more than 200 feet in height above the ground level at its site.

2. Any construction or alteration of greater height than an imaginary surface extending outward and upward at [a slope of] 100 to 1 for horizontal distance of 20,000 feet from the nearest point of the nearest runway of each [public-use airport, public-use airport under construction, or military airport] with a least one runway more than 3,200 feet in actual length, excluding heliports.

The FAA is serving as a cooperating agency under NEPA for the Phase 4b Project and is in regular communication with USACE and SAFCA regarding the project design and its potential effects on Airport property.

6.17 FEDERAL EMERGENCY MANAGEMENT AGENCY

6.17.1 LEVEE REQUIREMENTS

For a levee accredited by the Federal Emergency Management Agency (FEMA) as providing a 100-year level of flood risk reduction (0.01 AEP), the levee must be shown to satisfy several criteria, including protection of the embankment against erosion. Specific requirements are contained in 44 CFR Section 65.10.

6.17.2 FLOOD ZONE DESIGNATIONS

Flood zones are geographic areas that FEMA has defined according to varying levels of flood risk. These zones are depicted on a community's Flood Insurance Rate Map (FIRM) or Flood Hazard Boundary Map. Each zone reflects the severity or type of flooding in the area. In January 2008, FEMA proposed remapping the Natomas Basin as an AE zone, with the designation to take effect in December 2008. FEMA defines AE zones as areas with a 1% annual chance of flooding. The designation would result in the requirement that the bottom floor of all new buildings be constructed at or above base flood elevation—as little as 3 feet in some areas of Natomas but up to 20 feet above the ground level in much of the Basin. It is therefore anticipated that this designation would effectively stop any projects that are not issued building permits by the time the new map takes effect. An alternative to this designation, the A99 zone, may be applied where it can be shown that an area with a 1% annual chance of flooding will be protected by a Federal flood damage reduction system where construction has reached

specified legal requirements. The main requirements are that 100% of the cost of the flood damage reduction system restoration project must be authorized, 60% must be appropriated, 50% must be expended, and "critical features" must be under construction and 50% completed (FEMA 2007). Construction is not constrained and there are no FEMA-specified building elevation requirements with an A99 designation. Mandatory flood insurance purchase requirements apply to both designations, however.

6.18 SUSTAINABLE FISHERIES ACT

In response to growing concern about the status of United States fisheries, Congress passed the Sustainable Fisheries Act of 1996 (Public Law [PL] 104-297) to amend the Magnuson-Stevens Fishery Conservation and Management Act (PL 94-265), the primary law governing marine fisheries management in the Federal waters of the United States. Under the Sustainable Fisheries Act, consultation is required by NMFS on any activity that might adversely affect essential fish habitat (EFH). EFH includes those habitats that fish rely on throughout their life cycles. It encompasses habitats necessary to allow sufficient production of commercially valuable aquatic species to support a long-term sustainable fishery and contribute to a healthy ecosystem. The Sacramento River and the lowermost segment of the NEMDC have been designated as EFH by the Pacific Fishery Management Council.

Phase 4b Project-related impacts to EFH in the Sacramento River are discussed in Section 4.7, "Biological Resources," and mitigation measures are identified (see Impact 4.7-a, "Loss of Landside and Waterside Woodland and Shaded Riverine Aquatic Habitats").

6.19 RESOURCE CONSERVATION AND RECOVERY ACT

The primary Federal agency regulating the generation, transport, and disposal of hazardous substances is EPA, under the authority of the Resource Conservation and Recovery Act (RCRA). RCRA established an all-encompassing Federal regulatory program for hazardous waste that is administered in California by the Department of Toxic Substances Control (DTSC). Under RCRA, DTSC regulates the generation, transportation, treatment, storage, and disposal of hazardous waste. RCRA was amended in 1984 by the Hazardous and Solid Waste Amendments of 1984, which specifically prohibits the use of certain techniques for the disposal of various hazardous waste. The Federal Emergency Planning and Community Right-to-Know Act of 1986 imposes planning requirements to help protect local communities in the event of accidental release of an extremely hazardous substance.

Based on an extensive records search, one Cortese-listed site was identified within the Phase 4b Project construction footprint for Pumping Plant No. 8: the Olympian Oil site located at 4422 Northgate Boulevard (see **Plate 2-14**). Additionally, multiple sites were identified along the Sacramento River east levee with possible contamination issues. Other hazardous materials may exist within the Natomas Basin and/or may be brought in and used for project construction. The Phase 4b Project's potential impacts related to hazards and hazardous materials are described in Section 4.16, "Hazards and Hazardous Materials."

6.20 WORKER SAFETY REQUIREMENTS

The U.S. Department of Labor, Occupational Safety and Health Administration (OSHA) is responsible at the Federal level for ensuring worker safety. OSHA sets Federal standards for implementation of workplace training, exposure limits, and safety procedures for the handling of hazardous substances (as well as other hazards). OSHA also establishes criteria by which each state can implement its own health and safety program.

Implementation of the Phase 4b Project would create numerous employment opportunities, some of which may involve the handling of toxic, harmful, or hazardous substance as well as other hazards. The Phase 4b Project's potential impacts related to exposure to hazardous materials are described under Impact 4.16-c in Section 4.16, "Hazards and Hazardous Materials."

6.21 UNIFORM RELOCATION ASSISTANCE AND REAL PROPERTY ACQUISITION POLICIES ACT

All or portions of parcels within the Phase 4b Project footprint would need to be acquired for project construction. Federal, state, local government agencies, and others receiving Federal financial assistance for public programs and projects that require the acquisition of real property, must comply with the policies and provisions set forth in the Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970, as amended in 1987 (42 USC Section 4601 et seq.) (Uniform Act), and implementing regulation, 49 CFR Part 24. Relocation advisory services, moving costs reimbursement, replacement housing, and reimbursement for related expenses and rights of appeal are provided for in the Uniform Act.

Phase 4b Project implementation would require acquisition of property in the Phase 4b Project footprint to construct flood damage reduction facilities and improvements. Additionally, temporary relocation of residents may occur during portions of construction (i.e., during 24/7 construction near residences). Property acquisition and relocation services, compensation for living expenses for temporarily relocated residents, and negotiations regarding any compensation for temporary loss of business would be accomplished in accordance with the Uniform Relocation Assistance and Real Property Acquisition Policies Act.

6.22 FEDERAL EARTHQUAKE HAZARDS REDUCTION ACT

In October 1977, the U.S. Congress passed the Earthquake Hazards Reduction Act to "reduce the risks to life and property from future earthquakes in the United States through the establishment and maintenance of an effective earthquake hazards and reduction program." To accomplish this, the act established the National Earthquake Hazards Reduction Program (NEHRP). This program was significantly amended in November 1990 by the National Earthquake Hazards Reduction Program Act (NEHRPA), which refined the description of agency responsibilities, program goals, and objectives.

NEHRP's mission includes improved understanding, characterization, and prediction of hazards and vulnerabilities; improvement of building codes and land use practices; risk reduction through post-earthquake investigations and education; development and improvement of design and construction techniques; improvement of mitigation capacity; and accelerated application of research results. The NEHRPA designates FEMA as the lead agency of the program and assigns it several planning, coordinating, and reporting responsibilities. Other NEHRPA agencies include the National Institute of Standards and Technology, National Science Foundation, and the U.S. Geological Survey.

The closest active fault to the Natomas Basin is located approximately 15 miles to the northwest, as shown in **Table 3.4-1**. Because there are no active faults within or near the Phase 4b Project footprint, the risk of fault ground rupture is low. In addition, geotechnical investigations of borrow materials and flood risk reduction improvements are designed in consideration of the longevity of the levee system, including secondary seismic hazards such as shaking, liquefaction, subsidence, and seiches.

7 CONSULTATION AND COORDINATION

This chapter summarizes public and agency involvement activities undertaken by USACE and SAFCA that have been conducted to date, are ongoing, and/or will be conducted for this project, and which satisfy NEPA and CEQA requirements for public scoping and agency consultation and coordination.

Additionally, Native American consultation activities are described.

7.1 PUBLIC INVOLVEMENT UNDER NEPA AND CEQA

7.1.1 NOTICE OF INTENT, NOTICE OF PREPARATION, AND SCOPING MEETINGS

USACE published the notice of intent (NOI) to prepare the American River Common Features General Re-evaluation Report (GRR) EIS in the *Federal Register* (Vol. 73, No. 41) on February 29, 2008. A series of public scoping meetings were held in March 2008 to present information to the public and to receive public comments on the scope of the EIS. There is no mandated time limit to receive written comments in response to the NOI under NEPA. Because the Natomas PACR/Phase 4b Project is a component of the American River Common Features GRR, a separate NOI for the Natomas Post-authorization Change Report (PACR)/Phase 4b Project does not need to be re-issued. **Appendix A1** contains the NOI, the one comment letter received in 2008 (which is also summarized in **Table 7-1**), and copies of the posters for the March 2008 scoping meetings.

Table 7-1
Written Comments Received on the NOI

Commenter	Date
California Department of Transportation	April 1, 2008
► Requests clarification as to which portions of the project will use trucks to haul materials and which will use waterside barges for hauling materials. ► Requests a Traffic Management Plan including necessary mitigation, haul routes, dates of operation, and truck trip volumes be prepared in order for review. ► Notes that an encroachment permit will be required if electronic warning signs will be used within State right-of-way at work sites to warn public of trucks entering or leaving state highways. ► Expresses concern about piezometer locations and wells near the subgrade section of I-5 (the Boat Section) and requests these sites be identified and not be disturbed during levee improvement. ► Requests maps describing the project "activity areas" and clarification of the scope of the project and potential impacted highway and bridge structure areas. ► Requests identification and notification of any work near State right-of-way.	

Note: I-5 = Interstate 5

Source: Data Compiled by AECOM in 2009

On November 5, 2009, SAFCA issued a notice of preparation (NOP) for this EIS/EIR. In addition to the State Clearinghouse's distribution of the NOP to potentially interested state agencies, copies of the NOP were distributed to approximately 900 recipients, including Federal, state, regional, and local agencies; non-profit and private organizations; homeowners associations; partnerships; businesses; and individual residents in the project area to solicit input as to the scope and content of this EIS/EIR (see Section 7.4, "List of Recipients"). Because the distribution list likely did not account for all affected parties in the Phase 4b Project footprint, USACE and SAFCA published a notice in *The Sacramento Bee* on November 5, 2009. The NOP was circulated for a 30-day public comment period, in accordance with the State CEQA Guidelines, which closed on December 4, 2009. **Appendix A2** contains the NOP and comment letters received.

A joint NEPA/CEQA public scoping meeting was held on November 18, 2009 from 4:30 to 6:30 p.m. at the South Natomas Community Center in Sacramento, California, to brief interested parties on the Natomas PACR/Phase 4b Project and obtain the views of agency representatives and the public on the scope and content of this EIS/EIR. Copies of the posters for the November 18th scoping meeting are also included in **Appendix A2**.

Verbal and written comments were received during the scoping meeting, and additional written comments from agencies and individuals were received throughout the CEQA scoping period. All comment letters received during the scoping period are included in **Appendix A2** and are summarized in **Table 7-2**.

Table 7-2
Written Comments Received on the NOP

Commenter	Date
Federal Agencies	
Federal Aviation Administration	December 2, 2009
► Expresses concern regarding creation of habitat near the Airport that could potentially attract wildlife hazardous to aviation and increase wildlife-aircraft collision strikes. ► Requests that the EIS/EIR analyze whether the proposed improvements and mitigation measures are consistent with the guidelines in FAA AC 150/5200-33B. ► Recommends that a wildlife biologist meeting the requirements of FAA AC 150/5200-36 *Qualifications for Wildlife Biologists Conducting Wildlife Hazard Assessments* (June 28, 2006) be included in the team conducting the analysis. ► Recommends that the EIS/EIR select an alternative that includes managing vegetation on NLIP areas within 10,000 feet of the Airport so as to minimize its attractiveness to hazardous wildlife and minimize the potential for wildlife-aircraft collisions. ► Recommends that SAFCA and USACE contact SCAS regarding the County's efforts to minimize the attractiveness of the Airport to wildlife potentially hazardous to aircraft. ► Requests a paper copy and CD of the DEIS/DEIR when it is released for public review.	
State Agencies	
State of California Governor's Office of Planning and Research, State Clearinghouse and Planning Unit	November 5, 2009
► Courtesy notice that specifies that responsible agencies must transmit their comments on the scope and content of the NOP, focusing on specific information related to their own statutory responsibility, within 30 days of receipt of the NOP from the Lead Agency.	
California Highway Patrol	December 3, 2009
► Expresses concern regarding the project's adverse effects on traffic using Garden Highway and adjacent roadways. ► Expresses concern for higher volume of traffic caused by detours on West El Camino Avenue, Richards Boulevard, SR 160, and I-80.	
Local Agencies	
Sacramento County Airport System	December 3, 2009
► States that SCAS has nothing new to add to what SCAS has conveyed previously.	
Sacramento County Department of Transportation	November 25, 2009
► Expresses concern that truck haul routes on rural roadways will create a significant impact and shorten the life of the pavement. Asks that a maintenance agreement with SACDOT's Maintenance and Operations Section be negotiated. ► Requests that the proposed roadway closure and detour plans be coordinated with SACDOT. ► States that the project would result in a change of geometrics at the side street intersections with Garden Highway at Powerline Road and San Juan Road and requests proposed improvement plans be coordinated with SACDOT. ► Requests that power pole relocation be coordinated with SMUD and SACDOT to avoid conflicts with the intended bike/pedestrian path.	
Sacramento Metropolitan Air Quality Management District	November 18, 2009
► Confirms receipt of NOP and indicates that an NOP comment letter will not be provided.	

Table 7-2
Written Comments Received on the NOP

Commenter	Date
Sutter County, Community Services Department	November 23, 2009
► Requests the project's impacts to the proposed borrow site excavation and reclamation area east of the NCC and east Natomas Basin levee be analyzed based on its classification as Prime Farmland and Farmland of Statewide Importance by the California Department of Conservation. ► Requests that the reclamation of this site be to a use consistent with the County's Agriculture, 80-acre minimum General Plan designation (AG-80) and General Agricultural Zoning District (AG). ► States that removal of soil from proposed borrow sites is subject to SMARA and that a permit and reclamation plan is required to be approved by Sutter County. ► Recommends that SMARA be analyzed as part of the proposed environmental document and all feasible and effective mitigation be incorporated into the project. ► Requests analysis of potential impacts on Sankey Gap. ► Requests analysis of impacts on Pleasant Grove Cemetery and that feasible mitigation be incorporated into the project. ► Requests that the impacts to the "Out of Basin Mitigation Area" or "Area B" be evaluated and potential mitigation land be analyzed. ► Requests to be provided with all future notices regarding this project.	
Sutter County, Public Works Department	
► Requests an addendum to the Roadway Repairs Agreement dated August 21, 2009 due to the addition of the Triangle Properties Borrow Area and possible impacts to Fifield Road and Keys Road used as haul routes. ► Advises that a bridge rehabilitation project will begin in May 2010 on Pleasant Grove Road south of Keys Road causing traffic to possibly detour onto Keys Road and Fifield Road not allowing the contractor for borrow operations to use "wider than legal" equipment on these county roads.	
City of Sacramento, Parks and Recreation Department	December 1, 2009
► Notes the existence of several parks bordered by Garden Highway in Reaches A:16-20 including Park Site SN2 (Undeveloped; APN 274-0220-047); Shorebird Park (Developed; APN 274-0560-024 and 025); Natomas Oaks Park (Developed: APN 274-0320-023 and 033, 274-0050-033); Sand Cove Park (Developed; APN 274-0020-064, 274-0220-066, and 022), and McClellan Docks (Developed; APN 274-0030-020). ► Requests that each of the above parks be addressed and anticipated impacts assessed. In the event of unavoidable impacts related to access, tree removal/relocation (SN2) mitigation options are requested. ► Requests discussion of Gardenland Park (along NEMDC South) regarding access, shrinkage of acreage, and impacts to the planned improvements specified in the master plan approved in March 2009. ► Requests Fisherman's Lake Park and Open Space be included in discussion. ► Requests notification when the DEIS/DEIR is available to review.	
City of Sacramento, Department of Transportation	December 4, 2009
► States that prior to beginning of construction, a "Construction Traffic Control Plan" for the City of Sacramento streets should be prepared by the project proponent to the satisfaction of the City Traffic Engineer and subject to review by all affected agencies and a copy submitted to local emergency response agencies at least 14 days prior to commencement of construction that may partially or fully obstruct roadways. ► Notes that an encroachment permit will be required for all work within the public right-of-way, specifically for reconstruction of intersections and roadways. ► Identifies specific parcels related to possible impacts to mature heritage trees, bike trails, city parks, city streets, pump stations, and emergency access roads and requests they be evaluated for impacts. ► Requests that the DEIS/DEIR discuss the degree of change to the bike trail on the NEMDC levee and any detour routes or changes to access points. ► Requests clarity on any possible modifications to the bike trail along the West Canal (I-80 to San Juan Road) and provision of mitigation if necessary. ► Poses the following questions regarding the Natomas Levee Recreational Trail Project: Will the trail be continuous and a paved Class I bikeway at the conclusion of the project? Will the trail replace existing bike trails? Will this trail provide connection to existing bike trails that lead to and from the project site? Will construction of the paved surface require local jurisdictions to provide funding? If so, how will this be addressed? ► Requests that the City of Sacramento review the trail construction plans to ensure compliance with established standards and that locations where the trail crosses city streets will need detailed planning to ensure safe crossings.	

Table 7-2
Written Comments Received on the NOP

Commenter	Date
Organizations	
Garden Highway Community Association	December 4, 2009
► Expresses concern and states that SAFCA and USACE have not considered all alternatives based on an unbiased study to determine the most economically and environmentally sound project design for the NLIP and is therefore in violation of CEQA and NEPA requirements. ► States that "SAFCA and its contractors are in a race to remove highly sensitive habitat within the entire project footprint, despite the fact that alternative, less obtrusive levee improvement designs are gaining momentum and the fact that the Project is facing insurmountable fiscal problems." ► Suggests that SAFCA and USACE consider alternative designs to accomplish the necessary flood protection, the goal being to lessen the monetary, environmental, and property-loss cost. ► Suggests that 500-foot-wide berms are overkill and should be able to be reduced significantly and still achieve adequate flood protection. ► States that analysis of existing conditions must be evaluated measured against the "real conditions on the ground." ► States that a baseline of environmental conditions be established for the change in environmental conditions to be evaluated. ► States that the project plans fail to describe the existing physical environmental conditions to determine the significant adverse impacts on the existing environment but rather use a hypothetical computer model. ► States that there is a lack of evaluation of current levee and canal conditions. ► Requests that new Federal rules such as the more frequent flooding of the Yolo Bypass be considered in the plans including incorporating lowering of Sacramento River weirs as a long-term solution. ► Notes previous DFG comments in support of the idea that wildlife including woodlands, threatened and sensitive species habitat, and waters of the United States are not adequately considered and long-term mitigation may not be sufficient. ► Notes that the promise of creating 3 acres of woodland for each 1 acre destroyed does not consider the growing period for the new woodland. ► Suggests that SAFCA and its contractors are moving ahead with clear-cutting without funding in place for the planned mitigation. ► Expresses concern about the existence of an agreement between SAFCA and TNBC regarding post-reclamation land use of borrow sites. ► States that SAFCA and USACE have not evaluated the simultaneous multi-phase construction, which would be unreasonably harmful to wildlife, the environment, and Garden Highway residents. ► Expresses concern over the current position regarding encroachments and description regarding proposed action on the landside and waterside of the levee. ► Requests encroachments slated for removal be identified specifically. ► Expresses concern about proposed 24/7 construction and challenges whether it is justifiable. ► States a failure to address impacts to businesses along Garden Highway. ► Expresses concern over possible increased flood risk to waterside land owners within the NLIP area. ► Requests USACE divulge their position and methods of evaluating the possible increased flood risk to waterside properties. ► Expresses concern over changes in property values. ► Expresses concern about planned development after completion of the NLIP. ► States failure of NOP to mention the settlement agreement between SAFCA and GHCA. ► Expresses concern about methods used to obtain right-of-entry agreements from private property owners along Garden Highway. ► Requests that any further right-of-entry agreements be accompanied by a notification to the property owner as to "the legal authority upon which the agency relies, along with a full description of the associated rights afforded the property owners." ► "Objects to the 'taking' of private lands pursuant to the Eminent Domain laws under the guise that these lands are necessary for the development of the Project, when in fact the involved agency actually and surreptitiously plans to convey the condemned land to another private party, i.e., the airport." ► Concern as to the proposed funding mechanism related to the Natomas Levee Recreational Trail Project.	

Table 7-2
Written Comments Received on the NOP

Commenter	Date
Sacramento Area Bicycle Advocates	December 4, 2009
► Expresses appreciation that the Phase 4b Project includes the Natomas Levee Recreational Trail Project and notes benefits it will have on the community. ► Notes adverse impacts to existing bicycle routes for recreational and utilitarian purposes including Garden Highway and its intersecting streets and Ueda Parkway bike trail along the NEMDC. ► Suggests mitigation for these impacts including alternative bicycle access through or adjacent to construction areas, proper advance signage for detours or route changes, access to bicycle devices at traffic signals, signage for vehicle operators to ensure safety of bikers, maximum vehicle speed limits of 25 mph where separate bicycle lanes cannot be provided, and advance development of Traffic Control Plans that show traffic control measures for bicyclists with the plans reviewed and approved before construction begins and noticing to bicycle-interest organizations in the Sacramento area. ► Suggests establishing connections to the Ueda Parkway bike trail to Indiana Avenue, Senator Avenue, Rosin Court, Tandy Court, and North Market Boulevard during reconstruction.	
Individuals	
Dan Kaufman	November 9 and December 4, 2009
► Requests clarification as to why property located north of Sankey Road to Howsley Road is not identified as a potential borrow site. ► Requests notification of proposed plans related to this property.	
Shirley and Robert Wallace	November 10, 2009
► Requests clarification as to the extent of the identified "new potential borrow site" located on their property bordering Fifield Road in Pleasant Grove, Sutter County.	
Michael and Sara Johnson	November 25, 2009
► Expresses concern about property value dropping as a result of construction. ► Expresses concern regarding negative effects of proposed 24/7 construction on their family's health and well being. ► Expresses concern regarding unlivable conditions during construction and possible consequences. ► Expresses concern about lack of advanced notification to Swainson Way residents. ► Requests direct communication with homeowners on Swainson Way regarding levee improvements and construction impacts.	
Phil Perry	December 2, 2009
► Expresses concern about waterside vegetation preservation. ► Expresses concern about cutoff walls and levee degradation related to moisture content in soil. ► Requests a more specific design to identify the limits and evaluate the project's impacts. ► Requests clarification on modifications to pumping plants, specifically Pumping Plant No. 1. ► Expresses concern about proposed 24/7 construction in residential areas. ► States that vouchers for temporary housing during 24/7 construction are insufficient. ► States that a 250-foot-wide seepage berm is infeasible in the heavily populated Reach A:19B. ► Expresses concern that new work does not have a "discernable difference in flood protection from what SAFCA proposed back in the mid 1990s." ► Questions the need for additional work on the levee based on the *Natomas Levee Program Update* (March 20, 2008). ► Requests re-evaluation of plans to avoid overbuilding the levee in residential areas.	
Javed Siddiqui	December 2, 2009
► Expresses concern for preservation of historic, cultural, environmental, and economic value and benefits of resources potentially affected. ► Requests review and inclusion of *The Sacramento Bee* article about Heritage Oaks. ► Requests review of letters dated November 11 and 12, 2009. ► Requests that alternate option for seepage trench be explored to lessen the levee footprint.	

Table 7-2
Written Comments Received on the NOP

Commenter	Date
Kevin McRae	December 3, 2009
► Requests that vegetation removal within the levee right-of-way be minimized especially related to the taking of Heritage Oaks and waterside riparian habitat. ► Requests that USACE be sensitive to homeowner concerns regarding waterside encroachments. ► Requests that power poles be relocated to the landside as much as is practical for the safety and aesthetic concerns of residents. ► Requests that waterside residence structures (gates, fences, driveways) be modified or removed as little as possible.	
Roger Sherman	December 3, 2009
► Requests that April 2009 amendments to the State CEQA Guidelines for greenhouse gas emissions be discussed. ► Expresses concern about the level of evaluation and impact analysis related to Heritage Oak trees in Reach A:16.	
Robert Orr	December 3, 2009
► Expresses concern and requests elimination or significant mitigation of Garden Highway closures, 24/7 construction activities, destruction of landside encroachments (oak groves), and destruction of waterside encroachments (valley oaks).	
Dr. Del Wright and Patricia E. Nealon	December 4, 2009
► Expresses concern about Heritage Oaks slated for destruction. ► Requests that Javed Siddiqui's alternate plans be evaluated before the project moves forward.	
Ed and Patti Bronder	December 4, 2009
► Echoes comments submitted by Dr. Del Wright and Patricia E. Nealon.	
Melissa Brown	December 4, 2009
► Agrees and joins in concerns raised by GHCA, Mr. Sherman, and Mr. Siddiqui. ► Expresses concern about emergency vehicle access to 2317 Garden Highway (Reach A:16). ► Expresses concern as to impacts to well water quality, 24/7 construction impacts on Garden Highway; health impacts (asthma complications related to dust, diesel, and gasoline fumes); noise impacts; lighting during dusk and dawn hours; decrease in property value and tax implications; the denuding of the levees (and property and surrounding property); environmental impact to natural access to the river by wildlife (deer, squirrels, raccoons, possums, skunks, fox, beavers, hawks, owls, magpies, hummingbirds, ducks, geese and other birds, bees, butterflies, and other insects); appropriate mitigation for homeowners loss of quiet enjoyment of homes; and reduced value during construction. ► Expresses concern about slurry wall clean-up methods.	
Josh W. Harmatz	December 4, 2009
► Notes agreement with comments of fellow residents and GHCA. ► Specifically mentions preserving trees on the landside and waterside of the levee.	
Richard and Judee Myers	December 4, 2009
► Notes agreement with comments of fellow residents and GHCA.	
Tyson M. Shower	December 4, 2009
► Notes agreement with comments of fellow residents and GHCA. ► Notes concern regarding permitted encroachments (i.e., well, propane tank, and driveway). ► Notes obligation to SAFCA or USACE to be responsible for any relocation expenses that may occur.	
Melvin Borgman	December 4, 2009
► Asks how Sankey Gap and overflow of water particularly to the east side of the WP/SP Railroad at high-water events will be addressed. ► Asks to what elevation PGCC and NEMDC will be raised. ► Asks how erosion repair and rock slope protection will affect upstream water levels at PGCC and NEMDC. Will materials placed on the waterside of the levee increase water levels upstream? ► States that culverts along the PGCC are the only means of drainage for the areas between the WP/SP Railroad and the PGCC.	

Table 7-2
Written Comments Received on the NOP

Commenter	Date
► Expresses concern that fill material added to the waterside of the NCC south levee will restrict the westerly flow of water and increase uplift and lateral forces on bridges. Offers possible solutions including reinforced concrete overlay on levee surface, extending down to firm subsoil and excavating additional material under bridges to facilitate flow. ► Suggests using borrow sites for retention ponds for storm runoff and suggests deepening the NCC and PGCC to reduce flooding in areas upstream and using this material for borrow. ► Suggests that any material or structures placed waterside on the levee (Sacramento River left bank) will increase water levels upstream. ► Suggests additional/alternative actions to be included in the project including: improvements to the Yolo Bypass, levee setbacks at a minimum of 1,000 feet to provide more width to channels and lowering water levels in the river, removal of levees from "islands" created in the Delta and East Bay estuaries, and reduction or curtailment of discharge of drainage water into the river system during periods of high water. ► Notes the project's probable environmental impacts including increased risk of flooding in south Sutter County, particularly Pleasant Grove and damages that may be associated with such risk. ► Notes visual impacts to raising levees. ► Expresses concern about adequately addressing impacts of the project on surrounding communities.	
Vicki Pfingst and Susan Fast	December 4, 2009
► Agrees with comments from fellow residents and GHCA.	
Ronald Johnson	December 4, 2009
► Requests further information, limits, and right-of-way acquisition extent related to project design. ► Requests clarification on means to save Heritage Oaks and suggests eliminating seepage berms east of the I-80 Bridge. ► Requests clarification on waterside vegetation removal. ► Requests limits on noise and light pollution related to Garden Highway construction. ► States that 24/7 construction is unacceptable related to cutoff walls and suggests using double and triple crews instead. ► States that proposed power pole relocation from top of levee to bottom of slope is unacceptable and suggests burying them at shallow depths along the road serving the riverfront parcels. ► Requests clarification of impacts at "Tim Lewis" specific to the oak tree stand at west end of the reach, confirmation of the treatment for the top of the berm, and beautification at the 12-foot-wide transition slope that would extend to the sidewalk. ► Requests a design plan at Reaches A:19A and 19B showing the bike trail plans.	
Scoping Meeting	
Manuel Jardin	November 18, 2009
► Expresses concerns about the use of haul roads including Powerline, Del Paso, and San Juan Roads and requests that at least one of these remain open to the public and not be used as a haul road at any given time to avoid public interaction with large trucks. ► Requests that trucks used for hauling not be equipped with a compression break to reduce noise pollution.	
Kieth Seegmiller	November 18, 2009
► Expresses concern about the lead agency switching from SAFCA to USACE and losing contact with local agencies.	
Charlotte Borgman	November 18, 2009
► Expresses concern about increased water drainage to the east of the Natomas Basin and requests clarification of drainage plans.	

Notes: Airport = Sacramento International Airport; EIS/EIR = environmental impact report/environmental impact statement; FAA = Federal Aviation Administration; AC = Airport Circular; NLIP = Natomas Levee Improvement Program; SAFCA = Sacramento Area Flood Control Agency; USACE = U.S. Army Corps of Engineers; SCAS = Sacramento County Airport System; DEIS/DEIR = draft environmental impact report/draft environmental impact statement; NOP = notice of preparation; SR = State Route; I-80 = Interstate 80; SACDOT = Sacramento County Department of Transportation; SMUD = Sacramento Municipal Utility District; NCC = Natomas Cross Canal; SMARA = State Surface Mining and Reclamation Act; APN = Assessor's Parcel Number; PGCC = Pleasant Grove Creek Canal; NEMDC = Natomas East Main Drainage Canal; CEQA = California Environmental Quality Act; NEPA = National Environmental Policy Act; DFG = California Department of Fish and Game; TNBC = the Natomas Basin Conservancy; 24/7 = 24 hours per day, 7 days a week; GHCA = Garden Highway Community Association; WP/SP = Western Pacific/Southern Pacific

7.1.2 DEIS/DEIR

The DEIS/DEIR was distributed for public and agency review and comment, in accordance with NEPA and CEQA requirements. The review period began on July 2, 2010 and closed on August 16, 2010.

Four public meetings were held during the review period. These meetings included the following:

- July 13, 2010 from 5:00 p.m. to 7:00 p.m. at the South Natomas Community Center located at 2921 Truxel Road, Sacramento, California;
- July 15, 2010 at 3:00 p.m. (as part of the SAFCA Board of Directors Meeting) at the Sacramento City Council Chambers located at 915 I Street, Sacramento, California;
- July 21, 2010 from 5:30 p.m. to 7:30 p.m. at the Sacramento County Administration Building Hearing Room 1located at 700 H Street, Sacramento, California; and
- August 4, 2010 from 5:00 p.m. to 6:30 p.m. at the Pleasant Grove School located at 3075 Howsley Road, Sacramento, California.

In addition, written comments from the public, reviewing agencies, and stakeholders were accepted throughout the public comment period. These comments, along with the written responses to those comments, are contained in **Appendix I**, "Responses to Comments on the DEIS/DEIR," of this FEIS/FEIR. Corrections, revisions, additions, and/or deletions to the text of the DEIS/DEIR are provided in **Appendix I**. Deleted text is shown in ~~strikeout~~ and added text is shown in <u>underline</u>. These text revisions are not shown in the FEIS/FEIR as changes; the FEIS/FEIR contains a clean reprint of the document.

7.1.3 Next Steps in the Environmental Review Process

This FEIS/FEIR will be distributed for public and agency review and comment, in accordance with NEPA and CEQA requirements. NEPA requires a 30-day public review for an FEIS, whereas CEQA requires a 10-day (for commenting agencies only) review for an FEIR. For this FEIS/FEIR, the NEPA and CEQA review periods will run concurrently, with the CEQA review period ending before the NEPA review period.

After the CEQA review period, the SAFCA Board of Directors will consider certifying the EIR if it is determined to be in compliance with CEQA, and will rely on the certified EIR when considering project approval. To support a decision on the project, the SAFCA Board of Directors must prepare and adopt written findings for each significant environmental impact identified in the EIR; a Statement of Overriding Considerations, if needed; and a Mitigation Monitoring and Reporting Program (MMRP) to ensure implementation of the mitigation measures and project revisions, if any, identified in the EIR. Following EIR certification and project approval, a Notice of Determination (NOD) documenting the decision will be issued.

After the NEPA review period, USACE will consider the Phase 4b Project and issue its record of decision (ROD). The ROD will identify USACE's decision regarding the alternatives considered, address substantive comments received on the FEIS, and determine whether the Adjacent Levee Alternative (Proposed Action) complies with Sections 408, 404, and 10.

7.1.4 Other Public Outreach Activities

To help the community stay informed about current project activities, information is provided in a variety of ways:

- USACE and SAFCA each maintain Web sites (http://www.spk.usace.army.mil and http://www.safca.org/Programs_Natomas.html, respectively) that contain public documents related to the NLIP. Additionally, SAFCA's Web site contains public notices, project maps, schedule updates, news articles, SAFCA Board of Directors meeting agendas and meeting summaries, and other project-related materials;

- SAFCA periodically mails Executive Director Updates to property owners located adjacent to the NLIP project footprint;

- NLIP updates are provided at the monthly SAFCA Board of Directors meetings, which typically occur on the third Thursday of each month. These meetings are held at the Sacramento County Board of Supervisors Chambers at 700 H Street, Sacramento, California, 95814 and begin at 3:00 p.m.; and

- SAFCA has held several meetings with landowner groups and other interest groups during conceptual project design and will continue to meet with these groups to address concerns and interests.

7.1.5 MAJOR AREAS OF CONTROVERSY

Based on the comments received during the scoping period and the history of the NEPA and CEQA processes undertaken by USACE and SAFCA, respectively, the major areas of public controversy associated with the project are:

- temporary, construction-related effects (especially noise and access issues) on residents and businesses adjacent to the project levees (including potential 24/7 construction);

- the hydraulic modeling used to analyze the project's hydraulic impacts;

- construction-related impacts on cultural and biological resources;

- vegetation and tree removal and relocation of utilities, including power poles;

- removal of agricultural lands and loss of opportunity for future development; and

- SAFCA's ability to fund mitigation measures.

The first two issues were the subject of a lawsuit, filed in December 2007, by the Garden Highway Community Association challenging the Phase 2 EIR prepared by SAFCA, which was settled. A copy of the settlement agreement is included as **Appendix A3**, and applies to all affected Garden Highway residents. Many of the agreements made by SAFCA in this settlement agreement regarding construction practices also have been incorporated into the Phase 3–4a Projects or, as appropriate, in the mitigation measures for those project phases. SAFCA intends to voluntarily apply the design and construction provisions in the agreement to all Sacramento River east levee components of the Phase 4b Project in the event that SAFCA chooses to implement the Phase 4b Project without Federal participation. While USACE is not bound by the settlement agreement, USACE nevertheless plans to implement some of the measures contained therein; these measures are incorporated into the project or reflected, as appropriate, in the mitigation measures in this EIS/EIR.

Other issues, including potential 24/7 construction, vegetation and tree removal, relocation of utilities (including power poles), and impacts to agricultural lands have been raised in comment letters by affected property owners. USACE and SAFCA have and will continue to respond to these issues, most recently in responses to comments on the Phase 4a FEIS and FEIR. Additionally, USACE and SAFCA continues to work individually with these property owners to respond to concerns.

Allegations regarding construction-related impacts on cultural and biological resources and SAFCA's ability to fund mitigation measures were the subject of a Petition for Writ of Mandate and Complaint for Injunctive Relief (Petition) filed in March 2009 by the Garden Highway Community Association challenging the adequacy of the Phase 2 Supplemental EIR under CEQA. This suit was voluntarily dismissed on October 22, 2009. In June 2009, both the Garden Highway Community Association and the Association for the Environmental Preservation of the Garden Highway filed Petitions challenging certification of the Phase 3 EIR. Both petitions made allegations similar to those contained in the 2007 and March 2009 lawsuits, including the issues described above. In July 2009, the Association for the Environmental Preservation of the Garden Highway dismissed its lawsuit challenging the Phase 3 EIR.

In December 2009, both the Garden Highway Community Association and the Association for the Environmental Preservation of the Garden Highway filed Petitions challenging certification of the Phase 4a EIR.

7.2 NATIVE AMERICAN CONSULTATION

7.2.1 SECTION 106 COMPLIANCE

USACE is the lead agency for Native American consultation under NEPA. On May 1, 2008, the California State Historic Preservation Officer (SHPO) signed the Programmatic Agreement (PA) among USACE, SAFCA, and the SHPO, regarding the issuance of permission under the authority of Sections 408 and 404 for the NLIP Landside Improvements Project. USACE consulted the Ione Band of Miwok Indians, the Shingle Springs Band of Miwok Indians, and the United Auburn Indian Community, and invited them to concur in this PA. On June 23, 2008, the Central Valley Flood Protection Board concurred in the PA. The PA envisioned that preparation of inventory reports for consultation between USACE and the SHPO for identification of Areas of Potential Effect (APEs) would be based on project phases. USACE, SAFCA, and the SHPO compiled a list of members of the interested public who were provided notice of this PA. The Section 106 process requires that USACE make good faith efforts to identify and take into account the opinions and preferences of local Native Americans with cultural ties to the APE, as well as the public for historic preservation actions taken in accordance with the PA. Native American monitors have been assisting SAFCA in the treatment of Native American human remains and items associated with Native American burials discovered during project activities in accordance with California Public Resources Code Section 5097.98 and California Health and Safety Code Section 7050.5(b) and 7050.5(c).

In April 2008, in response to requests from the project archaeologists, the Native American Heritage Commission (NAHC) identified a Most Likely Descendant (MLD) for the project, Mr. John Tayaba of the Shingle Springs Rancheria. Mr. Tayaba was designated as the MLD because he is a member of the Shingle Springs Band of Miwok Indians, and the Tribe's aboriginal territory includes the NLIP project area. Mr. Tayaba is being consulted with in regard to the disposition of prehistoric remains encountered in preliminary archaeological investigations in the project area. Shingle Springs Rancheria is a Federally recognized tribe and is actively participating in consultation regarding the identification and treatment of cultural resources subject to Section 106 of the National Historic Preservation Act.

In implementing the provisions of the PA, USACE archaeologists, SAFCA, AECOM archaeologists, and tribal representatives meet biweekly to discuss project progress, and the general approach to inventory, evaluation, and treatment of cultural resources for the project. Discussions include specific consideration of preferred construction methods from a tribal perspective, and treatment of identified and significant resources. Section 106 consultation is ongoing, and conducted in close coordination with Native Americans.

7.2.2 NATIVE AMERICAN CONSULTATION UNDER CEQA

SAFCA is the lead agency for Native American consultation under CEQA. During the scoping period for the Phase 2 Project, EDAW/AECOM (now AECOM) sent a letter of inquiry to the NAHC on June 12, 2007, asking for information or concerns regarding the project area, as well as a list of individuals or organizations that might

have information or concerns regarding the project area. On June 19, 2007, Debbie Pilas-Treadway of the NAHC responded and indicated that no known sites were found in the Sacred Lands File that were located within the project area or in the immediate vicinity. Ms. Pilas-Treadway also provided a list of individuals who could be contacted concerning cultural resources in the project area. These individuals were sent contact letters on June 21, 2007, with information regarding the proposed project and a request for any information they might provide or concerns that they might have about the project. No written responses were received; therefore, follow-up phone calls were made on July 9, 2007. Only one individual, Rose Enos (referred to by the NAHC as "Miwok/Maidu"), answered. Ms. Enos expressed general concern regarding avoidance of burial sites and asked to be contacted if work is conducted on such sites. Phone messages were left for the remaining people on the contact list; however, no response from any of these individuals was received. The correspondence is included in **Appendix E2**.

In addition, Randy Yonemura of the Ione Band of the Miwok was contacted in January 2008 for information on areas of concern. Mr. Yonemura led an archaeologist on a field visit of the project area and provided anecdotal information on areas of potential Native American burials. Since spring 2008, Native American monitors have been observing archaeological field efforts, as appropriate, and offering insight and advice regarding cultural resources finds. USACE and SAFCA continue to consult closely with the MLD designated under California Public Resources Code 5097.98 regarding the effect of the NLIP on cultural resources of concern to the Native American community.

7.3 COORDINATION WITH OTHER FEDERAL, STATE, REGIONAL, AND LOCAL AGENCIES

Chapter 6, "Compliance with Federal Environmental Laws and Regulations," describes the project's compliance with applicable Federal laws and regulations, including consultation to date with various agencies. The following briefly summarizes these consultation and coordination efforts.

7.3.1 COORDINATION WITH THE FEDERAL AVIATION ADMINISTRATION AND THE SACRAMENTO COUNTY AIRPORT SYSTEM

The Federal Aviation Administration (FAA) is acting as a cooperating agency under NEPA for the Phase 4b Project. USACE and SAFCA met with the FAA and the Sacramento County Airport System (SCAS) on September 10, 2008, regarding project features within the Sacramento International Airport (Airport) north bufferlands. The FAA and SCAS have noted that the Airport has developed the Airport's *Wildlife Hazard Management Plan* (WHMP), with which the Phase 4b Project would comply, to the extent practicable and feasible, to ensure aviation safety. Further, the FAA and SCAS have expressed concern that the project, if inappropriately designed, could change existing vegetation and wildlife habitat in ways that could attract wildlife hazardous to aviation safety and increase wildlife-aircraft collisions.

SCAS provided comments on the Phase 4a DEIS/DEIR, to which USACE and SAFCA responded in the Phase 4a FEIS and FEIR, respectively. Additionally, the FAA provided a comment letter in response to the Phase 4b NOP.

The FAA continues to be involved in reviewing environmental documents related to the Landside Improvements Project. USACE and SAFCA meet with the FAA as needed to discuss design of project components as it relates to the Airport and to ensure that the project would not interfere with implementation of the WHMP.

7.3.2 RESOURCE AGENCY COORDINATION

Over the course of project planning and environmental review for the NLIP Landside Improvements Project, USACE and SAFCA have coordinated informally with the U.S. Fish and Wildlife Service (USFWS), the National Marine Fisheries Service (NMFS), the California Department of Fish and Game (DFG), and The Natomas Basin Conservancy (TNBC). **Table 7-3** includes permits and other resource agency coordination activities for past and

current NLIP project phases. A copy of the programmatic Biological Opinion and USACE Jurisdictional Determinations are included in **Appendix D**.

Table 7-3
NLIP Resource Agency Coordination[1]

Agency	Permit/Authorization/Approval	Status
Programmatic		
USFWS	Programmatic Biological Opinion	Issued October 2008; Amendment issued May 2009; Appendage issued September 2009; Appendage issued May 2010; Appendage issued October 2010
DFG, Central Valley RWQCB, USACE, and USFWS	Long-Term Management Plan Approval	Granted May 2009
Phase 2 Project		
USACE	Section 408 Permission	Granted January 2009
USACE	Section 404 Permit	Issued January 2009; amendment issued May 2009[2]; 2nd amendment issued August 2009; 3rd amendment issued February 2010
Central Valley RWQCB	Section 401 Water Quality Certification	Issued January 2009
DFG	Section 2081 Incidental Take Authorization	Issued May 2009
NMFS	Concurrence of Determination of Not Likely to Adversely Affect	January 2009
DFG	Section 1602 Streambed Alteration Agreement	Issued January 2009
USFWS	Biological Opinion	Issued October 2008; Amendment issued May 2009
USFWS	Fish and Wildlife Coordination Act Report	October 2008
Sacramento County	SMARA Exemption	Granted February 2009
Sutter County	SMARA Exemption	Granted February 2009
DFG, Central Valley RWQCB, USACE, and USFWS	Mitigation and Monitoring Plan	Approval granted May 2009
SWRCB	Section 402 NPDES General Construction Permit	Notice of Intent filed March 2009
Phase 3 Project[3]		
USACE	Section 408 Permission	Granted April 2010
USACE	Section 404 Permits[3]	Phase 3a permit received October 2009; Phase 3b permit received April 2010
USACE	Section 10 Permit	Phase 3a permit received October 2009; Phase 3b permit received April 2010
Central Valley RWQCB	Section 401 Water Quality Certifications[3]	Certifications received in September 2009 for Phase 3a and January 2010 for Phase 3b
DFG	Section 2081 Incidental Take Authorization	Issued June 2010

Table 7-3 NLIP Resource Agency Coordination[1]		
Agency	Permit/Authorization/Approval	Status
DFG	Section 1602 Streambed Alteration Agreement[4]	Landside canal footprint agreement received September 2009; later stages received February–April 2010
USFWS	Biological Opinion	Issued September 2009
NMFS	Concurrence of Determination of Not Likely to Adversely Affect (Phase 3b and 4a combined)	January 2010
USFWS	Fish and Wildlife Service Coordination Act Report	Draft received June 2009; final received October 2009
Sacramento County	SMARA Exemption	Exemption granted November 2009
DFG, Central Valley RWQCB, USACE, and USFWS	MMP	Approved by USACE September 2009; approved by all other agencies October 2009
SWRCB	Section 402 NPDES General Construction Permit	Notice of Intent submitted November 2009
Phase 4a Project		
USACE	Section 408 Permission	Anticipated October 2010
USACE	Section 404 Permit	Anticipated October 2010
USACE	Section 10 Permit	Anticipated October 2010
Central Valley RWQCB	Section 401 Water Quality Certification	August 2010
DFG	Section 2081 Incidental Take Authorization	Anticipated fall 2010
DFG	Section 1602 Streambed Alteration Agreement	Anticipated spring 2011
USFWS	Biological Opinion	Issued May 2010
NMFS	Concurrence of Determination of Not Likely to Adversely Affect (Phase 3b and 4a combined)	January 2010
USFWS	Fish and Wildlife Service Coordination Act Report	May 2010
Sacramento County	SMARA Permit and Exemption	Exemption granted November 2009 for most of the Fisherman's Lake Borrow Area, including Novak; Sacramento County determined that the northeastern corner of the Fisherman's Lake Borrow Area (called the Natomas Urban Development site) would require a SMARA permit
DFG, Central Valley RWQCB, USACE, and USFWS	Mitigation and Monitoring Plan	Approved by USACE September 2010; approval anticipated by all other agencies spring 2011
SWRCB	Section 402 NPDES General Construction Permit	Submitted July 2010

Table 7-3
NLIP Resource Agency Coordination[1]

Agency	Permit/Authorization/Approval	Status
Phase 4b Project		
USACE	Section 408 Permission	Would only be required for the Phase 4b Project if Federal authorization is not obtained and SAFCA chooses to proceed with Phase 4b Project implementation without Federal participation. Under this scenario, anticipated spring 2011
USACE	Section 404 Permit	Would only be required for the Phase 4b Project if Federal authorization is not obtained and SAFCA chooses to proceed with Phase 4b Project implementation without Federal participation. Under this scenario, anticipated spring 2011
USACE	Section 10 Permit	Would only be required for the Phase 4b Project if Federal authorization is not obtained and SAFCA chooses to proceed with Phase 4b Project implementation without Federal participation. Under this scenario, anticipated spring 2011
Central Valley RWQCB	Section 401 Water Quality Certification	Anticipated fall 2011
DFG	Section 2081 Incidental Take Authorization	Anticipated fall 2011
DFG	Section 1602 Streambed Alteration Agreement	Anticipated fall 2011
USFWS	Biological Opinion	October 2010
NMFS	Concurrence of Determination of Not Likely to Adversely Affect	Anticipated fall 2010
USFWS	Fish and Wildlife Service Coordination Act Report	October 2010
Sacramento County	SMARA Permit or Exemption	Anticipated fall 2011
DFG, Central Valley RWQCB, USACE, and USFWS	Mitigation and Monitoring Plan	Anticipated fall 2011
SWRCB	Section 402 NPDES Permit for General Construction	Anticipated fall 2011

Notes: USFWS = U.S. Fish and Wildlife Service; NMFS = National Marine Fisheries Service; DFG = California Department of Fish and Game; RWQCB = Regional Water Quality Control Board; USACE = U.S. Army Corps of Engineers; SMARA = Surface Mining and Reclamation Act; SWRCB = State Water Resources Control Board; NPDES = National Pollutant Discharge Elimination System

[1] Although Phase 1 Project permitting and regulatory requirements were fulfilled, they are not included in this table because construction is complete.

[2] The Phase 2 Project Section 404 permit was amended based on the Amended Phase 2 Biological Opinion.

[3] The Phase 3 Project Section 404 permit and 401 certification has been separated into 2 subphases (a and b).

[4] The Phase 3 Project DFG 1602 Streambed Alteration Agreement will be separated into multiple stages.

Source: Data compiled by AECOM in 2009

7.4 LIST OF RECIPIENTS

The following elected officials and representatives; government departments and agencies; non-profit organizations, partnerships, private organizations, and businesses; media; and individual property owners received a copy of the DEIS/DEIR or a notice that it was available.

7.4.1 ELECTED OFFICIALS AND REPRESENTATIVES

- Doris Matsui, Congresswoman, 5th Congressional District
- Tom McClintock, Congressman, 4th Congressional District
- Roger Dickinson, Sacramento County Supervisor, District 1
- Jimmie Yee, Sacramento County Supervisor, District 2
- Susan Peters, Sacramento County Supervisor, District 3
- Roberta MacGlashan, Sacramento County Supervisor, District 4
- Don Nottoli, Sacramento County Supervisor, District 5
- James Gallagher, Sutter County Supervisor, District 5
- Mayor Kevin Johnson, Sacramento City Council
- Ray Tretheway, Sacramento City Council, District 1
- Sandy Sheedy, Sacramento City Council, District 2
- Steve Cohn, Sacramento City Council, District 3
- Rob Fong, Sacramento City Council, District 4
- Lauren Hammond, Sacramento City Council, District 5
- Kevin McCarty, Sacramento City Council, District 6
- Robbie Waters, Sacramento City Council, District 7
- Bonnie Pannell, Sacramento City Council, District 8
- William Kristoff, West Sacramento City Council

7.4.2 GOVERNMENT DEPARTMENTS AND AGENCIES

UNITED STATES GOVERNMENT

- Bureau of Indian Affairs, Pacific Regional Office
- Federal Aviation Administration
- Federal Emergency Management Agency, Region IX
- National Marine Fisheries Service
- Natural Resources Conservation Service
- U.S. Bureau of Reclamation, Central Valley Operations
- U.S. Coast Guard
- U.S. Department of Agriculture, National Rural Development Council
- U.S. Environmental Protection Agency, Division 9
- U.S. Fish and Wildlife Service

TRIBAL GOVERNMENT

- Shingle Springs Rancheria

STATE OF CALIFORNIA

State agencies that will receive the EIS/EIR via the State Clearinghouse are marked (*)

- California Bay-Delta Authority
- California Air Resources Board*
- California Department of Boating and Waterways, Regulations Unit
- California Department of Conservation*
- California Department of Education*
- California Department of Fish and Game, Region 2
- California Department of General Services*
- California Department of Health Services*
- California Department of Transportation, District 3*
- California Department of Toxic Substances Control*

None.

9 LIST OF PREPARERS

This EIS/EIR was prepared by AECOM at the direction of USACE and SAFCA, with assistance from MBK Engineers, HDR Engineering, Mead & Hunt, Wood Rodgers, and Kleinfelder.

The following is a list of the individuals who prepared sections of the EIS/EIR, provided significant background materials, provided project description engineering details, or participated in preparing the EIS/EIR.

9.1 U.S. ARMY CORPS OF ENGINEERS, SACRAMENTO DISTRICT

Name	Title	Experience
Elizabeth Holland	Social Science Environmental Manager	24 years
Kathleen Dadey, Ph.D.	Chief, California Delta Branch, Regulatory	16 years
Dan Tibbitts, P.E.	Programs and Project Manager	18 years
Daniel Bell	Archaeologist	31 years
Greg Kukas, P.E.	Acting Chief, Hydrology and Hydraulics Branch	15 years
Lisa Clay	Assistant District Counsel	21 years

9.2 SACRAMENTO AREA FLOOD CONTROL AGENCY

Name	Title	Experience
Timothy Washburn, J.D.	Director of Planning	20 years
John Bassett, P.E.	Director of Engineering, Project Manager	27 years
Pete Ghelfi, P.E.	Director of Engineering	23 years
Peter Buck	Natural Resource Supervisor	21 years

9.3 AECOM

Name	Qualifications and Experience	Participation
Francine Dunn	B.A. Environmental Studies; 25 years experience	Principal-in-Charge, EIS/EIR Project Manager
Phil Dunn	B.S. Zoology; M.S. Fisheries Biology; 29 years experience	Principal, Senior Reviewer/Advisor
Sarah Henningsen	B.S. Community and Regional Development; 6 years experience	EIS/EIR Assistant Project Manager, Executive Summary, Introduction and Statement of Purpose and Need, Compliance with Federal Environmental Laws and Regulations, Consultation and Coordination
David Rader	B.A. Print Journalism; M.A. Business Economics; Certificate Program, Land Use and Environmental Planning; 6 years experience	EIS/EIR Assistant Project Manager; Alternatives; Hydrology and Hydraulics Reviewer; Cumulative and Growth-Inducing Impacts, and Other Statutory Requirements

Name	Qualifications and Experience	Participation
Melinda Rivasplata	B.A. Environmental Biology; 26 years experience	Agricultural Resources; Land Use, Socioeconomics, and Population and Housing; Recreation; Visual Resources
Marianne Lowenthal	B.S. Environmental Toxicology; 3 years experience	Geology, Soils, and Mineral Resources; Paleontological Resources; Utilities and Service Systems; Hazards and Hazardous Materials
Wendy Copeland	B.S. Plant Science; M.S. Plant Pathology; 11 years experience	Geology, Soils, and Mineral Resources and Paleontological Resources Senior Reviewer
Jason Barrett	B.S. Environmental Science; M.P.A. Land Use/Real Estate; 14 years experience	Water Quality, Transportation and Circulation
Kara Baker	B.A. Environmental Sciences/Political Science, M.S. Environmental Engineering; 6 years experience	Hydrology and Hydraulics
Sarah Bennett	B.S. Botany and Plant Pathology; M.S. Soils and Biogeochemistry; 4 years experience	Biological Resources
Mike Eng	B.S. Ecology; B.A. English; 6 years experience	Permitting Task Leader, Biological Resources Reviewer
Leo Edson	B.S. Biological Studies; 26 years experience	Biological Resources Senior Reviewer
Mike Aviña	B.A. Anthropology; J.D. Law; 14 years experience	Cultural Resources, Environmental Justice
Steve Heipel	B.S. Anthropology; 37 years experience	Cultural Resources Senior Reviewer
Sarah Sullivan	B.S. Environmental Management; M.P.A. Environmental Policy; 6 years experience	Air Quality
Greg Wolfe	B.A, Environmental Science; 22 years experience	Air Quality Senior Reviewer
Chris Shields	B.A. Environmental Studies; 4 years experience	Noise
Lisa Clement	B.S. Environmental and Resource Sciences; 11 years experience	Geographic Information Systems
Phi Ngo	B.A. Communication (Geographic Information Systems Minor); 4 years experience	Geographic Information Systems
Lorrie Jo Williams	B.S. Design; 22 years experience	Graphics
Deborah Jew	24 years experience	Word Processing, Document Production

9.4 MBK ENGINEERS

Name	Qualifications	Participation
Joseph D. Countryman, P.E.	B.S. Civil Engineering; 43 years experience	Hydraulic Modeling Review
Ric Reinhardt, P.E.	B.S. Civil Engineering; M.S. Civil Engineering; 14 years experience	Hydraulic Modeling Review
Mike Archer, P.E.	B.S. Civil Engineering; M.S. Civil Engineering; 26 years experience	Hydraulic Modeling

9.5 HDR ENGINEERING

Name	Qualifications	Participation
Christopher Krivanec, P.E., G.E.	B.S. Civil Engineering; M.S. Civil Engineering (Geotechnical); M.E. Civil Engineering (Geotechnical); 17 years experience	Project Manager for Sacramento River East Levee Design (provided relevant project description information)
Blake Johnson, P.E.	B.S. Civil Engineering; 19 years experience	Design Manager for Sacramento River East Levee Design (provided relevant project description information)
Elizabeth Baldi, P.E.	B.S. Civil Engineering; 6 years experience	Project Engineer for Sacramento River East Levee Design (provided relevant project description information)

9.6 MEAD & HUNT

Name	Qualifications	Participation
Steve Sullivan, P.E.	B.S. Civil Engineering; 28 years experience	Project Manager for Canal Design and Borrow Investigation (provided relevant project description information)
Marieke Armstrong	B.S. Ecology, Behavior, Evolution; M.S. Environmental Science; 11 years experience	Environmental Coordinator for Canal Design and Borrow Investigations (provided relevant project description information)

9.7 WOOD RODGERS

Name	Qualifications	Participation
Jonathan Kors, P.E.	B.S. Civil Engineering; 12 years experience	Project Manager for Natomas Cross Canal South Levee, Pleasant Grove Creek Canal West Levee, and Natomas East Main Drainage Canal West Levee Design (provided relevant project description information)
Carlos Contreras, P.E.	B.S. Civil Engineering; 11 years experience	Project Engineer for Natomas Cross Canal South Levee, Pleasant Grove Creek Canal West Levee, and Natomas East Main Drainage Canal West Levee Design (provided relevant project description information)
Peter Tobia, P.E.	B.S. Civil Engineering; 20 years experience	Quality Control Manager for Natomas Cross Canal South Levee, Pleasant Grove Creek Canal West Levee, and Natomas East Main Drainage Canal West Levee Design (provided relevant project description information)
Peter Blum	B.S. Civil Engineering; 11 years experience	Project Engineer for Pleasant Grove Creek Canal West Levee and Natomas East Main Drainage Canal West Levee Design (provided relevant project description information)

Topic **Page Number**

APPENDIX A

Public Outreach and Involvement

A1 NEPA Notice of Intent

DEPARTMENT OF DEFENSE

Department of the Army; Army Corps of Engineers

Notice of Intent To Prepare an Environmental Impact Statement for 408 Permission and 404 Permit to Three Rivers Levee Improvement Authority for the Feather River Levee Repair Project, California, Segment 2

AGENCY: Department of the Army, U.S. Army Corps of Engineers, DoD.

ACTION: Notice of intent.

SUMMARY: The action being taken is the preparation of an Environmental Impact Statement (EIS) for the issuance of both the 408 permission to the Central Valley Flood Protection Board and 404 Permit to Three Rivers Levee Improvement Authority (TRLIA) for their work on the Feather River Levee Repair Project (FRLRP). Under 33 U.S.C. 408, the Chief of Engineers grants permission to alter an existing flood control structure if it is not injurious to the public interest and does not impair the usefulness of such work. Under section 404 of the Clean Water Act, the District Engineer permits the discharge of dredged or fill material into waters of the United States if the discharge meets the requirements of the Environmental Protection Agency's 404(b)(1) guidelines and is not contrary to the public interest. The FRLRP is located in Yuba County, CA. TRLIA is requesting this permission and permit in order to complete construction along the east levee of the Feather River.

DATES: A public scoping meeting will be held March 10, 2008, 6:30 to 8:30 at the Yuba County Government Center, 915 8th Street, Marysville, CA. Send written comments by April 9, 2008 to the address below.

ADDRESSES: Send written comments and suggestions concerning this study to Mr. John Suazo, U.S. Army Corps of Engineers, Sacramento District, Attn: Planning Division (CESPK–PD–R), 1325 J Street, Sacramento, CA 95814. Requests to be placed on the mailing list should also be sent to this address.

FOR FURTHER INFORMATION CONTACT: Questions about the proposed action and EIS should be addressed to John Suazo at (916) 557–6719, e-mail: *john.suazo@usace.army.mil* or by mail to (see **ADDRESSES**).

SUPPLEMENTARY INFORMATION:

1. *Proposed Action.* The U.S. Army Corps of Engineers is preparing an EIS to analyze the impacts of the work proposed by TRLIA from the implementation of the FRLRP, Segment 2. The FRLRP, Segment 2 is being constructed by TRLIA to improve flood protection to portions of Yuba County and Reclamation District (RD) 784.

2. *Alternatives.* The EIS will address an array of flood control improvement alternatives along Segment 2. Alternatives analyzed during the investigation will include a combination of one or more flood protection measures. These measures include seepage berms, stability berms, setback levees, seepage cutoff walls, and relocation of a pump station.

3. *Scoping Process.* a. The Corps has initiated a process to involve concerned individuals, and local, State, and Federal agencies. A public scoping meeting will be held on March 10, 2008 to present information to the public and to receive comments from the public.

b. Significant issues to be analyzed in depth in the EIS include effects on hydraulic, wetlands and other waters of the U.S., vegetation and wildlife resources, special-status species, cultural resources, land use, fisheries, water quality, air quality, transportation, and socioeconomics; and cumulative effects of related projects in the study area.

c. The Corps is consulting with the State Historic Preservation Officer to comply with the National Historic Preservation Act, and the National Marine Fisheries Service and the U.S. Fish and Wildlife Service to comply with the Endangered Species Act. Coordination with the National Marine Fisheries Service has been completed; coordination with U.S. Fish and Wildlife Service is still ongoing.

d. A 45-day public review period will be provided for individuals and agencies to review and comment on the draft EIS. All interested parties are encouraged to respond to this notice and provide a current address if they wish to be notified of the draft EIS circulation.

4. *Availability.* The draft EIS is scheduled to be available for public review and comment in early 2008.

Dated: February 22, 2008.

Thomas C. Chapman,

COL, EN, Commanding.

[FR Doc. E8–3919 Filed 2–28–08; 8:45 am]

BILLING CODE 3710–EZ–P

DEPARTMENT OF DEFENSE

Department of the Army; Army Corps of Engineers

Notice of Intent To Prepare an Environmental Impact Statement for the American River Common Features General Reevaluation Report, Sacramento, CA

AGENCY: Department of the Army, U.S. Army Corps of Engineers; DOD.

ACTION: Notice of intent.

SUMMARY: The action being taken is the preparation of an environmental impact statement (EIS) for the American River Common Features General Reevaluation Report (GRR). The Common Features Project GRR will re-evaluate the currently authorized plan as well as develop and evaluate other viable alternatives, including a locally-preferred plan, with the goal of identifying a comprehensive plan that will lower the risk of flooding in and around the City of Sacramento. The Common Features Project GRR is located in Sacramento, Sutter and Yolo Counties, CA.

DATES: A series of public scoping meetings will be held as follows:

1. March 5, 2008, 5 to 7 p.m. at The Elk's Lodge.

2. March 6, 2008, 5 to 7 p.m. at Arden Park Community Center, Room A.

3. March 10, 2008, 3 to 6 p.m. at The Library Galleria East Meeting Room.

4. March 13, 2008, 5 to 7 p.m. at The Sierra Health Foundation.

Send written comments by April 11, 2008 to the address below.

ADDRESSES: Written comments and suggestions concerning this study may be submitted to Ms. Elizabeth Holland, U.S. Army Corps of Engineers, Sacramento District, Attn: Planning Division (CESPK–PD–R), 1325 J Street, Sacramento, CA 95814. Requests to be placed on the mailing list should also be sent to this address. The location of the public meetings is as follows; The Elks Lodge, 6446 Riverside Blvd., Sacramento, CA; Arden Park Community Center, 1000 La Sierra Drive, Sacramento, CA; Library Galleria, 828 ''I'' Street, Sacramento, CA; and Sierra Health Foundation, 1321 Garden Highway, Sacramento, CA.

FOR FURTHER INFORMATION CONTACT: Questions about the proposed action and EIS should be addressed to Liz Holland at (916) 557–6763, e-mail *Elizabeth.g.holland@usace.army.mil* or by mail to (see **ADDRESSES**).

SUPPLEMENTARY INFORMATION:

1. *Proposed Action.* The U.S. Army Corps of Engineers is preparing an EIS

to analyze the impacts of a range of alternatives that would lessen the risk of flooding in and around the City of Sacramento.

2. *Alternatives.* The EIS will address an array of flood control improvement alternatives that are intended to reduce flood risk within the project area. Alternatives analyzed during the investigation will include a combination of one or more flood protection measures. These measures include levee improvements (e.g., seepage berms, adjacent setback levees, seepage wells, seepage cutoff walls), revisions to system hydraulics through setbacks, levee raises, and/or more diversion of flow into the bypass system, and possible use of upstream lands for detention.

3. *Scoping Process.* a. A series of public scoping meeting will be held in early March, 2008 to present information to the public and to receive comments from the public. These meetings are intended to initiate the process to involve concerned individuals, and local, State, and Federal agencies.

b. Significant issues to be analyzed in depth in the EIS include effects on hydraulics, wetlands and other waters of the U.S., vegetation and wildlife resources, special-status species, esthetics, cultural resources, recreation, land use, fisheries, water quality, air quality, transportation, and socioeconomics; and cumulative effects of related projects in the study area.

c. The Corps is consulting with the State Historic Preservation Officer to comply with the National Historic Preservation Act and the U.S. Fish and Wildlife Service and National Marine Fisheries Service to comply with the Endangered Species Act. The Corps is also coordinating with the U.S. Fish and Wildlife Service to comply with the Fish and Wildlife Coordination Act.

d. A 45-day public review period will be provided for individuals and agencies to review and comment on the draft EIS. All interested parties are encouraged to respond to this notice and provide a current address if they wish to be notified of the draft EIS circulation.

4. *Availability.* The draft EIS is scheduled to be available for public review and comment in spring 2010.

Dated: February 15, 2008.

Thomas C. Chapman,

COL, EN, Commanding.

BILLING CODE 3710–EZ–P

DEPARTMENT OF DEFENSE

Department of the Navy

Meeting of the Ocean Research and Resources Advisory Panel

AGENCY: Department of the Navy, DoD.

ACTION: Notice.

SUMMARY: The Ocean Research and Resources Advisory Panel (ORRAP) will meet to discuss National Ocean Research Leadership Council (NORLC) and Interagency Committee on Ocean Science and Resource Management Integration (ICOSRMI) activities. All sessions of the meeting will be open to the public.

DATES: The meeting will be held on Tuesday, April 15, 2008 from 8 a.m. to 5:30 p.m. and Wednesday, April 16, 2008 from 8 a.m. to 1:30 p.m.

ADDRESSES: The meetings will be held at the Consortium for Ocean Leadership located at 1201 New York Ave, Suite 420, Washington, DC.

FOR FURTHER INFORMATION CONTACT: Dr. Charles L. Vincent, Office of Naval Research, 875 North Randolph Street, Suite 1425, Arlington, VA 22203–1995, telephone: 703–696–4118.

SUPPLEMENTARY INFORMATION: This notice is provided in accordance with the provisions of the Federal Advisory Committee Act (5 U.S.C. App. 2). The meeting will include discussions on ocean research to applications, ocean observing, professional certification programs, and other current issues in the ocean science and resource management communities. In order to maintain the meeting time schedule, members of the public will be limited in their time to speak to the Panel. Members of the public should submit written comments at least one week prior to the meeting to Dr. Charles L. Vincent, Office of Naval Research, 875 North Randolph Street, Suite 1425, Arlington, VA 22203–1995, telephone: 703–696–4118.

Dated: February 22, 2008.

T.M. Cruz,

Lieutenant, Office of the Judge Advocate General, U.S. Navy, Federal Register Liaison Officer.

DEPARTMENT OF DEFENSE

Department of the Navy

[USN–2008–0008]

Privacy Act of 1974; System of Records

AGENCY: Department of the Navy, DoD.

ACTION: Notice to Amend a System of Records.

SUMMARY: The Department of the Navy is amending a system of records notice in its existing inventory of record systems subject to the Privacy Act of 1974, (5 U.S.C. 552a), as amended.

DATES: This proposed action will be effective without further notice on March 31, 2008 unless comments are received which result in a contrary determination.

ADDRESSES: Send comments to the Department of the Navy, PA/FOIA Policy Branch, Chief of Naval Operations (DNS–36), 2000 Navy Pentagon, Washington, DC 20350–2000.

FOR FURTHER INFORMATION CONTACT: Mrs. Doris Lama at (202) 685–6545.

SUPPLEMENTARY INFORMATION: The Department of the Navy systems of records notices subject to the Privacy Act of 1974, (5 U.S.C. 552a), as amended, have been published in the **Federal Register** and are available from the address above.

The specific changes to the record system being amended are set forth below followed by the notice, as amended, published in its entirety. The proposed amendments are not within the purview of subsection (r) of the Privacy Act of 1974, (5 U.S.C. 552a), as amended, which requires the submission of a new or altered system report.

Dated: February 25, 2008.

American River Common Features General Evaluation Report
Notice of Preparation
SCH# 2005072046

Ms. Annalena Bronson
Central Valley Flood Protection Board
3310 El Camino Avenue, Room LL-40
Sacramento, CA 95821

Dear Ms. Bronson:

We have reviewed the American River Common Features General Re-evaluation Report Notice of Preparation documentation. Our comments are as follows:

- Caltrans' prior comments in our letters of July 27, 2005 and October 3, 2002 (copies enclosed) are still valid.

- In carrying out this project's levee improvement activities, it is very likely that truck haul routes used in transporting soil, rock, borrow and cleared vegetation disposal materials to and from the various proposed sites along the American and Sacramento Rivers and Natomas Cross Canal and Natomas East Main Drainage Canal could involve the use of Interstate 5, State Route (SR) 160, U.S. 50, SR51, and I-80. We note on page 2 in the "Study Area" discussion and on Page 6's map of the project levee areas that this "project's" scope is quite large. Clarification should be made regarding which of the multiple levee improvement areas will use trucks and which will use waterside barges to transport work materials.

- If off-site levee materials are being transported by truck to these work sites to modify levee bank areas and are using adjoining State roadway facilities, a project Traffic Management Plan (TMP) will be necessary. The TMP should be prepared for our review and include appropriate strategies to mitigate construction traffic impacts to the nearby roadway intersections, freeway interchanges, and mainlines. Truck haul routes and points of access to State roadway facilities used should be clarified in the plan. If Garden Highway will be used as an access to some of the improvement areas, the TMP should explain how Garden Highway is to be accessed, whether from I-5 or via a local road network. The project's individual levee site work plan dates should also be provided, if known, and the truck trip volumes. We recommend truck-hauling operations avoid peak traffic periods (6-10 AM and 3-7 PM) whenever possible. The Caltrans TMP Guidelines are enclosed for your use. For assistance, please contact Paul Wilkinson, the Caltrans District 3 Traffic Manager (DTM), at (916) 859-7978.

- If electronic warning signs are provided within State right-of-way at work sites to alert the traveling public of trucks entering or leaving State highways, an encroachment permit will be required. For permit assistance, please contact Julio Elvir at (530) 741-4204.

- Caltrans is interested in the work zone proximity of this project's planned levee improvements on the Sacramento River near the system of relief wells and piezometer installations near the downtown Sacramento I-5 freeway and within State property. Freeway Post Mile locations may have been established for these well and piezometer locations when they were installed to help prevent levee seepage near the subgrade section of Interstate 5 (more commonly called, "the Boat Section"). The distance of well locations from freeway bridge footings might have been specified as well to help locate where they are. We understand that Encroachment Permit # 0304-NMC-0918 was obtained from Caltrans District 3 in prior years when this installation work was done. Caltrans wishes to make sure that these wells and piezometer locations are not disturbed during the levee bank work. Preliminary planning installation maps, showing where the wells and piezometers were located in relation to our right-of-way lines and freeway facilities, and "As Built" maps, were prepared for Caltrans to update its right of way records of the Interstate 5 freeway corridor.

If you have any questions regarding these comments, please contact Ken Champion at (916) 274-0615.

Sincerely,

Dawn Cheser, Office Chief
Office of Transportation Planning - South

Sacramento River East Levee & Natomas Cross Canal Levee Modifications
Notice of Preparation
SCH# 2005072046

Ms. Annalena Bronson
The Reclamation Board
3310 El Camino Avenue, Room 110
Sacramento, CA 95821

Dear Ms. Bronson:

We have reviewed the Sacramento River East and Natomas Cross Canal Levee Modifications Project Notice Of Preparation documentation. We look forward to reviewing the draft Environmental Impact Report. Our comments are as follows:

- Our comments provided in our letter of October 3, 2002 (copy enclosed) are still valid.

- The document map of the Sacramento River work site shows Elverta and Power Line Roads as potential access roadways. If off-site levee materials are being transported by truck to this work site to modify these levees and are using adjoining State roadway facilities, a project Traffic Management Plan (TMP) will be necessary. The TMP should be prepared for our review and include appropriate strategies to mitigate construction traffic impacts to the nearby State Route 99/Elverta Road intersection and other nearby freeway interchanges. The TMP should also clarify whether Interstate 5 would be used via Power Line Road. The Caltrans TMP Guidelines are enclosed for your use. Truck haul routes and points of access to State roadway facilities used should be clarified in the plan. The planned project initiation and completion dates should also be noted, as well as truck trip volumes, daily hours of operations, and whether electronic warning signs are provided to alert the traveling public. We recommend truck hauling operations during non-peak traffic periods.

Please provide our office with a copy of the draft TMP requested above. If you have any questions regarding these comments, please contact Ken Champion at (916) 274-0615.

Sincerely,

Ms. Karen Enstrom
Reclamation Board
1416 Ninth Street, Room 1601
Sacramento, CA 95814

Dear Ms. Enstrom:

Thank you for the opportunity to comment on the above mentioned project. Our comments are as follows:

- The project documentation should provide a map (s) describing the project "activity areas" and any nearby State highway facilities in order to clarify the scope of project and potential impacted highway and bridge structure areas.

- Any flood control improvements and protection measures located near State right-of-way should be identified and Caltrans should be notified. Any work conducted within State right-of-way will require an encroachment permit. For assistance, Bruce Capaul at (530) 741-4408 should be contacted.

- Haul routes for transporting soil and construction materials and any State highways used should be provided in the project discussion.

Please provide our office with the requested information, a copy of the DEIR, copies

of draft mitigation measures, and any further action regarding this project. If you have any questions regarding these comments, please contact Ken Champion at (916) 274-0615.

Sincerely,

Posters from March 2008 Scoping Meetings

About the Re-evaluation Report

Flooding is a long-standing problem facing the Sacramento area. The recent floods of 1986 and 1997 devastated several communities, including homes, businesses, orchards and farmlands. In 1996 the Water Resources Development Act authorized the American River Common Features Project (CFP), designed to lessen flood risks in Sacramento. Since the authorization of the CFP 12 years ago, a great deal of progress has been made to improve the flood control system. However, new information and issues have been identified and new engineering standards have been instituted. As a result, there are continuing concerns about the integrity of Sacramento's flood control management system.

As a result, the U.S. Army Corps of Engineers plans to conduct a re-evaluation report called the American River Common Features General Re-evaluation Report (Common Features GRR) that will look at the existing CFP with the purpose of identifying alternatives to lower the risk of flooding to the City of Sacramento. The Common Features GRR will examine the City's flood management system as a whole, rather than on a site-by-site, project-by-project basis.

The purpose of the Common Features GRR is to review the CFP with the aim of making recommendations for changes or additions that will effectively and efficiently reduce flood risks within the American River Watershed. This includes the flood control features along the American and Sacramento Rivers that provide protection to the City of Sacramento and surrounding areas.

In a separate effort, the Sacramento Area Flood Control Agency (SAFCA) is currently working on a flood control program specific to Natomas to provide the area with 100-year flood protection as soon as possible, and ultimately, in cooperation with this study, 200-year protection. These improvements could be completed before the Common Features GRR is conducted because of the high risk of catastrophic flooding in Natomas. It is anticipated that SAFCA's program will eventually be incorporated into the Common Features GRR.

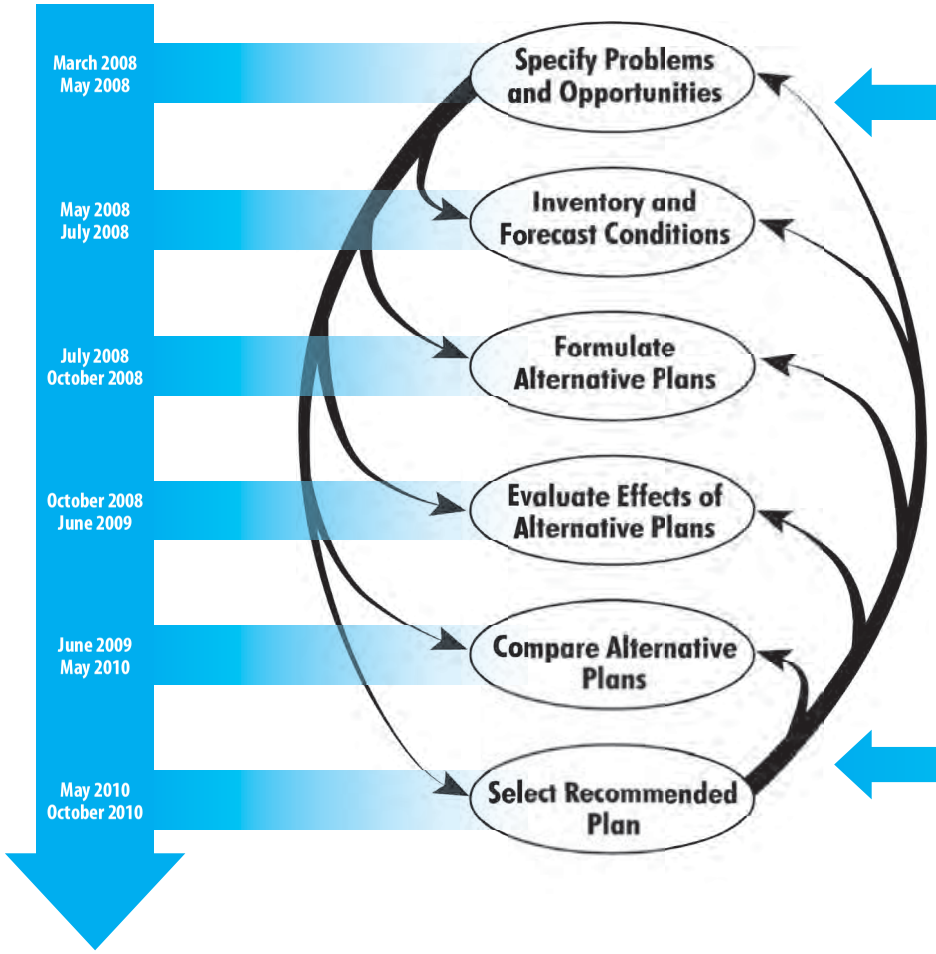
Planning Process

The Corps' "Beehive" diagram represents the six planning steps and the iterative process of Corps project planning.

Corps decision making is generally based on the accomplishment and documentation of all of these steps. It is important to stress the iterative nature of this process. As more information is acquired and developed, it may be necessary to reiterate some of the previous steps. The six steps, though presented and discussed in a sequential manner for ease of understanding, usually occur iteratively and sometimes concurrently. Iterations of steps are conducted as necessary to formulate efficient, effective, complete and acceptable plans.



Previous investigations and ongoing/completed projects will inform the Common Features GRR

Completed and Ongoing Projects

A great deal of progress has been made since the major flood events in 1986 and 1997. The projects listed below are examples of recent efforts to increase the level of flood protection in the Sacramento area. These efforts will inform and be coordinated with the Common Features GRR planning process.

American River Common Features Projects

- Slurry Wall Construction along the Lower American River (24 miles completed)
- Upstream Telemetry Gages (completed)
- Erosion Protection (4 sites completed)
- Jet Grouting/Alternative Methods (ongoing)
- Seepage Remediation along the Sacramento River (completed)
- Mayhew Levee Raise and Drain Closure (under construction)
- Levee Raising and Strengthening (various sites remaining)

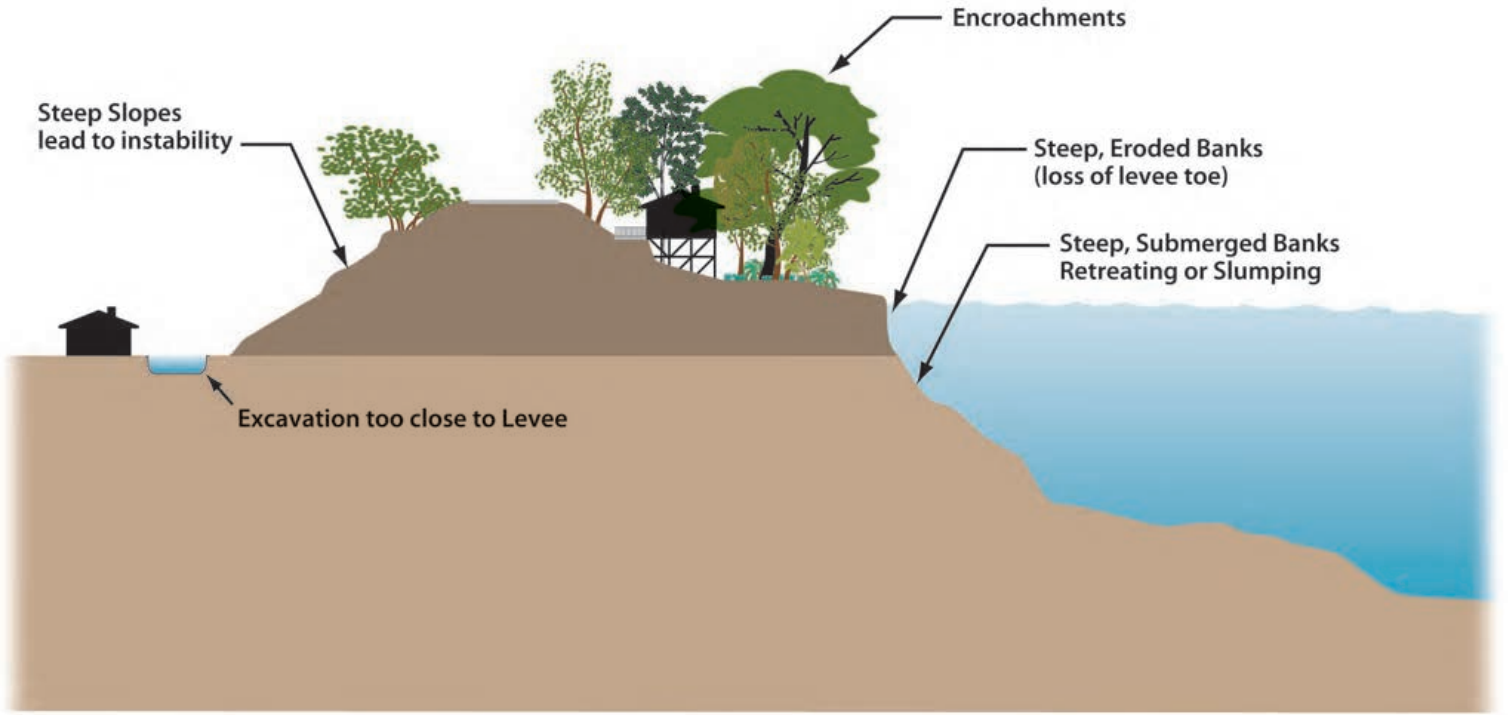
Other Major Flood Protection Projects

- Folsom Dam Reoperation (ongoing)
- Natomas Levee Improvement Project (ongoing)
- Sacramento River Bank Protection Project (Corps/CVFPB) (ongoing)
- West Sacramento Levee Improvement Project (Corps/City of West Sacramento) (ongoing)
- South Sacramento Streams Group Project (Corps/SAFCA) (ongoing)
- Joint Federal Project at Folsom Dam (Corps/Bureau of Reclamation/CVFPB/SAFCA)

US Army Corps of Engineers
SAFCA

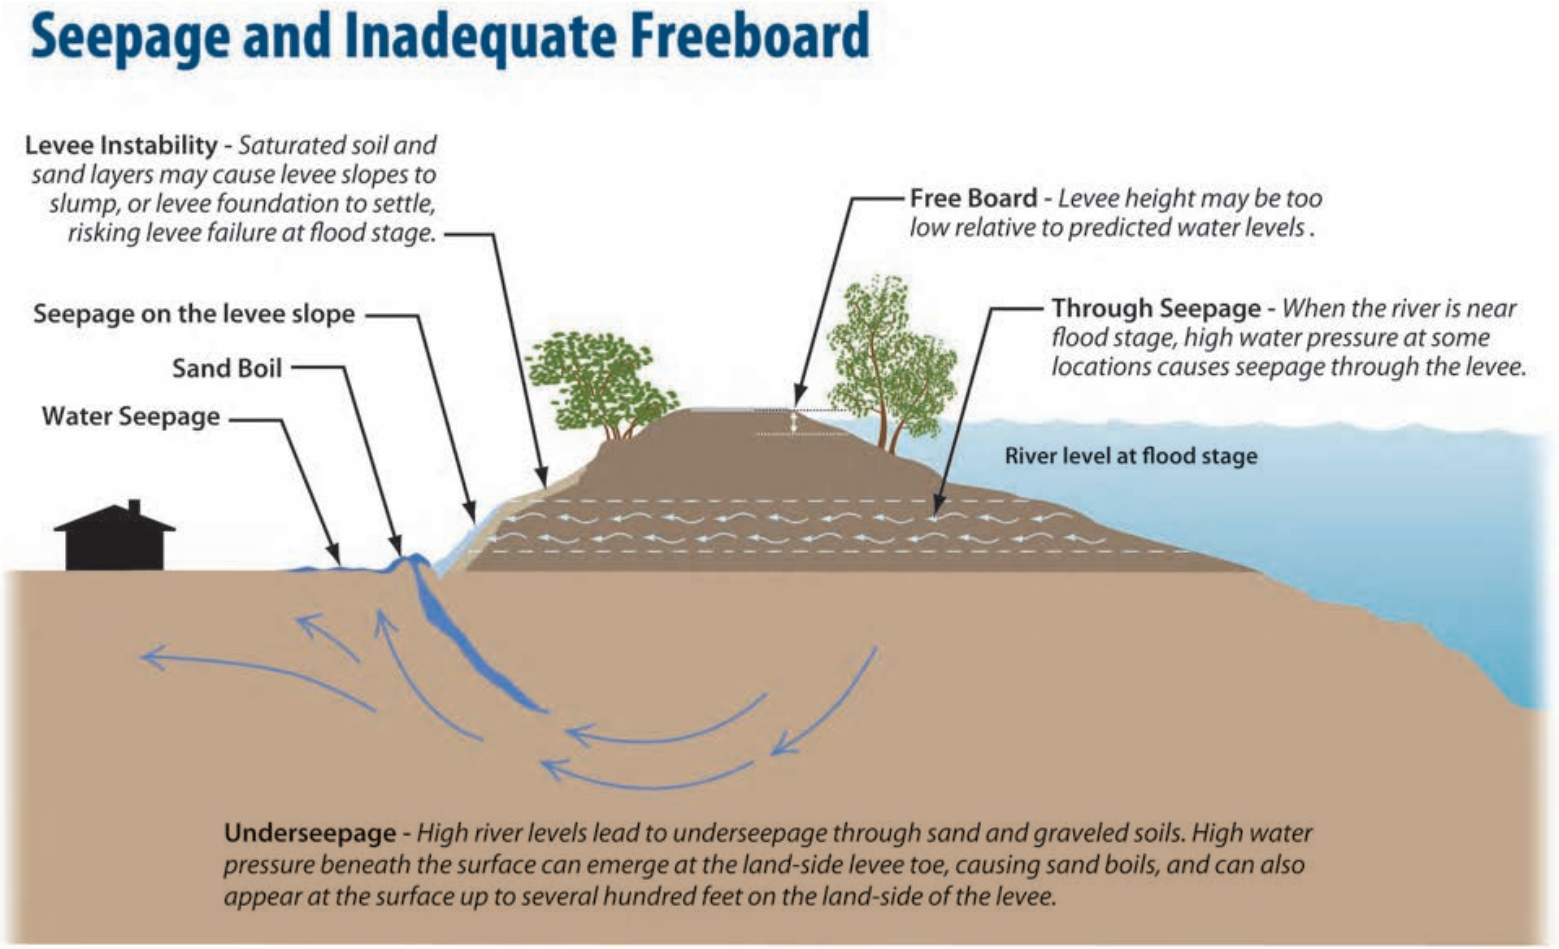
Typical Levee Deficiencies

Encroachments, Unstable Slopes, Erosion



- Unstable Slopes - irregular or overly steep slopes compromise the levee structure
- Encroachments including pools, homes, vegetation
- Erosion - water flow, wakes and waves, remove soil material, degrading the levee

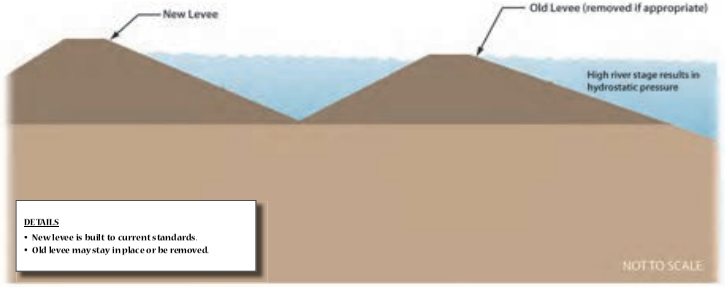
Typical Levee Deficiencies



- Inadequate Freeboard - levee height may be too low relative to predicted water levels

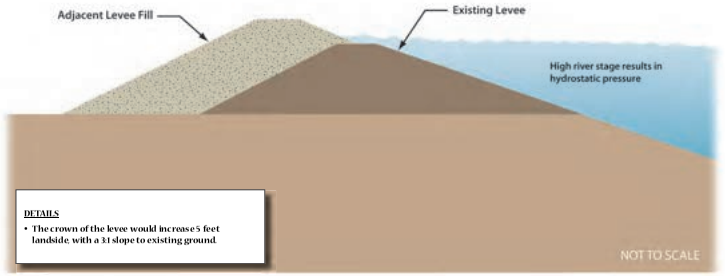
IMPROVEMENTS TO FLOOD CONTROL FEATURES THAT ADDRESS STABILITY, EROSION AND FREEBOARD

Setback Levee (stability, seepage, & freeboard)



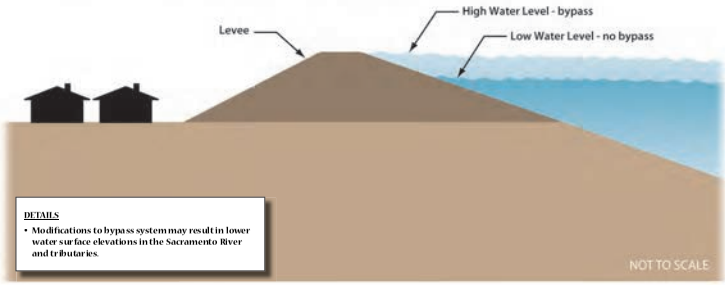
Concept:
A new levee is built toward the landside of an existing levee where the existing levee is not readily repairable or where more flooding capacity is desired.

Adjacent Levee Raise (stability, seepage, & freeboard)



Concept:
A new embankment strengthens the existing levee and enlarges the slopes.

Diversion to Bypass System (seepage, stability, & freeboard)



Concept:
Reducing water surface elevations by modifying diversion to the bypass system may also reduce seepage and stability issues by reducing hydrostatic pressure. Lower water surface elevations will also alleviate freeboard issues.

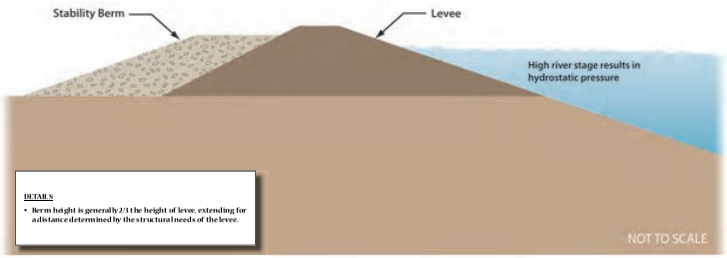
Diversion to Bypass System (seepage, stability, & freeboard)

U.S. Army Corps of Engineers

SAFCA

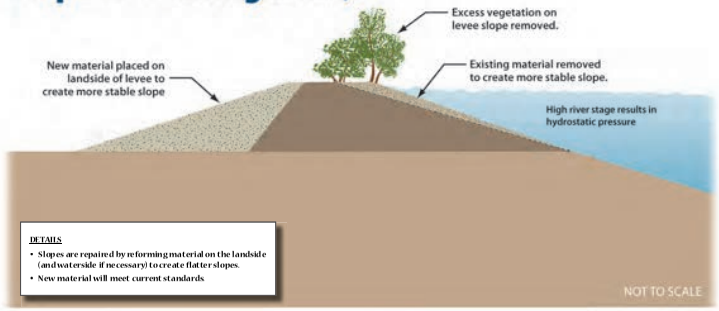
IMPROVEMENTS TO LEVEES THAT ADDRESS STABILITY, EROSION AND FREEBOARD

Stability Berm (stability)



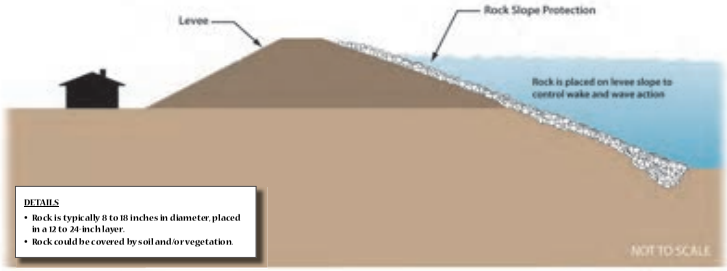
Concept:
Provides additional support to levee to increase strength.

Slope Flattening (stability)



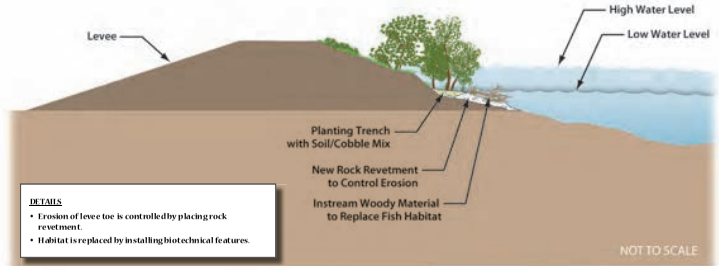
Concept:
Flatter slopes are more stable and less susceptible to erosion. Excess vegetation may inhibit levee maintenance and performance monitoring.

Rock Slope Protection (erosion)



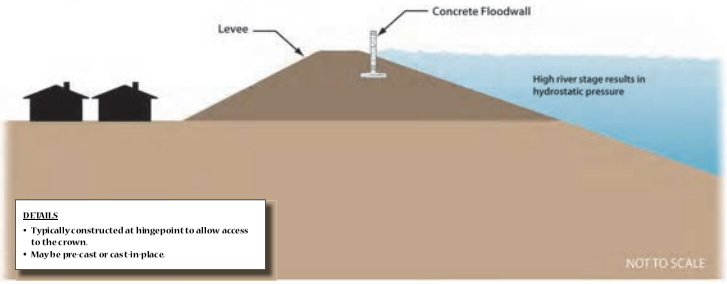
Concept:
Water-side erosion is prevented by placement of rock.

Biotechnical Erosion Protection (erosion)



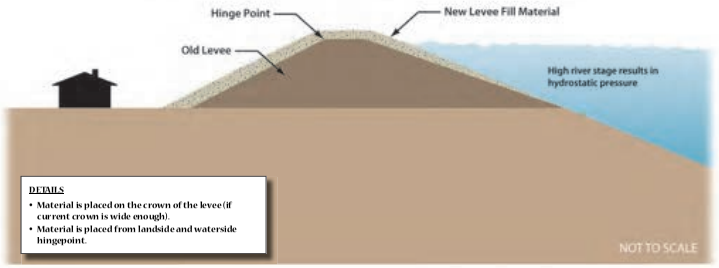
Concept:
Placing rock revetment at toe of eroding levee controls erosion. Installing biotechnical features replaces habitat and further controls erosion.

Flood Wall (freeboard)



Concept:
Additional levee height may be achieved through construction of a concrete wall on the levee crown.

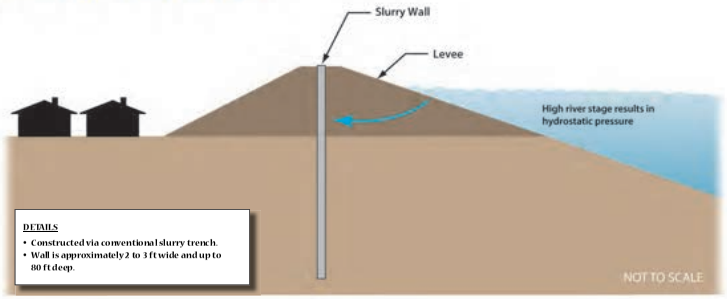
In-Place Levee Raise (freeboard)



Concept:
Flood protection is increased by adding material to crown and levee slope (land or water side).

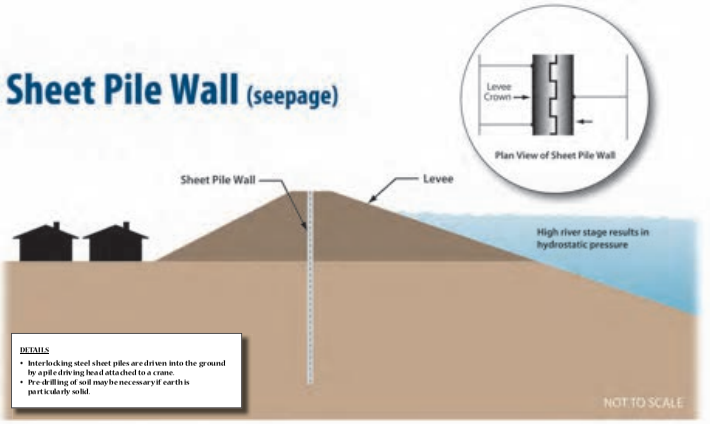
IMPROVEMENTS TO LEVEES THAT ADDRESS SEEPAGE

Slurry Wall (seepage)



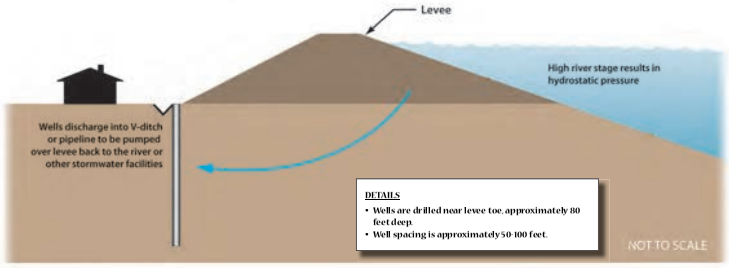
Concept:
Water pressure is contained and dispersed by a low-permeability wall constructed within the levee cross section.

Sheet Pile Wall (seepage)



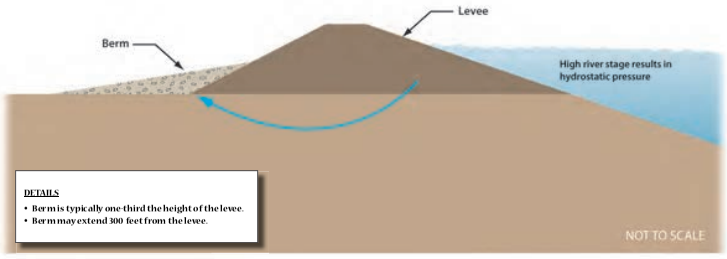
Concept:
Steel panels are driven into the levee core to provide a seepage barrier.

Relief Well (seepage)



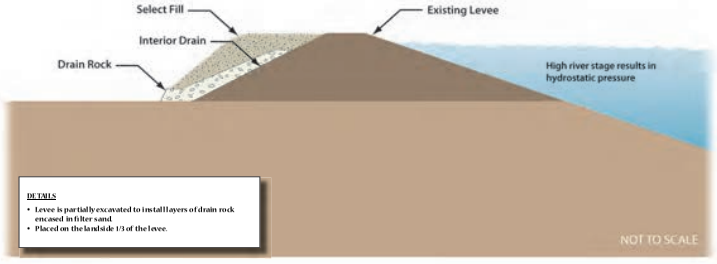
Concept:
Water pressure is relieved via passive wells, which control water discharge into a collection system.

Seepage Berm (seepage)



Concept:
Water pressure is contained and dispersed by a thickened soil layer.

Interior Drain (seepage)



Concept:
Capture any through-seepage and direct it away from the face of the levee.

The process of determining the scope, focus and content of an EIS/EIR is known as "scoping". Scoping is a part of the NEPA/CEQA process in which the general public, interested agencies and stakeholders provide comments to the Lead Agency to help identify the key issues, range of actions, alternatives, and environmental affects to be analyzed in the EIS/EIR.

The following issues related to this project have been identified to date:

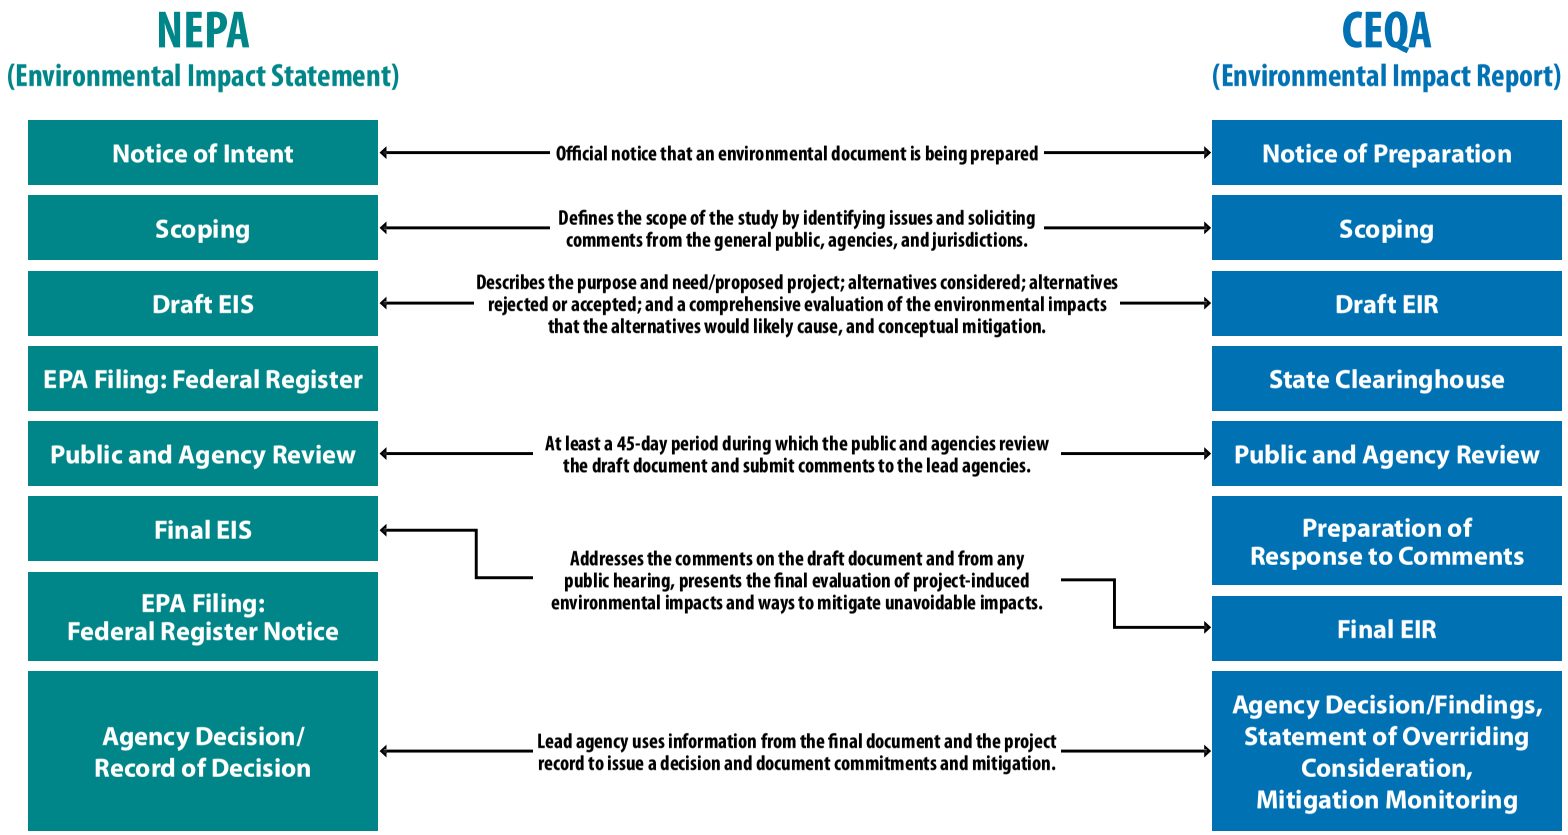
- Riparian vegetation and habitat effects;
- Cultural resources;
- Flood control and river hydraulic effect;
- Location of flood control infrastructure and effects on land use and access;
- Construction related effects such as those related to transportation, noise, and air quality;
- Economic issues

NEPA/CEQA Compliance

What is an EIS/EIR?

An EIS (Environmental Impact Statement) and an EIR (Environmental Impact Report) are documents that are required to comply with the National Environmental Policy Act (NEPA) and the California Environmental Quality Act (CEQA), respectively. The purpose of these documents is to analyze and disclose a project's potential effects on the natural and human environment and identify conservation measures and alternatives to avoid significant effects.

An EIS is prepared when there is Federal involvement in the project and an EIR is prepared when the project is subject to State or local jurisdiction. A joint document, an EIS/EIR, may be prepared when both a Federal and State agency are involved. The major steps to complying with both acts are outlined below.



A2 CEQA Notice of Preparation

Sacramento Area Flood Control Agency

NOTICE OF PREPARATION

To: Agencies and Interested Parties

From: Sacramento Area Flood Control Agency

Date: November 5, 2009

Subject: **Announcement of:**

1) **Notice of Preparation of an Environmental Impact Statement/Environmental Impact Report on the Natomas Post-authorization Change Report/Natomas Levee Improvement Program, Phase 4b Landside Improvements Project;**
2) **Public Scoping Meeting to be held on November 18, 2009; and**
3) **Scoping Comments due by December 4, 2009**

The Sacramento Area Flood Control Agency (SAFCA) and the U.S. Army Corps of Engineers (USACE), Sacramento District, intend to prepare a "joint" environmental impact statement (EIS)/environmental impact report (EIR), consistent with the National Environmental Policy Act (NEPA) (42 United States Code [USC] Section 4321 et seq.) and the California Environmental Quality Act (CEQA) (California Public Resources Code [PRC], Section 21000 et seq.; see also 14 California Code of Regulations [CCR] Sections 15220, 15222 [State CEQA Guidelines]), for the Natomas Post-authorization Change Report (Natomas PACR)/Natomas Levee Improvement Program (NLIP), Phase 4b Landside Improvements Project (Phase 4b Project) in the Natomas Basin in Sacramento and Sutter Counties, California. USACE, Sacramento District, will be the Federal lead agency for purposes of complying with NEPA, and SAFCA will be the state lead agency for compliance with CEQA.

PURPOSE OF THE NOTICE OF PREPARATION

In accordance with the State CEQA Guidelines (CCR Section 15082), SAFCA has prepared this notice of preparation (NOP) to inform responsible and trustee agencies and interested parties that an EIS/EIR will be prepared. The purpose of an NOP is to provide sufficient information about the proposed project and its potential environmental impacts to allow the Governor's Office of Planning and Research (OPR), responsible and trustee agencies, Federal agencies involved in approving or funding a project, and interested parties the opportunity to provide a meaningful response related to the scope and content of the EIS/EIR, including the significant environmental issues, reasonable alternatives, and mitigation measures that the responsible or trustee agency, or the OPR, will need to have explored in the EIS/EIR (State CEQA Guidelines CCR Section 15082[b]).

The project location, description, and probable environmental effects of the proposed project are presented below. An initial study has not been prepared because the EIS/EIR will address all issue areas and it is already known that the proposed project could have a significant effect on the environment. The EIS/EIR will also include feasible mitigation measures, where available, and consideration of a reasonable range of alternatives to avoid or substantially reduce the proposed project's significant adverse environmental impacts.

The purposes of this NOP are to:

1. briefly describe the proposed project and the anticipated content of the EIS/EIR to be prepared for the proposed project;

2. announce the public scoping meeting to facilitate public input and to be held: November 18, 2009, from 4:30 to 6:30 p.m. at South Natomas Community Center (Activity Room) located at 2921 Truxel Road in Sacramento, California; and

3. solicit input by December 4, 2009, from Federal, state, regional, and local agencies, and from interested organizations and individuals about the content and scope of the EIS/EIR, including the alternatives to be addressed and the potentially significant environmental impacts.

INTRODUCTION TO THE PHASE 4b PROJECT

The Phase 4b Project consists of improvements to a portion of the Natomas Basin's perimeter levee system (see **Exhibits 1, 2,** and **3** below) in the City of Sacramento and in Sutter and Sacramento Counties, California, associated landscape and irrigation/drainage infrastructure modifications, and habitat creation and management. A more detailed project description is provided below.

To implement the Phase 4b Project, SAFCA is requesting permission from USACE pursuant to Section 14 of the Rivers and Harbors Act of 1899 (33 United States Code [USC] 408, referred to as "Section 408") for alteration of Federal project levees; Section 404 of the Clean Water Act (33 USC 1344) for placement of fill into jurisdictional waters of the United States; and Section 10 of the Rivers and Harbors Act of 1899 (33 USC 403) for work performed in, over, or under navigable waters of the United States (such as excavation of material from or deposition of material into navigable waters).

SAFCA may also need to obtain several state, regional, and local approvals or permits to implement the Phase 4b Project in the event that USACE does not receive authorization to construct the Phase 4b Project. These include: CVFPB encroachment permit; California Surface Mining and Reclamation Act permit; Clean Water Act Section 401 water quality certification, Clean Water Act Section 402 National Pollutant Discharge Elimination System permit; California Fish and Game Code Section 2081 incidental take authorization; California Fish and Game Code Section 1602 streambed alteration agreement; encroachment permits from the California Department of Transportation, Sacramento County, Sutter County, and City of Sacramento; and authority to construct authorization from the Sacramento Metropolitan Air Quality Management District and the Feather River Air Quality Management District.

RELATIONSHIP TO OTHER U.S. ARMY CORPS OF ENGINEERS PLANNING DOCUMENTS

The EIS/EIR will support the approval of USACE's Natomas Basin General Re-evaluation Report (GRR) and Natomas PACR. The EIS/EIR will also support the final project phase of the NLIP, the Phase 4b Project.

The Natomas GRR covers the Sacramento Metropolitan Area. The American River drainage basin covers about 2,100 square miles northeast of Sacramento and includes portions of Placer, El Dorado, Sutter, and Sacramento Counties. The Natomas GRR considers flood risk management for the Natomas Basin. The GRR will consider the existing flood risk reduction projects together as a system, with the purpose of developing analysis tools that consider the flood risk reduction system as a whole and identifying a comprehensive plan that will lower the flood risk in Sacramento. Accordingly, USACE, SAFCA, and the California Department of Water Resources (DWR) seek to integrate planning, design, and implementation of enhanced flood risk reduction measures within the Natomas Basin study area.

The Natomas GRR will ultimately be incorporated into a larger and more broadly scoped investigation called the American River Common Features Project (Common Features Project) GRR. The Common Features Project GRR will consider the Sacramento River downstream of the American River to Freeport where Beach Lake levee forms the southern flank of the City of Sacramento's flood defenses. It should be noted that there are three basins in the GRR analysis that will be considered in the future: the American River-North Basin, Natomas Basin, and

the Greater Sacramento Basin located south of the American River. However, only the Natomas Basin is the subject of this EIS/EIR.

The Natomas GRR schedule has been accelerated due to the risk of levee failure in the Natomas Basin. The accelerated schedule will allow USACE to begin construction in 2011 and reduce the risk of flooding and billions of dollars of property damage in the Natomas Basin.

The EIS/EIR will summarize the NLIP project phases already completed by SAFCA and how the NLIP relates to USACE's Natomas Basin GRR and PACR. The EIS/EIR will be used for Natomas Basin GRR approval, for preparation of the Natomas PACR, and to support implementation of the Phase 4b Project. USACE plans to implement the Phase 4b Project. In the event the Natomas PACR is not approved by Congress, however, the EIS/EIR will support SAFCA's implementation of the Phase 4b Project should SAFCA choose to proceed without Federal participation.

RELATIONSHIP TO THE NATOMAS LEVEE IMPROVEMENT PROGRAM

The Phase 4b Project is a subphase of one of the four project phases of the NLIP Landside Improvements Project. The overall purpose of the NLIP is to bring the entire 42-mile Natomas Basin perimeter levee system into compliance with applicable Federal and state standards for levees protecting urban areas. The NLIP was first evaluated in SAFCA's programmatic *EIR on Local Funding Mechanisms for Comprehensive Flood Control Improvements for the Sacramento Area* (State Clearinghouse No. 2006072098). Volume II of that EIR contained a project-level evaluation of the Natomas Cross Canal South Levee Phase 1 Improvements (Phase 1 Project).

In 2007, SAFCA prepared the *EIR on the NLIP Landside Improvements Project* (Phase 2 EIR, State Clearinghouse No. 2007062016), which covers the three additional phases of "landside" improvements to the levees protecting the Natomas Basin, including the Phase 2 Project, Phase 3 Project, and Phase 4 Project. The Phase 2 Project was analyzed at a project-level and the remainder of the Landside Improvements Project (Phase 3 and 4 Projects) was analyzed at a program-level in the Phase 2 EIR. On November 29, 2007, the SAFCA Board of Directors certified the EIR and approved the Phase 2 Project. Following completion of the Phase 2 EIR, USACE prepared an EIS to meet USACE's NEPA requirements to support USACE's decisions on the permissions and permitting under Sections 408, 404, and 10. A record of decision (ROD) was signed by USACE in January 2009. The Phase 2 EIS also contained a project-level analysis of the Phase 2 Project and a program-level analysis of the Phase 3 and 4 Projects. Since certification of the Phase 2 EIR, SAFCA made modifications and refinements to the design of the Phase 2 Project. A supplemental EIR (SEIR) was prepared by SAFCA to evaluate these modifications, which the SAFCA Board of Directors certified in January 2009, at which time the Board also approved the modifications to the Phase 2 Project.

The Phase 3 Project was analyzed at a project-level in the *DEIS/DEIR on the NLIP Phase 3 Landside Improvements Project* (Phase 3 DEIS/DEIR, State Clearinghouse No. 2008072060), which was released for public review on February 13, 2009. Following public review, SAFCA prepared an FEIR to provide responses to comments on the Phase 3 DEIS/DEIR. The SAFCA Board of Directors certified the FEIR and approved the Phase 3 Project in May 2009. Separately, USACE prepared an FEIS to provide responses to comments received on the Phase 3 DEIS/DEIR; the Phase 3 FEIS was issued for public review in August 2009. After consideration of all comments received, USACE will consider whether to grant Section 408 permission, which will be documented in a ROD, in December 2009/January 2010. To construct the Phase 3 Project with minimal interruption of and conflict with drainage/irrigation services and special-status wildlife habitat (giant garter snake), some Phase 3 Project components (canal work, utility relocation, vegetation removal, and demolition of structures) need to be constructed in late 2009 and early 2010 in advance of the Phase 3 Project's major levee construction, which would begin in 2010. To facilitate this staged construction, a staged permitting approach was implemented for the Phase 3 Project. Specifically, irrigation and drainage infrastructure (termed the Phase 3a Project) was permitted by USACE and the Central Valley Regional Water Quality Control Board (Central Valley RWQCB) under Sections 404 and 401, respectively, of the Clean Water Act, in October 2009; this work would occur in late 2009

and early 2010, in advance of Phase 3 Project levee construction. Some vegetation removal also would occur during the non-nesting season for raptors and other bird species. A separate, but related, set of permits for the Phase 3 Project's Sacramento River east levee construction and related pumping plant improvements (termed the Phase 3b Project) is anticipated in late 2009; this work would occur in 2010 and 2011. The potential exists for up to 30% of the Phase 2 Project also to be constructed in 2010, concurrent with Phase 3 Project construction, or even potentially concurrently with the Phase 4a Project, depending on the timing and availability of funding and receipt of all required environmental clearances and permits.

The Phase 4 Project consists of two subphases (4a and 4b) to provide the flexibility to construct this phase over more than one construction season. The Phase 4 Project was analyzed at a program-level in the Phase 2 EIR. Each subphase has its own independent utility, can be accomplished with or without the other subphase, and provides additional flood risk reduction benefits to the Natomas Basin whether implemented individually or collectively. The Phase 4a Project was analyzed at a project-level in the *DEIS/DEIR on the NLIP Phase 4a Landside Improvements Project* (Phase 4a DEIS/DEIR, State Clearinghouse No. 2009032097), which was released for public review on August 28, 2009. Similar to the Phase 3 Project, USACE and SAFCA are preparing a separate FEIS and FEIR, respectively. The SAFCA Board of Directors will consider certification of the EIR and Phase 3 Project approval at its November 13, 2009 Board meeting. Separately, USACE will prepare an FEIS and issue it for a 30-day public review in early 2010. Phase 4a Project construction is planned to begin in 2010 and is anticipated to be completed in 2011, assuming receipt of all required environmental clearances and permits.

PROJECT OBJECTIVES OF THE NATOMAS LEVEE IMPROVEMENT PROGRAM

The following objectives were adopted by SAFCA in connection with the NLIP: (1) provide at least a 100-year level of flood risk reduction (0.01 Annual Exceedance Probability [AEP]) to the Natomas Basin as quickly as possible, (2) provide 200-year flood risk reduction to the Basin over time (0.005 AEP), and (3) avoid any substantial increase in expected annual damages as new development occurs in the Basin. The first two project objectives would reduce the residual risk of flooding sufficiently to meet the minimum requirements of Federal and state law for urban areas like the Natomas Basin. The third project objective is a long-term objective of SAFCA's.

Additional project objectives that have informed SAFCA's project design are to: (1) use flood damage reduction projects in the vicinity of the Sacramento International Airport (Airport) to facilitate management of Airport lands in accordance with the Airport's *Wildlife Hazard Management Plan* (Sacramento County Airport System [SCAS] 2007); and (2) use flood damage reduction projects to increase the extent and connectivity of the lands in the Natomas Basin being managed to provide habitat for giant garter snake, Swainson's hawk, and other special-status species.

PROPOSED PHASE 4b PROJECT

The Phase 4b Project would address underseepage, stability, erosion, penetrations, and levee encroachments along approximately 3.4 miles of the Sacramento River east levee in Reaches 16–20, approximately 6.4 miles of the Natomas East Main Drainage Canal (NEMDC) west levee between Elkhorn Boulevard and Sankey Road, and the windows left in the improvements done by the of previous phases at levee penetrations and road crossings on Natomas Cross Canal (NCC) south levee. The Phase 4b Project would also include relocation of the existing irrigation and drainage canals landside of the levee slopes, relocation and modifications of the pumping stations, bridges, encroachments, and any penetrations of the levee embankment. Removal of the vegetation within the levee right-of-way to address USACE requirements and any environmental mitigation are also included in the Phase 4b Project.

The Phase 4b Project includes the following major activities anticipated to begin in spring 2011, which will be analyzed at a project-level in the Phase 4b EIS/EIR:

- **Sacramento River East Levee Reaches 16–20: Levee widening/rehabilitation and seepage remediation**—Construct an adjacent levee with flattened landside slope and cutoff walls, seepage berms, and relief wells, where required, to reduce potential underseepage and seepage through the levee. Cutoff wall construction would be conducted 24 hours per day, 7 days per week (24/7).

- **American River North Levee Reaches 1–4: Slope flattening and seepage remediation**—Flatten the slope and install cutoff walls in the American River north levee from just east of Gateway Oaks Drive to Northgate Boulevard. Cutoff wall construction would be conducted 24/7.

- **NEMDC West Levee—Northern Segment: Levee raising, slope flattening, and seepage remediation**—Raise the levee in place or construct an adjacent levee, flatten slopes, and install cutoff walls from Sankey Road to just south of Elkhorn Boulevard. Cutoff wall construction would be conducted 24/7.

- **Pleasant Grove Creek Canal (PGCC) and NEMDC South: Levee raising and slope flattening**—Raise the levee in place or construct an adjacent levee and flatten slopes on the PGCC southwest levee and on the NEMDC southwest levee from Elkhorn Boulevard to Northgate Boulevard.

- **PGCC and NEMDC South: Waterside improvements**—Erosion repair and rock slope protection at locations where erosion around the outfall structures penetrating the levee was observed. Construct additional remediation to protect against damage caused by beavers and burrowing animals.

- **PGCC Culvert Remediation**—Upgrade or remove five culverts that currently drain the area east of the PGCC by passing water under the canal to canals along the landside of the PGCC southwest levee. Under the culvert removal option, construct detention basins east of the PGCC levee to provide replacement storage for drainage. Depending on the design of the detention basins, pumping stations may be needed to discharge water out of the basins and into the PGCC.

- **State Route (SR) 99 NCC Bridge Remediation**—Construct a moveable barrier system or a stop log gap at the south end of the SR 99 bridges to be used at high river stages to prevent overflow from reaching the landside of the NCC south levee. Modify the bridge deck connections to the supporting piers and abutments as needed to resist uplift pressure during high water stages. Install additional seepage remediation consisting of seepage cutoff walls where the bridges cross the NCC south levee.

- **West Drainage Canal**—Realign the West Drainage Canal to shift an approximately 1-mile portion, starting at Interstate 5 (I-5), to an alignment farther south of the Airport Operations Area. Modify the existing canal east of the alignment to reduce bank erosion and sloughing, decrease aquatic weed infiltration, improve Reclamation District (RD) 1000 maintenance access, and enhance giant garter snake habitat connectivity.

- **Riego Road Canal (Highline Irrigation Canal) Relocation**—Relocate approximately 4,000 feet of irrigation canal, approximately 250 feet of buried irrigation piping, and three irrigation turn-out structures away from the proposed levee footprint for the northern segment of the NEMDC west levee.

- **NCC South Levee Ditch Relocations**—Relocate the Vestal Drain ditch and Morrison Canal to reduce underseepage potential in Reaches 2, 5, and 6 of the NCC south levee.

- **Modifications to RD 1000 Pumping Plants**—Raise and/or replace the discharge pipes for Pumping Plant Nos. 1A and 1B along the Sacramento River east levee, and Pumping Plant Nos. 6 and 8 along the NEMDC west levee, to cross the levee above the 0.005 AEP design water surface elevation. Construct new outfall structures for Pumping Plant Nos. 6 and 8, requiring dewatering of portions of the NEMDC. Construction would be conducted 24/7.

- **Modifications to City of Sacramento Sump Pumps**—Raise and/or replace the discharge pipes for City Sump 160 (Sacramento River east levee Reach 19B), City Sump 58 (American River north levee), and City Sump 102 (NEMDC west levee at Gardenland Park) to cross the levee above the 0.005 AEP design water surface elevation. Construct new outfall structures, requiring dewatering of portions of the Sacramento River, the low-flow channel of the NEMDC along the waterside of the American River north levee, and the NEMDC. Relocate pump stations as needed to accommodate the proposed levee improvements. Construction would be conducted 24/7.

- **Borrow Site Excavation and Reclamation**—Excavate earthen material at the borrow sites and then return the sites to preconstruction uses or suitable replacement habitat. For levee improvements along the Sacramento River east levee (Reaches 16–20) and the American River north levee (Reaches 1–4), the South Fisherman's Lake Borrow Area and the West Lakeside School Site (**Exhibit 2**) are anticipated to be the primary source of soil borrow material. The Triangle Properties Borrow Area (**Exhibit 3**) would be the primary source of borrow material for levee improvements along the PGCC and NEMDC North. The South Fisherman's Lake Borrow Area, the West Lakeside School Site, and the Triangle Properties Borrow Area Areas will be fully analyzed in the EIS/EIR.

  The Fisherman's Lake Borrow Area, which was fully analyzed in the Phase 4a DEIS/DEIR, could provide additional borrow material for the Phase 4b Project. The Krumenacher borrow site and Twin Rivers Unified School District stockpile site (**Exhibit 2**), which were fully analyzed in the Phase 3 DEIS/DEIR and Phase 4a DEIS/DEIR, would be the source of borrow material for improvements to NEMDC South and back-up sources for NEMDC North.

- **Habitat Creation and Management**—Enhance connectivity between northern and southern populations of giant garter snake in the Natomas Basin by improving habitat conditions along the West Drainage Canal, and establish woodlands consisting of native riparian and woodland species in or around the Natomas Basin as compensation for woodland impacts along the Sacramento River east levee (Reaches 16–20), American River north levee, and NEMDC west levee.

- **Infrastructure Relocation and Realignment**—Relocate and realign private irrigation and drainage infrastructure (wells, pumps, canals, and pipes), and relocate utility infrastructure (power poles) as needed to accommodate the levee improvements and canal relocations.

- **Landside Vegetation Removal**—In Reaches 16–20 of the Sacramento River east levee, in Reaches 1–4 of the American River north levee, and in NEMDC South, clear landside vegetation to prepare for Phase 4b Project levee and canal improvement work.

- **Waterside Vegetation Removal**—Waterside vegetation would be removed due to modifications to pumping plants along the Sacramento River east levee, NEMDC west levee, and PGCC southwest levee.

- **Bank Protection**: **Sacramento River Left Bank**—Because the adjacent levee would be constructed in Sacramento River east levee Reaches 1–20 under the NLIP, no erosion protection is needed along the left bank of the Sacramento River. The distance from the projected levee slope of the new adjacent levee to the current bank location is sufficient to guarantee that bank erosion would not intrude into the projected levee slope in the near future. Bank protection would be constructed along the PGCC and NEMDC South to address the waterside erosion sites noted above.

- **American River Common Features Project**—Upgrade levees at locations along the American River upstream of Northgate Boulevard, including raising and/or reshaping levee sections and installing cutoff walls.

- **Right-of-Way Acquisition**—Acquire lands within the Phase 4b Project footprint along the Sacramento River east levee, American River north levee, NEMDC west levee, and at associated borrow sites.

- **Encroachment Management**—Remove encroachments as required to meet the criteria of USACE, CVFPB, and Federal Emergency Management Agency (FEMA). SAFCA would be required to submit a variance request to CVFPB, and then ultimately to USACE, requesting confirmation that SAFCA's adjacent levee design for the Sacramento River east levee and American River north levee sufficiently addresses USACE's guidance regarding vegetation on levees, if SAFCA chooses to implement the project without Federal participation.

The following additional project details are associated with the Phase 4b Project.

- **Cutoff Walls.** Three-foot-wide cutoff walls made of either soil-bentonite (SB), cement bentonite (CB), or soil-cement-bentonite (SCB) would be installed either through the existing levee or along the landside toe of the existing levee. Depending on the construction method used, the top of the cutoff walls would be at least 10 feet above the existing ground surface at the landside toe of the levee (within either the new adjacent setback levee) or in the existing levee, and extend up to a depth of 110 feet below ground surface in some areas. Locations and depths would be determined during final engineering design. The total linear extent would be approximately 17,700 feet along the Sacramento River east levee Reaches 16–20;approximately 9,400 feet along the American River north levee, and 35,700 feet along the NEMDC north west levee. Cutoff wall construction would be conducted 24/7.

- **Seepage Berms.** Sacramento River east levee seepage berm widths would extend up to 100 feet from the adjacent levee landside levee toe in Reaches 17–18, up to 250 feet from the adjacent levee landside levee toe in Reach 19A, and up to 300 feet from the adjacent levee landside toe in Reach 16. Depending upon the width, maximum thickness would be 6–7 feet. All berms would gradually slope downward to about 4 feet thick at the landside edge, with a 3H:1V slope to ground level. A gravel surface patrol road would be constructed near the outside edge of the seepage berm. Final locations of the seepage berms would be determined during final engineering design.

- **Relief Wells.** Sacramento River east levee relief wells would be constructed at selected locations where berms cannot be wide enough or walls deep enough to meet the required seepage remediation design parameters. Relief wells would also be constructed along some of the entrance channels to the landside pump stations. Relief wells would be spaced between 60–100 feet apart and would extend to depths of between 60–80 feet below the ground surface.

- **Measures to Reduce Impacts to Residences, Businesses, and Heritage Oaks.** Where residences, businesses, and heritage oak trees are located, measures would be employed to reduce the project footprint impacts to these resources, to the extent feasible given levee design and seepage remediation performance requirements. These measures could include reducing the width of the adjacent levee, seepage berms, and operations and maintenance access and utility corridors; and strategically using cutoff walls or seepage relief wells.

- **Power Pole Relocation.** Power poles that currently exist on the landside slope of the levee and at the landside levee toe would need to be relocated and/or rerouted to accommodate the widened levee footprint. To the extent feasible, mainline utility infrastructure, such as power poles, would be relocated beyond the landside levee toe. Some poles may need to be relocated to the waterside of the existing levee. No power poles would be relocated within the new levee prism. Tree pruning would likely be required in some locations to accommodate the power pole relocation and associated wires. SAFCA would conduct the relocations in coordination with the appropriate utility companies and the construction operations.

- **Removal or Modification of Landside Structures and Other Facilities.** Multiple residential and agricultural structures are located within the footprint of the levee improvements. These structures, and the facilities supporting them, would have to be modified, removed, or relocated out of the project footprint before the start of levee construction in those areas. Irrigation facility conveyance, distribution boxes, wells,

and standpipes within the footprint of the project features would be demolished and replaced as needed. Debris from structure demolition, power poles, utility lines, piping, and other materials requiring disposal would be hauled off-site to a suitable landfill. Demolished concrete could be sent to a concrete recycling facility. Wells and septic systems would be abandoned in accordance with the applicable state and county requirements. Drilling and development pumping of replacement wells would be conducted 24/7.

- **Garden Highway Closures.** Because of space constraints, in Sacramento River east levee Reaches 19B–20, the landside lane of Garden Highway would be closed for up to 6 months to allow for construction of a cutoff wall. In addition, because there would be no room for a two-way haul route at the toe of the existing levee, the waterside lane of Garden Highway would be used by haul trucks delivering materials. This lane would only be open to local traffic, with use of traffic controls. For levee improvements along the American River north levee, the Garden Highway/Arden-Garden Connector would be completely closed for up to 6 months between I-5 and Northgate Boulevard. Through traffic would be detoured to West El Camino Avenue, SR 160, and Richards Boulevard. Garden Highway would be closed at several locations, including City of Sacramento Pump 160 and RD 1000 Pumping Plant Nos. 1A and 1B, to allow for installation of pipes that need to be raised above the 0.005 AEP water surface profile.

- **Reconstruction of Intersections.** Garden Highway intersections at Natomas Park Drive, Truxel Road, Northgate Boulevard, and four additional ramps at private parcels would require degrading, rebuilding the embankment, and repaving to accommodate the installation of the American River north levee cutoff wall and levee slope flattening. Garden Highway intersections at Orchard Lane, Gateway Oaks Drive, and several additional ramps at private parcels would require degrading, rebuilding the embankment, and repaving to accommodate the installation of the Sacramento River east levee cutoff wall and levee slope flattening. The ramps would be reconstructed to the current general ramp and intersection geometry. The design would meet Sacramento County or City of Sacramento roadway design criteria, depending upon the jurisdiction. Where alternate access to the private properties is available, the private ramps would be removed and not replaced.

- **West Drainage Canal Realignment.** The proposed new alignment would abandon and reroute approximately 4,700 feet of the West Drainage Canal. The typical cross-section for the modified West Drainage Canal would require a right-of-way of up to 150 feet for approximately 1.2 miles. The realigned section of the canal would have a 30-foot bottom width, stable 3H:1V bank slopes on one or both sides, and a narrow, variable width bench on one side of the canal. A 20-foot-wide maintenance and inspection road would flank each side of the canal and would be slightly elevated above adjacent land to improve an all-weather road condition. Culverts would cross under the patrol road to allow continued drainage into the canal from adjacent fields. The realignment would include rerouting of a small section of the West Drainage Canal (starting at the M10 Drain south of I-5 which leads to RD 1000's Pumping Plant No. 5) to a north-south orientation to improve the management of adjacent agricultural parcels, and to move the canal farther from the Airport Operations Area in the vicinity of the west runway.

- **Riego Road Canal Relocation.** A portion of an irrigation canal owned by the Natomas Central Mutual Water Company (NCMWC) would be relocated to make room for the proposed improvements to the west levee of NEMDC North. The affected portion includes approximately 4,000 feet of irrigation canal, approximately 250 feet of buried irrigation piping, and three irrigation control turn-out structures. These facilities would be relocated outside of the levee footprint as part of the Phase 4b Project. To prevent disruptions, the NCMWC irrigation system would be replaced with in-kind facilities compatible with the new levee footprint to prevent disruption of irrigation service. The new canal would be a highline canal with 3H:1V side slopes and a maintenance road on each of the embankments. A right-of-way of up to 100-feet beyond the new levee footprint would be required for the new facility.

- **Natomas Levee Recreational Trail Project.** As part of the Phase 4b Project, a regional Class I (completely separated from traffic) bicycle and pedestrian trail is proposed to be constructed in an approximately 42-mile loop along the Natomas Basin levee perimeter in the northwestern portion of the City and County of

Sacramento and the southern portion of Sutter County. The exact alignment of the recreational trail, in terms of its placement in relation to levees and roadways, would be determined through detailed engineering design. Construction, operation, and maintenance of a recreation trail on the perimeter levee system would require a CVFPB encroachment permit with an endorsement by RD 1000. The proposed recreational trail is intended to provide a bicycle commuter route at the southern and eastern end of the Natomas Basin that would connect to the regional American River trail system.

ALTERNATIVES TO THE PROPOSED PHASE 4b PROJECT

Because the EIS/EIR will be a joint NEPA/CEQA document, it will fully evaluate the environmental impacts of the Phase 4b Project and the following two alternatives at an equal level of detail:

No-Action Alternative (No-Project Alternative for purposes of CEQA)—Under NEPA, the expected future without-project conditions; under CEQA, the existing condition at the time this NOP was published (November 5, 2009), as well as what would be reasonably expected to occur in the foreseeable future if the Phase 4b Project were not approved. The No-Action Alternative consists of two scenarios:

- **No Project Construction**—The No-Action Alternative consists of the conditions that would likely prevail in the Natomas Basin if no action at all were taken by SAFCA, the State, or USACE to further improve the Basin's perimeter levee system beyond the accomplishments of the Sacramento Urban Levee Reconstruction Project; the North Area Local Project; and the NLIP Phase 1, 2, 3, and 4a Projects. Under this scenario, key segments of this system would continue to provide less than 100-year flood risk reduction, and the entire Natomas Basin would be permanently designated as a special flood hazard area subject to development restrictions and mandatory flood insurance requirements pursuant to the regulations of the National Flood Insurance Program. SAFCA would not provide the Natomas Basin with at least a .01 AEP risk reduction by the end of 2010 and would not be able to facilitate achieving a 0.005 AEP risk reduction by the end of 2012.

- **Potential Levee Failure**—The same conditions with respect to development within the Natomas Basin as described above for the No Project Construction scenario would exist for the Potential Levee Failure scenario. Without additional improvements to the Natomas Basin perimeter levee system, wind and wave run-up or seepage conditions could cause portions of this system to fail, triggering widespread flooding and extensive damage to the Basin's existing residential, commercial, agricultural, and industrial structures. Extensive damage to utilities, roadways, and other infrastructure systems would also likely occur. The magnitude of the flood damage would depend upon the location of the levee breach, severity of the storm, and river flows at the time of a potential levee failure.

Fix-in-Place Alternative—All elements of the Fix-in-Place Alternative would be the same as described for the Proposed Action, except for the method of raising and rehabilitating the Sacramento River east levee, the extent of levee degradation and road closures required to construct cutoff walls, and the extent of encroachment removal along the levee. Differences from the Proposed Action are shown in italicized text below.

- **Sacramento River East Levee Reaches 16–20: Levee widening/rehabilitation and seepage remediation**—Upgrade levee in place with cutoff walls, seepage berms, and relief wells, where required, to reduce seepage potential. Cutoff wall construction would be conducted 24/7.

- **Landside Vegetation Removal**—Same as the Proposed Action*, except maximum extent of removal would likely be reduced.*

- **Waterside Vegetation Removal**—*In Reaches 16–20 of the Sacramento River east levee and Reaches 1–4 of the American River north levee, clear waterside vegetation to meet USACE vegetation guidance criteria. It is estimated that the numbers of acres of shaded riverine aquatic (SRA) habitat lost would be greater.* Same as Proposed Action for modifications to RD 1000 pump stations.

- **Encroachment Management**—Same as the Proposed Action, *except maximum extent of removal would likely be increased. SAFCA would not be eligible to request a variance and would need to fully comply with USACE's levee vegetation requirements.*

Alternatives that have already been addressed in previous environmental documents for the NLIP will be briefly summarized in the EIS/EIR for the Phase 4b Project and incorporated by reference. These alternatives include the following:

- Yolo Bypass Improvements;
- Reduced Natomas Urban Levee Perimeter;
- Construction of a New Setback Levee;
- Raise Levee in Place with a 1,000-Foot Levee Setback in the Upper 1.4 Miles along the Sacramento River East Levee;
- Construct an Adjacent Setback Levee with a 500-Foot Levee Setback in the Upper 1.4 Miles along the Sacramento River East Levee;
- No SAFCA Levee Improvements—Private Levees in Natomas;
- Natomas .01 AEP Flood Risk Reduction;
- No-Action Alternative—Airport Compartment Levee; and
- Cultural Resources Impact Reduction Alternative.

PROBABLE ENVIRONMENTAL IMPACTS OF THE PROPOSED PHASE 4b PROJECT

The EIS/EIR will describe the direct and indirect significant environmental impacts of the Phase 4b Project. The EIS/EIR will also evaluate the cumulative impacts of the project when considered in conjunction with the other phases of the Landside Improvements Project and other related past, present, and reasonably foreseeable future projects, including other USACE (408 permission) and SAFCA projects.

On the basis of programmatic environmental analyses of the Phase 4b Project in previous NEPA and CEQA documents and relevant environmental analyses of previous project phases, USACE and SAFCA have determined that the probable environmental effects of the Phase 4b Project are as follows:

- **Agricultural Resources:** Conversion of Important Farmland to nonagricultural use; temporary and permanent effects on agricultural productivity; and conflicts with lands under Williamson Act contracts.
- **Land Use, Socioeconomics, and Population and Housing:** Inconsistency with adopted land use plans and the Natomas Basin Habitat Conservation Plan; temporary disturbance and division of an existing community and temporary disruption of commercial activities during construction; potential displacement of existing housing, especially affordable housing; potential reduction in local or regional employment; and other potential socioeconomic impacts, the analysis of which is required by NEPA.
- **Geology, Soils, and Mineral Resources:** Potential soil erosion or loss of topsoil during construction; and potential loss of mineral resources.
- **Hydrology and Hydraulics:** Minimized flood risk; potential temporary and/or permanent alteration of local drainage patterns; potential effects on groundwater recharge.

- **Water Quality:** Temporary effects on water quality during construction.

- **Biological Resources:** Temporary disturbance or permanent loss of woodland habitats and wildlife corridors; temporary disturbance or permanent loss of jurisdictional waters of the United States; temporary disturbance or permanent loss of special-status plant species; temporary disturbance or permanent loss of special-status species habitats; construction disturbance or take of special-status terrestrial species, especially Swainson's hawk and giant garter snake; loss of fish or aquatic habitat through increased sedimentation and turbidity or release of contaminants during construction; and loss of SRA habitat.

- **Cultural Resources:** Temporary and/or permanent disturbance of known and unknown historic or archaeological resources.

- **Paleontological Resources:** Potential disturbance of unknown unique paleontological resources during earthmoving activities.

- **Transportation and Circulation:** Temporary increase in traffic and traffic hazards on local roadways during construction, including hauling; temporary closure of roadways, including full and partial closure of sections of Garden Highway and connecting ramps throughout the 6-month construction season; and temporary disruption of emergency service response times and access.

- **Air Quality:** Temporary and short-term increases in pollutant emissions associated with construction activities, including the potential overlap in construction of portions of the Phase 2, 3, and 4a Projects with the Phase 4b Project; and long-term increases in pollutant emissions.

- **Noise:** Temporary and short-term increases in noise and vibration levels near sensitive receptors during construction, including the need for 24/7 construction for cutoff walls and 24/7 construction associated with relocating wells away from the levee.

- **Recreation:** Addition of a new recreation trail on the improved Natomas Basin levee perimeter system; and potential construction-related closures of/impacts to recreational facilities in the project area.

- **Visual Resources:** Temporary and long-term changes in scenic views or visual character of the project area from the construction of project features and tree/vegetation removal and replanting.

- **Utilities and Service Systems:** Temporary disruption of irrigation supply; potential disruption of utility service from construction activities and from the relocation of power poles.

- **Hazards and Hazardous Materials:** Potential spills of hazardous materials during construction; potential exposure to hazardous materials at project sites during construction; potential for higher frequency of collisions between aircraft and wildlife at the Airport during construction and as a result of permanent changes in land cover; and increased exposure to wildland fire risk during construction.

- **Environmental Justice:** Potential for disproportionately high and adverse effects on minority or low income populations, including Tribal populations, the analysis of which is required by NEPA.

- **Cumulative and Growth-Inducing Impacts:** Potential cumulatively considerable incremental contributions from Phase 4b Project impacts in the areas of agricultural resources, water quality, fisheries, biological resources, cultural resources, air quality (including temporary and short-term generation of greenhouse gas emissions [CO_2] from project construction), noise, and visual resources; potential growth-inducing impacts from construction of the NLIP, including substantial new permanent employment opportunities, substantial short-term employment opportunities, and removal of an obstacle to additional growth and development in the Natomas Basin.

PUBLIC SCOPING MEETING

A joint EIS/EIR public scoping meeting, conducted by USACE and SAFCA, will be held during the 30-day NOP public review period to inform interested parties about the proposed project, and to provide agencies and the public with an opportunity to provide comments on the scope and content of the EIS/EIR. The joint scoping meeting will satisfy the meeting requirement for projects of statewide, regional, or areawide significance (see State CEQA Guidelines CCR Section 15082 [c]).

The meeting will be held on November 18, 2009, from 4:30 to 6:30 p.m., at 2921 Truxel Road (South Natomas Community Center) in Sacramento, California and will have an open-house format with multiple stations set up to highlight different aspects of the proposed project and the NEPA/CEQA process. Attendees will have the opportunity to ask questions and discuss the project and the EIS/EIR process with project team members and to provide oral and written comments. The meeting space is accessible to persons with disabilities and a court reporter will be available. Individuals needing special assistive devices will be accommodated to the best of SAFCA's ability. For more information, please contact John Bassett, SAFCA Director of Engineering, at least 48 hours before the meeting (contact information is provided below).

PROVIDING COMMENTS ON THE NOTICE OF PREPARATION

Interested parties may provide written or oral comments on the proposed content and scope of the EIS/EIR at the public scoping meeting or may provide written comments directly to SAFCA. **Written comments on the NOP must be provided to SAFCA at the earliest possible date, but must be received no later than 5 p.m. on Friday, December 4, 2009.** Agencies that will need to use the EIS/EIR when considering permits or other approvals for the proposed project should provide the name of a contact person. Comments provided by e-mail should include the name and address of the sender and include "Natomas PACR/NLIP Phase 4b Project NOP Scoping Comment" in the subject line. Please send all written and/or e-mail comments on the NOP to:

Subject: Scoping Comments on Environmental Impact Statement/Environmental Impact Report for Natomas Levee Improvement Program, Phase 4 (b), Landside Improvements Project

Dear Mr. Bassett:

The Federal Aviation Administration (FAA) is providing scoping comments on the environmental issues to be addressed in the joint Environmental Impact Statement/Environmental Impact Report (EIS/EIR) for the Natomas Levee Improvement Program (NLIP), Phase 4 (b), as requested in the Sacramento Area Flood Control Agency (SAFCA) Notice of Preparation dated November 5, 2009.

The FAA, through the Airport Improvement Program, has provided federal funds for various aviation development activities at the Sacramento International Airport. The proposed flood protection improvements would increase protection of these developments for which federal funds have been expended.

Sacramento International Airport is a certificated airport under 14 Code of Federal Regulations (CFR) Part 139 of the FAA's regulations. As a result of prior FAA 14 CFR 139 inspections at Sacramento International Airport, the airport is required to maintain and implement a Wildlife Hazard Management Plan. The Wildlife Hazard Management Plan represents an ongoing effort by the Sacramento County Airport System to reduce wildlife-aircraft strike hazards and habitat attracting wildlife hazardous to aircraft operations at Sacramento International Airport.

The proposed NLIP, Phase 4 (b), project, if inappropriately designed, could replace existing vegetation and wildlife habitat with vegetation, wetlands or open water habitats that could attract wildlife hazardous to aviation and increase wildlife-aircraft collision strikes at Sacramento International Airport. FAA Advisory Circular (AC) 150/5200-33B, *Hazardous Wildlife Attractants on or Near Airports*, recommends a separation distance of 10,000 feet between airports serving turbine-powered (jet) aircraft and habitats that can attract wildlife hazardous to aircraft, and recommends a separation distance of 5 miles between hazardous wildlife attractants and the edge of an airport's Area of Operations if the attractant could cause hazardous wildlife movement into or across the approach or departure airspace.

The EIS/EIR should analyze whether the proposed flood control improvements and mitigation measures associated with those improvements are consistent with the guidelines in FAA AC 150/5200-33B, whether the proposed project would increase the amount of habitat available for wildlife hazardous to aircraft, whether the project is likely to increase the potential of hazardous wildlife to move into or across approach or departure airspace of Sacramento International Airport, and whether the proposed project would be likely to increase the risk of wildlife-aircraft collisions at Sacramento International Airport. The FAA recommends that the EIS/EIR interdisciplinary team conducting this analysis include a wildlife biologist meeting the requirements of FAA AC 150/5200-36 *Qualifications for Wildlife Biologists Conducting Wildlife Hazard Assessments,* dated June 28, 2006

The FAA is particularly concerned that if the existing elevation of the I-5 Borrow Area or Fisherman's Lake Borrow Areas is reduced by the removal of soil that these areas could become stormwater retention basins, wetlands or open waters that would attract hazardous wildlife such as ducks, geese, or other waterbirds, that have a high potential for wildlife-aircraft collisions. We recommend that SAFCA and the Army Corps of Engineers consult the Department of Transportation FAA/Department of Defense AC 150/5320-5C, *Surface Drainage Design*, regarding the appropriate sizing of drainage facilities on or near airports. Typical airport drainage facilities are generally those that drain completely within 24 to 48 hours after a 5 or 10-year storm event.

The EIS/EIR should describe the proposed future vegetation/habitats of the I-5 and Fisherman's Lake Borrow Areas under each alternative and analyze whether the vegetation is likely attract hazardous wildlife and/or result in an increase in wildlife-aircraft collisions at Sacramento International Airport. In additional to wetland vegetation and open water areas, agricultural crops such as rice, grain crops, irrigated alfalfa, or sunflowers could also make the Borrow Areas more attractive to hazardous wildlife. Unirrigated, annual grassland habitat would typically be less attractive to hazardous wildlife in this area.

The FAA recommends that the EIS/EIR select an alternative that including managing vegetation on NLIP areas within 10,000 feet of Sacramento International Airport so as to minimize its attractiveness to hazardous wildlife and minimize the potential for wildlife-aircraft collisions. We also recommend that SAFCA and Army Corps of Engineers contact the Sacramento County Airport System regarding the County's efforts to minimize the attractiveness of Sacramento International Airport to wildlife potentially hazardous to aircraft.

Vegetation changes that reduce the attractiveness of the Borrow Areas for hazardous wildlife should be considered beneficial effects of the proposed project in terms of reducing the potential for wildlife-aircraft strike hazards. Also please note that the 2003 Memorandum of Agreement Between the Federal Aviation Administration, the U.S. Air Force, the U.S. Army, the U.S. Environmental Protection Agency, the U.S. Fish and Wildlife Service, and the U.S. Department of Agriculture to Address Aircraft-Wildlife Strikes addresses how these agencies, including the Army Corps of Engineers through the U.S. Army, are to consider and generally minimize wildlife-aircraft strike hazard issues while implementing their respective missions.

While the current proposal does not appear to propose use of airport property, please be advised that much of Sacramento International Airport is located on property acquired using a combination of Sacramento County and federal funds and the airport has received federal funding from various FAA Airport Improvement Program federal grants. If future actions to implement the proposed project require use of Sacramento International Airport property, one or more FAA approvals may also be required.

Please provide a paper copy and compact disk of the Draft EIS/EIR for this project when it is released for public review. Please contact FAA Environmental Protection Specialist Doug Pomeroy, telephone, 650-876-2778, extension 612, or e-mail Douglas.Pomeroy@faa.gov, if you have questions regarding this letter. The FAA documents mentioned in this letter are available on the FAA's public internet web site at www.faa.gov.

Sincerely,

Notice of Preparation

November 5, 2009

To: Reviewing Agencies

Re: Natomas Post-Authorization Change Report/Natomas Levee Improvement Program, Phase 4b Project
SCH# 2009112025

Attached for your review and comment is the Notice of Preparation (NOP) for the Natomas Post-Authorization Change Report/Natomas Levee Improvement Program, Phase 4b Project draft Environmental Impact Report (EIR).

Responsible agencies must transmit their comments on the scope and content of the NOP, focusing on specific information related to their own statutory responsibility, within 30 days of receipt of the NOP from the Lead Agency. This is a courtesy notice provided by the State Clearinghouse with a reminder for you to comment in a timely manner. We encourage other agencies to also respond to this notice and express their concerns early in the environmental review process.

Please direct your comments to:

John Bassett
Sacramento Area Flood Control Agency
1007 7th Street, 7th Floor
Sacramento, CA 95814

with a copy to the State Clearinghouse in the Office of Planning and Research. Please refer to the SCH number noted above in all correspondence concerning this project.

If you have any questions about the environmental document review process, please call the State Clearinghouse at (916) 445-0613.

Sincerely,

Scott Morgan
Acting Director

Document Details Report
State Clearinghouse Data Base

SCH# 2009112025
Project Title Natomas Post-Authorization Change Report/Natomas Levee Improvement Program, Phase 4b Project
Lead Agency Sacramento Area Flood Control Agency

Type NOP Notice of Preparation

Description The overall purpose of the Natomas Levee Improvement Program (NLIP) is to bring the entire 42-mile Natomas Basin perimeter levee system into compliance with applicable Federal and state standards for levees protecting urban areas. The Phase 4b - Project - a component of the NLIP - consists of improvements to a portion of the Natomas Basin's perimeter levee system and associated landscape, irrigation/drainage infrastructure modifications, and environmental mitigation, including habitat creation and management.

Mr. John Bassett, P.E., Director of Engineering
Sacramento Area Flood Control Agency
1007 7th Street, 7th Floor
Sacramento, CA 95814

Dear Mr. Bassett:

We have received the Notice of Preparation (NOP) regarding the proposed Natomas Post-Authorization Change Report/Natomas Levee Improvement Program, SCH #2009112025. Obviously, a project of this size and scope will have a significant impact on numerous roadways within Sacramento County. Of particular concern is the adverse effect this project will have on traffic utilizing Garden Highway and adjacent roadways. According to the NOP, traffic will be detoured onto West El Camino Avenue, Richards Boulevard, and State Route 160. Additionally, Interstate 80 may be impacted by the Garden Highway closures. These areas already experience high traffic volume which will be exacerbated by the detours.

While we realize the importance of sound levees, we also acknowledge the necessity to consider the influence of this major construction project on the motorists of the Sacramento area. Should you have any further questions regarding these issues, please contact myself or Lieutenant Deborah Pierce at (916) 338-6710.

Sincerely,

C. M. McGAGIN, Captain
Commander
North Sacramento Area

Sloatman, Lindsey

Subject: RE: NLIP EIS/EIR Phase 4(b) Scoping comment letter from FAA

Thanks, John. I got copied on this directly from Doug Pomeroy at FAA. We decided that it was necessary for SCAS to submit scoping comments. We had our new planner, Julie Car, look at our previous comments on the Phase 4a project in comparison to the Phase 4B project. Based on her review, we determined that SCAS had nothing new to add to what we've conveyed previously. –Greg Rowe

Julie: John Bassett is SAFCA's director of engineering, and Holly Gilchrist is the General Counsel (formerly with County Counsel). We have an excellent working relationship with SAFCA. –GR

SUBJECT: COMMENTS ON THE NOTICE OF PREPARATION (NOP) OF A DRAFT ENVIRONMENTAL IMPACT STATEMENT (EIS)/ENVIRONMENTAL IMPACT REPORT (EIR) ON THE POST-AUTHORIZATION CHANGE REPORT/NATOMAS LEVEE IMPROVEMENT PROGRAM PHASE 4B LANDSIDE IMPROVEMENTS PROJECT.

Dear Mr. Bassett:

The Sacramento County Department of Transportation (SACDOT) has reviewed the NOP for the above referenced project, dated November 5, 2009. We appreciate the opportunity to review this document and have the following comments to offer:

- The project proposes truck haul routes to access borrow and levee improvement sites via the County's rural roadways. As shown in Exhibit 2 – Phase 4b Construction Areas (Southern Portion), the potential on-road haul routes are Del Paso Road, Power Line Road, El Centro Road and San Juan Road. The project would add significant amounts of truck traffic to these rural roads and would result in an impact to the existing pavement structure. Typically, rural area pavement sections were designed to carry low traffic volumes. The project construction truck traffic would shorten the life of the pavement section and possibly result in damage to these roadways. We would ask that the project proponent enter into a maintenance agreement with the Maintenance and Operations Section of SACDOT. This agreement shall cover the maintenance and repair of any roadway damaged by the project's construction activities.

- The proposed roadway closure and detour plans shall be coordinated with SACDOT staff.

- The project would result in a change of geometrics at the side street intersections with the Garden Highway. These roadways include Power Line Road and San Juan Road. The project proponent shall coordinate the proposed improvement plans with SACDOT staff.

- Power pole relocation shall be coordinated with SMUD and SACDOT to avoid conflicts with the intended bike/pedestrian path.

We would like to extend our sincere thanks to SAFCA staff for working with SACDOT staff for the inclusion of the Natomas Levee Bicycle & Pedestrian Trail project in the NLIP Phase 4b DEIR analysis. After completion of the analysis, this project can successfully compete for the grant opportunities in the near future. We will continue to coordinate with City of Sacramento, Sutter County, SAFCA, RD1000, County Airports, US Army Corps of Engineers and Central Valley Flood Control Protection Board as this project moves forward through the planning, engineering and construction process. Should you have any questions, please feel free to contact me at (916) 874-6121 or Kamal Atwal at (916) 875-2844

Re: Response to the Notice of Preparation of an EIS/EIR on the Natomas Post-authorization Change Report/Natomas Levee Improvement Program, Phase 4b Landside Improvements Project

Dear Mr. Bassett,

Thank you for the opportunity to comment on the Notice of Preparation for the EIS/EIR on the Natomas Post-authorization Change Report/Natomas Levee Improvement Program, Phase 4b Landside Improvements Project. The County of Sutter has several areas of concern we wish to have analyzed as part of the proposed EIS/EIR.

- The proposed borrow site excavation and reclamation area located east of the Cross-Canal and east Natomas Basin levee has soils that are predominantly classified as Prime Farmland and Farmland of Statewide Importance by the Department of Conservation. The County requests the proposed project's impacts to this farmland be analyzed as part of the proposed environmental document. The County requests the reclamation of this site be to a use consistent with the County's Agriculture, 80-acre minimum General Plan designation (AG-80) and General Agricultural Zoning District (AG).

- The removal of soil from the proposed borrow site is subject to the State's Surface Mining and Reclamation Act (SMARA). As the lead agency under SMARA, a surface mining permit and reclamation plan is required to be approved by Sutter County. It is recommended the SMARA activity be analyzed as part of the proposed environmental document and all feasible and effective mitigation be incorporated into the project. Sutter County considers itself to be a responsible agency under CEQA for this portion of the proposed project and this letter constitutes our written reply as required by CEQA Guidelines Section 15096(b) (2).

- Sutter County requests the proposed environmental document discuss and analyze potential impacts the proposed project could have on the Sankey Gap.

- It appears by the Exhibit 3 map, included as part of the Notice of Preparation, the proposed borrow pit area will include land currently occupied by the Pleasant Grove Cemetery District cemetery. The District should be consulted about this proposed project and the County requests the proposed project's impacts on this cemetery be discussed and analyzed in the proposed environmental document and all feasible and effective mitigation be incorporated into the project.

- The proposed borrow site excavation and reclamation area location is within an "Out of Basin Mitigation Area" identified in the Natomas Basin Habitat Conservation Plan (NBHCP) otherwise known as "Area B." The County requests the proposed project's impacts be evaluated as to the end use's viability as potential mitigation land for the NBHCP be analyzed.

The issues discussed above are of paramount concern to the County of Sutter. As a responsible agency under CEQA for the borrow site excavation and reclamation area portion of the proposed project, we look forward to working with you to assure that all surface mining and reclamation impacts are properly analyzed and mitigated. Please provide our office with all future notices regarding this project.

Sincerely,

Douglas G. Libby, AICP
Principal Planner

Sent: Friday, November 06, 2009 2:16 PM
To: Bassett. John (MSA)
Cc: Al Sawyer
Subject: Natomas PACR/NLIP Phase 4b Project NOP

Dear Mr. Bassett, Director of Engineering,

In reviewing the Notice of Preparation document for the NLIP Phase 4b Landside Improvements, Sutter County requests an addendum to the Roadway Repairs Agreement dated August 21, 2008. The scope of Phase 4b identifies an additional borrow area (Triangle Properties Borrow Area) which will be analyzed as part of the project. Should the borrow site be utilized, Exhibit 3 identifies two additional county roads, Fifield Rd and Keys Rd as potential on-road haul routes. Fifield Rd is a paved roadway and Keys Rd is a gravel roadway over the portions identified in the exhibit. To date, the current Road Agreement has satisfied the concerns of both parties and the levee improvement projects have continued. Should the new borrow area be utilized in the Phase 4b project, per paragraph M (page 2 of 12) of the existing agreement, an addendum is needed to continue the cooperation and address these newly identified road segments.

Additionally, please be advised that beginning in May 2010, our department will begin a bridge rehabilitation project on Pleasant Grove Road south of Keys Road. The work will cause us to close Pleasant Grove Road to through traffic for up to 4 months and Sankey Road, Natomas Road and Howsley Road will be published as the Detour route. We expect Keys Rd and Fifield Rd to be used by local traffic as an alternate detour route. Consequently, your contractor for borrow operations could not use wider than legal equipment on these county roads.

Thank you for you continued cooperation and please contact me with any questions.

Subject: **Natomas PACR/NLIP Phase 4b Project NOP Scoping Comments**

Dear Mr. Bassett:

Thank you for the opportunity to comment on the above mentioned project. The City Department of Transportation (DOT) is providing separate comments dealing with bike / pedestrian trails, so I will not repeat comments provided by DOT on trails, except where they interface with public parks that may be impacted by the project. Because this will be a program level EIR/EIS, the comments are general in nature.

Sacramento River East Levee Reaches 16 – 20
Within this area of the project, the City of Sacramento has several public parks on the land side of the levee:

- Park Site SN2 (Undeveloped; APN 274-0220-047-0000) is located north of Garden Highway and east of I-80. This undeveloped park site is currently accessible only from Garden Highway.

- Shorebird Park (Developed; APN 274-0560-024-0000 and -025) is bounded by Garden Highway (south), Swainson Way (west) and Kittiwake Drive (north).

- Natomas Oaks Park (Developed; APN 274-0320-023-0000, 274-0320-033-0000 and 274-0050-033-0000) is located at the intersection of Gateway Oaks / Garden Highway. The park includes a large grove of native oaks and other large trees in the eastern 2/3 of the park. The western 1/3 of the park contains turf, a restroom and parking area.

The City also has the following parks situated between Garden Highway and the Sacramento River in this area:

- Sand Cove Park (Developed; APN 274-0020-064-0000, 274-0220-066-0000 and 274-0220-022-0000). This park remains in its natural state with the additions of a paved parking area and trail.

- McClellan Docks (Developed; APN 274-0030-020-0000) This site was quitclaimed to the City from the federal government. It is currently leased to the Drowning Accident Rescue Team.

The EIR/EIS should include a discussion of any anticipated impacts to the public parks along the Sacramento River. The project description implies a potential loss of parkland or potential loss of existing recreational amenities, if the affected parks are developed. In the event parkland or recreational amenities will be impacted, the document should include discussion on how the impacts will be mitigated.

The Park Site SN2 and Natomas Oaks Park have large stands of heritage oaks and other heritage trees that will likely be impacted by the levee project and (in the case of the Natomas Oaks Park) intersection reconstruction project at Gateway Oaks / Garden Highway. The EIR/EIS should include a discussion of how heritage and other tree removal impacts will be mitigated where avoidance is not possible.

Pleasant Grove Creek Canal and NEMDC South – Gardenland Park
This section of the project includes the City's Ueda Parkway, which extends on both sides of the NEMDC from the American River Parkway to the northern boundary of the City of Sacramento. A portion of the Parkway was developed in 2007 with a paved, levee-top bicycle / pedestrian trail, extending between the West El Camino bridge to Sotnip Road on the west side of the canal. As part of this phase of construction, ADA-compliant ramps were constructed on the water side of the levee at Silver Eagle and on the land side of the levee at Gardenland Park and West El Camino.

Raising the levee will impact the ADA-compliant approaches to the parkway trail. In particular, the access ramp at Gardenland Park, located at 310 Bowman Avenue, winds through the entire park. Raising the levee grade will impact this very long access ramp, and potentially the entire park. This impact will need to be included in the discussion (along with any other access points).

In addition, raising the levee will widen the 'footprint' of the levee, potentially impacting the size of the park that is usable for recreation purposes and the existing improvements in Gardenland Park. Please address this issue in the document.

Lastly in March 2009, a new master plan for Gardenland Park was approved by the Sacramento City Council. The EIR/EIS should also address impacts to the park's planned improvements. A copy of the master plan for Gardenland Park is included in this packet.

Borrow Site Excavation and Reclamation
Any impacts to the City's Fisherman's Lake Park or Open Space would need to be included in the discussion. The boundaries of both are located to the east of the proposed borrow sites, adjoining the City's western boundary.

As this project moves into its design and construction modes, we look forward to active coordination between the City, SAFCA USACE and other agencies, where City parks or recreational amenities are affected. We will do all within our power to keep this important project on schedule.

Please notify me when the draft EIR/EIS is available for review.

Respectfully submitted,

bassettj@saccounty.net

Dear Mr. Bassett:

Thank you for the opportunity to review and comment on the Natomas Post-Authorization Change Report/Natomas Levee Improvement Program, Phase 4b Landslide Improvements Project NOP, dated November 5, 2009. Our comments are as follows:

Construction will include disruptions to the transportation network near the project site and adjacent area, including the possibility of temporary lane closures, street closures, sidewalk closures, bikeway closures, and detours. Pedestrian, bicycle, and transit access may be disrupted. Heavy vehicles will access the site and may need to be staged for construction. These activities could result in degraded roadway operating conditions in the area.

Prior to beginning of construction, a "Construction Traffic Control Plan" for City of Sacramento streets shall be prepared by the applicant to the satisfaction of the City Traffic Engineer and subject to review by all affected agencies. The plan shall ensure that acceptable operating conditions on local roadways are maintained. A copy of the Construction Traffic Control Plan shall be submitted to local emergency response agencies and these agencies shall be notified at least 14 days before the commencement of construction that would partially or fully obstruct roadways. Specific requirements regarding the development of a Construction Traffic Control Plan can be provided upon request.

The project description indicates that various intersections and roadways will be reconstructed and designed in accordance with City of Sacramento roadway design standards. Please note that an encroachment permit will be required for all work within the public right of way.

The project description indicates construction of various flood control measures such as adjacent levee structure, flattening of landside slopes, cut-off walls, to mention a few. Within reaches 19A through 20A of the Sacramento River and reaches 1 through 4 of the American River, there are several areas where the construction of these measures could impact existing mature heritage trees, roadways, bike trails, fencing and city utilities. The NOP indicates that this information would be considered during final engineering design. Given the close proximity of these items and the existing levee, there could be conflicts with the desired engineering design. The environmental document should indicate the degree of changes to be made to these items as a result of the project. Any proposed changes to mature heritage trees, bike trails, city parks, city streets, pump stations, and emergency access roads could result in a significant impact resulting in mitigation. Additionally some parcels that may have specific concerns and indentified to date are included in an attachment to this letter.

The project description indicates raising or constructing an additional levee on the NEMDC between Elkhorn and Northgate Boulevard; this levee has an existing bike trail. The environmental document should indicate the degree of change that will occur to this bike trail. At a minimum, information on detour routes and any modifications to the access points should be included, such as at Gardenland Park.

The project description indicates levee modifications along the American River north of Northgate Boulevard which could include cut-off walls. Currently there are two bike trails that connect Arden-Garden to East Levee Road in this area. The environmental document should indicate the degree of change that will occur to this bike trail. At a minimum, information on detour routes should be included.

The project description indicates work to be done to the West Canal; however, it is not completely clear from the description and the maps if the proposed work will impact the existing bike trail that is along the West Canal from I-80 to San Juan Road. If this bike trail is affected, mitigation should be identified in the environmental document.

The Natomas Levee Recreational Trail Project is described as a 42 mile loop to be built in conjunction with the other levee improvements. The project description indicates that details will be considered in the final engineering design. Further description indicates that this trail will be provided as a bicycle commuter route connection to the American River Parkway. A number of questions arise with this proposal that should be addressed:

a) Will this trail be a continuous paved class I bikeway at the conclusion of the project?

b) Will this trail replace existing bike trails, such as those mentioned in the previous comment?

c) Will this trail provide connection to existing bike trails that lead to and from the project site (Natomas Main Drain, Garden Highway Bike Trail)?

d) Will construction of the paved surface require local jurisdictions to provide funding? If so, how will this be addressed?

e) The City of Sacramento will need to review how this trail will be constructed to ensure compliance with established standards. Locations where this trail crosses city streets will need detailed planning to insure safe crossings.

If you have any questions about these comments please contact Aelita Milatzo at (916) 808-1953.

Sincerely,

Hector Barron
City Traffic Engineer

Parcels with Specific Concerns

a) Assessor's Parcel Number 274-0220-047-0000 a city owned parcel and has many healthy mature heritage trees.

b) Assessor's Parcel Number 274-0480-058-0000 a bike trail access connecting to the Garden Highway. To the north of this parcel is the cul-de-sac for Marina Glen Way and two private home sites.

c) Assessor's Parcel Number 274-0610-066-0000 a bike trail south of Avocet Court and Swainson Way.

d) Assessor's Parcel Number 274-0560-025-0000 a city park (Shorebird Park).

e) Assessor's Parcel Number 274-0560-027-0000 a city pump station (Pump 160).

f) Assessor's Parcel Number 274-0560-042-0000 an access point for an emergency access road to Shorebird Drive.

g) Assessor's Parcel Number 274-0430-108-0000 two city streets to the north (Durazno Court and La Lima Way) and a small connecting trail between the streets.

h) Assessor's Parcel Number 274-0030-019-0000 an access point for an emergency access road and bike trail connection.

i) Assessor's Parcel Number 274-0680-001-0000 a business park development with a bike trail at the toe of the levee.

j) Assessor's Parcel Number 274-0320-104-0000 an office building development (Farm Bureau) with a bike trail at the toe of the levee.

k) Assessor's Parcel Number 274-0320-103-0000 an office building development (Sutter Health) with a bike trail at the toe of the levee.

l) Assessor's Parcel Number 274-0320-023-0000 a city park, which includes a nature preserve area and mature heritage oak trees.

m) Assessor's Parcel Number 274-0050-028-0000, 274-0050-029-0000, 274-0050-030-0000, 274-0050-031-0000, 274-0050-006-0000, a bike trail in the American River Parkway.

Garden Highway Community Association

RE: Comments on Phase 4b "Notice of Preparation"

SAFCA and US Army Corps of Engineers:

The Garden Highway Community Association (GHCA) is an incorporated community association whose membership includes nearly all waterside and landside property owners along the Garden Highway in the area addressed in SAFCA's Natomas Levee Improvement Program (NLIP). The GHCA supports increased flood protection for the Natomas Basin, as long as it is done in a fiscally responsible, environmentally conscious, and scientifically sound manner. At the same time, as most GHCA members live on or next to the NLIP, they have an enormous interest and concern in how this project is implemented.

Below is a list of comments and concerns regarding the Phase 4b Notice of Preparation.

1. Failure to Adequately Consider Alternative Designs

SAFCA and the USACE have failed to conduct a legitimate, unbiased study to determine the most economically and environmentally sound project design to bring the Natomas Basin up to the USACE 100 year flood protection standard. SAFCA and the USACE have summarily dismissed feasible alternatives that would lead to region-wide solutions to the flooding potential in the Natomas Basin and surrounding communities. They have also failed to make a rationale, "good faith" effort at minimizing the height and footprint of the adjacent levee system, especially in light of the lower and inferior levee systems both upstream and adjacent to the NLIP. Therefore, the project is not in compliance of CEQA and NEPA requirements.

Pursuant to the applicable environmental laws, the agencies responsible for this Project must rigorously explore and objectively evaluate all reasonable alternatives and must devote substantial consideration to each alternative consideration.

Notably, during a recent SAFCA Board meeting which discussed the Project, it was repeated several times that the levee improvement design is a "work in progress" and that certification of ongoing EIS phases was a "worst case scenario" for the environment and property rights. Unfortunately, current environment destruction adjacent to Garden Highway does not correlate with these "work in progress" and "worst case scenario" portrayals. Rather, SAFCA and its contractors are in a race to remove highly sensitive habitat within the ENTIRE project footprint, despite the fact that alternative, less obtrusive levee improvement designs are gaining momentum and the fact that the Project is facing insurmountable fiscal problems.

The GHCA strongly encourages SAFCA and the USACE to look outside the Project's predestined box and not "clear a construction path" through sensitive habitats and rich farmland based upon "worst case" design scenarios. There are obviously countless alternative designs that would accomplish the flood protection our region needs at a fraction of the monetary, environmental and property-loss cost. For example, simply narrowing the footprint of the "seepage berms" would result in mammoth savings in all three of these areas. These berms, designed to be 500 feet wide in some areas, are unprecedented in our region and seem highly unwarranted when compared to the existing 10-20 foot berms that previously handled several 100-year-floods (without the cut-off walls that will be added as a part of this project). More telling, as evidenced by design concessions to certain property owners, SAFCA and the USACE have shown by their own actions that the footprint of the seepage berms can be substantially narrowed without losing the flood protection it seeks.

CEQA also requires a realistic analysis of the existing physical environmental conditions affecting the Project. Several court decisions have determined that the impacts of a proposed project must be measured against the "real conditions on the ground." Save Our Peninsula Committee v. Monterey County Board of Supervisors (2001) 87 Cal.App.4th 99, 121. "An EIR must focus on impacts to the existing environment, not hypothetical situations." ibid. In determining whether a project's impacts may significantly affect the existing environment, there must be a "baseline" set of environmental conditions to use as a comparison to the anticipated project impacts. As the Court of Appeal has explained, "it is only against this baseline than any significant environmental effects can be determined." County of Amador v. El Dorado County Water Agency (1999) 76 Cal.App.4th 99, 952.

Despite these requirements, the plans for this Project fail to describe the existing physical environmental conditions in order to determine the Project's significant adverse impacts on the existing environment. Conversely, the entire NLIP design relies upon a computer simulation that describes a hypothetical physical condition, but does not describe the actual physical conditions on the ground, including the current condition of the west side levees along the Sacramento River and the north side levee along the Natomas Cross Canal. This comparison would answer the question of "levee parity" and whether any spots along the river side of the east levee improvements or west side of the Sacramento River in Yolo County, or north side of the Natomas Cross Canal in Sutter County, would be more vulnerable to flooding.

In other words, if the east side levee along the Sacramento River has sufficient freeboard to ensure safe containment of the "200-year" design water surface, then these improved levees will have a significant adverse effect on the existing lower levee, properties, and structures along the west side of the Sacramento River as well as the homes and residents along Garden Highway on the river side of the improved east side levees.

The failure to evaluate the impact of a Project on the existing physical environmental conditions frustrates "the central function of the EIR, to inform decision makers about the impacts of the proposed project on the existing environment." Save Our Peninsula Committee, supra, 87 Cal.App.4th at p. 127.

The Project's plans further fail to consider the impacts of mounting environmental legislation and biological opinions which will significantly impact alternative flood protection plans, summarily dismissed by SAFCA as "impossible" or "inconceivable." One such edict recently issued by the The National Marine Fisheries Service unveiled a complex set of rules, a "biological opinion", which will likely have enormous impacts on local flood protection practices with the goal of increasing the populations of winter and spring-run salmon, Central Valley steelhead and green sturgeon. According to Kate Poole, attorney at the Natural Resources Defense Council, "There's no question any more about the fact that the Bay-Delta ecosystem is in dire need of significant changes and fixes. This is one big step to do that."

The new federal rules require that reclamation districts find a way to flood the Yolo Bypass more often to improve salmon habitat, negating SAFCA's argument that the Yolo Bypass could not be used to divert more water from the Sacramento River than current rules permit. Moreover, SAFCA's concern that water diversion to the Yolo Bypass would be too costly to local water and flood agencies apparently did not negate the decision on the new rules. The ruling governs water operations of the California Department of Water Resources, who will share the cost of the new orders. Clearly, flooding the Yolo Bypass "more frequently" will require a lowering of the Sacramento River weirs – a proposal made by the GHCA during 2007 as a more effective, long-term solution in lieu of an eternal levee battle in the narrow channels of the Sacramento River.

2. Failure to Adequately Consider and Protect Wildlife

The United States Environmental Protection Agency has previously commented on the NLIP, noting its continued concern over the temporary and permanent effects the Project is expected to have on the waters of the United States and recommended the continued "close consultation and collaboration" with the U. S. Fish and Wildlife Agency, California Department of Fish and Game and The Natomas Basin Conservancy to "ensure effects on woodlands, threatened and sensitive species habitat and waters of the US are avoided and minimized." Overall, this Agency has previously classified prior EIS drafts associated with the NLIP as "Insufficient Information (EC-2)".

The California Department of Fish and Game "DFG" has also expressed serious concern regarding the environmental impacts of the NLIP:

- The DFG believes pertinent mitigation measures are potentially unenforceable and may not bring the impacts to fisheries and aquatic resources to below a level that is significant.

- The DFG has found transplantation of herbaceous plants is typically unsuccessful and should be considered experimental. Mitigation measures for any potentially unavoidable impacts to special-status plants should include additional measures to increase the chances of survival for the population in question. Mitigation sites should be permanently protected and managed in perpetuity.

- The DFG is concerned with potential impacts to raptor nesting behavior not currently addressed in the DEIR, especially with regard to 24/7 construction and an estimated 900-1000 haul trips per day to deliver fill material. The DFG "believes that each of these activities could potentially result in significant impacts to nesting raptors including nest abandonment, starvation of young, and/or reduced health and vigor of eggs or nestlings that could result in death."

- In their current form, the DFG opines that the environmental documents do not explore the potential impacts of nighttime construction activities on nesting raptors. Moreover, construction at night poses additional complications for the effectiveness of biological monitors in ensuring that appropriate buffer zones are in place around active nests and that birds do not abandon their nests.

- The DFG has noted that prior DEIRS do not provide a discussion of potential impacts to the Northern Harrier, a ground nesting raptor and does not consider avoidance or mitigation measures.

The GHCA further notes the NLIP purports to mitigate the loss of woodland habitat by the promise to create three acres of canopied woodlands for every one acre destroyed. This mitigation goal is fatally flawed in that there is no discussion, explanation and/or plan to address the environmental tragedy that will result from the 50 to 100 year period required for the "new" woodland habitat to be developed – assuming the planned mitigation goal is even reached.

Despite the failure to mitigate the significant adverse impacts resulting from the destruction of woodland habitat, and the lack of necessary funding to effect the planned mitigation related thereto, SAFCA and its contractors are currently proceeding with the destruction of woodland habitat and the clear-cutting of heritage oaks and other trees.

Further, the NLIP also proposes to utilize lands purchased by the Natomas Basin Conservancy ("Conservancy") as borrow areas. These borrow areas will provide the base material for the landside levee improvements on the south side levee along the Natomas Cross Canal and the east side levee along the Sacramento River. Despite SAFCA's proposed use of these lands, the Conservancy acquired these properties to offset urban development's significant adverse impacts on protected wildlife species within the Natomas Basin. The Conservancy acquires and manages these properties consistent with the Natomas Basin Habitat Conservation Plan. The GHCA believes there still is no agreement between the Conservancy and SAFCA on the use of Conservancy lands and how these lands will carry out their intended conservation purpose after the soil necessary for the construction of the levee improvements is removed. Thus, any claimed mitigation for the loss and disturbance of Conservancy land is impermissibly deferred to some future time after Project approval and implementation.

Despite the fact that the Project's agencies have been afforded several bites at the apple in an attempt to come up with acceptable environmental mitigation, it continues to gloss over the devastating impact the

Project will have on the sensitive habitat of protected species, including raptors, snakes and flora (see comments of the California Department of Fish and Game summarized above).

3. Failure to Study Simultaneous Multi-Phase Construction

SAFCA, and now the USACE, are currently postulating that multiple phases of the NLIP could be constructed simultaneously. This directly contravenes the construction impact and mitigation advanced in the prior environmental documents and creates new issues not previously studied or addressed. For example, there would be compounded effects of CO2 emissions, noise, dust, vibration, and disruption to wildlife that has not been analyzed. Compared to the original Phase 3 EIR, for example, emissions in just Sacramento County would raise from ROG 75 lb/day to 287 lb/day, NOX 413 lb/day to 1,476 lb/day, and PM10 971 lb/day to 3,847 lb/day if these phases are to be done simultaneously. Moreover, on page ES-16, "Air Quality," the Phase 3 DEIR references the "nonattainment status of the Feather River Air Quality Management District and the Sacramento Metropolitan Air Quality Management District for ozone and PM10." The GHCA contends the cumulative effect of simultaneous construction during multiple construction phases has not been sufficiently analyzed by the responsible agencies.

Furthermore, simultaneous construction could involve three or more phases of simultaneous, 24/7 construction. Given the grave impacts of just one 24/7 worksite, the GHCA believes SAFCA and the USACE certainly cannot justify multiple worksites operating in this manner. This impact would make the simultaneous Phases (2, 3, 4a, 4b) unreasonably harmful to wildlife, the environment, and Garden Highway residents.

4. Failure to Adequately Address Encroachments/Levee Prism

At page 7 of the NOP, Encroachment Management, the following proposed action appears: "Remove encroachments as required to meet the criteria of the USACE, CVFPB, and FEMA." Conversely, the Sacramento Division of USACE and SAFCA have repeatedly advised members of the GHCA that the "adjacent" levee adopted by the NLIP "should" remove the waterside trees, landscaping, fencing, and other vegetation and improvements from the "levee prism." In other words, these agencies believe implementation of the NLIP would spare these items from removal under even the most aggressive encroachment standards. Thus, the GHCA is concerned with the apparent unchanged position regarding encroachments as described in the current NOP.

Of utmost importance to property owners along Phase 4b, the USACE does not mention how they will treat vegetation and encroachments on either side of the levee where they decide not to build an "adjacent setback levee" and thus achieve a new levee prism. If a "one size fits all" approach of denuding levees is applied, it will completely contradict the long established local USACE procedures of planting trees to stabilize the levees, protect endangered wildlife and reduced wind-driven waves. We have also been told that many members of the scientific community believe trees and other vegetation improves the strength of a levee, especially in areas of the country that do not have to contend with hurricane strength winds. What are USACE's current views on this?

It also does not appear the USACE has identified what (if any) waterside encroachments will be subject to removal within the NLIP and what legal processes will be involved in condemnation of associated property rights. These questions are of utmost importance to the GHCA and its members. SAFCA has

also advised the GHCA it has maps of approximately 30,000 encroachments and all associated easements on the waterside of the levee. SAFCA recently revealed this database to the public, but there is no mention of the encroachments and/or vegetation that the involved flood agencies consider to be unacceptable. Research has revealed some vague, inadequately mapped easements dating back to the early 1900's which appear to show little or no support for any planned encroachment removal.

SAFCA has also stated "on the record" it is willing to help facilitate "post-facto" permits for encroachments that do not endanger the levee. Would the USACE also be willing to endorse this procedure? Unfortunately, because the property owners have no information as to what items SAFCA and the USACE feel are acceptable encroachments, Garden Highway properties are being left in the dark.

Overall, the members of the GHCA are very concerned about which "encroachments" might require removal and with the various easements SAFCA and/or its partners will attempt to claim. SAFCA has promised to work with each property owner to discuss and resolve issues regarding alleged encroachments, but thus far has taken no such action. Does the USACE plan on doing the same for Phase 4b? Currently, construction Phase 2 of the Project is underway, yet the GHCA is aware of no affected property owners having been contacted regarding encroachment or easement plans. This not only impacts existing improvements, but future improvements. The uncertainty also creates resale problems and negatively affects property values.

5. <u>Failure to Justify 24/7 Construction</u>

As accurately noted by the California Department of Fish and Game, previous EIRS/NEPA documents do not adequately address the potential impacts to raptor nesting especially with regard to 24/7 construction and an estimated 900-1000 haul trips per day to deliver fill material. The DFG "believes that each of these activities could potentially result in significant impacts to nesting raptors including nest abandonment, starvation of young, and/or reduced health and vigor of eggs or nestlings that could result in death." Moreover, the NOP does not explore the potential impacts of nighttime construction activities on nesting raptors. Moreover, construction at night poses additional complications for the effectiveness of biological monitors in ensuring that appropriate buffer zones are in place around active nests and that birds do not abandon their nests.

The NOP contends Cutoff Walls, wells and perhaps additional aspects of the Project require a 24/7 construction schedule. The residents along Garden Highway and the sensitive environment that exists in the riparian, river habitat adjacent thereto cannot be subjected to 24/7 construction simply because SAFCA or the USACE is running behind schedule on what might be perceived as an overly ambitious project. It is anticipated 24/7 construction during subsequent phases of the NLIP would have an exponentially adverse impact on property owners spanning many miles in all directions. Moreover, the use of trucks to get to and from the actual "construction" sites will expand the location of the impact far beyond the limited construction sites addressed by SAFCA and this NOP.

The GHCA also feels the NOP ignores both city and county (Sacramento and Sutter) noise ordinances. As such, the GHCA seeks an explanation as how the USACE plans to deal with violations of local noise ordinances.

6. Damage to Businesses

The NOP fails to address the impact of the project on the businesses that exist along and upon Garden Highway which thrive only because individuals seek the tranquility and peace of a rural, river atmosphere that is easily accessible, peaceful and enjoyable.

7. Hydrology

The hydrology reports postulated by SAFCA and its engineers in previous Phases conclude the improved levee system contemplated by the NLIP will not increase the flood risk to the waterside property owners within the NLIP. These reports are explicitly based upon the assumption that other surrounding Reclamation Districts will NEVER improve their levees. This assumption is improper, flawed and not in concert with the current push by adjacent Districts to fortify their levees. The threat of increased flood risk cannot be summarily dismissed and a funding mechanism must be included to deal with the financial impact of this impact.

Equally troubling, SAFCA admits its "design event analysis is not the same as the analysis procedure used by USACE." As the primary advertised goal of the NLIP is to obtain USACE certification, why is SAFCA deviating from the USACE event analysis? The previous SAFCA EIRS/NEPA documents further note that the USACE analysis "includes consideration of system uncertainties." Does this mean the SAFCA analysis does not account for "system uncertainties" such as the other side of the levee overtopping or failing?

Waterside residents adjacent to the NLIP are very concerned about increased flooding of their homes due to the levee being raised as much as three feet. SAFCA has systematically advised the GHCA not to worry, as levees will overtop or fail elsewhere. Unfortunately, it appears SAFCA's engineering analysis does not account for this or assumes the other levees will be raised and reinforced. If both sides of the levee are eventually raised, then the water capacity of the river will be increased. This would allow the upstream reservoirs to release more water during a flood event and subject residents to a much greater chance of flooding. The GHCA has been advised there is debate amongst USACE engineers as to which provides the better hydrological model, "perfect world" where you cannot take into account deficiencies in other parts of the levee, or "real world" where you can. What is USACE's view on this?

8. Property Values

The NOP, consistent with all prior SAFCA action related to the NLIP, wholly fails to address the impact of the Project on property values in the affected areas and has no funding mechanism in place to deal with the destruction of property values in and around the project that will ripen into eminent domain and inverse condemnation lawsuits. This exposure includes, but is not limited to, irreparable damage to property values which began when this project was first publically announced (at a time when real estate values were significantly higher than today), and will continue indefinitely into the future. The Project has stalled and prevented sales, land improvements and retirement plans. This trend will increase exponentially when active construction begins. Due the lack of a funding mechanism, the taxpayers will be left to shoulder yet another wave of unanticipated and undisclosed cost overruns.

9. Failure to Consider Environmental Impact of Development

While SAFCA publicly justifies the massive NLIP as a necessary cure for the imminent, Hurricane Katrina type flooding that could occur in the Natomas Basin in the event of a 100-year-flood, in reality SAFCA is simply trying to lift the building moratorium affecting the builders who have imprudently chosen to pave over rice fields in a "basin". These are the same developers who have spent hundreds of thousands of dollars supporting our local officials and lobbying for the right to resume rapid development within the floodplain. Without more "urban sprawl", these developers and the County of Sacramento are unable to tap into the "quick cash" that has been created from destroying our evaporating farm lands.

The GHCA contends that rather than encouraging additional urban sprawl, local agencies should be focusing on creating more housing in urban areas, i.e. building up, not out. Moreover, the failure of local agencies to curb their appetite for our farmlands will only increase traffic congestion, gas and carbon emissions and regional pollution at a time when universal fears and concerns over global warming, water scarcity and energy depletion is gaining momentum.

The GHCA contends the urban sprawl into the Natomas Basin, quite ironically, increases the flood potential for Natomas and surrounding communities. Vast farmland that previously collected and stored water during heavy storms, before slowly releasing it through natural underground seepage, has now been paved and improved with storm drains. Accordingly, thousands of acre feet of rainwater that previously rested safely within area farmland is now immediately collected and pumped into the Sacramento River. Historical flow charts from the Sacramento River during times of heavy storms confirm the negative impact Natomas Basin development is having on regional flood protection.

10. Failure of the Notice of Preparation to abide by the Settlement Agreement between SAFCA and the GHCA.

The "Notice of Preparation" in no way mentions the previously agreed to settlement agreement between SAFCA and the GHCA. While the GHCA understands the USACE is not SAFCA, as the assignee of certain aspects of the Project, the USACE is legally required to comply with all legally enforceable agreements entered into by SAFCA, the assignor. To hold otherwise would render the settlement agreement between SAFCA and the GHCA illusory.

11. Rights of Entry/Eminent Domain.

It has recently come to the attention of the GHCA that SAFCA has pursued Right of Entry Agreements from Garden Highway property owners without advising those property owners of any authority for the desired access and without advising owners of their associated rights. By withholding this critical information, SAFCA has in essence coerced many Garden Highway residents into making uninformed decisions under the bold threat of imminent litigation should they resist.

In response to a recent complaint by the GHCA, counsel for SAFCA has confessed that entry onto the private property of Garden Highway residents is being sought pursuant to the Eminent Domain laws of the State of California. However, pursuant to California Code of Civil Procedure Section 1245.010, SAFCA and/or its contractors must be "**authorized to acquire property for a particular use**" **before**

they may enter private property in order to "take photographs, studies, surveys, examinations, tests, soundings, borings, samplings, or appraisals or to engage in similar activities reasonably related to acquisition or use of the property for that use." Apparently, SAFCA has repeatedly misinformed property owners that SAFCA possesses this authority when, in reality, no such authority had ever been obtained.

Based upon the foregoing, the GHCA hereby submits that all involved flood agencies seeking permission to enter private property must notify the affected property owners **of the legal authority upon which the agency relies, along with a full description of the associated rights afforded the property owners**.

Lastly, the GHCA hereby objects to the "taking" of private lands pursuant to the Eminent Domain laws under the guise that these lands are necessary for the development of the Project, when in fact the involved agency actually and surreptitiously plans to convey the condemned land to another private party, i.e. the airport.

12. Natomas Levee Recreational Trail Project.

The GHCA is pleased a recreational trail is finally being included as part of the NLIP. Unfortunately there is no funding mechanism in place other than waiting on the Department of Transportation, which has admitted could take years. As SAFCA and the USACE are already spending millions of dollars protecting cultural resources of Native American Indians, the GHCA believes it would be practical to allocate a nominal sum of money to enhance the resources of the current living residents in the Natomas Basin. The simple modification of the design of the new levee crown from a gravel road to paved road would bear a meager cost and would streamline the bike path for the DOT.

13. Incorporation.

The GHCA also hereby incorporates by reference all comments asserted by Garden Highway property owners and/or their representatives in response to this portion of the NLIP.

In sum, while the GHCA appreciates the daunting task this Project presents to the involved flood agencies, its members strongly feel that a more rational design approach would substantially reduce these challenges, save the taxpayers hundreds of millions of dollars, preserve sensitive habitat and rich farmland and ultimately expedite recertification of the Natomas levees. Moreover, the GHCA implores the involved flood agencies to continue to acknowledge and adhere to the rights of all Garden Highway residents, businesses and property owners.

Respectfully submitted,

GARDEN HIGHWAY COMMUNITY ASSOCIATION

RE: Notice of Preparation of EIS/EIR on Phase 4b of the Natomas Levee Improvement Program

Dear Mr. Bassett:

Thank you for the opportunity to comment on the subject NOP. SABA works to ensure that bicycling is safe, convenient, and desirable for everyday transportation. Bicycling is the healthiest, cleanest, cheapest, quietest, most energy efficient, and least congesting form of transportation.

We are very pleased that the Phase 4b Project includes construction of the Natomas Levee Recreational Trail Project, a 42-mile bicycle and pedestrian Class I facility. This trail will tremendously enhance the recreational opportunities for bicyclists and pedestrians in the Sacramento region. It will also provide key linkages for bicycle commuters to access employment centers from the northern residential neighborhoods of Sacramento and its suburbs.

Construction of the Phase 4b Project will cause significant adverse impacts to existing bicycle routes for both recreational and utilitarian purposes. These important bicycle routes include the Garden Highway and its intersecting streets and roads and the Ueda Parkway bike trail along the western levee of the Natomas East Main Drainage Canal (also called Steelhead Creek). The NOP states that project construction may require closure of these bike routes for up to 6 months, a significant adverse impact on bicycle transportation.

To mitigate this significant adverse impact, the EIS/EIR must describe adequate mitigation including:

- Alternative bicycle access through or adjacent to construction areas,
- Proper advance signage for any detours or route changes,
- Access to bicycle devices at traffic signals,
- Signage for vehicle operators (for example, “share the road” signs and pavement symbols) and maximum vehicle speed limits of 25 mph where separate bicycle lanes cannot be provided,

- Advance development of Traffic Control Plans that show traffic control measures for bicyclists with the plans reviewed and approved before construction initiation by the Sacramento city and county bicycle coordinators, and
- Noticing to bicycle-interest organizations in the Sacramento area.

The Ueda Parkway bike trail currently has limited connections with surface streets in the neighborhoods near which it passes. Reconstruction of the Ueda Parkway bike trail after completion of the levee project should include establishing connections to the following surface streets:

- Indiana Ave
- Senator Ave
- Rosin Court
- Tandy Court
- North Market Blvd

SABA is an award-winning nonprofit organization with more than 1400 members. We represent bicyclists. Our aim is more and safer trips by bike. We are working for a future in which bicycling for everyday transportation is common because it is safe, convenient, and desirable. Bicycling is the healthiest, cleanest, cheapest, quietest, most energy efficient, and least congesting form of transportation.

Thank you for considering our comments.

Yours truly,

Jordan Lang
Project Assistant

John,

In response to SAFCA Notice dated November 5, 2009, would you please advise me of the proposed phase and year covering property located north of Sankey Road to Howsley Road. Also, please advise us why our property is not included in your Notice as a Potential Borrow Site, given that it has been considered in the past as a Basin as shown on the attached map due to the Sankey Spill.
Thank you.

Subject: Natomas PACR/NLIP Phase 4b Project NOP Scoping Comment

To whom it may concern,

My family lives at 2269 Swainson Way along Reach19b and I am very concerned for wellbeing of my family and property. While I understand the need for the levee work and the gravity of the situation if the levee work is not completed, my family will unjustly be affected.

My four month old son's room faces the levee, and per your documents, this work will take place 24 hours/seven days per week. My son and family's ability to obtain adequate and sound sleep will certainly be impeded and I am concerned that we all will suffer detrimental health problems if the construction goes on as planned. My infant son is especially at risk hearing damage/loss, allergies and/or other respiratory issues, and sleep deprivation.

My property value is absolutely going to drop as a result of a wall constructed outside my front door. In addition to the unavoidable loss of property value after levee work is complete, my dwelling may be unlivable during construction. The physical concerns outlined above, coupled with noise, dust and construction debris, will undoubtedly make my dwelling un-sellable and un-rentable during the construction phase of levee work. My family will have to find an alternate place to live and incur costs associated with moving and maintaining two households for the entire duration of construction. Additionally, our home will be at risk for damage by construction equipment, and if left unattended, break-in and/or vandalism.

Since there are multiple households on Swainson Way, I feel these concerns should be addressed directly with the home-owners. I for one did not receive notice of the meeting on November 18th until after the meeting had ended (it was later determined that the flyer was dropped off at the front door a mere 24 hours prior to the meeting). Considering the staggering impact the levee work will have on Swainson Way residents, the parties involved need to make a greater effort in informing and managing the concerns of residents affect by the construction on Reach 19b.

In order to maintain my right to legally challenge any and all aspects of the levee project, please note that this letter has been submitted via email prior to the December 4, 2009 for comments and a hard copy will be mailed via USPS as well.

RE: Comments related to the NOP for the Phase 4b Landside Improvements Project

Dear Mr. Bassett,

Is the USACE familiar with the term, A Morton's Fork?

Simply put, a Morton's Fork is a choice between two equally unpleasant alternatives or two lines of reasoning that lead to the same unpleasant conclusion. I.E., "between a rock and a hard place."

That is what this Notice of Preparation is serving us; a big heaping fork full of Morton.

What the NOP tells us is that while SAFCA may have been content to reinforce in-place the existing levee system, USACE believes the only way to lessen the risk of flood is to channelize the Sacramento River in a fashion similar to that taken by them with respect to the Los Angeles River back in the late 1930s.

This does not need to be the case.

A few years back, the initial design proposal for RD1000's Pumping Plant #1 Improvement Project was to completely denude all vegetation in the area, scrape the slope from the land to the water to a 21-degree angle, and install steel sheet piles opposite the pumping plant.

In other words, make the area a big, beautiful (to an engineer) bathtub drain.

While it is understandable why an engineer would believe this the best way to achieve the desired purpose, it fails to take into account the people, or the wildlife, that live here long after construction is complete.

This project proposes to follow the same logic as that initial RD1000 design proposal.

For example, Page 9 references landside vegetation removal under the "fix-in-place alternative," that would allow some landside vegetation to be saved, yet <u>all</u> waterside vegetation would be removed.

Why is USACE married to the idea that all vegetation is bad and what options are available to change their position? A recent Sacramento Bee article (06/28/2009, page B1) makes it clear that there is no scientific consensus supporting the hypothesis that vegetation is harmful to the operation of levees. In fact, there appears to be abundant research that shows vegetation is vital as it slows waterside bank erosion.

This leads to a somewhat obvious question; What happens to the waterside slope after an impermeable cutoff wall is placed in an existing levee?

Where seepage occurs, there would be a balance in moisture on the landside and waterside of the levee. By placing an additional slurry cutoff wall and/or adjacent levee berm, would that not cause more moisture to remain in the waterside slope and -- with a higher moisture content -- would it not result in a greater chance of liquefaction occurring during periods of high water level? Moreover, with that higher water level, could there not easily begin a process of erosion that would result in much of the waterside slope disintegrating into the river flow?

For instance, when was the last time you saw a slope of any kind on the waterside of a river with a wall? The natural action of the river is to scour away at its banks where there is no vegetation until it reaches an impermeable barrier… like a cutoff wall.

Homeowners on the waterside of the Garden Highway levee have already witnessed measurable ground subsidence of their properties subsequent to the previous slurry wall project of the mid 1990s. How does this NOP take into consideration that action?

While page 5 references the construction of adjacent landside levee with wider landside slope & seepage berms, no designs are offered to identify the actual impacts for the majority of the frontage along Reach 19B. The closest we get is, "measures would be employed to reduce the project footprint impacts to these resources (residences, business, heritage oaks) to the extent feasible given levee design and seepage remediation requirements."

How can environmental impacts be judged when project design & limits are not presented? We require some form of preliminary design to identify the limits and actual environmental impact that the project expects to make.

Page 5 also notes the modifications to RD1000 pumping plants are required. How will this fit in with the recent work the Corps *just completed* at pumping plant #1? Will this require them to tear-up the work?

Page 6 notes right-of-way acquisition of lands within the 4b project footprint. Again, this is an area of almost urban density and the NOP gives no guidance as to the extent of the project footprint.

Page 8 notes the three-foot-wide cutoff walls. The $100 million spent in the 1990s was primarily spent on cutoff walls. Are these walls inadequate? What happens to them?

Page 8 notes the reconstruction of Garden Highway intersections at Orchard and Gateway Oaks to accommodate levee slope flattening, but the properties east and west of these intersections are fully improved with minimum setback available for such construction.

Does USACE plan a program of imminent domain to acquire various properties in these areas and other areas? Again, there are no design proposals that allow us to ascertain the extent of the plans.

Page 5 endorses 24/7 construction for cut-off walls. While that may be logical for the more rural areas of Garden Highway, in the areas encompassed by this NOP that is wholly unfeasible. There are dozens of houses that would be in close proximity to the ongoing construction. The offered mitigation that SAFCA would provide vouchers for folks to find temporary housing is insufficient.

Page 7 references the seepage berm, up to 250' wide, in addition to the adjacent levee construction. While this may be feasible in parts of Reach 19A, it is ridiculous to assume it feasible for much – if any – of heavily populated Reach 19B.

The Los Angeles River used to be a natural river that regularly flooded. I understand the need of the Natomas area to be – relatively – safe from floods. As engineers, I understand the need to "fix" the problem to the best of your abilities, but this is not Los Angeles.

The area encompassed by the Phase 4b Project is heavily populated and heavily wooded. What the Corps proposes is – in effect – scorched earth and will scar this area for decades without a discernable difference in flood protection from what SAFCA proposed back in the mid 1990s.

Having lived in the Natomas area for over 20 years, I went through the first Natomas levee "fix" that USACE now says is inadequate, yet SAFCA's own reports indicate did a decent job making Natomas reasonably safe from flood.

From the Natomas Levee Improvement Program Update, March 20, 2008:
"Due to over $100 million in flood levee improvements expended between 1990 and 1998, the 1997 flood, which can reasonably be characterized as the largest flood event in the last 150 years, caused no significant levee problems for the Natomas Basin. The through-levee seepage which threatened to cause levee failures in the 1986 flood have been effectively controlled with the cut-off walls and seepage berms constructed by the Corps and SAFCA."

Overall, the NOP reads as being designed for a project destined for the rural areas of reaches 1 – 16 or is simply naive as to the types of residential densities found in the 4b project area. "Multiple residential and agricultural structures are located within the footprint of the levee improvement," is as much an understatement as it might be wishful thinking.

Please, go back to the drawing board. Do not subject the residents of Natomas to an overbuilt monstrosity of a levee fix required simply due to the Corps compensating for their failure in New Orleans.

Sincerely,

Phil Perry

Subject: RE: Premature Oak Tree Cutting Pursuant to Contract 4047

Mr. Buer:

The Garden Highway Community Association (GHCA) shares Mr. Cummings' concern.

Notably, during the SAFCA Board meeting on Friday, it was repeated several times that the levee improvement design is a "work in progress" and that certification of the Phase 4a EIS was a "worst case scenario" for the environment and property rights. With alternative, less obtrusive levee improvement designs gaining momentum, and in the face of the insurmountable fiscal problems facing this Project, the GHCA strongly encourages SAFCA to look outside its predestined box. We also urge SAFCA not to prematuredly "clear a construction path" through sensitive habitats and rich farmland based upon this "worst case" design scenario. This action would sadly transform the "worst case" into the "real case."

There are obviously countless alternative designs that would accomplish the flood protection our region needs at a fraction of the monetary, environmental and property-loss cost. For example, simply narrowing the

footprint of the “seepage berms” would result in mammouth savings in all three of these areas. These berms, designed to be 500 feet wide in some areas, are unprecedented in our region and seem highly unwarranted when compared to the existing 10-20 foot berms that previously handled several 100-year-floods (without the cut-off walls that will be added as a part of this project). More telling, as evidenced by design concessions to certain property owners, including the Teal Bend Golf Club, SAFCA has shown by its own actions that the footprint of the seepage berm can be substantially narrowed without losing the flood protection it seeks.

While we appreciate the daunting task this Project presents to SAFCA and its Board, we strongly feel that a more rational design approach would substantially reduce these challenges, save the taxpayers hundreds of millions of dollars, preserve sensitive habitat and rich farmland and ultimately expedite recertification of the Natomas levees.

Thank you for consideration.

David Ingram,
Director, GHCA

To: buers@SacCounty.net; Jay Davis
Cc: nottolid@SacCounty.net; David Ingram; Patrick Tully
Subject: Premature Oak Tree Cutting Pursuant to Contract 4047

Mr. Bauer: We note that you "promise" that SAFCA will not cut the thousands of trees on the landside of the Garden Highway in the NLIP Phases 3 and 4a until funding is secure to award levee construction contracts in these areas. We note the January 7 and March 1 "go ahead" dates in the tree cutting contract, Contract 4044. However, We also note that there are a great number of trees scheduled to be cut pursuant the demolition contract, Contract 4047. We understand that your suggested reason for including certain trees in Contract 4047 is because these trees are located in the path of canal work -- which is part of 4047. However, many, many large oak trees scheduled for destruction pursuant to 4047 are NOT in the path of canals. For example, a great number of trees on properties north of North Bayou Way (Bell property, Vanderford property, etc.) are not located in the path of a proposed canal. There are several other examples. If you are indeed sensitive to unnecessary mature oak tree cutting in this project, you should include ALL trees (other than ones directly impacting Contract 4047 work) in the "save until secure funding" concept.

We would appreciate meeting with your staff immediately to discuss the reasons for including the large amount of trees in Contract 4047 -- and in working with you to include the Contract 4047 non-impacting trees in the "save until secure funding" umbrella.

Springlike weather fools many flowering plants, so enjoy the show

LEZLIE STERLING Bee file, 2007

Cool weather followed by a warm spell and early rain tricked many plants, such as lilacs and narcissus, into thinking it was time to bloom.

Forget winter. Mother Nature seems ready for spring.

All over the Sacramento Valley, March and April flowers have jumped the calendar and started their annual display now – in November.

Lilacs and redbuds are pumping out blooms while often the same bushes are shedding fall leaves. Another spring staple, narcissus, is flowering four months ahead of its annual schedule.

Can plants be that confused? And if they're so out of sync now, what will happen next spring?

"My lilacs are blooming, too," says Warren Roberts, recently retired superintendent at the UC Davis Arboretum. "I've never seen so many bloom so early in the year.

"It's like a soprano in a chorus who jumps her cue," he adds. "It's certainly beautiful, but it would sound so much better if she waited to sing along with the group."

After four decades, Roberts retired this fall. (At his official goodbye party last month, his reception line stretched out for four hours). Besides staying active as an arboretum volunteer, he continues gardening and observing nature at work.

Western redbuds (*Cercis occidentalis*) on the UC Davis campus and along local highways also are bursting with purple blooms. Flowering narcissus – particularly paperwhites and the golden Soleil d'Or – are everywhere.

Blame the weather, Roberts says.

"We had some cool weather and it was just cool enough to give them some chilling (in the soil)," he explains. "Then, we warmed back up. We also got just a little light rain in early October before the big storm (Oct. 13). With that moisture and warm weather, it's making (the plants) think it's spring. It just arrived really early."

Slender sedge, top, is one of 35 species that would have been familiar and useful to the Patwin. Ryan Deering, center, coordinated the planting of the Native American Contemplative Garden. A 400-year-old oak, above, provides a living connection to the area's past.

FROM PAGE D1

In a heartfelt ceremony last weekend, about 130 people celebrated a Thanksgiving on a site used by the Patwin for more than 4,000 years.

"It was very quiet, very soft," Tatsch said. "There was a gentleness that was very pleasing."

Footsteps away was the cause of lingering pain. During the construction of the Mondavi Center in 1999, the remains of 13 Patwin were unearthed in what had been a village and sacred burial ground. Their remains dated between A.D. 700 and 1200.

During the 1800s, Patwin families were forcibly relocated from their Putah Creek home to missions. The names of several of these Patwin are commemorated on a central garden pillar.

"Everybody spoke from the heart," Tatsch said after the ceremony. "We didn't hide the fact that there was anger and sadness and that we didn't trust each other in the beginning. But now, we have formed a group of people with strong connections."

Added arboretum director Kathleen Socolofsky, "It was such an incredible event. This is much more than just a garden."

Past connects to present

Beside the Putah Creek streambed grows a 400-year-old oak tree. It was a sapling when the Pilgrims celebrated their first Thanksgiving in 1621 with the Wampanoag in what's now Massachusetts.

"This tree witnessed extreme change, both physical and cultural," said Warren Roberts, the arboretum's recently retired superintendent, who helped pick out the plants. "What makes this site unique is that it was part of history, not someplace else where history is being commemorated. It happened right here. This garden connects the history of our land with our current students and future generations."

Appropriately for a garden, it's a living history.

Said Tatsch: "That's a big accomplishment for the university to acknowledge that history. There's a Patwin community alive and well and living around us. At the same time, we honor those who are gone and the land that is their homeland."

Other honoring sites will dot the Davis campus, which sits on Patwin land. Each site features engraved basalt columns with words in both English and native Patwin. Made of volcanic stone, these 1,500-pound columns represent the Patwin people, their strength, their resilience. They also evoke connections.

"Listen to the natural world," reads one message, written by tribal elder Bill Wright. "This is a gift from the Creator. Pray so your spirit will be healthy and joyful."

A basalt column at the garden entrance starts visitors on a path of discovery: "Try to imagine this place with no building, no sidewalks, no roads ..."

Featuring 35 native plant used by local indigenous people, the garden serves a a lesson in American India studies and botany as well history. Valley oaks provid acorns, a major food sourc Alumroot, soaproot, yarrow sedges, deergrass, Oregon grape, redbud; each had multiple uses. Their Patwi names – some that had no been spoken in years – are listed along with English and botanical titles.

"There were so many us for some of these plants," said arboretum horticultur Ryan Deering, who coordinated the planting. "Take soaproot. It was used for food, soap, glue, brushes, medicine – so much stuff from one plant.

"We've already been approached by (Patwin) community members who wou like to use these redbuds f basket-making," Deering adds. "That's a wonderful idea."

American Indian studen helped in the planting. The garden's gently curving paths resemble the coils of basket.

Inspiration to others

"It feels very organic," sa Skip Mezger, the university landscape architect. "We've already gotten calls from other universities that wou like to do something like this. Hopefully, the garden will inspire others."

In recent weeks, river otters have made this site their home, too – a good sign.

"There is an essence to it Tatsch said. "It has now become a sacred space. There is a definite differen walking down that path.

"One of the beauties of this (project) is that garden won't be going away," she said. "Future generations may not have any idea how this came about, but they'll see those stones welcome them into the garden where they can get an idea of the history of this place."

Subject: DEC 4 last day for comments on Phase 4b "Notice of Preparation"..... Comments attached for inclusion and study by SAFCA and Corps of engineers.

John, Tim and Elizabeth:

I am sending herewith the following attachments, which we would like to submit to you include as comments/suggestions/ requests from our family related to the Environmental documents (EIR/EIS for CEQA/NEPA) for proposed improvements along the Sacramento River levees flood improvement program:

1 Copy of the article that appeared in the Bee regarding Heritage Oaks and their ties to Natomas Basin history and heritage.

2 Two letters dated November 11 and November 12, submitted to SAFCA on November 12, but was not included in the SAFCA presentation packet for the EIR certification on November 13, 2009 hearing.

3 Email to SAFCA on November 20, 2009 regarding proposed x-section for levee improvements with a floodwall and seepage berm for consideration and evaluation of this viable alternative.

We will continue to do our best to protect our historic, cultural, environmental and economic resources if it is possible to do so. We are asking SAFCA and the Corps of engineers to evaluate the historic, cultural, environmental and economic value and benefits of these valuable resources. We ask that you balance these benefits with the flood protection needs of the Natomas basin.

NEPA and CEQA requirements are not satisfied unless all viable alternatives that should have been considered in the EIR/EIS process are included.. As of now, not all reasonable alternatives that would minimize environmental impacts have been evaluated. Floodwalls with seepage trench alternative deserve to be evaluated.

We continue to hope that staff will evaluate our request before it is too late.

Please confirm receipt and acknowledgement that these and the previous information will be provided to the appropriate staff for inclusion in the EIR/EIS for CEQA/NEPA process.

Thank You!

Very Truly Yours,

Subject: DEC 4 last day for comments on Phase 4b "Notice of Preparation"

Hello All,

Just a reminder, Dec 4 is the last day to submit comments on Phase 4b "Notice of Preparation" (NOP).

While Phase 4b is similar to other Phases of the Natomas Levee Improvement Project, it is very different in the fact that the US Army Corps will be conducting the work instead of SAFCA.

We encourage as many residents as possible to provide comments so the Army Corps knows the concerns of Garden Highway property owners. The attached one page document contains highlights of the NOP and email addresses where you can send comments.

Thank You,

Gibson Howell

RE: Protest to adoption of Environmental Impact Statement and Environmental Impact Report on the Natomas Levee Improvement Program (SCH # 2009032097)

Dear John and Tim,

I have reviewed the documentation in the Draft and Final Environmental Impact Report and must protest the certification of the final EIR. My protest is based on the following:

1. Not all reasonable range of alternatives were evaluated consistent with the requirements of NEPA and CEQA because the alternative does not include floodwall, seepage cut off and pressure relief seepage trench alternatives.
2. The project is not in compliance with Section 2.1.1.1, pertaining to NEPA requirements (40 Code of Federal Regulations (CFR) 15012.14). An objective evaluation of all reasonable alternatives has not been included.
   a) All reasonable alternatives were not identified.
   b) Information that would allow reviewers to evaluate the comparative merits of the proposed action for all reasonable alternatives was not performed.
   c) Agencies preferred alternative did not thoroughly study all reasonable alternatives.
   d) NEPA requires the analysis of the proposed action and all reasonable alternatives at a substantially similar level of detail. The Council on Environmental Quality Regulations (40 CFR 1502.14) require agencies to rigorously explore and objectively evaluate all reasonable alternatives and to devote substantial treatment to each alternative considered. The EIR did not review floodwall and cut off wall with seepage trench alternatives at a similar level detail.

3. The project is not in compliance with Section 2.1.1.2 – CEQA Requirements: The California Code of Regulations (CCR) Section 15126.6(a) of the State CEQA Guidelines requires that an EIR:

   a) Describe a range of reasonable alternatives to a proposed project, or to the location of the project that would feasibly attain most of the basic project objectives but would avoid or substantially lessen any of the significant effects of the project.

   b) Evaluate the comparative merits of the alternatives.

4. The final EIR exhibits indicating "taking" major portions of our properties as necessary for the project. The resolution and agenda for the SAFCA meeting indicate that certain properties "taken" would be exchanged with the airport. I protest the "taking" of land as necessary to the project and then exchanging the land with a third party.

An EIR must consider a range of reasonably potentially feasible alternatives that will foster informed decision making and public participation. Not all reasonable alternatives for floodwall and cut off wall with seepage trench were considered.

Based on the fact that not all reasonable alternatives were considered and SAFCA design team is still investigating design issues, the final EIR can not be properly certified at this time.

I have been corresponding with your agency for the last two years in an attempt to have other reasonable alternatives considered for upgrading of flood protection. Unfortunately, I have been unsuccessful in obtaining a review by your agency of other reasonable alternatives. I am left with little choice but to formally protest certification of the EIR.

Please feel free to contact me if you have any questions or comments. Thank you.

RE: Protest to adoption of Environmental Impact Statement and Environmental Impact Report on the Natomas Levee Improvement Program (SCH # 2009032097) – Appended letter

Dear John and Tim,

I previously been in contact via correspondence and also testimony before SAFCA Board and State Flood Control Protection Board and expressed my concern that the project as currently proposed did not incorporate recommendation for bank protection as identified in the Natomas East Levee Evaluation Study 2006. That study identified sites I, J, K, L, & M that needed to be stabilized.

The Natomas East Levee Improvement Program for bank protection DEIR of September 2007 ~~1977~~ stated that the bank protection was to prevent erosion that could undermine or increase seepage through the existing levee by installing hardscape and prevent further retreat of existing river bank as a result of flood flow scour and wave erosion. The Proposed improvement would stabilize the bank to insure that the levees are not eroding during a large flood event.

In reading the alternatives carried forward under the Table ES-1, there is no river bank erosion control recommendation identified. Bank erosion proposes either a high or moderate risk to stability of Sacramento River East Levee at the identified locations downstream of I-5 where river flows and waves generated by boat wakes have weakened and under cut portions of the bank supporting the levee. The flood wall alternative, if adopted, would require that the bank protection improvement be implemented.

Because the current EIR did not consider the potentially feasible alternative for a flood wall that will foster informed decision making and public participation, the Environmental Impact Statement and the Environmental Impact Report is not in compliance with NEPA

requirements (40 Code of Federal Regulations (CFR) 15012.14) and the California Code of Regulations (CCR) Section 15126.6(a).

Pleased also see that attached email to you dated 11/8/09 requesting 9 documents which have not been received to date. In addition, I understand that SAFCA consultants are working toward providing missing information/justification. This information is necessary for an informed decision process.

Please append this information to my letter dated 11/11/09. I would I appreciate receiving your comments. Thank your for your courtesy and cooperation.

Sincerely,

John and Tim:

On October 21, I forwarded to you my initial response to the information I received. I support your efforts for providing 100-year flood protection to the Natomas Basin and am anxious to work together and reform the project that offers the highest net benefits formulated to minimize the negative environmental impacts and maximizes the cost effectiveness. I have attached herewith a copy of my letter sent to you on October 21st and a copy of the information list indicating 9 items that you were going to provide but have not been received to date. Please let me know.

I look forward to working with you.

Thank You!

US Army Corps of NLIP Phase 4b Notice of Preparation (NOP)

Comments Due by 4 Dec 2009

If you live South of San Juan Rd, this affects YOU!!!

The Sacramento Area Flood Control Agency (SAFCA) is handing over implementation and construction for levee improvement Phase 4b (Reaches 16 – 20, essentially Garden Highway from San Juan Road SOUTH to the American River) to the US Army Corps of Engineers.

Please send your comments to:

Liz Holland, USACE
Elizabeth.g.Holland@usace.army.mil

AND

John Bassett, SAFCA Director of Engineering:
bassettj@saccounty.net

Important items affecting YOUR property include:

- Removal of the vegetation within the levee right-of-way to address USACE requirements
- Construction of an adjacent levee, flattened landside slope, cutoff walls, seepage berms, and relief wells. Cutoff wall construction would be conducted 24 hours per day, 7 days per week (24/7).
- Raise and/or replace the discharge pipes for 4 RD 1000 and city pumping plants located on Garden Hwy from South of I-80 to Northgate Blvd. Construction would be conducted 24/7.
- Clearing of landside vegetation to prepare for Phase 4b levee and canal improvement work.
- Acquiring lands and/or right-of way within the Phase 4b Project footprint along the Sacramento River.
- Removal of waterside encroachments as required to meet the criteria of USACE, Central Valley Flood Protection Board (CVFPB), and Federal Emergency Management Agency (FEMA).
- Power pole relocation, some poles may need to be relocated to the waterside of the existing levee.
- Removal or modification of landside homes, structures, and other facilities.
- Extensive Garden Highway partial and complete closures, up to 6 months at a time.
- Use of Garden Highway for heavy haul trucks delivering materials, possibly involving 1000's of trips.
- Proposed 42-mile recreational bike/walking trail along the Natomas Basin levee perimeter.

Ms. Liz Holland, USACE

Re: NLIP Phase 4b NOP Comments

Dear Mr. Bassett and Ms Holland:

My family has resided for over fifteen years on the waterside of the Garden Highway in Sacramento.

I have been a local businessman and home owner in this county since 1986.

After reviewing the NLIP DEIR and Phase 4b NOP, I would make the following comments:

1) VEGETATION- that removal of the vegetation within the levee right-of-way be minimized, especially the taking of **"Heritage oaks" and waterside riparian habitat**.

2) WATERSIDE ENCROACHMENTS- that in the removal of waterside encroachments, the **USACE be sensitive to homeowner concerns**, while being responsible in application of criteria of the Central Valley Flood Protection Board (CVFPB) and FEMA.

3) POWER POLES- that **power poles be relocated to the landside** as much as is practical, for the safety and esthetic concerns of current residents.

4) RESIDENCE STRUCTURES- that waterside residence structures, such as gates, fences, driveways be **modified or removed as little as is possible**.

Yours truly,

Kevin McRae

Subject: Comments on NLIP Phase 4b Notice of Preparation (NOP) for inclusion

John Bassett, Tim Wahsburn, Elizabeth Holland,

I understand the last day to provide comments to the NLIP Phase 4b Notice of Preparation is December 4, 2009. I have two comments for inclusion;

1. In April 2009 the California Governor's Office of Planning and Research submitted to the Secretary for Natural Resources its proposed amendments to the State CEQA Guidelines for greenhouse gas emissions as required by Senate Bill 97 (Chapter 185, 2007). It is law now and guidelines to follow perhaps in January but I do not see anything in the NOP and I believe there should be.
2. Near my residence in Reach 16 across from the wildlife passthru there are thousands of oak trees. These serve as our connection to the Native American culture and heritage, some are 400 years old about the same time the pilgrams were celebrating the first Thanksgiving in 1621! Given the importance of protecting the oak trees overall in connection with the NLIP and in particular the density of Oaks in Phase 4b (landside stretch approx. 2400 Garden Highway) I do not believe there is appropriate environmental impact or accommodation.

Please confirm receipt by Reply email and if necessary I can provide via US mail.

Thank You,

Roger Sherman

Greetings:

Exactly 36 years ago we purchased our home on Garden Highway; it's been a wonderful place to raise our children and generally enjoy some of the best aspects of life in Sacramento.

The greatest disruption to the tranquility of our riverfront neighborhood was probably the installation of the slurry wall. When was that? Fifteen years ago perhaps? But it appears that the present plans for levee reconstruction will be far more disruptive and long-lasting. My primary concerns are:

Garden Highway closures
24 hour construction activity
Destruction of landside "encroachments," i.e., oak groves
Destruction of waterside "encroachments," i.e., valley oaks, many probably 100 years old

The elimination or significant mitigation of these elements in the next phase of the plan would be a most welcome development!

Robert Orr

Jim Bassett, Tim Washburn, Elizabeth Holland:

We share the concerns voiced by Mr. Roger Sherman below. Specifically, destruction of the oak trees and the impact to the wild life all along the Garden Hwy has not been adequately addressed. There are indeed thousands of Heritage Oaks, which are "protected" slated for destruction.

In addition, Mr Javeed Siddiqui has proposed an alternative, less environmentally destructive methodology to achieve the results necessary to provide flood protection. We respectfully request that you review his proposal and respond prior to engaging in this project.

Best regards,

Dr. Del Wright

Subject: RE: [SRPOA:] Comments on NLIP Phase 4b Notice of Preparation (NOP) for inclusion

Jim Bassett, Tim Washburn, Elizabeth Holland:

We share the concerns voiced by Mr. Roger Sherman below. Specifically, destruction of the oak trees and the impact to the wild life all along the Garden Hwy has not been adequately addressed. There are indeed thousands of Heritage Oaks, which are “protected” slated for destruction.

In addition, Mr Javeed Siddiqui has proposed an alternative, less environmentally destructive methodology to achieve the results necessary to provide flood protection. We respectfully request that you review his proposal and respond prior to engaging in this project.

Best regards,

Dr. Del Wright

Subject: [SRPOA:] Comments on NLIP Phase 4b Notice of Preparation (NOP) for inclusion

John Bassett, Tim Wahsburn, Elizabeth Holland,

I understand the last day to provide comments to the NLIP Phase 4b Notice of Preparation is December 4, 2009. I have two comments for inclusion;

1. In April 2009 the California Governor's Office of Planning and Research submitted to the Secretary for Natural Resources its proposed amendments to the State CEQA Guidelines for greenhouse gas emissions as required by Senate Bill 97 (Chapter 185, 2007). It is law now and guidelines to follow perhaps in January but I do not see anything in the NOP and I believe there should be.
2. Near my residence in Reach 16 across from the wildlife passthru there are thousands of oak trees. These serve as our connection to the Native American culture and heritage, some are 400 years old about the same time the pilgrams were celebrating the first Thanksgiving in 1621! Given the importance of protecting the oak trees overall in connection with the NLIP and in particular the density of Oaks in Phase 4b (landside stretch approx. 2400 Garden Highway) I do not believe there is appropriate environmental impact or accommodation.

Please confirm receipt by Reply email and if necessary I can provide via US mail.

Thank You,

Roger Sherman

Subject: Response to USACE of NLIP Phase 4b NOP

Dear Ms. Holland, Mr. Bassett and Mr. Washburn,

My husband, Don Fraulob, his 92 year old mother and I live at 2315 Garden Highway, Reach 16 as I understand it.

We join in the concerns raised by Mr. Howell on behalf of our association, Mr. Sherman and Mr. Siddiqui.

In addition, we have never had any assurance that the proposals have addressed and/or resolved:

1. the impact on the ability of emergency vehicles to get to our home in case my 92 year old mother-in-law has a medical emergency;
2. the impact on our well water;

3. whether the existing Garden Highway can handle the 24/7 trucks;

4. the impact on our health. In my case, I have asthma and am very reactive to dust, diesel and gasoline fumes;

5. the noise that will interfere with the enjoyment of our home. As it is we are across from the weir. The work starts before daylight using powerful construction lighting. The noise of rocks being loaded onto a barge, together with the vehicle back-up alarms is extremely disruptive;

6. the decrease in value of our homes for property tax purposes;

7. the denuding of the levees, our property and surrounding property;

8. the environmental impact on the natural access to the river by wildlife. The southern border of our property is traveled by deer, squirrels, raccoons, possums, skunks, fox and even beavers from time to time. In addition, hawks, owls, magpies, hummingbirds, ducks, geese and many other birds face disruption and probable decimated numbers, as well as bees, butterflies and other insects necessary for pollination;

9. the appropriate mitigation for the homeowners for the loss of quiet enjoyment of our homes as well as reduced value during the many years of planned construction.

We appreciate the need for flood protection, however it is not at all clear that the damage to the environment, historical lands and quality of life is outweighed by the hoped for protection. I was happy to see that a recreational bike/walk trail is proposed. If this does develop, it would seem that a natural path would be the existing Garden Highway with the new set-back levee handling the 24/7 trucks and future traffic.

Lastly, the last major construction project, during which a trench was dug and filled with slurry, resulted in asphalt, petroleum and who knows what other toxic waste being dumped across the street from our home. I hope the that this project will have a better clean up record.

I urge the corps to address these and the other concerns raised by my neighbors before further construction is undertaken.

Respectfully,

Melissa Brown

Dear Ms. Holland, Mr. Bassett and Mr. Washburn,

To my embarrassment, I listed our address as 2315 Garden Highway.

It is **2517** Garden Highway. 2315 is our office address, which indicates I am spending too much time here.

Please note that correction.

Thank you,

Melissa Brown

Subject: Garden Hwy Construction

To SAFCA and Army Corps,

Please note my agreement with the comments of my fellow residents and the analysis of the GH homeowners association. We want the tree's to stay and would like assurances that the beauty of the Garden Hwy corridor will not be altered. The safety of the Sacramento basin is of concern to us all, and I am sure there is a middle ground that would not involve the removal or encroachments on the water side or the tree's on the land side of the hwy.

Thank you for your consideration.

RE: Comments on Phase 4b "Notice of Preparation"

SAFCA and US Army Corps of Engineers:

The Garden Highway Community Association (GHCA) is an incorporated community association whose membership includes nearly all waterside and landside property owners along the Garden Highway in the area addressed in SAFCA's Natomas Levee Improvement Program (NLIP). The GHCA supports increased flood protection for the Natomas Basin, as long as it is done in a fiscally responsible, environmentally conscious, and scientifically sound manner. At the same time, as most GHCA members live on or next to the NLIP, they have an enormous interest and concern in how this project is implemented.

Below is a list of comments and concerns regarding the Phase 4b Notice of Preparation.

1. Failure to Adequately Consider Alternative Designs

SAFCA and the USACE have failed to conduct a legitimate, unbiased study to determine the most economically and environmentally sound project design to bring the Natomas Basin up to the USACE 100 year flood protection standard. SAFCA and the USACE have summarily dismissed feasible alternatives that would lead to region-wide solutions to the flooding potential in the Natomas Basin and surrounding communities. They have also failed to make a rationale, "good faith" effort at minimizing the height and footprint of the adjacent levee system, especially in light of the lower and inferior levee systems both upstream and adjacent to the NLIP. Therefore, the project is not in compliance of CEQA and NEPA requirements.

Pursuant to the applicable environmental laws, the agencies responsible for this Project must rigorously explore and objectively evaluate all reasonable alternatives and must devote substantial consideration to each alternative consideration.

Notably, during a recent SAFCA Board meeting which discussed the Project, it was repeated several times that the levee improvement design is a "work in progress" and that certification of ongoing EIS phases was a "worst case scenario" for the environment and property rights. Unfortunately, current environment destruction adjacent to Garden Highway does not correlate with these "work in progress" and "worst case scenario" portrayals. Rather, SAFCA and its contractors are in a race to remove highly sensitive habitat within the ENTIRE project footprint, despite the fact that alternative, less obtrusive levee improvement designs are gaining momentum and the fact that the Project is facing insurmountable fiscal problems.

The GHCA strongly encourages SAFCA and the USACE to look outside the Project's predestined box and not "clear a construction path" through sensitive habitats and rich farmland based upon "worst case" design scenarios. There are obviously countless alternative designs that would accomplish the flood protection our region needs at a fraction of the monetary, environmental and property-loss cost. For example, simply narrowing the footprint of the "seepage berms" would result in mammoth savings in all three of these areas. These berms, designed to be 500 feet wide in some areas, are unprecedented in our region and seem highly unwarranted when compared to the existing 10-20 foot berms that previously handled several 100-year-floods (without the cut-off walls that will be added as a part of this project). More telling, as evidenced by design concessions to certain property owners, SAFCA and the USACE have shown by their own actions that the footprint of the seepage berms can be substantially narrowed without losing the flood protection it seeks.

CEQA also requires a realistic analysis of the existing physical environmental conditions affecting the Project. Several court decisions have determined that the impacts of a proposed project must be measured against the "real conditions on the ground." Save Our Peninsula Committee v. Monterey County Board of Supervisors (2001) 87 Cal.App.4th 99, 121. "An EIR must focus on impacts to the existing environment, not hypothetical situations." ibid. In determining whether a project's impacts may significantly affect the existing environment, there must be a "baseline" set of environmental conditions to use as a comparison to the anticipated project impacts. As the Court of Appeal has explained, "it is only against this baseline than any significant environmental effects can be determined." County of Amador v. El Dorado County Water Agency (1999) 76 Cal.App.4th 99, 952.

Despite these requirements, the plans for this Project fail to describe the existing physical environmental conditions in order to determine the Project's significant adverse impacts on the existing environment. Conversely, the entire NLIP design relies upon a computer simulation that describes a hypothetical physical condition, but does not describe the actual physical conditions on the ground, including the current condition of the west side levees along the Sacramento River and the north side levee along the Natomas Cross Canal. This comparison would answer the question of "levee parity" and whether any spots along the river side of the east levee improvements or west side of the Sacramento River in Yolo County, or north side of the Natomas Cross Canal in Sutter County, would be more vulnerable to flooding.

In other words, if the east side levee along the Sacramento River has sufficient freeboard to ensure safe containment of the "200-year" design water surface, then these improved levees will have a significant adverse effect on the existing lower levee, properties, and structures along the west side of the Sacramento River as well as the homes and residents along Garden Highway on the river side of the improved east side levees.

The failure to evaluate the impact of a Project on the existing physical environmental conditions frustrates "the central function of the EIR, to inform decision makers about the impacts of the proposed project on the existing environment." Save Our Peninsula Committee, supra, 87 Cal.App.4th at p. 127.

The Project's plans further fail to consider the impacts of mounting environmental legislation and biological opinions which will significantly impact alternative flood protection plans, summarily dismissed by SAFCA as "impossible" or "inconceivable." One such edict recently issued by the The National Marine Fisheries Service unveiled a complex set of rules, a "biological opinion", which will likely have enormous impacts on local flood protection practices with the goal of increasing the populations of winter and spring-run salmon, Central Valley steelhead and green sturgeon. According to Kate Poole, attorney at the Natural Resources Defense Council, "There's no question any more about the fact that the Bay-Delta ecosystem is in dire need of significant changes and fixes. This is one big step to do that."

The new federal rules require that reclamation districts find a way to flood the Yolo Bypass more often to improve salmon habitat, negating SAFCA's argument that the Yolo Bypass could not be used to divert more water from the Sacramento River than current rules permit. Moreover, SAFCA's concern that water diversion to the Yolo Bypass would be too costly to local water and flood agencies apparently did not negate the decision on the new rules. The ruling governs water operations of the California Department of Water Resources, who will share the cost of the new orders. Clearly, flooding the Yolo Bypass "more frequently" will require a lowering of the Sacramento River weirs – a proposal made by the GHCA during 2007 as a more effective, long-term solution in lieu of an eternal levee battle in the narrow channels of the Sacramento River.

2. Failure to Adequately Consider and Protect Wildlife

The United States Environmental Protection Agency has previously commented on the NLIP, noting its continued concern over the temporary and permanent effects the Project is expected to have on the waters of the United States and recommended the continued "close consultation and collaboration" with the U. S. Fish and Wildlife Agency, California Department of Fish and Game and The Natomas Basin Conservancy to "ensure effects on woodlands, threatened and sensitive species habitat and waters of the US are avoided and minimized." Overall, this Agency has previously classified prior EIS drafts associated with the NLIP as "Insufficient Information (EC-2)".

The California Department of Fish and Game "DFG" has also expressed serious concern regarding the environmental impacts of the NLIP:

- The DFG believes pertinent mitigation measures are potentially unenforceable and may not bring the impacts to fisheries and aquatic resources to below a level that is significant.

- The DFG has found transplantation of herbaceous plants is typically unsuccessful and should be considered experimental. Mitigation measures for any potentially unavoidable impacts to special-status plants should include additional measures to increase the chances of survival for the population in question. Mitigation sites should be permanently protected and managed in perpetuity.

- The DFG is concerned with potential impacts to raptor nesting behavior not currently addressed in the DEIR, especially with regard to 24/7 construction and an estimated 900-1000 haul trips per day to deliver fill material. The DFG "believes that each of these activities could potentially result in significant impacts to nesting raptors including nest abandonment, starvation of young, and/or reduced health and vigor of eggs or nestlings that could result in death."

- In their current form, the DFG opines that the environmental documents do not explore the potential impacts of nighttime construction activities on nesting raptors. Moreover, construction at night poses additional complications for the effectiveness of biological monitors in ensuring that appropriate buffer zones are in place around active nests and that birds do not abandon their nests.

- The DFG has noted that prior DEIRS do not provide a discussion of potential impacts to the Northern Harrier, a ground nesting raptor and does not consider avoidance or mitigation measures.

The GHCA further notes the NLIP purports to mitigate the loss of woodland habitat by the promise to create three acres of canopied woodlands for every one acre destroyed. This mitigation goal is fatally flawed in that there is no discussion, explanation and/or plan to address the environmental tragedy that will result from the 50 to 100 year period required for the "new" woodland habitat to be developed – assuming the planned mitigation goal is even reached.

Despite the failure to mitigate the significant adverse impacts resulting from the destruction of woodland habitat, and the lack of necessary funding to effect the planned mitigation related thereto, SAFCA and its contractors are currently proceeding with the destruction of woodland habitat and the clear-cutting of heritage oaks and other trees.

Further, the NLIP also proposes to utilize lands purchased by the Natomas Basin Conservancy ("Conservancy") as borrow areas. These borrow areas will provide the base material for the landside levee improvements on the south side levee along the Natomas Cross Canal and the east side levee along the Sacramento River. Despite SAFCA's proposed use of these lands, the Conservancy acquired these properties to offset urban development's significant adverse impacts on protected wildlife species within the Natomas Basin. The Conservancy acquires and manages these properties consistent with the Natomas Basin Habitat Conservation Plan. The GHCA believes there still is no agreement between the Conservancy and SAFCA on the use of Conservancy lands and how these lands will carry out their intended conservation purpose after the soil necessary for the construction of the levee improvements is removed. Thus, any claimed mitigation for the loss and disturbance of Conservancy land is impermissibly deferred to some future time after Project approval and implementation.

Despite the fact that the Project's agencies have been afforded several bites at the apple in an attempt to come up with acceptable environmental mitigation, it continues to gloss over the devastating impact the

Project will have on the sensitive habitat of protected species, including raptors, snakes and flora (see comments of the California Department of Fish and Game summarized above).

3. Failure to Study Simultaneous Multi-Phase Construction

SAFCA, and now the USACE, are currently postulating that multiple phases of the NLIP could be constructed simultaneously. This directly contravenes the construction impact and mitigation advanced in the prior environmental documents and creates new issues not previously studied or addressed. For example, there would be compounded effects of CO2 emissions, noise, dust, vibration, and disruption to wildlife that has not been analyzed. Compared to the original Phase 3 EIR, for example, emissions in just Sacramento County would raise from ROG 75 lb/day to 287 lb/day, NOX 413 lb/day to 1,476 lb/day, and PM10 971 lb/day to 3,847 lb/day if these phases are to be done simultaneously. Moreover, on page ES-16, "Air Quality," the Phase 3 DEIR references the "nonattainment status of the Feather River Air Quality Management District and the Sacramento Metropolitan Air Quality Management District for ozone and PM10." The GHCA contends the cumulative effect of simultaneous construction during multiple construction phases has not been sufficiently analyzed by the responsible agencies.

Furthermore, simultaneous construction could involve three or more phases of simultaneous, 24/7 construction. Given the grave impacts of just one 24/7 worksite, the GHCA believes SAFCA and the USACE certainly cannot justify multiple worksites operating in this manner. This impact would make the simultaneous Phases (2, 3, 4a, 4b) unreasonably harmful to wildlife, the environment, and Garden Highway residents.

4. Failure to Adequately Address Encroachments/Levee Prism

At page 7 of the NOP, Encroachment Management, the following proposed action appears: "Remove encroachments as required to meet the criteria of the USACE, CVFPB, and FEMA." Conversely, the Sacramento Division of USACE and SAFCA have repeatedly advised members of the GHCA that the "adjacent" levee adopted by the NLIP "should" remove the waterside trees, landscaping, fencing, and other vegetation and improvements from the "levee prism." In other words, these agencies believe implementation of the NLIP would spare these items from removal under even the most aggressive encroachment standards. Thus, the GHCA is concerned with the apparent unchanged position regarding encroachments as described in the current NOP.

Of utmost importance to property owners along Phase 4b, the USACE does not mention how they will treat vegetation and encroachments on either side of the levee where they decide not to build an "adjacent setback levee" and thus achieve a new levee prism. If a "one size fits all" approach of denuding levees is applied, it will completely contradict the long established local USACE procedures of planting trees to stabilize the levees, protect endangered wildlife and reduced wind-driven waves. We have also been told that many members of the scientific community believe trees and other vegetation improves the strength of a levee, especially in areas of the country that do not have to contend with hurricane strength winds. What are USACE's current views on this?

It also does not appear the USACE has identified what (if any) waterside encroachments will be subject to removal within the NLIP and what legal processes will be involved in condemnation of associated property rights. These questions are of utmost importance to the GHCA and its members. SAFCA has

also advised the GHCA it has maps of approximately 30,000 encroachments and all associated easements on the waterside of the levee. SAFCA recently revealed this database to the public, but there is no mention of the encroachments and/or vegetation that the involved flood agencies consider to be unacceptable. Research has revealed some vague, inadequately mapped easements dating back to the early 1900's which appear to show little or no support for any planned encroachment removal.

SAFCA has also stated "on the record" it is willing to help facilitate "post-facto" permits for encroachments that do not endanger the levee. Would the USACE also be willing to endorse this procedure? Unfortunately, because the property owners have no information as to what items SAFCA and the USACE feel are acceptable encroachments, Garden Highway properties are being left in the dark.

Overall, the members of the GHCA are very concerned about which "encroachments" might require removal and with the various easements SAFCA and/or its partners will attempt to claim. SAFCA has promised to work with each property owner to discuss and resolve issues regarding alleged encroachments, but thus far has taken no such action. Does the USACE plan on doing the same for Phase 4b? Currently, construction Phase 2 of the Project is underway, yet the GHCA is aware of no affected property owners having been contacted regarding encroachment or easement plans. This not only impacts existing improvements, but future improvements. The uncertainty also creates resale problems and negatively affects property values.

5. <u>Failure to Justify 24/7 Construction</u>

As accurately noted by the California Department of Fish and Game, previous EIRS/NEPA documents do not adequately address the potential impacts to raptor nesting especially with regard to 24/7 construction and an estimated 900-1000 haul trips per day to deliver fill material. The DFG "believes that each of these activities could potentially result in significant impacts to nesting raptors including nest abandonment, starvation of young, and/or reduced health and vigor of eggs or nestlings that could result in death." Moreover, the NOP does not explore the potential impacts of nighttime construction activities on nesting raptors. Moreover, construction at night poses additional complications for the effectiveness of biological monitors in ensuring that appropriate buffer zones are in place around active nests and that birds do not abandon their nests.

The NOP contends Cutoff Walls, wells and perhaps additional aspects of the Project require a 24/7 construction schedule. The residents along Garden Highway and the sensitive environment that exists in the riparian, river habitat adjacent thereto cannot be subjected to 24/7 construction simply because SAFCA or the USACE is running behind schedule on what might be perceived as an overly ambitious project. It is anticipated 24/7 construction during subsequent phases of the NLIP would have an exponentially adverse impact on property owners spanning many miles in all directions. Moreover, the use of trucks to get to and from the actual "construction" sites will expand the location of the impact far beyond the limited construction sites addressed by SAFCA and this NOP.

The GHCA also feels the NOP ignores both city and county (Sacramento and Sutter) noise ordinances. As such, the GHCA seeks an explanation as how the USACE plans to deal with violations of local noise ordinances.

6. Damage to Businesses

The NOP fails to address the impact of the project on the businesses that exist along and upon Garden Highway which thrive only because individuals seek the tranquility and peace of a rural, river atmosphere that is easily accessible, peaceful and enjoyable.

7. Hydrology

The hydrology reports postulated by SAFCA and its engineers in previous Phases conclude the improved levee system contemplated by the NLIP will not increase the flood risk to the waterside property owners within the NLIP. These reports are explicitly based upon the assumption that other surrounding Reclamation Districts will NEVER improve their levees. This assumption is improper, flawed and not in concert with the current push by adjacent Districts to fortify their levees. The threat of increased flood risk cannot be summarily dismissed and a funding mechanism must be included to deal with the financial impact of this impact.

Equally troubling, SAFCA admits its "design event analysis is not the same as the analysis procedure used by USACE." As the primary advertised goal of the NLIP is to obtain USACE certification, why is SAFCA deviating from the USACE event analysis? The previous SAFCA EIRS/NEPA documents further note that the USACE analysis "includes consideration of system uncertainties." Does this mean the SAFCA analysis does not account for "system uncertainties" such as the other side of the levee overtopping or failing?

Waterside residents adjacent to the NLIP are very concerned about increased flooding of their homes due to the levee being raised as much as three feet. SAFCA has systematically advised the GHCA not to worry, as levees will overtop or fail elsewhere. Unfortunately, it appears SAFCA's engineering analysis does not account for this or assumes the other levees will be raised and reinforced. If both sides of the levee are eventually raised, then the water capacity of the river will be increased. This would allow the upstream reservoirs to release more water during a flood event and subject residents to a much greater chance of flooding. The GHCA has been advised there is debate amongst USACE engineers as to which provides the better hydrological model, "perfect world" where you cannot take into account deficiencies in other parts of the levee, or "real world" where you can. What is USACE's view on this?

8. Property Values

The NOP, consistent with all prior SAFCA action related to the NLIP, wholly fails to address the impact of the Project on property values in the affected areas and has no funding mechanism in place to deal with the destruction of property values in and around the project that will ripen into eminent domain and inverse condemnation lawsuits. This exposure includes, but is not limited to, irreparable damage to property values which began when this project was first publically announced (at a time when real estate values were significantly higher than today), and will continue indefinitely into the future. The Project has stalled and prevented sales, land improvements and retirement plans. This trend will increase exponentially when active construction begins. Due the lack of a funding mechanism, the taxpayers will be left to shoulder yet another wave of unanticipated and undisclosed cost overruns.

9. Failure to Consider Environmental Impact of Development

While SAFCA publicly justifies the massive NLIP as a necessary cure for the imminent, Hurricane Katrina type flooding that could occur in the Natomas Basin in the event of a 100-year-flood, in reality SAFCA is simply trying to lift the building moratorium affecting the builders who have imprudently chosen to pave over rice fields in a "basin". These are the same developers who have spent hundreds of thousands of dollars supporting our local officials and lobbying for the right to resume rapid development within the floodplain. Without more "urban sprawl", these developers and the County of Sacramento are unable to tap into the "quick cash" that has been created from destroying our evaporating farm lands.

The GHCA contends that rather than encouraging additional urban sprawl, local agencies should be focusing on creating more housing in urban areas, i.e. building up, not out. Moreover, the failure of local agencies to curb their appetite for our farmlands will only increase traffic congestion, gas and carbon emissions and regional pollution at a time when universal fears and concerns over global warming, water scarcity and energy depletion is gaining momentum.

The GHCA contends the urban sprawl into the Natomas Basin, quite ironically, increases the flood potential for Natomas and surrounding communities. Vast farmland that previously collected and stored water during heavy storms, before slowly releasing it through natural underground seepage, has now been paved and improved with storm drains. Accordingly, thousands of acre feet of rainwater that previously rested safely within area farmland is now immediately collected and pumped into the Sacramento River. Historical flow charts from the Sacramento River during times of heavy storms confirm the negative impact Natomas Basin development is having on regional flood protection.

10. Failure of the Notice of Preparation to abide by the Settlement Agreement between SAFCA and the GHCA.

The "Notice of Preparation" in no way mentions the previously agreed to settlement agreement between SAFCA and the GHCA. While the GHCA understands the USACE is not SAFCA, as the assignee of certain aspects of the Project, the USACE is legally required to comply with all legally enforceable agreements entered into by SAFCA, the assignor. To hold otherwise would render the settlement agreement between SAFCA and the GHCA illusory.

11. Rights of Entry/Eminent Domain.

It has recently come to the attention of the GHCA that SAFCA has pursued Right of Entry Agreements from Garden Highway property owners without advising those property owners of any authority for the desired access and without advising owners of their associated rights. By withholding this critical information, SAFCA has in essence coerced many Garden Highway residents into making uninformed decisions under the bold threat of imminent litigation should they resist.

In response to a recent complaint by the GHCA, counsel for SAFCA has confessed that entry onto the private property of Garden Highway residents is being sought pursuant to the Eminent Domain laws of the State of California. However, pursuant to California Code of Civil Procedure Section 1245.010, SAFCA and/or its contractors must be "**authorized to acquire property for a particular use**" **before**

they may enter private property in order to "take photographs, studies, surveys, examinations, tests, soundings, borings, samplings, or appraisals or to engage in similar activities reasonably related to acquisition or use of the property for that use." Apparently, SAFCA has repeatedly misinformed property owners that SAFCA possesses this authority when, in reality, no such authority had ever been obtained.

Based upon the foregoing, the GHCA hereby submits that all involved flood agencies seeking permission to enter private property must notify the affected property owners **of the legal authority upon which the agency relies, along with a full description of the associated rights afforded the property owners**.

Lastly, the GHCA hereby objects to the "taking" of private lands pursuant to the Eminent Domain laws under the guise that these lands are necessary for the development of the Project, when in fact the involved agency actually and surreptitiously plans to convey the condemned land to another private party, i.e. the airport.

12. Natomas Levee Recreational Trail Project.

The GHCA is pleased a recreational trail is finally being included as part of the NLIP. Unfortunately there is no funding mechanism in place other than waiting on the Department of Transportation, which has admitted could take years. As SAFCA and the USACE are already spending millions of dollars protecting cultural resources of Native American Indians, the GHCA believes it would be practical to allocate a nominal sum of money to enhance the resources of the current living residents in the Natomas Basin. The simple modification of the design of the new levee crown from a gravel road to paved road would bear a meager cost and would streamline the bike path for the DOT.

13. Incorporation.

The GHCA also hereby incorporates by reference all comments asserted by Garden Highway property owners and/or their representatives in response to this portion of the NLIP.

In sum, while the GHCA appreciates the daunting task this Project presents to the involved flood agencies, its members strongly feel that a more rational design approach would substantially reduce these challenges, save the taxpayers hundreds of millions of dollars, preserve sensitive habitat and rich farmland and ultimately expedite recertification of the Natomas levees. Moreover, the GHCA implores the involved flood agencies to continue to acknowledge and adhere to the rights of all Garden Highway residents, businesses and property owners.

Respectfully submitted,

GARDEN HIGHWAY COMMUNITY ASSOCIATION

Subject: RE: [SRPOA:] Response to USACE of NLIP Phase 4b NOP

John and Elizabeth,

My family resides at 6941 Garden Hwy and agrees with these comments and all comments previously submitted. Additionally, we are concerned with the encroachment issue. Like many other Garden Highway residents, we have permitted encroachments that have appeared on SAFCA's encroachment list. For example, a well, propane tank and driveway. To remove and relocate any of the alleged encroachments will be prohibitively expensive and SAFCA, USACE or any other responsible entity will be obligated to pay for any relocation of any alleged encroachments. Please address these impacts as well. Thank you.

Subject: [SRPOA:] Response to USACE of NLIP Phase 4b NOP

Dear Ms. Holland, Mr. Bassett and Mr. Washburn,

My husband, Don Fraulob, his 92 year old mother and I live at 2315 Garden Highway, Reach 16 as I understand it.

We join in the concerns raised by Mr. Howell on behalf of our association, Mr. Sherman and Mr. Siddiqui.

In addition, we have never had any assurance that the proposals have addressed and/or resolved:

1. the impact on the ability of emergency vehicles to get to our home in case my 92 year old mother-in-law has a medical emergency;
2. the impact on our well water;
3. whether the existing Garden Highway can handle the 24/7 trucks;
4. the impact on our health. In my case, I have asthma and am very reactive to dust, diesel and gasoline fumes;

5. the noise that will interfere with the enjoyment of our home. As it is we are across from the weir. The work starts before daylight using powerful construction lighting. The noise of rocks being loaded onto a barge, together with the vehicle back-up alarms is extremely disruptive;

6. the decrease in value of our homes for property tax purposes;
7. the denuding of the levees, our property and surrounding property;
8. the environmental impact on the natural access to the river by wildlife. The southern border of our property is traveled by deer, squirrels, raccoons, possums, skunks, fox and even beavers from time to time. In addition, hawks, owls, magpies, hummingbirds, ducks, geese and many other birds face disruption and probable decimated numbers, as well as bees, butterflies and other insects necessary for pollination;

9. the appropriate mitigation for the homeowners for the loss of quiet enjoyment of our homes as well as reduced value during the many years of planned construction.

We appreciate the need for flood protection, however it is not at all clear that the damage to the environment, historical lands and quality of life is outweighed by the hoped for protection. I was happy to see that a recreational bike/walk trail is proposed. If this does develop, it would seem that a natural path would be the existing Garden Highway with the new set-back levee handling the 24/7 trucks and future traffic.

Lastly, the last major construction project, during which a trench was dug and filled with slurry, resulted in asphalt, petroleum and who knows what other toxic waste being dumped across the street from our home. I hope the that this project will have a better clean up record.

I urge the corps to address these and the other concerns raised by my neighbors before further construction is undertaken.

Respectfully,
Melissa Brown

Attention: John Bassett, Director of Engineering

Subject: NOP: Natomas Levee Landside Improvement Project Phase 4b

Mr. Bassett:

In reviewing the Notice of Preparation of the Environmental Impact Statement/Environmental Impact Report for the Natomas Levee Improvement Program, Phase 4b Landside improvement Project, I have the following questions and comments:

►NEMDC West Levee – Northern segment: How will the "Sankey Gap" and the overflow of water, particularly water which overflows on the east side of the W.P./S.P railroad at high water events be addressed?

►Pleasant Grove Creek Canal (PGCC) and NEMDC levee raising: To what elevation are these levees to be raised?

►PGCC and NEMDC Waterside improvements: How will erosion repair and rock slope protection effect upstream water levels? Any material placed inside (water side) of the levee will increase water levels upstream.

►PGCC Culvert Remediation: These culverts are the only means of drainage for the areas between the W.P./S.P. railroad and the PGCC.

►State Route (SR) 99 NCC Bridge Remediation: The material added to the inside (water side) of the NCC south levee will restrict the westerly flow of water thus increase uplift and lateral forces on the bridges. This fill should be removed back to original profile. A reinforced concrete overlay could be placed on the levee surface, extending down to firm subsoil. Excavate additional material under bridges to facilitate flow under the bridges.

►Borrow Site Excavation and Reclamation: Borrow sites should be utilized for retention ponds for storm water run off. The NCC and PGCC should be used for borrow material as deepening these canals would reduce flooding of upstream areas, particularly areas immediately east of the W.P./S.P. railroad.

►Bank Protection: Sacramento River Left Bank-Encroachment Management: Any material or structures placed inside (water side) the levee will increase water elevations upstream.

Alternative actions which should be included in the project:

►Improvements to the Yolo Bypass.

►Set levees back a minimum of 1000 feet to provide more width to channels thus lowering water elevation in the river.

►Remove levees from "islands" created in the Delta and East Bay estuaries.

►Reduce or curtail discharge of drainage water into the river system during periods of high water levels.

Probable environmental impacts of the proposed Phase 4b Project:

Raising levees and placing material inside levees in the Sacramento River, the Natomas Cross Canal and the Pleasant Grove Creek Canal will increase the risk of flooding in other areas of south Sutter County, particularly in the Pleasant Grove area. In addition to potential damage to homes and farms, Pleasant Grove School, Fire Department, Post Office and cemetery are also threatened, as well as Catlett Substation (PG&E at Fifield Road).

The raised levees are also a visual barrier.

Previous EIS/EIR documents have failed to adequately address impacts of these projects on the surrounding communities. Since the bulk of the funding is provided by State and Federal general funds, these project should benefit the broader region, not just one isolated area at the detriment of neighboring communities.

Respectfully submitted,

Melvin Borgman

To Elizabeth Holland, etal

I also share the concerns of my neighbors. This project should not reduce our quality of life and enjoyment of our homes. The river is a Sacramento treasure and should be appreciated as such. I ask that all means be taken to complete this project with peace, beauty, and enjoyment of the properties be considered.

Thank you for attention to these matters.

Sincerely,

Vicki Pfingst and Susan Fast and our pets

Sacramento, CA 95814

Dear Mr. Bassett,

RE: Natomas Levee Improvement Program Phase 4b Landside Improvements Project

Subject: EIR NOP Comments

I am a homeowner within the River Oaks Community Association (ROCA) and my property is located within 800 feet of Garden Highway. After review of the NOP dated November 5, 2009, I have several concerns that either further information needs to be provided, mitigation provided, or both.

- **Construct adjacent landside levee with wider landside slope & seepage berms** (page 5)-Nothing has actually been designed to identify the actual impacts for the majority of the River Oaks frontage (Reach 19B), only that "measures would be employed to reduce the project footprint impacts to these resources (residences, business, heritage oaks) to the extent feasible given levee design and seepage remediation requirements" (page 7).
    - How can environmental impacts be judged when project design & limits are not presented? Some form of preliminary design is needed to identify the actual project limits and thus determine the Environmental Impact that the project expects to make. Otherwise, there is no way to trust that the level of feasibility isn't set so low that anything can be done.
    - Reconstruction of intersections at Orchard and Gateway Oaks is also noted (page 8) to accommodate levee slope flattening (ie widening), but the properties east and west of these intersections are fully improved with minimum setback available for such. Again, project limits need to be determined.
    - Right-of-way acquisition (page 6) to acquire lands is noted, yet extents not determined. Again, project limits need to be determined.
- **Landside vegetation removal** (page 6)- All landside vegetation will be cleared, with the measures noted above for heritage oaks. Clarification on actual means to save these trees needs to be made, and where trees will not be saved those locations need to be presented. In Reach 19A there is a large stand of oaks near I-80 that were to be part of a future park but are clearly in the path of a seepage berm. Perhaps a seepage berm (noted further below) should not be used for anything east of the 1-80 bridge as it would

negatively impact the trees, but rather implement the to be determined designs of Reach 19B throughout.

- **Waterside vegetation removal** (page 6)- Is this only at locations where pumping plant modifications are occurring? It seems that is the intent, but the language is not clear.
- **Construction on Garden Hwy** (Page 8)- Requirements need to be added that guarantee equipment will not exceed a certain decibel level, and that light pollution will not exceed a certain foot-candle level at homes.
- **24/7 construction for cut-off walls** (page 5)- This is not acceptable, particularly for residential properties closest to the levee. If work needs to be accelerated, double and triple crews should be used, a max of 16 hrs/day where work adjoins residential.
- **Power pole relocation** (page 7)- Relocating the existing land side power poles from the top of the levee down to the bottom of the slope is not acceptable. These are a real eyesore to put into our neighborhoods that were built to specifically avoid these and are a serious concern. Rather, these utilities should be kept up on the road serving the riverfront parcels, but undergrounded and placed at shallow depths above the 0.005 AEP flood surface elevation similar to the reconstructed pump station discharge pipes. Any above grade facilities can be placed on either side of the road.
- **Seepage berm, up to 250' wide in addition to the adjacent levee construction at Tim Lewis** (page 7)-. Given that the distance from the top of levee to the back of sidewalk along Wheelhouse Ave is 330', construction (which consists of adjacent levee construction, the berm, and transition slope down to ground level) will extend all the way to the sidewalk.
    - Clarify impacts to the oak tree stand on the west end of the reach.
    - If this berm will be constructed, confirm the treatment to the top of it.
    - Provide beautification at the 12' wide transition slope behind the sidewalk.
- **Bike trail along south side of Natomas Basin** (Page 8)- Preliminary levee improvement design through Reach 19A & Reach 19B needs to be provided with this shown incorporated.

Please incorporate these comments into your documentation. If you have any questios, please feel free to contact me via email or USPS mail.

Sincerely,

Ronald Johnson, P.E.

22 NATIONWIDE DEPOSITION & VIDEOGRAPHY SERVICES

23 701 Battery Street, 3rd Floor

24 San Francisco, CA 94111

25 (415) 981-3948

MR. JARDIN: My name is Manuel Jardin.

My concerns have to do mainly with safety and noise pollution. As far as safety is concerned, I'm concerned about the off road, haul roads they're going to use. Specifically Power Line Road and Del Paso Road and also San Juan Road. I wish that they would not use those roads simultaneously. So for instance, if they're using Power Line and Del Paso that they not use San Juan so that the public without encountering any of the trucks or anything else. And vise versa if they're using San Juan that they not use Del Paso and Power Line. That's my first concern.

And my second concern has to do with noise pollution. And that is that if they're using trucks to do their hauling, I would request that they not use what's called a compression break. Sometimes they're also known as Jake Brakes. And those are brakes on the engine that really emit a very loud noise, and if they're going to be working seven days a week or even

six days a week 12 hours a day with that many trucks and they're using their compression breaks, it's going to create a lot of noise for the residents.

MR. SEEGMILLER: I have comments that are related to my concerns based on this reading only. My name is Keith K-e-i-t-h. Last name Seegmiller,

S-e-e-g-m-i-l-l-e-r, 2598 Garden Highway. I am 1000 yards south of the ending of Project 4a. Approximately. I am in the northern portion of reach 16. I own property on both sides of Garden Highway, an undeveloped lot on the river side and my home on the land side. I am concerned, based only on this reading here, that at the conclusion of Project 4a SAFCA will declare its job done and will hence forth relinquish all responsibility for this project. That's what I read in here. The Corps of Engineers will then be the public phase of phase 4b. I do not like that.

So I guess what I'm saying at that point I think we as residents lose all contact with any local agency. And it's clear that the agency, SAFCA, now believes that at the end of 4a they will have achieved their goal of the 100 year flood protection and there goal of getting FEMA to lift there moratorium of building. As a matter of realistic politics, that's the end of SAFCA's concerns. And therefore I see them

abdicating and walking away from the project because the money from this forth the money and going to come from the federal share and the Corps will dictate how that money is used. Not withstanding any agreements that we have with SAFCA. All of those will be -- that's a serious concern. It makes me very nervous.

If I think of anything else I'll come back.

MS. BORGMAN: I'm Charlotte Borgman, C-h-a-r-l-o-t-t-e B-o-r-g-m-a-n. I live at 3559 Howsley Road in Pleasant Grove. Part of my concern is what is being done to mitigate the increase in water to the east of the Natomas Basin when the levy on the west side is raised and the water level in the canals and the river both river and Natomas Cross Canal and the Pleasant Grove Creek canal is raised then the drainage, where is it supposed to go? How does it get out? Is it backing up on me and causing me a problem? In previous EIRs when we've questioned that. We have been told that there is an insignificant amount. By the time we have done five or six or eight or ten insignificant amounts then it becomes a significant amount as far as I see. So help.

I do hereby certify that the foregoing meeting was taken at the time and place therein stated; that the testimony of said parties was reported by me, a shorthand reporter and a disinterested person, and was under my supervision thereafter transcribed into typewriting.

Mr. Bassett:

I am a partner of the C. Morrison Ranch in Pleasant Grove. To provide a meaningful response to an EIR/EIS I need information regarding the relocation of the Morrison Canal.

The single statement "Relocate the Vestal Drain ditch and Morrison Canal to reduce underseepage potential" does not tell me where the canal will be relocated, how the relocation will be accomplished, how the relocation might affect our property, and will the relocation interrupt the irrigation season.

Please provide details for the relocation of the Morrison Canal in the EIR/EIS.

Respectfully,

Charlotte Borgman

Re: NOP, Phase 4b, NLIP **CC:**

- **Comments:**

Attached: Letter regarding the NOP for Phase 4b of the Natomas Levee Improvement Project.

Posters from November 18, 2009 Scoping Meeting

Station 1 – Introduction

Relationship to other USACE Planning Documents

AMERICAN RIVER COMMON FEATURES PROJECT

- Authorized in 1996 under the Water Resources Development Act
- Designed to lessen flood risks in Sacramento and strengthen the American River levees so they can safely pass a flow of 160,000 cubic feet per second
- The project has installed roughly 23 miles of cutoff wall up to depths of 80 feet, raised levees to provide adequate levee height, addressed slope stability issues, and corrected some erosion problems
- New issues have emerged and new engineering standards have been instituted since the authorization of the American River Common Features Project

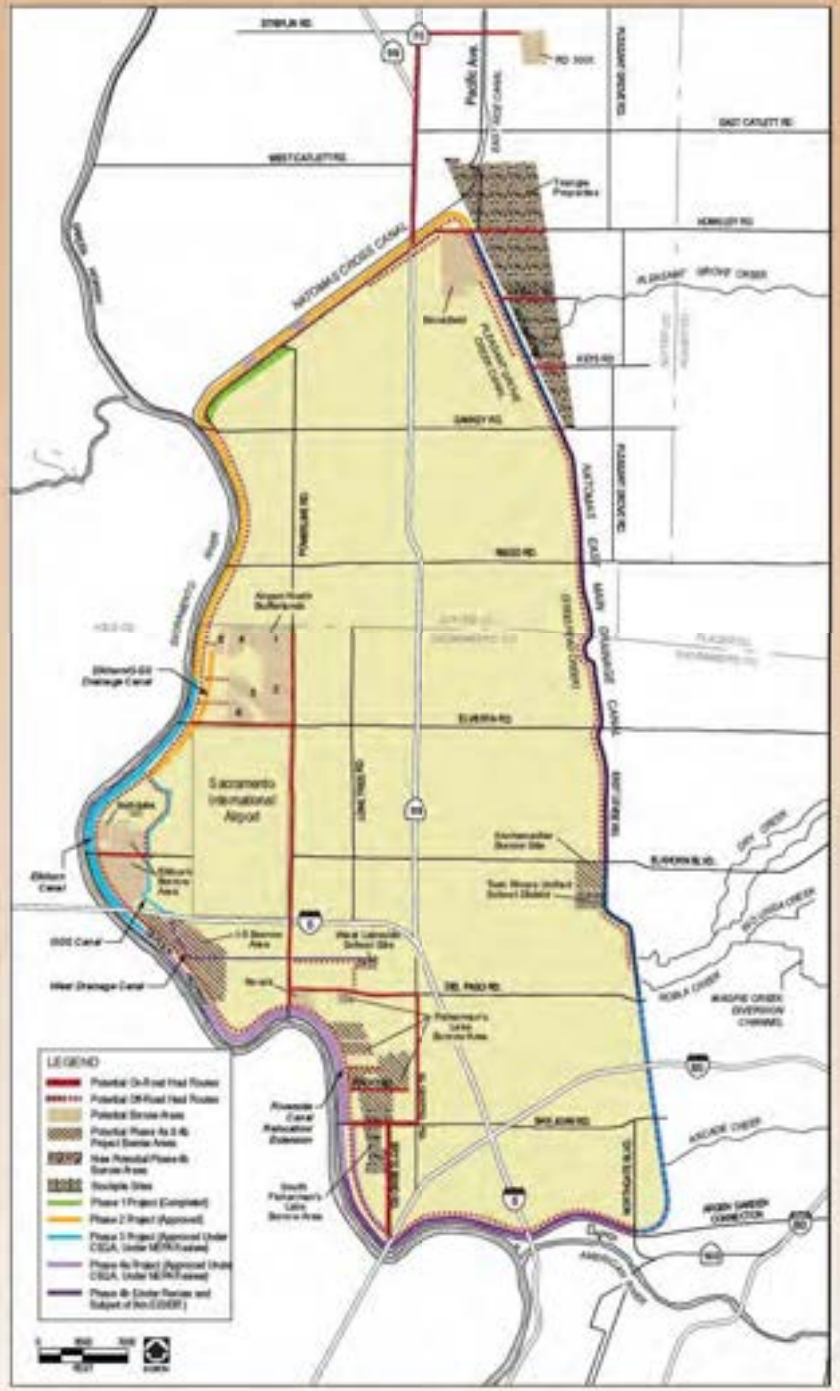
GENERAL RE-EVALUATION REPORT

- In light of new issues and standards, the General Re-evaluation Report (GRR) will look at the existing American River Common Features Project with the purpose of identifying alternatives to lower the risk of flooding in the City of Sacramento
- Three basins in the GRR analysis will be considered: the American River North Basin, Natomas Basin, and the Greater Sacramento Basin located south of the American River
- The EIS/EIR will be used for Natomas Basin GRR approval, for preparation of the Natomas Post-authorization Change Report (PACR), and to support implementation of the Natomas Levee Improvement Program Phase 4b Project Landside Improvements Project
- USACE plans to implement the Phase 4b Project
- In the event the Natomas PACR is not approved by Congress, the EIS/EIR will support SAFCA's implementation of the Phase 4b Project should SAFCA choose to proceed without Federal participation

American River Common Features General Re-evaluation Report Study Area

Station 2 – Project Location and Background

CEQA = California Environmental Quality Act
EIR = environmental impact report
EIS = environmental impact statement
GGS = giant garter snake
NEPA = National Environmental Policy Act
RD = reclamation district



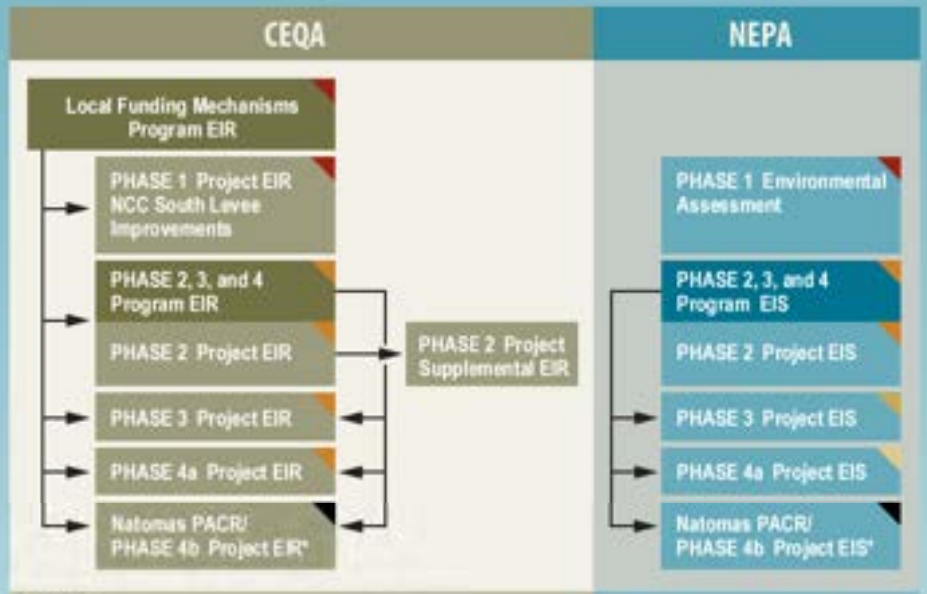
Station 3 – History of the Natomas Basin Flood Damage Reduction System

Year/Timeframe	Flood Damage Reduction Project/Event
1911–1915	Natomas Basin reclaimed: levees and interior drainage constructed
1917–1967	Levees authorized as part of the SRFCP; construction on the SRFCP is initiated and completed in stages
1968	NFIP authorized
1978	First NFIP 100-year Flood Maps issued by FEMA
1986	Major floods lead to SRFCP system re-evaluation
1989	FEMA issues new 100-year Flood Maps encompassing most of the city of Sacramento
1990–1993	Congress provides funding for the Sacramento Urban Levee Reconstruction Project
1993–1998	SAFCA carries out the NALP
1996	Congress authorizes raise and strengthening of Sacramento River east levee and strengthening of American River north levee
1997	Major flood in SRFCP
1998	USACE certifies Natomas Basin levees for 100-year FEMA flood protection
1999	Congress authorizes raise and strengthening of the NCC south levee
1999	Post-1997 Flood Assessment recognizes underseepage as a threat
2000	USACE initiates Natomas Basin Common Features Design
2002	USACE conducts public scoping meetings
2003	USACE Levee Task Force completes development of deep underseepage criteria
2004	USACE adopts Standard Operating Procedures for Urban Levee Design
2004–2006	SAFCA evaluates Natomas Basin levees
2004	USACE initiates General Re-Evaluation of the Common Features Project
2006	USACE recommends levee decertification based on new geotechnical information and new standards
2006	SAFCA initiates the NLIP
2006	SAFCA Board of Directors certifies the EIR for the Phase 1 Project, and USACE adopts a Finding of No Significant Impact and grants permission pursuant to Section 408 for the Phase 1 Project
2007	SAFCA Board of Directors certifies the EIR for the Phase 2 Project
2008	USACE issues the Draft and Final EIS for the Phase 2 Project
2008	USACE issues NOI for the General Re-evaluation of the Common Features Project
2008	SAFCA completes construction of the Phase 1 Project
2009	USACE issues the Phase 2 EIS ROD, granting permission pursuant to Sections 408, 404, and 10 for the Phase 2 Project
2009	SAFCA Board of Directors certifies the Supplement to the EIR for the Phase 2 Project
2009	SAFCA Board of Directors certifies the EIR for Phase 3 Project
2009	USACE prepares Final EIS for the Phase 3 Project
2009	USACE and SAFCA issue Draft EIS/EIR for the Phase 4a Project
2009	USACE issues Phase 3a ROD
2009	SAFCA Board of Directors certifies the Phase 4a EIR
2009	SAFCA issues NOP for the Natomas PACR/Phase 4b Project

EIR = environmental impact report
EIS = environmental impact statement
FEMA = Federal Emergency Management Agency
NALP = North Area Local Project
NCC = Natomas Cross Canal
NFIP = National Flood Insurance Program
NLIP = Natomas Levee Improvement Program
NOI = notice of intent
NOP = notice of preparation
PACR = Post-authorization Change Report
ROD = record of decision
SAFCA = Sacramento Area Flood Control Agency
SEIR = Supplemental EIR
SRFCP = Sacramento River Flood Control Project
USACE = U.S. Army Corps of Engineers

Station 4 – National Environmental Policy Act and California Environmental Quality Act

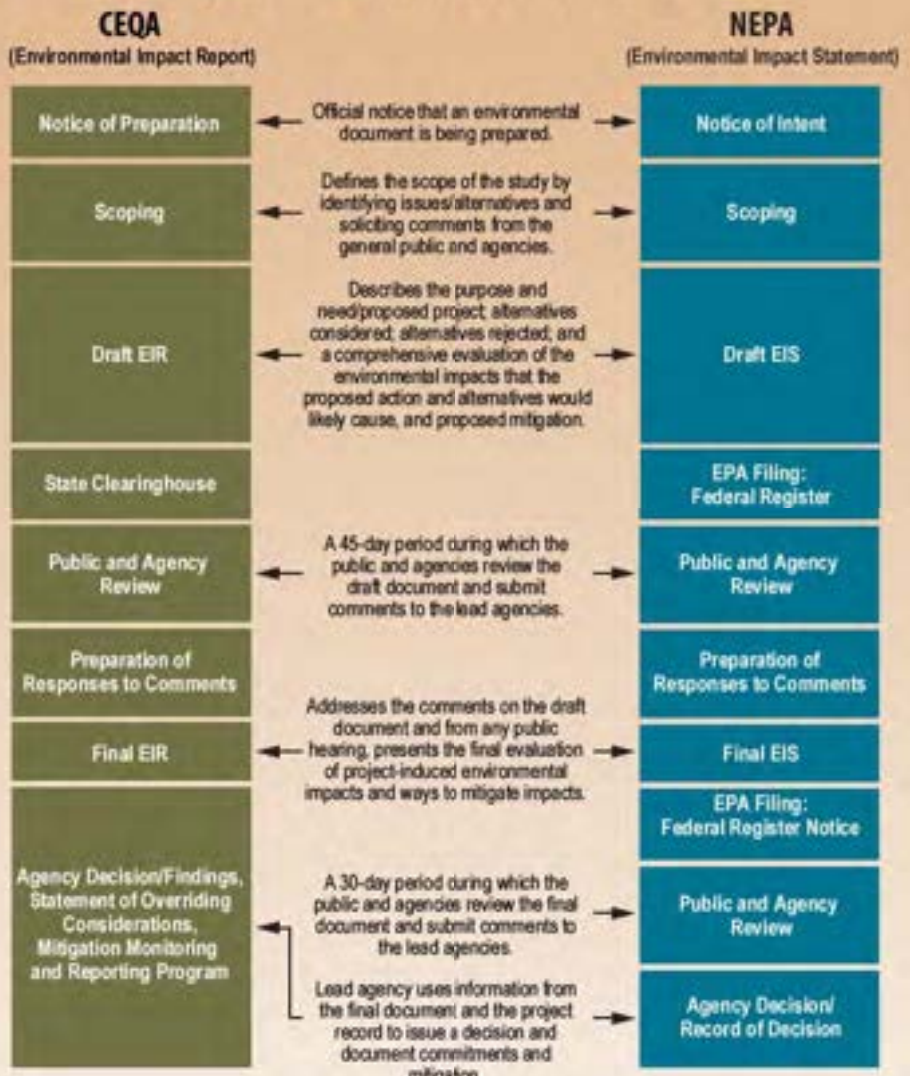
CEQA and NEPA Compliance



*Natomas PACR/Phase 4b EIS/EIR Process Timeline

Issue NOI	Feb 29, 2008
Issue NOP	Nov 5, 2009
Close of Scoping Period	Dec 4, 2009
Release of Public Draft EIS/EIR	Early Spring 2010
Comment Period	Spring 2010
Issue Final EIS/Final EIR	Summer 2010
Issue ROD and Certify Final EIR	Late Fall 2010

Understanding the CEQA and NEPA Processes



Station 5 – Levee Problems and Needs

SAFCA's Project Objectives

- Provide at least a 0.01 Annual Exceedance Probability (AEP) (100-year) level of flood protection to the Natomas Basin as quickly as possible
- Provide 0.005 AEP (200-year) protection to the Natomas Basin over time

NEED FOR ACTION

- Inadequate levee height
- Through-levee seepage and foundation underseepage with excessive hydraulic gradients
- Embankment instability
- Susceptibility to riverbank erosion and scour

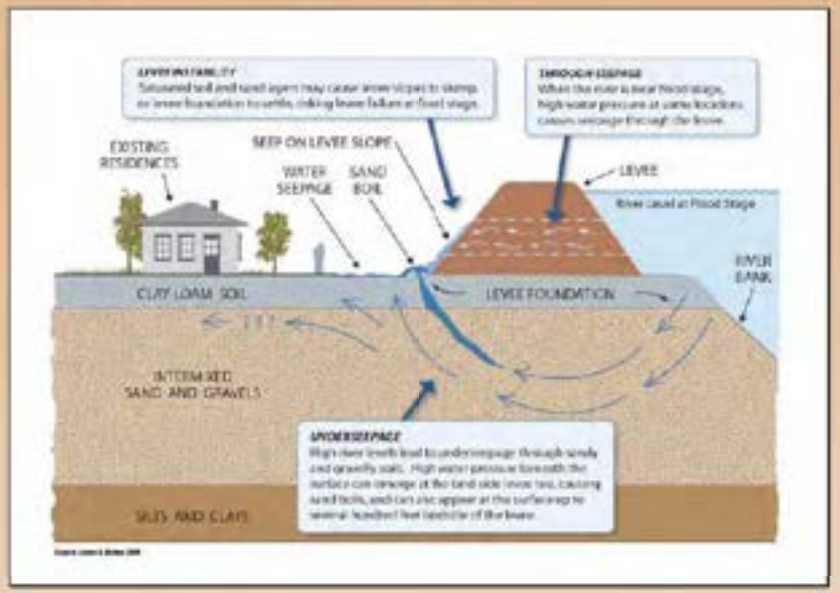
USACE PERMITTING REQUIRED (if SAFCA proceeds without Federal participation)

- Permission to alter Federal project levees under Section 408 of the Rivers and Harbors Act of 1899
- Permission to place fill in jurisdictional Waters of the United States under Section 404 of the Clean Water Act
- Permission to perform work in, under, or over navigable waters, and excavation of material from or deposition of material into navigable waters under Section 10 of the Rivers and Harbors Act of 1899

RELATIONSHIP TO THE GENERAL RE-EVALUATION OF THECOMMON FEATURES PROJECT

- USACE initiated a General Re-evaluation (GRR) of the Natomas Basin elements of the Common Features Project
- The EIS/EIR will be used for Natomas Basin GRR approval, for preparation of the Natomas Post-authorization Change Report (PACR), and support implementation of the Natomas Levee Improvement Program (NLIP) Phase 4b Landside Improvements Project (Phase 4b Project)
- USACE plans to implement the NLIP Phase 4b Project; however, in the event that the Natomas PACR is not approved by Congress, the EIS/EIR will support SAFCA's implementation of the Phase 4b Project if SAFCA chooses to move forward without Federal participation

Natomas Basin Levee Deficiencies



Levee Encroachments

Station 6 – Natomas Levee Improvements Program
Phase 4b Landside Improvements Project

Location of Phase 4b Project Components

Summary of the Natomas Levee Improvement Program Phase 4b Project Components

LEVEE REPAIR

- Sacramento River east levee Reaches 16-20
- American River north levee Reaches 1-4
- NEMDC North (west levee)
- PGCC (west levee) and NEMDC South (west levee)
- Cutoff wall construction along the Sacramento River east levee and American River north levee
- Seepage berm and cutoff wall construction and relief well installation along the Sacramento River east levee

WATERSIDE EROSION REMEDIATION

- PGCC and NEMDC South

ROADWAY MODIFICATIONS

- SR 99 NCC bridge remediation at the south end of the SR 99 bridge

DRAINAGE MODIFICATIONS

- PGCC culvert remediations
- Realignment of the West Drainage Canal
- Realignment of the Riego Road Canal (highline irrigation canal)
- NCC South Levee ditch relocations

MODIFICATIONS TO PUMPING PLANTS AND SUMP PUMPS

- RD 1000 Pumping Plant Nos. 1A and 1B along the Sacramento River Pumping Plant Nos. 6 and 8 along the NEMDC
- Modifications to City of Sacramento Sump Pumps: City Sump 160 along the Sacramento River east levee Reach 19B, City Sump 58 along the American River north levee, and City Sump102 along the NEMDC at Gardenland Park

HABITAT CREATION AND MANAGEMENT

- Enhance connectivity and improve habitat along the West Drainage Canal
- Establish woodlands consisting of native riparian and woodland species in or around the Natomas Basin as compensation for woodland impacts along the Sacramento River east levee (Reaches 16-20), American River north levee, and NEMDC west levee

REQUIRED RELOCATION REALIGNMENT AND REMOVAL OF ENCROACHMENT

- Relocation and realignment of private irrigation and drainage infrastructure (wells, pumps, canals, and pipes)
- Relocation of utility infrastructure as needed
- Clear landside vegetation in Reaches 16-20 of the Sacramento River east levee, Reaches 1-4 of the American River north levee, and the west levee of NEMDC South
- Remove waterside vegetation to prepare for modifications to pumping plants along the Sacramento River east levee, American River north levee, and NEMDC west levee
- Removal or modification of landside structures including multiple residential, business, and agricultural structures located within the Phase 4b Project footprint
- Removal of encroachments (all Phase 4b Project levees)

BORROW SITE EXCAVATION AND RECLAMATION

- South Fisherman's Lake Borrow Area
- West Lakeside School Site
- Triangle Properties Borrow Area
- Krumenacher Borrow Site
- Twin River Unified School District Stockpile Site

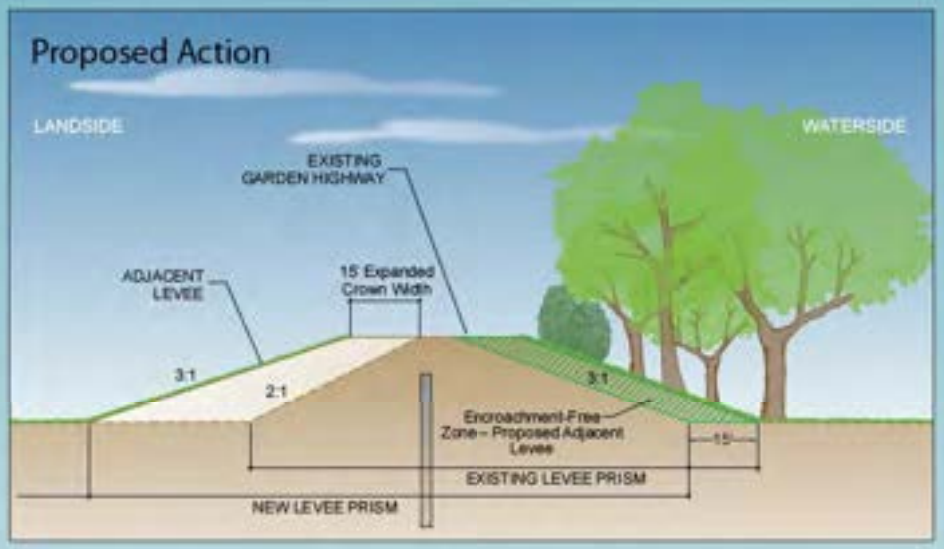
NATOMAS LEVEE RECREATION TRAIL PROJECT

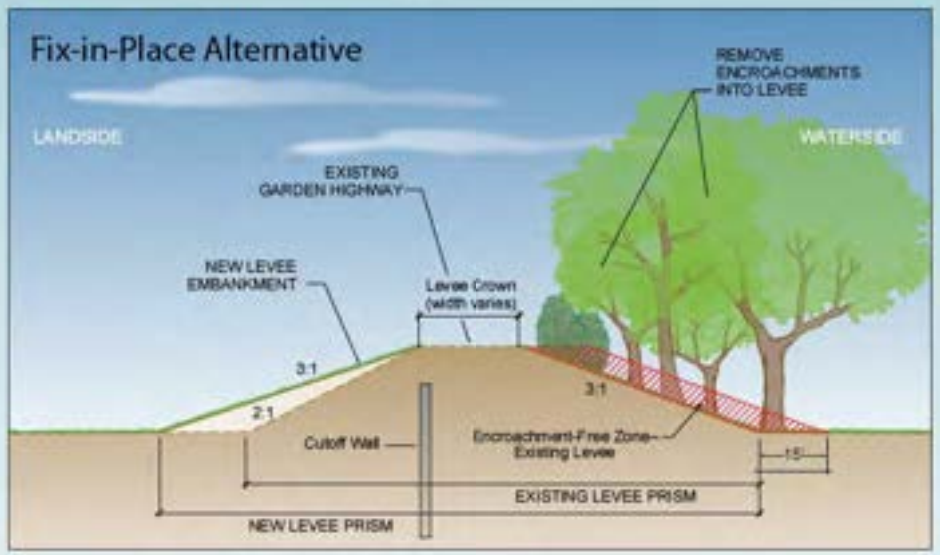
- Class I (completely separated from traffic where feasible) bicycle and pedestrian trail along the Natomas Basin levee perimeter (approximately 42 miles)

NCC = Natomas Cross Canal
NEMDC = Natomas East Main Drainage Canal
PGCC = Pleasant Grove Creek Canal
RD = reclamation district
SR 99 = State Route 99

Station 7 – Phase 4b Project Action Alternatives

Action Alternatives	No-Action Alternatives
Proposed Action	No Project Construction
Fix-in-Place	Potential Levee Failure





Comparison of Major Project Components of the Action Alternatives

All elements of the Fix-in-Place Alternative would be the same as described for the Proposed Action, except for the method of raising and rehabilitating the Sacramento River east levee, the extent of levee degradation and road closures required to construct cutoff walls, and the extent of encroachment removal along the levee. Differences from the Proposed Action are shown in italicized text below.

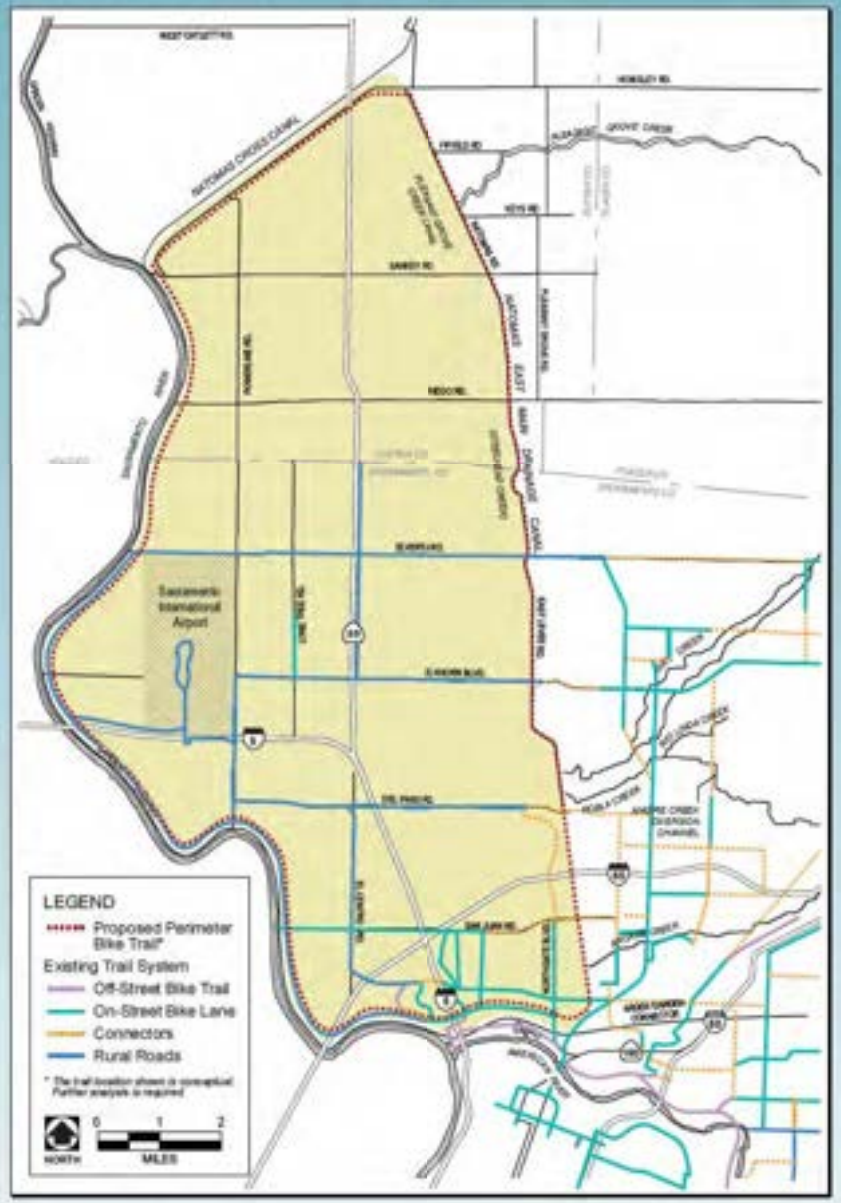
Component	Proposed Action	Fix-in-Place Alternative
Sacramento River East Levee Reaches 16–20: Levee Widening/Rehabilitation and Seepage Remediation	Construct an adjacent levee	*Upgrade levee in place*
Landside Vegetation Removal	Reaches 16–20 of the Sacramento River east levee, Reaches 1–4 of the American River north levee, NEMDC South, and for preparation of canal improvement work	Same as the Proposed Action, *except maximum extent of removal would likely be reduced*
Waterside Vegetation Removal	Waterside vegetation would be removed due to modifications to pumping plants along the Sacramento River east levee, NEMDC west levee, and PGCC west levee	*In Reaches 16–20 of the Sacramento River east levee and Reaches 1–4 of the American River north levee, clear waterside vegetation to meet USACE vegetation policy criteria* *It is estimated that the numbers of acres of shaded riverine aquatic habitat lost would be greater.* Same as Proposed Action for modifications to RD 1000 pump stations
Encroachment Management	Remove encroachments as required to meet the criteria of USACE, CVFPB, and FEMA	Same as the Proposed Action, *except maximum extent of removal would likely be increased* *SAFCA would need to fully comply with USACE's levee vegetation policy requirements*

CVFPB = Central Valley Flood Protection Board
FEMA = Federal Emergency Management Agency
NEMDC = Natomas East Main Drainage Canal
PGCC = Pleasant Grove Creek Canal
RD = reclamation district
SAFCA = Sacramento Area Flood Control Agency
USACE = United States Army Corps of Engineers

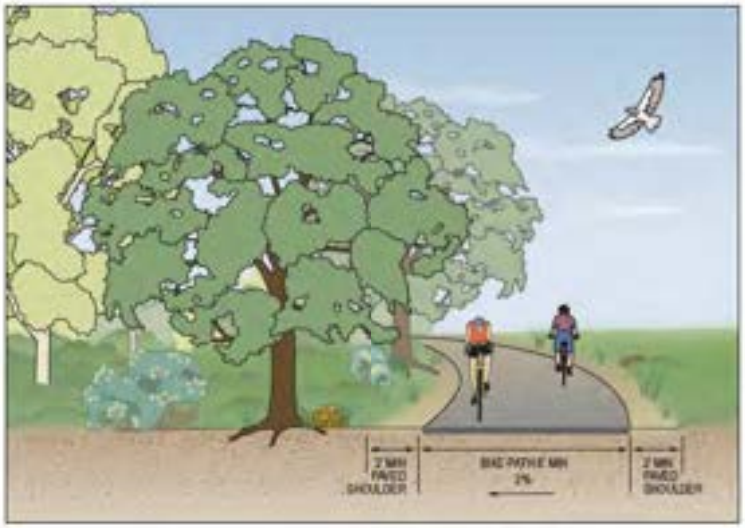
Station 8 – Proposed Natomas Basin Perimeter Bike Trail

Natomas Basin Perimeter Bike Trail

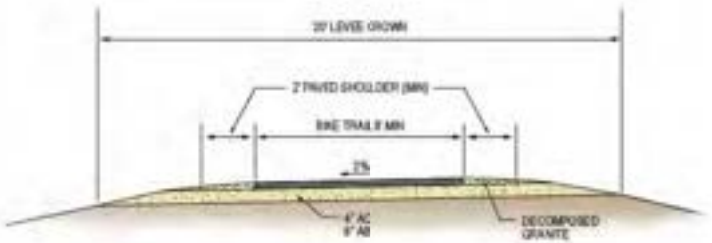
Goal: This regional trail would provide a bicycle commuter route at the southern and eastern end of the Natomas Basin that would connect to the regional American River trail system.



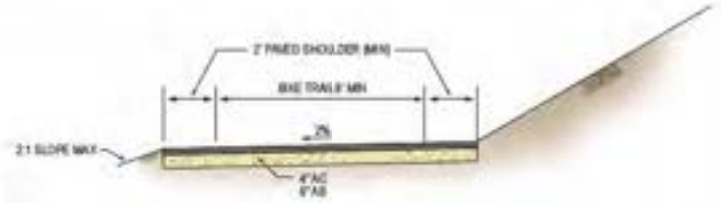
Design Concepts



Conceptual Illustration of Perimeter Bike Trail



Typical Cross Section of Bike Trail on Top of the Levee



Typical Cross Section of Bike Trail on Toe of the Levee

* The trail designs and locations shown are conceptual. Further analysis is required.

Station 9 – Project Commitments

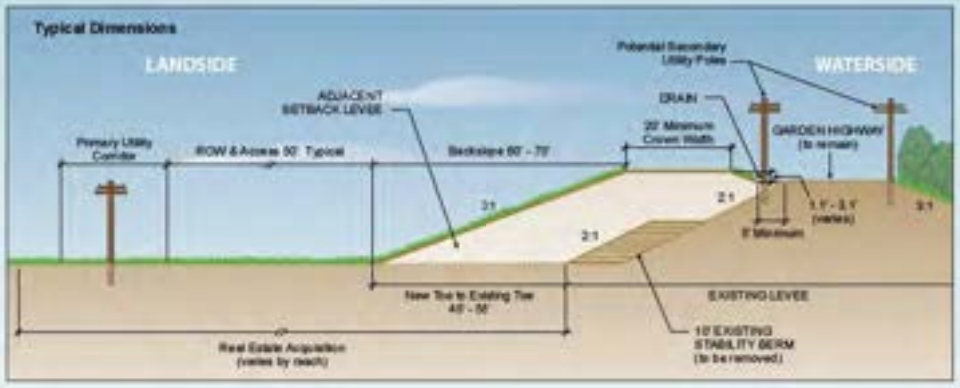
Construction Methods

Hauler and excavator on levee crown

Levee embankment grading

Construction of a slurry cutoff wall

Utility Pole Relocations



Impact Reduction Methods

Impact	Project Commitments
Construction Noise, Dust, and Vibration	▸ Dust control best management practices ▸ Vibration monitoring ▸ Written notification prior to construction activity within 500 feet of homes and businesses ▸ Minimized traffic on Garden Highway
Traffic Management and Safety	▸ Implementation of traffic safety and control measures in each construction season ▸ City, county, and Caltrans review of traffic control plans ▸ Use of traffic control personnel and signage ▸ Point-of-contact to address public concerns about construction activity
Nuisance to Residents along Garden Highway	▸ Reimbursement provided for temporary relocation to nearby hotels for residences within 500 feet of 24-hours per day, 7days per week cutoff wall construction schedules ▸ Temporary relocation during other 24-hour construction schedules (e.g., pump stations) considered on a case-by-case basis
Encrochments on Residences and Heritage Oaks	▸ Avoidance measures*: – Reduce width of adjacent setback levee seepage berms, and operations and maintenance/utility corridor – Use cutoff walls or seepage relief wells * Where feasible under levee design and seepage remediation performance requirements

Station 10 – Probable Phase 4b Project Environmental Impacts

On the basis of preliminary evaluation, programmatic environmental analyses of the Phase 4b Project in previous NEPA and CEQA documents, and relevant environmental analyses of previous project phases, USACE and SAFCA have determined that the probable environmental effects of the Phase 4b Project are as follows:

AIR QUALITY, NOISE, AND TRAFFIC

- Temporary, short-term effects during construction
- Cumulative effects of possible combined construction phases
- 24/7 construction for some elements of the project

AGRICULTURAL LAND CONVERSION

- Conversion of farmland to nonagricultural uses
- Temporary conversion during borrow operations

BIOLOGICAL RESOURCES

- Temporary disturbance or permanent loss of habitats, wildlife corridors, and special-status species
- Loss of woodland and shaded riverine aquatic habitat and sensitive aquatic habitat

CULTURAL RESOURCES

- Temporary and/or permanent disturbance of known and unknown historic or prehistoric resources

LAND USE AND PLANNING

- Physically divide an established community

TRANSPORTATION AND CIRCULATION

- Temporary increase in traffic and traffic hazards
- Full or partial Garden Highway closure for up to 6 months

CUMULATIVE GROWTH-INDUCTING IMPACTS

- Agricultural Resources
- Water Quality
- Fisheries
- Biological Resources
- Cultural Resources
- Air Quality
- Noise
- Visual Resources

GROWTH-INDUCING IMPACTS

- Create new permanent employment opportunities
- Short-term employment opportunities
- Removal of an obstacle to additional growth and development in the Natomas Basin

A3 SAFCA and Garden Highway Settlement Agreement

SETTLEMENT AGREEMENT

This Settlement Agreement ("Agreement" is made as of this 18th day of April 2008 by and between GARDEN HIGHWAY COMMUNITY ASSOCIATION, Inc., a California not-for-profit corporation ("GHCA"), and the Sacramento Area Flood Control Agency, a joint exercise of powers agency created by a Joint Exercise of Powers Agreement made pursuant to Government Code section 6500 *et seq.* ("SAFCA"). GHCA and SAFCA are referred to collectively herein as the "Parties" and each individually as a "Party."

RECITALS

A. The project at issue here is the Natomas Levee Improvement Program ("NLIP") Landside Improvements Project (the "Project"). It includes improvements to the Natomas Cross Canal south levee and the Sacramento River east levee, construction of a new Giant Garter Snake/Drainage Canal, relocation of a portion of the Natomas Mutual Water Company's Elkhorn Canal, and affiliated land recontouring and habitat creation, as more particularly described in the environmental impact report ("EIR") discussed below.

B. SAFCA is entrusted with the reduction of flood risk in the Sacramento region. It is the lead agency for the Project under the California Environmental Quality Act ("CEQA"); Public Resources Code section 21000 *et seq.*

C. GHCA is an incorporated association of landowners who reside in the "Project Area," as depicted and defined in Exhibit A hereto.

D. SAFCA analyzed a regional program of flood control improvements for the Sacramento area, which included improvements to Folsom Dam, the American River, and the South Streams Group, as well as the Natomas Levee Improvement Program (collectively the "Program"), in an Environmental Impact Report on Local Funding Mechanisms for

Comprehensive Flood Control Improvements for the Sacramento Area ("Local Funding EIR"). SAFCA certified the Local Funding EIR in February 2007. SAFCA intends for the Program to provide the Natomas Basin with at least a 100-year level of flood protection by the end of 2010 and a 200-year level of flood protection by the end of 2012.

E. SAFCA analyzed the Project, which is a part of the broader regional Program, in a separate Environmental Impact Report that is "tiered," within the meaning of CEQA, from the Local Funding EIR. The actions analyzed in the NLIP Landside EIR include land side improvements to the levee system in the Natomas Basin and related landscape modifications and drainage and infrastructure improvements, all to be undertaken between 2008 and 2010. The NLIP Landside EIR presents a project-level analysis of the 2008 construction components and a program-level analysis of the 2009-2010 elements. The 2009-2010 elements will require additional environmental review based on more detailed design plans.

F. On November 29, 2007, the SAFCA Board approved Resolution 07-105, which certified the environmental impact report prepared for the Natomas Levee Improvement Program Landside Improvements project; adopted findings and a statement of overriding considerations, mitigation measures, and a mitigation monitoring and reporting program; and approved the Natomas Levee Improvement Program Landside Improvements Project 2008 construction projects, consisting of the "Natomas Cross Canal Phase 2 Improvement Project" and the "Sacramento River East Levee Phase 1 Improvement Project (reaches 1 through 4b)."

G. On December 19, 2007, GHCA filed a Petition for Writ of Mandate and Complaint for Injunctive Relief ("Petition") in Sacramento Superior Court (Case No. 34-2007-00883632-CU-WM-GDS) against SAFCA. The Petition challenges SAFCA's approval of

the 2008 construction components and alleges that the NLIP Landside EIR does not comply with CEQA.

H. In January 2008, the United States Army Corps of Engineers ("USACE") completed a hydraulic analysis of the Natomas Basin, which found that the Natomas Basin has less than a 30-year level of flood protection.

I. On February 7, 2008, SAFCA filed its Answer to the Petition, and on February 19, 2008 SAFCA filed its Notification and Lodging of the Administrative Record. GCHA and SAFCA filed their Statements of Issues on March 7, 2008 and March 17, 2008, respectively.

J. Pursuant to stipulation of the Parties, in March 2008 GHCA and SAFCA engaged in two days of mediation. The mediation resulted in a stipulation for settlement, the majority of which is reproduced below as part of the final Settlement Agreement.

K. Accordingly, the Parties enter into this Agreement to address GHCA's concerns and allow the portion of the Project approved by Resolution 07-105 to proceed. Nevertheless, SAFCA intends to apply the design and construction practices set forth in Paragraphs 1 through 9, below, to the entirety of the Project, as applicable.

AGREEMENT

NOW, THEREFORE, in consideration of the foregoing recitals, which are hereby incorporated by reference, and of the mutual covenants set forth herein, and for other good and valuable consideration, the receipt and adequacy is hereby acknowledged, the Parties agree as follows:

1. Power Pole and Overhead Power Line Placement. To the extent that the main electrical power transmission lines and poles serving the Garden Highway must be relocated or replaced to accommodate the Project, the relocation or replacement shall occur east of the new

adjacent levee and in a manner that appropriately accommodates private land side improvements and properties. Existing main electrical power transmission lines and poles on the water side of the existing Garden Highway levee that do not need to be relocated or replaced to accommodate the Project may be left in place. No new main electrical power transmission lines and poles shall be installed on the water side of the Garden Highway levee.

Consistent with sound engineering practices that prioritize the following, individual service lines shall: (i) use existing configurations and facilities, and (ii) any new poles shall be placed on the land side of Garden Highway, subject to the approval of the United States Army Corps of Engineers ("USACE"), Central Valley Flood Protection Board ("CVFPB"), and any other regulatory public agencies and the utility companies.

SAFCA shall advocate power line and pole locations consistent with this provision to the USACE, CVFPB, and other regulatory agencies and utilities by way of one-time master letters, attached hereto as Exhibits B and C, approved as to form by the SAFCA Board as part of this Agreement and signed by the SAFCA Executive Director. These letters, attached as Exhibits B and C, have received the prior approval of GHCA's attorney.

If the property owner and SAFCA cannot agree on a location of an individual service line pole from among locations that are otherwise acceptable to the USACE, CVFPB, other regulatory agencies and the utility provider, SAFCA agrees to pay the cost of a referee, who is a qualified registered civil engineer and agreeable to both Parties, to decide the dispute over the location of the individual service line pole.

SAFCA agrees to provide working drawings sixty (60) days to GCHA's contact person designated pursuant to Paragraph 5, below, in advance of commencing construction of power poles and lines for which locations would be changed as part of the Project.

2. Removal of Encroachments and Existing Landscaping and Fencing. As part of this Agreement, the SAFCA Board directs the SAFCA Executive Director to write a letter, the approved form of which is attached hereto as Exhibit B, to the responsible regulatory agencies advocating SAFCA's project design, which requires minimal removal of encroachments. This letter, attached as Exhibit B, has received the prior approval of GHCA's attorney.

Once SAFCA determines that the Sacramento River east levee is certifiable for the Federal Emergency Management Agency's ("FEMA") flood protection purposes, SAFCA shall make its best efforts to get written agreement from the USACE, CVFPB, and Reclamation District 1000 ("RD1000") that no additional encroachments on the water side of the Garden Highway levee need to be removed.

3. Damage to Existing Wells, Septic Systems, Concrete Structures, etc. As part of the notice provided pursuant to Paragraph 8, below, SAFCA shall give property owners within the Project Area (see Exhibit A) an informational package, which shall have received the prior approval of Petitioner's attorney, advising the property owners that pre-project inspections of their properties are important and that SAFCA will conduct a free pre-construction inspection of the property, but only if requested by the property owner. The scope of the inspection and documentation will be determined by SAFCA in consultation with the property owner.

SAFCA will provide a copy of its February 2008 study entitled, "Evaluation of Potential Groundwater Impacts Due to Proposed Sacramento River East Levee Improvements with Emphasis on Reaches 2 & 3" to the GHCA contact person designated pursuant to Paragraph 5, below. If requested by a property owner within the Project Area, SAFCA will test the owner's domestic well water before and after Project construction for the presence of bentonite, concrete, and cement.

4. Drainage Lines. No roadside swales shall be included in the design of the new adjacent levee downstream of Power Line Road. Consistent with sound engineering practices, and subject to the approval of the USACE, CVFPB, and the Regional Water Quality Control Board ("RWQCB"), any new drainage outfall lines required by the Project shall be buried pipes, located along property lines, and drain to the river. If a property owner does not want a new drain line located along the property line, he or she may request that the drain line be placed elsewhere on his or her property.

SAFCA shall advocate the location, design, and outfall of the drain lines consistent with this provision to the USACE, CVFPB, and the RWQCB by way of one-time master letters, attached hereto as Exhibits B and D, approved as to form by the SAFCA Board as part of this Agreement and signed by the SAFCA Executive Director. These letters, attached as Exhibits B and D, have received the prior approval of GHCA's attorney.

If the property owner and SAFCA cannot agree on a location for a new drain line from among locations that are otherwise acceptable to the USACE, CVFPB, and the RWQCB, SAFCA agrees to pay the cost of a referee, who is a qualified registered civil engineer and agreeable to both parties, to decide the dispute over the location of the drain line.

5. Construction Monitoring. SAFCA agrees to cooperate with a construction monitoring committee established by GHCA to resolve reasonable complaints regarding SAFCA or its contractors' construction activities for the Projects improvements in accordance with this provision. Within fifteen (15) days of the Effective Date of this Agreement, GHCA shall notify SAFCA of the name of a contact person, who shall be a member of GHCA's construction monitoring committee, for purposes of having one contact point for communicating with SAFCA's Ombudsperson and keeping GHCA apprised of the construction schedule for the

Project pursuant to Paragraph 8, below. A complaint procedure and hierarchy shall be developed by the GHCA's contact person and SAFCA's Ombudsperson in time to be included in the informational packet referenced in Paragraph 3, above. In addition, the information packet will include SAFCA's instructions to its contractors regarding appropriate use of the Garden Highway. SAFCA agrees to resolve all complaints pertaining to dangerous activities immediately and to resolve all other reasonable complaints in an expeditious manner.

SAFCA shall prohibit the use of earth moving equipment or haul trucks on the Garden Highway in conjunction with the Project.

6. Relocation. Where a property owner occupies a residence on property to be acquired for the Project, SAFCA will allow up to twelve (12) months, rather that the statutory allowance of three (3) months, for the owner to relocate off the property. The 12 month period shall be counted from the first written offer.

7. Study of Improving Flood Conveyance in Yolo Bypass. SAFCA agrees to provide GHCA with documents prepared by SAFCA synthesizing information gathered by USACE, CVFPB, DWR, and SAFCA regarding the feasibility of increasing flood conveyance through the Yolo Bypass. SAFCA believes these documents are characteristic of the state of knowledge regarding this flood control alternative as of 2003 when these documents were prepared.

8. Construction Schedule. SAFCA will provide GHCA with a timeline for the phased completion of the Project that indicates the role of the various agencies involved in implementing or permitting the Project. SAFCA will post its construction schedule for the Project on the SAFCA website. The schedule shall be updated on a monthly basis. A hard copy of the schedule and monthly updates shall be mailed to the GHCA contact person identified in

Paragraph 5, above. In addition, SAFCA will post a "60-day notice" of Planned Construction on the SAFCA website. A hard copy of the "60-day notice" shall be mailed to the GHCA contact person identified in Paragraph 5, above. "Planned Construction" will not include construction in the event of an emergency or construction necessary to remedy a condition discovered after completion of the Project. However, SAFCA will provide whatever notice is possible under the circumstances to affected, adjacent landowners prior to any emergency or remedial work.

For property owners who request prior inspections/documentation, the inspection/documentation must be scheduled prior to the start of construction within the specified reach of the Sacramento River where Project construction will commence.

9. Bicycle Trail. The Parties agree that the new adjacent levee would provide a good opportunity for creation of a new bicycle trail along the top of the levee consistent with applicable levee operation and maintenance requirements. SAFCA is prepared to work with GHCA and other interested parties in securing funding for a feasibility analysis for this bicycle trail and, based on the results of this feasibility analysis, to secure funding for construction, operation, and maintenance of the bicycle trail.

10. Dismissal of Action. Within five (5) business days of the Effective Date, GHCA shall execute and file a Request for Entry of Dismissal with Prejudice of Case Number 34-2007-00883632-CU-WM-GDS at the Sacramento County Superior Court. The Entry of Dismissal with Prejudice shall have the effect of dismissing the Action against all of the Parties named in the Action. The Parties agree to request that the trial court, in response to said request, enter an order reserving jurisdiction to enforce the Agreement pursuant to Code of Civil Procedure section 664.6, unless the trial court, for whatever reason, will not sign the proposed order reserving jurisdiction, as described immediately below. The Parties agree to submit a proposed

order reserving jurisdiction in the trial court pursuant to a Stipulation and Order substantially in the following form:

> Petitioner/Plaintiff and Respondent/Defendant have entered into a Settlement Agreement ("the Agreement"), a copy of which is attached hereto as Exhibit 1.
>
> The Agreement includes terms anticipating that the trial court enter an order reserving jurisdiction to enforce the Agreement pursuant to Code of Civil Procedure section 664.6.
>
> THEREFORE, it is hereby STIPULATED by Petitioner/Plaintiff and Respondent/Defendant that, and Petitioner/Plaintiff and Respondent/Defendant jointly request that, this Court reserve jurisdiction to enforce the Agreement pursuant to Code of Civil Procedure section 664.6 and this written stipulation of the parties.

In the event that, for whatever reason, the trial court does not grant GHCA's request to enter the proposed order described immediately above, and thus declines to make this Agreement enforceable pursuant to Code of Civil Procedure section 664.6, the Agreement shall instead be enforceable by either party through the filing of new litigation alleging a breach of the Agreement.

11. Attorney's Fees and Costs. SAFCA shall pay, within five business (5) days after the Effective Date of this Agreement, attorney's fees and costs incurred by GHCA in connection with the litigation and settlement of this Action (Sacramento County Superior Court Case No. 34-2007-00883632-CU-WM-GDS) in the sum of $55,000.00 by check made payable to the law firm of Kenyon Yeates, LLP. If GHCA accepts this offer without change, GHCA waives any right to seek recovery of any additional money from SAFCA in connection with the dismissed claims. SAFCA shall bear its own attorney's fees and costs.

12. Mutual Release and Waiver. Except for the rights and obligations set forth in this Agreement, each Party agrees and covenants as follows:

(a) To forever release, quit and discharge the other party and its respective officers, employees, agents, and officials from any and all claims, causes of action, action, rights,

theories, contentions, demands, obligations, suits, losses, costs, expenses, attorneys' fees, liens, liabilities and indemnities of any nature whatsoever, based on contract, tort, statute, or other legal or equitable theory of recovery, whether on account of past, present or potential future liability, whether known or unknown, or any type or character whatsoever, insofar as any of the same related to or arose out of, or could have related, or could have arisen out of the dispute set forth in the foregoing Recitals to this Agreement. The Parties intend this release to apply only to the 2008 Construction Projects, which were analyzed at a project level in the NLIP Landside EIR and were approved by the SAFCA Board of Directors on November 29, 2007. The Parties do not intend the settlement agreement and this mutual release and waiver to apply to the 2009-2010 construction phase, which was analyzed at a program level in the NLIP Landside EIR and has not yet been approved by the SAFCA Board of Directors.

(b) To expressly waive any right or claim of right to assert hereafter that any claim, demand, and/or obligation has, through ignorance, oversight or error been omitted from the terms of this Agreement and further expressly waive any right or claim of right that each may have under the law under any jurisdiction to the effect that those releases herein given do not apply to unknown or unstated claims. It is the express intent of the Parties to waive any and all claims they may have against the other party hereto insofar as any of the same, directly or indirectly, relate to the Project, including any which are presently known, unsuspected, unanticipated, or undisclosed. The Parties hereto acknowledge that they are apprised of the provisions of Civil Code section 1542 which provides:

> **A general release does not extend to claims which the creditor does not know or suspect to exist in his favor at the time of executing the release, which if known by him must have materially affected his settlement with the debtor.**

Having been so apprised, each party elects to waive and does waive all rights that may be granted to them pursuant to Civil Code section 1542 and to assume all risks, known or unknown, covered by this release.

(c) Never to commence, recommence, appeal, or seek certiorari or other review by any court, state or federal, and/or other proceeding against any other party to this Agreement that is based in whole or in part upon the claims, demands, causes of action, obligations, damages and/or liabilities released by this Agreement.

13. Entire, Sole and Final Agreement. This Agreement constitutes the entire understanding between the Parties with respect to the matters set forth herein. Except as otherwise provided herein, this Agreement is intended to be the final expression of the Agreement between the Parties with respect to the subject matter of this Agreement and supersedes and fully and completely extinguishes any prior understandings or agreements by or between the Parties, whether oral or in writing.

14. Amendments. This Agreement may not be modified, supplemented, or amended, or any of its provisions waived, except in writing by the party against whom such modification, supplementation, amendment, or waiver is sought. Any modification, supplementation, amendment, or waiver that would materially affect the rights of both Parties must be signed by both Parties.

15. Warranty of Authority. Each person signing this Agreement warrants to each other party that he or she is authorized by the party on whose behalf he or she is signing to execute this Agreement and to bind such party to the terms of this Agreement.

16. Time of the Essence. Time is of the essence for this Agreement.

17. Mutual Cooperation. The Parties agree to cooperate in good faith to carry out the provisions and intent of this Agreement, including timely execution and delivery of other documents necessary to carry out its provisions. Each of the Parties shall execute and deliver to the others all such further instruments and documents, and take all other such actions, as may be reasonably necessary to carry out the terms and provisions of this Agreement and secure to the others the full and complete enjoyment of their respective rights and privileges hereunder. The Parties agree to meet and confer in good faith to try to resolve any conflicts arising under this Agreement prior to bringing any actions in court to enforce this Agreement.

18. Severability. If any term or provision of this Agreement, or the application of any term or provision of this Agreement to a particular situation, shall be finally found to be void, invalid, illegal or unenforceable by a court of competent jurisdiction, then notwithstanding such determination, such term or provision shall remain in force and effect to the extent allowable by such ruling and all other terms and provisions of this Agreement or the application of this Agreement to other situations shall remain in force and effect.

19. Agreement Admissible in Enforcement Action. The Parties agree that this Agreement is admissible in any action to enforce this Agreement. Nothing in this Agreement shall be used as an admission of any fact or matter in any other challenge.

20. Construction. This Agreement, and each of the provisions hereof, is the product of negotiations between the Parties and their respective attorneys. Each of the Parties hereto expressly acknowledges and agrees that this Agreement shall not be deemed to have been prepared by or drafted by any particular party hereto. The rule of construction to the effect that any ambiguities are to be resolved against the drafting party shall not be employed in the interpretation of this Agreement.

21. Third Party Beneficiaries. Nothing in this Agreement shall be construed to confer any rights or impose any obligations upon any person or entity not a Party to this Agreement.

22. Governing Law. This Agreement shall be governed by and construed in accordance with the laws of the State of California.

23. Headings and Captions. The headings and captions used in this Agreement are for convenience and ease of reference only, and are not intended to be part of the body of this Agreement, nor are they intended to be referred to in construing the provisions of this Agreement.

24. Exhibits. All exhibits referenced in this Agreement are made part of and incorporated herein.

25. Notices. All notices and other communications in connection with this Agreement shall be in writing and shall be personally delivered, sent by first class United States mail, sent by telefacsimile ("fax") with original sent by United State Postal Service or reputable overnight courier for delivery the following day, or sent by reputable overnight courier to the addresses and fax numbers set forth below. Any Party may at any time change its address or fax number for the delivery of notice upon five (5) days written notice to the other Party.

26. Understanding of Terms. This Agreement is executed voluntarily by each of the Parties without any duress or undue influence on the part of, or on behalf of, any of them. Each of the Parties to this Agreement has read and fully understands the meaning of each provision of this Agreement and has relied on independent advice and representation of legal counsel in entering into this Agreement.

27. Binding Effect. This Agreement and its terms shall be binding upon and inure to the benefit of the Parties hereto and their respective successors, assignees, buyers, grantees, vendees, transferees, officers, directors, principals, agents, employees, representatives, attorneys, insurers and sureties, and any others claiming through or under of having the right to claim through or under any or all of them, wherever located.

28. Equitable Relief. Each Party hereto expressly agrees that the provisions of this Agreement shall be specifically enforceable by either Party and, except as specifically provided

in Paragraphs 1, 3, and 4 of this Agreement for the payment of costs and expenses incurred in a dispute, each Party hereto waives and relinquishes all claims for damages arising from a claim based on breach of this Agreement by any other Party. In the event of breach of any term or provision of this Agreement or any duty or obligation hereunder, remedies shall be limited to bringing an action for specific performance and recovery of such costs and expenses provided for in Paragraphs 1, 3, and 4 of this Agreement.

29. Execution in Counterparts. This Agreement may be executed in counterparts, and photocopies, facsimile copies, or electronic copies of this Agreement may be used as originals. Each such counterpart, photocopy, facsimile copy, or electronic copy of this Agreement shall be deemed an original, but all of which together shall constitute one and the same instrument and shall have the same force and effect as if a single original had been executed by all Parties.

30. Settlement of Disputed Claims. The Parties hereto understand and agree that this settlement is a compromise of disputed claims, and that no Party's actions under this Agreement shall be construed as an admission of liability.

31. Effective Date. This Agreement shall become effective upon execution by all Parties.

IN WITNESS WHEREOF, the Parties have executed this Agreement as of the date and year first set forth above.

RE: Encroachment Permit for SAFCA Natomas Levee Improvement Program Landside Improvements Project

Dear Sirs:

On March 21, 2008, the Central Valley Flood Protection Board (Board) issued Permit 18159-3 BD to SAFCA to improve portions of the Sacramento River east levee as part of the Agency's Natomas Levee Improvement Program (NLIP) Landside Improvements Project (Project). Permit condition Fourteen states that no work authorized by this permit shall be performed until the Board and the Department of Water Resources (Department) have received, reviewed and approved a complete set of final plans and specifications for the Project. In order to satisfy this condition, under separate cover SAFCA has submitted the required final plans and specifications for review and approval by the Board and the Department.

The purpose of this letter is to highlight several key features of the Project and underscore the SAFCA's commitment to ensuring that these features are incorporated into the final design. First, the final design calls for construction of a new levee adjacent to the existing Sacramento River east levee along Garden Highway. A key objective of this design is to preserve the existing Garden Highway and minimize the removal of levee encroachments located on private lands along the water side of this roadway. SAFCA intends to work closely with the Board and the Department to achieve this objective in a manner that is consistent with the Board's Supplemental Standards for Control of Residential Encroachments in Reclamation District 1000, which are found in Section 133 of Title 23 of the California Code of Regulations.

Second, in order to accommodate the Project footprint and minimize the effects of the Project on residences along the Garden Highway, the final design calls for relocation of portions of the existing main electrical transmission system, including poles and powerlines that provide electricity to these residences, into a new utility operation and maintenance corridor for which

right-of-way has been acquired east of the new adjacent levee. In addition, SAFCA has sought to avoid relocating existing secondary poles and individual service lines that link the main transmission line to the residences. To the extent that such relocations are necessary, wherever possible the new secondary poles have been located along the landside of the Garden Highway between the roadway pavement and the new adjacent levee.

Third, SAFCA has incorporated new storm water drainage facilities into the final design to offset the potential increase in storm water that would otherwise be discharged from the Garden Highway onto the private parcels occupying the water side of the levee. These drainage facilities consist of a collection swale located between the new adjacent levee and the Garden Highway, and new pipes and drainage outfall lines to drain collected storm water to the river. Where these outfalls cross private property, they are located along existing parcel boundaries in buried pipes that drain to the river [or in an alternative location selected in consultation with the property owner].

SAFCA requests that the Board and the Department approve these Project features as shown in the final design package. However, if for any reason the Board or the Department determines that the proposed location of electrical or drainage facilities is unacceptable, SAFCA requests that the Board and/or the Department identify alternative locations that would be acceptable so that affected property owners may have an opportunity to work with SAFCA in selecting from among these alternatives. Please contact us if you have any questions in this regard. We look forward to working with you to continue to improve flood protection for the Natomas Basin.

Very truly yours,

Stein M. Buer
Executive Director

RE: Relocation of Electrical and Telephone Utility Poles and Lines
SAFCA Natomas Levee Improvement Program Landside Improvements Project,
[Year] Construction Projects

Dear [Name]:

SAFCA has undertaken the Natomas Levee Improvement Program ("NLIP") Landside Improvements Project (“Project”) in order to provide increased flood protection to the Natomas Basin. The Project will require relocation of utility poles and lines along the levee system in order to accommodate the widened levee and related infrastructure.

Enclosed with this letter please find plans which identify SAFCA’s proposed locations for installation of new poles and lines and relocation of existing facilities to accommodate the footprint of the Project. In order to minimize the effects of the Project on Garden Highway residences, these locations have been selected so as to ensure that no new main transmission lines and poles are installed on the water side of the Garden Highway. In addition, SAFCA has sought to avoid relocating poles that support individual service lines. To the extent such relocations are necessary, wherever possible the new poles have been located on the land side of the Garden Highway.

SAFCA believes the proposed utility relocation plan is consistent with sound engineering practices and we look forward to your approval. However, if for any reason [utility provider] determines that any proposed utility pole location is unacceptable, we request that [utility provider] identify alternative locations that would be acceptable so that the affected property owners may have an opportunity to work with SAFCA in selecting from among these alternatives.

Please contact us if you have any questions or concerns. We appreciate your cooperation on this important Project to improve flood protection for the Natomas Basin.

Very truly yours,

Stein M. Buer
Executive Director

RE: Request for Waste Discharge Requirements for Drainage Pipes and Outfalls
Natomas Levee Improvement Program
Landside Improvements Project, [Year] Construction Projects

Dear [Name]:

SAFCA has undertaken the Natomas Levee Improvement Program ("NLIP") Landside Improvements Project ("Project") in order to provide increased flood protection to the Natomas Basin. The Project will involve the construction of a new adjacent levee on the land side of the existing Sacramento River east levee along the Garden Highway. The section of the adjacent levee between the Natomas cross Canal and Powerline Road will be raised above the elevation of the existing levee. This grade difference results in a change in the drainage pattern associated with the eastern side of the roadway.

Enclosed with this letter please find SAFCA's application for waste discharge requirements associated with the new storm water drainage facilities which are proposed to offset the potential increase in storm water that would otherwise be redirected from eastern side of the Garden Highway onto the private parcels occupying the water side of the levee. These drainage facilities consist of a collection swale located between the new adjacent levee and the Garden Highway, and new pipes and drainage outfall lines to drain collected storm water to the river. In order to minimize the effects of the Project on Garden Highway residences, where these outfalls cross private property, SAFCA has sought to locate the new drainage pipes and outfalls along existing parcel boundaries in buried pipes that drain to the river [or in an alternative location approved by the property owner].

SAFCA believes that the Project and the enclosed application for waste discharge requirements are consistent with sound engineering practices, the Settlement Agreement between the Garden Highway Community Association and SAFCA, and the Porter-Cologne Water Quality Control Act. Accordingly, we request that the Regional Board approve this application. However, if for any reason the Regional Board determines that the location of any proposed new pipe or outfall line is unacceptable, we request that the Regional Board identify alternative

locations that would be acceptable so that the affected property owners may have an opportunity to work with SAFCA in selecting from among these alternatives.

Please contact us if you have any questions or concerns. We look forward to your cooperation on this important Project to improve flood protection for the Natomas Basin.

Very truly yours,

Stein M. Buer
Executive Director

APPENDIX B

Project Description

B1 Alternatives Formulation and Screening Details

APPENDIX B1
ALTERNATIVES FORMULATION AND SCREENING DETAILS

This appendix contains more detailed information on the alternatives evaluation process that was summarized in Chapter 2, "Alternatives," of this EIS/EIR.

1.1 INTRODUCTION

This appendix describes the alternatives related to the Natomas Levee Improvement Program (NLIP) Landside Improvements Project that were considered to provide additional flood risk reduction to the Natomas Basin consistent with the project objectives described in Chapter 1, "Introduction and Statement of Purpose and Need" of this EIS/EIR. The Phase 4b Project builds upon a program of improvements analyzed in previous environmental documents for achieving flood risk damage reduction for the 53,000-acre Natomas Basin, which is encircled by 42 miles of levees. Although they provide contrasting advantages and disadvantages, each of the action alternatives is considered feasible based on relevant economic, environmental, social, technological, and legal factors. Three alternatives are evaluated at an equal level of detail in this EIS/EIR:

- No-Action Alternative,
- Adjacent Levee Alternative (Proposed Action), and
- Fix-in-Place Alternative.

These alternatives represent a reasonable range of alternatives, consistent with the requirements of NEPA and CEQA and when considered in the context of prior alternatives analyses described in previous environmental documents and which are incorporated by reference in this EIS/EIR. The action alternatives under consideration have been formulated to feasibly accomplish the primary objectives of the project as discussed in Chapter 1, "Introduction and Statement of Purpose and Need," of this EIS/EIR, which includes reducing the risk of flooding to the Natomas Basin. The action alternatives include components that could avoid or substantially lessen one or more of the project's significant effects.

The NLIP design criteria in terms of maximum water surface elevation and maximum flow at key locations along the Natomas Basin perimeter levee system are identified in **Table B1-1**.

Table B1-1
NLIP Design Criteria: Water Surface Elevation and Maximum Flow

Location	100-year (0.01 AEP) FEMA Criteria Flood [1]		200-year (0.005 AEP) NLIP Design Criteria Flood [2]	
	Maximum Water Surface Elevation (feet) NAVD88	Maximum Flow (cfs)	Maximum Water Surface Elevation (feet) NAVD88	Maximum Flow (cfs)
Sacramento River at Verona	43.40	117,000	44.85	143,000
Latitude of Verona	NA	528,000	NA	622,000
NCC at PGCC	43.73	NA[3]	45.24	NA[3]
NEMDC near Main Avenue	38.98	14,500	40.89	17,100

Notes: AEP = Annual Exceedance Probability; cfs = cubic feet per second; FEMA = Federal Emergency Management Agency; NAVD = North American Vertical Datum of 1988; NCC = Natomas Cross Canal; NEMDC = Natomas East Main Drainage Canal; NLIP = Natomas Levee Improvement Program; PGCC = Pleasant Grove Creek Canal

1.1.1 NEPA/CEQA REQUIREMENTS FOR EVALUATION OF ALTERNATIVES

1.1.1.1 NEPA REQUIREMENTS

The NEPA Council on Environmental Quality Regulations (40 Code of Federal Regulations Section 15012.14) for EIS requirements are briefly described in Chapter 1, "Introduction and Statement of Purpose and Need," of this EIS/EIR.

1.1.1.2 CEQA REQUIREMENTS

The CEQA requirements for an EIR (as noted in the California Code of Regulations [CCR] Section 15126.6[a] of the State CEQA Guidelines) are briefly described in Chapter 1, "Introduction and Statement of Purpose and Need," of this EIS/EIR.

2.1 ALTERNATIVES FORMULATION

USACE and SAFCA formulated the project and a reasonable range of alternatives that would achieve the specific project objectives through the following steps:

- identification of the deficiencies in the Natomas levee system that must be addressed to provide at least 100-year flood risk reduction (0.01 annual exceedance probability [AEP]) as quickly as possible;
- identification of the deficiencies in the Natomas levee system that must be addressed to provide 200-year flood risk reduction (0.005 AEP);
- identification of feasible remedial measures to address the deficiencies;
- determination of the likely environmental impacts of the remedial measures;
- development of a reasonable range of flood damage reduction alternatives for implementing the remedial measures; and
- identification of measures to ensure that each alternative would improve aviation safety, minimize impacts on significant cultural resource sites, and enhance habitat values.

Alternatives screening for the overall NLIP has been undertaken in a systematic manner through several environmental documents as described later in this appendix. A description of the flood risk reduction measures that SAFCA considered for developing alternatives is provided below.

2.1.1 TYPES OF FLOOD RISK REDUCTION MEASURES CONSIDERED

Designing effective flood risk reduction measures is an iterative process that involves identifying, evaluating, and comparing measures and preliminary alternatives to develop a reasonable range of final alternative plans for consideration by decision makers and the general public. For the NLIP Landside Improvements Project, engineering measures were developed and considered that alone or in various combinations would address the project objectives.

The engineering measures that were considered for the Phase 4b Project must meet several criteria. The design selected must adequately improve performance of the levee so that Federal Emergency Management Agency (FEMA) certification is possible. Generally, the requirements are to provide a sufficient height of levee raise so that the levee height is adequate, levee stability meets levee design criteria, and/or seepage through or beneath the levee is reduced to levels acceptable to USACE. Measures considered are described below.

2.1.1.1 LEVEE IMPROVEMENTS

USACE has divided the flood damage reduction improvements within the Natomas Basin into nine reaches (Reaches A–I). USACE's reach designations differ from SAFCA's reach designations, which are more finely subdivided than the USACE system for the Sacramento River east levee, American River north levee, and the NCC. Lettered reaches follow the USACE designation, while numbered reaches follow the SAFCA designations:

- Sacramento River east levee: Reach A:16–20
- Sacramento River east levee: Reach B:5A–15
- Sacramento River east levee: Reach C:1–4B
- NCC: Reach D:1–7
- PGCC: Reach E: there are no SAFCA reaches, just station numbers
- NEMDC North: Reaches F–G
- NEMDC South: Reach H
- American River north levee: Reach I:1–4

Sacramento River East Levee (Reach A:16–20)

The existing levee in Sacramento River east levee Reach A:16–20 currently meets height requirements, and, therefore, no levee raise is necessary in this reach. However, the levee needs to be upgraded to meet USACE requirements regarding seepage through the levee and its foundation, slope stability, and free access for inspection, maintenance, and emergency flood fighting. Two engineering options were analyzed for the levee upgrade: the Fix-in-Place Method and the Adjacent Levee Method. Because these options have potentially different effects on the environment, they are analyzed as the two action alternatives in this EIS/EIR:

- **Fix-in-Place Method.** Most levee reaches in the Natomas Basin have a 2-to-1 horizontal-to-vertical (2H:1V) landside slope, which may not meet criteria for slope stability or access on the levee for maintenance and operation. This condition is found on Sacramento River east levee Reach A:16–20, which is a component of the Phase 4b Project. Using the Fix-in-Place method, the remedy would be to flatten the slope to a minimum 3-to-1 horizontal-to-vertical (3H:1V) landside slope by adding fill on top of the existing landside levee slope, thereby widening the base of the levee prism but not expanding the width of the levee crown (**Plate 2-1**, upper illustration). The Fix-in-Place method is compatible with the seepage remediation methods described under Section 2.1.3.2. By leaving the levee prism in the current alignment, this method requires vegetation clearance on the waterside of the levee to comply with USACE levee guidance that requires the removal of vegetation greater than 2 inches in diameter on the levee slopes and within 15 feet of the waterside and landside levee toes (USACE 2000). However, in reaches where the existing levee is already wide enough that the levee prism is considered clear of vegetation, such as in American River north levee Reach I:1–4, the Fix-in-Place method may be used to reduce the theoretical levee footprint to avoid encroachments on the landside.

  While the levee footprint (its base) size may not be substantially altered, mitigation for loss of habitat would be required by various regulatory agencies. Where the widening results in filling waters of the United States, including wetlands, mitigation would be required, generally at a 1:1 replacement ratio. Where the widening occurs on the landside or waterside and trees that provide habitat or are otherwise protected exist, the mitigation requirement is to plant replacement woodlands and/or shaded riverine aquatic (SRA) habitat. In some instances, irrigation and drainage ditches and canals exist at the toe of the levee, and would require relocation to ensure USACE's seepage and stability criteria are met. Widening of the existing levee may require the purchase of additional easements and/or rights-of-way, including areas for utilities and planting/replacement woodlands and other habitats. Proper construction of the widened levee may require excavation of a keyway trench in the foundation area at the toe of the levee.

- **Adjacent Levee Method.** This method combines slope flattening to 3H:1V with a widening of the existing levee crown by 15 to 20 feet on the landside. The concept of an adjacent levee is that the levee prism would

be shifted landward (as shown in **Plate 2-1**, lower illustration), such that much of the vegetation on the waterside of the existing levee would be less likely to need to be cleared for levee operation and maintenance (see Section 2.1.3.4, "Management of Levee Vegetation and Structural Encroachments," below). This design potentially reduces the need to remove vegetation on the waterside to meet USACE vegetation guidance criteria. The irrigation and drainage ditches and canals that exist at the toe of the levee may require relocation farther to the landside. Construction of an adjacent levee may also require the purchase of additional easements and/or rights-of-way, including areas for utilities and planting of replacement woodlands and other habitats. Proper construction of the adjacent levee foundation often requires excavation of an inspection trench in the foundation soils. Because the Natomas Basin's natural levees have been augmented by human efforts, it is possible to find buried prehistoric features at considerable depth in the landside footprint.

Raised adjacent levees have been constructed or are in the approval process for Sacramento River east levee Reach C:1 to part way through Reach B:13 (Phase 2, 3, and 4a Projects). From the remainder of Sacramento River east levee Reach B:12 to Reach A:20 (Phase 4a and 4b Projects), the existing levee has sufficient height, and the proposed adjacent levee would be at the same height as the existing levee. The Phase 2, 3, and 4a Projects are summarized in Section 4.18, "Summary of Environmental Impacts and Mitigation Measures from Previous Natomas Levee Improvement Program Phase 1–4a Landside Improvements Projects," of this EIS/EIR.

Pleasant Grove Creek Canal and Natomas East Main Drainage Canal West Levee (North of Natomas East Main Drainage Canal Stormwater Pumping Station)

Two engineering options are also available for reaches where levee raising is required to meet the level of risk reduction required by the State for urbanized areas, such as the Natomas Basin. In the Phase 4b Project, these raises are proposed for the west levees of the Pleasant Grove Creek Canal (PGCC) (Reach E) and the Natomas East Main Drainage Canal (NEMDC) North (Reaches F–G). These options have similar environmental effects, and they are analyzed as part of both the Adjacent Levee Alternative (Proposed Action) and Fix-in-Place Alternative:

- **Raise-in-Place Method.** Raising the levee in place would require the existing levee footprint to be widened at its base on one or both sides. This method may require replacement of public roadways that may be located on the crown of the levee. Although the levee footprint (its base) size may not be substantially altered, mitigation for loss of habitat would be required by various regulatory agencies. In some instances, irrigation and drainage ditches and canals exist at the toe of the levee, and would require relocation. Widening of the existing levee may require the purchase of additional easements and/or rights-of-way, including areas for utilities and planting/replacement woodlands and other habitats. Proper construction of the widened levee may require excavation of a keyway trench in the foundation area at the toe of the levee.

- **Adjacent Levee Raise Method.** In lieu of modifying the existing levee, a levee raise may also be achieved by constructing a new landside embankment adjoining the existing levee. This approach, which is similar to the adjacent levee method described above, allows sufficient levee height to be achieved without degrading the existing levee and rebuilding public roadways that may be located on top of the existing levee. However, it requires excavation of additional suitable material to build the adjacent structure. The irrigation and drainage ditches and canals that exist at the toe of the levee may require relocation farther to the landside. Construction of an adjacent levee may also require the purchase of additional easements and/or rights-of-way, including areas for utilities and planting of replacement woodlands and other habitats. Because the west levees of the PGCC and NEMDC, north of the NEMDC Stormwater Pumping Station, already substantially comply with levee vegetation guidance criteria, the adjacent levee is not needed as an option to avoid vegetation removal on the waterside (see 2.1.3.4, "Management of Levee Vegetation and Structural Encroachments," in Chapter 2, "Alternatives," in this EIS/EIR).

2.1.1.2 SEEPAGE REMEDIATION

Pre-NLIP existing seepage remediation in the Natomas Basin has primarily addressed seepage through the levee embankment (through-seepage). Through-seepage occurs when the waterside slope is loaded by high river stage for a sufficient time to develop a steady state condition in the levee embankment in which water is seeping on the levee landside slope, removing material from the levee embankment by internal erosion and leading to slope instability. Through-seepage is the movement of water through the levee itself, when high-flow conditions, and/or wind and wave action exist on the waterside of the levee. Through-seepage may be addressed by construction of cutoff walls through the levee prism or drained stability berms on the landside slope. The cutoff walls provide a low-permeability barrier to water flow through the levee. Drained stability berms prevent levee material from being removed, drains the seepage water away from the levee, and also increases the stability of the levee slope. Underseepage or seepage through the levee foundation occurs during prolonged high river stages and results in high gradients at the levee landside toe due to build-up of the water pore pressure in the levee foundation to a high limit which may lead to levee collapse due to piping (removal of material from the levee foundation through sand boils [**Plate 1-4**]) or slope instability due to high water pore pressures in the foundation soils. Excessive underseepage gradients can be addressed by cutoff walls, seepage berms, and relief wells, or using a combination of these measures, which are discussed below.

Cutoff Walls

Cutoff walls use specialized earthen materials (often bentonite clay) constructed in the levee embankment, which extend into the levee foundation to a sufficient depth to reduce the seepage gradient at the landside toe of the levee below an allowable limit. Specialized equipment allows the cutoff walls to reach deep into the subsurface, to depths of 120 feet (**Plate 2-2**). Often the levee crown is "degraded," meaning that the levee embankment is excavated to create a wide working platform for the construction equipment to install the cutoff wall. A fully penetrating cutoff wall installed deep enough to reach a lower impervious layer in the foundation may reduce the seepage gradient to a very low limit. A partially penetrating wall, which does not reach the lower impervious strata in the foundation, may reduce the seepage gradient by increasing the seepage path, but sometimes the reduction is not sufficient to drop the gradient below the maximum allowable limit and an additional seepage berm or relief well is required. Fully penetrating cutoff walls are generally preferred, if it is constructible, because they are the least costly (particularly if a soil-bentonite [SB] mix is used and the depth of wall is less than 85 feet); are the most reliable under uncertain hydraulic and geotechnical conditions (e.g., water surface elevations above design and variations in foundation soil conditions); and, when combined with an adjacent levee, minimize construction disturbance outside the levee footprint.

If a fully penetrating wall is not feasible due to the foundation conditions (the lower impervious layer is non-existent or at a depth not possible to be reached with the existing equipment), then partially penetrating walls eventually supplemented with additional methods of seepage mitigation (such as seepage berms or relief well) may be used. Eventually, partially penetrating walls may be completely replaced by seepage berms or relief wells.

Seepage Berms

Seepage berms are wide, shallow features with relatively flat surface slopes graded to drain landward. They are typically constructed using material excavated from borrow sites. The berms may be constructed of any impervious material from the borrow sites or, to increase the berms efficiency and decrease the berm width, the random berm material may be placed on a free drainage layer 2–2.5 feet thick placed on a 6 inches of filter material to prevent removal of the fine foundation material by piping. Seepage berms may extend between a minimum of 80 feet to up to 500 feet landside of the toe of the levee or the adjacent levee (**Plate 2-3**). In areas of limited space, seepage berms are supplemented with relief wells at the landside toe of the seepage berms.

Constructing seepage berms rather than cutoff walls avoids the deep ground-disturbing work that may adversely affect cultural resources that may be present, while still achieving flood damage reduction objectives. It is

possible to construct a seepage berm using specialized equipment that minimizes vibration and pressure on the immediate subsurface environment. This construction method is often used where sensitive historical features may be expected near the ground surface, and relief wells are omitted. A seepage berm without relief wells extends the levee footprint farther landside and depending upon adjacent land use, may require relocation of permanent structures or take affected agricultural land out of production, as well as other environmental impacts.

Relief Wells

Relief wells are controlled artificial springs that relieve the confined water pressures to safe values. This reduces the potential for the removal of soil via piping or internal erosion caused by the uplift pressures beneath elements of the levee or beneath landward soil next to the levee. Relief wells are usually spaced about 50–150 feet apart to decrease the gradients at the levee toe below the maximum allowable gradient between two adjacent wells and allow water to flow without pumping during times of high water table. Piezometers are used as a tool to verify relief well performance by measuring the hydrostatic pressure between the wells. Because relief wells may only flow on an intermittent basis, sometimes several years apart, it is necessary to conduct regular maintenance of relief wells to ensure that they perform properly (**Plate 2-4**). Relief wells also require collection of water flowing through the wells during high river stages, which is then discharged back into the river through a pumping station. This may require excavation of a ditch along the landside toe of the levee or seepage berm or collecting the water through an underground piping system.

Pre-NLIP existing seepage remediation in the Natomas Basin has primarily addressed through-seepage. Through-seepage is the movement of water through the levee itself, when high-flow conditions, and/or wind and wave action exist on the waterside of the levee. Through-seepage may be addressed by construction of cutoff walls through the levee prism or a drained stability berm on the landside slope. The cutoff walls provide a low-permeability barrier to water flow through the levee. Underseepage occurs below the levee prism, and is caused by the buildup of water pressure in the subsurface foundation soils, when high river stages are present on the waterside of the levees. This pressure can be great enough to force water through the earthen foundation layers under the levee. The water finds a pathway of less resistance and exits at the landside ground surface. Excessive underseepage gradients can be corrected through the use of cutoff walls, seepage berms, and relief wells, which are discussed below. Current construction methods can correct underseepage and be compatible with the underseepage improvement methods employed for Phase 2 and 3 Project construction.

2.1.1.3 Bank Erosion Control

Bank erosion poses either a high or moderate risk to the stability of the Sacramento River east levee at several locations upstream and downstream of Interstate 5 (I-5) where river flows and waves generated by boat wakes have weakened and undercut portions of the bank supporting the levee. The adjacent levee design would address the potential instability created by these bank erosion processes by enlarging the levee section and moving the levee foundation landward away from the eroding bank. These bank erosion processes could also be addressed by installing rock revetments or other engineered structures along the eroding banks so as to reduce further erosion and protect the foundation of the levee (as proposed for the NEMDC South; see Section 2.3.3.2, “Sacramento River East Levee,” under “Pleasant Grove Creek Canal and Natomas East Main Drainage Canal – South Waterside Improvements,” in Chapter 2, “Alternatives,” of this EIS/EIR).

2.1.1.4 Management of Levee Vegetation and Structural Encroachments

USACE levee guidance requires the removal of vegetation greater than 2 inches in diameter on the levee slopes and within 15 feet of the waterside and landside levee toes (USACE 2000). USACE levee guidance also requires an assessment of encroachments on the levee slopes, including utilities, fences, structures, retaining walls, driveways, and other features that penetrate the levee prism (see Section 2.3.4.11, “Structural Encroachments,” in Chapter 2, “Alternatives,” of this EIS/EIR). Substantial encroachments are present on the Sacramento River east levee with a smaller number of encroachments on the other Natomas levees.

Vegetation Variance Request

SAFCA and the Central Valley Flood Protection Board (CVFPB), the non-Federal sponsors of the NLIP, are requesting a variance from the standard vegetation guidelines set forth in USACE's Engineering Technical Letter 1110-2-571 (USACE 2009a). Under this variance, vegetation would be allowed to remain on all or a portion of the waterside slope and berm of several of the levee segments comprising the perimeter levee system protecting the Natomas Basin. The following sections describe the levee segments that would be covered by this variance. Sections 2.3, "Proposed Action," and 2.4, "Fix-in-Place Alternative," in Chapter 2, "Alternatives," of this EIS/EIR describe the vegetation removal assumptions used by this EIS/EIR to provide environmental analysis to support consideration of this variance request.

Adjacent Levees

One of the objectives of constructing an adjacent levee along the Sacramento River east levee is to facilitate acceptable management of existing vegetation and structural encroachments along the waterside of this levee. By making the levee wider and effectively moving the "designated levee" section landward (**Plate 2-1**, lower illustration), the separation between waterside vegetation and the levee prism would be increased, thus reducing the conflicts between applicable USACE levee operation and maintenance requirements, and waterside vegetation and structural encroachments. Because this design would allow vegetation to remain on the waterside under the proposed variance, valuable riparian habitat would be preserved, benefiting several special-status species. This riparian habitat, which is shown on **Plates 3-4c** and **3-4d**, also provides a migration corridor habitat for a variety of wildlife species that inhabit the Natomas Basin.

Section 2.3.4.10, "Vegetation Management," in Chapter 2, "Alternatives," of this EIS/EIR provides additional information on the relationship of the Adjacent Levee Alternative (Proposed Action) with management of levee vegetation. Construction of the adjacent levee would also involve removal of vegetation within 15 feet of the landside toe of the widened levee. The adjacent levee has been constructed and/or approved for Sacramento River east levee Reaches C:1–4B and B:5A–15 as part of the Phase 2 and 3 Projects.

Other segments of the Natomas Basin perimeter levee system may already be in compliance with levee vegetation guidance criteria or may qualify for a variance within the next several years because: (1) vegetation did not exist or has already been cleared within the 15-foot clearance zone; (2) these segments were previously overbuilt to the point where their levee prism could be considered clear of waterside or landside vegetation and would potentially qualify for a variance; or (3) planned improvements would ensure compliance through waterside slope flattening, shifting levee crowns in a landward direction, and removing any vegetation that would penetrate the levee prism. Levee segments falling into this category include most of the Natomas Cross Canal (NCC) south levee (Reach D:1–7), the PGCC west levee (Reach E), and the west levee of the NEMDC north of the NEMDC Stormwater Pumping Station (Reaches F–G).

Overbuilt Levees

An overbuilt levee is defined as a levee with land and waterside slopes of at least 3H:1V and a virtual levee crown (measured at the design water surface elevation) that is at least 35-feet wide (designated levee crown). Similar to the adjacent levee, the overbuilt levee allows for considering that the levee prism meets the criteria of having a 15-foot vegetation free zone from the projected waterside toe, such that much of the vegetation on the waterside of the existing levee is less likely to need to be cleared for levee operation and maintenance. Like the adjacent levee, to be in compliance, trees would not be allowed to remain within the area extending 15 feet landward from the toe of the overbuilt levee out to 15 feet from the toe of the projected waterside slope.

The American River north levee is an extension of the Sacramento River east levee that extends from I-5 to Northgate Boulevard, where it becomes the west levee of NEMDC South. This segment of the Natomas perimeter levee system is considered an overbuilt levee and may qualify for a variance from USACE levee vegetation guidance because it was widened beyond standard levee dimensions to support the Arden-Garden Connector

transportation project. Also considered overbuilt and potentially eligible for a variance is the segment of the west levee of NEMDC South that extends from Northgate Boulevard to the Arden-Garden Connector. Although these levee segments are overbuilt to the extent that they may not need vegetation clearance on the waterside if a variance is granted, on the landside an extensive number of trees would be removed to accommodate the expanded levee footprint, including removal of vegetation within 15 feet of the new landside levee toe.

Non-Conforming Levees

The lower portion of the NEMDC west levee from the NEMDC Stormwater Pumping Station to Northgate Boulevard presents more challenging vegetation management options. This portion of the levee system was raised and strengthened by SAFCA in 1995–1996 as part of the American River Watershed Project authorized by Congress in the 1993 Defense Appropriations Act. The authorized project called for raising the levee to protect the Natomas Basin from the combined effects of high flows in the American River channel and high flows in Dry Creek and Arcade Creek, the tributary streams that drain foothill watersheds east of Natomas. SAFCA widened the existing levee section to the landside and raised the levee by two to three feet. Urban development along the landside of the levee constrained the space available for the project and the improved levee was designed and constructed with a 2:1 landside slope.

Project construction required landside tree removal to accommodate the widened footprint of the improved levee. However, with the concurrence of USACE and the State, to minimize the project's environmental effects, trees were allowed to remain in the maintenance area along the landside toe of the improved levee and along the waterside slope of the levee and waterside berm. It was felt that these trees would not impair the performance of the improved levee because there was adequate visibility of and access to both sides of the levee to conduct routine maintenance and flood fighting activities. Nor was there any significant concern regarding the impact of the remaining trees on the safety or structural integrity of the improved levee. Although nearly overtopped and subjected to prolonged high flow during the flood of 1986, the old levee had performed well with few signs of stress. With its increased height, the new levee performed even better during the flood of 1997. However, this levee is no longer considered in compliance with USACE levee vegetation guidance, and avoidance of landside tree clearing in this maintenance area would require a variance from USACE.

The Phase 3 Project analyzed the installation of cutoff walls through portions of the NEMDC west levee where it crosses the old streambeds of Dry Creek, Arcade Creek and Magpie Creek. The Phase 4b Project proposes construction of cutoff walls along the entire length of the NEMDC and PGCC west levee. Installation of these cutoff walls would address the risk of destabilizing underseepage in these locations which occupy approximately one-half the length of the levee between the NEMDC Stormwater Pumping Station and Northgate Boulevard. This risk was not considered to be substantial when the improvements described above were designed and constructed. Insofar as vegetation on or near the improved levee has also now been identified as a risk factor, removal would be required for all non-native trees from within the vegetation-free zone; all native trees that have a diameter at breast height (dbh) of four inches or less; and all larger native trees that are located in the upper two-thirds of the waterside slope, the crown, or within 15 feet of the landside toe (or within the right-of-way, if less than 15 feet).

Life Cycle Management Program

The following five risk factors are associated with levee vegetation:

- access (trees could obstruct access for routine maintenance and flood fighting);
- visibility (trees could impair routine levee inspection and high water condition monitoring);
- slope stability (trees could contribute to slope instability);
- seepage (tree roots could create seepage pathways); and
- windthrow (overturned trees could create destabilizing slip planes).

For non-conforming levees that may be granted a variance, implementation of a Life Cycle Management (LCM) program would use GIS- and field-based evaluation tools to ensure that new trees would not become established in the vegetation-free zone, and trees allowed to remain in this zone would be carefully monitored, trimmed and, if necessary, removed if they become an unacceptable risk to the performance of the levee due to age or infirmity.

3.1 ALTERNATIVES CONSIDERED IN PREVIOUS ENVIRONMENTAL ANALYSES AND INCORPORATED BY REFERENCE

This section describes the alternatives analysis performed in previous documents from which this EIS/EIR is tiered. The alternatives analyses from the documents listed below are incorporated by reference, herein. This material is provided here to summarize the scope of analysis that has already been performed and thus to show which alternatives have been eliminated from further analysis or rejected by previous agency decisions.

The alternatives analyses incorporated herein by reference are from the following environmental documents:

- *Environmental Impact Report on Local Funding Mechanisms for Comprehensive Flood Control Improvements for the Sacramento Area*, State Clearinghouse No. 2006072098 (Local Funding EIR) (SAFCA 2007a);
- *Environmental Impact Report on the Natomas Levee Improvement Program, Landside Improvements Project*, State Clearinghouse No. 2007062016 (Phase 2 EIR) (SAFCA 2007b);
- *Environmental Impact Statement for 408 Permission and 404 Permit to Sacramento Area Flood Control Agency for the Natomas Levee Improvement Project* (Phase 2 EIS) (USACE 2008);
- *Supplement to the Environmental Impact Report on the Natomas Levee Improvement Program, Landside Improvements Project—Phase 2 Project*, State Clearinghouse No. 2007062016 (Phase 2 SEIR) (SAFCA 2009a);
- *Addendum to the Environmental Impact Report on the Natomas Levee Improvement Program, Landside Improvements Project – Phase 2 Project*, State Clearinghouse No. 2007062016 (Phase 2 EIR 1st Addendum) (SAFCA 2009c);
- *2nd Addendum to the Environmental Impact Report on the Natomas Levee Improvement Program, Landside Improvements Project – Phase 2 Project*, State Clearinghouse No. 2007062016 (Phase 2 EIR 2nd Addendum) (SAFCA 2009d);
- *Environmental Impact Statement and Environmental Impact Report on the Natomas Levee Improvement Program, Phase 3 Landside Improvements Project*, State Clearinghouse No. 2008072060 (Phase 3 EIS and EIR) (USACE 2009b and SAFCA 2009b);
- *Addendum to the Environmental Impact Report on the Natomas Levee Improvement Program, Phase 3 Landside Improvements Project*, State Clearinghouse No. 2008072060 (Phase 3 EIR Addendum) (SAFCA 2009e); and
- *Environmental Impact Statement and Environmental Impact Report on the Natomas Levee Improvement Program, Phase 4a Landside Improvements Project*, State Clearinghouse No. 2009032097 (Phase 4a EIS and EIR) (USACE 2010 and SAFCA 2009f).

Relevant portions of these documents, where specifically noted, are summarized throughout this EIS/EIR. Printed copies of these documents are available to the public at USACE's office at 1325 J Street, Sacramento, California and at SAFCA's office at 1007 7th Street, 7th Floor, Sacramento, California, during normal business hours, and

are also available on USACE's Web site, at http://www.spk.usace.army.mil and at SAFCA's Web site, at http://www.safca.org/Programs_Natomas.html.

3.1.1 ALTERNATIVES CONSIDERED IN THE LOCAL FUNDING EIR

In the Local Funding EIR (SAFCA 2007a), SAFCA analyzed the environmental effects associated with the creation of a new assessment district to fund necessary flood damage reduction measures in the Sacramento region. This funding supports projects including the NLIP, and thus analyzes, at a programmatic level, the environmental effects for a program of flood damage reduction projects in the region, including the NLIP. The project objective used to screen alternatives for the project was the identification and creation of a source of funding that would allow SAFCA to provide 100-year flood risk reduction (0.01 AEP) for developed areas within SAFCA's jurisdiction, and to lay the groundwork for creation of 200-year flood risk reduction (0.005 AEP) over time (SAFCA 2007a: 7-2).

- **Proposed Project.** The proposed project alternative consisted of creation of an assessment district and a development fee program to fund improvements along the portions of Sacramento and American Rivers within SAFCA's jurisdiction. This alternative was determined to provide sufficient funds for project objectives (SAFCA 2007a: 3-1).

- **No Project (Alternative 1).** In this alternative, SAFCA considered the impact of neither creating nor seeking new funding mechanisms for flood damage reduction. This would limit flood damage reduction projects to current efforts to provide 100-year flood risk reduction along the American River and the South Sacramento Streams Group and thus would not meet project objectives (SAFCA 2007a: 7-2).

- **No New Public Funding; Private Levees in Natomas (Alternative 2).** This alternative assumed the same conditions as the No-Project Alternative but looked at the probable effect of private levee construction for residential development projects (SAFCA 2007a: 7-2). This alternative was eliminated because it would increase projected flood damages without a commensurate reduction in flood risk (SAFCA 2007a: 7-7).

- **Natomas 100-Year Protection (Alternative 3).** SAFCA analyzed the impacts associated with creation of one new assessment district which would provide only 100-year flood risk reduction to the Natomas Basin, and would use funding raised through existing Capital Assessment District Number 3 to provide the local share of the cost of completing improvements to provide 100-year flood risk reduction to the lower American River and South Sacramento Streams Group areas (SAFCA 2007a: 7-2). This alternative was eliminated because it would fail to provide groundwork for the creation of 200-year protection over time (SAFCA 2007a: 7-8).

- **Reduced Natomas Levee Perimeter (Alternative 4).** Under this alternative, SAFCA considered construction of a new levee across the Natomas Basin in lieu of improving the south levee of the NCC and the upper reach of the east levee of the Sacramento River. This alternative would have reduced the project footprint and would have excluded the northern undeveloped portion of the Basin both from flood risk reduction and the assessment districts to be created (SAFCA 2007a: 7-2). This alternative was eliminated because it would have a much larger footprint than proposed improvements in the Natomas Basin (SAFCA 2007a: 7-11), and it would be subject to potential veto by Reclamation District (RD) 1000 (SAFCA 2007a: 7-12).

The Local Funding EIR analyzed the ability of these alternatives to meet the project objectives and determined that only the proposed project would meet project goals (SAFCA 2007a: 7-14). In addition, the Local Funding EIR analyzed the environmental effects of the various alternatives and concluded that Alternative 3 was the environmentally superior alternative. Alternative 3 would have eliminated or reduced a range of significant effects associated with creation of a new assessment district; however, it was not selected because it would not meet the important project objective of laying the groundwork for 200-year flood risk reduction (0.005 AEP). The proposed project alternative was selected because it would meet all of the project objectives.

3.1.2 ALTERNATIVES CONSIDERED IN THE PHASE 2 EIR AND PHASE 2 EIS

In the Phase 2 EIR (SAFCA 2007b) and Phase 2 EIS (USACE 2008), SAFCA and USACE, respectively, analyzed construction of flood damage reduction measures required to protect the Natomas Basin at a program level (Phase 3 and 4 Projects) and a project level (Phase 2 Project). The project objectives used to screen alternatives consisted of developing 100-year flood risk reduction (0.01 AEP) in the Natomas Basin as quickly as possible, developing 200-year flood risk reduction (0.005 AEP) over time, and ensuring that new development in Sacramento's floodplains would not substantially increase the risk of flooding. Project-specific objectives included reducing hazards to aviation safety in the vicinity of the Sacramento International Airport, and enhancing habitat values in the Natomas Basin for giant garter snake, Swainson's hawk, and other special-status species. (Note: below, page numbers are provided for the Phase 2 EIR only.)

- **Construct an Adjacent Setback Levee along the Sacramento River East Levee.** This alternative was analyzed as the proposed project, carried forward in the EIR as Alternative 1. This project consisted of constructing an adjacent setback levee on the Sacramento River east levee. Other improvements included levee raising and seepage remediation on the Sacramento River east levee, the NCC south levee, and the Pleasant Grove Creek Canal (PGCC) west levee. Other project components included improvements to major irrigation and drainage infrastructure, habitat creation and management, and right-of-way acquisition (SAFCA 2007b: 6-6, 6-7). This alternative was determined to meet project objectives (SAFCA 2007b: 6-7).

- **Raise Levee in Place with a 1,000-Foot Levee Setback in the Upper 1.4 Miles along the Sacramento River East Levee.** This alternative would have provided a location for a substantial amount of tree planting on the waterside of the levee, contributing to offsetting mitigation for the loss of trees that could have been removed along the existing levee to meet USACE criteria. This alternative was eliminated because it was unlikely that the new setback levee would provide 100-year flood risk reduction per USACE criteria (SAFCA 2007b: 6-11).

- **Construct an Adjacent Setback Levee with a 500-Foot Levee Setback in the Upper 1.4 Miles along the Sacramento River East Levee.** This alternative was evaluated because it would provide the opportunity for partially offsetting the loss of landside tree groves through the establishment of new riparian plantings in the levee setback area as well as woodland plantings on the landside of the adjacent setback levee. This alternative was eliminated because it would require substantially greater quantities of borrow material with greater impacts on important farmland and transportation and circulation (SAFCA 2007b: 6-19, 6-20).

- **No-Project Alternative—No Flood Control Improvements in Natomas.** Consideration of a no-project alternative is required under CEQA. Under this alternative, it was assumed that the Natomas Basin flood damage reduction system would not be improved. This alternative was eliminated because it would not meet project objectives (SAFCA 2007b: 6-14).

- **No SAFCA Levee Improvements—Private Levees in Natomas.** This alternative was analyzed assuming no SAFCA project providing flood risk reduction in the Basin, thus causing private developers to separately fund individual flood risk reduction in the form of private compartment levees that would protect new developments. This was eliminated because it would only partially meet the first objective of providing 100-year flood risk reduction and it would potentially lead to increased fragmentation of habitat for special-status species (SAFCA 2007b: 6-15).

The proposed project was identified as the environmentally superior alternative after all alternatives were compared relative to their foreseeable effects (SAFCA 2007b: 6-25). The proposed project was selected for implementation.

After the November 29, 2007 certification of the Phase 2 EIR, SAFCA made minor modifications to the design of the Phase 2 Project. The Phase 2 SEIR (SAFCA 2009a) was prepared by SAFCA to evaluate these modifications;

the SAFCA Board of Directors certified the SEIR on January 29, 2009, at which time the Board also approved the modifications to the Phase 2 Project. No new alternatives were identified in the Phase 2 SEIR. Subsequently, two addenda to the Phase 2 EIR were prepared by SAFCA to evaluate additional minor modifications to the Phase 2 Project; the 1st Addendum to the Phase 2 EIR (SAFCA 2009c) was certified by the SAFCA Board of Directors on June 8, 2009 and the 2nd Addendum to the Phase 2 EIR (SAFCA 2009d) was certified on August 20, 2009. No new alternatives were identified in these Phase 2 addenda.

3.1.3 ALTERNATIVES CONSIDERED IN THE PHASE 3 EIS AND EIR

In the Phase 3 EIS and EIR, USACE and SAFCA analyzed construction of flood damage reduction measures required to protect the Natomas Basin at a project level for the Phase 3 Project (USACE 2009 and SAFCA 2009b). The following alternatives were analyzed at an equal level of detail:

- **No-Action Alternative**—Under NEPA, the expected future without-project conditions; under CEQA, the existing condition at the time the notice of preparation was published (July 18, 2008), as well as what would be reasonably expected to occur in the foreseeable future (two scenarios) if the Phase 3 Project were not approved.

- **Proposed Action**—Construction of an adjacent setback levee along the Sacramento River east levee and improvements to the PGCC west levee and the NEMDC west levee from Elkhorn Boulevard to Northgate Boulevard.

- **Levee Raise-in-Place Alternative**—Raising of the Sacramento River east levee in place and improvements to the PGCC west levee and the NEMDC west levee from Elkhorn Boulevard to Northgate Boulevard.

The Proposed Action and one action alternative (the Levee Raise-in-Place Alternative) were developed for consideration for the Phase 3 Project with a focus on improvements to the Sacramento River east levee (Reach B:5A–9B). Phase 3 Project improvements to the PGCC west levee, the NEMDC west levee, and landscape and irrigation/drainage system modifications would be similar under the Proposed Action and the Levee Raise-in-Place Alternative.

Development of the Proposed Action and the Levee Raise-in-Place Alternative included substantial planning based on consideration of effects on wetlands and other waters of the United States, woodlands, giant garter snake habitat, and other habitats. Accordingly, levee improvements were designed to avoid or minimize such effects where practicable and feasible. However, several agricultural canals or portions of canals and small seasonal wetlands exist near the levee toe along the Sacramento River east levee, PGCC west levee, and NEMDC west levee. These would require filling under either the Proposed Action or the Levee Raise-in-Place Alternative because their proximity to the existing levees places them within the expanded landside levee footprint or adjacent maintenance access under the Proposed Action and the Levee Raise-in-Place Alternative. Similarly, portions of several woodland groves extend into the proposed footprint of the flood damage reduction features along the landside of the Sacramento River east levee under the Proposed Action and the Levee Raise-in-Place Alternative and would need to be removed and/or relocated. Consequently, effects on wetlands and other waters of the United States and on other habitats along the landside of the levees were very similar for the Proposed Action and the Levee Raise-in-Place Alternative, and the same compensation strategies were proposed for unavoidable effects.

The Levee Raise-in-Place Alternative differed from the Proposed Action in that it would result in the (1) removal of waterside trees along the Sacramento River east levee to conform with USACE guidance regarding levee encroachments, and (2) loss of waters of the United States due to the implementation of erosion control improvements along the waterside toe of Sacramento River east levee. These effects would require a different compensation strategy than for the Proposed Action because, under the Proposed Action, these actions would not occur on the waterside of the levee.

In terms of flood risk reduction system design, the Proposed Action and the Levee Raise-in-Place Alternative differed in terms of how they would achieve the required levee height increases along the Sacramento River east levee. Therefore, the differences between the Proposed Action and the Levee Raise-in-Place Alternative, including effects on habitats, were the result of these Sacramento River east levee design differences.

The Proposed Action was identified as the environmentally superior alternative after all alternatives were compared relative to their foreseeable effects. The Proposed Action was approved for implementation by the SAFCA Board of Directors on May 21, 2009.

Since certification of the Phase 3 EIR, SAFCA has made minor modifications to the design of the Phase 3 Project. An addendum to the Phase 3 EIR (SAFCA 2009e) was prepared by SAFCA to evaluate these modifications; the SAFCA Board of Directors certified the Addendum and approved the modifications to the Phase 3 Project on September 17, 2009. No new alternatives were identified in the Phase 3 addendum.

3.1.4 ALTERNATIVES CONSIDERED IN THE PHASE 4a EIS AND EIR

In the Phase 4a EIS and EIR, USACE and SAFCA analyzed construction of flood damage reduction measures required to protect the Natomas Basin at a project level for the Phase 4a Project (USACE 2010 and SAFCA 2009f). The following alternatives were analyzed at an equal level of detail:

- **No-Action Alternative**—Under NEPA, the expected future without-project conditions; under CEQA, the existing condition at the time the notice of preparation was published (March 27, 2009), as well as what would be reasonably expected to occur in the foreseeable future (two scenarios) if the Phase 4a Project were not approved.

- **Proposed Action**—An adjacent levee would be constructed along the Sacramento River east levee, raised in Reach B:10–11B and at the same height as the existing levee in Reach B:12–15; and, where required, cutoff walls, seepage berms, and relief wells would be installed for seepage remediation. A cutoff wall would be installed for additional seepage remediation in Reach 4B. In two locations, the NCC south levee would be raised, a cutoff wall would be installed, and existing pumps would be modified or replaced to reflect raising the discharge pipes above the 200-year design flood elevation (0.005 AEP). The Riverside Canal would be relocated and extended. Parcels within the Fisherman's Lake Borrow Area would be used as the primary source of soil borrow for Phase 4a Project construction; those parcels excavated for borrow material would be reclaimed as agricultural land, grassland, or managed marsh depending on their location and existing land use. Wells would be constructed to provide a water supply for habitat features.

- **Raise and Strengthen Levee in Place (RSLIP) Alternative**—The Sacramento River east levee would be raised in place in Reach B:10–12 and strengthened in place in Reach B:12–15 and seepage remediation and erosion control measures would be implemented. The RSLIP Alternative would be the same as described for the Proposed Action except for the method of levee raising and rehabilitation, the extent of levee degrade to construct cutoff walls, and extent of encroachment removal along the Sacramento River east levee.

The Proposed Action and the RSLIP Alternative were developed for consideration for the Phase 4a Project with a focus on improvements to the Sacramento River east levee (Reach B:10–15). Phase 4a Project improvements to the NCC south levee, relocation and extension of the Riverside Canal, and modifications to the landscape and irrigation/drainage system would be similar under the Proposed Action and the RSLIP Alternative.

As noted above, the Proposed Action and the RSLIP Alternative would use differing methods to achieve the required levee height increases along the Sacramento River east levee for flood damage reduction. Therefore, the differences between the Proposed Action and the RSLIP Alternative, including effects on habitats, are the result of these differences in design of the Sacramento River east levee.

The Proposed Action was identified as the environmentally superior alternative after all alternatives were compared relative to their foreseeable effects. The Proposed Action was approved for implementation by the SAFCA Board of Directors on November 13, 2009.

3.2 ALTERNATIVES CONSIDERED, BUT ELIMINATED FROM FURTHER CONSIDERATION IN PREVIOUS ENVIRONMENTAL ANALYSES AND INCORPORATED BY REFERENCE

Numerous alternatives have been considered by USACE and SAFCA to reduce flood risk in the Natomas Basin. These alternatives were evaluated and eliminated from further consideration during completion of previous environmental documents.

The following alternatives were reviewed and eliminated from further consideration as described below:

- **Yolo Bypass Improvements.** This measure would involve lengthening the Fremont Weir and widening the Yolo Bypass to increase the amount of flood water conveyed through the bypass and reduce the amount of flood water conveyed through the Sacramento River channel downstream of the weir. This alternative was eliminated because: (1) it would be too costly for SAFCA to implement; (2) levee height increases and substantial seepage and slope stability remediation would still be required for the Natomas perimeter levee system, adding to costs; (3) these improvements lie outside of SAFCA's jurisdiction and would require Federal, State, and local cooperation and funding; and (4) the project objective of restoring 100-year (0.01 AEP) design flood levels to the Natomas Basin could not be achieved as quickly as possible. (Considered and eliminated in Phase 2 EIS.)

- **Reduced Natomas Urban Levee Perimeter.** This measure would involve construction of a cross levee running east to west across the Natomas Basin along an alignment north of Elkhorn Boulevard to protect existing developed areas in the City and County of Sacramento. This alternative was eliminated because: (1) it is inconsistent with current Federal and State authorizations and would strand Federal, State, and local investments already made in improving the NCC south levee and Sacramento River east levee pursuant to past Congressional authorization; (2) it would result in the need to raise State Route (SR) 99 or otherwise protect SR 99 from flooding; (3) it would divide Reclamation District (RD) 1000 and disrupt several portions of the Natomas Basin irrigation and drainage system and require reconfiguration of these systems; (4) it would present significant barriers to achieving the goals of the *Natomas Basin Habitat Conservation Plan* (NBHCP); (5) it would have substantially greater costs than other alternatives without achieving any additional flood damage reduction benefit; and (6) it would leave a portion of the Basin currently planned for development by Sutter County (i.e., *Sutter Pointe Specific Plan* mixed-use development project) outside the urban levee perimeter and likely cause Sutter County to exercise its rights under SAFCA's joint exercise of powers agreement to prevent the expenditure of Consolidated Capital Assessment District funds on this measure. (Considered and eliminated in Local Funding EIR and Phase 2 EIS.)

- **Construction of a New Setback Levee.** This alternative would involve construction of a 5-mile-long levee along the northern reaches of the Sacramento River east levee parallel to the existing levee alignment but set back from the existing alignment by 500–1,000 feet. This alternative was eliminated because it is infeasible due to: (1) the presence of waterside residences along the existing levee from the southern end of Sacramento River east levee Reach C:2 to the American River north levee, and the need to maintain access to these residences from Garden Highway; (2) the proximity of the Sacramento River east levee to the Airport, and the need to prevent project features from increasing potential hazards to aviation safety; and (3) the possibility that utility relocations (power poles) and flood damage reduction measures could encroach into surface slopes of runway approach zones. (Considered and eliminated in Phase 2 EIR and Phase 2 EIS.)

Two additional alternatives were considered for the Phase 3 EIS and EIR but were eliminated from further consideration. These alternatives, as well as the rationale for eliminating them from further consideration, are described in the following subsections.

3.1.1 NO-ACTION ALTERNATIVE—AIRPORT COMPARTMENT LEVEE

The Phase 2 EIS evaluated and eliminated from further consideration the No-Action Alternative—Airport Compartment Levee Alternative. The prior discussion of this alternative, which is hereby incorporated by reference, is summarized as follows.

With no authorization for the subsequent project phases (Phase 3, 4a, and 4b Projects), which are part of the overall NLIP, SAFCA would not meet timing objectives for providing the Natomas Basin with at least a 100-year level of flood risk reduction and achieving a 200-year level of protection. Federal and state floodplain regulations would effectively prevent new development in most of the Natomas Basin. The Airport would either be compelled to operate within its existing footprint, abandoning its current plans for expansion and modernization, or, alternatively, the Airport may construct its own limited flood damage reduction structure (i.e., a ring levee) to protect existing facilities and its expansion area. As of December 31, 2007, the leases for rice production on fields north of the Airport expired and were not renewed; hence, rice production has been discontinued on these fields to reduce wildlife hazards to aviation safety. These leases will not be renewed.

Table B1-2 summarizes the impacts identified in the Phase 2 EIS associated with implementation of the Airport Compartment Levee. The Phase 2 EIS concluded that significant impacts could occur. However, because there were no detailed design plans for this alternative, it was not possible to accurately determine exactly what environmental impacts could occur; therefore, one could also have concluded that the potential impacts were too speculative for meaningful consideration.

For the reasons provided in the Phase 2 EIS (listed below), this alternative was not carried forward for further evaluation in the Phase 3 EIS and EIR or Phase 4a EIS and EIR, nor is it carried forward for further evaluation in this EIS/EIR:

- construction of a separate levee around the Airport would be under the responsibility and jurisdiction of another agency (Sacramento County Airport System [SCAS]), over which SAFCA would have no jurisdiction, and would require a lengthy process that is completely separate from the Proposed Action;
- the timeline for that process is unknown and there are no design plans that would enable an accurate evaluation of potential environmental impacts; and
- the action would require SCAS to prepare a separate CEQA and potentially NEPA)environmental document.

In addition to those reasons provided in the Phase 2 EIS, design plans are not available for this alternative, thus preventing USACE and SAFCA from accurately evaluating its potential impacts; implementation of the Airport Compartment Levee would not meet any of the goals and objectives of the project; the residents, residences, and businesses within the Natomas Basin would not receive flood risk reduction; implementation of the Airport Compartment Levee would only protect the Airport; and SCAS has not proposed such a project and, therefore, this alternative is not considered a reasonable alternative.

3.1.2 CULTURAL RESOURCES IMPACT REDUCTION ALTERNATIVE

The Phase 3 Project's Proposed Action included construction primarily of deep cutoff walls in the Sacramento River east levee Reach B:5A–9B, which would require excavation and placement of slurry at great depths along these reaches. The Sacramento River east levee has the potential to contain buried and undiscovered cultural

Table B1-2 Summary of Impacts: No-Action Alternative—Airport Compartment Levee	
Issue Area	Impacts
Agricultural Resources	A substantial conversion of Important Farmland to nonagricultural uses would likely occur in the footprint of the flood risk reduction features, given that the Airport is surrounded by agricultural land, much of which is Important Farmland. However, the amount of such conversion is uncertain because no concept plan for an Airport flood damage reduction system has been developed, and the footprint size and location are unknown. This impact could be significant.
Topography, Geology, and Soils	Construction-related activities would result in localized soil erosion effects. This impact would be significant.
Hydrology and Hydraulics	The Basin's existing residential, commercial, and industrial structures and their contents would continue to remain subject to a relatively high risk of flooding. Substantial alteration of local drainage systems around the Airport and of drainage patterns would result. This impact would be significant unless a substantial redesign of local drainage systems were included in the design of the Airport flood risk reduction system.
Water Quality	Construction-related activities would result in adverse effects to water quality. Construction activity would involve ground disturbance and the potential for contaminants to enter local waterways either from direct spills, or from stormwater runoff. These impacts could be significant.
Fisheries	Construction-related activities would result in adverse effects on water quality in agricultural canals. These effects could, in turn, result in localized water quality degradation in receiving water bodies (e.g., the Sacramento River) and affect habitats and the physical health of individual fish and species populations in those water bodies. This impact could be significant.
Sensitive Aquatic Habitats	Construction of a compartment levee would require the fill of portions of several agricultural canals in the Airport vicinity, which may be jurisdictional waters of the United States. This impact would be significant. Because there is no conceptual design for a compartment levee, the amount of fill of potentially jurisdictional waters cannot be estimated.
Vegetation and Wildlife	Numerous elements of the irrigation and drainage system in the west-central portion of the Natomas Basin would likely be severed and would need to be rerouted with construction of a compartment levee. Ditches and canals in the basin serve as critical corridors for movement of aquatic species, and this movement could be significantly disrupted by construction of an Airport flood risk reduction system.
Special Status Terrestrial Species	The compartment levee, as well as construction-related activities would likely affect habitat for some special-status plants in ditches and canals. A concept plan for such a flood risk reduction system has not been developed, therefore, the likelihood and extent of such an impact is not predictable and cannot be estimated. The construction footprint might include areas where elderberry shrubs are present and would have to be relocated. The compartment levee would likely cross several irrigation and/or drainage canals in the west-central portion of the Natomas Basin that may provide habitat for giant garter snake, adversely affecting the habitat and potentially resulting in take of individual snakes. This impact would be significant.
Cultural Resources	The compartment levee would significantly alter elements of RD 1000. It is possible that historic-era resources of significance could be encountered during construction. Known prehistoric site CA-Sac-16/H south of the Airport would likely be adversely affected. Construction-related activities could encounter previously undiscovered cultural resources and potentially encounter human remains. These impacts would be significant.
Paleontological Resources	Construction-related activities could damage unique paleontological resources. This impact could be significant.
Transportation and Circulation	Construction-related activities could cause temporary traffic delays, temporarily increase emergency service response times, and interfere with emergency service access. These impacts would be significant.

Table B1-2 Summary of Impacts: No-Action Alternative—Airport Compartment Levee	
Issue Area	Impacts
Air Quality	Construction-related activities would result in the temporary and short-term generation of ROG, NO_X, and PM_{10} emissions. Construction-related activities would likely result in the temporary, short-term generation of diesel exhaust emissions. These impacts would be significant.
Noise	Construction-related activities would generate temporary and intermittent noise that could be near individual noise-sensitive locations. This potential impact could be significant; however, because concept design for such a levee has not been developed, it is not possible to estimate the potential magnitude or location of an impact.
Recreation	It is unlikely that any recreational uses would be affected, because there are no recreational facilities in the vicinity of the Airport. There would be no impact.
Visual Resources	The presence and movement of heavy construction equipment, construction-generated dust, and the presence of the compartment levee in the landscape would likely temporarily and permanently degrade the existing visual character and/or quality of the Natomas landscape. This impact would be significant.
Utilities and Service Systems	Significant temporary interruptions of irrigation supply could occur if construction activities result in damage to irrigation infrastructure or otherwise render the infrastructure inoperable at a time when it is needed (e.g., reconnections to water supply sources are not completed by the time crop irrigation must begin). This impact would be significant.
Hazards and Hazardous Materials	It is assumed that construction would not cause any significant hazards associated with the transport and handling of hazardous materials because the applicable regulations would be followed. Previously unknown or undocumented hazardous materials could be present in construction areas (including borrow sites). Excavation at or near areas of currently unrecorded soil and/or groundwater contamination could result in the exposure of construction workers, the general public, and the environment to hazardous materials. This impact could be significant.
Wildfire Hazards	Physical and weather conditions could combine to lead to a high risk of fire hazard, and construction equipment or construction practices could ignite fires that may result in wildland fires and expose people or structures to a significant risk of loss, injury, or death under some circumstances. This potential impact would be significant.
Notes: RD = Reclamation District; ROG = Reactive Organic Gases; NO_X = oxides of nitrogen; PM_{10} = respirable particulate matter with an aerodynamic diameter of 10 micrometers or less Source: USACE 2008; data compiled by EDAW (now AECOM) in 2008	

resources that are difficult to detect by inspecting the ground surface. The Proposed Action under the Phase 3 Project, therefore, has the potential to result in significant and unavoidable impacts to known prehistoric resources, previously unidentified cultural resources, and interred human remains. Unlike other resources, the magnitude of potential impacts on previously undiscovered cultural resources and interred human remains is harder to discern because there are few feasible ways to investigate the presence of these resources within the footprint of deep cutoff walls proposed for construction along the Sacrament River east levee. Deep cutoff walls require excavation into strata that are currently beneath existing levees. Because of the potential magnitude of these impacts, the Phase 3 EIS and EIR analyzed an alternative means of remediating seepage along the Sacramento River east levee to determine if it would be possible to reduce impacts on cultural resources. This alternative consisted of construction of a 500-foot-wide seepage berm on the landside of the levee instead of construction of deep cut-off walls. The analysis of this alternative concluded that while a berm may reduce impacts on any resources identified adjacent to the Sacramento River east levee, it would dramatically increase the potential for impacts on undiscovered cultural deposits as well as other resources, and thus was eliminated.

Construction of a 500-foot-wide seepage berm rather than primarily deep cutoff walls in these reaches would avoid the deep ground disturbing work associated with cultural resource impacts while still achieving flood damage reduction objectives. Construction of a 500-foot-wide seepage berm would have more than doubled the borrow material requirement for the Sacramento River east levee Reach B:5A–9B component of the Phase 3 Project's Proposed Action from approximately 1.8 million cubic yards (cy) to 3.8 million cy.

Table B1-3 compares impacts for the Proposed Action under the Phase 3 Project and the Cultural Resources Impact Reduction Alternative. Impacts to cultural resources and aviation safety hazards would be reduced by the construction of a 500-foot-wide berm. Of the 16 issue areas analyzed, impacts on ten of the issue areas were considered to be more severe with the Cultural Resources Impact Reduction Alternative. Approximately four impacts were determined to be generally similar. One impact was reduced ("24/7" noise associated with construction of deep cut-off walls) and one impact potentially less impacted by construction of a seepage berm.

Because the Cultural Resources Impact Reduction Alternative would have resulted in a net increase in the number, intensity, and severity of environmental impacts compared to the Phase 3 Project Proposed Action, and because implementation of the 500-foot-wide seepage berm would have resulted in the permanent displacement of residences and temporary closure, disruption, and redesign of portions or all of the Teal Bend Golf Club, it was eliminated from further consideration, and thus was not carried forward for detailed analysis in the Phase 3 EIS and EIR.

Although this alternative was eliminated for the Phase 3 Project due to the reasons cited above, 500-foot-wide seepage berms was analyzed in the Phase 4a EIS and EIR as part of the Phase 4a Project Proposed Action to represent the worst-case scenario because it is anticipated that at least one very large cultural site may require avoidance (CA-Sac-16/H), and additional previously undiscovered cultural resource sites may be present.

The locations and widths of the seepage berms would be determined during final engineering design. The use of seepage berms would take into the consideration overall impacts to resources and whether residences, heritage oak trees, or other sensitive resources would be affected. SAFCA would employ measures to minimize the project footprint to avoid these resources to the extent feasible, under levee design and seepage remediation performance requirements.

3.3 ADDITIONAL ALTERNATIVE CONSIDERED, BUT ELIMINATED FROM FURTHER CONSIDERATION––UPSTREAM TRANSITORY STORAGE

3.1.3.1 ROBBINS BASIN (RECLAMATION DISTRICT 1500) TRANSITORY STORAGE

This alternative would utilize the RD 1500 basin as an upstream transitory storage site (or off-stream storage). Flood waters would be diverted into the basin via an un-gated or gated weir. The preliminary design locates the weir at River Mile (RM) 69.50 on the Sutter Bypass and is 5280 feet long. For this alternative to successfully perform, it is necessary for the basin to be empty at the start of weir flow. To assure this, it was assumed that all levees surrounding the basin are improved.

The target stage for diverting water into the basin is 40.4 feet (National Geodetic Vertical Datum of 1929 [NGVD29]). This is equal to the minimum elevation of the surrounding existing condition levees. The stage of 40.38 corresponds to a storage space of 987,862 acre-feet. Exit gates and/or weirs would also be needed to drain the water from the basin after the flood peak. They would be located at the lowest spot in basin, in the left levee of the Sacramento River at about RM 85.00, about one mile upstream of the Fremont Weir.

Table B1-3
Comparison of Impacts: Phase 3 Project Proposed Action and Cultural Resources Impact Reduction Alternative

Issue Area	Proposed Action	Cultural Resources Impact Reduction Alternative (500-Foot-Wide Seepage Berm)
Hydrology and Hydraulics	Significant	Greater impacts to local drainage infrastructure
Water Quality	Significant	Similar
Fisheries	Significant	Similar
Sensitive Aquatic Habitats	Significant	Greater impacts to potentially jurisdictional features (loss of an additional 17.13 acres of riparian habitat, 7.58 acres of seasonal wetlands, and 0.88 acre of freshwater marsh)
Vegetation and Wildlife	Significant	Greater impacts to woodlands (additional loss of 14 acres of woodland habitat)
Special-Status Terrestrial Species	Significant	Greater impacts to Swainson's hawk foraging and nesting habitat (loss of an additional 185 acres of Swainson's hawk foraging habitat [47 acres of high quality foraging alfalfa crop habitat and 14 acres of Swainson's hawk nesting habitat—woodlands])
Cultural Resources	Significant and unavoidable Greater impacts to undiscovered cultural resources and interred human remains from deep cut-off wall construction	Potentially greater impacts to undiscovered cultural resources and interred human remains resulting from increased borrow materials usage (from 1.8 million cy to 3.8 million cy) for 500-foot-wide seepage berm
Paleontological Resources	Significant	Potentially greater impacts associated with greater borrow material excavation (from 1.8 million cy to 3.8 million cy)
Transportation and Circulation	Significant and unavoidable	Potentially greater impacts to traffic. Increase borrow use would more than double haul route usage and potentially significantly increase truck traffic on Elkhorn Boulevard
Air Quality	Significant and unavoidable	Greater severity of significant and unavoidable impacts with greater borrow material excavation (from 1.8 million cy to 3.8 million cy)
Noise	Significant and unavoidable	Similar, with exception of 24/7 construction associated with cut-off wall construction (lesser)
Recreation	Significant	Greater due to temporary closure and disruption of the Teal Bend Golf Club and likely need to redesign all or portions of the golf course. Since it is likely infeasible to construct a seepage berm within the golf course, requiring the proposal for cut-off walls in this area to remain unaffected, the impact would remain similar within the golf course.
Visual Resources	Significant and unavoidable	Greater impacts to oak woodlands and existing views from removal of trees from the loss of 14 acres of woodland habitat
Utilities and Service Systems	Significant	Greater temporary impacts and relocations of existing irrigation infrastructure and utilities. Greater impacts resulting from permanent relocation of residences within the footprint of the 500-foot-wide berm
Hazards and Hazardous Materials	Significant	Potentially less impacts from fewer requirements for night lighting, potentially resulting in less aviation hazard
Wildfire Hazards	Significant	Similar

Source: Compiled by EDAW (now AECOM) in 2008

The stage in the Sacramento River at RM 69.9983 (about halfway between the Cross Canal and American River confluences) would be reduced by up to 2.3 feet for the 200-year (0.005 AEP) event under this alternative. This reduction in water surface elevation is not significant enough to preclude the need for levee modification.

3.1.3.2 NICOLAUS BASIN (RECLAMATION DISTRICT 1500) TRANSITORY STORAGE

This alternative would utilize the RD1001 basin as an upstream transitory storage site (or off-stream storage). Flood waters would be diverted into the basin via a gated weir approximately 500 feet long. The preliminary design locates the weir at RM8.501 on the Feather River. For this alternative to successfully perform, it is necessary for the basin to be empty at the start of weir flow. To assure this, it was assumed that all levees surrounding the basin are improved.

The target stage for diverting water into the basin is 42.0 feet (NGVD29). This is equal to the minimum elevation of the surrounding existing condition levees. The stage of 42.0 corresponds to a storage space of 25,000 acre-feet. Exit gates and/or weirs would also be needed to drain the water from the basin after the flood peak. They would be located at the lowest spot in the basin, along the left levee of the Sacramento River.

The stage in the Sacramento River at RM 69.9983 (about halfway between the Cross Canal and American River confluences) would be reduced by up to 1.8 feet for the 200-year (0.005 AEP) event under this alternative. This reduction in water surface elevation is not significant enough to preclude the need for levee modification.

3.1.3.3 ELKHORN BASIN (RECLAMATION DISTRICTS 537, 827, 785, 1600) TRANSITORY STORAGE

This alternative would utilize the Elkhorn basin as a transitory storage site (or off-stream storage). Flood waters are diverted into the basin via an un-gated weir. The preliminary design locates the weir at RM 69.00 on the Sacramento River, and it is 10,560 feet long. For this alternative to successfully perform, it is necessary for the basin to be empty at the start of weir flow. To assure this, it was assumed that all levees surrounding the basin are improved.

The target stage for diverting water into is 30.27 feet (NGVD29). This is equal to the minimum elevation of the surrounding existing condition levees. The stage of 30.27 corresponds to a storage space of 225,000 acre-feet. Exit gates/weirs would also be needed to drain the water from Elkhorn Basin after the flood peak.

The stage in the Sacramento River at RM 69.9983 (about halfway between the Cross Canal and American River confluences) would be reduced by up to 0.9 feet for the 200-year (0.005 AEP) event under this alternative. This reduction in water surface elevation is not significant enough to preclude the need for levee modification.

Table B1-4
Transitory Storage Basins

Basin	Maintaining Agencies	Acres	Miles of Levee	Land Use	Population
Robbins	RD 1500	65,692	59.4	Rural	900
Nicolaus	RD 1001	37,393	30.2	Rural	1,311
Elkhorn	RD 1600, RD 827, RD785, RD 537	12,323	31.8	Rural	172

Source: Information provided by USACE in 2010

Table B1-5 Preliminary Cost Estimates for Transitory Storage Alternatives		
Action	Cost	Sub-total/Total
Robbins Basin (Reclamation District 1500) Transitory Storage		
Cost to Improve Levees	331,632 levee feet @ $2,000/levee foot	$663,264,000
Cost of Land for Storage	65,692 acres @ $5,000/acre	$328,460,000
Cost to Construct Weirs (inlet/outlet)	2 weirs @ $2,000,000 each	$4,000,000
Construct Ring Levee around Robbins	10,000 lf @ $7,000/levee foot	$70,000,000
Total		**$1,065,724,000**
Nicolaus Basin (RD 1001) Transitory Storage1		
Cost to Improve Levees	159,456 levee feet @ $2,000/levee foot	$318,912,000
Cost of Land for Storage	37,393 acres @ $5,000/acre	$186,965,000
Cost to Construct Weirs (inlet/outlet)	2 weirs @ $2,000,000 each	$4,000,000
Construct Ring Levee around Nicolaus	5,000 lf @ $7,000/levee foot	$35,000,000
Total		**$544,877,000**
Elkhorn Basin (RD 537, 827, 785, 1600) Transitory Storage2		
Cost to Improve Levees	167,904 levee feet @ $2,000/levee foot	$335,808,000
Cost of Land for Storage	12,323 acres @ $5,000/acre	$61,615,000
Cost to Construct Weirs (inlet/outlet)	2 weirs @ $2,000,000 each	$4,000,000
Total		**$ 401,423,000**

[1] Connecting to existing levee along Feather River.

[2] These estimates do not include costs to purchase or raise structures.

Source: Information provided by USACE in 2010

As discussed above, various upstream detention measures were evaluated as part of this EIS/EIR. Initial evaluation indicates that these measures would not be cost-effective. The water levels in Natomas would not be reduced to a significant degree to justify the costs associated with implementing the alternative. These costs include: construction of intake and outtake structures for water to enter and leave the detention basins, improvement of the perimeter levees around the detention basin(s) to current standards, and acquisition of real estate easements for water storage and to purchase and/or relocate existing properties in the basins. Transitory storage would not alleviate the need to implement other measures to address the seepage, stability, erosion, and vegetation and encroachment issues facing the existing Natomas Basin perimeter levees.

Because of the extent and likely cost of these improvements, this alternative would require an unprecedented degree of State, Federal, and local cooperation and funding. For this reason, this alternative was not pursued as a component of the Phase 4b Project, but is considered worthy of further evaluation as part of the State's pending update of the State plan of flood protection for the Central Valley.

4.1 ALTERNATIVES CARRIED FORWARD FOR EVALUATION IN THIS EIS/EIR

The following alternatives are carried forward for detailed analysis in this EIS/EIR and are described in detail in Chapter 2, "Alternatives":

- **No-Action Alternative**—Under NEPA, the expected future without-project conditions; under CEQA, the existing condition at the time the notice of preparation was published (November 5, 2009) as modified by

what would be reasonably expected to occur in the foreseeable future if the Phase 4b Project were not approved (two scenarios are proposed).

- **Adjacent Levee Alternative (Proposed Action)**—An adjacent levee would be constructed along the Sacramento River east levee Reach A:16–20; and, where required for this levee, cutoff walls, seepage berms, and relief wells would be installed for seepage remediation. A cutoff wall would be installed in the American River north levee east of Gateway Oaks Drive to Northgate Boulevard, and the landside slope would be flattened. The NEMDC west levee would be raised in place or widened from just south of Elkhorn Boulevard to Sankey Road, and the landside slope would be flattened and seepage remediation would be constructed as necessary. Waterside erosion protection would be constructed in locations along the PGCC and NEMDC (south of Elkhorn Boulevard). Culverts located beneath the PGCC would be upgraded or removed, and replacement flood storage would be provided as needed. At the SR 99 crossing of the NCC, seepage remediation would be installed and a moveable barrier system would be constructed to prevent overflow from reaching the landside of the NCC south levee. The western portion of the West Drainage Canal would be realigned to the south, and the remaining portion of the existing canal would be improved to reduce bank erosion and sloughing, decrease aquatic weed infiltration, improve RD 1000 maintenance access, and enhance giant garter snake habitat connectivity. Irrigation canals and ditches would be relocated either to make room for expanded levee sections or to reduce underseepage potential. Discharge pipes for RD 1000 pumping plants and City of Sacramento sump pumps would be raised to cross the levee above design flood water surface elevation. Parcels in the South Fisherman's Lake and Triangle Properties Borrow Areas and at the West Lakeside School Site would be excavated and reclaimed as agricultural land. Woodland groves would be established to compensate for impacts along the Sacramento River east levee Reach A:16–20, American River north levee Reach I:1-4, and NEMDC.

- **Fix-in-Place Alternative**—The Sacramento River east levee would be improved in place in Sacramento River east levee Reach A:16–20 and seepage remediation would be implemented. The Fix-in-Place Alternative would be the same as described for the Adjacent Levee Alternative (Proposed Action) except that the crown of the Sacramento River east levee would not be widened. This type of levee improvement would narrow the overall landside footprint by 15 feet but would require a greater extent of levee degrade to construct cutoff walls and a greater extent of encroachment removal along the Sacramento River east levee compared to the Adjacent Levee Alternative (Proposed Action).

The above three alternatives are described in detail in Chapter 2, "Alternatives," of this EIS/EIR. The Adjacent Levee Alternative (Proposed Action) and the Fix-in-Place Alternative were developed for consideration with a focus on improvements to the Sacramento River east levee Reach A:16–20. Phase 4b Project improvements to the American River east levee Reach I:1-4, NEMDC west levee, PGCC west levee, NCC south levee, West Drainage Canal, and modifications to the landscape and irrigation/drainage system would be similar under the Adjacent Levee Alternative (Proposed Action) and the Fix-in-Place Alternative.

As noted above, the Adjacent Levee Alternative (Proposed Action) and Fix-in-Place Alternative would use differing methods to achieve flood damage reduction objectives for the Sacramento River east levee Reach A:16–20. Therefore, the differences between the Adjacent Levee Alternative (Proposed Action) and Fix-in-Place Alternative, including effects on habitats, are the result of these differences in design of the Sacramento River east levee. These effects are more fully described in Chapter 4, "Environmental Consequences and Mitigation Measures," of this EIS/EIR.

B2 NEPA and/or CEQA Standards and Checklist Applicable to Borrow Areas Used by the Phase 4b Project

APPENDIX B2
NEPA AND/OR CEQA STANDARDS AND CHECKLIST APPLICABLE TO BORROW AREAS USED BY THE PHASE 4b PROJECT

This appendix reviews the standards that apply to preparation of NEPA and/or CEQA documents, and provides USACE and SAFCA with a tool for determining whether subsequent project-related activities within borrow areas used by the Phase 4b Project (described in Chapter 2, "Alternatives," of this EIS/EIR) will require further environmental documentation under either NEPA or CEQA. An environmental checklist is provided to identify the appropriate level of documentation for satisfying NEPA and/or CEQA.

This checklist concept has been developed as a tool to maximize flexibility for screening and selecting specific borrow sites within the proposed borrow areas for the Phase 4b Project. While several properties have been identified within the proposed borrow areas from which borrow may be removed, ongoing investigations will be required to determine the most suitable location(s) for excavating borrow. Therefore, there is insufficient information for some of the proposed borrow sites to make a final selection of specific properties in this EIS/EIR. Accordingly, this checklist will be used to inform USACE and/or SAFCA to determine if specific borrow sites proposed within this EIS/EIR have been analyzed at a sufficient level of detail, under NEPA and/or CEQA, or if further environmental review is required. If further environmental review and analysis is required, this checklist will help guide USACE and SAFCA in determining the appropriate level of NEPA and/or CEQA compliance.

Under NEPA, a supplemental environmental impact statement (supplemental EIS) is required when changes in the proposed action are "relevant to environmental concerns," (40 Code of Federal Regulations [CFR] Section 1502.9[1][i]), or when there are "significant new circumstances or information relevant to environmental concerns and bearing on the proposed action or its impacts" (40 CFR Section 1502.9[1][ii]). In general, this means that a supplemental EIS is required if new and potentially significant impacts that were not previously disclosed or identified in a public NEPA document are identified in association with a subsequent activity. Courts have further interpreted this requirement to indicate that when new mitigation measure(s) are identified that would reduce some of the impacts of a Federal action subject to NEPA, an SEIS is required if that measure itself would result in new significant impacts that were not previously disclosed in the EIS (*National Wildlife Federation v. Marsh* 721 F.2d 767, [11th Cir.] 1983).

USACE NEPA regulations incorporate the Council on Environmental Quality standard to determine when a supplemental EIS is required (33 CFR Section 230.13):

> Environmental Impact Statement (EIS). (b) Supplements. A supplement to the draft or final EIS should be prepared whenever required as discussed in 40 CFR Section 1502.09(c).

The USACE NEPA regulations, however, provide that "District commanders may also publish periodic factsheets and/or other supplemental information documents on long-term or complex EISs to keep the public informed on the status of the proposed action" (33 CFR Section 230.13[d]). USACE will use this standard to screen subsequent activities, if they are subject to NEPA.

1. TIERING FROM PROGRAM-LEVEL ANALYSIS UNDER CEQA

The following rules from CEQA and the State CEQA Guidelines provide for screening subsequent project activities in a program through the use of a checklist to determine if the project activities have received sufficient CEQA review, or if another CEQA compliance document is required. CEQA and the State CEQA Guidelines

specify the criteria for determining whether additional environmental review is required and, if so, what form of additional environmental document is appropriate.

- Where a program EIR has been prepared for a series of related actions and activities (in this case, the previous environmental documents completed for the NLIP), the lead agency may use a checklist to determine whether subsequent site-specific activities, such as the use of a specific property as a borrow site, were covered in the prior EIR(s) (State CEQA Guidelines California Code of Regulations [CCR] Section 15168[c][4]; see also CCR Sections 15152[d] and [f]).

- If the lead agency determines that none of the conditions specified in State CEQA Guidelines CCR Section 15162, discussed below, that trigger the need for a subsequent EIR or negative declaration have occurred and no new effects could occur or no new mitigation is required, the lead agency may approve the activity. No additional environmental document is required. (State CEQA Guidelines CCR Section 15168[c]][2]).

- Pursuant to State CEQA Guidelines CCR Section 15162, if the lead agency determines that any of the following conditions have occurred, either a supplemental or subsequent EIR shall be prepared:

    - Substantial changes to the project, substantial changes in circumstances, or new information show either new significant effects or a substantial increase in the severity of previously identified significant effects; or

    - New information shows that mitigation measures or alternatives which were previously identified as infeasible, and would substantially reduce the severity of one or more significant effects, are now found to be feasible, but the project proponent declines to adopt them; or

    - New information shows that considerably different mitigation measures or alternatives from those analyzed in the prior EIR(s) would substantially reduce the severity of one or more significant effects, are now found to be feasible, but the project proponent declines to adopt them.

- If any of the State CEQA Guidelines CCR Section 15162 conditions described above are present, but only minor changes or revisions to a previous EIR are required, the lead agency may prepare a supplement to the EIR. The supplemental EIR shall focus only on those changes or revisions that are necessary to make the previous study adequate and shall be circulated as a draft and final supplemental EIR (State CEQA Guidelines CCR Section 15163).

- If the lead agency determines that a subsequent activity requires some minor technical changes or revisions to a previously completed EIR or negative declaration, but none of the conditions described below require either a supplemental or a subsequent EIR, the lead agency may prepare an addendum to the EIR or negative declaration and attach the addendum to the final EIR or adopted negative declaration. No public circulation is required (State CEQA Guidelines CCR Section 15164).

- In some circumstances, a subsequent negative declaration may be warranted (see State CEQA Guidelines CCR Section 15152[g]).

2. CEQA CHECKLIST FOR SCREENING SUBSEQUENT SELECTION OF BORROW SITES

This checklist will be used to review impacts applicable to specific properties within the identified borrow areas that would be used by the Phase 4b Project, once they are proposed for use, for the purpose of determining whether and what additional CEQA environmental review is required. The checklist involves a three-step process for determining whether a specific borrow site has been sufficiently analyzed, or if the use of the borrow site

would require preparation of a new CEQA compliance document. The checklist also can provide guidance to USACE for determining the appropriate NEPA compliance document, if needed.

First, the project proponent(s) will review the impacts that were identified as "less than significant" in the checklist below and fill out the checklist accordingly. If the use of the borrow site would contribute to these impacts, the project proponent(s) will determine whether the contribution of borrow site operations would result in a significant impact. If a new significant impact would result, a supplemental or subsequent EIR will be required and prepared.

Next, for impacts that the checklist shows previously analyzed and disclosed as "significant," and for which the project proponent(s) identified and adopted mitigation measures that would reduce those impacts to less-than-significant levels, the project proponent(s) will determine whether the borrow site operations would contribute to those impacts. If the borrow site operations contribute to those impacts, but implementation of the mitigation measures and environmental commitments identified in the previous environmental documents completed for the NLIP, which were previously adopted and incorporated into the project, would mitigate that contribution to a less-than-significant level, the borrow site's contribution to those impacts will not trigger the need to prepare a new CEQA compliance document. If the use of the borrow site would cause these impacts to become significant impacts even after implementation of identified mitigation, SAFCA will prepare the appropriate CEQA compliance document, as described above.

The project proponent(s) will also use the checklist to determine if the borrow site operations would contribute to identified significant and unavoidable impacts. If the borrow site operations cause or contribute to any of the previously analyzed and disclosed significant or potentially significant and unavoidable impacts, SAFCA will determine if the borrow site's contribution was included when calculating the severity of the impact. If the borrow site's contribution to that impact was included in the impacts previously analyzed in the previous environmental documents completed for the NLIP and/or this EIS/EIR, no new CEQA compliance document will be required. If the borrow site's contribution was not included in the impacts analyzed in the aforementioned documents, a new EIR, EIR addendum, or potentially a mitigated negative declaration would be required and prepared.

Finally, the project proponent(s) will use the checklist to determine if the use of the proposed borrow sites would result in new impacts that were not previously disclosed in the aforementioned documents or would affect resources that were not identified when analyzing previously disclosed impacts. If so, SAFCA would prepare the appropriate CEQA compliance document, as described above.

Hydrology and Hydraulics	Impact 4.5-a: Hydraulic Impacts on Other Areas and Exposure to Flood Risk	Not Applicable ☐ Yes ☐ No ☐
	Impact 4.5-c: Effects on Groundwater	Not Applicable ☐ Yes ☐ No ☐
Biological Resources	Impact 4.7-k: Impacts to Fish Species Associated with Operation of Pumping Plants and Surface Drains	Not Applicable ☐ Yes ☐ No ☐
Air Quality	Impact 4.11-b: General Conformity with the Applicable Air Quality Plan	Not Applicable ☐ Yes ☐ No ☐
	Impact 4.11-c: Long-Term Changes in Emissions of ROG, NO_X, and PM_{10} Associated with Project Implementation	Not Applicable ☐ Yes ☐ No ☐
	Impact 4.11-d: Exposure of Sensitive Receptors to Toxic Air Emissions	Not Applicable ☐ Yes ☐ No ☐
Noise	Impact 4.12-d: Long-Term Increases in Project-Generated Noise	Not Applicable ☐ Yes ☐ No ☐
	Impact 4.12-e: Temporary and Short-Term Exposure of People Working in the Project Area to Excessive Airport Noise Levels	Not Applicable ☐ Yes ☐ No ☐
Recreation	Impact 4.13-a: Effects Related to the Proposed Natomas Levee Class 1 Bike Trail Project	Not Applicable ☐ Yes ☐ No ☐
	Impact 4.13-c: Temporary Changes in Recreational Opportunities during Project Construction Activities	Not Applicable ☐ Yes ☐ No ☐
Utilities and Service Systems	Impact 4.15-c: Increases in Solid Waste Generation	Not Applicable ☐ Yes ☐ No ☐
Hazards and Hazardous Materials	Impact 4.15-a: Accidental Spills of Hazardous Materials	Not Applicable ☐ Yes ☐ No ☐
	Impact 4.15-g: Potential for Higher Frequency of Collisions between Aircraft and Wildlife at Sacramento International Airport	Not Applicable ☐ Yes ☐ No ☐

Impacts Identified as "Less than Significant" after Mitigation Implementation			
Issue Area	Impact	Mitigation Measure	Would the use of the borrow site result in significant impacts, and would the application of identified mitigation reduce the impact to a less-than-significant level?
Land Use, Socioeconomics, and Population and Housing	Impact 4.3-b: Inconsistency with the Natomas Basin Habitat Conservation Plan	Mitigation Measure 4.3-b: Implement Mitigation Measure 4.7-l, "Ensure that Project Encroachment Does Not Jeopardize Successful Implementation of the NBHCP and Implement Mitigation Measures 4.7-a and 4.7-c through 4.7-h"	Not Applicable ☐ Yes ☐ No ☐
Geology, Soils, and Mineral Resources	Impact 4.4-a: Potential Temporary Localized Soil Erosion during Construction	Mitigation Measure 4.4-a(1): Implement Mitigation Measure 4.6-a, "Implement Standard Best Management Practices, Prepare and Implement a Stormwater Pollution Prevention Plan, and Comply with National Pollutant Discharge Elimination System Permit Conditions" Mitigation Measure 4.4-a(2): Secure and Implement the Conditions of the California Surface Mining and Reclamation Act Permit or Exemption	Not Applicable ☐ Yes ☐ No ☐
Hydrology and Hydraulics	Impact 4.5-b: Alteration of Local Drainage	Mitigation Measure 4.5-b(1): Coordinate with Landowners and Drainage Infrastructure Operators, Prepare Final Drainage Studies as Needed, and Implement Proper Project Design Mitigation Measure 4.5-b(2): Prepare Hydraulic Study, and Design and Implement Lower Dry Creek Woodland Planting Areas to Avoid Adverse Hydraulic Effects	Not Applicable ☐ Yes ☐ No ☐
Water Quality	Impact 4.6-a: Temporary Impacts on Water Quality from Stormwater Runoff, Erosion, or Spills	Mitigation Measure 4.6-a: Implement Standard Best Management Practices, Prepare and Implement a Stormwater Pollution Prevention Plan, and Comply with National Pollutant Discharge Elimination System Permit Conditions	Not Applicable ☐ Yes ☐ No ☐

Impacts Identified as "Less than Significant" after Mitigation Implementation			
Issue Area	Impact	Mitigation Measure	Would the use of the borrow site result in significant impacts, and would the application of identified mitigation reduce the impact to a less-than-significant level?
	Impact 4.6-b: Impacts to Sacramento River Water Quality from Pleasant Grove Creek Canal Detention Basin Discharges	Mitigation Measure 4.6-b: Implement Best Management Practices and Comply with NPDES Permit Conditions for a Point-Source Discharge	Not Applicable ☐ Yes ☐ No ☐
	Impact 4.6-c: Effects on Water Quality from Groundwater Discharged by Relief Wells	Mitigation Measure 4.6-c: Conduct Groundwater Quality Tests, Notify the Central Valley RWQCB, and Comply with the Central Valley RWQCB's Waste Discharge Requirements and NPDES Permit	Not Applicable ☐ Yes ☐ No ☐
Biological Resources	4.7-c: Direct and Indirect Impacts to Jurisdictional Waters of the United States	Mitigation Measure 4.7-c: Minimize Effects on Jurisdictional Waters of the United States; Complete Detailed Design of Habitat Creation Components and Secure Management Agreements to Ensure Compensation of Waters Filled or Dewatered; and Comply with Section 404, Section 401, Section 10, and Section 1602 Permit Processes	Not Applicable ☐ Yes ☐ No ☐
	4.7-d: Potential Loss of or Disturbance to Special-Status Plant Species and Their Habitats	Mitigation Measure 4.7-d: Minimize Impacts on Special-Status Plant Species	Not Applicable ☐ Yes ☐ No ☐
	4.7-e: Giant Garter Snake Mortality, Injury, and/or Disturbance to Habitat	Mitigation Measure 4.7-e: Minimize the Potential for Direct Loss of Giant Garter Snake Individuals, Implement All Upland and Aquatic Habitat Improvements and Management Agreements to Ensure Adequate Compensation for Loss of Habitat, and Obtain Incidental Take Authorization	Not Applicable ☐ Yes ☐ No ☐
	4.7-g: Potential Loss and/or Direct Impact of Elderberry Shrubs and/or Potential Loss of Valley Elderberry Longhorn Beetle	Mitigation Measure 4.7-g: Conduct Focused Surveys for Elderberry Shrubs as Needed, Implement All Woodland Habitat Improvements and All Management Agreements, Ensure Adequate Compensation for Loss of Shrubs, and Obtain Incidental Take Authorization	Not Applicable ☐ Yes ☐ No ☐

Impacts Identified as "Less than Significant" after Mitigation Implementation			
Issue Area	Impact	Mitigation Measure	Would the use of the borrow site result in significant impacts, and would the application of identified mitigation reduce the impact to a less-than-significant level?
	4.7-h: Impacts on Northwestern Pond Turtle and Burrowing Owl	Mitigation Measure 4.7-h: Conduct Focused Surveys for Northwestern Pond Turtles, Relocate Turtles, Minimize Potential Impacts on Burrowing Owls, and Relocate Owls as Needed	Not Applicable ☐ Yes ☐ No ☐
	4.7-i: Disturbance to Special-Status Vernal Pool Crustaceans	Mitigation Measure 4.7-i: Survey for Presence or Absence of Vernal Pool Invertebrates, Avoid Disrupting Vernal Pool Habitat, and Implement Measures to Mitigate Loss of Habitat	Not Applicable ☐ Yes ☐ No ☐
	4.7-j: Temporary Construction-related Impacts to Fish and Aquatic Habitats	Mitigation Measure 4.7-j: Implement Mitigation Measure 4.6-a, "Implement Standard Best Management Practices, Prepare and Implement a Stormwater Pollution Prevention Plan, Prepare and Implement a Spill Containment Plan, and Comply with National Pollutant Discharge Elimination System Permit Conditions;" Implement a Feasible Construction Work Window that Minimizes Impacts to Special-Status Fish Species for Any In-Water Activities; and Implement Operational Controls and a Fish Rescue Plan that Minimizes Impacts to Fish Associated with Cofferdam Construction and Dewatering	Not Applicable ☐ Yes ☐ No ☐
	4.7-l: Impacts on Successful Implementation of Habitat Conservation Plans	Mitigation Measure 4.7-l: Ensure that Project Encroachment Does Not Jeopardize Successful Implementation of the NBHCP and Implement Mitigation Measures 4.7-a and 4.7-c through 4.7-h	Not Applicable ☐ Yes ☐ No ☐
Cultural Resources	Impact 4.8-a: Potential Changes to Elements of Reclamation District 1000 and the Rural Landscape District	Mitigation Measure 4.8-a: Incorporate Mitigation Measures to Documents Regarding Any Elements Contributing to RD 1000 and Rural Landscape District and Distribute the Information to the Appropriate Repositories	Not Applicable ☐ Yes ☐ No ☐

Impacts Identified as "Less than Significant" after Mitigation Implementation			
Issue Area	Impact	Mitigation Measure	Would the use of the borrow site result in significant impacts, and would the application of identified mitigation reduce the impact to a less-than-significant level?
Paleontological Resources	Impact 4.9-a: Disturbance of Unknown Unique Paleontological Resources during Earthmoving Activities	Mitigation Measure 4.9-a: Conduct Construction Personnel Training and, if Paleontological Resources are Found, Stop Work Near the Find and Implement Mitigation in Coordination with a Professional Paleontologist	Not Applicable ☐ Yes ☐ No ☐
Transportation and Circulation	Impact 4.10-c: Temporary and Short-Term Disruption of Emergency Service Response Times and Access	Mitigation Measure 4.10-c: Implement Mitigation Measure 4.10-a, "Prepare and Implement a Traffic Safety and Control Plan for Construction-Related Truck Trips"	Not Applicable ☐ Yes ☐ No ☐
	Impact 4.10-d: Conflict with Adopted Policies, Plans, or Programs Supporting Alternative Transportation	Mitigation Measure 4.10-d: Prepare and Implement a Bicycle Detour Plan for Project Area Roadways and Bike Trails, Including Garden Highway and the NEMDC Levees	Not Applicable ☐ Yes ☐ No ☐
Noise	Impact 4.12-b: Temporary and Short-term Exposure of Sensitive Receptors to, or Temporary and Short-term Generation of, Excessive Groundborne Vibration	Mitigation Measure 4.12-b: Implement Vibration-Reducing Construction Practices, Prepare and Implement a Groundborne Vibration Control Plan, and Monitor and Record Construction Groundborne Vibration Near Sensitive Receptors	Not Applicable ☐ Yes ☐ No ☐
Recreation	Impact 4.13-c: Temporary Changes in Recreational Opportunities during Project Construction Activities	Mitigation Measure 4.13-c(1): Prepare and Implement a Bicycle Detour Plan for All Bicycle Trails and On-Street Bicycle Routes, Provide Detours for Bicycle Facilities, and Coordinate with City and/or County Departments of Parks and Recreation to Repair of Damage to Recreational Facilities Mitigation Measure 4.13-c(2): Provide Construction Period Information on Recreational Facility Closures and Detours and Provide Detours for Alternate Routes to Marinas	Not Applicable ☐ Yes ☐ No ☐

Impacts Identified as "Less than Significant" after Mitigation Implementation			
Issue Area	Impact	Mitigation Measure	Would the use of the borrow site result in significant impacts, and would the application of identified mitigation reduce the impact to a less-than-significant level?
Utilities and Service Systems	Impact 4.15-a: Potential Temporary Disruption of Irrigation Water Supply	Mitigation Measure 4.15-a: Coordinate with Irrigation Water Supply Users Before and During All Irrigation Infrastructure Modifications and Implement Measures to Minimize Interruptions of Supply	Not Applicable ☐ Yes ☐ No ☐
	Impact 4.14-b: Potential Disruption of Utility Service	Mitigation Measure 4.15-b: Verify Utility Locations, Coordinate with Utility Providers, Prepare and Implement a Response Plan, and Conduct Worker Training with Respect to Accidental Utility Damage	Not Applicable ☐ Yes ☐ No ☐
Hazards and Hazardous Materials	Impact 4.16-b: Potential Land Use Constraints Due to Contamination within the Pumping Plant No. 8 Footprint and Potential Exposure of Construction Workers and the General Public to Contaminated Groundwater	Mitigation Measure 4.16-b: Cooperate with Olympian Oil and Regulatory Agencies to Preserve, Modify, or Close Existing Groundwater Monitoring Wells at the Olympian Oil Site	Not Applicable ☐ Yes ☐ No ☐
	Impact 4.16-c: Potential Exposure of Construction Workers and the General Public to Hazardous Materials Encountered at Project Sites	Mitigation Measure 4.16-c(1): Complete Recommendations Included in Phase I and/or II ESAs and Implement Required Measures Mitigation Measure 4.16-c(2): Complete Phase I and/or II ESAs, Soil, and/or Groundwater Investigations in Phase 4b Project Footprint Areas Not Covered by the Existing Phase I and/or II ESAs, and Implement Required Measures (e.g., Site Management and/or Other Contingency Plans)	Not Applicable ☐ Yes ☐ No ☐
	Impact 4.16-d: Interference with an Adopted Emergency Evacuation Plan	Mitigation Measure 4.16-d: Implement Mitigation Measure 4.10-a, "Prepare and Implement a Traffic Safety and Control Plan for Construction-Related Truck Trips," and Mitigation Measure 4.10-c, "Notify Emergency Service Providers about Project Construction and Maintain	Not Applicable ☐ Yes ☐ No ☐

Impacts Identified as "Less than Significant" after Mitigation Implementation			
Issue Area	Impact	Mitigation Measure	Would the use of the borrow site result in significant impacts, and would the application of identified mitigation reduce the impact to a less-than-significant level?
		Emergency Access or Coordinate Detours with Providers"	
	Impact 4.16-e: Possible Hazardous Emissions or Handling of Hazardous or Acutely Hazardous Materials, Substances, or Waste within One-Quarter Mile of an Existing or Proposed School	Mitigation Measure 4.16-e: Notify the Natomas Unified School District and Affected Schools within One-Quarter Mile of Project Construction Activities	Not Applicable ☐ Yes ☐ No ☐
	Impact 4.16-h: Potential Exposure to Wildland Fires	Mitigation Measure 4.16-h: Prepare and Implement a Fire Management Plan to Minimize Potential for Wildland Fires	Not Applicable ☐ Yes ☐ No ☐
Environmental Justice	Impact 4.17-a: Potential to Have a Disproportionate High and Adverse Environmental Impact on any Minority or Low-Income Populations	Mitigation Measure 4.17-a: Increase the Direct Benefits of the Project for the Ancestors of the Native American Tribes	Not Applicable ☐ Yes ☐ No ☐

Impacts Identified as "Significant and Unavoidable"			
Issue Area	Impact	Mitigation Measure	After implementation of mitigation (if available), would the level of severity/intensity be equal to or less than as described in this EIS/EIR? Was the borrow sites' contribution to this impact identified in a previous document (if relevant)?
Agricultural Resources	Impact 4.2-a: Conversion of Important Farmland to Non-agricultural Uses	Mitigation Measure 4.2-a: Minimize Important Farmland Conversion to the Extent Practicable and Feasible	Not Applicable ☐ Yes ☐ No ☐
	Impact 4.2-b: Conflict with Lands under Williamson Act Contracts	Mitigation Measure 4.2-b: Minimize Impacts on Agricultural Preserve Land and Williamson Act–Contracted Land; Comply with California Government Code Sections 51290–51293; and Coordinate with Landowners and Agricultural Operators	Not Applicable ☐ Yes ☐ No ☐

Impacts Identified as "Significant and Unavoidable"			
Issue Area	Impact	Mitigation Measure	After implementation of mitigation (if available), would the level of severity/intensity be equal to or less than as described in this EIS/EIR? Was the borrow sites' contribution to this impact identified in a previous document (if relevant)?
Land Use, Socioeconomics, and Population and Housing	Impact 4.3-a: Inconsistency with Airport Master Plan, Airport Comprehensive Land Use Plan, and Airport Wildlife Hazard Management Plans	Mitigation Measure 4.3-a: Implement Mitigation Measure 4.16-g, "Consult with SCAS and the FAA during Design of the Proposed Natomas Levee Class I Bike Trail to Implement Appropriate Airport Safety Precautions"	Not Applicable ☐ Yes ☐ No ☐
	Impact 4.3-c: Inconsistency with the American River Parkway Plan and Wild and Scenic Rivers Act	No mitigation is available	Not Applicable ☐ Yes ☐ No ☐
	Impact 4.3-d: Potential to Physically Divide or Disrupt an Established Community	Mitigation Measure 4.3-d: Notify Residents and Businesses of Project Construction and Road Closure Schedules; and Implement Mitigation Measures 4.10-a, "Prepare and Implement a Traffic Safety and Control Plan for Construction-Related Truck Trips," and 4.10-c, "Notify Emergency Service Providers about Project Construction and Maintain Emergency Access or Coordinate Detours with Providers"	Not Applicable ☐ Yes ☐ No ☐
Biological Resources	Impact 4.7-a: Loss of Landside and Waterside Woodland and Shaded Riverine Aquatic Habitats	Mitigation Measure 4.7-a: Minimize Effects on Woodland Habitat; Implement Woodland Habitat Improvements and Management Agreements; Compensate for Loss of Habitat; and Comply with Section 7 of the Federal Endangered Species Act, Section 2081 of the California Endangered Species Act, and Section 1602 of the California Fish and Game Code	Not Applicable ☐ Yes ☐ No ☐
	Impact 4.7-b: Disruption to and Loss of Existing Wildlife Corridors	Mitigation Measure 4.7-b: Implement Mitigation Measures 4.7-a, "Minimize Effects on Woodland Habitat; Implement Woodland Habitat Improvements and Management Agreements; Compensate for	Not Applicable ☐ Yes ☐ No ☐

Impacts Identified as "Significant and Unavoidable"			
Issue Area	Impact	Mitigation Measure	After implementation of mitigation (if available), would the level of severity/intensity be equal to or less than as described in this EIS/EIR? Was the borrow sites' contribution to this impact identified in a previous document (if relevant)?
		Loss of Habitat; and Comply with Section 7 of the Federal Endangered Species Act, Section 2081 of the California Endangered Species Act, and Section 1602 of the California Fish and Game Code," and 4.7-e, "Minimize the Potential for Direct Loss of Giant Garter Snake Individuals, Implement All Upland and Aquatic Habitat Improvements and Management Agreements to Ensure Adequate Compensation for Loss of Habitat, and Obtain Incidental Take Authorization"	
	4.7-f: Impacts on Swainson's Hawk and Other Special Status Birds	Mitigation Measure 4.7-f: Minimize Potential Impacts on Swainson's Hawk and Other Special-Status Birds Foraging and Nesting Habitat, Monitor Active Nests during Construction, Implement All Upland and Agricultural Habitat Improvements and Management Agreements to Compensate for Loss of Quantity and Quality of Foraging Habitat, Obtain Incidental Take Authorization; and Implement Mitigation Measure 4.7-a, "Minimize Effects on Woodland Habitat, Implement all Woodland Habitat Improvements and Management Agreements, Compensate for Loss of Habitat, and Comply with Section 7 of the Federal Endangered Species Act, Section 2081 of the California Endangered Species Act, and Section 1602 of the California Fish and Game Code"	
Cultural Resources	Impact 4.8-b: Potential Damage or Disturbance to Known Archaeological or Architectural Resources	Mitigation Measure 4.8-b: Avoid Ground Disturbance Near Eligible and Listed Resources to the Extent Feasible, Prepare a	Not Applicable ☐ Yes ☐ No ☐

Impacts Identified as "Significant and Unavoidable"			
Issue Area	Impact	Mitigation Measure	After implementation of mitigation (if available), would the level of severity/intensity be equal to or less than as described in this EIS/EIR? Was the borrow sites' contribution to this impact identified in a previous document (if relevant)?
	from Ground-Disturbance or Other Construction-Related Activities	Finding of Effect, and Resolve Any Adverse Effects through Preparation of an HPTP	
	Impact 4.8-c: Potential Damage to or Destruction of Previously Unidentified or Undiscovered Cultural Resources from Ground-Disturbance or Other Construction-Related Activities	Mitigation Measure 4.8-c: Train Construction Workers before Construction, Monitor Construction Activities, Stop Potentially Damaging Activities, Evaluate Any Discoveries, and Resolve Adverse Effects on Eligible Resources, if Encountered	Not Applicable ☐ Yes ☐ No ☐
	Impact 4.8-d: Potential Discovery of Human Remains during Construction	Mitigation Measure 4.8-d: Stop Work Within An Appropriate Radius Around the Find, Notify the Applicable County Coroner and Most Likely Descendant, and Treat Remains in Accordance with State Law and Measures Stipulated in an HPTP Developed in Consultation between the Project Proponent(s) and the SHPO	Not Applicable ☐ Yes ☐ No ☐
Transportation and Circulation	Impact 4.10-a: Temporary and Short-Term Increases in Traffic on Local Roadways	Mitigation Measure 4.10-a: Prepare and Implement a Traffic Safety and Control Plan for Construction-Related Truck Trips	Not Applicable ☐ Yes ☐ No ☐
	Impact 4.10-b: Temporary and Short-Term Increases in Traffic Hazards on Local Roadways	Mitigation Measure 4.10-b: Implement Mitigation Measure 4.10-a, "Prepare and Implement a Traffic Safety and Control Plan for Construction-Related Truck Trips"	Not Applicable ☐ Yes ☐ No ☐
Air Quality	Impact 4.11-a: Temporary and Short-Term Emissions of ROG, NO_X, and PM_{10} during Construction	Mitigation Measure 4.11-a: Implement Applicable District-Recommended Control Measures to Minimize Temporary Emissions of ROG, NO_X, and PM_{10} during Construction	Not Applicable ☐ Yes ☐ No ☐

Impacts Identified as "Significant and Unavoidable"			
Issue Area	Impact	Mitigation Measure	After implementation of mitigation (if available), would the level of severity/intensity be equal to or less than as described in this EIS/EIR? Was the borrow sites' contribution to this impact identified in a previous document (if relevant)?
Noise	Impact 4.12-a: Generation of Temporary and Short-Term Construction Noise	Mitigation Measure 4.12-a: Implement Noise-Reducing Construction Practices, Prepare and Implement a Noise Control Plan, and Monitor and Record Construction Noise Near Sensitive Receptors	Not Applicable ☐ Yes ☐ No ☐
	Impact 4.12-c: Temporary and Short-term Exposure of Residents to Increased Traffic Noise Levels from Truck Hauling Associated With Borrow Activity	Mitigation Measure 4.12-c: Implement Noise-Reduction Measures to Reduce the Impacts of Haul Truck Traffic Noise	Not Applicable ☐ Yes ☐ No ☐
Recreation	Impact 4.13-a: Effects Related to the Proposed Natomas Levee Class 1 Bike Trail Project	No feasible mitigation is available	Not Applicable ☐ Yes ☐ No ☐
	Impact 4.13-b: Permanent Disruption of Recreational Activities and Facilities	Mitigation Measure 4.13-b: Compensate City of Sacramento Department of Parks and Recreation for Loss of Parkland and Park Amenities	Not Applicable ☐ Yes ☐ No ☐
Visual Resources	Impact 4.14-a: Alteration of Scenic Vistas, Scenic Resources, and Existing Visual Character of the Project Area	Mitigation Measure 4.14-a: Implement Mitigation Measures 4.7-a, "Minimize Effects on Woodland Habitat; Implement all Woodland Habitat Improvements and Management Agreements; Compensate for Loss of Habitat; and Comply with Section 7 of the Federal Endangered Species Act, Section 1602 of the California Fish and Game Code, and Section 2081 of the California Endangered Species Act Permit Conditions," and 4.13-b, "Compensate City of Sacramento Department of Parks and Recreation for Loss of Parkland and Park Amenities"	Not Applicable ☐ Yes ☐ No ☐

Impacts Identified as "Significant and Unavoidable"			
Issue Area	Impact	Mitigation Measure	After implementation of mitigation (if available), would the level of severity/intensity be equal to or less than as described in this EIS/EIR? Was the borrow sites' contribution to this impact identified in a previous document (if relevant)?
	Impact 4.14-b: New Sources of Light and Glare that Adversely Affect Views	Mitigation Measure 4.14-b: Direct Lighting Away from Adjacent Properties	Not Applicable ☐ Yes ☐ No ☐
Hazards and Hazardous Materials	Impact 4.16-g: Aircraft Safety Hazards Resulting from Project Implementation	Mitigation Measure 4.16-g: Consult with SCAS and the FAA during Design of the Proposed Natomas Levee Class I Bike Trail to Implement Appropriate Airport Safety Precautions	Not Applicable ☐ Yes ☐ No ☐

CHECKLIST SUMMARY	
Are there new significant impacts in addition to those discussed above? If yes, describe using an attachment to this checklist.	Yes ☐ No ☐
Are there significant impacts discussed above that are substantially more severe than discussed in this EIS/EIR? If yes, explain on an attachment to this checklist.	Yes ☐ No ☐
Are there significant impacts discussed in the Phase 2 EIR (program level) that are substantially more severe than previously disclosed? If yes, explain on an attachment to this checklist.	Yes ☐ No ☐
Are additional mitigation measures or alternatives? Are they feasible or considerably different from the previously adopted mitigation measures? If yes, explain on an attachment to this checklist.	Yes ☐ No ☐
Is additional environmental documentation required? If yes, specify type of environmental compliance document required: • EIR Addendum • Mitigation Negative Declaration • Supplemental EIR • Subsequent EIR • Supplemental EIS	 Yes ☐ No ☐ Yes ☐ No ☐ Yes ☐ No ☐ Yes ☐ No ☐ Yes ☐ No ☐

B4 Summary of the Mitigation Measures Adopted for the NLIP Phase 1–4a Projects

APPENDIX B4
SUMMARY OF MITIGATION MEASURES ADOPTED IN CONNECTION WITH THE NATOMAS LEVEE IMPROVEMENT PROGRAM, PHASE 1–4a LANDSIDE IMPROVEMENTS PROJECTS

The U.S. Army Corps of Engineers (USACE), Sacramento District and the Sacramento Area Flood Control Agency (SAFCA) have prepared and certified/approved various environmental documents for the Natomas Levee Improvement Program (NLIP) Phase 1–4a Landside Improvements Projects (Phase 1–4a Projects). This appendix contains a summary (in tabular form) of the mitigation measures contained in those certified/approved environmental documents and adopted in connection with the Phase 1–4a Projects.

The table columns contain the following information:

Mitigation Number: Lists the mitigation measures by number, as designated in each of the previous NLIP environmental documents, by issue area. For example, the project phase is followed by the mitigation measure number that corresponds to the certified/approved environmental document for that phase (i.e., Phase 1: 3.3-a, Phase 2: 3.2-b, Phase 3: 4.1-a, Phase 4a: 4.2-a).

Mitigation Measure: Provides the text of the mitigation measures (by issue area), as presented in the Phase 4a EIS and EIR, each of which has been adopted and incorporated into the project. The Phase 4a EIS and EIR are referenced because these environmental documents contain the most up-to-date mitigation commitments. It is important to note that although the mitigation commitments may apply to more than just the Phase 4a Project, the mitigation language has evolved with each certified and approved document, as new information becomes available, as more refined engineering and design details are available for each project phase, from lessons learned in the field (primarily from Phase 2 Project construction) on the most effective techniques, and from ongoing coordination and consultation with regulatory agencies. Although the mitigation language has been modified in some of the mitigation measures, the essence of the mitigation commitment has remained the same, but has been enhanced and/or refined.

Project Phase: Distinguishes what mitigation measures apply to what project phases.

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
Agricultural Resources					
Phase 2: 3.2-b **Phase 3: 4.1-a** **Phase 4a: 4.2-a**	**Minimize Important Farmland Conversion to the Extent Practicable and Feasible**				
	(a) Borrow sites shall be configured to minimize the fragmentation of lands that are to remain in agricultural use. Contiguous parcels of agricultural land of sufficient size to support their efficient use for continued agricultural production shall be retained to the extent practicable and feasible. (b) To the extent practicable and feasible, when expanding the footprint of a flood damage reduction facility (e.g., levee or berm) onto agricultural land, the most productive topsoil from the construction footprint shall be salvaged and redistributed to less-productive agricultural lands in the vicinity of the construction area that could benefit from the introduction of good-quality soil. By agreement between the implementing agencies or landowners of affected properties and the recipient(s) of the topsoil, the recipient(s) shall be required to use the topsoil for agricultural purposes. SAFCA shall implement all terms and conditions of agreements. (c) During project construction, use of utilities that are needed for agricultural purposes (including wells, pipelines, and power lines) and of agricultural drainage systems shall be minimized so that agricultural uses are not substantially disrupted. (d) Disturbance of agricultural land and agricultural operations during construction shall be minimized by locating construction staging areas on sites that are fallow, that are already developed or disturbed, or that are to be discontinued for use as agricultural land, and by using existing roads to access construction areas to the extent possible. (e) To the extent feasible, lands acquired for flood damage reduction purposes shall also be used as mitigation land for Natomas Basin Habitat Conservation Plan (NBHCP) programs so that agricultural land conversion is minimized.		√	√	√

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
Phase 2: 3.2-b	(f) Agricultural conservation easements shall be acquired at a 1:1 ratio (i.e., 1 acre on which easements are acquired to 1 acre of Prime Farmland, Unique Farmland, and Farmland of Statewide Importance removed from agricultural use), and the lands on which the easements are acquired shall be maintained in agricultural use.		√		
Phase 3: 4.1-b **Phase 4a: 4.2-b**	**Minimize Impacts on Agricultural Preserve Land and Williamson Act–Contracted Land; Comply with Government Code Sections 51290–51293; and Coordinate with Landowners and Agricultural Operators** (a) SAFCA shall comply with California Government Code Sections 51290–51295 with regard to acquisition of Williamson Act contracted lands as follows: ► The policy of the state, consistent with the purpose of the Williamson Act to preserve and protect agricultural land, is to avoid, whenever practicable, locating public improvements and any public utilities improvements in agricultural preserves. If it is necessary to locate within a preserve, it shall be on land that is not under contract (Government Code Section 51290[a][b]). More specifically, the basic requirements are: • Whenever it appears that land within a preserve or under contract may be required for a public improvement, the public agency or person shall notify the California Department of Conservation (DOC) and the city or county responsible for administering the preserve (Government Code Section 51291[b]). • Within 30 days of being notified, DOC and the city or county shall forward comments, which shall be considered by the public agency or person (Section 51291[b]). ► The contract shall be terminated when land is acquired by eminent domain or in lieu of eminent domain (Government Code Section 51295). ► DOC and the city or county shall be notified before project completion of any proposed substantial changes to the public improvement (Government Code Section 51291[d]).			√	√

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
	► DOC shall be notified within 10 working days upon completion of the acquisition (Section 51291[c]). ► If, after acquisition, the acquiring public agency determines that the property will not be used for the proposed public improvement, before returning the land to private ownership, DOC and the city or county administering the involved preserve shall be notified. The land shall be reenrolled in a new contract or encumbered by an enforceable restriction at least as restrictive as that provided by the Williamson Act (Government Code Section 51295).			√	√
	(b) SAFCA shall coordinate with landowners and agricultural operators to sustain existing agricultural operations, at the landowners' discretion, within the project area until the individual agricultural parcels are needed for project construction.			√	√
	(c) Properties that were under Williamson Act contract prior to conversion for borrow use and that are owned by SAFCA or are acquired by SAFCA shall be reenrolled under Williamson Act contract upon reclamation to agricultural use if those properties can be covered by the Williamson Act.				√
Land Use, Socioeconomics, and Population and Housing					
Phase 3: 4.2-c **Phase 4a: 4.3-c**	**Notify Residents and Businesses of Project Construction and Road Closure Schedules; Comply with the Garden Highway Settlement Agreement** a) SAFCA shall provide residents and business owners located adjacent to the construction areas with information regarding construction activities including contact information and complaint procedures and with a construction timeline and shall post its construction schedule on the SAFCA Web site. Information shall include road closures and detour information. The schedule shall be updated on a regular basis.			√	√

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
	b) SAFCA shall apply the following measures to power line relocations: To the extent that the main electrical power transmission lines and poles serving the Garden Highway must be relocated or replaced to accommodate the project, the relocation or replacement shall occur east of the new adjacent levee and in a manner that appropriately accommodates private landside improvements and properties. Existing main electrical power transmission lines and poles on the waterside of the existing Garden Highway levee that do not need to be relocated or replaced to accommodate the project may be left in place. No new main electrical power transmission lines and poles shall be installed on the waterside of the Garden Highway levee. Consistent with sound engineering practices that prioritize the following, individual services shall: (1) use existing configurations and facilities, and (2) any new poles shall be placed on the landside of Garden Highway, subject to the approval of U.S. Army Corps of Engineers (USACE), the Central Valley Flood Protection Board (CVFPB), and any other regulatory public agencies and utility companies. If the affected property owner and SAFCA cannot agree on a location of an individual service line pole from among locations that are otherwise acceptable to USACE, CVFPB, other regulatory agencies, and the utility provider, SAFCA shall pay the cost of a referee, who is a qualified registered civil engineer and agreeable to both the affected property owner and SAFCA, to decide the dispute over the location of the individual service line pole.			√	√
	c) SAFCA shall apply the following measure to encroachments: Once SAFCA determines that the Sacramento River east levee is certifiable for the Federal Emergency Management Agency's (FEMA's) flood protection purposes, SAFCA shall make its best efforts to get written agreement from USACE, CVFPB, and RD 1000 that no additional encroachments on the waterside of the Garden Highway levee need to be removed.			√	√

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
	d) SAFCA shall implement the following measures before and during construction: (i) SAFCA shall give property owners within the project area an informational package advising the property owners that pre-project inspections of their properties are important and that SAFCA will conduct a free preconstruction inspection of the property, but only if requested by the affected property owner. The scope of the inspection and documentation shall be determined by SAFCA in consultation with the property owner. For property owners who request prior inspections/ documentation, the inspection/documentation must be scheduled prior to the start of construction within the specified reach of the Sacramento River east levee where project construction will commence. (ii) If requested by a property owner within the project area, SAFCA shall test the owner's domestic well water before and after project construction for the presence of bentonite, concrete, and cement. (iii) SAFCA shall cooperate with a construction monitoring committee established by local residents and businesses to resolve reasonable complaints regarding SAFCA or its contractors' construction activities for the projects improvements in accordance with this provision. A complaint procedure and hierarchy shall be developed by the committee and SAFCA's Ombudsperson in time to be included in the informational packet referenced in subsection (i), above. In addition, the information packet shall include SAFCA's instructions to its contractors regarding appropriate use of the Garden Highway. SAFCA agrees to resolve all complaints pertaining to dangerous activities immediately and to resolve all other reasonable complaints in an expeditious manner. (iv) SAFCA shall prohibit the use of earth-moving equipment or haul trucks on the Garden Highway in conjunction with project construction.			√	√

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
	(v) SAFCA shall provide local residents and businesses with a timeline for the phased completion of the project that indicates the role of the various agencies involved in implementing or permitting the project. SAFCA shall post its construction schedule for the project on the SAFCA Web site. The schedule shall be updated on a monthly basis. In addition, SAFCA shall post a "60-day notice" of Planned Construction on the SAFCA Web site. "Planned Construction" shall not include construction in the event of an emergency or construction necessary to remedy a condition discovered after completion of the project. However, SAFCA shall provide whatever notice is possible under the circumstances to affected, adjacent landowners prior to any emergency or remedial work.			√	√
	e) SAFCA shall apply the following measures to drainage line location and relocation: No roadside swales shall be included in the design of the new adjacent levee downstream of Powerline Road. Consistent with sound engineering practices, and subject to the approval of USACE, CVFPB, and the Regional Water Quality Control Board (RWQCB), any new drainage outfall lines required by the project shall be buried pipes, located along property lines, and drain to the river. If a property owner does not want a new drain line located along the property line, he or she may request that the drain line be placed elsewhere on his or her property. If the property owner and SAFCA cannot agree on a location for a new drain line from among locations that are otherwise acceptable to USACE, CVFPB, and Central Valley RWQCB, SAFCA shall pay the cost of a referee, who is a qualified registered civil engineer and agreeable to both parties, to decide the dispute over the location of the drain line.			√	√
	f) Where a property owner occupies a residence on property to be acquired for the project, SAFCA shall allow up to 12 months, rather that the statutory allowance of 3 months, for the owner to relocate off the property. The 12-month period shall be counted from the first written offer. g) SAFCA shall provide notice as feasible for emergency construction or remedial construction.			√	√

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
Phase 3: 4.2-c	b) SAFCA shall comply with the provisions of the Garden Highway Settlement Agreement including provisions regarding complaint procedures, power pole plans, encroachment removal plans, and construction schedule.			√	
Geology, Soils, and Mineral Resources					
Phase 3: 4.3-a(2) **Phase 4a: 4.4-a(2)**	**Secure and Implement the Conditions of the California Surface Mining and Reclamation Act Permit or Exemption** In the event that any borrow site activity is determined to be subject to the California Surface Mining and Reclamation Act (SMARA), SAFCA shall secure and implement the conditions contained in the SMARA permit or exemption as administered and issued by the local agency (applicable county).			√	√
Phase 4a: 4.4-b	**Conduct Soil Core Sampling in Areas of the Phase 4a Project Footprint Designated as MRZ-3** SAFCA shall retain a qualified geologist to analyze soil core samples extracted from proposed borrow sites, to depth of at least 3 feet, in areas that are designated as MRZ-3. In the event that a clean layer of economically viable aggregate is discovered, the county, DOC, and other appropriate agencies shall be notified. In addition, the horizontal extent of available aggregate shall be delineated by a qualified geologist.				√
Hydrology and Hydraulics					
Phase 2: 3.4-b **Phase 3: 4.4-b** **Phase 4a: 4.5-b**	**Coordinate with Landowners and Drainage Infrastructure Operators, Prepare Final Drainage Studies as Needed, and Implement Proper Project Design** During project design, SAFCA's project engineers shall coordinate with owners and operators of local drainage systems and landowners served by the systems. This coordination shall enable the project engineers to evaluate the pre-project and postproject drainage needs and the design features to consider in project design any project-related substantial drainage disruption or alteration in runoff that would increase the potential for local flooding.				

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
	If substantial alteration of runoff patterns or disruption of a local drainage system could result from a project feature, a final drainage study shall be prepared and implemented as part of project design. The study shall consider the design flows of any existing facilities that would be crossed by project features and shall develop appropriate plans for relocation or other modification of these facilities and construction of new facilities, as needed, to ensure that the altered systems provide drainage services during and after construction that are equivalent to the drainage services that were provided prior to construction. If no drainage facilities (e.g., ditches, canals) would be affected, but project features would have a substantial adverse impact on runoff amounts and/or patterns, then new drainage systems shall be included in the design of project improvements to ensure that the project would not result in new or increased local flooding. Any necessary features to remediate project-induced drainage problems shall be constructed before the project is completed or as part of the project, depending on site-specific conditions. Any additional coordination with landowners and drainage infrastructure operators related to future selection of borrow sites in the Fisherman's Lake Area shall be completed by SAFCA before commencement of any earth-moving activities.		√	√	√
Phase 3: 4.4-c	**Monitor Landside Production Wells along the Natomas East Main Drainage Canal (NEMDC) for Effects on Yield, and Remediate Effects if Necessary** SAFCA shall implement a program to monitor groundwater elevations within 500 feet of the NEMDC west levee to determine what effects, if any, occur on the yield of shallow domestic wells following installation of cutoff walls in this area of the NLIP. In the event that the yield of any of these wells is measurably reduced, SAFCA shall arrange with the owners of affected wells to retrofit or replace these wells to provide pre-construction yields.			√	

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
Water Quality					
Phase 1: 3.3-a/ 3.4-a/3.5-a **Phase 2: 3.3-a/ 3.5-a/ 3.6-a** **Phase 3: 4.5-a** **Phase 4a: 4.6-a**	**Implement Standard Best Management Practices, Prepare and Implement a Stormwater Pollution Prevention Plan, and Comply with National Pollutant Discharge Elimination System Permit Conditions** SAFCA shall file a Notice of Intent (NOI) to discharge stormwater associated with construction activity with the Central Valley RWQCB. Final design and construction specifications shall require the implementation of standard erosion, siltation, and good housekeeping Best Management Practices (BMPs). Construction contractors shall be required to prepare and implement a Stormwater Pollution Prevention Plan (SWPPP) and comply with the conditions of the National Pollutant Discharge Elimination System (NPDES) general stormwater permit for construction activity. The SWPPP shall describe the construction activities to be conducted, BMPs that will be implemented to prevent discharges of contaminated stormwater into waterways, and inspection and monitoring activities that shall be conducted.	√	√	√	√
	The SWPPP shall include the following: ► pollution prevention measures (erosion and sediment control measures and measures to control nonstormwater discharges and hazardous spills), ► demonstration of compliance with all applicable Central Valley RWQCB standards and other applicable water quality standards, ► demonstration of compliance with regional and local standards for erosion and sediment control, ► identification of responsible parties, ► detailed construction timelines, and ► a BMP monitoring and maintenance schedule.	√		√	√

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
	BMPs shall include the following: ► conduct all work according to site-specific construction plans that identify areas for clearing, grading, and revegetation so that ground disturbance is minimized; ► install silt fences near riparian areas or streams to control erosion and trap sediment, and reseed cleared areas with native vegetation; ► stabilize disturbed soils of the new or raised levees, existing levee removal areas, and borrow sites before the onset of the winter rainfall season; and ► stabilize and protect stockpiles from exposure to rain and potential erosion.			√	√
	The SWPPP also shall specify appropriate hazardous materials handling, storage, and spill response practices to reduce the possibility of adverse impacts from use or accidental spills or releases of contaminants. Specific measures applicable to the project include, but are not limited to, the following: ► develop and implement strict on-site handling rules to keep potentially contaminating construction and maintenance materials out of drainages and other waterways; ► conduct all refueling and servicing of equipment with absorbent material or drip pans underneath to contain spilled fuel, and collect any fluid drained from machinery during servicing in leak-proof containers and deliver to an appropriate disposal or recycling facility; ► maintain controlled construction staging and fueling areas at least 100 feet away from channels or wetlands to minimize accidental spills and runoff of contaminants in stormwater; ► prevent substances that could be hazardous to aquatic life from contaminating the soil or entering watercourses; ► maintain spill cleanup equipment in proper working condition. Clean up all spills immediately according to the spill prevention and response plan;			√	√

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
	► develop a slurry spill contingency plan to respond to a potential for bentonite slurry spill and prevent slurry from entering the Sacramento River or NCC; and ► immediately notify the California Department of Fish and Game (DFG) and the Central Valley RWQCB of any spills and cleanup procedures.				
	BMPs shall be applied to meet the "maximum extent practicable" and "best conventional technology/best available technology" requirements and to address compliance with water quality standards. A monitoring program shall be implemented during and after construction to ensure that the project is in compliance with all applicable standards and that the BMPs are effective.	√	√	√	√
Phase 2: SEIR 3.2-a **Phase 3: 4.5-b** **Phase 4a: 4.6-b**	**Implement Standard Best Management Practices and Comply with NPDES Permit** SAFCA and its contractor(s) for construction shall implement a suite of stormwater quality BMPs designed to remove contaminants from water discharging through the Garden Highway outlets. These BMPs shall be based on the strategies for effectively integrating stormwater quality management into project design described in *Stormwater Quality Design Manual for Sacramento and South Placer Regions* (May 2007). Treatment control measures such as vegetated swales and vegetated filter strips shall be used, depending upon the design requirements of the levee. BMPs shall meet "maximum extent practicable" and "best conventional technology/best available technology" requirements, and comply with NPDES permit conditions.		√	√	√

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
Phase 2: 3.5-b **Phase 4a: 4.6-c**	**Conduct Groundwater Quality Tests, Notify the Central Valley RWQCB, and Comply with the RWQCB's Waste Discharge Authorization and NPDES Permit** SAFCA, in coordination with RD 1000, shall ensure that groundwater in the vicinity of potential relief well locations is tested during project design and before well construction, to ensure that discharge of extracted groundwater does not exceed maximum contaminant levels specified in Title 22. SAFCA shall provide the Central Valley RWQCB with the results of these water quality tests and a conceptual plan for how the relief wells will be used (e.g., extracting and discharging groundwater), and shall comply with any waste discharge requirements and the NPDES permit issued by the Central Valley RWQCB.		√		√
Phase 3: 4.5-c	**Implement Best Management Practices and Comply with NPDES Permit Conditions for a Point-Source Discharge** Prior to operation of Pumping Plant No. 2 for discharge of water into the Sacramento River, SAFCA and RD 1000 shall file a report of waste discharge with RWQCB and comply with NPDES permit conditions (See Mitigation Measure 4.5-a for more information on BMPs and the SWPPP).			√	
Biological Resources					
Phase 3: 4.8-a **Phase 4a: 4.7-a**	**Minimize Effects on Woodland Habitat; Implement all Woodland Habitat Improvements and Management Agreements; Compensate for Loss of Habitat; and Comply with Section 7 of the Federal Endangered Species Act, Section 1602 of the California Fish and Game Code, and Section 2081 of the California Endangered Species Act Permit Conditions** ▸ Native woodland areas shall be identified and the primary engineering and construction contractors shall ensure, through coordination with a qualified biologist retained by SAFCA, that construction is implemented in a manner that minimizes disturbance of such areas to the extent feasible. Temporary fencing shall be used during construction to prevent disturbance of native trees that are located adjacent to construction areas but can be avoided.			√	√

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
	▸ SAFCA shall coordinate with U.S. Fish and Wildlife Service (USFWS), National Marine Fisheries Service (NMFS), DFG, and the Sacramento County Airport System (SCAS) (if on Airport property) to ensure that all woodland habitat improvements of the NLIP are created and managed. SAFCA shall prepare a project-specific Mitigation and Monitoring Plan (MMP) and append the programmatic Long-Term Management Plan (LTMP) to ensure the creation and long-term management of these components before construction commences. SAFCA shall enter into agreements with the appropriate local entity responsible for long-term management of these created woodland habitats and shall coordinate with USFWS, NMFS, and DFG to ensure that performance standards and long-term management goals that are required by the regulatory agencies with jurisdiction over these resources will be specifically detailed and outlined in the MMP and LTMP. All performance standards and long-term management goals will be in full compliance with the Endangered Species Act (ESA) and California Endangered Species Act (CESA). SAFCA shall implement all terms and conditions of the agreements.			√	√
	▸ Sacramento River waterside riparian woodland areas that provide shaded riverine aquatic (SRA) habitat functions shall be identified and the primary engineering and construction contractors shall ensure, through coordination with a qualified biologist retained by SAFCA, that construction is implemented in a manner that minimizes disturbance of such areas to the extent feasible. Temporary fencing shall be used during construction to prevent disturbance of trees and shrubs that are located adjacent to construction areas but can be avoided.			√	√

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
	► Sacramento River waterside riparian forest and scrub (canopy acreage) shall be restored using ratios established by NMFS. Mitigation shall be 1:1 for in-kind mitigation and 3:1 for mitigation above the levee bench hinge (a surrogate for the ordinary high water mark (OHWM) for impacts below the levee bench hinge (OHWM). Mitigation shall be conducted using native plant species, including an assemblage of grasses, sedges, shrubs, and trees. At maturity, the riparian vegetation community would provide SRA functions. SAFCA shall develop a detailed woodland planting design and management protocols in coordination with USFWS, NMFS, and DFG. A monitoring plan with performance criteria shall be developed to determine the progress of the woodland habitats towards providing adequate mitigation.				√
	► The criteria for measuring performance shall be used to determine if the habitat improvement is trending toward sustainability (reduced human intervention) and to assess the need for adaptive management (e.g., changes in design or maintenance revisions). These criteria must be met for the habitat improvement to be declared successful, both during a particular monitoring year and at the end of the establishment period. These performance criteria, shall be developed in consultation with USFWS, NMFS, and DFG, and shall include, but not be limited to: • percent survival of planted trees (from 65–85%), • percent survival of transplanted trees (from 60–85%), and • percent relative canopy cover (from 5–35%).				√
	► SAFCA shall also enter into agreements with entities responsible for long-term management of created SRA habitats to ensure that performance standards and long-term management goals are met. SAFCA shall provide assurances for habitat creation and management goals that are required by regulatory agencies with jurisdiction over these resources will be specifically detailed and outlined in the LTMP and MMP. Such agreements shall be coordinated with USFWS, NMFS, and DFG. SAFCA shall implement all terms and conditions of the agreements.			√	√

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
	▸ A Section 1602 Streambed Alteration Agreement from DFG shall be obtained before any trees within a stream zone under DFG jurisdiction are removed. SAFCA shall comply with all terms and conditions of the streambed alteration agreement including measures to protect fish habitat or to restore, replace, or rehabilitate any SRA habitat on a no-net-loss basis.			√	√
	▸ USACE shall initiate Section 7 consultation with NMFS under Section 7 of the Federal ESA and SAFCA shall consult or coordinate with DFG under CESA regarding potential impacts of the loss of SRA habitat on Federally listed fish species and state-listed fish species, respectively. SAFCA shall implement any additional measures developed through the ESA Section 7 and CESA consultation processes, including Section 2081 permit conditions, to ensure no net loss of SRA habitat functions.			√	√
Phase 1: 3.5-a (b) **Phase 2: 3.6-b**	**Restore, Replace, or Rehabilitate Loss of Degraded SRA Habitat Function and Comply with Section 1602 Permit Conditions** SAFCA or its representative shall consult with DFG regarding potential disturbance to fish habitat, including SRA, and shall obtain a streambed alteration agreement, pursuant to Section 1602 of the California Fish and Game Code, for construction work associated with levee improvements made on the water side of a levee, if needed. SAFCA shall comply with all permit conditions of the streambed alteration agreement to protect fish habitat or to restore, replace, or rehabilitate any habitat on a no-net-loss basis.	√	√		

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
Phase 2: 3.7-a (SEIR 3.3-a)	**Minimize Effects on Sensitive Habitats, Develop a Habitat Management Plan to Ensure Compensation for Unavoidable Adverse Effects, and Comply with Section 404, Section 401, and Section 1602 Permit Processes**				
	Areas of sensitive habitat shall be identified and the primary engineering and construction contractors shall ensure, through coordination with a qualified biologist retained by SAFCA, that staging areas and access routes are designed to minimize disturbance of canals and ditches, seasonal wetlands, and woodland patches. Trees within the Sacramento County portion of the project area that qualify as Native Oaks or Heritage Trees under Sacramento County's tree preservation ordinance shall be identified. All sensitive habitats and protected trees that are located adjacent to construction areas, but can be avoided, shall be protected by temporary fencing during construction. SAFCA shall develop a Mitigation Monitoring Plan (MMP) to address establishment and management of aquatic (i.e., GGS/Drainage Canal and marsh/seasonal wetland habitat) and woodland habitats that are created as part of the proposed project in order to ensure that the performance standard of no net loss of sensitive habitat is met. The MMP shall identify the measures and performance criteria during the initial mitigation monitoring period (8 years) and shall be submitted to federal and state agencies for review and approval prior to project construction.		√		
	GGS/Sensitive Aquatic Habitats Mitigation for impacts to aquatic habitat include the construction of a new GGS/Drainage canal, relocation of the Elkhorn Irrigation Canal, and preservation of rice fields. The GGS Canal shall create jurisdictional waters of the United States, and include banks that are designed to facilitate shoreline growth of freshwater marsh plants, plantings of native perennial grasses on the upper canal banks for better giant garter snake cover, and creation of giant garter snake hibernacula (rock piles keyed into the bank). This habitat shall be protected in perpetuity through an easement. In addition, to the extent feasible, the Elkhorn Irrigation Canal shall be relocated near the new GGS/Drainage Canal to provide the potential for additional aquatic habitat (its main function would still be irrigation).		√		

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
	A monitoring program with performance criteria shall be developed to determine the progress of the GGS/Drainage canal towards achieving the performance standard of no net loss. The criteria for measuring performance shall be used to determine if the habitat is trending toward sustainability (reduced human intervention) and to assess the need for adaptive management (e.g., changes in mitigation design or maintenance revisions). These criteria must be met in order for the mitigation site to be declared successful, both during a particular monitoring year and at the end of the establishment period. These performance criteria, which shall be developed in consultation with DFG and USFWS, shall include, but are not limited to: ► percent total cover (from 85–90%), ► percent relative cover by wetland species (from 85–90%), ► percent relative cover by native species (from 50–85%), and ► water level controlled to within +/- 6 inches of design water level.		√		
	Vegetation assessments of the GGS/Drainage Canal shall be conducted annually for native perennial grasses (during the appropriate peak flowering period). The presence of giant garter snakes shall be monitored and recorded along this canal, consistent with monitoring methods currently conducted for SAFCA and TNBC elsewhere in the Natomas Basin. All monitoring shall occur for the full monitoring period or until the performance criteria are met, whichever period is longer. Waterline plug plantings (sedges and rushes) may not be mowed once established. All areas seeded with perennial grasses shall be mowed to a height of between 6–12 inches above ground. The primary function and service of the Elkhorn Canal is to deliver irrigation water to users throughout the Natomas Basin. The water supply within the Elkhorn Canal shall vary depending on the needs of those users. Therefore, the performance standard for the Elkhorn Canal is the delivery of irrigation water.		√		

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
	Woodlands To mitigate impacts to woodland habitats, woodland corridors and groves shall be established. In addition, existing woodlands located within project acquisition areas adjacent to the new groves shall be preserved. Generally, the woodland mitigation areas shall vary somewhat depending on the characteristics of their unique locations. Trees under 10 inches diameter at breast height (dbh) located within the project footprint (mostly valley oaks), that can be feasibly relocated shall be transplanted into woodland mitigation areas. Elderberry shrubs located within the project footprint that can be feasibly relocated shall be transplanted into woodland mitigation areas.		√		
	The botanical species composition of individual clusters and rows shall mimic vegetation types commonly found along the Sacramento River, including: ► Valley oak woodland ► Mixed riparian forest, cottonwood-dominant ► Shallow scrub (at moist soil sites or depressions) ► Sycamore and oak savanna (with native perennial grassland) ► Elderberry shrub/scrub		√		
	A monitoring plan with performance criteria shall be developed to determine the progress of the woodland habitats towards providing adequate mitigation. The criteria for measuring performance shall be used to determine if the mitigation is trending toward sustainability (reduced human intervention) and to assess the need for adaptive management (e.g., changes in mitigation design or maintenance revisions). These criteria must be met in order for the mitigation site to be declared successful, both during a particular monitoring year and at the end of the establishment period. These performance criteria, which shall be developed in consultation with DFG and USFWS, shall include, but are not limited to: ► Percent survival of planted trees (from 65–85%) ► Percent survival of transplanted trees (from 60–85%) ► Percent relative canopy cover (from 5–35%)		√		

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
	Field assessments of woodland planting areas shall be conducted once per year. The timing of these assessments shall be adjusted according to annual site-specific conditions, but assessments shall generally occur in late summer. To measure percent survival of trees and shrubs, each plant shall be inspected and the species of each live plant shall be recorded. Qualitative assessments shall be recorded to track the health and vigor of each species for adaptive management of the mitigation sites.		√		
	To determine the success of the woodland plantings as a functioning ecosystem, percent canopy shall be estimated each fall by recording the extent of woodland habitat on aerial photographs, or using repeat transects or fixed radius plots at ground level. The timing of these assessments shall be adjusted according to annual site-specific conditions, but assessments shall generally occur in late summer or early fall while trees are still in full foliage. The results of these assessments shall also be used to determine where replanting should occur to maintain suitable Swainson's hawk habitat. All monitoring shall occur for the full monitoring period or until the performance criteria are met, whichever is longer.		√		
	A Long-Term Management Plan (LTMP) shall be implemented by SAFCA in connection with the NLIP Landside MMP. The LTMP shall establish the long-term management practices (post establishment period success criteria) and land protection mechanisms that shall be implemented as each phase of the NLIP is approved and permitted. Land ownership and management responsibilities shall be held by SAFCA, RD 1000, NCMWC, TNBC, and the SCAS.		√		
	Applicable permits, including a Section 404 permit from the USACE, Section 401 certification from the Central Valley RWQCB, and a Section 1602 streambed alteration agreement from DFG, shall be obtained before any impact on the relevant resources occurs. All permit terms and conditions adopted through these permitting processes shall be implemented.		√		

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
Phase 1: 3.6-a	Sensitive Habitats: Avoid Sensitive Habitats to the Extent Feasible, Comply with Section 404 and Section 1602 Permit Processes as Needed, and Mitigate on a No-Net-Loss Basis				
	The primary engineering and construction contractors shall ensure, through coordination with a qualified biologist retained by SAFCA, that construction zones, staging areas, and access routes are designed to minimize disturbance of sensitive habitats to the extent feasible and practicable. All sensitive habitat that can be avoided shall be protected during construction by temporary fencing, as appropriate. A protective barrier shall be installed below the construction zone on the water side of the NCC south levee to minimize potential for incidental fallback of material into the NCC during project construction. Construction activity within the seasonal wetland shall be minimized to the maximum extent feasible and practical. Qualified biologists shall regularly monitor construction to ensure these impact avoidance and minimization measures are properly implemented. SAFCA shall consult with the USACE to determine whether the potential for incidental fallback of material into the NCC and/or disturbance of the seasonal wetland during project construction can be adequately avoided to preclude the need for USACE authorization. If such authorization would be required, the Section 404 permitting process shall be completed and the acreage of affected jurisdictional habitat shall be rehabilitated. Habitat rehabilitation shall be by feasible methods agreeable to the USACE. SAFCA shall implement minimization and rehabilitation measures adopted through the permitting process.	√			

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
	SAFCA shall also consult with DFG regarding impacts to the NCC levee and unavoidable effects to riparian habitat. A streambed alteration agreement shall be obtained, if necessary, and affected woodland shall be replaced and/or rehabilitated in accordance with DFG regulations and as specified in the streambed alteration agreement, if warranted. Habitat restoration, rehabilitation, and/or replacement shall be conducted in a manner that ensures there is no net loss of riparian habitat functions and values and shall be at a location and by methods agreeable to DFG. SAFCA shall implement minimization and compensation measures adopted through the permitting process.	√			
Phase 3: 4.6-a	**Implement a Feasible Construction Work Window that Minimizes Impacts to Special-Status Fish Species for Any In-Water Activities; and Implement Operational Controls and a Fish Rescue Plan that Minimizes Impacts to Fish Associated with Cofferdam Construction and Dewatering**				
	SAFCA shall identify and implement feasible in-water construction work windows in consultation with National Marine Fisheries Service (NMFS), U.S. Fish and Wildlife Service (USWFS), and DFG. In-water work windows shall be timed to occur when sensitive fish species/life stages are not present or least susceptible to disturbance (e.g., July 1–October 31). This measure would reduce potential construction-related direct impacts to fish from potential dredging and/or construction of the cofferdam and dewatering, and/or the placement of rock riprap because all in-water work would occur during the period of time that sensitive fish (or life stages) would be least likely to be present in the construction area.			√	

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
	The cofferdam sheetpiles at the outfall structure construction site shall be installed using a vibratory hammer that minimizes underwater sound pressure levels to the greatest extent feasible to minimize effects to sensitive fish species. Hammers shall only be used during daytime hours and shall commence at low energy levels and slowly build to impact force. If it is determined that a higher-intensity percussion hammer would be required for installing the cofferdam, avoidance of potential adverse effects would be achieved by consulting with NMFS, USFWS, and DFG to determine the appropriate actions, which may include surveying the outfall site to determine fish presence prior to installation, and possibly modifying the work window accordingly.			√	
	To reduce the potential for fish stranding or minimize the potential for harm during cofferdam dewatering activities, SAFCA or its contractor shall implement a fish rescue plan. Prior to the closure of the cofferdam in the Sacramento River, seining by a qualified fisheries biologist (with a current DFG collection permit) would be conducted within the cofferdam using a small-mesh seine to direct and move fish out of the cofferdam area. Upon completion of seining, the entrance to the cofferdam will be blocked with a net to prevent fish from entering the cofferdam isolation area before the cofferdam is completed. Once the cofferdam is completed and the area within the cofferdam is closed and isolated, additional seining will be conducted within the cofferdam to remove any remaining fish. Once most of the fish have been removed from the isolated area, portable pumps with intakes equipped with 1.75 mm mesh screen shall be used to dewater to a depth of 1.5-2 feet. A qualified biologist would implement further fish rescue operations using electrofishing and dip nets. All fish that are captured will be placed in clean 5-gallon buckets and/or coolers filled with Sacramento River water, transported downstream of the construction area, and released back into suitable habitat in the Sacramento River with minimal handling. After all fish have been removed using multiple seine passes, electrofishing, and dip nets (as necessary) portable pumps with screens (see above) will be used for final dewatering. NMFS, USFWS, and DFG shall be notified at least 48 hours prior to the fish rescue.			√	

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
Phase 3: 4.7-a Phase 4a: 4.7-c	**Minimize Effects on Jurisdictional Waters of the United States; Complete Detailed Design of Habitat Creation Components and Secure Management Agreements to Ensure Compensation of Waters Filled; and Comply with Section 404, Section 401, Section 10, and Section 1602 Permit Processes**				
	► Waters of the United States, including wetlands, shall be identified and the primary engineering and construction contractors shall ensure, through coordination with a qualified biologist(s), that construction is implemented in a manner that minimizes disturbance of canals, ditches, and seasonal wetlands. Temporary fencing shall be used during construction to prevent disturbance of waters of the United States that are located adjacent to construction areas but can be avoided.			√	√
	► To mitigate for permanent impacts to sensitive aquatic resources, at least 1 acre of aquatic habitat (irrigation/drainage canal) or 1 acre of seasonal wetland shall be created for every acre that is lost to ensure no net loss of sensitive aquatic habitat. The mitigation ratio that is ultimately required will be determined by USACE through the Section 404 permitting process.			√	√
	► Features planned in the Phase 4a Project (under both action alternatives), would provide aquatic habitat that has been designed to offset the effects described above. These features include the creation of aquatic habitat resulting from construction of the relocated Riverside Canal and creation of managed marsh in the vicinity of Fisherman's Lake, much of which would meet the criteria for Waters of the United States, including wetlands.				√

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
	► Develop and implement a Mitigation and Monitoring Plan and Long-Term Management Plan in coordination with and subject to approval of USACE, USFWS, and DFG. The MMP and LTMP shall provide complete detailed designs of habitat creation components, performance standards and management protocols. SAFCA shall also enter into agreements with entities responsible for long-term management of created canals and marsh habitats to ensure that performance standards and long-term management goals that are required by the regulatory agencies with jurisdiction over these resources will be met and specifically detailed and outlined in the LTMP and MMP. All performance standards and long-term management goals will be in full compliance with ESA and CESA. SAFCA shall secure all such agreements and implement all conditions of the agreements.			√	√
	► Obtain the following applicable permits prior to the start of construction activities that would affect the resources covered by these permits: an individual permit pursuant to Section 404 of the CWA and Section 10 of the Rivers and Harbors Act from USACE, Section 401 certification from the Central Valley RWQCB, and a Section 1602 Streambed Alteration Agreement from DFG. All requirements of these permitting processes shall be implemented by SAFCA.			√	√
Phase 2: 3.7-b Phase 3: 4.9-a	**Conduct Focused Surveys for Special-Status Plants, Minimize Effects, Transplant Unavoidable Individual Plants, and Develop Management Plans for Transplanted Populations**				
	Before any ground-disturbing activities begin, a qualified biologist retained by SAFCA shall conduct surveys for special-status plants in appropriate habitat within the project footprint, in accordance with USFWS and/or DFG guidelines and at the appropriate time of year when the target species would be clearly identifiable. If no special-status plants are found during focused surveys, no further action shall be required.		√	√	

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
	► If special-status plants are found in the project footprint, areas of occupied habitat shall be identified and the primary engineering and construction contractors shall ensure, through coordination with the biologist, that construction activities are implemented in a manner that minimizes disturbance of these areas (e.g., temporary fencing shall be used during construction to protect all occupied habitat that is located adjacent to construction areas that can be avoided).		√	√	
	► If special-status plants are present in areas that cannot be avoided, SAFCA shall coordinate with USFWS and DFG to determine whether transplanting would be appropriate to further minimize adverse effects. Affected plants may potentially be transplanted to the GGS/Drainage Canal, if feasible. At least 1 acre of irrigation/drainage canal or marsh habitat shall be created for every acre of occupied special-status plant habitat that is lost. ► If special-status plants cannot be avoided, seed shall be collected and propagated at a DFG-approved nursery to provide additional plantings and transplanted during the dormant season if feasible to an approved site. Additionally, a mitigation plan shall be developed and approved by DFG. The plan shall include success criteria and specific requirements for planting, monitoring, and remediation in the event that success criteria cannot be met. Mitigation sites shall be permanently protected and managed in perpetuity.			√	

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
Phase 2: 3l.7-b	If special-status plants are found, areas of occupied habitat shall be identified and the primary engineering and construction contractors shall ensure, through coordination with the biologist, that staging areas and access routes are designed to minimize disturbance of these areas. All occupied habitat that is located adjacent to construction areas, but can be avoided, shall be protected by temporary fencing during construction. If special-status plants are present in areas that cannot be avoided, plants that would be affected shall be transplanted to the GGS/Drainage Canal, if feasible. If this is infeasible (i.e., because the created habitat is not suitable at the time transplantation is required), an alternative transplantation location (e.g., TNBC preserves), approved by USFWS and DFG, shall be utilized. A plan to address management of the transplanted populations and their habitat shall be developed. The management plan shall be approved by USFWS and DFG and shall, at a minimum, establish specific success criteria (e.g., no net loss of occupied special-status plant habitat), specify remedial measures to be undertaken if success criteria are not met (e.g., enhancement of habitat quality and additional monitoring), and describe short- and long-term maintenance of the transplantation site. Long-term protection of the special-status plants, and funding for management of their habitat, shall be provided through appropriate mechanisms to be determined by SAFCA, in consultation with the regulatory agencies and other entities cooperating in implementation of the proposed project.		√

Phase 1: 3.6-c Phase 2: SEIR 3.3-b Phase 3: 4.9-c Phase 4a: 4.7-e	**Minimize the Potential for Direct Loss of Giant Garter Snake Individuals, Implement All Upland and Aquatic Habitat Improvements and Management Agreements to Ensure Adequate Compensation for Loss of Habitat, and Obtain Incidental Take Authorization**				
	▸ The engineering and design consultants and primary construction contractors shall ensure, through coordination with a qualified biologist retained by SAFCA, that construction is implemented in a manner that minimizes disturbance of giant garter snake habitat (e.g., temporary fencing shall be used during construction to protect all aquatic and adjacent upland habitat that is located adjacent to construction areas that can be avoided).	√	√	√	√
	▸ Additional measures consistent with the goals and objectives of the NBHCP shall be implemented to minimize the potential for direct injury or mortality of individual giant garter snakes during project construction.	√			
	▸ Such measures shall be finalized in consultation with USFWS and DFG, and are likely to include conducting worker awareness training, timing initial ground disturbance to correspond with the snake's active season (as feasible in combination with project needs and minimizing disturbance of nesting Swainson's hawks), dewatering aquatic habitat before fill, conducting preconstruction surveys, erecting fencing around habitat features that can be avoided to ensure that these remain undisturbed by construction vehicles and personnel, conducting biological monitoring during construction, and removing any temporary fill or construction debris and restoring temporarily disturbed areas to their pre-project conditions according to the USFWS's *Guidelines for the Restoration and/or Replacement of Giant Garter Snake Habitat* (USFWS 1997).	√	√	√	√

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
	► SAFCA shall coordinate with USFWS, DFG, and SCAS (if on Airport property) to ensure that the NLIP's aquatic and upland habitat improvements are created and managed. SAFCA shall prepare a project-specific MMP and programmatic LTMP to ensure the creation and long-term management of these components before construction commences. SAFCA shall enter into agreements with the appropriate local entity responsible for long-term management of these created giant garter snake habitats and shall coordinate with USFWS and DFG to ensure that performance standards and long-term management goals required by the regulatory agencies with jurisdiction over these resources will be specifically detailed and outlined in the LTMP and MMP. ► All performance standards and long-term management goals will be in full compliance with ESA and CESA. SAFCA shall implement all terms and conditions of the management agreements.		√	√	√
	► SAFCA shall implement all measures developed through informal consultation with UWFWS and DFG, as well as any additional measures adopted through a formal permitting process, if applicable.	√			
	► Where borrow sites would result in impacts to giant garter snake habitat over more than one construction season, the work shall progress in cells that will be incrementally developed as habitat or returned to agricultural use as the borrow activities are completed such that no area would be used in consecutive years or such that replacement habitat is available prior to loss of existing habitat.				√
	► Authorization for take of giant garter snake under the ESA and CESA shall be obtained. All measures subsequently adopted through the permitting process shall be implemented.	√	√	√	√
Phase 1: 3.6-e Phase 2: SEIR 3.3-c Phase 3: 4.9-f Phase 4a: 4.7-f	**Minimize Potential Impacts on Swainson's Hawk and Other Special-Status Birds Foraging and Nesting Habitat, Monitor Active Nests during Construction, Implement All Upland and Agricultural Habitat Improvements and Management Agreements to Compensate for Loss of Quantity and Quality of Foraging Habitat, Obtain Incidental Take Authorization**				

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
	► The primary engineering and design consultants and primary construction contractors shall ensure, through coordination with a qualified biologist retained by SAFCA, that construction is implemented in a manner that minimizes disturbance of potential nesting habitat for special-status birds through the following activities: ► The biologist shall conduct preconstruction surveys to identify active special-status bird nests near construction areas.	√	√	√	√
	• Surveys for nesting birds shall be conducted before project activities are initiated during the nesting season (March 1–September 15). Surveys shall be conducted in accordance with standardized protocols and NBHCP requirements.	√	√	√	√
	• Removal of potential nesting habitat shall be conducted during the non-nesting season, to the extent feasible and practicable, to minimize the potential for loss of active nests. • If an active nest is found, the biologist shall determine an appropriate buffer that minimizes potential for disturbance of the nest, in coordination with DFG. No project activities shall commence within the buffer area until a qualified biologist confirms that the nest is no longer active or the birds are not dependent on it. • Monitoring shall be conducted during construction and by a qualified biologist to ensure that project activity does not result in detectable adverse effects on the nesting pair or their young. • The size of the buffer may vary, depending on the nest location, nest stage, construction activity, and monitoring results. If implementation of the buffer becomes infeasible or construction activities result in an unanticipated nest disturbance, DFG shall be consulted to determine the appropriate course of action.	√	√	√	√

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
	► The biologist shall conduct preconstruction surveys to identify active nests within 0.50 mile of construction areas, in accordance with DFG guidelines. Surveys shall be conducted in accordance with NBHCP requirements and *Recommended Timing and Methodology for Swainson's Hawk Nesting Surveys in California's Central Valley* (Swainson's Hawk Technical Advisory Committee 2000).	√	√	√	√
	► SAFCA shall coordinate with USFWS, DFG, and SCAS (if on Airport property) to ensure that the NLIP's woodland, upland, and agricultural habitat improvements are created and managed. SAFCA shall prepare a project-specific MMP and programmatic LTMP to ensure the creation and long-term management of these components before construction commences. SAFCA shall enter into agreements with the appropriate local entity responsible for long-term management of these created Swainson's hawk habitats and shall coordinate with USFWS and DFG to ensure that performance standards and long-term management goals that are required by the regulatory agencies with jurisdiction over these resources will be specifically detailed and outline in the LTMP and MMP. All performance standards and long-term management goals will be in full compliance with ESA and CESA. SAFCA shall implement all terms and conditions of the management agreements.			√	√
	► The criteria for measuring performance shall be used to determine if the habitat improvement is trending toward sustainability (reduced human intervention) and to assess the need for adaptive management (e.g., changes in design or maintenance revisions). These criteria must be met for the habitat improvement to be declared successful, both during a particular monitoring year and at the end of the establishment period. Performance criteria for managed grasslands shall be developed in consultation with USFWS, NMFS, and DFG, and shall include, but not be limited to: • percent cover of invasive species (<1%), • percent cover of nonnative herbaceous plants (<10–25%), and • percent absolute cover of native species (>50–80%).		√	√	√

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
	► Authorization for take of Swainson's hawk under CESA shall be obtained. All measures subsequently adopted through the permitting process shall be implemented.			√	√
Phase 2: SEIR 3.3-c	SAFCA shall develop and implement an MMP to address management of grassland habitats that are created as part of the proposed project in order to ensure that the performance standard of no net loss of sensitive habitat is met. To mitigate impacts on cropland and grassland suitable for Swainson's hawk foraging habitat, SAFCA shall create managed native perennial grassland habitats on the new levee slopes, seepage berms, access right-of-ways, and canal embankments. This grassland shall provide moderate-quality Swainson's hawk foraging habitat. In addition, grasslands on and adjacent to canal banks shall provide basking and aestivation habitat for giant garter snake.		√		
	► The MMP shall include methods to create the grasslands, including native grass mixes which shall be seeded along new levee slopes and seepage berms, staging areas, and adjacent maintenance and utility rights-of-way. Seed material shall be purchased from a reputable nursery and must be from local genetic stock within 200 miles of the project site unless otherwise approved by a qualified ecologist. The native grass mix shall include the following:Purple needlegrass (*Nassella pulchra*) ► Creeping wildrye (*Leymus triticoides*) ► Six weeks grass (*Vulpia microstachys*) ► Slender wheatgrass (*Elymus trachycaulus*) ► Meadow barley (*Hordeum brachyantherum*) ► An initial baseline assessment of grassland mitigation sites shall be conducted following the initial drill seeding program, and then a monitoring program with performance criteria shall be developed to determine the progress of the grassland habitats towards providing adequate mitigation.		√		

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
Phase 1: 3.6-f	Special-Status Nesting Birds: Identify Habitat and Nest Locations, Minimize Potential Impacts, Monitor Active Nests during Construction, and Mitigate in Consultation with USFWS and DFG as Needed				
	The primary engineering and construction contractors shall ensure, through coordination with a qualified biologist retained by SAFCA, that construction zones, staging areas, and access routes are designed to minimize disturbance and removal of nesting habitat for special-status nesting birds to the extent feasible and practicable. Nesting habitat that cannot be avoided shall be removed during the non-nesting season, to the extent feasible and practicable. To avoid potential impacts to active nests of special-status birds, pre-construction surveys shall be conducted and buffers implemented. A qualified biologist shall conduct preconstruction surveys to identify active special-status bird nests along the NCC, within 500 feet of construction areas. Surveys shall be conducted in accordance with NBHCP requirements. If an active nest is found, an appropriate buffer to minimize impacts and maintain consistency with the goals and objectives of the NBHCP shall be determined by a qualified biologist. No project activities shall commence within the buffer area until a qualified biologist confirms that the nest is no longer active or the birds are not dependent upon it. The size of the buffer may vary, depending on the nest location, nest stage, and construction activity. Monitoring shall be conducted by a qualified biologist to ensure project activity does not result in detectable adverse effects to the nesting pair or their young. SAFCA shall consult with USFWS and DFG regarding measures to avoid and minimize disturbance of active nests and shall implement all measures deemed appropriate and feasible during this consultation.	√			
Phase 3: 4.9-b Phase 4a: 4.7-g	**Conduct Focused Surveys for Elderberry Shrubs as Needed, Implement all Woodland Habitat Improvements and all Management Agreements, Ensure Adequate Compensation for Loss of Shrubs, and Obtain Incidental Take Authorization**				

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
	► A qualified biologist retained by SAFCA shall conduct focused surveys of elderberry shrubs within 100 feet of the project footprint, in accordance with USFWS guidelines. All elderberry shrubs with potential to be affected by project activities shall be mapped, the number of stems greater than 1 inch in diameter on each shrub that requires removal shall be counted, and these stems shall be searched for beetle exit holes. ► The engineering and design consultants and primary construction contractors shall ensure, through coordination with the biologist, that construction is implemented in a manner that minimizes disturbance of areas that support elderberry shrubs (e.g., temporary fencing shall be used during construction to protect all elderberry shrubs that are located adjacent to construction areas but can be avoided). Shrubs that require removal shall be transplanted to the woodland creation areas, if feasible, when the plants are dormant (November through the first 2 weeks of February) to increase the success of transplanting. If none of the areas of suitable habitat to be created as part of the project would be available before the impact would occur, alternative transplantation locations (e.g., other SAFCA mitigation areas or The Natomas Basin Conservancy [TNBC] preserves) shall be identified and shall be approved by USFWS. ► The number of replacement elderberry plantings shall be determined based on USFWS guidelines, which require replacement ratios ranging from 1:1 to 8:1 for lost stems at least 1 inch in diameter, depending on the size of the affected stems and presence or absence of beetle exit holes. Associated native species shall be planted at ratios ranging from 1:1 to 2:1 for each elderberry planting.			√	√

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
	▸ SAFCA shall coordinate with USFWS, DFG, and SCAS (if on Airport property) to ensure that the NLIP's woodland habitat improvements are created and managed. SAFCA shall prepare a project-specific MMP and programmatic LTMP to ensure the creation and long-term management of these components before construction commences. SAFCA shall enter into agreements with the appropriate local entity responsible for long-term management of these created woodland habitats and shall coordinate with USFWS and DFG to ensure that performance standards and long-term management goals that are required by regulatory agencies with jurisdiction over these resources will be specifically detailed and outlined in the LTMP and MMP. All performance standards and long-term management goals will be in full compliance with the ESA and CESA. SAFCA shall implement all terms and conditions of the management agreements USACE shall initiate consultation activities with USFWS under Section 7 of the ESA, and authorization for take of valley elderberry longhorn beetle under the ESA shall be obtained if it is determined, in consultation with USFWS, that shrub removal is likely to result in such take. All measures subsequently developed through the Section 7 consultation process shall be implemented by SAFCA.			√	√
Phase 2: 3.7-c	**Minimize Effects on Valley Elderberry Longhorn Beetle, Conduct Focused Surveys, Develop a Management Plan to Ensure Adequate Compensation for Unavoidable Adverse Effects, and Obtain Incidental Take Authorization** The primary engineering and construction contractors shall ensure, through coordination with a qualified biologist retained by SAFCA, that staging areas and access routes are designed to minimize disturbance of areas that support elderberry shrubs. All elderberry shrubs that are located adjacent to construction areas, but can be avoided, shall be protected by temporary fencing during construction.		√		

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
	Before the initiation of any ground-disturbing activities, the biologist shall conduct surveys for elderberry shrubs within 100 feet of the impact area, in accordance with USFWS guidelines. All elderberry shrubs with potential to be affected by project activities shall be mapped, the number of stems greater than 1 inch in diameter on each shrub that requires removal shall be counted, and these stems shall be searched for beetle exit holes. Shrubs that are removed shall be transplanted to the woodland creation areas, if feasible. If none of the areas of suitable habitat to be created as part of the proposed project would be available before the impact would occur, alternative transplantation locations (e.g., other SAFCA mitigation areas or TNBC preserves) shall be identified. SAFCA shall develop and implement a plan to address establishment and management of the elderberry shrubs and associated species plantings to compensate for unavoidable effects on elderberry shrubs. The plan shall, at a minimum, describe requirements for transplantation of shrubs that require removal; specify the number of replacement elderberry shrubs and associated native plants to be established and associated success criteria; specify remedial measures to be undertaken if mitigation success criteria are not met; and describe short- and long-term maintenance and management. The number of replacement plantings shall be determined based on USFWS guidelines, which require replacement ratios ranging from 1:1 to 8:1 for lost stems at least 1 inch in diameter, depending on the size of the affected stems and presence or absence of beetle exit holes. Associated native species shall be planted at ratios ranging from 1:1 to 2:1 for each elderberry planting. Long-term protection of the planting area for elderberry and associated species, and funding for its management, shall be provided through appropriate mechanisms to be determined by SAFCA, USFWS, and other entities cooperating in implementation of the proposed project.		√		

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
	The management plan shall be reviewed and approved by USFWS before removal of any elderberry shrubs. Authorization for take of valley elderberry longhorn beetle under ESA shall be obtained if it is determined, in consultation with USFWS, that shrub removal is likely to result in such take. All measures subsequently developed through informal consultation with USFWS shall be implemented, as well as any additional measures adopted through a formal permitting process, if applicable.		√		
Phase 2: 3.7-e & 3.7-g **Phase 3: 4.9-e & 4.9-g** **Phase 4a: 4.7-h**	**Conduct Focused Surveys for Northwestern Pond Turtles, Relocate Turtles, Minimize Potential Impacts on Burrowing Owls, and Relocate Owls as Needed** ► A qualified biologist retained by SAFCA shall conduct surveys for northwestern pond turtle in aquatic habitats to be dewatered and/or filled during project construction. Surveys shall be conducted immediately after dewatering and before fill of aquatic habitat suitable for pond turtles. If pond turtles are found, the biologist shall capture them and move them to nearby areas of suitable habitat that would not be disturbed by project. ► The engineering and design consultants and primary construction contractors shall ensure, through coordination with a qualified biologist retained by SAFCA, that construction is implemented in a manner that minimizes disturbance of potential nesting habitat for burrowing owls (e.g., removal of potential nesting habitat shall be conducted during the non-nesting season, to the extent feasible and practicable, to minimize the potential for loss of active nests).		√	√	√

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
	► The biologist shall conduct preconstruction surveys to identify occupied burrowing owl burrows in the vicinity of construction areas. Surveys for burrowing owl shall be conducted before project activities are initiated at any time of year. Surveys shall be conducted in accordance with standardized protocols, including DFG's *Staff Report on Burrowing Owl Mitigation* (DFG 1995), and NBHCP requirements. If an occupied nest burrow is found, an appropriate buffer that minimizes potential for disturbance of the nest shall be determined by the biologist, in coordination with DFG. No project activities shall commence within the buffer area until a qualified biologist confirms that the nest is no longer active or the birds are not dependent on it. Monitoring shall be conducted by a qualified biologist to ensure that project activity does not result in detectable adverse effects on the nesting pair or their young. The size of the buffer may vary, depending on the nest location, nest stage, construction activity, and monitoring results. If implementation of the buffer becomes infeasible or construction activities result in an unanticipated nest disturbance, DFG shall be consulted to determine the appropriate course of action.		√	√	√
	► If an occupied burrowing owl burrow that does not support an active nest is found, SAFCA shall develop and implement a relocation plan, in coordination with and subject to approval of DFG and USFWS and consistent with requirements of the NBHCP, DFG's *Staff Report on Burrowing Owl Mitigation* (DFG 1995), and the Airport *Wildlife Hazard Management Plan* (WHMP). Relocation is anticipated to occur through passive exclusion of owls from the project site (using one-way doors at the burrow entrances). The owls would then be able to reoccupy the area after construction is complete. Because the project would generally result in temporary disturbance of burrowing owl habitat and conversion from one suitable habitat type to another, no mitigation for temporary burrow or habitat loss would be required.		√	√	√

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
Phase 3: 4.6-a **Phase 4a: 4.7-i**	**Implement a Feasible Construction Work Window that Minimizes Impacts to Special-Status Fish Species for Any In-Water Activities, and Implement Operational Controls and a Fish Rescue Plan that Minimizes Impacts to Fish Associated with Cofferdam Construction and Dewatering** ► SAFCA shall implement Mitigation Measure 4.6-a, as described in Section 4.6, "Water Quality." This measure requires filing a Notice of Intent (NOI) with the Central Valley RWQCB; implementing standard erosion and siltation measures and best management practices (BMPs); preparing and implementing a storm water pollution prevention plan (SWPPP); preparing and implementing a spill containment plan; and complying with the conditions of the National Pollutant Discharge Elimination System (NPDES) general stormwater permit for construction activity. ► SAFCA shall identify and implement feasible in-water construction work windows in consultation with NMFS and DFG. In-water work windows shall be timed to occur when sensitive fish species/life stages are not present or least susceptible to disturbance (e.g., July 1–October 1). This measure would reduce potential construction-related direct impacts to fish from dredging and/or construction of the cofferdam and dewatering, general in-water construction, and/or the placement of rock riprap because all in-water work would occur during the period of time that sensitive fish (or life stages) would be least likely to be present in the construction area. ► USACE shall initiate Section 7 consultation with NMFS under Section 7 of the ESA, and SAFCA shall consult with DFG under CESA regarding potential construction-related impacts to Federally listed fish species and state-listed fish species, respectively. SAFCA shall implement any additional measures developed through the ESA Section 7 and CESA consultation processes, including Section 2081 permit conditions, to ensure that impacts are avoided and/or minimized.			√	√

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
	► The cofferdam sheetpiles at the outfall structure construction site and the piles at the South Lauppe Pumping Plant site shall be installed using a vibratory hammer when possible to minimize underwater sound pressure levels to the greatest extent feasible and associated effects to sensitive fish species. Vibratory hammers/pile drivers shall only be used during daytime hours and shall commence at low energy levels and slowly build to impact force. If it is determined that a higher-intensity percussion hammer or pile driver would be required for installing the cofferdam or pilings, avoidance of potential adverse effects would be achieved by consulting with NMFS, USFWS, and DFG to determine the appropriate actions, which may include surveying the outfall site to determine fish presence prior to installation, and possibly modifying the work window accordingly. ► To reduce the potential for fish stranding or minimize the potential for harm during cofferdam dewatering activities, SAFCA or its contractor shall implement a fish rescue plan. Prior to the closure of the cofferdam in the Sacramento River, seining by a qualified fisheries biologist (with a current DFG collection permit) will be conducted within the cofferdam using a small-mesh seine to direct and move fish out of the cofferdam area. Upon completion of seining, the entrance to the cofferdam will be blocked with a net to prevent fish from entering the cofferdam isolation area before the cofferdam is completed. Once the cofferdam is completed and the area within the cofferdam is closed and isolated, additional seining will be conducted within the cofferdam to remove any remaining fish. Once most of the fish have been removed from the isolated area, portable pumps with intakes equipped with 1.75 mm mesh screen shall be used to dewater to a depth of 1.5–2 feet. A qualified biologist shall implement further fish rescue operations using electrofishing and dip nets. All fish that are captured will be placed in clean 5-gallon buckets and/or coolers filled with Sacramento River water, transported downstream of the construction area, and released back into suitable habitat in the Sacramento River with minimal handling. After all fish have been removed using multiple seine passes, electrofishing, and dip nets (as necessary) portable pumps with screens (see above) will be used for final dewatering. NMFS, USFWS, and DFG shall be notified at least 48 hours prior to the fish rescue.			√	√

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
Phase 2: 3.7-i Phase 3: 4.9-h Phase 4a 4.7-k	**Ensure that Project Encroachment Does Not Jeopardize Successful Implementation of the NBHCP**				
	Based on the current value-per-acre, SAFCA shall contribute funds to TNBC to offset direct impacts to TNBC reserves on an acre-per-acre basis, drawing upon TNBC's existing land surplus			√	√
	SAFCA shall coordinate with TNBC to determine the most effective means of ensuring that the small encroachment onto reserves that would result from project implementation does not adversely affect the ability to meet the minimum-size and mitigation-ratio requirements of the NBHCP, require revision of existing management plans, and/or affect revenue-generation requirements. SAFCA shall, in coordination with TNBC, identify and implement necessary actions to ensure that encroachment does not jeopardize successful implementation of the NBHCP. Such actions may include direct supplementation of TNBC funding to offset losses in revenue generation, management of portions of the reserve that are encroached upon by project		√		
Cultural Resources					
Phase 1: 3.7-a	Document Alterations and Distribute the Information to the Appropriate Repositories Consistent with previous mitigation efforts for alterations to RD 1000, a qualified professional archaeologist or architectural historian shall document the alterations made to the NCC levee and distribute the information to the appropriate repositories.	√			

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
Phase 2: SEIR 3.4-a Phase 4.10-a Phase 4a: 4.8-a	**Incorporate Mitigation Measures to Documents Regarding Any Elements Contributing to RD 1000 and Rural Landscape District and Distribute the Information to the Appropriate Repositories** The management of the cultural resources that constitute the contributing elements of RD 1000 is governed by the PA. Because the elements of the RD 1000 historic landscape district have already been recorded, a new inventory of these resources is not required under Stipulation IV(A) of the PA. After an APE has been determined per Stipulation III(C), a qualified architectural historian shall determine if contributing elements of the district are present in the APE. If contributing elements are present, the architectural historian shall update records for these resources and evaluate those elements to determine if they retain integrity. Because much of the Natomas Basin has been developed, it is possible that changes to the setting have diminished the integrity and thus eligibility of contributing elements in the APE. If the elements in the APE retain eligibility, the architectural historian shall make a finding of effect.		√	√	√
	If there is an adverse effect to a contributing element (under Section 106) or a significant impact on the resource's integrity as an historical resource (under CEQA), the architectural historian shall review existing HAER documentation and determine whether any augmentation of this documentation is needed. The original documentation for the American River Watershed Project (completed in 1997) contemplated changes to the setting of the district and thus provided comprehensive documentation to record the district before urbanization (Peak & Associates 1997). This original documentation was intended to adequately recorded and preserve records of the elements that may be affected. However, if this documentation is not sufficient for adversely affected and contributing elements, SAFCA shall prepare an Historic Property Treatment Plan (HPTP) stipulating additional HAER documentation, or other similar treatment as required under Stipulation V(A). After consultation with USACE and the State Historic Preservation Officer (SHPO), SAFCA shall implement the required documentation or treatment prior to construction. Any additional documentation that is needed shall be prepared and distributed to appropriate public repositories.		√	√	√

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
Phase 3: 4.10-c **Phase 4a: 4.8-b**	**Avoid Ground Disturbance Near Eligible and Listed Resources to the Extent Feasible, Prepare a Finding of Effect, and Resolve Any Adverse Effects through Preparation of an HPTP** ► Complete an evaluation of identified resources, and determine the effect of each phase of work on all eligible or listed resources in accordance with Stipulation IV(A) of the PA. ► Consult with USACE, the SHPO, the MLD and other consulting parties such as Native American individuals and organizations, to develop appropriate treatment or mitigation in an HPTP, per Stipulation V(A) of the PA if the project would result in adverse effects on eligible resources.			√	√
	► Document the site and avoid further effects by protecting the resource through capping per management under an HPTP or other avoidance measures where feasible. Where physical impacts cannot be avoided and such physical impacts could damage the data these sites contain, including mortuary components, further mitigation may be required. Such mitigation may consist of data recovery excavations to retrieve those values and mortuary assemblages that contain significance for archaeology after consultation with and the agreement of the Native American most likely descendent (MLD), where possible. ► Monitor potentially destructive construction in the vicinity of documented resources, as required under the Construction Monitoring and Inadvertent Discovery Plan.			√	√
Phase 2: 3.8-c(1)	**Avoid Ground Disturbance Near Known Prehistoric Archaeological Sites CA-Sac-485/H and the Barney Mound to the Extent Feasible, and Conduct Resource Documentation and Data Recovery at CA-Sac-485/H as Needed**				

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
	For CA-Sac-485/H ► SAFCA and its engineers for canal design and construction shall consult with a qualified professional archaeologist during project design to delineate the extent of potentially significant deposits east of the mapped location of CA-Sac-485/H and shall design ground-disturbing work to avoid the deposits as feasible and practicable. ► The archaeologist shall determine an appropriate radius around the site for monitoring adjacent construction work, and SAFCA shall retain an archaeological monitor and Native American monitor to be present during this work. ► If prehistoric resources are discovered, a professional archaeologist shall assess the significance of the find and recommend additional work such as data recovery to retrieve the materials that convey the significance of the resource.		√		
	For the Barney Mound: ► SAFCA and its engineers for borrow excavation shall consult with a qualified professional archaeologist during project design to delineate the extent of potentially significant deposits in the vicinity of the Barney Mound. SAFCA shall restrict all ground disturbance for borrow removal to areas beyond the significant deposits as feasible and practicable. ► SAFCA shall retain an archaeological monitor and Native American monitor to be present during adjacent construction work. ► If prehistoric resources are discovered, a professional archaeologist shall assess the significance of the find and recommend additional work such as data recovery to retrieve the materials that convey the significance of the resource.		√		

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
Phase 2: 3.8-c(2)	**Avoid Ground Disturbance near Known Prehistoric Archaeological Site CA-Sac-485/H to the Extent Feasible, and Conduct Resource Documentation and Data Recovery as Needed** ► If ground disturbance may be conducted within 500 feet of known prehistoric resources (CA-Sac-485/H,), SAFCA and its engineers for levee design and construction shall consult with a qualified professional archaeologist during project design to delineate the extent of potentially significant deposits around the recorded locations. If feasible and practicable, the project activities shall be designed to avoid disturbance of the resource. The archaeologist shall determine an appropriate radius around the site for monitoring adjacent construction work, and SAFCA shall retain an archaeological monitor and Native American monitor to be present during this work.		√		
	► If, in the judgment of the archaeologist, project activities would disturb the resource and these impacts cannot be avoided, the archaeologist shall prepare and implement a research design and treatment plan. Before any construction-related ground disturbance begins in the vicinity of the resource, a professional archaeologist shall carry out a testing program based on the plan to determine whether the resource meets the definition of a unique archaeological resource or a historical resource as defined by CEQA. If the construction activity is part of a federal undertaking, all actions shall be conducted in compliance with Section 106 of the NHPA. If the resource is determined to be ineligible for listing on the CRHR or the NRHP, no further mitigation is required. If the resource appears to meet the definition of a unique archaeological resource or a historical resource or property (under NHPA), the archaeologist shall perform a program of data recovery in coordination with a Native American monitor to retrieve the materials that convey the significance of the resource.		√		
Phase 2: SEIR 3.4-b	**Avoid Ground Disturbance near Known Prehistoric Archaeological Site CA-Sac-485/H to the Extent Feasible and Prepare and Implement a Historic Properties Treatment Plan.**				

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
	SAFCA shall implement the following measures required by the PA (Appendix C) to address potential significant impacts on CA-SAC-485/H associated with Phase 2 Project construction impacts:		√		
	► Prior to start of construction, SAFCA shall prepare an HPTP as required under the PA (Stipulation V[A]). ► The HPTP shall address the effect of construction of a seepage berm on CA-SAC-485/H, including the effects of operating heavy equipment on the site during construction and of the placement of a seepage berm over the resource		√		
	► The HPTP shall recommend an appropriate program of research and analysis for any portion of the assemblage removed from the site during test excavations. SAFCA shall then consult with USACE, the SHPO, and appropriate Native American individuals and entities regarding the recommendations of the HPTP. ► To the extent possible, SAFCA shall minimize or avoid direct impacts on the site by carefully selecting equipment with consideration given to the pressure the construction equipment will place on the site and the capability of the assemblage to withstand these impacts. SAFCA shall also minimize the impact of the weight of the berm on the site through engineering and design to the maximum extent possible. ► Upon concurrence from USACE and the SHPO, SAFCA shall implement the HPTP. The HPTP shall account for and incorporate the concerns of all consulting parties, to the extent possible, given project goals, as required under Section 106. ► During construction, SAFCA shall monitor construction at this location and within an appropriate radius. This monitoring shall be governed by a plan for monitoring and response to inadvertent discoveries that has been approved by USACE, as required in the PA (Stipulation V[B]).		√		

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
Phase 1: 3.7-b Phase 2: 3.8-d	**Perform Research and/or Surveys, Brief Workers Before Construction, Monitor Construction, Halt Potentially Damaging Activities, Investigate and Avoid Resources to the Extent Feasible, and Conduct Resource Documentation and Data Recovery as Needed**				
	► A qualified archaeologist shall survey all accessible portions of the proposed areas of project disturbance if they have not been surveyed within the previous 5 years, and shall document and evaluate the significance of any resources that are found during the surveys. If any resources are found during the surveys that may be considered historical or unique resources under CEQA, the steps described in Mitigation measure 3.8-c for known resources shall be followed.		√		
	► Before construction begins, a qualified professional archaeologist shall give a presentation and training session to all construction personnel so that they can assist with identification of undiscovered cultural materials and avoid them where possible.	√	√		
	► A qualified archaeologist shall monitor all ground-disturbing construction activities along the Sacramento River east levee and at other locations determined by the archaeologist to be sensitive for subsurface cultural resource deposits. If a previously unidentified archaeological resource is uncovered during construction, construction activities shall be halted within 50 feet of the find and the construction contractor, SAFCA, and other appropriate parties shall be notified regarding the discovery.		√		

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
	The archaeologist shall determine whether the resource is significant under CEQA or the NHPA and shall develop appropriate mitigation. If the resource is found to be a unique archaeological resource or a historical resource, the archaeologist shall recommend additional actions deemed necessary for the preservation or documentation of the resource. Such actions may include (but shall not be limited to) measures such as testing for subsurface features, additional background research, additional resource documentation, avoidance of the resource, or additional monitoring of construction activity to minimize any effects. SAFCA shall ensure that necessary protection actions are implemented before construction resumes within 50 feet of the site. The preferred mitigation is preservation in place of as much of the resource as possible through project modification or protective measures. In many cases, archaeological data recovery can mitigate impacts to a less-than-significant level. However, construction activities may encounter unique or historical archaeological resources that cannot be protected or recovered and for which adequate data recovery may not be feasible.	√	√		
Phase 3: 4.10-d **Phase 4a: 4.8-c**	**Train Construction Workers before Construction, Monitor Construction Activities, Stop Potentially Damaging Activities, Evaluate Any Discoveries, and Resolve Adverse Effects on Eligible Resources, if Encountered.**				
	▸ SAFCA shall complete surveys to identify cultural resources in the Phase 4a Project footprint, as identified in the Phase 2 EIR (SAFCA 2007:3.8-31) at the program level. ▸ Mitigation Measure 3.4-d from the SEIR prepared for the Phase 2 Project is copied below and shall be implemented, as appropriate within the footprint of the Proposed Action (SAFCA 2009: 3.4-10).			√	√
Phase 2: SEIR 3.4-d	**Conduct Additional Backhoe and Canine Forensic Investigations As Appropriate**				
	To increase the data set for identifying buried sites under the existing levee, SAFCA shall recommend that the following additional mitigation measures be adopted by USACE during Section 106 consultation:		√		√

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
	► Additional inventory may be conducted at appropriate intervals along the Sacramento River east levee, using a backhoe excavator, to increase the sample of information at depths below 6 feet that cannot be reached with conventional shovel test methods.		√	√	√
	► Such methods may be used only when necessary to address potential project-related effects to cultural resources because other methods are ineffective or project circumstances dictate that such resources must be identified in advance of construction. USACE and SAFCA shall consult with the MLD regarding the use of such methods. USACE and SAFCA recognize the Tribe's preference for less invasive methods of investigation such as the use of canine forensics.				√
	► Where this process or additional inventory efforts reveal other resources, SAFCA recommends the use of canine forensic investigations as a way of identifying interred human remains with minimal disturbance, and for further refinement of an understanding of the constituents of identified resources		√	√	√

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
	► Before construction begins, a qualified professional archaeologist retained by SAFCA shall give a presentation and training session to all construction personnel so that they can assist with identification of undiscovered cultural resource materials and avoid them where possible. Such training shall note the importance of these materials to Native American groups that attach cultural significance to resources in the project area. A qualified archaeologist shall monitor ground-disturbing construction activities along the Sacramento River east levee. In areas of known sacred value, such as archaeological sites containing Native American burials, a Native American monitor will be present to observe potentially destructive construction activities and to ensure proper treatment of human remains in accordance with State law. If a previously unidentified archaeological resource is uncovered during construction, construction activities shall be halted in the vicinity of the find and the construction contractor, SAFCA, USACE, the MLD, and the NAHC (if appropriate), and other appropriate parties shall be notified regarding the discovery. Where construction would consist of cutoff walls excavated in a bentonite and/or cement slurry, SAFCA and USACE anticipate that it will not be possible to identify the precise location of any materials found in spoils or at soil mixing stations, thus construction cannot stop during excavation of cutoff walls if resources are discovered in spoils.			√	√
	► SAFCA shall then consult with USACE and the SHPO to determine the eligibility of the resource. If SAFCA and USACE, in consultation with the SHPO, concur that the resource is eligible and the project may result in adverse effects on the resource, SAFCA shall prepare and implement an HPTP as required under the PA, Stipulation V(A). The HPTP shall be prepared in consultation with USACE, the SHPO, and other appropriate consulting parties such as Native American individuals or organizations.			√	√
	► Work may only resume when either all necessary treatment has been performed under the HPTP, or construction in the vicinity will not result in adverse effects, and that work does not encroach within 30 meters of the known boundaries of the resource, or the boundaries designated by the SHPO, per the PA, Stipulation V(B)(2). All treatment stipulated in the HPTP shall be performed by SAFCA, in consultation with USACE.			√	√

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
Phase 1: 3.7-b	Suspend Potentially Damaging Activity, Investigate Resources, Avoid to the Extent Feasible, and Conduct Resource Documentation and Data Recovery as Needed ► Before the commencement of construction, a qualified professional archaeologist shall give a presentation to all construction personnel regarding the likelihood and type of resources that might be found during construction operations associated with the individual flood control projects, and measures that shall be taken in the event that potential archaeological or historical resources are found during construction.	√			
	► If unrecorded cultural resources (e.g., unusual amounts of shell, animal bone, bottle glass, ceramics, structure/building remains, etc.) are encountered during construction activity, all ground-disturbing activities shall be restricted within a 100-foot radius of the find or a distance determined by a qualified professional archaeologist to be appropriate based on the potential for disturbance of additional cultural resource materials. ► A qualified archaeologist shall identify the materials, determine their potential to meet the definition of a unique archaeological resource or a historical resource in Section 15064.5, and formulate appropriate measures for their treatment, which shall be implemented by the agency implementing the project. Potential treatment methods for significant and potentially significant resources may include, but would not be limited to, no action (i.e., resources determined not to be significant), avoidance of the resource through changes in construction methods or project design, and implementation of a program of testing and data recovery, in accordance with all applicable federal and state requirements.	√			

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
	For unique archaeological resources and archaeological historical resources, the preferred mitigation is preservation in place of as much of the resource as possible, where feasible, through project modification or protective measures. In many cases, archaeological data recovery can mitigate impacts that cannot be avoided. However, construction activities may encounter unique archaeological resources and archaeological historical resources that cannot be protected or recovered and for which adequate data recovery may not be feasible. For example, resources encountered during excavation through the NCC levee for construction of a cutoff wall are likely to be unrecoverable.				
Phase 2: SEIR 3.4-c **Phase 3: 4.10-e** **Phase 4a: 4.8-d**	**Stop Work Within An Appropriate Radius Around the Find, Notify the Applicable County Coroner and Most Likely Descendant, and Treat Remains in Accordance with State Law and Measures Stipulated in an HPTP Developed in Consultation between USACE, SAFCA, and the SHPO** If human remains are uncovered during ground-disturbing activities, SAFCA shall cease all ground-disturbing activities within the vicinity of the find, if known. If the discovery occurs in spoils removed from construction of cutoff walls, the remains shall be treated in accordance with state law. Because cutoff walls are constructed at great depth within a slurry of soil and bentonite and/or cement, SAFCA and USACE anticipate that it will not be possible to pinpoint the location of human remains that may be disinterred during construction of these features and it will not be feasible or useful to stop construction. Discovered remains removed from cutoff wall spoils will be treated as required by state law, as follows. SAFCA's archaeological monitors and/or the contractor shall notify the relevant county coroner and a SAFCA-retained archaeologist skilled in osteological analysis to determine the nature of the remains. If the coroner determines that the remains are those of a Native American, he or she must contact the NAHC by phone within 24 hours of making that determination (Health and Safety Code Section 7050[c]). The NAHC will designate an MLD who may decide how to reinter the remains with appropriate dignity in an appropriate location.		√	√	√

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
	Prehistoric remains are usually found in the context of an archaeological site. The treatment of any associated site shall be in consultation with the MLD, as required under the PA and Mitigation Measure 4.8-c. It is unlikely, but also possible, that ground-disturbing work may disinter human remains associated with an historic burial, not subject to the jurisdiction of the NAHC. Such a resource shall be treated as an archaeological discovery as required by Mitigation Measure 3.4-d from the SEIR prepared for the Phase 2 Project.			√	√
Phase 1: 3.7-c Phase 2: SEIR 3.4-e	**Halt Work Within 100 Feet (Phase 1)/50 Feet (Phase 2) of the Find, Notify the County Coroner and Most Likely Descendant, and Implement Appropriate Treatment of Remains**				
	► If human remains are uncovered during ground-disturbing activities, all ground-disturbing activities shall cease within a 100-foot radius (Phase 1)/50-foot radius (Phase 2) of the find, and SAFCA or its designated representative shall be notified. In accordance with the California Health and Safety Code, if human remains are uncovered during ground-disturbing activities, SAFCA and/or the contractor shall notify the county coroner of the county in which the remains are uncovered (Sutter or Sacramento) and a professional archaeologist to determine the nature of the remains. The coroner is required to examine all discoveries of human remains within 48 hours of receiving notice of a discovery on private or state lands (Health and Safety Code Section 7050.5[b]). If the coroner determines that the remains are those of a Native American, he or she must contact the NAHC by phone within 24 hours of making that determination (Health and Safety Code Section 7050[c]). The NAHC will designate a Most Likely Descendant (MLD) to dispose of the remains with appropriate dignity.	√	√		

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
	► After a determination that the remains are of prehistoric Native American origin, SAFCA shall coordinate with the MLD for reburial of the remains and associated grave goods in an appropriate location. If the MLD fails to make a recommendation or re-inter the remains, further treatment will conform to PRC Section 5097 et seq. and other appropriate authorities. ► The discovery of prehistoric burials often reveals locations sensitive for the occurrence of additional archaeological material. Newly discovered prehistoric resources associated with human remains shall be evaluated, and if the resource is eligible for the CRHR or the NRHP and the project would result in adverse effects to those eligible resources, SEIR Mitigation Measure 3.4-c shall be implemented.		√		
Phase 2: SEIR 3.4-c	**Evaluate NLIP-7 and NLIP-22. If the Resources are Eligible, Avoid Disturbance to the Extent Feasible, and Prepare and Implement a Historic Properties Treatment Plan.** ► Complete an evaluation of NLIP-7 and NLIP-22 resources, and determine the effect of Phase 2 work on all eligible or listed resources in accordance with Stipulation IV(A) of the PA. ► Consult with USACE, the SHPO, and other consulting parties such as Native American individuals and organizations, to develop appropriate treatment or mitigation in an HPTP, as required by Stipulation V(A) of the PA, if the project would result in adverse effects on eligible resources. ► If the resources are deemed to be eligible, document the sites and avoid or reduce adverse effects by minimizing disturbance from construction of the berm. Where physical impacts cannot be avoided and such physical impacts could damage the data these sites may contain, further excavation shall be conducted in order to support documentation of the resource as required under Section 110(b) of the NHPA, or, in the alternative, data recovery excavations to retrieve those values and mortuary assemblages that contain significance for archaeology and Native American culture after consultation with and the agreement of the Native American MLD tribe.		√		

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
	▸ Monitor all construction in the vicinity of documented and eligible resources, as required under the pending construction monitoring and inadvertent discovery plan.		√		
Paleontological Resources					
Phase 1: 3.8-a **Phase 2: 3.9-a** **Phase 3: 4.11-a** **Phase 4a: 4.9-a**	**Conduct Construction Personnel Training and, if Paleontological Resources Are Found, Stop Work Near the Find and Implement Mitigation in Coordination with a Professional Paleontologist** Before the start of construction and/or borrow activities in the Riverbank Formation or the Modesto Formation, construction personnel involved with earthmoving activities shall be informed by SAFCA of the possibility of encountering fossils, the appearance and types of fossils likely to be seen during construction activities, and the proper notification procedures should fossils be encountered. This worker training may be either (1) prepared and presented by an experienced field archaeologist at the same time as construction worker education on cultural resources, or (2) prepared and presented separately by a qualified paleontologist.	√	√	√	√
	If paleontological resources are discovered during earthmoving activities, the construction crew shall immediately stop work in the vicinity of the find. SAFCA shall retain a qualified paleontologist to evaluate the resource and prepare a mitigation plan in accordance with SVP guidelines (1995). The mitigation plan may include a field survey, construction monitoring, sampling and data recovery procedures, museum storage coordination for any specimen recovered, and a report of findings. Recommendations made by the paleontologist, in consultation with SAFCA, shall be implemented before construction activities can resume at the site where the paleontological resources were discovered.	√	√	√	√

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
Transportation and Circulation					
Phase 1: 3.9-b Phase 2: 3.10-a Phase 3: 4.12-a Phase 4a: 4.10-a	**Prepare and Implement a Traffic Safety and Control Plan for Construction-Related Truck Trips** Before the start of construction in each construction season, SAFCA and its primary contractors for engineering and construction shall develop a coordinated construction traffic safety and control plan to minimize the simultaneous use of roadways by different construction contractors for material hauling and equipment delivery to the extent feasible and to avoid and minimize potential traffic hazards on local roadways during construction.		√	√	√
	Upon selection of borrow sites within the Elkhorn Borrow Area, the traffic safety and control plan shall reflect affected roadways. Items (a) through (e) of this mitigation measure, as listed below, shall be integrated as terms of the construction contracts.				
	(a) The plan shall outline phasing of activities and the use of multiple routes to and from off-site locations to minimize the daily amount of traffic on individual roadways. SAFCA shall ensure that the construction contractors enforce the plans throughout the construction periods.		√	√	√
	(b) The construction contractors shall develop a traffic safety and control plan for the local roadways that would be affected by construction traffic. Before the initiation of construction-related activity involving high volumes of traffic, the plan shall be submitted for review by Caltrans and the agencies of the local jurisdictions (Sutter County, Sacramento County, and/or City of Sacramento) having responsibility for roadway safety at and between project sites. The plan shall call for the following elements:	√	√	√	√
	▸ posting warnings about the potential presence of slow-moving vehicles;	√	√	√	√
	▸ using traffic control personnel when appropriate; and	√		√	√
	▸ placing and maintaining barriers and installing traffic control devices necessary for safety, as specified in Caltrans's *Manual of Traffic Controls for Construction and Maintenance Works Zones* and in accordance with city/county requirements (Caltrans 1996).	√	√	√	√

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects

Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
	The contractor shall train construction personnel in appropriate safety measures as described in the plan and shall implement the plan. The plan shall include the prescribed locations for staging equipment and parking trucks and vehicles. Provisions shall be made for overnight parking of haul trucks to avoid causing traffic or circulation congestion.		√	√	√
	(c) Consistent with Phase 4a Mitigation Measure 4.11-a "Implement Applicable District-Recommended Control Measures to Minimize Temporary Emissions of reactive organic gases (ROG), oxides of nitrogen (NO_X), and respirable particulate matter less than 10 microns in diameter (PM_{10}) during Construction," the track-out of bulk material onto public paved roadways as a result of operations, or erosion, shall be minimized by the use of track-out and erosion control, minimization, and preventive measures. Tracked-out materials shall be removed within 1 hour from adjacent streets anytime such material track-out extends for a cumulative distance of greater than 50 feet onto any paved public road during active operations. All visible roadway dust tracked out upon public paved roadways as a result of active operations shall be removed at the conclusion of each work day when active operations cease, or every 24 hours for continuous operations. Wet sweeping or a high-efficiency particulate air (HEPA) filter equipped vacuum device shall be used for roadway dust removal				√
	All operations shall limit and expeditiously remove, as necessary, the accumulation of project-generated mud or dirt from adjacent public streets at least once every 24 hours if substantial volumes of soil have been carried onto adjacent paved public roadways during project construction.	√	√	√	
	(d) Construction of project features along the Sacramento River east levee shall be accommodated through the creation of temporary haul roads along the landside of the adjacent levee and berm footprint. Garden Highway shall not be used for earthen materials hauling activities.		√	√	√
	(e) A Transportation Management Plan shall be prepared and submitted to Caltrans District 3 to cover any points of access from the state highway system for haul trucks and other construction equipment.			√	√

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
	(f) Before the start of the construction season, SAFCA shall coordinate with Sacramento and Sutter Counties and the City of Sacramento to address maintenance and repair of affected roadways resulting from increased truck traffic.		√	√	√
	(g) Before project construction begins, SAFCA shall provide notification of project construction to all appropriate emergency service providers in Sutter County, Sacramento County, and/or the City of Sacramento and shall coordinate with providers throughout the construction period to ensure that emergency access through construction areas is maintained.	√	√	√	√
	(h) Before the start of construction, SAFCA and its primary contractors shall coordinate with Sutter County, Sacramento County, and/or the City of Sacramento regarding any closures of any public roadways.			√	√
Phase 4a: 4.10-d	**Prepare and Implement a Bicycle Detour Plan for Project Area Roadways, Including Garden Highway**				
	► Before the start of construction, SAFCA or its primary contractor shall prepare a bicycle detour plan for roadways that would be affected by project construction activities, including Garden Highway, in consultation with the County Alternative Modes Coordinator and/or City of Sacramento Bicycle and Pedestrian Coordinator as applicable. The detour plan shall include posted signs clearly indicating closure points, truck haul routes, detour routes, and informational signs to notify motorists and bicyclists to share the roads. Signs shall be posted outside of the immediate project area in order to notify bicyclists of closure points and detours. The detour plan shall be in place before the start of construction and shall be maintained and implemented throughout the construction period.				√
Air Quality					
Phase 3: 4.13-a **Phase 4a: 4.11-a**	**Implement Applicable District-Recommended Control Measures to Minimize Temporary Emissions of ROG, NO_X, and PM_{10} during Construction**		√	√	√

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
	Construction in Sutter County (Feather River Air Quality Management District [FRAQMD]) For portions of the project occurring in Sutter County, FRAQMD's *Indirect Source Review Guidelines* and online CEQA guidance provide mitigation measures for reducing short-term air quality impacts. As recommended by FRAQMD, SAFCA shall ensure that the following mitigation measures are implemented during all project construction activities to the extent practicable.	√	√	√	√
	In addition, construction of the proposed levee improvements are required to comply with all applicable FRAQMD rules and regulations, in particular Rule 3.0 (Visible Emissions), Rule 3.16 (Fugitive Dust Emissions), and Rule 3.15 (Architectural Coatings).		√	√	√
	1. SAFCA shall implement a Fugitive Dust Control Plan that includes the following measures:	√	√	√	√
	► All earthmoving operations should be suspended when winds exceed 20 miles per hour or when winds carry dust beyond the property line despite implementation of all feasible dust control measures. ► Construction sites shall be watered as directed by the Sutter County Department of Public Works or FRAQMD and as necessary to prevent fugitive dust violations. ► An operational water truck shall be on-site at all times. Apply water to control dust as needed to prevent visible emissions violations and off-site dust impacts.	√	√	√	√
	► On-site dirt piles or other stockpiled particulate matter shall be covered, wind breaks installed, and water and/or soil stabilizers employed to reduce wind blown dust emissions. Incorporate the use of approved nontoxic soil stabilizers to all inactive construction areas according to manufacturers' specifications.	√	√	√	√
	► All transfer processes involving a free fall of soil or other particulate matter shall be operated in such a manner as to minimize the free-fall distance and fugitive dust emissions.	√	√	√	√

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
	► Apply approved chemical soil stabilizers to all inactive construction areas (previously graded areas that remain inactive for 96 hours), including unpaved roads and employee/equipment parking areas, according to the manufacturers' specifications.	√	√	√	√
	► To prevent track-out, wheel washers shall be installed where project vehicles and/or equipment exit onto paved streets from unpaved roads. Vehicles and/or equipment shall be washed before each trip. Alternatively, a gravel bed or rumble strip may be installed as appropriate at vehicle/equipment site exit points to effectively remove soil buildup on tires and tracks to prevent/diminish track-out.	√	√	√	√
	► Paved streets shall be swept frequently (at least once per day by water sweeper with reclaimed water recommended; wet broom) if soil material has been carried onto adjacent paved, public thoroughfares from the project site.	√	√	√	√
	► Provide temporary traffic control as needed during all phases of construction to improve traffic flow, as deemed appropriate by the Sutter County Department of Public Works and/or Caltrans and to reduce vehicle dust emissions. An effective measure is to enforce vehicle traffic speeds at or below 15 miles per hour on unpaved roads.	√	√	√	√
	► Reduce traffic speeds on all unpaved surfaces to 15 miles per hour, where feasible, and reduce unnecessary vehicle traffic by restricting access. Provide appropriate training, on-site enforcement, and signage.	√			
	► Where restricting vehicle speeds on unpaved surfaces to 15 miles per hour would make timely completion of the project infeasible, SAFCA shall cooperate with FRAQMD to implement alternative dust control measures that would be at least as effective in reducing fugitive dust emissions. Such measures may include increased frequency in applying water to the unpaved roads in the vicinity of sensitive receptors and reducing speeds in the vicinity of sensitive receptors.		√	√	√
	► Reestablish ground cover on the construction site as soon as possible, through seeding and watering.	√	√	√	√

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
	► Open burning is yet another source of fugitive gas and particulate emissions, and it shall be prohibited at the project site. No open burning of vegetative waste (natural plant growth wastes) or other legal or illegal burn materials (trash, demolition debris, etc.) may be conducted at the project site. Vegetative wastes should be chipped or delivered to waste to energy facilities (permitted biomass facilities), mulched, composted, or used for firewood. It is unlawful to haul waste materials off-site for disposal by open burning.	√	√	√	√
	2. Construction equipment exhaust emissions shall not exceed FRAQMD Regulation III, Rule 3.0, Visible Emissions Limitations (40% opacity or Ringelmann 2.0). Operators of vehicles and equipment found to exceed opacity limits shall take action to repair the equipment within 72 hours or remove the equipment from service. Failure to comply may result in a notice of violation.	√	√	√	√
	3. SAFCA shall be responsible for ensuring that all construction equipment is properly tuned and maintained before and during on-site operation.	√	√	√	√
	4. Minimize idling time to 10 minutes, to conserve fuel and minimize emissions.	√	√	√	√
	5. Use existing power sources (e.g., power poles) or clean fuel generators rather than temporary diesel-powered generators.	√	√	√	√
	6. Portable engines and portable engine-driven equipment units used at the project work site, with the exception of on-road and off-road motor vehicles, may require California Air Resources Board (ARB) Portable Equipment Registration with the state or a local district permit. The owner/operator shall be responsible for arranging appropriate consultations with ARB or FRAQMD to determine registration and permitting requirements before equipment is operated at the site.	√	√	√	√

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
	7. SAFCA shall assemble a comprehensive inventory list (i.e., make, model, engine year, horsepower, and emission rates) of all heavy-duty off-road (portable and mobile) equipment (50 horsepower [hp] and greater) that will be used an aggregate of 40 or more hours for the construction project and apply the following mitigation measure:	√	√	√	√
	► Reduce NO_X emissions from off-road diesel-powered equipment: SAFCA shall provide a plan for approval by FRAQMD demonstrating that the heavy-duty (equal to or greater than 50 hp) off-road equipment to be used in the construction project, including owned, leased and subcontractor vehicles, shall achieve a project wide fleet-average 20% NO_X reduction and 45% particulate reduction[1] compared to the most recent ARB fleet average at time of construction.	√	√	√	√
	8. SAFCA shall enter into a voluntary emissions reduction agreement with the FRAQMD to mitigate the portion of construction-generated emissions of NOX that exceeds EPA's applicable threshold for general conformity purposes. The calculation of the fee shall be determined in coordination with the FRAQMD and paid prior to the occurrence of any construction-related activities within areas under the jurisdiction of the FRAQMD.			√	√
Phase 1: 3.10-a	6. Develop a traffic plan to minimize traffic flow interference from construction activities. The plan may include advance public notice of routing, use of public transportation, and satellite parking areas with a shuttle service. Schedule operations affecting traffic for off-peak hours. Minimize obstruction of through-traffic lanes. Provide a flag person to guide traffic properly and ensure safety at construction sites.		√		

[1] Acceptable options for reducing emissions may include use of late-model engines, low-emission diesel products, alternative fuels, engine retrofit technology (Carl Moyer Guidelines), and after-treatment products; voluntary off-site mitigation projects; providing funds for air district off-site mitigation projects; and/or other options as they become available. FRAQMD should be contacted to discuss alternative measures.

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
	Construction in Sacramento County (Sacramento Metropolitan Air Quality Management District [SMAQMD]) For portions of the project occurring in Sacramento County, SMAQMD's Guide to Air Quality Assessment in Sacramento County (SMAQMD 2004) provides mitigation measures for reducing short-term air quality impacts. As recommended by SMAQMD, SAFCA shall ensure that the following mitigation measures are implemented during all project construction activities to the extent practicable and feasible.			√	√
	► SAFCA shall prepare a construction emissions dust control plan(s) in accordance with SMAQMD recommendations that reduces fugitive dust emissions by at least 85% (or shall provide calculations based on SMAQMD-approved methodologies showing that emissions would be reduced to less than 100 tons per year assuming a conservative reduction of 75% with typical mitigation). All grading operations shall be suspended when fugitive dust levels exceed levels specified by SMAQMD rules. SAFCA and its primary construction contractors shall ensure that dust is not causing a nuisance beyond the property line of the construction site.			√	√
	► If overlapping construction phases in Sacramento County create unmitigated PM_{10} emissions in excess of 400 TPY SAFCA shall use advanced dust suppressant materials (such as EnviroTac II) on all unpaved roadways and stockpiled materials to ensure 95% or greater control of fugitive dust and a reduction of PM_{10} emissions below 100 TPY.				√
	Overlapping Phases where this would apply includes all work on the Sacramento River east level for the Phase 3 and 4a Projects.				√

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
	▸ SAFCA shall develop a plan, in consultation with SMAQMD, demonstrating that the heavy-duty (>50 hp), off-road vehicles to be used in the construction project (including owned, leased, and subcontractor vehicles) shall achieve a project-wide fleet-average 20% NO_X reduction and 45% particulate reduction compared to the most recent ARB fleet average at the time of construction.2		√	√	√
Phase 2: 3.11-a	▸ Acceptable options for reducing emissions include the use of late-model engines, low-emission diesel products, alternative fuels, particulate-matter traps, engine retrofit technology, after-treatment products, and/or such other options as become available.		√		
	▸ A comprehensive inventory of all off-road construction equipment equal to or greater than 50 hp that will be used for an aggregate of 40 or more hours during any portion of project construction shall be submitted to SMAQMD. The inventory shall be updated and submitted monthly throughout the duration of the project, except that an inventory shall not be required for any 30-day period in which no construction operations occur. At least 48 hours before heavy-duty off-road equipment is used, SAFCA shall provide SMAQMD with the anticipated construction timeline, including the start date, and the name and phone number of the contractor's project manager and on-site foreman.		√	√	√

2 Acceptable options for reducing emissions include the use of late-model engines, low-emission diesel products, alternative fuels, particulate-matter traps, engine retrofit technology, after-treatment products, and/or such other options as become available.

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
	► Emissions from off-road, diesel-powered equipment used on the project site shall not exceed 40% opacity for more than 3 minutes in any 1 hour. Any equipment found to exceed 40% opacity (or Ringelmann 2.0) shall be repaired immediately, and SMAQMD shall be notified of noncompliant equipment within 48 hours of identification. A visual survey of all in-operation equipment shall be made at least weekly. A monthly summary of visual survey results shall be submitted to SMAQMD throughout the construction period, except that the monthly summary shall not be required for any 30-day period in which no construction operations occur. The monthly summary shall include the quantity and type of vehicles surveyed, as well as the dates of each survey. SMAQMD and/or other officials may conduct periodic site inspections to determine compliance.		√	√	√
	► SAFCA shall pay SMAQMD an off-site mitigation fee for implementation of any proposed alternatives for the purpose of reducing impacts to a less-than-significant level.		√	√	√
	► Calculation of fees associated with subsequent improvement plans/project phases shall be conducted at the time of project approval. The applicable fee rate shall be determined and the total fee shall be calculated based on the fee rate in effect at the time that subsequent environmental documents are prepared. The fee for subsequent construction projects shall be remitted to SMAQMD before groundbreaking.		√	√	√
	SAFCA shall pay into SMAQMD's off-site construction mitigation fund to further mitigate construction-generated emissions of NO_X that exceed SMAQMD's daily emission threshold of 85 lb/day. The calculation of daily NO_X emissions is based on the cost to reduce 1 ton of NO_X at the time when the document is prepared (currently $16,000 per ton [Phase 4a-11/09]). The determination of the final mitigation fee shall be conducted in coordination with SMAQMD before any demolition or ground disturbance occurs for any project phase. Calculation of and payment of the fee for all subsequent project phases shall also be included in the CEQA MMRP for the project.		√	√	√

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
	All Project Construction				
	SAFCA shall implement the following additional measures to reduce construction emissions of PM_{10} comprising fugitive dust and mobile-exhaust and ozone precursors throughout the project area:		√	√	√
	► Open burning of removed vegetation shall be prohibited. Vegetation material shall be chipped on-site or delivered to waste-to-energy facilities to the extent feasible. ► An operational water truck shall be on-site at all times. Water shall be applied to control dust as needed to prevent dust impacts off-site. ► Unpaved areas subject to vehicle traffic, including employee parking areas and equipment staging areas, shall be stabilized by being kept wet, treated with a chemical dust suppressant or soil binders, or covered. ► The track-out of bulk material onto public paved roadways as a result of operations, or erosion, shall be minimized by the use of track-out and erosion control, minimization, and preventive measures, and removed within 1 hour from adjacent streets such material anytime track-out extends for a cumulative distance of greater than 50 feet onto any paved public road during active operations. ► All visible roadway dust tracked out upon public paved roadways as a result of active operations shall be removed at the conclusion of each work day when active operations cease, or every 24 hours for continuous operations. Wet sweeping or a HEPA filter equipped vacuum device shall be used for roadway dust removal. ► Low-sulfur fuel shall be used for stationary construction equipment. ► Existing power sources or clean fuel generators shall be used rather than temporary power generators to the extent feasible.		√	√	√

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
	► Low-emission on-site stationary equipment shall be used. ► Vehicle speeds on unpaved roadways shall be limited to 15 miles per hour. ► Idling time for all heavy-duty equipment shall be limited to 5 minutes.		√	√	√
	► Install ARB-certified Level 3 diesel particulate filters (DPF) on a minimum of 15% of the total number of off-road (non-street legal) diesel-powered construction equipment pieces with an engine size equal to or greater than 50 hp throughout the duration of the project. For fleets with 6 or fewer total applicable equipment pieces, a DPF shall be installed on a minimum of one engine. All DPFs shall be kept in working order and maintained in operable condition according to manufacturer's specifications. At the time of writing, a list of ARB-certified Level 3 DPF can be found at http://www.arb.ca.gov/diesel/verdev/level3/level3.htm.			√	√
	► Install Level 3 ARB-certified DPF that are functional and kept in working order to meet manufacturer's specifications throughout the duration of the project on at least 15% of the total pieces of off-road (non-street legal) construction equipment on the project site over 50 hp (a minimum of one diesel particulate filter for fleets with 6 or less total pieces).		√	√	√

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
	SMAQMD has also recently released since publication of the [Phase 4a] DEIS/DEIR, draft BMPs for consideration as practical alternatives to reduce construction-generated greenhouse gas (GHG) emissions. SAFCA shall implement a range of measures to reduce GHG emissions, which may include the following: ▸ improve fuel efficiency from construction equipment by reducing unnecessary idling (modify work practices, install auxiliary power for driver comfort); performing equipment maintenance (inspections, detect failures early, corrections); training equipment operators in proper use of equipment; using the proper size of equipment for the job; and using equipment with new technologies (repowered engines, electric drive trains); ▸ use alternative fuels for generators at construction sites such as propane or solar, or use electrical power; ▸ encourage and provide carpools, shuttle vans, transit passes, and/or secure bicycle parking for construction worker commutes; ▸ reduce electricity use in the construction office by using compact fluorescent bulbs, powering off computers every day, and replacing heating and cooling units with more efficient ones; ▸ recycle or salvage non-hazardous construction and demolition debris (goal of at least 75% by weight); ▸ use locally sourced or recycled materials for construction materials (goal of at least 20% based on costs for building materials, and based on volume for roadway, parking lot, and sidewalk and curb materials); and ▸ develop a plan to efficiently use water for adequate dust control.				√

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
Noise					
Phase 1: 3.11-a **Phase 2: 3.12-a** **Phase 3: 4.14-a** **Phase 4a: 4.12-a**	**Implement Noise-Reducing Construction Practices, Prepare and Implement a Noise Control Plan, and Monitor and Record Construction Noise Near Sensitive Receptors** **All Project Construction** Measures that shall be used to reduce noise impacts shall include the following:	√	√	√	√
	► Equipment shall be used as far away as practical from noise-sensitive uses. ► All construction equipment shall be equipped with noise-reduction devices such as mufflers to minimize construction noise and all internal combustion engines shall be equipped with exhaust and intake silencers in accordance with manufacturers' specifications. ► Equipment that is quieter than standard equipment shall be used, including electrically powered equipment instead of internal combustion equipment where use of such equipment is a readily available substitute that accomplishes project tasks in the same manner as internal combustion equipment.	√	√	√	√
	► Construction site and haul road speed limits shall be established and enforced. ► The use of bells, whistles, alarms, and horns shall be restricted to safety warning purposes only.		√	√	√
	► Noise-reducing enclosures shall be used around stationary noise-generating equipment (e.g., compressors and generators).	√	√	√	√

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
	► Fixed construction equipment (e.g., compressors and generators), construction staging **and** stockpiling areas, and construction vehicle routes shall be located at the most distant point feasible from noise-sensitive receptors. ► When noise sensitive uses are within close proximity and subject to prolonged construction noise, noise-attenuating buffers such as structures, truck trailers, or soil piles shall be located between noise generation sources and sensitive receptors.		√	√	√
	► Before construction activity begins within 500 feet of one or more residences or businesses, written notification shall be provided to the potentially affected residents or business owners, identifying the type, duration, and frequency of construction activities. Notification materials shall also identify a mechanism for residents or business owners to register complaints with the appropriate jurisdiction if construction noise levels are overly intrusive. The distance of 500 feet is based on the 60-dBA contour of the loudest anticipated construction activity.		√	√	√
	► If noise-generating activities are conducted within 300 feet (Phase 1)/100 feet (Phases 2, 3, 4a) of noise-sensitive receptors (the 70-dBA noise contour of construction noise), the primary contractor shall continuously measure and record noise levels generated as a result of the proposed work activities. Sound monitoring equipment shall be calibrated before taking measurements and shall have a resolution within 2 dBA. Monitoring shall take place at each activity operation adjacent to sensitive receptors. The recorded noise monitoring results shall be furnished weekly to SAFCA.	√	√	√	√
	► The primary contractor shall prepare and implement a detailed noise control plan based on the proposed construction methods. This plan shall identify specific measures to ensure compliance with the noise control measures specified above. The noise control plan shall be submitted to and approved by SAFCA before any noise-generating construction activity begins.	√		√	√

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
	24/7 Project Construction ► When construction of cutoff walls takes place during nighttime hours (between 10:00 p.m. and 6:00 a.m.), SAFCA shall honor requests from affected residents to provide reasonable reimbursement of local hotel or short-term rental stays for the period of time that cutoff wall construction takes place within 500 feet of the residents requesting reimbursement.		√	√	√
	► When construction of groundwater wells (including up to two weeks of continuous pump testing for each well) or modifications to Pumping Plant Nos. 3 and 5 takes place during nighttime hours (between 10:00 p.m. and 6:00 a.m.) and the resulting noise levels exceed the applicable County noise standard (i.e., 45 dBA L_{eq} and 65 dBA L_{max} for Sutter County and 45 dBA L_{50} and 65 dBA L_{max} for Sacramento County), SAFCA shall honor requests from affected residents to provide reasonable reimbursement of local hotel or short-term rental stays for the period of time that construction of groundwater wells or modifications to Pumping Plant Nos. 3 and 5 takes place within 500 feet of the residents requesting reimbursement.				√
Phase 2: 3.12-a	► The primary contractor shall prepare a detailed noise control plan based on the construction methods proposed. This plan shall identify specific measures to ensure compliance with the noise limits specified above. The noise control plan shall be submitted to and approved by SAFCA before any noise-generating construction activity begins. ► Construction of cutoff walls in Reaches 1 and 4A of the Sacramento River east levee shall be limited to the hours of 6 a.m. to 8 p.m., Monday through Saturday, with only maintenance activities on Sunday.		√		
Phase 3: 4.14-b	**Implement Measures to Minimize Construction-Related Vibration Effects (Phase 2) and at the Pumping Plant No. 2 Site (Phase 3)**				

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
	▸ Pile driving shall be conducted as far as practicable from the residential structure. ▸ Vibration monitoring equipment shall be placed at the property line adjacent to large equipment and, with owner approval, at the back of the residential structure adjacent to the large equipment. ▸ A preconstruction and postconstruction survey shall be conducted to assess potential architectural damage from pile driving at the residence near the RD 1000 Pumping Plant No. 2 site which is owned by RD 1000 and/or Natomas Central Mutual Water Company (NCMWC). The survey shall include visual inspection of the structure and documentation of the structure by means of photographs and video. This documentation shall be reviewed with the individual owner prior to any construction activity. Postconstruction monitoring of the structure shall be performed to identify (and repair, if necessary) damage, if any, from construction vibrations. Any damage shall be documented with photographs and video.		√	√	
Phase 3: 4.14-c **Phase 4a: 4.12-c**	**Implement Noise-Reduction Measures to Reduce the Impacts of Haul Truck Traffic Noise**				
	▸ All heavy trucks shall be equipped with noise-control (e.g., muffler) devices in accordance with manufacturers' specifications. ▸ All haul trucks shall be inspected before use and a minimum of once per year to ensure proper maintenance and presence of noise-control devices (e.g., lubrication, nonleaking mufflers, and shrouding). ▸ Before haul truck trips are initiated during a construction season on roads within 600 feet of residences (Phase 2)/160 feet of residences (Phase 3&4a) (the 60-dBA noise contour of haul truck traffic), written notification shall be provided to the potentially affected residents identifying the hours and frequency of haul truck trips. Notification materials shall also identify a mechanism for residents to register complaints with the appropriate jurisdiction if haul truck noise levels are overly intrusive or occur outside the exempt daytime hours for the applicable jurisdiction.		√	√	√

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
Recreation					
Phase 2: 3.13-b	**Compensate the City of Sacramento for Encroachments that Cause Permanent Loss of the Recreational Use of Affected Recreational Facilities** ► Before the start of construction, SAFCA shall compensate the City of Sacramento for any loss of land on the Costa Park site. The negotiated compensation may be in the form of payment, replacement land, or other in-kind compensation for the permanent loss of recreational use at the affected site.		√		
Phase 3: 4.15-a	**Prepare and Implement a Bicycle Detour Plan for all Bicycle Trails and On-street Bicycle Routes, Including the Ueda Parkway Trail and Garden Highway, Provide Construction Period Information on Recreational Facility Closures and Detours, Provide Detours for Bicycle Facilities, and Coordinate with Recreation Agencies to Allow Them to Repair Damage to Recreational Facilities**				
	► Before the start of construction, prepare a bicycle detour plan for all bicycle paths and on-street bicycle routes, including the Ueda Parkway Bicycle Trail and Garden Highway, in consultation with the County and/or City of Sacramento Bicycle and Pedestrian Coordinator as applicable. The detour plan shall include posted signs clearly indicating closure points, detour routes, roadway markings to designate temporary bike lanes, and informational signs to notify motorists to share the roads with bicyclists. Signs shall be posted at major entry points for bicycle trails and routes to notify users of closure points and detours. The detour plan shall be in place before the start of construction and shall be maintained and implemented throughout the construction period. ► Provide construction period information on recreational facility closures and detours. ► Upon completion of the levee improvements, coordinate with the City and/or County (where applicable) for the City and/or County (where applicable) to restore access and repair any construction related damage to recreational facilities, including the Ueda Parkway bicycle trail.			√	

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
Phase 3: 4.15-b	**Provide Construction Period Information on Recreational Facility Closures and Detours and Provide Detours for Access Routes to Alternate Boat Launch Ramps and Marinas** ▸ Provide public information through the media and on SAFCA's Web site regarding detours and alternative access routes to public and private recreational facilities affected by project construction. SAFCA shall coordinate with the City of Sacramento Recreation and Parks Department to make available information to the public regarding closure of public recreational facilities, detours and alternate sites available.			√	
Visual Resources					
Phase 3: 4.16-b	**Direct Lighting Away from Adjacent Properties** (a) SAFCA shall require that nearby residents be notified in advance of nighttime construction activities. (b) SAFCA shall require that construction and security lighting be shielded and directed downward to minimize the spill of light onto adjacent properties.			√	
Utilities and Service Systems					
Phase 2: 3.14-a **Phase 3: 4.17-a** **Phase 4a: 4.14-a**	**Coordinate with Irrigation Water Supply Users Before and During All Irrigation Infrastructure Modifications and Minimize Interruptions of Supply**		√		√
	SAFCA and its primary contractors for engineering design and construction shall ensure that the measures listed below are implemented to minimize the potential for irrigation water supply interruptions during construction activities.				√

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
	► Coordinate the timing of all modifications to irrigation supply infrastructure with the affected infrastructure owners and water supply users, either directly or through NCMWC. ► Include detailed scheduling of the phases of modifications/replacement of existing irrigation infrastructure components in project design and in construction plans and specifications. ► Plan and complete modifications of irrigation infrastructure for the nonirrigation season to the extent feasible. ► Provide for alternative water supply, if necessary, when modification/replacement of irrigation infrastructure must be conducted during a period when it would otherwise be in normal use by an irrigator. ► Ensure either that (1) users of irrigation water supply do not, as a result of physical interference associated with the project, experience a substantial interruption in irrigation supply when such supply is needed for normal, planned farming operations (i.e., a decrease in level of service in comparison with the existing level of service), or (2) users of irrigation water supply that experience a substantial decrease in an existing level of service that meets the established standards for the project area are compensated in kind for losses associated with the reduction in level of service.		√	√	√
Phase 2: 3.15-b **Phase 4a: 4.14-b**	**Verify Utility Locations, Coordinate with Utility Providers, Prepare and Implement a Response Plan, and Conduct Worker Training with Respect to Accidental Utility Damage** Before construction begins, SAFCA and its primary contractors shall coordinate with USACE, the CVFPB, and applicable utility providers to implement orderly relocation of utilities that need to be removed or relocated.		√		√

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
	Power pole relocations shall be coordinated with SMUD and SACDOT to avoid conflicts with the SACDOT-proposed bike/pedestrian path. Existing main electrical power transmission lines and poles on the waterside of the existing Garden Highway levee that do not need to be relocated or replaced to accommodate the project may be left in place. No new main electrical power transmission lines and poles shall be installed on the waterside of Garden Highway. Consistent with sound engineering practices that prioritize the following, individual service lines shall: (1) use existing configurations and facilities, and (2) any new poles shall be placed on the landside of Garden Highway, subject to the approval of USACE, the CVFPB, and any other regulatory public agencies and utility companies				√
	► SAFCA and its primary construction contractors shall provide the following: Notification of any potential interruptions in service shall be provided to the appropriate agencies and affected landowners. ► Before the start of construction, utility locations shall be verified through field surveys and the use of the Underground Service Alert services. Any buried utility lines shall be clearly marked in the area of construction on the construction specifications in advance of any earthmoving activities.		√		√
	► Before the start of construction, a response plan shall be prepared to address potential accidental damage to a utility line. The plan shall identify chain of command rules for notification of authorities and appropriate actions and responsibilities to ensure the safety of the public and workers. Worker education training in response to such situations shall be conducted by the contractor. The response plan shall be implemented by SAFCA and its contractors during construction activities. ► Utility relocations shall be staged to minimize interruptions in service.		√	√	√
Phase 2: 3-15-b	► No new utility poles shall be located on the water side of Garden Highway in the vicinity of existing waterside residences unless there is no feasible alternative for providing service to these residences.		√		

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
Phase 3: 4.17-b	► Additionally, upon borrow site selection within the Elkhorn Borrow Area, further verification of utility locations, coordination with utility providers, preparation and implementation of a response plan, and any required construction worker training with respect to accidental utility damage shall be completed before any earth-moving activities take place.			√	
Hazards and Hazardous Materials					
Phase 3: 4.18-b(1) **Phase 4a: 4.15-b(1)**	**Complete Phase I and/or II ESAs and Implement Recommended Measures**				
	NLIP Phase 4a Phase I ESA sites Before the start of any construction activities, SAFCA shall ensure that Phase I ESAs are completed for all sites subject to ground disturbance, and that any additional site evaluations that be recommended in the Phase I ESAs are conducted. For the following sites where Phase I ESAs have been completed, the following additional evaluations (as recommended in the applicable Phase I ESAs) shall be completed prior to start of construction or earthmoving activities:				√
	Assessor's Parcel Number (APN) 201-0330-019 ► Conduct a limited Phase II ESA to evaluate for pesticide residues, and the possible presence of petroleum and/or other hazardous materials associated with on-site ASTs and drums.				√
	APNs 225-0010-038, 225-0010-041, and 225-0010-043 ► Conduct a limited Phase II ESA to evaluate for pesticide residues, and the possible presence of petroleum and/or other hazardous materials associated AST tanks and an on-site vehicle.				√
	► Conduct a geophysical survey to assess the presence of a possible underground storage tank (UST) and if present, collect soil and/or groundwater samples to evaluate if contamination exists.				√
	APNs 225-0090-014, 225-0110-050, 225-0101-007, 225-0101-057, 225-0101-058, 225-0101-061, 225-0110-018, and 225-0110-051				

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
	► Conduct a limited Phase II ESA to evaluate for pesticide residues.				√
	APN 225-0090-040 (Novak Property)				
	► As recommended in the Phase I ESA (Kleinfelder 2009a), a limited Phase II ESA was completed to evaluate for pesticide residues. The possible presence of petroleum and/or other hazardous materials associated with on-site ASTs, car batteries, burn areas, and drums shall be evaluated before the start of earth-moving activities.				√
	APN 225-0090-069				
	► Conduct a limited Phase II ESA to evaluate for pesticide residues.				
	► Conduct a geophysical survey to assess the presence of a possible UST and if present, collect soil and/or groundwater samples to evaluate if contamination exists.				√
	APNs 225-0101-003, 225-0101-004, 225-0101-005, 225-0101-006				√
	► Conduct a limited Phase II ESA to evaluate for pesticide residues.				
	► Conduct a geophysical survey to assess the presence of a possible UST and if present, collect soil and/or groundwater samples to evaluate if contamination exists.				√
	APN 225-0210-026				
	► Conduct a limited Phase II ESA to evaluate for pesticide residues and residual chemical concentrations related to petroleum product surface staining.				√
	APNs 225-0110-019, 225-0110-020, and 225-0110-037 (Huffstutler Trust/Johnson Property)				
	► Conduct additional Phase II ESA work to further evaluate for potentially hazardous materials discussed in the Phase I ESA, including potential hydrocarbon contamination, miscellaneous refuse, unlabeled containers, and compounds found in aboveground and underground structures.				

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
	► Retain an Industrial Hygienist to prepare a Construction Worker Health and Safety Plan. The Construction Worker Health and Safety Plan Shall include, but shall not be limited to: personal protective equipment for workers, a delineation of the horizontal and vertical extent of elevated arsenic levels, a list of required monitoring equipment to be onsite during contaminated soil excavation (e.g., air quality meter), and proper procedures in the event that stained soil is encountered. ► Retain a qualified professional to conduct an Ecological Risk Assessment. The Ecological Risk Assessment shall include, but shall not be limited to: potential chemicals of concern, biological characterization of the site, identification of potential exposure pathways, ecological receptors, and recommendations for and implementation of remediation, if necessary.				√
	APNs 201-0250-015, 201-0270-002, and 201-0270-037 (South Sutter, LLC Borrow Site) ► Conduct a Phase II ESA to evaluate for potentially hazardous materials discussed in the Phase I ESA, including potential miscellaneous refuse, unlabeled containers, and ASTs may have impacted the soil. ► Remove, as appropriate, items on site, such as the AST, car batteries, unlabeled storage tanks, debris, and water wells in accordance with regional, local, state, and Federal regulations.				√
Phase 3: 4.18-b(1)	***NLIP Phase 3 Phase I ESA sites*** Before the start of any construction activities, SAFCA shall ensure that all recommendations from the Kleinfelder Phase I ESA, listed below, are implemented by the property owner in compliance with applicable rules and regulations:			√	
	The Yuki Pear Farm (Assessor's Parcel Number [APN] 201-0150-033):				
	► Conduct further investigation and implement all feasible remedial actions recommended in the Phase II ESA.				

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
	▸ Consult with the Sacramento County Environmental Management Department regarding any hazardous materials actions that may be necessary during future use of the site. ▸ Continue sampling from monitoring wells on a quarterly basis. ▸ Stockpile and sample soil for dichloro-diphenyl-trichloroethane (DDT) and dichlorodiphenyldichloroethylene (DDE) before removal.			√	
Phase 2: 3.16-b(1)	**Ensure that Contaminants Are Not Present at Unacceptable Levels on the Yuki Farms Site Near the Location of Project Construction Activities** Before the start of any construction activities on the Sacramento County–owned property known as "Yuki Farms," SAFCA shall ensure that (1) any issues of documented soil or groundwater contamination on the property have been resolved by Sacramento County in accordance with federal, state, and local requirements; or (2) a qualified hazardous materials specialist, through soil and groundwater testing, has determined that any previously documented contamination site on the property is sufficiently distant from areas of project-related disturbance to ensure that hazardous materials at the site will not be encountered during construction activity and would not migrate into water carried in the new canals and pose a threat to the safety of construction workers, the general public, or the environment.		√		
	Dunmore Borrow Site (APN 201-0120-031): Properly abandon wells, in accordance with applicable Federal, state, and local requirements, if found within the site and determined to be no longer needed.			√	
	Brookfield Borrow Site (APN 35-080-021): ▸ Properly dispose of buckets containing waste found on-site at a licensed disposal facility.			√	
	APNs 201-0150-040, 201-0150-041, 201-0150-042:				
	▸ Obtain requirements from State of California Department of Oil, Gas, and Geothermal Resources (DOGGR) for construction activities near the dry hole.				

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
	▸ Investigate the presence of an underground conveyance pipeline that may be present on the Shell Oil easement and if found, coordinate with the owner to avoid or minimize impacts on said pipeline during construction activities, or relocate the pipeline if it is determined to be necessary.			√	
	APNs 201-0150-055, 201-0140-059: ▸ Consult with DOGGR and the gas well lease holder if the idle gas well would be disturbed during construction activities; if so, then implement all recommendations for safe project operations as provided by DOGGR following the initial consultation. ▸ Confirm the presence of water wells and septic systems and perform appropriate actions to abandon them in accordance with state and local requirements.			√	
	APN 201-0270-028: ▸ Complete a Phase II ESA to determine the presence of lead contamination associated with petroleum products. ▸ Determine if the former underground storage tanks (USTs) are located on site, and if they have been properly abandoned and/or removed.			√	
	APN 201-0270-048: ▸ Complete a Phase II ESA to determine if the damaged automotive battery observed on site has contaminated soil.			√	
	APN 201-0280-037: ▸ Determine if a 100-gallon UST is located on site. If it exists, confirm proper abandonment practices.			√	
	APN 201-0280-044: ▸ Complete a Phase II ESA to determine elevated concentrations of chemicals remain on site.			√	

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
	Sites with Historical Agricultural Use: ▸ Conduct a limited sampling program (Phase II ESA) to analyze concentrations of organochlorine pesticides, organophosphorous pesticides, chlorinated herbicides, and selected metals residues. ▸ Investigate presence and location of asbestos-containing irrigation pipes. ▸ Implement all feasible remedial action recommendations contained in the Phase II ESA.			√	
Phase 1: 3.15-a **Phase 2: 3.16-b(2)**	**Prepare a Worker Health and Safety Plan, and Implement Appropriate Measures to Minimize Potential Exposure to Unknown Hazardous Materials**				
	If, during site preparation and construction activities, previous undiscovered or unknown evidence of hazardous materials contamination is observed or suspected through either obvious or implied site characteristics (e.g., stained or odorous soil), construction activities shall immediately cease in the area of the find. A qualified hazardous materials specialist shall assess the construction site and shall collect and analyze soil samples, if needed, from the site. If contaminants at unacceptable levels are identified in the samples, SAFCA or its primary construction contractor shall implement measures in accordance with federal and state regulations before beginning construction activities. SAFCA shall require all contractors to prepare a worker health and safety plan before the start of construction activities. This plan shall identify, at a minimum, all contaminants that could be encountered during construction activity; all appropriate worker, public health, and environmental protection equipment and procedures to be used during project activities; emergency response procedures; the most direct route to the nearest hospitals; and a site safety officer. The plan shall describe actions to be taken should hazardous materials be encountered on-site, including protocols for handling hazardous materials and preventing their spread and emergency procedures to be taken.	√	√		

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
Phase 3: 4.18-b(2) **Phase 4a: 4.15-b(2)**	**Complete Investigations Related to the Extent to Which Soil and/or Groundwater May Have Been Contaminated in Areas Not Covered by the Phase I and/or II ESAs and Implement Required Measures (e.g., Site Management and/or Other Contingency Plans)**				
	For parcels that will be used for borrow activities or where earthmoving activities would occur, SAFCA shall ensure that the contractor complete the following prior to start of construction and earthmoving activities:				√
	► Prepare a site management plan, subject to SAFCA review and approval that contains protocols and procedures for excavation, use, disposal, and handling of soil containing pesticide residues or contaminants, and for identifying possible contamination during construction. The plan shall include measures for the safe transport, use, and disposal of pesticide residue impacted soil and building debris removed from the site. Soil reuse may include: containing portions of the affected topsoil within the core of seepage berms, with an overlay of clean soil to prevent surface runoff caused by rainfall erosion on the topsoil materials; rip, mix, and/or amend affected topsoil that is re-spread onto borrow sites, levee, and/or berm surfaces, to provide a plant growth medium and reduce the concentration of pesticide residues in the soil; establish native perennial grasses and other perennial vegetation cover (e.g., hay, alfalfa) on these planted surfaces to reduce sediment runoff that may be caused by rainfall erosion or surface irrigation; and improve the drainage of agricultural lands used as borrow/mitigation sites to reduce ponded water and minimize the discharge of sediments into nearby drainages. In the event that impacted groundwater is encountered during site excavation activities, the contractor shall report the chemical concentrations to the appropriate regulatory agencies, dewater the excavated area, and treat the groundwater to remove the chemicals before discharge. The contractor shall be required to comply with applicable Federal, state, regional, and local laws. The plan shall outline measures for specific handling and reporting procedures for hazardous materials and disposal of hazardous materials removed from the site at an appropriate off-site disposal facility. The plan shall include, but shall not be limited to: delineations of the horizontal and vertical extent and concentration of soil contamination; a list				√ √

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects

Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
	of required monitoring equipment to be onsite during soil excavation (e.g., an air quality meter shall be used at the fenceline during dust-producing activities); sampling and analysis protocol for additional soil investigations; a list of necessary agencies to be contacted if chemical concentrations in water, air, and/or soil exceed set threshold limits; and a list of necessary permits, reports, or other compliance mechanisms.				
	▸ Retain an industrial hygienist to prepare a construction worker health and safety plan. The construction worker health and safety plan shall include, but not be limited to: personal protective equipment for workers, a delineation of the horizontal and vertical extent of elevated arsenic levels, a list of required monitoring equipment to be on-site during contaminated soil excavation (e.g., air quality meter), and proper procedures in the event that stained soil is encountered.				√
	▸ Retain a qualified professional to conduct an ecological risk assessment on sites found to contain levels of contaminant exceeding pertinent ecological risk levels. The ecological risk assessment shall include, but not be limited to: potential chemicals of concern, biological characterization of the site, identification of potential exposure pathways, ecological receptors, and recommendations for and implementation of remediation, where feasible and practicable.				√
	▸ Retain an air quality specialist to monitor the concentration of particulates of concern in the air at the project fenceline, adjacent to residential property to ensure compliance with Federal, state, regional, and local regulations, to the extent feasible and practicable. Airborne particulate monitoring should be performed in the on-site worker's breathing zone using the Particulate Not Otherwise Specified (NOS) concentrations standard of 5 mg/m^3 as well as at the project boundaries using the Fenceline Particulate NOS goal of 0.3 mg/m^3.				√

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
	► Retain a licensed contractor to remove USTs, ASTs, and stained soils in accordance with applicable Federal, state, regional, and local regulations. ► Retain a licensed contractor to remove and dispose of asbestos cement pipe found within the project area in accordance with applicable Federal, state, regional, and local regulations. ► Retain a licensed contractor to remove septic systems, water wells, and other underground structures, as needed, in accordance with applicable Federal, state, regional, and local regulations. ► Retain an asbestos specialist who is certified by the California Occupational Safety and Health Administration (Cal/OSHA) The asbestos specialist shall investigate whether asbestos-containing materials or lead-based paints are present before demolition of on-site buildings and utilities. If materials containing asbestos or lead are found, they shall be removed by an accredited contractor in accordance with EPA and Cal/OSHA standards. In addition, activities (construction or demolition) in the vicinity of these materials shall comply with Cal/OSHA asbestos and lead worker construction standards. The materials containing asbestos and lead shall be disposed of properly at an appropriate off-site disposal facility.			√	√
	► Obtain an assessment conducted by the Sacramento Municipal Utility District and/or Pacific Gas & Electric Company pertaining to the contents of the existing pole-mounted transformers that would be relocated as part of the Phase 4a Project. The assessment shall determine whether existing on-site electrical transformers contain polychlorinated biphenyls (PCBs) and whether there are records of spills from such equipment. If equipment containing PCBs is identified, the maintenance and/or disposal of the transformer shall be subject to the regulations of the Toxic Substances Control Act under the authority of the Sutter County Environmental Health Division and Sacramento County Environmental Management Department.			√	√
	► Identify oil and gas well locations. Prepare and implement a California Department of Oil, Gas, and Geothermal Resources well review program, if necessary.				√

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
	► Notify the appropriate Federal, state, regional, and local agencies, as required, if evidence of previously undiscovered soil or groundwater contamination (e.g., stained soil, odorous groundwater) is encountered during construction activities. Areas with chemical concentrations exceeding regulatory levels shall be cleaned up in accordance with recommendations made by the Sutter County Environmental Health Division, Sacramento Environmental Management Department, Central Valley RWQCB, DTSC or other appropriate Federal, state, regional, or local regulatory agencies as generally described above.			√	√
Phase 3: 4.18-b(2)	► Conduct Phase I ESAs, and if necessary, Phase II ESAs, and/or other appropriate testing and include, as necessary, analysis of soil and/or groundwater samples for the potential contamination sites that have not yet been covered by previous investigations before construction activities begin. Similar appropriate testing for borrow sites selected within the Elkhorn Borrow Area shall be completed before any earth-moving activities. Recommendations in the Phase I and II ESAs to address any contamination that is found shall be implemented before initiating ground-disturbing activities in these areas.			√	
	Implement the following measures before ground-disturbing or demolition activities begin within each project phase to reduce health hazards associated with potential exposure to hazardous substances:			√	

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
	► Prepare a site plan that identifies any necessary remediation activities appropriate for proposed land uses, including excavation and removal of on-site contaminated soils, and redistribution of clean fill material on the project site. The plan shall include measures that ensure the safe transport, use, and disposal of contaminated soil and building debris removed from the site. In the event that contaminated groundwater is encountered during site excavation activities, the contractor shall report the contamination to the appropriate regulatory agencies, dewater the excavated area, and treat the contaminated groundwater to remove contaminants before discharge into the sanitary sewer system. The contractor shall be required to comply with the plan and applicable Federal, state, and local laws. The plan shall outline measures for specific handling and reporting procedures for hazardous materials and disposal of hazardous materials removed from the site at an appropriate off-site disposal facility.			√	
Phase 4a: 4.15-c	**Review Design Specifications and Prepare and Implement an Impact Avoidance and contingency Plan in Consultation with Wickland Pipelines, LLC** Prior to issuance of construction contract bid requests for the Phase 4a Project, SAFCA and its engineering and design consultants shall ensure that Wickland Pipelines, LLC has approved design specifications and impact avoidance and safety measures for construction activities within 50 feet of the jet fuel pipeline (CCR Title 8, Section 1541). Construction specifications to be approved with Wickland Pipelines, LLC include, but are not limited to, the type of construction and equipment (e.g., bulldozers, graders, excavators) and the location and depth of earth-moving activities near the pipeline (i.e., 50 feet). All excavation and construction in the vicinity (i.e., 50 feet) of the jet fuel pipeline shall be undertaken in strict conformity with the most recent version of the Best Practice of the Common Ground Alliance available.				√

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
	Prior to the start of earthmoving activities, an impact avoidance and contingency plan shall be prepared and implemented by SAFCA in consultation with Wickland Pipelines, LLC. The plan shall include, but shall not be limited to: ► a contingency plan for actions to take in the event of damage to the pipeline or release of jet fuel, which shall include chain of command and notification procedures, worker safety, pipeline security, wildlife care, response procedures, necessary permits for response actions, and waste handling and disposal; ► a worker health and safety plan and worker training that shall consider personal protective equipment, operations safety within 50 feet of the pipeline, and a contact list for reporting and obtaining medical service; and ► a method to provide the Airport with jet fuel in the event that the pipeline incurs substantial damage. Agreements made between SAFCA, SAFCA's contractor, and Wickland Pipelines, LLC shall be in compliance with applicable Federal and state regulations (e.g., Hazardous Liquid Pipeline Safety Act, Pipeline Safety Improvement Act of 2002, Cal OSHA regulations).				√
Phase 2: 3.16-e Phase 3: 4.18-c Phase 4a: 4.15-d	**Notify State and Local Emergency Management Agencies about Project Construction and Coordinate Any SR 99/70 Detours with these Agencies to Ensure That Any Need for Emergency Use Is Not Significantly Impaired**		√	√	√
	(a) SAFCA shall implement [Phase 2 Project] Mitigation Measures 3.10-a, 3.10-b, and 3.10-c.		√		
	(b) During project design, SAFCA shall coordinate with Caltrans to plan detours through the NCC south levee construction area at SR 99/70 that will ensure an acceptable flow of traffic through this area.		√		

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects					
Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
	(c) Before the beginning of construction, SAFCA shall notify the California Highway Patrol and the Sutter County, Sacramento County, and City of Sacramento emergency management agencies of the timing and nature of detours and traffic controls required on SR 99/70 during project construction. SAFCA shall coordinate with these agencies and Caltrans to ensure that information on potential traffic delays and impairment of the use of this highway as an emergency evacuation route are appropriately publicized, as determined necessary by these agencies.		√		
	SAFCA shall implement [Phase 3 Project] Mitigation Measure 4.12-a to avoid impairment of the use of SR 99/70 as an emergency evacuation route.			√	
	SAFCA shall implement [Phase 4a Project] Mitigation Measures 4.10-a and 4.10-c, set forth in Section 4.10, "Traffic and Circulation" to avoid impairment of the use of SR 99/70 as an emergency evacuation route.				√
Phase 3: 4.18-d **Phase 4a: 4.15-e**	**Notify the Natomas Unified School District and Applicable Schools with Jurisdiction within One-Quarter Mile of Project Construction Activities** SAFCA shall provide written notification of the project to each of the affected schools and the Natomas and Twin Rivers Unified School Districts within 30 days prior to certification of this EIS/EIR and shall consult with the Natomas and Twin Rivers Unified School Districts regarding the potential impacts on schoolchildren from hazards associated with project implementation.			√	√

Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
Phase 2: 3.16-c Phase 3: 4.19-a Phase 4a: 4.15-f	**Coordinate Work in the Critical Zone with Airport Operations and Restrict Night Lighting Within and Near the Runway Approaches** ► No borrow activities shall be conducted within the Airport Critical Zone during nighttime hours. ► All project-related nighttime lighting that is in, or is aligned with, the Airport runway approach zones (Natomas Cross Canal south levee Reaches 1–4, and Sacramento River east levee Reaches 1–11B) shall be directed downward to avoid potential interference with nighttime aircraft operations. ► SAFCA shall ensure that the SCAS is informed in advance of the timing and nature of all construction activities within the Airport Critical Zone, and shall coordinate with SCAS during final project design to ensure that all appropriate safety precautions within the Airport Critical Zone are incorporated into the construction plans.		√	√	√
	► Additionally, requirements provided by the Federal Aviation Administration (FAA), not incorporated into this document, shall be followed. ► SAFCA shall submit the FAA form 7460-1, Notice of Proposed Construction or Alteration, which notifies the FAA of construction or alteration that might affect navigable airspace. This form must be submitted to the FAA at least 30 days before the earlier of the following dates: (1) the date the proposed construction or alteration is proposed to begin, or (2) the date an application for a construction permit is to be filed.			√	√

Project Phase and Mitigation Measure No.	Mitigation Measure	Phase 1 Project	Phase 2 Project	Phase 3 Project	Phase 4a Project
Phase 2: 3.16-d	**Implement Measures to Avoid Substantial Increases in Hazardous Wildlife within the Critical Zone or Wildlife Collisions with Aircraft** A qualified biologist, retained by SAFCA, shall conduct a wildlife-aircraft strike analysis to determine to what extent the proposed project could increase the potential for wildlife collisions with aircraft, and how the project could be modified to reduce any potential increase in wildlife collisions. The analysis, which shall be completed as part of project design of Airport borrow sites and of woodland plantings within the Critical Zone (2009–2010 construction), shall include the following: ► A summary of existing information on wildlife-aircraft strikes at the Airport, relevant research conducted at the Airport and other airports in the United States, and a description of the sources of uncertainty resulting from insufficient data. ► A comparison of current land use and habitat types in the Natomas Basin with anticipated land use changes over the next 20 years (i.e., the period covered by the Airport's master plan). The purpose of this analysis will be to predict how anticipated land use changes will influence the diversity, abundance, and distribution of hazardous wildlife in the vicinity of the Airport. Particular attention will be given to analyzing potential effects of implementing the proposed project on hazardous wildlife populations. ► An analysis of the anticipated effects of project implementation on the frequency and patterns of wildlife-aircraft strikes at the Airport. ► Mitigation options, including alternative designs for habitat compensation sites, on-site versus off-site mitigation opportunities, and monitoring and adaptive management options that could be implemented if it is determined that the overall project could result in a no net increase of risk to aircraft.		√		
	If the wildlife-aircraft strike analysis concludes that implementation of project elements proposed for construction in 2009–2010 would not result in an increase the potential for wildlife collisions with aircraft, no further mitigation is necessary.		√		

Summary of Mitigation Measures Adopted in Connection with the Natomas Levee Improvement Program, Phase 1–4a Landside Improvements Projects

	If the wildlife-aircraft strike analysis concludes that project elements proposed for construction in 2009–2010 could increase the potential for wildlife collisions with aircraft, SAFCA shall implement the following mitigation: ▸ SAFCA, in consultation with SCAS and the FAA, shall design and implement mitigation and/or modify the proposed project as needed until it is determined by SCAS and the FAA that the proposed project would not substantially increase the risk of wildlife collisions with aircraft		√		
Phase 2: 3.16-f **Phase 3: 4.20-a** **Phase 4a: 4.15-h**	**Prepare and Implement a Fire Management Plan to Minimize Potential for Wildland Fires**				
	SAFCA and its primary contractors for engineering design and construction shall prepare and implement a fire management plan in coordination with the appropriate emergency service and/or fire-suppression agencies of the applicable local jurisdictions before beginning project construction. The plan shall describe fire prevention and response methods, including fire precaution, presuppression, and suppression measures that are consistent with the policies and standards of the affected jurisdictions. All materials and equipment required for implementation of the plan shall be maintained on-site. All construction personnel shall be made familiar with the contents of the plan before construction activities begin.		√	√	√
Phase 3: 4.20-a	The plan shall be amended, as appropriate, upon selection of borrow sites within the Elkhorn Borrow Area.			√

Environmental Justice					
Phase 3: 4.21-a **Phase 4a: 4.16-a**	**Increase the Direct Benefits of the Project for the Ancestors of the Native American Tribes**				
	As part of the Phase 4a Project, SAFCA proposes to acquire various properties in the Natomas Basin as compensation for the project's potential impacts, as required under Federal and state laws. As part of the process for restoring these lands, SAFCA shall implement the following measures to address environmental justice and increase the direct benefits to the ancestors of the Native American tribes that would bear disproportionate adverse effects: ► consult with appropriate Native American representatives to identify plant species of value for traditional cultural uses; ► consult with Native American representatives to identify traditional cultural activities that could occur on these lands, consistent with habitat conservation and safety objectives; ► to the extent feasible, include identified plant species in the planting palettes developed for habitat conservation; ► to the extent feasible, establish easements or other protective measures on these properties that include access for appropriate Native American representatives for plant gathering and other traditional cultural activities; and ► where feasible, also provide access to appropriate Native American representatives to the river front on acquired parcels that have access to the Sacramento River, provided that access does not permit the construction of physical structures on the levee, beaches, or in the river without prior approval from the appropriate regulatory agency.			√	√

LIST OF FIGURES

1. OVERVIEW

The Sacramento Area Flood Control Agency (SAFCA) is proposing to raise and strengthen portions of the federal project levee system protecting the Natomas Basin in Sacramento and Sutter Counties in order to provide urban development in the basin with at least a 100-year level of flood protection as quickly as possible, while laying the groundwork for providing at least a 200-year level of flood protection over time. This effort is referred to as the Natomas Levee Improvement Program (or "NLIP"). It is part of a larger program of improvements, including modifications to Folsom Dam that would provide the Sacramento area as a whole with at least a 200-year level of flood protection.

Under applicable federal law, no federal project levee or related flood control facility may be altered unless: Congress has authorized the alteration; or, pursuant to 33 U.S.C. 408, the Secretary of the Army acting through the Chief of Engineers of the U.S. Army Corps of Engineers ("USACE") has granted permission for the alteration based on a determination that the proposed work will not be injurious to the public interest and will not otherwise impair the usefulness of the affected facility. Under Title 23 of the California Water Code, such alterations must also be either authorized by the State Legislature; or permitted by the California Central Valley Flood Protection Board ("Board"), formerly the Reclamation Board. In order to coordinate these federal and state decision-making processes, the Board's recent practice has been to issue a letter to the USACE requesting permission for proposed alterations after the Board has made its own determination that the work will not have a detrimental impact on the affected flood control system.

At the heart of both processes is an analysis of the hydraulic effects of the proposed alteration. SAFCA has historically conducted this analysis by evaluating the potential effects of its levee improvement projects on water surface elevations in the stream and river channels in the project area and in the larger watershed within which the project is situated. This approach was used to evaluate the flood related impacts of the NLIP for purposes of meeting the requirements of the California Environmental Quality Act (CEQA). Specifically, SAFCA's engineering consultant, MBK Engineers ("MBK"), has used a UNET hydraulic computer model of the Sacramento River Flood Control Project ("SRFCP"), which was reviewed and approved for use for this project in 2006 by the USACE Sacramento District, to compare existing conditions in the waterways surrounding the Natomas Basin and in the larger SRFCP with and without the NLIP improvements and the other improvements comprising the 200-year flood protection program for the Sacramento area. MBK's initial routings assumed that the levees outside the project area would fail when overtopped. However, in order to test the sensitivity of this assumption, a later set of routings was performed assuming that none of these levees would fail even if overtopped.

The results of the initial routings were presented in the program-level Environmental Impact Report ("EIR") on Local Funding Mechanisms for Comprehensive Flood Control Improvements for the Sacramento Area, which was certified by the SAFCA Board of Directors in February 2007. Using the same methodology, the analysis was performed again and presented in the Draft EIR for the NLIP Landside Improvements Project in September 2007. The 'no levee failure' routings were performed thereafter and presented in the Landside Improvements Final EIR, which was certified by the SAFCA Board in November 2007. The modeling showed that the

proposed NLIP improvements by themselves would not significantly increase any of the identified water surface elevations in the river channels comprising the SRFCP. Moreover, when the NLIP improvements are analyzed as part of the larger 200-year flood protection program for the Sacramento area, including modifications to Folsom Dam, the result is a lowering of water surface elevations for the 100-year and 200-year floods along the lower Sacramento River for most of the reach adjacent to the Natomas Basin. On this basis, SAFCA has concluded that the NLIP improvements would not cause any significant hydraulic impacts.

2. SRFCP SYSTEM BACKGROUND

The perimeter levee system around the Natomas Basin is part of a larger integrated system of levees, dams, and bypass channels comprising the SRFCP (Figure 1). This system encompasses six historic flood basins in the Sacramento Valley (Butte, Colusa, Sutter, Feather, Yolo, and American Flood Basins) and the sub-basins contained therein. Planning, design, and construction of the SRFCP has been ongoing since the early 1900s under the leadership of the USACE and the State of California (State), with local levee and reclamation districts playing a principal role in operating and maintaining the system.

The SRFCP levees were set close to the river channel in order to improve navigation by having the rivers scour hydraulic mining sediments. The design of the system assumed no levee failures, but included five engineered diversions and one natural overflow diversion. The natural diversion is to Butte Basin, which is at the head of the SRFCP levees. This diversion did not include flowage easements because the Butte Basin is a historic flood basin. The five engineered diversions include two additional diversions to Butte Basin (Moulton and Colusa Weirs), one diversion to the Sutter Bypass (Tisdale Weir), and two diversions to the Yolo Bypass (Fremont and Sacramento Weirs). All of the engineered diversions included the acquisition of property rights to support the diversions. The deliberate planning, construction, and maintenance of the diversions ensured that they would function during flood conditions and serve as reliable features of the flood project.

Initially, the river channel and bypass levees in each segment of the system were constructed based on a standard geometry. The levees were designed with a predetermined freeboard allowance tied to specified flows and associated water surface elevations, generally matched to the 1907 and 1909 floods, adjusted for loss of floodplain storage by construction of the SRFCP. Over time, the standard levee section was increased because of numerous levee failures. The minimum standard levee changed from a levee with a top width of 10 feet to one with a top width of 20 feet. In addition, the design flows were modified substantially on the Feather and American Rivers. This was the result of floods that occurred after 1909, which demonstrated these rivers could produce substantially greater flows than occurred during the 1907 and 1909 floods. Because numerous levee failures occurred along the Feather River levees between 1920 and 1934, these levees were set back and enlarged to accommodate greater flows. These changes were summarized in memorandums issued by the USACE which define the minimum freeboard requirements for each segment of the SRFCP, collectively referred to as the "USACE 1957 Profile." Over the years, the capability of the SRFCP to provide higher levels of flood protection was greatly expanded by the construction of five major multiple-purpose reservoirs

(Shasta, Black Butte, Oroville, New Bullards Bar, and Folsom Reservoirs), containing 2.7 million acre-feet of flood control storage space.

The record floods of 1986 and 1997 triggered additional system modifications. Although these floods were significantly larger than the 1907 and 1909 floods, the availability of reservoir storage largely prevented flows in the system from exceeding the design of the SRFCP. Nevertheless, numerous project levees experienced unexpectedly severe stress and some failed. This experience caused the USACE, the State, and their local partners to perform a series of geotechnical evaluations on the SRFCP levees and to adopt new, more rigorous levee design standards, including updated standards for seepage through and under project levees. To meet these standards, USACE, the State, and local flood control agencies have made substantial investments in addressing identified deficiencies in levees throughout the SRFCP and in improving the level of flood protection provided by the levees, particularly in urban areas. Federal, State and local support for these levee improvements has been secured under several federally authorized projects, including the Sacramento Urban Levee Reconstruction Project, the American River Watershed Investigation, the West Sacramento Levee Improvement Project, and the Yuba River Basin Project. In the aftermath of the flooding of New Orleans, these authorized projects are being expanded to support an even broader scope of urban levee improvement activity.

The evolution of these urban levee improvements is occurring within a SRFCP management framework that has historically allowed necessary adaptations to the system without undermining its basic operational principles. These principles may be summarized as follows. First, the SRFCP is not intended to provide a uniform level of flood protection (statistical probability of flooding) to the various sub-basins within the protected area. Rather, each sub-basin is protected by levees that are required to at least meet the SRFCP minimum geometrical standards, including freeboard reflecting the water surface profile prescribed for that segment of the system. Second, each sub-basin's flood protection is dependent on the fitness of its own levees and not on the condition (or failure) of any other sub-basin's levees. Accordingly, each sub-basin has the right to keep its levees in the fittest possible condition to ensure that these levees will perform as reliably as possible in a flood. This right ensures the orderly operation and maintenance of the system since even the most modest levee work has the potential to trigger a "transfer of risk" from one sub-basin to another, at least in theory; and there are no data or modeling tools available to quantify such transfers of risk, assess their significance, or determine how they might be mitigated. Third, for this reason, the administration of the SRFCP has historically relied on "change in design water surface elevation" as the guideline for evaluating the effects of any proposed levee work.

The strictest scrutiny is given to levee work involving physical changes in the geometry of the river channel since these changes have the most potential to alter water surface elevations prescribed by the SRFCP design water surface profiles (SRFCP 1957 profiles). This work includes placement of fill or construction of structures in the floodway, construction of new levees, relocation of existing levees, excavation within the floodway, construction of large berms for protecting riverbanks, raising an existing levee, construction of a new bypass, and planting of vegetation within the floodway. Landside levee work of the type proposed as part of the NLIP, such as placing a cutoff wall in a levee, adding a seepage berm to a levee, placing a field of

seepage relief wells along a levee, raising a levee, widening a levee (increased top width), and relocating a seepage ditch, is also strictly scrutinized; but is not likely to cause impacts.

The standard procedure for this evaluation is to use hydrologic and hydraulic computer modeling tools such as, HEC-1, HEC-2, UNET, HEC-RAS, RMA2, FESWMS, etc. The analysis consists of calibrating the hydraulic model to historic flood events using high-water marks and stream gage data. The calibration activity is normally conducted on a system-wide basis instead of a site-specific basis. However, data available for computer model calibration can be sparse or nonexistent. In addition, assumptions must be made regarding reservoir operations. Because all of the reservoirs that contribute to the operation of the SRFCP (Shasta, Black Butte, Oroville, New Bullards Bar and Folsom) are governed by water control manuals issued by USACE, current reservoir operations are assumed to continue except where it is reasonably foreseeable that the current operation would change. Examples of such changes are at the Folsom Dam and Reservoir: where Congress has directed USACE to formalize the variable space storage operation that has been in effect by agreement between SAFCA and the U.S. Bureau of Reclamation since 1995; and where water control structures are being modified as part of the Folsom Dam Joint Federal Project.

3. APPROACH TO MODELING ANALYSIS

As discussed above, in order to evaluate the hydraulic impacts of the levee alterations proposed as part of the NLIP, MBK used a UNET hydraulic computer model calibrated to historic flood events using high-water marks and stream gage data gathered in connection with the 1997 Flood. The UNET model is a one-dimensional, unsteady flow hydraulic model. It characterizes the hydraulic capacity of the system by use of channel and bypass cross-sections, most of which are positioned every ¼ mile throughout the system. Figure 2 displays the geographical extent of the UNET model. Figure 3 provides the UNET model river mile stationing around the Natomas Basin. Results of the model calibration are shown in Figures 4 through 7.

The hydraulic impacts of the levee alterations proposed as part of the NLIP were evaluated based on the potential of the proposed levee alterations to increase one or more of the SRFCP's recognized design water surface elevations: (1) the SRFCP 1957 water surface profiles that serve as the minimum design standard for the SRFCP; (2) the 100-year flood elevations that govern management of SRFCP protected floodplains under the National Flood Insurance Program (33 CFR. 65.10); and (3) the 200-year water surface elevations that are likely to govern implementation of floodplain management standards recently adopted by the State Legislature (Statutes of 2008, Chapter 364 [adding Water Code Section 9602(i)]). In addition, SAFCA has provided information on the project impacts to the 500-year flood elevation. This flood represents an extreme flood event and is the largest flood event for which hydrologic input data has been developed for the hydraulic simulation model.

The modeling runs compare the "Existing", "Without Project" and "With Project" conditions under each of the above flood scenarios. The Existing Condition analysis provides an evaluation of the levee and reservoir system as it exists in December 2009. The Without Project condition assumes implementation of federally authorized improvements to Folsom Dam and anticipated

improvements to the levees protecting existing urban areas outside the Natomas Basin (American River Basin, West Sacramento, Yuba Basin, and Sutter Basin) so as to provide these areas with 200-year flood protection. The With Project condition adds the improvements proposed as part of the NLIP to the Without Project condition. The NLIP improvements consist of levee raises on the Sacramento River, Natomas Cross Canal, PGCC, and NEMDC in the locations shown in Figure 3. The magnitude of the levee raise is shown in the levee profile plots provided in Figures 8 through 11. All fill related to the levee raises would occur on the landside of the levees with the exception of an approximately one mile reach of the Natomas Cross Canal where some waterside fill would be required. Figure 12 shows a typical section showing the waterside fill. The low spots in the PGCC levee at Howsley Road and Sankey Road (see Figure 10) are not raised and are assumed to retain their existing configurations in the With Project condition. The levee raising that is part of the Phase 4B EIS/EIR is located on the PGCC and NEMDC, as shown in Figures 3, 10 and 11. The with project condition also includes shaded riverine aquatic habitat mitigation on the Sacramento River from river mile 79.2 to river mile 77.75, erosion repair and rock bank protection at three locations on the PGCC and two locations on the NEMDC, and low flow channel realignment in the NEMDC at Interstate 80. The shaded riverine aquatic habitat mitigation, which consists of increased bank vegetation, was modeled by increasing the bank Manning's n roughness coefficient from 0.045 to 0.10. The PGCC erosion repair was not included in the hydraulic model since it is in an area that is controlled by backwater from the Sacramento River during large flood events; and therefore, would not affect the peak flood stages on the PGCC. The NEMDC erosion repair sites, which include rock berms along the low flow channel, were modeled by modifying the affected cross-sections as shown in Figures 13 and 14. The low flow channel realignment was not included in the hydraulic model since it would not change the cross-sectional area of the NEMDC; and therefore, would not affect the hydraulic capacity of the NEMDC.

In order to compare these conditions, assumptions about the performance of SRFCP levees under flow conditions that exceed the design of the levee system are necessary for the 100-year, 200-year, and 500-year floods. At the request of the USACE, the hydraulic impact analysis assumed that levees would overtop without failing. For comparison purposes, an additional analysis was completed to show impacts with the assumption that levee failures would occur if water reaches the top of levee. The assumptions supporting these modeling scenarios are summarized in Table 1.

Table 1. Definition of Model Assumptions for Various Conditions			
Condition	**Top of Levee Assumption**	**Levee Failure Assumption**	**Reservoir Ops Assumption**
Existing	Existing top of levee grade December 2009 (including California Levee Database information)	Levees overtop without failing.	Existing reservoirs and current (2009) operation criteria
Without Project	Same as Existing with the following changes. Urban area levees outside the Natomas Basin are assumed to have levees at 200-year water surface + 3 feet of freeboard. NLIP levees same as Existing Condition.	Levees overtop without failing.	Same as Existing except Folsom Dam will be operated in accordance with the Joint Federal Project currently under construction
With Project	Same as Without Project except NLIP levees raised to design level	Levees overtop without failing.	Same as Without Project
Sensitivity Analysis - Existing	Same as Existing	Levees fail when water reaches top of levee.	Same as Existing
Sensitivity Analysis - Without Project	Same as Without Project	Levees fail when water reaches top of levee.	Same as Without Project
Sensitivity Analysis - With Project	Same as With Project	Levees fail when water reaches top of levee.	Same as Without Project

As noted above, the Without Project condition assumes that urban areas (outside the Natomas Basin) will be provided with 200-year protection. This is the most likely near term future condition of the levee system based on the information currently available. This condition is reasonable based on California voters' November 2006 approval of a bond measure that would provide over $3 billion for urban levee improvements in the Central Valley. Additionally, in September 2007, the State Legislature enacted the Central Valley Flood Protection Act of 2008 (Act), Water Code Section 9600 et seq., which was signed into law by the governor in October 2007. The Act is based on the following findings:

- The Central Valley of California is experiencing unprecedented development, resulting in the conversion of historically agricultural lands and communities to densely populated residential and urban centers.

- The legislature recognizes that by their nature, levees, which are earthen embankments typically founded on fluvial deposits, cannot offer complete protection from flooding, but can decrease the frequency of flooding.

- The legislature recognizes that the level of flood protection afforded rural and agricultural lands by the original flood control system would not be adequate to protect those lands if they are developed for urban uses, and that a dichotomous system of flood protection for urban and rural lands has developed through many years of practice.

- The legislature further recognizes that levees built to reclaim and protect agricultural land may be inadequate to protect urban development unless those levees are significantly improved.

- Cities and counties rely upon federal floodplain information when approving developments, but the information available is often out of date and the flood risk may be greater than that indicated using available federal information.

- The legislature recognizes that the current federal (FEMA) flood standard is not sufficient for urban and urbanizing areas within flood prone areas throughout the Central Valley.

  (Statutes of 2007, Chapter 364, Section 9.)

Based on these findings, the Act embraces a new flood protection standard for urban areas (defined as "developed areas in which there are 10,000 residents or more") located in levee-protected floodplains in the Central Valley. This new "urban level of flood protection" is defined as "the level of protection that is necessary to withstand flooding that has a 1-in-200 chance of occurring in any given year using criteria consistent with, or developed by, the Department of Water Resources." (Statutes of 2007, Chapter 364 [adding Water Code Section 9602(i)]).

4. RESULTS OF MODELING ANALYSIS

The flood routings described herein indicate that under the Existing condition, all SRFCP levees would contain the SRFCP 1957 design flood profile. The 100-year flood would overtop some non-urban levees, but this flood would be contained by all urban levees under the Existing condition. The 200-year flood would generate multiple levee overtopping locations in several non-urban areas under both the Existing and Without Project conditions and along the Lower American River under the Existing condition. However, this flood would be effectively contained under both the Existing and Without Project conditions by all existing urban levees outside the American River basin, including the levees around the Natomas Basin. The 500-year flood would cause massive levee overtopping affecting all segments of the system under the Existing and Without Project conditions. Only West Sacramento and the Natomas Basin would avoid overtopping under these conditions with upstream levee failures. Table 2 provides a summary of the extent of levee overtopping in the Without Project condition simulations.

Table 2. Extent of Levee Overtopping, Without Project Conditions, Levees Overtop Without Failing (all values approximate)

River	Leveed Length (miles)	Approximate Length of Overtopped Levee (miles)					
		Left Bank [a]			Right Bank [a]		
		100-yr	200-yr	500-yr	100-yr	200-yr	500-yr
American River	13	0	0	5.1	0	0	7.8
Feather River	50	0	0	5.9	0	0	7.5

Wadsworth Canal	4	0	0	0	1.6	1.9	2.9
Yolo Bypass	37	0	0.3	2.3	0	0	0

[a] Left and right bank reference based on downstream facing orientation.

Tables 3, 4 and 5 summarize the computed maximum water surface elevations at several locations in and around the project area for the Existing, Without Project, and With Project conditions for the 100-year, 200-year and 500-year flood events, respectively, for the levee overtop without failure condition.

Computed water surface elevation profiles for each of the key flow conditions in the project area (Sacramento River channel downstream of the Fremont Weir) are shown in Figures 15 through 30. Figures 15 through 18 show the relationship between the 1957 design and the height of the levees for the Sacramento River, Natomas Cross Canal, PGCC, and NEMDC, respectively. Figure 15 also shows the locations in which the non-urban Sacramento River west levee would be raised to meet the minimum freeboard requirements of the SRFCP 1957 design standard under the sensitivity analysis. Figures 19 through 22 show the profile of the current 100-year flood. Figures 23 through 26 show the profile of the 200-year design condition (no levee failure) flood. Figures 23 through 26 also show the likely 200-year water surface profile assuming upstream levee failures in non-urban areas. Figure 23 shows that the current height of the Sacramento River east levee along the Natomas Basin is essentially at the same elevation as the 200-year (no levee failure) design water surface profile and considerably higher than the likely water surface profile assuming upstream levee failures. It also shows the extent to which the Sacramento River west levee across from Natomas would be overtopped in a 200-year flood. Figures 27 through 30 show the profiles for the 500-year flood with upstream levee failures. The 500-year (with levee failures) water surface elevation in the Sacramento River channel is lower throughout the most critical portion of this reach than the 200-year (no levee failure) design water surface elevation. As reflected in Figures 27 through 30, under the likely assumption that upstream levees will fail when water reaches the top of the levee, the water surface elevations around Natomas would be dramatically lower than the 200-year (no levee failure) profile that was used for design of NLIP. This 200-year levee design condition thus represents a worst-case scenario for the Sacramento River and the Natomas Cross Canal, and underscores the high

degree of protection against Natomas Basin levee overtopping that would be provided by the design of the NLIP improvements.

5. SUPPORT OF IMPACT ANALYSIS METHODOLOGY

California Legislature

Consistent with its approval of a new more rigorous standard for urban flood protection, the State Legislature also approved "the project features necessary to provide a 200-year level of flood protection along the American and Sacramento Rivers and within the Natomas Basin as described in the final engineer's report dated April 19, 2007, adopted by the Sacramento Area Flood Control Agency." (Statutes of 2007, Chapter 641 [amending Water Code Section 12670.14(b)]). Moreover, in connection with this approval, the legislature adopted the following findings and declarations (Statutes of 2007, Chapter 641, Section 1[k]):

> *As evidenced by the environmental impact reports certified in connection with these projects, including the hydrology and hydraulics impact analysis set forth in the environmental impact report prepared by the Sacramento Area Flood Control Agency with regard to local funding mechanisms for comprehensive flood control improvements for the Sacramento area dated February 2007, the increase in flood protection associated with improving the American and Sacramento River levees and modifying Folsom Dam will be accomplished without altering or otherwise impairing the design flows and water surface elevations prescribed as part of the Sacramento River Flood Control Project. Accordingly, these improvements will not result in significant adverse hydraulic impacts to the lands protected by the Sacramento River Flood Control Project. Thus, it is not necessary or appropriate to require these projects to include hydraulic mitigation.*
>
> *The projects authorized in Section 12670.14 of the Water Code will increase the ability of the existing flood control system in the lower Sacramento Valley to protect heavily urbanized areas within the City of Sacramento and the Counties of Sacramento and Sutter against very rare floods without altering the design flows and water surface elevations prescribed as part of the Sacramento River Flood Control Project or impairing the capacity of other segments of the Sacramento River Flood Control Project to contain these design flows and to maintain water surface elevations. Accordingly, the projects authorized in that section will not result in significant adverse hydraulic impacts to the lands protected by the Sacramento River Flood Control Project and neither the Reclamation Board nor any other state agency shall require the authorized projects to include hydraulic mitigation for these protected lands.*

Although these findings are not legally binding, they indicate the legislature's concurrence with SAFCA's approach to analyzing hydraulic impacts. Congressional authorization for raising and strengthening a twelve-mile reach of the Sacramento River east levee in the 1996 Water Resources Development Act ("WRDA"), and for raising and strengthening all five-plus miles of the NCC south levee in the 1999 WRDA, without in either case requiring hydraulic mitigation, offers additional indirect legislative support for SAFCA's approach.

USACE HQ

USACE has been using a risk-based analysis for economic evaluation for some time and has been moving to a risk-based analysis for system performance, largely for certification of levees for FEMA. However, in his memo dated *August 2, 2007, Subject: Section 408 Approval of a Flood Control Project Alteration - Sacramento River Flood Control Project, Feather and Yuba Rivers, California* (copy enclosed), Deputy Director of Civil Works Steven L. Stockton indicated that the discussion of flood protection in terms such as 100-year or 200-year level of protection is acceptable to comply with NEPA and other environmental statues. However, a risk-based analysis as required by ER 1105-2-100 and ER 1105-2-101 will be needed to determine the terms of any eventual Section 104 reimbursement. SAFCA has prepared and submitted a risk-based analysis to USACE as part of the 408 Summary Report for Phase 3.

6. NLIP COORDINATION WITH REGIONAL IMPROVEMENTS

SAFCA's approach to providing an urban standard of flood protection to the Natomas Basin is being replicated in the other urbanizing sub-basins in the lower Sacramento Valley (West Sacramento, Marysville extending south to Reclamation District 784, and Yuba City). However, these improvements are intended to complement rather than substitute for pursuing improvements on a regional scale that would improve the flow of water through the Yolo and Sacramento Bypass systems and lower water surface elevations throughout the lower Sacramento Valley. In 2002 through 2003, SAFCA made substantial investments in hydraulic studies and analyses of the improvements that would be required to move more flood water into and through the Yolo Bypass during large flood events in the Sacramento-Feather River watershed to reduce flows and water surface elevations in the Sacramento River channel downstream of the Fremont weir. The Lower Sacramento River Regional Project Initial Report (SAFCA 2003) indicated that this could be accomplished by widening the Fremont weir; setting back the levees on the east side of the Yolo Bypass; discharging flood flows into the Sacramento Deep Water Ship Channel; and eliminating low, restricted elevation levees at the lower end of the Yolo Bypass. However, these improvements would be extremely costly and time consuming to implement; they would occur entirely outside SAFCA's jurisdiction; and would require extraordinary cooperation among affected federal, state, and local interests; and they would not resolve the seepage problems affecting the Sacramento River east levee and the Natomas Cross Canal south levee adjacent to the Natomas Basin. For these reasons, SAFCA concluded that this alternative would not achieve the objectives of the NLIP; and therefore, it was not carried forward for further analysis.

On a long-term basis; however, regionally oriented improvements to the Yolo and Sacramento Bypass systems may help to address potential changes in hydrology due to climate change and may reduce the risk of uncontrolled flooding on a system-wide basis. Although this flooding is most likely to occur in lightly populated agricultural areas, reducing its frequency by increasing the conveyance capacity of the SRFCP would avoid the cost of repairing and reconstructing damaged levees and other public infrastructure and would increase public support for the "dichotomous system of flood protection for urban and rural lands" that exists in the Sacramento Valley. Early implementation of the NLIP, as well as early implementation of proposed

improvements to SRFCP levees protecting other urban areas, would not preclude any of the alternatives contemplated for the update of the Central Valley Flood Protection Plan.

7. CONCLUSION

Raising and strengthening portions the federal project levee system protecting the Natomas Basin in Sacramento and Sutter Counties as proposed by SAFCA would not result in any significant, adverse hydraulic impacts to other sub-basins protected as part of the SRFCP. Furthermore, these improvements would be consistent with the principles that have guided the management of the SRFCP over the past century and with the policies adopted by the State Legislature calling for an immediate and comprehensive effort to increase the level of flood protection provided to Sacramento and the other urban areas within the SRFCP. The NLIP improvements would also be consistent with the direction given by Congress when it approved raising and strengthening 12 miles of the Sacramento River east levee (WRDA 1996) and 5.3 miles of the Natomas Cross Canal south levee (WRDA 1999).

Memorandum

Date:	July 9, 2009
To:	Liz Holland, USACE, Karen McCartney and Madelyn Martinez, NMFS
From:	Chris Fitzer, EDAW/AECOM
Subject:	Shaded River Aquatic Habitat Mitigation Memo for SAFCA NLIP Phase 2 and 3 Projects
Distribution:	Peter Buck, SAFCA, Mike Eng, Steve Chainey, Debra Bishop, EDAW/AECOM

1 INTRODUCTION

Sacramento Area Flood Control Agency's (SAFCA) Natomas Levee Improvement Project (NLIP) will include, as part of the levee improvement construction, improvements to pumping plants and construction of drainage outfalls along the waterside of the Sacramento River east levee. Construction of these features necessitates the removal, and thus temporary and permanent impact of shaded riverine aquatic (SRA) along the Sacramento River. SAFCA has prepared a conceptual mitigation plan for the impacts to SRA. SRA mitigation will compensate for the loss of habitat for special-status fish and their prey along the Sacramento River.

Estimated losses of shaded riverine aquatic habitat from the Phase 2 and 3 SAFCA NLIP Projects will be mitigated for by the creation of SRA habitat along the waterside of the Sacramento River east levee. SRA habitat is the nearshore aquatic habitat occurring at the interface between a river and adjacent woody riparian habitat. The principal attributes of this cover type are: (1) an adjacent bank composed of natural substrates supporting riparian vegetation that either overhangs or protrudes into the water; and (2) water that contains variable amounts of submerged vegetation or woody debris, such as leaves, logs, branches, and roots and has variable depths, velocities, and currents. Riparian habitat provides structure and food for fish species including those that are state and/or federally listed. Shade decreases water temperatures in the river, while low overhanging branches can provide sources of food for fish by attracting terrestrial insects. As riparian areas mature and deteriorate, the leaves and branches fall into the river, creating structurally complex habitat consisting of in-stream woody material (IWM) that furnishes refugia for fish from predators, creates variable water velocities at a micro-scale used by a range of life stages, and provides habitat for fish and aquatic invertebrates.

SRA habitat creation will include the planting of native trees and shrubs on the waterside of the Sacramento River east levee in areas where there is currently no or limited canopy cover. As the trees mature, they will overhang the river, providing SRA habitat and associated functions. Replacement of SRA habitat that has been lost, primarily through anthropogenic causes, will result in more contiguous SRA habitat along the Sacramento River thereby improving the conditions for special-status fish that use this segment of the Sacramento River.

2 Mitigation Planning and Design

2.1 Mitigation Plan Summary

The SRA habitat mitigation site is located in Reach 1 along the Sacramento River east levee north of the areas where SRA habitat will be affected by the Phase 2 and 3 SAFCA NLIP Project (Phase 2 and 3 Project; Exhibit 1). SRA mitigation includes creating approximately 2.69 acres of SRA habitat. Creating approximately 2.69 acres of SRA habitat on the waterside of the Sacramento River east levee (Garden Highway levee) will provide compensatory mitigation for the loss of 1.89 acres of SRA habitat on the waterside of the Sacramento River east levee. The loss of SRA habitat on the Sacramento River east levee would result from the removal of riparian trees and shrubs on the waterside of the levee necessary for levee improvements in the Phase 2 and 3 Projects including: Pumping Plant No. 2 outfall reconstruction; modifications to Prichard and Elkhorn pumping plant infrastructure; and the construction of surface drain outlets to accommodate the rise of the adjacent levee (1.39 acres). Mitigation is also being conducted for the estimated loss of 0.5 acres of SRA from the construction of surface drain outlets in the Phase 2 SAFCA NLIP Project (Phase 2 Project). Estimates for SRA habitat impacts are considered conservatively high based on preliminary design plans. NMFS has determined that the trees and shrubs on the waterside of the NCC levee do not provide SRA habitat functions because the physical and hydrologic conditions associated with the NCC channel do not provide habitat value for federally listed fish species.

The creation of SRA habitat will compensate for losses through plantings along a segment of riverbank slope (the area from the waterline to the hinge of the levee terrace) and levee terrace (the bench from 10’ waterside of the levee toe to the hinge of the riverbank slope) along the existing Sacramento River east levee adjacent to the Sacramento River. Following mitigation, this segment of river bank will provide more contiguous habitat for listed fish species that use the Sacramento River for rearing and as a migration corridor.

2.2 Mitigation Description

The SRA mitigation site will be created on the waterside of the Sacramento River east levee (Reach 1) from approximately 0.4 mile south of Sankey Road to approximately 0.7 mile north of Riego Road. (Exhibit 1) The Assessor’s Parcel Numbers (APN) included in the mitigation site are 35-020-010, 35-020-014, 35-020-006, 35-020-005, 35-030-012, and the waterside portions of 35-020-019 and 35-030-008.

Portions of the mitigation site are currently sparsely vegetated with riparian trees and shrubs as well as a primarily nonnative herbaceous understory. Other areas are currently completely unvegetated, with large gaps in the continuity of the riparian forest corridor. SRA habitat creation will be focused in areas along the riverbank slope and the levee terrace where riparian vegetation does not currently exist (see Exhibits 2a, 2b, and 3). The existing USACE mitigation site shown in 2a is not part of the mitigation plan and will be avoided.

Portions of the riverbank slope at the mitigation site without SRA canopy cover will be planted with trees, shrubs, and willow cuttings. Depending upon site-specific conditions, this may include localized planting within riprap (angular rocks approximately 8–16 inches in diameter) and placement of soil. In areas of the riverbank slope where there is a layer of soil covering the riprap, willow cuttings will be planted in the spaces between the riprap (Exhibit 2a, “Willow Cuttings”). The portions of the levee terrace without riparian cover will be planted with native trees, shrubs, and herbaceous species. Prior to planting, areas will be treated with an approved broad-leaved selective herbicide (i.e., Milestone VM) to reduce the growth of invasive plants. An approximate 10-foot-wide portion of the levee terrace adjacent to toe of the levee (base of the slope from Garden Highway to the levee terrace) will remain unplanted to avoid an existing maintenance road.

2.3 Characteristics of Design Reference Site

Through modifications to the banks of the Sacramento River, including the construction of the Sacramento River east levee and the development of land on the riverbank, the natural riparian vegetation along the Sacramento River has been altered or lost in many places. There is, however, an approximately 1-mile segment of riverbank along the waterside of the east levee that is densely vegetated and serves as a reference site for the SRA mitigation area (see Exhibit 4). The reference site is located between the Sacramento/Sutter County line and the RD 1000 Pumping Plant No. 2 (near Prichard Lake Road) in Reaches 4a through 4b (see Exhibits 1 and 4). The reference site provides fairly uninterrupted canopy cover for the entire area on the waterside of the levee. This reference site was selected for the higher quality/quantity of SRA habitat that currently exist at this site compared to the mitigation site (e.g., amount of shade, cover, habitat, and botanical complexity), the similarity in constraints to the mitigation site (e.g., riverbank modified into a levee and resulting disconnected floodplain), and the proximity to the mitigation site. Because the existing maintenance road bisecting the mitigation site will need to be maintained, once plantings have matured, the canopy on the levee terrace portion of the mitigation site is expected to provide less cover than the reference site.

2.4 Compensation Ratios

The Phase 3 Project is conservatively estimated to impact approximately 1.39 acres of SRA habitat along the Sacramento River east levee. Phase 3 Project impacts would result from reconstruction of the Pumping Plant No. 2 outfall, modifications to Prichard and Elkhorn pumping plants, and the construction of new surface drainage outlets. There is also a conservative estimate of 0.5 acres of impacts on SRA habitat along the Sacramento River east levee from the construction of new surface drainage outlets in the Phase 2 Project.

The total impact area of 1.89 acres is a conservative estimate based on preliminary design plans and may be reduced in the future through additional impact avoidance and minimization efforts. Furthermore, some of the areas disturbed by Phases 2 and 3 Project construction will be replanted with native riparian vegetation, and a portion of the surrounding area that does not have riparian cover (trees and shrubs) may be enhanced with additional plantings providing SRA habitat. Detailed construction design plans will provide more information to enable the determination of how much of each impact/construction site will be available for planting or replanting following construction. This is anticipated to further reduce the estimated permanent area of impacts to SRA habitat from the Phase 2 and 3 Projects. The resource agencies will be immediately notified of any changes in the impact acreage calculations.

The NMFS requires a 1:1 compensation ratio for in-kind SRA mitigation, and a 3:1 compensation ratio for non-in-kind SRA mitigation. That is, impacts below the ordinary high-water mark (OHWM) must be mitigated at a 1:1 ratio with habitat created below the OHWM or at a 3:1 ratio with SRA habitat created above the OHWM; impacts above the OHWM can be mitigated at a 1:1 ratio with in-kind habitat created above the OHWM. NMFS determined that for the purpose of identifying impacts and mitigation requirements for the NLIP Project, the levee terrace hinge (location of the change in angle from the levee terrace to the riverbank slope) would serve as a surrogate for the OHWM.

The acreage of SRA impacts and mitigation below and above the OHWM is summarized in Table 1. The total amount of mitigation is estimated to be approximately 0.8 acre greater than what is required to mitigate the loss of SRA habitat in the Phase 2 and 3 Projects. This additional SRA acreage may be used to offset SRA impacts that may occur in other project phases, upon resource agency approval.

Table 1 **Impact and Mitigation Acreages for Shaded Riverine Aquatic Habitat**		
Impacted Area	Impacted SRA (acres)	Mitigation Area (acres)
Above OHWM	1.68	1.59 (Levee Terrace)
Below OHWM	0.21	0.9 (Levee Slope)
Total	**1.89**	**2.69**
Source: Data compiled by EDAW in 2009		

3 Implementation Plan

3.1 Resource Protection Measures

Best Management Practices for SRA Habitat Creation
The following measures shall be implemented to avoid and minimize potential adverse effects on water quality:

- All work within the existing floodway (i.e., waterside) of the Sacramento River shall not take place during the designated flood season (i.e., November 1 to April 15) and shall not begin until evaluation of upstream conditions (e.g., reservoir storage and snowpack) indicate that inundation of these areas is unlikely to occur.

- All local, state, and federal regulations and environmental requirements regarding turbidity-reduction measures shall be complied with, including the following: obtain and comply with relevant agency permits (e.g., DFG Streambed Alteration Agreement, Central Valley Regional Water Quality Control Board (CVRWQCB) Clean Water Act Section 401 Certification, Section 404 permit); develop and implement a storm water pollution prevention plan (SWPPP) that identifies specific best management practices (BMPs) to avoid and minimize impacts on water quality during construction activities; and comply with the conditions of the National Pollutant Discharge Elimination System (NPDES) general stormwater permit for construction activity. SAFCA shall file a notice of intent to discharge stormwater with the State Water Resources Control Board (SWRCB) prior to initiating construction activities. The SWPPP shall provide detailed construction timelines and a BMP monitoring and maintenance schedule. Standard erosion control measures shall be designed to reduce the potential for soil erosion and sedimentation of waterways and drainage channels.

At a minimum, the following specific BMPs are proposed for implementation:

- Conduct all work according to site-specific construction plans that identify areas for clearing, grading, and revegetation so that ground disturbance is minimized;

- Avoid native riparian and wetland vegetation wherever possible and identify vegetation to be retained for habitat maintenance (i.e., as identified through preconstruction biological surveys), cover cleared areas with mulches, install silt fences near riparian areas or waterways to control erosion and trap sediment, and reseed cleared areas with native vegetation;

- Stockpiling of construction materials, including portable equipment, vehicles and supplies, including chemicals, shall be restricted to the designated construction staging areas, exclusive of any riparian or wetland areas;

- All litter, debris, unused materials, equipment, and supplies shall be removed daily from any areas below the OHWM and deposited at an appropriate disposal or storage site;

- Stabilize disturbed soils of construction areas before the onset of the winter rainfall season;
- Stabilize and protect stockpiles from exposure to erosion and flooding.

The SWPPP also shall specify appropriate hazardous materials handling, storage, and spill response practices to reduce the possibility of adverse impacts from use or accidental spills or releases of contaminants. Specific measures applicable to the project include, but are not limited to, the following:

- SAFCA's contractors shall comply with all applicable SWRCB and CVRWQCB standards and other applicable water quality standards;
- Develop and implement strict on-site handling rules to keep construction and maintenance materials out of drainages and waterways;
- Conduct all refueling and servicing of equipment on the landside of the levee and with absorbent material or drip pans underneath to contain spilled fuel. Collect any fluid drained from machinery during servicing in leak-proof containers and deliver to an appropriate disposal or recycling facility;
- Maintain controlled construction staging, site entrance, concrete washout, and fueling areas on the landside of the levees or at least 100 feet away from waterways or wetlands to minimize accidental spills and runoff of contaminants in stormwater; and
- Maintain spill cleanup equipment in proper working condition. Clean up all spills immediately according to the spill prevention and response plan, and immediately (within 24 hours) notify NMFS, USFWS, DFG, and the CVRWQCB of any spills and cleanup procedures. Report all such spills, and the success of the efforts to clean them, in post-construction compliance reports.

The following measures shall be implemented to avoid and minimize potential direct adverse effects to special-status fish species:

- A worker awareness training program shall be conducted for construction crews before the start of construction activities. The program shall include a brief overview of sensitive fisheries and aquatic resources (including riparian habitats) on the project site, measures to minimize impacts on those resources, and conditions of relevant regulatory permits.
- Although no in-water work is projected, any in-water construction activities that occur shall be conducted during months when special-status fish species/sensitive life stages are least likely to be present or less susceptible to disturbance (e.g., July 1 to October 31). If any in-water work is to be conducted, a qualified biologist or resource specialist shall be present during such work to monitor construction activities and ensure compliance with mitigation requirements and terms and conditions of permits issued by regulatory agencies.

The following measure shall be implemented to avoid and minimize potential direct adverse effects to SRA:

- SAFCA would ensure that all construction activities located on the waterside of the Sacramento River east levee and/or NEMDC west levee, including clearing, pruning, and trimming of riparian vegetation, and/or removal of large woody debris (LWD) (especially vegetation and LWD that provides SRA habitat functions), are supervised by a qualified biologist to ensure these activities result in minimal loss of this vegetation/habitat types. All sensitive SRA habitats that are not specified to be affected by the proposed project would be identified and fenced off using orange construction fencing or similar materials. Sensitive SRA habitat information shall be incorporated

into project bid specifications along with a requirement for contractors to avoid these sensitive habitats. Any SRA habitat (including riparian vegetation and LWD) that is lost or disturbed as a result of project construction activities shall be restored, replaced, or rehabilitated on a no-net-loss basis using the specified compensations ratios (above).

3.2 Mitigation Design

Site preparation (particularly for the levee terrace) may include mowing to control invasive and noxious plants, clearing of invasive and noxious brush and trees, disking soil, and applying broadleaf selective herbicide to invasive and noxious plants. No off-site soil disposal is anticipated, with the exception of a small amount of surface soils with root fragments of rhizomatous invasive plants. A location for disposal of these soils has not been determined, but the soils will be disposed of at a location and in a manner to avoid any impacts on sensitive resources.

The SRA mitigation site will include the planting of native riparian trees, shrubs, and herbaceous species. Within the SRA mitigation site, the areas that will be planted vary depending on the characteristics of their unique locations and substrate characteristics (see Exhibits 2a and 2b). In general, three areas will be planted: (1) the levee terrace, (2) the riverbank slope, and (3) willow cuttings on the soil-covered riverbank slope (see Exhibit 3). The plantings will include native trees, shrubs, and herbaceous species suitable to the riparian zone and adapted to a range of inundation frequencies and durations. Tables 2 and 3 below include the plant species, sizes, typical spacing, and seed quantities that will be used for the three planting areas.

Table 2
Tree and Shrub Species Chosen for Planting the Three Regions of the SRA Mitigation Site

Region	Botanical Name	Common Name	Plant Size	Plant Spacing
Terrace Planting	*Acer negundo*	Boxelder	Treepot4	10 ft on center
	Populus fremonti	Cottonwood	Deepot	10 ft on center
	Quercus lobata	Valley oak	Treepot4	10 ft on center
	Baccharis glutinosa	Mule-fat	Deepot	10 ft on center
	Rosa california	California wild rose	Treeband	10 ft on center
	Artemesia douglasiana	Mugwort	Treeband	5 ft on center
	Carex barbarae	Santa Barbara sedge	Treeband	5 ft on center
	Clematis lasiantha	Pipestem clematis	Treeband	5 ft on center
	Rubus ursinus	California blackberry	Treeband	5 ft on center
Exposed Riprap Slope Planting	*Populus fremonti*	Cottonwood	Deepot	5 ft on center
	Salix gooddingii	Black willow	Deepot	5 ft on center
	Salix lasiolepis	Arroyo willow	Deepot	5 ft on center
Willow Cuttings (soil-covered slope)	*Salix gooddingii*	Black willow	Cutting	5 ft on center

Table 3
Herbaceous Species Chosen for the Seed Mix for the Terrace of the SRA Mitigation Site

Botanical Name	Common Name	Application Rate (lbs/acre)	Seeding Rate (PLS*/acre)
Artemesia douglasiana	*Mugwort*	5	72
Bromus carinatus	*California brome*	5	72
Carex barbarae	*Santa Barbara sedge*	5	72
Elymus glaucus	*Blue wildrye*	5	72
Leymus triticoides	*Creeping wildrye*	5	72

Notes: * Pure live seed (PLS) = (% germination X % purity)/100
Source: Data compiled by EDAW in 2009

The levee terrace will be planted with treepot, treeband, and deepot containers (Table 2) as well as seed mix for native grass and herbaceous species (Table 3). The majority of the riverbank slope consists of exposed 8- to 16-inch riprap. This region will be planted with deepot cottonwoods and willows (Table 2). The area of the riverbank slope that consists of riprap covered by roughly 12 inches of soil will be planted with willow cuttings in the spaces between the riprap. Additional soil may be added to aid in the establishment and proliferation of the cuttings.

All plant material will be obtained from reputable nurseries. The nurseries will include those that specialize in native revegetation material propagated from local genetic stock from within 200 miles of the Phase 2 and 3 Projects unless otherwise approved by a qualified ecologist.

3.3 Maintenance during Establishment Period

Table 4 presents the maintenance schedule for SRA; further details are provided below.

Table 4
Maintenance Schedule

Activity	Frequency
Site inspection	Inspect monthly during the first 6 months, then a minimum of twice per year for 3 years or until success criteria are met.
Weed Control	Spot spray one or two times per year during the spring and late summer as needed until year 3 success criteria are met.
Debris removal	Remove excessive thatch buildup, as needed for fire safety.

Source: Data compiled by EDAW in 2009

Maintenance activities within the SRA mitigation area will be conducted with the primary goal of ensuring the survival of all planted trees and shrubs and a native-plant understory. Weed control is crucial for achieving these goals; weeds must be controlled during the first 3 years so that they do not compete with planted or seeded native species. Weed control will continue for up to 3 years as needed or until success criteria are met (if longer than 3 years).

Weeds will be controlled through mechanical (e.g., string trimming, hand pulling) and chemical (selective herbicide registered for use near water) means, depending on site-specific variables (e.g., weed species size and invasiveness, topography, proximity to water's edge). All planted areas will be inspected twice per year, in the spring and summer/fall, and treated as necessary.

All planted areas will be irrigated with bubblers, drips lines, or spray heads. Successful plant establishment will be assured by a 3-year performance-based and legally enforceable contract awarded to a qualified revegetation contractor (see below), and by frequent site inspections by SAFCA of work in progress.

4 Monitoring Plan

4.1 Success Criteria

After the SRA mitigation site has been constructed and planted, a 3-year monitoring program will be conducted to determine the site's progress toward meeting established success criteria. The created habitat will be considered successful when it exhibits the success criteria specified in Table 5 below. A relative canopy cover of 15% at the end of the third year would provide partial SRA coverage. Over time, the trees and shrubs will mature and provide full SRA coverage consisting of a closed canopy and an understory with woody scrub vegetation.

Table 5
Shaded Riverine Aquatic Habitat Success Criteria

Year	Survival of Planted Trees and Shrubs (%)	Relative Canopy Cover (%)
1	85	5
2	85	10
3	80	15

Source: Data compiled by EDAW in 2009

If a success criterion is not met during any monitoring year, replacement plantings or adaptive management techniques will be implemented, and that year's monitoring will be repeated the following year until each success criterion is met without additional intervention. Thus, the success criteria specified in year 3 must be reached without human intervention (e.g., irrigation, replacement planting).

4.2 Monitoring Methods and Schedule

Field assessments of SRA planting areas will be conducted twice per year. The timing of these assessments will be adjusted according to annual site-specific conditions, but assessments will generally occur in the spring and summer/fall. To measure percent survival of trees and shrubs, each plant will be inspected and the species of each live plant will be recorded. Qualitative assessments will be recorded to track the health and vigor of each species for use with adaptively managing the mitigation site.

To determine the success of the SRA plantings as a functioning ecosystem, percent canopy will be estimated each summer/fall by recording the extent of SRA habitat on aerial photographs, or using repeat transects or fixed radius plots at ground level. The timing of these assessments will be adjusted according to annual site-specific conditions, but assessments will generally occur in late summer or early fall while trees are still in full foliage. The results of these assessments will also be used to determine where replanting should occur, if necessary, to maintain sufficient SRA habitat.

Monitoring of SRA habitats will be recorded independently for each type of planted area (i.e., on the riprap slope below the levee terrace, on the soil-covered portion of the riverbank slope, and on the levee terrace) because they have slightly different planting regimes and maintenance needs specific to their unique location/type of planting. All monitoring will occur for 3 years or until the success criteria are met, whichever period is longer.

1.0 Introduction

The Sacramento Area Flood Control Agency (SAFCA) requested that Luhdorff and Scalmanini, Consulting Engineers (LSCE) conduct an investigation of the potential groundwater impacts of levee improvements proposed by SAFCA along portions of the levees surrounding the Natomas Basin. These include the Sacramento River East Levee, the Natomas Cross Canal (NCC) South Levee, the Pleasant Grove Creek Canal (PGCC) West Levee, the Natomas East Main Drainage Canal (NEMDC) and Steelhead Creek West Levee, and the American River North Levee. Most of the proposed levee improvements will have no effect on groundwater, but there are potential effects due to land use changes, slurry cutoff walls, new or relocated canals, and borrow site excavation. LSCE (2008a) prepared a preliminary evaluation on the effects of proposed Sacramento River East Levee slurry cutoff walls in a previous report entitled *Evaluation of Potential Groundwater Impacts Due to Proposed Sacramento River East Levee Improvements with Emphasis on Reaches 2 and 3*. The information in this report updates and supercedes the contents of the previous report.

This report includes detailed water budgets prepared for the Natomas Basin to evaluate the groundwater impacts of all proposed SAFCA construction activities. The water budgets are partially based on the results of two existing numerical groundwater flow models that together simulate the North and South American Subbasins (including the Natomas Basin) in Sutter, Placer, and Sacramento Counties. Water Resources and Information Management Engineering, Inc. (WRIME) updated these models in 2007-2008 to better reflect existing and predicted future land and water use in the Natomas Basin. Some of the groundwater budget results summarized below are based on the 2030 simulations, which are summarized in LSCE (2008b). A groundwater budget for proposed SAFCA construction activities was calculated separately and was used to evaluate the cumulative impacts of these activities on existing and future groundwater conditions in the Natomas Basin and the North American Subbasin.

1.1 Report Revisions

This is a revised version of the report submitted to SAFCA on November 14, 2008. Revisions to this and other reports prepared for the Natomas Levee Improvement Project (NLIP) Phase 3 Project Environmental Impact Report (EIR)/Environmental Impact Statement (EIS) were necessary due to a requirement by the U.S. Army Corps of Engineers (USACE) that all elevations be converted from the NGVD 1929 vertical datum to the NAVD 1988 vertical datum. Revisions based on the datum change were made to one table and 13 figures in the report.

Other changes to the report were made to reflect updated plans for slurry cutoff walls surrounding the Natomas Basin. As of April 2009, planned mitigation for levee seepage calls for additional cutoff walls along a number of reaches the Sacramento River East Levee, the PGCC West Levee, the NEMDC West Levee, and the American River North Levee. However, many of these planned cutoff walls are shallower than those previously proposed.

Changes to the analysis of potential slurry cutoff wall impacts were also necessitated by recent revisions to a groundwater flow model prepared by Kleinfelder, Inc. (Kleinfelder) to estimate seepage beneath the Sacramento River East Levee with and without slurry cutoff walls. That analysis was originally summarized in a report entitled *Evaluation of Cutoff Walls Impact on Groundwater Recharge, Sacramento River East Levee, Natomas Levee Improvement Project, Sacramento and Sutter Counties, California*. (Kleinfelder, December 19, 2007). The revised report is dated April 21, 2009. The analysis of the potential groundwater impacts of slurry cutoff walls in this report is partially based on results of the 2009 Kleinfelder model.

1.2 Project Description

The analysis of groundwater impacts in this report relies on project descriptions for proposed SAFCA construction activities obtained from a variety of sources. These include the Draft and Final EIR for the NLIP prepared by EDAW (2007a and 2007b) and the Draft EIS prepared by USACE (2008). Design and engineering work for most of these projects is still in progress, so assumptions were made about the most likely configuration of each project. In cases where even preliminary project descriptions were not available, a conservative option was selected for analysis. Assumptions about many of these projects were provided primarily via personal communications (pers. comm.) with David Rader of EDAW and Marieke Armstrong of Mead & Hunt (M&H). Other information was provided by Wood Rodgers and the engineering team at Kleinfelder.

1.2.1 Levee Improvements

Groundwater impacts from proposed levee improvements are primarily limited to the potential effects of land use changes and slurry cutoff walls. Slurry cutoff walls and seepage berms are proposed mitigation measures to reduce problems of excess seepage beneath the levees, but no direct groundwater impacts are expected from seepage berms because they would be above the water table. The slurry cutoff walls are intended to reduce seepage beneath the levees, and impacts resulting from this reduction are addressed in this report. The location of the five levees discussed below are shown in **Figure 1-1**. A total of about 29 miles of slurry cutoff walls is currently proposed.

Sacramento River East Levee – Levee improvements will require land use changes, including removal of 20 acres of rice, 175 acres of field crops, and five acres of orchard. Slurry cutoff walls are proposed for 12 reaches (total of 10.1 miles) of the 18.1 mile length of the East Levee. These cutoff walls will range in depth from about 14 to 115 feet, with an average depth of about 65 feet.

Natomas Cross Canal South Levee – Proposed land use changes along the NCC South Levee will require removal of about five acres of rice fields. Slurry cutoff walls are being constructed for the entire length (about 5.4 miles) of the NCC. These cutoff walls are projected to be about 70 feet deep. Approximately 5,400 lineal feet (lf) of cutoff wall was installed in 2007, and another 3,600 lf was planned to be installed in 2008.

Pleasant Grove Creek Canal West Levee – The PGCC West Levee is about 3.3 miles long, and slurry cutoff walls ranging in depth from 20 to 50 feet are currently proposed for about

14,000 lf of the levee. Proposed land use changes along the PGCC West Levee would require removal of about 50 acres of rice fields.

Natomas East Main Drainage Canal West Levee – The NEMDC and Steelhead Creek West Levee is about 13.3 miles long. Improvements to the NEMDC West Levee are in the early planning stages, but slurry cutoff walls are being considered for about 8.7 miles of the levee. The estimated depths of these cutoff walls are range from 30 to 45 feet for the North NEMDC and 30 to 53 feet for the South NEMDC. Land use changes due to NEMDC levee improvements have not been evaluated, but irrigated agriculture is limited to the northern portion of the levee and effects are expected to be minimal.

American River North Levee – The American River North Levee is about 2.2 miles long in the Natomas Basin. Plans for improvements to this levee are in the very early planning stages, but slurry cutoff walls are under consideration for the entire length of the levee. Proposed cutoff walls would have an estimated depths of approximately 35 feet for Reaches 1 and 2 and 80 feet for Reaches 3 and 4. There is no irrigated agriculture in this area to be affected by levee improvements.

1.2.2 Canal Improvements

SAFCA is planning to construct one new canal in the Natomas Basin and relocate or improve three existing canals. This construction will necessitate land use changes, including the loss of irrigated agricultural land. Although seepage from existing canals has not been quantified, it is considered to be a significant contributor to groundwater recharge in the Natomas Basin. The new and relocated canals will be unlined and will result in an overall increase in the rate of canal seepage. The proposed locations of new and existing canals discussed below are shown on **Figure 1-1**.

Giant Garter Snake/Drainage Canal – SAFCA plans to construct a new Giant Garter Snake (GGS) and Drainage Canal east and roughly parallel to the Sacramento River East Levee. The GGS/Drainage Canal will be about 4.4 miles long and 50 feet wide at the waterline, and will be unlined. A total of 45 acres of the land where the GGS/Drainage Canal will be constructed is currently planted to field crops.

West Drainage Canal – The GGS/Drainage Canal begins at the terminus of the West Drainage Canal. A number of improvements to the West Drainage Canal are planned, including rerouting of about 4,700 lf of the existing canal. The overall length of the canal will increase from about 3.6 to 3.9 miles, and the average width at the waterline will increase from 30 to 72 feet.

Elkhorn Canal – The Elkhorn Canal, which is located east of the Sacramento River East Levee and northwest of the Sacramento International Airport (SIA), is about 3.8 miles long and 16 feet wide. SAFCA plans to relocate this canal to make room for levee improvements. The relocated canal will be about 4.2 miles long and 32 feet wide. Approximately one mile of the existing Elkhorn Canal is lined with concrete, and about 6,000 lf of the relocated canal is proposed to be lined. In addition, two sections of the relocated canal (total of about 3,950 lf), primarily through the Teal Bend Golf Course, would be piped.

Riverside Canal – This canal, which is located east of the Sacramento River East Levee in the southwestern corner of the Natomas Basin is about 3.7 miles long and seven feet wide. SAFCA plans to relocate the Riverside Canal to accommodate levee construction, and the new canal would be about 3.9 miles long and ten feet wide.

1.2.3 Borrow Sites

SAFCA will require several borrow sites in the Natomas Basin to obtain sufficient soil for the proposed levee and canal improvements. The locations of these borrow sites are shown on **Figure 1-1**.

Airport North Bufferlands – The Airport North Bufferlands borrow site consists of 737 acres owned by the SIA and located north of the airport. Approximately 630 acres of this site that had previously been planted to rice have recently been removed from rice cultivation or other land uses that would attract water fowl at the request of the Federal Aviation Agency (FAA) and is currently fallow. SAFCA plans to remove about four to six feet of borrow material and restore the site to non-irrigated grassland.

Brookfield Property – The Brookfield property consists of 353 acres at the northern tip of the Natomas Basin. Approximately 325 acres of this property is currently planted to rice, and SAFCA plans to restore it to rice cultivation after removing the borrow material. The current crop mix is about 50% regular rice and 50% wild rice (Jack DeWit, pers. comm., July 8, 2008). Up to six feet of soil will be excavated, including one foot of topsoil that will be stockpiled and replaced after borrow operations are complete. The property is currently irrigated with groundwater, but SAFCA plans to provide the infrastructure so that most of the property can be irrigated with surface water after removal of borrow material. Engineering work is still in progress, but SAFCA estimates that about 80 percent of the property would be irrigated with surface water in the future after reclamation is complete.

Fisherman's Lake – The Fisherman's Lake borrow site is located at the northern end of the existing Fisherman's Lake in the southwestern portion of the Natomas Basin. Engineering work has not been completed for this site, but SAFCA estimates that about 100 acres of land currently planted to rice would be used for borrow material and would be restored to managed marsh.

1.3 Potential Impacts

The purpose of this report is to evaluate the potential groundwater impacts of SAFCA's proposed construction activities. These potential impacts can be grouped into three general categories:

1) Changes in groundwater recharge. These will occur due to land use changes and canal improvements. Specifically, the conversion of land from irrigated to non-irrigated land uses will reduce groundwater recharge, and canal construction and widening will increase groundwater recharge.
2) Changes in groundwater flow. Groundwater flow beneath the levees surrounding the Natomas Basin will be reduced due to the proposed slurry cutoff walls. Reductions in groundwater flow will generally be in the form of:
    a) Reduced groundwater recharge from the Sacramento and American Rivers;
    b) Reduced subsurface inflow from the north beneath the NCC; or

c) Reduced subsurface outflow to the east beneath the PGCC and NEMDC.

3) Changes in groundwater pumping.

Other potential groundwater impacts include:

- Groundwater quality degradation in the Natomas Basin due to reduced inflow of good quality recharge from the River and reduced groundwater outflow; and
- Impacts to the yield of wells located along levees where the cutoff walls would be constructed.

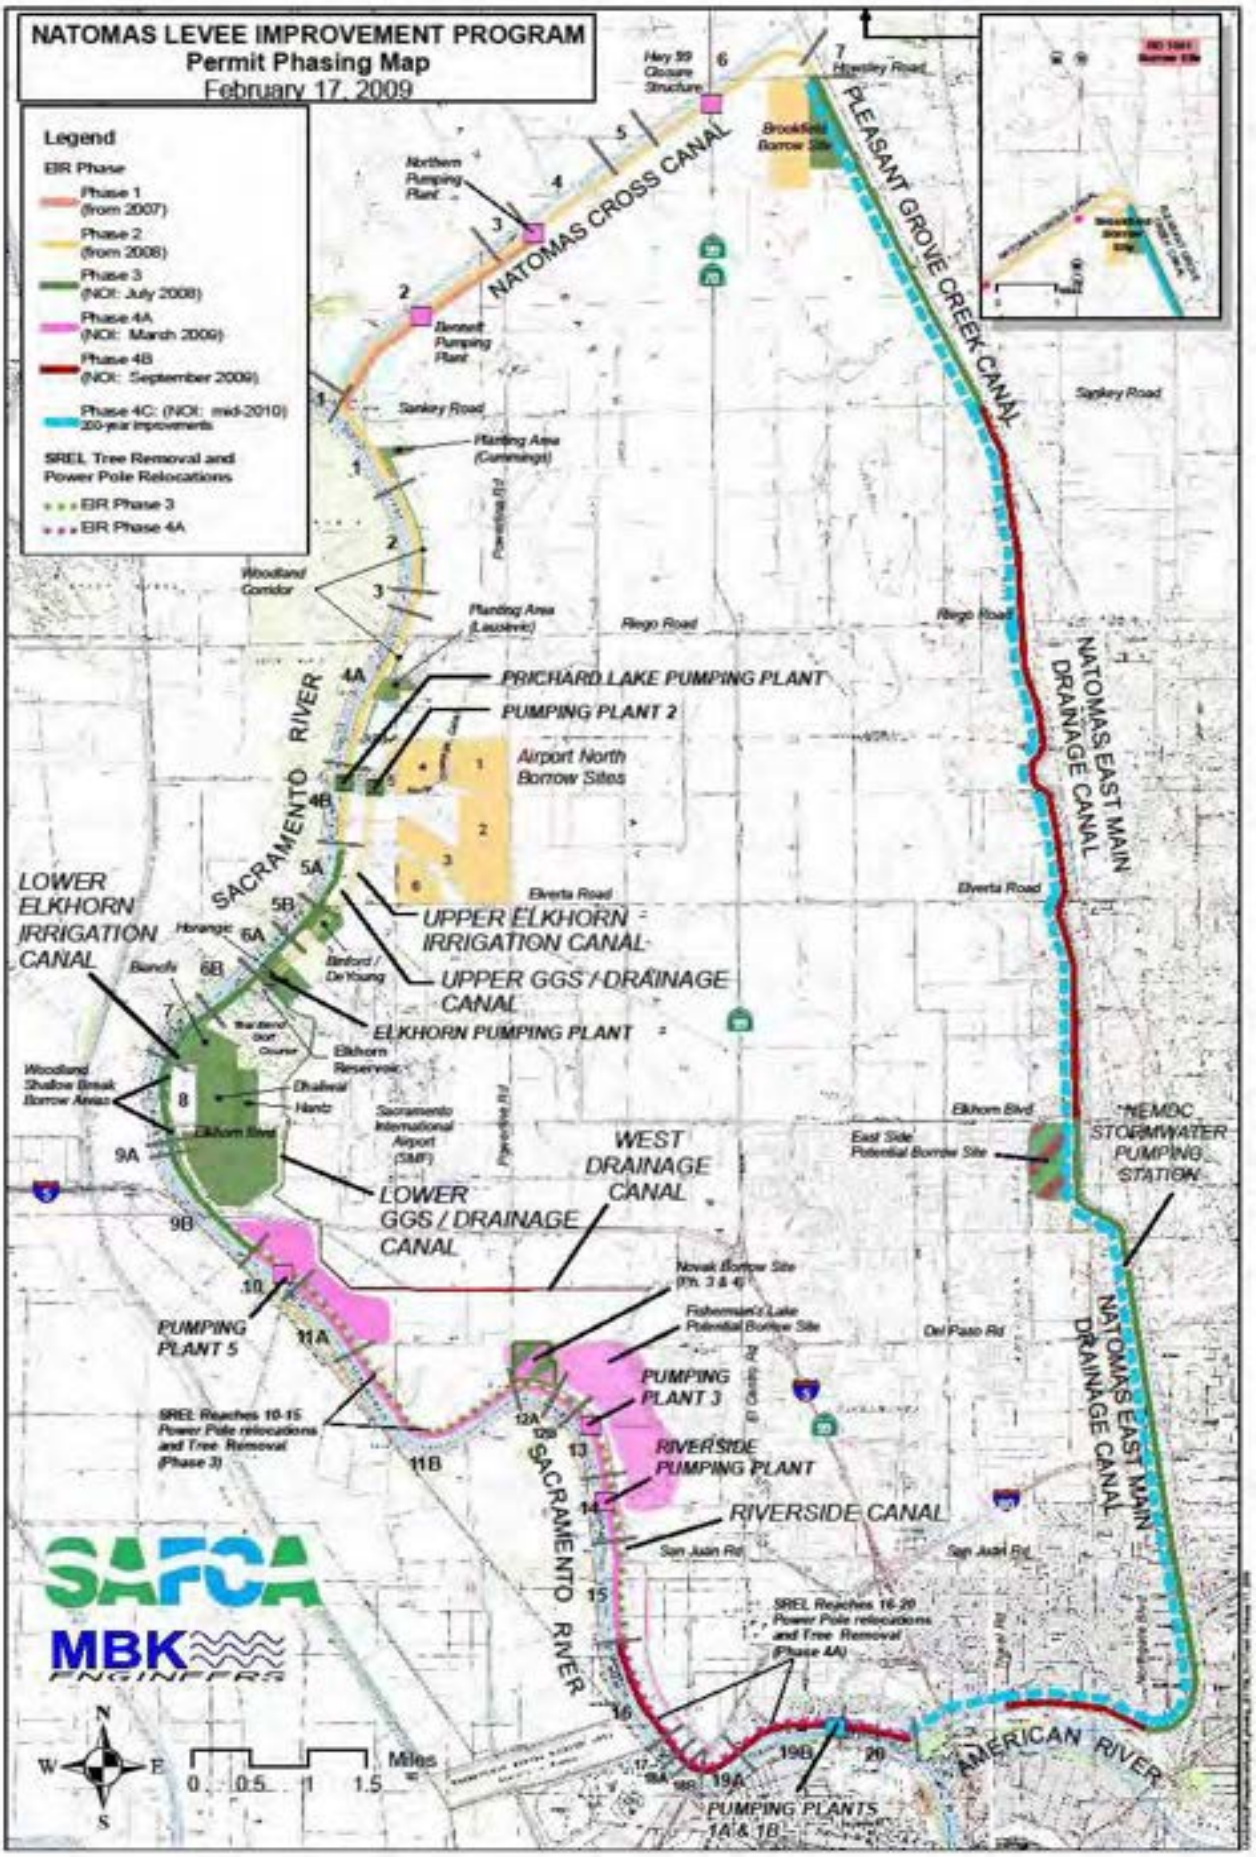

Figure 1-1
Proposed SAFCA Construction Locations
for Natomas Levee Improvement Program

2.0 Hydrogeologic Conditions

2.1 Land Use and Water Supply

The Natomas Basin was used as the primary study area for the water budgets discussed below. As shown on **Figure 1-1**, the Natomas Basin is located on the east side of the Sacramento River, between the rural community of Pleasant Grove and the City of Sacramento, in Sutter and Sacramento counties. It consists of about 54,400 acres of agricultural and urban land surrounded by the Sacramento River on the west, the NCC on the north, the PGCC and the NEMDC on the east, and the American River on the south. Except for the SIA and the Teal Bend Golf Course, urban development in the area is primarily limited to the southeast corner of the Natomas Basin at present. This is expected to change in the future as several large developments are in the planning stages.

The Natomas Basin is surrounded by 42 miles of levees, which are maintained by Reclamation District No. 1000 (RD 1000). RD 1000 also operates and maintains a large drainage system within its boundaries to recirculate or dispose of agricultural and urban runoff. This system includes seven large pumping plants and 180 miles of canals and ditches.

Land use in the Natomas Basin is primarily agricultural, with rice being the primary crop. Approximately 28,700 acres were irrigated in 2004, and rice accounted for about 79 percent of the total. Other crops include alfalfa, clover, and oat hay; tomatoes and sugar beets; and crops such as wheat and safflower that are rotated with rice and tomatoes. Most of the agricultural land is irrigated by surface water diverted from the Sacramento River by Natomas Central Mutual Water Company (NCMWC). Much of the information provided below is based on the NCMWC Draft Groundwater Management Plan (2002) and the Integrated Water Resources Management Plan (American States Water Company, et al., 2006).

NCMWC operates three primary river diversions on the Sacramento River. Water is also diverted at two locations from the NCC. Water diverted from the NCC flows from north to south, while water diverted from the River flows generally from west to east, then south. NCMWC's surface water diversions average about 100,000 acre-feet per year (afy). This includes an estimated 10,000 afy diverted during the fall and winter to reflood fields for rice straw decomposition.

NCMWC completed the installation of a tailwater recirculation system in 1986 so that drainage water can be reused during the irrigation season to improve Sacramento River water quality, reduce river diversions, and increase overall efficiency. The recirculation system recaptures tailwater for re-use either directly to fields or back into the main irrigation canals. In recent years, NCMWC has relied heavily on recycled tailwater to supplement its Sacramento River entitlement. Tailwater is recycled partly because it cannot be discharged back to the Sacramento River due to water quality regulations. During a normal irrigation season, all agricultural drainage water is recirculated during the rice growing season, which typically ends in August.

The NCMWC Draft Groundwater Management Plan contains an estimate of 30,000 afy of recycled tailwater (NCMWC, 2002).

Approximately 3,300 acres of agricultural land are irrigated primarily with groundwater. This includes the entire northeastern portion of the Natomas Basin, which is not served by the existing NCMWC surface water distribution systems. The total groundwater pumpage in the Natomas Basin was estimated to be about 24,500 af in 2004 (LSCE, 2008b). Most of this was agricultural pumpage and included about 18,500 af in Sutter County and 6,000 af in Sacramento County.

The Natomas Basin Conservancy (NBC) currently owns over 4,000 acres of land in the Natomas Basin. The NBC began land acquisitions after completion of the Natomas Basin Habitat Conservation Plan (NBHCP) by the U.S. Fish and Wildlife Service and the California Department of Fish and Game in 1997. The NBHCP specified that lands be acquired for habitat conservation as mitigation for the effects of urban development in the Natomas Basin on endangered species and other wildlife. Under the terms of the NBHCP, NBC will ultimately acquire about 8,750 acres of land to mitigate the loss of approximately 17,500 acres slated for development. Most of the NBC mitigation lands have historically been planted to rice, and NBC plans to keep 50 percent of the lands in rice production and convert 25 percent to managed marsh and another 25 percent to upland habitat. As of 2004, approximately 475 acres had been converted to managed marsh.

Irrigated acreage within the Natomas Basin has decreased in recent years as more land has been converted to urban uses. Land use estimates indicate that the acreage irrigated with surface water decreased by about 4.7 percent per year between 1996 and 2006 (American States Water Company, et al., 2006). NCMWC land use data indicate that the amount of irrigated shareholder lands decreased by about 5.2 percent per year between 2004 and 2007.

2.2 Groundwater Basin and Subbasin Description

The Natomas Basin does not represent a groundwater basin or subbasin as defined by the California Department of Water Resources (DWR). It is located within the North American Subbasin, which is part of the Sacramento Valley Groundwater Basin. The North American Subbasin is located along the eastern edge of the Sacramento River Valley and encompasses about 351,000 acres in Sutter, Placer, and Sacramento counties. The North American Subbasin is bounded by the Bear River on the north, the Feather and Sacramento Rivers on the west, the American River on the south, and the approximate edge of the alluvial aquifer in the Sierra Nevada foothills on the east. The North American Subbasin and adjacent groundwater subbasins are shown on **Figure 2-1**.

2.3 Geology of the Natomas Basin

Prior to development, groundwater in the northern portion of the North American Subbasin flowed to the west and southwest from the Sierra Nevada toward the Feather and Sacramento Rivers. Most wells in the subbasin pump groundwater from either the volcanic Mehrten Formation or the overlying alluvial deposits, which have a westerly dip toward the axis of the valley. The following summary of geologic conditions in the Natomas Basin is based primarily

on the *Feasibility Report, American Basin Conjunctive Use Project* (DWR, 1997). This summary focuses on the shallow aquifers that could potentially be impacted by the proposed slurry cutoff walls.

The thickness of the fresh water-bearing deposits in the Natomas Basin increases from about 1,100 feet in the northeast to over 2,000 feet in the southwest. These deposits can be divided into upper and lower aquifer systems. The division between the two aquifer systems is inexact due to data limitations and the difficulty in accurately determining formation contacts. DWR (1997) indicates that the upper aquifer system consists of saturated Laguna Formation and younger sediments that collectively extend to a depth of 200 to 300 feet. For purposes of this study, the upper zone is defined as the upper 300 feet of the aquifer system, and the lower zone is assumed to extend from a depth of 300 feet to the base of fresh water.

The upper aquifer system in the Natomas Basin generally appears to be unconfined or semi-confined due to the presence of clay and silt confining layers within and underlying the upper zone. Sands and gravels in the upper zone are generally thin and laterally discontinuous, and there are thick sequences of fine-grained strata between the more permeable aquifer materials.

The youngest geologic units in the Natomas Basin are flood basin deposits and alluvium. Laterally extensive exposures generally occur along the western margin, adjacent to and within the active channels of the Sacramento River. The flood basin deposits are predominantly fine-grained sediments that have accumulated in flood basins along the major rivers of the Sacramento Valley. The flood basin deposits consist primarily of silt and clay, which yield little water to wells. The flood basin deposits also contain local lenses of sand and gravel deposited by the migrating ancestral river channels. These lenses have high permeabilities and can yield large quantities of groundwater to wells. The thickness of the flood basin deposits in the subbasin ranges up to 100 feet (Olmstead and Davis, 1961).

The alluvium consists primarily of sand, gravel, and silt, with minor amounts of clay, deposited in Recent geologic time (last 10,000 years) by the Sacramento River. Although the alluvium is highly permeable, it is too thin to represent a significant groundwater source. Most high-yield wells completed in the recent alluvium also draw groundwater from underlying formations.

Underlying the alluvium, the Riverbank and Modesto formations of Pleistocene age consist of a heterogeneous mixture of silt, sand, gravel, and clay. The units exhibit large variability in grain size over short distances, both laterally and vertically. The maximum combined thickness of the two units is 50 to 75 feet in the subbasin. On average, these units have moderate permeability but contain some coarser zones with high permeability (Olmstead and Davis, 1961).

The Laguna Formation of Pliocene age and the Turlock Lake Formation of early Pleistocene-age underlie the Riverbank and Modesto formations. Both formations consist primarily of a heterogeneous mixture of interbedded silt, clay, and sand. They contain a few gravel lenses, which are poorly sorted and have relatively low permeability. In general, these two formations are more fine-grained than overlying units, although it is difficult to determine subsurface contacts from drillers' logs. Wells completed in clean Laguna Formation sands and gravels can

produce significant quantities of groundwater. The combined thickness of the two units in the subbasin is probably less than 200 feet.

The lower aquifer system consists of non-marine, Mehrten Formation deposits and includes a smaller percentage of coarse-grained sediments. However, individual coarse-grained zones in the lower aquifer are typically thicker than in the upper aquifer. In some areas, the lower aquifer is further divided into two distinct units. The upper unit is comprised of gray to black andesitic sand and associated lenses of stream gravel containing andesitic cobbles and boulders interbedded with thicker blue or brown clay. The lower unit has been described as a dense, hard, gray tuff breccia. It is composed of angular pieces and blocks of andesite in a cemented matrix of andesite, devitrified lapilli, and ash derived from volcanic eruptions in the Sierra Nevada. Based on information from DWR monitoring wells, the Mehrten Formation is at least 900 feet thick near the Sacramento Airport, and the typical lower unit gray tuff does not occur at that location. The lower zone exhibits more confinement than the upper zone but is still considered to be semi-confined. There is a delayed response to imposed stresses in the upper aquifer, indicating hydraulic interconnection between these water-bearing strata.

2.4 Aquifer Hydraulic Conductivity

The ability of an aquifer to transmit water is measured by its hydraulic conductivity (which is closely related to permeability) and saturated thickness; the product of these two parameters is commonly known as aquifer transmissivity. The hydraulic conductivity of alluvial aquifer materials varies over many orders of magnitude, with fine-grained materials (clay and silt) at the bottom of the range and coarse-grained materials (sand and gravel) at the top. Most groundwater flow occurs through sand units, which are much more common in the subsurface than gravels. The hydraulic conductivity of sands is highly variable, depending on grain size, sorting, and cementation.

Long-term, constant-rate pumping tests are the preferred method for estimating hydraulic conductivity and other aquifer properties. Other field methods include short-term pumping tests and slug tests. If borehole logs are available, equations that estimate hydraulic conductivity based on grain-size distribution can be used in the absence of test data. The most common of these is the Kozeny-Carman equation (Kozeny, 1927 and Carman, 1937 and 1956) which has been used by Kleinfelder and URS Corporation (URS) to estimate the hydraulic conductivity of geologic materials beneath the east levee.

As further discussed below, the hydraulic conductivity of sand units underlying the levees is a primary input and the source of greatest uncertainty for models used to estimate seepage beneath the levees. A summary of hydraulic conductivity estimates for the Natomas Basin is provided in **Table 2-1**. The estimates vary by more than an order of magnitude, from 14 to 488 feet per day (ft/day), with a mean of 116 ft/day and a median of 51 ft/day. Values at the low end of the range were estimated by Kleinfelder using the Kozeny-Carman equation, and the highest value was estimated from a short-term pumping test. LSCE estimated a hydraulic conductivity of 36 ft/day based on an aquifer test conducted in the Paulson well in southern Sutter County (LSCE, 2008b).

Groundwater flow models that encompass the North American Subbasin also have relatively high hydraulic conductivities in the Natomas Basin. Hydraulic conductivity estimates used in

numerical groundwater flow models are typically adjusted during the calibration process. A groundwater flow model of the Sacramento Valley developed by DWR (1978) used hydraulic conductivity estimates of 51 to 139 ft/day for the upper layer of the model in the Natomas Basin. The groundwater models discussed in Chapter 4 have hydraulic conductivities in the upper layer ranging from 33 to 118 ft/day in the Natomas Basin.

Table 2-1
Hydraulic Conductivity Estimates in Natomas Basin

Estimated By	Location	Hydraulic Conductivity (ft/day)	Material Type	Source
Kleinfelder (2007)[1]	-	14	Sand with 3-7% silt	Kozeny-Carman equation
	-	28	Sand with 0-2% silt	Kozeny-Carman equation
URS (2007)[2]	STA 217+00	56	Sand to silty-sand	Kozeny-Carman equation
		283	Gravel	Kozeny-Carman equation
LSCE	Bianchi Wells 1 and 2	33-49	Sand to silty-sand	Estimated from specific capacity
	Lennar Westlake Well 1	488	Fine to coarse sand with gravel	2-hour pump test (11/21/00) in well perforated 112-132 ft.
	Lennar Paulson Well	36	Sand to silty-sand	36-hour pump test (7/3/07) in well perforated 185-397 ft.

3.0 Groundwater Levels and Flow

3.1 Sacramento River East Levee Piezometers

DWR has conducted groundwater level monitoring at a number of wells in the Natomas Basin since 1948. DWR monitored approximately 20 wells in 2003 but only 7 wells in 2007. In addition to the wells monitored by DWR, a series of shallow piezometers was constructed along the Sacramento River East Levee in the Natomas Basin to collect groundwater level data for previous investigations of seepage beneath the levee. A total of 38 piezometers has been installed along the levee since 1991, and at least some groundwater level data are available for 27 of these. Groundwater elevations measured in these piezometers have been plotted in order to determine the location and seasonal fluctuations of gaining and losing reaches along the Sacramento River East Levee. The 27 piezometers with water level data include four installed by Kleinfelder in 1998, 13 installed by USACE in 2001, and ten installed by Kleinfelder in 2004. The construction of the piezometers is summarized in **Table 3-1**, and the piezometer locations are shown on **Figure 3-1**. The piezometers range in depth from 12 to 90 feet, but most are between 25 and 50 feet deep. Many of the piezometers are paired based either on depth (shallow vs. deep) or location (closer to the River vs. further away). The latter pairings are particularly useful to show the direction and magnitude of the hydraulic gradient near the River.

Water level measurements at the piezometers have been intermittent, resulting in varying periods of record for water level data between 1999 and 2007. Data from the USACE piezometers are the most useful because the wellhead elevations have been surveyed and manual water level measurements are available. The USACE piezometers have a period of record from January 2002 to October 2003.

The Kleinfelder piezometers were not surveyed at the time of installation, and those installed in 1998 have a short period of record (December 2005 to April 2006). The piezometers installed by Kleinfelder in 2001 have a longer period of record (October 2004 to July 2006). There are no manual measurements available for these piezometers, however, and some of the transducer data are questionable as discussed below. The Kleinfelder piezometers were surveyed by LSCE on February 28 and 29, 2008 using survey-grade Global Positioning System (GPS) equipment with a vertical accuracy of at least one inch. The survey results are shown in **Table 3-1**. No bollards were installed to protect these piezometers, and two of them (PZ-4 and PZ-7) had been destroyed (apparently by farm equipment) by the time of the survey.

Data from the shallow levee piezometers were combined with other water level data to prepare contour maps of equal groundwater elevation for the North American Subbasin and more detailed maps for the Natomas Basin. The contour maps were prepared prior to the GPS survey of the Kleinfelder piezometers; therefore, data from these piezometers were not used to create the contour maps. Hydrographs were also prepared showing groundwater elevations in 23 piezometers and estimated stage in the Sacramento River adjacent to the piezometers. These contour maps and hydrographs were used to evaluate gaining and losing conditions along the

Sacramento River and to estimate the hydraulic gradient between the River and the shallow aquifer.

3.2 Groundwater Elevation Contour Maps

Groundwater elevations and flow directions in the study area are illustrated on groundwater elevation contour maps. DWR (1997) includes spring water level contour maps for the years 1950, 1960, 1965, 1970, 1977, 1980, 1985, 1990, and 1992. As noted by DWR, groundwater generally flowed in a southwesterly direction (from the foothills toward the axis of the valley) under pre-development conditions. Groundwater levels began to decline during the 1940s (or earlier), and the 1960 water level contour map shows three pumping depressions. From north to south, these were located east of Nicolaus, near Pleasant Grove, and near the eastern edge of the Natomas Basin along the Sutter-Sacramento County line. By 1965, the pumping depression east of Nicolaus had largely disappeared, but the pumping depression near Pleasant Grove had deepened and merged with that along the eastern edge of the Natomas Basin. The 1980 DWR contour map shown on **Figure 3-2** indicates that, by 1980, the pumping depression southeast of Pleasant Grove had deepened to about –30 feet msl and merged with a deeper pumping depression beneath McClellan Air Force Base (AFB) in Sacramento County. These pumping depressions are centered about three miles east of the eastern edge of the Natomas Basin. Note that elevations shown on **Figures 3-2** and **3-3** are based on the NGVD 1929 vertical datum. These are copies of historical water level contour maps that cannot be converted to a newer datum. All other elevations in this report are based on the NAVD 1988 datum.

A fall 1997 groundwater elevation contour map for all of Sacramento County prepared by the Sacramento County Water Resources Division and reproduced in NCMWC (2002) is shown on **Figure 3-3**. This contour map indicates that the McClellan AFB pumping depression was linked with two other pumping depressions centered beneath the City of Elk Grove and east of the City of Galt. The Elk Grove pumping depression is the largest and deepest of the three, with a groundwater elevation below –70 feet msl at the center. The Pleasant Grove and McClellan AFB pumping depressions are located in the North American Subbasin; the other two depressions are located in the South American Subbasin.

The DWR and Sacramento County groundwater elevation contour maps were developed using data from wells of variable and often unknown perforated intervals. These composite maps must be considered approximations that do not reflect the fact that groundwater elevations can be significantly different in wells of different depths. Hydrographs of DWR's multiple-completion monitoring wells show that deeper wells in the area typically have lower groundwater elevations than shallower wells because most groundwater pumping occurs from deeper zones, which are more confined. Upper zone groundwater elevation contour maps were prepared for this study, as discussed below.

Water level data for wells completed in the upper zone in the North American Subbasin were evaluated to select recent periods with sufficient data for contouring purposes. Because the primary focus of this investigation is on groundwater flow in the Natomas Basin, contour maps were prepared for periods for which data from the USACE levee piezometers (the only piezometers with surveyed wellhead elevations prior to 2008) were available, and spring and fall

contour maps were prepared for 2003. Two versions of the 2003 contour maps were created, one showing the entire subbasin and another showing a more detailed view of the Natomas Basin. Data from about 90 wells were used to prepare each map. The subbasin-scale groundwater elevation contour maps have a contour interval of ten feet; the more detailed maps have a two-foot contour interval. The periods selected for groundwater elevation contour maps, area of coverage, and the number of wells used for each map are as follows:

- **Figure 3-4:** Spring 2003 (North American Subbasin),
- **Figure 3-5**: Spring 2003 (Natomas Basin),
- **Figure 3-6**: Fall 2003 (North American Subbasin),
- **Figure 3-7**: Fall 2003 (Natomas Basin).

The spring 2003 groundwater elevation contour map for the North American Subbasin (**Figure 3-4**) shows that the direction of groundwater flow in the upper zone in most of the subbasin is toward the pumping depression centered in the McClellan AFB area, which had a minimum elevation of about –40 feet msl based on data from McClellan AFB monitoring wells. The northeastern portion of the subbasin is the only area where the groundwater flow direction was not toward the McClellan AFB pumping depression on **Figure 3-4**. The direction of groundwater flow in the northeastern area is toward the Bear and Feather Rivers, which indicates that both rivers were gaining in the spring of 2003. A gaining reach occurs when groundwater levels are higher than the river stage, creating a gradient for groundwater to flow to the river. Losing conditions occur when the river stage is higher than groundwater levels adjacent to the river, which results in recharge from the River to the aquifer.

The Sacramento River west of the Natomas Basin appeared to be a losing reach in spring 2003. Groundwater elevations shown on **Figure 3-4** range from about 20 feet msl in the northern and northwestern portions of the Natomas Basin to about –15 feet msl in the southeastern corner. The direction of groundwater flow was easterly toward the McClellan AFB pumping depression. The hydraulic gradient was relatively flat especially in the northern half of the study area (about three ft/mile) but became much steeper along the eastern edge (up to 20 ft/mile).

In order to provide additional detail on groundwater elevations and flow directions in the Natomas Basin, the spring 2003 water level data were re-contoured with a contour interval of two feet. The resulting map, shown on **Figure 3-5**, confirms that the direction of groundwater flow was easterly across most of the Natomas Basin. All reaches of the Sacramento River appeared to be losing in the spring of 2003, but the magnitude of the hydraulic gradient near the River gradually increases from north to south. In the northern portion of the Natomas Basin, the hydraulic gradient for flow away from the River was less than three ft/mile. In the southern portion, the easterly hydraulic gradient increased to about nine ft/mile.

The fall 2003 groundwater elevation contour map shown on **Figure 3-6** is generally similar to the spring 2003 map, and the direction of groundwater flow was essentially the same during both periods. Comparison of the two contour maps indicates that fall groundwater levels along the Sacramento River were five to ten feet lower than in the spring, but levels at these two times were similar in the eastern portion of the Natomas Basin. Fall 2003 groundwater levels were

also similar to spring levels in the McClellan AFB pumping depression but were about ten feet lower than in the spring in the pumping depression in southwestern Placer County.

Figure 3-7 shows fall 2003 groundwater levels in the Natomas Basin re-contoured with a contour interval of two feet. Although groundwater levels in fall 2003 were lower along the Sacramento River than in the spring, the general direction of groundwater flow was still easterly in most of the study area. The only exception is the northern portion of the Natomas Basin where the direction of groundwater flow was to the south-southwest parallel to the Sacramento River. These reaches of the River appear to be neutral (no significant gain or loss) in fall 2003. Losing conditions prevailed in the southern reaches, but the gradient for flow away from the River was less steep than in the spring.

3.3 Hydrographs of Groundwater Levels and River Stage

Water level hydrographs were prepared for the shallow piezometers along the Sacramento River East Levee in order to evaluate seasonal variations in gaining and losing conditions. In addition to groundwater elevation data from the levee piezometers, river stage estimates are also shown on the hydrographs. Under separate contract for SAFCA, MBK Engineers (MBK) used stage data from the Verona, Bryte, and I Street gages (**Figure 3-8**) to estimate the daily average stage at each piezometer location based on a linear interpolation (Mike Archer, MBK, pers. comm., January 22, 2008). One source of error in the stage estimates is that tidal effects at the Bryte and I Street gages do not propagate upstream to the Verona gage. However, MBK checked the estimates against stage profiles simulated with a calibrated Hydrologic Engineering Center (HEC) surface water model, and concluded that the stage estimates were reasonable.

Hydrographs of groundwater elevations in the shallow piezometers and estimated Sacramento river stage are shown from north to south on **Figures 3-9** through **3-16**. Where piezometers are paired based on distance from the River, data from both piezometers are plotted on the same hydrograph using different symbols. As discussed above, losing conditions occur when groundwater elevations are lower than river stage. For the paired piezometers, a gradient away from the River indicates losing conditions, while a gradient toward the River indicates gaining conditions. The groundwater level data are color coded on the hydrographs, with data showing losing conditions plotted in red and data showing gaining conditions plotted in blue. For the piezometers with surveyed elevations, stage estimates can also be compared with measured groundwater elevations to indicate gaining or losing conditions at unpaired piezometer locations. The groundwater level data plotted on these hydrographs are also color coded to show gaining or losing conditions. Uncertainty in the data is highlighted by the fact that a number of hydrographs show gaining conditions in the spring and fall of 2003 even in the southern half of the Natomas Basin, while the groundwater elevation contour map (**Figure 3-8**) shows losing conditions in this area.

During the winter when the river stage is high, all hydrographs show losing conditions and steep gradients for groundwater flow away from the River. The results are much more variable during the rest of the year when the river stage is lower. Hydraulic gradients are relatively flat during periods of low stage, and gradient reversals appear to be common. Gaining conditions are most likely to occur during the summer and fall when the river stage is lowest. There is more

uncertainty about the determination of gaining or losing conditions during the summer and fall because groundwater levels and river stage are similar during these periods. There is also uncertainty during periods of rapidly declining stage because groundwater levels decline at a slower rate than river stage. Continuous data would be needed during these periods to accurately determine the fluctuations between gaining and losing conditions.

Gaining and losing reaches vary by both location and time. URS (2003) indicated that river stage was approximately nine to ten feet above groundwater levels at high stage and one to three feet below groundwater levels at low stage at the northernmost USACE piezometer (2F-01-15N). At the southernmost USACE piezometer (2F-01-19S), river stage was approximately four to five feet above groundwater levels at high stage and one to 1.5 feet below groundwater levels at low stage. For USACE paired piezometers 2F-01-26N and 28N, URS noted that groundwater levels were about 1.25 feet higher in the piezometer closer to the River during high stage and generally similar during low stage. For paired piezometers 2F-01-68N and 69N, URS indicated that groundwater levels were about three feet higher in the piezometer closer to the River during high stage and generally similar during low stage. URS also noted that groundwater levels tended to lag river stage by several days (URS, 2003). The individual hydrographs are discussed below.

Figure 3-9 shows hydrographs of the northernmost piezometers. This includes USACE piezometer 2F-01-15N in Reach 2 and paired Kleinfelder piezometers PZ-7 and PZ-8 in Reach 4a. The hydrograph of 2F-01-15N shows losing conditions during periods of high stage in the winter and spring and gaining conditions during the rest of the year. This is the deepest of the levee piezometers with a screened interval of 80 to 90 feet. This makes the comparison with river stage less valid, but there are no nearby shallow piezometers to show the head difference between shallow and deeper zones. Paired piezometers PZ-7 and PZ-8 show losing conditions during a limited period of record (intermittent from October 13, 2004 to July 12, 2006). The fact that the groundwater elevations were notably lower than the stage estimates for all periods suggests inaccuracies in either the stage estimates, the wellhead elevation, or the water level measurements. The indication of consistently losing conditions should be considered questionable since most other piezometers show a mix of gaining and losing conditions.

Figure 3-10 shows hydrographs of paired USACE piezometers 2F-01-26N and 28N in Reach 4b and paired Kleinfelder piezometers PZ-5D and PZ-6D in Reach 6b. Both piezometer pairs show generally losing conditions during the winter and spring and consistently gaining conditions during the summer and fall. The continuous transducer data from the Kleinfelder piezometers clearly show losing conditions at high stage and gaining conditions at low stage during the winter and spring. This effect is especially noticeable from December 2004 to May 2005 but also occurred during the winter and spring of 2005-2006.

Figure 3-11 show hydrographs of unpaired USACE piezometers 2F-01-51N in Reach 8 and 2F-01-49N in Reach 9a, and **Figure 3-12** show hydrographs of unpaired USACE piezometers 2F-01-56N in Reach 9b and 2F-01-62N in Reach 11b. Compared against estimated river stage, all four piezometers show mostly losing conditions except during periods of rapidly fluctuating stage in the spring and periods of very low stage during the fall. The spring of 2003 was the longest period of gaining conditions during the 22-month period of record.

Figure 3-13 shows hydrographs of paired Kleinfelder PZ-3 and PZ-4 and USACE piezometers 2F-01-68N and 69N in Reach 11b. Piezometers PZ-3 and PZ-4 show losing conditions based on groundwater level data during the entire period of record (October 13, 2004 to October 7, 2006). As for piezometers PZ-7 and PZ-8, the fact that the groundwater elevations were notably lower than the stage estimates for all periods suggests inaccuracies in either the stage estimates, the wellhead elevation, or the water level measurements. The indication of consistently losing conditions should be considered questionable since most other piezometers show a mix of gaining and losing conditions. The data from paired USACE piezometers 2F-01-68N and 69N in Reach 11b are more similar to piezometers in other reaches, with losing conditions occurring during periods of high stage and a mixture of gaining and losing conditions during the rest of the year. Gaining conditions occurred primarily in the spring of 2002 and during periods of lowest stage.

Figure 3-14 shows hydrographs of unpaired USACE piezometers 2F-01-05S in Reach 13 and 2F-01-15S in Reach 15 compared with estimated stage. Most of the data from 2F-01-05S appear to be questionable, with low groundwater levels in the spring and higher levels during the summer, especially in 2002. The data from USACE piezometer 2F-01-15S in Reach 13 track the estimated stage much more closely, but the estimated stage appears to be low relative to the groundwater levels. In particular, the indication of gaining conditions during almost all of 2002 is probably incorrect. The stage estimates appear to be more accurate from December 2002 through October 2003, with losing conditions during periods of high or rising stage and gaining conditions during periods of low or declining stage.

Figure 3-15 shows hydrographs of unpaired USACE piezometers 2F-01-17S and 2F-01-19S in Reach 16 compared with estimated stage. Both piezometers have similar hydrographs, and the estimated stage tracks the groundwater data closely. The hydrographs generally show losing conditions during periods of high or rising stage and gaining conditions during periods of low or declining stage.

Figure 3-16 shows hydrographs of paired Kleinfelder piezometers in Reaches 18b and 19a. The transducers in Kleinfelder piezometers PZ-1 and PZ-2 were not working during most of the monitoring period. Almost all of the data that were collected in January and June-August 2005 show gaining conditions, which is inconsistent with the other piezometers. Water level measurements in paired Kleinfelder piezometers LMW-1 and LMW-4 were made manually, but the measurements made prior to January 2006 appear to be too high when compared with the estimated stage. The measurements made from December 2005 to April 2006 appear to be more reasonable but were made only during periods of high stage. The groundwater level data indicate losing conditions throughout this period.

Depths to water measured in the USACE piezometers located on the land side levee toe typically range from about six feet during the winter to about 18 feet during the summer and fall. This represents a seasonal fluctuation of only about 12 feet. Similarly high groundwater levels and small seasonal fluctuations have been observed at DWR's multiple-completion wells elsewhere in the Natomas Basin. The small seasonal fluctuations are due to a combination of the buffering effect of recharge from the River and from rice fields throughout the Natomas Basin and the fact that most pumping is from deeper zones. Recharge from rice irrigation in the summer months

keeps shallow groundwater levels high and is a primary factor in the gaining conditions observed at many of the levee piezometers during periods of low stage.

3.4 Hydraulic Gradient Estimates

The differences in hydraulic head between the paired piezometers and also between the unpaired piezometers and the estimated River stage are tabulated in **Table 3-2**, and these head differences were used to estimate the hydraulic gradient. Losing conditions are indicated by positive head differences and hydraulic gradients, and negative values indicate gaining conditions. Head differences were calculated for the entire period of record and range from about –3 feet to more than 11 feet. For paired piezometers that have been surveyed, head differences were calculated based on both groundwater data and stage estimates.

Average annual head differences and hydraulic gradients were calculated for each individual or paired piezometer based on the most recent 12-month period for which data are available. Due to the problems with some of the piezometer data discussed above, hydraulic gradients were not calculated for USACE piezometer 2F-01-15S and Kleinfelder piezometers PZ-1, PZ-2, LMW-1, and LMW-4. For the two sets of paired USACE piezometers, gradients were estimated by comparing the estimated stage with head in the piezometer closest to the River. Because more data were available from the USACE piezometers during the winter and spring, an average hydraulic gradient was calculated for each month. The monthly gradients were then averaged to determine the average hydraulic gradient for the 12-month period.

As shown in **Table 3-2**, the minimum hydraulic gradient at each piezometer location ranged from –0.0098 to 0.0003 ft/ft, with an average of –0.0039 ft/ft. The minimum hydraulic gradient was negative at all but one site, which indicates gaining conditions. The maximum hydraulic gradient ranged from 0.0054 to 0.0239 ft/ft, with an average of 0.0161 ft/ft. The magnitude of the average maximum hydraulic gradient (0.0239 ft/ft) is more than twice as large as the average minimum gradient (–0.0098 ft/ft) because the gradient is steeper during periods of high stage.

Average monthly hydraulic gradients were calculated for 13 piezometer locations (individual or paired), and an average annual gradient was calculated by averaging the monthly values. As shown in **Table 3-2**, the average annual hydraulic gradient at each piezometer ranged from 0.0006 to 0.0089 ft/ft. All of the average annual hydraulic gradients were positive, which indicates that all reaches exhibited losing conditions over the 12-month period. Although the groundwater elevation contour maps show steeper gradients in the southern portion of the Natomas Basin, there are too many sources of error in the gradient estimates to allow quantification of these spatial variations.

The average annual hydraulic gradient for all piezometers shown in **Table 3-2** was 0.0032 ft/ft or about 17 ft/mile. This represents the estimated average annual gradient for seepage loss from the River to the shallow aquifer based on a combination of piezometer data and estimated stage. This gradient is almost twice as steep as the maximum gradient east of the Sacramento River shown on the spring and fall 2003 groundwater elevation contour maps for the Natomas Basin (**Figures 3-5** and **3-7**). The groundwater contour maps are based on groundwater data only and have too large a scale to show the gradient between these closely spaced piezometers. The

steeper gradient near the River calculated above is also due to the low permeability of the riverbed and the fact that the greatest head differences between surface water and groundwater occur during periods of high stage.

Table 3-1
Construction of Sacramento River East Levee Piezometers in Natomas Basin

4.0 Water Budgets for Existing and Future Groundwater Conditions in the Natomas Basin

4.1 IGSM Models

In order to evaluate the cumulative effects of SAFCA's proposed construction activities on groundwater conditions, a pair of existing numerical groundwater flow models were used to simulate groundwater conditions in the North American Subbasin and calculate groundwater budgets for the Natomas Basin. The models are based on the Integrated Groundwater and Surface Water Model (IGSM) platform developed by Montgomery Watson, Inc. (MW) in the 1990s. As discussed below, model results were used to calculate groundwater budgets for existing conditions (based on 2004) and future conditions (based on 2030).

The Sacramento County IGSM model is referred to as the SACIGSM and was originally developed by MW in 1993. The SACIGSM was updated by MW in 1995 and by WRIME in 2005, 2007, and 2008. The IGSM model for the Sutter/Placer County portion of the North American Subbasin is referred to as the North American River (NAR) IGSM and was originally developed by MW in 1995. The NARIGSM was subsequently updated by DWR (1997) and MW (2001). The grids used for both models are shown on **Figure 4-1**.

The IGSM models were updated most recently by WRIME in 2008 to reflect more current conditions in the Natomas Basin in order to simulate the groundwater impacts of the proposed Sutter Pointe Specific Plan development in southeastern Sutter County, which were summarized in the *Sutter Pointe Specific Plan Groundwater Supply Assessment* prepared by LSCE (2008b) . WRIME linked the NARIGSM and SACIGSM models and used them to simulate the effect of variations in the rate, timing, and location of pumping to supply the proposed Sutter Pointe development along with other land use and pumping projected for a 35-year simulation period that included different water year types.

IGSM is a finite element, quasi three-dimensional numerical groundwater flow model that simulates all major components of the hydrologic cycle. These include precipitation, runoff, evaporation, consumptive use, groundwater recharge, groundwater extraction and injection, and subsurface inflow and outflow along the model boundaries. As indicated in the model name, the simulation also includes interactions between surface water (streams and lakes) and groundwater. The primary components of the groundwater budget calculated by IGSM are:

Inflows

- Deep percolation from rainfall and irrigation applied water;
- Recharge due to stream seepage;
- Recharge from other sources such as irrigation canals and recharge ponds;
- Boundary inflows from outside the model area; and
- Subsurface inflows from adjacent model areas.

Outflows

- Groundwater pumping;
- Outflow to streams and rivers;
- Subsurface outflows to adjacent model areas; and
- Boundary outflows.

4.1.1 Sacramento County IGSM Model

The Sacramento County IGSM model covers most of Sacramento County and includes portions of northern San Joaquin County and western Amador County (**Figure 4-1**). The model is physically represented as a three-layer system consisting of the following layers: 1) the uppermost layer represents the unconfined or semi-confined aquifer system consisting of alluvial sediments that overlie the Mehrten Formation, 2) the middle layer represents the confined aquifer system of the Mehrten Formation, and 3) the lowermost layer represents groundwater of generally poorer quality in marine sediments underlying the Mehrten Formation. Near the southern boundary of the Natomas Basin, Layer 1 is about 200 feet thick and is overlain and underlain by aquitards with thicknesses of about 60 and 130 feet, respectively. Layer 2 starts at a depth of about 360 feet and is over 1,500 feet thick in this area. Layering of the SACIGSM model in the southern portion of the Natomas Basin is shown on **Figure 4-2** (see **Figure 4-1** for cross-section location). All groundwater pumping is simulated in the two upper layers.

Boundary conditions were established to designate heads for all boundary nodes and allow for surface and subsurface flows through the model boundaries. Boundary conditions reported by WRIME (2007) are as follows:

- The eastern boundary of the model is a no flow boundary but incorporates surface-water inflow to the model based on ungaged watersheds.

- General head conditions are used for the southern boundary (along the Mokelumne River). The heads for this boundary are obtained from the Stanislaus Basin IGSM, which has a simulation period ending in 1993, and values of head in nodes along this boundary in 1995 to 2004 use values from 1993.

- The western model boundary is along the Sacramento River. The northern section (north of Pocket Road) uses general head boundary conditions provided by the Central Valley IGSM (CVIGSM). The southern section of the western boundary (south of Pocket Road) is simulated as a constant head boundary. Both the general head and constant head conditions are interpolated from prior model nodes to the updated SACIGSM nodes for the western boundary. Because the general heads in the prior SACIGSM stop in 1995, the updated SACIGSM uses the 1995 values for subsequent years (1996 to 2004).

- General head conditions are used for the northern model boundary. These heads are provided by the NARIGSM, which was run concurrently with the SACIGSM. The linkage between the two models was done by correlating the boundary nodes of the models, updating the NARIGSM from monthly to daily time steps, and using the 1995 general heads in the NARISGM for subsequent years (1996 to 2004).

4.1.2 North American River IGSM Model

As shown on **Figure 4-1**, the NARIGSM includes the portions of eastern Sutter County and western Placer County that comprise the northern two-thirds of the North American Subbasin. This includes the Sutter County portion of the Natomas Basin. In 2001, the NARIGSM was refined to better assess groundwater impacts resulting from the water supply project and program alternatives being considered for the Regional Water Master Plan (MWH, 2001). The data sets that were updated included land use, streamflow, agricultural demand, surface-water diversions, urban water demand, groundwater pumping, precipitation, and groundwater levels.

The layering of the NARIGSM is similar to that of the SACIGSM. In the Sutter County portion of the Natomas Basin, Layer 1 extends from about 80 to 300 feet in depth and is overlain and underlain by aquitards. Layer 2 extends from about 420 to 1,400 feet in depth.

The boundaries for the NARIGSM were developed based on a combination of geological, hydrological, and political boundaries. MWH (1995) describes the original model boundaries as follows:

- The western model boundary is the Feather and Sacramento Rivers, which are an important source of recharge that create a groundwater divide in the upper aquifer system. General head conditions are used for this boundary based on the regional CVIGSM.

- The southern model boundary follows the Placer/Sacramento and Sutter/Sacramento County lines, and extends from the Sacramento River in the west to the eastern edge of the groundwater basin. This boundary is also the northern boundary of the SACIGSM. General head conditions are used for this boundary. As described above, the SACIGSM was linked to the NARIGSM to achieve consistent heads along this boundary.

- The eastern model boundary represents the geologic boundary between the Sacramento Valley Groundwater Basin and the Sierra Nevada foothills. No flow conditions are used for this boundary.

- The northern model boundary is the Bear River, which coincides with the Placer/Yuba and Sutter/Yuba County lines. General head conditions are used for this boundary based on the regional CVIGSM.

4.2 Model Inputs

Both the calibration and the future conditions simulations were run for a 35-year simulation period based on 1970-2004 hydrologic conditions. This was a period of approximately average precipitation, which included three single-dry years and three periods of multiple-dry years based on DWR's Sacramento River Basin Index. Initial conditions (starting heads) for the beginning of the calibration period were established using historical groundwater levels published by DWR to generate regional groundwater level contour maps and assign initial (September/October

1969) groundwater levels to each model node. Initial conditions for the 2030 simulation are discussed in Section 4.4 below.

The IGSM models simulate transient conditions whereby hydraulic heads and groundwater flow can vary with time. Discretization over time occurs by dividing the continuous simulation period into time steps. Both models originally used monthly time steps, but have since been updated to use daily time steps (WRIME, 2007). Some model inputs such as streamflow and precipitation are daily, while others such as surface-water deliveries and municipal and industrial (M&I) groundwater pumping are monthly. Agricultural water demands are estimated by the model based on historical crop acreage, soil moisture requirements, effective rainfall, potential evapotranspiration (ET), and irrigation efficiency.

The aquifer properties required by the model include hydraulic conductivity, storage coefficient, and specific yield for each layer. In the Natomas Basin, the hydraulic conductivity used for Layer 1 ranges from 33 to 118 ft/day across the Natomas Basin. Hydraulic conductivities are lower in Layer 2 (15-20 ft/day) and Layer 3 (3-12 ft/day).

Specific yield values used in the models range from 0.08 to 0.12 for the NARIGSM and from 0.04 to 0.20 for the SACIGSM. Storage coefficients in the Natomas Basin area ranged from 1.4×10^{-4} to 1.4×10^{-3} in Layer 1 to 3.5×10^{-5} to 3.0×10^{-4} in Layer 2, and 3.0×10^{-5} to 3.0×10^{-3} in Layer 3.

4.2.1 Simulation of Streams

To simulate streamflow, the IGSM models calculate a water balance for each stream element. The stream elements are a series of one-dimensional line elements that are used to describe the stream system in the model area. The gain or loss due to stream-aquifer interaction is computed based on head in the stream (stage) and head in the underlying aquifer (WRIME, 2006). The stream stage is computed using stage-discharge relationships at the corresponding stream node. Input data for the stream system include:

- Stream configuration;
- Stream node elevation;
- Stream channel cross section;
- Stage-discharge relationship;
- Stream inflows at boundary (including surface-water flow entering the model area and also gains or losses of the stream system due to stream-aquifer interaction);
- Tributary inflows;
- Wastewater discharges to streams; and
- Streamflow diversions that remove water from the stream system.

In the Natomas Basin, only the Sacramento and American Rivers are simulated as streams (recharge from smaller streams and canals is included in areal recharge estimate discussed below).

4.2.2 Areal Recharge

The IGSM models account for a number of processes in the soil zone, including ET, direct runoff, infiltration, and deep percolation from rainfall and applied water (WRIME, 2006). ET is computed based on crop consumptive use requirements and available soil moisture. Direct runoff from rainfall and applied water is computed using a modified Soil Conservation Service (SCS) runoff curve number method. Input data for simulation of hydrologic processes in the soil zone include (MW, 1995; WRIME, 2006):

- Initial soil moisture;
- Rainfall;
- Land use category;
- SCS hydrologic soil group;
- Minimum soil moisture requirements for each crop type;
- Crop consumptive use (amount of applied water consumptively used to satisfy ET or soil moisture requirements);
- Root zone depth for each crop; and
- Surface drainage pattern.

The two primary sources of water to the soil zone in agricultural and urban areas are precipitation and applied water. Agricultural areas in the NARIGSM area tend to have the largest amount of deep percolation due to the volume of irrigation water applied to rice fields in addition to the natural rainfall, while the amount of deep percolation from non-irrigated areas is relatively small (MW, 1995).

Water infiltrating beyond the soil zone (deep percolation) results in groundwater recharge. IGSM models simulate the vadose zone with the mathematical equation of unsaturated flow solved numerically at every time step (WRIME, 2006). The vadose zone is divided into a number of discrete layers of specified thickness; the water passing through the soil zone becomes the inflow to the uppermost vadose zone layer. This process repeats until the outflow from the last vadose zone layer becomes inflow to the first layer of the aquifer system. As discussed further in Chapter 5, deep percolation is a significant inflow component of the overall groundwater budget.

4.2.3 Model Calibration

Calibration is the process of adjusting parameters used in the model so that the model approximates the observed behavior of the aquifer system, especially measured groundwater levels. After the model is calibrated, it can be used to evaluate the response of the aquifer system to new or changing stresses. The original model calibration period for both IGSM models was water years 1970-1990. For the current versions of the models, the calibration period has been extended to water years 1970-1995 for the NARIGSM (MWH, 2001) and to 1970-2004 for the SACIGSM (WRIME, 2007).

During the calibration process, model generated heads were compared against measured water levels at selected calibration wells. In total, 81 calibration wells were used for the NARIGSM,

and 138 wells were used for calibration of the SACIGSM. The models were found to generally produce simulated water levels that were in good agreement with observed values under various hydrologic conditions. For the northern portion of the SACIGSM model, including the Sacramento County portion of the Natomas Basin, WRIME (2007) reported that 76 percent of the simulated heads fell within ten feet of observed heads.

Since they were last calibrated (2001 for the NARIGSM and 2007 for the SACIGSM), a number of changes have been made to both models. A check of the calibration was performed in fall 2007 after the refinement of the hydraulic conductivity values in the Natomas Basin to match recent aquifer test data provided by LSCE. Additional updates and refinements were made to the models through late 2007 and early 2008, but were considered to have only a minor effect on the calibration.

Since the models are an approximation of the physical system, they do not exactly reproduce observed groundwater levels. Although the calibration was considered acceptable for the primary intended purpose of the model (regional planning), there are notable differences between measured and simulated heads in the Natomas Basin. In particular, calibration hydrographs included in LSCE (2008b) and WRIME (2007) show declining heads at some of the Natomas Basin calibration wells over the 1970-2004 period. This is not supported by actual data, which generally show stable or increasing water levels since the early 1980s except for small seasonal fluctuations.

4.3 Water Budget for Existing Conditions

The groundwater budget for existing conditions in the Natomas Basin is based on the final water year of the 1970-2004 calibration period for the SACIGSM model. For the NARIGSM model, the calibration period ended in 1995, but the simulation period was extended to 2004 to create the water budget. Although a number of other IGSM simulations have been conducted for different purposes, the calibration period simulation was considered the best available representation of existing groundwater conditions in the Natomas Basin.

The groundwater budget for the end of the calibration simulation (2004) is shown in **Table 4-1** and summarized below The results are grouped into inflow and outflow components, and the change in storage represents the difference between the inflow and outflow.

Inflow Components

- Deep Percolation – This includes infiltration from precipitation, applied irrigation water, seepage from ditches and canals, and recharge from smaller streams. Deep percolation is assumed to be greatest from agricultural land planted to rice. A deep percolation rate of 1.32 acre-feet per acre per year (af/ac/yr), not including precipitation, was estimated for rice in the Natomas Basin (WRIME, 2008). The simulated deep percolation shown in **Table 4-1** totaled 31,429 af in 2004.

- Net Recharge from Streams – The direction of flow between streams and the underlying aquifer can vary seasonally or by reach. Flow from a stream to the aquifer system (losing

conditions) is classified as inflow to the groundwater basin, and flow from the aquifer system to a stream (gaining conditions) is classified as outflow. For the Natomas Basin, only flow to and from the Sacramento and American Rivers is included in this component. Although there is some seasonal variation, all reaches of the Sacramento and American Rivers were simulated as losing in 2004. The simulated net recharge from streams shown in **Table 4-1** was 6,469 afy for the Sacramento River and 1,086 afy for the American River.

- Net Boundary Inflow – This represents groundwater inflow or outflow through model boundaries. The Sacramento River forms the western boundary of both IGSM models, and positive values of boundary inflow represent groundwater flow from the west beneath the Sacramento River. Boundary inflow from the west shown in **Table 4-1** totaled 10,365 afy. Available water level data do not show a noticeable gradient for significant groundwater flow beneath the Sacramento River from the west. Therefore, some of this boundary inflow, especially that which occurs in Layer 1, may actually represent additional recharge from the Sacramento River.

- Subsurface Inflow – This component represents groundwater inflow from one model subregion to another. As shown in **Table 4-1**, there is a small amount of inflow from the north beneath the NCC (241 afy) and a larger amount of inflow from the south beneath the American River (2,714 afy).

Outflow Components

- Subsurface Outflow – This component represents groundwater outflow from one model subregion to another. For the 2004 simulation, there was a large amount of outflow from the Natomas Basin to the east (21,738 afy), as shown in **Table 4-1**.

- Groundwater Pumping – This represents the largest outflow component and, in the Natomas Basin, is primarily for agricultural use. The simulated groundwater pumping shown in **Table 4-1** is 35,537 afy.

Change in Storage

- Change in Storage – The basic equation for a water budget is:

  Inflow – Outflow = Change in Storage.

  A positive change in storage indicates rising groundwater levels while a negative change in storage indicates declining groundwater levels. As discussed above, hydrographs indicate that groundwater levels in the Natomas Basin are generally stable but show small fluctuations in response to climatic conditions. 2004 was classified as a normal year based on DWR's Sacramento River Basin Index, but precipitation in the Sacramento area was slightly below average. The simulated change in storage shown in **Table 4-1** is –4,971 afy.

This reduction in groundwater storage means that simulated heads were declining at the end of the calibration simulation. A decline in groundwater storage of almost 5,000 afy divided by the area of the Natomas Basin represents a small decrease in storage on a per acre basis (less than 0.1 af/ac/yr). As discussed above, the specific yield used in the model ranges from 0.04 to 0.20. Assuming a specific yield of 0.10, the simulated decrease in storage equates to an average decrease in head of about one foot.

4.4 Simulation of Future Conditions

The water budget for future conditions discussed below is based on a simulation conducted by WRIME to estimate the effect of proposed land and water use changes due to proposed developments in the North American Subbasin on groundwater conditions in 2030. For this scenario, the IGSM models were run for a 35-year simulation period based on 1970-2004 hydrologic conditions. As discussed above, this was a period of approximately average precipitation, which included three single-dry years and three periods of multiple-dry years based on DWR's Sacramento River Basin Index. This simulation represents proposed future land and water uses in the Natomas Basin, including the Sutter Pointe development at buildout (labeled Scenario 2B in LSCE, 2008b).

The 2030 simulation is based on estimated conditions in the groundwater basin in 2030 without SAFCA's construction activities. Future water supply conditions for northern Sacramento County were primarily based on Urban Water Management Plans for individual water districts in the area. As reported by WRIME (2007), most of the plans indicate a significant transition from groundwater to surface-water utilization to meet municipal water demands. Future water supply conditions for Placer County were based on several sources including the *Western Placer County Groundwater Management Plan* prepared by MWH (2007) on behalf of the City of Roseville, City of Lincoln, Placer County Water Agency, and California American Water. Water demand and supply data for proposed developments such as Placer Vineyards and Placer Ranch were obtained from the Specific Plan, EIR, or Notice of Preparation for each development.

The 2030 water budget presented below is based on Scenario 2B in LSCE (2008b), which includes full buildout of the Sutter Pointe development along with the other developments in the North American Subbasin discussed above. All agricultural land uses in the proposed development areas are simulated as being replaced by M&I land uses by 2030. Groundwater usage in the Sutter Pointe area is projected to be 13,072 afy in a normal year, which represents about 52 percent of the total demand M&I water demand, with the remainder supplied by surface water.

4.4.1 Water Budget for Future Conditions

The groundwater budget for the simulation of future conditions (2030) without SAFCA's planned construction is shown in **Table 4-1**. The future conditions water budget is based on the last 23 years of the simulation period (1982-2004). Precipitation during this period was approximately average, and this period includes nine wet years, four normal years, two single-dry years, and two multiple-dry periods (1987-1992 and 2001-2002) based on the Sacramento River 40-30-30 Index.

There are significant differences between the water budgets for the 2004 and 2030 simulations shown in **Table 4-1**. Many of these differences are due to much higher heads east of the Natomas Basin in 2030 due to the planned transition from groundwater to surface water to meet M&I demands in northern Sacramento County. Heads are also higher in most of the Natomas Basin due in part to reduced pumping outside of the Sutter Pointe area. Higher heads result in less recharge from streams, less boundary inflow, and less subsurface outflow for the Natomas Basin water budget.

There are also differences between the values shown in **Table 4-1** for the 2030 simulation and the Scenario 2B results summarized in LSCE (2008b). These differences occurred because the latter simulation included an area of about 1,000 acres east of the Natomas Basin in southern Sutter County, which was removed from the area used for the water budget in **Table 4-1**. Due to the additional area, deep percolation and groundwater pumping were 2,300 and 3,000 afy higher, respectively, for the Scenario B water budget (LSCE, 2008b).

The inflow components shown in **Table 4-1** are deep percolation (27,187 afy), which represents a reduction of 4,242 afy from 2004 due to increased urbanization. Recharge from streams is 1,100 afy for the Sacramento River and –500 afy for the American River. The negative recharge for the American River indicates that it is simulated as a gaining reach for this model run. The total net recharge from streams (600 afy) is 6,955 afy lower than for the 2004 simulation. Boundary inflow from the west in 2030 (3,700 afy) is 6,665 afy lower than in 2004. Subsurface inflow from the north (3,700 afy) is 745 afy higher, however, due primarily to drawdown caused by proposed Sutter Pointe pumping in southern Sutter County. The 2030 simulation also shows only 1,200 afy of subsurface outflow to the east (20,538 afy less than in 2004) and 800 afy of subsurface outflow to the south due to expected pumping reductions in the southern portion of the Natomas Basin. The total pumpage in the 2030 simulation is 31,615 afy, which is 3,922 afy lower than in 2004. The average change in storage was 1,572 afy, which indicates generally increasing heads over the simulation period.

Table 4-1
Simulated Groundwater Budgets for Natomas Basin
(Not Including SAFCA Activities)

	Water Budget Component	2004 Simulation[1] (afy)	2030 Simulation[2] (afy)	Difference (afy)
Inflow	Deep Percolation (Including Canal Seepage)	31,429	27,187	4,242
	Recharge from Sacramento River	6,469	1,100	5,369
	Recharge from American River	1,086	-500	1,586
	Boundary Inflow from West	10,365	3,700	6,665
	Subsurface Inflow from North	241	3,700	-3,459
	Subsurface Inflow from South	2,714	0	2,714
	Total Inflow	**52,304**	**35,187**	**17,117**
Outflow	Groundwater Pumping	35,537	31,615	3,922
	Subsurface Outflow to East	21,738	1,200	20,538
	Subsurface Outflow to South	0	800	-800
	Total Outflow	**57,275**	**33,615**	**23,660**
Inflow minus Outflow	**Change in Storage**	**-4,971**	**1,572**	**-6,543**

1. Based on final year of calibration simulation (LSCE, 2008b).
2. Based on 1982-2004 average for Sutter Pointe Project Scenario 2B (LSCE, 2008b).

LUHDORFF & SCALMANINI CONSULTING ENGINEERS

Figure 4-1
Model Grids for SACIGSM and NARIGSM Groundwater Flow Models

5.0 Effects of SAFCA Construction Activities

Most of SAFCA's proposed levee improvements will have no effect on groundwater in the Natomas Basin, but the proposed slurry cutoff walls are intended to reduce seepage beneath the levees and will affect groundwater conditions. Some of SAFCA's construction activities will involve land use changes that will reduce groundwater recharge. This reduction will be at least partially offset by seepage from new and relocated canals, which will increase groundwater recharge. Finally, water supply changes at the Brookfield property borrow site will result in a large reduction in groundwater pumping. A summary of assumptions about proposed SAFCA construction activities used to prepare water budgets and evaluate impacts is provided in **Table 5-1**. The groundwater impacts of proposed slurry cutoff walls are addressed in Chapter 6; the groundwater impacts of SAFCA's other proposed construction activities are summarized below.

5.1 Deep Percolation from Irrigated Agricultural Land

Most groundwater recharge in the Natomas Basin results from deep percolation of applied irrigation water. As shown in **Table 5-2**, estimates of applied water for various crops range from 2.5 af/ac/yr for field crops, grains, and hay to 6.5 af/ac/yr for rice (LSCE, 2008b). Most of this water is consumed by ET but some goes to tailwater runoff and deep percolation. The amount of deep percolation is estimated to range from about ten percent of applied water for field crops (0.25 af/ac/yr) to 17 percent of applied water for orchards (0.68 af/ac/yr). These estimates represent deep percolation from irrigation only; they do not include deep percolation from direct precipitation in the winter and spring. Deep percolation from precipitation was estimated to be about 0.23 af/ac/yr and is not included in the estimates because it would occur regardless of land use (except for areas covered by pavement or other impermeable materials). Estimates of deep percolation from applied water for other crops include 0.77 af/ac/yr for rice, 0.41 af/ac/yr for grains and hay, and 0.61 af/ac/yr for pasture (LSCE, 2008b).

5.2 Land Use Changes Due to Levee Construction

Proposed levee construction activities that will affect land use include raising levees, modifying levee slopes, and adding seepage berms. As summarized in **Table 5-1**, planned improvements to the Sacramento River East Levee will require about 486.5 acres of land and will result in the loss of about 20 acres of rice, 175 acres of field crops, and five acres of orchard (EDAW, 2008). Proposed improvements to other levees are expected to result in the loss of an additional five acres of rice along the NCC South Levee and 50 acres of rice along the PGCC West Levee. Improvements to the NEMDC West Levee are still in the design phase, but irrigated crop land is limited to the northern portion of this levee and any changes in agricultural land use are expected to be small. No agricultural land would be affected by improvements to the American River North Levee, which is located within the City of Sacramento.

Table 5-3 shows existing and future agricultural land uses affected by proposed levee improvements and the resulting change in deep percolation from applied water. The estimated

loss of deep percolation is 74 afy for the Sacramento River East Levee, seven afy for the NCC South Levee, and 66 afy for the PGCC West Levee.

5.3 Effects of Canal Improvements

Construction of the new GGS/Drainage Canal and relocation/improvement of three existing canals will increase groundwater recharge in the Natomas Basin. The new GGS/Drainage Canal and most of the relocated canals will be unlined, which will result in additional seepage from the canals to the underlying aquifer. Canal construction activities will also necessitate land use changes, including the loss of some irrigated agricultural land. The assumptions shown in **Table 5-1** were used to estimate the effects of land use changes and seepage from the canals for the water budget. For canals that would be relocated, this includes the total length of the existing and relocated canals, the length of any lined or piped segments, the approximate width of the canals at the waterline, existing land uses for the area where the relocated canal would be constructed, and the proposed future land uses for the existing canal that would be removed.

5.3.1 Giant Garter Snake/Drainage Canal

The new GGS/Drainage Canal will be about 23,200 feet (4.4 miles) long and will extend from the west end of the West Drainage Canal at the south to Pumping Plant No. 2 (east of the Pritchard Lake Pumping Plant) at the north (**Figure 1-1**). The new canal will be entirely unlined, with an average width at the waterline of about 50 feet including benches.

Construction of the GGS/Drainage Canal and associated infrastructure will require about 58.5 acres of land, as indicated in **Table 5-1**. Approximately 45 acres of this area is currently planted to field crops such as corn (EDAW, 2008). As shown in **Table 5-3**, the total amount of deep percolation that will be lost due to the removal of these field crops is estimated to be 11 afy.

The loss of deep percolation of applied water would be offset by increased seepage from the canal. Kleinfelder (2009) used the SEEP/W groundwater flow model to estimate seepage from a two-mile segment of the new GGS/Drainage canal. The canal was simulated with a ten-foot width and an underlying soil hydraulic conductivity of 10^{-5} cm/sec. The canal was simulated as being filled with about five feet of water from May through December, but some seepage was also assumed to occur during the winter. The Kleinfelder seepage estimate was 1.4 af/1,000 lf or 1.4×10^{-4} af per square foot of wetted canal area (af/ft^2). For the total length (23,200 lf) and average width (50 feet) of the GGS/Drainage Canal, this represents a seepage rate of 162 afy, as shown in **Table 5-4**. As discussed below, the estimated seepage rate per wetted area (1.4×10^{-4} af/ft^2) was also used to estimate increased seepage due to relocation or improvement of the West Drainage Canal, the Elkhorn Canal, and the Riverside Canal.

5.3.2 West Drainage Canal

The West Drainage Canal is located south of I-5 and the SIA (**Figure 1-1**) and is about 19,000 feet long. Approximately 4,700 lf of this canal is proposed to be relocated. The existing canal is unlined, and the relocated segment of the canal is also planned to be unlined. In addition to the partial relocation, SAFCA plans to widen the entire canal from about 30 feet to 72 feet, including a bench area that will be planted to tules (EDAW, 2008; M&H, 2008). As shown in **Table 5-1**,

only about 1.5 acres of the area where the relocated canal will be constructed is currently planted to field crops. The loss of deep percolation from applied water due to the canal relocation is estimated to be 0.4 afy (**Table 5-3**).

Canal seepage was estimated using the seepage rate calculated from the Kleinfelder model for the GGS/Drainage Canal (1.4×10^{-4} af/ft^2). As shown in **Table 5-4**, seepage from the existing West Drainage Canal was estimated to be about 80 afy. Due to lengthening and widening of the canal, the future seepage rate is projected to be 208 afy, which represents an increase of 128 afy.

5.3.3 Elkhorn Canal

The existing Elkhorn Canal is located just east of the Sacramento River East Levee (**Figure 1-1**) and is about 19,850 feet (3.8 miles) long and 16 feet wide. Approximately one mile of the existing canal is concrete lined. The canal is being relocated farther east to make room for levee widening and other improvements. The relocated canal will be about 22,300 feet long and 32 feet wide. Approximately 6,100 lf of the relocated canal are planned to be lined, and another 2,950 lf would be piped. This includes the 2,050 lf alignment crossing the Teal Bend Golf Course and another 900 lf adjacent to an area of existing homes (M&H, 2008).

As shown in **Table 5-1**, relocation of the Elkhorn Canal and associated infrastructure will require about 30 acres of land. Most of the area where the new canal will be constructed is currently planted to irrigated crops. As shown in **Table 5-3**, there are about 15 acres of field crops, three acres of orchard, and 11 acres of grain, hay, and pasture. The loss of deep percolation due to removal of these crops is estimated to be 11 afy.

Canal seepage was estimated similarly to the West Drainage Canal, using the seepage rate calculated from the Kleinfelder model for the GGS/Drainage Canal (1.4×10^{-4} af/ft^2). As shown in **Table 5-4**, seepage from the existing Elkhorn Canal was estimated to be about 33 afy. The seepage rate of the relocated canal is projected to be 59 afy, which represents an increase of 27 afy.

5.3.4 Riverside Canal

The existing Riverside Canal is located just east of the southern portion of the Sacramento River East Levee in the Natomas Basin (**Figure 1-1**) and is about 19,600 feet (3.7 miles) long and seven feet wide. The Riverside Canal is also being relocated farther east to make room for levee improvements. The relocated canal is planned to be about 20,550 feet long and ten feet wide (M&H, 2008).

As shown in **Table 5-1**, relocation of the Riverside Canal and associated infrastructure will require about 54 acres of land. Most of the area where the new canal will be constructed is currently planted to irrigated crops. As shown in **Table 5-3**, there are about four acres of rice, 33 acres of field crops, six acres of orchard, and seven acres of grains, hay, and pasture. The loss of deep percolation due to removal of these crops is estimated to be 21 afy.

Canal seepage was again estimated using the seepage rate calculated from the Kleinfelder model for the GGS/Drainage Canal (1.4×10^{-4} af/ft^2). As shown in **Table 5-4**, seepage from the

existing Riverside Canal was estimated to be 19 afy. The seepage rate of the relocated canal is projected to be 29 afy, which represents an increase of ten afy.

5.4 Effects of Borrow Sites

Excavation of the three borrow sites that will be the primary source of soil for SAFCA's proposed levee improvements and other construction activities will have effects on groundwater recharge in the Natomas Basin. **Table 5-1** includes a summary of assumptions about the borrow sites that were used for water budget estimates. These include the area of each borrow site and existing and proposed future land uses.

5.4.1 Airport North Bufferlands

The Airport North Bufferlands is a 737-acre site located north of the SIA (**Figure 1-1**). Approximately 630 acres of this site that had previously been planted to rice has recently been removed from rice cultivation or other land uses that would attract water fowl by the SIA. SAFCA plans to remove about four to six feet of borrow material from this site, which is currently considered non-irrigated grassland. Topsoil will be stockpiled and replaced after borrow operations are complete, and future land uses are not expected to change after reclamation of the site. As shown in **Table 5-3**, there will be no change in deep percolation from this site as a result of SAFCA's activities.

5.4.2 Brookfield Property

The Brookfield property consists of 353 acres at the northern tip of the Natomas Basin. Approximately 325 acres of this property is currently planted to rice, and SAFCA plans to restore most of this site to rice cultivation. Up to six feet of soil will be excavated, including one foot of topsoil that will be stockpiled and replaced after borrow operations are complete.

SAFCA plans to return about 286 acres of the Brookfield property to rice cultivation after construction activities are complete. The remaining 39 acres of rice fields would be lost due to construction along the PGCC West Levee and other factors. As shown in **Table 5-3**, an estimated 51 afy of deep percolation will be lost due to the conversion of rice land to other uses. The Brookfield property is currently irrigated entirely with groundwater, but SAFCA plans to provide the infrastructure so that most of the borrow site can be irrigated with surface water in the future. Engineering work is still in progress, but current estimates are that about 80 percent of the property would be irrigated with surface water rather than groundwater after reclamation (M&H, 2008). The current crop mix is about 50 percent regular rice and 50 percent wild rice (Jack DeWit, pers. comm., July 8, 2008). Regular rice and wild rice have estimated water demands of 6.5 and 6.0 af/ac/yr, respectively. Therefore, current groundwater pumpage to irrigate this property is estimated to be about 2,030 afy. This would be reduced by 1,625 afy due to the planned transition from groundwater to surface water.

In addition to increasing heads in the vicinity of the Brookfield site, the reduction in pumping would also result in increased groundwater outflow from the northern portion of the Natomas Basin. An analytical groundwater model based on the Theis (1935) equation for groundwater flow in a confined aquifer was used to estimate the amount of water level recovery that would

occur due to the reduced pumping. An aquifer transmissivity of 7,620 ft^2/day and a storage coefficient of 0.001 were used for this simulation based on LSCE (2008b). The maximum simulated water level recovery beneath the Brookfield property was about 17 feet at the end of the irrigation season in September. At the midpoint of the PGCC West Levee (south of the Brookfield property), the simulated recovery ranged from 1.6 to 7.6 feet, with an average annual value of 3.8 feet. This would result in an average increase in the hydraulic gradient for flow to the east of about 4.4×10^{-5} ft/ft. The increase in subsurface outflow was estimated using Darcy's Law (Darcy, 1856), which can be written as:

$$Q = KAi$$

where: Q = volumetric flow rate,
K = hydraulic conductivity of the porous medium,
A = cross-sectional area of the porous medium, and
i = hydraulic gradient.

The cross-sectional area was estimated based on the assumption that almost all of the flow would occur in the upper 400 feet of the aquifer system. Using this equation, the increase in subsurface outflow from the Natomas Basin was predicted to be 76 afy.

5.4.3 Fisherman's Lake

Fisherman's Lake – The Fisherman's Lake borrow site is located at the northern end of Fisherman's Lake in the southwestern portion of the Natomas Basin. Engineering work has not been completed for this site, but the current estimate is that about 400 acres of land would be used for borrow material.

As shown in **Table 5-1**, current land uses on this site are 49 acres of rice, 266 acres of field crops, and 85 acres of managed marsh. After reclamation, there would be about 175 acres of managed marsh and 225 acres of non-irrigated grassland or woodland. As shown in **Table 5-3**, the creation of managed marsh will result in an increase in deep percolation of 51 afy. Overall, however, there will be a net loss in deep percolation of 15 afy due to the conversion of field crops to non-irrigated grassland.

5.5 Summary

This chapter summarized the groundwater impacts of SAFCA's proposed construction activities, with the exception of slurry cutoff walls, which are addressed in Chapter 6. The above analysis included three types of groundwater impacts:

- Land use changes due to levee and canal improvements and borrow sites will result in the conversion of some irrigated agricultural land to non-irrigated land uses, which will reduce groundwater recharge from deep percolation of applied water. The total loss of deep percolation from applied water is estimated to be 256 afy, as shown in **Table 5-3**.
- The new and relocated canals would result in increased groundwater recharge due to additional canal seepage. The total estimated increase in canal seepage is 327 afy, as shown in **Table 5-4**.

- There will be a large reduction in groundwater pumping due to the planned shift in water supply from groundwater to surface water for 80 percent of the Brookfield property. The reduction in pumping is estimated to be about 1,625 afy. This will result in higher heads and increased groundwater outflow in the northern portion of the Natomas Basin.

1. Includes 85 ac of managed marsh at the Fisherman's Lake borrow site.
2. Deep percolation from applied water estimated to be 0.77 af/ac/yr for rice and managed marsh by LSCE (2008b).
3. Deep percolation from applied water estimated to be 0.25 af/ac/yr for field crops by LSCE (2008b).
4. Deep percolation from applied water estimated to be 0.68 af/ac/yr for orchards by LSCE (2008b).
5. Deep percolation from applied water estimated to be 0.41 af/ac/yr for grains/hay and 0.61 af/ac/yr for pasture by LSCE (2008b). A weighted average of 0.47 af/ac was used above.
6. Design of NEMDC levee improvements is in the early stages, and there is no current estimate of land use changes due to levee constructiion. An estimate of 50 ac of rice based on the PGCC was also used for the NEMDC because land uses west of the northern portion of the NEMDC are similar to the PGCC. Land uses west of the southern portion of the NEMDC are urbanized or vacant.

Table 5-4
Effects of SAFCA's Proposed Canal Construction on Canal Seepage

Canal Name		Total Length (ft)	Length of Lined or Piped Segments (ft)	Length of Unlined Portion (ft)	Width at Waterline (ft)	Area at Waterline[1] (ft^2)	Seepage Rate per Sq. Foot[2] ($af/ft^2/yr$)	Total Seepage Rate (afy)	Seepage Increase (afy)

2. Based on results of Kleinfelder (2009) seepage model for portion of GGS/Drainage Canal.

6.0 Effects of Slurry Cutoff Walls

Slurry cutoff walls are currently proposed for a total of about 29 miles of the levees surrounding the Natomas Basin. This includes about ten miles of the Sacramento River East Levee, all (5.4 miles) of the NCC South Levee, 2.7 miles of the PGCC West Levee, 4.3 miles of the northern NEMDC West Levee, 4.1 miles of the southern NEMDC West Levee, and all (2.2 miles) of the American River North Levee. Proposed seepage mitigation including slurry cutoff walls is summarized in **Table 6-1** for the Sacramento River East Levee and in **Table 6-2** for the NCC South Levee, the PGCC West Levee, the NEMDC West Levee, and the American River North Levee. The proposed cutoff wall locations are shown on **Figure 6-1**.

Groundwater flow beneath the levees with and without the proposed cutoff walls was estimated by various methods. These methods and the resulting estimates are discussed in this section. Groundwater flow beneath the Sacramento River East Levee and the NCC South Levee with and without slurry cutoff walls was estimated by both URS and Kleinfelder using the SEEP/W groundwater flow model. The most recent estimates were made by Kleinfelder and are summarized below. LSCE used a spreadsheet model to develop a revised estimate for the Sacramento River East Levee.

No modeling has been done to estimate the impacts of proposed slurry cutoff walls along the other three levees that surround the Natomas Basin. For these areas, groundwater flow without slurry cutoff walls was estimated based on the IGSM models discussed in Chapter 4. Two different simulations were used for this purpose: one representing existing conditions based on 2004 data, and the other representing future conditions in 2030. Based on the model results, estimates of groundwater flow per cross-sectional area were developed. For the reaches where slurry cutoff walls are proposed, the estimated flow per cross-sectional area was reduced by a fixed percentage based on the Kleinfelder model results for the Sacramento River East Levee.

6.1 Sacramento River East Levee

Measures proposed to mitigate seepage problems beneath the Sacramento River East Levee are shown in **Table 6-1**. The current plan includes some form of mitigation for all reaches. Slurry cutoff walls are currently proposed for 13 reaches, seepage berms are proposed for 13 reaches, relief wells are proposed for ten reaches, and jet grouting is proposed at one reach. The reaches where cutoff walls are proposed are shown in **Figure 6-1**.

6.1.1 Kleinfelder Model

Kleinfelder (2009) used the SEEP/W groundwater flow model to estimate seepage beneath the Sacramento River East Levee with and without slurry cutoff walls and summarized the results in a report entitled *Evaluation of Cutoff Walls Impact on Groundwater Recharge, Sacramento River East Levee, Natomas Levee Improvement Project, Sacramento and Sutter Counties, California*. SEEP/W is a two-dimensional, finite-element model based on Darcy's Law (Darcy, 1856). As discussed in Chapter 5, the inputs to Darcy's equation are the hydraulic conductivity, the

hydraulic gradient, and the cross-sectional area for groundwater flow. SEEP/W has the capability to simulate flow in multiple layers, and a separate hydraulic conductivity is required for each layer. Hydraulic conductivities used in the Kleinfelder model ranged from 0.028 ft/day for clay to 283 ft/day for gravel. The maximum hydraulic conductivity used for the permeable layers in most reaches was 14 ft/day (representing sand). The Kleinfelder model was based on a previous mitigation plan that included a total of 42,300 lf of slurry cutoff walls in 12 reaches.

The SEEP/W model allows both steady-state and transient simulations to be conducted. As discussed below, a transient simulation was conducted for one station, but the results were not used in the overall seepage estimate. The reported model results were based on steady-state simulations conducted for four stations, which were considered to be representative of the different geologic conditions observed on geologic profiles created from borehole data. The modeled stations were located at Stations 27+00 in Reach 1, 70+00 in Reach 2, 217+00 in Reach 4b, and 353+00 in Reach 7b. Model results from these stations were applied to other reaches with similar geology. The percentage of the entire length of the Sacramento River East Levee represented by each modeled station was 11 percent for Station 27+00, 23 percent for Station 70+00, 42 percent for Station 217+00, and 24 percent for Station 353+00.

Kleinfelder used an "average" groundwater elevation of 17.25 ft msl for all simulations. This was compared against river stage at the Verona gage ranging from 17.25 to 34.25 ft msl in one-foot increments to calculate the gradient between the River and shallow groundwater. The steady-state model was run separately for each stage height, and the estimated seepage was multiplied by the number of days that the stage was calculated to be at each elevation based on data from 1995-2007. The lowest stage height (17.25 ft msl) had the longest duration (20 days/year), and the three highest stage heights (32.25, 33.25, and 34.25 ft msl) each had a duration of ten days/year.

Since almost all of the groundwater flow occurs in the sand layers, the model is very sensitive to the hydraulic conductivity used for sands. A hydraulic conductivity of 14 ft/day was used for sand layers in three of the four modeled reaches, and the calculated seepage rate was relatively low (2.6 to 13.4 afy/1,000 lf) in these reaches. Hydraulic conductivities of 56 and 283 ft/day were used for sand and gravel, respectively, at Station 217+00, and the resulting seepage rate was much higher (129 afy/1,000 lf). These seepage estimates were multiplied by the length of each reach to estimate the total seepage, and the results are shown in **Table 6-3**. The total seepage was estimated to be about 5,650 afy without slurry cutoff walls using this approach.

The model was rerun for Stations 70+00 and 353+00 with the slurry cutoff walls in place to estimate the effect of the cutoff walls. A hydraulic conductivity of 2.8×10^{-3} ft/day was estimated for the cutoff walls. For Station 70+00, the cutoff wall was assumed to fully penetrate the permeable sand layer and a seepage reduction of 85 percent was calculated. At Station 353+00, the cutoff wall was assumed to not fully penetrate the permeable sand layer and was calculated to reduce seepage by only 40 percent. The model results for the four stations were multiplied by one of these percentages to estimate the impacts of the other cutoff walls. The 85 percent reduction was used for reaches where the cutoff wall was considered to fully penetrate the permeable sand layer, and the 40 percent reduction was used for reaches where the wall

would not be fully penetrating. As shown in **Table 6-3**, the total amount of groundwater flow that would be blocked by the eight miles of proposed slurry cutoff walls is about 1,320 afy.

A transient version of the model was created for Station 70+00 to check the results of the steady-state simulations. The transient model was run with and without the slurry cutoff walls for a one-year period divided into 34 time steps. Groundwater elevations and river stage were allowed to fluctuate based on stage measured at the Verona gage and groundwater levels at USACE piezometer 2F-01-15N. Seepage without the cutoff wall calculated with the transient model was three times higher than that calculated with the steady-state model. Seepage through the cross-sectional area where the cutoff wall would be constructed was about four times higher with the transient model as compared to the steady-state model. On a percentage basis, the calculated flow reduction for the transient model was about 70 percent, which is less than the 85 percent reduction calculated with the steady-state model.

Overall, the Kleinfelder transient model results appear to be more realistic than the steady-state results. This would be expected since steady-state models require an assumption of equilibrium conditions and cannot simulate conditions that vary with time. For this reason, transient model results are considered more accurate for most applications. However, steady-state model results had to be used for Kleinfelder's overall seepage estimate shown in **Table 6-3** because only one station was simulated with the transient model. As discussed below, some of the Kleinfelder transient model results were used for LSCE's evaluation of cutoff wall impacts on seepage from the River and head changes in private wells along the east levee.

On a percentage basis, the transient and steady-state models showed varying results for flow reductions caused by the cutoff walls. Based on the transient model, a flow reduction of 70 percent due to horizontal flow through a fully-penetrating cutoff wall was considered to be a reasonable estimate. This estimate is considered to be conservative in that it does not account for increased vertical flow beneath the cutoff walls or horizontal flow around the cutoff walls. A three-dimensional model would be expected to show a somewhat smaller flow reduction due to the cutoff walls.

6.1.2 LSCE Seepage Estimates

Since almost all of the groundwater flow beneath the levees occurs in the permeable sand and gravel layers, a seepage estimate equivalent to the SEEP/W model can be obtained by simply calculating groundwater flow in the sand and gravel layers using Darcy's equation. An updated version of the estimate made by LSCE (2008a) is summarized in **Table 6-4** and discussed in this section. As noted above, Darcy's equation states that the volumetric rate of groundwater flow is equal to the product of the hydraulic conductivity, the cross-sectional area, and the hydraulic gradient (Darcy, 1856). Groundwater flow for 57 reaches or sub-reaches was estimated separately and then summed to estimate the total net recharge from the River. The term "net recharge" is used because the hydraulic gradient used for the simulations is an average value that accounts for the fact that the Sacramento River fluctuates between gaining and losing conditions over the course of the year. On an annual basis, however, all reaches of the Sacramento River in the Natomas Basin appear to be losing, as discussed above in Chapter 3.

For these seepage estimates, groundwater flow in fine to medium sands was estimated separately from that in coarse sands and gravels. For each category, the hydraulic conductivity and gradient were assumed to be constant for all reaches. Hydraulic conductivities used in the model are based on estimates summarized in **Table 2-1**. A hydraulic conductivity of 28 ft/day was used for the fine to medium sands, which is higher than the estimate used by Kleinfelder for three of the stations simulated with the SEEP/W model (14 ft/day). A hydraulic conductivity of 140 ft/day was used for coarse sands and gravels, which is within the range of estimates used by Kleinfelder for similar materials at Station 217+00 (56 to 283 ft/day).

The hydraulic gradient used for the Darcy's Law estimate was 0.0032 ft/ft based on the average annual value estimated in LSCE (2008a). As discussed in Section 4, this hydraulic gradient accounts for the large seasonal fluctuations observed in the hydrographs of groundwater levels and estimated stage. Steep positive gradients (losing conditions) occurring during periods of rising and high stage are partially offset by shallow negative gradients (gaining conditions) during periods of declining and low stage. Although the groundwater contour maps show that the gradient is steeper in the southern portion of the Natomas Basin, the piezometer data and stage estimates were not accurate enough to allow this spatial variability to be quantified.

For each reach, the saturated thickness of permeable sands and gravels was estimated from the geologic profiles, which contain data for the upper 100 to 120 feet of the aquifer system. The permeable saturated thickness for fine to medium sands ranged from eight to 80 feet, with an average of 46 feet. The permeable saturated thickness for coarse sands and gravels ranged from zero to 53 feet, with an average of seven feet. These thicknesses were multiplied by the length of each reach to estimate the cross-sectional area for groundwater flow. Because the overall length of the Sacramento River East Levee is about 18 miles, the total cross-sectional area is very large (about 5.8 million square feet or 134 acres).

As shown in **Table 6-4**, the estimated groundwater flow in each reach ranges by several orders of magnitude, from one to about 2,200 afy. The total estimated groundwater flow in the shallow aquifer without slurry cutoff walls is 8,450 afy. Although the coarse sand and gravel layers account for only 23 percent of the total saturated thickness, groundwater flow in these layers accounts for 60 percent of the total estimated flow. The total flow is about 50 percent more than was estimated by Kleinfelder using the steady-state SEEP/W model but is less than would be expected had Kleinfelder applied its transient model to all reaches.

The estimated effect of the slurry cutoff walls was partially based on the Kleinfelder transient model results. The estimate of a 70 percent reduction in groundwater flow obtained with the transient model was used for reaches where the cutoff wall fully penetrated the permeable sand layer. LSCE's interpretation of the geologic profiles indicates that the slurry cutoff walls will only be fully penetrating for portions of five of the 13 reaches where cutoff walls are proposed. For the other eight reaches, a 70 percent flow reduction was assumed for the depth of the cutoff wall and no flow reduction below the bottom of the cutoff wall. Using this approach, the effect of the cutoff walls is estimated to range from two to 70 percent of the total flow in these reaches. The estimated flow reduction due to all proposed cutoff walls is 884 afy, as shown in **Table 6-4**. This represents a reduction of about ten percent of the total estimated recharge from the Sacramento River.

The estimate of slurry cutoff wall impacts in **Table 6-4** is based on existing groundwater conditions in the Natomas Basin. In order to estimate impacts in 2030, the hydraulic gradient was increased to reflect the steeper gradient that would occur in the northern portion of the Natomas Basin primarily due to pumping to supply the proposed Sutter Pointe development. As shown in **Table 6-5**, the magnitude of the predicted increase ranges from a maximum of 0.0018 ft/ft in Reaches 2 and 3 to zero in Reaches 14 through 20. The total estimated recharge from the River without slurry cutoff walls would increase to 9,340 afy, and the estimated flow reduction due to all proposed cutoff walls would increase to 992 afy. These flow reductions are also summarized in **Table 6-6**, which shows the estimated groundwater flow through the cross-sectional area of the proposed slurry cutoff walls with and without the walls for all levees surrounding the Natomas Basin based on existing/2004 and future/2030 conditions.

Like the Kleinfelder model results, the reduction in flow due to the proposed slurry cutoff walls calculated by LSCE is conservative because the model only accounts for horizontal flow through the cutoff walls. Increased vertical flow beneath the cutoff walls and increased horizontal flow around the ends of the cutoff walls are not included in the model, which means that the actual flow reduction would be less than simulated. The reduction in groundwater flow beneath the levee due to the cutoff walls equates to reduced recharge from the Sacramento River to the Natomas Basin. During periods when the River is losing, heads will be lower on the land side of the levee and higher on the river side due to the impedance caused by the cutoff walls and the resultant reduction in groundwater flow. Flow that would be impeded by the cutoff walls would be expected to remain in the River, which will provide a benefit to downstream users.

6.2 Natomas Cross Canal South Levee

6.2.1 Kleinfelder Model

Slurry cutoff walls are currently under construction along the NCC South Levee as summarized in **Table 6-2**. Seepage beneath the NCC South Levee with and without slurry cutoff walls was estimated by Kleinfelder using the SEEP/W groundwater flow model. The model results are included in a report entitled *Evaluation of Cutoff Walls Impact on Groundwater Recharge, Natomas Cross Canal South Levee, Natomas Levee Improvement Project, Sacramento and Sutter Counties, California* (Kleinfelder, 2008) and are summarized below.

Hydraulic conductivities used in the model ranged from 0.028 ft/day for clay to 28 ft/day for sand. The maximum hydraulic conductivity is an order of magnitude less than the 283 ft/day used for some reaches of the Sacramento River East Levee because boreholes drilled along the NCC South Levee did not encounter significant gravel lenses. However, the permeable sand layers were assigned a hydraulic conductivity of 28 ft/day, which is double that used for the model of the Sacramento River East Levee.

Kleinfelder conducted both steady state and transient simulations were conducted for the NCC South Levee, but the results of the transient simulations were not used for the overall seepage estimate. The reported model results were based on steady-state simulations conducted for three stations, which were considered to be representative of the different geologic conditions observed on geologic profiles created from borehole data. The modeled stations were located at Stations 135+00 (Reach 4), 183+00 (Reach 5), and 213+00 (Reach 6). Stations 135+00 and

183+00 were modeled as having two relatively thin sand layers separated by a clay layer. Station 213+00 was modeled as having a single thicker sand layer. Model results from these stations were applied to other reaches with similar geology. The percentage of the entire length of the NCC South Levee represented by each modeled station was 35 percent for Station 135+00, 40 percent for Station 183+00, and 25 percent for Station 213+00.

An "average" depth to water of 7.5 feet was used for all simulations. This equates to a groundwater elevation of about 27.6 to 34.6 ft msl and was compared against NCC stage ranging from about 19.6 to 36.6 ft msl in one-foot increments to calculate the gradient between the canal and shallow groundwater. The steady-state model was run separately for each stage height, and the estimated seepage was multiplied by the number of days that the stage was calculated to be at each elevation based on data from the Sacramento River Verona gage for 1995-2007. The lowest stage height (19.6 ft msl) had the longest duration (about 20 days/year), and the three highest stage heights (34.6, 35.6, and 36.6 ft msl) each had a duration of about ten days/year.

Unlike its seepage model of the Sacramento River East Levee, Kleinfelder modeled all three stations of NCC South Levee using the same hydraulic conductivity (28 ft/day) for the most permeable layers. Therefore, the simulated seepage for the NCC was much less variable. Station 135+00 had the lowest estimated seepage rate (3.1 afy/1,000 lf). Station 183+00 had a seepage rate of 9.8 afy/1,000 lf, and Station 213+00 had a seepage rate of 9.1 afy/1,000 lf. These seepage estimates were multiplied by the length of each reach, and the total seepage was estimated to be about 218 afy without slurry cutoff walls using this approach.

The model was rerun for all three stations with the slurry cutoff walls in place to estimate the effect of the cutoff walls on seepage from the NCC. A hydraulic conductivity of 2.8×10^{-3} ft/day was assumed for the cutoff walls. For Station 135+00, the cutoff wall was assumed to fully penetrate both sand layers, resulting in an estimated seepage reduction of 90 percent. For Station 183+00, however, the cutoff wall was assumed to penetrate only the upper sand layer, which resulted in an estimated seepage reduction of 30 percent. For Station 213+00, the cutoff wall was assumed to fully penetrate the single sand layer, which also resulted in an estimated seepage reduction of 90 percent. The model results for the four stations were multiplied by one of these percentages to estimate the impacts of the other cutoff walls, and the total amount of groundwater flow that would be blocked by the slurry cutoff walls along the NCC South Levee under existing conditions was estimated to be 126 afy. This represents 90 percent of the flow through the cutoff wall cross section and 58 percent of the total flow calculated by the model. A flow reduction of 90 percent is considered to be high, and the flow reduction estimated from Kleinfelder's transient simulation for the Sacramento River East Levee was used for LSCE's seepage estimates discussed below.

6.2.2 LSCE Seepage Estimates

The Kleinfelder model of the NCC provides an estimate of canal seepage by does not include groundwater flow from the north into the Natomas Basin (beneath the NCC). As discussed in Chapter 4, this flow was estimated to be 241 afy based on the 2004 IGSM simulation. As shown in **Table 6-6**, the total flow into the Natomas Basin from the north is estimated as the sum of the groundwater flow estimated by the IGSM model and canal seepage estimate with the SEEP/W

model (218 afy). Approximately 80 afy of this flow is estimated to pass through the cross-sectional area of the proposed slurry cutoff walls, and a flow reduction of 70 percent was assumed due to the cutoff walls. The total estimated flow reduction shown in **Table 6-6** is 56 afy, or 12 percent of the total flow.

The impacts of slurry cutoff walls along the NCC South Levee were estimated similarly for 2030 conditions in **Table 6-6**. Seepage from the NCC was assumed to be relatively constant in future years, but groundwater flow beneath the NCC South Levee was estimated to be much larger (about 3,700 afy) in 2030 (**Table 4-1**) due primarily to steeper gradients caused by proposed M&I pumping in the Sutter County portion of the Natomas Basin. It is assumed that almost all of this flow would occur in the upper 400 feet of the aquifer system. Flow through the cross-sectional area where cutoff walls are proposed was estimated to be 686 afy, and a 70 percent flow reduction due to the slurry cutoff walls was again assumed. The estimated flow reduction for the 2030 simulation is 480 afy.

6.3 Pleasant Grove Creek Canal West Levee

Proposed slurry cutoff walls along the PGCC West Levee are summarized in **Table 6-2**, and the cutoff wall locations are shown on **Figure 6-1**. As discussed above, no modeling has been done to estimate the impacts of proposed slurry cutoff walls along the PGCC West Levee, the NEMDC West Levee, and the American River North Levee. For these levees, groundwater flow without slurry cutoff walls was estimated based on the IGSM groundwater model results discussed in Chapter 4. Based on the model results, an estimate of groundwater flow per cross-sectional area was developed for the 2004 and 2030 simulations (**Table 6-6**). For the reaches where slurry cutoff walls are proposed, flow through the cross-sectional area of the cutoff walls was reduced by a fixed percentage (70 percent) based on the Kleinfelder transient model results for the Sacramento River East Levee.

As discussed in Chapter 4, the IGSM model results show relatively large volumes of groundwater outflow from the Natomas Basin to the east beneath the PGCC and NEMDC for the 2004 simulation. The model results indicate much less outflow in 2030 due to higher heads east of the Natomas Basin resulting from the planned transition from groundwater to surface water to meet M&I demands in northern Sacramento County.

Flow beneath the PGCC West Levee with and without slurry cutoff walls is estimated in **Table 6-6**. Groundwater flow to the east beneath the levee without cutoff walls was estimated to be 4,512 afy based on the 2004 IGSM simulation and 233 afy based on the 2030 simulation. It was assumed that almost all of this flow occurs in the upper 400 feet of the aquifer system, which corresponds to Layer 1 and the upper portion of Layer 2 of the IGSM models. The slurry cutoff walls along the PGCC West Levee were assumed to be about 14,000 feet long with an average depth of 38 feet. Groundwater flow through this cross section without the cutoff walls was estimated to be 341 afy and 19 afy, based on the 2004 and 2030 simulations, respectively. The estimated flow reduction due to the slurry cutoff walls is assumed to be 70 percent or 238 afy for the 2004 simulation and 13 afy for the 2030 simulation. These flow reductions will be at least partially offset by the estimated increase in groundwater outflow beneath the PGCC due to pumping reductions planned for the Brookfield borrow site.

6.4 Natomas East Main Drainage Canal West Levee

Proposed slurry cutoff walls along the NEMDC West Levee are summarized in **Table 6-2**, and the cutoff wall locations are shown on **Figure 6-1**. The impacts of proposed slurry cutoff walls along the NEMDC West Levee were estimated similarly to the PGCC West Levee in **Table 6-6**. Groundwater flow to the east beneath the northern and southern portions of the NEMDC West Levee was estimated separately. For the northern NEMDC West Levee, groundwater flow to the east beneath the levee without cutoff walls was estimated to be 9,132 afy based on the IGSM 2004 simulation and 504 afy based on the 2030 simulation. As for the PGCC, it was assumed that almost all of this flow occurs in the upper 400 feet of the aquifer system. The slurry cutoff walls along the northern NEMDC West Levee were assumed to be 22,800 feet long and an average of 37 feet deep. Groundwater flow through this cross-sectional area without the cutoff walls was estimated to be 541 afy and 30 afy, based on the 2004 and 2030 simulations, respectively. A 70 percent flow reduction due to the slurry cutoff walls was again assumed based on the Kleinfelder transient simulation for the Sacramento River East Levee. The estimated flow reduction is 378 afy for the 2004 simulation and 21 afy for the 2030 simulation.

For the southern NEMDC West Levee, groundwater flow to the east beneath the levee without cutoff walls was estimated to be 8,156 afy based on the IGSM 2004 simulation and 450 afy based on the 2030 simulation, as shown in **Table 6-6**. The slurry cutoff walls along the southern NEMDC West Levee were assumed to be 23,100 feet long and an average of 45 feet deep. Groundwater flow through this cross-sectional area without the cutoff walls was estimated to be 665 afy and 37 afy, respectively, based on the 2004 and 2030 simulations. The estimated flow reduction is 466 afy for the 2004 simulation and 26 afy for the 2030 simulation.

6.5 American River North Levee

Slurry cutoff walls are currently proposed for the entire length of the American River North Levee, as shown on **Table 6-2** and **Figure 6-1**. The impacts of these slurry cutoff walls were estimated similarly to the PGCC and NEMDC West Levees in **Table 6-6**. This was assumed to be a generally losing reach under current conditions, and recharge from the American River to the Natomas Basin was estimated to be 1,086 afy based on the IGSM 2004 simulation. For the 2030 simulation, the direction of groundwater flow is indicated to be toward the River (gaining conditions), and simulated groundwater flow to the River was 500 afy. For both simulations, it was assumed that almost all of the flow to and from the River occurs in the upper 200 feet of the aquifer system. Planning for slurry cutoff walls along the American River North Levee is in the early stages, but cutoff walls are currently proposed to extend the entire length of the levee (11,560 lf) and average 55 feet deep.

Groundwater flow through the cross-sectional area where cutoff walls are proposed was estimated to be 301 afy away from the River for the 2004 simulation and –139 afy toward the River for the 2030 simulation. A 70 percent flow reduction due to the slurry cutoff walls was again assumed based on the Kleinfelder transient simulation for the Sacramento River East Levee. The estimated reduction in flow from the River was 211 afy for the 2004 simulation as shown in **Table 6-6**. The estimated reduction in flow to the River was 97 afy for the 2030 simulation.

6.6 Summary

The proposed slurry cutoff walls are expected to reduce groundwater flow beneath the levees as intended. Cutoff wall impacts shown in **Table 6-6** were estimated separately based on simulations of existing (or 2004) and future (2030) conditions. Estimates were based on models by Kleinfelder (2009) and LSCE (2008a) and IGSM model results (WRIME, 2007 and LSCE, 2008b). The predicted impacts of cutoff walls beneath each of the five levees surrounding the Natomas Basin are based on both the existing/2004 and future/2030 results because the impact varies both by location and simulation period. The results show that the impact to groundwater supplies in the Natomas Basin is greatest due to proposed cutoff walls along the Sacramento River East Levee. For the entire Natomas Basin, reduced recharge from the Sacramento and American Rivers is largely offset by reduced groundwater outflow to the east for the 2004 simulation. The total predicted impact of all slurry cutoff walls is only 68 afy based on "existing" or 2004 conditions.

The impact of slurry cutoff walls is predicted to be greater based on future/2030 conditions due to several factors. Gradients are expected to be steeper in the northern portion of the Natomas Basin due to pumping to supply the proposed Sutter Pointe development. This will increase groundwater flow beneath the Sacramento River East Levee and the NCC South Levee, and there will be a corresponding increase in flow reductions caused by slurry cutoff walls. At the same time, the IGSM model predicts less groundwater outflow to the east beneath the PGCC and NEMDC West Levees due to reduced pumping east of the Natomas Basin. The total predicted impact of all slurry cutoff walls increases to 1,315 afy for the future/2030 scenario.

There are also potential groundwater impacts east of the Natomas Basin, primarily because the proposed slurry cutoff walls beneath the PGCC and NEMDC West Levees will reduce groundwater outflow to the east. These impacts are predicted to occur primarily under existing conditions (based on the 2004 simulation) because the gradient for groundwater flow to the east is estimated to be much steeper under existing/2004 conditions. As shown in **Table 6-6**, the reduction in groundwater outflow beneath the PGCC and NEMDC West Levees is estimated to be 1,082 afy based on the 2004 simulation. The predicted reduction in groundwater outflow to the east decreases to 60 afy for the 2030 simulation.

As discussed above, these estimates of slurry cutoff wall impacts are conservative in that they do not account for increased vertical flow beneath the cutoff walls or horizontal flow around the cutoff walls. A three-dimensional model would be expected to show somewhat smaller flow reductions due to the cutoff walls.

1. Hydraulic conductivity based on estimates in Table 2-1.
2. Hydraulic gradient based on annual average value in Table 3-2.
3. Assumes a 70% reduction in flow through the cutoff wall based on the Kleinfelder transient model results (Kleinfelder, 2009).

Table 6-5
Darcy's Law Estimate of Groundwater Recharge from Sacramento River to Natomas Basin With and Without Slurry Cutoff Walls
(Including Increase in Hydraulic Gradient Due to Additional Pumping in 2030)

Reach	Stations	Proposed Mitigation Includes Cutoff Wall	Length of Reach (ft)	Length of Cutoff Wall (ft)	Cutoff Wall Depth (ft)	Cutoff Wall Bottom Elev. (ft msl)	Average Ground-Water Elev. Figure 6-1
Proposed Slurry Cutoff Walls Surrounding Natomas Basin

7.0 Groundwater Impacts of SAFCA Construction Activities

The effects of SAFCA's proposed construction activities on groundwater conditions in the Natomas Basin were evaluated using the water budget approach discussed above. Water budget impacts resulting from land use changes and canal construction were addressed in Chapter 5, and water budget impacts due to proposed slurry cutoff walls were addressed in Chapter 6. All of the predicted impacts of SAFCA's activities are summarized in **Table 7-1** for existing/2004 conditions and in **Table 7-2** for future/2030 conditions. This chapter also addresses cumulative impacts for 2004 and 2030 conditions based on the groundwater budgets calculated by the IGSM models.

7.1 Levee Improvements

Groundwater impacts from proposed levee improvements are primarily limited to the effects of land use changes and slurry cutoff walls. No direct groundwater impacts are expected from increasing the height or width of levees, modifying levee slopes, or building seepage berms because all of this construction would be above the water table.

Proposed land use changes will result in the loss of about 20 acres of rice, 175 acres of field crops, and five acres of orchard along the Sacramento River East Levee. Other land use changes include the loss of five acres of rice along the NCC South Levee and 50 acres of rice along the PGCC West Levee. As shown in **Tables 7-1** and **7-2**, these changes are estimated to reduce deep percolation from applied water by a total of 105 afy.

Estimated reductions in groundwater flow beneath the levees due to the proposed slurry cutoff walls are shown in **Table 6-6** based both on simulations of "existing" (or 2004) and future (2030) conditions. Estimated inflow reductions for existing conditions shown in **Table 7-1** include 105 afy of deep percolation, 1,095 afy of recharge from the Sacramento and American Rivers, and 56 afy of inflow to the Natomas Basin beneath the NCC. The total estimated inflow reduction is 1,256 afy. The reduction in subsurface outflow from the Natomas Basin beneath the PGCC and NEMDC is estimated to be 1,083 afy. The estimated effect of all proposed slurry cutoff walls based on the simulation of existing conditions will be to reduce groundwater storage in the Natomas Basin by about 173 afy.

Estimated inflow reductions for 2030 conditions shown in **Table 7-2** include 105 afy of deep percolation, 895 afy of recharge from the Sacramento and American Rivers, and 480 afy of inflow to the Natomas Basin beneath the NCC. The total estimated inflow reduction is 1,480 afy. The reduction in subsurface outflow from the Natomas Basin beneath the PGCC and NEMDC is estimated to be 60 afy. The estimated effect of all proposed slurry cutoff walls based on the 2030 simulation would be to reduce groundwater storage in the Natomas Basin by about 1,420 afy.

7.2 Canal Improvements

The construction of the new GSS/Drainage Canal and relocation and improvements to the West Drainage Canal, the Elkhorn Canal, and the Riverside Canal will affect deep percolation from applied water (due to land use changes) and seepage from the canals. For all four canals, deep percolation is estimated to decrease by 41 afy and canal seepage is estimated to increase by 327 afy (**Tables 7-1** and **7-2**). The net effect of proposed canal construction would be to increase groundwater storage in the Natomas Basin by about 285 afy.

7.3 Borrow Sites

Excavation and reclamation of the Brookfield and Fisherman's Lake borrow sites is expected to have an indirect effect on groundwater conditions due to proposed land use and water supply changes. No such changes are planned for the Airport North Bufferlands borrow site.

At the Brookfield borrow site, approximately 325 acres are currently planted to rice, and SAFCA plans to restore about 286 acres to rice cultivation after construction activities are complete. As shown in **Tables 7-1** and **7-2**, an estimated 30 afy of deep percolation will be lost at this site due to the reduction in irrigated acreage. The Brookfield site is currently irrigated entirely with groundwater, but SAFCA plans to provide the infrastructure so that about 80 percent of the borrow site can be irrigated with surface water after reclamation. This transition would reduce groundwater pumping by about 1,625 afy. Groundwater levels will increase due to the reduced pumping, resulting in an increase in subsurface outflow beneath the PGCC of about 76 afy.

At the Fisherman's Lake borrow site, about 400 acres of land would be used for borrow material, including 49 acres currently planted to rice, 266 acres of field crops, and 85 acres of managed marsh. After reclamation, there would be about 175 acres of managed marsh and 225 acres of non-irrigated grassland or woodland. The predicted net loss in deep percolation is 36 afy at this site, as shown in **Tables 7-1** and **7-2**.

The reduction in groundwater pumping at the Brookfield site more than offsets the loss of deep percolation at all borrow sites. The net effect of excavation and reclamation of all borrow sites would be to increase groundwater storage by about 1,483 afy.

7.4 Summary of SAFCA Groundwater Impacts

The totals at the bottom of **Tables 7-1** and **7-2** show the combined effect of SAFCA's proposed construction activities based on exising/2004 and future/2030 conditions, respectively. For both simulations, deep percolation is estimated to decrease by 213 afy, seepage from canals is estimated to increase by 327 afy, and groundwater pumping is estimated to decrease by 1,625 afy. Other changes for existing/2004 conditions include decreases in net recharge from streams (1,095 afy), subsurface inflow (56 afy), and subsurface outflow (1,007 afy). Summing these terms results in an increase in groundwater storage in the Natomas Basin of 1,595 afy for existing/2004 conditions, which means that groundwater levels would be expected to increase slightly due to all construction activities. The reduction in subsurface outflow would have a slightly negative effect on groundwater levels and storage east of the Natomas Basin.

The totals at the bottom of **Table 7-2** show the combined effect of SAFCA's proposed construction activities based on future conditions in 2030. Estimated changes in deep percolation, seepage from canals, and groundwater pumping are the same as for existing/2004 conditions. The estimated reduction in net recharge from streams (895 afy) is smaller than for the 2004 simulation, and the reduction in subsurface inflow (480 afy) is larger. Groundwater storage in the Natomas Basin is predict to increase due to the proposed construction, but by a smaller amount (348 afy). Subsurface outflow to the east is predicted to increase slightly in 2030 (by 16 afy). These small changes would have a slightly positive effect on groundwater levels and storage in and near the Natomas Basin.

7.5 Cumulative Effects

The cumulative impacts of SAFCA's construction activities on existing groundwater conditions based on the 2004 and 2030 IGSM simulation are shown in **Tables 7-3** and **7-4**. On these tables, the estimated SAFCA impacts discussed above are added to the groundwater budget for the Natomas Basin discussed in Chapter 4. The 2004 groundwater budget showed a total groundwater inflow to the Natomas Basin of 52,304 afy without the effects of SAFCA's activities and 51,267 afy including the proposed construction (**Table 7-3**). There is a similar reduction in groundwater outflow from 57,275 afy without SAFCA's construction activities to 54,643 afy including the construction. The simulated reduction in groundwater storage for 2004 is 4,971 afy without SAFCA, which represents an average water level decline of about one foot. The decrease in groundwater storage would be smaller (3,376 afy) due to SAFCA's construction activities. Overall, SAFCA's proposed construction would have a small positive impact on groundwater supplies in the Natomas Basin based on existing conditions. Outside of the Natomas Basin, the predicted reduction in groundwater outflow to the east (1,007 afy) would have a small negative impact on groundwater levels and storage within the cones of depression east of the Natomas Basin, but groundwater outflow is still estimated to be large (20,731 afy).

The estimate of the cumulative impacts of SAFCA's construction activities based on the simulation of future (2030) groundwater conditions is summarized in **Table 7-4**. The 2030 groundwater budget shows that the total groundwater inflow to the Natomas Basin without the effects of SAFCA's activities (35,187 afy) would decrease to 33,926 afy including SAFCA proposed construction. This is offset by a reduction in groundwater outflow from 33,615 afy without SAFCA's construction activities to 32,006 afy including SAFCA's activities. The simulation shows an increase in groundwater storage in 2030 of 1,572 afy without SAFCA. The results indicate that, on average, SAFCA's construction activities will have a positive effect on groundwater levels in the Natomas Basin, resulting in an additional increase in storage of 348 afy (to 1,920 afy). Subsurface outflow to the east is predicted to be much smaller in 2030 (only 1,200 afy without SAFCA's construction activities), but would increase by 16 afy due to SAFCA's proposed construction. Overall, SAFCA's activities would have a slightly positive effect on groundwater levels and storage within and east of the Natomas Basin in 2030.

8.0 Effects on Groundwater Quality and Private Wells

8.1 Potential Groundwater Quality Impacts

The primary potential groundwater quality impact of SAFCA's proposed construction activities is a slight reduction in groundwater recharge to the Natomas Basin, including stream recharge and deep percolation from rice fields and other irrigated farmland. This recharge is generally of high quality, especially the stream recharge, which typically has very low salinity and few contaminants. Seepage from canals is another source of good quality recharge, and this will increase due to SAFCA's proposed canal construction. Water recharged via deep percolation has somewhat higher salinity than river water due to the use of recycled tailwater and the effects of ET.

As estimated above, the combined effect of SAFCA's proposed construction activities on existing groundwater conditions would be to reduce low-salinity recharge from rivers and canals by 768 afy and reduce groundwater outflow beneath the PGCC and NEMDC by 1,007 afy. The combined effect of these inflow and outflow reductions would be expected to slightly increase salt accumulation in the Natomas Basin and have a small effect on groundwater quality east of the Natomas Basin. However, these reductions represent less than two percent and five percent of the total estimated groundwater inflow and outflow to and from the Natomas Basin, and the water quality impacts are not expected to be measurable.

For future groundwater conditions in 2030, the combined effect of SAFCA's proposed construction activities would be to reduce low-salinity groundwater recharge from rivers and canals by 568 afy and groundwater outflow to the east by 16 afy. Again, the overall effect of these changes on future groundwater quality would be small.

In the vicinity of the Brookfield borrow site, groundwater quality would improve due to the transition from groundwater to surface water for about 80 percent of the rice acreage. Groundwater quality would improve in this area because deep percolation from fields irrigated with surface water will have lower salinity than from fields irrigated with groundwater.

The slurry cutoff walls will be constructed primarily of soil mixed with bentonite, but Portland cement may be used as an additive in some cases. Bentonite is a naturally occurring form of clay, and Portland cement is made from limestone and clay. Neither bentonite nor cured Portland cement are water soluble, and grouts composed of both materials are widely used in the water well industry. Both bentonite and cement are used to construct seals in wells drilled for various purposes, including drinking water supply. No groundwater contamination would be expected due to construction of the proposed slurry cutoff walls and other improvements proposed for the levees surrounding the Natomas Basin.

Although SAFCA's proposed construction activities would cause slight groundwater quality impacts in some areas and improvements in other areas, the effects would be too small to be

measurable. The overall effect of SAFCA's proposed construction on future groundwater quality in the Natomas Basin can be considered negligible.

8.2 Potential Impacts to Private Wells

8.2.1 Private Well Locations and Construction

For the *Sacramento River Basinwide Water Management Plan*, DWR reviewed drillers' logs in the Natomas Basin and reported that average well depths were 149 feet for domestic wells, 313 feet for irrigation wells, 378 feet for industrial wells, and 308 feet for municipal wells (DWR, 2003c). The majority of the wells in the Natomas Basin are either domestic or agricultural wells, which typically extract groundwater from the upper aquifer system as defined above.

Figure 8-1 shows wells with known or estimated locations in and near the Natomas Basin. "Private wells" shown along the Sacramento River East Levee and the NCC South Levee are primarily domestic wells mapped by M&H (Stephen Sullivan, pers. comm., January 23, 2008) but include some irrigation wells. Well numbers provided for these wells correspond to numbers assigned by M&H. Similar mapping of private wells along the PGCC and NEMDC West Levees is still in progress, and well locations along the eastern edge of the Natomas Basin shown on **Figure 8-1** are estimated based on parcel boundaries. Only a portion of the estimated well locations in the Valley View Acres (VVA) community, located along the NEMDC north of Del Paso Road and east of Sorento Road, are shown on the map due to the high density of domestic wells in this area.

In addition to domestic wells, **Figure 8-1** also shows wells with water level data mapped by LSCE based on locations provided by DWR and other sources. Symbols used for these wells indicate the depth zone (upper, lower, multiple, and unknown). Most of these are agricultural wells, M&I wells, or monitoring wells. If available, the wells are numbered based on the last four digits of the State Well Number.

Approximately 138 private wells along the Sacramento River East Levee have been mapped by M&H (2008), and these are grouped by depth and type in **Table 8-1**. There are 103 domestic wells, 15 irrigation wells, and 20 wells used for other or unknown purposes in this area. Monitoring and municipal wells are not included on this table. All of the domestic wells are less than 300 feet deep, and 84 percent are between 100 and 200 feet deep. All but one of the irrigation wells are also less than 300 feet deep, with six wells between 100 and 200 feet deep and eight wells between 200 and 300 feet deep. The average depth of the private wells along the Sacramento River East Levee is 158 feet. As reported by LSCE (2008a), approximately two-thirds of these wells are located on the river side of the levee and one-third on the land side. The average depth of these wells is 151 feet on the river side of the levee and 163 feet on the land side. The land side wells are slightly deeper on average because they include more irrigation wells.

As shown in **Table 8-1**, nine wells along the NCC South Levee were mapped by M&H (2008). These include one domestic well and eight irrigation wells. The domestic well is between 100 and 200 feet deep. One of the irrigation wells is between 100 and 200 feet deep, three are

between 200 and 300 feet deep, two are between 300 and 400 feet deep, and two are of unknown depth. The average depth of wells with depth information is 260 feet.

There are about 150 residences in the VVA community, situated on about 300 acres of land west of the NEMDC. The VVA community is supplied by groundwater, and each residence is assumed to have a domestic well. Compilation of construction information for these wells is still in progress, but M&H has provided drillers' logs for 27 VVA wells to date. These wells range in depth from 65 to 290 feet, with an average of 122 feet. Most of the drillers' logs do not show the perforated interval, but it is expected to be below the depth of the cutoff wall proposed for this portion of the NEMDC West Levee (53 feet) for almost all wells.

8.2.2 Potential Impacts

Kleinfelder (2009) estimated the water level changes due to the slurry cutoff walls along the Sacramento River East Levee using the steady-state and transient versions of the seepage model discussed above. The transient version of the model is considered to be more accurate, and the changes in head due to the proposed slurry cutoff wall along one reach of the Sacramento River East Levee predicted by the transient model are shown on **Figure 8-2**. On the river side of the levee, the predicted effects of the cutoff walls are negligible at low stage, and there would be a slight increase in head (less than one foot) at high stage. On the land side of the levee, the Kleinfelder simulation shows that heads would be from one to 6.5 feet lower (average of 2.2 feet) due to the cutoff wall during the winter months when the direction of groundwater flow is away from the River. During the rest of the year, the direction of groundwater flow is toward the River because gaining conditions are simulated with the model. Under these conditions, land side groundwater levels are predicted to be up to 1.5 feet higher (average of 0.9 foot) with the cutoff wall in place. These small effects are considered to be negligible even for the shallowest domestic wells (less than 100 feet deep). No measurable decreases in well yields or increases in pumping costs are expected due to slurry cutoff walls along the Sacramento River East Levee.

Similar modeling has not been conducted for wells along the PGCC or NEMDC, but cutoff walls would be expected to have similarly small effects near the eastern edge of the Natomas Basin. Since the general direction of groundwater flow in this area is to the east, static groundwater levels will increase slightly west of the levee and decrease slightly east of the levee. Shallow wells on either side of the levee could experience slightly lower pumping water levels because the cutoff wall will act as a low permeability boundary that will reduce the aerial extent and increase the depth of the cone of depression. This effect will be small because the production zone for most wells is below the bottom of the proposed cutoff walls. No measurable decreases in well yields or increases in pumping costs are expected due to the slurry cutoff walls. Overall, no measurable effects on groundwater levels or quality are expected for wells in or near the Natomas Basin due to SAFCA's proposed construction activities.

Simulated Groundwater Elevations from Kleinfelder Transient Model With and Without Slurry Cutoff Walls

9.0 Summary of Potential Impacts

Most of SAFCA's proposed levee improvements will have no effect on groundwater in the Natomas Basin, but the proposed slurry cutoff walls are intended to reduce seepage beneath the levees and will affect groundwater conditions. Some of SAFCA's construction activities will involve land use changes that will reduce groundwater recharge. This reduction will be at least partially offset by seepage from new and relocated canals, which will increase groundwater recharge. Finally, water supply changes at the Brookfield property borrow site will result in a large reduction in groundwater pumping.

The effects of SAFCA's proposed construction activities on groundwater conditions in the Natomas Basin were evaluated using the water budget approach and other methods discussed above. Potential impacts resulting from land use changes and canal construction were addressed in Chapter 5, potential impacts due to proposed slurry cutoff walls were addressed in Chapter 6, and the potential cumulative impacts were addressed in Chapter 7. The analysis of potential impacts to groundwater quality and private wells was discussed in Chapter 8. Each of these potential impacts is summarized below.

9.1 Potential Water Budget Impacts

9.1.1 Levee Improvements

Groundwater impacts from proposed levee improvements are primarily limited to the effects of land use changes and slurry cutoff walls. No direct groundwater impacts are expected from increasing the height or width of levees, modifying levee slopes, building seepage berms, or other construction above the water table.

Proposed land use changes for all five levees will result in the loss of about 75 acres of existing rice, 175 acres of field crops, and five acres of orchard. These changes are estimated to reduce deep percolation from applied water by a total of 105 afy.

Groundwater flow reductions due to the slurry cutoff walls were estimated based on simulations of "existing" (or 2004) and future (2030) conditions. The combined effect of all proposed slurry cutoff walls along the levees surrounding the Natomas Basin for existing/2004 conditions is estimated to reduce groundwater inflow by 1,256 afy and groundwater outflow by 1,083 afy, resulting in a reduction in groundwater storage in the Natomas Basin of about 173 afy (**Table 7-1**). For 2030 conditions, groundwater inflow is predicted to be reduced by 1,480 afy and groundwater outflow by 60 afy, resulting in a reduction in groundwater storage of about 1,420 afy (**Table 7-2**).

9.1.2 Canal Improvements

The construction of the new GSS/Drainage Canal and relocation and improvements to the West Drainage Canal, the Elkhorn Canal, and the Riverside Canal will affect deep percolation from

applied water (due to land use changes) and seepage from the canals. For all four canals, deep percolation is estimated to decrease by 41 afy and canal seepage is estimated to increase by 327 afy. The net effect of proposed canal construction would be to increase groundwater storage in the Natomas Basin by about 285 afy (**Tables 7-1** and **7-2**).

9.1.3 Borrow Sites

Excavation of two of the three primary borrow sites is expected to have an indirect effect on groundwater conditions due to proposed land use and water supply changes. At the Brookfield borrow site, approximately 325 acres are currently planted to rice, and SAFCA plans to restore about 286 acres to rice cultivation after construction activities are complete. At the Fisherman's Lake borrow site, about 400 acres of land would be used for borrow material, including 49 acres currently planted to rice, 266 acres of field crops, and 85 acres of managed marsh. After reclamation, there would be about 175 acres of managed marsh and 225 acres of non-irrigated grassland or woodland. No land use changes are planned at the Airport North Bufferlands borrow site due to airport safety considerations. The predicted net loss in deep percolation for all borrow sites is 67 afy.

The Brookfield borrow site is currently irrigated entirely with groundwater, but SAFCA plans to provide the infrastructure so that about 80 percent of the borrow site can be irrigated with surface water after reclamation. This transition would reduce groundwater pumping in the Natomas Basin by about 1,625 afy. The reduction in groundwater pumping at the Brookfield site more than offsets the loss of deep percolation at all borrow sites. The reduced pumping would also result in slightly increased groundwater outflow from the northern portion of the Natomas Basin. The net effect of excavation and reclamation of all borrow sites will be to increase groundwater storage by about 1,483 afy (**Tables 7-1** and **7-2**).

9.1.4 Summary of Potential Water Budget Impacts

The combined effects of SAFCA's proposed construction activities for both existing and future conditions include estimated decreases in deep percolation (213 afy) and groundwater pumping (1,625 afy) and an increase in seepage from canals (327 afy). The effect on other water budget components varies between the existing/2004 and future/2030 simulations. For the existing/2004 period, there are predicted decreases in net recharge from streams (1,095 afy), subsurface inflow (56 afy), and subsurface outflow (1,083 afy), and groundwater storage is estimated to increase by 1,596 afy. This means that groundwater levels in the Natomas Basin would be expected to increase slightly due to SAFCA's construction activities. The estimated reduction in subsurface outflow (1,007 afy) would result in a small decrease in groundwater levels and storage east of the Natomas Basin.

For the 2030 period, decreases in groundwater inflow include net recharge from streams (895 afy) and subsurface inflow (480 afy). There would be a smaller increase groundwater storage (348afy) and a small increase in subsurface outflow (16 afy) as compared to the existing/2004 simulation. These changes would have a slight positive effect on groundwater levels in or near the Natomas Basin.

The cumulative impacts of SAFCA's proposed construction activities on existing and future groundwater conditions were based primarily on the 2004 and 2030 IGSM simulations discussed in Chapter 4. The 2004 simulation results show a reduction in groundwater storage of 4,971 afy in the Natomas Basin without SAFCA's construction; this equates to an average head decline of about one foot. The decrease in groundwater storage would be smaller (3,376 afy) due to SAFCA's construction activities. Subsurface outflow from the Natomas Basin to the east would decrease from 21,738 to 20,731 afy due to SAFCA's activities. Overall, SAFCA's activities would have a small positive impact on groundwater supplies in the Natomas Basin and a small negative impact on groundwater conditions east of the Natomas Basin.

The 2030 IGSM simulation provides an estimate of the cumulative impacts of SAFCA's construction activities on future groundwater conditions. The results of the 2030 simulation show a positive change in groundwater storage in the Natomas Basin of 1,572 afy, which would increase slightly to 1,920 afy due to SAFCA's activities. There would be a very small increase in groundwater outflow (from 1,200 to 1,216 afy). Overall, the cumulative impact of SAFCA's proposed construction activities on future groundwater levels in and near the Natomas Basin is predicted to be slightly positive.

9.2 Potential Water Quality Impacts

This investigation also included a summary of potential impacts to groundwater quality due to SAFCA's construction activities. The primary potential groundwater quality impact will be a slight reduction in groundwater recharge to the Natomas Basin, including stream recharge and deep percolation from rice fields and other irrigated farmland. This recharge is generally of high quality, especially the stream recharge, which has very low salinity. Seepage from canals is another source of good quality recharge, and increased seepage due to SAFCA's proposed canal construction will offset some of the reductions in groundwater recharge due to slurry cutoff walls. In the vicinity of the Brookfield borrow site, groundwater quality would improve due to the transition from groundwater to surface water for about 80 percent of the rice acreage. No groundwater contamination would be expected due to construction of the proposed slurry cutoff walls and other improvements proposed for the levees surrounding the Natomas Basin.

SAFCA's proposed construction activities would cause slight groundwater quality degradation in some areas and improvements in other areas. The overall effect would likely be a slight increase in salt accumulation in the aquifers underlying the Natomas Basin. However, this impact would be too small to be measurable.

9.3 Potential Impacts to Private Wells

The majority of the domestic wells along the Sacramento River East Levee are between 100 and 200 feet deep, and irrigation wells in this area are slightly deeper. The average depth of the domestic and irrigation wells along the Sacramento River East Levee is 158 feet. Evaluation of well construction along the PGCC and NEMDC is still in progress, but there are about 150 residences in the VVA community with mostly shallow domestic wells. The drillers' logs for wells in this area that have been cataloged to date show an average well depth of 122 feet. Most of the drillers' logs do not show the perforated interval, but it is expected to be below the depth

of the cutoff wall proposed for this portion of the NEMDC West Levee (53 feet) for almost all wells.

Kleinfelder estimated the water level changes due to the slurry cutoff walls along the Sacramento River East Levee using the SEEP/W groundwater model. On the river side of the levee, the predicted effect of the cutoff wall is negligible at low stage, and there would be a slight increase in head (less than one foot) at high stage. On the land side of the levee, the model results show that, on average, heads would be about 2.2 feet lower during the winter months and 0.9 foot higher during the rest of the year with the cutoff wall in place. In both cases, any impacts would be small enough to be considered negligible even for the shallowest domestic wells (less than 100 feet deep). No measurable decrease in groundwater levels or well yields or increase in pumping costs is expected due to the slurry cutoff walls.

Although similar modeling has not been conducted for wells along the PGCC or NEMDC, cutoff walls would be expected to have similarly small effects in this area. Static groundwater levels will increase slightly west of the levee and decrease slightly east of the levee. Shallow wells on either side of the levee could experience slightly lower pumping water levels because the cutoff wall will act as a low permeability boundary. This effect will be small because the production zone for most wells is below the depth of the proposed cutoff walls. No measurable decreases in well yields or increases in pumping costs are expected due to slurry cutoff walls. Overall, no measurable effects on groundwater levels or quality are expected for wells in or near the Natomas Basin due to SAFCA's proposed construction activities.

C3 Evaluation of Cutoff Walls' Impact on Groundwater Recharge (Kleinfelder)

December 19, 2007
Revised April 21, 2009
File No.: 72834

Mr. Timothy Washburn
SAFCA
1007 7th Street, 7th Floor
Sacramento, CA 95814

Subject: **Evaluation of Cutoff Walls Impact on Groundwater Recharge**
Sacramento River East Levee
Natomas Levee Improvement Project
Sacramento and Sutter Counties, California

Dear Mr. Washburn:

This Memorandum is a revised version of a draft memorandum submitted to you on December 19, 2007. The analyses and data presented in December 2007 memo have been converted to the North American Vertical Datum (NAVD 88). The updated memorandum does not reflect any changes to the proposed remedial design and/or site subsurface characterization model that may have occurred since December 2007.

One of the design alternatives considered for remediation of the Sacramento River East Levee from Reach 1 to Reach 20 includes construction of cutoff walls through an adjacent levee. These soil-bentonite (SB) walls are proposed to mitigate underseepage concerns and reduce exit seepage gradients to the acceptable levels, according to the established project criteria.

A concern has been raised that the SB walls could potentially impede seepage from the river through the levee foundation and adversely impact groundwater recharge landward of the levee. To address these concerns, we have performed simplified seepage analyses to estimate seepage flow from the river into the aquifer under both existing conditions and with cutoff walls in place.

Based on the design recommendations provided by Kleinfelder, the SB wall material should have permeability of about 5×10^{-7} cm/sec or lower and will extend at least 5 feet into a fine grained layer(s) underneath the permeable near surface foundation layer. To account for the variability of the slurry and the potential for construction defects, for this study the SB wall was modeled with and average overall permeability of 1×10^{-6} cm/sec.

In addition, we have evaluated potential seepage loss from the proposed Giant Garter Snake ditch. This new 2 mile long unlined canal will be located approximately 500 to 1,000 feet landward of the levee toe and will follow the existing levee alignment between Stations 200+00 and 305+00. In general, the canal will be filled with water during summer month and will be dry during the winter months. During periods of time when the canal is filled with water, seepage through its bottom and side slopes may temporarily affect the groundwater table in the area.

General Assumptions

- Idealized stratigraphic models at Stations 27+00, 70+00, 217+00, and 353+00 were selected to represent the range of subsurface conditions along the Sacramento River East Levee. Analyses at Station 217+00 are based on the stratigraphy model developed by URS, as presented in the URS "Draft Subsurface Investigation Report for Sacramento River East Levee, Natomas General Reevaluation Report" prepared for US Army Corps of Engineers, Sacramento District, dated 18 July 2007. Analyses at Stations 27+00, 70+00, and 353+00 are based on the models developed by Kleinfelder as presented in the Draft Basis of Design Report (Kleinfelder, 2007).
- Total length and location of the SB wall were estimated based on the information provided in the Final Draft Basis of Design Report dated December 18, 2007 and in the Alternatives Analysis Report for Seepage Mitigation Revision 1 dated September 24, 2007. Two representative cross-sections (Stations 70+00 and 353+00) have been selected to represent the proposed wall locations and depths.
- Seepage analyses were completed using steady state and transient analysis procedures with the finite element program SEEP/W version 6.17, provided with the GeoStudio 2004 package. These analyses do not account for 3-D effects, such as flow around the cutoff wall.
- Typical seasonal river level fluctuations were estimated based on the information provided by the Department of Water Resources (DWR), Division of Flood Management (http://cdec.water.ca.gov/queryStation.html) for the Sacramento River gage at Verona. River stage data recorded at Verona from 11/26/1995 to 11/26/2007 are presented on Plates 1 through 5 and summarized in a tabular form on Plate 6.
- Elevation of the groundwater table landward of the levee was estimated based on piezometer data obtained from "Final Observation Wells Report II: for Reaches North and South of Powerline Road", prepared by URS.
- All elevations in this memorandum are referenced in North American Vertical Datum (NAVD 88). Elevations referenced in previous reports and other sources of information are based on the National Geodetic Vertical Datum (NGVD 29). To correct from NGVD29 datum to NAVD88 datum elevations should be adjusted by 2.28 feet (NAVD88 = NGVD29 + 2.28 feet).
- River gage data reported by DWR was in the United States Engineering Datum (USED). In the Sacramento and San Joaquin River Basins, the adjustment from USED to NGVD29 varies from gaging station to gaging station within a range of 2.48 feet to 3.2 feet. According to the DWR website, the commonly used adjustment, when not otherwise known, is 3.0 feet. Elevations reported in USED

are approximately 3 feet higher than elevations reported in NGVD29 and 0.72 feet lower than elevations reported in NAVD88.

- Seepage parameters selected for this study are consistent with those presented in the Basis of Design Report. Permeability values used in each analysis case are shown on plates presenting the results.
- Only recharge due to seepage from the river was considered. The model does not account for flow into or out of the system due to precipitation, pumping or regional groundwater flow that maybe occurring from a direction parallel to the levee axis.

Analysis Approach

We have performed simplified seepage analyses to estimate seepage flow from the river into the aquifer under both existing conditions and with cutoff walls in place we have further evaluated the impact of the proposed canal construction and operation based on the methodology outlined below. The following sections of this memo discuss analysis assumptions and details and present the results.

1. Review available historical data and develop representative average river level and ground water table hydrographs.
2. Perform series of steady state seepage analyses at four representative cross-sections to estimate seepage through levee foundation under the existing conditions as a function of river elevation. Boundary conditions used in steady state seepage modeling simulations are defined below. Fixed-head boundary conditions set to the water surface elevations were applied along the boundary nodes of the upstream slope, river bottom, and the upstream (riverside) vertical edge of the model. Nodes along the bottom of the model were modeled as no flow boundary (zero total flux boundary condition). Infinite elements with fixed-head boundary conditions were used along the right vertical edge of the model. The total head along the vertical edge was set to an estimated groundwater table elevation landward of the levee. The landside slope of the levee and the ground surface were modeled as potential seepage exit surfaces.
3. Using results from Steps 1 and 2 for each representative cross-section estimate seepage flow under the existing conditions over a typical year report seepage quantities in acre-feet per year per 1,000 feet of levee.
4. Using results from Step 3 and subsurface condition profiles at the landside toe of the levee, estimate seepage flow under the existing conditions over the entire length of the levee. Report seepage quantities in acre-feet per year.
5. Perform series steady state seepage analyses at two representative cross-sections (Stations 70+00 and 353+00) to estimate seepage through the levee foundation with a cutoff wall in place as a function of river elevation.
6. Using results from Steps 1 and 5, for Stations 70+00 and 353+00 estimate seepage flow with a cutoff wall in place over a typical year. Report seepage quantities in acre-feet per year per 1,000 feet of levee.
7. Using results from Steps 4 and 6, calculate reduction in seepage quantities at Stations 70+00 and 353+00 due to the cutoff wall.

8. Using river and groundwater table hydrographs from Step 1, perform transient seepage analyses at Station 70+00 with and without the cutoff wall. The purpose of this analysis is two-fold: 1) better understand the impact of the cutoff wall on the recharge of the aquifer throughout the year; 2) verify percent reduction estimated based on the steady state analysis.
9. Using results from Steps 4 and 7 and subsurface condition profiles at the landside toe of the levee, estimate impact of the cutoff wall construction over the entire length of the levee. Report seepage quantities in acre-feet per year.
10. Perform transient analysis at Station 70+00 with the cutoff wall and canal to estimate seepage from the canal during a typical year.

Analysis Results

Step1

Historical data recorded by the Sacramento River gage station at Verona from 11/26/1995 to 11/26/2007 are plotted on Plates 1 through 5. We have estimated typical number of days per year that river level remains at a given elevation as presented on Plate 6. The water surface rarely exceeds Elevation 35. The highest water surface included in our analyses was El. 34.25. Based on historical data, the water surface remains at this level approximately 1% of the year. We have also developed a representative (approximately average) annual river hydrograph (river level as a function of time) as shown graphically on Plate 7 and in tabular format on Plate 8. Transient seepage analyses utilized this hydrograph as a time-dependent boundary condition on the river side of the model.

Data from piezometer 2F-01-15N located north of Powerline Road indicates that the ground water elevation varies throughout the year from about 5 to 15 feet below ground level (see Attachment A). Based on the piezometer data, we have developed a representative groundwater table hydrograph as shown on Plate 7. Transient seepage analyses utilized this hydrograph as a time-dependent boundary condition on the landside of the model. For our steady state analyses we have set the groundwater table at 7 feet below ground surface, or Elevation 17.25.. Our assumption of Elevation 17.25 is also supported by the groundwater contour maps from County of Sacramento, Department of Water Resources for the spring and fall. The groundwater contours immediately landward of the levee near Reach 4B indicate groundwater elevations greater than 10 feet but generally less than 20.

Steps 2 and 3

Estimated seepage quantities through the levee foundation as a function of river elevation under the existing conditions (no cutoff wall) at Stations 27+00, 70+00, 217+00, and 353+00 are summarized in Table 1 and presented on Plate 9. A range of river levels above the ground water table was considered in the analyses. As discussed in Step 1, the highest river level considered was El. 34.25. Seepage analyses results for WSE at Elevation 34.25 are presented graphically on Plates 10 through 13. As shown in Table1 and graphically on Plate 9, the seepage quantities increase two orders of magnitude as the river level rises from Elevation 17.25 to 34.25. These results also indicate Station 217+00 provides the greatest contribution to the aquifer recharge landward of the levee. For a given river stage, estimated seepage quantities at Station 217+00 are approximately 100 times greater than the estimated quantities at the other three stations. Seepage quantities at Stations 27+00, 70+00, and 353+00 are approximately the same order of magnitude. The higher seepage quantities at Station 217+00 are primarily due to the presence of thick highly permeably sand and gravel layers in the foundation.

The second result worth noting is the aquifer only recharges when the river level is above the groundwater elevation. When the river elevation is below the groundwater table (Elevation 17.25), the direction of the seepage flow in the model is reversed, indicating flow out of the aquifer.

Table 1
Estimated Seepage Quantities Versus River Stage
Existing Conditions

Model Elevation	27+00 Flow Existing Conditions	70+00 Flow Existing Conditions	217+00 Flow Existing Conditions	353+00 Flow Existing conditions

34.25	5.07E+00	4.21E+00	1.06E+02	1.51E+01
Total Flux Acre ft/yr/1000ft	3.9	2.6	129.4	13.2

Notes: 1. All fluxes in ft^3/day/ft unless noted otherwise.
2. Elevations in the seepage models were adjusted to a nearest mesh node. Model Elevations are lower than elevations in NAVD88 by 0.03 feet.

Step 4

The total length of the Sacramento River East Levee between Station 0+00 (Reach 1) and Station 960+00 (Reach 20) is approximately 18.1 miles. The general profile for the subsurface conditions along the levee crown/landside toe is provided in Attachment B. In general, the subsurface conditions profile is comprised of five units. These strata listed in order of increasing depth include: existing levee, surficial clay/fine grain soil blanket, silty and clayey sand layer, clean sand layer, gravel layer, and a lower clay/lower permeability soil region. As shown in Table 2, conditions at Station 27+00 are representative of approximately 1.8 miles or 11 percent of the entire length of the Sacramento River East Levee. Conditions at Station 70+00 are representative of

approximately 4 miles or 23 percent of the entire length of the Sacramento River East Levee. Conditions at Station 217+00 are representative of approximately 7.6 miles or 42 percent of the entire length of the Sacramento River East Levee. Conditions at Station 353+00 are representative of approximately 4.7 miles or 24 percent of the entire length of the Sacramento River East Levee. Accordingly, the total estimated flow from the Sacramento River through the levee foundation between Station 0+00 and Station 960+00 is approximately 5,650 acre-feet per year.

Total Seepage ac-ft/year				**5,650**

Steps 5 and 6

Cutoff soil-bentonite (SB) walls are currently proposed at thirteen locations along the east levee, as summarized in Table 3. The total length of the proposed SB walls is

approximately 8 miles. The proposed depth of the wall varies from location to location based on the subsurface conditions and the required underseepage mitigation. Idealized cross-sections at Stations 70+00 and 353+00 were selected to represent the range of conditions at the proposed cutoff wall locations. At Station 70+00 where the surficial clay blanket is relatively thin and the underlying permeable layer is relatively shallow, the wall would completely penetrate the sand layer and key into the clay layer beneath. On the other hand at Station 353+00, only a partially penetrating cutoff wall is required. Proposed depth of the wall relative to the estimated bottom of the permeable layer at each location is presented in Table 3.

Table 3
Proposed Cutoff Wall Locations

Reach	Stations	Length of Stretch	Proposed depth of wall, Elevation	Depth of Sand layer, Elevation	Representative station for wall impact evaluation
2	48+00 to 100+00	5,200	-25	-25	70+00
3	100+00 to110+00	1,000	-25	-10	70+00
6	280+00 to 330+00	5,000	-70	-65	70+00
7	330+00 to 362+00	3,200	-60	-50	70+00

17	832+00 to 842+00	1,000	-25	-100	353+00
18	842+00 to 857+00	1,500	-25	-100	353+00
19a	857+00 to 875+00	1,800	-25	-100	353+00
19b	875+00 to 925+00	5,000	-25	-40	353+00

We have performed a series of steady state seepage analyses to estimate seepage quantities through the levee foundation with an SB wall in place. The analyses results for Stations 70+00 and 353+00 with the river WSE at Elevation 34.25 are presented on Plates 14 and 15. Total flow through a flux section located immediately landward of the SB wall was calculated with and without the cutoff wall in place. The two results were compared to estimate the groundwater recharge effects of the cutoff wall. Seepage quantities as a function of river stage are summarized in Table 4.

Notes: 1. All fluxes in ft^3/day/ft unless noted otherwise.
2. Elevations in the seepage models were adjusted to a nearest mesh node.

Step 7

Based on the results of steady state seepage analyses presented in Table 4, the cutoff wall could potentially reduce seepage through the foundation by 40 to 85 percent depending on the subsurface conditions and the proposed depth of the wall. At the locations where the wall fully penetrates the permeable sand layer (Station 70+00) seepage quantities could be reduced by approximately 85 percent. At the locations, where the cutoff is shallow and only partially penetrates the sand layer (Station 353+00), the reduction would be approximately 40 percent.

Step 8

To verify and validate steady state seepage analyses described above, we have performed transient seepage analyses for Station 70+00. The purpose of these analyses was to better understand effects of seasonal groundwater table fluctuations on the estimated seepage quantities with and without the cutoff wall and more accurately model typical river conditions throughout the year. Time-dependent boundary conditions assigned to the riverside and the landside of the model as shown on Plate 16 and summarized in a tabular form on Plate 8 were used in these analyses. Seepage quantity computations were performed at 34 time steps, starting in February and ending a year later.

Transient seepage analyses results are presented on Plates 17 through 20. Existing seepage flow regime during typical winter and summer conditions is illustrated on Plates

17 and 18 respectively. Seepage conditions with the cutoff wall in place are shown on Plates 19 and 20. The plates show calculated seepage velocity vectors which illustrate the direction and the amount of flow - the larger the arrow, the higher the velocity and the larger the flow. A consistent scale was used on all four plates for easier visual comparison. The results indicate seepage occurs primarily through the permeable foundation sand layer and the existing sand levee. The flow is significantly higher during the elevated river stages (winter). Further, conditions may exist during the year when the river water surface is lower than the groundwater table. During these periods of time, the direction of the flow is reversed indicating seepage flow toward the river as illustrated on Plate 18.

Seepage quantities through the levee foundation with and without the cutoff wall as a function of time are presented on Plate 21. Positive seepage quantities indicate flow from the river landward of the levee while the negative sign indicates flow in the opposite direction. As shown on Plate 21, construction of the cutoff wall impedes flow in both direction and as a result may prevent flow into the river during the summer months.

Based on the transient seepage analyses, flow through the levee foundation at Station 70+00 without the wall is estimated at 5.6 acre-ft/year per 1,000 feet of the levee. Seepage through the levee foundation with the wall in place is approximately 1.7 acre-ft/year per 1,000 feet. Compared to the steady state analyses results for the same station, the transient seepage analyses indicate higher seepage quantities. For example, as shown in Table 4, steady-state seepage quantities estimated for Station 70+00 are 2.6 acre-ft/year per 1,000 feet for the existing conditions and approximately 0.4 acre-ft/year per 1,000 feet of the levee with the cutoff wall in place. The estimated reduction in flow due to the wall is comparable for both types of analyses. Based on the transient analysis, the seepage quantities would be reduced by about 70% compared to 85% estimated from the steady-state seepage analyses. Accordingly, we conclude the steady state seepage analyses conservatively approximate the effect of the cutoff walls.

Step 9

The overall effect of the cutoff wall construction can be estimated based on the information presented in Table 5.

Total Seepage				**5,650**		**4,330**	

The results presented in Table 5 indicate the construction of cutoff walls could potentially reduce the groundwater aquifer recharge landward of the levee by approximately 20-25%. Seepage through the levee foundation without the wall is estimated at 5,650 acre-feet per year. Seepage with the SB cutoff wall in place is approximately 4,330 acre-feet per year. The resulting impact to the groundwater recharge is approximately 1,300 acre-feet per year. In our opinion, these results are likely conservative and represent the upper-bound estimate. The actual impact is likely lower, due to 3-D effects that cannot be assessed with the existing modeling.

Step 10

A new 2 mile long canal will be constructed along the east levee between Stations 200+00 and 305+00. This canal, shown in plan in Attachment C, will be located approximately 500 to 1,000 feet landward of the levee toe and will follow the existing

levee alignment. In general, the canal will be filled with water during summer months and will be dry during the winter months (See Plate 7).

We have evaluated the impact of the canal operation on the groundwater conditions in the area. Transient analyses were performed to estimate seepage quantities from and into the canal at various times throughout the year. The analyses were performed for Station 70+00 with a cutoff wall in place. The canal cross-section was incorporated into the transient analysis model described in Step 8 above as a 8 feet deep and 10 feet wide ditch with 3H:1V side slopes positioned 1,000 ft landward of the levee. The canal was assumed to be filled with up to 5 feet of water from May through November and was allowed to seep in the winter, modeled as a free seepage discharge face. The canal operation was modeled as another time-dependent boundary condition applied, as shown on Plate 22. The canal will be excavated through the surficial clay blanket which consists primarily of CL with some CH and ML soils with percent fines between 50 and 70 percent. The permeability of this layer is estimated at 10^{-5} cm/sec. This permeability was assigned to the surface layer to represent base-case conditions. The clay blanket thickness varies across the site and excavation of the canal may result in a complete removal of the surficial clay at some locations. To account for variability in subsurface conditions and the possibility of a complete removal of the clay blanket, we have conducted a sensitivity analysis with permeability of the surface layer increased by one order of magnitude (10^{-4} cm/sec). The results of this analysis provide an upper bound estimate of seepage losses from the canal.

Seepage quantities were calculated using a flux line placed along the perimeter of canal cross-section. Positive and negative quantities indicate flow from and into the ditch, respectively. The estimated seepage quantities as a function of time are shown on Plate 23. Based on the results of the transient analyses, seepage loss is estimated at 1.4 acre-t/year per 1,000 feet of the canal for base-case conditions. Only positive flow (flow from the canal) was considered in these computations. Seepage loss over the entire length of the canal is estimated at 15 acre-ft per year. The upper bound estimate is approximately 90 acre-ft per year.

We have also evaluated the combined impact of the cutoff wall construction and the canal operation on the groundwater table in the vicinity of the levee. This evaluation was performed based on the results of transient seepage analysis described in Steps 8 and 10. Seepage quantities as a function of time are shown graphically on Plate 24. Positive and negative quantities indicate flow from and into the river, respectively. Seepage quantities were calculated using a flux line placed immediately landside of the cutoff wall. In addition, groundwater table elevation was estimated as a function of time at the location halfway between the existing levee and the proposed canal. The results, provided on Plate 25, indicate minimal impact of the canal during winter months. However, during summer months groundwater table elevation in the immediate vicinity of the proposed wall locations could increase by as much as 3 feet. This increase is likely due to the combined effect of the cutoff wall preventing backflow into the river and the additional inflow from the canal.

Conclusions

The key findings and conclusions presented in this memorandum are as follows:

- Under the existing conditions seepage from the Sacramento River through the levee foundation along Sacramento River East Levee between Stations 00+00 and 960+00 is estimated to be about 5,650 acre-ft/year.
- At the proposed wall locations seepage flow could be reduced locally by up 85 percent, depending on stratigraphy and proposed wall depth.
- The overall impact of the proposed cutoff walls is estimated at approximately 1,300 acre-ft/year (20 percent reduction of the total recharge rate)
- The cutoff wall could impede seepage flow towards the river in the summer months when the river level is low.
- Construction of an irrigation canal may increase aquifer recharge by approximately 15 to 90 acre-ft per year.
- Construction of the cutoff wall and the canal may locally increase the groundwater levels up to 3 feet in the summer months.

Due to the limitations of the model, the analyses can only provide an order-of-magnitude estimate of the seepage quantities. Additional analyses with a three-dimensional model such as MODFLOW are recommended to properly characterize groundwater flow regime in the area account for 3-Dimensional effects and quantify the impact of the proposed SB cutoff wall on the aquifer recharge.

If you have questions regarding this design or require additional information, please contact either Elena Sossenkina at (303) 237-6601 or the undersigned.

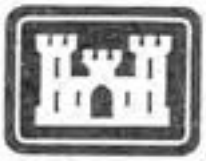
Prepared by:
URS.

Prepared For:



US Army Corps of Engineers
Sacramento District

24 November 2003

AUTHORITY: WATER RESOURCES DEVELOPMENT ACT OF 1996

General Observations

No major storm events causing high river stages occurred during the entire monitoring period. During both winters, the river stage rose between 15 and 20 feet. The river stages and piezometer levels were generally highest in December through the end of January and gradually decreased after January.

The results of the monitoring program are discussed and evaluated herein in three parts: a general review of the monitoring results, a comparison of river stages and piezometer levels, and a qualitative correlation between analysis results and monitoring results. Conclusions and recommendations are presented subsequently.

General Review of Monitoring Results

A continuous record of monitoring results of river stages and landside piezometer levels was obtained during this monitoring program. Only the relatively deep USACE piezometers gave meaningful results. The RD-1000 piezometers were installed too high to yield meaningful data during this period of relatively low river stages.

As noted, no significant high-river-stage events occurred during the monitoring period. Nevertheless, the piezometer data showed significant rises in the groundwater levels in response to higher river stages. The piezometer levels were always well below the ground surface on the landside of the levee, consequently no evidences of upward seepage were expected, and none were observed.

Comparisons of Piezometer Levels to River Stages

The first comparison is between piezometer levels at the landside levee toe and river stages, made for two locations. The Verona (VON) gage is located near 2F-01-15 (North of Powerline Road) as shown in Figure 2-1. The correlation between river stage recorded at VON and ground water level recorded at piezomter 2F-01-15 is depicted in Figure 5-1. Also shown in this figure is the comparison of piezometer 2F-01-19 with two gages, Bryte (BRY) and RD1000, which are located south of Powerline (see Figure 2-1). The findings from these comparisons are shown in Figure 5-1 and they indicate the following:

2F-01-15 N:

Two distinct trends are evident.

- The river stages were approximately 1 to 3 feet below the ground water levels in the piezometer during low river stage.
- The river stages were approximately 9 to 10 feet above the ground water levels in the piezometer during high river stage.
- Note that Piezometer 2F-01-15 N is installed in an area of reported incidences of seepage and boils.

2F-01-19 S:

Two distinct trends are evident.

- The river stages were approximately 1 to 1.5 feet below the ground water levels in the piezometer during low river stage.
- The river stages were approximately 4 to 5 feet above the ground water levels in the piezometer during high river stage.
- Note that no incidence of seepage and boils were reported at the location of this piezometer

The subsurface conditions at these two piezometer locations are shown in Figures 5-1 b and 5-1c. The sand aquifer in 2F-01-15N and 2F-01-19S starts at depths of 73.5 feet and 32.5 feet, respectively. The soil above the sand aquifer is fine grained soil consisting of clay, silt, and silty sand. The difference between the river stage and water level at the piezometer during the peak river stage is higher for piezometer 2F-01-15N for than piezometer 2F-01-19 S. The reason for the more pronounced time lag in Piezometer 2F-01-15 N is probably caused by the thicker and less pervious blanket which slows the percolation time.

Comparison of Water Levels between Near-field and Far-field Piezometers

The second comparison is between piezometer levels at different distances from the landside levee toe and river stages, at two locations. This comparison was made for piezometers relatively aligned in a transverse direction to the river.

1. Piezometers 2F-01-26 and 2F-01-28 (both north of Powerline Road) are located on the landside toe and about 250 feet from the landside levee toe, respectively. The comparison of the two readings is shown in Figure 5-2.

The ground water level at the near-toe piezometer is generally about 1.25 ft higher than the far-field piezometer during high river stage, while the ground water levels are similar during low river stage.

2. Piezometers 2F-01-68 and 2F-01-69 (both north of Powerline Road) are located about 50 feet and 200 feet, respectively, from the levee toe. The comparisons of these readings are shown in Figure 5-3.

The ground water level at the near-toe piezometer is generally about 3.0 feet higher than the far-field piezometer during high river stage, while the water levels are generally similar during low river stage.

Qualitative Correlation between Monitoring Results and Analysis Results

This correlation was made qualitatively only, using results of previous underseepage analyses (URS 2002d and 2002e). The scope of the monitoring program did not include additional underseepage analyses.

First, there was an apparent slight time lag of not more than several days between river stage peaks and piezometer level peaks, as seen in Figure 5-1. This amount of time lag was expected based on transient seepage analyses. Considering that a high river stage typically lasts several days, use of steady-state underseepage analyses is justified and is not expected to lead to any significant conservatism in analysis results.

Second, as expected, the measured piezometer levels resemble the river stages but show lower amplitude. This is expected as a result of seepage head losses in the aquifer between the seepage entrance point and the landside measuring location. For the same reason, the piezometer levels farther from the levee toe are lower than those near the levee.

Conclusions

The monitoring results demonstrate the rapid response of landside seepage conditions to changes in river stages. The groundwater response to higher river stage has a short time lag and relatively smaller attenuation of the peaking amplitudes. The results did not allow any correlation between measured flood stage and surface seepage effects, because of the lack of high river stages during the monitoring period.

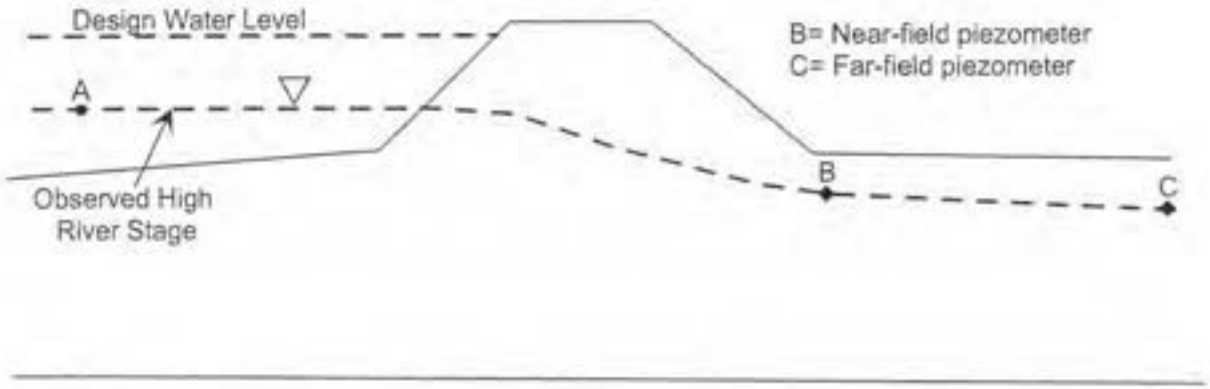


Figure 5-4- Schematic of Locations of Near-field and Far-field Piezometers

Nevertheless, the river stage, near-field and far-field piezometer readings are providing a window into a better assessment of the far-field boundary conditions and overall calibration of the model. As far as numerical seepage modeling is concerned, the observed water levels at points A, B, and C can be used for the calibration. This calibration will serve to minimize the uncertainty in selecting the appropriate boundary conditions, especially the far-field boundary condition and to provide insight into the estimate of the in-situ permeability of the soil. This calibrated model can then be used to predict the seepage response of the levee system for higher design water level.

Recommendations

Two recommendations are drawn from this monitoring program:

- We recommend the continuation of the piezometer and river stage monitoring program. However, the frequency of the monitoring program could be revisited. We also recommend that only Sacramento River and I-Street gages be monitored.

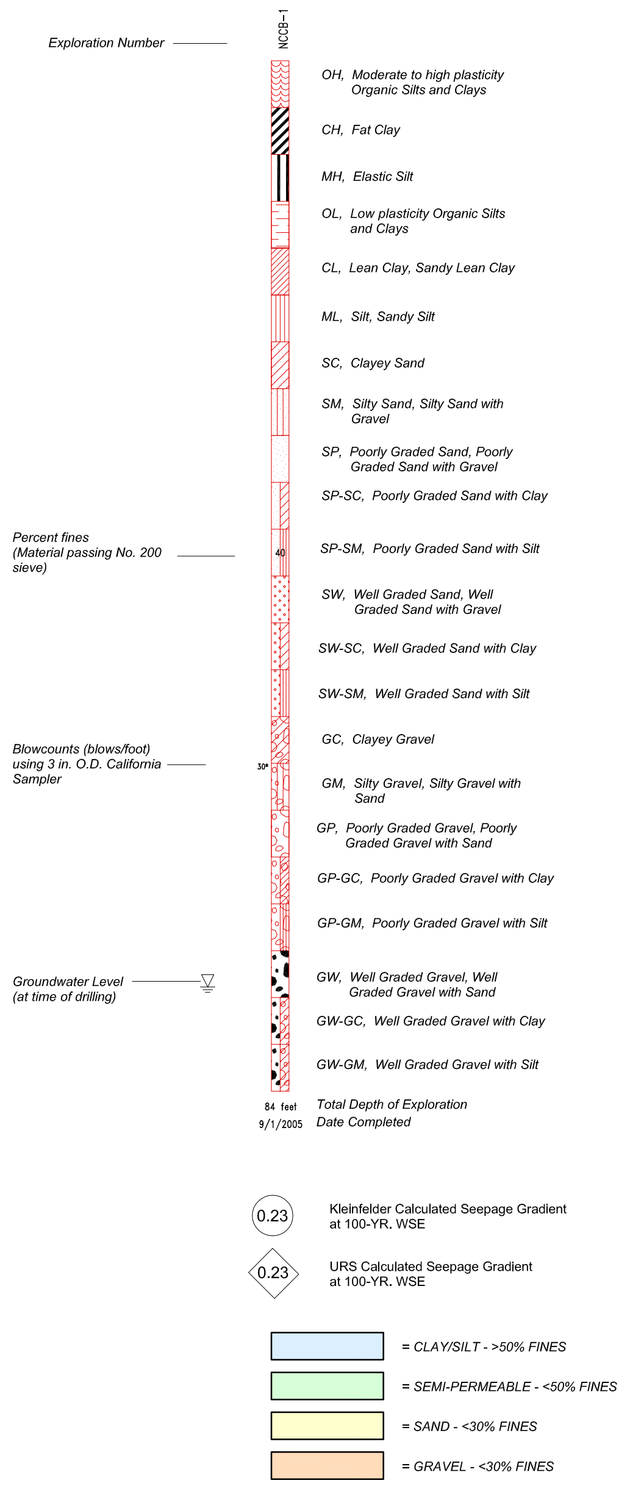
ATTACHMENT B

SUBSURFACE PROFILE
SACRAMENTO RIVER EAST LEVEE

LOG LEGEND



Notes:

1. Base drawings for these levee profiles, obtained in August 2005 from the Sacramento District U.S. Army Corps of Engineers (USACE) and used with their permission, include stick logs of previous explorations, a levee crown profile, a landside levee toe profile, notes regarding levee performance and completed levee improvements, and elevation scale based on the 1929 National Geodetic Vertical Datum (NGVD, 1929).

2. Logs of the following explorations were added to the USACE base drawings: Kleinfelder 2006 borings (SRE-06-XX); Kleinfelder 2005 borings (SRB-XX); Kleinfelder 2003/2004 Borings S-03-1, S-03-2, S-03-3, S-03-4.

3. Locations of explorations shown are approximate. See Plate 2A through 2E for approximate plan locations of explorations.

4. The log legend shown applies to Kleinfelder 2005 borings (SRB-XX) and Kleinfelder 2006 borings (SRE-06-XX). Caution is advised in using the legend for interpretation of other explorations.

5. Logs represent general soil conditions observed at the point of exploration on the date indicated. Refer to Kleinfelder's 2005 report and Kleinfelder's 2006 report for more detail on the Kleinfelder 2005 borings (SRB-XX) and 2006 borings (SRE-06-XX).

6. Lines separating strata on logs represent approximate boundaries only. Actual transitions may be gradual.

7. No warranty is provided as to the continuity of soil conditions between individual sample locations.

8. Approximate top of boring elevations for Kleinfelder 2006 borings (SRE-06-XX) were obtained using GPS equipment survey; Kleinfelder 2005 borings (SRB-XX) were estimated using topographic data obtained by USACE 1997.

9. The 1/100 AEP and 1/200 AEP water surface profiles shown were provided by MBK Engineerson August 18, 2006. See report for an explanation of these profiles and conditions.

10. Details regarding completed levee improvements have been added to those already on the USACE levee profile base drawings and were obtained from the USACE. Extents of completed levee improvements shown are approximate and are the same as indicated on the USACE profiles. Refer to USACE as-built drawings for actual extents.

C4 Potential Impacts of Phase 4b Project Slurry Cutoff Walls (Luhdorff & Scalmanini Consulting Engineers)

TECHNICAL MEMORANDUM

LUHDORFF & SCALMANINI CONSULTING ENGINEERS

DATE: January 28, 2010 **FILE NO.:** 07-1-084

TO: David Rader, AECOM
John Bassett, SAFCA
Timothy Washburn, SAFCA

FROM: Glenn Browning

SUBJECT: POTENTIAL IMPACTS OF SLURRY CUTOFF WALLS PROPOSED FOR PHASE 4B OF THE NATOMAS LEVEE IMPROVEMENT PROGRAM

The proposed locations and depths of some of the slurry cutoff walls recommended by consultants of the Sacramento Area Flood Control Agency (SAFCA) for the levees surrounding the Natomas Basin continue to change as the engineering and design work for the Natomas Levee Improvement Program (NLIP) proceeds. The groundwater impacts of slurry cutoff walls as proposed in April 2009 were evaluated in a report prepared by Luhdorff & Scalmanini, Consulting Engineers (LSCE) on May 4, 2009, entitled *Evaluation of Potential Groundwater Impacts Due to Proposed Construction for Natomas Levee Improvement Program.* That analysis has now been updated to reflect current slurry cutoff wall recommendations. The evaluation discussed below is focused on construction activities planned for Phase 4b but includes all slurry cutoff walls proposed as of December 2009 so that cumulative impacts can be estimated.

Currently Proposed Slurry Cutoff Walls

Proposed construction activities under Phase 4b include slurry cutoff walls along the following levees:

- Sacramento River East Levee (SREL) Reaches 16 through 20 (entire length);
- North Natomas East Main Drainage Canal (NEMDC) West Levee (Reaches 8, 12, 14, and 15); and
- American River North Levee (ARNL) Reaches 1 through 4 (entire length).

These and other currently proposed slurry cutoff walls are summarized below.

Sacramento River East Levee

Currently proposed cutoff wall locations and depths along all reaches of the SREL were provided by HDR (December 17, 2009) based on recommendations made by Kleinfelder (see **Table 1**). The reaches where cutoff walls are proposed based on the April and December 2009 recommendations are shown on **Figure 1**. Major changes since April 2009 include several

reaches of the SREL where previously proposed cutoff walls would no longer be constructed based on current recommendations:

- Reaches 4B and 5A (Stations 214+00 to 229+00);
- Reach 9B (Stations 460+00 to 468+00);
- Reach 13 (Stations 679+50 to 700+00);
- Reach 14 (Stations 700+00 to 732+00); and
- Reach 15 (Stations 735+00 to 780+00).

Cutoff walls were not previously proposed for Reaches 16 through 20, but current recommendations call for cutoff walls to potentially be constructed along these five reaches (the Phase 4b construction area). Due to relatively deep sands in this area, the proposed depth of the cutoff walls proposed for Reach 16 through the northern portion of Reach 19B is 117 feet. The proposed depth of cutoff walls in the remaining reaches ranges from 81 to 109 feet.

There were also a number of changes to the depths of previously proposed cutoff walls. The locations and depths of all currently proposed slurry cutoff walls along the SREL are shown in **Table 1**. With the addition of slurry cutoff walls along Reaches 16 through 20, the total length of proposed cutoff walls along all reaches of the SREL increased from 53,450 feet in April 2009 to 64,583 feet in December 2009.

Table 1 also shows the estimated average groundwater elevation based on groundwater elevation contour maps for spring and fall 2003 included in LSCE (2009). Due to the buffering effect of the Sacramento River, groundwater elevations are relatively constant along the SREL except for seasonal fluctuations. Groundwater elevations in this area were documented in LSCE (2009) based on data from a number of shallow piezometers along the SREL. The 2003 groundwater elevations provide a reasonable approximation of both current (2010) and expected future (2030) groundwater elevations in this area. In order to estimate groundwater flow with and without the cutoff walls, as discussed below, the average saturated thickness of the aquifer materials through which the cutoff walls in each reach would be constructed was estimated based on these groundwater elevations. An average saturated thickness of 52 feet for all cutoff wall locations along the SREL was estimated by calculating the total saturated cross-sectional area (about 3,387,000 square feet) and dividing by the total length of the proposed cutoff walls.

Other Levees

Currently proposed cutoff wall locations and depths along the Natomas Cross Canal (NCC), the Pleasant Grove Creek Canal (PGCC), the NEMDC, and the ARNL are shown in **Table 2**. This information was provided by Wood Rodgers (December 16, 2009) for the NCC, PGCC, and NEMDC and by HDR (December 17, 2009) for the ARNL, based on recommendations made by Kleinfelder. Major differences between this and the April 2009 plan include two changes to cutoff walls along the NEMDC North: a cutoff wall is now proposed along Reach 15, and the cutoff wall previously proposed along Reach 10 has been dropped. The currently proposed cutoff walls are deeper in Reaches 8 and 14 and shallower in Reach 12. There are also several changes to cutoff walls proposed along the NEMDC South. Previously proposed cutoff walls

have been dropped from Reaches 3 and 5, and a new cutoff wall has been added in Reach 7B. For the ARNL, the recommended cutoff wall depths have increased for Reaches 1 and 2 and decreased for Reaches 3 and 4. The reaches where cutoff walls are proposed based on the April and December 2009 recommendations are shown on **Figure 1**.

Existing groundwater elevations along these levees were also estimated based on the average of groundwater elevation shown on contour maps for spring and fall 2003 included in the LSCE (2009) report. Although groundwater elevations are more variable away from the Sacramento River, the 2003 groundwater elevations provide the best available approximation of existing conditions over this large area. Because groundwater elevations are significantly lower beneath the eastern edge of the Natomas Basin, several of the cutoff walls proposed for the PGCC and NEMDC are now expected to be entirely above the average water table elevation. However, there is uncertainty about these groundwater elevations because shallow piezometers have not been installed along these canals.

Groundwater elevations are projected to change in future years, and estimates for future conditions are based on a 2030 simulation conducted with the groundwater flow models used to estimate groundwater elevations and flow for the LSCE (2009) report. These simulations were conducted by WRIME using two groundwater flow models based on the Integrated Groundwater and Surface Water Model (IGSM) platform, as summarized in WRIME (2007) and LSCE (2008). The North American River IGSM and the Sacramento County IGSM models were linked to conduct these simulations. The results of the 2030 simulation showed lower groundwater elevations beneath the NCC and the PGCC due to increased pumping to supply the proposed Sutter Point development in the northern portion of the Natomas Basin. Groundwater elevations were predicted to be higher beneath the NEMDC and the ARNL due to the planned reduction in groundwater pumping east and south of the Natomas Basin. The average saturated thicknesses of the shallow aquifer materials above the tip (bottom) of the cutoff walls in each reach based on estimated groundwater elevations under existing and future conditions are shown in **Table 2**.

The slurry cutoff wall under construction along the NCC is planned to run the entire length of the NCC South Levee (28,700 feet), but a portion of the wall beneath and adjacent to the Highway 99 bridge may not be constructed. The cutoff wall along the NCC will range in depth from 56 to 80 feet (measured from the top of the levee), and the entire length of the wall will extend below the water table through an average saturated thickness of about 52 feet under existing conditions. Groundwater levels are predicted to be lower beneath the NCC and the PGCC in 2030, as discussed above, and the estimated saturated thickness to the tip of the cutoff wall along the NCC is about six feet less (46 feet) under future conditions.

Slurry cutoff walls are currently planned for about 14,000 linear feet of the PGCC West Levee, and cutoff wall depths from the top of the levee would range from 25 feet in Reach 3 to 47 feet in Reach 1. The cutoff wall proposed for Reach 3 would not extend below the estimated average water table elevation. The average saturated thickness for all cutoff wall depths along the PGCC is estimated to be about 13 feet for existing conditions and nine feet for future conditions.

Slurry cutoff walls are currently planned for four reaches of the North NEMDC West Levee (about 21,700 linear feet). Cutoff wall depths would range from 15 feet in Reach 12 to 62 feet in Reach 8 (measured from the top of the levee). The tip of the cutoff wall proposed for Reach 12 would be above the estimated average water table elevation, but cutoff walls proposed for the other three reaches would be partially saturated. The average saturated thickness to the tips of the cutoff walls for all four reaches is estimated to be about five feet for existing conditions and 17 feet for future conditions.

Slurry cutoff walls are currently planned for four reaches of the South NEMDC West Levee (18,775 linear feet) and would range in depth from 33 to 73 feet below the top of the levee. The tips of the proposed cutoff walls would be below the estimated average water table elevation for portions of two reaches (2A and 4A) based on existing conditions and above the average water table elevation for the other reaches. Since groundwater elevations are expected to be higher in future years, only the cutoff wall proposed for Reach 7C is predicted to be unsaturated in 2030. The estimated average saturated thickness for all reaches is about two feet for existing conditions and 17 feet for future conditions.

Slurry cutoff walls are currently planned for the entire length of the ARNL (11,571 feet) and would range in depth from 44 to 60 feet below the top of the levee. The shallowest cutoff walls (44 to 45 feet deep) would be located in Reaches 1A, 1B, and 2A, and the tips of these cutoff walls would extend only one to three feet below the estimated average water table elevation under existing conditions. The estimated saturated thickness above the cutoff wall tips would increase to 14 or 15 feet under future conditions. Cutoff walls proposed for Reaches 2B, 3, and 4 would be 60 feet deep and would extend below the estimated average water table elevation for 10 to 15 feet under existing conditions and 30 feet under future conditions. The average saturated thickness of all cutoff wall depths along the ARNL is estimated to be is about eight feet for existing conditions and 25 feet for future conditions.

Potential Impacts of Slurry Cutoff Walls

In the LSCE (2009) report, the groundwater impacts of SAFCA's proposed construction activities were evaluated using a water budget approach. Recharge from the Sacramento River represents the majority of the groundwater inflow into the Natomas Basin, and the total amount of recharge was estimated by LSCE using Darcy's Law (Darcy, 1856). Groundwater flow beneath the other levees surrounding the Natomas Basin was based on the results of the IGSM simulations discussed above (WRIME, 2007 and LSCE, 2008). Flow estimates for existing and future conditions were based on simulations of 2004 and 2030 groundwater conditions, respectively.

Slurry cutoff walls that extend below the water table will reduce groundwater flow into or out of the Natomas Basin. Estimates of groundwater flow reductions due to slurry cutoff walls are shown in **Table 3**, which is revised from Table 6-6 in the LSCE (2009) report. These estimates are based in part on a two-dimensional transient groundwater flow model used by Kleinfelder to estimate flow reductions due to the cutoff wall proposed for a portion of Reach 2 of the SREL.

The hydraulic conductivity of the cutoff walls is recommended by Kleinfelder to be a maximum of $5x10^{-7}$ cm/sec, but the Kleinfelder model used a larger hydraulic conductivity ($1x10^{-6}$ cm/sec) to account for potential irregularities in the walls. The model results indicate that flow through the cross-sectional area of the cutoff walls would be reduced by about 70 percent due to the walls (Kleinfelder, 2009).

As shown in **Table 3**, recharge from the Sacramento River is estimated to be 8,450 acre-feet per year (afy) under existing conditions based in part on the hydraulic gradients calculated using groundwater elevations measured in shallow piezometers and estimated River stage at each piezometer location. The flow is projected to increase to about 9,340 afy in 2030 due to steeper hydraulic gradients resulting from increased groundwater pumping within the Natomas Basin, especially in the Sutter Pointe area. Flow through the cross-sectional area of the proposed slurry cutoff walls is estimated to be about 1,490 afy under existing conditions and 1,650 afy under 2030 conditions. It is assumed that the proposed cutoff walls would reduce this flow by 70 percent based on the results of the Kleinfelder (2009) model discussed above. The total estimated flow reduction shown in **Table 3** is 1,044 afy for existing conditions and 1,154 afy for 2030 conditions; both reductions represent about 12 percent of the total estimated groundwater flow beneath the SREL.

Groundwater flow into the Natomas Basin also occurs from the north beneath the NCC. As shown in **Table 3**, this flow is estimated to be about 460 afy under existing conditions and is projected to increase to about 3,920 afy due to the steeper hydraulic gradient expected as a result of increased pumping in 2030. Flow through the cross-sectional area of the cutoff walls is estimated to be 59 afy under existing conditions and 450 afy under future conditions. Based on a 70 percent flow reduction due to the cutoff walls, groundwater flow into the Natomas Basin beneath the NCC South Levee would be reduced by 42 afy (9 percent of the total) under existing conditions and 315 afy (8 percent of the total) under future conditions.

Groundwater typically flows out of the Natomas Basin to the east beneath the PGCC and NEMDC. As summarized in **Table 3**, groundwater flow to the east beneath the PGCC without cutoff walls was estimated to be about 4,450 afy for existing conditions and 250 afy for future conditions. The reduced outflow in 2030 is partially based on an assumption of greatly reduced pumping in the area east of the Natomas Basin in future years due to the planned transition from groundwater to surface water supply. This would allow water levels to recover and reduce the gradient for groundwater outflow from the Natomas Basin beneath the PGCC and NEMDC. In the immediate vicinity of the PGCC, however, groundwater levels are predicted to be lower in 2030 due to pumping by proposed municipal wells in the Sutter Pointe area.

Currently proposed slurry cutoff walls along the PGCC West Levee would be about 14,000 feet long with an average depth of 36 feet. Because most of this depth is above the estimated average water table elevation, groundwater flow through this cross-sectional area without cutoff walls is estimated to be only 119 afy under existing conditions and four afy under future conditions. The estimated flow reduction due to the slurry cutoff walls is 83 afy (two percent of the total) for existing conditions and three afy (one percent of the total) for future conditions.

Estimates of flow beneath the North and South NEMDC West Levees with and without slurry cutoff walls under existing and future conditions are summarized in **Table 3**. As for the PGCC, groundwater outflow to the east beneath the NEMDC (both North and South) is expected to be lower in 2030 based primarily on the assumption of greatly reduced pumping east of the Natomas Basin in future years.

Groundwater flow to the east beneath the NEMDC North without cutoff walls was estimated to be about 9,130 afy for existing conditions and 500 afy for future conditions. Currently proposed slurry cutoff walls along the NEMDC North would be about 21,700 linear feet with an average depth of 43 feet. Most of this depth will be above the estimated average water table elevation, and groundwater flow through this cross-sectional area without cutoff walls is estimated to be only 72 afy under existing conditions and 13 afy under future conditions. The estimated flow reduction due to the proposed slurry cutoff walls is 50 afy (one percent of the total) for existing conditions and nine afy (two percent of the total) for future conditions.

Groundwater flow to the east beneath the NEMDC South without cutoff walls is estimated to be about 8,160 afy under existing conditions and 450 afy under future conditions. Currently proposed slurry cutoff walls along the NEMDC South would be about 18,880 linear feet with an average depth of 54 feet. Most of this depth will be above the estimated average water table elevation, and groundwater flow through this cross-sectional area without cutoff walls is estimated to be only 29 afy under existing conditions and 11 afy under future conditions. The estimated flow reduction due to the slurry cutoff walls is 20 afy (less than one percent of the total) for existing conditions and eight afy (two percent of the total) for future conditions.

The IGSM model results indicate that recharge from the American River is the primary source of groundwater inflow to the Natomas Basin beneath the ARNL. Groundwater inflow beneath the ARNL is estimated to be about 1,090 afy under existing conditions. For future conditions, the results of the 2030 IGSM simulation indicates that groundwater levels in this area will increase enough that this reach of the American River will become a gaining reach, with groundwater flowing toward the River from the north. The estimated groundwater outflow in 2030 is 500 afy.

Slurry cutoff walls are proposed for the entire length of the ARNL with an average depth of 55 feet. Most of this depth is above the estimated average water table elevation under existing conditions, and groundwater inflow through this cross-sectional area without cutoff walls is estimated to be only 46 afy. More of the cutoff walls would be saturated under future conditions, and groundwater outflow is estimated to be 63 afy. For existing conditions, the estimated reduction in groundwater inflow due to the slurry cutoff walls is 32 afy (three percent of the total). For future conditions, the estimated reduction in groundwater outflow due to the cutoff walls is 44 afy (nine percent of the total).

On a cumulative basis, slurry cutoff walls proposed for the levees surrounding the Natomas Basin will reduce the net groundwater inflow to the Natomas Basin. As shown in **Table 3**, the estimated total flow reduction is 963 afy under existing conditions. This is considerably more than was estimated in the LSCE (2009) report (68 afy) for two reasons:

- The length and depth of proposed cutoff walls has increased along the Sacramento River, which is the primary source of recharge to the Natomas Basin; and
- Fewer cutoff walls are currently proposed along the NEMDC (both North and South), which results in a smaller reduction in groundwater outflow from the Natomas Basin.

The estimated total flow reduction is 1,404 afy under future conditions, which is only slightly more than the estimated flow reduction in the LSCE (2009) report (1,315 afy). The estimated flow reduction is greater for future conditions primarily because of the increased gradient for groundwater inflow from the west (beneath the SREL) and the north (beneath the NCC) predicted by 2030. Some of this additional flow would be blocked by proposed slurry cutoff walls along the SREL and the NCC.

The proposed slurry cutoff walls will result in slightly lower groundwater elevations on the land side of the SREL and NCC and slightly higher groundwater elevations on the water side of those levees. Proposed slurry cutoff walls along the PGCC and NEMDC will have the opposite effect, i.e. water levels will be slightly higher on the land side and slightly lower on the water side. As further discussed below, these changes are not expected to be measurable in most of the domestic and irrigation wells near the levees.

Potential Impacts of All Proposed SAFCA Construction Activities

In the LSCE (2009) report, the effects of SAFCA's proposed construction activities were evaluated for both existing and future conditions using a water budget to estimate the total impact of SAFCA's activities on groundwater conditions in the Natomas Basin. Although slurry cutoff walls will have the greatest effect on groundwater conditions, as discussed above, there will also be effects due to:

- Land use changes associated with proposed levee improvements, canal improvements, and borrow site excavation;
- Increased seepage from canals due to proposed canal improvements; and
- Reduced groundwater pumping at the Brookfield borrow site due to the planned transition to surface water supply.

Assumptions that were used to estimate changes to the water budget due to these construction activities are summarized in **Table 4**, which is revised from Table 5-1 in LSCE (2009). This table has been updated to show currently proposed cutoff walls lengths and depths, but data were not available to update other estimates shown in the table. Any changes to these estimates are assumed to be relatively small. Changes to the groundwater budget for the Natomas Basin due to SAFCA's proposed construction activities are summarized in **Table 5** for existing conditions and **Table 6** for future conditions.

Levee Improvements

Groundwater impacts from proposed levee improvements are primarily limited to the effects of slurry cutoff walls and land use changes. No direct groundwater impacts are expected from

increasing the height or width of levees, modifying levee slopes, or building seepage berms because all of this construction would be above the water table. Based on data summarized in the LSCE (2009) report, proposed land use changes will result in the loss of about 20 acres of rice, 175 acres of field crops, and five acres of orchard along the SREL. Other land use changes include the loss of five acres of rice along the NCC South Levee and 50 acres of rice along the PGCC West Levee. As shown in **Tables 5** and **6**, these changes are estimated to reduce deep percolation from applied water by a total of 105 afy.

In addition to deep percolation, estimated inflow reductions for existing conditions shown in **Table 5** include recharge from the Sacramento and American Rivers (1,076 afy) and inflow to the Natomas Basin beneath the NCC (42 afy). The total estimated inflow reduction is 1,222 afy. The reduction in subsurface outflow from the Natomas Basin beneath the PGCC and NEMDC is estimated to be 154 afy. The estimated effect of all proposed levee improvements would be to reduce groundwater storage in the Natomas Basin by about 1,068 afy based on existing conditions.

Estimated inflow reductions for future conditions are shown in **Table 6** and include deep percolation (105 afy), recharge from the Sacramento and American Rivers (1,109 afy), and inflow to the Natomas Basin beneath the NCC (315 afy). The total estimated inflow reduction is 1,529 afy. The reduction in subsurface outflow from the Natomas Basin beneath the PGCC and NEMDC is estimated to be 20 afy. The estimated effect of all proposed levee improvements based on future conditions would be to reduce groundwater storage in the Natomas Basin by about 1,509 afy.

Canal Improvements

The construction of the new GSS/Drainage Canal and relocation and improvements to the West Drainage Canal, the Elkhorn Canal, and the Riverside Canal will affect deep percolation from applied water (due to land use changes) and seepage from the canals. For all four canals, deep percolation is estimated to decrease by 41 afy and canal seepage is estimated to increase by 327 afy (**Tables 5** and **6**). The net effect of proposed canal construction would be to increase groundwater storage in the Natomas Basin by about 285 afy.

Borrow Sites

Excavation and reclamation of the Brookfield and Fisherman's Lake borrow sites is expected to have an indirect effect on groundwater conditions due to proposed land use and water supply changes. No such changes are planned for the Airport North Bufferlands borrow site.

At the Brookfield borrow site, approximately 325 acres are currently planted to rice, and SAFCA plans to restore about 286 acres to rice cultivation after construction activities are complete. As shown in **Tables 5** and **6**, an estimated 30 afy of deep percolation will be lost at this site due to the reduction in irrigated acreage. The Brookfield site is currently irrigated entirely with groundwater, but SAFCA plans to provide the infrastructure so that about 80 percent of the

borrow site can be irrigated with surface water after reclamation. This transition would reduce groundwater pumping on the Brookfield property by about 1,625 afy. Groundwater levels will increase due to the reduced pumping, resulting in an increase in subsurface outflow beneath the PGCC of about 76 afy.

At the Fisherman's Lake borrow site, about 400 acres of land would be used for borrow material, including 49 acres currently planted to rice, 266 acres of field crops, and 85 acres of managed marsh. After reclamation, there would be about 175 acres of managed marsh and 225 acres of non-irrigated grassland or woodland. The predicted net loss in deep percolation is 36 afy at this site, as shown in **Tables 5** and **6**.

The reduction in groundwater pumping at the Brookfield site more than offsets the loss of deep percolation at all borrow sites. The net effect of excavation and reclamation of all borrow sites would be to increase groundwater storage by about 1,483 afy.

Summary of Impacts to Groundwater Flow and Storage

The totals at the bottom of **Tables 5** and **6** show the estimated combined effect of SAFCA's proposed construction activities based on existing and future groundwater conditions, respectively. For both periods, deep percolation is estimated to decrease by 213 afy; seepage from canals is estimated to increase by 327 afy; and groundwater pumping is estimated to decrease by 1,625 afy. Other changes for existing conditions (**Table 5**) include decreases in net recharge from streams (1,076 afy), subsurface inflow (42 afy), and subsurface outflow to the east (78 afy). Summing these terms results in an increase in groundwater storage in the Natomas Basin of 700 afy for existing conditions, which means that groundwater levels would be expected to increase slightly due to all proposed construction activities.

The totals at the bottom of **Table 6** show the combined effect of SAFCA's proposed construction activities based on future conditions in 2030. Estimated changes in deep percolation, seepage from canals, and groundwater pumping are the same as for existing conditions. The estimated reduction in net recharge from streams (1,109 afy) is similar to existing conditions, and the reduction in subsurface inflow (315 afy) is larger. Subsurface outflow to the east is predicted to increase slightly (by 56 afy). Future groundwater storage in the Natomas Basin is predicted to increase due to the proposed construction, but by a smaller amount (259 afy).

The small increase in groundwater storage predicted due to SAFCA's proposed construction activities under both existing and future conditions would have a slightly positive effect on groundwater levels and storage in the Natomas Basin. The effect on subsurface outflow to the east would be slightly negative for existing condition and slightly positive for future conditions.

Effects on Groundwater Quality

The primary potential groundwater quality impact of SAFCA's proposed construction activities is a slight reduction in groundwater recharge to the Natomas Basin, including stream recharge

and deep percolation from rice fields and other irrigated farmland. This recharge is generally of high quality, especially the stream recharge, which typically has very low salinity and few contaminants. Water recharged via deep percolation has somewhat higher salinity than river water due to the use of recycled tailwater and the effects of evapotranspiration. Some of these reductions would be offset by increased seepage from canals, which is another source of good quality recharge.

As estimated above, the combined effect of SAFCA's proposed construction activities on existing groundwater conditions would be to reduce recharge from rivers and canals by 1,076 afy and reduce groundwater outflow beneath the PGCC and NEMDC by 78 afy. The combined effect of these inflow and outflow reductions would be expected to slightly increase salt accumulation in the Natomas Basin and east of the Natomas Basin. However, these reductions represent only about two percent of the total estimated groundwater inflow to the Natomas Basin and less than 0.4 percent of the total estimated groundwater outflow from the Natomas Basin, and the water quality impacts are not expected to be measurable.

For future groundwater conditions, the combined effect of SAFCA's proposed construction activities would be to reduce groundwater recharge from rivers and canals by 1,109 afy. Groundwater outflow to the east is predicted to increase by 56 afy. Again, the overall effect of these changes on future groundwater quality would be small.

Effects on Private Wells

The locations of private wells near the levees surrounding the Natomas Basin mapped by Mead and Hunt (M&H, December 28, 2009) are shown on **Figure 2**. These well locations are approximate based primarily on information shown on Well Completion Reports obtained from the Department of Water Resources (DWR). This mapping is incomplete because Well Completion Reports are not available for all wells, many wells with Well Completion Reports could not be located, and field surveys have not been conducted to confirm well locations in most areas. In areas that contain a high density of domestic wells, such as Reaches 16-18 of the SREL, the majority of the domestic wells have not been mapped. Most of the wells shown on **Figure 2** are used for either domestic or irrigation purposes; but industrial, municipal, and monitoring wells are also included.

Table 7 summarizes the water supply wells mapped by M&H within one mile of the levees where slurry cutoff walls are proposed to be constructed during Phase 4b. This table shows only water supply wells; monitoring wells are ignored for this analysis. The table includes 27 wells along Reaches 16 through 20 of the SREL; 26 wells along Reaches 8, 12, 14, and 15 of the NEMDC North; and seven wells along Reaches 1-4 of the ARNL.

Shallow wells on either side of the levee could experience slightly lower pumping water levels because the cutoff walls will act as low permeability barriers that could reduce the areal extent and increase the depth of the cone of depression that forms around a pumped well. This effect would only occur when the production zone of the well is above the tip of the adjacent cutoff

wall. This effect would not occur and no decrease in well yield or increase in pumping cost would be expected when the production zone of the well is below the tip of the slurry cutoff walls. That is the case for almost all irrigation, industrial, and municipal wells because those wells are typically much deeper than the deepest cutoff walls proposed for the levees surrounding the Natomas Basin. As discussed below, it is also the case for all domestic wells mapped along the NEMDC North and the ARNL and for most of the mapped domestic wells along Reaches 16-20 of the SREL. There are a few shallow domestic wells along the SREL that have the potential to be impacted by relatively deep cutoff walls proposed for those reaches. As summarized below, however, any impacts are expected to be small.

Sacramento River East Levee

A more detailed map of private wells along Reaches 16 through 20 of the SREL is presented on **Figure 3**. The water supply wells mapped by M&H in this area (green circles) are summarized in **Table 7**:

- Reach 16 – 11 domestic wells and one irrigation well;
- Reach 18 – one domestic and one irrigation well;
- Reach 19A – one domestic well;
- Reach 19B – four domestic wells, three irrigation wells, and three municipal wells; and
- Reach 20 – one domestic and one "lake" well.

Reaches 19A through 20 of the SREL are highly urbanized, and some of the mapped domestic and irrigation wells in this area are probably unused or abandoned. However, it is assumed that almost all of the properties containing houses along Reaches 16-18 and most of the water side properties in Reaches 19A and 19B rely on domestic wells for water supply. This means that the existing mapping based on DWR Well Completion Reports shows only a small percentage of the wells in this area. The 65 orange circles on **Figure 3** represent house locations shown on Google Earth that do not have a previously mapped well on the property. Only one potential well location is shown on properties that contain multiple houses, although some of these may contain multiple wells. A few of the water side properties in Reach 19B are connected to the City of Sacramento (City) water distribution system, but most still use domestic wells for water supply (M&H, 2010). The construction features of the unmapped wells are unknown but would logically be similar to those of nearby mapped wells.

The 18 domestic wells mapped along Reaches 16-20 of the SREL range in depth from 90 to 180 feet, with an average of 131 feet. As shown in **Table 7**, eight of those wells are located on the water side of the levee and ten are on the land side. Slurry cutoff walls will result in slightly higher groundwater levels on the upgradient side of the cutoff wall and slightly lower water levels on the downgradient side. However, there is some uncertainty about whether the direction of groundwater flow is consistently to the east or varies seasonally in this area. Hydrographs of water levels measured in shallow piezometers in Reaches 16 and 18 included in LSCE (2009) indicate that groundwater flows away from the Sacramento River in the winter and spring but may flow toward the River in the summer and fall. In contrast, groundwater elevation contour maps prepared for 2003 show groundwater flow to the east in both the spring and fall (LSCE,

2009). It is possible that the gradient reversal indicated on the hydrographs occurs only in the uppermost zone, while the flow direction is consistently to the east in deeper zones tapped by water supply wells. If that is the case, there would be a slightly greater likelihood of impacts for the land side wells.

Measurable impacts due to slurry cutoff walls are considered unlikely at most of the wells along Reaches 16-20 of the SREL for one or more of the following reasons:

- The well is considerably deeper than the tip of the adjacent cutoff wall;
- The top of the perforated interval is below or only slightly above the tip of the proposed cutoff wall;
- The well is located relatively far away from the levee;
- The well is unused; or
- The well is scheduled for replacement because it is within the footprint of proposed levee improvements.

Most of the wells mapped along Reaches 16-20 of the SREL will not be impacted by proposed slurry cutoff walls due the well depth, construction, or distance from the levee. One irrigation well (in Reach 18) is within the proposed levee construction footprint and is currently scheduled for replacement. The replacement well will be deep enough to avoid potential cutoff wall impacts. Some of the other wells within the construction footprint shown on **Figure 3** may also be replaced, but this has not yet been determined.

A few of the mapped and unmapped wells along Reaches 16-20 of the SREL have a potential to be impacted by planned slurry cutoff walls because they do not meet at least one of the above criteria. However, any decreases in well yield or other impacts to private wells due to the proposed slurry cutoff walls would be expected to be small. Well capacity data are limited in Reaches 16-20, but the capacities of domestic wells located further north along the SREL average more than 60 gallons per minute (gpm) based on initial well test results shown on Well Completion Reports. The only well capacity estimate available for a domestic well in Reaches 16-20 shown in **Table 7** is also 60 gpm. With such high capacities, domestic wells only need to pump for a few minutes a day to meet normal water demands. This results in very localized individual cones of depression that would must likely not reach the adjacent cutoff wall. If a cone of depression does reach the cutoff wall, there could be some additional drawdown and decrease in pumping capacity. Due to the short pumping cycles, however, any impacts would not be expected to be measurable.

<u>NEMDC North</u>

There are 13 domestic wells, 11 irrigation wells, and two industrial wells that have been mapped by Mead & Hunt along Reaches 8, 12, 14, and 15 of the NEMDC North within one mile of the levee. The irrigation and industrial wells range in depth from 133 to 952 feet, with an average of 359 feet. These wells are too deep to be impacted by the slurry cutoff walls proposed for this area.

The 13 domestic wells mapped along the NEMDC North range in depth from 96 to 220 feet, with an average of 153 feet. Five of these wells are located on the land side (west) of the levee and eight are located east of the canal. Most of the drillers' logs available for these domestic wells do not show perforated intervals, but the top of the perforations would likely be below the tip of the adjacent cutoff wall for almost all wells. The depths of the proposed cutoff walls range from about 20 to 60 feet below the toe of the levee. Most of the cutoff wall depths would be above the estimated average water table elevation. As discussed above, the average saturated thickness for the proposed cutoff walls in all four reaches is estimated to be only about five feet for existing conditions and 17 feet for future conditions. The combination of relatively deep wells and relatively shallow cutoff walls means that no impacts to nearby domestic wells would be expected.

American River North Levee

As shown in **Table 7**, nine wells along Reaches 1-4 of the ARNL were mapped by M&H (2008). These include two domestic wells, three irrigation wells, and two municipal wells. Five wells are located on the land side of the North Levee, and two wells are located on the water side. This area is within the City limits, and some of the mapped domestic and irrigation wells may be unused or abandoned. The slurry cutoff walls proposed for this area are relatively shallow, and no impacts to nearby wells are expected.

Summary

The effects of SAFCA's proposed construction activities on groundwater conditions were evaluated in the LSCE (2009) report. That evaluation has been updated in this memorandum due to changes in the proposed locations and depths of slurry cutoff walls to be constructed along the levees surrounding the Natomas Basin during Phase 4b. The impacts of slurry cutoff walls on groundwater flow were evaluated for both existing conditions and future conditions in 2030 because groundwater levels are predicted to change in future years due to changes in groundwater pumping patterns.

Slurry cutoff walls along the SREL and the NCC South Levee will reduce groundwater inflow to the Natomas Basin beneath those levees, and slurry cutoff walls along the PGCC and NEMDC will reduce groundwater outflow from the Natomas Basin. On a cumulative basis, all proposed slurry cutoff walls will reduce the net groundwater inflow to the Natomas Basin. The estimated total flow reduction is about 960 afy under existing conditions and 1,400 afy under future conditions.

In addition to slurry cutoff walls, groundwater flow and storage will also be affected by other proposed construction activities, as summarized in LSCE (2009). Deep percolation from irrigated farmland will decrease due to land use changes, seepage from canals will increase due to canal improvements, and groundwater pumping will decrease due to the planned transition to surface water supply at the Brookfield borrow site. The net effect of all proposed construction activities will be a slight increase in groundwater levels and storage in the Natomas Basin (about

700 afy for existing conditions and 260 afy for future conditions). The effect on subsurface outflow to the east would be slightly negative for existing condition (-80 afy) and slightly positive for future conditions (60 afy).

There would also be small effects on groundwater quality because the proposed construction activities would result in slight groundwater quality degradation in some areas and improvements in other areas. The primary impact would be increased salt accumulation in the Natomas Basin (due to reduced groundwater inflow from the west and north) and east of the Natomas Basin (due to reduced groundwater outflow to the east). However, these reductions represent a small percentage of the total estimated groundwater inflow and outflow, and the water quality impacts are not expected to be measurable.

Well construction data and approximate locations are available for a number of private domestic and irrigation wells near the levees surrounding the Natomas Basin. However, well construction details and locations have not been determined for the majority of the domestic wells along Reaches 16-20 of the SREL. Shallow wells on either side of the levee could experience slightly lower pumping water levels because the cutoff walls will act as low permeability barriers that will reduce the areal extent and increase the depth of the cone of depression. This effect would only occur when the production zone of the well is above the tip of the adjacent cutoff wall. No decreases in well yields or increases in pumping costs are expected when the production zone of the well is below the tip of the slurry cutoff wall. That is the case for almost all irrigation, industrial, and municipal wells because those wells are much deeper than the deepest cutoff walls proposed for the levees surrounding the Natomas Basin. As discussed below, it is also the case for all domestic wells mapped along the NEMDC North and the ARNL and most of the domestic wells along Reaches 16-20 of the SREL.

There are a few mapped and unmapped domestic wells along Reaches 16-20 of the SREL that have the potential to be impacted by relatively deep slurry cutoff walls proposed for those reaches. However, any decreases in well yield or other impacts to private wells due to the proposed cutoff walls would be expected to be small. One of the main reasons for this is that available well capacity data indicate that domestic well capacities along the SREL average more than 60 gpm. With such high capacities, domestic wells only need to pump for a few minutes a day to meet normal water demands. This will result in very localized cones of depression that may even not reach the adjacent cutoff wall. If a cone of depression does reach the cutoff wall, there will be some additional drawdown and decrease in well yield, but this is not expected to be measurable.

1. Positive values indicate groundwater inflow; negative values indicate goundwater outflow.
2. Source of total flow estimate = Table 6-4 (LSCE, May 2009).
3. Source of total flow estimate = Table 6-5 (LSCE, May 2009).
4. Source of total flow estimate = groundwater inflow from 2004 IGSM simulation (241 afy) plus canal seepage estimated by Kleinferlder (218 afy) (LSCE, May 2009).
5. Source of total flow estimate = groundwater inflow from 2030 IGSM simulation (3,700 afy) plus canal seepage estimated by Kleinferlder (218 afy) (LSCE, May 2009).
6. Source of total flow estimate = IGSM 2004 simulation (LSCE, May 2009).
7. Source of total flow estimate = IGSM 2030 simulation (LSCE, May 2009).
8. Existing conditions based on average of spring and fall 2003 groundwater elevations shown on Figures 3-5 and 3-7 (LSCE, May 2009). For all levees except SREL, 2030 groundwater elevations based on Scenario 2B IGSM simulation (Figure 6-11, LSCE, 2008). For SREL, 2030 groundwater elevations assumed to be the same as existing conditions.
9. Increased groundwater inflow (or decreased outflow) shown as positive value; increased outflow (or decreased inflow) is shown as negative. 70% flow reduction assumed for slurry cutoff walls based on Kleinfelder (2009).

Table 4
SAFCA Construction Assumptions for Water Budget Estimates

	Total Length (ft)	Slurry Cutoff Walls		Canals		Total Area (ac)	Existing Agricultural Land Uses	Future Land Uses	Notes/Sources
		Length (ft)	Average Depth (ft)	Length of Lined or Piped Segments (ft)	Average Width at Waterline (ft)				
Levees									
Sacramento River East Levee	96,000	64,583	76	-	-	486.5	20 ac rice, 175 ac field crops, 5 ac orchard	Levee	HDR (December 17, 2009); Land use based on EDAW Table 3

RE: **Natomas Levee Improvement Project**
Natomas East Main Drainage Canal Erosion Protection Design

1. INTRODUCTION

This memorandum briefly describes the erosion protection designs **nhc** developed to treat two erosion sites along the westerly levee of the Natomas East Main Drainage Canal (NEMDC). The erosion assessments are described in a technical memorandum to SAFCA (**nhc** 2008). Erosion sites are located along the NEMDC downstream of SAFCA Pump Station 15 at the Dry Creek confluence and near the confluence with Arcade Creek.

2. NEMDC at Dry Creek Confluence Erosion Site

In 1996, SAFCA constructed a pump station in the NEMDC upstream of the confluence with Dry Creek. The pump station discharge infrastructure includes a 20ft wide concrete low flow channel along the right portion of the NEMDC (looking downstream) and three 72-inch discharge pipes spanning the remainder of the channel. Outflow from the three 72-inch discharge pipes outlet to a 30 foot long rock slope that is sloped at 3 horizontal to 1 vertical. An aerial view of the site is shown in photograph 1. As part of the NEMDC Units 2A and 3C Levee Improvement Project, SAFCA armored the right bank concrete retaining wall with rock riprap. The rock extends from about 20 feet upstream of the downstream end of the concrete retaining wall and about 200 feet downstream of the downstream end of the concrete retaining wall (JCE 1995, Spinks 1997). The Stone Protection Detail on sheet D-2 of the as-built plans (Spinks 1997) show the rock placed at a 3 horizontal to 1 vertical slope and at a thickness of 18 inches above the waterline and 24 inches below the waterline. The detail also shows a 5-foot thick rock key along the toe of the stone protection.

During field visits in 2008 and 2009, **nhc** observed that the slope and the thickness of the stone protection are not consistent with the details shown on the as-built plans (Spinks 1997). Much of the stone protection appears to have launched into the channel and lies near the slope toe. **nhc** estimated the rock slope protection to slope at about 1 horizontal to 1 vertical and observed numerous gaps between the stone protection that exposed the stream bank material. The rock slope protection appears to be comprised of rock with a b-axis of about 10 to 18 inches long. Photographs 2, 3, and 4 illustrate the slope and exposed stream bank material and rock slope protection.

nhc calculated a stable riprap gradation by applying the 100-year and 500-year hydraulic model results (MBK 2008) to the U.S. Army Corps of Engineers method for rock slope protection (USACE 1994). The rock gradation estimated using this method was smaller than the rock riprap observed in the field. This observation suggests that the scour producing flow characteristics are not captured by the hydraulic model or that the scour producing flow events do not occur during these flow scenarios. Scour producing flow conditions likely occur during seasonal high flows when the pump station and spillway are in operation and flow conditions are variable. Scour may also occur when water levels are relatively low in the NEMDC and inflows from Dry Creek are relatively high.

nhc recommends rock slope protection with the gradation shown in Table 1 to adequately protect the bank from erosion and protect the toe from scour. **nhc**'s recommended rock slope protection measures are shown on the plans and details in Attachment A.

100	463	185
50	137	93
15	69	29

3. NEMDC at Arcade Creek Confluence Erosion Site

A portion of the west bank lies inside the 3:1 template and is actively eroding. The upstream limit of the erosion site is about 200 feet downstream of the confluence with Arcade Creek and extends downstream from this point about 130 feet. Photograph 5 shows an aerial view of the site. Vegetation on the opposite bank (left bank) appears to constrict the flow near the erosion site and direct moderate and high flows towards the erosion site. Bank erosion along the right bank is shown in Photographs 6 and 7.

nhc proposes to stabilize this site by lining the actively eroding portion of the stream with rock slope protection. The banks upstream and downstream of the erosion site are nearly vertical and are susceptible to erosion due to block failure. **nhc** extended the bank protection about 110 feet upstream and about 130 feet downstream from of the erosion site to transition into more stable portions of the bank. The stable rock size as calculated using the US Army Corps of Engineers method for calculating slope protection is smaller that their recommended minimum size to prevent theft and vandalism of revetment. Hence, **nhc** 's proposed rock gradation is based on the US Corps of Engineers recommended size to prevent theft and vandalism. The proposed gradation is shown in

Table 2. Plans and details with the rock slope protection design is provided in Attachment B.

NOTES:

1. BANK PROTECTION AT THIS SITE INCLUDES A ROCK RIPRAP BLANKET BETWEEN STATIONS 1+42 AND 1+68, ROCK REVETMENT BANK PROTECTION WITH A LAUNCHABLE TOE FROM STATIONS 1+68 TO 4+50. SMOOTH TRANSITIONS SHALL BE USED BETWEEN BANK PROTECTION TYPES. SMOOTH TRANSITIONS SHALL BE USED AT THE UPSTREAM AND DOWNSTREAM END TO MATCH THE EXISTING GRADE LINES.
2. ROCK BLANKET SHALL BE FILLED OVER EXISTING GROUND TO A MINIMUM THICKNESS OF 1.5'. TRANSITIONS FROM 1.5H:1V SECTION TO THE BLANKETED AREA SHALL BE SMOOTH.

NOTES

1. ROCK RIPRAP SHALL BE BLOCKY IN SHAPE, COMPETENT ANGULAR ROCK FREE FROM SEAMS AND CRACKS AND WITH A MINIMUM SPECIFIC GRAVITY OF 2.6. ROCK RIPRAP SHALL BE PLACED TO THE LINES AND GRADES SHOWN IN A MANNER THAT PRODUCES A WELL GRADED MASS. ROCK SHALL BE GRADED, WITHOUT GAPS IN ROCK SIZES. THE ROCK SIZE IN WHICH 100 PERCENT OF ROCK IS FINER IS 18" ROCK.
2. TOP OF BANK BENCH WIDTH VARIES. THE BENCH SHALL BE AT A MINIMUM WIDE ENOUGH SUCH THAT A MINIMUM ROCK THICKNESS OF 1.5' AT THE TOP OF SLOPE. EXISTING BANK LINES SHALL BE MATCHED.
3. CHANNEL BED ELEVATIONS VARY ALONG THE LENGTH OF THE BANK PROTECTION TO BE INSTALLED. WHERE ELEVATIONS ARE LESS THAN 13.0' THE THICKNESS OF ROCK AT THE TOE WILL BE THICKER TO MAINTAIN AN ELEVATION OF 15.5'. A MINIMUM THICKNESS OF 2.0' IS REQUIRED FOR THE TOE PROTECTION.
4. ROCK BLANKET AND 1.5H:1V ROCK BANKS SHALL HAVE A MINIMUM ROCK THICKNESS OF 1.5'
5. UPSTREAM AND DOWNSTREAM ROCK KEYS SHALL BE FILLED TO GRADE AT A MINIMUM THICKNESS OF 3.0'.

RE: **Natomas Levee Improvement Project**
(DRAFT) Pleasant Grove Creek Canal Erosion Analysis

INTRODUCTION

This memorandum reports our erosion analysis for the Pleasant Grove Cross Canal (PGCC) West Levee along the Natomas Basin. The objective of the analysis is to review erosion processes, evaluate the significance of erosion at design floods to levee stability, and provide concept-level recommendations to address erosion that might prevent certification.

BACKGROUND

The "*Natomas Levee Evaluation Program: Erosion Assessment (February 2006)"* provided an initial reconnaissance of the PGCC (Subreaches 1 and 2). No active erosion sites were identified along the West Levee and no repairs were recommended, other than maintenance (beaver dams; tree fall). We re-inspected the West Levee of the PGCC in May 2008 and again did not identify any active erosion sites. Given the lack of active erosion, our analysis has focused on predicting whether or not the erosion that might occur during the design flood, either from in-channel velocities and stresses or from wind waves, is significant to levee stability.

Our results rely on the hydrology and water surface elevations provided by MBK Engineers (2008) in their Supplemental Report, additional model output not included in their report (such as velocities) and the results of a third flood scenario developed by MBK Engineers. We also relied on the wind wave analysis included in Mead and Hunt (2008).

EXISTING PGCC WEST LEVEE CONDITIONS

The PGCC West Levee extends about 3.3 miles south southeast from its junction with the Natomas Cross Canal to its terminus at Sankey Road. Natomas Road sits on the top of the levee and armors the crest with asphalt concrete. Levee crest elevations and design water surface profiles for the PGCC are provided by MBK Engineers (2008). The 200-year water level in the PGCC is a maximum of 45.2 feet NAVD88; new level crest elevations will be set to 48.2 feet NAVD88. The existing crest elevations are up to 1.5 feet below the new design elevation at the northern end of the PGCC West levee, near the Natomas Cross Canal.

Existing waterside slopes are generally steeper than 3:1 (horizontal to vertical). The slope from the edge of the Natomas Road to the west side of the inspection road along the toe of the levee was usually a little less than 2:1 and the side slope was steepest near the top of the levee. Overall slopes from the waterside levee crest to the far side of the inspection road (edge of the low flow channel) were generally less than 3:1. The waterside slope is covered with grass; levee soils appear to be poorly graded sands and sands with silt, assumed to be equivalent to a sandy loam (geotechnical results for the levee investigations are not yet available).

The PGCC is confined on the east side by a levee or railway embankment that appears to be several feet lower than the crest of the West Levee. The east levee is also breached by the three tributaries that flow into the PGCC, Curry Creek at Mile 2.8 (upstream of Key Road), Pleasant Grove Creek at Mile 2.3 (just downstream of Key Road) and the Pierce-Robert Drain at Mile 1.0 (between Fifield and Howsley Road). MBK Engineers (2008) provides 100- and 200-year inflow hydrographs for the three tributaries.

The bottom width of the PGCC increases from the south to the north. Near Sankey Road the bottom width is about 60 to 70 feet; by Key Road it is about 200 feet; and by Fifield Road, it 300 to 350 feet. The canal bottom, above the low flow channel, appears to be formed in silty clay soils and is covered by aquatic vegetation, reeds, and grasses. The low flow channel is cut into the canal bed adjacent to the inspection road; it is several feet deep and the bed appears to be formed in the local soils and is covered by a thick, saturated, mud where it was inspected.

The PGCC is crossed by a ford at Key Road and bridges at Fifield and Howsley Roads. The ford at Key Road is as much as five feet above the local channel bottom and includes a 4-foot diameter round CMP set near the bottom grade. Field inspection shows a small scour hole downstream of the culvert exit and no obvious evidence of failure of the roadway from overtopping or from scour downstream of the road. Rock riprap for wave protection has been placed on the southern side of Key Road, near both the west and east levees.

The Fifield and Howsley Road bridges are about 200 to 220 feet wide; embankments carry the roads from the east abutments across the canal to the levee or railway grade. The abutments of the Fifield Bridge are wrapped in riprap and riprap has been placed along the southern face of the road embankment and along the waterside edge of the east levee. Inspections show little evidence of recent scour at the piers or through the bridge section. The Howsley Road Bridge also has riprap placed for wind wave protection along the south side of the road embankment. Field inspection showed no evidence of scour at the right (east) abutment or piers but a deep section through the piers and old concrete footings near the left (west) abutment. Wading indicated deep exposure of the footings. Coarse rock on the channel bottom may have been placed as scour protection, suggesting past problems at the bridge. We did not complete a detailed inspection, given the water depths.

The PGCC includes the Howsley Gap at the Howsley Road Bridge crossing (MBK Engineers 2008). Here, the levee crest is lowered for approximately 100 feet on either side of the road centerline. Elevations are up to 3 feet below the existing local crest (43 feet NAVD88 in the middle of the gap compared to 46 to 46.5 feet NAVD88 on the nearby crest). The levee crest in the gap is reinforced with concrete; however the landslide slopes of the levee and the road embankment are not armored.

PROPOSED PGCC WEST LEVEE CONDITIONS

The proposed upgrades for the PGCC West Levee consist of constructing a 30-foot wide levee crest to the landside of the existing crest, placed so that a "theoretical" 3:1 levee slope from the crest to the inside edge of the inspection road lies within the existing slope. No re-grading of the waterside slope is proposed and concept drawings indicate that the existing roadway surface will remain. The levee crest will be raised as required and seepage protection constructed on the landside of the levee (Wood Rodgers 2008).

EROSION BY INSTREAM FLOWS

Erosion by instream flows may be a result of channel velocities that occur during the design flows, natural scour, contraction scour through bridge openings, or local scour around obstructions such as trees and pump stations. In general, our analysis of potential erosion by in-channel velocities is based on comparing predicted velocities to the permissible or allowable velocities appropriate for the levee slope materials and vegetation. Scour was evaluated from regime equations or by incorporating predicted velocities into equations that predict local scour.

IN-CHANNEL HYDRAULICS

MBK Engineers calculated the hydraulic conditions in the PGCC with their unsteady 1-D UNET model. Results are reported for 10 cross sections distributed upstream and downstream of the tributaries inflows and the two bridges (see Figure 1). Model inputs include tributary hydrographs and the Sacramento River hydrograph at the downstream end of the Natomas Cross Canal (NCC). Model outputs include section-averaged velocities, depths and water surface elevations over time. Velocity distributions within the sections are expected to be complex, particularly where the tributaries flow into the canal at right angles, but the model provides no details. Table 1 summarizes the highest velocities observed at five of the cross sections.

The velocities are quoted for three different scenarios. These are: 1) 200 year inflows with a 200 year flow in the Sacramento River (MBK Engineers, 2008); 2) 100 year inflows with a 100 year design flow in the Sacramento River (MBK Engineers, 2008); and 3) 200 year inflows with a 2 year flow in the Sacramento River. The last scenario was judged to be a reasonable worse case scenario that would produce the highest velocities in the PGCC. The PGCC is backwatered from the Sacramento River resulting in relatively low velocities throughout the canal for the three scenarios. The highest velocities are observed just downstream of Pleasant Grove Creek (R53 s1.48) and at the northern outlet (R55 s0) for the third scenario.

Table 1: Peak Velocities in the PGCC.

Cross-Section*	**200 Year Inflow 200 Year Sac. River**	**100 Year Inflow 100 Year Sac. River**	**200 Year Inflow 2 Year Sac. River**
R55 s0	2.4 ft/s	2.4 ft/s	3.3 ft/s
R55 s0.68	1.3 ft/s	1.3 ft/s	2.3 ft/s
R53 sS0	1.2 ft/s	1.2 ft/s	2.0 ft/s
R53 s1.48	2.8 ft/s	2.9 ft/s	3.1 ft/s
R51 s0	1.3 ft/s	1.6 ft/s	1.1 ft/s

*MBK Engineers' Sacramento River UNET Model (5/7/08)

PERMISSIBLE OR ALLOWABLE VELOCITIES

The general condition to be met for levee design and certification is no appreciable erosion during the base or design flood, in this case the 200-year peak flow.

Insert Figure 1 (MBK Engineers cross sections)

One approach to evaluating the erosion potential during extreme floods is to compare the hydraulic, bed and bank material and vegetation conditions observed in the PGCC to the design values for a "threshold" channel, where this refers to a channel where movements of its boundary materials are negligible during the design flood (see NRCS 2007 for further discussion). Design of such channels can be based on allowable velocities, shear stresses or tractive powers and there is a long history of guidance for design criteria and design procedures for these types of channels. Based on recommendations in the NRCS handbook and the inability to accurately calculate shear stresses under the design condition in the backwatered channel, we have adopted allowable velocities to evaluate potential erosion in the PGCC. The procedures in the NRCS handbook are intended for design of shallow irrigation canals excavated in unprotected earth or grass lined floodways and may not be strictly applicable to the PGCC.

In this section, the main interest is whether or not the grass-covered levee slopes will erode during the design flow; erosion of the stream bed is discussed in more detail in the next section. Review of NRCS (2007) and other literature suggests that the grasses observed on the bank will likely provide similar protection to that of various bunched or tufted grasses such as alfalfa, essentially a relatively low standard of erosion protection. Recommended allowable velocities are 3.5 ft/sec over erosion-resistant soils and 2.5 ft/sec over easily eroded soils. Reference to Fischenich (2001) suggests that the grasses are similar to Class C turf; typically having a stand height of approximately 6 inches and fair to good overall density. Quoted permissible velocities from Fischenich (2001) are 3.5 ft/s. This analysis suggests that 3.5 ft/sec is a good initial estimate of the permissible velocity for the grass-covered levee slopes.

Adjustments to the permissible velocities for the levee slopes are required for channel curvature, bank slope, depth of flow, and the frequency and duration of flow, as outlined in the SCS (1977) procedure for earthen canals (see summary in NRCS 2007). The PGCC is straight and the design floods are extreme, so no adjustments are required for curvature or frequency. The recommended factor for depth is 1.4 and for bank slope is 0.8. On this basis, the final permissible velocity is 3.9 ft/sec. The duration of high velocities is relatively short – less than one day – and the permissible velocity was not adjusted for this factor.

Based on the estimated permissible velocity and the maxima quoted in Table 1, the grass cover on the waterside levee slope should resist erosion during the design flow. Shear stress is generally recommended for design of grass-lined channels and such an approach might change the conclusions drawn from the permissible velocities.

We also examined permissible velocities for the levee soils, if they were exposed to design flow because of loss of vegetation or other factors. Assuming that the soils are a sandy loam (geotechnical investigations are not yet complete), the initial permissible velocity is 1.75 ft/sec, assuming clear water conditions during the design flow. Adopting the adjustments above, the final value for the soil on the levee slope is 2.0 ft/sec. These permissible velocities for the soil are exceeded at several sections in Table 1, suggesting erosion will occur along parts of the west levee if the grasses are disturbed or eroded.

One final consideration is that the velocities reported in Table 1 are section averages that do not account for velocity distribution or velocity fluctuations that occur near the channel boundaries. The highest velocities in the UNET model are reported where tributaries enter into the PGCC. These locations will also experience high turbulence due to the added momentum and mixing, which will increase the shear stress exerted on the PGCC levee slopes and could potentially exceed the erosional strength of the vegetated soil. We recommend adding bank protection to the west levee waterside slope near the confluences of the PGCC with Pleasant Grove and Curry

Creeks. This added bank protection would ideally extend from about 50 feet upstream of the confluence to approximately 100 feet downstream and consist of a layer of 6 to 8 inch quarry rock placed on the slope and covered by soil and grass vegetation.

BED OR CHANNEL SCOUR

Scour is defined as lowering of the bed below its normal level as a result of erosion during a significant flow. Scour that lowers bed levels adjacent to the waterside toe of the levee may result or contribute to slope failure and may also shorten seepage paths. Most scour analyses address bed adjustments in alluvium. The PGCC appears to be formed in local soils, with limited sediment inflows. Typical regime type scour equations may not provide good estimates of the scour that occurs without consideration of whether the bed is erodible by the imposed flows.

Naming conventions for different types of scour vary from one source to another. As discussed here, "natural" scour refers to lowering of the bed as a result of a large flow in the absence of other interference. "Contraction" (or general) scour refers to the scour that occurs in a bridge waterway opening when flood flows are constricted. "Local" scour occurs around obstructions such as bridge piers, trees, intakes, etc and is discussed further below.

Natural Scour

The potential for natural scour in the PGCC can be estimated by comparing regime depths appropriate for the design flows to observed depths. Where regime depths are greater that observed depths, scour might be expected, assuming that the bed is erodible by the imposed velocities and that high velocities last long enough to develop the scour. Downstream of Pleasant Grove Creek, the 200-year peak discharge is about 9,000 cfs and channel widths exceed 300 feet. Applying Lacey's equation (1929; see May et al 2002; TAC 2004), the regime depth for the 200-year peak can be estimated as:

$$y_R = q_R^{2/3}/F_{bo}^{1/3} \qquad (1)$$

where y_R is the regime depth (feet), q is the discharge intensity calculated from the 300 foot width, and F_{bo} is the silt factor, assumed to be 0.7 for this channel. Such a silt factor is for fine sand and provides a very conservative estimate of the regime depth. The regime depth is estimated to be about 14 feet based on equation (1). Similar regime depths for the 200-year flow are calculated from Simon and Albertson's (1963) regime equations for their Type 3 channel (cohesive bed and banks). Based on the regime depth and a Z-factor of 1.1 suitable for the straight channel of the PGCC, the scoured depth might reach a maximum of 15 feet. Such an estimate is likely conservative, as the canal does not appear to meet typical regime dimensions and the silt factor may be considerably larger the assumed value, reflecting erosion resistance.

The channel bottom in the lower half of the PGCC is at about 26 to 27 feet NAVD 88 (Psomas); 200-year water surface elevations are about 45 feet NAVD88 with 200-year water levels in the Sacramento River (MBK Engineers; Figure 32) and about 41 feet NAVD88 with 2-year water levels in the Sacramento River. Based on the above, minimum depths are about 14 to 15 feet. Given that observed depths equal or exceed estimated scour depths, that the bed materials are thought to be of low erodibility and that the duration of high velocities is relatively short, we anticipate no natural scour in the canal during the design scenarios discussed earlier.

Contraction Scour

Both the Howsley and Fifield Road Bridges constrict the width of the PGCC. A variety of approaches are available to assess the effect of the bridge constrictions on potential scour depths

through the opening. One is to calculate the potential scour depth in the bridge section from that in the upstream channel from a ratio of the discharge intensities (TAC 2004) as below:

$$y_B = y_R (q_B/q_R)^{m} \quad (2)$$

Here, y_R and q_R are as defined above, q_B is the discharge intensity through the bridge calculated from the 200-year peak flow and a width of 200 feet and y_B is the regime depth through the bridge. The superscript, m, is estimated to be 0.7. Given the adopted power, this approach is equivalent to that in the US FHWA manual (Richardson and Davis 1995). We have not further narrowed the bridge opening to reflect blockage by debris or factors.

Based on equation (2), the regime depth through the bridge is about 19 feet and the depth of scour might be a maximum of 20 feet. Such scoured depths would be below the bed at the two bridges, suggesting the potential for some scour during the design flood with 2-year water levels in the Sacramento River. The potential to achieve such scour depends on the erodibility of the bed and the duration of the peak velocities. Allowable velocities, based on assuming that the bed materials are silty clay are about 3.5 ft/sec (NRCS 2007). Adjusted for depth, the final permissible velocity is about 4.6 ft/sec. Reference to TAC (2004) suggests competent mean velocities of about 4 ft/sec for the flow depth, and assuming average erodibility for the bed material (TAC 2004). Based on quoted maximum average velocities near the bridge opening of 3.5 ft/sec, only limited scour would be expected through the openings.

The left (west) abutment of the Fifield Bridge is partly protected by riprap, and bed erosion is likely to be slow. On this basis, erosion at this abutment is unlikely to be a concern for the stability of the west levee. Further downstream, at the Howsley Road Bridge, the low flow channel is adjacent to the left (west) abutment, there are significant pier obstructions in the channel, riprap is lacking around the abutment, and the channel appears to have experienced scour in the past. We recommend either further investigations of scour potential through this opening or placing riprap around the left (west) abutment.

Local Scour

Obstructions such as piers, pump stations, and valve boxes (Figures 2 and 3) might also result in local scour holes during floods. These may be significant to erosion of the levee where the structures are on the levee slope or at the levee toe.

Figure 2: Typical Pump Station in PGCC

Figure 2 shows existing scour downstream of a pump station along the PGCC west levee. It is difficult to estimate the potential scour for the three-dimensional flow around the station during the design flow. A very conservative scour estimates was based on the results of Bormann and Julien (1991), which calculate the equilibrium depth of scour (below the bed) downstream of submerged grade control structures. The computed maximum depth of scour from their relationship is about 7 feet. This is certainly too large because it does not account for the high relative submergence and the small percentage of flow area disrupted by the pump station. However, assuming that the scour is similar to that resulting from a bridge pier, the depth of scour will be about equivalent to the width of the pump station, or at least a few feet. Such scour may result in significant steepening of the existing waterside levee slopes.

Given the low maximum velocities, their infrequent occurrence, and the resistant bed materials, scour will develop slowly, but will eventually erode into the toe of the levee slope. We recommend adding an apron of 8 inch to 10 inch rock on the levee slope behind the pump structures and along the downstream bank, with a launchable toe.

Maximum potential scour depths were also calculated for the valve boxes observed on the levee slopes (Figure 2). Based on Froelich's bridge scour equation (Fischenich and Landers 2000) a maximum depth of scour of about 2 feet is predicted around the valve boxes. The equation assumes cohesionless soil and neglects the added erosional resistance provided by the vegetation on the levee. If a scour hole forms around the structure, it will likely extend 6 to 10 feet downstream of the structure, with a top width of less than 6 feet (ASCE Sedimentation Manual, section 10.4 p 525). Given the low velocities, erosion resistance provided by the grass cover, and the increased size of the new levee section, we do not expect local scour around the valve boxes to affect the performance of the levee.

Figure 3: Typical Valve Box in PGCC

EROSION BY WIND WAVES

REVIEW OF PREVIOUS STUDIES

Mead & Hunt (2008) provided a wind wave analysis for the PGCC that used deepwater wave equations to compute maximum wave effects at three locations. Methods to estimate fetch lengths (based on the extent of the 500-year FEMA floodplain) and wind speeds are described in their memorandum.

Table 2 compares the Mead & Hunt computed wavelengths to their average channel depths (these depths are conservative). The table shows that wavelength-to-depth ratios (L/d) slightly exceed a value of 2.0 at the three sites. Typically, when the L/d ratio exceeds 2.0, the waves are assumed to be shallow water waves; deep water waves have L/d ratios less than 2.0. Unfortunately, the commonly used shallow water and deepwater wave equations do not agree for L/d ratios very close to 2.0. Hurdle and Stive (1989) provided a revised version of the 1984 Shore Protection

Manual wave equations that are asymptotic to the shallow water wave equations for high L/d ratios and to the deepwater wave equations for low L/d ratios but provided a more reasonable transition between the equations when the L/d ratio is near 2.0.

Table 2: Length-to-Depth Ratios of Mead and Hunt (2008) Computed Waves

Cross-Section	Average Depth, d (ft)	Reported Wave Period, T (s)	Calculated Wavelength, L† (ft)	L/d
287+00	17.00	3.0	46.1	2.7
377+00	17.00	2.8	40.2	2.4
456+00	17.00	3.2	52.2	3.0

†$L=T^2*g/(2*\pi)$, (Dean and Dalrymple, 2002)

We re-calculated the maximum wave heights at the three locations with the Hurdle and Stive (1989) wave height equation, using the fetch lengths, over-water wind speeds and other parameters reported by Mead & Hunt (2008). The results of the calculations are in Table 3; the revised total wave effects are now all less than 3 feet.

Table 3: nhc Revised Wind Wave Effects

Cross-Section	Wave Height (ft)	Run-up (ft)	Wind Surge (ft)	Setup (ft)	Total Wave Effect (ft)
287+00	2.56	1.5	0.7	0.4	2.7
377+00	2.15	1.6	0.6	0.3	2.5
456+00	2.62	1.7	0.8	0.4	2.9

Total water level (TWL) is the sum of the flood elevation and total wave effects. The new levee crest will be set to the calculated 200-year flood elevation (MBK Engineers 2008) plus three feet of freeboard. Based on this design condition, the levee will not be overtopped at the three analysis sites and we anticipate that the levee crest will be above the TWL along nearly all of the PGCC West Levee. On this basis, erosion will be mainly confined to the levee slope, as discussed in the next section. Two special sites where water levels overtop the levee crest are then discussed in the final section.

LEVEE SLOPE EROSION BY WIND WAVES

The theoretical basis for wind wave erosion along shorelines is not fully developed (Dean and Dalrymple, 2002). The process is complicated by the oscillatory and highly turbulent nature of the breaking waves coupled with the many unknowns prevalent in sediment transport applications. Although there are a variety of approaches for estimating wave induced erosion, these models tend to be simple. Previous experience (**nhc**, 2008) has shown that typical approaches used in coastal engineering applications are not well-suited for application in riverine environments. Given these difficulties, a simplistic geometric approach was developed to determine the theoretical worse case wind wave erosion.

The geometric approach used in this study follows the MKA method provided in the *Coastal Flood Hazard Mapping and Analyses for the Pacific Coast of the United States* (FEMA, 2004). This method estimates the maximum potential erosion on the riverside of the levee that could be expected due to wind waves during a single storm event. The change in shoreline position during a storm is calculated from the increase in the TWL due to the storm and an assumed equilibrium profile slope. For this particular application, we assumed that the eroded bench slope is horizontal and the eroded scarp face is vertical. This is consistent with the expected beach profile for fine

sand (slopes of approximately 20H:1V to 50H:1V) (Dean and Darlymple, 2002) and with wave cut benches observed on levees along the Sacramento River. Figure 4 shows this configuration.

The MKA approach assumes that the wave cut bench forms at the static water level (SWL), which is defined as the TWL minus the wave runup. Erosion is concentrated between the SWL and the TWL as the shoreline slope in this region is cut down to the equilibrium beach slope. The elevation of the wave runup decreases with the levee slope lowering the TWL and resulting in the formation of a vertical scarp face. (The wave runup on a vertical face is approximately equal to the breaking wave height.) In this study, the breaking wave height was larger than all runup values prompting the use of the breaking wave height to get a conservative maximum TWL value (TWL_{max}). The MKA approach (see FEMA 2004) predicts that the shoreward recession of the wave cut slope continues until it intersects the initial profile at the elevation of the TWL. For a horizontal bench and vertical scarp on an initial uniform slope, the recession distance is simply mH_b as shown in Figure 3.

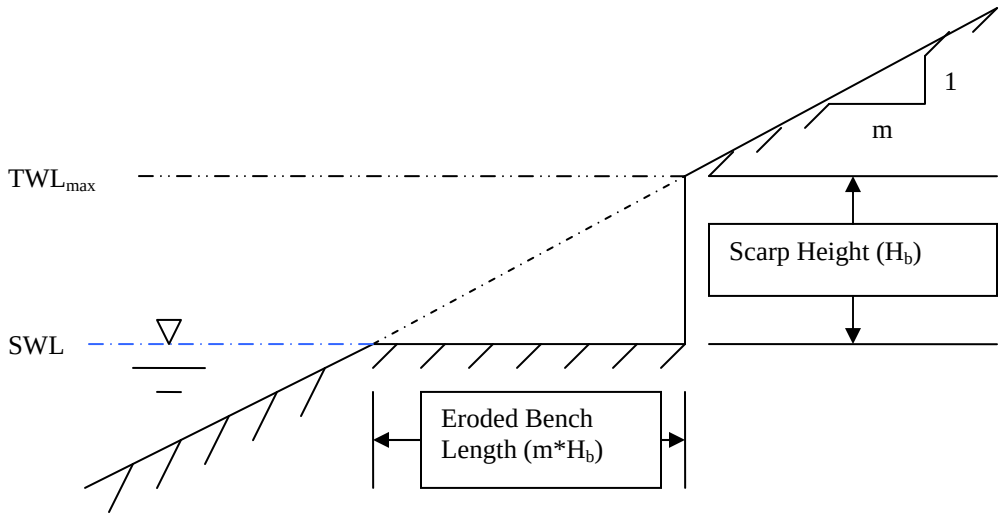

Figure 4: Basic Layout of Wave Cut Bench on Levee Slope

Table 4 provides the breaking wave heights and the maximum bench lengths that could potentially be cut by wind waves into the existing 2:1 levee slopes. Although the natural angle of repose for the levee material is much less than vertical, the assumption of a near vertical scarp is thought to be reasonable for a short duration of time (days). The wind duration necessary to maximize the wave heights is less than one hour and it is unlikely that sufficient erosion and transport of levee soils could occur in this time to develop the geometry shown in Figure 4, particularly if the waterside slopes remain grass-covered and the existing asphalt road is retained near the top of the slope where waves are likely to intersect.

Table 4: Selected Results of Wind Wave Erosion

Cross-Section	Breaking Wave Height H_B, ft	Duration of Maximum Wave Heights (hrs.)	Eroded Bench Length (m*H_B), ft
287+00	2.9	0.38	5.8
377+00	2.4	0.47	4.8
456+00	3.0	0.62	6.0

Despite the very conservative assumptions, the maximum length of erosion into the levee near the crest will not penetrate the levee slope to the theoretical 3:1 levee slope that will be the new levee face after the upgrades. As such, wind wave attack is not expected to cause significant erosion of the levee prism.

LEVEE CREST OVERTOPPING SITES

Two special cases of overtopping are discussed in the second following section: Howsley Gap, where the levee crest is lowered and the PGCC South Levee at Sankey Road. At these sites, the levee crest elevation is less than the TWL resulting in potential erosion of both the levee crest and the landside levee slope.

Levee Crest Erosion at Howsley Gap

MBK Engineers provided flow hydrographs through the Howsley gap for the 200 year design flood computed with their 1-D unsteady UNET model. Taking into account the low tailwater condition that would be apparent on the landside of the levees a steep energy slope would exist across the gap potentially forcing the water into critical flow velocities. Peak critical velocities were computed based on the flow hydrographs and gap section provided by MBK Engineers for conditions both with and without wind waves. The calculated velocities ranged between 9 ft/s and 11 ft/s.

The levee crest at the Howsley gap is armored with cast-in-place concrete which will adequately resist the erosive forces of the overtopping flow. However, the landside slope of the levee on either side of Howsley Road and the road embankment slopes are not armored. If flows are diverted onto these slopes, erosion will occur rapidly and potentially undercut the road, the concrete crest, or the landside slopes and cause catastrophic levee failure. It is therefore recommended that the landside levee slopes and the road embankments on either side of Howsley Road be armored. The pavement of Howsley Road immediately west of the PGCC should also be monitored to ensure adequate structural integrity.

PGCC South Levee

The PGCC South Levee near Sankey Road forms the end of the PGCC and ponds water in the southern part of the PGCC. Some of the water overflows the right (east) levee and passes through the Sankey Gap. Inspection of the South Levee indicates that it has rock armor buried beneath the soil on the waterside face but it does not appear to have any armoring on its crest or landside slopes (leading to Sankey Road). The elevation of the crest of the South Levee is up to 1.5 feet lower than the existing west levee and sits as low as 0.5 ft above the 200 year water surface elevation along part of the levee.

Velocities calculated for the design wind waves exceed 9 ft/s on the water side of the south levee and 3 ft/s on the land side slope with flow depths near 0.25 feet. The 9 ft/s and oscillatory nature of the waves could potentially erode to the levee crest and result in a breach that increased the

flows into Sankey Gap. We recommend that either this levee be raised or that the crest and landslide slope be armored with 12 inch rip rap.

CONCLUSIONS AND RECOMMENDATIONS

This memorandum reports on our erosion analysis for the West Levee of the Pleasant Grove Creek Canal. Our analysis addressed erosion that might result from in-channel hydraulics, natural, contraction and local scour, and erosion that result from wind waves, including overtopping. We have relied on MBK Engineers (2008) and Mead & Hunt (2008) for hydraulic and wind wave analysis to assist the erosion analysis.

Our inspections of the West Levee in October 2005 and in May 2008 both showed no evidence of active erosion. Consequently, we focused on predicting the erosion that might occur during the design flood, based on three scenarios developed by MBK Engineers. Where erosion appears to be significant to levee integrity, we have recommended concept-level protective works. The analytic techniques employ conservative assumptions, as documented in the memorandum.

Our review of the studies by Mead & Hunt suggested that their approach to calculating potential wave effects along the levee should be revised. Re-calculated wave heights resulted in total wave effects less than 3 feet, or less than the freeboard proposed by MBK Engineers (2008). This implies that there will be no wave overtopping of the levee crest after the upgrades are completed, except at two special locations – Howsley Gap and the South Levee at Sankey Road. Based on this revision, our wave erosion analysis addressed only the waterside levee slope.

In general, the erosion analysis suggests that the upgraded levee will not experience significant velocity, scour or wind wave erosion during the design flood. However, this conclusion is based on maintaining existing vegetation on the waterside slopes as the underlying levee soils appear to be susceptible to erosion without the grass cover (this conclusion may be revised when we review the geotechnical results). We also recommend some specific treatments along the West Levee to address local erosion issues. Further detailed investigations may alter some of our conclusions but we recommend the following as preliminary measures:

- Place riprap on the west levee waterside slopes opposite the confluences with Curry and Pleasant Grove Creeks. Such protection should extend from the toe to the top of slope for about 50 feet upstream and 100 feet downstream of the confluences. The rock can be covered with soil and grass.
- Place riprap around the left (west) abutment of the Howsley Road Bridge or carry out sufficient investigations to determine that it is not needed.
- Place rock or other protection along the Howsley Road embankment and along the landside of the West Levee near the Howsley Road gap to prevent erosion undermining the gap or affecting the landslide slope.
- Place riprap to armor the levee slopes and toe in the vicinity of pump stations, where potential scour might steepen levee slopes
- Raise the crest of the South Levee at Sankey Road or armor the levee crest and landside slopes to prevent wave overtopping erosion and diversion of additional flow to Sankey Gap from a partial levee breach.

Subject: Section 7 Programmatic Formal Consultation on the Natomas Levee Improvement Program, Landside Improvements Project, Sacramento and Sutter Counties, California

Dear Mr. Piccola:

This is in response to the U.S. Army Corps of Engineers (Corps) June 9, 2008, request for consultation with the U.S. Fish and Wildlife Service (Service) on the proposed Natomas Levee Improvement Program, Landside Improvements Project (proposed project) in Sacramento and Sutter Counties, California. Your request was received in our office on June 11, 2008. This document represents the Service's programmatic biological opinion on the effects of the action to two federally-listed threatened species: the valley elderberry longhorn beetle (*Desmocerus californicus dimorphus*) and the giant garter snake (*Thamnophis gigas*) and project-level biological opinion for Phase 2 work for the same species, in accordance with section 7 of the Endangered Species Act of 1973, as amended (16 U.S.C. 1531 *et seq.*) (Act).

This biological opinion is based on information provided in the Corps' letter requesting consultation and their biological assessment. A complete administrative record is on file at the Sacramento Fish and Wildlife Office.

CONSULTATION HISTORY

September 25, 2006. The Sacramento Area Flood Control Agency (SAFCA) had a meeting with the Service to briefly describe the conceptual Natomas Levee Improvement Project.

May 10, 2007. The SAFCA made a presentation of their Natomas Levee Improvement Program Conceptual Plan to the Natomas Joint Vision, which included staff from the Service, California Department of Fish and Game (CDFG), the City of Sacramento, the Sacramento International Airport (Airport), and the Corps. This presentation included additional details and conceptual project designs.

October 29, 2007. The Service and the CDFG sent a joint comment letter to SAFCA on the Natomas Levee Improvement Project's Draft Environmental Impact Report.

January 11, 2008. The SAFCA, the Corps, the Service, and CDFG began holding coordination meetings on the Natomas Levee Improvement Project to discuss project description and schedule.

January 24, 2008. The SAFCA, the Corps, the Service, and CDFG held a coordination meeting, which included John Roberts from the Natomas Basin Conservancy (TNBC) to discuss project effects.

March 28, 2008. The Service met with SAFCA and Congresswoman Doris Matsui to discuss the project and schedule of the project.

June 17, 2008. The SAFCA and the Corps held a meeting with CDFG and the Service to discuss work proposed for construction in 2009.

June 25, 2008. The Corps, EDAW, CDFG, and Service held a meeting to go over the effects of the project on specific cover-types.

July 2, 2008. The Service met again with Congresswoman Doris Matsui to discuss the schedule of the biological opinion.

July 9, 2008. The Service met with SAFCA, EDAW, CDFG, and the Corps to discuss endowments and easements for the conservation measures. The Service advised SAFCA that any thing other than a conservation easement for protection of compensation areas would take a great deal of time to work through.

July 10, 2008. The Corps, EDAW, SAFCA, CDFG, and Service held a meeting to discuss effects and schedule of the project.

July 15, 2008. The Service and Corps met with SAFCA to resolve schedule differences for the biological opinion. The Service committed to completing the biological opinion by September 24, 2008.

July 17, 2008. The Service provided a request via e-mail for 39 additional acres of managed marsh creation as part of the compensation strategy. This request was sent to EDAW, SAFCA, Corps, and CDFG.

July 21, 2008. The Service, Corps, EDAW, SAFCA, and CDFG met to discuss project effects and compensation strategy.

September 9, 2008. The SAFCA provided an updated compensation strategy based on landuse changes at borrow sites on Sacramento County Airport lands.

September 17, 2008. SAFCA, EDAW, and the Service had a meeting in which SAFCA proposed an idea to develop a compensation bank within the Natomas Basin.

September 19, 2008. The Service responded to the proposal submitted by SAFCA for a compensation bank and suggested that in order to provide a biological opinion to the Corps and SAFCA by September 24, 2008, SAFCA not include compensation banking as part of their project description. The Service also suggested that placing a conservation easement on ½ of the area borrowed at Brookfield would help compensate for effects due to the project.

September 21, 2008. SAFCA's consultant provided an e-mail which agreed to the Service's September 19, 2008, e-mail.

BIOLOGICAL OPINION

Description of Action Area

The proposed project area is located in the Natomas Basin in northern Sacramento and southern Sutter Counties, generally bounded by leveed reaches of the Natomas Cross Canal (NCC) on the north, the Sacramento River on the west, the American River on the south, and the Pleasant Grove Creek Canal (PGCC) and Natomas East Main Drainage Canal (NEMDC)/Steelhead Creek on the east. This project, which is part of the larger Natomas Levee Improvement Program (NLIP) being undertaken by SAFCA, consists of three construction phases, generally occurring between 2008 and 2011. Construction Phase 2 includes the 5.3-mile NCC south levee, the Sacramento River east levee from the NCC south levee to 2,000 feet south of the North Drainage Canal (Reaches 1-4B), the Elkhorn Main Irrigation Canal (Elkhorn Canal) between the North Drainage Canal and the Elkhorn Reservoir settling basin, the site of Reclamation District (RD) 1000 Pumping Plant No. 2, and adjacent land. Construction Phase 3 includes the Sacramento River east levee south of the limits of the Phase 2 improvements to just south of (I-5) (Reaches 5A–9B), the PGCC west levee, the NEMDC west levee between Elkhorn Boulevard and

Northgate Boulevard, the area between Elkhorn Reservoir and the West Drainage Canal where a new canal designed to provide drainage and associated giant garter snake habitat (referred to in this document as the "GGS/Drainage Canal") would be constructed, the portion of the West Drainage Canal north of Interstate 5 (I-5), the Elkhorn Canal downstream of Elkhorn Reservoir, and RD 1000 Pumping Plant No. 2. Construction Phase 4, which is still undergoing study, includes the Sacramento River east levee south of the limits of the Phase 3 improvements to the junction with the American River north levee (Reaches 10–20), the NEMDC west levee between Sankey Road and Elkhorn Boulevard, the Riverside Main Irrigation Canal (Riverside Canal), and the West Drainage Canal south of I-5 to Fisherman's Lake. Phase 1 of the project occurred during the summers of 2007 and 2008 and consisted of placing slurry wall along 9,700 linear feet of the Natomas Cross Canal (Service file number 1-1-07-F-0207).

Because the Corps and SAFCA only have a detailed project description for Phase 2 of the entire Natomas Levee Improvement Project, this biological opinion analyzes the landscape effects of the project for all Phases (2, 3, and 4) but will only analyze and provide incidental take coverage for Phase 2. Each subsequent phase will initiate section 7 consultation with the Service under the umbrella of this programmatic biological opinion.

Overview of NLIP Landside Improvements Project

The SAFCA is designing the NLIP in coordination with the Federal and state flood control project sponsors, the Corps, and the State of California Central Valley Flood Protection Board (formerly The Reclamation Board), to address the deficiencies in the Natomas levee system with a focus on achieving a 100-year level of flood protection by 2011. This will require improving the following landside conditions along the NCC south levee, the Sacramento River east levee, and the PGCC and NEMDC west levees:

- Inadequate freeboard—The NCC south levee and portions of the Sacramento River east levee are not high enough to provide at least 3 feet of freeboard above the 100-year water surface elevation. Additional reaches do not provide 3 feet of freeboard above the 200-year design water surface elevation.
- Underseepage and through-seepage vulnerability—Most of the levee reaches do not meet recently adopted Federal criteria for safely containing underseepage and through-seepage when the water surface in the adjacent channel reaches the 100-year elevation or, in some cases, the 200-year elevation.

The NLIP Landside Improvements project encompasses addressing freeboard deficiencies through levee raises; addressing seepage potential using a combination of seepage berms, cutoff walls, and relief wells; and acquiring additional right-of-way to construct the improvements and to prevent encroachment into the flood control system. In addition, the project has been designed to include an enlarged levee embankment (adjacent setback levee) along the land side of the existing Sacramento River east levee to minimize the need for substantial removal of vegetation and structural encroachments on the water side of this levee in compliance with Corps guidance. These improvements would include recontouring the levee slopes where necessary to provide a

3:1 horizontal-to-vertical (3H:1V) waterside slope and a 3H:1V (preferred) or 2H:1V (maximum) landside slope.

The specific goal of the NLIP Landside Improvements Project is to provide at least 100-year flood protection as quickly as possible while laying the groundwork to achieve at least urban-standard (200-year) flood protection over time.

Additional project objectives that influenced SAFCA's project design were to:

(1) use flood control projects in the vicinity of the Sacramento County Airport to facilitate better management of Airport lands to reduce hazards to aviation safety, and

(2) use flood control projects to enhance habitat quality and values by increasing the extent and connectivity of the lands in the Natomas Basin being managed to provide habitat for the giant garter snake, the Swainson's hawk, and other special-status species.

Recognizing the importance of securing maximum Federal support for the flood control project, SAFCA has explored implementation approaches that also advance the achievement of Federal aviation and wildlife protection objectives where complementary opportunities exist. Accordingly, the proposed project includes the following elements:

- The project would include construction of the GGS/Drainage Canal to provide giant garter snake habitat and some drainage infrastructure west of the Airport. Construction of these facilities would allow for dewatering of the ditch running along the western portion of the Airport runway system, which the airport recognizes as a flight safety hazard, by offsetting the effects on drainage and irrigation needs and giant garter snake habitat.

- The project would combine SAFCA's need for levee embankment and berm material with the Sacramento County Airport System's (SCAS) need to modify the condition and management of Airport bufferlands so as to reduce wildlife hazards affecting Airport operations in a manner that enhances the connectivity of areas managed specifically for their habitat value.

Existing Project Facilities and Potential Borrow Sites

Construction activities for all project phases would take place within the Natomas Basin, except for potential development of a borrow site on RD 1001 land northeast of the basin. The following subsections describe the existing flood control facilities, their general setting, and adjacent irrigation infrastructure and the potential borrow sources for the project as provided by the Corps in their Environmental Impact Statement for the proposed project.

Flood Control and Irrigation Facilities

Natomas Cross Canal South Levee

The NCC is a 5.3-mile-long channel that carries water from several tributary watersheds in western Placer County and eastern Sutter County to the Sacramento River. The NCC begins at the PGCC and East Side Canal and extends southwest to its confluence with the Sacramento River near the Sankey Road/Garden Highway intersection. During periods of flooding, the Sutter Bypass, Sacramento River, and NCC all contribute to raised water elevations that can affect the NCC levees. For engineering purposes, the south levee is divided into seven reaches. Much of the south levee contains an existing stability berm with an internal drainage system. Levee slopes are approximately 3H:1V on the water side and 2H:1V on the land side.

There is an approximately 80- to 100-foot maintenance access area on the landside of the levee through most of the NCC's length. Farms and rural residences are located on both sides of the NCC, with rice the primary crop under cultivation. The Lucich North and Frazer Habitat Preserves, maintained by TNBC, lie south of the NCC south levee from the eastern end of Reach 2 through the western end of Reach 6. A drainage canal, referred to as the Vestal Drain, runs parallel to the NCC south levee through much of Reach 2, approximately 100 feet from the landside levee toe. There is a private irrigation pump and irrigation canal at the landside levee toe in Reach 1. Natomas Central Mutual Water Company's (NMWC) Bennett Pumping Plant and RD 1000's Pumping Plant No. 4 are located in Reach 2, and the NMWC Northern Pumping Plant is located in Reach 3. The NMWC North Main Canal runs parallel to the levee through Reaches 4 and 5, approximately 100 feet from the landside levee toe.

Sacramento River East Levee

An 18-mile-long section of the east levee of the Sacramento River protects the west side of the Natomas Basin between the NCC and the American River. For planning purposes, the levee is divided into 20 reaches. Garden Highway is located on top of the levee crown within all 20 reaches. A drained, 10-foot-wide stability berm is present on the landside slope of the levee between the NCC and Powerline Road (Reaches 1–11). Cutoff walls to address through-levee seepage remediation were previously constructed through the levee in Reaches 12–20. The land uses along the levee vary from north to south. Along the landside, Reaches 1–13 are bordered mainly by private agricultural lands containing a few rural residences, Airport bufferlands, and two farmed TNBC parcels. Teal Bend Golf Club is west of the Airport, adjacent to the levee along Reach 6. The parcels bordering Reaches 14–18 contain more residences, several rural estates, and three TNBC parcels. The landside of Reaches 19 and 20 are bordered by residential subdivisions, a business park, the City of Sacramento's Natomas Oaks Park, undeveloped Costa Park site, and Shorebird Park.

Several irrigation canals, pipelines, wells, and pump stations exist along the Sacramento River east levee. The Elkhorn Canal and the Riverside Canal are key agricultural irrigation canals in the NMWC system. The Elkhorn Canal runs parallel to the Sacramento River east levee from the

North Drainage Canal in Reach 4B through Reach 8 and into the start of Reach 9 (1,250 feet south of Elkhorn Boulevard); this canal is supplied by the Prichard and Elkhorn Pumping Plants on the Sacramento River. The Riverside Canal extends from just north of Reach 13 to the middle of Reach 19 and is supplied by the Riverside Pumping Plant, on the Sacramento River just north of Radio Road. Several lateral canals connect to the Elkhorn and Riverside Canals. The existing Elkhorn and Riverside Canals are highline canals that use gravity flow to deliver water for irrigation by maintaining water levels above the surrounding ground levels. These canals have earthen embankments with side slopes that are nearly vertical, requiring regular maintenance. Approximately 1 mile of the existing Elkhorn Canal is concrete lined and the entire Riverside Canal is concrete lined.

In addition to the NMWC irrigation systems, there are several landowner-operated systems along the levee. These facilities are located primarily in Reaches 1–4A and 9–12, in areas not currently served by the NMWC systems. The areas are serviced by either well pumps on the landside or river pumps, which discharge into buried pipelines, small irrigation ditches, or directly onto fields. The distribution systems run along the landside toe of the levee to supply fields that slope away from the levee. There are approximately nine small pumping plants that provide water from the river and approximately 10 groundwater well pumps.

Several drainage pumping plants are operated by RD 1000 along the Sacramento River east levee. These facilities pump drain water from the main drainage canal system into the river. They include Pumping Plant No. 2, located in Reach 4B; Pumping Plant No. 5, located in Reach 10; Pumping Plant No. 3, located in Reach 13; and Pumping Plant No. 1, located in Reach 20A. Pumping Plant No. 2 was temporarily removed as part of an emergency levee repair in 2006 and would be replaced as an element of the proposed project in the 2009–2010 construction phases. In addition to these RD 1000 pumping stations, the City of Sacramento operates the Willow Creek drainage pumping station, which is located in Reach 19B.

Pleasant Grove Creek Canal West Levee

The PGCC west levee extends southerly from the east end of the NCC south levee to the north end of the NEMDC/Steelhead Creek levee near the Sankey Road crossing. The PGCC west levee protects the Natomas Basin from flood flows from Pleasant Grove Creek and other creeks in western Placer County, as well as from water that backs up in the NCC during high river stages in the Sacramento River. Levee slopes are generally 2H:1V on both the water side and land side of the levee. Natomas Road is located on top of the levee crown. No berms support this levee. A private canal extends parallel to the PGCC west levee for about 1,500 feet at the landside levee toe. Farms and scattered rural residences are located on the landside of the PGCC west levee, and a manufacturing facility and a railroad siding are located within several hundred feet of the levee, just south of Sankey Road.

Natomas East Main Drainage Canal

The 13.3-mile NEMDC/Steelhead Creek west levee extends southerly from the south end of the PGCC west levee near the Sankey Road crossing to Northgate Boulevard. The NEMDC west levee protects the Natomas Basin from flood flows from Arcade and Dry Creeks, as well as from water during high river stages in the American River. Natomas and East Levee Roads are located on top of the levee crown. Private canals extend parallel to portions of the NEMDC west levee landside levee toe. Farms and scattered rural residences are located on the land side of the northern portion of the NEMDC west levee (between Sankey Road and Elkhorn Boulevard), while the southern portion (generally south of Del Paso Road to Northgate Boulevard) is bordered by urban and commercial/industrial development.

The SAFCA NEMDC stormwater pumping station, a facility that is connected to the NEMDC/Steelhead Creek west levee and the Dry Creek north levee, is situated between Del Paso Road and Elkhorn Boulevard. Other pumping stations occur along the NEMDC west levee, including NMWC Pumping Plant Nos. 6 and 8, which pump water out of the Natomas Basin for in-basin drainage and flood control. RD 1000 operates Pumping Plant Nos. 6 and 8 and City of Sacramento operates Pump Station No. 102 on the NEMDC west levee.

Borrow Sites

Borrow sites are areas from which earthen materials would be removed for use in construction. Where borrow sites would be used over more than one construction season, the work would progress in cells that would be incrementally developed as habitat or returned to agricultural use as the borrow activities are completed. Several properties have been identified as likely sources of soil borrow, mainly for use in the improvements to the Sacramento River east levee. The SAFCA has identified the following preferred borrow sources for the construction of the flood control and irrigation infrastructure improvements for construction Phases 2, 3, and 4, and a redundant source that may be pursued if negotiations regarding the preferred sources are unsuccessful or additional quantities are found to be needed during construction:

- Brookfield property (Phases 2, and 3 preferred): Private property west of the PGCC at Fifield Road, which was in rice cultivation in 2008. Material from this property could be used along the NCC south levee and the upper reaches of the Sacramento River east levee in construction Phase 2 and on the PGCC west levee in construction Phases 3. While the overall property may be used as borrow during multiple years, no area of the property would be used for consecutive years. After the removal of borrow material, the land would be returned to rice cultivation in the same season or if too late to plant, then in the following season.

- Airport bufferlands north of the Airport complex (Phases 2 and 3 preferred, Phase 4 potential): Sacramento County property north of Elverta Road and west of Powerline Road. These lands could provide soil for use along the middle reaches of the Sacramento River east levee in construction Phases 2 and 3. They could also provide material for

construction in the lower reaches of the levee in construction Phase 4, if needed. While the overall property may be used as borrow during multiple years, no area of the property would be used for consecutive years. After the removal of borrow material, the borrow areas, which are currently either fallow agricultural lands or ruderal grassland, would be returned to fallow agricultural fields.

- Fisherman's Lake area (Phase 4 preferred): Privately owned parcels between TNBC-managed habitat areas. Several parcels, which are currently planted in rice, orchards, or field crops, may be suitable sources of borrow material for use in the lower reaches of the Sacramento River east levee and are strategically situated for creation of habitat that would link existing TNBC parcels.

- Krumenacher property (Phase 3 preferred): Private parcel at the intersection of East Levee Road and Elkhorn Boulevard. This parcel is a component of the Natomas Panhandle, identified in the Natomas Basin Habitat Conservation Plan (NBHCP) and development of this parcel is already covered by a July 25, 2007, biological opinion (1-1-06-F-0294). This land, which is primarily grassland, could provide a borrow source for the levee widening improvements to the NEMDC.

- Twin Rivers Unified School District (Phase 3 preferred): Material stockpiled on property owned by Twin Rivers Unified School District, immediately south of Krumenacher. This parcel is a component of the Natomas Panhandle, identified in the NBHCP, and development of this parcel is already covered by a July 25, 2007, biological opinion (1-1-06-F-0294). This material could provide a borrow source for the levee widening improvements to the NEMDC.

- Horangic/Private Property Northwest of Garden Highway and Reservoir Road (Phase 3 preferred): Private parcel located in Reach 6A along the Sacramento River east levee. The portion of this site that would not be in the levee footprint could provide borrow material for seepage berms in Reaches 5A–5B. The site would be shallow-graded for borrow material and returned to field crops.

- Binford deYoung/Private Property Southwest of Garden Highway and Elverta Road (Phase 3 preferred): Private parcel located in Reach 5B along the Sacramento River east levee. The portion of this site that would not be in the levee footprint could provide borrow material for seepage berms in Reaches 5A–5B. The site would be shallow-graded for borrow material and returned to field crops.

- Bianchi/Private Property Northwest of Garden Highway and Reservoir Road (Phase 3 potential): Private parcel located in Reach 7 along the Sacramento River east levee. This property could borrow material for levee construction south of the Teal Bend Golf Club. The site would be shallow graded for borrow material and returned to field crops.

- Pacific Terrace (Phase 3 preferred): A 276-acre site located north of I-5 and east of Schoolhouse Road. Approximately 120 acres of this site could be used for levee construction south of the Teal Bend Golf Club. The site would be shallow graded for borrow material and returned to field crops.

- Novak property (Phase 3 preferred, Phase 4 potential): A SAFCA-owned, 94-acre property located south of Del Paso Road and east of Powerline Road in Reach 12A along the Sacramento River east levee. The site could be used for levee construction south of the Teal Bend Golf Course. The site would be shallow graded for borrow material and returned to grassland or field crops.

- RD 1001 (Phase 4 potential): Existing and future borrow sites owned by RD 1001, about 5 miles northeast of the Natomas Basin along Pacific Avenue. Material from the sites could be used in constructing Phase 4.

Overview of the Project Elements

The elements of the proposed project are categorized into five broad, overlapping categories:

- levee raising and seepage remediation,
- improvements to major irrigation and drainage infrastructure,
- acquisition of right-of-way within the footprint of the proposed features, at borrow sites, and to prevent encroachment and provide for maintenance access along the land side of the flood control facilities,
- habitat development and management for giant garter snakes and Swainson's hawks, and
- additional actions to meet Federal Emergency Management Agency requirements: encroachment management and bridge crossing modifications.

Levee Raising and Seepage Remediation

General Methods - The following subsections provide an overview of the approaches to addressing freeboard deficiencies and seepage potential that would be used in various combinations on the NCC south levee and Sacramento River east levee, and the PGCC and NEMDC west levees.

Raising, Widening and Flattening Levees (Phases 2, 3 ,4)

The entire NCC south levee, much of the Sacramento River east levee and a portion of the PGCC west levee at Sankey Road lack the required 3 feet of freeboard above the 100-year water surface profile. To meet overall NLIP goals, SAFCA would increase the levee freeboard sufficiently in freeboard-deficient areas to meet the desired minimum of 3 feet of freeboard above the 200-year water surface profile. The levee height increases would be accomplished through raises of the existing NCC south levee or through construction of the raised adjacent setback levee adjacent to the existing Sacramento River east levee:

- Raise of existing levee (NCC south levee). For a minor raise of the levee crown elevation (typically 6 inches or less), the raise may be limited to the levee crown area, provided that there is enough existing crown width to accommodate the raise without narrowing the crown to a width that is less than the minimum requirement. For most of the NLIP levee raises, however, a greater crown raise is required and/or the levee slopes must be flattened. The required crown elevation would be met through a full levee raise. Full levee raises consist of an embankment raise from the landside or waterside toe (or both) upward to the increased crown elevation. This requires partially excavating the levee slope to provide a working platform for equipment, typically 10 feet wide, and rebuilding the levee to the appropriate elevation by benching the new embankment material into the existing embankment material.

- Adjacent setback levee (Sacramento River east levee). The proposed adjacent setback levee adjoining the Sacramento River east levee would be constructed with a crown elevation 3 feet above the 200-year water surface profile. In the upper reaches, where the existing levee has freeboard deficiencies of as much as 3 feet, the crown of the adjacent setback levee would be higher than the existing levee and Garden Highway roadway. In the lower reaches, where the existing levee has sufficient freeboard, the adjacent setback levee would be the same height as the existing levee.

The only levee segment that lacks adequate levee height that would be maintained at its current elevation is the PGCC west levee at Sankey Road because the flows through this levee segment into the interior of the Natomas Basin during a Federal Emergency Management Agency (FEMA) 100-year or "200-year" design event are not damaging and are subject to management as part of the basin's interior drainage system. Along the NEMDC west levee between Northgate Boulevard and Elkhorn Boulevard, the levee currently meets FEMA 100-year levee height requirements and also meets the "200-year" plus 3 feet of levee height design for the top of the levee profile.

The final levee configuration must meet the Corps criteria of a 20-foot-wide minimum crown, a 3H:1V waterside slope, and a 3H:1V (preferred) or 2H:1V (maximum) landside slope. Because the levees in most of the project reaches currently have landside slopes of 2H:1V, the proposed project includes flattening these slopes to at least a 3H:1V profile, and preferably 5H:1V. The PGCC west levee would be expanded on the land side to provide a levee width to encompass, at a minimum, a theoretical 3H:1V waterside slope, a crown width of at least 20 feet, and a landside slope of at least 3H:1V. The intent of the landside expansion is to preserve the existing Natomas Road and East Levee Road, which are County/City-maintained roads located on top of the existing PGCC and NEMDC west levees. Levee widening and slope flattening would also occur along the NEMDC west levee between Elkhorn Boulevard and the NEMDC stormwater pumping station.

Seepage Remediation

Underseepage problems can occur where levees are constructed on low-permeability foundation soil (silt and clay) underlain by a layer of higher permeability (sand and gravel). Excessive

underseepage makes the levee susceptible to failure during periods of high river stage. Under these conditions, seepage travels horizontally under the levee and then is forced vertically upward through the low-permeability foundation layer, often referred to as a "blanket." Failure of the blanket can occur either by uplift, a condition in which the blanket does not have enough weight to resist the confined pressure acting on the bottom of the blanket, or by piping (internal erosion) caused by water flowing under high vertical gradients through the erodible blanket and carrying fine soil particles out of the foundation materials. Through-seepage is seepage through a levee embankment that can occur during periods of high river stage. Depending on the duration of high water and the permeability of embankment soil, seepage may exit the landside face of the levee. Seepage can also pass directly through pervious layers in the levee if such layers are present. Under these conditions, the stability of the landside levee slope may be reduced.

During Phases 2–4, along the Sacramento River east levee, cutoff walls would be constructed through the adjacent levee in some reaches, and 100-foot-wide earthen seepage berms would be constructed in others for seepage remediation. Although portions of this reach of the Natomas perimeter levee system are considered susceptible to seismically induced ground shaking, such a condition would likely not cause deformation of the soil-bentonite (SB) walls in the adjacent levee because of its malleability and location farther away from the river channel, where levee failure is more likely to occur in association with seismically induced collapse of the river bank. Additionally, because an SB seepage cutoff wall is constructed lower in the levee section, it is not likely to be significantly affected by failure of the levee itself if the levee were to collapse. Relief wells cause the least amount of construction disturbance but require routine maintenance of the wells themselves and the drainage and pumping facilities necessary to support them. Seepage berms are feasible where there is sufficient room for construction.

Phase 2 includes the construction of a seepage cutoff wall through the levee crown of the NCC within Reaches 3–7. Phase 3 includes the construction of SB cutoff walls within the PGCC west levee where required to provide seepage remediation. Along the NEMDC west levee between the NEMDC stormwater pumping station and Northgate Boulevard, an SB or soil-cement-bentonite cutoff wall would likely be constructed.

Major Irrigation and Drainage Infrastructure Modifications

There are two major canal systems in the Natomas Basin: an irrigation system owned and operated by NMWC and a drainage system owned and operated by RD 1000. The NMWC pumps water into the basin to provide irrigation water to its shareholders for agricultural use within the basin. During winter (October–April), drainage is primarily rainfall runoff; during summer (May–September), drainage water from agricultural fields is typically recirculated for irrigation. Because the basin is surrounded by levees, all excess drainage within the basin must be pumped out. In general, irrigation water is pumped into the basin from the Sacramento River and NCC and returned to the perimeter rivers and canals via RD 1000's drainage system. In the southern part of the Natomas Basin, the City of Sacramento also operates several drainage pump stations that serve residential areas.

As a result of the planned levee improvements in the Natomas Basin, the irrigation canals currently at the toe of the Sacramento River east levee (the Elkhorn Canal and the Riverside Canal) would be replaced by new irrigation canals set back from the existing levee farther to the east. Where constraints exist, certain portions of the canals would be piped. The existing and proposed irrigation canals are highline canals, which means that the bottom of the canal is roughly equal to the surrounding ground elevation. Irrigation canals would be constructed high enough to raise water levels above the levels of the adjacent fields to allow for gravity flow into the fields.

A new drainage canal would be constructed to improve the connectivity of giant garter snake habitat between the North Drainage Canal and West Drainage Canal. The proposed GGS/Drainage Canal would be constructed with the top of bank roughly at existing ground level to facilitate drainage. Material excavated to construct the GGS/Drainage Canal would generally be used to construct the embankments of the adjacent highline irrigation canals. Some import and export of soil materials for levee construction would be required to accommodate the phasing of the activities. The following subsections provide an overview of these irrigation and drainage infrastructure modifications.

Relocation of the Elkhorn and Riverside Canals

General Construction Plan for Relocated Canals - The Elkhorn and Riverside Canals would be constructed with sufficient height to raise water levels above the levels of adjacent fields. Design water levels would be based on existing levels at service points along the alignments and the tops of embankments would provide for 1 foot of freeboard. To provide for stable banks, side slopes of 3H:1V would be used. The invert of canals would be lined with concrete to control vegetation and to allow for maintenance with minimal disturbance of aquatic habitat along the water's edge.

To avoid interruptions in service along the existing irrigation canals, the relocated canals would be constructed and operational before construction of planned levee improvements that would conflict with the existing irrigation canals. Thus, in any particular reach, the new canal would be constructed before the levee improvements in that same reach. Approximately half of the new Elkhorn Canal (North Drainage Canal to Elkhorn Reservoir) is planned for construction in Phase 2. The GGS/Drainage Canal from the North Drainage Canal to Elkhorn Reservoir also would be constructed in Phase 2, because this section would run parallel to and within the same right-of-way as the proposed Elkhorn Canal in this area. Concurrent construction of these new irrigation and drainage facilities would facilitate the use of excavated material from the GGS/Drainage Canal excavation for use as embankment material along the Elkhorn Canal. The remainder of the Elkhorn Canal and GGS/Drainage Canal would be constructed in Phase 3, and the new Riverside Canal would be constructed during the Phase 4.

Elkhorn Canal - Approximately 22,300 feet of the Elkhorn Canal would be relocated to accommodate the levee construction. This facility is a main irrigation canal that services NMWC Central and Elkhorn systems from the Prichard and Elkhorn Pumping Plants on the Sacramento River. Approximately 1 mile of the existing Elkhorn Canal is concrete lined, including segments

between Elverta Road and the Elkhorn Pumping Plant and also just north and south of Elkhorn Road; the remainder is earth lined.

The proposed alignment of the new Elkhorn Canal is based primarily on the extent of the planned levee improvements. The canal was sited as close as possible to the projected toe of the new levee (with allowance made for a 5H:1V landside levee slope). After this initial alignment was determined, a number of site-specific factors were considered and used to refine the alignment. The resulting alignment minimizes conflicts with known cultural resources sites and existing trees and is roughly parallel to the projected levee toe.

North of Elkhorn Reservoir, the maximum bottom width of the new canal would be 12 feet. The canal embankments would be approximately 7 feet tall with 15-foot-wide patrol roads along the top of the embankments with a two percent grade sloped down towards the canal. The vegetated side slopes would be 3H:1V to provide for stable banks. Overall, the width of the canal would be approximately 140 feet, with additional width required for a buffer and maintenance area for the canal construction north of Elkhorn Reservoir.

To minimize project impacts on the existing Teal Bend Golf Club, the alignment of the Elkhorn Canal through the golf course would be piped (approximately 3,200 feet). Two 36-inch pipes would be aligned parallel to the levee toe land side of the flood control facility corridor. This alignment would avoid existing golf course infrastructure to the extent possible.

South of Teal Bend, the Elkhorn Canal would return to an open channel parallel to the toe of the new levee. The majority of this reach of earthen canal has a design bottom width of 5 feet, with a minimum of 1 foot of levee height and 3H:1V side slopes. A 15–foot-wide patrol road would be located on the top of the field side of the canal; the other embankment would be 8 feet wide on the crown. The only portion of the new canal that would have a concrete-lined invert would be the 4,100-foot section where the existing canal is lined. The remaining 2,900 feet of new canal would be earthen-lined. To avoid impacts on existing residences, a second section (approximately 950 feet through the Mortensen and Breese properties) of the Elkhorn Canal may be piped using a single 36-inch pipe. The materials to construct the Elkhorn Canal would come primarily from the construction of the GGS/Drainage canal north of I-5. However, a small amount of import from the Airport north borrow sites is expected to be used to support construction of a portion of Phase 2 improvements.

Riverside Canal - Approximately 18,600 feet of the Riverside Canal would be relocated to accommodate the levee construction. This facility is a main irrigation canal that services NMWC Riverside system. The supply for this canal is the Riverside Pumping Plant. The canal flows south along the landside toe of the levee to approximately Bryte Bend Road. The canal south of Bryte Bend Road has not been used in recent years. The canal north of the Riverside Pumping Plant is supplied by relifted water at RD 1000's Pumping Plant No. 3. From Pumping Plant No. 3, the canal flows north approximately 950 feet and turns away from the levee. The entire existing Riverside Canal is concrete lined, although much of the concrete lining is broken and in poor condition.

Like the Elkhorn Canal alignment, the alignment of the Riverside Canal would be based primarily on the extent of the planned levee improvements. The canal would be sited as close as possible to the projected toe of the new levee (allowing for a 5H:1V landside levee slope). After this initial alignment is determined, a number of other factors would be considered and used to refine the alignment. One-half to three-quarters of a mile south of San Juan Road southward to I-80, there are a number of residences along the landside toe of the levee. To avoid bisecting these private properties, it is likely that the Riverside Canal alignment would follow the eastern property line of these parcels. The final alignment would also aim to minimize conflicts with existing trees and other site-specific constraints that are identified during design. Based on these site-specific factors and the variation of the proposed seepage remediation methods in different reaches, the alignment would be only roughly parallel to the projected levee toe. The proposed bottom width of the relocated Riverside Canal would be determined during final design to meet existing capacity needs.

Construction of the New GGS/Drainage Canal - The new GGS/Drainage Canal would enhance habitat functionality by permanently linking known giant garter snake population centers and TNBC properties in the northern and southern reserve areas that are managed for GGS habitat, thus, improving habitat connectivity between the North Drainage Canal and West Drainage Canal and augmenting movement opportunities for this species within the Natomas Basin. This would link emerging blocks of managed giant garter snake habitat in the vicinity of Prichard Lake north of the Airport and around Fisherman's Lake south of the Airport. In addition to providing giant garter snake habitat, the GGS/Drainage Canal would intercept flows from non-Airport property sources. Irrigation and drainage water currently flowing into the Airport West Ditch from non-Airport property would be incorporated into the GGS/Drainage Canal.

The GGS/Drainage Canal would generally extend parallel to the Sacramento River east levee, extending from the North Drainage Canal at the RD 1000 Pumping Plant No. 2 in the north to the West Drainage Canal in the south, approximately 1,000 feet south of Elkhorn Boulevard. The GGS/Drainage Canal construction would include reconstruction of the West Drainage Canal from I-5 to Fisherman's Lake. The length of the entire GGS/Drainage Canal, including the reconstruction, would be approximately 43,800 linear feet. The GGS/Drainage Canal would have a series of check structures along its length to maintain consistent water levels in the low-flow channel of the canal during the snake's active season (April–October). Supplemental water would be provided from NMWC irrigation system. The low-flow channel would have a top width of approximately 50 feet and an average depth of approximately 6 feet. Vegetation would be managed within the canal excavation and on the banks by mowing.

The portion of the GGS/Drainage Canal that would be constructed in Phase 2 is north of Elkhorn Reservoir would be parallel and approximately 30 feet west of the edge of the Elkhorn Canal. Thus, the alignment was based on the same factors as discussed above for the Elkhorn Canal. North of Reservoir Road the canal would be set back a minimum of 200 feet from the projected levee toe to minimize concerns of excessive seepage exit gradients in the bottom of the canal.

The canal in this location would have a 10-foot bottom width and vegetated 3H:1V side slopes. The canal would be approximately five feet deep with two percent grade sloped down towards the canal from the edge of the Elkhorn Canal embankment and the adjacent ground for a distance of 12 feet to allow for a patrol road. The depth would be sufficient to provide a minimum water depth of 4.5 feet with allowance for 1 foot of water level variance and a minimum of 1 foot of freeboard. The footprint of the GGS/Drainage Canal is approximately 50 feet wide. A 30-foot right-of-way would separate the proposed GGS/Drainage Canal from the proposed relocated Elkhorn Canal.

South of Elkhorn Reservoir, the new canal would be constructed with roughly the same proportions as the segment north of Elkhorn Reservoir, with one notable exception. Between the sedimentation basin and Walnut Road, for a total of 2,200 feet, a 15-foot-wide managed tule (*Scirpus acutus*) bench would be constructed alongside the main channel. This bench would typically be seasonally inundated with water, similar to a managed marsh, and which would drain into the main channel. The 5,900-foot segment of the canal between the southeastern corner of Teal Bend Golf Club and the West Drainage Canal would have a 50-foot-wide managed tule bench.

The GGS/Drainage Canal north of Teal Bend Golf Club would be managed primarily as a linear high-quality giant garter snake habitat and movement corridor, with stormwater drainage a secondary function during major storm events, which typically occur in the snake's inactive season. South of Teal Bend Golf Club, the canal would also serve as a primary giant garter snake habitat area and movement corridor, but the volume of stormwater drainage would increase in a southerly direction as the canal collects additional runoff as a result of the natural slope of the basin. Winter storm–related runoff exceeding the capacity of the West Drainage Canal south of I-5 would be pumped into the Sacramento River using RD 1000's Pumping Plant No. 3, consistent with existing stormwater management practice.

The shoreline and lower bank of the GGS/Drainage Canal (including the improved West Drainage Canal) would be planted or managed to promote tule/cattail (*Typha latifolia*) vegetation as suitable cover and foraging habitat for giant garter snake. However, management of the canal would also require removal of noxious aquatic weeds that obstruct the flow of water. A secure water supply would ensure that water of a suitable quality is present and flowing at low velocity in the canal during the active season of the giant garter snake, and that the water surface would be managed within a range of approximately 1 foot to provide consistent cover from predators along the tule fringe of canal banks. Input of supplemental canal water would begin at a diversion point on the North Drainage Canal at the north end of the new GGS/Drainage Canal. Other points of inflow may occur at downstream locations.

Removal of Airport West Ditch

To take advantage of common construction practices and to maximize the use of common facilities, the rearrangement of irrigation and drainage facilities required to provide for rerouting of flows that contribute to the Airport West Ditch would be undertaken in conjunction with these

proposed NLIP improvements in construction Phase 3. This work would include modifications and extension of existing irrigation infrastructure and modification of some local drainage conveyance facilities.

Removal of Culvert and Reconstruction at Pumping Plant No. 2

The project would include the removal of a deep culvert beneath the levee section at the RD 1000 Pumping Plant No. 2 location and the replacement of a relocated RD 1000 Pumping Plant No. 2, which was removed from the western end of the North Drainage Canal in response to underseepage observed during extended winter storms in January 2006.

Land Acquisition

Several of the measures described above would increase the footprint of the flood control system: levees would be widened on the land side as a result of raising, constructing an adjacent setback levee, and flattening the waterside and/or landside slopes. In addition, a 50- to 100-foot-wide access and maintenance corridor would be established at the landside toes of the levees. The proposed improvements also include woodland corridors and groves to replace trees that are removed from within the levee footprint and maintenance access areas, and canal construction east of the flood control features. The SAFCA also would acquire adjacent land for relocation of infrastructure from the flood control corridor and planned improvements outside the flood control corridor (e.g., the GGS/Drainage Canal), with appropriate easements provided to utility owners upon completion of the work. To meet its project footprint needs, SAFCA would acquire private lands in fee and would acquire an easement interest where the project features would be on Airport land (owned by Sacramento County). Where the project footprint would overlie land owned and managed by TNBC, SAFCA may either purchase the land in fee or obtain easements.

Additional Actions to Meet FEMA Requirements

Encroachment Management (Phases 3 and 4)

Corps levee guidance requires the removal of vegetation greater than 2 inches in diameter on the levee slopes and within 15 feet of the waterside and landside levee toes. The Corps levee guidance also requires an assessment of encroachments on the levee slopes, including utilities, fences, structures, retaining walls, driveways, and other features that penetrate the levee prism. Substantial encroachments are present on the Sacramento River east levee. One of the objectives of constructing an adjacent setback levee along the Sacramento River east levee is to facilitate acceptable management of existing vegetation and structural encroachments along the water side of this levee. By moving the hypothetical waterside slope of the levee (the "levee template") landward, the adjacent levee would significantly reduce most of the conflicts between these encroachments and applicable Corps levee operation and maintenance requirements. Should any of these existing encroachments be determined to reduce the integrity of the levee, increase flood risk unacceptably, or impede visibility or access to the waterside levee slope, the encroachments would need to be removed. Removal of some waterside slope encroachments may be required by

the end of 2011 to ensure that the levee system meets Federal criteria for the 100-year level of protection. Along the land side of the proposed adjacent setback levee, encroachment removal would typically be accomplished as part of the landside levee improvements. This activity would include the relocation of utility poles that are on the existing landside slope of the levee.

Bridge Crossings (Phase 4)

Under applicable Federal requirements, the plane of the northbound and southbound bridge crossings of SR 99/70 over the NCC must be 4 feet above the 100-year water surface elevation in the NCC. The 100-year water surface elevation is 44.4 NAVD 88. The soffit (underside) elevation of the northbound crossing is 44.9 NAVD 88, and the soffit elevation of the southbound crossing is 42.9 NAVD 88. Accordingly, during construction of Phase 4 the following options must be considered for implementation in conjunction with the California Department of Transportation:

(1) Raise both bridge crossings as necessary to meet minimum FEMA clearance requirements.
(2) Provide for installation of a closure structure across the southbound crossing in the event of a 100-year or greater flood.
(3) Replace the bridge rail structures on the east and west sides of the bridge crossings and modify the levees connecting to these structures to provide at least 4 feet of levee height above the 100-year water surface elevation. Under any of these options, at least the northbound crossing could remain open for use during a 100-year flood event.

Investigations to Aid Project Planning and Design

Geo-technical Investigations

Additional exploration of geotechnical conditions is anticipated to be required in Phases 2–4 along the NCC south levee, Sacramento River east levee, PGCC west levee, NEMDC/Steelhead Creek west levee, and American River north levee to facilitate refinement of design for flood facility improvements. Exploration of subsurface conditions would primarily be conducted by drilling borings. Borings along the levees would generally be drilled to depths of 60-120 feet below the ground surface using either a rubber-tire truck-mounted drill rig or an all-terrain drill rig equipped with an 8-inch-diameter hollow-stem auger and a 4-inch-diameter rotary wash drill bit. Hollow-stem augers would generally be used to drill through the levee fill and would be left in place to act as temporary casing and protection against hydraulic fracturing of the levee. Rotary wash drilling methods would be used below the augers. Borings located at and landward of the levee toe would be drilled using rotary wash drilling methods.
Exploration of potential borrow sites will also be required to assess suitability of the material. Such exploration could include boring methods similar to those described above, but to shallower depths (10–12 feet below grade). Test pit excavation would be conducted using a tire-mounted backhoe to depths of 10–12 feet below grade. The test pits would likely be 1–3 feet wide along dirt roadways and 3–6 feet wide in agricultural fields by about 10 feet long. Samples

would be obtained by hand with shovels from the excavated materials. When the bottom depth has been reached, the test pits would be loosely backfilled with the spoils with minor compaction effort. In the dirt roadways, the backfilled materials would be compacted with more effort to maintain drivability and safety.

Cultural Resources Investigations

Archeological surveys within potential flood control facility improvement footprints and potential borrow sites are required to facilitate project planning in Phases 2–4 and satisfy requirements under Section 106 of the National Historic Preservation Act. The surveys would include up to three stages of work. All excavation work in Stages 1 and 2 would be conducted with hand tools, such as shovels and trowels. Stage 1 entails digging shovel test pits 15 inches in diameter and up to 3 feet deep to evaluate the characteristics of subsurface material; these test pits would be backfilled immediately. Depending on archeological evidence found within the shovel test pits, Stage 2 work may be initiated to allow for a more thorough site investigation. This Phase would include excavation of 1-meter-square and 5-foot-deep test units. These test units may need to remain open for several days until examination can be completed. Any sites requiring deeper excavation to further investigate subsurface features identified in the first two stages would be included in Stage 3. This stage would require the use of machinery, such as a backhoe.

Conservation Strategy Overview

According to SAFCA, the project conservation strategy will support and significantly contribute towards the emergence of an urban habitat refuge in the Natomas Basin. The refuge is projected to occupy approximately 15,000 acres once the NBHCP objectives and other proposed conservation programs are completed. Through habitat creation, restoration, and preservation, SAFCA will increase the amount of protected habitat available for NBHCP-covered species. Further, SAFCA's proposed plan will consolidate large areas of habitat, assisting in the expansion of TNBC reserve blocks in the northwestern and southwestern regions of the Basin. Finally, the construction of new canals and the establishment of woodland corridors will greatly improve the connectivity between core habitat reserves that are distributed throughout the Basin, and substantially increase acreage and patch size of these critical habitats.

Overall, the proposed project is an opportunity to employ a landscape-scale vision, helping to advance the goals and objectives of the NBHCP and assist the Federal Aviation Administration (FAA), Corps, and the local Reclamation Districts in achieving their goals. The SAFCA's Natomas Landside Improvements Project presents a unique, one-time opportunity to reconfigure habitat and connective corridors in the Basin at a landscape scale.
Rather than a piecemeal approach to habitat protection, SAFCA's proposed project secures and expands the amount of habitat protected in the Basin, establishes the components that tie the preserves and disparate mitigation sites together in perpetuity under public ownership, and increases the quality and viability of this emerging urban reserve. Refer to the June 18, 2008, *Conceptual Mitigation, Management, and Monitoring Plan* document (prepared by EDAW for

SAFCA) for a more complete summary of the conceptual strategy for creating/enhancing/preserving, protecting, and managing habitats in the Natomas Basin in perpetuity. The following subsections provide an overview of the primary goals and landscape-level benefits of this habitat conservation strategy.

Increase Amount of Protected Habitat

While the project will result in loss and reconfiguration of landside habitats adjacent to the widened levees in the Natomas Basin, the proposed project has been specifically designed to minimize impacts to these landside habitats, and to avoid impacts to riparian habitats along the Sacramento River and NCC. The construction of an adjacent setback levee and installation of seepage cutoff walls enable SAFCA to retain the mature riparian tree corridor and numerous Swainson's hawk nests that are located along the waterside of the Natomas Basin levees. The project's conservation strategy includes the preservation, enhancement, and creation of over 1,300 acres of compensatory habitats in the Natomas Basin, including:

- 72.98 acres of created, managed marsh,
- 616.15 acres of created, managed grasslands,
- 154.37 acres of canals (16 canal miles) and associated uplands,
- 140.85 acres of landside valley oak woodlands and savannah (125 acres created and 15.85 acres preserved),
- 175 acres of preserved rice fields, and
- 150 acres or more of agricultural field crops.

The project will result in the creation of a larger contiguous area protected and managed for the giant garter snakes and Swainson's hawks than currently exists.

Expansion and Consolidation of Protected Habitat in the Natomas Basin

The project will consolidate large areas of habitat, assisting in the expansion and infill of TNBC reserve blocks in the northwestern and southwestern regions of the Basin. The SAFCA will acquire several properties to provide compensatory habitat, either in the form of preserved rice and agricultural crop fields or created managed marsh, managed grasslands, or landside woodlands. Many of these properties are contiguous with existing TNBC reserves or other completed or planned mitigation habitats. Protecting habitat adjacent to existing TNBC reserves and other mitigation sites creates a larger contiguous area managed for giant garter snake and Swainson's hawk than currently exists. This increases the habitat value, sustainability, and functions that these individual properties would otherwise provide in isolation, contributing to giant garter snake and Swainson's hawk recovery in the Basin.

Strengthen Connectivity between TNBC Reserves

The proposed enhancements of existing Basin landscapes are important to the successful implementation of the NBHCP, along with the acquisition and permanent protection of mitigation land. The connective canal and woodland corridors that SAFCA proposes to establish

and/or improve are enhancements that will aid in NBHCP implementation, providing TNBC with an opportunity to improve its overall performance towards the goals of the NBHCP. Canal corridors will provide enhanced habitat functionality by permanently linking TNBC properties in the north and Fisherman's Lake reserve areas that are managed for the giant garter snake and other covered species.

Mitigation, Management, and Monitoring Plan

A *Mitigation and Monitoring Plan* (MMP) and a *Long-Term Management Plan* (LTMP) for the compensatory habitat components are being prepared to guide SAFCA and its partners as they manage the compensatory land components in perpetuity. The MMP would address the habitat creation and preservation components of the NLIP Landside Improvements project. The MMP and LTMP would establish specific success criteria for the habitat components, specify remedial measures to be undertaken if success criteria are not met (e.g., adaptive management, physical adjustments, additional monitoring), and describe short- and long-term management and maintenance of the habitat lands. The MMP and LTMP would also describe the strategies for the long-term protection of these habitats and funding for the management as provided through appropriate mechanisms, which would be determined by SAFCA, the regulatory agencies, and other entities cooperating in the implementation of the project.

Plan Goal

The goal of the MMP and LTMP is to ensure that the conservation values of the preserved, restored, and created habitats are maintained in good condition in perpetuity. The MMP and LTMP would discuss specific management strategies designed to maintain the conservation values for each of the habitat mitigation components and identifies performance criteria used to determine the success of the mitigation habitats. The biological goals include: (1) the preservation of the abundance and diversity of native species, and particularly special-status species, in the mitigation habitats; (2) the protection of the habitat features from the effects of indiscriminate land uses that may adversely impact mitigation habitats; and (3) the restoration of any adverse condition within the mitigation habitat areas that may affect or potentially affect these areas.

Implementing Mechanisms for Long-Term Protection and Management

The MMP and LTMP would describe the framework for the protection and management of the mitigation habitat components of the NLIP Landside Improvements project. The actual implementation of this framework would be enacted through easements, stakeholder-specific management agreements or memoranda of understandings, and contractual agreements. These contractual agreements would focus on the management obligations specific to each management entity, and describe the demonstrated financial and legal assurances necessary to implement the MMP and LTMP to protect and manage the habitat mitigation components in perpetuity. These contractual agreements would be subject to review and approval by USFWS, Corps, and CDFG, and enforced by SAFCA, in perpetuity, and by Corps through permit issuance.

Management Entities for Project Features

Agencies and organizations anticipated to have management responsibility for proposed project features are SAFCA, RD 1000, NMWC, the Airport, and TNBC.

Sacramento Area Flood Control Agency

SAFCA would be responsible for the design and construction of all levee improvements, maintenance access and inspection roads and rights-of-way, replacement canals and associated drainage and irrigation structures, and habitat creation sites. In addition, SAFCA would be responsible for all necessary land acquisitions and easements to construct the project features and achieve the project objectives. However, once these project features are completed, most of the land or land management responsibility would be conferred by SAFCA to the other management entities described below. Memoranda of agreement, land ownership transfers, or management endowments and contracts would be used by SAFCA to transfer land management responsibility to the appropriate public agency or nonprofit land management organization. At the end of the project construction period, all project lands would be in public ownership and/or would be under the permanent control of a natural resource conservation entity.

Reclamation District 1000

The mission and purpose of RD 1000 is to operate and maintain the flood protection levees surrounding the Natomas Basin and to operate and maintain the internal drainage system to evacuate agricultural and urban stormwater and incidental runoff. The RD 1000 would be responsible for the management of the proposed levee improvements, reconstructed Pumping Plant No. 2, and drainage features. Typical maintenance activities include mowing grassland along levee slopes, berms, and rights-of-way, removing sediment and noxious aquatic weeds from the canals, and managing bank vegetation.

Natomas Central Mutual Water Company

The NMWC is a nonprofit mutual water company with the primary focus of keeping the water conveyance functioning to serve the company shareholders. Intensive maintenance to maximize agricultural irrigation services throughout the basin is generally conducted in a given year on only 10 percent of the approximately 100 miles in the Natomas Basin canal system operated by NMWC. The NMWC would be responsible for maintaining and managing the relocated Elkhorn and Riverside Canals and existing irrigation canals. The relocated canals would be maintained in the same manner as the existing canals. Typical maintenance activities include operating and repairing water control structures and barrier gates, periodically removing sediment and noxious aquatic weeds from the canals, repairing canal roads, managing bank vegetation, and mowing grassland along canal and road rights-of-way. However, the relocated Elkhorn and Riverside Canals would have improved levees, better water control structures, and wider roads and rights-of-way than the existing canals. These improvements are expected to ease annual canal management efforts, allowing for a proportionately greater focus on maintenance and operations and less need for system repair and dredging.

Sacramento County Airport System
The SCAS manages the Sacramento County–owned bufferlands outside the Airport Operations Area. All project components on land under SCAS management would remain in public ownership but project land must be protected in perpetuity for the benefit of the giant garter snake.

The Natomas Basin Conservancy
The TNBC acquires and manages land for the purpose of meeting the objectives of the NBHCP. To meet the mitigation goals of the NBHCP, developers of projects pay a mitigation fee to TNBC when they apply for building permits. The TNBC then uses the mitigation fees to acquire, restore, and manage mitigation lands to provide habitat for protected species and maintain agriculture in the Natomas Basin. The TNBC owns approximately 30 mitigation properties totaling more than 4,500 acres. Private land acquired by SAFCA and converted to managed marsh, preserved in rice, or used for woodland establishment would be conveyed to TNBC after creation of permanent habitats as marsh, woodlands, and habitat buffer zones. The SAFCA may also contract with TNBC for management elements of some habitat features (e.g., the GGS/Drainage Canal).

Stakeholder-Specific Management Agreements

The MMP will describe the framework for the design and management of the mitigation habitat components of the proposed project. The actual implementation of this framework will be enacted through Stakeholder-Specific Management Agreements. These contractual agreements will focus on the management obligations specific to each entity, and describe the demonstrated financial and legal assurances necessary to implement the MMP and protect and manage the habitat mitigation components in perpetuity. These contractual agreements will be subject to review and approval by the Service, Corps, and CDFG, and enforced by SAFCA, in perpetuity, and by Corps through permit issuance.

Funding Mechanism
Funding for implementation of the MMP and LTMP has been incorporated into the overall budget for implementation of the NLIP Landside Improvements project. SAFCA anticipates funding for project construction, monitoring, and long-term management will be provided through the Consolidated Capital Assessment District and existing Operations and Management District. The Consolidated Capital Assessment District was created to provide local cost share for flood control project within the Sacramento Urban Area. It was adopted on April 26, 2007, after voters who would be within the assessment district voted to approve the assessment. A portion of the District Assessment Fee would be encumbered to specifically implement the MMP and LTMP. This District funding source will sunset in 2037, at which point, the funding would transition into a non-wasting endowment. The endowment would be built over time through a 2-year advance of the fee into the account.

Project Phasing

The proposed project is comprised of three phases of construction, spanning approximately 3 years. Phase 2 of the NLIP Landside Improvements project, for which SAFCA is currently requesting a permit, is described and analyzed in detail in this permit application, while Phases 3 and 4, for which subsequent requests for permits will be submitted, are described and analyzed at a more general, program level of detail in this document.

Phase 2 Work

Table 1 summarizes the major elements of Phase 2 of the Landside Improvements project (proposed project) and the general timeframes in which the elements are expected to be implemented. Note that although seepage berms are depicted as the primary means of providing underseepage remediation along the Sacramento River east levee, the use of cutoff walls continues to be evaluated, and cutoff walls will likely be implemented instead of berms in several locations. Each of the main project elements are described in more detail below.

Levee Raising and Seepage Remediation

Natomas Cross Canal South Levee

The proposed project would include raising the entire NCC south levee (Station 0+00 to Station 287+50, Reaches 1 to 7) and would continue the construction of a seepage cutoff wall from the eastern terminus of the NCC South Levee Phase 1 Improvements (NCC Phase 1 Improvements) initiated in 2007 (Station 0+00 to Station 61+00, beginning of Reach 1 to approximately middle of Reach 2) to the eastern end of the NCC south levee (approximately Station 56+00 to Station 287+50, approximately the middle of Reach 2 to end of Reach 7). NCC Reaches correspond roughly to the following Stations: Reach 1 (Station 0 to Station 3); Reach 2 (Station 4 to Station 103), Reach 3 (Station 103 to Station 123), Reach 4 (Station 123 to Station 170), Reach 5 (Station 171 to Station 195), Reach 6 (Station 195 to Station 277), and Reach 7 (Station 278 to Station 287). Phase 2 would include the construction of the NCC south levee component, which is anticipated to occur over one construction seasons, beginning in May 2009 and ending in October 2009. The primary construction activities are described below.

Preparation for construction of the cutoff wall would begin with using scrapers (or other suitable equipment, depending on the slope) to clear and grub/strip the surface to a depth of 2 inches to remove low-growing vegetation, loose stone, and surface soils. The aggregate base from the operating road also would be removed and stockpiled for later reuse. Waste material would be hauled to an off-site location.

Table 1
Summary of the Major Elements of Phase 2 of the Proposed Project

Project Element	Proposed Activity and Timing
Levee raising and seepage remediation: NCC south levee	Raise and realign the NCC south levee to provide additional freeboard and more stable waterside and landside slopes and to reduce the need for removal of waterside vegetation. (May–October 2009) Construct a seepage cutoff wall through the levee crown in Reaches 3–7. (May–October 2009)
Levee raising and seepage remediation: Sacramento River east levee (adjacent setback levee)	Construct a raised adjacent setback levee from the NCC to just south of the North Drainage Canal (Reaches 1–4B) with a 100-foot seepage berm in Reach 4A and a 300-foot seepage berm in Reach 4B. (May–October 2009) Relocate utility poles. (November-December 2008)
Improvements to major irrigation and drainage infrastructure	Construct a new canal designed to provide drainage and associated giant garter snake habitat (the GGS/Drainage Canal) between the North Drainage Canal and Elkhorn Reservoir. (May–October 2009) Relocate the Elkhorn Canal (highline irrigation canal) between the North Drainage Canal and Elkhorn Reservoir in anticipation of the filling of the existing Elkhorn Canal at the toe of the Sacramento River east levee. (May–October 2009) Remove a deep culvert at the location of Pumping Plant No. 2. (May–October 2009)
Habitat enhancement, creation and management	Establish vegetative habitat features in the new GGS/Drainage Canal. (Fall 2009) Recontour and create habitat on lands used as borrow sources. (Fall 2009) Establish grassland on the adjacent setback levee slopes and seepage berms. (Fall 2009) Install woodland plantings to offset the loss of portions of tree groves in the landside levee footprint. (Fall 2008–Fall 2009)
Right-of-way acquisition	Acquire right-of-way through fee title or easement interest within the footprint of the project features, at the borrow sites and along the flood control system. (Before construction)

Notes: Elkhorn Canal = Elkhorn Main Irrigation Canal; GGS = Giant Garter Snake; NCC = Natomas Cross Canal

Construction of the cutoff wall would include degrading the existing levee to a depth equal to one-half its total height (approximately 9 feet). A 70-foot-deep cutoff wall would be constructed for a total length of 23,150 linear feet (2 million square feet), with the method of installation at the contractor's discretion. Given anticipated schedule constraints, a three-heading, double-shift

work schedule is anticipated. Material degraded to support cutoff wall construction would be compacted at the landside toe of the levee to support the levee raising operation described below. Unsuitable material generated from cutoff wall construction would be disposed of off-site.

Raising of the Natomas Cross Canal South Levee

Levee raising would occur throughout the entire length of the NCC to provide three feet of freeboard over the design water surface profile (this requires raising the levee approximately three feet). Throughout most of the NCC, this would be accomplished by setting the levee back towards the landside, such that there is a theoretical 3H:1V waterside slope extending from the existing waterside toe to the new waterside top. Following degrading of the levee for cutoff wall construction, the new levee crown would be constructed such that the actual waterside slope extends to meet the point of degrade on the waterside slope. This actual slope would be 3H:1V or flatter. The new levee crown would have a width of twenty feet and the new landside slope would be 3H:1V. Where an existing stability berm is present, it would be stripped and incorporated into the new levee prism. Any portion of the berm outside of the limits of new fill would be trimmed back to conform to the new landside 3H:1V slope. Where the berm is fully incorporated, it would be stripped and trimmed as necessary to accommodate placement of new fill material around it. Existing drain pipes exiting the berm would be extended to daylight landward of the new levee landside toe.

Throughout Reaches 6 and 7, Sutter County infrastructure (Howsley Road and related features) and private residences are close to the NCC south levee. To avoid the infrastructure and residences, between Station 215+00 and 245+00 (central portion of Reach 6, from just west of State Route (SR) 70/99 to just east of SR 70/99), the levee would be raised waterward, encroaching on the NCC channel approximately 30 feet. Between Stations 245+00 and 279+50 (remaining portion of Reach 6), the levee would be raised on the landside, similar to Stations 54+00 through 215+00 (approximately the middle of Reach 2 to initial portion of Reach 6). Smooth transition distances of up to 200–500 feet would link the waterward and landward raises.

Vegetation would be removed from the waterside slope in all locations above the elevation corresponding with the projection of the landside levee toe on the waterside slope. Between Station 0+00 and 54+00 (Reach 1 through first half of Reach 2), where there is significant vegetation on the waterside slope above this elevation, the levee would be set back an additional fifteen feet to provide a "root-free" zone on the levee slope, and the vegetation would remain.

Removal of Structures

Relocation of Howsley Road, the Morrison Canal, a roadway drainage pump station, and three residences and outbuildings would be required by landward levee raises in Reaches 6 and 7. If hydraulic modeling indicates that unacceptable hydraulic impacts would not result from waterside levee raising in Reaches 6 and 7, only two structures in Reach 7 (a residence and a semimobile trailer) would require relocation as a result of the proposed levee improvements.

Utility Modifications and Miscellaneous Work

Pipelines penetrate the NCC south levee at four locations: Odysseus Farms (Bolen Ranch); NMWC waterside Bennett Pumping Plant; NMWC Northern Pumping Plant; and RD 1000's landside Pumping Plant No. 4. None of these penetrations comply with current Corps regulations; therefore, the pipelines would be raised to have their inverts above the 200-year water surface elevation and would be equipped with waterside shutoff valves. If pipes are corroded, they may have to be replaced down the waterside slope of the levee.

As part of raising the pump station discharge pipelines that cross the NCC south levee, canals south of the levee would need to be relocated farther from the levee toe in the following locations: the RD 1000 Vestal Drain and NMWC Bennett Canal between Station 55+50 and Station 61+50 (middle of Reach 2) and the NMWC North Main Canal between Station 120+00 and Station 123+50 (end of Reach 3 to beginning of Reach 4) and between Station 216+00 and 218+00 (Reach 6, just west of SR 70/99). The ditch segments would be moved about 100 feet farther away from the levee toe. Some of this work may be accomplished by NMWC as part of its American Basin Fish Screen Project, but the timing of this NMWC project is uncertain. If the work is not accomplished by NMWC, SAFCA would relocate the canals at the time that the pipelines are raised.

Between Station 0+00 and Station 19+00 (beginning of Reach 1 through first eighth of Reach 2) of the NCC south levee, SAFCA intends to obtain a landside levee maintenance access area to match the 80- to 100-foot wide maintenance access area already established for the levee. This area is currently in active rice fields. Once the maintenance access area is established, this area would be filled to be above the agricultural field grade to prevent encroachment by farming operations into the maintenance access area and to provide an operating road at the levee toe. Between Station 99+00 and Station 124+00 (end of Reach 2 through Reach 3), a low-lying area between the levee's landside toe and an operating road for the Lucich North Habitat Preserve would be filled to raise the grade of the operating road at the landside toe.

In 1996, as part of SAFCA's NCC and PGCC Levee Project, 200 feet of floodwall was installed to raise the NCC levee around the State Route (SR) 99/70 bridges over the NCC. The top of wall for this floodwall is at elevation 44.80 feet (National Geodetic Vertical Datum 29). To conform to current levee criteria, the floodwall would need to be raised to elevation 49.3 feet.

Construction Staging Areas and Postconstruction Site Condition

Construction staging would take place in areas adjacent to the NCC south levee, within the maintenance access areas between Stations 0+00 and 56+00, 61+00 and 96+50, 99+00 and 216+00, and 251+00 and 281+00. Cutoff wall construction would require temporary establishment of three on-site slurry batch plants that would occupy about 1–2 acres each. Each batch plant site would likely contain tanks for water storage, a pug mill mixer, bulk bag supplies of bentonite, bentonite and cement storage silos, cyclone mixers, pumps, and generators. The sites would also include slurry tanks to store the blended slurries temporarily until they are

pumped to the work sites. Slurry constituents would be mixed with water at the batch plant and the mixture would be pumped from the tanks through pipes to the cutoff wall construction work sites.

After construction, the levee slopes and any previously vegetated areas disturbed during construction, including staging areas, would be seeded with a grass mix.

Sacramento River East Levee Reaches 1–4B

Phase 2 of construction would begin in 2009 for the Sacramento River east levee, which includes an adjacent levee extending from the northern end of Reach 1 at the NCC south levee through Reach 4B (approximately Station 0+00 to Station 226+00). Also included in Phase 2 is: installation of cutoff wall in Reach 2 of the adjacent levee; construction of a 100-foot seepage berm in Reach 4A and 300-foot berm in Reach 4B; planting of woodlands in a corridor and fallow fields extending from the lower end of Reach 1 through portions of Reach 4A; and reconstruction of the intersections of Sankey Road and Riego Road with Garden Highway.

An adjacent setback levee is proposed in lieu of in-place modification of the existing Sacramento River east levee, which has substantial structural and vegetation encroachments along its water side. The adjacent-levee raise would involve the construction of a new embankment adjacent to the existing levee. A minimum 5-foot-wide shoulder would extend from the landside edge of the crown of the existing levee to the water side of the new adjacent setback levee embankment. A 3H:1V slope would extend up to the crown of the adjacent setback levee. The crown would be at least 20 feet wide and would be topped with an aggregate base access road for inspection and maintenance. The adjacent setback levee would have a 5H:1V landside slope, except for approximately 5,000 feet in Reaches 2 and 3, which would be 3H:V1. It would be constructed of compacted random fill material from borrow sources and from the excavation of the existing landside stability berm.

It is assumed that a main construction staging area for this phase would be located on approximately 5 acres near Riego Road. The area would be fenced and would be used for the contractor's and engineer's construction trailers, parking for personnel, machine maintenance tools and parts, possibly water trucks, and the storage of fuels and other materials to be used for construction. The project right-of-way along the construction area also would be used for staging of construction materials and equipment. Personnel, equipment, and imported materials would reach the project site via SR 99/70, Sankey Road, Riego Road, and Elverta Road. The primary corridors where construction activity would take place are the adjacent levee alignment and existing dirt roads used for access to the work areas; soil borrow areas; and paved roads, including Powerline, Sankey, and Riego Roads.

Improvements to Reaches 1–4B are anticipated to occur over one construction season, beginning in May 2009 and ending in October 2009. The primary construction activities are described below.

Site Preparation (Tree Removal, Clearing, Grubbing, and Stripping)- Site preparation would entail removing trees and other large vegetation from the construction area and stripping the top 6 inches of material from the landside slope of the existing levee, the footprint of the adjacent setback levee, the seepage berm areas, and the 50-foot-wide permanent maintenance access corridor. Large roots and deleterious material would then be grubbed from the working area. To the extent feasible, trees that must be removed from within the footprint of the adjacent setback levee or berms would be relocated outside of the footprint to new woodland planting areas, where a substantial number of new trees would also be planted. Excess earth materials (organic soils, roots, and grass from borrow areas and the adjacent levee foundation and excavated material that does not meet levee embankment criteria) would be used in the reclamation of borrow areas or hauled off-site to landfills. Cleared vegetation (i.e., trees, brush) would be hauled off-site to landfills.

Relocation of Irrigation Ditch - Odysseus Farms, located at the junction of the NCC south levee and Sacramento River east levee, maintains a private irrigation ditch that is situated within the proposed footprint of the adjacent setback levee. This private irrigation ditch is situated along the top of an existing berm in Reach 1 within the proposed footprint of the adjacent setback levee. Before filling of the existing ditch, a new ditch would be constructed in Reach 1 to serve irrigation needs for agricultural uses of the land along this reach. The new ditch would be constructed from Station 0+00 to Station 25+00 and would be elevated, similar to the existing canal, to allow for gravity flow southward from the NCC. The relocated ditch would cross under Sankey Road through a culvert and meet the existing canal lateral at Station 25+00. The existing ditch would be drained and any unsuitable material from the ditch bottom would be excavated and hauled off-site. To maintain irrigation system continuity, this relocation work would need to be implemented prior to May 1, 2009, as facilities begin operations prior to May and are continually in operation through the end of summer, thus presenting limited opportunities for relocation during the levee construction work window.

Removal of Landside Structures and Other Facilities - Residences and other farm structures that are within the proposed footprint of the adjacent setback levee embankment, berms, and maintenance areas at Station 35+00 in Reach 1 (house, barn, and shed) would have to be removed or relocated farther from the flood control facilities before the start of levee construction. Irrigation facility collection/distribution boxes, wells, and standpipes within the footprint of the flood control features would be demolished and replaced as needed. Debris from structure demolition, power poles, utility lines, piping, and other materials requiring disposal would be hauled off-site to a suitable landfill. As feasible, demolished concrete could be sent to a concrete recycling facility. Wells and septic systems would be abandoned in accordance with the applicable state and county requirements. Some utility poles would be relocated after October 1, 2008, after permit issuance; the removal of other landside structures and facilities would not occur until May of 2009.

Excavation of Stability Berm and Inspection Trench
The existing stability berm along the levee would be excavated and the soil and drain rock would be stockpiled for use in the construction of the adjacent setback levee. The geotextile fabric from the drain layer would be discarded. A 3-foot-deep inspection trench would also be excavated along the foundation of the adjacent levee raise area after stripping has occurred. The purpose of this trench is to expose or intercept any undesirable underground features such as old drain tile, water or sewer lines, other debris, animal burrows, buried logs, or pockets of unsuitable material (e.g., sand lenses). After inspection, the trench would be backfilled and compacted as part of the embankment construction.

Construction of Adjacent Levee Raise and Cutoff Walls
Borrow material would be excavated from several locations in the project area and would be delivered to the levee construction sites by scrapers or haul trucks where it would be spread by motor graders and compacted by sheepsfoot rollers to build the adjacent levee up to a height equal to about two-thirds of the height of the existing levee. This would create a working platform for cutoff wall installation using an excavator with a long-stick boom capable of digging a trench to a maximum depth of approximately 80 feet. Bentonite slurry would be pumped into the trench during excavation to prevent caving. The soil excavated from the trench would be mixed with bentonite and backfilled into the trench to create the cutoff wall.

Reconstruction of Garden Highway at Intersections - The Garden Highway intersections at Sankey and Riego Roads would require reconstruction to accommodate the raised adjacent setback levee. It is anticipated that Garden Highway would be extended up and onto the widened adjacent levee at these locations to meet with the secondary roads. Approach embankments at the intersections would be enlarged and the entire intersections would be repaved. Intersecting roads would be raised at a slope of 15H:1V, extending the approach embankment approximately 350 feet outward from the levee. The side slopes of the raised embankments would be at a 3H:1V slope.

Installation of Surface Drainage Outlets across Garden Highway - Between the adjacent setback levee and the Garden Highway pavement, new storm drain facilities would be constructed to convey surface water beneath Garden Highway and toward the Sacramento River. A drainage swale collection system would convey runoff water to drop inlets located approximately 1,000 feet apart along an approximately 22,800-foot-long section of the improved levee, and new 12-inch diameter pipe laterals would convey the water beneath Garden Highway to the waterside slope berm. Excavation of a trench across Garden Highway and down the waterside levee slope would be required; those segments of Garden Highway where excavation occurs would have to be reconstructed. Single-lane traffic controls and through-traffic detours would be required during construction Phase 2. Drainage outlets would be located on the waterside levee berm, above the two-year ordinary high water mark. The construction of the drainage outlets entail the excavation of a 100 square foot area, of which the lower eighteen to twenty-four inches would be filled with a gravel/cobble mix, and the upper six to twelve inches would be an open depression. Water exiting the drainage outlets would settle in the depression, and then flow overland to the Sacramento River.

Site Restoration and Demobilization - Following construction, the levee slopes, seepage berms, maintenance access right-of-way, and any previously vegetated areas disturbed during construction would be seeded with a grass mix. Any construction debris would be hauled to an appropriate waste facility. Equipment and materials would be removed from the site, and staging areas and any temporary access roads would be restored to preproject conditions. Demobilization would likely occur in various locations as construction proceeds along the project alignment.

Major Irrigation and Drainage Infrastructure Modifications

Elkhorn Canal - The Phase 2 construction plan would include the new Elkhorn Canal from the North Drainage Canal to Elkhorn Reservoir, between Reach 4B and Reach 6B. On the north end, the new canal would be connected with the existing Prichard Pumping Plant outfall and an outlet to the North Drainage Canal would be constructed. An outfall to provide for connection to RD 1000 Pumping Plant No. 2, during its construction in Phase 3, would be incorporated into the Phase 2 canal construction to minimize the need for future canal disturbance. The discharge pipes from the Prichard Pumping Plant would be extended to the relocated canal. The outlet to the North Drainage Canal would be combined with the GGS/Drainage Canal outfall with a gated control structure in the irrigation canal and a piped outlet to the North Drainage Canal.

At the southern end, the relocated Elkhorn Canal would connect into an earthen-lined sediment basin. The sedimentation basin would consist of a number of watered, earthen-bottomed chambers separated by weirs, which may be concrete or rock covered. The basins would have 3H:1V embankments that are 15-foot-wide at the top to provide maintenance equipment access. The total area of basins including the embankments is approximately 9.6 acres, with nearly 3.3 acres of water surface. The proposed sediment basin would be connected to Elkhorn Reservoir with a temporary pipe and outfall structure. During construction Phase 3 (see below), Elkhorn Reservoir would be dewatered and piping from the Elkhorn Pumping Plant would be extended to the new sediment basin, at which time the Elkhorn Reservoir sediment basin would be abandoned and filled.

The GGS/Drainage Canal would be constructed parallel to and within the same right-of way as the Elkhorn Canal. These features would be constructed concurrently to facilitate the use of excavated material from the GGS/Drainage Canal for use as embankment material along the Elkhorn Canal.

The primary construction stages for Elkhorn Canal are described in the subsections below.

Clearing and Grubbing/Stripping

Preparation for canal construction would entail using bulldozers/scrapers to clear and grub/strip the surface to a depth of 4–6 inches and remove low-growing vegetation and loose surface soils. Suitable materials removed during this stage could be stockpiled. Unsuitable material would be wasted and hauled off-site. The right-of-way for the canal that would need to be cleared (including the GGS/Drainage Canal right-of-way) is approximately 225 feet wide.

Bulldozers/scrapers and front-end loaders would be used to excavate and move material. Water trucks would be used to control dust and dump trucks would be used to haul unsuitable materials away.

This phase of construction would commence immediately after mobilization and would most likely occur in multiple sections of the Elkhorn Canal and GGS/Drainage Canal alignments simultaneously.

Pump Discharge Pipe Extension

Because the Elkhorn Canal would be relocated farther from NMWC pumping plants than the existing canal, additional pipe would need to be installed to maintain the connections between the pumping plants and the irrigation canals. In particular, discharge pipes would need to be extended at Prichard Pumping Plant and Elkhorn Pumping Plant. Pipes would be transported to the site on flatbed trucks. Excavators and backhoes would be used to dig the pipe trenches and lay the sections of welded steel pipe and backfill the trench. The trench would be deep enough to provide for a minimum of 12 inches of cover. A small compactor would be used to compact the soil over the pipe. The construction of pipelines at the existing Prichard Pumping Plant would occur during Phase 2 of construction, and at the Elkhorn Pumping Plant pipeline construction would occur during Phase 3 of construction.

Prichard Pumping Plant Connection

A new concrete transition structure would be constructed at the north end of the existing Elkhorn Canal to connect the existing Prichard outfall box culvert to the new Elkhorn Canal. Three reinforced concrete discharge pipes, two 36-inch and one 30-inch, approximately 600 feet in length, would be constructed in parallel from the new transition structure to the proposed distribution box located approximately 250 feet south of the western end of the North Drainage Canal. These pipes would connect the Prichard Pumping Plant outfall to the distribution box. From the distribution box, two 54-inch reinforced concrete discharge pipes, approximately 30 feet long, would connect the box to the new Elkhorn Canal.

The concrete distribution box footprint would be approximately 25 foot by 30 foot. A 60-inch discharge pipe stub and 48-inch intake pipe stub would be constructed on the north side of the distribution box. These stubs will provide for future connections of the distribution box to the North Drainage Canal and Pumping Plant No. 2.

Water Control Facility Construction

New facilities that would be constructed include distribution boxes, gate valves, cast-in-place concrete headwalls and control structures, culverts, and a proposed earthen-lined sediment basin adjacent to Elkhorn Reservoir. Backhoes and excavators would be used to excavate material for the new facilities. Precast distribution boxes, pipes, and other appurtenances would be transported to the site on flatbed trucks. Other concrete facilities would be poured in place and concrete would be transported to the site in ready-mix and boom concrete pumper trucks. Small compactors would be used to compact fill material around the facilities.

Embankment and Access Road Construction

The existing Elkhorn Canal is a highline canal, and construction of its replacement would require little or no excavation but a large amount of borrow material. The bottom of the new Elkhorn Canal channel would be approximately at existing ground level. During construction, borrow material would be required to build up the embankments of the new canal, which would be approximately 4 feet above the channel bottom with 3H:1V side slopes. Bulldozers and graders would be used to move and shape the embankment material, sheepsfoot and smooth drum rollers would be used to compact the embankment material, and water trucks would be used on-site for dust control and moisture conditioning.

Canal Lining

The bottom 6 to 12 inches of the Elkhorn Canal channel would be lined with concrete to provide for maintenance between seasons while minimizing impacts on the adjacent canal banks. Ready-mix and concrete pumper trucks would be required to apply the concrete to the bottom of the channel. It is anticipated that approximately 3,000 cubic yards of concrete would be required in construction Phase 2 for the proposed Elkhorn Canal lining.

Irrigation Interconnections

This phase includes work required to interconnect the relocated Elkhorn Canal with the existing irrigation canals within the Natomas Basin. Excavators and backhoes would be used to trench any connectors and motor graders would be used to shape the embankments. A water truck would be used to control dust and provide moisture conditioning during the excavation and construction of the interconnection facilities. Canal interconnections would be performed before the abandonment of the existing Elkhorn Canal.

Central Main Flume Connection

A second concrete distribution box would be constructed to connect the Elkhorn Canal to the Central Main Flume. The box will be located at the intersection of the Elkhorn Canal with the Central Main Flume with a footprint that is approximately 19 feet by 49 feet and will be tied into the existing concrete flume. Three 48-inch slide gates would be constructed on both the north and south ends of the box to connect the box to the Elkhorn Canal both north and south of the flume. A 6 foot by 6 foot reinforced concrete box culvert on the east end of the distribution box would connect to an outfall structure and the end of the flume.

Erosion Control

Erosion control measures would be installed before the start of construction and would be maintained throughout the construction period to prevent sedimentation of adjacent waterways. A hydroseeding truck would be used at the end of construction to seed any disturbed area. Water trucks would be used throughout the construction period to control dust in any disturbed areas.

Irrigation Canal Abandonment

As the newly constructed canal is completed and operable, the existing Elkhorn Canal would be abandoned. Irrigation flows would be rerouted to the new canal and the existing canal would be dewatered and abandoned. The filling of the abandoned Elkhorn Canal in Reach 4B would take

place as part of Phase 2 of levee construction and in Reaches 5A to 6B would take place as part of the Phases 3 and 4 of levee construction. Portions of farm canals and other irrigation canals would be abandoned because of the relocation of the Elkhorn Canal. Such segments that are outside the footprint of the proposed levee improvements would be filled after the relocation of the Elkhorn Canal is completed. Dump trucks would be used to haul fill material to those canals, rollers would be used to compact the fill, and water trucks would be used for dust control.

Demobilization/Cleanup

This phase includes dismantling any temporary facilities, hauling away any leftover construction materials, and cleaning up the site. All disturbed areas would be reseeded and graded to drain. A front-end loader and dump trucks would be used to move materials. This phase of construction would also entail general cleanup and hauling away unused and waste materials. All construction equipment would be removed.

Scheduling for Phase 2 Construction of the Elkhorn Canal

The segment of the Elkhorn Canal from the Prichard Pumping Plant to the Elkhorn sedimentation basin would be constructed between May and October 2009. The segment of the Elkhorn Canal from the Central Main Flume to the Elkhorn sedimentation basin would be constructed between May and October 2009.

Phase 2 Construction on New GGS/Drainage Canal - The Phase 2 construction plan would include the construction of the GGS/Drainage Canal from the North Drainage Canal to the slough east of Elkhorn Reservoir, between Reach 4B and Reach 6B. The GGS/Drainage Canal and Elkhorn Canal would be parallel and separated by a 20-foot right-of-way access. The GGS/Drainage Canal would tie into the North Drainage Canal east of the proposed location of replacement RD 1000 Pumping Plant No. 2. Crossing of the Elkhorn Canal and tie-in to the North Drainage Canal are anticipated to be made via open, arching culverts (e.g., "Con-Arch" culverts) that allow the GGS/Drainage Canal to pass under the Elkhorn Canal and the access road on the south side of the North Drainage Canal without being confined to pipes.

Because portions of the GGS/Drainage Canal and the Elkhorn Canal would be constructed parallel within the same right-of way, they would be constructed concurrently during Phase 2 construction. This approach would facilitate the use of material from the GGS/Drainage Canal excavation for use as embankment material along the Elkhorn Canal. Construction of the GGS/Drainage Canal would include the same construction phases as described above for the Elkhorn Canal, with a few exceptions. Unlike the Elkhorn Canal, the GGS/Drainage Canal would not be concrete lined. The top of bank for the GGS/Drainage Canal would be approximately at existing ground level. During construction, a trench at least 6 feet deep and an average width of 55 feet would need to be excavated for the construction of the GGS/Drainage Canal. Reclamation would include planting tules on the sloped banks. Backhoes would be used to prepare the planting areas and a water truck would be used to control dust.

Removal of Culvert at Pumping Plant No. 2 Site - SAFCA would undertake a second phase of the levee repairs and facility removal adjacent to the RD 1000 Pumping Plant No. 2 site at the

west end of the North Drainage Canal as part of the proposed project. This phase of work would include: (1) excavating and removing approximately 400 feet of the existing levee section adjacent to the Pumping Plant No. 2 site to expose a deep culvert and possible voids under the levee, (2) removing the deep culvert, (3) reconstructing the levee adjacent to the pumping plant sump with levee embankment fill, and (4) demolishing, removing, and relocating the pumping plant remnants within the project footprint. The last activity, reconstruction of the pumping plant, would be conducted in the 2009 construction phase and is described in the next subsection. The project-related work would be confined to an area of approximately 2.3 acres. A stockpile and staging area of approximately 4.5 acres would be established near the work area.

Excavation limits would be extended to reconstruct the levee section adjacent to the sump and to reach areas where anomalies were identified during a geophysical investigation of the site. An area on the water side of the sheet pile wall would be excavated to lower the ground surface so as to reduce the loading on the sheet pile and excavation shoring system as the excavation takes place on the land side of the sheet piles. Excavated material would be stored on the site along the dewatered section of the North Drainage Canal, east of the abandoned sump, and in an adjacent agricultural field along the canal.

During excavation, the remnants of the pumping plant would be demolished and removed. This work includes relocation of a 36-inch irrigation supply pipe that is within the excavation limits. A temporary plastic fabric-lined ditch at the outfall of this pipe would also be relocated to provide for sufficient staging and stockpile areas. A short irrigation system 'outage' would be required to allow for relocation of the pipe and ditch.

Heavy equipment required for construction includes semi flatbed and/or box trucks to deliver equipment and materials; a crane to drive sheet pilings for additional shoring needs; dump trucks to haul debris, stockpile excavated levee material, and import select soil materials for levee reconstruction; two hydraulic excavators; two dozers for stripping and stockpiling material, a grader, water truck, and front-end loader for maintenance of haul roads and stockpiles; and a roller compactor for levee construction.

Habitat Enhancement, Development, and Management

Habitat enhancements and developments planned for Phase 2 of project construction include: the northern segments of the relocated Elkhorn Canal and the newly constructed GGS/Drainage Canal between the North Drainage Canal and Elkhorn Reservoir; the preservation and establishment of landside woodlands along the Sacramento River east levee; the creation of managed grasslands on the newly constructed levee slopes, seepage berms, access rights-of-ways, and canal embankments; and the preservation of rice land. Please refer to the June 18, 2008, *Conceptual Mitigation, Management, and Monitoring Plan* document (prepared by EDAW for SAFCA) for a more complete summary of the conceptual strategy for creating/enhancing/preserving, protecting, and managing habitats in the Natomas Basin in perpetuity.

The proposed project would offset temporary and permanent effects to habitat of listed species through the creation, enhancement, and preservation of habitat in the basin. The construction of the Elkhorn Canal and GGS/Drainage Canal, including their management elements, are described above in more detail. Design and management elements for the managed grasslands, landside woodlands, and rice fields are summarized below.

Managed Grasslands

Levee Slopes and Seepage Berms - Levee improvements would result in landside slopes that are less steep than the existing slopes, and several reaches of the Sacramento River east levee would have adjoining 80- to 300-foot-wide earthen seepage berms with a nearly flat slope (50H:1V or less). Parallel to the landside toe of enlarged levees and seepage berms would be maintenance access roads and seepage relief wells in some locations. Additional setback buffer lands would flank some of these features, and property acquisition for the proposed project may leave SAFCA with remnant portions of acquired parcels that are nonessential to flood control uses. With the exception of the crown of the levee, these areas would be managed as grassland. Most grassland would be mowed or grazed throughout the growing season, with an emphasis on mowing procedures and stubble height to optimize these areas for Swainson's hawk foraging habitat. However, the primary purpose and management priority of levees and seepage berms would continue to be flood risk reduction, for which RD 1000 has principal management and maintenance responsibility, and they would be maintained in accordance with Corps and Central Valley Flood Protection Board operations and maintenance requirements.

Canal Embankments - The side slopes of the new GGS/Drainage Canal and relocated Elkhorn and Riverside Canals would be flatter than typical canal slopes in the Natomas Basin and consistent (3H:1V), resulting in greatly reduced erosion and sedimentation. Vegetation on the banks could easily be mowed to a specified stubble height using cutter blades instead of the existing, high-disturbance practice of flail mowing or scraping vegetation from the banks and canal with a drag bucket. These improved canal maintenance practices would substantially reduce disturbance and incidental mortality of giant garter snakes that use bank and shoreline vegetation as cover and feeding habitat.

Landside Woodlands

Woodlands consisting of native riparian species would be planted east of the maintenance corridor along the Sacramento River east levee improvements. In Phase 2, tree and shrub species, including elderberry shrubs (*Sambucus mexicana*), would be planted on approximately 30 acres of existing cropland or fallow or currently unused sites. Groves would generally be at least 50-100 feet wide and several hundred feet long. Wide woodland corridors would promote successful nesting by a variety of native birds deeper within the grove canopy, where nest parasitism by crows, cowbirds, and starlings is less of a factor in breeding success. At maturity, stand structure would vary from closed canopy woodland to grassland savanna vegetation types.

Planting sites would require suitable soil conditions, water supply during a 3- to 5-year establishment phase, reduced risk of wildfire, and minimal depth to seasonally high groundwater or other natural water sources to sustain trees once irrigation ceases. A mixture of native riparian

species would be planted, but predominant species would be Valley oak (*Quercus kelloggii*), the primary tree species that would be affected by the proposed improvements to the Sacramento River east levee, and cottonwood (*Populus fremontii*), which is a preferred nest tree for Swainson's hawks in the basin and is faster growing than Valley oak. Establishment of woody vegetation would likely require more than one technique, including seeding in winter, flood irrigation, drip or agricultural-scale spray heads, cuttings, and acorn planting.

Where trees would be removed from existing groves to make way for the proposed flood control system features, they would be transplanted in new locations, including newly planted groves, to the extent feasible. The woodland planting areas would provide locations for transplanting any elderberry shrubs that would need to be moved from the proposed footprint of flood risk reduction improvements.

Rice Fields

Brookfield - The Brookfield property is a 353-acre private property that is located between Howsley Road and Fifield Road, west of the PGCC west levee. As of the summer of 2008, the property is currently in rice cultivation.

Up to 160 acres of the site may be utilized for borrow operations in Phase 2. After the completion of borrow excavation, the 160 acres would be returned to rice and at least ½ of the 353-acre site would be preserved in perpetuity. The removal of borrow material would entail excavating the site to a depth of up to approximately 6 feet, with an approximate net yield of approximately 3.6 million cubic yards of soil from the site. One foot of topsoil would be removed and stockpiled for reuse during reclamation of the site. This borrow material would be used for levee improvements along the NCC south levee (construction Phase 2), PGCC west levee (construction Phase 3), and possibly the NEMDC west levee (construction Phase 4); however, no area of the property would be used in consecutive years. Following the removal of borrow material for the levee construction, the site would be graded and returned to rice cultivation.

Currently, the site is irrigated from on-site wells. To provide irrigation to the site following the excavation of borrow material, the irrigation canal along the south side of the site would be deepened and reconfigured from the Brookfield site westward to the culvert under SR 99/70. Additionally, a field irrigation ditch would be constructed within the Brookfield site to provide irrigation water from the adjacent highline canal to the fields. Grading of the site would be performed at a slope that would allow the water to flow back to the drainage canals running along the west and south side of the property. The water from the eastern fields would be drained into a canal along the west side of the pasture land and into the southern drainage canal. The drainage channel along the west and south side of the property would be modified to allow the site to drain following borrow excavation.

Modifications include widening all canals to an 8-foot bottom width with 3H:1V side slopes. Specific canal improvements could include modification of approximately 4,480 feet of the

RD 1000 canal that borders the south end of the site, modification of 3,670 feet of the private north-south drainage ditch along the west edge of the property, creation of a 900-foot long drainage ditch along the west edge of the pasture lands, and modification of a 6,350 foot long section of the drainage canal along SR 99/70 from the RD 1000 canal south. Improvements of the drainage canal along SR 99/70 may require land acquisition of up to 25 acres to account for the additional width of the channel and flatter side slopes.

Reclamation of Other Borrow Sites

Borrow sites would provide material for Phase 2 flood control and irrigation infrastructure modifications. Following excavation of the borrow material, these sites would be reclaimed for postconstruction uses.

Airport North Borrow Sites - The Airport's north bufferlands have been historically farmed as rice fields and field crops. However, based on FAA requirements to reduce hazardous wildlife attractants near runways, the Airport has opted to not renew rice leases on its bufferlands. Thus, these lands are currently either fallow agricultural fields or ruderal grassland. After borrow activities, these sites would be returned to their current condition.

Cut depths for all the borrow sites would be approximately 4–6 feet. Following the excavation of the borrow sites, disturbed areas would be finish graded to standard irrigation slopes so that the sites would drain and not have any standing water in less than 10-year storm events. Excavated soils not used for borrow material, such as the organic surface layer or soils considered unsuitable for levee construction, would be stockpiled and respread on-site following excavation. Any unsuitable borrow material would be stockpiled on-site and graded back into the restoration of the site. Revegetation activities would include erosion control on excavated slopes (i.e., hydroseeding) and application of fertilizer.

Overview of Construction Phases 3 and 4

Table 2 summarizes the major elements of Phases 3 and 4 of the proposed project and the anticipated general timeframes in which the elements are expected to be implemented. Note that although seepage berms are depicted as the primary means of providing underseepage remediation along the Sacramento River east levee, the use of cutoff walls continues to be evaluated, and cutoff walls will likely be implemented instead of berms in several locations.

Levee Raising and Seepage Remediation

Sacramento River East Levee Reaches 5A–20A

Improvements to the Sacramento River east levee would continue in construction Phases 3 and 4, and would extend from Reach 5A (below Station 226+00) through Reach 20A (Station 925+50). It is anticipated that construction of improvements to the Sacramento River east levee would encompass Reaches 5A-9B in construction Phase 3 and Reaches 10-20A in construction Phase 4. The construction season is assumed to be mid-April – November for both construction phases. The following descriptions of design and construction of the improvements to the Sacramento

Table 2
Summary of the Major Elements of Phase 3 and 4

Project Element	Proposed Activity and Timing
Levee raising and seepage remediation: Sacramento River east levee (adjacent setback levee)	Construct an adjacent setback levee along Stations 55+00 to 68+00 in Reach 2 and from just south of the North Drainage Canal to the American River north levee (Reaches 5A–20B), raised where needed to provide adequate freeboard, with seepage berms, relief wells, and cutoff walls for seepage remediation as required (specific seepage remediation measures are still under study). (May 1, 2009–November 1, 2010)
Levee widening and flattening and seepage remediation: PGCC west levee	Widen the levee between Howsley Road and Sankey Road to allow for seepage remediation and flatten the levee on the water side to meet Corps criteria. Construct cutoff walls or seepage berms where required. (April–November 2009)
Levee widening and flattening and seepage remediation: NEMDC west levee	Widen levee and flatten slope between Elkhorn Blvd and NEMDC stormwater pumping station. (April–November 2009) Construct a seepage cutoff wall from NEMDC stormwater pumping station to Northgate Blvd where required. (April–November 2009)
Improvements to major irrigation and drainage infrastructure	Construct the new GGS/Drainage Canal between Elkhorn Reservoir and the West Drainage Canal, and improve the West Drainage Canal to provide enhanced giant garter snake habitat. (May 1–November 1, 2009) Implement Airport West Ditch improvements in connection with construction of the GGS/Drainage Canal to allow the Airport to decommission the agricultural irrigation function of this facility and eliminate the hazards currently associated with it. The Airport stormwater detention function provided by this ditch would continue. The ditch would therefore be recontoured as a gently sloping swale to facilitate periodic maintenance such as mowing. (May 1–November 1, 2009) Relocate the Riverside Canal and the Elkhorn Canal downstream of Elkhorn Reservoir (specific alignments to be determined) and fill the existing canals. (May 1–November 1, 2009, and May 1-November 1, 2010) Construct RD 1000 Pumping Plant No. 2. (April 1, 2009–September 1, 2010)
Habitat enhancement, creation and management	Establish habitat enhancements in the new GGS/Drainage Canal and improved West Drainage Canal. (Fall 2009) Recontour and create marsh and managed grassland on lands used as borrow sources. (Fall or spring after borrow excavation in 2009 and 2010) Establish grassland on the adjacent setback levee slopes and seepage berms. (Fall after construction in 2009 and 2010) Install woodland plantings to offset the loss of portions of tree groves in the landside levee footprint (locations to be determined). (Fall 2009 and 2010)
Additional actions to meet FEMA requirements: encroachment management on the Sacramento River east levee, and bridge crossing modifications at the NCC	Remove encroachments from a portion of the water side and land side of the Sacramento River east levee as needed to ensure that the levee can be certified as meeting the minimum requirements of the NFIP and Corps design criteria (specific criteria still under discussion). (Timing to be determined) Modify the SR 99/70 crossing of the NCC as needed to meet FEMA requirements. (Timing to be determined)
Right-of-way acquisition	Acquire right-of-way through fee title or easement interest within the footprint of the project features, at the borrow sites and along the flood control system. (Before construction)

Notes: Airport = Sacramento International Airport; Elkhorn Canal = Elkhorn Main Irrigation Canal; FEMA = Federal Emergency Management Agency; GGS = Giant Garter Snake; NCC = Natomas Cross Canal; NFIP = National Flood Insurance Program; PGCC = Pleasant Grove Creek Canal; RD = Reclamation District; Riverside Canal = Riverside Main Irrigation Canal; SR = State Route; Corps = U.S. Army Corps of Engineers

River east levee proposed for construction Phases 3 and 4 are described in less detail than construction Phase 2 (improvements to the NCC south levee and Sacramento River east levee Reaches 1–4B) because they are not as far along in the project design process.

Required Freeboard Increases and Proposed Underseepage Remediation - Levee crown raises are required to provide adequate freeboard above the 100-year design water surface elevation in Reaches 5A–10 and above the 200-year design water surface elevation in Reaches 11A and 11B. Downstream of Reach 11B (Powerline Road), there is adequate freeboard above the 200-year design water surface elevation, and levee crown raises are not required. Substantial structural encroachments and large amounts of woody vegetation are present on the waterside slope of the existing levee, and the adjacent setback levee is proposed to extend through Reaches 5A–19A to avoid the need for extensive removal of the existing vegetation and encroachments on the waterside slope to meet Corps criteria. The existing levee in Reaches 19B–20B already has a wide crown, and extensive residential development is located along the landside levee toe; therefore, construction of the adjacent setback levee is not proposed for these reaches. The adjacent setback levee would extend outward at least 11 feet from the landside edge of the existing levee crown and would have a 3H:1V landside slope.

Underseepage remediation is required in many of the reaches from 5A through 20A. Reach 20B has sufficient freeboard for the 200-year water surface elevation and a cutoff wall (constructed by Corps in 2000) that meets current design criteria. Because this wall was constructed to an adequate depth, this reach does not need additional seepage remediation. Based on the results of geotechnical investigations, engineering and cost considerations, and land use constraints, cutoff walls are proposed for Reaches 5A–20A.

Removal of Landside Structures and Vegetation - Removal of some residences, other structures, and woodland vegetation, including mature trees, would be required to create ample space for the adjacent setback levee, berms, and maintenance access corridor. It is anticipated that residences would be removed at Station 62+00 in Reach 2, Station 245+00 in Reach 5A, Station 368+00 in Reach 8, Station 436+50 in Reach 9A, Station 468+00 in Reach 10, and at several locations along Reaches 15 through 18.

Miscellaneous Construction Elements and Postconstruction Site Condition - Modifications of roadway intersections with Garden Highway, utility relocations, removal of pumps and wells, and relocation of private canals would be similar to these activities as described for the improvements to Sacramento River east levee Reaches 1–4B. As described for Reaches 1–4B, after construction, the levee slopes, seepage berms, maintenance access right-of-way, and any previously vegetated areas disturbed during construction would be seeded with a grass mix.

Pleasant Grove Creek Canal West Levee

The PGCC west levee is vulnerable to seepage and has stability concerns. The proposed project includes improvements to 17,400 feet of the PGCC west levee, beginning at the east end of the NCC improvements at Howsley Road and extending southerly to Sankey Road. Construction is

anticipated to proceed in Phases 3 and 4 on this component of the NLIP. Details of the proposed improvements will be developed based on additional geotechnical studies and cost analysis. The improvements are expected to consist of the following:

- widening of the levee to provide a minimum top width of 20 feet to accommodate safe lane widths for Natomas Road;
- flattening the water side of the levee to a 3H:1V slope;
- reconstructing the landside levee slope with new, select material to create a 3H:1V slope (the existing slope ranges from 2:1 to 2.5:1);
- from its intersection with Howsley Road and continuing one quarter mile south, raising the widened levee one to two-tenths of a foot to provide 3 feet of levee height on the 100-year design water surface profile; and
- constructing a SB cutoff wall through three separate reaches, totaling approximately 5,000 lineal feet, to coincide with areas where streams historically flowed east to west through the current PGCC alignment.

Irrigation and drainage canals at the landside toe of the existing levee would need to be relocated to the west to accommodate the berm construction. Several structures associated with the industrial facility near the southern end of the PGCC would need to be relocated.

The postproject site condition (grass-covered levee slopes and berms) and long-term maintenance practices would be as described above for the NCC south levee and Sacramento River east levee.

Natomas East Main Drainage Canal West Levee

The NEMDC west levee is vulnerable to seepage and has stability concerns. The proposed project includes improvements to the NEMDC west levee, beginning from Sankey Road south to Northgate Boulevard. Construction is anticipated to proceed in Phases 3 and 4 on this component of the NLIP. Details of the proposed improvements will be developed based on additional geotechnical studies and cost analysis. The improvements are expected to consist of the following:

- From the NEMDC pump station (between Elkhorn Boulevard and Del Paso Road) south to Northgate Boulevard, approximately 25,000 linear feet of cutoff wall is to be constructed to a depth of up to 80 feet from the levee crown. The existing maintenance easement on this stretch of the NEMDC will not accommodate levee reshaping or levee degrading beyond what is necessary to provide a minimum working platform for cutoff wall installation. Additionally, structures in close proximity of the landside levee toe make additional maintenance easement acquisition impractical. Where asphalt-concrete surfacing is present at the levee crown, it would be removed and disposed of off site. Following completion of the cutoff wall, the levee crown would be reconstructed and the operating road surface restored.

- North of the NEMDC pump station, to Elkhorn Boulevard, levee widening and slope flattening will occur similar to what is described for the PGCC west levee. These project components include:
  - widening of the levee to provide a minimum top width at least 20 feet to accommodate safe lane widths for Natomas and East Levee Roads;

- flattening the water side of the levee to a 3H:1V slope; and
- reconstructing the landside levee slope with new, select material to create a 3H:1V slope.

The postproject site condition and long-term maintenance practices would be as described above for the NCC south levee and Sacramento River east levee.

Major Irrigation and Drainage Infrastructure Modifications

Elkhorn and Riverside Canals

Construction Phases 3 and 4 would include the relocation of the remainder of the Elkhorn Canal (south of Elkhorn Reservoir) and the relocation of the Riverside Canal and would include the same construction phases as described for Phase 2. Timing of the new canal construction would be critical to avoid interruptions in irrigation service. The remainder of the relocated Elkhorn Canal, from Elkhorn Reservoir south, and the relocated Riverside Canal would be constructed before existing canals are filled in as part of the levee improvements in Reaches 6B–9A scheduled for construction Phase 3 and 12–20B scheduled for construction in Phase 4.

In addition to the general canal construction activities described for construction Phase 2, Elkhorn Reservoir would be dewatered and piping from the Elkhorn Pumping Plant would be extended to the new settling basin, at which time Elkhorn Reservoir would be abandoned and filled. The pipelines from the Elkhorn and Riverside Pumping Plants to the relocated irrigation canals would be constructed.

Phase 3 Construction of the New GGS/Drainage Canal

Phase 3 construction phase would include the construction of the GGS/Drainage Canal from north of Teal Bend Golf Course to the West Drainage Canal and improvements to the West Drainage Canal to enhance habitat value for giant garter snake. Because the GGS/Drainage Canal would be approximately 3.5–5.5 feet lower in elevation than the Elkhorn Canal, it would cross underneath the Elkhorn Canal, approximately 350 feet north of Elkhorn Reservoir, likely through a structure similar to that described above for the northern crossing. Reclamation would include planting tules on the sloped banks. In the portion of the canal below I-5, tules would be planted above the canal bench. Backhoes would be used to prepare the planting areas and a water truck would be used to control dust. A 2,200-foot-long section of the GGS/Drainage Canal between the sedimentation basin and Walnut Road as well as the 2,850-foot-long section of the existing West Drainage Canal would include a 15-foot-wide managed tule bench, which would typically be inundated with water and drain into the main channel. The 5,900-foot-long section between the southeastern corner of Teal Bend Golf Course and the West Drainage Canal would have a 50-foot-wide managed tule bench.

Removal of Airport West Ditch

As part of a safety survey conducted by the FAA for the Airport, the FAA expressed concern that the Airport West Ditch provides habitat for wildlife that potentially create a hazard to aircraft. The FAA recommended relocation of the ditch to alleviate the hazard. Additionally, a longstanding problem has existed with leakage from a 24-inch pipeline, resulting in marshy

conditions along its route, approximately 11,000 feet between the intake structure and delivery point at the Airport pumps. During the past year the Airport began receiving all of its domestic (drinking) water supply from the City of Sacramento via a pipeline and storage tank project. Two of the on-Airport water wells previously used to provide domestic water were connected to the Airport's landscape irrigation piping system, and the water supply to the "leaky underground pipe" was deactivated. All of the Airport's landscape irrigation needs are now provided on-site, and there is no need for the leaky pipe to remain in place. Irrigation water provided by NMWC still flows south through the Airport West Ditch, however, whereupon it is pumped to privately owned farms west of the Airport. The proposed project would include the construction of canal improvements to allow for decommissioning of the agricultural irrigation function of the ditch.

During storms, the Airport West Ditch receives stormwater runoff from a portion of the impervious surfaces on the west side of the Airport. Depending on the water volume, some of the stormwater is retained in the ditch until it can drain off-site to the Sacramento River. Therefore, the stormwater detention function of the Airport West Ditch must continue. In addition to the habitat-related safety issues, the ditch presents a physical obstruction hazard to planes that may leave the runway during adverse takeoff or landing situations. Therefore, the final stage of this project component would consist of regrading the Airport West Ditch to a gently sloping swale that can be easily maintained through mowing or other means. The more gradual gradient would also pose a lower threat to aircraft that may unexpectedly exit the runway.

To take advantage of common construction practices and to maximize the use of common facilities, the rearrangement of irrigation and drainage facilities required to provide for rerouting of flows that contribute to the Airport West Ditch would be accomplished along with the proposed NLIP improvements. The proposed GGS/ Drainage Canal would intercept many of the Airport West Ditch's off-site irrigation and drainage sources and reroute flows outside of the Airport Operations Area. The intent is to reroute year-round flows through the GGS/Drainage Canal. Additional irrigation infrastructure improvements required to reroute these flows would be implemented along with the GGS/Drainage Canal construction. Equipment that would be utilized in this reconfiguration includes excavators, loaders, compactors, dump trucks, water trucks, hydroseeding trucks, and generators.

Pumping Plant No. 2 Reconstruction and Relocation

Pumping Plant No. 2 would be reconstructed and relocated as part of the proposed project at the western end of the North Drainage Canal, approximately 900 feet east of the centerline of the levee in the vicinity of the intersection with the P6 Drain. Long discharge pipes would extend over the levee to the Sacramento River. The work is expected to take place in construction Phase 3. Two 42-inch steel discharge pipes, approximately 850 feet long, would connect the two 300-horsepower pumps from the pump station to a new concrete outfall structure in the Sacramento River. The new outfall structure would be constructed close to the location of the original Pumping Plant No. 2 outfall structure. Equipment required for construction of Pumping Plant No. 2 include an excavator, dozer, loader, crane, boom truck, pile driver, concrete pump, generator, and water truck.

Habitat Enhancement, Development, and Management

Habitat enhancements and developments planned for Phases 3 and 4 of project construction include: the southern segments of the relocated Elkhorn Canal and the newly constructed GGS/Drainage Canal between the Elkhorn Reservoir and the West Drainage Canal and the relocated Riverside Canal; additional establishment of landside woodlands along the Sacramento River east levee; continued creation of managed grasslands on the newly constructed levee slopes, seepage berms, access rights-of-ways, and canal embankments; the creation of managed marsh in the southern areas of the basin; and preservation of additional rice and agricultural upland cropland. Please refer to the June 18, 2008, *Conceptual Mitigation, Management, and Monitoring Plan* document (prepared by EDAW for SAFCA) for a more complete summary of the conceptual strategy for creating, enhancing, preserving, protecting, and managing habitats in the Natomas Basin in perpetuity. Similar to Phase 2, temporary and permanent effects to habitats of listed species that result from the implementation of Phases 3 and 4 would be offset through the creation, enhancement, and preservation of habitat in the basin.

Programmatic Biological Opinion Implementing Procedure

Because the Corps and SAFCA only have a detailed project description for Phase 2 of the entire Natomas Levee Improvement Project, this biological opinion analyzes the landscape effects of the project for all Phases (2, 3, and 4) but will only analyze and provide incidental take coverage for Phase 2. For each subsequent phase, the Corps will initiate section 7 consultation with the Service under the umbrella of this programmatic biological opinion. The following process will be used when implementing projects under this programmatic biological opinion:

1. The Corps will submit a letter requesting that the proposed phase be tiered to this programmatic biological opinion and provide the Service the following:
    a. Project maps, which includes reaches under construction, cover types within the construction/maintenance boundary.
    b. Project schedule.
    c. An inventory of any elderberry stems >1 inch diameter that are within 100 feet of project actions and the number of shrubs and stems that would be transplanted and when and where they would be transplanted.
    d. A description of how compensation measures from the preceding phase are being implemented and the schedule for completion of those measures.

2. The Service will review new information that may reveal effects not considered previously and review the information provided to determine whether the activities described under future Phases were programmatically analyzed in this document.

3. The Corps and SAFCA should involve the Service on Phase 3 and Phase 4 early in the process to allow the Service an opportunity to comment on project descriptions and expedite the completion of biological opinions for those phases.

Giant Garter Snake

Status of the Species

Listing. The Service published a proposal to list the giant garter snake as an endangered species on December 27, 1991 (56 FR 67046). The Service reevaluated the status of the snake before adopting the final rule, which listed as a threatened species on October 20, 1993 (58 FR 54053). Critical habitat has not been designated for the giant garter snake.

Description. The giant garter snake is one of the largest garter snakes species reaching a total length of approximately 64 inches (162 centimeters). Females tend to be slightly longer and proportionately heavier than males. Generally, the snakes have a dark dorsal background color with pale dorsal and lateral stripes, although coloration and pattern prominence are geographically and individually variable (Hansen 1980; Rossman *et al.* 1996).

Historical and Current Range. Giant garter snakes formerly occurred throughout the wetlands that were extensive and widely distributed in the Sacramento and San Joaquin Valley floors of California (Fitch 1940; Hansen and Brode 1980; Rossman and Stewart 1987). The historical range of the snake is thought to have extended from the vicinity of Chico, Butte County, southward to Buena Vista Lake, near Bakersfield, in Kern County (Fitch 1940; Fox 1948; Hansen and Brode 1980; Rossman and Stewart 1987). Early collecting localities of the giant garter snake coincide with the distribution of large flood basins, particularly riparian marsh or slough habitats and associated tributary streams (Hansen and Brode 1980). Loss of habitat due to agricultural activities and flood control have extirpated the snake from the southern one third of its range in former wetlands associated with the historic Buena Vista, Tulare, and Kern lake beds (Hansen 1980; Hansen and Brode 1980).

Upon Federal listing in 1993, the Service identified 13 separate populations of giant garter snakes, with each population representing a cluster of discrete locality records (Service 1993). The 13 populations largely coincide with historical flood basins and tributary streams throughout the Central Valley: (1) Butte Basin, (2) Colusa Basin, (3) Sutter Basin, (4) American Basin, (5) Yolo Basin/Willow Slough, (6) Yolo Basin/Liberty Farms, (7) Sacramento Basin, (8) Badger Creek/Willow Creek, (9) Caldoni Marsh/White Slough, (10) East Stockton--Diverting Canal & Duck Creek, (11) North and South Grasslands, (12) Mendota, and (13) Burrel/Lanare.

The known range of the giant garter snake has changed little since the time of listing. In 2005, giant garter snakes were observed at the City of Chico's wastewater treatment facility, approximately ten miles north of what was previously believed to be the northernmost extent of the species' range (D. Kelly pers. comm. 2006; E. Hansen pers. comm. 2006). The southernmost known occurrence is at the Mendota Wildlife Area in Fresno County. No sightings of giant garter snakes south of Mendota Wildlife Area within the historic range of the species have been made since the time of listing (Hansen 2002).

Essential Habitat Components. Endemic to wetlands in the Sacramento and San Joaquin valleys, the giant garter snake inhabits marshes, sloughs, ponds, small lakes, low gradient streams, and other waterways and agricultural wetlands, such as irrigation and drainage canals, rice fields and the adjacent uplands (Service 1999a). Essential habitat components consist of: (1) wetlands with adequate water during the snake's active season (early-spring through mid-fall) to provide food and cover; (2) emergent, herbaceous wetland vegetation, such as cattails and bulrushes, for escape cover and foraging habitat during the active season; (3) upland habitat with grassy banks and openings in waterside vegetation for basking; and (4) higher elevation uplands for over-wintering habitat with escape cover (vegetation, burrows) and underground refugia (crevices and small mammal burrows) (Hansen 1988). Snakes are typically absent from larger rivers and other bodies of water that support introduced populations of large, predatory fish, and from wetlands with sand, gravel, or rock substrates (Hansen 1988; Hansen and Brode 1980; Rossman and Stewart 1987). Riparian woodlands do not provide suitable habitat because of excessive shade, lack of basking sites, and absence of prey populations (Hansen 1988).

Foraging Ecology. Giant garter snakes are the most aquatic garter snake species and are active foragers, feeding primarily on aquatic prey such as fish and amphibians (Fitch 1941). Because the giant garter snake's historic prey species are either declining, extirpated, or extinct, the predominant food items are now introduced species such as carp (*Cyprinus carpio*), mosquito-fish (*Gambusia affinis*), larval and sub-adult bullfrogs (*Rana catesbiana*), and Pacific chorus frogs (*Pseudacris regilla*) (Fitch 1941; Hansen 1988; Hansen and Brode 1980, 1993; Rossman *et al.* 1996).

Reproductive Ecology. The giant garter snake breeding season extends through March and April, and females give birth to live young from late July through early September (Hansen and Hansen 1990). Although growth rates are variable, young typically more than double in size by one year of age, and sexual maturity averages three years in males and five years for females (Service 1993b).

Movements and Habitat Use. The giant garter snake is highly aquatic but also occupies a terrestrial niche (Service 1999a; Wylie *et al.* 2004a). The snake typically inhabits small mammal burrows and other soil and/or rock crevices during the colder months of winter (*i.e.*, October to April) (Hansen and Brode 1993; Wylie *et al.* 1995; Wylie *et al.* 2003a), and also uses burrows as refuge from extreme heat during its active period (Wylie *et al.* 1997; Wylie *et al.* 2004a). While individuals usually remain in close proximity to wetland habitats, the Biological Resource Division of the U.S. Geological Survey (BRD) has documented snakes using burrows as much as 165 feet (50 meters) away from the marsh edge to escape extreme heat, and as far as 820 feet (250 meters) from the edge of marsh habitat for over-wintering habitat (Wylie *et al.* 1997). Giant garter snakes have been observed tens to hundreds of meters distant from any water body in various types of habitat. Upland habitat is essential for snakes because it provides overwintering hibernacula and areas for which snakes to thermoregulate (regulate their body temperature), and small mammal burrows which are used by snakes for ecdysis (shedding of the skin). Upland habitat may be particularly important for neonates (newly born) giant garter snakes, which may

use the uplands more frequently than adults, possibly seeking terrestrial prey, such as earthworms or other insects.

In studies of marked snakes in the Natomas Basin, snakes moved about 0.25 to 0.5 miles (0.4 to 0.8 kilometers) per day (Hansen and Brode 1993). Total activity, however, varies widely between individuals; individual snakes have been documented to move up to 5 miles (8 kilometers) over a few days in response to dewatering of habitat (Wylie *et al.* 1997) and to use up to more than 8 miles (12.9 kilometers) of linear aquatic habitat over the course of a few months. Home range (area of daily activity) averages about 0.1 mile^2 (25 hectares) in both the Natomas Basin and the Colusa National Wildlife Refuge (NWR) (Wylie 1998a; Wylie *et al.* 2002), yet can be as large as 14.5 miles^2 (3744 hectares) (Wylie and Martin 2004).

Rice fields have become important habitat for giant garter snakes, particularly associated canals and their banks for both spring and summer active behavior and winter hibernation (Hansen 2004; Wylie 1998b). While within the rice fields, snakes forage in the shallow water for prey, utilizing rice plants and vegetated berms dividing rice checks for shelter and basking sites (Hansen and Brode 1993). In the Natomas Basin, habitat used consisted almost entirely of irrigation ditches and established rice fields (Wylie 1998a; Wylie *et al.* 2004b), while in the Colusa NWR, snakes were regularly found on or near edges of wetlands and ditches with vegetative cover (Wylie *et al.* 2003a). Telemetry studies also indicate that active snakes use uplands extensively, particularly where vegetative cover exceeds 50 percent in the area (Wylie 1998b).

Predators. Giant garter snakes are killed and/or eaten by a variety of predators, including raccoons (*Procyon lotor*), striped skunks (*Mephitis mephitis*), opossums (*Didelphis virginiansa*), bull frogs (*Rana catesbiana*), hawks (*Buteo* sp.), egrets (*Casmerodius albus, Egretta thula*), river otters (*Ludra canadensis),* and great blue herons (*Ardea herodias*) (Dickert 2003; Wylie *et al.* 2003c; G. Wylie pers. comm. 2006). Many areas supporting snakes have been documented to have abundant predators; however, predation does not seem to be a limiting factor in areas that provide abundant cover, high concentrations of prey items, and connectivity to a permanent water source (Hansen and Brode 1993; Wylie *et al.* 1995).

Reasons for Decline and Threats to Survival. The current distribution and abundance of the giant garter snake is much reduced from former times (Service 1999a). Prior to reclamation activities beginning in the mid- to late-1800s, about 60 percent of the Sacramento Valley was subject to seasonal overflow flooding providing expansive areas of snake habitat (Hinds 1952). Now, less than 10 percent, or approximately 319,000 acres (129,000 hectares), of the historic 4.5 million acres (1.8 million hectares) of Central Valley wetlands remain (U.S. Department of Interior 1994), of which very little provides habitat suitable for the giant garter snake. Loss of habitat due to agricultural activities and flood control have extirpated the snake from the southern one-third of its range in former wetlands associated with the historic Buena Vista, Tulare, and Kern lakebeds (Hansen 1980; Hansen and Brode 1980).

Valley flood wetlands are now subject to cumulative effects of upstream watershed modifications, water storage and diversion projects, as well as urban and agricultural development. The Central Valley Project (CVP), the largest water management system in California, created an ecosystem altered to such an extent that remaining wetlands depend on highly managed water regimes (U.S. Department of Interior 1994). Further, the implementation of CVP has resulted in conversion of native habitats to agriculture, and has facilitated urban development through the Central Valley (Service 1999a). For instance, residential and commercial growth with the Central Valley is consuming an estimated 15,000 acres of Central Valley farmland each year (American Farmland Trust 1999), with a project loss of more than one million acres by the year 2040 (USGS 2003). Environmental impacts associated with urbanization include loss of biodiversity and habitat, alternation of natural fire regimes, fragmentation of habitat from road construction, and degradation due to pollutants. Further, encroaching urbanization can inhibit rice cultivation (J. Roberts pers. comm. 2006). Rapidly expanding cities within the snake's range include Chico, Yuba City, the Sacramento area, Galt, Stockton, Gustine, and Los Banos.

Ongoing maintenance of aquatic habitats for flood control and agricultural purposes eliminates or prevents the establishment of habitat characteristics required by snakes (Hansen 1988). Such practices can fragment and isolate available habitat, prevent dispersal of snakes among habitat units, and adversely affect the availability of the snake's food items (Hansen 1988; Brode and Hansen 1992). For example, tilling, grading, harvesting and mowing may kill or injure giant garter snakes (Wylie *et al.* 1997). Biocides applied to control aquatic vegetation reduce cover for the snake and may harm prey species (Wylie *et al.* 1995). Rodent control threatens the snake's upland estivation habitat (Wylie *et al.* 1995; Wylie *et al.* 2004a). Restriction of suitable habitat to water canals bordered by roadways and levee tops renders snakes vulnerable to vehicular mortality (Wylie *et al.* 1997). Rolled erosion control products, which are frequently used as temporary berms to control and collect soil eroding from constriction sites, can entangle and kill snakes (Stuart *et al.* 2001; Barton and Kinkead 2005). Livestock grazing along the edges of water sources degrades water quality and can contribute to the elimination and reduction of available quality snake habitat (Hansen 1988; E. Hansen, pers. comm. 2006), and giant garter snakes have been observed to avoid areas that are grazed (Hansen 2003). Fluctuation in rice and agricultural production affects stability and availability of habitat (Paquine *et al.* 2006; Wylie and Casazza 2001; Wylie *et al.* 2003b, 2004b).

Other land use practices also currently threaten the survival of the snake. Recreational activities, such as fishing, may disturb snakes and disrupt thermoregulation and foraging activities (E. Hansen pers. comm. 2006). While large areas of seemingly suitable snake habitat exist in the form of duck clubs and waterfowl management areas, water management of these areas typically does not provide the summer water needed by the species (Beam and Menges 1997; Dickert 2005; Paquin *et al.* 2006).

Nonnative predators, including introduced predatory game fish, bullfrogs, and domestic cats, can threaten snake populations (Dickert 2003; Hansen 1986; Service 1993; Wylie *et al.* 1995; Wylie *et al.* 2003c). Nonnative competitors, such as the introduced water snake (*Nerodia fasciata*) in

the American River and associated tributaries near Folsom, may also threaten the giant garter snake (Stitt *et al.* 2005).

The disappearance of giant garter snakes from much of the west side of the San Joaquin Valley was approximately contemporaneous with the expansion of subsurface drainage systems in this area, providing circumstantial evidence that the resulting contamination of ditches and sloughs with drainwater constituents (principally selenium) may have contributed to the demise of giant garter snake populations. Dietary uptake is the principle route of toxic exposure to selenium in wildlife, including giant garter snakes (Beckon *et al.* 2003). Many open ditches in the northern San Joaquin Valley carry subsurface drainwater with elevated concentrations of selenium, and green sunfish (*Lepomis cyanellus*) have been found to have concentrations of selenium within the range of concentrations associated with adverse affects on predator aquatic reptiles (Hopkins *et al.* 2002; Saiki 1998). Studies on the effects of selenium on snakes suggest that snakes with high selenium loads in their internal organs can transfer potentially toxic quantities of selenium to their eggs (Hopkins *et al.* 2004) and also demonstrate higher rates of metabolic activity than uncontaminated snakes (Hopkins *et al.* 1999).

Status with Respect to Recovery. The draft recovery plan for the giant garter snake subdivides its range into four proposed recovery units (Service 1999a): (1) Sacramento Valley Recovery Unit; (2) Mid-Valley Recovery Unit; (3) San Joaquin Valley Recovery Unit; and (4) South Valley Recovery Unit.

The Sacramento Valley Unit at the northern end of the species' range contains sub-populations in the Butte Basin, Colusa Basin, and Sutter Basin (Service 1999a; Service 2006). Protected snake habitat is located on State refuges and refuges of the Sacramento National Wildlife Refuge (NWR) Complex in the Colusa and Sutter Basins. Suitable snake habitat is also found in low gradient streams and along waterways associated with rice farming. This northernmost recovery unit is known to support relatively large, stable sub-populations of giant garter snakes (Wylie *et al.* 1995; Wylie *et al.* 1997; Wylie *et al.* 2002; Wylie *et al.* 2003a; Wylie *et al.* 2004a). Habitat corridors connecting subpopulations, however, are either not present or not protected, and are threatened by urban encroachment.

The Mid-Valley Unit includes sub-populations in the American, Yolo, and Delta Basins (Service 1999a; Service 2006). The status of Mid-Valley sub-populations is very uncertain; each is small, highly fragmented, and located on isolated patches of limited quality habitat that is increasingly threatened by urbanization (E. Hansen 2002, 2004; Service 1993; Wylie 2003; Wylie and Martin 2004; Wylie *et al.* 2004b; Wylie *et al.* 2005; G. Wylie pers. comm. 2006). The American Basin sub-population, although threatened by urban development, receives protection from the Metro Air Park and Natomas Basin Habitat Conservation Plans, which share a regional strategy to maintain a viable snake sub-population in the Natomas Basin.

The San Joaquin Valley Unit, which includes sub-populations in the San Joaquin Basin, formerly supported large snake populations, but numbers have severely declined, and recent survey efforts indicate numbers are extremely low compared to Sacramento Valley sub-populations (Dickert

2002, 2003; Hansen 1988; Williams and Wunderlich 2003; Wylie 1998a). Giant garter snakes currently occur in the northern and central San Joaquin Basin within the Grassland Wetlands of Merced County and the Mendota Wildlife Area of Fresno County; however, these sub-populations remain small, fragmented, and unstable, and are probably decreasing (Dickert 2003, 2005; G. Wylie pers. comm., 2006).

The South Valley Unit included sub-populations in the Tulare Basin, however, agricultural and flood control activities are presumed to have extirpated the snake from the Tulare Basin (Hansen 1995). Comprehensive surveys for this area are lacking and where habitat remains, the giant garter snake may be present.

Since 1995, BRD has studied snake sub-populations at the Sacramento, Delevan, and Colusa NWRs and in the Colusa Basin Drain within the Colusa Basin, at Gilsizer Slough within the Sutter Basin, at the Badger Creek area of the Cosumnes River Preserve within the Badger Creek/Willow Creek area of the Delta Basin, and in the Natomas Basin within the American Basin (Hansen 2003, 2004; Wylie 1998a, 1998b, 2003; Wylie *et al.* 1995; Wylie *et al.* 2002; Wylie *et al.* 2003a, 2004a; Wylie *et al.* 2003b, 2004b). These areas contain the largest extant giant garter snake sub-populations. Outside of protected areas, however, snakes are still subject to all threats identified in the final rule. The other sub-populations are distributed discontinuously in small, isolated patches, and are vulnerable to extirpation by stochastic environmental, demographic, and genetic processes (Goodman 1987).

The draft recovery criteria require multiple, stable sub-populations within each of the four recovery units, with sub-populations well-connected by corridors of suitable habitat. This entails that corridors of suitable habitat between existing snake sub-populations be maintained or created to enhance sub-population interchange to offset threats to the species (Service 1999a). Currently, only the Sacramento Valley Recovery Unit is known to support relatively large, stable giant garter snake populations. Habitat corridors connecting sub-populations, even in the Sacramento Valley Recovery Unit, are either not present or not protected. Overall, the future availability of habitat in the form of canals, ditches, and flooded fields are subject to market-driven crop choices, agricultural practices, and urban development, and are, thus, uncertain and unpredictable.

Environmental Baseline

American Basin. The proposed project is located within the American Basin snake population, in the Mid Valley Recovery Unit (Service 1999a). Seventy-nine CNDDB (2007) records are known from the American Basin. These records include the Natomas Basin, the Middle-American Basin just north of the Natomas Cross Canal, Rio Oso and associated tributaries, as well as other locations within the Basin.

Within the greater American Basin, the Natomas Basin is bounded on the west by the Sacramento River levee, on the north by the Natomas Cross Canal (NCC), on the east by the Natomas East Main Drainage Canal (NEMDC), and on the south by the American River levee.

The NBHCP applies to the 53,537-acre (21,666-hectare) area interior to the toes of the levees surrounding the Natomas Basin, located in the northern portion of Sacramento County and the southern portion of Sutter County. The baseline analysis done for the NBHCP found that, as of 2001, the Natomas Basin supported approximately 24,567 acres (9,942 hectares) of aquatic giant garter snake habitat. Of that, approximately 96 acres (39 hectares) are ponds and seasonally wet areas, 22,693 acres (9,184 hectares) are rice fields, and 1,778 acres (720 hectares) are canals (CH2M Hill 2002).

The BRD conducted giant garter snake studies in the Natomas Basin, including areas owned and managed by The Natomas Basin Conservancy (TNBC) (Wylie 1998a; Wylie *et al.* 2000; Wylie *et al.* 2003b, 2004b). Eric Hansen is now over-seeing these surveys (Jones and Stokes 2005). Surveys have established the presence of giant garter snakes throughout the Basin, including nearly all the TNBC properties with suitable habitat for the snake. The TNBC's marsh and rice land preserves are being managed with the goal to maintain viable sub-populations of the giant garter snake and the NBHCP's other wetland dependent species. Density estimates in the Natomas Basin range from 6 to 64 snakes per mile (4 to 40 snakes per kilometer) depending on the trapping location (Wylie *et al.* 2004b). Wylie *et al.* (2003b) suggest that TNBC properties have the potential to provide habitat to sustain snake populations in the Natomas Basin. They propose that development of giant garter snake habitat on TNBC lands should proceed as quickly as practical. In the Sacramento Valley, water is being purchased from rice growers and exported to the south. Fallowing of land appears to reduce or eliminate snake capture success in adjacent canals (Wylie *et al.* 2004b). If land fallowed by water sales increases in the Basin, the habitat managed by TNBC becomes all the more important for protecting snake sub-populations (Wylie *et al.* 2004b). Also, development projects in the southern end of the Natomas Basin will eliminate local snake sub-populations, particularly when there is no avenue of escape from construction activity (Wylie *et al.* 2003b).

Biologists funded by the Sacramento Area Flood Control Agency are conducting population dynamics studies in the Middle-American Basin, which lies north of the NCC (Hansen 2003, 2004); the Natomas Basin lies to the south of the NCC. Most giant garter snakes in the Middle-American Basin occur near the NCC and Main Canal where more rice and aquatic habitat is available. However, no snakes have been found to move within or across the NCC itself, suggesting that snakes are not moving between the middle-American Basin and the Natomas Basin. If the NCC represents a barrier to movement within the greater American Basin, then giant garter snakes may be present in two separate and genetically isolated sub-populations, requiring separate conservation and management. This type of genetic differentiation is known in giant garter snakes as revealed by regional subdivision in mitochondrial DNA haplotypes (Paquin *et al.* 2006).

The BRD has conducted studies at Gilsizer Slough, surrounding lands, and associated irrigation canals (Wylie *et al.* 1995; Wylie *et al.* 1997). Giant garter snakes were shown to use canal, marsh, and rice habitat (Wylie *et al.* 1995; Wylie *et al.* 1997). Snakes were particularly associated with irrigated canals that had thickly vegetated slopes. Fifty-five percent of telemetered snakes used rice fields at some time (Wylie *et al.* 1997). Because of few recaptures

and no clearly defined capture/recapture events, estimation of total numbers of giant garter snakes in the Gilsizer area was not possible; however, BRD speculates that numbers may be in the hundreds. Much of the Gilsizer Slough area is protected by the State. Also, 162 acres (66 hectares) of the Slough is protected as a result of mitigation for the Wild Goose Gas Pipeline and State Route 70-Algodon Road Interchange projects.

Factors Affecting the Snake within the Action Area - A number of State, local, private, and unrelated Federal actions have occurred within the action area (Natomas Basin) and adjacent region affecting the environmental baseline of the species. Some of these projects have been subject to prior section 7 consultation. These actions have resulted in both direct and indirect effects to giant garter snake habitat within the region. Projects affecting the environment in and around the action area include bridge replacements over the NEMDC and Steelhead Creek at Main Avenue, the Lower Dry Creek and Robia Creek Levee Improvement project, the Lower Northwest Interceptor project, and the North Natomas Comprehensive Drainage project.

The Sacramento International Airport has recently changed landuse of lands they own north of the west runway. Until recently, this land had been leased to local farmers and has been actively farmed in rice. The Airport has not proposed any compensation nor have they initiated consultation with the Service in order to examine the effects the loss of this rice would have on giant garter snakes within the Natomas Basin. There is a loss of at least 617 acres of active rice that served as aquatic habitat for the giant garter snake on Airport property. The Airport has decided to not renew rice leases on this land based on a November 17, 2005, letter from the FAA which listed corrective actions they required the Sacramento County Airport to complete in order to avoid legal actions from the FAA. As of December 31, 2007, all of the leases for rice on SCAS lands were terminated. At the date of this biological opinion, the FAA has not initiated section 7 consultation with the Service on the effects to giant garter snakes of their Federal action to have the Sacramento County Airport terminate the rice leases.

On-going development within the Natomas Basin also affects the snake and its habitat. In February of 2002, the Service issued an incidental take permit (ITP) to the Metro Air Park Property Owners Association (MAPPOA) for development activities associated with the implementation of the Metro Air Park Habitat Conservation Plan (MAPHCP). On June 27, 2003, the Service issued ITPs to the City of Sacramento, Sutter County, and TNBC for activities associated with the implementation of the Final NBHCP (City of Sacramento *et al.* 2003). The TNBC is the plan operator responsible for acquiring and managing habitat mitigation lands for the MAPHCP and NBHCP. The MAPHCP and NBHCP permits authorized incidental take of the giant garter snake and several other species resulting from the development of 17,500 acres (7,082 hectares) of land in the Natomas Basin; of this, approximately 8,512 acres (3,445 hectares) is suitable giant garter snake habitat (*e.g.*, ponds, canals, and rice fields) (Service 2003). A key component of the MAPHCP and NBHCP's Operating Conservation Strategy (OCS) is the acquisition of 0.5 acre (0.2 hectare) of habitat mitigation lands for every acre of land developed within the permit areas. A total of 75 percent of the mitigation lands protected under the plans will be suitable for the giant garter snake, with 50 percent in rice fields and 25 percent restored to managed marsh. Once the MAPHCP and NBHCP permit areas have been built out,

approximately 6,562 acres (2,656 hectares) of habitat will have been acquired/restored and will be actively managed for the giant garter snake, including 4,375 acres (1,771 hectares) of rice fields and 2,187.5 acres (521 hectares) of managed marsh.

As of December 31, 2006, the City of Sacramento had authorized grading on 6,785 acres (2,746 hectares) in the NBHCP permit area; Sutter County had not issued any urban development permits in the NBHCP permit area. In September of 2003, MAPPOA graded 800 acres (324 hectares) of the Metro Air Park site to prepare the site for development. Of the disturbed area, 190.4 acres (77 hectares) will be immediately developed; the remaining area will revert to agricultural use until it is eventually developed. As of December 31, 2007, no additional land has been graded at Metro Air Park. As of December 31, 2007, TNBC had acquired 4,092 acres (1,656 hectares) of lands to mitigate the impacts of these two HCPs.

The Service and CDFG consider the entire Natomas Basin as potential habitat for the snake because the lands are of generally uniform character and capable of restoration. To survive in the Basin, giant garter snakes require large blocks of wetland and adjacent upland habitat distributed throughout three population centers and connected to each other through a system of canals and other aquatic features. Brode and Hansen (1992) stated that the Basin provides the most important habitat remaining for the snake and observed that snake habitat within the Basin occurs in three large areas that are separated by major highways. Area 1 is defined as lands north of I-5 and west of State Route 99/70 (SR 99/70). Important habitat areas include Prichard Lake, the North Drain Canal, and its associated rice fields. Area 2 is defined as the lands south and west of I-5, and it's most important habitat area is Fisherman's Lake. Area 3 is defined as the lands east of I-5 and SR 99/70. The most important component of Area 3 is "Snake Alley", an area comprised of the North Main Canal and its associated rice fields and irrigation ditches on the east side of SR 99/70. The authors hypothesized that snakes could move between the three areas through large box culverts under the major highways. Brode and Hansen (1992) attributed the snake's continued success in the Basin to the numerous irrigation ditches, rice fields, and especially the extensive network of irrigation canals, feeder canals, and drains. The authors concluded by presenting a conceptual conservation plan for the snake in the Basin. This plan was based upon a minimum of one core habitat in each of the geographic areas with connecting canals to ensure snakes could move between each of the three areas. The Corps and SAFCA's proposed project is located in portions of all three areas. Much of the borrow and construction would occur within Area 1 along the Sacramento River east levee and near the North Main Canal and Area 2 adjacent to Fisherman's Lake and along the West Drainage Canal.

The continuing practice of fallowing rice fields on and around Airport property due to FAA corrective actions letter, and throughout the Natomas Basin, threatens the viability of giant garter snake populations and the effectiveness of the NBHCP OCS. Irrigated rice is important as foraging, shelter, and basking habitat for the snake. Rice may serve a particularly important role for snakes in the Natomas Basin as compared to its role as habitat in other parts of the species range. Rice, and other wetlands, adjacent to the ditches and canals may serve as vital nursery habitat for young giant garter snakes and as "way stations" for snakes as they make their way through the extensive ditch and canal system in the Natomas Basin. In particular, rice may be an

important resource for juvenile giant garter snakes by providing large amounts of cover and small prey for the juveniles to feed on late in the summer.

According to the CNDDB (2008), there are 40 records of giant garter snakes within the Natomas Basin and all of them are within 5 miles of the proposed project. Giant garter snakes have been documented on and directly adjacent to portions of the project area and within canals and ditches in the general area that are hydrologically connected with the aquatic features on the proposed project site. As described in the *Movements and Habitat Use* section of this biological opinion, snakes can travel considerable distances over the course of days and years in both aquatic and uplands habitats.

The proposed project area contains habitat components suitable for giant garter snake feeding, resting, mating, and other essential behaviors, as well as for movement corridors. Because of the biology and ecology of the giant garter snake, the presence of suitable habitat within the proposed project, and observations of the species, the Service has determined that the giant garter snake is reasonably certain to occur within the action area and be affected by the proposed project.

Valley Elderberry Longhorn Beetle

Status of the Species

Listing. The beetle was listed as a threatened species under the Act on August 8, 1980 (45 FR 52803). Critical habitat for the species was designated and published in 50 CFR §17.95. Two areas along the American River in the Sacramento metropolitan area have been designated as critical habitat for the beetle. The first area designated as critical habitat for this species is along the lower American River at River Bend (formerly Goethe) and Ancil Hoffman parks (American River Parkway Zone) and the second area is at the Sacramento Zone, an area about a half mile from the American River downstream from the American River Parkway Zone. In addition, an area along Putah Creek, Solano County, and the area west of Nimbus Dam along the American River Parkway, Sacramento County, are considered essential habitat, according to *The Valley Elderberry Longhorn Beetle Recovery Plan* (USFWS 1984). These critical habitat areas and essential habitat areas within the American River parkway and Putah Creek support large numbers of mature elderberry shrubs with extensive evidence of use by the beetle.

Life History. The elderberry shrub (*Sambucus* sp.) is the sole host plant for the valley elderberry longhorn beetle. Elderberries are locally common components of the remaining riparian forest and savannah landscapes, and to a lesser extent the mixed chaparral-foothill woodlands, of the Central Valley. The occupancy rates of the beetle are reduced in non-riparian habitats (e.g., Talley *et al.* in press), indicating that riparian elderberry habitat an important habitat type for the beetle.

Use of elderberry shrubs by the beetle, a wood borer, is rarely apparent. Frequently, the only exterior evidence of the shrub's use by the beetle is an exit hole created by the larva emerging just prior to the pupal stage. Observations of elderberry shrubs along the Cosumnes River and in the

Folsom Lake area indicate that larval beetles can be found in elderberry stems with no apparent exit holes; the larvae either succumb prior to constructing an exit hole or not developed sufficiently to construct one. Larvae appear to be distributed in stems which are 1.0 inch or greater in diameter at ground level and can occur living stems. *The Valley Elderberry Longhorn Beetle Recovery Plan* (USFWS 1984) and Barr (1991) further describe the beetle's life history.

Population Structure. The beetle is a specialist on elderberry plants, and tends to have small population sizes and occurs in low densities (Barr 1991; Collinge *et al.* 2001). It has been observed feeding upon both blue and red elderberry (USFWS 1984, Barr 1991) with stems greater than or equal to one inch in diameter (Barr 1991). Sightings of the beetle are rare and in most circumstances, evidence of the beetle is derived from the observation of the exit holes left when adults emerge from elderberry stems. The beetle tends to occur in areas with higher elderberry densities, but has lower exit hole densities than a closely related species, the California elderberry longhorn beetle (Collinge *et al.* 2001).

Distribution and Range. When the beetle was listed in 1980, the species was known from less than ten localities along the American River, the Merced River, and Putah Creek. By the time the *Valley Elderberry Longhorn Beetle Recovery Plan* was prepared in 1984, additional occupied localities had been found along the American River and Putah Creek. As of 2005, the California Range wide distribution extends from the Sacramento River in Shasta County, southward to an area along Caliente Creek in Kern County (CNDDB 2005). The CNDDB contained 190 occurrences for this species in 44 drainages throughout the Central Valley. However, the number of records should be viewed with caution as a record does not necessarily indicate a unique population. In many cases, there are multiple records within close proximity to one another within the same watershed or river. For example, 24 records are known within two miles of the American River (CNDDB 2006).

The beetle is considered a poor disperser based on the spatial distribution of occupied shrubs (Barr 1991; Collinge *et al.* 2001). Huxel and Hastings (1999) used computer simulations of colonization and extinction patterns based on differing dispersal distances, and found that the short dispersal simulations best matched the 1997 census data in terms of site occupancy. This suggests that dispersal and colonization are limited to nearby sites. At spatial scales greater than 6.2 miles, such as across drainages, beetle occupancy appears to be strongly influenced by regional extinction and colonization processes, and colonization is constrained by limited dispersal (Collinge *et al.* 2001; Huxel and Hastings 1999). Except for one occasion, drainages examined by Barr that were occupied in 1991, remained occupied in 1997 (Collinge *et al.* 2001; Huxel and Hastings 1999). The one exception was Stoney Creek, which was occupied in 1991, but not in 1997. All drainages found by Barr (1991) to be unoccupied in 1991, were also unoccupied in 1997. Collinge *et al.* (2001) further found that while the proportions of occupancy were similar, the number of sites examined containing elderberry and the density of elderberry at sites had decreased since Barr (1991), resulting in fewer occupied sites and groups. Studies suggest that the beetle is unable to re-colonize drainages where the species has been extirpated, because of its limited dispersal ability (Barr 1991; Collinge *et al.* 2001). This data suggests that drainages unoccupied by the beetle remain unoccupied.

Reasons for Decline and Threats to Survival. The beetle continues to be threatened by habitat loss and fragmentation, predation by the non-native Argentine ants (*Linepithema humile*) (Holway 1998; Huxel 2000; Huxel and Hastings 1999; Huxel *et al.* 2001; Ward 1987), and possibly other factors such as pesticide drift, non-native plant invasion, improper burning regimes, off-road vehicle use, rip-rap bank protection projects, wood cutting, and over-grazing by livestock.

Habitat Loss - Habitat destruction is one of the most significant threats to the beetle. Riparian forests, the primary habitat for the beetle, have been severely depleted throughout the Central Valley over the last two centuries as a result of expansive agricultural and urban development (Huxel *et al.* 2001; Katibah 1984; Roberts *et al.* 1977; Thompson 1961). As of 1849, the rivers and larger streams of the Central Valley were largely undisturbed. They supported continuous bands of riparian woodland four to five miles in width along some major drainages, such as the lower Sacramento River, and generally about two miles wide along the lesser streams (Thompson 1961). Most of the riverine floodplains supported riparian vegetation to about the 100-year flood line (Katibah 1984).

A large human population influx occurred after 1849, however, and much of the Central Valley riparian habitat was rapidly converted to agriculture and used as a source of wood for fuel and construction to serve a wide area (Thompson 1961). The clearing of riparian forests for fuel and construction made this land available for agriculture (Thompson 1961). Natural levees bordering the rivers, once supporting vast tracts of riparian habitat, became prime agricultural land (Thompson 1961). As agriculture expanded in the Central Valley, needs for increased water supply and flood protection spurred water development and reclamation projects. Artificial levees, river channelization, dam building, water diversion, and heavy groundwater pumping further reduced riparian habitat to small, isolated fragments (Katibah 1984). In recent decades, these riparian areas have continued to decline as a result of ongoing agricultural conversion as well and urban development and stream channelization. As of 1989, there were over 100 dams within the Central Valley drainage basin, as well as thousands of miles of water delivery canals and streambank flood control projects for irrigation, municipal and industrial water supplies, hydroelectric power, flood control, navigation, and recreation (Frayer *et al.* 1989). Riparian forests in the Central Valley have dwindled to discontinuous strips of widths currently measurable in yards rather than miles.

Some accounts state that the Sacramento Valley supported approximately 775,000 to 800,000 acres of riparian forest as of approximately 1848, just prior to statehood (Smith 1977; Katibah 1984). No comparable estimates are available for the San Joaquin Valley. Based on early soil maps, however, more than 921,000 acres of riparian habitat are believed to have been present throughout the Central Valley under pre-settlement conditions (Huxel *et al* 2001; Katibah 1984). Another source estimates that of approximately 5,000,000 acres of wetlands in the Central Valley in the 1850s, approximately 1,600,000 acres were riparian wetlands (Warner and Hendrix 1985; Frayer *et al.* 1989).

Based on a California Department of Fish and Game riparian vegetation distribution map, by 1979, there were approximately 102,000 acres of riparian vegetation remaining in the Central Valley. This represents a decline in acreage of approximately 89 percent as of 1979 (Katibah 1984). More extreme figures were given by Frayer *et al.* (1989), who reported that woody riparian forests in the Central Valley had declined to 34,600 acres by the mid-1980s (from 65,400 acres in 1939).

An even more recent analysis, completed by The Central Valley Historic Mapping Project, observed similar decreases in the amount of riparian habitat (Geographic Information Center 2003). Loss of riparian habitat between 1900 and 1990 in the Central Valley was about 96% in the southern portion of the Valley (Kern County to Fresno County) (16,000 acres remaining), 84% in the middle Valley (Merced County to San Joaquin County) (21,000 acres remaining) and 80% in the northern Valley (Sacramento and Solano counties to Shasta County) (96,000 acres remaining). Although these studies have differing findings in terms of the number of acres lost (most likely explained by differing methodologies), they attest to a dramatic historic loss of riparian habitat in the Central Valley.

Habitat Fragmentation - Destruction of riparian habitat in central California has resulted not only in a significant acreage loss, but also has resulted in beetle habitat fragmentation. Fahrig (1997) states that habitat fragmentation is only important for habitats that have suffered greater than 80 percent loss. Riparian habitat in the Central Valley, which has experienced greater than 90 percent loss by most estimates, would meet this criterion as habitat vulnerable to effects of fragmentation. Existing data suggests that beetle populations, specifically, are affected by habitat fragmentation. Barr (1991) found that small, isolated habitat remnants were less likely to be occupied by beetles than larger patches, indicating that beetle subpopulations are extirpated from small habitat fragments. Barr (1991) and Collinge *et al.* (2001) consistently found beetle exit holes occurring in clumps of elderberry bushes rather than isolated bushes, suggesting that isolated shrubs do not typically provide long-term viable habitat for this species.

Habitat fragmentation can be an important factor contributing to species declines because: (1) it divides a large population into two or more small populations that become more vulnerable to direct loss, inbreeding depression, genetic drift, and other problems associated with small populations; (2) it limits a species' potential for dispersal and colonization; and (3) it makes habitat more vulnerable to outside influences by increasing the edge:interior ratio (Primack 1998).

Small, isolated subpopulations are susceptible to extirpation from random demographic, environmental, and/or genetic events (Shaffer 1981; Lande 1988; Primack 1998). While a large area may support a single large population, the smaller subpopulations that result from habitat fragmentation may not be large enough to persist over a long time period. As a population becomes smaller, it tends to lose genetic variability through genetic drift, leading to inbreeding depression and a lack of adaptive flexibility. Smaller populations also become more vulnerable to random fluctuations in reproductive and mortality rates, and are more likely to be extirpated by random environmental factors. When a sub-population becomes extinct, habitat fragmentation

reduces the chance of recolonization from any remaining populations. The effect of habitat fragmentation likely is exacerbated by the poor dispersal abilities of the beetle (Collinge *et al* 2001; Talley 2005).

Habitat fragmentation not only isolates small populations, but also increases the interface between habitat and urban or agricultural land, increasing negative edge effects such as the invasion of non-native species (Huxel *et al.* 2001; Huxel 2000) and pesticide contamination (Barr 1991). Several edge effect-related factors may be related to the decline of the beetle.

Predation - The invasive Argentine ant (*Linepithema humile*) is a potential threat to the beetle (Huxel 2000). This ant is both an aggressive competitor and predator on native fauna that is spreading throughout riparian habitats in California and displacing assemblages of native arthropods (Ward 1987; Human and Gordon 1997; Holway 1998). The Argentine ant requires moisture and it may thrive in riparian or irrigated areas. A negative association between the presence of the ant and beetle exit holes was observed along Putah Creek in 1997 (Huxel 2000). This aggressive ant could interfere with adult mating or feeding behavior, or prey on eggs and larvae (e.g., Way *et al.* 1992). Surveys along Putah Creek found beetle presence where Argentine ants were not present or had recently colonized, but the beetle was absent from otherwise suitable sites where Argentine ants had become well-established (Huxel, in prep.). Between 1998 and 2002, the number of sites infested by the Argentine ant increased by 3 along Putah Creek and the American River (30 sites total were examined) (Huxel 2000; Holyoak and Talley 2001). The Argentine ant has been expanding its range throughout California since its introduction around 1907, especially in riparian woodlands associated with perennial streams (Holway 1998; Ward 1987). Huxel (in prep.) concluded that, given the potential for Argentine ants to spread with the aid of human activities such as movement of plant nursery stock and agricultural products, this species may come to infest most drainages in the Central Valley along the valley floor, where the beetle is found.

The beetle is also likely preyed upon by insectivorous birds, lizards, and European earwigs (*Forficularia auricularia*) (Klasson *et al.* 2005). These three predators move freely up and down elderberry stems searching for food. The European earwig is a scavenger and omnivore that was often found feeding on tethered mealworm (*Tenebrio monitor*) larvae. The earwig may be common in riparian areas and it may lay its eggs in dead elderberry shrubs. The earwig, like the Argentine ant, requires moisture and is often found in large numbers in riparian and urban areas. Earwig presence and densities tended to be highest in mitigation sites likely because of the irrigation, although this needs to be statistically tested (Klasson *et al.* 2005).

Pesticide Drift - Direct spraying with pesticides and related pesticide drift is a potentially harmful factor for the beetle. A wide range of such spraying is done to control mosquitoes, crop diseases, and undesirable plants and insects. Although there have been no studies specifically focusing on the direct and indirect effects of pesticides on the beetle, evidence suggests that the species may be adversely affected by some pesticide applications. Commonly used pesticides within the range of the beetle include insecticides, most of which are broad-spectrum and likely toxic to the beetle; herbicides, which may harm or kill its host elderberry plants; and broad-spectrum

pesticides toxic to many forms of life. The greatest pesticide use occurs in the San Joaquin Valley. Four counties in this region had the highest use: Fresno, Kern, Tulare, and San Joaquin (CDPR 2006). The peak timing of application depends on the chemical agent and other factors including the activity period of the targeted pest insects; the use of the agents may coincide with the most vulnerable period of beetle adult activity, egg-laying and initial larval exposure on the outside of elderberry stems (Talley *et al.* 2006). The California Department of Pesticide Regulation (CDPR) in 1997 listed 239 pesticide active ingredients applied in proximity to locations of beetle (same square mile per Marovich and Kishaba 1997 cited in Talley *et al.* 2006). Pesticide active ingredients sold in California have averaged on the order of 600 million pounds per year since about 1998 (CDPR 2006).

Pesticide use reported to the CDPR is only a fraction of the pesticides sold in California each year. About two-thirds of the active ingredients sold in a given year are not subject to use reporting, including home-use pesticide products. Recent studies of major rivers and streams documented that 96 percent of all fish, 100 percent of all surface water samples and 33 percent of major aquifers contained one or more pesticides at detectable levels (Gilliom 1999). Pesticides were identified as one of the 15 leading causes of impairment for streams included on the Clean Water Act section 303(d) lists of impaired waters. Because the beetle occurs primarily in riparian habitat, the contamination of rivers and streams likely has affects on this species and its habitat. Given the amount and scope of pesticide use, along with unreported household and other uses, and the proximity of agriculture to riparian vegetation in the Central Valley, it appears likely that pesticides are affecting the beetle and its elderberry habitat.

Invasive Plant Species - Invasive exotic plant species may significantly alter the habitat of the beetle. Without adequate eradication and control measures these non-native species may eliminate elderberry shrubs and other native plants. Pest plants of major importance in Central Valley riparian systems include black locust (*Robinia pseudoacacia*), giant reed (*Arundo donax*), red sesbania (*Sesbania punicea*), Himalayan blackberry (*Rubus armeniacus*), tree of heaven (*Ailanthus altissima*), Spanish broom (*Spartium junceum*), Russian olive (*Eleagnus angustifolia*), edible fig (*Ficus carica*), and Chinese tallowtree (*Sapium sebiferum*). Non-woody invasives such as ripgut brome (*Bromus diandrus*), foxtail barley (*Hordeum murinum*), *Lolium multiflorum*, and starthistle/knapweed (*Centaurea* spp.) also may impair elderberry germination or establishment, or elevate the risk of fire. Invasive plant control efforts often are limited by funding, labor, coordination with landowners, and the resilience and spread of their target plants. No rangewide assessment has been completed on the overall degree of impact of invasive plants on the beetle and its habitat. However, there are a number of local efforts to control invasive riparian plant species. For example, the American River Parkway has invasive species removal efforts by Sacramento Weed Warriors (a community stewardship project associated with the California Native Plant Society) and others, and the Cosumnes River Preserve has a group of volunteers who regularly remove exotics and restore native habitats (Talley *et al.* 2006).

Other Threats - Several other factors may threaten the beetle including fire, flooding, and over-grazing by livestock. The condition of elderberry shrubs can be adversely affected by fire, which is often common at the urban-wildland interface. Brush fires initially have a negative effect on

shrub condition and, therefore, beetle larvae through direct burning and stem die-off. A year after fire, however, surviving elderberry resprout and display rapid stem growth (Crane 1989). Fires often scarify the hard elderberry seed coat leading to germination of seedlings the following season (Crane 1989). Frequent or repeated fire, however, may kill remaining shoots, root crowns and seeds, causing elderberry to be eliminated from an area for many years since recruitment by seeds is patchy and generally slow (Crane 1989). Elderberry shrubs appeared suitable for the beetle two to six years after burning, but were often uninhabited, with the presence of old, burned exit holes suggesting pre-burn occupancy and post-burn vacancy (Talley *et al.* 2006.). The post-fire lag in occupancy is likely the result of the limited movements of the beetle. Beetle occupancy occurred six to seven years post burn and, as in the alluvial plain of the American River Parkway, is about the same within the post-burn compared with unburned areas (Talley *et al.* in press). No quantitative studies of the net effects of fire on the v beetle have been undertaken (e.g., examining beetle and elderberry through time after burns or in areas with varying burn frequencies and magnitude).

The beetle can tolerate flooding of its riparian habitat. The animal has higher occupancy rates in riparian than non-riparian habitats, and associations between the beetle and proximity to rivers were either not observed or there was a weak positive correlation with nearness to the river (Halstead and Oldham 1990; Talley 2005; Talley *et al.* in press). These findings illustrate that the beetle is not likely harmed by flooding and that higher habitat quality may be associated with rivers. In addition, if elderberry, a facultative riparian shrub, can withstand flooding, then the beetle likely will survive these events. Most floods occur during winter or early spring when the beetle is in its early life history stages, so that the effects of floods are even less likely to affect the beetle. If the shrub is exposed to prolong flooding (i.e. anoxia) and becomes severely stressed, then the beetle may be affected. The duration and magnitude of flooding at which elderberry stresses is uncertain and the levels of stress that affect the beetle is also unknown. Elderberry shrubs have adaptations that plants use to persist with flooding such as lenticels and aerenchyma, demonstrating that it is probably at least somewhat flood tolerant. Finally, if an area is flooded too frequently so that elderberry cannot survive then no beetles would be able to inhabit the area (Talley 2005).

Another potential factor in the beetle's decline is the effects of inappropriate levels of livestock grazing, which can result in destruction of entire elderberry plants and inhibition of elderberry regeneration. Cattle, sheep and goats readily forage on new elderberry growth, and goats will consume even decadent growth. Well-manicured stands of elderberries, such as occurs due to livestock grazing, have generally been shown to have a relative absence of beetles (USFWS 1984). The effects on the beetle of both grazing and exotic plant invasions are likely significantly exacerbated by the problem of habitat fragmentation of elderberries. Such fragmentation increases the edge:interior ratio of habitat patches, thereby facilitating the adverse effects of these outside influences.

Environmental Baseline

The beetle currently inhabits the Central Valley from southern Shasta County south to Kern County in the San Joaquin Valley (Barr 1991; Talley *et al.* 2006). Within this range, there are approximately 190 records of the animal, largely based on exit holes, (CNDDB 2006; Talley *et al.* 2006).

The beetle was listed as a threatened species due to the loss of its riparian habitat (USFWS 1980). Quantifying the loss of elderberry shrubs as a result of the agricultural and urban development over the past 200 years is near impossible. However, recent studies have identified plant communities that are associated with elderberry (Vaghti *et al.* submitted) and estimating loss of these communities offers insight into the loss of the beetle and its habitat. Lang *et al.* (1989) observed fewer numbers of elderberry shrubs in the lower reach (i.e., between Sacramento and Colusa) of the Sacramento River than the northern reach (i.e., Chico to Red Bluff). They attributed this difference to the loss of elderberry shrubs and riparian habitat in the southern reach of the Sacramento River as a result of extensive flood control activities such as the construction and maintenance of levees. The Central Valley Historic Mapping Project (Geographic Information Center 2003) observed similar decreases in the amount of riparian habitat. Loss of riparian habitat between 1900 and 1990 in the Central Valley was about 96% in the southern portion of the Valley (Kern County to Fresno County) (16,000 acres remaining), 84% in the middle Valley (Merced County to San Joaquin County) (21,000 acres remaining) and 80% in the northern Valley (Sacramento and Solano counties to Shasta County) (96,000 acres remaining).

In addition to the riparian habitat loss described by Lang *et al.* (1989), both the number of sites with elderberry shrubs and the density of elderberry within sites decreased between studies of the same areas in 1991 and 1997 which resulted in a lower number of occupied sites and shrub groups (Barr 1991; Collinge *et al.* 2001). Holyoak and Talley (2001) investigated natural recruitment and mortality rates of elderberry at seven sites along Putah Creek and the American River that had been previously sampled by Collinge *et al.* (2001). They observed that mortality and recruitment rates were similar between the two areas, illustrating that elderberry shrubs likely replace themselves in these relatively undisturbed areas.

In the northern portion of the beetle's range along the Sacramento River and 13 of its tributaries (including lands in Butte, Placer, Sacramento, Shasta, Sutter, Tehama, Yolo and Yuba counties), the beetle occurs in drainages that function as distinct, relatively isolated metapopulations (Collinge *et al.* 2001). Half of the 14 drainages in the Sacramento Valley surveyed by Barr (1991) in 1991 and again by Collinge *et al.* (2001) in 1997 remained unoccupied in both studies. The beetle experienced extirpation in two drainages and neither were recolonized. Collinge *et al.* (2001) concluded that because of dispersal limitations, unoccupied drainages were likely to remain unoccupied and those where the resident beetle population became extirpated were not likely to be recolonized. One of the implications of their results for conservation was that there is little chance that natural populations would recover following declines (Collinge *et al.* 2001).

The increase in the amount of riparian habitat through restoration and compensation efforts is valuable, but remains small in comparison to estimated historic losses of the habitat. Approximately 50,000 acres of existing riparian habitat has been protected in the Sacramento and San Joaquin Valley since 1980. In addition, approximately 5,000 acres of habitat has been restored for the benefit of the beetle (including planting of elderberries) and another 1,600 acres of riparian habitat has been restored however, no elderberry plantings were included (Talley *et al.* 2006). An undetermined amount of additional habitat has been restored as a result of compensation for section 7 projects. Despite the efforts of a number of agencies and organizations, the 5,000 acres of restoration activities is less than 1 percent of the estimated 890,000 acres of the historic riparian habitat lost in the Central Valley. Loss of the beetle and its habitat continues, including conversion of agricultural lands, urban development and other activities that are often unreported. The ability of restoration and enhancement of conservation sites to fully compensate for adverse effects to the animal and its lost remnant natural habitat, is uncertain (Holyoak *et al.* in press).

Evidence of the beetle, in the form of exit holes, have been found within some of the elderberry shrubs which would be transplanted as part of work under Phase 2. Additionally, evidence of valley elderberry longhorn beetles was documented in the California Natural Diversity Database 2008, along the Sacramento River in the southern portion of the Natomas Basin. The action area contains components that can be used by the listed animal for feeding, resting, mating, and other essential behaviors. Therefore, the Service believes that the valley elderberry longhorn beetle is reasonably certain to occur within the action area because of the biology and ecology of the animal, the presence of suitable habitat in and adjacent to the action area, as well as recent observations of this listed species.

Effects of the Proposed Action

Giant garter snake

Direct Effects

Overall Project

Land use changes due to SAFCA's project include the permanent loss of up to 299.65 acres of row and field crop, 78.48 acres of fallow agricultural fields (some of which was previously active rice), 45.03 acres of orchard, 127.98 acres of rice, and 30.37 acres of open water and other non-canal wetlands. The project includes a gain of 89.11 acres of woodland, 356.12 acres of grassland, 72.98 acres of managed marsh, and 65.88 acres of canals.

Depending on how the grasslands are managed, the conversion of row crop and fallow agricultural fields to grassland could be beneficial to giant garter snakes. Agricultural areas typically have high levels of disturbance due to crop maintenance and harvesting activities. Mortality of snakes by farm equipment would be highly likely. Fallow agricultural fields may lack adequate cover for snakes and increase the risk of predation. Some of the grassland would

be created on the slopes of the new levees and berms. While these grasslands would be subject to greater human disturbance than non-levee grasslands, due to maintenance requirements from the Corps, they would still suffer less disturbance than an active agricultural field. Flood control structures need to allow easy visual inspection from the top of the levee during the spring and fall. While RDs have varying ways of complying with this requirement, SAFCA is proposing to have RD 1000 mow levee slopes to a height which would allow for visual inspection but also be high enough to reduce the chance of coming into contact with a snake. The Corps also requires that the levee slopes receive rodent control measures to keep ground burrowing mammals from burrowing into the sides of the levee. This could include grouting ground squirrel holes closed, which would remove potential hibernacula for giant garter snakes in the winter months to using a rodenticide which would lessen the number of ground squirrels in the area.

Giant garter snakes are not typically found in orchards because of the high amount of overstory cover, therefore there would be a benefit to giant garter snake due to the loss of 45.03 acres of orchard habitat. However, SAFCA proposes to create an additional 89.11 acres of woodland to compensate for effects to Swainson's hawk nesting trees. It is not expected that giant garter snakes will use dense woodland areas. Therefore, this represents a net loss of 44.08 acres of habitat that is not expected to be used by giant garter snakes.

Because of the project, 72.98 acres of rice would be permanently converted to an upland habitat type. The SAFCA has proposed to compensate for the loss of rice by creating 70 acres of managed marsh on 55 acres of existing rice fields and 15 acres of annual grassland near Fisherman's Lake. Overall there would be a loss of 127.98 acres of rice from the Natomas Basin. Additionally, there will be a temporary loss of rice within the Natomas Basin due to borrow excavation from the Brookfield site. A total of 353 acres of rice would be unavailable for giant garter snakes in the Natomas Basin for one year due to borrow activities. The loss of rice reduces the amount and availability of habitat, including summer water, for the snake. Due to the large amount of rice that has been fallowed in the Natomas Basin (37 percent loss of active rice between 2004 and 2007), any additional loss of rice, even for 1 season, has a direct effect on giant garter snakes. Flooded rice fields act as seasonal marshes and produce high numbers of tadpoles, frogs and mosquitofish. Effects associated with reduced available summer water in the form of rice field habitat also include displacement of individual giant garter snakes from familiar habitat areas and result in giant garter snakes foraging over a wider area. Giant garter snakes may move to other areas of suitable habitat, but will encounter increased mortality from vehicles, exposure to temperature extremes, predation, and human disturbance while migrating to new areas. Migrating snakes or snakes using a larger foraging area may displace resident snakes or compete for food and shelter resources with resident snakes, resulting in reduced survivorship and fecundity of both resident and immigrant snakes.

Adverse effects from the reduction of rice fields may be greatest for gravid females, juveniles, and neonate snakes. Gravid females spend significant time basking in mid to late summer while incubating young, and thus may have reduced survivorship or fecundity if displaced from familiar retreats and basking sites (giant garter snakes are live bearers and contribute significant resources to brooding offspring). Abundant food resources are also essential for females to both

recover body mass after giving birth and to survive the overwintering period when the snakes do not forage. Abundant food resources are also essential to the survival of juveniles and neonates. Giant garter snakes typically double their weight in the first year, with rapid growth likely necessary to reach a size class no longer susceptible to predation by non-native predatory fish and bullfrogs. The reduced availability of rice fields will result in less small prey for young snakes, which would inhibit growth, result in delayed sexual maturation and decreased births and recruitment of individuals into the population. This could potentially skew the age structure of the population to older giant garter snakes. Juveniles and neonates also rely on developing sufficient body mass prior to overwintering in order to survive long periods without foraging. Temporary or permanent loss of rice fields will not only remove habitat, but will also have adverse effects on reproduction, recruitment, and survival of the snake that will continue to affect giant garter snake populations well beyond the project time frame.

To offset the effects of the permanent loss of 127.98 acres of rice and the temporary effects to 356 acres of rice in the basin, SAFCA proposes to create 72.98 acres of managed marsh and permanently protect 175 acres of rice. Managed marsh has the capability to provide higher quality habitat for giant garter snakes because the habitat is available for the snake year round, will be subject to less human disturbance from farming activities, protected in perpetuity with a Conservation Easement, and will hold water for longer periods of time than a rice field typically does. Providing protection in perpetuity in the form of a Conservation Easement on 175 acres of rice fields would also benefit the snake because the rice farming at this site would be managed by TNBC and would assure more "snake-friendly" rice habitat than a typical rice field.

SAFCA proposes to affect 14 acres of irrigation and drainage canals that are vitally important for giant garter snakes both for foraging and movement within the basin. The loss of a canal within the basin even for a single season could have a large detrimental effect to giant garter snakes and their ability to access areas within the Natomas Basin for foraging and cover. To minimize any temporal effects of filling irrigation and drainage ditches, SAFCA has proposed to construct the replacement irrigation canals and GGS/Drainage Canal before most of the fill of existing ditches and canals occurs, providing some time for habitat development before the loss. In some cases these canals would be created a full year in advance of filling existing canals. Additionally, SAFCA has proposed to create better aquatic canal habitat for giant garter snakes by assuring that the new GGS/Drainage Canal would have a minimum water depth of 4.5 feet between April and October, which is the active season for the giant garter snake. This reliable water supply will provide a corridor between TNBC reserves in the Fisherman's Lake area and reserves along the North Drainage Canal in the northwestern portion of the Natomas Basin. About 31.24 acres of giant garter snake canal and 38.43 acres of irrigation canal would be created with this project. An integral part of the GGS/Drainiage Canal is 10.21 acres of the benches that would be created intermittently along the canal. These benches would be inundated in the summer months and allow for the growth of vegetation which would provide both cover and a food source for giant garter snakes. While the canal itself provides connectivity between two core areas for giant garter snakes, the benches along the canal would provide the food source, cover, and potential nursery grounds for snakes as they travel between the two areas.

SAFCA proposes to purchase long-term water contracts from NCMWC to provide water for both the managed marsh and GGS/Drainage Canal. While the Service expects the GGS/Drainage Canal to provide benefits to giant garter snakes in the Natomas Basin by providing connectivity and offsetting the effects of their project, there is some concern regarding the long term protection of the canal because the project description does not provide a Conservation Easement on this feature. The SAFCA has assured the Service that it can provide the necessary protection through another type of easement for the giant garter snake and the Service is willing to work with SAFCA to create the language for the easement that satisfies all of the interested parties. However, it is the Service's preference that a Conservation Easement be placed on this feature and if agreement cannot be reached on the language of the easement, than the Service will have to reanalyze their effects and the GGS/Drainage Canal would be viewed as a minimization measure for their effects not a compensation measure.

Phase 2 Construction

Phase 2 construction includes work along the NCC and reaches 1-4B along the Sacramento River east levee. The Corps and SAFCA have proposed to complete the majority of the work during the active season of the giant garter snake (May 1 to October 1). Construction during this time would occur in 61.1 acres of developed land, 139.6 acres of annual grassland, 645.5 acres of row and field crop and fallow agriculture, 1.5 acres of orchard, 185 acres of rice (25 would be a permanent effect, 160 acres would be a temporary effect), 2 acres of canals and ditches, 22 acres of open water and other non-canal wetlands, and 10.3 acres of woodland. At the end of the construction season the proposed land cover types will be 53.5 acres of developed land, 30 acres of created woodland, 15.85 acres of preserved woodland, 168 acres of levee slope grassland, 123 acres of grassland on seepage berms and canal embankments, 19 acres of irrigation canal, 13.5 acres of GGS/Drainage Canal, and 175 acres of preserved rice. The newly created cover-types with the project would protected from future development through either a flood control easement, conservation easement, or drainage easement.

Phase 2 construction would primarily occur between May 1 and October 1. The only components of Phase 2 work which would occur outside of the giant garter snake's active season would be relocation of power poles, relocation of private irrigation pipelines, canals, and wells, and the removal, transplantation, and/or planting of trees and elderberry shrubs that are located in the Phase 2 footprint. To reduce the likelihood of disturbing or killing a giant garter snake that may be overwintering in uplands that would be affected this winter, SAFCA has proposed to erect exclusionary fencing around the areas where they would be working prior to October 1. This fence would be monitored daily prior to and during construction to insure that there are no breaches that a snake could get through. This should remove the chance that project construction would kill giant garter snakes when they are working in the winter months.

The remainder of the project would be constructed during the active period (May 1 – October 1) for the snake, resulting in a decreased risk of direct mortality of snakes. However, given the number of acres of aquatic and upland giant garter snake habitat affected within Phase 2, it is highly likely effects to snakes would include removal of cover and basking sites, filling or crushing of burrows or crevices, obstructing snake movement, and decreasing the prey base, and

may result in the direct disturbance, displacement, injury, and/or mortality of snakes. Snakes may disperse across or may bask on existing roads, and thus may be killed or injured by construction equipment or other vehicles accessing the project site.

Compensation for the loss of rice in Phase 2 would occur during Phase 4 with the creation of 72.98 acres of managed marsh along the western boundary of Fisherman's Lake. The creation of managed marsh at this location would connect to existing TNBC Preserve lands which currently are in managed marsh which would enlarge a core area for giant garter snakes in the Natomas Basin. While the Service recognizes the benefit of enlarging managed marsh within the Fisherman's Lake area, there would be a temporal loss of aquatic habitat for giant garter snake between when rice is converted to upland in Phase 2 and when marsh is created in Phase 4. If for some reason the Corps and SAFCA either do not complete all the project phases or do not provide the 72.98 acres of managed marsh in 2011, then they would have to reinitiate consultation with the Service as outlined on page 79 of this biological opinion.

Within the construction of Phase 2, SAFCA has proposed to create canal habitat in advance of canal that would be filled in Phase 3. This helps to offset effects due to the filling of canal which would be a loss of aquatic habitat for snakes, by allowing the new canals to become established in advance and also allow vegetation to begin to grow along the banks, which would provide cover from predation for the giant garter snake.

Valley Elderberry Longhorn Beetle

Effects to the valley elderberry longhorn beetle may occur with the transplantation of elderberry shrubs outside of the footprint of the levee enlargement. Loss of an elderberry shrub or even a stem can result in direct mortality of valley elderberry longhorn beetles or affect valley elderberry longhorn breeding and feeding because adult beetles rely solely on elderberry flowers for food and must lay their eggs on elderberry stems to successfully reproduce.

All three phases of the project have potential to affect about 40 elderberry shrubs through transplantation. This action will adversely affect the valley elderberry longhorn beetle. Any beetle larvae occupying these plants are likely to be killed when the plants are removed. An additional number of elderberry shrubs would remain where they currently are however, construction work would occur within 100 feet but no closer than 20 feet from the dripline of an elderberry shrub.

Temporal loss of habitat will occur. Although mitigation for impacts on the beetle involve creation or restoration of habitat, it generally takes five or more years for elderberry plants to become large enough to support beetles, and it generally takes 25 years or longer for riparian habitats to reach their full value (USFWS 1994). Temporal loss of habitat will temporarily reduce the amount of habitat available to beetles and may cause fragmentation of habitat and isolation of subpopulations. In cases where the proposed project will reduce the canopy closure of riparian forests, an edge effect is created that could result in reduced habitat quality for the

beetles. Beetles disperse poorly and the systematic removal of elderberry shrubs from a relatively connected river corridor has adverse effects well outside of the project's footprint.

Proposed avoidance and minimization measures should minimize adverse effects resulting from elderberry stem trimming or elderberry transplantation.

Effects of Phase 2 Construction to Valley Elderberry Longhorn Beetle

Table 3 lists the elderberry shrub stem counts and sizes which would be transplanted as part of the Phase 2 construction. Effects to the valley elderberry longhorn beetle due to transplantation of these shrubs are described above. Elderberry shrubs would be transplanted and elderberry seedlings and associated natives would be planted at one of the following properties: Rio Ramaza, Cummings, or Lasuevic.

Table 3. Elderberry Stem Sizes and Compensation

Location	Stems (maximum diameter at ground level)	Exit Hole on Shrub (Yes or No)	Elderberry Seedling Ratio	Associated Native Plant Ratio	Number of Stems Observed	Required Elderberry Plantings	Required Associated Native Plant Plantings
Riparian	stems ≥1" & ≤3"	No	2:1	1:1	33	66	66
		Yes	4:1	2:1	57	228	456
Riparian	stems > 3" & <5"	No	3:1	1:1	16	48	48
		Yes	6:1	2:1	13	78	156
Riparian	stems > 5"	No	4:1	1:1	16	64	64
		Yes	8:1	2:1	16	128	256
Non-riparian	stems ≥1" & ≤3"	No	1:1	1:1	23	23	23
		Yes	2:1	2:1	5	10	20
Non-riparian	stems > 3" & <5"	No	2:1	1:1	8	16	16

Total replacement plantings						681	1,139
Total Elderberry shrubs to be transplanted						23	
1,820 /10 = 182 valley elderberry longhorn beetle credits or 7.52 acres							

Cumulative Effects

Cumulative effects include the effects of future State, Tribal, local, or private actions affecting listed species that are reasonably certain to occur in the area considered in this biological opinion. Future Federal actions not related to this proposed action are not considered in determining the cumulative effects, but are subject to separate consultation requirements pursuant to section 7 of the Act.

The effectiveness of the NBHCP's Operating Conservation Strategy (OCS) relies on the City of Sacramento and Sutter County limiting development to a combined total of 15, 517 acres within their respective permit areas. The proposed project site is located outside the permitted development area, and SAFCA is not a permittee under the NBHCP; however, the plan assumes no significant new development in the basin outside of the City of Sacramento and Sutter County permit areas. The NBHCP outlines a carefully constructed OCS that balances reasonable development in the Basin with conservation of snake habitat in order to maintain a viable population of giant garter snakes in the basin and avoid jeopardy to this threatened species. The NBHCP and MAPHCP allow for urban development of certain areas (totaling up to 17,500 acres) in the Basin in return for the preservation of, and in some cases, restoration and management of 8,725 acres, in an interconnected preserve system, which when added to the baseline of agricultural and undeveloped lands in the basin, will conserve the Natomas Basin snake population. While the proposed project does not increase the number of developed acres beyond the 17,500 contemplated under the NBHCP and MAPHCP, it does change (in some cases, permanently) habitat types from one type to another. Loss of habitat which the 22 covered species of the NBHCPs may use include 299.65 acres of row and field crop, 78 acres of fallow fields, 45.03 acres of orchard, and 30.37 acres of open water and other non-canal wetlands. Increases in the following habitat types would occur with the project: 89.11 acres of woodland, 356.12 acres of grassland, 72.98 acres of managed marsh, and 65.88 acres of canal. While there would be a change in habitat types within the basin, the NBHCP covered species would still be able to use the habitats that SAFCA's project would be creating and development would be precluded from these areas through conservation easements, flood control easements, and drainage easements.

While SAFCA is not a signatory to the NBHCP, the plan sets forth a regional conservation strategy that covers the entire basin. The NBHCP's efficacy in maintaining a viable population of giant garter snake in the Basin depends, in significant part, on the retention of a sufficient amount of undeveloped acreage throughout the Basin, to support giant garter snake.[1] The NBHCP operates under the assumption that agricultural land in the Basin would continuously rotate between crop types, and therefore all land provides habitat for all 22 of the NBHCP covered species, including the giant garter snake.

---

1 In NWF v. Norton, 2005 U.S. Dist LEXIS 33768, Judge Levi upheld the NBHCP and its strategy to protect the GGS in the Natomas Basin. However, in footnote 13 of the opinion, he cautioned that, "the Service and those seeking an ITP in the future will face an uphill battle if they attempt to argue that additional development in the basin beyond the 17,500 acres will not result in jeopardy" to the snake.

SAFCA's proposed project will directly affect existing land that has been preserved as mitigation for either the NBHCP or MAPHCP. During Phase 2 of the project, 1.63 acres of fallow row and grain crop would be affected at the Atkinson Preserve and 4.09 acres of alfalfa and 5.72 acres of wheat would be affected at the Huffman West Preserve. During Phase 4 of the project, 1.98 acres of alfalfa, 0.05 acre of developed, 0.83 acre of ruderal, and 0.48 acre of valley oak woodland would be affected at the Alleghany 50 Preserve and 0.044 acre of valley oak woodland and 0.00034 acre of riparian scrub would be affected at the Cummings Preserve. These areas would be replaced with levee slope covered in grassland. As provided for in the NBHCP (IV.C.2.c.(1)) SAFCA shall "pay for the value of replacing every acre of reserve land impacted." To accomplish this SAFCA has proposed to acquire existing TNBC land not currently dedicated to mitigation to offset acre-per-acre losses. This existing TNBC land would consist of rice, not the upland habitat types affected. The SAFCA will fund the perpetual maintenance, monitoring, and enhancement of these preserves for the benefit of the covered species. Because this land is currently and will be maintained in rice, this will benefit the giant garter snake.

The proposed project would positively affect the biological connectivity between and within two of the Basin's three major geographical areas and TNBC's preserve lands. The GGS/Drainage Canal that SAFCA proposes to construct would provide connectivity between the population of snakes and the TNBC preserves around Fisherman's Lake with the population of snakes and TNBC preserves in the northwest portion of the Natomas Basin near the North Drainage Canal. The SAFCA would provide guaranteed water in the canal between April and October, which would create aquatic connectivity. In an effort to increase the habitat quality of the corridor, SAFCA will create benches along the canal, which would be shallowly inundated in the summer months to provide a prey base support emergent marsh vegetation which would provide cover for the giant garter snake. The SAFCA proposes to manage this canal in perpetuity for the giant garter snake, and proposes to encumber the canal with an easement in which the conservation values prevail over drainage values. The SAFCA's plan to construct this canal would benefit connectivity and strengthen the success of the NBHCP.

In December 2008, FEMA will issue a new flood map for the Natomas Basin. This would place all of Natomas into the AE zone, which would require that builders place the bottom floor of new construction up to 20 feet above ground level to keep it out of the floodplain. This would effectively stop new construction in Natomas. While not directly growth-facilitating, the proposed project would serve planned and reasonably foreseeable growth by providing flood protection to the Natomas Basin which is currently an impediment to future growth (planned or otherwise) in the Natomas Basin. It is likely that some of the growth (commercial, municipal, and residential) in the Natomas Basin will not require section 7 consultation with the Service for compliance with the Act, and will not obtain take coverage pursuant to section 10 of the Act. Currently, the NBHCP and the East Contra Costa HCP are the only two permitted regional HCPs in the Sacramento area, although Placer, Yolo, South Sacramento, Yuba, and Sutter are all developing regional HCPs. Until these regional HCPs are finalized, there is no mechanism to provide "take" coverage for projects with no Federal nexus besides these projects pursuing their own individual HCPs. Some "take" of listed species is likely to occur for which no

minimization, avoidance, and compensation/mitigation measures for federally-listed species are implemented.

SAFCA, the Corps, the city of Sacramento, Sacramento County, and Sutter County should understand that future development within the Natomas Basin could negatively affect the NBHCP and MAPHCP and potentially jeopardize the giant garter snake in the Natomas Basin. Any additional "take" of listed species outside what has been analyzed in this biological opinion or the NBHCP and MAPHCP cannot occur without appropriate permits or consultations with the Service and CDFG.

The cumulative effects of reasonable foreseeable projects in the Natomas Basin may pose a significant threat to the eventual recovery of the giant garter snake. The following proposed projects could significantly affect the sustainability of giant garter snakes in the Natomas Basin when considered cumulatively with the proposed Natomas Levee Improvement Project:

- The proposed Greenbriar residential development is located on an approximately 577-acre site south of Elkhorn Boulevard and west of State Highway 99. Development on this site could result in the loss of giant garter snake habitat adjacent to Lone Tree Canal, depending on the configuration of houses and infrastructure.
- Natomas Joint Vision, as currently proposed by the City of Sacramento and Sacramento County, is to develop approximately 6,000 acres in the area of the County outside of the City's permitted area under the NBHCP.
- Sacramento International Airport's Master Plan would enlarge the airport on land currently owned by the airport and would occur through 2020. Much of the land slated for airport expansion is currently in agricultural production.

Other projects which are reasonably foreseeable and should be considered cumulative with the proposed project, but for which the Service has little to no information about the extent of their effects to giant garter snakes, include:

- Camino Norte
- Downtown Natomas Airport Light Rail
- Pacific Gas & Electric Line 406/407 Pipeline
- Sacramento Municipal Utility District Powerline – Elkhorn Substation
- Sutter Pointe Specific Plan

Conclusion

After reviewing the current status of the giant garter snake and valley elderberry longhorn beetle, the environmental baseline for the species, the effects of the proposed project, and the cumulative effects on this species, it is the Service's biological opinion that the proposed Natomas Landside Improvements Project, as described herein, is not likely to jeopardize the continued existence of

the giant garter snake or valley elderberry longhorn beetle. The project will not result in a net destruction or adverse modification of valley elderberry longhorn critical habitat.

The Corps and SAFCA have proposed to improve flood protection for the Natomas Basin above what currently exists. Two HCPs currently exist within the Natomas Basin and are based on future development occurring within the permit area of the MAPHCP and NBHCP. The baselines and assumptions for which these HCPs were developed were based on no additional development occurring within the basin outside of these permit areas and no change in landuse practices. Sacramento County and the City of Sacramento are already proposing additional development outside of the existing permit areas. Additionally, the Natomas Basin has experienced a large amount of rice fallowing both in land held by private farmers and leases terminated on Sacramento County Airport property. While the Service has concluded that SAFCA's project would not jeopardize the giant garter snake or valley elderberry longhorn beetle, it does facilitate growth within the Natomas Basin, which would require additional analysis to determine if this growth could jeopardize any of the 22 species covered by the MAPHCP and NBHCP. If growth outside of the permit areas were to occur within the Natomas Basin, these future projects must have a higher conservation outcome than currently exists in the HCPs and must be closely coordinated with the Service.

INCIDENTAL TAKE STATEMENT FOR PHASE 2 CONSTRUCTION

Section 9 of the Act and Federal regulation pursuant to section 4(d) of the Act prohibit the take of endangered and threatened species, respectively, without special exemption. Take is defined as harass, harm, pursue, hunt, shoot, wound, kill, trap, capture or collect, or to attempt to engage in any such conduct. Harass is defined by the Service as an intentional or negligent act or omission which creates the likelihood of injury to a listed species by annoying it to such an extent as to significantly disrupt normal behavioral patterns which include, but are not limited to, breeding, feeding or sheltering. Harm is defined by the Service to include significant habitat modification or degradation that results in death or injury to listed species by impairing behavioral patterns including breeding, feeding, or sheltering. Incidental take is defined as take that is incidental to, and not the purpose of, the carrying out of an otherwise lawful activity. Under the terms of section 7(b)(4) and section 7(o)(2), taking incidental to and not intended as part of the agency action is not considered to be prohibited taking under the Act, provided that such taking is in compliance with this Incidental Take Statement.

The measures described below are nondiscretionary for listed species in Phase 2 of this opinion and must be implemented by the Corps in order for the exemption in section 7(o)(2) to apply. The Corps has a continuing duty to regulate the activity that is covered by this incidental take statement. If the Federal agency (1) fails to adhere to the terms and conditions of the incidental take statement, and/or (2) fails to retain oversight to ensure compliance with these terms and conditions, the protective coverage of section 7(o)(2) may lapse.

Amount or Extent of Take

Giant Garter Snake

The Service anticipates that incidental take of the snake will be difficult to detect or quantify for the following reasons: giant garter snakes are cryptically colored, secretive, and known to be sensitive to human activities. Snakes may avoid detection by retreating to burrows, soil crevices, vegetation, or other cover. Individual snakes are difficult to detect unless they are observed, undisturbed, at a distance. Most close-range observations represent chance encounters that are difficult to predict. It is not possible to make an accurate estimate of the number of snakes that will be harassed, harmed or killed during Phase 2 construction activities (staging areas, work on canal banks, soil borrow areas, and vehicle traffic to and from borrow areas). In instances when take is difficult to detect, the Service may estimate take in numbers of species per acre of habitat lost or affected as a result of the action. Therefore, the Service anticipates that all giant garter snakes inhabiting 187 acres of aquatic and 818.9 acres of upland habitat may be harassed, harmed, or 2 giant garter snakes killed by loss and destruction of habitat, as a result of the project.

Valley Elderberry Longhorn Beetle

The Service expects that incidental take of the valley elderberry longhorn beetle will be difficult to detect or quantify. The cryptic nature of these species and their relatively small body size make the finding of an injured or dead specimen unlikely. The species occurs in habitats that make them difficult to detect. Due to the difficulty in quantifying the number of beetles that will be taken as a result of the proposed action, the Service is quantifying take incidental to the project as the number of elderberry stems one inch or greater in diameter at ground level (beetle habitat) that will become unsuitable for beetles due to direct or indirect effects as a result of Phase 2 construction. Therefore, the Service estimates that all beetles inhibiting 23 elderberry plants containing stems 1 inch or greater at ground level (118 stems between 1-3 inches, 39 stems between 3 and 5 inches and 35 stems $\geq$5 inches; see Table 3 in the text) will become unsuitable as a result of the proposed action.

Effect of the Take

The Service has determined that this level of anticipated take is not likely to result in jeopardy to the giant garter snake, or valley elderberry longhorn beetle, and will not result in the destruction or adverse modification of designated critical habitat because in the case of the giant garter snake critical habitat has not been designated and it is outside of the critical habitat for valley elderberry longhorn beetle.

Reasonable and Prudent Measures

The following reasonable and prudent measures are necessary and appropriate to minimize the effect of the proposed project on the giant garter snake and valley elderberry longhorn beetle.

1. The Corps and SAFCA shall implement the project as proposed in the biological assessment and this biological opinion.

2. Effects of harassment of individual giant garter snakes within the proposed project, and of the loss or degradation of the species' habitat shall be minimized.

3. Effects of harassment of individual valley elderberry longhorn beetle, and of the loss and degradation of the species' habitat shall be minimized.

Terms and Conditions

In order to be exempt from the prohibitions of section 9 of the Act, the Corps must ensure compliance with the following terms and conditions, which implement the reasonable and prudent measures described above. These terms and conditions are nondiscretionary.

1. The following terms and conditions implement reasonable and prudent measure one (1):

    a. The Corps and SAFCA shall minimize the potential for incidental take of the giant garter snake and valley elderberry longhorn beetle resulting from the project related activities by implementation of the project description as described in the biological assessment and the project description of this biological opinion.

    b. If requested, before, during, or upon completion of ground-breaking and construction activities, the project proponents shall allow access by Service and/or California Department of Fish and Game personnel to the project site to inspect project effects to the snake and valley elderberry longhorn beetle.

    c. A Service approved Worker Environmental Awareness Training Program for construction personnel shall be conducted by a Service-approved biologist for all construction workers prior to the commencement of construction activities. The program shall provide workers with information on their responsibilities with regard to the giant garter snake and valley elderberry longhorn beetle, an overview of the life-history of the species, information on take prohibitions, and protections afforded the species under the Act. Written documentation of the training must be submitted to the Sacramento Fish and Wildlife Office within 30 days of the completion of training. As needed, training shall be conducted in Spanish for Spanish language speakers and other languages as needed or necessary.

    d. The applicants shall include a copy of this biological opinion within its solicitations for design and construction of the proposed project making the primary contractor responsible for implementing all requirements and obligations included within the biological opinion, and to educate and inform all other contractors involved in the project as to the requirements of the biological opinion.

2. The following terms and conditions implement reasonable and prudent measure two (2):

   a. The project proponents shall minimize the potential for harm or harassment of the snake resulting from project-related activities by implementation of the conservation measures as described in the Corps' Biological Assessment and appearing in the project description (pages 3-44) of this biological opinion.

   b. At least 30 calendar days prior to initiating construction activities, the project proponents shall submit the names and curriculum vitae of the biological monitor(s) for the proposed project. Monitors shall have the ability to differentiate giant garter snakes from other snakes and the authority to stop construction activities if a snake is encountered during construction until appropriate corrective measures have been completed or until the snake is determined to be unharmed.

   c. For Phase 2 work which would occur outside of the giant garter snake active window (power pole relocations and private irrigation canal relocation) exclusion fencing would be placed around upland areas that giant garter snakes could use to overwinter. The exclusionary fencing would be monitored everyday prior to and during construction to ensure that openings do not develop that would allow the entry of a giant garter snake into the construction area.

   d. Construction activity shall be conducted between May 1 and October 1. This is the active period for the snake and direct mortality is lessened, because snakes are expected to actively move and avoid danger. If it appears that construction activity may go beyond October 1, the project proponents shall contact the Service as soon as possible, but not later than July 15 of the year in question, to determine if additional measures are necessary to minimize take.

   e. The project proponents shall implement Best Management Practices (BMPs) to prevent sediment from entering areas containing snake habitat, including, but not limited to, silt fencing, temporary berms, no cleaning of equipment in or near snake habitat, installation of vegetative strips, and temporary sediment disposal.

   f. Runoff from dust control and oil and other chemicals used in other construction activities shall be retained in the construction site and prevented from flowing into areas containing snake habitat. The runoff shall be retained in the construction areas by creating small earthen berms, installing silt fences or hay-bale dikes, or implementing other measures on the construction site to prevent runoff from entering the habitat of the snake.

   g. Project-related vehicles shall observe a 20-mile-per-hour speed limit within construction areas, except on County roads and State and Federal highways. This

is particularly important during periods when the snake may be sunning or moving on roadways.

h. To avoid attracting snake predators, all trash items, such as wrappers, cans, bottles, and food scraps, must be disposed of in closed containers and removed at least once a day from the entire project site.

i. Within 24-hours prior to the commencement of construction activities, the site shall be inspected by a Service-approved biologist. The biologist will provide the Service with a written report that adequately documents the monitoring efforts within 24-hours of commencement of construction activities. Snakes encountered during construction activities shall be allowed to move away from the area on their own volition. The biologist shall notify the Service immediately if any listed species are found on-site, and will submit a report, including date(s), location(s), habitat description, and any corrective measures taken to protect the species found. The biologist shall be required to report any take to the Service immediately by telephone at (916) 414-6600 and by electronic mail or written letter addressed to the Deputy Assistant Field Supervisor, within one (1) working day of the incident. The project area shall be re-inspected by the monitoring biologist whenever a lapse in construction activity of two weeks or greater has occurred.

j. Erosion control structures will be installed concurrently with construction. Erosion control structures will be constructed so runoff will be directed away from sensitive habitats. Tightly woven fiber netting (mesh size less than 0.25 inch) or similar material shall be used for erosion control or other purposes at the project site to ensure giant garter snakes and other reptiles or amphibians are not trapped by the erosion control material. This limitation will be communicated to the contractor through use of Special Provisions included in the bid solicitation package. Coconut coir matting is an acceptable erosion control material. No plastic mono-filament matting shall be used for erosion control. The edge of the material shall be buried in the ground to prevent giant garter snakes and other reptiles and amphibians from crawling underneath the material. Erosion control measures shall direct water flow into existing drainages or disperse water across vegetated areas in order to avoid concentrating water.

k. Movement of heavy equipment to and from the project site shall be restricted to established roadways to minimize habitat disturbance. Stockpiling of construction materials, including portable equipment, vehicles, and supplies, shall be restricted to the designated construction staging area and exclusive of aquatic habitat avoidance areas. Aquatic snake habitat adjacent to the project area shall be flagged and avoided by all construction personnel.

l. To the extent feasible, the project proponents shall confine clearing of vegetation and scraping, or digging, of soil to the minimal area necessary to facilitate construction activities.

m. High visibility fencing shall be placed to prevent encroachment of construction personnel and equipment into areas containing snake habitat. The fencing shall be inspected before the start of each work day and maintained by the project proponents until completion of the project. The fencing may be removed only when the construction of the project is completed.

n. After completion of construction activities, any temporary fill and construction debris shall be removed. As described in the biological assessment and the project description of this biological opinion, the project proponents will restore all snake habitat subject to temporary ground disturbances, including storage and staging areas and temporary roads. These areas shall be re-contoured, if appropriate, and re-vegetated with appropriate locally-collected native plant species to promote restoration of the area to pre-project conditions. All temporary fill and construction debris shall be removed. An area subject to "temporary" disturbance includes any area that is disturbed during the project, but that, after project completion, will not be subject to further disturbance and has the potential to be re-vegetated. Appropriate methods and plant species used to re-vegetate such areas will be determined on a site-specific basis in consultation with the Service and the CDFG. Restoration work may include replanting emergent vegetation. Refer to the Service's *Guidelines for the Restoration and/or Replacement of Giant Garter Snake Habitat.* A written report shall be submitted to the Service within ten (10) working days of the completion of construction at the project site.

o. The Corps and SAFCA shall ensure compliance with the reporting requirements.

p. Prior to construction on May 1, 2009, the Corps and SAFCA will have the following documents completed and approved by the Service:

- drainage easement language for the GGS/Drainage Canal;
- Mitigation and Monitoring Plan and Long-Term Management Plan;
- encumbrances on a portion of the District Assessment Fee; and
- contract with NCMWC to provide reliable water for the GGS/Drainage Canal and managed marsh.

3. The following terms and conditions implement reasonable and prudent measure three (3):

a. The procedures outlined in the Service's *Conservation Guidelines for the Valley Elderberry Longhorn Beetle* dated July 9, 1999, shall be followed for all actions

related to the proposed project.

b. Elderberry shrubs will be fenced with high visibility construction fencing. In areas where the typical 20-foot buffer from the dripline of the elderberry shrub is encroached on, the fencing will be placed as far from the elderberry shrub's dripline as construction activities will allow.

c. A biological monitor will be present on site when work will encroach on the 20-foot elderberry buffer. The monitor will have the authority to stop construction within 20 feet of the shrub if unauthorized take of the beetle occurs. The monitor shall contact the Service immediately to determine what corrective measures need to be taken.

d. Compensation plantings shall occur within the same year as the transplantation of the elderberry shrubs. The selection of the final compensation site for elderberry shrubs shall be coordinated with the Service. A Service reviewed plan for the longterm maintenance and monitoring of the elderberry compensation site shall be completed prior to transplantation.

Reporting Requirements

A post-construction compliance report prepared by the monitoring biologists must be submitted to the Chief of the Endangered Species Division (Central Valley) at the Sacramento Fish and Wildlife Office within thirty (30) calendar days of the completion of construction activity or within thirty (30) calendar days of any break in construction activity lasting more than thirty (30) calendar days. This report shall detail: (i) dates that groundbreaking at the project started and the project was completed; (ii) pertinent information concerning the success of the project in meeting compensation and other conservation measures; (iii) an explanation of failure to meet such measures, if any; (iv) known project effects on the giant garter snake, if any; (v) occurrences of incidental take of any these species; and (vi) other pertinent information.

The Corps must require SAFCA to report to the Service immediately any information about take or suspected take of federally-listed species not authorized in this biological opinion. The SAFCA must notify the Service within 24 hours of receiving such information. Notification must include the date, time, and location of the incident or of the finding of a dead or injured animal. In the case of a dead animal, the individual animal should be preserved, as appropriate, and held in a secure location until instructions are received from the Service regarding the disposition of the specimen or the Service takes custody of the specimen. The Service contact persons is, Chief of the Endangered Species Division (Central Valley) at (916) 414-6600, and the Resident Agent-in-charge of the Service's Law Enforcement Division at (916) 414-6660.

Any contractor or employee who during routine operations and maintenance activities inadvertently kills or injures a listed wildlife species must immediately report the incident to their

representative. This representative must contact the CDFG immediately in the case of a dead or injured listed species. The CDFG contact for immediate assistance is State Dispatch at (916) 445-0045.

CONSERVATION RECOMMENDATIONS

Section 7(a)(1) of Act directs Federal agencies to utilize their authorities to further the purposes of the Act by carrying out conservation programs for the benefit of endangered and threatened species. Conservation recommendations are discretionary agency activities that can be implemented to further the purposes of the Act, such as preservation of endangered species habitat, implementation of recovery actions, or development of information and data bases.

1. The Corps and SAFCA should assist in the implementation of the draft, and when published, the final Recovery Plan for the giant garter snake.

2. The Corps and SAFCA should provide funding to researchers studying topics identified by the Service in the draft, and when published, the final Recovery Plan for the giant garter snake.

3. The Corps should use environmental restoration authorities to acquire and restore garter snake habitat from willing sellers.

To be kept informed of actions minimizing or avoiding adverse effects or benefiting listed and proposed species or their habitats, the Service requests notification of the implementation of any conservation recommendations.

REINITIATION - CLOSING STATEMENT

This concludes formal consultation with the Corps on the Natomas Levee Improvement Project. As provided in 50 CFR 402.16, re-initiation of formal consultation is required where discretionary Federal agency involvement or control over the action has been maintained (or is authorized by law) and if: (1) the amount or extent of incidental take is exceeded; (2) new information reveals effects of the proposed action may affect listed species or critical habitat in a manner or to an extent not considered in this opinion; (3) the agency action is subsequently modified in a manner that causes an effect to listed species or critical habitat that was not considered in this opinion; or (4) a new species or critical habitat is designated that may be affected by the proposed action. In instances where the amount or extent of incidental take is exceeded, any operations causing such take must cease pending re-initiation.

If you have any questions regarding this biological opinion on the Natomas Landside Improvements Project, please contact Jennifer Hobbs at (916) 414-6541 or Jana Milliken, Sacramento Valley Branch Chief.

Sincerely,

Ken Sanchez
Acting Field Supervisor

Sacramento, California 95814

Subject: Section 7 Programmatic Formal Consultation on the Natomas Levee Improvement Program, Landside Improvements Project, Sacramento and Sutter Counties, California

Dear Mr. Piccola:

This is in response to your March 31, 2009, request to amend the formal consultation with the U.S. Fish and Wildlife Service (Service) on the Natomas Levee Improvement Program, Landside Improvements Project (proposed project) in Sacramento and Sutter Counties, California, dated October 9, 2008 (File 81420-2008-F-0195-5). Your request was received on April 1, 2009. Your request was received in our office on June 11, 2008. This document represents the Service's concurrence to amend the programmatic biological opinion on the effects of the action to two federally-listed threatened species: the valley elderberry longhorn beetle (*Desmocerus californicus dimorphus*) and the giant garter snake (*Thamnophis gigas*), in accordance with section 7 of the Endangered Species Act of 1973, as amended (16 U.S.C. 1531 *et seq.*) (Act).

The Sacramento Area Flood Control Agency (SAFCA) recently made changes to the conservation strategy of their project. The Service, the U.S. Army Corps of Engineers (Corps), and SAFCA believed the change in the conservation strategy was substantial and re-initiation of consultation was necessary. Given the programmatic nature of this consultation, the Service is amending the project description and effects analysis within this biological opinion. Paragraphs that contain changes from the October 9, 2008, document have been bolded. This programmatic biological opinion supersedes the October 9, 2008, programmatic biological opinion.

This biological opinion is based on information provided in the Corps' letter requesting consultation and their biological assessment. A complete administrative record is on file at the Sacramento Fish and Wildlife Office.

CONSULTATION HISTORY

September 25, 2006. SAFCA had a meeting with the Service to briefly describe the conceptual Natomas Levee Improvement Project.

May 10, 2007. SAFCA made a presentation of their Natomas Levee Improvement Program Conceptual Plan to the Natomas Joint Vision, which included staff from the Service, California Department of Fish and Game (CDFG), the City of Sacramento, the Sacramento International Airport (Airport), and the Corps. This presentation included additional details and conceptual project designs.

October 29, 2007. The Service and the CDFG sent a joint comment letter to SAFCA on the Natomas Levee Improvement Project's Draft Environmental Impact Report.

January 11, 2008. SAFCA, the Corps, the Service, and CDFG began holding coordination meetings on the Natomas Levee Improvement Project to discuss project description and schedule.

January 24, 2008. SAFCA, the Corps, the Service, and CDFG held a coordination meeting, which included John Roberts from the Natomas Basin Conservancy (TNBC) to discuss project effects.

March 28, 2008. The Service met with SAFCA and Congresswoman Doris Matsui to discuss the project and schedule of the project.

June 17, 2008. SAFCA and the Corps held a meeting with CDFG and the Service to discuss work proposed for construction in 2009.

June 25, 2008. The Corps, EDAW, CDFG, and Service held a meeting to go over the effects of the project on specific cover-types.

July 2, 2008. The Service met again with Congresswoman Doris Matsui to discuss the schedule of the biological opinion.

July 9, 2008. The Service met with SAFCA, EDAW, CDFG, and the Corps to discuss endowments and easements for the conservation measures. The Service advised SAFCA that any thing other than a conservation easement for protection of compensation areas would take a great deal of time to work through.

July 10, 2008. The Corps, EDAW, SAFCA, CDFG, and Service held a meeting to discuss effects and schedule of the project.

July 15, 2008. The Service and Corps met with SAFCA to resolve schedule differences for the biological opinion. The Service committed to completing the biological opinion by September 24, 2008.

July 17, 2008. The Service provided a request via e-mail for 39 additional acres of managed marsh creation as part of the compensation strategy. This request was sent to EDAW, SAFCA, Corps, and CDFG.

July 21, 2008. The Service, Corps, EDAW, SAFCA, and CDFG met to discuss project effects and compensation strategy.

September 9, 2008. SAFCA provided an updated compensation strategy based on landuse changes at borrow sites on Sacramento County Airport lands.

September 11, 2008. The Service provided EDAW with comments on the draft language for a drainage easement on the GGS/Drainage Canal.

September 17, 2008. SAFCA, EDAW, and the Service had a meeting in which SAFCA proposed an idea to develop a compensation bank within the Natomas Basin.

September 19, 2008. The Service responded to the proposal submitted by SAFCA for a compensation bank and suggested that in order to provide a biological opinion to the Corps and SAFCA by September 24, 2008, SAFCA not include compensation banking as part of their project description. The Service also suggested that placing a conservation easement on ½ of the area borrowed at Brookfield would help compensate for effects due to the project.

September 21, 2008. SAFCA's consultant provided an e-mail, which agreed to the Service's September 19, 2008, e-mail.

September 24, 2008. The Service sent the Corps and SAFCA a draft biological opinion for the Landside Improvement Project.

September 29, 2008. SAFCA's consultant EDAW provided comments to the Service on the draft biological opinion.

October 9, 2008. The Service sent the final biological opinion to the Corps and SAFCA.

February 5, 2009. The Service, CDFG, SAFCA, EDAW, Sacramento County, John Roberts from the TNBC, and Reclamation District (RD) 1000 met to discuss the GGS/Drainage Canal easement and each agencies roles and responsibilities.

February 11, 2009. The Service provided SAFCA's attorney Fran Layton with our comments on the GGS/Drainage Canal easement language.

February 12, 2009. SAFCA's attorney spoke to Lynn Cox, Department of Interior Solicitor, and indicated that as had been previously discussed the TNBC would not be 3rd party beneficiary on the GGS/Drainage Canal easement where the canal crosses airport property because Sacramento County Airport System (SCAS) wanted them removed. Additionally, SCAS also wanted language inserted into the easement, which would give them the ability to modify the GGS/Drainage Canal, should the Federal Aviation Authority request it but that they would consult with the Service and CDFG prior to working within the GGS/Drainage Canal and provide compensation for effects.

February 24, 2009. The Service, CDFG, SAFCA, EDAW, Corps, and Sacramento County met to discuss the language of the easement along the GGS/Drainage Canal. Agreement was reached at this meeting. Because SAFCA would not place the GGS/Drainage Canal under a conservation easement they would provide additional compensation near Fisherman's Lake, which would have a conservation easement placed on it.

March 4, 2009. The Service, CDFG, and EDAW met to discuss effects acreages for the entire project. EDAW indicated at the meeting that SAFCA may not create aquatic benches on any portion of the GGS/Drainage Canal. The Service indicated that if that was the case than the programmatic biological opinion would have to be amended.

March 31, 2009. The Corps re-initiates consultation on the programmatic biological opinion.

BIOLOGICAL OPINION

Description of Action Area

The proposed project area is located in the Natomas Basin in northern Sacramento and southern Sutter Counties, generally bounded by leveed reaches of the Natomas Cross Canal (NCC) on the north, the Sacramento River on the west, the American River on the south, and the Pleasant Grove Creek Canal (PGCC) and Natomas East Main Drainage Canal (NEMDC)/Steelhead Creek on the east. This project, which is part of the larger Natomas Levee Improvement Program (NLIP) being undertaken by SAFCA, consists of three construction phases, generally occurring between 2008 and 2011. Construction of Phase 2 includes the 5.3-mile NCC south levee, the Sacramento River east levee from the NCC south levee to 2,000 feet south of the North Drainage Canal (Reaches 1-4B), the Elkhorn Main Irrigation Canal (Elkhorn Canal) between the North Drainage Canal and the Elkhorn Reservoir settling basin, the site of RD 1000 Pumping Plant No. 2, and adjacent land. Construction of Phase 3 includes the Sacramento River east levee south of the limits of the Phase 2 improvements to just south of Interstate 5 (I-5) (Reaches 5A–9B), the PGCC west levee, the NEMDC west levee between Elkhorn Boulevard and Northgate

Boulevard, the area between Elkhorn Reservoir and the West Drainage Canal where a new canal designed to provide drainage and associated giant garter snake habitat (referred to in this document as the "GGS/Drainage Canal") would be constructed, the portion of the West Drainage Canal north of I-5, the Elkhorn Canal downstream of Elkhorn Reservoir, and RD 1000 Pumping Plant No. 2. Construction Phase 4, which is still being designed, includes the Sacramento River east levee south of the limits of the Phase 3 improvements to the junction with the American River north levee (Reaches 10–20), the NEMDC west levee between Sankey Road and Elkhorn Boulevard, the Riverside Main Irrigation Canal (Riverside Canal), and the West Drainage Canal south of I-5 to Fisherman's Lake. Phase 1 of the project occurred during the summers of 2007 and 2008 and consisted of placing slurry wall along 9,700 linear feet of the Natomas Cross Canal (Service file number 1-1-07-F-0207).

Because the Corps and SAFCA only have a detailed project description for Phase 2 of the entire Natomas Levee Improvement Project, this biological opinion analyzes the landscape effects of the project for all Phases (2, 3, and 4) but will only analyze and provide incidental take coverage for Phase 2. Each subsequent phase will initiate section 7 consultation with the Service under the umbrella of this programmatic biological opinion.

Overview of NLIP Landside Improvements Project

SAFCA is designing the NLIP in coordination with the Federal and state flood control project sponsors, the Corps, and the State of California Central Valley Flood Protection Board (formerly The Reclamation Board), to address the deficiencies in the Natomas levee system with a focus on achieving a 100-year level of flood protection by 2011. This will require improving the following landside conditions along the NCC south levee, the Sacramento River east levee, and the PGCC and NEMDC west levees:

- Inadequate freeboard—The NCC south levee and portions of the Sacramento River east levee are not high enough to provide at least 3 feet of freeboard above the 100-year water surface elevation. Additional reaches do not provide 3 feet of freeboard above the 200-year design water surface elevation.

- Underseepage and through-seepage vulnerability—Most of the levee reaches do not meet recently adopted Federal criteria for safely containing underseepage and through-seepage when the water surface in the adjacent channel reaches the 100-year elevation or, in some cases, the 200-year elevation.

The NLIP Landside Improvements project encompasses addressing freeboard deficiencies through levee raises; addressing seepage potential using a combination of seepage berms, cutoff walls, and relief wells; and acquiring additional right-of-way to construct the improvements and to prevent encroachment into the flood control system. In addition, the project has been designed to include an enlarged levee embankment (adjacent setback levee) along the land side of the existing Sacramento River east levee to minimize the need for substantial removal of vegetation and structural encroachments on the water side of this levee in compliance with Corps guidance.

These improvements would include recontouring the levee slopes where necessary to provide a 3:1 horizontal-to-vertical (3H:1V) waterside slope and a 3H:1V (preferred) or 2H:1V (maximum) landside slope.

The specific goal of the NLIP Landside Improvements Project is to provide at least 100-year flood protection as quickly as possible while laying the groundwork to achieve at least urban-standard (200-year) flood protection over time.

Additional project objectives that influenced SAFCA's project design were to:

(1) use flood control projects in the vicinity of the Sacramento County Airport to facilitate better management of Airport lands to reduce hazards to aviation safety, and

(2) use flood control projects to enhance habitat quality and values by increasing the extent of the lands in the Natomas Basin being managed to provide habitat for the giant garter snake, the Swainson's hawk, and other special-status species.

Recognizing the importance of securing maximum Federal support for the flood control project, SAFCA has explored implementation approaches that also advance the achievement of Federal aviation and wildlife protection objectives where complementary opportunities exist. Accordingly, the proposed project includes the following elements:

- The project would include construction of the GGS/Drainage Canal to provide giant garter snake habitat and some drainage infrastructure west of the Airport. Construction of these facilities would allow for dewatering of the ditch running along the western portion of the Airport runway system, which the airport recognizes as a flight safety hazard, by offsetting the effects on drainage and irrigation needs and giant garter snake habitat.

- The project would combine SAFCA's need for levee embankment and berm material with the SCAS's need to modify the condition and management of Airport bufferlands so as to reduce wildlife hazards affecting Airport operations in a manner that enhances the connectivity of areas managed specifically for their habitat value.

Existing Project Facilities and Potential Borrow Sites

Construction activities for all project phases would take place within the Natomas Basin, except for potential development of a borrow site on RD 1001 land northeast of the basin. The following subsections describe the existing flood control facilities, their general setting, and adjacent irrigation infrastructure and the potential borrow sources for the project as provided by the Corps in their Environmental Impact Statement for the proposed project.

Flood Control and Irrigation Facilities

Natomas Cross Canal South Levee

The NCC is a 5.3-mile-long channel that carries water from several tributary watersheds in western Placer County and eastern Sutter County to the Sacramento River. The NCC begins at the PGCC and East Side Canal and extends southwest to its confluence with the Sacramento River near the Sankey Road/Garden Highway intersection. During periods of flooding, the Sutter Bypass, Sacramento River, and NCC all contribute to raised water elevations that can affect the NCC levees. For engineering purposes, the south levee is divided into seven reaches. Much of the south levee contains an existing stability berm with an internal drainage system. Levee slopes are approximately 3H:1V on the water side and 2H:1V on the land side.

There is an approximately 80- to 100-foot maintenance access area on the landside of the levee through most of the NCC's length. Farms and rural residences are located on both sides of the NCC, with rice the primary crop under cultivation. The Lucich North and Frazer Habitat Preserves, maintained by the TNBC, lie south of the NCC south levee from the eastern end of Reach 2 through the western end of Reach 6. A drainage canal, referred to as the Vestal Drain, runs parallel to the NCC south levee through much of Reach 2, approximately 100 feet from the landside levee toe. There is a private irrigation pump and irrigation canal at the landside levee toe in Reach 1. Natomas Central Mutual Water Company's (NMWC) Bennett Pumping Plant and RD 1000's Pumping Plant No. 4 are located in Reach 2, and the NMWC Northern Pumping Plant is located in Reach 3. The NMWC North Main Canal runs parallel to the levee through Reaches 4 and 5, approximately 100 feet from the landside levee toe.

Sacramento River East Levee

An 18-mile-long section of the east levee of the Sacramento River protects the west side of the Natomas Basin between the NCC and the American River. For planning purposes, the levee is divided into 20 reaches. Garden Highway is located on top of the levee crown within all 20 reaches. A drained, 10-foot-wide stability berm is present on the landside slope of the levee between the NCC and Powerline Road (Reaches 1–11). Cutoff walls to address through-levee seepage remediation were previously constructed through the levee in Reaches 12–20. The land uses along the levee vary from north to south. Along the landside, Reaches 1–13 are bordered mainly by private agricultural lands containing a few rural residences, Airport bufferlands, and two farmed the TNBC parcels. Teal Bend Golf Club is west of the Airport, adjacent to the levee along Reach 6. The parcels bordering Reaches 14–18 contain more residences, several rural estates, and three TNBC parcels. The landside of Reaches 19 and 20 are bordered by residential subdivisions, a business park, the City of Sacramento's Natomas Oaks Park, undeveloped Costa Park site, and Shorebird Park.

Several irrigation canals, pipelines, wells, and pump stations exist along the Sacramento River east levee. The Elkhorn Canal and the Riverside Canal are key agricultural irrigation canals in the NMWC system. The Elkhorn Canal runs parallel to the Sacramento River east levee from the

North Drainage Canal in Reach 4B through Reach 8 and into the start of Reach 9 (1,250 feet south of Elkhorn Boulevard); this canal is supplied by the Prichard and Elkhorn Pumping Plants on the Sacramento River. The Riverside Canal extends from just north of Reach 13 to the middle of Reach 19 and is supplied by the Riverside Pumping Plant, on the Sacramento River just north of Radio Road. Several lateral canals connect to the Elkhorn and Riverside Canals. The existing Elkhorn and Riverside Canals are highline canals that use gravity flow to deliver water for irrigation by maintaining water levels above the surrounding ground levels. These canals have earthen embankments with side slopes that are nearly vertical, requiring regular maintenance. Approximately 1 mile of the existing Elkhorn Canal is concrete lined and the entire Riverside Canal is concrete lined.

In addition to the NMWC irrigation systems, there are several landowner-operated systems along the levee. These facilities are located primarily in Reaches 1–4A and 9–12, in areas not currently served by the NMWC systems. The areas are serviced by either well pumps on the landside or river pumps, which discharge into buried pipelines, small irrigation ditches, or directly onto fields. The distribution systems run along the landside toe of the levee to supply fields that slope away from the levee. There are approximately nine small pumping plants that provide water from the river and approximately 10 groundwater well pumps.

Several drainage pumping plants are operated by RD 1000 along the Sacramento River east levee. These facilities pump drain water from the main drainage canal system into the river. They include Pumping Plant No. 2, located in Reach 4B; Pumping Plant No. 5, located in Reach 10; Pumping Plant No. 3, located in Reach 13; and Pumping Plant No. 1, located in Reach 20A. Pumping Plant No. 2 was temporarily removed as part of an emergency levee repair in 2006 and would be replaced as an element of the proposed project in the 2009–2010 construction phases. In addition to these RD 1000 pumping stations, the City of Sacramento operates the Willow Creek drainage pumping station, which is located in Reach 19B.

Pleasant Grove Creek Canal West Levee

The PGCC west levee extends southerly from the east end of the NCC south levee to the north end of the NEMDC/Steelhead Creek levee near the Sankey Road crossing. The PGCC west levee protects the Natomas Basin from flood flows from Pleasant Grove Creek and other creeks in western Placer County, as well as from water that backs up in the NCC during high river stages in the Sacramento River. Levee slopes are generally 2H:1V on both the water side and land side of the levee. Natomas Road is located on top of the levee crown. No berms support this levee. A private canal extends parallel to the PGCC west levee for about 1,500 feet at the landside levee toe. Farms and scattered rural residences are located on the landside of the PGCC west levee, and a manufacturing facility and a railroad siding are located within several hundred feet of the levee, just south of Sankey Road.

Natomas East Main Drainage Canal

The 13.3-mile NEMDC/Steelhead Creek west levee extends southerly from the south end of the PGCC west levee near the Sankey Road crossing to Northgate Boulevard. The NEMDC west levee protects the Natomas Basin from flood flows from Arcade and Dry Creeks, as well as from water during high river stages in the American River. Natomas and East Levee Roads are located on top of the levee crown. Private canals extend parallel to portions of the NEMDC west levee landside levee toe. Farms and scattered rural residences are located on the land side of the northern portion of the NEMDC west levee (between Sankey Road and Elkhorn Boulevard), while the southern portion (generally south of Del Paso Road to Northgate Boulevard) is bordered by urban and commercial/industrial development.

SAFCA's NEMDC stormwater pumping station, a facility that is connected to the NEMDC/Steelhead Creek west levee and the Dry Creek north levee, is situated between Del Paso Road and Elkhorn Boulevard. Other pumping stations occur along the NEMDC west levee, including NMWC Pumping Plant Nos. 6 and 8, which pump water out of the Natomas Basin for in-basin drainage and flood control. The RD 1000 operates Pumping Plant Nos. 6 and 8 and City of Sacramento operates Pump Station No. 102 on the NEMDC west levee.

Borrow Sites

Borrow sites are areas from which earthen materials would be removed for use in construction. Where borrow sites would be used over more than one construction season, the work would progress in cells that would be incrementally developed as habitat or returned to agricultural use as the borrow activities are completed. Several properties have been identified as likely sources of soil borrow, mainly for use in the improvements to the Sacramento River east levee. SAFCA has identified the following preferred borrow sources for the construction of the flood control and irrigation infrastructure improvements for construction Phases 2, 3, and 4, and a redundant source that may be pursued if negotiations regarding the preferred sources are unsuccessful or additional quantities are found to be needed during construction:

- Brookfield property (Phases 2, and 3 preferred): Private property west of the PGCC at Fifield Road, which was in rice cultivation in 2008. Material from this property could be used along the NCC south levee and the upper reaches of the Sacramento River east levee in construction Phase 2 and on the PGCC west levee in construction Phases 3. While the overall property may be used as borrow during multiple years, no area of the property would be used for consecutive years. After the removal of borrow material, the land would be returned to rice cultivation in the same season or if too late to plant, then in the following season.

- Airport bufferlands north of the Airport complex (Phases 2 and 3 preferred, Phase 4 potential): Sacramento County property north of Elverta Road and west of Powerline Road. These lands could provide soil for use along the middle reaches of the Sacramento River east levee in construction Phases 2 and 3. They could also provide material for

construction in the lower reaches of the levee in construction Phase 4, if needed. While the overall property may be used as borrow during multiple years, no area of the property would be used for consecutive years. After the removal of borrow material, the borrow areas, which are currently either fallow agricultural lands or ruderal grassland, would be returned to fallow agricultural fields.

- Fisherman's Lake area (Phase 4 preferred): Privately owned parcels between TNBC-managed habitat areas. Several parcels, which are currently planted in rice, orchards, or field crops, may be suitable sources of borrow material for use in the lower reaches of the Sacramento River east levee and are strategically situated for creation of habitat that would link existing TNBC parcels.

- Krumenacher property (Phase 3 preferred): Private parcel at the intersection of East Levee Road and Elkhorn Boulevard. This parcel is a component of the Natomas Panhandle, identified in the Natomas Basin Habitat Conservation Plan (NBHCP) and development of this parcel is already covered by a July 25, 2007, biological opinion (1-1-06-F-0294). This land, which is primarily grassland, could provide a borrow source for the levee widening improvements to the NEMDC.

- Twin Rivers Unified School District (Phase 3 preferred): Material stockpiled on property owned by Twin Rivers Unified School District, immediately south of Krumenacher. This parcel is a component of the Natomas Panhandle, identified in the NBHCP, and development of this parcel is already covered by a July 25, 2007, biological opinion (1-1-06-F-0294). This material could provide a borrow source for the levee widening improvements to the NEMDC.

- Horangic/Private Property Northwest of Garden Highway and Reservoir Road (Phase 3 preferred): Private parcel located in Reach 6A along the Sacramento River east levee. The portion of this site that would not be in the levee footprint could provide borrow material for seepage berms in Reaches 5A–5B. The site would be shallow-graded for borrow material and returned to field crops.

- Binford deYoung/Private Property Southwest of Garden Highway and Elverta Road (Phase 3 preferred): Private parcel located in Reach 5B along the Sacramento River east levee. The portion of this site that would not be in the levee footprint could provide borrow material for seepage berms in Reaches 5A–5B. The site would be shallow-graded for borrow material and returned to field crops.

- Bianchi/Private Property Northwest of Garden Highway and Reservoir Road (Phase 3 potential): Private parcel located in Reach 7 along the Sacramento River east levee. This property could borrow material for levee construction south of the Teal Bend Golf Club. The site would be shallow graded for borrow material and returned to field crops.

- Novak property (Phase 3 preferred, Phase 4 potential): A SAFCA-owned, 94-acre property located south of Del Paso Road and east of Powerline Road in Reach 12A along the Sacramento River east levee. The site could be used for levee construction south of the Teal Bend Golf Course. The site would be shallow graded for borrow material and returned to grassland or field crops.

- **Additional borrow sites may be needed in the event that the currently identified sites are not able to supply all of the required fill material. In order to ensure that adequate fill material is available for the project, the Elkhorn Borrow Area has been identified as an area where additional borrow sites may be created. Borrow in this area would be reclaimed in the same manner as the other borrow sites already identified, as would conservation measures.**

Overview of the Project Elements

The elements of the proposed project are categorized into five broad, overlapping categories:
- levee raising and seepage remediation,
- improvements to major irrigation and drainage infrastructure,
- acquisition of right-of-way within the footprint of the proposed features, at borrow sites, and to prevent encroachment and provide for maintenance access along the land side of the flood control facilities,
- habitat development and management for giant garter snakes and Swainson's hawks, and
- additional actions to meet Federal Emergency Management Agency requirements: encroachment management and bridge crossing modifications.

Levee Raising and Seepage Remediation

General Methods - The following subsections provide an overview of the approaches to addressing freeboard deficiencies and seepage potential that would be used in various combinations on the NCC south levee and Sacramento River east levee, and the PGCC and NEMDC west levees.

Raising, Widening and Flattening Levees (Phases 2, 3 ,4)

The entire NCC south levee, much of the Sacramento River east levee and a portion of the PGCC west levee at Sankey Road lack the required 3 feet of freeboard above the 100-year water surface profile. To meet overall NLIP goals, SAFCA would increase the levee freeboard sufficiently in freeboard-deficient areas to meet the desired minimum of 3 feet of freeboard above the 200-year water surface profile. The levee height increases would be accomplished through raises of the existing NCC south levee or through construction of the raised adjacent setback levee adjacent to the existing Sacramento River east levee:

- Raise of existing levee (NCC south levee). For a minor raise of the levee crown elevation (typically 6 inches or less), the raise may be limited to the levee crown area, provided that

there is enough existing crown width to accommodate the raise without narrowing the crown to a width that is less than the minimum requirement. For most of the NLIP levee raises, however, a greater crown raise is required and/or the levee slopes must be flattened. The required crown elevation would be met through a full levee raise. Full levee raises consist of an embankment raise from the landside or waterside toe (or both) upward to the increased crown elevation. This requires partially excavating the levee slope to provide a working platform for equipment, typically 10 feet wide, and rebuilding the levee to the appropriate elevation by benching the new embankment material into the existing embankment material.

- Adjacent setback levee (Sacramento River east levee). The proposed adjacent setback levee adjoining the Sacramento River east levee would be constructed with a crown elevation 3 feet above the 200-year water surface profile. In the upper reaches, where the existing levee has freeboard deficiencies of as much as 3 feet, the crown of the adjacent setback levee would be higher than the existing levee and Garden Highway roadway. In the lower reaches, where the existing levee has sufficient freeboard, the adjacent setback levee would be the same height as the existing levee.

The only levee segment that lacks adequate levee height that would be maintained at its current elevation is the PGCC west levee at Sankey Road because the flows through this levee segment into the interior of the Natomas Basin during a Federal Emergency Management Agency (FEMA) 100-year or "200-year" design event are not damaging and are subject to management as part of the basin's interior drainage system. Along the NEMDC west levee between Northgate Boulevard and Elkhorn Boulevard, the levee currently meets FEMA 100-year levee height requirements and also meets the "200-year" plus 3 feet of levee height design for the top of the levee profile.

The final levee configuration must meet the Corps criteria of a 20-foot-wide minimum crown, a 3H:1V waterside slope, and a 3H:1V (preferred) or 2H:1V (maximum) landside slope. Because the levees in most of the project reaches currently have landside slopes of 2H:1V, the proposed project includes flattening these slopes to at least a 3H:1V profile, and preferably 5H:1V. The PGCC west levee would be expanded on the land side to provide a levee width to encompass, at a minimum, a theoretical 3H:1V waterside slope, a crown width of at least 20 feet, and a landside slope of at least 3H:1V. The intent of the landside expansion is to preserve the existing Natomas Road and East Levee Road, which are County/City-maintained roads located on top of the existing PGCC and NEMDC west levees. Levee widening and slope flattening would also occur along the NEMDC west levee between Elkhorn Boulevard and the NEMDC stormwater pumping station.

Seepage Remediation

Underseepage problems can occur where levees are constructed on low-permeability foundation soil (silt and clay) underlain by a layer of higher permeability (sand and gravel). Excessive underseepage makes the levee susceptible to failure during periods of high river stage. Under these conditions, seepage travels horizontally under the levee and then is forced vertically

upward through the low-permeability foundation layer, often referred to as a "blanket." Failure of the blanket can occur either by uplift, a condition in which the blanket does not have enough weight to resist the confined pressure acting on the bottom of the blanket, or by piping (internal erosion) caused by water flowing under high vertical gradients through the erodible blanket and carrying fine soil particles out of the foundation materials. Through-seepage is seepage through a levee embankment that can occur during periods of high river stage. Depending on the duration of high water and the permeability of embankment soil, seepage may exit the landside face of the levee. Seepage can also pass directly through pervious layers in the levee if such layers are present. Under these conditions, the stability of the landside levee slope may be reduced.

During Phases 2–4, along the Sacramento River east levee, cutoff walls would be constructed through the adjacent levee in some reaches, and 100-foot-wide earthen seepage berms would be constructed in others for seepage remediation. Although portions of this reach of the Natomas perimeter levee system are considered susceptible to seismically induced ground shaking, such a condition would likely not cause deformation of the soil-bentonite (SB) walls in the adjacent levee because of its malleability and location farther away from the river channel, where levee failure is more likely to occur in association with seismically induced collapse of the river bank. Additionally, because an SB seepage cutoff wall is constructed lower in the levee section, it is not likely to be significantly affected by failure of the levee itself if the levee were to collapse. Relief wells cause the least amount of construction disturbance but require routine maintenance of the wells themselves and the drainage and pumping facilities necessary to support them. Seepage berms are feasible where there is sufficient room for construction.

Phase 2 includes the construction of a seepage cutoff wall through the levee crown of the NCC within Reaches 3–7. In Phase 3, a SB or soil-cement-bentonite cutoff wall will be constructed along the NEMDC west levee between Elkhorn Boulevard and Northgate Boulevard. The SB cutoff walls will also be constructed within the PGCC west levee where required to provide seepage remediation. In Phase 4, a cutoff wall will be constructed in the American River north levee between Gateway Oaks Drive and Northgate Boulevard (Reaches 1-4) to reduce seepage potential where required.

Major Irrigation and Drainage Infrastrueture Modifications

There are two major canal systems in the Natomas Basin: an irrigation system owned and operated by NMWC and a drainage system owned and operated by RD 1000. The NMWC pumps water into the basin to provide irrigation water to its shareholders for agricultural use within the basin. During winter (October–April), drainage is primarily rainfall runoff; during summer (May–September), drainage water from agricultural fields is typically recirculated for irrigation. Because the basin is surrounded by levees, all excess drainage within the basin must be pumped out. In general, irrigation water is pumped into the basin from the Sacramento River and NCC and returned to the perimeter rivers and canals via RD 1000's drainage system. In the southern part of the Natomas Basin, the City of Sacramento also operates several drainage pump stations that serve residential areas.

As a result of the planned levee improvements in the Natomas Basin, the irrigation canals currently at the toe of the Sacramento River east levee (the Elkhorn Canal and the Riverside Canal) would be replaced by new irrigation canals set back from the existing levee farther to the east. Where constraints exist, certain portions of the canals would be piped. The existing and proposed irrigation canals are highline canals, which means that the bottom of the canal is roughly equal to the surrounding ground elevation. Irrigation canals would be constructed high enough to raise water levels above the levels of the adjacent fields to allow for gravity flow into the fields.

A new drainage canal would be constructed to provide aquatic connectivity of giant garter snake habitat between the North Drainage Canal and West Drainage Canal. The proposed GGS/Drainage Canal would be constructed with the top of bank roughly at existing ground level to facilitate drainage. Material excavated to construct the GGS/Drainage Canal would generally be used to construct the embankments of the adjacent highline irrigation canals. Some import and export of soil materials for levee construction would be required to accommodate the phasing of the activities. The following subsections provide an overview of these irrigation and drainage infrastructure modifications.

Relocation of the Elkhorn and Riverside Canals

General Construction Plan for Relocated Canals - The Elkhorn and Riverside Canals would be constructed with sufficient height to raise water levels above the levels of adjacent fields. Design water levels would be based on existing levels at service points along the alignments and the tops of embankments would provide for 1 foot of freeboard. To provide for stable banks, side slopes of 3H:1V would be used. The invert of canals would be lined with concrete to control vegetation and to allow for maintenance with minimal disturbance of aquatic habitat along the water's edge.

To avoid interruptions in service along the existing irrigation canals, the relocated canals would be constructed and operational before construction of planned levee improvements that would conflict with the existing irrigation canals. Thus, in any particular reach, the new canal would be constructed before the levee improvements in that same reach. Approximately half of the new Elkhorn Canal (North Drainage Canal to Elkhorn Reservoir) is planned for construction in Phase 2. The GGS/Drainage Canal from the North Drainage Canal to Elkhorn Reservoir also would be constructed in Phase 2, because this section would run parallel to and within the same right-of-way as the proposed Elkhorn Canal in this area. Concurrent construction of these new irrigation and drainage facilities would facilitate the use of excavated material from the GGS/Drainage Canal excavation for use as embankment material along the Elkhorn Canal. The remainder of the Elkhorn Canal and GGS/Drainage Canal would be constructed in Phase 3, and the new Riverside Canal would be constructed during the Phase 4.

Elkhorn Canal - Approximately 22,300 feet of the Elkhorn Canal would be relocated to accommodate the levee construction. This facility is a main irrigation canal that services NMWC Central and Elkhorn systems from the Prichard and Elkhorn Pumping Plants on the Sacramento River. Approximately 1 mile of the existing Elkhorn Canal is concrete lined, including segments

between Elverta Road and the Elkhorn Pumping Plant and also just north and south of Elkhorn Road; the remainder is earth lined.

The proposed alignment of the new Elkhorn Canal is based primarily on the extent of the planned levee improvements. The canal was sited as close as possible to the projected toe of the new levee (with allowance made for a 5H:1V landside levee slope). After this initial alignment was determined, a number of site-specific factors were considered and used to refine the alignment. The resulting alignment minimizes conflicts with known cultural resources sites and existing trees and is roughly parallel to the projected levee toe.

North of Elkhorn Reservoir, the maximum bottom width of the new canal would be 12 feet. The canal embankments would be approximately 7 feet tall with 15-foot-wide patrol roads along the top of the embankments with a two percent grade sloped down towards the canal. The vegetated side slopes would be 3H:1V to provide for stable banks. Overall, the width of the canal would be approximately 140 feet, with additional width required for a buffer and maintenance area for the canal construction north of Elkhorn Reservoir.

To minimize project impacts on the existing Teal Bend Golf Club, the alignment of the Elkhorn Canal through the golf course would be piped (approximately 3,200 feet). Two 36-inch pipes would be aligned parallel to the levee toe land side of the flood control facility corridor. This alignment would avoid existing golf course infrastructure to the extent possible.

South of Teal Bend, the Elkhorn Canal would return to an open channel parallel to the toe of the new levee. The majority of this reach of earthen canal has a design bottom width of 5 feet, with a minimum of 1 foot of levee height and 3H:1V side slopes. A 15–foot-wide patrol road would be located on the top of the field side of the canal; the other embankment would be 8 feet wide on the crown. The only portion of the new canal that would have a concrete-lined invert would be the 4,100-foot section where the existing canal is lined. The remaining 2,900 feet of new canal would be earthen-lined. To avoid impacts on existing residences, a second section (approximately 950 feet through the Mortensen and Breese properties) of the Elkhorn Canal may be piped using a single 36-inch pipe. The materials to construct the Elkhorn Canal would come primarily from the construction of the GGS/Drainage canal north of I-5. However, a small amount of import from the Airport north borrow sites is expected to be used to support construction of a portion of Phase 2 improvements.

Riverside Canal - Approximately 18,600 feet of the Riverside Canal would be relocated to accommodate the levee construction. This facility is a main irrigation canal that services NMWC Riverside system. The supply for this canal is the Riverside Pumping Plant. The canal flows south along the landside toe of the levee to approximately Bryte Bend Road. The canal south of Bryte Bend Road has not been used in recent years. The canal north of the Riverside Pumping Plant is supplied by relifted water at RD 1000's Pumping Plant No. 3. From Pumping Plant No. 3, the canal flows north approximately 950 feet and turns away from the levee. The entire existing Riverside Canal is concrete lined, although much of the concrete lining is broken and in

poor condition. **To control vegetation and to allow for canal maintenance with minimal disturbance of aquatic habitat along the water's edge, the invert of the new canal may be concrete lined.**

Like the Elkhorn Canal alignment, the alignment of the Riverside Canal would be based primarily on the extent of the planned levee improvements. The canal would be sited as close as possible to the projected toe of the new levee (allowing for a 5H:1V landside levee slope). After this initial alignment is determined, a number of other factors would be considered and used to refine the alignment. One-half to three-quarters of a mile south of San Juan Road southward to I-80, there are a number of residences along the landside toe of the levee. To avoid bisecting these private properties, it is likely that the Riverside Canal alignment would follow the eastern property line of these parcels. The final alignment would also aim to minimize conflicts with existing trees and other site-specific constraints that are identified during design. Based on these site-specific factors and the variation of the proposed seepage remediation methods in different reaches, the alignment would be only roughly parallel to the projected levee toe. The proposed bottom width of the relocated Riverside Canal would be determined during final design to meet existing capacity needs.

Construction of the New GGS/Drainage Canal - The GGS/Drainage Canal would maintain existing aquatic connectivity and compensate for the permanent loss of giant garter snake habitat due to the filling of the Airport West Ditch. In addition to providing giant garter snake habitat, the GGS/Drainage Canal would intercept flows from non-Airport property sources. Irrigation and drainage water currently flowing into the Airport West Ditch from non-Airport property would be incorporated into the GGS/Drainage Canal.

The GGS/Drainage Canal would generally extend parallel to the Sacramento River east levee, extending from the North Drainage Canal at the RD 1000 Pumping Plant No. 2 in the north to the West Drainage Canal in the south, approximately 1,000 feet south of Elkhorn Boulevard. South of I-5, the existing RD 1000 West Drainage Canal may be modified to provide improved snake habitat value in the reach between I-5 and Fisherman's Lake. This reach of the GGS/Drainage Canal has yet to be designed but could include improvements that benefit the giant garter snake, including improved bank slopes and enhanced aquatic habitat and vegetative cover. The length of the entire GGS/Drainage Canal, including the reconstruction, would be approximately 43,800 linear feet. The GGS/Drainage Canal would have a series of cheek structures along its length to maintain consistent water levels in the low-flow channel of the canal during the snake's active season (April–October). Supplemental water would be provided from NMWC irrigation system. The low-flow channel would have a top width of approximately 50 feet and an average depth of approximately 6 feet. Vegetation would be managed within the canal excavation and on the banks by mowing.

The portion of the GGS/Drainage Canal that would be constructed in Phase 2 is north of Elkhorn Reservoir would be parallel and approximately 30 feet west of the edge of the Elkhorn Canal. Thus, the alignment was based on the same factors as discussed above for the Elkhorn Canal.

North of Reservoir Road the canal would be set back a minimum of 200 feet from the projected levee toe to minimize concerns of excessive seepage exit gradients in the bottom of the canal. The canal in this location would have a 10-foot bottom width and vegetated 3H:1V side slopes. The canal would be approximately five feet deep with two percent grade sloped down towards the canal from the edge of the Elkhorn Canal embankment and the adjacent ground for a distance of 12 feet to allow for a patrol road. The depth would be sufficient to provide a minimum water depth of 4.5 feet with allowance for 1 foot of water level variance and a minimum of 1 foot of freeboard. The footprint of the GGS/Drainage Canal is approximately 50 feet wide. A 30-foot right-of-way would separate the proposed GGS/Drainage Canal from the proposed relocated Elkhorn Canal. South of Elkhorn Reservoir, the new canal would be constructed with roughly the same proportions as the segment north of Elkhorn Reservoir.

The GGS/Drainage Canal north of Teal Bend Golf Club would be managed as a linear high-quality giant garter snake habitat, with stormwater drainage a secondary function during major storm events, which typically occur in the snake's inactive season. South of Teal Bend Golf Club, the canal would also serve as giant garter snake habitat area, but the volume of stormwater drainage would increase in a southerly direction as the canal collects additional runoff as a result of the natural slope of the basin. Winter storm–related runoff exceeding the capacity of the West Drainage Canal south of I-5 would be pumped into the Sacramento River using RD 1000's Pumping Plant No. 3, consistent with existing stormwater management practice.

The shoreline and lower bank of the GGS/Drainage Canal (including the improved West Drainage Canal) would be planted or managed to promote tule/cattail (*Typha latifolia*) vegetation as suitable cover and foraging habitat for giant garter snake. However, management of the canal would also require removal of noxious aquatic weeds that obstruct the flow of water. A secure water supply would ensure that water of a suitable quality is present and flowing at low velocity in the canal during the active season of the giant garter snake, and that the water surface would be managed within a range of approximately 1 foot to provide consistent cover from predators along the tule fringe of canal banks. Input of supplemental canal water would begin at a diversion point on the North Drainage Canal at the north end of the new GGS/Drainage Canal. Other points of inflow may occur at downstream locations.

Reconfiguration of Airport West Ditch

To take advantage of common construction practices and to maximize the use of common facilities, the rearrangement of irrigation and drainage facilities required to provide for rerouting of flows that contribute to the Airport West Ditch would be undertaken in conjunction with these proposed NLIP improvements in construction Phase 3. This work would include modifications and extension of existing irrigation infrastructure and modification of some local drainage conveyance facilities.

Removal of Culvert and Reconstruction at Pumping Plant No. 2

The project would include the removal of a deep culvert beneath the levee section at the RD 1000 Pumping Plant No. 2 location and the replacement of a relocated RD 1000 Pumping Plant No. 2, which was removed from the western end of the North Drainage Canal in response to underseepage observed during extended winter storms in January 2006.

Modifications to Pumping Plants (Phases 3 and 4)

The NCMWC pumping facilities that provide water to the Elkhorn and Central Main Canals (Prichard and Elkhorn Pumping Plants) would need to be modified to accommodate the new height of the Sacramento River east levee during Phase 3. The discharge piping would be raised above the "200-year" flood level to maintain the design level of flood risk reduction and would be extended to the relocated irrigation canals. Some replacement of pumping equipment and earthen intake channel reconstruction would be required to improve the system.

Land Acquisition

Several of the measures described above would increase the footprint of the flood control system: levees would be widened on the land side as a result of raising, constructing an adjacent setback levee, and flattening the waterside and/or landside slopes. In addition, a 50- to 100-foot-wide access and maintenance corridor would be established at the landside toes of the levees. The proposed improvements also include woodland corridors and groves to replace trees that are removed from within the levee footprint and maintenance access areas, and canal construction east of the flood control features. SAFCA also would acquire adjacent land for relocation of infrastructure from the flood control corridor and planned improvements outside the flood control corridor (e.g., the GGS/Drainage Canal), with appropriate easements provided to utility owners upon completion of the work. To meet its project footprint needs, SAFCA would acquire private lands in fee and would acquire an easement interest where the project features would be on Airport land (owned by Sacramento County). Where the project footprint would overlie land owned and managed by TNBC, SAFCA may either purchase the land in fee or obtain easements.

Additional Actions to Meet FEMA Requirements

Encroachment Management (Phases 3 and 4)

Corps levee guidance requires the removal of vegetation greater than 2 inches in diameter on the levee slopes and within 15 feet of the waterside and landside levee toes. The Corps levee guidance also requires an assessment of encroachments on the levee slopes, including utilities, fences, structures, retaining walls, driveways, and other features that penetrate the levee prism. Substantial encroachments are present on the Sacramento River east levee. One of the objectives of constructing an adjacent setback levee along the Sacramento River east levee is to facilitate acceptable management of existing vegetation and structural encroachments along the water side

of this levee. By moving the hypothetical waterside slope of the levee (the "levee template") landward, the adjacent levee would significantly reduce most of the conflicts between these encroachments and applicable Corps levee operation and maintenance requirements. Should any of these existing encroachments be determined to reduce the integrity of the levee, increase flood risk unacceptably, or impede visibility or access to the waterside levee slope, the encroachments would need to be removed. Removal of some waterside slope encroachments may be required by the end of 2011 to ensure that the levee system meets Federal criteria for the 100-year level of protection. Along the land side of the proposed adjacent setback levee, encroachment removal would typically be accomplished as part of the landside levee improvements. This activity would include the relocation of utility poles that are on the existing landside slope of the levee.

Bridge Crossings (Phase 4)

Under applicable Federal requirements, the plane of the northbound and southbound bridge crossings of SR 99/70 over the NCC must be 4 feet above the 100-year water surface elevation in the NCC. The 100-year water surface elevation is 44.4 NAVD 88. The soffit (underside) elevation of the northbound crossing is 44.9 NAVD 88, and the soffit elevation of the southbound crossing is 42.9 NAVD 88. Accordingly, during construction of Phase 4 the following options must be considered for implementation in conjunction with the California Department of Transportation:

(1) Raise both bridge crossings as necessary to meet minimum FEMA clearance requirements.
(2) Provide for installation of a closure structure across the southbound crossing in the event of a 100-year or greater flood.
(3) Replace the bridge rail structures on the east and west sides of the bridge crossings and modify the levees connecting to these structures to provide at least 4 feet of levee height above the 100-year water surface elevation. Under any of these options, at least the northbound crossing could remain open for use during a 100-year flood event.

Investigations to Aid Project Planning and Design

Geo-technical Investigations

Additional exploration of geotechnical conditions is anticipated to be required in Phases 2–4 along the NCC south levee, Sacramento River east levee, PGCC west levee, NEMDC/Steelhead Creek west levee, and American River north levee to facilitate refinement of design for flood facility improvements. Exploration of subsurface conditions would primarily be conducted by drilling borings. Borings along the levees would generally be drilled to depths of 60-120 feet below the ground surface using either a rubber-tire truck-mounted drill rig or an all-terrain drill rig equipped with an 8-inch-diameter hollow-stem auger and a 4-inch-diameter rotary wash drill bit. Hollow-stem augers would generally be used to drill through the levee fill and would be left in place to act as temporary casing and protection against hydraulic fracturing of the levee.

Rotary wash drilling methods would be used below the augers. Borings located at and landward of the levee toe would be drilled using rotary wash drilling methods.

Exploration of potential borrow sites will also be required to assess suitability of the material. Such exploration could include boring methods similar to those described above, but to shallower depths (10–12 feet below grade). Test pit excavation would be conducted using a tire-mounted backhoe to depths of 10–12 feet below grade. The test pits would likely be 1–3 feet wide along dirt roadways and 3–6 feet wide in agricultural fields by about 10 feet long. Samples would be obtained by hand with shovels from the excavated materials. When the bottom depth has been reached, the test pits would be loosely backfilled with the spoils with minor compaction effort. In the dirt roadways, the backfilled materials would be compacted with more effort to maintain drivability and safety.

Cultural Resources Investigations

Archeological surveys within potential flood control facility improvement footprints and potential borrow sites are required to facilitate project planning in Phases 2–4 and satisfy requirements under Section 106 of the National Historic Preservation Act. The surveys would include up to three stages of work. All excavation work in Stages 1 and 2 would be conducted with hand tools, such as shovels and trowels. Stage 1 entails digging shovel test pits 15 inches in diameter and up to 3 feet deep to evaluate the characteristics of subsurface material; these test pits would be backfilled immediately. Depending on archeological evidence found within the shovel test pits, Stage 2 work may be initiated to allow for a more thorough site investigation. This Phase would include excavation of 1-meter-square and 5-foot-deep test units. These test units may need to remain open for several days until examination can be completed. Any sites requiring deeper excavation to further investigate subsurface features identified in the first two stages would be included in Stage 3. This stage would require the use of machinery, such as a backhoe.

Conservation Strategy Overview

The project conservation strategy would contribute toward the establishment of a habitat reserve in the increasingly urbanized landscape of the Natomas Basin. The refuge is projected to occupy approximately 15,000 acres once the NBHCP objectives and other proposed conservation programs are completed. Through habitat creation, restoration, and preservation, SAFCA will increase the amount of protected habitat available for NBHCP-covered species above the project amount from the HCPs. Further, SAFCA's proposed plan will consolidate large areas of habitat, assisting in the expansion of TNBC reserve blocks in the northwestern and southwestern regions of the Basin. Finally, establishment of woodland corridors will greatly improve the connectivity between core habitat reserves that are distributed throughout the Basin, and substantially increase acreage and patch size of these critical habitats.

Overall, the proposed project is an opportunity to employ a landscape-scale vision, helping to advance the goals and objectives of the NBHCP and assist the Federal Aviation Administration

(FAA), Corps, and the local Reclamation Districts in achieving their goals. SAFCA's Natomas Landside Improvements Project presents a unique, one-time opportunity to reconfigure habitat and connective corridors in the Basin at a landscape scale.

Rather than a piecemeal approach to habitat protection, SAFCA's proposed project secures and expands the amount of habitat protected in the Basin, establishes the components that tie the preserves and disparate mitigation sites together in perpetuity under public ownership, and increases the quality and viability of this emerging urban reserve. Refer to the March 13, 2009, Draft (and subsequent revisions) *Programmatic Long-Term Management Plan* document (prepared by EDAW for SAFCA) for a more complete summary of the conceptual strategy for creating/enhancing/preserving, protecting, and managing habitats in the Natomas Basin in perpetuity. The following subsections provide an overview of the primary goals and landscape-level benefits of this habitat conservation strategy.

Increase Amount of Protected Habitat

While the project will result in loss and reconfiguration of landside habitats adjacent to the widened levees in the Natomas Basin, the proposed project has been specifically designed to minimize impacts to these landside habitats, and to avoid impacts to riparian habitats along the Sacramento River and NCC. The construction of an adjacent setback levee and installation of seepage cutoff walls enable SAFCA to retain the mature riparian tree corridor and numerous Swainson's hawk nests that are located along the waterside of the Natomas Basin levees. The project's conservation strategy includes the preservation, enhancement, and creation of almost 1,500 acres of compensatory habitats in the Natomas Basin, including:

- **100 acres of created, managed marsh,**
- **850 acres of created, managed grasslands,**
- **60 acres of canals and 80 acres of associated uplands,**
- **140 acres of preserved and created landside valley oak woodlands,**
- **175 acres of preserved rice fields, and**
- **150 acres of agricultural field crops.**

The project will result in the creation of a larger contiguous area protected and managed for the giant garter snake, valley elderberry longhorn beetle, Swainson's hawk, and other NBHCP-covered species than currently exists.

Expansion and Consolidation of Protected Habitat in the Natomas Basin

The project will consolidate large areas of habitat, assisting in the expansion and infill of TNBC reserve blocks in the northwestern and southwestern regions of the Basin. SAFCA will acquire several properties to provide compensatory habitat, either in the form of preserved rice and agricultural crop fields or created managed marsh, managed grasslands, or landside woodlands. Many of these properties are contiguous with existing TNBC reserves or other completed or planned mitigation habitats. Protecting habitat adjacent to existing TNBC reserves and other

mitigation sites creates a larger contiguous area managed for giant garter snake and Swainson's hawk than currently exists. This increases the habitat value, sustainability, and functions that these individual properties would otherwise provide in isolation, contributing to giant garter snake and Swainson's hawk recovery in the Basin.

Strengthen Connectivity between the TNBC Reserves

The proposed enhancements of existing Basin landscapes are important to the successful implementation of the NBHCP, along with the acquisition and permanent protection of mitigation land. **The connective woodland corridors that SAFCA proposes to establish and/or improve are enhancements that will aid in NBHCP implementation, providing TNBC with an opportunity to improve its overall performance towards the goals of the NBHCP in regards to woodlands. The establishment of a landside woodland corridor would provide more nesting and perching habitat for Swainson's hawks in the basin than cnrrently exists, and bring potential nesting and perching sites in closer proximity to areas that are managed as foraging habitat for this species in the basin.**

Mitigation, Management, and Monitoring Plan

Mitigation and monitoring plan (MMP) and a programmatic long-term management plan (LTMP) for the compensatory habitat components are being prepared to guide SAFCA and its partners as they manage the compensatory land components in perpetuity. The MMPs would address the habitat creation and preservation components of the NLIP Landside Improvements project. The MMPs and LTMP would establish specific success criteria for the habitat components, specify remedial measures to be undertaken if success criteria are not met (e.g., adaptive management, physical adjustments, additional monitoring), and describe short- and long-term management and maintenance of the habitat lands. The MMPs and LTMP would also describe the strategies for the long-term protection of these habitats and funding for the management as provided through appropriate mechanisms, which would be determined by SAFCA, the regulatory agencies, and other entities cooperating in the implementation of the project.

The goal of the MMPs and LTMP is to ensure that the conservation values of the preserved, restored, and created habitats are maintained in good condition in perpetuity. The MMPs and LTMP would discuss specific management strategies designed to maintain the conservation values for each of the habitat mitigation components and identify performance criteria used to determine the success of the mitigation habitats. The biological goals include: (1) the preservation of the abundance and diversity of native species, and particularly special-status species, in the mitigation habitats; (2) the protection of the habitat features from the effects of indiscriminate land uses that may adversely impact mitigation habitats; and (3) the restoration of any adverse condition within the mitigation habitat areas that may affect or potentially affect these areas.

Implementing Mechanisms for Long-Term Protection and Management

The MMPs and LTMP would describe the framework for the protection and management of the mitigation habitat components of the NLIP Landside Improvements project. The actual implementation of this framework would be enacted through easements, stakeholder-specific management agreements or memoranda of understandings, and contractual agreements. These contractual agreements would focus on the management obligations specific to each management entity, and describe the demonstrated financial and legal assurances necessary to implement the MMPs and LTMP to protect and manage the habitat mitigation components in perpetuity. These contractual agreements would be subject to review and approval by the Service, Corps, and CDFG, and enforced by SAFCA, in perpetuity, and by Corps through permit issuance.

Management Entities for Project Features

Agencies and organizations anticipated to have management responsibility for proposed project features are SAFCA, RD 1000, NMWC, and TNBC.

Sacramento Area Flood Control Agency
SAFCA would be responsible for the design and construction of all project components, including compensatory habitat. Once the project features are completed, most of the land or land management responsibility would be conferred by SAFCA to the other management entities. Memoranda of understanding, land ownership transfers, or management endowments and contracts would be used by SAFCA to transfer land management responsibility to the appropriate public agency or nonprofit land management organization.

Reclamation District 1000
The mission and purpose of RD 1000 is to operate and maintain the flood protection levees surrounding the Natomas Basin and to operate and maintain the internal drainage system to evacuate agricultural and urban stormwater and incidental runoff. The RD 1000 would be responsible for the management of the proposed levee improvements, reconstructed Pumping Plant No. 2, and drainage features. Typical maintenance activities include mowing grassland along levee slopes, berms, and rights-of-way, removing sediment and noxious aquatic weeds from the canals, and managing bank vegetation.

Natomas Central Mutual Water Company
The NMWC is a nonprofit mutual water company with the primary focus of keeping the water conveyance functioning to serve the company shareholders. The NMWC would be responsible for maintaining and managing the relocated Elkhorn and Riverside Canals. The relocated canals would be maintained and operated in the same manner as the existing canals. Typical maintenance activities include operating and repairing water control structures and barrier gates, periodically removing sediment and noxious aquatic weeds from the canals, repairing canal roads, managing bank vegetation, and mowing grassland along canal and road rights-of-way. However, the relocated Elkhorn and Riverside Canals would have improved levees, better water

control structures, and wider roads and rights-of-way than the existing canals. These improvements are expected to ease annual canal management efforts, allowing for a proportionately greater focus on maintenance and operations and less need for system repair and dredging.

The Natomas Basin Conservancy
The TNBC acquires and manages land for the purpose of meeting the objectives of the NBHCP. The TNBC owns approximately 30 mitigation properties totaling more than 4,500 acres. Private land acquired by SAFCA and converted to managed marsh, preserved in rice, or used for woodland establishment would be conveyed to the TNBC after creation of these habitats. SAFCA may also contract with the TNBC for management elements of some habitat features (e.g., the GGS/Drainage Canal).

Management Agreements

The MMPs will describe the framework for the design and management of the mitigation habitat components of the proposed project. The actual implementation of this framework will be enacted through Management Agreements. These contractual agreements will focus on the management obligations specific to each entity, and describe the demonstrated financial and legal assurances necessary to implement the MMPs and protect and manage the habitat mitigation components in perpetuity. These contractual agreements will be subject to review and approval by the Service, Corps, and CDFG, and enforced by SAFCA, in perpetuity, and by Corps through permit issuance.

Funding Mechanism
Funding for implementation of the MMP and LTMP, including construction, monitoring, and long-term management of the compensatory habitat components, has been incorporated into the overall budget for implementation of the NLIP Landside Improvements project. Funding for the management and administration of the various habitat components will be negotiated through agreements with RD 1000 (GGS/Drainage Canal management, managed grasslands), TNBC (rice fields, field crops, landside woodlands, and GGS/Drainage Canal administration), and NCMWC (water).

SAFCA anticipates funding for the agreements with RD 1000 and NCMWC will be provided on an annual basis from the special assessments collected as part of the Consolidated Capital Assessment District (CCAD). In order to ensure timely payment for the services rendered under these agreements, SAFCA will maintain reserve accounts with balances sufficient to support annual funding for two years for each agreement. Upon termination of the CCAD in 2037, these payments will be covered by assessments collected as part of SAFCA's existing Operation and Maintenance Assessment District. Funding for the agreement with TNBC will be provided through a non-wasting endowment funded by CCAD assessments.

Project Phasing

The proposed project is comprised of three phases of construction, spanning approximately 3 years. Phase 2 of the NLIP Landside Improvements project, for which SAFCA is currently requesting a permit, is described and analyzed in detail in this permit application, while Phases 3 and 4, for which subsequent requests for permits will be submitted, are described and analyzed at a more general, program level of detail in this document.

Phase 2 Work

Table 1 summarizes the major elements of Phase 2 of the Landside Improvements project (proposed project) and the general timeframes in which the elements are expected to be implemented. Note that although seepage berms are depicted as the primary means of providing underseepage remediation along the Sacramento River east levee, the use of cutoff walls continues to be evaluated, and cutoff walls will likely be implemented instead of berms in several locations. Each of the main project elements are described in more detail below.

Levee Raising and Seepage Remediation

Natomas Cross Canal South Levee

The proposed project would include raising the entire NCC south levee (Station 0+00 to Station 287+50, Reaches 1 to 7) and would continue the construction of a seepage cutoff wall from the eastern terminus of the NCC South Levee Phase 1 Improvements (NCC Phase 1 Improvements) initiated in 2007 (Station 0+00 to Station 61+00, beginning of Reach 1 to approximately middle of Reach 2) to the eastern end of the NCC south levee (approximately Station 56+00 to Station 287+50, approximately the middle of Reach 2 to end of Reach 7). NCC Reaches correspond roughly to the following Stations: Reach 1 (Station 0 to Station 3); Reach 2 (Station 4 to Station 103), Reach 3 (Station 103 to Station 123), Reach 4 (Station 123 to Station 170), Reach 5 (Station 171 to Station 195), Reach 6 (Station 195 to Station 277), and Reach 7 (Station 278 to Station 287). Phase 2 would include the construction of the NCC south levee component, which is anticipated to occur over one construction seasons, beginning in May 2009 and ending in October 2009. The primary construction activities are described below.

Preparation for construction of the cutoff wall would begin with using scrapers (or other suitable equipment, depending on the slope) to clear and grub/strip the surface to a depth of 2 inches to remove low-growing vegetation, loose stone, and surface soils. The aggregate base from the operating road also would be removed and stockpiled for later reuse. Waste material would be hauled to an off-site location.

Construction of the cutoff wall would include degrading the existing levee to a depth equal to one-half its total height (approximately 9 feet). A 70-foot-deep cutoff wall would be constructed for a total length of 23,150 linear feet (2 million square feet), with the method of installation at the contractor's discretion. Given anticipated schedule constraints, a

Table 1
Summary of the Major Elements of Phase 2 of the Proposed Project

Project Element	Proposed Activity and Timing
Levee raising and seepage remediation: NCC south levee	Raise and realign the NCC south levee to provide additional freeboard and more stable waterside and landside slopes and to reduce the need for removal of waterside vegetation. (May–October 2009) Construct a seepage cutoff wall through the levee crown in Reaches 3–7. (May–October 2009)
Levee raising and seepage remediation: Sacramento River east levee (adjacent setback levee)	Construct a raised adjacent setback levee from the NCC to just south of the North Drainage Canal (Reaches 1–4B) with a 100-foot seepage berm in Reach 4A and a 300-foot seepage berm in Reach 4B. (May–October 2009) Relocate utility poles. (November-December 2008)
Improvements to major irrigation and drainage infrastructure	Construct a new canal designed to provide drainage and associated giant garter snake habitat (the GGS/Drainage Canal) between the North Drainage Canal and Elkhorn Reservoir. (May–October 2009) Relocate the Elkhorn Canal (highline irrigation canal) between the North Drainage Canal and Elkhorn Reservoir in anticipation of the filling of the existing Elkhorn Canal at the toe of the Sacramento River east levee. (May–October 2009) Remove a deep culvert at the location of Pumping Plant No. 2. (May–October 2009)
Habitat enhancement, creation and management	Establish vegetative habitat features in the new GGS/Drainage Canal. (Fall 2009) Recontour and create habitat on lands used as borrow sources. (Fall 2009) Establish grassland on the adjacent setback levee slopes and seepage berms. (Fall 2009) Install woodland plantings to offset the loss of portions of tree groves in the landside levee footprint. (Fall 2008–Fall 2009)
Right-of-way acquisition	Acquire right-of-way through fee title or easement interest within the footprint of the project features, at the borrow sites and along the flood control system. (Before construction)

Notes: Elkhorn Canal = Elkhorn Main Irrigation Canal; GGS = Giant Garter Snake; NCC = Natomas Cross Canal

three-heading, double-shift work schedule is anticipated. Material degraded to support cutoff wall construction would be compacted at the landside toe of the levee to support the levee raising operation described below. Unsuitable material generated from cutoff wall construction would be disposed of off-site.

Raising of the Natomas Cross Canal South Levee

Levee raising would occur throughout the entire length of the NCC to provide three feet of freeboard over the design water surface profile (this requires raising the levee approximately three feet). Throughout most of the NCC, this would be accomplished by setting the levee back towards the landside, such that there is a theoretical 3H:1V waterside slope extending from the existing waterside toe to the new waterside top. Following degrading of the levee for cutoff wall construction, the new levee crown would be constructed such that the actual waterside slope extends to meet the point of degrade on the waterside slope. This actual slope would be 3H:1V or flatter. The new levee crown would have a width of twenty feet and the new landside slope would be 3H:1V. Where an existing stability berm is present, it would be stripped and incorporated into the new levee prism. Any portion of the berm outside of the limits of new fill would be trimmed back to conform to the new landside 3H:1V slope. Where the berm is fully incorporated, it would be stripped and trimmed as necessary to accommodate placement of new fill material around it. Existing drain pipes exiting the berm would be extended to daylight landward of the new levee landside toe.

Throughout Reaches 6 and 7, Sutter County infrastructure (Howsley Road and related features) and private residences are close to the NCC south levee. To avoid the infrastructure and residences, between Station 215+00 and 245+00 (central portion of Reach 6, from just west of State Route (SR) 70/99 to just east of SR 70/99), the levee would be raised waterward, encroaching on the NCC channel approximately 30 feet. Between Stations 245+00 and 279+50 (remaining portion of Reach 6), the levee would be raised on the landside, similar to Stations 54+00 through 215+00 (approximately the middle of Reach 2 to initial portion of Reach 6). Smooth transition distances of up to 200–500 feet would link the waterward and landward raises.

Vegetation would be removed from the waterside slope in all locations above the elevation corresponding with the projection of the landside levee toe on the waterside slope. Between Station 0+00 and 54+00 (Reach 1 through first half of Reach 2), where there is significant vegetation on the waterside slope above this elevation, the levee would be set back an additional fifteen feet to provide a "root-free" zone on the levee slope, and the vegetation would remain.

Removal of Structures

Relocation of Howsley Road, the Morrison Canal, a roadway drainage pump station, and three residences and outbuildings would be required by landward levee raises in Reaches 6 and 7. If hydraulic modeling indicates that unacceptable hydraulic impacts would not result from waterside levee raising in Reaches 6 and 7, only two structures in Reach 7 (a residence and a semimobile trailer) would require relocation as a result of the proposed levee improvements.

Utility Modifications and Miscellaneous Work

Pipelines penetrate the NCC south levee at four locations: Odysseus Farms (Bolen Ranch); NMWC waterside Bennett Pumping Plant; NMWC Northern Pumping Plant; and RD 1000's landside Pumping Plant No. 4. None of these penetrations comply with current Corps regulations; therefore, the pipelines would be raised to have their inverts above the 200-year water surface elevation and would be equipped with waterside shutoff valves. If pipes are corroded, they may have to be replaced down the waterside slope of the levee.

As part of raising the pump station discharge pipelines that cross the NCC south levee, canals south of the levee would need to be relocated farther from the levee toe in the following locations: the RD 1000 Vestal Drain and NMWC Bennett Canal between Station 55+50 and Station 61+50 (middle of Reach 2) and the NMWC North Main Canal between Station 120+00 and Station 123+50 (end of Reach 3 to beginning of Reach 4) and between Station 216+00 and 218+00 (Reach 6, just west of SR 70/99). The ditch segments would be moved about 100 feet farther away from the levee toe. Some of this work may be accomplished by NMWC as part of its American Basin Fish Screen Project, but the timing of this NMWC project is uncertain. If the work is not accomplished by NMWC, SAFCA would relocate the canals at the time that the pipelines are raised.

Between Station 0+00 and Station 19+00 (beginning of Reach 1 through first eighth of Reach 2) of the NCC south levee, SAFCA intends to obtain a landside levee maintenance access area to match the 80- to 100-foot wide maintenance access area already established for the levee. This area is currently in active rice fields. Once the maintenance access area is established, this area would be filled to be above the agricultural field grade to prevent encroachment by farming operations into the maintenance access area and to provide an operating road at the levee toe. Between Station 99+00 and Station 124+00 (end of Reach 2 through Reach 3), a low-lying area between the levee's landside toe and an operating road for the Lucich North Habitat Preserve would be filled to raise the grade of the operating road at the landside toe.

In 1996, as part of SAFCA's NCC and PGCC Levee Project, 200 feet of floodwall was installed to raise the NCC levee around the State Route (SR) 99/70 bridges over the NCC. The top of wall for this floodwall is at elevation 44.80 feet (National Geodetic Vertical Datum 29). To conform to current levee criteria, the floodwall would need to be raised to elevation 49.3 feet.

Construction Staging Areas and Postconstruction Site Condition

Construction staging would take place in areas adjacent to the NCC south levee, within the maintenance access areas between Stations 0+00 and 56+00, 61+00 and 96+50, 99+00 and 216+00, and 251+00 and 281+00. Cutoff wall construction would require temporary establishment of three on-site slurry batch plants that would occupy about 1–2 acres each. Each batch plant site would likely contain tanks for water storage, a pug mill mixer, bulk bag supplies of bentonite, bentonite and cement storage silos, cyclone mixers, pumps, and generators. The sites would also include slurry tanks to store the blended slurries temporarily until they are

pumped to the work sites. Slurry constituents would be mixed with water at the batch plant and the mixture would be pumped from the tanks through pipes to the cutoff wall construction work sites.

After construction, the levee slopes and any previously vegetated areas disturbed during construction, including staging areas, would be seeded with a grass mix.

Sacramento River East Levee Reaches 1–4B

Phase 2 of construction would begin in 2009 for the Sacramento River east levee, which includes an adjacent levee extending from the northern end of Reach 1 at the NCC south levee through Reach 4B (approximately Station 0+00 to Station 226+00). Also included in Phase 2 is: installation of cutoff wall in Reach 2 of the adjacent levee; construction of a 100-foot seepage berm in Reach 4A and 300-foot berm in Reach 4B; planting of woodlands in a corridor and fallow fields extending from the lower end of Reach 1 through portions of Reach 4A; and reconstruction of the intersections of Sankey Road and Riego Road with Garden Highway.

An adjacent setback levee is proposed in lieu of in-place modification of the existing Sacramento River east levee, which has substantial structural and vegetation encroachments along its water side. The adjacent-levee raise would involve the construction of a new embankment adjacent to the existing levee. A minimum 5-foot-wide shoulder would extend from the landside edge of the crown of the existing levee to the water side of the new adjacent setback levee embankment. A 3H:1V slope would extend up to the crown of the adjacent setback levee. The crown would be at least 20 feet wide and would be topped with an aggregate base access road for inspection and maintenance. The adjacent setback levee would have a 5H:1V landside slope, except for approximately 5,000 feet in Reaches 2 and 3, which would be 3H:V1. It would be constructed of compacted random fill material from borrow sources and from the excavation of the existing landside stability berm.

It is assumed that a main construction staging area for this phase would be located on approximately 5 acres near Riego Road. The area would be fenced and would be used for the contractor's and engineer's construction trailers, parking for personnel, machine maintenance tools and parts, possibly water trucks, and the storage of fuels and other materials to be used for construction. The project right-of-way along the construction area also would be used for staging of construction materials and equipment. Personnel, equipment, and imported materials would reach the project site via SR 99/70, Sankey Road, Riego Road, and Elverta Road. The primary corridors where construction activity would take place are the adjacent levee alignment and existing dirt roads used for access to the work areas; soil borrow areas; and paved roads, including Powerline, Sankey, and Riego Roads.

Improvements to Reaches 1–4B are anticipated to occur over one construction season, beginning in May 2009 and ending in October 2009. The primary construction activities are described below.

Site Preparation (Tree Removal, Clearing, Grubbing, and Stripping) - Site preparation would entail removing trees and other large vegetation from the construction area and stripping the top 6 inches of material from the landside slope of the existing levee, the footprint of the adjacent setback levee, the seepage berm areas, and the 50-foot-wide permanent maintenance access corridor. Large roots and deleterious material would then be grubbed from the working area. To the extent feasible, trees that must be removed from within the footprint of the adjacent setback levee or berms would be relocated outside of the footprint to new woodland planting areas, where a substantial number of new trees would also be planted. Excess earth materials (organic soils, roots, and grass from borrow areas and the adjacent levee foundation and excavated material that does not meet levee embankment criteria) would be used in the reclamation of borrow areas or hauled off-site to landfills. Cleared vegetation (i.e., trees, brush) would be hauled off-site to landfills.

Relocation of Irrigation Ditch - Odysseus Farms, located at the junction of the NCC south levee and Sacramento River east levee, maintains a private irrigation ditch that is situated within the proposed footprint of the adjacent setback levee. This private irrigation ditch is situated along the top of an existing berm in Reach 1 within the proposed footprint of the adjacent setback levee. Before filling of the existing ditch, a new ditch would be constructed in Reach 1 to serve irrigation needs for agricultural uses of the land along this reach. The new ditch would be constructed from Station 0+00 to Station 25+00 and would be elevated, similar to the existing canal, to allow for gravity flow southward from the NCC. The relocated ditch would cross under Sankey Road through a culvert and meet the existing canal lateral at Station 25+00. The existing ditch would be drained and any unsuitable material from the ditch bottom would be excavated and hauled off-site. To maintain irrigation system continuity, this relocation work would need to be implemented prior to May 1, 2009, as facilities begin operations prior to May and are continually in operation through the end of summer, thus presenting limited opportunities for relocation during the levee construction work window.

Removal of Landside Structures and Other Facilities - Residences and other farm structures that are within the proposed footprint of the adjacent setback levee embankment, berms, and maintenance areas at Station 35+00 in Reach 1 (house, barn, and shed) would have to be removed or relocated farther from the flood control facilities before the start of levee construction. Irrigation facility collection/distribution boxes, wells, and standpipes within the footprint of the flood control features would be demolished and replaced as needed. Debris from structure demolition, power poles, utility lines, piping, and other materials requiring disposal would be hauled off-site to a suitable landfill. As feasible, demolished concrete could be sent to a concrete recycling facility. Wells and septic systems would be abandoned in accordance with the applicable state and county requirements. Some utility poles would be relocated after October 1, 2008, after permit issuance; the removal of other landside structures and facilities would not occur until May of 2009.

Excavation of Stability Berm and Inspection Trench

The existing stability berm along the levee would be excavated and the soil and drain rock would be stockpiled for use in the construction of the adjacent setback levee. The geotextile fabric from

the drain layer would be discarded. A 3-foot-deep inspection trench would also be excavated along the foundation of the adjacent levee raise area after stripping has occurred. The purpose of this trench is to expose or intercept any undesirable underground features such as old drain tile, water or sewer lines, other debris, animal burrows, buried logs, or pockets of unsuitable material (e.g., sand lenses). After inspection, the trench would be backfilled and compacted as part of the embankment construction.

Construction of Adjacent Levee Raise and Cutoff Walls
Borrow material would be excavated from several locations in the project area and would be delivered to the levee construction sites by scrapers or haul trucks where it would be spread by motor graders and compacted by sheepsfoot rollers to build the adjacent levee up to a height equal to about two-thirds of the height of the existing levee. This would create a working platform for cutoff wall installation using an excavator with a long-stick boom capable of digging a trench to a maximum depth of approximately 80 feet. Bentonite slurry would be pumped into the trench during excavation to prevent caving. The soil excavated from the trench would be mixed with bentonite and backfilled into the trench to create the cutoff wall.

Reconstruction of Garden Highway at Intersections - The Garden Highway intersections at Sankey and Riego Roads would require reconstruction to accommodate the raised adjacent setback levee. It is anticipated that Garden Highway would be extended up and onto the widened adjacent levee at these locations to meet with the secondary roads. Approach embankments at the intersections would be enlarged and the entire intersections would be repaved. Intersecting roads would be raised at a slope of 15H:1V, extending the approach embankment approximately 350 feet outward from the levee. The side slopes of the raised embankments would be at a 3H:1V slope.

Installation of Surface Drainage Outlets across Garden Highway - Between the adjacent setback levee and the Garden Highway pavement, new storm drain facilities would be constructed to convey surface water beneath Garden Highway and toward the Sacramento River. A drainage swale collection system would convey runoff water to drop inlets located approximately 1,000 feet apart along an approximately 22,800-foot-long section of the improved levee, and new 12-inch diameter pipe laterals would convey the water beneath Garden Highway to the waterside slope berm. Excavation of a trench across Garden Highway and down the waterside levee slope would be required; those segments of Garden Highway where excavation occurs would have to be reconstructed. Single-lane traffic controls and through-traffic detours would be required during construction Phase 2. Drainage outlets would be located on the waterside levee berm, above the two-year ordinary high water mark. The construction of the drainage outlets entail the excavation of a 100 square foot area, of which the lower eighteen to twenty-four inches would be filled with a gravel/cobble mix, and the upper six to twelve inches would be an open depression. Water exiting the drainage outlets would settle in the depression, and then flow overland to the Sacramento River.

Site Restoration and Demobilization - Following construction, the levee slopes, seepage berms, maintenance access right-of-way, and any previously vegetated areas disturbed during

construction would be seeded with a grass mix. Any construction debris would be hauled to an appropriate waste facility. Equipment and materials would be removed from the site, and staging areas and any temporary access roads would be restored to preproject conditions. Demobilization would likely occur in various locations as construction proceeds along the project alignment.

Major Irrigation and Drainage Infrastructure Modifications

Elkhorn Canal - The Phase 2 construction plan would include the new Elkhorn Canal from the North Drainage Canal to Elkhorn Reservoir, between Reach 4B and Reach 6B. On the north end, the new canal would be connected with the existing Prichard Pumping Plant outfall and an outlet to the North Drainage Canal would be constructed. An outfall to provide for connection to RD 1000 Pumping Plant No. 2, during its construction in Phase 3, would be incorporated into the Phase 2 canal construction to minimize the need for future canal disturbance. The discharge pipes from the Prichard Pumping Plant would be extended to the relocated canal. The outlet to the North Drainage Canal would be combined with the GGS/Drainage Canal outfall with a gated control structure in the irrigation canal and a piped outlet to the North Drainage Canal.

At the southern end, the relocated Elkhorn Canal would connect into an earthen-lined sediment basin. The sedimentation basin would consist of a number of watered, earthen-bottomed chambers separated by weirs, which may be concrete or rock covered. The basins would have 3H:1V embankments that are 15-foot-wide at the top to provide maintenance equipment access. The total area of basins including the embankments is approximately 9.6 acres, with nearly 3.3 acres of water surface. The proposed sediment basin would be connected to Elkhorn Reservoir with a temporary pipe and outfall structure. During construction Phase 3 (see below), Elkhorn Reservoir would be dewatered and piping from the Elkhorn Pumping Plant would be extended to the new sediment basin, at which time the Elkhorn Reservoir sediment basin would be abandoned and filled.

The GGS/Drainage Canal would be constructed parallel to and within the same right-of way as the Elkhorn Canal. These features would be constructed concurrently to facilitate the use of excavated material from the GGS/Drainage Canal for use as embankment material along the Elkhorn Canal.

The primary construction stages for Elkhorn Canal are described in the subsections below.

Clearing and Grubbing/Stripping

Preparation for canal construction would entail using bulldozers/scrapers to clear and grub/strip the surface to a depth of 4–6 inches and remove low-growing vegetation and loose surface soils. Suitable materials removed during this stage could be stockpiled. Unsuitable material would be wasted and hauled off-site. The right-of-way for the canal that would need to be cleared (including the GGS/Drainage Canal right-of-way) is approximately 225 feet wide. Bulldozers/scrapers and front-end loaders would be used to excavate and move material. Water

trucks would be used to control dust and dump trucks would be used to haul unsuitable materials away.

This phase of construction would commence immediately after mobilization and would most likely occur in multiple sections of the Elkhorn Canal and GGS/Drainage Canal alignments simultaneously.

Pump Discharge Pipe Extension

Because the Elkhorn Canal would be relocated farther from NMWC pumping plants than the existing canal, additional pipe would need to be installed to maintain the connections between the pumping plants and the irrigation canals. In particular, discharge pipes would need to be extended at Prichard Pumping Plant and Elkhorn Pumping Plant. Pipes would be transported to the site on flatbed trucks. Excavators and backhoes would be used to dig the pipe trenches and lay the sections of welded steel pipe and backfill the trench. The trench would be deep enough to provide for a minimum of 12 inches of cover. A small compactor would be used to compact the soil over the pipe. The construction of pipelines at the existing Prichard Pumping Plant would occur during Phase 2 of construction, and at the Elkhorn Pumping Plant pipeline construction would occur during Phase 3 of construction.

Prichard Pumping Plant Connection

A new concrete transition structure would be constructed at the north end of the existing Elkhorn Canal to connect the existing Prichard outfall box culvert to the new Elkhorn Canal. Three reinforced concrete discharge pipes, two 36-inch and one 30-inch, approximately 600 feet in length, would be constructed in parallel from the new transition structure to the proposed distribution box located approximately 250 feet south of the western end of the North Drainage Canal. These pipes would connect the Prichard Pumping Plant outfall to the distribution box. From the distribution box, two 54-inch reinforced concrete discharge pipes, approximately 30 feet long, would connect the box to the new Elkhorn Canal.

The concrete distribution box footprint would be approximately 25 foot by 30 foot. A 60-inch discharge pipe stub and 48-inch intake pipe stub would be constructed on the north side of the distribution box. These stubs will provide for future connections of the distribution box to the North Drainage Canal and Pumping Plant No. 2.

Water Control Facility Construction

New facilities that would be constructed include distribution boxes, gate valves, cast-in-place concrete headwalls and control structures, culverts, and a proposed earthen-lined sediment basin adjacent to Elkhorn Reservoir. Backhoes and excavators would be used to excavate material for the new facilities. Precast distribution boxes, pipes, and other appurtenances would be transported to the site on flatbed trucks. Other concrete facilities would be poured in place and concrete would be transported to the site in ready-mix and boom concrete pumper trucks. Small compactors would be used to compact fill material around the facilities.

Embankment and Access Road Construction

The existing Elkhorn Canal is a highline canal, and construction of its replacement would require little or no excavation but a large amount of borrow material. The bottom of the new Elkhorn Canal channel would be approximately at existing ground level. During construction, borrow material would be required to build up the embankments of the new canal, which would be approximately 4 feet above the channel bottom with 3H:1V side slopes. Bulldozers and graders would be used to move and shape the embankment material, sheepsfoot and smooth drum rollers would be used to compact the embankment material, and water trucks would be used on-site for dust control and moisture conditioning.

Irrigation Interconnections

This phase includes work required to interconnect the relocated Elkhorn Canal with the existing irrigation canals within the Natomas Basin. Excavators and backhoes would be used to trench any connectors and motor graders would be used to shape the embankments. A water truck would be used to control dust and provide moisture conditioning during the excavation and construction of the interconnection facilities. Canal interconnections would be performed before the abandonment of the existing Elkhorn Canal.

Central Main Flume Connection

A second concrete distribution box would be constructed to connect the Elkhorn Canal to the Central Main Flume. The box will be located at the intersection of the Elkhorn Canal with the Central Main Flume with a footprint that is approximately 19 feet by 49 feet and will be tied into the existing concrete flume. Three 48-inch slide gates would be constructed on both the north and south ends of the box to connect the box to the Elkhorn Canal both north and south of the flume. A 6 foot by 6 foot reinforced concrete box culvert on the east end of the distribution box would connect to an outfall structure and the end of the flume.

Erosion Control

Erosion control measures would be installed before the start of construction and would be maintained throughout the construction period to prevent sedimentation of adjacent waterways. A hydroseeding truck would be used at the end of construction to seed any disturbed area. Water trucks would be used throughout the construction period to control dust in any disturbed areas.

Irrigation Canal Abandonment

As the newly constructed canal is completed and operable, the existing Elkhorn Canal would be abandoned. Irrigation flows would be rerouted to the new canal and the existing canal would be dewatered and abandoned. The filling of the abandoned Elkhorn Canal in Reach 4B would take place as part of Phase 2 of levee construction and in Reaches 5A to 6B would take place as part of the Phases 3 and 4 of levee construction. Portions of farm canals and other irrigation canals would be abandoned because of the relocation of the Elkhorn Canal. Such segments that are outside the footprint of the proposed levee improvements would be filled after the relocation of the Elkhorn Canal is completed. Dump trucks would be used to haul fill material to those canals, rollers would be used to compact the fill, and water trucks would be used for dust control.

Demobilization/Cleanup

This phase includes dismantling any temporary facilities, hauling away any leftover construction materials, and cleaning up the site. All disturbed areas would be reseeded and graded to drain. A front-end loader and dump trucks would be used to move materials. This phase of construction would also entail general cleanup and hauling away unused and waste materials. All construction equipment would be removed.

Scheduling for Phase 2 Construction of the Elkhorn Canal

The segment of the Elkhorn Canal from the Prichard Pumping Plant to the Elkhorn sedimentation basin would be constructed between May and October 2009. The segment of the Elkhorn Canal from the Central Main Flume to the Elkhorn sedimentation basin would be constructed between May and October 2009.

Phase 2 Construction on New GGS/Drainage Canal - The Phase 2 construction plan would include the construction of the GGS/Drainage Canal from the North Drainage Canal to the slough east of Elkhorn Reservoir, between Reach 4B and Reach 6B. The GGS/Drainage Canal and Elkhorn Canal would be parallel and separated by a 20-foot right-of-way access. The GGS/Drainage Canal would tie into the North Drainage Canal east of the proposed location of replacement RD 1000 Pumping Plant No. 2. Crossing of the Elkhorn Canal and tie-in to the North Drainage Canal are anticipated to be made via open, arching culverts (e.g., "Con-Arch" culverts) that allow the GGS/Drainage Canal to pass under the Elkhorn Canal and the access road on the south side of the North Drainage Canal without being confined to pipes.

Because portions of the GGS/Drainage Canal and the Elkhorn Canal would be constructed parallel within the same right-of way, they would be constructed concurrently during Phase 2 construction. This approach would facilitate the use of material from the GGS/Drainage Canal excavation for use as embankment material along the Elkhorn Canal. Construction of the GGS/Drainage Canal would include the same construction phases as described above for the Elkhorn Canal, with a few exceptions. The top of bank for the GGS/Drainage Canal would be approximately at existing ground level. During construction, a trench at least 6 feet deep and an average width of 55 feet would need to be excavated for the construction of the GGS/Drainage Canal. Reclamation would include planting tules on the sloped banks. Backhoes would be used to prepare the planting areas and a water truck would be used to control dust.

Removal of Culvert at Pumping Plant No. 2 Site - SAFCA would undertake a second phase of the levee repairs and facility removal adjacent to the RD 1000 Pumping Plant No. 2 site at the west end of the North Drainage Canal as part of the proposed project. This phase of work would include: (1) excavating and removing approximately 400 feet of the existing levee section adjacent to the Pumping Plant No. 2 site to expose a deep culvert and possible voids under the levee, (2) removing the deep culvert, (3) reconstructing the levee adjacent to the pumping plant sump with levee embankment fill, and (4) demolishing, removing, and relocating the pumping plant remnants within the project footprint. The last activity, reconstruction of the pumping plant, would be conducted in the 2009 construction phase and is described in the next subsection.

The project-related work would be confined to an area of approximately 2.3 acres. A stockpile and staging area of approximately 4.5 acres would be established near the work area.

Excavation limits would be extended to reconstruct the levee section adjacent to the sump and to reach areas where anomalies were identified during a geophysical investigation of the site. An area on the water side of the sheet pile wall would be excavated to lower the ground surface so as to reduce the loading on the sheet pile and excavation shoring system as the excavation takes place on the land side of the sheet piles. Excavated material would be stored on the site along the dewatered section of the North Drainage Canal, east of the abandoned sump, and in an adjacent agricultural field along the canal.

During excavation, the remnants of the pumping plant would be demolished and removed. This work includes relocation of a 36-inch irrigation supply pipe that is within the excavation limits. A temporary plastic fabric-lined ditch at the outfall of this pipe would also be relocated to provide for sufficient staging and stockpile areas. A short irrigation system 'outage' would be required to allow for relocation of the pipe and ditch.

Heavy equipment required for construction includes semi flatbed and/or box trucks to deliver equipment and materials; a crane to drive sheet pilings for additional shoring needs; dump trucks to haul debris, stockpile excavated levee material, and import select soil materials for levee reconstruction; two hydraulic excavators; two dozers for stripping and stockpiling material, a grader, water truck, and front-end loader for maintenance of haul roads and stockpiles; and a roller compactor for levee construction.

Habitat Enhancement, Development, and Management

Habitat enhancements and developments planned for Phase 2 of project construction include: the northern segments of the relocated Elkhorn Canal and the newly constructed GGS/Drainage Canal between the North Drainage Canal and Elkhorn Reservoir; the preservation and establishment of landside woodlands along the Sacramento River east levee; the creation of managed grasslands on the newly constructed levee slopes, seepage berms, access rights-of-ways, and canal embankments; and the preservation of rice land. Please refer to the Phase 2 MMP for a more complete summary of the conceptual strategy for creating/enhancing/preserving, protecting, and managing habitats in the Natomas Basin in perpetuity.

The proposed project would offset temporary and permanent effects to habitat of listed species through the creation, enhancement, and preservation of habitat in the basin. The construction of the Elkhorn Canal and GGS/Drainage Canal, including their management elements, are described above in more detail. Design and management elements for the managed grasslands, landside woodlands, and rice fields are summarized below.

Managed Grasslands

Levee Slopes and Seepage Berms - Levee improvements would result in landside slopes that are less steep than the existing slopes, and several reaches of the Sacramento River east levee would

have adjoining 80- to 300-foot-wide earthen seepage berms with a nearly flat slope (50H:1V or less). Parallel to the landside toe of enlarged levees and seepage berms would be maintenance access roads and seepage relief wells in some locations. Additional setback buffer lands would flank some of these features, and property acquisition for the proposed project may leave SAFCA with remnant portions of acquired parcels that are nonessential to flood control uses. With the exception of the crown of the levee, these areas would be managed as grassland. Most grassland would be mowed or grazed throughout the growing season, with an emphasis on mowing procedures and stubble height to optimize these areas for Swainson's hawk foraging habitat. However, the primary purpose and management priority of levees and seepage berms would continue to be flood risk reduction, for which RD 1000 has principal management and maintenance responsibility, and they would be maintained in accordance with Corps and Central Valley Flood Protection Board operations and maintenance requirements.

Canal Embankments - The side slopes of the new GGS/Drainage Canal and relocated Elkhorn and Riverside Canals would be flatter than typical canal slopes in the Natomas Basin and consistent (3H:1V), resulting in greatly reduced erosion and sedimentation. Vegetation on the banks could easily be mowed to a specified stubble height using cutter blades instead of the existing, high-disturbance practice of flail mowing or scraping vegetation from the banks and canal with a drag bucket. These improved canal maintenance practices would substantially reduce disturbance and incidental mortality of giant garter snakes that use bank and shoreline vegetation as cover and feeding habitat.

Landside Woodlands

Woodlands consisting of native riparian species would be planted east of the maintenance corridor along the Sacramento River east levee improvements. In Phase 2, tree and shrub species, including elderberry shrubs (*Sambucus mexicana*), would be planted on approximately 30 acres of existing cropland or fallow or currently unused sites. Groves would generally be at least 50-100 feet wide and several hundred feet long. Wide woodland corridors would promote successful nesting by a variety of native birds deeper within the grove canopy, where nest parasitism by crows, cowbirds, and starlings is less of a factor in breeding success. At maturity, stand structure would vary from closed canopy woodland to grassland savanna vegetation types.

Planting sites would require suitable soil conditions, water supply during a 3- to 5-year establishment phase, reduced risk of wildfire, and minimal depth to seasonally high groundwater or other natural water sources to sustain trees once irrigation ceases. A mixture of native riparian species would be planted, but predominant species would be Valley oak (*Quercus kelloggii*), the primary tree species that would be affected by the proposed improvements to the Sacramento River east levee, and cottonwood (*Populus fremontii*), which is a preferred nest tree for Swainson's hawks in the basin and is faster growing than Valley oak. Establishment of woody vegetation would likely require more than one technique, including seeding in winter, flood irrigation, drip or agricultural-scale spray heads, cuttings, and acorn planting.

Where trees would be removed from existing groves to make way for the proposed flood control system features, they would be transplanted in new locations, including newly planted groves, to

the extent feasible. The woodland planting areas would provide locations for transplanting any elderberry shrubs that would need to be moved from the proposed footprint of flood risk reduction improvements.

Rice Fields

Brookfield - The Brookfield property is a 353-acre private property that is located between Howsley Road and Fifield Road, west of the PGCC west levee. As of the summer of 2008, the property is currently in rice cultivation.

Up to 160 acres of the site may be utilized for borrow operations in Phase 2. After the completion of borrow excavation, the 160 acres would be returned to rice and at least ½ of the 353-acre site would be preserved in perpetuity. The removal of borrow material would entail excavating the site to a depth of up to approximately 6 feet, with an approximate net yield of 3.6 million cubic yards of soil from the site. One foot of topsoil would be removed and stockpiled for reuse during reclamation of the site. This borrow material would be used for levee improvements along the NCC south levee (construction Phase 2), PGCC west levee (construction Phase 3), and possibly the NEMDC west levee (construction Phase 4); however, no area of the property would be used in consecutive years. Following the removal of borrow material for the levee construction, the site would be graded and returned to rice cultivation.

Currently, the site is irrigated from on-site wells. To provide irrigation to the site following the excavation of borrow material, the irrigation canal along the south side of the site would be deepened and reconfigured from the Brookfield site westward to the culvert under SR 99/70. Additionally, a field irrigation ditch would be constructed within the Brookfield site to provide irrigation water from the adjacent highline canal to the fields. Grading of the site would be performed at a slope that would allow the water to flow back to the drainage canals running along the west and south side of the property. The water from the eastern fields would be drained into a canal along the west side of the pasture land and into the southern drainage canal. The drainage channel along the west and south side of the property would be modified to allow the site to drain following borrow excavation.

Modifications include widening all canals to an 8-foot bottom width with 3H:1V side slopes. Specific canal improvements could include modification of approximately 4,480 feet of the RD 1000 canal that borders the south end of the site, modification of 3,670 feet of the private north-south drainage ditch along the west edge of the property, creation of a 900-foot long drainage ditch along the west edge of the pasture lands, and modification of a 6,350 foot long section of the drainage canal along SR 99/70 from the RD 1000 canal south. Improvements of the drainage canal along SR 99/70 may require land acquisition of up to 25 acres to account for the additional width of the channel and flatter side slopes.

Reclamation of Other Borrow Sites

Borrow sites would provide material for Phase 2 flood control and irrigation infrastructure modifications. Following excavation of the borrow material, these sites would be reclaimed for postconstruction uses.

Airport North Borrow Sites - The Airport's north bufferlands have been historically farmed as rice fields and field crops. However, based on FAA requirements to reduce hazardous wildlife attractants near runways, the Airport has opted to not renew rice leases on its bufferlands. Thus, these lands are currently either fallow agricultural fields or ruderal grassland. After borrow activities, these sites would be returned to their current condition.

Cut depths for all the borrow sites would be approximately 4–6 feet. Following the excavation of the borrow sites, disturbed areas would be finish graded to standard irrigation slopes so that the sites would drain and not have any standing water in less than 10-year storm events. Excavated soils not used for borrow material, such as the organic surface layer or soils considered unsuitable for levee construction, would be stockpiled and respread on-site following excavation. Any unsuitable borrow material would be stockpiled on-site and graded back into the restoration of the site. Revegetation activities would include erosion control on excavated slopes (i.e., hydroseeding) and application of fertilizer.

Overview of Construction Phases 3 and 4

Table 2 summarizes the major elements of Phases 3 and 4 of the proposed project and the anticipated general timeframes in which the elements are expected to be implemented. Note that although seepage berms are depicted as the primary means of providing underseepage remediation along the Sacramento River east levee, the use of cutoff walls continues to be evaluated, and cutoff walls will likely be implemented instead of berms in several locations.

Levee Raising and Seepage Remediation

Sacramento River East Levee Reaches 5A–20A

Improvements to the Sacramento River east levee would continue in construction Phases 3 and 4, and would extend from Reach 5A (below Station 226+00) through Reach 20A (Station 925+50). It is anticipated that construction of improvements to the Sacramento River east levee would encompass Reaches 5A-9B in construction Phase 3 and Reaches 10-20A in construction Phase 4. The construction season is assumed to be mid-April – November for both construction phases. The following descriptions of design and construction of the improvements to the Sacramento River east levee proposed for construction Phases 3 and 4 are described in less detail than construction Phase 2 (improvements to the NCC south levee and Sacramento River east levee Reaches 1–4B) because they are not as far along in the project design process.

Table 2
Summary of the Major Elements of Phase 3 and 4

Project Element	Proposed Activity and Timing
Levee raising and seepage remediation: Sacramento River east levee (adjacent setback levee)	Construct an adjacent setback levee along Stations 55+00 to 68+00 in Reach 2 and from just south of the North Drainage Canal to the American River north levee (Reaches 5A–20B), raised where needed to provide adequate freeboard, with seepage berms, relief wells, and cutoff walls for seepage remediation as required (specific seepage remediation measures are still under study). (May 1, 2009–November 1, 2010)
Levee widening and flattening and seepage remediation: PGCC west levee	Widen the levee between Howsley Road and Sankey Road to allow for seepage remediation and flatten the levee on the water side to meetCorps criteria. Construct cutoff walls or seepage berms where required. (April–November 2009)
Levee widening and flattening and seepage remediation: NEMDC west levee	Widen levee and flatten slope between Elkhorn Blvd and NEMDC stormwater pumping station. (April–November 2009) Construct a seepage cutoff wall from NEMDC stormwaterpumping station to Northgate Blvd where required. (April–November 2009)
Improvements to major irrigation and drainage infrastructure	Construct the new GGS/Drainage Canal between Elkhorn Reservoir and the West Drainage Canal, and improve the West Drainage Canal to provide enhanced giant garter snake habitat. (May 1–November 1, 2009) Implement Airport West Ditch improvements in connection with construction of the GGS/Drainage Canal to allow the Airport to decommission the agricultural irrigation function of this facility and eliminate the hazards currently associated with it. The Airport stormwater detention function provided by this ditch would continue. The ditch would therefore be recontoured as a gently sloping swale to facilitate periodic maintenance such as mowing. (May 1–November 1, 2009) Relocate the Riverside Canal and the Elkhorn Canal downstream of Elkhorn Reservoir (specific alignments to be determined) and fill the existing canals. (May 1–November 1, 2009, and May 1-November 1, 2010) Construct RD 1000 Pumping Plant No. 2. (April 1, 2009–September 1, 2010)
Habitat enhancement, creation and management	Establish habitat enhancements in the new GGS/Drainage Canal and improved West Drainage Canal. (Fall 2009) Recontour and create marsh and managed grassland on lands used as borrow sources. (Fall or spring after borrow excavation in 2009 and 2010) Establish grassland on the adjacent setback levee slopes and seepage berms. (Fall after construction in 2009 and 2010) Install woodland plantings to offset the loss of portions of tree groves in the landside levee footprint (locations to be determined). (Fall 2009 and 2010)
Additional actions to meet FEMA requirements: encroachment management on the Sacramento River east levee, and bridge crossing modifications at the NCC	Remove encroachments from a portion of the water side and land side of the Sacramento River east levee as needed to ensure that the levee can be certified as meeting the minimum requirements of the NFIP andCorps design criteria (specific criteria still under discussion). (Timing to be determined) Modify the SR 99/70 crossing of the NCC as needed to meet FEMA requirements. (Timing to be determined)
Right-of-way acquisition	Acquire right-of-way through fee title or easement interest within the footprint of the project features, at the borrow sites and along the flood control system. (Before construction)

Notes: Airport = Saeramento International Airport; Elkhorn Canal = Elkhorn Main Irrigation Canal; FEMA = Federal Emergency Mgmnent Agency; GGS = Giant Garter Snake; NCC = Natomas Cross Canal; NFIP = National Flood Insurance Program; PGCC = Pleasant Grove Creek Canal; RD = Reclamation District; Riverside Canal = Riverside Main Irrigation Canal; SR = State Rou€prps = U.S. Army Corps of Engineers

Required Freeboard Increases and Proposed Underseepage Remediation - Levee crown raises are required to provide adequate freeboard above the 100-year design water surface elevation in Reaches 5A–10 and above the 200-year design water surface elevation in Reaches 11A and 11B. Downstream of Reach 11B (Powerline Road), there is adequate freeboard above the 200-year design water surface elevation, and levee crown raises are not required. Substantial structural encroachments and large amounts of woody vegetation are present on the waterside slope of the existing levee, and the adjacent setback levee is proposed to extend through Reaches 5A–19A to avoid the need for extensive removal of the existing vegetation and encroachments on the waterside slope to meet Corps criteria. The existing levee in Reaches 19B–20B already has a wide crown, and extensive residential development is located along the landside levee toe; therefore, construction of the adjacent setback levee is not proposed for these reaches. The adjacent setback levee would extend outward at least 11 feet from the landside edge of the existing levee crown and would have a 3H:1V landside slope.

Underseepage remediation is required in many of the reaches from 5A through 20A. Reach 20B has sufficient freeboard for the 200-year water surface elevation and a cutoff wall (constructed by Corps in 2000) that meets current design criteria. Because this wall was constructed to an adequate depth, this reach does not need additional seepage remediation. Based on the results of geotechnical investigations, engineering and cost considerations, and land use constraints, cutoff walls are proposed for Reaches 5A–20A.

Removal of Landside Structures and Vegetation - Removal of some residences, other structures, and woodland vegetation, including mature trees, would be required to create ample space for the adjacent setback levee, berms, and maintenance access corridor. It is anticipated that residences would be removed at Station 62+00 in Reach 2, Station 245+00 in Reach 5A, Station 368+00 in Reach 8, Station 436+50 in Reach 9A, Station 468+00 in Reach 10, and at several locations along Reaches 15 through 18.

Miscellaneous Construction Elements and Postconstruction Site Condition - Modifications of roadway intersections with Garden Highway, utility relocations, removal of pumps and wells, and relocation of private canals would be similar to these activities as described for the improvements to Sacramento River east levee Reaches 1–4B. As described for Reaches 1–4B, after construction, the levee slopes, seepage berms, maintenance access right-of-way, and any previously vegetated areas disturbed during construction would be seeded with a grass mix.

Pleasant Grove Creek Canal West Levee

The PGCC west levee is vulnerable to seepage and has stability concerns. The proposed project includes improvements to 17,400 feet of the PGCC west levee, beginning at the east end of the NCC improvements at Howsley Road and extending southerly to Sankey Road. Construction is anticipated to proceed in Phases 3 and 4 on this component of the NLIP. Details of the proposed improvements will be developed based on additional geotechnical studies and cost analysis. The improvements are expected to consist of the following:

- widening of the levee to provide a minimum top width of 20 feet to accommodate safe lane widths for Natomas Road;
- flattening the water side of the levee to a 3H:1V slope;
- reconstructing the landside levee slope with new, select material to create a 3H:1V slope (the existing slope ranges from 2:1 to 2.5:1);
- from its intersection with Howsley Road and continuing one quarter mile south, raising the widened levee one to two-tenths of a foot to provide 3 feet of levee height on the 100-year design water surface profile; and
- constructing a SB cutoff wall through three separate reaches, totaling approximately 5,000 lineal feet, to coincide with areas where streams historically flowed east to west through the current PGCC alignment.

Irrigation and drainage canals at the landside toe of the existing levee would need to be relocated to the west to accommodate the berm construction. Several structures associated with the industrial facility near the southern end of the PGCC would need to be relocated.

The postproject site condition (grass-covered levee slopes and berms) and long-term maintenance practices would be as described above for the NCC south levee and Sacramento River east levee.

Natomas East Main Drainage Canal West Levee

The NEMDC west levee is vulnerable to seepage and has stability concerns. The proposed project includes improvements to the NEMDC west levee, beginning from Sankey Road south to Northgate Boulevard. Construction is anticipated to proceed in Phases 3 and 4 on this component of the NLIP. Details of the proposed improvements will be developed based on additional geotechnical studies and cost analysis. The improvements are expected to consist of the following:

- From the NEMDC pump station (between Elkhorn Boulevard and Del Paso Road) south to Northgate Boulevard, approximately 25,000 linear feet of cutoff wall is to be constructed to a depth of up to 80 feet from the levee crown. The existing maintenance easement on this stretch of the NEMDC will not accommodate levee reshaping or levee degrading beyond what is necessary to provide a minimum working platform for cutoff wall installation. Additionally, structures in close proximity of the landside levee toe make additional maintenance easement acquisition impractical. Where asphalt-concrete surfacing is present at the levee crown, it would be removed and disposed of off site. Following completion of the cutoff wall, the levee crown would be reconstructed and the operating road surface restored.

- North of the NEMDC pump station, to Elkhorn Boulevard, levee widening and slope flattening will occur similar to what is described for the PGCC west levee. These project components include:
  - widening of the levee to provide a minimum top width at least 20 feet to accommodate safe lane widths for Natomas and East Levee Roads;
  - flattening the water side of the levee to a 3H:1V slope; and
  - reconstructing the landside levee slope with new, select material to create a 3H:1V slope.

The postproject site condition and long-term maintenance practices would be as described above for the NCC south levee and Sacramento River east levee.

Major Irrigation and Drainage Infrastructure Modifications

Elkhorn and Riverside Canals

Construction Phases 3 and 4 would include the relocation of the remainder of the Elkhorn Canal (south of Elkhorn Reservoir) and the relocation of the Riverside Canal and would include the same construction phases as described for Phase 2. Timing of the new canal construction would be critical to avoid interruptions in irrigation service. The remainder of the relocated Elkhorn Canal, from Elkhorn Reservoir south, and the relocated Riverside Canal would be constructed before existing canals are filled in as part of the levee improvements in Reaches 6B–9A scheduled for construction Phase 3 and 12–20B scheduled for construction in Phase 4.

In addition to the general canal construction activities described for construction Phase 2, Elkhorn Reservoir would be dewatered and piping from the Elkhorn Pumping Plant would be extended to the new settling basin, at which time Elkhorn Reservoir would be abandoned and filled. The pipelines from the Elkhorn and Riverside Pumping Plants to the relocated irrigation canals would be constructed.

Phase 3 Construction of the New GGS/Drainage Canal

Phase 3 construction phase would include the construction of the GGS/Drainage Canal from north of Teal Bend Golf Course to the West Drainage Canal and improvements to the West Drainage Canal to enhance habitat value for giant garter snake. Because the GGS/Drainage Canal would be approximately 3.5–5.5 feet lower in elevation than the Elkhorn Canal, it would cross underneath the Elkhorn Canal, approximately 350 feet north of Elkhorn Reservoir, likely through a structure similar to that described above for the northern crossing. Reclamation would include planting tules on the sloped banks. In the portion of the canal below I-5, tules would be planted above the canal bench. Backhoes would be used to prepare the planting areas and a water truck would be used to control dust. A 2,850-foot-long section of the existing West Drainage Canal would include a 15-foot-wide managed tule bench, which would typically be inundated with water and drain into the main channel.

Removal of Airport West Ditch

As part of a safety survey conducted by the FAA for the Airport, the FAA expressed concern that the Airport West Ditch provides habitat for wildlife that potentially create a hazard to aircraft. The FAA recommended relocation of the ditch to alleviate the hazard. Additionally, a longstanding problem has existed with leakage from a 24-inch pipeline, resulting in marshy conditions along its route, approximately 11,000 feet between the intake structure and delivery point at the Airport pumps. During the past year the Airport began receiving all of its domestic (drinking) water supply from the City of Sacramento via a pipeline and storage tank project. Two of the on-Airport water wells previously used to provide domestic water were connected to the Airport's landscape irrigation piping system, and the water supply to the "leaky underground

pipe" was deactivated. All of the Airport's landscape irrigation needs are now provided on-site, and there is no need for the leaky pipe to remain in place. Irrigation water provided by NMWC still flows south through the Airport West Ditch, however, whereupon it is pumped to privately owned farms west of the Airport. The proposed project would include the construction of canal improvements to allow for decommissioning of the agricultural irrigation function of the ditch.

During storms, the Airport West Ditch receives stormwater runoff from a portion of the impervious surfaces on the west side of the Airport. Depending on the water volume, some of the stormwater is retained in the ditch until it can drain off-site to the Sacramento River. Therefore, the stormwater detention function of the Airport West Ditch must continue. In addition to the habitat-related safety issues, the ditch presents a physical obstruction hazard to planes that may leave the runway during adverse takeoff or landing situations. Therefore, the final stage of this project component would consist of regrading the Airport West Ditch to a gently sloping swale that can be easily maintained through mowing or other means. The more gradual gradient would also pose a lower threat to aircraft that may unexpectedly exit the runway.

To take advantage of common construction practices and to maximize the use of common facilities, the rearrangement of irrigation and drainage facilities required to provide for rerouting of flows that contribute to the Airport West Ditch would be accomplished along with the proposed NLIP improvements. The proposed GGS/ Drainage Canal would intercept many of the Airport West Ditch's off-site irrigation and drainage sources and reroute flows outside of the Airport Operations Area. The intent is to reroute year-round flows through the GGS/Drainage Canal. Additional irrigation infrastructure improvements required to reroute these flows would be implemented along with the GGS/Drainage Canal construction. Equipment that would be utilized in this reconfiguration includes excavators, loaders, compactors, dump trucks, water trucks, hydroseeding trucks, and generators.

Pumping Plant No. 2 Reconstruction and Relocation

Pumping Plant No. 2 would be reconstructed and relocated as part of the proposed project at the western end of the North Drainage Canal, approximately 900 feet east of the centerline of the levee in the vicinity of the intersection with the P6 Drain. Long discharge pipes would extend over the levee to the Sacramento River. The work is expected to take place in construction Phase 3. Two 42-inch steel discharge pipes, approximately 850 feet long, would connect the two 300-horsepower pumps from the pump station to a new concrete outfall structure in the Sacramento River. The new outfall structure would be constructed close to the location of the original Pumping Plant No. 2 outfall structure. Equipment required for construction of Pumping Plant No. 2 include an excavator, dozer, loader, crane, boom truck, pile driver, concrete pump, generator, and water truck.

Habitat Enhancement, Development, and Management

Habitat enhancements and developments planned for Phases 3 and 4 of project construction include: the southern segments of the relocated Elkhorn Canal and the newly constructed GGS/Drainage Canal between the Elkhorn Reservoir and the West Drainage Canal and the relocated Riverside Canal; additional establishment of landside woodlands along the Sacramento

River east levee; continued creation of managed grasslands on the newly constructed levee slopes, seepage berms, access rights-of-ways, and canal embankments; the creation of managed marsh in the southern areas of the basin; and preservation of additional rice and agricultural upland cropland. Similar to Phase 2, temporary and permanent effects to habitats of listed species that result from the implementation of Phases 3 and 4 would be offset through the creation, enhancement, and preservation of habitat in the basin.

Programmatic Biological Opinion Implementing Procedure

Because the Corps and SAFCA only have a detailed project description for Phase 2 of the entire Natomas Levee Improvement Project, this biological opinion analyzes the landscape effects of the project for all Phases (2, 3, and 4) but will only analyze and provide incidental take coverage for Phase 2. For each subsequent phase, the Corps will initiate section 7 consultation with the Service under the umbrella of this programmatic biological opinion. The following process will be used when implementing projects under this programmatic biological opinion:

1. The Corps will submit a letter requesting that the proposed phase be tiered to this programmatic biological opinion and provide the Service the following:
    a. Project maps, which includes reaches under construction, cover types within the construction/maintenance boundary.
    b. Project schedule.
    c. An inventory of any elderberry stems >1 inch diameter that are within 100 feet of project actions and the number of shrubs and stems that would be transplanted and when and where they would be transplanted.
    d. A description of how compensation measures from the preceding phase are being implemented and the schedule for completion of those measures.

2. The Service will review new information that may reveal effects not considered previously and review the information provided to determine whether the activities described under future Phases were programmatically analyzed in this document.

3. The Corps and SAFCA should involve the Service on Phase 3 and Phase 4 early in the process to allow the Service an opportunity to comment on project descriptions and expedite the completion of biological opinions for those phases.

Please refer to the October 9, 2008, biological opinion for the giant garter snake and valley elderberry longhorn beetle Status of the Species and Baseline.

Effects of the Proposed Action

Giant garter snake

Direct Effects

Overall Project

Land use changes due to SAFCA's project include the permanent loss of up to 395.75 acres of row and field crop including fallow fields (some of which was previously active rice), 65.52 acres of orchard, and 113.75 acres of rice. The project includes an increase of 46.42 acres of woodland, 521.79 acres of grassland, 93.71 acres of managed marsh, and 31.38 acres of canals.

Depending on how the grasslands are managed, the conversion of row crop and fallow agricultural fields to grassland could be beneficial to giant garter snakes. Agricultural areas typically have high levels of disturbance due to crop maintenance and harvesting activities. Mortality of snakes by farm equipment would be highly likely. Fallow agricultural fields may lack adequate cover for snakes and increase the risk of predation. Some of the grassland would be created on the slopes of the new levees and berms. While these grasslands would be subject to greater human disturbance than non-levee grasslands, due to maintenance requirements from the Corps, they would still suffer less disturbance than an active agricultural field. Flood control structures need to allow easy visual inspection from the top of the levee during the spring and fall. While RDs have varying ways of complying with this requirement, SAFCA is proposing to have RD 1000 mow levee slopes to a height which would allow for visual inspection but also be high enough to reduce the chance of coming into contact with a snake. The Corps also requires that the levee slopes receive rodent control measures to keep ground burrowing mammals from burrowing into the sides of the levee. This could include grouting ground squirrel holes closed, which would remove potential hibernacula for giant garter snakes in the winter months to using a rodenticide which would lessen the number of ground squirrels in the area.

Giant garter snakes are not typically found iu orchards because of the high amount of overstory cover, therefore there would be a benefit to giant garter snake due to the loss of 65.52 acres of orchard habitat. However, SAFCA proposes to create an additional 46.42 acres of woodland to compensate for effects to Swainson's hawk nesting trees. It is unlikely that giant garter snakes will use dense woodland areas. Therefore, this represents a net loss of 19.10 acres of habitat that is unlikely to be used by giant garter snakes.

Because of the project, 65.50 acres of rice would be permanently converted to an upland habitat type. SAFCA has proposed to compensate for the loss of rice by creating 65.50 acres of managed marsh on 48 acres of existing rice fields and 18 acres of annual grassland/fallow crops/row and field crop near Fisherman's Lake. Overall, there would be a loss of 113.50 acres of rice from the Natomas Basin. Additionally, there will be a temporary loss of rice within the Natomas Basin due to borrow excavation from the Brookfield site. The Brookfield site would be used over two seasons with no one area being

out of production for more than one season. About 160 acres would be out of production and unavailable to giant garter snake during Phase 2 and a separate 190 acres would be out of production and unavailable to giant garter snake the next year during Phase 3. The loss of rice reduces the amount and availability of habitat, including summer water, for the snake. Due to the large amount of rice that has been fallowed in the Natomas Basin (37 percent loss of active rice between 2004 and 2007), any additional loss of rice, even for 1 season, has a direct effect on giant garter snakes. Flooded rice fields act as seasonal marshes and produce high numbers of prey species such as tadpoles, frogs and mosquitofish. Effects associated with reduced available summer water in the form of rice field habitat also include displacement of individual giant garter snakes from familiar habitat areas and result in giant garter snakes foraging over a wider area. Giant garter snakes may move to other areas of suitable habitat, but will encounter increased mortality from vehicles, exposure to temperature extremes, predation, and human disturbance while migrating to new areas. Migrating snakes or snakes using a larger foraging area may displace resident snakes or compete for food and shelter resources with resident snakes, resulting in reduced survivorship and fecundity of both resident and immigrant snakes.

Adverse effects from the reduction of rice fields may be greatest for gravid females, juveniles, and neonate snakes. Gravid females spend significant time basking in mid to late summer while incubating young, and thus may have reduced survivorship or fecundity if displaced from familiar retreats and basking sites (giant garter snakes are live bearers and contribute significant resources to brooding offspring). Abundant food resources are essential for females to both recover body mass after giving birth and to survive the overwintering period when the snakes do not forage and to the survival of juveniles and neonates. Giant garter snakes typically double their weight in the first year, with rapid growth likely necessary to reach a size class no longer susceptible to predation by non-native predatory fish and bullfrogs. The reduced availability of rice fields will result in less small prey for young snakes, which would inhibit growth, result in delayed sexual maturation and decreased births and recruitment of individuals into the population. This could potentially skew the age structure of the population to older giant garter snakes. Juveniles and neonates also rely on developing sufficient body mass prior to overwintering in order to survive long periods without foraging. Temporary or permanent loss of rice fields will not only remove habitat, but will also have adverse effects on reproduction, recruitment, and survival of the snake that will continue to affect giant garter snake populations well beyond the project time frame.

To offset the effects of the permanent loss of 113.50 acres of rice and the temporary effects to 350 acres of rice in the basin, SAFCA proposes to create 65.5 acres of managed marsh and permanently protect 175 acres of rice. Managed marsh has the capability to provide higher quality habitat for giant garter snakes because the habitat is available for the snake year round, will be subject to less human disturbance from farming activities, protected in perpetuity with a Conservation Easement, and will hold water for longer periods of time than a rice field typically does. Providing protection in perpetuity in the form of a Conservation Easement on 175 acres of rice fields would also benefit the snake because the

rice farming at this site would be managed by the TNBC and would assure more "snake-friendly" rice habitat than a typical rice field.

SAFCA proposes to affect 29.42 acres of irrigation and drainage canals that are vitally important for giant garter snakes both for foraging and movement within the basin. The loss of a canal within the basin even for a single season could have a large detrimental effect to giant garter snakes and their ability to access areas within the Natomas Basin for foraging and cover. The Elkhorn and Riverside Canals would be relocated away from the toe of the existing levee and moved between 400 to 800 feet away from their current location. To minimize any temporal loss of canal habitat for the giant garter snake, SAFCA has proposed to construct the replacement canal a year prior to filling the existing irrigation canals. This serves two purposes; to prevent an interruption in irrigation service and to allow vegetation to develop along the canal banks, which will provide cover for the giant garter snakes. About 54.94 acres of upland habitat is currently available to giant garter snakes along the Elkhorn and Riverside Canals. This area includes annual grassland/ruderal areas and excludes active row and field crops within 200 feet of the canals. While giant garter snakes can and do utilize upland habitat farther than 200 feet from aquatic habitat SAFCA will only be temporarily affecting habitat outside of this area through borrow excavation. Borrow activities near the irrigation canal relocations would be conducted primarily on active alfalfa fields. A small amount of orchard and fallowed agricultural lands would also be excavated for borrow. Giant garter snakes do not typically use alfalfa as upland habitat due to the high amount of disturbance through mowing and harvesting, though they may travel through them to reach aquatic habitat. Borrowing activities on the active and fallowed agricultural fields would temporarily affect the snakes by causing them to potentially have to travel longer distances to reach aquatic habitat; however this would only occur for one season and landuse on the borrow sites would return to current conditions. About 49.36 acres of upland habitat would be created adjacent to the relocated Elkhorn and Riverside Canals. Uplands along the Elkhorn and Riverside Canals would be vegetated with native perennial grasses.

Two sections of the Elkhorn Canal would be piped to avoid infrastructure. About 3,200 feet of canal would be piped near Teal Bend Golf Club and another 1,000 feet would be piped south of the golf club to avoid existing residences. Piping the irrigation canals for such long lengths would adversely affect connectivity. Given the lack of light, vegetation, and prey species that would be found within the pipes, giant garter snakes would most likely avoid using the pipes to reach up- or downstream aquatic habitat. Snakes, which may be using the newly constructed canals, may then have to travel over land to reach other aquatic habitat and will encounter increased mortality from vehicles, exposure to temperature extremes, predation, and human disturbance while migrating to new areas. To compensate for reducing connectivity by piping a large segment of the Elkhorn Canal, SAFCA is constructing the GGS/Drainage Canal, which will have a reliable source of water and run parallel to the Elkhorn Canal, though about 4,500 feet to the east.

SAFCA will be filling 19.27 acres of drainage ditches and marsh habitat. The majority of the acreage is due to the filling of the Airport West Drain. To compensate for the loss of habitat SAFCA has proposed to build the GGS/Drainage Canal and to compensate with 19.27 acres of managed marsh with a conservation easement near Fisherman's Lake. There are about 8.94 acres of upland habitat that is associated with the ditches and marsh. Because the aquatic features are going to be filled, this area will no longer serve the same function of adjacent upland habitat for the giant garter snake. SAFCA will be creating and preserving a small amount of upland habitat adjacent to the GGS/Drainage Canal and also creating 8.94 acres of managed marsh with a conservation easement near Fisherman's Lake. The GGS/Drainage Canal will be sloped to minimize maintenance and will have the side slopes planted with perennial grasses along the upper slope and rushes and sedges along the water's edge. The segment of the GGS/Drainage Canal, which would be built parallel to the Airport West Ditch, would be constructed in the same season as the Airport West Ditch will be filled. Unfortunately, this will not allow time for vegetation to become established on the banks and any snakes using the newly constructed GGS/Drainage canal would be subject to higher predation due to the lack of cover. SAFCA has proposed to create better aquatic canal habitat for giant garter snakes by assuring that the new GGS/Drainage Canal would have a minimum water depth of 4.5 feet between April and October, which is the active season for the giant garter snake.

SAFCA proposes to purchase long-term water contracts from NCMWC to provide water for both the managed marsh and GGS/Drainage Canal. While the Service expects the GGS/Drainage Canal to provide benefits to giant garter snakes in the Natomas Basin by offsetting the effects of their project, there is some concern regarding the long term protection of the canal because the project description does not provide a Conservation Easement on this feature. SAFCA has negotiated with the SCAS on an easement for the GGS/Drainage Canal where it crosses their property. The SCAS reserves the right to make changes to the canal should the Federal Aviation Administration require them to do so for purposes of aircraft safety. These changes to the canal could result in take of the giant garter snake. Should the SCAS make changes to the canal, they would still have to undergo consultation with the Service to analyze the effects of their project on federally listed species. Upon consulting with the Service and CDFG, the easement includes language that SCAS will compensate for any damages resulting from their actions to federally or state listed species through restoration or replacement of habitat. However, even with these provisions the easement does not provide the protection that is typically placed on compensation lands. SAFCA will be providing additional compensation lands at a 1:1 ratio of upland and aquatic habitat affected due to the filling of the Airport West Ditch in addition to creating the GGS/Drainage Canal. Therefore, SAFCA will create 28.21 acres of managed marsh near Fisherman's Lake with a conservation easement to compensate for 19.27 acres of aquatic habitat the majority of which is along the Airport West Ditch and 8.94 acres of upland habitat, which is suitable for giant garter snake and is associated with the aquatic features being affected.

Phase 2 Construction

Phase 2 construction includes work along the NCC and reaches 1-4B along the Sacramento River east levee. The Corps and SAFCA have proposed to complete the majority of the work during the active season of the giant garter snake (May 1 to October 1). Construction during this time would occur in 61.1 acres of developed land, 139.6 acres of annual grassland, 645.5 acres of row and field crop and fallow agriculture, 1.5 acres of orchard, 185 acres of rice (25 would be a permanent effect, 160 acres would be a temporary effect), 2 acres of canals and ditches, 22 acres of open water and other non-canal wetlands, and 10.3 acres of woodland. At the end of the construction season the proposed land cover types will be 53.5 acres of developed land, 30 acres of created woodland, 15.85 acres of preserved woodland, 168 acres of levee slope grassland, 123 acres of grassland on seepage berms and canal embankments, 19 acres of irrigation canal, 13.5 acres of GGS/Drainage Canal, and 175 acres of preserved rice. The newly created cover-types with the project would protected from future development through either a flood control easement, conservation easement, or drainage easement.

Phase 2 construction would primarily occur between May 1 and October 1. The only components of Phase 2 work which would occur outside of the giant garter snake's active season would be relocation of power poles, relocation of private irrigation pipelines, canals, and wells, and the removal, transplantation, and/or planting of trees and elderberry shrubs that are located in the Phase 2 footprint. To reduce the likelihood of disturbing or killing a giant garter snake that may be overwintering in uplands that would be affected this winter, SAFCA has proposed to erect exclusionary fencing around the areas where they would be working prior to October 1. This fence would be monitored daily prior to and during construction to insure that there are no breaches that a snake could get through. This should remove the chance that project construction would kill giant garter snakes when they are working in the winter months.

The remainder of the project would be constructed during the active period (May 1 – October 1) for the snake, resulting in a decreased risk of direct mortality of snakes. However, given the number of acres of aquatic and upland giant garter snake habitat affected within Phase 2, it is highly likely effects to snakes would include removal of cover and basking sites, filling or crushing of burrows or crevices, obstructing snake movement, and decreasing the prey base, and may result in the direct disturbance, displacement, injury, and/or mortality of snakes. Snakes may disperse across or may bask on existing roads, and thus may be killed or injured by construction equipment or other vehicles accessing the project site.

Compensation for the loss of rice in Phase 2 would occur during Phase 4 with the creation of 65.50 acres of managed marsh along the western boundary of Fisherman's Lake. The creation of managed marsh at this location would connect to existing TNBC Preserve lands which currently are in managed marsh which would enlarge a core area for giant garter snakes in the Natomas Basin. While the Service recognizes the benefit of enlarging managed marsh within the Fisherman's Lake area, there would be a temporal loss of aquatic habitat for giant garter snake between when rice is converted to upland in Phase 2 and when marsh is created in Phase 4. If for some reason the Corps and SAFCA either do not complete all the project phases or do not

provide the 65.50 acres of managed marsh in 2011, then they would have to reinitiate consultation with the Service as outlined on page 79 of this biological opinion.

Within the construction of Phase 2, SAFCA has proposed to create canal habitat in advance of canal that would be filled in Phase 3. This helps to offset effects due to the filling of canal which would be a loss of aquatic habitat for snakes, by allowing the new canals to become established in advance and also allow vegetation to begin to grow along the banks, which would provide cover from predation for the giant garter snake.

Valley Elderberry Longhorn Beetle

Effects to the valley elderberry longhorn beetle may occur with the transplantation of elderberry shrubs outside of the footprint of the levee enlargement. Loss of an elderberry shrub or even a stem can result in direct mortality of valley elderberry longhorn beetles or affect valley elderberry longhorn breeding and feeding because adult beetles rely solely on elderberry flowers for food and must lay their eggs on elderberry stems to successfully reproduce.

All three phases of the project have potential to affect about 40 elderberry shrubs through transplantation. This action will adversely affect the valley elderberry longhorn beetle. Any beetle larvae occupying these plants are likely to be killed when the plants are removed. An additional number of elderberry shrubs would remain where they currently are however, construction work would occur within 100 feet but no closer than 20 feet from the dripline of an elderberry shrub.

Temporal loss of habitat will occur. Although mitigation for impacts on the beetle involve creation or restoration of habitat, it generally takes five or more years for elderberry plants to become large enough to support beetles, and it generally takes 25 years or longer for riparian habitats to reach their full value (USFWS 1994). Temporal loss of habitat will temporarily reduce the amount of habitat available to beetles and may cause fragmentation of habitat and isolation of subpopulations. In cases where the proposed project will reduce the canopy closure of riparian forests, an edge effect is created that could result in reduced habitat quality for the beetles. Beetles disperse poorly and the systematic removal of elderberry shrubs from a relatively connected river corridor has adverse effects well outside of the project's footprint.

Proposed avoidance and minimization measures should minimize adverse effects resulting from elderberry stem trimming or elderberry transplantation.

Effects of Phase 2 Construction to Valley Elderberry Longhorn Beetle

Table 3 lists the elderberry shrub stem counts and sizes which would be transplanted as part of the Phase 2 construction. Effects to the valley elderberry longhorn beetle due to transplantation of these shrubs are described above. Elderberry shrubs would be transplanted and elderberry seedlings and associated natives would be planted at one of the following properties: Rio Ramaza, Cummings, or Lasuevic.

Table 3. Elderberry Stem Sizes and Compensation

Location	Stems (maximum diameter at ground level)	Exit Hole on Shrub (Yes or No)	Elderberry Seedling Ratio	Associated Native Plant Ratio	Number of Stems Observed	Required Elderberry Plantings	Required Associated Native Plant Plantings
Riparian	stems ≥1" & ≤3"	No	2:1	1:1	33	66	66
		Yes	4:1	2:1	57	228	456
Riparian	stems > 3" & <5"	No	3:1	1:1	16	48	48
		Yes	6:1	2:1	13	78	156
Riparian	stems > 5"	No	4:1	1:1	16	64	64
		Yes	8:1	2:1	16	128	256
Non-riparian	stems ≥1" & ≤3"	No	1:1	1:1	23	23	23
		Yes	2:1	2:1	5	10	20
Non-riparian	stems > 3" & <5"	No	2:1	1:1	8	16	16
		Yes	4:1	2:1	2	8	16
Non-riparian	stems > 5"	No	3:1	1:1	2	6	6
		Yes	6:1	2:1	1	6	12
Total replacement plantings						681	1,139
Total Elderberry shrubs to be transplanted						23	
1,820 /10 = 182 valley elderberry longhorn beetle credits or 7.52 acres							

Cumulative Effects

Cumulative effects include the effects of future State, Tribal, local, or private actions affecting listed species that are reasonably certain to occur in the area considered in this biological opinion. Future Federal actions not related to this proposed action are not considered in determining the cumulative effects, but are subject to separate consultation requirements pursuant to section 7 of the Act.

The effectiveness of the NBHCP's OCS relies on the City of Sacramento and Sutter County limiting development to a combined total of 15, 517 acres within their respective permit areas. The proposed project site is located outside the permitted development area, and SAFCA is not a permittee under the NBHCP; however, the plan assumes no significant new development in the basin outside of the City of Sacramento and Sutter County permit areas. The NBHCP outlines a carefully constructed OCS that balances reasonable development in the Basin with conservation of snake habitat in order to maintain a viable population of giant garter snakes in the basin and avoid jeopardy to this threatened species. The NBHCP and MAPHCP allow for urban development of certain areas (totaling up to 17,500 acres) in the Basin in return for the preservation of, and in some cases, restoration and management of 8,725 acres, in an interconnected preserve system, which when added to the baseline of agricultural and undeveloped lands in the basin, will

conserve the Natomas Basin snake population. While the proposed project does not increase the number of developed acres beyond the 17,500 contemplated under the NBHCP and MAPHCP, it does change (in some cases, permanently) habitat types from one type to another. Loss of habitat, which the 22 covered species of the NBHCPs may use, include 395.75 acres of row and field crop, 65.52 acres of orchard, and 113.75 acres of rice. Increases in the following habitat types would occur with the project: 46.42 acres of woodland, 521.79 acres of grassland, 93.71 acres of managed marsh, and 31.38 acres of canal. While there would be a change in habitat types within the basin, the NBHCP covered species would still be able to use the habitats that SAFCA's project would be creating and development would be precluded from these areas through conservation easements, flood control easements, and drainage easements.

While SAFCA is not a signatory to the NBHCP, the plan sets forth a regional conservation strategy that covers the entire basin. The NBHCP's efficacy in maintaining a viable population of giant garter snake in the Basin depends, in significant part, on the retention of a sufficient amount of undeveloped acreage throughout the Basin, to support giant garter snake.[1] The NBHCP operates under the assumption that agricultural land in the Basin would continuously rotate between crop types, and therefore all land provides habitat for all 22 of the NBHCP covered species, including the giant garter snake.

SAFCA's proposed project will directly affect existing land that has been preserved as mitigation for either the NBHCP or MAPHCP. During Phase 2 of the project, 1.63 acres of fallow row and grain crop would be affected at the Atkinson Preserve and 4.09 acres of alfalfa and 5.72 acres of wheat would be affected at the Huffman West Preserve. During Phase 4 of the project, 1.98 acres of alfalfa, 0.05 acre of developed, 0.83 acre of ruderal, and 0.48 acre of valley oak woodland would be affected at the Alleghany 50 Preserve and 0.044 acre of valley oak woodland and 0.00034 acre of riparian scrub would be affected at the Cummings Preserve. These areas would be replaced with levee slope covered in grassland. As provided for in the NBHCP (IV.C.2.c.(1)) SAFCA shall "pay for the value of replacing every acre of reserve land impacted." To accomplish this SAFCA has proposed to acquire existing TNBC land not currently dedicated to mitigation to offset acre-per-acre losses. This existing TNBC land would consist of rice, not the upland habitat types affected. SAFCA will fund the perpetual maintenance, monitoring, and enhancement of these preserves for the benefit of the covered species. Because this land is currently and will be maintained in rice, this will benefit the giant garter snake.

Creating connectivity between the preserve lands is a primary goal of the NBHCP. The NBHCP references the irrigation and drainage canals as a means of connecting preserve lands. SAFCA will be replacing any canals, which they affect during construction on the levees with the exception of the areas which would be piped to avoid the golf course or

---

1 In NWF v. Norton, 2005 U.S. Dist LEXIS 33768, Judge Levi upheld the NBHCP and its strategy to protect the GGS in the Natomas Basin. However, in footnote 13 of the opinion, he cautioned that,"the Service and those seeking an ITP in the future will face an uphill battle if they attempt to argue that additional development in the basin beyond the 17,500 acres will not result in jeopardy" to the snake.

residences. Relocated irrigation canals will still be accessible via lateral canals, which run to the surrounding row and field crops, however, it is likely that summer water availability in those areas is not consistent. SAFCA will be building the GGS/Drainage Canal, which will connect the North Drainage Canal to the West Drainage Canal, which eventually empties into Fisherman's Lake. Water will be maintained in the canal during the giant garter snakes' active season (April to October). Unfortunately, the north/south aquatic connection will travel about 8 miles through a landscape of primarily row and field crop and annual grassland with no rice agriculture. While there has not been a study of giant garter snake use of canals with varying surrounding landuses, previous studies have found increased detection of giant garter snakes in canals which are immediately adjacent to rice or managed marsh versus canals which are surrounded by upland habitat (Wylie *et al.* 2002b, 2004b). While the possibility exists for a random snake to travel up or down the GGS/Drainage Canal between the northern preserves and the Fisherman's Lake preserves, without "way stations" of rice or managed marsh spread out along the aquatic corridor to provide cover and prey items, it is highly unlikely that this corridor would provide genetic exchange between the two preserve areas.

In December 2008, FEMA will issue a new flood map for the Natomas Basin. This would place all of Natomas into the AE zone, which would require that builders place the bottom floor of new construction up to 20 feet above ground level to keep it out of the floodplain. This would effectively stop new construction in Natomas. While not directly growth-facilitating, the proposed project would serve planned and reasonably foreseeable growth by providing flood protection to the Natomas Basin which is currently an impediment to future growth (planned or otherwise) in the Natomas Basin. It is likely that some of the growth (commercial, municipal, and residential) in the Natomas Basin will not require section 7 consultation with the Service for compliance with the Act, and will not obtain take coverage pursuant to section 10 of the Act. Currently, the NBHCP and the East Contra Costa HCP are the only two permitted regional HCPs in the Sacramento area, although Placer, Yolo, South Sacramento, Yuba, and Sutter are all developing regional HCPs. Until these regional HCPs are finalized, there is no mechanism to provide "take" coverage for projects with no Federal nexus besides these projects pursuing their own individual HCPs. Some "take" of listed species is likely to occur for which no minimization, avoidance, and compensation/mitigation measures for federally-listed species are implemented.

SAFCA, the Corps, the city of Sacramento, Sacramento County, and Sutter County should understand that future development within the Natomas Basin could negatively affect the NBHCP and MAPHCP and potentially jeopardize the giant garter snake in the Natomas Basin. Any additional "take" of listed species outside what has been analyzed in this biological opinion or the NBHCP and MAPHCP cannot occur without appropriate permits or consultations with the Service and CDFG.

The cumulative effects of reasonable foreseeable projects in the Natomas Basin may pose a significant threat to the eventual recovery of the giant garter snake. The following proposed

projects could significantly affect the sustainability of giant garter snakes in the Natomas Basin when considered cumulatively with the proposed Natomas Levee Improvement Project:

- The proposed Greenbriar residential development is located on an approximately 577-acre site south of Elkhorn Boulevard and west of State Highway 99. Development on this site could result in the loss of giant garter snake habitat adjacent to Lone Tree Canal, depending on the configuration of houses and infrastructure.
- Natomas Joint Vision, as currently proposed by the City of Sacramento and Sacramento County, is to develop approximately 6,000 acres in the area of the County outside of the City's permitted area under the NBHCP.
- Sacramento International Airport's Master Plan would enlarge the airport on land currently owned by the airport and would occur through 2020. Much of the land slated for airport expansion is currently in agricultural production.

Other projects which are reasonably foreseeable and should be considered cumulative with the proposed project, but for which the Service has little to no information about the extent of their effects to giant garter snakes, include:

- Camino Norte
- Downtown Natomas Airport Light Rail
- Pacific Gas & Electric Line 406/407 Pipeline
- Sacramento Municipal Utility District Powerline – Elkhorn Substation
- Sutter Pointe Specific Plan

Conclusion

After reviewing the current status of the giant garter snake and valley elderberry longhorn beetle, the environmental baseline for the species, the effects of the proposed project, and the cumulative effects on this species, it is the Service's biological opinion that the proposed Natomas Landside Improvements Project, as described herein, is not likely to jeopardize the continued existence of the giant garter snake or valley elderberry longhorn beetle. The project is outside of critical habitat for the valley elderberry longhorn beetle and critical habitat has not been designated for the giant garter snake, therefore there is no affect to critical habitat as a result of this project.

The Corps and SAFCA have proposed to improve flood protection for the Natomas Basin above what currently exists. Two HCPs currently exist within the Natomas Basin and are based on future development occurring within the permit area of the MAPHCP and NBHCP. The baselines and assumptions for which these HCPs were developed were based on no additional development occurring within the basin outside of these permit areas and no change in landuse practices. Sacramento County and the City of Sacramento are already proposing additional development outside of the existing permit areas. Additionally, the Natomas Basin has experienced a large amount of rice fallowing both in land held by private farmers and leases terminated on Sacramento County Airport property. While the Service has concluded that

SAFCA's project would not jeopardize the giant garter snake or valley elderberry longhorn beetle, it does facilitate growth within the Natomas Basin, which would require additional analysis to determine if this growth could jeopardize any of the 22 species covered by the MAPHCP and NBHCP. If growth outside of the permit areas were to occur within the Natomas Basin, these future projects must have a higher conservation outcome than currently exists in the HCPs and must be closely coordinated with the Service.

INCIDENTAL TAKE STATEMENT FOR PHASE 2 CONSTRUCTION

Section 9 of the Act and Federal regulation pursuant to section 4(d) of the Act prohibit the take of endangered and threatened species, respectively, without special exemption. Take is defined as harass, harm, pursue, hunt, shoot, wound, kill, trap, capture or collect, or to attempt to engage in any such conduct. Harass is defined by the Service as an intentional or negligent act or omission which creates the likelihood of injury to a listed species by annoying it to such an extent as to significantly disrupt normal behavioral patterns which include, but are not limited to, breeding, feeding or sheltering. Harm is defined by the Service to include significant habitat modification or degradation that results in death or injury to listed species by impairing behavioral patterns including breeding, feeding, or sheltering. Incidental take is defined as take that is incidental to, and not the purpose of, the carrying out of an otherwise lawful activity. Under the terms of section 7(b)(4) and section 7(o)(2), taking incidental to and not intended as part of the agency action is not considered to be prohibited taking under the Act, provided that such taking is in compliance with this Incidental Take Statement.

The measures described below are nondiscretionary for listed species in Phase 2 of this opinion and must be implemented by the Corps in order for the exemption in section 7(o)(2) to apply. The Corps has a continuing duty to regulate the activity that is covered by this incidental take statement. If the Federal agency (1) fails to adhere to the terms and conditions of the incidental take statement, and/or (2) fails to retain oversight to ensure compliance with these terms and conditions, the protective coverage of section 7(o)(2) may lapse.

Amount or Extent of Take

Giant Garter Snake

The Service anticipates that incidental take of the snake will be difficult to detect or quantify for the following reasons: giant garter snakes are cryptically colored, secretive, and known to be sensitive to human activities. Snakes may avoid detection by retreating to burrows, soil crevices, vegetation, or other cover. Individual snakes are difficult to detect unless they are observed, undisturbed, at a distance. Most close-range observations represent chance encounters that are difficult to predict. It is not possible to make an accurate estimate of the number of snakes that will be harassed, harmed or killed during Phase 2 construction activities (staging areas, work on canal banks, soil borrow areas, and vehicle traffic to and from borrow areas). In instances when take is difficult to detect, the Service may estimate take in numbers of species per acre of habitat

lost or affected as a result of the action. Therefore, the Service anticipates that all giant garter snakes inhabiting 187 acres of aquatic and 818.9 acres of upland habitat may be harassed, harmed, or 2 giant garter snakes killed by loss and destruction of habitat, as a result of the project.

Valley Elderberry Longhorn Beetle

The Service expects that incidental take of the valley elderberry longhorn beetle will be difficult to detect or quantify. The cryptic nature of these species and their relatively small body size make the finding of an injured or dead specimen unlikely. The species occurs in habitats that make them difficult to detect. Due to the difficulty in quantifying the number of beetles that will be taken as a result of the proposed action, the Service is quantifying take incidental to the project as the number of elderberry stems one inch or greater in diameter at ground level (beetle habitat) that will become unsuitable for beetles due to direct or indirect effects as a result of Phase 2 construction. Therefore, the Service estimates take incidental to the project as death, injury, harassment, and harm of all beetles inhabiting the 23 elderberry plants containing stems 1 inch or greater at ground level (118 stems between 1-3 inches, 39 stems between 3 and 5 inches and 35 stems $\geq$5 inches; see Table 3 in the text).

Effect of the Take

The Service has determined that this level of anticipated take is not likely to result in jeopardy to the giant garter snake, or valley elderberry longhorn beetle, and will not result in the destruction or adverse modification of designated critical habitat because in the case of the giant garter snake critical habitat has not been designated and it is outside of the critical habitat for valley elderberry longhorn beetle.

Reasonable and Prudent Measures

The following reasonable and prudent measures are necessary and appropriate to minimize the effect of the proposed project on the giant garter snake and valley elderberry longhorn beetle.

1. The Corps and SAFCA shall implement the project as proposed in the biological assessment and this biological opinion.

2. Effects of harassment of individual giant garter snakes within the proposed project, and of the loss or degradation of the species' habitat shall be minimized.

3. Effects of harassment of individual valley elderberry longhorn beetle, and of the loss and degradation of the species' habitat shall be minimized.

Terms and Conditions

In order to be exempt from the prohibitions of section 9 of the Act, the Corps must ensure compliance with the following terms and conditions, which implement the reasonable and prudent measures described above. These terms and conditions are nondiscretionary.

1. The following terms and conditions implement reasonable and prudent measure one (1):

    a. The Corps and SAFCA shall minimize the potential for incidental take of the giant garter snake and valley elderberry longhorn beetle resulting from the project related activities by implementation of the project description as described in the biological assessment and the project description of this biological opinion.

    b. If requested, before, during, or upon completion of ground-breaking and construction activities, the project proponents shall allow access by Service and/or California Department of Fish and Game personnel to the project site to inspect project effects to the snake and valley elderberry longhorn beetle.

    c. A Service approved Worker Environmental Awareness Training Program for construction personnel shall be conducted by a Service-approved biologist for all construction workers prior to the commencement of construction activities. The program shall provide workers with information on their responsibilities with regard to the giant garter snake and valley elderberry longhorn beetle, an overview of the life-history of the species, information on take prohibitions, and protections afforded the species under the Act. Written documentation of the training must be submitted to the Sacramento Fish and Wildlife Office within 30 days of the completion of training. As needed, training shall be conducted in Spanish for Spanish language speakers and other languages as needed or necessary.

    d. The applicants shall include a copy of this biological opinion within its solicitations for design and construction of the proposed project making the primary contractor responsible for implementing all requirements and obligations included within the biological opinion, and to educate and inform all other contractors involved in the project as to the requirements of the biological opinion.

2. The following terms and conditions implement reasonable and prudent measure two (2):

    a. The project proponents shall minimize the potential for harm or harassment of the snake resulting from project-related activities by implementation of the conservation measures as described in the Corps' Biological Assessment and appearing in the project description (pages 3-44) of this biological opinion.

    b. At least 30 calendar days prior to initiating construction activities, the project proponents shall submit the names and curriculum vitae of the biological

monitor(s) for the proposed project. Monitors shall have the ability to differentiate giant garter snakes from other snakes and the authority to stop construction activities if a snake is encountered during construction until appropriate corrective measures have been completed or until the snake is determined to be unharmed.

c. For Phase 2 work which would occur outside of the giant garter snake active window (power pole relocations and private irrigation canal relocation) exclusion fencing would be placed around upland areas that giant garter snakes could use to overwinter. The exclusionary fencing would be monitored everyday prior to and during construction to ensure that openings do not develop that would allow the entry of a giant garter snake into the construction area.

d. Construction activity shall be conducted between May 1 and October 1. This is the active period for the snake and direct mortality is lessened, because snakes are expected to actively move and avoid danger. If it appears that construction activity may go beyond October 1, the project proponents shall contact the Service as soon as possible, but not later than July 15 of the year in question, to determine if additional measures are necessary to minimize take.

e. The project proponents shall implement Best Management Practices to prevent sediment from entering areas containing snake habitat, including, but not limited to, silt fencing, temporary berms, no cleaning of equipment in or near snake habitat, installation of vegetative strips, and temporary sediment disposal.

f. Runoff from dust control and oil and other chemicals used in other construction activities shall be retained in the construction site and prevented from flowing into areas containing snake habitat. The runoff shall be retained in the construction areas by creating small earthen berms, installing silt fences or hay-bale dikes, or implementing other measures on the construction site to prevent runoff from entering the habitat of the snake.

g. Project-related vehicles shall observe a 20-mile-per-hour speed limit within construction areas, except on County roads and State and Federal highways. This is particularly important during periods when the snake may be sunning or moving on roadways.

h. To avoid attracting snake predators, all trash items, such as wrappers, cans, bottles, and food scraps, must be disposed of in closed containers and removed at least once a day from the entire project site.

i. Within 24-hours prior to the commencement of construction activities, the site shall be inspected by a Service-approved biologist. The biologist will provide the Service with a written report that adequately documents the monitoring efforts

within 24-hours of commencement of construction activities. Snakes encountered during construction activities shall be allowed to move away from the area on their own volition. The biologist shall notify the Service immediately if any listed species are found on-site, and will submit a report, including date(s), location(s), habitat description, and any corrective measures taken to protect the species found. The biologist shall be required to report any take to the Service immediately by telephone at (916) 414-6600 and by electronic mail or written letter addressed to the Deputy Assistant Field Supervisor, within one (1) working day of the incident. The project area shall be re-inspected by the monitoring biologist whenever a lapse in construction activity of two weeks or greater has occurred.

j. Erosion control structures will be installed concurrently with construction. Erosion control structures will be constructed so runoff will be directed away from sensitive habitats. Tightly woven fiber netting (mesh size less than 0.25 inch) or similar material shall be used for erosion control or other purposes at the project site to ensure giant garter snakes and other reptiles or amphibians are not trapped by the erosion control material. This limitation will be communicated to the contractor through use of Special Provisions included in the bid solicitation package. Coconut coir matting is an acceptable erosion control material. No plastic mono-filament matting shall be used for erosion control. The edge of the material shall be buried in the ground to prevent giant garter snakes and other reptiles and amphibians from crawling underneath the material. Erosion control measures shall direct water flow into existing drainages or disperse water across vegetated areas in order to avoid concentrating water.

k. Movement of heavy equipment to and from the project site shall be restricted to established roadways to minimize habitat disturbance. Stockpiling of construction materials, including portable equipment, vehicles, and supplies, shall be restricted to the designated construction staging area and exclusive of aquatic habitat avoidance areas. Aquatic snake habitat adjacent to the project area shall be flagged and avoided by all construction personnel.

l. To the extent feasible, the project proponents shall confine clearing of vegetation and scraping, or digging, of soil to the minimal area necessary to facilitate construction activities.

m. High visibility fencing shall be placed to prevent encroachment of construction personnel and equipment into areas containing snake habitat. The fencing shall be inspected before the start of each work day and maintained by the project proponents until completion of the project. The fencing may be removed only when the construction of the project is completed.

n. After completion of construction activities, any temporary fill and construction debris shall be removed. As described in the biological assessment and the project description of this biological opinion, the project proponents will restore all snake habitat subject to temporary ground disturbances, including storage and staging areas and temporary roads. These areas shall be re-contoured, if appropriate, and re-vegetated with appropriate locally-collected native plant species to promote restoration of the area to pre-project conditions. All temporary fill and construction debris shall be removed. An area subject to "temporary" disturbance includes any area that is disturbed during the project, but that, after project completion, will not be subject to further disturbance and has the potential to be re-vegetated. Appropriate methods and plant species used to re-vegetate such areas will be determined on a site-specific basis in consultation with the Service and the CDFG. Restoration work may include replanting emergent vegetation. Refer to the Service's *Guidelines for the Restoration and/or Replacement of Giant Garter Snake Habitat.* A written report shall be submitted to the Service within ten (10) working days of the completion of construction at the project site.

o. The Corps and SAFCA shall ensure compliance with the reporting requirements.

p. Prior to construction on May 1, 2009, the Corps and SAFCA will have the following documents completed and approved by the Service:

- drainage easement language for the GGS/Drainage Canal;
- Mitigation and Monitoring Plan and Long-Term Management Plan;
- encumbrances on a portion of the District Assessment Fee; and
- contract with NCMWC to provide reliable water for the GGS/Drainage Canal and managed marsh.

3. The following terms and conditions implement reasonable and prudent measure three (3):

a. The procedures outlined in the Service's *Conservation Guidelines for the Valley Elderberry Longhorn Beetle* dated July 9, 1999, shall be followed for all actions related to the proposed project.

b. Elderberry shrubs will be fenced with high visibility construction fencing. In areas where the typical 20-foot buffer from the dripline of the elderberry shrub is encroached on, the fencing will be placed as far from the elderberry shrub's dripline as construction activities will allow.

c. A biological monitor will be present on site when work will encroach on the 20-foot elderberry buffer. The monitor will have the authority to stop

construction within 20 feet of the shrub if unauthorized take of the beetle occurs. The monitor shall contact the Service immediately to determine what corrective measures need to be taken.

d. Compensation plantings shall occur within the same year as the transplantation of the elderberry shrubs. The selection of the final compensation site for elderberry shrubs shall be coordinated with the Service. A Service reviewed plan for the longterm maintenance and monitoring of the elderberry compensation site shall be completed prior to transplantation.

Reporting Requirements

A post-construction compliance report prepared by the monitoring biologists must be submitted to the Chief of the Endangered Species Division (Central Valley) at the Sacramento Fish and Wildlife Office within thirty (30) calendar days of the completion of construction activity or within thirty (30) calendar days of any break in construction activity lasting more than thirty (30) calendar days. This report shall detail: (i) dates that groundbreaking at the project started and the project was completed; (ii) pertinent information concerning the success of the project in meeting compensation and other conservation measures; (iii) an explanation of failure to meet such measures, if any; (iv) known project effects on the giant garter snake, if any; (v) occurrences of incidental take of any these species; and (vi) other pertinent information.

The Corps must require SAFCA to report to the Service immediately any information about take or suspected take of federally-listed species not authorized in this biological opinion. SAFCA must notify the Service within 24 hours of receiving such information. Notification must include the date, time, and location of the incident or of the finding of a dead or injured animal. In the case of a dead animal, the individual animal should be preserved, as appropriate, and held in a secure location until instructions are received from the Service regarding the disposition of the specimen or the Service takes custody of the specimen. The Service contact persons are, Chief of the Endangered Species Division (Central Valley) at (916) 414-6600, and the Resident Agent-in-charge of the Service's Law Enforcement Division at (916) 414-6660.

Any contractor or employee who during routine operations and maintenance activities inadvertently kills or injures a listed wildlife species must immediately report the incident to their representative. This representative must contact the CDFG immediately in the case of a dead or injured listed species. The CDFG contact for immediate assistance is State Dispatch at (916) 445-0045.

CONSERVATION RECOMMENDATIONS

Section 7(a)(1) of Act directs Federal agencies to utilize their authorities to further the purposes of the Act by carrying out conservation programs for the benefit of endangered and threatened species. Conservation recommendations are discretionary agency activities that can be implemented to further the purposes of the Act, such as preservation of endangered species habitat, implementation of recovery actions, or development of information and data bases.

1. The Corps and SAFCA should assist in the implementation of the draft, and when published, the final Recovery Plan for the giant garter snake.

2. The Corps and SAFCA should provide funding to researchers studying topics identified by the Service in the draft, and when published, the final Recovery Plan for the giant garter snake.

3. The Corps should use environmental restoration authorities to acquire and restore garter snake habitat from willing sellers.

To be kept informed of actions minimizing or avoiding adverse effects or benefiting listed and proposed species or their habitats, the Service requests notification of the implementation of any conservation recommendations.

REINITIATION - CLOSING STATEMENT

This concludes formal consultation with the Corps on the Natomas Levee Improvement Project. As provided in 50 CFR 402.16, re-initiation of formal consultation is required where discretionary Federal agency involvement or control over the action has been maintained (or is authorized by law) and if: (1) the amount or extent of incidental take is exceeded; (2) new information reveals effects of the proposed action may affect listed species or critical habitat in a manner or to an extent not considered in this opinion; (3) the agency action is subsequently modified in a manner that causes an effect to listed species or critical habitat that was not considered in this opinion; or (4) a new species or critical habitat is designated that may be affected by the proposed action. In instances where the amount or extent of incidental take is exceeded, any operations causing such take must cease pending re-initiation.

If you have any questions regarding this biological opinion on the Natomas Landside Improvements Project, please contact Jennifer Hobbs at (916) 414-6541 or Jana Milliken, Chief, Sacramento Valley Branch at (916) 414-6645.

Sincerely,

for Susan K. Moore
Field Supervisor

Subject: Re-initiation of Formal Consultation for the Natomas Levee Improvement Program, Landside Improvements Project, Phase 2 Biological Opinion, Sacramento and Sutter Counties, California

Dear Mr. Piccola:

This is in response to your August 13, 2009, request to amend the project description of the biological opinion written by the U.S. Fish and Wildlife Service (Service) on the Natomas Levee Improvement Program, Landside Improvements Project Phase 2 (proposed project) in Sacramento and Sutter Counties, California, dated October 9, 2008 (File 81420-2008-F-0195-5) and amended on May 6, 2009. The Corps has requested changes to the project description including adding work at Pumping Plant 34, removal of a section of the Central Main Flume, Elkhorn Pump Plant Pipeline, and a change in the timing of construction of other activities. These changes have resulted in a change to the previous effects analysis. This document represents the Service's concurrence to amend the Phase 2 biological opinion on the effects of the action to two federally-listed threatened species: the valley elderberry longhorn beetle (*Desmocerus californicus dimorphus*) and the giant garter snake (*Thamnophis gigas*), in accordance with section 7 of the Endangered Species Act of 1973, as amended (16 U.S.C. 1531 *et seq.*) (Act).

This amendment is based on: (1) your August 13, 2009, e-mail requesting re-initiation under section 7 of the Service's May 6, 2009, amended biological opinion (biological opinion); (2) the memo prepared by EDAW dated August 12, 2009; (3) the August 12 and 13, 2009, e-mails from the U.S. Army Corps of Engineers (Corps) including information regarding the valley elderberry longhorn beetle; and (4) other information available to the Service.

The following changes are made to the May 6, 2009, amended biological opinion:

1. On page 29, change first sentence of last paragraph from:

Improvements to Reaches 1–4B are anticipated to occur over one construction season, beginning in May 2009 and ending in October 2009.

To:

Improvements to Reaches 1–4B are anticipated to occur over one construction season. Reach 1 will be completed by October 2009 and Reaches 2-4B will extend through November 15, 2009. After October 1, 2009, construction will consist of compacting of newly constructed levee embankment, hydroseeding, and demobilization.

2. On page 32, insert following paragraph after second paragraph under Major Irrigation and Drainage Infrastructure Modifications:

Construction of the sedimentation basin would occur between August 15 and November 15, 2009. Aquatic features in this area are heavily shaded by dense riparian woodlands. Areas which could support overwintering giant garter snakes would be disturbed prior to October 1 and fenced with exclusionary fencing.

3. Insert the following paragraphs on page 33 prior to Prichard Pumping Plant Connection:

Pumping Plant Number 4 Outfall Raising

The RD 1000's Pumping Plant Number 4 site is located along the NCC south levee and pumps water from the Natomas basin into the NCC. In order to modify Pump Plant Number 4's outfall to the 200-year flood elevation the area surrounding the outfall must be dewatered by constructing a rock cofferdam. The rock cofferdam would be composed of angular washed rock and placed so that it binds with the underlying rock already in the channel and creates a stable configuration. The cofferdam would prevent water from entering the work site while allowing water to flow around the work zone. After the rock has been placed with an excavator, the contractor would place a thin layer of 3/4- to 1-1/2-inch washed crushed rock over the streamside surface of the cofferdam. The contractor would then place a rubberized liner that would form the water barrier of the dam and minimize the potential for water leakage. After construction, the contractor would pump water out of the enclosed work area using a pump and intake and discharge hoses. The intake hose would be fitted with a screen with a ¼-inch mesh opening.

After the area surrounding the outfall is dewatered, the outfall would be excavated in order to build the concrete outfall structure. During construction of the new outfall structure, additional pumping would likely be required to maintain the lowered water elevation within the cofferdam. After construction of the outfall structure, the contractor would use some of the rock from the cofferdam to fill in the area around the Pumping Plant Number 4 discharge outfall structure. After the initial placement of rock is complete, water would be pumped into the cofferdam area to equalize the water pressure on the rubberized liner. The liner would then be removed. The contractor would then carefully remove the remaining rock that is located above the elevation of the new plant outfall apron. The rock would be stacked on the bank for later removal to a different location on the project outside of the stream zone. About 0.07 acre of giant garter snake aquatic habitat would be changed permanently from natural bank to hardened bank from this construction. This work would occur after May 1, 2010.

4. Insert the following paragraph on page 34 under Central Main Flume Connection:

The Central Main Flume is constructed in an earthen berm slightly above the existing grade. The flume is narrow and concrete lined. A portion of the flume is located under the footprint of proposed improvements to the Sacramento River east levee. An additional 625-foot-long segment of Central Main Flume between the western edge of the new canal alignments and the eastern edge of the levee improvements footprint will need to be removed as part of the project. Removal of the flume would involve an excavator or other piece of heavy equipment working from one side of the flume to break up the concrete and remove the rubble. This section of the Central Main Flume has little open water and is shaded by oak woodland along its entire length. However, there are some small ditches that run parallel along the Central Main Flume that would be filled in as a result of the project. This would result in the loss of 0.12 acre of aquatic giant garter snake habitat and 0.06 acre of upland giant garter snake habitat. SAFCA proposes to create 0.18 acre of managed marsh near Fisherman's Lake during Phase 4A.

5. Insert the following paragraph on page 34 after the Central Main Flume Connection section:

Elkhorn Pumping Plant

As part of the construction of the sediment basin, SAFCA would have to relocate the outfall for the Elkhorn Pumping Plant to the new sediment basin. A temporary 36-inch pipe will be fit to the existing 42-inch metal pipe within the outfall structure and will extend across the Elkhorn Reservoir into the new sediment basin. Water from the Elkhorn Pumping Plant will outfall into the sediment basin rather than the existing Elkhorn Reservoir when the sediment basin construction is completed. Installation of the new pipes would require temporary dewatering of a portion of the existing Elkhorn Reservoir using sandbag cofferdams. The water in the pipeline alignment will be pumped onto upland and allowed to infiltrate. The discharge area for the pumped water will have silt fence around it. Once the pipeline alignment is dewatered, the ground will be excavated with spoils contained within the cofferdam limits. The pipes will be installed and the trench will be backfilled. However, in order to protect the pipes an extra 2-foot of cover will be placed over the pipes, above existing ground level, resulting in a change in the aquatic area of the Elkhorn Reservoir. These construction activities would result in a permanent loss of 0.10 acre and temporary loss of 0.18 acre of aquatic habitat for giant garter snake and temporary loss of 0.16 acre of upland habitat for giant garter snake. SAFCA proposes to create 0.10 acre of managed marsh near Fisherman's Lake during Phase 4 of the project.

6. On page 35, change the second paragraph from:

The segment of the Elkhorn Canal from the Prichard Pumping Plant to the Elkhorn sedimentation basin would be constructed between May and October 2009. The segment of the Elkhorn Canal from the Central Main Flume to the Elkhorn sedimentation basin would be constructed between May and October 2009.

To:

The segment of the Elkhorn Canal from the Prichard Pumping Plant to the Elkhorn sedimentation basin would be constructed between August 1 and November 15, 2009. The segment of the Elkhorn Canal from the Central Main Flume to the Elkhorn sedimentation basin would be constructed between September 15 and December 15, 2009. All areas would be disturbed prior to October 1 and giant garter snake exclusion fencing will be placed prior to October 1, 2009, in areas that are potential overwintering sites for giant garter snakes.

7. On page 50, change the Phase 2 Giant Garter Snake Effects section from:

Phase 2 construction includes work along the NCC and reaches 1-4B along the Sacramento River east levee. The Corps and SAFCA have proposed to complete the majority of the work during the active season of the giant garter snake (May 1 to October 1). Construction during this time would occur in 61.1 acres of developed land, 139.6 acres of annual grassland, 645.5 acres of row and field crop and fallow agriculture, 1.5 acres of orchard, 185 acres of rice (25 would be a permanent effect, 160 acres would be a temporary effect), 2 acres of canals and ditches, 22 acres of open water and other non-canal wetlands, and 10.3 acres of woodland. At the end of the construction season the proposed land cover types will be 53.5 acres of developed land, 30 acres of created woodland, 15.85 acres of preserved woodland, 168 acres of levee slope grassland, 123 acres of grassland on seepage berms and canal embankments, 19 acres of irrigation canal, 13.5 acres of GGS/Drainage Canal, and 175 acres of preserved rice. The newly created cover-types with the project would be protected from future development through either a flood control easement, conservation easement, or drainage easement.

Phase 2 construction would primarily occur between May 1 and October 1. The only components of Phase 2 work which would occur outside of the giant garter snake's active season would be relocation of power poles, relocation of private irrigation pipelines, canals, and wells, and the removal, transplantation, and/or planting of trees and elderberry shrubs that are located in the Phase 2 footprint. To reduce the likelihood of disturbing or killing a giant garter snake that may be overwintering in uplands that would be affected this winter, SAFCA has proposed to erect exclusionary fencing around the areas where they would be working prior to October 1. This fence would be monitored daily prior to and during construction to insure that there are no breaches that a snake could get through. This should remove the chance that project construction would kill giant garter snakes when they are working in the winter months.

The remainder of the project would be constructed during the active period (May 1 – October 1) for the snake, resulting in a decreased risk of direct mortality of snakes. However, given the number of acres of aquatic and upland giant garter snake habitat affected within Phase 2, it is highly likely effects to snakes would include removal of cover and basking sites, filling or crushing of burrows or crevices, obstructing snake movement, and decreasing the prey base, and may result in the direct disturbance, displacement, injury, and/or mortality of snakes. Snakes may disperse across or may bask on existing roads, and thus may be killed or injured by construction equipment or other vehicles accessing the project site.

To:

Phase 2 construction includes work along the NCC and reaches 1-4B along the Sacramento River east levee. Construction would occur in 61.1 acres of developed land, 139.8 acres of annual grassland, 645.5 acres of row and field crop and fallow agriculture, 1.5 acres of orchard, 185 acres of rice (25 would be permanently affected, 160 acres would be temporarily affected), 2.35 acres of canals and ditches, 22 acres of open water and other non-canal wetlands, and 10.3 acres of woodland. At the end of the construction season the proposed land cover types will be 53.5 acres of developed land, 30 acres of created woodland, 15.85 acres of preserved woodland, 168 acres of levee slope grassland, 123 acres of grassland on seepage berms and canal embankments, 19 acres of irrigation canal, 13.5 acres of GGS/Drainage Canal, and 175 acres of preserved rice. The newly created cover-types with the project would be protected from future development through either a flood control easement, conservation easement, or drainage easement.

SAFCA has proposed to conduct some of the Phase 2 construction outside of the giant garter snake active season (between May 1 and October 1). These include relocation of power poles, relocation of private irrigation pipelines, canals, and wells, the removal, transplantation, and/or planting of trees and elderberry shrubs that are located in the Phase 2 footprint, construction of pipes from the Elkhorn Pumping Plant to the Elkhorn Reservoir, Sacramento River east levee Reaches 2-4B, upper Elkhorn Canal and Upper GGS/Drainage Canal construction, and a new sedimentation basin. To reduce the likelihood of disturbing or killing a giant garter snake that may be overwintering in uplands that would be affected during the inactive season (October through April), SAFCA has proposed to erect exclusionary fencing prior to October 1 around areas where snakes would be likely to overwinter. This fence would be monitored daily prior to and during construction to insure that there are no breaches that a snake could get through. This should lessen the chance that project construction would kill overwintering giant garter snakes. Many of the canals have been without water this year, which would make the areas that SAFCA proposes to construct in the winter less attractive to the giant garter snake due to their use of aquatic features for feeding and movement. Additionally, for the construction of pipes from the Elkhorn Pumping Plant to the Elkhorn Reservoir, Sacramento River east levee Reaches 2-4B, upper Elkhorn Canal and Upper GGS/Drainage Canal construction, and new sedimentation basin construction at these sites would begin prior to October 1, 2009 which is when the snakes begin to search for sites suitable for overwintering. Disturbance of these areas prior to snakes finding them for overwintering would likely cause them to seek other areas.

The remainder of the project would be constructed during the active period (May 1 – October 1) for the snake, which can result in a decreased risk of direct mortality of snakes because snakes are more active during these months. However, given the number of acres of aquatic and upland giant garter snake habitat affected within Phase 2, it is highly likely effects to snakes would include removal of cover and basking sites, filling or crushing of burrows or crevices, obstructing snake movement, and temporary loss of aquatic habitat which decreases the prey base, and may result in the direct disturbance, displacement, injury, and/or mortality of snakes. Snakes may disperse across or may bask on existing roads, and thus may be killed or injured by construction equipment or other vehicles accessing the project site.

8. On page 56, change the Phase 2 Incidental Take Statement from:

Giant Garter Snake

The Service anticipates that incidental take of the snake will be difficult to detect or quantify for the following reasons: giant garter snakes are cryptically colored, secretive, and known to be sensitive to human activities. Snakes may avoid detection by retreating to burrows, soil crevices, vegetation, or other cover. Individual snakes are difficult to detect unless they are observed, undisturbed, at a distance. Most close-range observations represent chance encounters that are difficult to predict. It is not possible to make an accurate estimate of the number of snakes that will be harassed, harmed or killed during Phase 2 construction activities (staging areas, work on canal banks, soil borrow areas, and vehicle traffic to and from borrow areas). In instances when take is difficult to detect, the Service may estimate take in numbers of species per acre of habitat lost or affected as a result of the action. Therefore, the Service anticipates that all giant garter snakes inhabiting 187 acres of aquatic and 818.9 acres of upland habitat may be harassed, harmed, or 2 giant garter snakes killed by loss and destruction of habitat, as a result of the project.

To:

Giant Garter Snake

The Service anticipates that incidental take of the snake will be difficult to detect or quantify for the following reasons: giant garter snakes are cryptically colored, secretive, and known to be sensitive to human activities. Snakes may avoid detection by retreating to burrows, soil crevices, vegetation, or other cover. Individual snakes are difficult to detect unless they are observed, undisturbed, at a distance. Most close-range observations represent chance encounters that are difficult to predict. It is not possible to make an accurate estimate of the number of snakes that will be harassed, harmed or killed during Phase 2 construction activities (staging areas, work on canal banks, soil borrow areas, and vehicle traffic to and from borrow areas). In instances when take is difficult to detect, the Service may estimate take in numbers of species per acre of habitat lost or affected as a result of the action. Therefore, the Service anticipates that all giant garter snakes inhabiting 187.35 acres of aquatic and 818.9 acres of upland habitat may be harassed, harmed, or 3 giant garter snakes killed by loss and destruction of habitat, as a result of the project. The number of snakes killed has been increased because some of the construction schedule has been changed to occur in the winter months when snakes are less mobile and more likely to be killed due to construction activities.

The Service has reviewed the changes in the project description and analyzed the effects to the giant garter snake due to these changes. The Service's biological opinion is that the proposed Natomas Landside Improvements Project changes are not likely to jeopardize the continued existence of the giant garter snake.

This concludes formal consultation with the Corps on the amended Natomas Levee Improvement Program, Landside Improvements Project Phase 2. As provided in 50 CFR §402.16, re-initiation of formal consultation is required where discretionary Federal agency involvement or control

over the action has been maintained (or is authorized by law) and if: (1) the amount or extent of incidental take is exceeded; (2) new information reveals effects of the agency action that may affect listed species or critical habitat in a manner or to an extent not considered in this opinion; (3) the agency action is subsequently modified in a manner that causes an effect to the listed species or critical habitat that was not considered in this opinion; or (4) a new species is listed or critical habitat designated that may be affected by the action. In instances where the amount or extent of incidental take is exceeded, any operations causing such take must cease pending re-initiation.

If you have any questions regarding this biological opinion on the Natomas Landside Improvements Project Phase 2, please contact Jennifer Hobbs at (916) 414-6541 or Jana Milliken, Chief, Sacramento Valley Branch at (916) 414-6645.

Sincerely,

Peter A. Cross

Subject: Phase 3 Section 7 Appendage to the Programmatic Biological Opinion for the Natomas Levee Improvement Program, Landside Improvements Project, Sacramento and Sutter Counties, California

Dear Mr. Piccola:

This is in response to your April 2, 2009, request for formal consultation with the U.S. Fish and Wildlife Service (Service) on the Natomas Levee Improvement Program (NLIP), Landside Improvements Project Phase 3 (proposed project) in Sacramento and Sutter Counties, California. Your request was received on April 6, 2009. A programmatic biological opinion was completed on October 9, 2008 (File 81420-2008-F-0195-5) and amended on April 6, 2009 (File 81420-2008-F-0195-R001). The programmatic biological opinion analyzed the entire proposed project on the landscape level and because details of the project were only available for Phase 2, provided an incidental take statement for only that phase of the project. This biological opinion will examine the details of the Phase 3 portion of the project and the effects of the action to two federally-listed threatened species: the valley elderberry longhorn beetle (*Desmocerus californicus dimorphus*)(beetle) and the giant garter snake (*Thamnophis gigas*)(snake) in accordance with section 7 of the Endangered Species Act of 1973, as amended (16 U.S.C. 1531 *et seq.*) (Act). Critical habitat has been designated for the beetle; however, the proposed project is not located within nor will it affect critical habitat for the beetle or any other federally-listed species. Critical habitat has not been designated for the giant garter snake.

This biological opinion is based on information provided in the U.S. Army Corps of Engineers' (Corps) letter requesting consultation and their biological assessment. A complete administrative record is on file at the Sacramento Fish and Wildlife Office.

CONSULTATION HISTORY FOR PHASE 3

December 23, 2008. EDAW, the consultant to the Sacramento Area Flood Control Agency (SAFCA), provided the Service with an administrative draft Phase 3 biological assessment.

January 8, 2009. EDAW held a meeting with SAFCA, the Corps, California Department of Fish and Game (CDFG), and the Service to discuss the Phase 3 project and schedule.

February 25, 2009. The Service provided SAFCA comments on the Phase 3 administrative draft biological assessment.

April 6, 2009. The Service received the April 2, 2009, biological assessment from the Corps. The Service also met with SAFCA, CDFG, EDAW, and the Corps to discuss incidental take coverage of activities described in the long-term management plan for the upper GGS/Drainage Canal and Brookfield rice. It was agreed that this biological opinion would include the project description and analyze effects for the long-term maintenance of the GGS/Drainage Canal and Brookfield rice.

July 10, 2009. The Service, SAFCA, EDAW, Corps, and CDFG met to discuss a change in project description. SAFCA proposed working outside of the giant garter snake window for portions of the Phase 3 work. The Service requested an updated project description to include updated conservation measures. SAFCA agreed to provide a memo to the Corps for transmittal to the Service the first week of August.

BIOLOGICAL OPINION

Description of Action Area

The proposed project area is located in the Natomas Basin in northern Sacramento and southern Sutter Counties, generally bounded by leveed reaches of the Natomas Cross Canal (NCC) on the north, the Sacramento River on the west, the American River on the south, and the Pleasant Grove Creek Canal (PGCC) and Natomas East Main Drainage Canal (NEMDC)/Steelhead Creek on the east. This project, which is part of the larger NLIP being undertaken by SAFCA, consists of three construction phases, generally occurring between 2008 and 2011. Construction of Phase 3 includes: the Sacramento River east levee south of the limits of the Phase 2 improvements to just south of Interstate 5 (I-5) (Reaches 5A–9B) and vegetation clearing along reaches 10-12A; the PGCC west levee; the NEMDC west levee between Elkhorn Boulevard and Northgate Boulevard; the area between Elkhorn Reservoir and the West Drainage Canal where a new canal designed to provide drainage and associated giant garter snake habitat (referred to in this document as the "GGS/Drainage Canal") would be constructed; the Elkhorn Canal downstream of Elkhorn Reservoir; the Airport West Ditch; and Reclamation District (RD) 1000 Pumping Plant No. 2.

As greater flood protection will be provided for the entire Natomas Basin, the action area includes the entire Natomas Basin.

Description of Proposed Action

Overview of NLIP Landside Improvements Project

The SAFCA is designing the NLIP in coordination with the Federal and state flood control project sponsors, the Corps, and the State of California Central Valley Flood Protection Board (formerly The Reclamation Board), to address the deficiencies in the Natomas levee system with a focus on achieving a 100-year level of flood protection by 2011. This will require improving the following landside conditions along the NCC south levee, the Sacramento River east levee, and the PGCC and NEMDC west levees:

- Inadequate freeboard—The NCC south levee and portions of the Sacramento River east levee are not high enough to provide at least 3 feet of freeboard above the 100-year water surface elevation. Additional reaches do not provide 3 feet of freeboard above the 200-year design water surface elevation.
- Underseepage and through-seepage vulnerability—Most of the levee reaches do not meet recently adopted Federal criteria for safely containing underseepage and through-seepage when the water surface in the adjacent channel reaches the 100-year elevation or, in some cases, the 200-year elevation.

The NLIP Landside Improvements project encompasses addressing freeboard deficiencies through levee raises; addressing seepage potential using a combination of seepage berms, cutoff walls, and relief wells; and acquiring additional right-of-way to construct the improvements and to prevent encroachment into the flood control system. In addition, the project has been designed to include an enlarged levee embankment (adjacent setback levee) along the land side of the existing Sacramento River east levee to minimize the need for substantial removal of vegetation and structural encroachments on the water side of this levee in compliance with Corps guidance. These improvements would include recontouring the levee slopes where necessary to provide a 3:1 horizontal-to-vertical (3H:1V) waterside slope and a 3H:1V (preferred) or 2H:1V (maximum) landside slope.

The specific goal of the NLIP Landside Improvements Project is to provide at least 100-year flood protection as quickly as possible while laying the groundwork to achieve at least urban-standard (200-year) flood protection over time.

Additional project objectives that influenced SAFCA's project design were to:

(1) use flood control projects in the vicinity of the Sacramento County Airport to facilitate better management of Airport lands to reduce hazards to aviation safety, and

(2) use flood control projects to enhance habitat quality and values by increasing the extent and connectivity of the lands in the Natomas Basin being managed to provide habitat for the giant garter snake, the Swainson's hawk, and other special-status species.

Recognizing the importance of securing maximum Federal support for the flood control project, SAFCA has explored implementation approaches that also advance the achievement of Federal aviation and wildlife protection objectives where complementary opportunities exist. Accordingly, the proposed project includes the following elements:

- The project would include construction of the GGS/Drainage Canal to provide giant garter snake habitat and some drainage infrastructure west of the Airport. Construction of these facilities would allow for dewatering of the ditch running along the western portion of the Airport runway system, which the airport recognizes as a flight safety hazard, by offsetting the effects on drainage and irrigation needs and giant garter snake habitat.

- The project would combine SAFCA's need for levee embankment and berm material with the Sacramento County Airport System's (SCAS) need to modify the condition and management of Airport bufferlands so as to reduce wildlife hazards affecting Airport operations in a manner that enhances the connectivity of areas managed specifically for their habitat value.

Levee Raising and Seepage Remediation

Sacramento River East Levee Reaches 5A-12

Phase 3 construction on the Sacramento River east levee would include improvements from the northern end of Reach 5A through Reach 9B, a distance of approximately 4.5 miles. In addition, vegetation removal would occur along the levee in Reaches 10 through 12A to prepare this segment of the levee improvements footprint for Phase 4 construction. Phase 3 project work along the Sacramento River east levee includes:

- construction of an adjacent levee in Reaches 5A-9B;
- installation of conventional soil bentonite (SB) cutoff walls and/or deep soil mix cutoff walls where necessary along the proposed adjacent levee;
- construction of a 100-foot-wide seepage berm in Reaches 5A through 6A;
- installation of relief wells, spaced at 60- to 100-foot intervals, approximately 20 feet beyond the toe of the 100-foot seepage berm locations;
- removal of trees and 63 elderberry shrubs (*Sambucus sp.*) from Reaches 10 through 12A to prepare for construction of a 500-foot-wide berm and the Riverside Canal realignment that would be conducted in Phase 4;
- planting of 130-foot-wide woodland groves in areas between Reaches 7 through 8 and between Reaches 8 through 9B; and
- reconstruction of the intersections of Elverta Road, Elkhorn Boulevard, North Bayou Road, and private and semi-public access ramps with Garden Highway.

The primary construction staging area would be located on two approximately 1-acre sites, one near Elkhorn Boulevard and one near Elverta Boulevard. The area would be fenced and used for the contractor's and engineer's construction trailers, parking for personnel, machine maintenance tools and parts, possibly water trucks, and the storage fuels and other materials to be used for construction. The project right-of-way along the construction area also would be used for staging of construction materials and equipment.

Unless otherwise noted in the following project description levee improvements for this phase are anticipated to be constructed between May and November of 2009 and 2010. Demobilization, and site restoration (e.g., hydroseeding, gravelling) would extend through November. Where construction activities would occur outside of the specified work window for listed species, SAFCA has and will continue to coordinate with the Corps, the Service, and CDFG to implement conservation measures proposed within this project description.

Site Preparation (Tree Removal, Clearing, Grubbing, and Stripping)

Site preparation would entail removing trees and other large vegetation from the Phase 3 construction area and stripping the top 6 to 12 inches of material from the landside slope of the existing levee and the footprint of the adjacent setback levee and seepage berm (as applicable). Trees within the utility and operations and maintenance corridors would be avoided where possible. Where trees cannot be retained, the permanent maintenance access corridor will be cleared but not stripped. Large roots, tree stumps and deleterious material would then be grubbed from the working area.

To the extent feasible, trees that must be removed from within the Phase 3 footprint would be removed during the winter (between November 15, 2009 and February 15, 2010) prior to the construction season to avoid disturbing the nesting behavior of special-status birds in the spring. Trees suitable for relocation would be transplanted outside of the footprint into new woodland planting areas, where a substantial number of new trees would also be planted. Large trees which cannot be transplanted would be felled about 3 feet above ground level and stumps would temporarily be left in place until construction of the levee begins in May 2010. Logs would be cut into rounds with handheld equipment and removed from site with light vehicles. Cleared vegetation (i.e., trees, brush) would be hauled off-site to landfills or bio-recycling facilities.

Vegetation, primarily trees and elderberry shrubs, would be removed within the partial conceptual footprint of the Phase 4 footprint of the Sacramento River east levee (Reaches 10-12A), as needed, during the annual dormant season (November 1 to February 15). Removal of vegetation from the future Phase 4 footprint will allow this to occur during the elderberry dormant season and when migratory birds are not nesting, lessening the effects to these speices. This footprint consists of the adjacent setback levee, a seepage berm that may be up to 500-feet-wide, depending on site conditions, a 50-foot-wide operations and maintenance corridor, and 20-foot-wide utility corridor, resulting in a total flood control footprint that is approximately 670 feet wide. In addition, vegetation would also be removed in the partial conceptual footprint of the relocated Riverside Canal, which is directly adjacent to the landside edge of the flood control

footprint. This operation will require removal of some trees and relocation/removal of elderberry shrubs, which occur mostly adjacent to existing roads. Large trees would be felled and disposed of as described above. Small trees, where feasible, and elderberry shrubs currently existing on the Cummings Preserve would be relocated to 0.5-acre area onsite. Other elderberry shrubs and small trees would be relocated to the woodland corridor. A minimal amount of ground disturbance in specific areas would occur.

Relocation and Removal of Landside Structures, Irrigation Ditches and Other Facilities

Residences and other farm structures that are within the proposed footprint of the flood control facilities and the GGS/Drainage Canal would have to be removed or relocated farther from the flood control facilities before the start of levee construction in those areas. Demolition would begin in the fall of 2009 and would require up to 60 days to complete. The majority of the work would be completed by February 15, 2010.

Private irrigation wells that are located within the proposed levee improvements footprint of the Sacramento River East Levee would need to be removed and reconstructed. Reconstruction of the private irrigation wells would start in the fall of 2009, and would require 60 days to complete. The majority of the work would be completed by December 15, 2009, when weather conditions are likely to limit earthwork construction activities. Remaining earthwork construction activities would need to resume when conditions dry in the spring to allow operation when irrigation season begins in April. After construction of the wells, installation of the pumping equipment, well testing, and heavy equipment access could extend up to 6 months, but would involve limited ground disturbance. Existing facilities within the levee construction footprint would be capped once the new wells were operational, however demolition and removal of the capped wells would occur concurrently with the levee construction which is to begin May 2010.

Utility poles that currently exist on the landside slope of the levee and at the landside levee toe would need to be relocated and/or rerouted to accommodate the widened levee footprint. In order to sustain power supply to customers, about 60 power poles need to be relocated within the Phase 3 project area prior to the initiation of levee construction which is expected to begin May 1, 2010. The footprint of each power pole is about 1.76 square feet (cumulatively 0.002 acre) and each pole would be placed in the ground 7 feet deep. Existing power poles will be pulled out from the ground as straight as possible by truck-mounted equipment. Installation of new poles would require drilling equipment with a drill (no larger than 24 inches in diameter) mounted on a truck. Power pole relocation would require 12 weeks to complete and would begin October 2009. To the extent feasible, mainline utility poles would be relocated beyond the landside levee toe or berms, and a secondary line of distribution poles would be relocated to the drainage swale area between the existing levee and the adjacent levee. Some poles may need to be relocated to the water side of the existing levee. Tree pruning would likely be required in some locations to accommodate the poles and wires. The relocations would be conducted in coordination with the utility companies and the construction operations.

Debris from structure demolition, power poles, utility lines, piping, and other materials requiring disposal would be hauled off-site to a suitable landfill. Wells and septic systems would be abandoned in accordance with the applicable state and county requirements.

Excavation of Stability Berm and Inspection Trench

The existing stability berm along the levee would be excavated and the material would be used in the construction of the seepage berms. The geotextile fabric from the drain layer would be discarded to a suitable landfill. Prior to the construction of the adjacent levee, a 6-foot-deep inspection trench would be excavated. After inspection, the trench would be backfilled and compacted as part of the embankment construction with material from the borrow sites. The material from the inspection trench would be stockpiled and used either in the adjacent setback levee or the seepage berm.

Construction of Adjacent Levee, Cutoff Walls, and Seepage Berms

Borrow material from the borrow source would be delivered to the levee construction sites by scrapers or haul trucks where it would be spread by motor graders and compacted by sheepsfoot rollers to build the adjacent levee. In those areas where a cutoff wall is required, the adjacent levee would be built up to a height equal to about one-third of the proposed levee. This would create a working platform for cutoff wall installation using an excavator with a long-stick boom capable of digging a trench to a maximum depth of approximately 85 feet. Bentonite slurry would be pumped into the trench during excavation to prevent caving. The soil excavated from the trench would be mixed with bentonite and backfilled into the trench to create the cutoff wall. The working platform would also be used for cutoff wall installation using a machine capable of injecting and mixing the bentonite slurry with the soil simultaneously to a maximum depth of approximately 115 feet. Between Reaches 5B through 6A, borrow material would be spread and compacted for construction of the seepage berms.

Installation of Relief Wells and Monitoring Wells

Relief wells may be installed adjacent to the seepage berms. Relief wells would be spaced at 100-foot intervals approximately 20 feet beyond the toe of the berm. Monitoring wells (piezometers) would be constructed at varying intervals along all reaches.

Reconstruction of Garden Highway at Intersections

The Garden Highway intersections at Elverta Road, Elkhorn Boulevard, and North Bayou Road would require reconstruction to accommodate the raised adjacent setback levee. It is anticipated that Garden Highway would be extended up and onto the widened adjacent levee at these locations to meet with the secondary roads. Approach embankments at the intersections would be enlarged and the entire intersections would be repaved. The intersecting roads would be raised at a slope of 15H:1V, extending the approach embankment approximately 500 feet outward from the levee. The side slopes of the raised embankments would be at a 3H:1V or

2H:1V slope depending on embankment soil type. Traffic control measures and detours would be required during this phase of construction. Private access ramps and access ramps at secondary roadways would also be raised.

Installation of Surface Drainage Outlets Across Garden Highway

The portion of levee between the adjacent setback levee and the Garden Highway pavement would include new storm drainage collection facilities to convey surface water beneath Garden Highway and toward the Sacramento River. A grassed surface collection system (drainage swale) would convey runoff water to drop inlets, and new pipe laterals would convey the water beneath Garden Highway to new outfalls in the berm along the east bank of the Sacramento River. In most locations, the outfalls would be placed above the ordinary high water mark (OHWM) on the 'bench' adjacent to the levee. The location of the cross culverts would be selected to minimize impacts on existing residential properties and riparian vegetation, including trees. The drainage pipes vary from 12 to 18 inches in diameter. The discharge would vary with the magnitude of precipitation events and is anticipated to exceed 1 cubic foot per second (cfs) during substantial rain events. These discharge pipes would require minor landscape improvements to prevent erosion and ensure that applicable water quality standards are met. Rock slope protection (rip rap) would be installed on the surface of the 'bench' to prevent erosion below the outfalls. Excavation of a trench to install the culvert piping across Garden Highway would be required, and those segments where excavation occurs would have to be reconstructed. Single-lane traffic controls and through-traffic detours would be required during this phase of construction.

Site Restoration and Demobilization

Upon completion of construction activities, the levee slopes and the tops of the seepage berms would be hydroseeded. An aggregate base road would be constructed on the crown of the new levee. Any construction debris would be hauled to an appropriate waste facility. Equipment and materials would be removed from the site, and staging areas and any temporary access roads would be restored to pre-project conditions. Demobilization would likely occur in various locations as construction proceeds along the project alignment.

Pleasant Grove Creek Canal West Levee

General Plan for Phase 3 Construction

The PGCC west levee would be expanded to the landside to provide a levee width to encompass, at a minimum, a theoretical 3H:1V waterside slope, a crown width of at least 20 feet, and a landside slope of at least 3H:1V. Beginning just south of its intersection with Howsley Road and continuing one quarter mile south, the widened levee would be raised one to two-tenths of a foot to provide 3 feet of levee height on the 100-year design water surface profile. South of the levee raising section, the new levee width would be increased to provide a base on surface profile. South of the levee raising section, the new levee width would be increased to provide a base on

which to construct seepage remediation improvements. A SB cutoff wall would extend through the entire PCGG west levee, totaling approximately 17,400 lineal feet, to coincide with areas where streams historically flowed east to west through the current PGCC alignment. The cutoff wall beginning at Howsley Road could potentially overlap for 100 - 500 feet with the NCC cutoff wall constructed as part of the Phase 2 project.

Some rock slope protection would be required on the land side of the levee at Howsley Road, where the 100-year stormwater could pass through this lower section of the levee. Five existing culverts that pass beneath the PGCC west levee and extend to the east side of the canal would be replaced with pipe materials and pipe closure devices meeting Corps standards for levee penetrations. Rock slope protection on the waterside would also be required for erosion control purposes. Primary construction activities are described below.

Cutoff Wall Construction

To provide a stable working surface for cutoff wall construction, and to mitigate potential levee through-seepage, the widened levee would first be constructed up to an elevation at least one third of its ultimate height. The working surface would be constructed by hauling earthen material to the levee from the borrow site using elevating scrapers or trucks. The cutoff wall would then be constructed through the widened levee, to a depth of approximately 60 feet from the existing levee crown. The conventional, long reach excavator method would be used to construct approximately 5,000 lineal feet of cutoff wall. A 3,000-foot-long cutoff wall would be constructed at the downstream end of the PGCC, and two separate 1,000-foot-long reaches would be constructed opposite of where Pleasant Grove Creek enters the PGCC from the east and where Curry Creek enters the PGCC from the east.

Levee slope flattening, and widening along the landside of the PGCC west levee is anticipated to require 475,000 cubic yards of import material (including material as described above to construct a cutoff wall working platform). This material is anticipated to be hauled from the Brookfield borrow site using elevating scrapers for the majority of the PGCC west levee.

Placement of Rock Slope Protection Control on the Waterside and Landside Levee Slopes

Current erosion and wind and wave analyses indicate that select areas of the PGCC west levee may require the placement of rock slope protection on the waterside levee slope to provide additional erosion control. Where creeks flow into the PGCC from the east, the waterside slope opposite the creek entrance would be armored with rock slope protection. Some rock slope protection would also be required on the landside of the levee at Howsley Road, where levee overtopping from wave action could affect this section of the levee.

Work on the waterside of the PGCC west levee may require reshaping the waterside levee slope to be flatter then its current 2:1 slope to conform to current Corps criteria. This may be accomplished by trimming back the waterside slope, which would require relocation of Natomas

Road, or by placing additional fill material on the waterside of the levee slope. This is an issue currently under evaluation by SAFCA's design team.

Utility Modifications

Numerous private irrigation facilities along the PGCC west levee would be disrupted by the proposed levee improvements and would be replaced as part of the Phase 3 improvements. These private structures, consisting of nine landside water wells and one private river pump, service the adjacent agricultural fields. The water wells would be relocated outside of the flood control footprint (by drilling replacement wells and abandoning the existing wells). The river pump discharge pipes through the levee would be raised and anti-siphon valves added. In addition to the wells and river pump, there is approximately 4,300 feet of local irrigation canals and approximately 1,600 feet of buried irrigation piping that would be relocated. The private irrigation facilities would be replaced with in-kind structures compatible with the new levee footprint to prevent disruption of service in the fields.

Natomas East Main Drainage Canal West Levee

General Plan for Phase 3 Construction

Improvements identified for the NEMDC west levee include cutoff wall installation, levee widening, and slope flattening. From the NEMDC stormwater pumping station south to Northgate Boulevard, cutoff walls are to be constructed to a depth of up to 80 feet from the levee crown. The existing maintenance area on this stretch of the NEMDC west levee would not accommodate levee reshaping or levee degrading beyond what is necessary to provide a minimum working platform for cutoff wall installation. Additionally, structures in close proximity of the landside levee toe make additional maintenance area acquisition impractical. Therefore, this wall is anticipated to be a cement-bentonite wall constructed by the conventional, long reach excavator method, or a soil-cement-bentonite wall constructed by the Deep Soil Mixing or Trench Remixing Deep method. North of the NEMDC stormwater pumping station to Elkhorn Boulevard, landside levee widening and maintenance area acquisition would occur similar to what is described for the PGCC levee above.

Cutoff Wall Construction

To provide a working platform for construction of the cutoff wall, at a minimum, the surface of the gravel operating road would be removed and stockpiled for later reuse. East Levee Road and Ueda Bikeway asphalt pavement would also be removed for construction of the cutoff wall. Depending on the equipment used to construct the wall, the levee may be degraded between 2 or 3 feet to provide additional working width. Approximately 7,000 linear feet of cutoff wall would be constructed to a depth of 80 feet, approximately 8,000 lineal feet of cutoff wall would be constructed to a depth of 60 feet, and approximately 10,000 linear feet would be constructed to a depth of 45 feet. Following completion of the cutoff wall, the levee crown would be

reconstructed and the operating road surface restored to gravel roadway or asphalt pavement depending on the existing road surface.

Levee Flattening and Widening

Landside levee widening and slope flattening work at the NEMDC west levee is scheduled to occur between Elkhorn Boulevard and the NEMDC stormwater pumping station. Approximately 225,000 cubic yards of imported earthen material would be required. A potential borrow source at the intersection of East Levee Road and Elkhorn Boulevard (Krumenacher property or Twin River Unified School District property) has been identified as the likely source of borrow material for this segment of the project. Where levee improvements are located within 1 mile of the borrow site, elevating scrapers would likely be used to haul the material to the levee. Hydraulic excavators and off-road dump trucks may also be used to load and haul the material from the borrow site.

Major Irrigation and Drainage Infrastructure Modifications

Phase 3 Construction on Elkhorn Canal

During Phase 3, approximately 10,350 feet of the Elkhorn Canal would be relocated and reconstructed several hundred feet east of the landside toe of the Sacramento River east levee (Reaches 6B-9B, south of Elkhorn Reservoir). Approximately 4,100 feet of the existing Elkhorn Canal south of the Elkhorn Reservoir sedimentation basin is concrete-lined, and the remainder is earthen-lined, except for the section that would be piped. The bottom of the canal, which would be approximately 5 feet wide, would be high enough to raise irrigation water levels above the levels of adjacent fields so that these fields could be fed by gravity flow. To control vegetation and to allow for canal maintenance with minimal disturbance of aquatic habitat along the water's edge, approximately 4,700 lineal feet of the invert of the canal may be concrete-lined; this corresponds to segments where the existing canal is lined. The canal would be confined by approximately 4-foot-high earthen embankments designed to provide one foot of levee height above irrigation water operating levels. To provide for stable banks, the side slopes of the canal would be 3H:1V. A 15-foot-wide patrol road would be located on top of the field side embankment; the other embankment would be approximately 8 feet wide.

To avoid existing infrastructure to the extent possible, approximately 3,200 feet of the canal would be piped through the Teal Bend Golf Club. Two 36-inch pipes would be aligned parallel to the levee toe landside of the flood control facility corridor. Approximately 950 additional feet of the canal may be piped through the Mortensen and Breese properties to avoid impacts on existing residences; a single 36-inch pipe is expected to be used in this section.

The Phase 3 portion of the relocated Elkhorn canal and the GGS/Drainage Canal would be constructed concurrently. Timing of the new canal construction would be critical to avoid interruption in irrigation service. Temporary connections may need to be constructed to avoid agricultural service interruptions to adjacent properties. The major construction stages are described below.

Clearing and Grubbing/Stripping

Prior to construction, the canal right-of way surface would be cleared and stripped to a depth of 4 to 6 inches, with removal of low-growing vegetation and loose surface soils. Suitable materials removed during this stage could be stockpiled. Unsuitable material would be hauled off-site. Prior to any excavation, utility poles in the path of the canal construction would need to be relocated. Natural gas pipelines, wells, and other gas facilities would be avoided or reconfigured in the design of the Elkhorn Canal and GGS/Drainage Canal.

Embankment and Access Road Construction

Up to 246,000 cubic yards of material required to construct the embankments of the Elkhorn Canal would come primarily from the construction of the GGS/Drainage Canal excavation and would be required for construction of Phase 3 of the Elkhorn Canal between Elkhorn reservoir and I-5. Borrow material from the GGS/Drainage Canal excavation would be utilized to build up the embankments of the replacement Elkhorn Canal, which would have a top elevation approximately 4 feet above the channel bottom and 3H:1V side slopes.

Concrete-lined sections of the canal would utilize boom trucks and concrete pumps to apply the concrete to the bottom of the channel. Piped sections would be constructed by excavating open trenches, laying the pipe, and backfilling to provide adequate cover material.

Water Control Facility Construction

Approximately 25 field services (water turnout points), roadway crossings, and diversion boxes are located along the entire length of canal. The turnouts, roadway crossings, and diversion boxes would need to be replaced as part of the proposed project. New facilities that would be constructed include distribution boxes, gate valves, cast-in-place concrete headwalls and control structures, and culverts. Backhoes and excavators would be used to excavate material for the new facilities. Precast distribution boxes, pipes, and other appurtenances would be transported to the site on trucks. Other concrete facilities would be cast in place and concrete would be transported to the site in redimix trucks. Small compactors would be used to compact fill material around the facilities. Portions of farm canals and other irrigation canals would be abandoned because of the relocation of the Elkhorn Canal. Segments that are outside the footprint of the proposed levee improvements would be filled after the relocation of the Elkhorn Canal is completed.

Erosion Control and Demobilization/Cleanup

Erosion control measures would be installed prior to the start of construction and maintained throughout the duration of the construction to minimize sedimentation of adjacent waterways. A hydroseeding truck would be used at the end of the construction to seed any disturbed areas. Water trucks would be used throughout the construction to control dust in any disturbed areas. Following construction, all disturbed areas would be vegetated and the construction site would be

generally cleaned up including hauling off of unused and waste materials. All construction equipment would be taken off-site.

Phase 3 Construction on New GGS/Drainage Canal

The Phase 3 portion of the GGS/Drainage Canal would begin at the Elkhorn Reservoir and connect to the West Drainage Canal. The GGS/Drainage Canal would have a series of check structures along its length to maintain consistent water levels in the low-flow channel of the channel during the giant garter snake's active season (May through October). Water would be provided from Natomas Central Mutual Water Company's (NCMWC) irrigation system. The GGS/Drainage Canal would cross Jacobs Slough through a control structure with two flashboard risers on the GGS/Drainage Canal and two box culverts on the slough. The level of water in various parts of the slough would be controlled by raising or lowering the flashboards. The normal operating level of the slough would be its existing normal water surface elevation. No borrow materials are anticipated to be needed to construct the GGS/Drainage Canal. As the Phase 3 portion of the relocated Elkhorn Canal and the GGS/Drainage Canal would be constructed concurrently, material excavated during the construction of the GGS/Drainage Canal would be used for construction of the Elkhorn Canal. Timing of the new canal construction would be critical to avoid interruptions in irrigation service. Temporary connections may need to be constructed to avoid agricultural service interruptions to adjacent properties. The following section outlines the construction timing for the GGS/Drainage Canal and the Elkhorn Canal. The GGS/Drainage Canal would not have any concrete lining. The top of bank for the GGS/Drainage Canal would be approximately at existing ground level. During construction, a trench at least 6 feet deep with an average width of 55 feet would be excavated to construct the canal. The canal would have a 10-foot bottom width and vegetated 3H:1V side slopes. The depth would be sufficient to provide a minimum water depth of 4.5 feet with allowance for 1 foot of water level variance and a minimum of 1 foot of levee height.

A 2,200-foot-long section of the GGS/Drainage Canal between the sedimentation basin and Walnut Road would include a 15-foot-wide managed upland bench. The 5,900-foot-long section between the southeastern corner of Teal Bend Golf Club and the West Drainage Canal would have a 35-foot-wide managed upland bench. This bench, which would be periodically irrigated with canal water and drain into the main channel, would be planted with perennial native grasses, similar to the surrounding uplands. Restoration would include planting tules on the sloped banks. Backhoes would be used to prepare the planting areas and a water truck would be used to control dust.

A sediment collector ditch is proposed to be created at grade and parallel to the maintenance right-of-way on the east site of the lower GGS/Drainage Canal, between the segment of the new canal that extends from about the southeastern corner of the Teal Bend Golf Club to the West Drainage Canal. Tailwater and stormwater drainage from agricultural fields adjacent to the lower GGS/Drainage Canal will be collected in this 3-foot-deep, 8- to 11-foot-wide ditch where most of the sediment volume will settle. Existing overland flow and collector drains will be consolidated into six outfalls entering the canal. These local field drains will be directed into the

sediment control ditch at small check structures. Water released from the sediment control ditches to the lower GGS/Drainage Canal will be managed using water control structures at six locations along the length of the ditch, where water will enter the canal through 15- to 20-foot-wide shallow, grassy swales. During the growing season and the giant garter snake's active season, water will only be in the ditch and grassy swales when adjacent fields are being irrigated.

Construction Schedule for the Lower Elkhorn Canal and GGS/Drainage Canal

In order to maintain NCMWC's irrigation service while the levee improvements are being constructed (between May 1 and October 1, 2010), SAFCA's goal is to construct the open channel portion of the Elkhorn Canal south of the Teal Bend Golf Club prior to the onset of the irrigation season, which begins approximately April 15, 2010. The GGS/Drainage Canal would be constructed concurrently to facilitate the use of material from the GGS/Drainage Canal excavation for use as embankment material along the Elkhorn Canal. Not all of the construction for these two canals would occur during the giant garter snake's inactive season. During the winter of 2009/2010, SAFCA proposes to limit construction on the Elkhorn Canal to the area immediately south of Teal Bend Golf Club south of its terminus and construction on the GGS/Drainage Canal would extend from 200 feet south of Jacobs Slough along Schoolhouse Road to 200 feet north of the West Drainage Canal. This work would also include the demolition of structures at the Ferreira and Pacific Terrace properties, which are located within the GGS/Drainage Canal alignment.

Construction is expected to begin in November 2009 and would require three months to complete. The construction of the piped portion of the Elkhorn Canal through the Teal Bend Golf club and the connection points of the GGS/Drainage Canal at Jacobs Slough and the West Drainage Canal, as well as much of the vegetation establishment and fine grading, would be delayed until after May 1, 2010.

Potential aquatic habitat for giant garter snakes within this area includes the existing Elkhorn Canal, Jacobs Slough, Schoolhouse Road ditch, some lateral canals extending off of Elkhorn Canal, Schoolhouse Road ditch, and the West Drainage Canal. The majority of the Elkhorn Canal proposed for construction prior to May 1, 2010, is more than 200 feet away from aquatic habitat for giant garter snakes. Two small portions of the open channel construction would occur within 200 feet of aquatic habitat: 1) where the Elkhorn Canal begins immediately south of Teal Bend Golf Club; and 2) the piped segment in the middle of the Sacramento River east levee Reach 8. Another portion of the open channel construction would cross a drainage ditch that extends along West Elkhorn Boulevard.

The northern and southern terminous points for the GGS/Drainage Canal construction would be at least 200 feet away from aquatic habitat (Jacobs Slough on the north and West Drainage Canal on the south). At the southern end of the GGS/Drainage Canal a mobile pump would be placed on a trailer with its intake pipe in the southern end of the GGS/Drainage Canal and the outfall in the West Drainage Canal. The operation of the mobile pump will be timed sporadically to allow silt in the GGS/Drainage Canal to settle between pumping events. To prevent erosion in the

West Drainage Canal, about 400 square feet of 18-inch-thick rip-rap would be placed in the canal to line the pump outfall.

Most of the GGS/Drainage Canal constructed during the winter of 2009/2010 would occur parallel to the Schoolhouse Road ditch. Schoolhouse Road is immediately east of the ditch and the GGS/Drainage Canal would be constructed east of Schoolhouse Road and would occur on actively farmed lands (primarily alfalfa and some row crop).

The haul route will be along West Elkhorn Boulevard. Some surface improvements to support the haul road function would be necessary and will be accomplished within the existing road surface. A drainage ditch is located along the road. If an off-road haul route is required, bridges would be used to cross aquatic habitat and the areas would be disturbed and fences prior to October 1, 2009.

Modifications to Pumping Plants

Reconstruction of Pumping Plant Number 2

As part of Phase 3 improvements, Pump Plant 2 would be reconstructed at a site located farther away from the levee than the location of the old site. The outfall of Pump Plant 2 would be reconstructed at the same location of the bank of the Sacramento River. Water would be conveyed from the pump to the outfall by three 36-inch pipes. The outfall pipes would be reinforced with concrete structural components and flap gates would be provided for each of the discharge pipes to prevent water backflow. The piping and outfall would be designed to discharge water at a maximum velocity of 12 feet per second. Pumping capacity of the reconstructed Pump Plant 2 facilities would approximately match historical capacity, which is based on the capacity to pump drainage water from the Natomas Basin during a 100-year base flood event. However, to maintain the equivalent capacity, some additional pumping horsepower would be needed to overcome the losses in pumping rate associated with longer discharge pipes and higher discharge head due to raising the pipes above the "200-year" design water surface elevation.

A sheetpile cofferdam would be used to dewater a small area (less than 0.05 acre) on the bank of the Sacramento River where the outfall for Pump Plant 2 would be reconstructed. The sheetpiles for construction of the cofferdam would be installed using a pneumatic hammer sequentially from the upstream to the downstream limits of the construction area and the resulting structure would connect to the bank and effectively isolate the construction area. After construction of the sheetpiles the area behind the cofferdam would be dewatered using a pump with a screened inlet. A concrete erosion control platform would be constructed immediately beneath the outfall pipes and riprap would be placed in a localized area on the waterside of the sheetpile and the disturbed levee area to prevent future erosion and scour. After dewatering and construction is complete, the sheetpile would be cut down to a level that is flush with the concrete erosion control platform and riprap. A fish rescue plan would be developed and implemented to ensure that fish are not harmed or stranded during dewatering or other construction activities.

Prichard and Elkhorn Pumping Plants Modifications

In general, water is pumped into the Basin using NCMWC facilities and drainage within the Basin is pumped to the river via RD 1000's drainage system and pumping plants. Under the Phase 3 Project, the discharge pipes are required to cross the levee above the new "200-year" design flood elevation. To accommodate this, the existing gate structure for the NCMWC Prichard and Elkhorn irrigation pumping plants would need to be removed and the existing pumps would be replaced to allow similar performance after the levee improvements and pipe-raising/replacement. Any work done to the pumps would occur once the pumps are pulled from the platforms using cranes from the riverbank or from barges. At both pumping plants, new impellers, pump bowls, and shafts would be required. For both pumping plants, the existing pumping plant superstructures include a pump platform and bridge out into the river channel. The pipes are hung under the pumping plant platform over the water such that replacement would require working over the water. The pump platform superstructures would require rehabilitation to accommodate the new pipes and to provide stability during construction. For Prichard Pumping Plant, this would include using a diver to add concrete sleeves to the pilings to provide additional support for structure improvements and new equipment. At the Elkhorn Pumping Plant, pile improvements would also be required in addition to repair of the existing retaining wall. For the removal and re-installation of the pumps, some localized minor maintenance dredging under the pump house may be required to clear sediment buildup, if any around the pump bows. Dredging would be performed by divers with dredging hoses over a period of less than 2 weeks at each Pumping Plant (as necessary). For removal of the manifold structure and gate structures, the use of a backhoe, pneumatic hammer, a front-end loader, and haul truck would likely be required during construction. Electrical equipment for the pumps would be replaced and the new equipment would be placed on a pad that would be constructed on the waterside bench above the "200-year" water surface elevation (and above the OHWM). The products of demolition from changes to the pumping plants and infrastructure would be wasted and removed from the site or salvaged and returned to NCMWC.

At Prichard Pumping Plant, there are two 36-inch pipes and one 30-inch pipe that connect from the pump house at the end of the platform to a concrete vault located at the top of the riverbank on the waterside of Garden Highway. From the concrete vault to the gate vault located at the waterside shoulder of the levee, there is one 72-inch pipe. From the gate vault through the levee to the Elkhorn Canal the pipe is 72-inch with a 60-inch grouted liner, which transitions into a 6-foot by 6-foot box culvert landside of the levee. Replacement pipes would include two 36-inch pipes and one 30-inch pipe continuous from the pumps through the levee to the canal outfall. Excavation at the Prichard site would be required to remove and replace these existing pipes and install new pipes. The excavation area from the concrete vault to the waterside top of existing levee is estimated to be 0.3 acre. Some minor excavation on waterside of vault would be required above the OHWM to expose the pipes, which are partially buried. Modifications at Elkhorn Pumping Plant would be similar to those at Prichard Pumping Plant. One 24-inch pipe and one 30-inch pipe connect the pumps in the river to the concrete gate house. One 42-inch pipe connects the gate house to the existing sedimentation basin. Replacement pipes would include one 24-inch and one 36-inch from the pumps through the levee to the canal outfall.

Excavation at the Elkhorn site would be required to remove and replace the existing pipes. The excavation area from the platform to the waterside top of existing levee is estimated to be 0.2 acre. Some excavation on the waterside of gate house would be required above the OHWM to expose the pipes, which are partially buried.

Modifications to Irrigation Infrastructure

Private Irrigation Modifications

The proposed levee improvements in Phase 3 would also impact private irrigation facilities including agricultural wells, private river pumps, and canals along Reaches 9B-12 of the Sacramento River east levee and along the PGCC west levee. These facilities would generally be relocated landward to move them outside of the flood control footprint and reconstructed in-kind. Discharge piping from river pumps in these reaches would be raised and extended. Some pipe raising in the lower reaches of the Sacramento River would be deferred until the new adjacent levee is constructed to allow for pipe raising.

Airport West Ditch Reconfiguration

The Airport West Ditch would be reconfigured and redesigned in coordination with construction of the GGS/Drainage Canal. The NLIP's new GGS/Drainage Canal would intercept the year-round irrigation and drainage sources from adjacent private farms, which currently flow into the Airport West Ditch and the Airport Operations Area. Additional irrigation infrastructure required to reroute these flows would be implemented along with the new GGS/Drainage Canal construction.

The existing Airport West Ditch is up to seven feet deep. This depth and the irrigation and drainage water that flows through the ditch results in standing water conditions that attract wildlife that creates a potential hazard to aircraft. Filling and leveling the ditch would involve placing a two feet deep layer of aggregate in the bottom of the existing ditch, than covering that layer with earthen fill to just below the invert of the existing runway storm drain pipes that outfall into the ditch.

The ditch cross section would be re-graded to form a shallow drainage swale with flattened side slopes to accommodate mowing operations required for vegetation control. The swale would be approximately five feet deep with 5H:1V side slopes. In general practice, a minimum side slope to accommodate machinery access for mowing operations is 3H:1V. The swale is outside the Runway Safety Area in accordance with FAA Advisory Circular 150/5300-13. Sacramento County Airport System (SCAS) would be responsible for maintenance of the proposed swale.

Geotechnical Investigations along Portions of Phase 4 Project Footprint

SAFCA needs to conduct an exploration of geotechnical conditions in the Natomas Basin as a component of the NLIP Landside Improvements project. Geotechnical borings are necessary to complete the preliminary design process for the upcoming Phase 4 project, and identify the

footprint of the levee repairs so that the environmental team members can then determine the effects of the proposed action.

Geotechnical field investigations would include a series of soil test borings and characterization of conditions underlying the levee system. The subsurface conditions at the site will be explored by drilling borings to depths between 80 and 120 feet below existing grade . Borings will be drilled using a truck-mounted drill rig equipped with either a 4- or 8-inch diameter solid or hollow stem auger. The borings will be drilled on the crest of the existing levee, the landside toe of the levee, and/or at locations approximately 100 to 200 feet away from the landside toe. The landside toe borings will be drilled on the maintenance road at the base of the levees where possible but would be drilled in open fields where no roads exist. One rubber-tire truck-mounted drill rig with a support truck would be onsite during the geotechnical explorations. The toe boring sites are generally accessible for truck mounted drilling equipment via the maintenance road.

Geotechnical investigations are proposed within the Phase 4 project area at numerous sites including: Sacramento River east levee reaches 15-20 (31 borings), the American River north levee (17 borings), and the northern segment of the NEMDC west levee between Sankey Road and Elkhorn Boulevard (57 borings). Geotechnical investigations would begin in the fall of 2009 and would require 90 days to complete. Some of the borings are within 100 feet of elderberry shrubs; however none of the borings will occur closer than 20 feet from the dripline of an elderberry shrub. Borings that are within an area that giant garter snakes (5 borings along the Sacramento River east levee) could be overwintering will be postponed until May 1, 2010.

Habitat Enhancement, Development, and Management

Several project components involve the replacement and/or creation of habitat for listed species, including the construction of the southern 10,350-foot segment of the relocated Elkhorn Canal downstream of Elkhorn Reservoir, the construction of the southern 13,200-foot segment of the GGS/Drainage Canal between Elkhorn Reservoir and the West Drainage Canal, and the creation of managed grasslands on the newly constructed levee slopes, seepage berms access rights-of-ways, and canal embankments. The project also incorporates other habitat enhancements and developments planned for Phase 3 of project construction including the preservation and establishment of landside woodlands and waterside riparian forest and scrub along the Sacramento River east levee and the preservation of agricultural upland cropland. The construction of the Elkhorn Canal and GGS/Drainage Canal are described above in more detail. Please refer to the *Mitigation and Monitoring Plan, Natomas Levee Improvement Program, Landside Improvements Project (Phase 2)* document for a more complete summary of the strategy for creating/enhancing/preserving, protecting, and managing habitats in the Natomas Basin in perpetuity. A Phase 3 project Mitigation and Management Plan for these habitat components is currently being developed; a Programmatic Long-term Management Plan is also being developed and would include site-specific management plans for each of the habitat components. Design elements for the canals, managed grasslands, landside woodlands, waterside riparian forest and scrub, and agricultural croplands are summarized below.

Canals

GGS/Drainage Canal

The GGS/Drainage Canal north of Teal Bend Golf Club (golf club) would be managed by RD 1000 primarily as giant garter snake habitat, with stormwater drainage a secondary function during major storm events, which typically occur in the snake's inactive season. South of Teal Bend Golf Club, the canal would also serve as a giant garter snake habitat area, but the volume of stormwater drainage would increase in a southerly direction as the canal collects additional runoff as a result of the natural slope of the basin. Winter storm-related runoff exceeding the capacity of the West Drainage Canal south of I-5 would be pumped into the Sacramento River using RD 1000's Pumping Plant Number 3, consistent with existing stormwater management practice.

The shoreline and lower bank of the GGS/Drainage Canal would be planted or managed to promote tule vegetation as suitable cover and foraging habitat for giant garter snake. However, management of the canal would also require removal of noxious aquatic weeds that obstruct the flow of water. A secure water supply would ensure that water of a suitable quality is present and flowing at low velocity in the canal during the active season of the giant garter snake, and that the water surface would be managed within a range of approximately 1 foot to provide consistent cover from predators along the tule fringe of canal banks. Input of supplemental canal water would begin at a diversion point on the North Drainage Canal at the north end of the new GGS/Drainage Canal. Other points of inflow may occur at downstream locations.

Elkhorn Canal

The Elkhorn Canal will be relocated to enable management of existing NCMWC water supply infrastructure affected by levee widening. This canal is the primary source of surface irrigation water for rice and other irrigated crops throughout the basin, including the Natomas Basin Conservancy (TNBC) reserves that are managed for rice and marsh. Secondary functions include water filtration, sediment storage, and wildlife habitat.

The relocated Elkhorn Canal would continue to be managed for irrigation function, and would be maintained and operated in the same manner as the existing NCMWC canals. The bank slopes of the relocated canal would be 3H:1V, in contrast to the over-steepened, eroding banks on the existing canal. This would reduce the frequency and level of bank disturbance, require less need for system repair and dredging, and provide more continuous and higher quality shoreline cover for giant garter snake and other semiaquatic species. There will be two sections of the Elkhorn Canal that will be piped, one to avoid the golf club and one to avoid a residence.

Managed Grasslands

Levee Slopes and Seepage Berms

Most grasslands would be mowed or grazed throughout the growing season, with an emphasis on mowing procedures and stubble height (generally 6-12 inches) to optimize these areas for Swainson's hawk foraging habitat. This management regime is in accordance with the Corps and state guidelines for levee inspection. The primary purpose and management priority of levees and seepage berms would continue to be flood risk reduction, for which RD 1000 has principal management and maintenance responsibility, and they would be maintained in accordance with the Corps and Central Valley Flood Protection Board operations and maintenance requirements.

Canal Embankments

The side slopes of the new GGS/Drainage Canal and relocated Elkhorn Canal would be flatter than typical canal slopes in the Natomas Basin and consistent (3H:1V), resulting in greatly reduced erosion and sedimentation. Vegetation on the banks could easily be mowed to a specified stubble height using cutter blades instead of the existing, high-disturbance practice of flail mowing or scraping vegetation from the banks and canal with a drag bucket. These improved canal maintenance practices would reduce disturbance and mortality of giant garter snakes that use bank and shoreline vegetation as cover and feeding habitat.

Landside Woodlands

In Phase 3, woodlands consisting of native riparian species would be planted east of the maintenance corridor along the Sacramento River east levee improvements. Tree and shrub species, including elderberry shrubs, would be planted on approximately 18.5 acres of existing cropland, fallow, or currently unused sites in a woodland corridor along Reaches 7-9B of the Sacramento River east levee. An additional 2.5 acres of existing woodlands would be preserved along the proposed woodland corridor. At least another 15 acres of woodlands would be established on a site as yet to be determined. Groves would generally be at least 50-100 feet wide and several hundred feet long. At maturity, stand structure would vary from closed canopy woodland to grassland savanna vegetation type.

Planting sites would require suitable soil conditions, water supply during a 3- to 5-year establishment phase, reduced risk of wildfire, and minimal depth to seasonally high groundwater or other natural water sources to sustain trees once irrigation ceases. A mixture of native riparian species would be planted, but predominant species would be Valley oak (*Quercus lobata*), the primary tree species that would be affected by the proposed improvements to the Sacramento River east levee, and cottonwood (*Populus fremontii*), which is a preferred nest tree for Swainson's hawks in the basin and is faster growing than valley oak. Establishment of woody vegetation would likely require more than one technique, including seeding in winter, flood irrigation, drip or agricultural-scale spray heads, cuttings, and acorn planting.

Where trees would be removed from existing groves to make way for the proposed flood control system features, they would be transplanted in new locations, including newly planted groves, to the extent feasible. The woodland planting areas would provide locations for transplanting any elderberry shrubs that would need to be moved from the proposed footprint of flood risk reduction improvements.

Waterside Riparian Forest and Scrub (Shaded Riverine Aquatic)

Sacramento River waterside riparian forest and scrub will be restored using native species, including an assemblage of grasses, sedges, shrubs, and trees. Effects on riparian forest habitat are due to modifications of the pumping plant. At maturity, the riparian vegetation community would provide shaded riverine aquatic habitat (SRA) functions. SRA habitat is defined as the nearshore aquatic habitat occurring at the interface between a river and adjacent woody riparian habitat. The principal attributes of this cover type are: (1) an adjacent bank composed of natural, eroding substrates supporting riparian vegetation that either overhang or protrude into the water; and (2) water that contains variable amounts of woody debris, such as leaves, logs, branches, and roots and has variable depths, velocities, and currents. Riparian habitat provides structure (through SRA habitat) and food for fish species, including special-status fish species addressed in this document. Shade decreases water temperatures, while low overhanging branches can provide sources of food by attracting terrestrial insects. As riparian areas mature, the vegetation sloughs off into the rivers, creating structurally complex habitat consisting of large woody debris (LWD) that furnishes refugia from predators, creates higher water velocities, and provides habitat for aquatic invertebrates.

Agricultural Croplands

Up to 60 acres of upland field cropland would be preserved in perpetuity at one of the following (or combination of) the following borrow sites:

Private Property in Reach 7 of the Sacramento River East Levee/Bianchi Parcel
This 86-acre property is located along the Sacramento River east levee in Reach 7, southeast of Garden Highway and the Teal Bend Golf Club. The property is currently farmed as field crops. The portion of the site that is outside the levee improvement and canal construction footprints could be excavated to an average depth of 4 feet to provide borrow material for Phase 3 improvements to the Sacramento River east levee south of the Teal Bend Golf Club. The borrow site would be returned to field crops following excavation.

South Sutter, LLC/Thornton
This 97-acre parcel, located east of Garden Highway and north of Elkhorn Boulevard in Reach 8 of the Sacramento River east levee, is owned by South Sutter, LLC. The property is currently farmed as field crops. Preliminary estimates indicated that the property could be excavated to an average depth of 5 feet to generate up to 484,000 cubic

yards of potential borrow material for the Phase 3 Project segment of the Sacramento River east levee. This property would be returned to field crops following excavation.

These two borrow sites, as well as other potential sites located in the Elkhorn Borrow Area that would be returned to field crops following excavation, would be either partially or entirely preserved as agricultural cropland in perpetuity.

Reclamation of Other Borrow Sites

Borrow sites would provide material for Phase 3 flood control and irrigation infrastructure modifications. Following excavation of the borrow material, these sites would be reclaimed for post-construction uses.

Airport North Borrow Sites

The Airport's north bufferlands historically have been mostly farmed as rice fields and field crops. However, based on FAA requirements to reduce hazardous wildlife attractants near runways, the Airport has opted to not renew rice leases on its bufferlands. Thus, these lands are currently either fallow agriculture fields or ruderal grassland. After borrow activities, these sites would be reclaimed as grasslands.

Excavated soils not used for borrow material, such as the organic surface layer or soils considered unsuitable for levee construction, would be stockpiled and respread on-site following excavation. Any unsuitable borrow material would be stockpiled on-site and graded back into the restoration of the site. Revegetation activities would include erosion control on excavated slopes (i.e., hydroseeding), application of fertilizer, and seeding.

Brookfield

The Brookfield property is a 348-acre private property that is located between Howsley Road and Fifield Road, west of the PGCC west levee. As of summer of 2008, the property was in rice cultivation. As a component of the Phase 2 project a conservation easement will be recorded over a portion of this site (up to 175 acres) to preserve rice lands in perpetuity.

The removal of borrow material would entail excavating up to 190 acres of the site to a depth of up to approximately 6 feet, with an approximate net yield of approximately 3.6 million cubic yards of soil from the site. One foot of topsoil would be removed and stockpiled for reuse during reclamation of the site. This borrow material would be used for levee improvements along the PGCC west levee in Phase 3. Other portions of the site may be used as a borrow source for levee improvements along the NCC south levee (Phase 2) and possibly the NEMDC west levee (Phase 4); however, no area of the property would be used for more than one year. Following the removal of borrow material for the levee construction, the site would be graded and returned to rice cultivation.

Currently, the site is irrigated from on-site wells. To provide irrigation to the site following the excavation of borrow material, existing irrigation and drainage canals on the site would be modified to improve surface water delivery and facilitate site draining. Additional field irrigation ditches may be constructed within the Brookfield site to provide irrigation water from the adjacent highline canal to the fields. Grading of the site would be performed at a slope that would allow the water to flow back to the drainage canals running along the west and south side of the property.

Krumenacher Trust Property

The Krumenacher Trust property consists of an approximately 118-acre parcel located at the southwest corner of West Elkhorn Boulevard and the NEMDC. The owners have approached SAFCA to see if suitable arrangements could be developed to grade the site and generate borrow material for use along the NEMDC west levee. This parcel is a component of the Natomas Panhandle, identified in the Natomas Basin Habitat Conservation Plan (NBHCP), and development of this parcel is already covered by a biological opinion issued by the Service on July 25, 2007 (Service file number 1-1-06-F-0294) and amendment on December 18, 2007 (Service file number 81420-2008-F-0471).

Novak

The 94-acre Novak property is located in the vicinity of Fisherman's Lake, northeast of Garden Highway and Powerline Road. SAFCA has purchased this property in fee for the project. The property is currently farmed as field crops and orchard. This orchard would be removed as part of the project. The southern part of the property would be used for the levee footprint. The remaining acres could be excavated to an average depth of 4 feet to provide borrow material for Phase 3 and Phase 4 improvements to the Sacramento River east levee. Following borrow grading, the site would be topsoiled (12 inches thick) and reclaimed to an upland for a suitable commercial crop or a native perennial grassland.

Private Property in Reach 5B of the Sacramento River East Levee/Binford DeYoung Parcel

This property consists of 48 acres southeast of Garden Highway and Elverta Road on three parcels. The property is currently farmed as field crops. Approximately 34 acres of the site that is outside the levee improvement and canal construction footprints could be excavated to an average depth of 2 feet to provide borrow material for Phase 3 improvements along the Sacramento River east levee. The borrow site would be returned to field crops following excavation.

Private Property in Reach 6A of the Sacramento River East Levee/Horangic Parcel

This property consists of 71 acres northeast of Garden Highway and the Teal Bend Golf Club. The property is currently farmed as field crops. Approximately 20 acres of the site that is outside the levee improvement and canal construction footprints could be excavated to an average depth of 2

feet to provide borrow material for Phase 3 improvements to the Sacramento River east levee. The borrow site would be returned to field crops following excavation.

Twin Rivers Unified School District High School Site

The Twin Rivers Unified School District (formerly Grant Joint Union High School District site) is presently constructing a high school campus on several parcels of land south of Elkhorn Boulevard and west of the NEMDC west levee. During site grading operations, somewhere between 150,000 and 200,000 cubic yards of material were excavated to allow the school site to be graded compatibly with improvements proposed for neighboring properties. This excess soil may be available to SAFCA if suitable arrangements can be made for its removal from the site. The material would most likely be used by SAFCA for the NEMDC west levee improvements. This parcel is a component of the Natomas Panhandle, identified in the NBHCP, and development of this parcel is already covered by a July 25, 2007, biological opinion (Service file number 1-1-06-F-0294).

Longterm Maintenance of GGS/Drainage Canal, Brookfield Rice, and Landside Woodlands

GGS/Drainage Canal

RD 1000 will conduct routine maintenance activities, including water-level management, debris and sediment removal, canal bank repair, aquatic weed management, and terrestrial vegetation management, in order to maintain the desired functions and conditions of the upper and lower GGS/Drainage Canal. RD 1000 will prepare an annual operation and maintenance letter report to be submitted to the Corps and Service for review by the end of each maintenance year. The letter report will provide a summary of canal maintenance activities completed during the year, as well as routine maintenance activities and special projects planned for the upcoming year. RD 1000 will follow the incidental take avoidance and minimization measures within this biological opinion.

Water Level Management and Water Supply

Water for the GGS/Drainage Canal will be provided from the NCMWC irrigation system, or from groundwater wells located on SAFCA property. Water depth in the canal is designed to be 4.5 feet ± 0.5 feet, which will minimize growth of submerged aquatic weeds and limit tules to the shallow margins to maintain flow capacity. The upper GGS/Drainage Canal will be divided into five segments by a series of water control structures along its length to manage the water level in the canal. The lower GGS/Drainage Canal will have water control structures about every 2,000 feet to manage the water level in the canal. Water flow will be maintained at an estimated 5 cubic feet per second to avoid eutrophication and anaerobic conditions in the canal. Water will be supplied to the upper and lower GGS/Drainage Canal during the giant garter snake active season (May 1st to October 1st).

Debris and Sediment Removal

Debris and sediment removal is the act of removing accumulated earthen matter (soil, mineral particles, and/or organic debris) that accumulates in the GGS/Drainage Canal. Suspended matter in the water may gradually drop out of suspension as the water moves through the GGS/Drainage Canal, thereby creating a layer of organic and fine mineral sediment on the bed of the canal, decreasing canal capacity and promoting invasion by aquatic weeds. Debris and sediment removal will be warranted when RD 1000 can no longer maintain the design conditions of a particular segment of the GGS/Drainage Canal.

Debris and sediment removal activities will mostly be conducted under dewatered conditions; however, due to groundwater seepage and stormwater drainage demands, dewatering may not always be possible in some canal segments. A segment of the canal would be dewatered and sediment and debris removal would occur within two weeks of dewatering. Debris and sediment removal would occur in no more than 20 percent of the in the upper GGS/Drainage Canal each year and up to 50 percent of the lower GGS/Drainage Canal each year with a recurrence of 4 to 6 years. The addition of the sediment collector ditch on the lower GGS/Drainage Canal should lessen the need to conduct sediment removal in the lower GGS/Drainage Canal because most of the sediment will drop out in the sediment collector ditch and will be removed periodically during the giant garter snake's active season. No more than one segment of the canal will be dewatered at any given time. Coffer dams may be used to dewater only a short length of the canal within a segment, thereby leaving water in most of the segment. The water control structures will be used to hold water in the other segments of the canal while debris and sediment removal activities are taking place. If debris and sediment removal is carried out under watered conditions, careful operation of equipment will be employed to reasonably avoid damage to the canal banks.

Debris and sediment will be removed with the use of specialized equipment designed to avoid or minimize canal bank disturbance. The equipment will operate from the maintenance road and use a specialized hydraulic arm and bucket to scoop debris and sediment from the bed of the canal. Movement of the equipment will be limited to the maintenance road to avoid canal bank disturbance. Debris and sediment removed will be placed on the road away from the canal bank. Spoils placed on the road will be allowed to dry for 6 to 12 months and then be graded to become part of the road. Alternatively, spoils may be placed on adjacent agricultural properties with permission from adjacent property owners or land managers. The spoils will be removed from the canal and placed directly on the adjacent property. The spoils will be allowed to dry and will be distributed and incorporated into the adjacent property by the adjacent property owner or land manager. Where it is not feasible to place spoils on the operation and maintenance road or on adjacent agricultural properties, the spoils will be hauled to a predetermined disposal site.

However, because the upper GGS/Drainage Canal is designed to minimize maintenance requirements (e.g., 3H:1V slopes, vegetated banks, greater width and flow capacity), debris and sediment removal will likely occur less frequently. The scheduling of debris and sediment

removal activities will be determined by RD 1000 staff, and will be included in the annual operation and maintenance letter report.

The preferred timing of debris and sediment removal is during the giant garter snake inactive season (October 1st to May 1st). Dewatering the canal allows the equipment operator to see the canal bottom and submerged banks, and avoid damaging the banks while removing the debris and sediment. If necessary, debris and sediment removal may occur during the giant garter snake active season (May 1st to October 1st), preferably under dewatered conditions.

While removing debris and sediment under dewatered conditions is preferred, dewatering the canal may not always be possible in some segments due to groundwater seepage and stormwater drainage demands during the giant garter snake inactive season. Debris and sediment removal may also be conducted under watered conditions during the giant garter snake inactive season.

Canal Bank Repair

Repairing canal banks may be required to reestablish the canal's original design cross section, carrying capacity, and structural integrity in the event of canal bank deterioration. Deterioration becomes evident in the form of sloughing and slumping of the canal banks, limiting the canal's carrying capacity and decreasing the structural integrity of the banks. The scheduling of bank repair activities will be determined by RD 1000 staff, and will be included in the annual operation and maintenance letter report.

Bank repair activities will mostly be conducted under dewatered conditions; however, due to groundwater seepage, dewatering may not always be possible. Water control structures and coffer dams will be used to dewater segments or preferably small portions of a segment. No more than one segment of the canal will be dewatered at any given time. Bank repair activites will occur during the giant garter snake active season. Dewatered sections will have bank repair activities conducted within two weeks of dewatering a segment. Due to groundwater seepage, irrigation delivery schedules, and stormwater drainage, complete dewatering may not always be possible, therefore, this activity may be conducted under watered conditions, generally in October. A preconstruction survey for giant garter snakes will need to be conducted by a qualified biologist prior to construction activities under both watered and dewatered conditions.

Bank repairs conducted under dewatered conditions will require soil to be imported to the site, unless a local source of soil is available. Site preparation in advance of soil placement will include the grubbing of vegetation from the damaged bank and compaction of the existing canal bank surface. For bank repairs that are greater than 10 feet in length, the existing canal bank may be cut back to allow the new soil to be keyed-in. Soil will be delivered to the project site by truck or other large equipment, using the operation and maintenance road. The placement and distribution of the soil will be done either by hand or mechanically, using a backhoe, hydraulic arm excavator, or small bulldozer depending on the size of the area to be repaired. The repaired canal bank will be compacted by hand-operated compactors (also referred to as "wackers"), by wheel rolling with heavy equipment or sheepsfoot roller, or tamping with the excavator/backhoe

bucket or vibratory compaction equipment. Disturbed areas will be reseeded with native perennial grass seed at the completion of the bank repair.

If bank repairs must be conducted under watered conditions, rip rap (6- to 12-inch diameter rock) will be placed on the lower portion of the canal slope with an excavator or backhoe and "tamped" into the slope toe using the bucket of the excavator or backhoe.

No plastic, monofilament, jute, or similar erosion control matting that could entangle snakes shall be placed by RD 1000 or its contractors in or within 200 feet of the upper GGS/Drainage Canal. Possible substitutions include coconut coir matting, straw, tackified hydro seeding compounds, or other material approved by the Service and CDFG.

The GGS/Drainage Canal is designed to reduce the potential for bank erosion and the resulting need for bank repair activities. Bank repair activities will be conducted on an as-needed basis. Based on RD 1000's experience with managing other canals in the Natomas Basin, bank repair activities for the upper GGS/Drainage Canal are anticipated to be infrequent (i.e., one project every 10 years) and small scale (10 to 100 linear feet). However, soil conditions, river levels and groundwater levels could affect the frequency of erosion repairs and will need to be evaluated over time.

Vegetation Management and Invasive Weed Control Activities

Vegetation management and invasive weed control is the use of physical/mechanical, ecological, and/or chemical techniques to support establishment of native and/or desirable aquatic, wetland, and upland vegetation, and reduction or suppression of nonnative and/or undesirable aquatic, wetland, and upland vegetation (i.e., noxious weeds) within and adjacent to the upper GGS/Drainage Canal.

The techniques described below will be used by RD 1000 and its contractors to manage vegetation in the upper GGS/Drainage Canal area. These vegetation management techniques may be used separately or in combination by RD 1000. Likewise, because RD 1000 currently utilizes many different types of vegetation control on other drainage canals in RD 1000's service area, the list of vegetation management techniques described below is not intended to be exclusive. If RD 1000 intends to implement vegetation management techniques in the upper GGS/Drainage Canal area that are not identified below, RD 1000 will discuss these with SAFCA and the Service and CDFG to determine if an amendment to the site specific management plan is required. Additionally, any new vegetation management method may adversely affect the giant garter snake and may require a section 7 consultation or habitat conservation plan. RD 1000 will include a summary of vegetation management practices in the annual operation and maintenance letter report.

Aquatic Vegetation Management

Hand Pulling/Cutting - Manual removal of aquatic vegetation by may be accomplished by field personnel entering the GGS/Drainage Canal under watered conditions, pulling/cutting the plants,

and depositing the material on the operation and maintenance road. Vegetation removed in this manner is allowed to desiccate to be later hauled away and burned, composted off-site, or incorporated into the existing access road fill. This technique is typically employed when equipment access is restricted, because it is labor-intensive, expensive, and can present worker safety issues. Site-specific hand pulling/cutting may be employed throughout the year to maintain the functionality of the canal, especially at water control drop structures.

Excavator/Backhoe Vegetation Removal - A hydraulic long-arm excavator or backhoe will be used to remove aquatic vegetation accumulations causing GGS/Drainage Canal blockages. This equipment is used to harvest the aquatic vegetation by dislodging it and placing the plant remains on the operation and maintenance road. Vegetation removed in this manner is allowed to desiccate and is later hauled away and burned or composted off-site. This technique is employed under watered or dewatered conditions and may be employed throughout the year when aquatic vegetation growth is severe and restricts water flow in the GGS/Drainage Canal.
Water Level Manipulation - Water level manipulation involves dewatering segments of the GGS/Drainage Canal to expose submersed aquatic plants. These plants depend on water for physical support because they lack a protective epidermal cell wall (or hardened cuticle layer) making them susceptible to desiccation. The canal segment must remain dewatered until aquatic vegetation has completely desiccated, or has been removed from the canal channel.

Chemical Treatment - Use of both contact and systemic herbicides can be valuable for the suppression of aquatic weeds. Use of selective herbicides, in contrast to broad spectrum herbicides that may cause mortality of desirable bank vegetation, may be required. These herbicides will be evaluated for their potential affect on non-targeted vegetation and animals by a State-licensed Pest Control Advisor prior to application. Chemicals not approved for use in or near water will be avoided. If herbicides and/or pesticides are used in the GGS/Drainage Canal, they will be applied in accordance with label instructions under the direction of a State-licensed Pest Control Advisor and applied by State-licensed pesticide applicators or employees under their direct supervision. Chemical treatments would be applied in October, after the irrigation season and before the flood season. The water would be held for 10 days in each confined segment of the canal that is being treated.

Upland Vegetation Management
The uplands adjacent to the upper GGS/Drainage Canal will be managed as native perennial grasslands. The grasslands will be maintained primarily to provide cover for giant garter snakes, and secondarily as foraging habitat for Swainson's hawks.

Grazing - Small-hoofed animals, such as sheep or goats, can be used to manage upland and wetland vegetation adjacent to the upper GGS/Drainage Canal. Grazing has been successfully employed by TNBC in its operations. Grazing for noxious weed control should typically be conducted in spring after the dominant noxious weed species have flowered, but before they have set seed. Timing will vary depending on weather conditions, and should be based on observations made by RD 1000 staff. Grazing will not occur between May 1st and July 1st to allow native perennial grasses to set seed. Grazing to control vegetation height should be

conducted between July 1st and October 1st. The use of grazing animals shall be evaluated to ensure that hoofed animals are not causing bank erosion or damage to a viable perennial grassland cover. Large-hoofed livestock, such as cattle, will not be used.

Mowing - Mowing is utilized to control terrestrial vegetation on operation and maintenance roads and canal banks to the water line. Mowing is accomplished utilizing a wheeled tractor with boom mounted flail mower and/or a rear attached flail mower or a self-contained riding-type mower. All mowers are provided with height gages which are set to leave the remaining vegetation approximately 6- to 12-inches tall, except for access roads where vegetation will be cut to leave the access roads clean of cover. Vegetation along the canal banks will be mowed, when necessary, only to the high-water mark when the canal is watered. Mowing for noxious weed control should typically be conducted in spring after the dominant noxious weed species have flowered, but before they have set seed. Timing will vary depending on weather conditions, and should be based on observations made by RD 1000 staff. As feasible and based on fire hazard potential, mowing should not occur between May 1st and July 1st to allow native perennial grasses to set seed, unless noxious weed control is the highest priority. Mowing to control vegetation height should be conducted between July 1st and October 1st; however, burrowing owl nesting sites will be avoided during this time period.

Prescribed Burning - If conditions are conducive, (e.g., favorable wind conditions and sufficient fuel material), burning has been shown to be effective in the reduction of organic matter (i.e., thatch) on canal banks or adjacent uplands. Prescribed burning should be used infrequently, primarily when other vegetation management methods are inadequate. Prescribed burning must be conducted in coordination with the local fire district and in accordance with all laws and local ordinances. Prescribed burning to control vegetation in the upper GGS/Drainage Canal area shall be conducted only between November 1st and April 1st. Due to proximity to the Airport runways, prescribed burning will not be used along the lower GGS/Drainage Canal.

Chemical Treatment - Use of both contact and systemic herbicides can be valuable for the suppression of terrestrial weedy plants. These herbicides will be evaluated for their potential affect on non-targeted vegetation and animals, by a State-licensed Pest Control Advisor prior to application. Chemicals not approved for use in or near water will not be used. If herbicides and/or pesticides are used in the GGS/Drainage Canal, they will be applied in accordance with label instructions under the direction of a State-licensed Pest Control Advisor and applied by State-licensed pesticide applicators or employees under their direct supervision.

Giant Garter Snake Brookfield Rice

The Brookfield property will be preserved as productive rice fields, and will include portions of irrigated wetlands as defined by Corps Regulatory Branch under Sec. 404 of the Clean Water Act. Rice fields enhance the forage and refugia habitat available to giant garter snakes. Protecting rice fields in the northeast Natomas Basin, as will occur at the Brookfield property, and managing them in perpetuity as giant garter snake habitat, will enhance the viability and resilience of giant garter snake populations in the Natomas Basin. Irrigation ditches used for

water delivery and drainage for the rice fields provide giant garter snake habitat, as well as connectivity between the targeted properties, including Brookfield, and habitat on other properties with rice fields and managed wetlands both east and west of State Route 99.

SAFCA will also seek to improve surface-water irrigation to the Brookfield property in order to reduce the site's dependence on groundwater. Until surface water supplies are made available to the Brookfield property, the giant garter snake rice habitat will be irrigated from on-site wells. TNBC will either farm the property, or contract with a farm tenant to grow rice on the property. TNBC and/or the farm tenant will manage water delivery to the rice field throughout the rice growing- and winter-seasons to maintain a sustainable rice production operation and maximize habitat benefits to giant garter snake. Water levels will be maintained approximately 6 inches deep during the growing season.

Rice Production

TNBC will manage the Brookfield property for sustainable rice production, which will include occasional crop rotations. Crop rotations are necessary to address conditions, such as soil depletion, resistant weeds, and insect or pest control. Hired field workers will observe the NBHCP's giant garter snake take minimization practices to ensure they do not intentionally harm or kill snakes on the giant garter snake rice habitat properties. The rice tenant will be required to conduct irrigation ditch maintenance in a wildlife friendly manner (as described below). Because the Brookfield property will be managed by TNBC, it will be managed in compliance with practices approved as part of the NBHCP.

Rice is typically planted in May and harvested between late August and October, depending on the planting date, rice variety, seasonal growth progress, and rainfall events that may interrupt the harvesting process. The rice is harvested with combines, collected in a storage tank on the combine, transferred to a grain cart, and transferred to a truck.

After rice harvest and drainage of rice fields, rice stubble or straw decomposition is managed with different practices to minimize disease and residue. Several approaches are used:

- The rice stubble is disced or chopped and subsequently flooded via irrigation.
- The rice stubble is disced prior to winter rains. No irrigation water is applied.
- The rice stubble is plowed to bury the residue, typically after one of the above practices have been applied.
- The rice stubble is cut, windrowed, baled, and removed from the field with little stubble remaining on the field.
- The rice stubble is burned in the fall or spring. The amount of burning allowed is limited. See the rice field burning section below for more detail.

Crop Rotation and Fallowing

Crop rotation and fallowing maintains the long-term viability of the agricultural land, and provides improved habitat diversity in the Natomas Basin. It is recommended that between 10

and 25 percent of the rice fields be followed and planted with a cover crop each year. However, it is critical that irrigation and drainage ditches adjacent to fallowed fields continue to convey water, and that adjacent rice fields are planted in rice. The use of fallowing and crop rotation provides multiple benefits, including: improved soil condition; reduced pesticide use; reduced fertilizer use; improved water quality; increased habitat diversity; and improved disease, pest, and weed control. The amount of rice fields fallowed in any given year can be influenced by water availability, plant disease, weed resistance, insect infestation, soil nutrient depletion, the prevailing market price of rice, and the practicality of planting non-rice crops under local field conditions. Crop rotations include such crops as wheat, rye, oats, barley, clover, vetch, safflower, and similar cover crops.

Irrigation Ditch Maintenance

TNBC will conduct irrigation ditch maintenance on the Brookfield property according to practices recommended in the NBHCP. The following practices are adapted from TNBC's:

- When ditch cleaning is necessary, vegetation will be maintained on both ditch banks to the greatest extent practicable, by excavating only from the channel bottom, lifting the spoils straight up, and placing them away from the ditch banks; or if it is not possible to maintain vegetation on both ditch banks during channel excavation, vegetation must always be maintained on one bank.
- Movement of heavy equipment will be confined to existing roadways to the greatest extent practicable to minimize habitat disturbance.
- Excavation activities will be conducted between May 1st and October 1st; if excavation is needed outside of this window, the Service and CDFG must be consulted for permission to proceed.
- Before ditches are excavated, the ditch will be de-watered for a minimum of two weeks before cleaning begins.
- Maintenance activities along ditches, such as mowing and discing, will maintain buffer strips of standing vegetation along the ditch.
- Mowing herbaceous vegetation growing along ditch banks from the top of bank down to the waterline will be avoided to the greatest extent practicable except when management of noxious weeds is called for.
- If mowing is used to control terrestrial vegetation beyond the top of the channel banks, the height of the vegetation after mowing will be at least 6 inches.
- Use of aquatic herbicides to control invasive aquatic vegetation will be minimized to the greatest extent practicable, and use shall be consistent with manufacturer's recommendations and all applicable laws and regulations.
- Prescribed burning used to control vegetation along ditch banks will be conducted using methods that avoid harm to giant garter snakes.
- Driving over snakes that are observed on roads will be avoided at all times.

Noxious Weed Control Activities

The vegetation management techniques described below may be used separately or in combination. If TNBC intends to implement vegetation management techniques on the Brookfield property that are not identified below, TNBC will discuss these with the Service and CDFG to determine if an amendment to the site specific management plan is required. Additionally, any new vegetation management method may adversely affect the giant garter snake and may require a section 7 consultation or habitat conservation plan. The techniques set forth below will guide activities by TNBC in managing noxious weeds on the Brookfield property.

Water Level Manipulation - Water level manipulation involves the dewatering of rice fields and irrigation ditches and exposure of submersed aquatic plants. These plants depend on water for physical support since such plants lack a protective epidermal cell wall (or hardened cuticle layer) making them susceptible to desiccation. The rice field or irrigation ditch must remain dewatered until aquatic vegetation has completely desiccated, or has been removed.

Grazing - Use of sheep or goats, can be used to manage upland and wetland vegetation adjacent to the rice fields. Grazing for noxious weed control should be conducted typically in the spring before the weeds have set seed. Timing will vary depending on weather conditions and weed types, and should be based on observations made by TNBC.

Mowing - Mowing and chopping are utilized to control terrestrial vegetation on maintenance roads and upland areas adjacent to rice fields. All mowing and chopping equipment will be provided with height gages which can be set to allow remaining vegetation to be approximately 6 to 12 inches tall, except for access roads where vegetation can be cut to leave the access roads clean of cover. Vegetation along the water-side of irrigation ditches should only be mowed when treating a noxious weed infestation. Mowing for noxious weed control should be conducted typically in the spring before the dominant noxious weed species have set seed; however, certain weeds will require treatment later in the year. Timing will vary depending on weather conditions and weed types, and should be based on observations made by TNBC. The use of mechanical vegetation control methods should be avoided during cool weather (typically in February, March, October, and November) if there is risk that giant garter snakes are not in hibernation.

Prescribed Burning - If conditions are conducive (e.g., favorable wind conditions and sufficient fuel material), burning has been shown to be effective in the reduction of organic matter (i.e., thatch) in grassland areas. Prescribed burning should be used infrequently, primarily when other vegetation management methods are inadequate. Prescribed burning must be conducted in accordance with all laws and local ordinances. Prescribed burning by TNBC or its farm tenants to control noxious weeds, thatch, disease, or undesirable insects on the Brookfield property shall be conducted only between November 1st and April 1st, except when rice is out of rotation.

Rice Straw Burning - Burning of rice straw has been in decline since the passage in the early 1990s of the Rice Straw Burning Reduction Act. Today, rice growers may only burn a maximum

of 25 percent of their fields and only when significant levels of disease are present. Because of its proximity to urban areas, it is difficult to get a burn permit in the Natomas Basin. Appropriate burn timing facilitates nutrient release into rice growing area substrate. Any such rice straw burning activities shall be subject to all laws regarding burning activities.

Hand Pulling/Cutting - Manual removal of aquatic and terrestrial vegetation by pulling and/or cutting (with a string trimmer or other cutting tool) is accomplished by field personnel entering the croplands, pulling/cutting the plants, and depositing the material on the side of fields. Typically, vegetation removed in this manner is allowed to desiccate and is later hauled away and burned or composted off-site. This technique is only employed when equipment access is restricted because it is labor-intensive, expensive, and can present worker safety issues. Hand pulling/cutting may be employed throughout the year to maintain the ecological or agricultural functionality of the crop.

Chemical - Use of both contact and systemic herbicides can be valuable for the suppression of aquatic and terrestrial weedy plants both within and adjacent to the rice fields. A State-licensed Pest Control Advisor will evaluate these herbicides for their potential affect on non-targeted vegetation and animals prior to application. During the initial application of rice field aquatic herbicides, herbicide-laden irrigation water within the rice fields will be held in compliance with State and Federal pesticide use regulation. At the end of this period, irrigation water may again be released. Chemicals not approved for use in or near water will not be used. If herbicides and/or pesticides are used on the Brookfield property, they will be applied in accordance with label instructions under the direction of a State-licensed Pest Control Advisor and applied by State-licensed pesticide applicators or employees under their direct supervision.

Landside Woodlands

About 140 acres of landside woodlands will be created and/or preserved throughout all the Phases of the proposed project. The design of landside woodland habitats will include valley oak savanna with grassland, elderberry shrub clusters, mixed riparian forest, native grassland, riparian scrub, as well as a mosaic of closed canopy oak, sycamore, and cottonwood woodland. Long-term management and maintenance of the woodlands will be the responsibility of TNBC. The woodland mitigation will be managed to support growth, survival, and natural regeneration of planted, transplanted, and existing native trees, shrubs, and perennial grasses. Maintenance requirements will be minimal and will focus on the following activities: noxious weed management, nonnative woody vegetation management, plant disease and insect infestation management, thatch management, and fire hazard prevention. Additionally, trespass and associated illegal activities, such as dumping, vandalism, camping, poaching, and drug-related activities, will require regular patrolling and reporting to law enforcement agencies. Management of the landside woodlands will be consistent with the Service's July 9, 1999, *Conservation Guidelines for the Valley Elderberry Longhorn Beetle*, which are designed to avoid any adverse effects to the beetle.

Conservation Measures

Valley Elderberry Longhorn Beetle

The following measures shall be implemented to avoid, minimize, and compensate potential adverse effects on valley elderberry longhorn beetle:

- Worker awareness trainings for construction personnel shall be conducted by a qualified biologist approved by the Service before the commencement of construction activities and as needed when new personnel begin work on the project. The program shall inform all construction personnel about the life history and status of the beetle, the need to avoid damaging the elderberry plants, measures to avoid and minimize impacts on this species and its habitat, the conditions of relevant regulatory permits, and the possible penalties for not complying with these requirements. Written documentation of the training shall be submitted to the Service within 30 days of the completion of training.
- All elderberry shrubs that are located adjacent to construction areas, but can be avoided, shall be protected through establishment of a fenced avoidance area. The high visibility fencing shall be placed at least 20 feet from the dripline of the shrubs, unless otherwise approved by the Service. This fencing shall prevent the encroachment of construction personnel and vehicles and protect the shrubs.
- No insecticides, herbicides, or other chemicals that might harm the beetle or its host plant shall be used within 100 feet of the elderberry shrubs.
- Dirt roadways and disturbed areas within 100 feet of elderberry shrubs shall be watered at least twice a day to minimize dust emissions.
- The 14 elderberry shrubs that are currently on TNBC Cummings Preserve lands would be relocated within the preserve, east of their existing location and outside of the project footprint. SAFCA proposes to compensate for the loss of 0.5 acre of preserve land that would be converted to elderberry savannah by providing TNBC with 0.5 acre of upland habitat within SAFCA's compensation land surrounding Fisherman's Lake. Because these 14 elderberry shrubs are compensation for effects from the NBHCP, SAFCA will provide 14 additional elderberry seedlings and 14 additional associated natives within their woodland corridor.
- All other elderberry shrubs that require removal shall be transplanted to the woodland corridors and woodland restoration/creation areas. If none of the areas of suitable habitat to be created as part of the proposed project would be available before the impact would occur, alternative transplantation locations (e.g., TNBC preserves, Airport lands) shall be identified to the Service for approval.
    - If feasible, based on the Service authorization, elderberry shrubs shall be transplanted when the plants are dormant (November through the first 2 weeks of February) to increase the success of transplanting. If it is not feasible to transplant elderberry shrubs during their dormant season, compensation would be increased by 2.5 times. Transplantation would not

occur during the beetle's flight season (March 15–June 15). A qualified biologist shall be available to monitor transplanting activity.

- Elderberry shrubs to be transplanted shall be cut back 3 to 6 feet from the ground or to 50% of their height (whichever is taller) by removal of branches and stems. The trunk and all stems measuring 1 inch in diameter or greater at ground level that are removed shall be replanted. All leaves on the shrubs shall be removed.
- Shrubs shall be removed with a truck-mounted hydraulic tree spade, backhoe, front end loader, or other suitable equipment. When a shrub is being excavated, as much of the root ball as possible shall be removed and replanted immediately at the mitigation site. Care shall be taken to ensure that the soil is not dislodged from the root ball. Typically, the transplant hole is first excavated by the tree spade and deep-watered. Then the shrubs are transplanted with the same tree spade and immediately transported to the planting hole.
- The planting area shall be at least 1,800 square feet (0.04 acre) for every transplanted elderberry shrub. In this 1,800-square-foot area, associated tree and shrub species for each elderberry shrub shall also be planted. The root ball shall be planted so that the top is level with the existing ground and the soil shall be compacted so that settlement is minimized.
- A watering basin measuring at least 3 feet in diameter with a continuous berm (approximately 8 inches wide at the base and 6 inches high) shall be constructed around each transplanted elderberry shrub. Upon completion of planting, soil shall be saturated with water. No fertilizers or other supplements or paint shall be used on the shrubs. The frequency of watering shall be determined based on soil conditions present at the mitigation site. Either a drip irrigation system or watering truck shall be used to provide water to the site.

- Each elderberry stem measuring 1 inch or greater in diameter at ground level that is adversely affected (i.e., transplanted) shall be replaced with elderberry seedlings and seedlings of associated species, in accordance with the Service's *Conservation Guidelines for the Valley Elderberry Longhorn Beetle*, July 9, 1999. Elderberry seedlings or cuttings shall be replaced at ratios ranging from 1:1 to 8:1 (new plantings to affected stems), depending on the diameter of the affected elderberry stems and the presence of beetle exit holes. Native plants shall be planted, in association with the replacement elderberry shrub seedlings or cuttings, at 1:1 (for shrubs without evidence of beetle exit holes) or 2:1 (for shrubs with evidence of beetle exit holes) ratios. Stock of seedlings and/or cuttings shall be obtained from local sources. Table 1 lists the number of elderberry stems that would be affected and the proposed compensation plantings.
- A restoration, monitoring, and management plan shall be prepared and implemented. This plan shall specify how the woodland/elderberry habitat creation areas would be managed to ensure that the appropriate habitat conditions are provided. The plan shall, at a minimum, describe requirements for transplantation of shrubs that require removal;

specify the number of replacement elderberry shrubs and associated native plants to be established and associated success criteria; specify remedial measures to be undertaken if mitigation success criteria are not met; and describe short- and long-term maintenance and management. Long-term protection of the planting area for elderberry and associated species, and funding for its management, shall be provided through appropriate mechanisms to be determined by SAFCA, the Service, and other entities cooperating in implementation of the proposed project. The plan shall be reviewed and approved by the Service prior to implementation.

Table 1. Elderberry Stem Sizes and Compensation

Location	Stems (maximum diameter at ground level)	Exit Hole on Shrub (Yes or No)	Elderberry Seedling Ratio	Associated Native Plant Ratio	Number of Stems Observed	Required Elderberry Plantings	Required Associated Native Plant Plantings
Riparian	stems ≥1" & ≤3"	No	2:1	1:1	8	16	16
		Yes	4:1	2:1	14	56	112
Riparian	stems > 3" & <5"	No	3:1	1:1	3	9	9
		Yes	6:1	2:1	3	18	36
Riparian	stems > 5"	No	4:1	1:1	4	16	16
		Yes	8:1	2:1	4	32	64
Non-riparian	stems ≥1" & ≤3"	No	1:1	1:1	204	204	204
		Yes	2:1	2:1	37	74	148
Non-riparian	stems > 3" & <5"	No	2:1	1:1	43	86	86
		Yes	4:1	2:1	9	36	72
Non-riparian	stems > 5"	No	3:1	1:1	31	93	93
		Yes	6:1	2:1	15	90	180
Elderberry replacements for Cummings Preserve						14	14
Total replacement plantings						744	970
Total Elderberry shrubs to be transplanted						77	
1,714 /10 = 171.4 valley elderberry longhorn beetle credits or 7.08 acres							

Giant Garter Snake

The following measures shall be implemented to avoid, minimize, and compensate potential adverse effects on giant garter snake:

- Worker awareness trainings for construction personnel shall be conducted by a qualified biologist approved by the Service and CDFG before commencement of construction activities and as needed when new personnel begin work on the project. The program shall inform all construction personnel about the life history and status of the snake, the need to avoid damaging suitable habitat and causing snake mortality, measures to avoid

and minimize impacts on this species and its habitats, the conditions of relevant regulatory permits, and the possible penalties for not complying with these requirements.

- Written documentation of the training shall be submitted to the Service and CDFG within 30 days of the completion of training.
- Construction and other ground-disturbing activities within 200 feet of suitable aquatic habitat for the giant garter snake shall not commence before May 1, with initial ground disturbance expected to correspond with the snake's active season (as feasible in combination with minimizing disturbance of nesting Swainson's hawks). Initial ground disturbance shall be completed by October 1.
- Some components of the proposed project may occur prior to the beginning of the defined giant garter snake active season. Activities, such as utility relocations, removal of residential or agricultural structures, and removal, transplantation, and planting of trees and elderberry shrubs, would be conducted before May 1. The removal of trees and elderberry shrubs corresponds to the avoidance and minimization measures for valley elderberry longhorn beetle (e.g., the Service guidelines specify that elderberry shrubs shall be transplanted between November 1 and February 15) and Swainson's hawk (e.g., CDFG guidelines specify that trees should be removed outside of the raptor nesting season, which is generally between March 1 and July 31).
- Some components of the proposed project may occur beyond the end of the defined giant garter snake active season and up to November 31 of all construction years. For example, demobilization and site restoration (e.g., hydroseeding, gravelling) activities may extend through November of all years. However, these activities would not generally be within 200 feet of potential aquatic habitat. SAFCA does not anticipate any construction activities to occur within potential giant garter snake habitat outside of this species' active season. Should limited construction need to occur in snake habitat outside of the active season, however, SAFCA would coordinate with the Corps, Service, and CDFG. Further, SAFCA recognizes that it may be necessary to implement additional avoidance and minimization measures for project activities that occur beyond October 1.
- Any aquatic habitat for the snake that is dewatered shall remain dry for at least 15 consecutive days after April 15 and before excavating or filling of the dewatered habitat. If complete dewatering is not possible, potential snake prey (e.g., fish and tadpoles) shall be removed so that snakes and other wildlife are not attracted to the construction area.
- Within 24 hours before the commencement of ground-disturbing activities, areas within 200 feet of suitable aquatic habitat for giant garter snakes shall be surveyed for giant garter snakes by a qualified biologist. The biologist shall provide the Service with written documentation of the monitoring efforts within 48 hours after the survey is completed. The action area shall be re-inspected by a qualified biologist whenever a lapse in construction activity of 2 weeks or greater has occurred. A qualified biologist shall be present on-site during initial ground disturbance activities. The biologist shall be available throughout the construction period and shall conduct weekly monitoring visits to ensure avoidance and minimization measures are being properly implemented.
- Before the commencement of construction activities, high-visibility fencing shall be erected to protect suitable giant garter snake habitat that is located adjacent to

construction areas, but can be avoided, from encroachment of personnel and equipment. The fencing shall be inspected before the start of each work day and maintained by SAFCA and construction personnel until completion of the project. The fencing shall be removed only when the construction within a given area is completed. This fencing shall conform to the specifications detailed in the measure below.

- Tightly woven fiber netting (mesh size less than 0.25 inch) or similar material shall be used for erosion control and other purposes at the project site to ensure that giant garter snakes are not trapped or become entangled by the erosion control material. Coconut coir matting is an acceptable erosion control material. No plastic mono-filament matting shall be used for erosion control. The edge of the material shall be buried in the ground to prevent giant garter snakes from crawling underneath the material. Erosion control structures shall be constructed so runoff shall be directed away from sensitive habitats, directing water flow into existing drainages or disperse water across vegetated areas to avoid concentrating water.
- The number of access routes, the number and size of staging areas, and the total area of the proposed project activity shall be limited to the minimum necessary. Routes and boundaries shall be clearly demarcated. Movement of heavy equipment to and from the project site shall be restricted to established roadways and designated staging areas to minimize habitat disturbance. Project-related vehicles shall observe a 20-mile-per-hour speed limit within construction areas, except on county roads and on state and Federal highways.
- All snakes encountered shall not be harassed, harmed, or killed and shall be allowed to leave the construction area on their own volition. If any snake is observed retreating into an underground burrow within the project limits, no construction shall be allowed within a 50-foot radius of the burrow. A 50-foot radius nondisturbance buffer zone shall be established until a qualified biologist can make a determination that the snake is or is not a giant garter snake. If a qualified biologist determines that a giant garter snake has retreated into an underground burrow within the project limits, and the area of the burrow cannot be avoided by the project, then under the approval, supervision and direction of the Service and a qualified biologist, the burrow shall be excavated to allow personnel with appropriate authority to capture and handle the giant garter snake to relocate the giant garter snake outside of the action area. The biologist shall notify the Service immediately if any listed species are found on-site, and shall submit a report, including date(s), location(s), habitat description, and any corrective measures taken to protect the species found.
- During construction operations, stockpiling of construction materials, portable equipment, vehicles, and supplies shall be restricted to the designated construction staging areas. All heavy equipment, vehicles, and supplies shall be stored at the designated staging area at the end of each work period.
- To eliminate an attraction to predators of the giant garter snake, all food-related trash items, such as wrappers, cans, bottles, and food scraps, shall be disposed of in closed containers.

- After construction activities are complete, any temporary fill or construction debris shall be removed and temporarily disturbed areas restored to their preproject conditions. An area subject to "temporary" disturbance includes any area that is disturbed during the project, but that, after project completion, shall not be subject to further disturbance and has the potential to be revegetated. All giant garter snake habitats subject to temporary ground disturbances, including storage and staging areas and temporary roads, shall be restored. These areas shall be recontoured, if appropriate, and revegetated with appropriate native plant species to promote restoration of the area to preproject conditions. Appropriate methods and plant species used to revegetate such areas shall be determined on a site-specific basis in consultation with the Service and CDFG and in accordance with the Service's *Guidelines for the Restoration and/or Replacement of Giant Garter Snake Habitat.*
- SAFCA shall maintain and monitor temporarily disturbed areas of giant garter snake habitat for 1 year following the completion of construction and restoration activities. Monitoring reports documenting restoration of these areas shall be submitted to the Service upon the completion of the restoration implementation and 1 year after the restoration implementation. Monitoring reports shall include photo-documentation and shall describe when restoration was completed, what materials were used, specified plantings, and justifications of any substitutions to the Service-recommended guidelines.
- As summarized above under the "Habitat Enhancement, Development, and Management)" section, unavoidable adverse effects to giant garter snake habitat shall be compensated through the creation and preservation of suitable aquatic and upland habitat for this species.

Jeopardy Determination
